Currants.—Next to the Gooseberry, the Currant is the fruit which will bring the quickest return to the fruit-farmer. The Red Currant is subject to the ravages of the same abomination as the Gooseberry—the grub of the sawfly, but not to the same extent; but it suffers infinitely more from the birds. Not only do the blackbird and the missel thrush make their voracious raids upon it—I say nothing of the song thrush, for his appetite is not of the same insatiable nature, and he is always welcome to as much as he can eat in return for his song—but robins and other small birds keep nibbling at it; so much so, that what with their depredations and those of the wasps, I have never yet been able to get a quarter of a crop from my Red Currant bushes, and I cannot therefore recommend it as a crop for a fruit farm unless it is planted in sufficient quantity to justify the employment of a man to protect it during the season of ripening. Still, if any should wish to try, they will find the Raby Castle the finest of all varieties, and an abundant bearer.

But the Black Currant is my favourite fruit—not for its intrinsic excellence, for anything more nasty I cannot imagine; but because, first, no grub that I know will prey upon its leaves; and second, no bird will touch it as long as any other possible kind of food is to be had. Thirdly, it always bears freely; and fourthly, it is always in great demand.

Here are four undeniable excellencies, and if you add to this that it is easily propagated and will produce as large a profit per square yard as any fruit I know, I recommend it to the particular notice of all fruit-farmers whose soil is suitable for it. The bush, also, if planted in the manner suggested above, leaving all the eyes in the cuttings, will continue to bear for many years if properly managed, though the fruit diminishes in size as the plants grow older.

As a proof of the profitable nature of the Black Currant I may mention that in one small plantation I have for two years carefully calculated the produce, and I find that it has varied from 3*d*. to 4*d*. the square yard, or, if taken at the higher price, about £80 per acre. The bushes should be planted like the Gooseberry, 6 feet from each other; and in pruning, it should be remembered that a plan the very opposite to that which succeeds with the Red Currant must be adopted. In the Red Currant you must cut out all the new wood to a single eye and leave the old, whereas in the Black Currant you must cut out old wood and leave the new—this at any rate when the bushes are fairly established. Till this is the case the young wood should be shortened to three or four eyes, or the branches will not grow with sufficient vigour to support the fruit.

I do not recommend the Raspberry for the same reason as the Red Currant. The birds will take the greater portion of the crop unless it be constantly watched, and unless the plantation is large it will not justify the employment of a special watcher while the fruit is ripe; and I am now advocating the cause of small fruit farms, on which one family only is employed.

PROLONGING THE STRAWBERRY SEASON.

I hope in this attempt to give some directions for prolonging the Strawberry season, I shall be sufficiently plain to be understood, and to any question asked through the Journal I will try to give a prompt reply. I must remark that it is not by any skill of mine that I have produced crops of Strawberries late in the season, and indeed in a commercial point of view it would not be worth my while, as I find they are little cared for. There appears to be a sort of prejudice against them, an impression that they are without flavour, and persons do not care to purchase them. I think, however, that the reverse is rather the case. The Strawberries are very distinct from the same variety at the ordinary season, so much so that I would defy the greatest epicure to say what variety he was eating; for appearance, colour, shape, flesh, and flavour are all different, at least it is so with me, as indeed Dr. Hogg and others to whom I have sent fruit can testify.

Perhaps there is no fruit grown so capricious as the Strawberry; for in the same soil where one variety will not even live, another quite luxuriates, and this is even the case with kinds nearly related to each other, such as British Queen and Carolina Superba. Most persons grow such late varieties as Elton, Filbert Pine, Frogmore Late Pine, and Myatt's Eleanor, in order to obtain a late supply. With these and a little careful management —or perhaps I ought to say experienced rather than careful, for what is very easy to the experienced is far otherwise to the merely informed—you may obtain Strawberries late in summer and in autumn with very little, if any, intermission, except, perhaps, a week or two—the last week of July and first or second week of August—but even then the gap may be filled up by May Queen, to be succeeded by Sir Walter Scott, Black Prince, and a sort of which I will try to obtain the name. I had it eight or nine years ago from Mr. Nicholson, of Eaglescliff, with about forty other varieties, and lost its name. It is a very distinct variety, and no doubt well known in the trade. For late summer and autumn-fruiting it is very superior, continuing to bear from about the second or third week of August till the second or third week of October. Next in succession and the best of all, taking every point into consideration, is Patrick's Seedling. Those which were shown by Mr. Fulford, Clifton, at the Bristol and Clifton Chrysanthemum and Fruit Show on the 8th and 9th inst. were the same variety; many of them were about two or three to the ounce. With careful management these will carry you till the end of November. President bears a few good berries from the end of October till the end of

November, as does John Powell. Other varieties that I have fruited are Swainstone's Seedling, Rivers's Eliza, La Constante, and Myatt's Quinquefolia, but they will not at all compare with the former for fertility. I would advise trying these, and if you find you succeed tolerably well after one season, you may purchase them as certain and prolific croppers. I am rather a large grower both as regards number of varieties and extent of ground.

I ought to mention some varieties that will not fruit at all, although a few of them may be induced to flower. The old Carolina, for example, has profuse and fine healthy flowers as large as a half-crown, but I do not remember to have ever gathered one fruit. British Queen, La Châlonnaise, Carolina Superba, and Mr. Radclyffe flower very sparingly or not at all; Princess Alice Maude and Goliath (Kitley's) have only an occasional fruit; whilst Dr. Hogg and Souvenir de Kief bear few but fine berries.

My Strawberry garden is on the south side of a hill, sloping abruptly and very stony, so as to be quickly affected by drought; the consequence has therefore been not only a frequent loss of the crop, but sometimes the destruction of the plants, and such a drying-up of the foliage that you might take it in your hand and reduce it to powder. The first time I had a crop I at once saw that it was after a period of rest that a crop of fruit was produced, whether in consequence of the cold of winter or the dry heat of summer. Then came the question how this could be effected artificially, and my experience has shown me that the best way is to have your plants in some way under control, and it may be done in the following ways. For a bed select some sheltered spot, either by a wall (of course not your ordinary fruit wall), or by some evergreen shrubs, and with an aspect as nearly south as possible; take out the soil to at least 3 feet deep, and not more than 4 feet wide; fill the excavated space to the depth of quite 2 feet with stones and rubble, and the remaining foot with good open soil. Thus will be secured thorough drainage, which is absolutely necessary for the production of a crop, and such a bed or border should be made to slope very rapidly—if 4 or 5 inches to the foot so much the better.

Planting may be done in various ways; for instance, you may employ plants previously used for forcing, especially any that have failed to bear a crop; these, if they have been forced early, will come in by the end of July. You may plant very early in the spring, but planting at the ordinary time—August or September—is much better. Plants put in during the spring should have every encouragement to make growth, while those planted early in August will need no care. Allow the ordinary plants to grow on till some of the fruit is nearly ripe, and then place spare lights over them when it rains, and at night if rain is expected; for particular attention must be paid to give the period of rest. You may make a framework for lights, or whatever may be used to keep off rain (lights, or glass covering of some sort being, of course, the best) in the following way:—Select some tolerably straight poles, cut them into 2½-feet lengths, make one end somewhat pointed, bore holes with an iron bar, at the width of the lights apart, to the depth of about 18 inches, and with a wooden mallet drive in each pole till you have about 1 foot above your bed or border, and on the tops of these nail lengthwise common battens. The same material will do to nail across between each light, unless the lights are very large and heavy, and then, of course, something stronger will be necessary; but it will be found that posts fixed in this way will be much firmer than those put in by digging a hole and ramming the soil about them, to say nothing about disturbing the ground. Some fastening will be needed at the top to prevent the lights running down, which they otherwise would do.

Having by the means described brought the plants into a state of rest, although only for two or three weeks, they may be again started into growth (but if only one variety is grown, some must have a longer rest in order that a succession may be kept up), by removing the lights altogether, and leaving the plants to themselves till the fruit is near maturity; then recourse must be had to lights again, in order to keep off excessive rain, which would materially injure the berries both in texture and flavour, but the plants will be much better uncovered save in very heavy and continuous rain. About the end of September it will be necessary to be on guard against frost, for a severe frost will greatly injure the fruit, and a very slight frost will injure the flowers.

This mode of treatment will carry us on to the middle of November with tolerable safety, but cannot be depended upon afterwards. If, then, it is desired to continue the succession say another month, such a result can only be attained with pot plants, and these must not be forced plants of the previous spring, for although the latter grow well in the open ground when planted out, they will not produce a good crop in autumn if kept in pots. It will be necessary to have good plants, and these you may obtain as follows. If it were three months earlier one might get plants just as for early forcing—that is, by plunging small pots in the ground, and fixing the runner on the soil by laying upon them small stones, and when they were well rooted taking them up, giving them a shift into a larger pot, and wintering them in the usual way. But as this cannot be done now, the next best method is to take up plants early with balls, pot, and plunge the pots up to the rims in a bed of ashes about 4 feet wide, growing them on in just the same way as those planted out in beds, only not starting them into growth till two or three weeks later than those in the beds. They will thrive best in the bed of ashes till about the beginning of September or later, care being taken to keep off excessive wet and frost as directed for those planted out. In an orchard house the plants will succeed admirably with abundance of air till late in November, but after that time they should be removed to the back shelf of a greenhouse, where they will be near the glass and have plenty of light and air; or if you want them to come on a little more rapidly, place them in a position where they may have a little heat, but it must be very little, otherwise you will lose your crop, or a considerable portion of it.

Naturally the same variety continues a long time in bearing. From Patrick's Seedling, for instance, I gathered for about nine weeks, but there was only one gathering last week; the interval between that and the preceding gathering was two or three days over a week, and we gathered only once in the week previous, but up till then twice a-week. The other variety of which I cannot give the name, which is very handsome and good under the same circumstances, and treated just like Patrick's Seedling, comes in quite three or four weeks earlier, but will not produce longer than seven or eight weeks, and then the late gatherings are poor. The crop comes in more at one time than that of Patrick's Seedling.

I must say again, Be careful in the resting season to keep the plants as healthy as possible. I have never had so abundant a crop as I have had this season, for the plants were injured before, and I should have failed to give such directions last season as I am able to do this. I have no doubt many of your correspondents will beat me altogether in about two seasons. My gatherings altogether have been about fifty-nine quarts, it may be a few more, and principally from the two varieties, and many of the berries were very fine both as to size, appearance, and flavour.

If anyone should be desirous to make a bed at once he may do so if possessing an abundance of spare plants, otherwise it will be much better to plant in very mild weather at the end of February or in March, for many of the plants put in at this season would run a great risk of being thrown out of the ground by the frost and killed. Do not keep the plants unnecessarily covered, for under the lights there will be a draught of air which in the autumn is very chilly, and, although it does not hurt the fruit so much as wet, it injures the flowers.—G. Lee, *Clevedon.*

SELECT ROSES.

Mr. W. Paul's selection of Roses will, no doubt, be of much service to many of your readers. After several years' experience as a Rose-grower on a loam with a clay subsoil, I find the following answer my purpose as exhibition flowers:—Alfred Colomb, Abel Grand, Madame la Baronne de Rothschild, Madame Vidot, Marie Baumann, Charles Lefebvre, Duke of Edinburgh, Maréchal Niel, Pierre Notting, Sénateur Vaisse, Louis Van Houtte, and Belle Lyonnaise.—William Caudwell.

I think "An Amateur, *South of Ireland*," has been too hasty in his condemnation of Marie Baumann if, as I judge from his letter, though I may be mistaken, he has decided from a single plant. I am eliciting the opinions of Rose-growers as to the best twelve and thirty-six Roses, and hope to be able to publish the returns in your next number. At present I have fourteen lists sent to me in answer to my request, and thirteen out of the fourteen place Marie Baumann among the first twelve; the fourteenth places it first in the list of the next twenty-four. This, as far as the returns go, makes Marie Bau-

mann third in the list, only Maréchal Niel and Baroness Rothschild being named by everyone. However, I am only anticipating matters, and hope to be able to publish the full list next week.—C. P. Peach.

BEDDING PLANTS IN 1871.—No. 4.

I must apologise to some of your readers for having delayed so long in sending this communication on bedding plants, but I have had my time so occupied with other matters that I have not been able to find the opportunity of finishing my notes.

I have not very much to alter or to add to what I said on the Bronze and Gold section last year. I have had twenty-four varieties or so on trial this year. At present I think those raised by Mr. Laing, of the firm of Downie, Laird, & Laing, incomparably the best. Of these Impératrice Eugénie, the finest in point of colour, is of too tender a growth for many gardens, but is worth all the care and attention that can be paid to it, and is especially good as a pot plant. As a bedder, however, it is not so good as Crown Prince. This has a much more vigorous habit, and retains the golden yellow of its leaves longer than any other I have as yet tried. It is glorious both in spring and autumn, and does not turn green as many others, such as Beauty of Calderdale, Her Majesty, Beauty of Oulton, &c. It is invaluable, too, as a pot plant for exhibition on account of its good habit, but in order to make a good plant it should be pinched-in from the first.

Brilliancy, another of Mr. Laing's, is also very fine in point of colour; in fact, at times in pots it excels even Crown Prince, but it has not so good a constitution or habit.

For those who require a golden bed with very little marking, I can recommend Mrs. Lewis Lloyd, very dwarf-growing, with a spreading habit; and Sceptre d'Or, of a more upright habit than the last, and making an almost self yellow bed, the bronze zone not being very distinctly marked, and shading off into the leaf, but the gold in the centre and outside of the leaf being very good.

Of the sorts which are by this time very fairly known, I think the best are Duke of Edinburgh and E. G. Henderson, both very much alike, Ebor, and Kentish Hero. These are of good constitution and growth, and though not so fine in their gold or bronze as Crown Prince, Impératrice Eugénie, and Brilliancy, still do not turn green.

Other sorts well worth retaining are Mrs. Allan Lowndes, a fine pot plant; Prima Donna, Fairy Ring, Countess of Kellie, and Princess of Wales. They all require good treatment, especially in the winter, and ought to be planted in favourable ground. Those which I discard are Black Knight, James Richards, and Black Douglas, all of which have their zones too dark, and are apt to turn green; also Beauty of Calderdale, Beauty of Ribblesdale, Sybil, Princess Alice, &c. Their name at present seems legion, Mr. Bull alone sending out forty or so last season, having separated them into three distinct classes, as Bronzes grown for their foliage; Bronzes remarkable for the beauty of their flowers; and, thirdly, those remarkable for peculiarity of shades of colours. Amongst these forty it is probable that only two or three can be worth much, as all Mr. Bull's strain have too much green in them to please me, and it is more probable still, that strip them of their flowers (and it is to be borne in mind that they should be grown for their foliage and not for their flowers), they would hardly be distinguished one from another.

There are three other promising sorts which I have not sufficiently tested yet; these are Reine Victoria, Marquis of Lorne, and Earl of Rosslyn. I have also omitted one which I think may be considered as a Variegated Bronze, called Columbine, raised at Chiswick, and which has a lighter shade of green running across both the bronze zone and the inner and outer rings of colour, and which this year proved very bright and effective. One reason which induces me especially to mention this is once more to protest against the Bronzes being classified as variegated Geraniums, as they have no more claim to the title than any of the old dark Zonal varieties, as Baron Ricasoli, Symmetry, Baron Hugel, &c. They do not, in short, variegate or sport from the seedling in the same way as Tricolors or Silver-edged plants, and we may soon have a strain of Variegated Bronzes.

The next section I come to are the Tricolors; their name again is legion. A list sent me the other day by a grower in the trade contained 113 sorts, and I think for all practical purposes ten or twelve are sufficient. I have found none yet to beat Lady Cullum, and next to it Sophia Dumaresque. I have not yet tried Achievement, Mrs. Headley, Princess of Wales, and some others of the high-priced kinds, as I have not hitherto considered them worth their market price, though Mrs. Headley is likely to be a step in advance even of Lady Cullum. Mr. Pearson has also some fine varieties in Mr. Sanday, Mrs. Edge, Countess of Manvers, and also Edith Pearson, which I have tried and succeeded with. Queen of the Tricolors, which was not good with me last year, was good this. Louisa Smith has not sufficient zone, while Sophia Cusack and Lucy Grieve do not grow. One of the very best I have tried is one of Messrs. Bell & Thorpe's called Macbeth, very stout in the texture of the leaf, good zone, and a strong grower. I have no doubt it will ultimately prove a fine border plant.

Of the Gold-leaved and Gold-edged section I have not much to say. I still prefer Cloth of Gold to Crystal Palace Gem, and where it can be made to grow the old Golden Chain is best of all, but I do not intend for the future to grow any more. Golden Feather Pyrethrum supplies the place of gold-leaved Geraniums without trouble; and where the Pyrethrum does not harmonise there is gold variegated Arabis, the larger variegated Periwinkle, and other hardy gold-variegated plants which do not take up house room, and give comparatively no trouble.

The Silver Tricolors have only proved with me useful as pot plants, and I do not think any of the new ones I have seen much superior to Italia Unita, unless I except Lass o'Gowrie.

Of White-edged Zonals I still prefer Flower of Spring, as being the most compact in its habit, short-jointed, and full of foliage, and if only sufficient use is made of the old plants there is none superior. May Queen (Turner's), and Pearl (Pearson's), are its two greatest rivals, but I confess I still prefer Flower of Spring to either of them. Alma still keeps up its superiority to Bijou, which, though very white in the leaf, is of such bad habit and of so rough an outline as not to be worth keeping. Miss Kingsbury is good, but not so good as I expected.

To quit the subject of Pelargoniums, there are other bedding plants that have been invaluable this summer. First, I would mention Little Gem Lobelia. This for the third year has proved to be all that could be desired; it is the only Lobelia I know that with good growth clothes itself fully with green foliage before it blooms. It is very compact in its habit, free-blooming, short-jointed, but is a much better grower than the Pumila section, in colour like Paxtoni. We only want a dark blue of the same habit to have all we require, and I am in hopes another Lobelia I have tried this year, Indigo Blue, will be nearly as good. The dark blue Lobelia, Pumila elegans, has also done very well with me, and a white, or very nearly white one, called Pearl. I may mention of Lobelia Little Gem, that a row planted from a spent hotbed about the 18th of May was in full beauty by the middle of July, and lasted in good bloom till the end of September, and everyone who saw it said it was the most perfect line of Lobelia ever seen. It began to bloom about the first week in June, and the cuttings were all struck in the spring—early in February.

Ageratum Imperial Dwarf also proved a most valuable plant, good both for rows and beds. Tom Thumb was too dwarf with me, but would be very good for those who like pincushion beds with succulents, as the Echeverias, Sempervivums, and Alternantheras, but which I am obliged to own do not please my taste, as there is too much floricultural millinery about them, and they do not harmonise with other beds. Beds such as that which Messrs. Veitch planted in the large tent at Nottingham are interesting *per se*, and curious for the number of plants that can be put into a very small space, but individually they give me no pleasure after I have once seen them, and ought when they are used to stand in a place by themselves.

More use ought to be made, I think, of Petunias. One raised by Messrs. Bell & Thorpe, called Single Beauty, has some of the richest and most varied colours I ever saw in any Petunia, and from its freedom of blooming and habit of growth it would be sure of making a fine bed.

In spite of all that has been said against Beet, because it is esculent, I still think it by far the best of the dark-coloured-foliaged plants; my only trouble was with the sparrows, which are too fond of it when young. I cannot see that it makes the leaf a whit less beautiful because the root happens to be useful as a kitchen-garden crop; we might as well not grow the Pyrethrum because it is a Chamomile, and puts one in mind of Norton's pills. I have tried four sorts, but found three of them identical—they are Dell's, Osborn's, and Carter's Crimson Beet. Nutting's Dwarf Selected was different, but not so good. Some seed which was kindly given me on trial by Mr. Sutherland, of Castle Howard, and saved by him, was very good and

true, and the plants were very dwarf, and grew to the same height. I think it is the same as the Belvoir Castle strain. I have never seen any plants that contrast so well with the Centaurea as Beet.

Of Calceolarias, the old Aurea floribunda has answered exceedingly well with me again this year, never having seen the inside of a house or pot. The cuttings are inserted in rows in the open ground in light soil, and protected only with a frame, loose straw being thrown over the frame, and the sides earthed-up in very cold weather.

I cannot endorse all that has been said in favour of the Violas; they do not last long enough to please me. They are very good for spring gardening, which is their proper place; but to hybridise back with the Viola cornuta is to my mind merely introducing again an inferior strain of Pansy, and I have never yet seen a bed of Violas satisfactory in August that was also good in the spring. A beautiful effect can be produced in spring by rows or beds of choice Belgian or Show Pansies, and nothing is more interesting than to raise seedlings, and to make use of them in spring gardening, but I am still a sceptic as to the use of Viola cornuta, lutea, Perfection, &c., for summer and autumn. Space warns me to conclude.—C. P. Peach.

FORCING VEGETABLES.—No. 3.

ASPARAGUS.

I believe Asparagus was one of the first culinary vegetables to which the art of forcing was applied, it having been sold in the London markets in good condition and early in the year as far back as the seventeenth century. I am not surprised at this, for, according to my experience, there is no vegetable more easily and successfully forced than Asparagus, and yet the forcing of this and other vegetables is not carried to the extent that their importance demands it should. The high price realised for a hundred heads in Covent Garden during the forcing season would lead one to suppose that either very few engage in its cultivation, or that the demand for it must be very great. Perhaps both causes combine to raise the price, and should, therefore, be a sufficient reason, for all those who can, to force their own Asparagus. I hope to be able to show that neither expensive contrivances nor any very extraordinary skill is required to force this vegetable successfully.

The most general way of forcing this vegetable is by making dung beds, and placing garden frames upon them. For this purpose sufficient manure should be collected in a heap, and well prepared by frequently mixing and turning it, so as to get out all rank heat and steam, and which, for the bed or for external linings to the frame, is the best mode of preparation, a rank heat from the outside, or a thick steam inside, being very detrimental to the crop. The thickness of the bed may be from 3 to 4 feet, and the size a little larger than the frame that is to be put on it, and if leaves are to be obtained, a third of them mixed with dung will help to sweeten and also moderate the heat in the bed. When the frame is on, put the lights on also, and allow it to remain till the heat is well up and the manure thoroughly sweated itself, then level the surface, and beat it down moderately firm. Some would recommend treading it, but I do not advise that, for it is possible to get the bed too firm, and thus prevent the heat from rising; the weight of the soil and of the roots will press the manure firm enough, and cool the bed considerably. Before planting, a layer of soil over the bed 3 inches thick will be sufficient, and the roots should be placed together level, and in regular order, all over the bed. Afterwards cover the whole with some fine light earth, taking care that all spaces between the roots are well filled up, and the crowns covered to the depth of 3 or 4 inches, when the bed may be considered finished, and the lights placed over the whole; if the heat, however, becomes too strong, and the weather is mild, they may be taken off for several hours in the day until the roots begin to grow, but not after that. The treatment of the bed will now consist in giving plenty of air daily, regulated, of course, by the heat in the bed and the state of the weather. Asparagus requires a less degree of heat to bring it to perfection than almost any other vegetable, as witness how soon the heads make their appearance above ground out-doors after a few mild days in spring. A temperature of from 50° to 60°, but not more, with sun heat, will be found sufficient. It will, of course, grow in a much higher temperature if it is necessary to force it for any specified time, but to produce strong heads with colour and good flavour, the above temperature, with proper ventilation and light, will grow it well. If the heads are required in a blanched state, the light must be excluded by covering over with litter or mats; but the flavour is not in any case so good, nor do I think the heads look so tempting on the table, as much of their delicious appearance is destroyed.

I think it is as well at this stage to say a few words about the plants and their preparation for forcing. I am not so particular about the age of the plants as some gardeners are, believing, and, in fact, knowing by experience, that if the bed from which they are to be taken has produced a good preceding crop, and the plants are strong and vigorous, it matters little what age the plants may be, although in the forcing of many subjects—Strawberries, for instance—youth is necessary to secure vigour. In the case, however, of Asparagus it matters little if the bed be from twelve to twenty years old, if the roots and crowns are sound. I find it preferable when much of this vegetable is forced to grow the plants in single rows, instead of in beds of the usual width, because when required for forcing they can be taken up entire, and without that mutilation of the fleshy roots which must result from tearing them out of a bed when they have all become matted together.

But many gardeners have not the space to grow Asparagus otherwise than in beds, and still they force good Asparagus. I have never found that much watering is required when Asparagus is forced on dung beds; generally one good watering when the buds begin to vegetate will be sufficient, and this should be with water of the same temperature as the bed. Some gardeners apply a sprinkling of salt over the bed at the time of forcing, but, in my opinion, that does no good whatever then, and if given at all should be applied in a liquid state with the watering, or, better still, given on the out-door bed the season previous to its being taken up for forcing. Another way of forcing Asparagus is by making up a bed of faggots, brushwood, or any other open material, in the same way as a dung bed, only a foot or so higher; on the top of these a thin layer of prepared manure should be placed, and upon the last the frame, the heat being kept up by external linings. This is a most excellent plan where manure is scarce. Greater care is necessary in applying the linings that the heat may not be too rank, as it will have easier access to the body of the frame than by the mode above described.

Such are the modes of forcing Asparagus generally adopted, and to be recommended not only for their complete success, but also on the score of economy. In many places, however, where neatness and order are strictly attended to, pits heated by hot water are used instead of dung beds, and are quite as successful and less troublesome, though the expense of erecting such places is a matter for consideration if plenty of manure and leaves are to be had. Forcing Asparagus by means of hot water requires additional care, owing to the tendency of fire heat to make the bed too hot and dry. Water must be carefully supplied in quantities sufficient to keep the soil in the best state for vegetation, remembering always that Asparagus does not require a strong heat to force it successfully. Asparagus is also sometimes forced in boxes, and placed in any forcing house, pit, or frame. The roots may also be planted in the borders of the early forcing vinery or Peach house where no Vine roots are likely to ramble, and many good dishes may be thus produced. All these makeshift plans are very convenient when the general crop is likely to run short, or if an extra dish or two is needed at any particular time.

There is one other method of forcing Asparagus, which originated many years ago, but instead of being generally adopted it is confined to market gardeners and large private establishments, where exceedingly large quantities of this vegetable are required. It is that of forcing the roots as they stand in the open ground, either by digging trenches by the side of the bed and heating by dung linings, or by hot-water pipes under the bed; in either case the beds must be covered by a framework of boards and glass. No doubt there is in the end a saving in all this preparation for those who need such large supplies, but I do not think it is a method for general adoption, especially for the small grower.

Forcing may commence any time after the summer's growth is matured and the tops cut off. I saw a bed in Sir Henry Lupton's garden, near Ashford, in the first week of November, from which most of the produce had been cut, and another coming on in a most promising manner. I understood from the skilful gardener, that early in October was their usual time to commence forcing; but I think November is a very proper time to begin. A bed should be made up five or six weeks before wanted, and in order to keep up a proper succes-

sion another bed should be made every three weeks or a little less. A good deal of judgment must be exercised by the cultivator, for dung beds are more or less affected by the weather and the state of the manure when the beds are made up; one bed will not always produce the same quantity as the other. The greatest care must be taken in cutting the produce from off a forcing bed when the shoots are very thick. They should be cut by a long narrow instrument, thrusting it into the ground almost perpendicularly by the side of the shoot intended to be cut; if used slantingly the chances are that you destroy the other successional growths, and very much injure the crop.—Thomas Record.

NOTES FROM A PEACH HOUSE.

In the warm house Early Beatrice Peach was ripe on May 21st, and good; Early Louise followed in a week; in another week Early Rivers and Early Alfred, then came Early Silver, and very soon after it Rivers's White Nectarine. None of the old sorts were within a month of any of these, and those early sorts from the middle house were before Early Grosse Mignonne in the warm one. Malta was the earliest of the old sorts, and is one of the very best under glass. Some trees I kept under glass till July, and then plunged outside; one of these was Magdala, and the fruit from it was better than I believed a Peach could be. This variety is first-rate under glass, but I expect it should be grown on a wall to have it as it should be, unless we have recourse to early starting under glass, and final ripening outside, a method that always gives fruit of the highest flavour. Of the others under glass, Alexandra Noblesse, Nectarine Peach, and, above all, Princess of Wales, were the best. Dr. Hogg, Crimson Galande, and Dagmar are all inferior when forced, but very fine in the cold house.

Of the Nectarines I have less to say, but Albert, Albert Victor, Pine Apple, Stanwick, Elruge, Victoria, and Rivers's White were, as usual, magnificent. One seedling of my own, raised from Hardwicke set with the pollen of Victoria, promises very well, being very like the Stanwick, but early and seemingly having no tendency to cracking. This is its second season of bearing, and I overcropped it and shifted it into a larger pot when it was stoning, so that I did not think it right to send you any of the fruit, but if it goes on as well next year, you shall see what it is. This, then, is the result of my experience in the present season. Mr. Rivers's Early Beatrice, Louise, Early Rivers, Early Silver, Rivers's Early York, Magdala, Alexandra Noblesse, and Princess of Wales gave a complete succession from the 21st of May to the end of September, and with Malta are all that anyone need care to grow under glass with a small amount of heat from January to June.

If Mr. Rivers's new varieties prove as good out of doors, we shall soon cease to hear of the great mass of the older ones. Early Beatrice is quite hardy here out of doors, and ripened even this summer. Early Rivers, Early Silver, and the other derivatives of the White Nectarine will not suit a cold or cool climate, as they are all inclined to be acid. I do not think the progress of the Nectarines is so great as that of the Peaches, for I think some of the old varieties of Nectarines hold their ground firmly as yet; but I trust our old friend may yet live to see as wonderful a progeny from some of his new varieties as he has done from the Peaches, such a success as I believe no pomologist has ever reached before.—W. Kingsley.

THE GOLDEN HAMBURGH GRAPE.

The manner in which this Grape was abused some few years ago will, doubtless, still be fresh in the memory of the majority of your readers; but, strange to say, I took a fancy to it from the beginning, not because it was supported by such eminent authorities as Messrs. Cramb and Pearson, but simply through its excellent quality and appearance whenever I had seen it. My experience goes to prove that many a good new Grape is condemned and destroyed too hastily. A Vine, more than any plant, requires age—that is, four or more years, to bring out and establish its true character and value. Here are two Vines—one in the early, the other in the late house, planted, I have no doubt, at the time they were sent out. I never wish for better Grapes than those which came from the former—splendid berries, almost transparent, and well-shouldered symmetrical bunches, averaging from 3 to 4 lbs. in weight. Besides its fruiting qualities, it is a variety of the strongest constitution, making in each case the most vigorous growth, not impeded in the least by the impure atmosphere of this locality. I consider it one of the best white Grapes we have for early forcing.

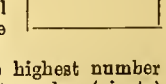
A great deal has been written lately both for and against the Golden Champion, but as I have not seen it growing, I shall wait until next season, when I shall be in a position to send a report upon it, accompanied with a sample of Grapes. The Vines of the last-mentioned have made extraordinarily strong short-jointed rods for the last two seasons; so I think we shall be able to form a tolerably correct opinion of what it will be when thoroughly established.—Thomas Turner, *The Gardens, Beaufort Lodge.*

DENDROBIUM HETEROCARPUM.

We have recently had a plant of the above flowering with greater freedom than I ever remember having seen. Two of the growths, measuring respectively 11 and 13 inches, have produced, the longer eighteen, the other thirteen flowers. I never heard of more flowers on one growth before, although there may have been instances, for the plant is by no means a new inmate of our Orchid houses, having been in cultivation some thirty years. Good old species are often pushed aside to make place for new comers. This certainly ought not to be the case with Dendrobium heterocarpum, for, although it may not be quite so attractive to the eye as some of the genus, it is most deliciously sweet-scented, and its lasting properties should at once make it a favourite; for if placed in a cool house, and kept comparatively dry, it will continue in good condition from six to eight weeks, forming a splendid object at this dull season of the year.—C. J. W., *The Gardens, Ferniehurst.*

LABELLING FRUIT TREES.

I take a thin sheet of lead, and have it cut into pieces about 1¼ inch long and ¾-inch wide; then with a blunt chisel about ⅛ inch wide, upon each label I impress numbers in Roman characters by means of a gentle tap with a hammer. I make a small hole at the left-hand side of the label with a pricker, which can without difficulty be made to penetrate a thin sheet of lead, through which I put a piece of lead wire. The label is then complete and ready for tying on the tree. See the accompanying representation.



It will be noticed that eighty-nine is the highest number that can be made with the chisel, for the next number (ninety) will have a C in it, but I assume that an amateur will not have so many as eighty varieties of any one species of fruit trees; but if a higher number than eighty-nine be required, a C can easily be obtained from some of the shops.

I have a book in which I keep a correct list of all my fruit trees, so that on referring to it I can with ease tell any kind of fruit tree I happen to have, and can almost as easily find such tree. Each page is headed thus—

No.	Name.	Size.	Use.	Remarks.	Season.

In the first column is the number of a tree, and a corresponding number is also on the label attached to the tree. In the second column is the variety of fruit which the tree bears; and the third and fourth columns are respectively for the size and use of the fruit. I generally arrange my fruit into three sizes, No. 1 being the largest, No. 2 smaller, and No. 3 the smallest. The fifth column speaks for itself; and in the sixth column is the month in which the fruit is in season. I number each class of fruit trees separately and distinctly from the others. For Apples, Pears, &c., I commence with No. 1 respectively, and each variety has the same number. If I had ten trees of the same variety of Pear, each tree would have the same number attached to it, and only one reference in my fruit-book.—W. B. A.

Cornick v. Black.—I do not intend to appeal to any third party to corroborate what I have previously stated, nor hold any controversy with Mr. Cornick. My object was simply to state to the best of my knowledge what I heard in Court, and I distinctly remember hearing the defendant's counsel in the course of his address using the words I did, and particularly in reference to some transaction in which more

had been given for some Strawberries (I believe they were) than could possibly be made out of them when they were offered for sale. Surely if the facts were different the statements should have been refuted at the time; if they were I did not hear it, and am much obliged to Mr. Cornick for correcting me and supplying the information he has done. —THOMAS TAYLOR.

[We cannot insert more relative to this trial.—EDS.]

DIAGONAL CORDONS FOR PEARS.

I HAVE frequently advocated in the Journal this style of training, and I have a few more experiences to quote here. That which has immediately called forth these notes is the question of new and select Pears, diagonal cordons being the very best calculated to test the relative merits of such. Here we have planted two walls, which are already producing results. I am thus enabled to state that the observations of some of your correspondents are confirmed, the more so as neighbours—and I may call them pupils in a friendly way—have also by this method given us the benefit of their experiences.

New Pears require at least several years, and culture in differing soils and climates, before they can be accepted generally as standard fruits; and so that method which enables us to ascertain their qualities the soonest must be the most valuable. This the diagonal cordon does better than any other form, the horizontal being insufficiently developed to represent a good-sized tree, being, in fact, antagonistic in idea to such; while the diagonal, representing the natural angle formed by a branch with the main stem, and having a larger area of bearing wood and leaf, holds a position midway between the other forms. Nothing equals the diagonal in simplicity of pruning, for while with horizontals we require dwarfing stocks (which, as in the case of Apple trees on the French Paradise, have the disadvantage of exposing the root fibres to the air whenever heavy rains occur, and this dangerously whenever the border slopes) in the case of the diagonal we are independent of all such considerations. Nor have we any vertical shoots to restrain as in horizontals; the upper side of the diagonal grows freely enough, and is too apt to dwarf the under side, but does not by any means give any real trouble or care. The advantage of removal are equal in either form; their periods of maturity are also equal.

I have nothing to say against horizontal cordons as such; on the contrary, I have just patented a "cordon case" expressly to suit them, which I hope will please some readers of this Journal, and as to such as depreciate what they have not even seen, we must be content to leave the "case" to stand on its own merits. This is the good old way. So I repeat, Grow by all means abundance of horizontal cordons, especially such as suit my "case"—Peaches and Apricots are best—and then you will relish these little improvements in culture, such as the glass cover which slides off, the back which removes, and especially the floor which lowers all at will, the whole of which my old friend at Sawbridgeworth likes very much indeed. With such aids it would be odd if others did not succeed as well as myself in ripening Peaches for Covent Garden before Midsummer-day. This is not bad practice for a case which any lady could attend to. The grandest orchard house could not do more if unheated. Grapes, of course, would do equally well—better, possibly.

Not, however, to wander from our subject, let me confirm what others state as to the beauty and excellence of certain Pears. The one which has most struck me here is the Souvenir du Congrès, which was so beautiful in colour that I made an accurate sketch of it on canvas. It will prove a good market sort for this reason alone, being far more showy than the kindred Williams's Bon Chrêtien, and not unlike it in flavour. I should also think it prolific, for the trees on the wall near it did not bear equally. This specimen was juicy and mellow—to be strictly accurate, not without a suspicion of grittiness in the texture, but not to any damaging extent.

We had many other new Pears from these walls of cordons, grown in pairs side by side, thus testing their relative qualities in the fairest, and, at the same time, the speediest manner possible. These it would be improper to report upon, some being produced on cordons naturally of feeble habit, and requiring another season, and others not being autumnal sorts, and so unripe. But is it not evident that anyone planting a wall of diagonal cordon Pear trees at this time, if he also purchase trees two seasons old (as far as the newness of the sorts allowed), and attending to them with ordinary care, such as good walls call for—is it not evident that such a grower would realise results, gain experience undreamt of before, and, what is of no little consequence, form his own ideas of what Pears suited his taste?

Diagonal Pear cordons double-grafted, as some of mine are, on the Quince, two seasons old, purchased with promising buds —what a change from the days when "Pears were planted for one's heirs!"

Say a grower having a good wall 10 or 12 feet high, wired at the usual intervals—horizontal wiring is the best—purchases two hundred Pears, maiden trees, in pairs of sorts. This will give him one hundred varieties, which he can select out of many old and new Pears. Let him make a good trench along that wall, taking the usual precautions to have a well-drained border filled-in with fresh, maiden soil to place over the tender root-fibres. Then let him lay in the trees at 16 inches interval against the wires at an angle of 70° for the first season, not lowering them to 45° till, say, the third season. Growth should be encouraged to restore root action disturbed by change of position. The shoots should be merely equalised, unless very gross, and the leader steered by a light guiding rod at the proper angle. What mystery is there in all this which a lad would not fathom? Only common observation is needed, and no doubt need be felt as to results. The shoots at the winter regulation will all be cut-in to two buds, and the leader shortened by one-third to a fruit bud. Next summer these two buds will push forth, and these young shoots should be stopped back to 4 inches as soon as eight buds are developed; the second growth to 2 inches as soon as four are seen; the third growth to 1 inch as soon as two are seen. At the winter pruning all these will be cut back. If a fruit bud be clearly visible at the base, we may cut back to it; if doubtful, leave a bud beyond, and the next season will establish it as a permanent bearing fruit bud.

All these rules, seemingly empirical, are, however, useful in practice. After a time one becomes careless, and it is then good to read up the subject again.

The leader should be shortened very little, or not at all; at any rate, if well grown it will soon take care of itself. This supposes, of course, that the fruitful shoots have been well tended, and are becoming thick, healthy, and have plenty of fruit buds. Then the tree seems to advance of itself, and requires the mildest amount of skill. While your neighbours are wearying over the even-balancing of the wings of their "British fane," and covering their walls with slow stages of wood, having to extend each way as well as to rise vertically, your diagonals will be soon covered with handsome fruit, and you a judge of its value by the sure way of tasting. Your hundred varieties, being likewise in pairs, will enable you soon to compete at provincial shows with a dozen dishes of six or twelve fine Pears of varieties quite unknown, even by name, to your neighbours. You may lose the prize you seek for this reason, but it is not much loss after all, and you will still be far ahead of your competitors when knowledge has reached your judges. Remember also to thin with an unsparing hand, and every year you will have the same average of crop to rely on, increased, let me note, by the natural development of the trees.

Should you be dissatisfied with any variety, it is easy to remove it, and the short period which will render the trees fruitful will obviate any long uncertainty. What is the value of such a tree compared to your priceless time and labour?

These are some of the advantages of diagonal cordons. There are other forms, such as the standard, whereby to test varieties, but trees so trained are far longer in producing their fruit, are more difficult to train properly, and do not, as a rule, produce such handsome fruit as those on walls. We hear of splendid specimens grown on standards, and doubt not that for market purposes this is the best way; but where one man can raise a handsome Pear from a standard a score will be found unable to do so.

Let me hint to amateurs, Leave these trees to market gardeners, and to exceptionally good soils and local temperatures, keeping, of course, what suits your gardens for the bulk—shall I say the rougher part?—of your crop, and reserve for diagonal cordons on your walls a good place, and for the very best sort you can find or fancy. In this way all exigencies will be provided for. Where much is required cordons alone will not suit, but they are the most suitable to test new sorts and to grow them for the table, for succession, and for exhibition. It is possible that in these conditions your greatest triumphs will be found; at any rate, a vast amount of knowledge of Pears

will be obtained—a knowledge which will give you power. Already I could direct you to friends or pupils whose thousand trees, all pruned by themselves, would surprise many. What are one thousand or two thousand trees to such men on the cordon system? And think how much they must know of Pears and Apples! Pear and Apple trellises are simply splendid on the diagonal system, though I prefer walls for them. These standard trellises are placed in similar conditions to standards near them—the same soil, the same climate, the same pruner; where one succeeds the other will also. Should you desire many of one choice sort, then have ten or twenty cordons of it. Moreover, it has struck me that anyone planting such a Pear and Apple avenue might with advantage make use of some kind of light portable protection. As, of course, each side of the avenue would be composed of two rows of diagonal cordons (running different ways is best), these protecting shields could be attached between the two rows, which are but a few inches apart, or placed only on one side—that most exposed—at pleasure, thus sheltering both. In the spring they would aid to set the fruit, and be retained till July in position. During July and August they might be removed and replaced for September, only until the fruit was gathered. M. André Leroy used to employ with success straw thinly plaited behind his diagonal Apricots, and the light protecting walls which Mr. Rendle advertises, but which I have not yet seen, seem to me a most practical idea for such cordons.

I must pause here, though there is much to be added, only mentioning as excellent results of what is here advocated, that I had seven Pears of Belle Angevine [Uvedale's St. Germain] on a single cordon, weighing under 17 lbs. This is not remarkably heavy, but the Pear in question is exceptionally loose in texture, and weighs comparatively little. The colour, however, reminded me of the French Pears. We had Chaumontel of 1 lb. weight, General Todtleben very large and good, Beurré Superfin, all Huyshe's Pears, Rivers's Passe Crassanne, Summer Beurré d'Aremberg, Joséphine de Malines, Marie Guise, Dr. Trousseau, and many others, all ripe, and growing side by side, while the next season I am expecting to fruit a whole host of Mr. Rivers's very newest sort.

There are also here a number of Plum cordons, by which I test any sort. Of these, the Transparent Gage is one of the best. Of Jefferson we have too much; though fine, it often lacks flavour here. We have a large fan on a west wall, and two cordons on a south wall, and can say, without having any doubt, where it succeeds best. Many Cherry cordons I have removed, as the trees grow too fast for this style. Many sorts about which I am continually asked have been destroyed, as of little merit. I see them in the lists of all nurserymen the same as ever, and they may suit other soils, but my mind is made up about them.—Thomas C. Bréhaut, *Richmond House, Guernsey.*

CHRYSANTHEMUMS AT MR. FORSYTH'S, STOKE NEWINGTON.

Although Mr. Forsyth has not this year exhibited any of those admirable specimen plants with which he has gained so many prizes, his show of Chrysanthemums is nevertheless the best we know of near London. Indeed since Messrs. Salter, after many years of persecution by the suburban railways, which were ever threatening to take away their ground, and at last succeeded, we know of no place where so many varieties are grown, and grown so well, as at Mr. Forsyth's. Notwithstanding the season is generally acknowledged to have been very unfavourable to Chrysanthemums, the blooms to be seen in his show-house are but little inferior in size and quality to those we have seen in previous years. We noted the following as particularly good—viz., Jardin des Plantes and its sport Bronze Jardin des Plantes, the latter being especially fine; Mrs. George Rondle, Queen of England, John Salter, Empress of India, very fine; White Globe, Alfred Salter, remarkably fine; Golden John Salter, Prince Alfred, Venus, Miss Mary Morgan; delicate pink, one of the new kinds of 1869; Beverley, Golden Beverley, Lady Harding, Guernsey Nugget, Prince of Wales, Lady Talfourd, beautifully quilled; Princess Beatrice, and Lady Margaret.

Of new kinds Mr. Forsyth has an ample store, in which both large-flowering and Japanese varieties are represented; but these are so backward in their flowering that we cannot offer any opinion as to their probable merits. We shall therefore only name a few of them. Mrs. Wreford Major, rose, pink stripe, light centre; Miss Hope, silver white, shaded with lilac; Mrs. Moggeridge, white, shaded with pink, of compact growth; Ondine, and Beauty of Stoke. Of Japanese kinds there are Cry Kang, Criterion, and several others. There was also a promising pale rose Anemone-flowered variety called Princess Louise.

NOTES ON HOT-WATER PIPES, FLUES, AND PROTECTION.

Hot-water Pipes Sunk.—One correspondent tells us that he has studied the pages of the Journal, and has had as many pipes as would have been deemed necessary, and yet even in this frost of merely 8° or 10° he cannot obtain the heat required. It turns out on inquiry that the pipes, instead of being exposed fully on all sides, are sunk in a trench beneath the floor, covered over with stones, with gratings every 8 feet or so to let up the heat, as he was told by eminent scientific men that heat could not be kept down, that it must and would rise and get into the air. We must refer him for consolation to those men in whom he trusted. We shall only say that under such circumstances more than half as much more piping, we would almost say double the quantity, would be required than if the piping were thoroughly exposed.

Another correspondent complains of want of heat; his pipes, too, are placed in a trench, bricked on each side, and shelving nicely from top to bottom. Acting on the best advice, he has had the pipes painted of a mellow stone colour, and in order that no heat should be lost but all radiated, the sides of the trench have been painted of a shining black. The pipes are covered with a grating of iron and of wood, both rather open to let the heat pass freely. Here, too, we may remark that the pipes sunk may not be sufficient, as something like a third more would be required to give the heat of pipes exposed, but as they are they could scarcely have less fair play. For the free passage of heat, the wooden trellis will be far inferior to the iron one. True, heat will pass off from pipes of any colour, and yet the slightest consideration will show that the colouring of the pipes and sides is wrong. No doubt the white-coloured pipes will feel warm to the hand, but, on the whole, the white colour is better for conduction and reflection than free radiation. The colour of the sides is the very best for absorption, and thus takes off the heat into the bricks and the adjacent soil. Make your pipes black, if even with lamp black and a little oil, and the sides very white with paint or lime-wash; then, from the free radiation of heat from the pipes, and the reflection of heat from the side walls, we should be surprised if the consumption of the same amount of fuel did not throw nearly a third more heat into the atmosphere of the house.

Flues.—The complaints are endless, chiefly because, though the furnace bars have been well sunk, and there is a good rise to the flue, the smoke in long flues will come back, smothering you, and refuse to go along as it ought to do. The complaints are trifling in the case of small houses where the flues are short. In flues from 50 to 70 feet in length, when long unused, there is apt to be an accumulation of heavy damp air, even when the flue is clean. In somewhat short flues lighting a wisp of dry straw in the top of the chimney, and when that is flaring, lighting a similar wisp at the furnace, will often make all right, as the heavy damp air will thus be dislodged. But frequently in long flues, not used, perhaps, from March to November, this mode of proceeding will not be effectual, and therefore for them we recommend soot doors, one or two of which when opened, and a small fire put in, with such an amount of draught as would insure combustion, will generally do away with the evil. One gentleman says, "No wonder my flue would not draw; for, would you believe it? on examining the inside not only moisture, but even water-drops hang along the sides. Where could such moisture come from?" We can hardly answer the last query, but we can well believe the statement. We have had sore eyes and nausea besides from a long flue that makes several turns in a long wall after coming from beneath a boiler. Free draught seemed out of the question. The sides of the flue were beaded with moisture, and there could be no free draught until that was dispelled, and we had therefore to open first one and then another of the soot doors, and make a brisk fire in the flue with straw, shavings, and dry wood, so as to heat the flue and dissipate the moisture, and then the furnace drew well. There is another remedy which we have often tried when we were threatened to be smoked out of a stokehole; but though often very quick and certain in its operation we are almost afraid to mention it,

because in careless hands it would be attended with danger, and that is placing a little gunpowder on the lazy incandescent fuel in the furnace. This, when hard driven, we have sometimes resorted to. We have never used more than would be required for the charge of a common gun, wrapped it up carefully in paper, and then put three or four more folds of paper over it, shut the ashpit and other doors, opened the furnace door, and threw the parcel on the burning fuel, and there was plenty of time to get out out of the way before the explosion took place. This rarifies the air, and the draught thus obtained is kept up. We have never known the slightest injury done to anything if the quantity and care were as stated above, but there is danger if done at all recklessly, and that has deterred us from mentioning it, though the plan is often resorted to by washerwomen when they find the draught deficient in the wash-house copper. In such a case less than half the above quantity ought to do. If, however, flues are properly constructed, and have a good rise from the furnace bars, the great preventive against back smoke and want of draught when the fire is lighted at the first frost, is to use a little forethought, and light a brisk little fire now and then in a bright sunny day in September and October. This will secure a dry flue when you want it for use. With all our knowledge of flues we cannot account for this—we have seen two long flues, as much as possible alike in construction, height of chimney, &c., and the one if unused for a twelvemonth would roar away, like a fire out of doors, as soon as lighted, and the other would need humouring until the flue became heated and the heavy air rarified. In short, with flues in houses of from 20 to 30 feet in length there is seldom any difficulty, and if there is the least, a small fire in a soot-box at the bottom of the chimney will make all right. For such small houses, for combining neatness, firing from the outside, economy in first outlay, and economy of fuel, no means of heating will compare with the flue well cleaned and attended to. In all such small houses neatness, efficiency, and comfort in winter will be combined if the flue is inconspicuous and the top of it forms a part of the tiled pathway.

One more word on protection. We must remind our readers that shutting a stable door will not constitute safety unless every opening is attended to. We once lost a fine lot of plants in a pit though no frost could penetrate through the glass. The heat of the summer was so intense that it had drawn, without our noticing it, the wall-plate from its bedding. When the mischief was done we found that in many places we could put our fingers in. In cold pits, too, in severe weather we have known frost penetrate the brick wall when it could not pass in by the glass. To avoid this we have often placed a thin layer of straw tied neatly against exposed walls and sides of frames. Even in the case of brick pits used for forcing, when there was from 3 to 5 feet of brick wall exposed, the covering of that neatly with straw or other non-conducting material made a great difference to the amount of heat required inside. The wall then became a store-house of warmth instead of a continual waster. For this purpose we would much prefer that all such walls should be built hollow; they would be much cooler in summer and warmer in winter.—R. F.

ENTOMOLOGICAL SOCIETY'S MEETING.

The first meeting of this Society was held on the 6th November in the rooms of the Linnean Society at Burlington House. In the absence of the President, Professor Westwood, V.P., was in the chair. The meeting was very numerously attended, and a long list of entomological works presented to the Society's library since the last meeting was read, and thanks ordered to be sent to the various donors. Mr. Charles V. Riley, official entomologist of the State of St. Louis, North America, was elected a member of the Society. This gentleman has recently paid a visit to England and France, and has made some interesting observations on the Vine disease produced by the ravages of Phylloxera vastatrix.

Mr. Davis exhibited a number of admirably preserved caterpillars of Lepidopterous insects, amongst which were various destructive species, especially the great Goat Moth in all its stages, forming a most instructive series of illustrations of entomological biology.

Mr. F. Bond exhibited specimens of Zygæna exalans, a new British Burnet-Moth captured by Dr. Buchanan White in Braemar, and Catocala Fraxini recently captured in the Regent's Park, where other individuals had also been taken; also a remarkable suffused specimen of Sphinx Elpenor, the central portion of each fore wing being almost denuded of scales. The Rev. A. Matthews exhibited Throscus carinifrons and Cryphalus Piceæ, two small species of Beetles new to Britain. Mr. McLachlan exhibited specimens of both sexes of the singular wingless Bittacus, sent to him from North America by Dr. Hagen.

Mr. H. Vaughan exhibited specimens of the dark-coloured variety of Triphæna orbona from Scotland, known as T. Curtisii, but which he considered as a variety of the former, and Mr. Lewis made some observations on the synonymy of the species. The former gentleman also exhibited a singular nearly black specimen of Hipparchia galathea from Kent; and Mr. A. Müller a very large spongy oak gall from North America, also impregnated and unimpregnated eggs of Siballula flaveola.

Professor Westwood exhibited specimens of Formica herculeana, a very large species of Ant, being reputed, but not hitherto proved, to be a British species, of which great numbers had been found in a perfectly fresh state in the proventriculus of a specimen of the great black Woodpecker, Picus Martius, brought to the Oxford Museum, and stated to have been obtained near that city. He also exhibited drawings of two male specimens of Papilio Crino from Ceylon, in one of which some of the veins of the fore wings were partially clothed with brown hairs, of which the other specimen was destitute, the latter being the normal state of the species. Mr. F. Smith exhibited one of the Noctuidæ, apparently belonging to the genus Aplecta, captured alive by Mr. Gwyn Jeffreys at sea, two hundred miles from Nova Scotia.

Mr. Briggs read a paper on Zygæna Trifolii and its larva, detailing the result of his observations for many years past, and arriving at the conclusion that two distinct forms or species of Bornet-Moths had hitherto been confused in this country under that name.

ROOT SHOWS.

Messrs. Sutton & Sons, of Reading, held their twenty-second annual Root Show on the 18th inst. Some of Sutton's Champion Swedes, grown by H. Allsop, Esq., Hindlip Court, Worcester, weighed 28 lbs. each; the whole twenty-four roots averaged 22 lbs. each, and carried off the £10 10s. silver cup. These were followed by some remarkably fine specimens grown by J. Culverhouse, Esq., Abergavenny, F. King, Esq., Eastbury, and W. Joyce, Esq., Waterford. Mr. J. Cave's twelve prize roots of Sutton's Mammoth Long Red Mangold weighed 485 lbs.; one, a perfect giant, weighed 58 lbs. Those shown by Lord Ormathwaite and the Marquis of Ailesbury were also very fine. The Turnip classes were unusually good, but Kohl Rabi was not so fine as usual. Carrots, Cabbage, Onions, and Potatoes were excellent. The Judges were Messrs. Davies, Spearing, and Wilkins.

Messrs. Carter & Co., of High Holborn, also hold an annual Root Show, at which liberal prizes are given. This year it was held on Friday last at the premises of the Pneumatic Dispatch Company, and the different roots exhibited were characterised by great excellence. Some roots of Carter's Mammoth Prize Long Red Mangold weighed between 50 and 60 lbs.; and the Imperial Hardy Swedes were of great size, twenty-four turning the scale at upwards of 4 cwt. The collections included Carter's Champion Intermediate Mangold, the new Purple-top Mammoth Turnip, the Devonshire Greystone Turnip, and the Warden Mangold. Potatoes, Carrots, and Parsnips were also very clean and good. The Oxheart Cabbage from Mr. Robinson, which gained the prize, weighed 70 lbs. The Judges were Mr. Brebner, Norfolk Farm, Windsor, and Mr. Graham, of Bagshot Park.

DRYING FLOWERS.

The articles needed for drying flowers in rotundity of form are, river, lake, or sea sand (this is called white sand, it is sometimes of a bluish grey tint), a wire sieve with a wooden cover to fit its base, a paper knife, and a camel's-hair pencil. The flowers for this method of preservation, as for flat drying, must be freshly plucked, and without dew or any other dampness. Everything about this work must be thoroughly clean. The sand must be rubbed and rinsed in clean water till the water flowing through it is as clear as that from a well. Then put it in clean crockery dishes to dry. It must be perfectly dry and just blood-warmth when the flowers occupy it.

When the sand is of the right temperature, close the cover over the base of the sieve, and pour it in till it fills the whole space beneath the wire cloth. Place the flowers in an upright or natural position by inserting their stems in the apertures of the wire-cloth till they rest firmly in this sand below. Do not crowd them, nor, if sprays or panicles are dried, let the flowers overlap each other to injure their form. Fold a sheet of stiff white paper to make a cone-shaped tunnel, and pour the warm sand through this around and under and within the flowers. The cone should be folded to give the smallest possible stream of sand. After filling in around the flowers, sand must be sifted over them, warm, to the depth of half an inch. Then set the sieve where it will keep the temperature of 70° steadily, till the flowers are dry.—(*Horticulturist*).

Revival of Fruit Trees.—George B. Wood, M. D., reiterates the arguments urged as to the benefit arising from the copious use of potassa salts in the manures applied to fruit trees. This experience bears out the view that the manure should be in accordance with the chemical composition of the plant to be

recruited by it. The form in which he prefers to apply the salt is in that of ashes of plants which contain a large per-centage of it, such as Potato stems, Beans, &c., which contain as much as five per cent. In the autumn of 1869 he dug round the stems of half the trees in an old orchard, which had not borne fruit for five or six years, to the depth of 5 inches, and filled up the space with about half a bushel of fresh ashes. In the following spring and summer a dividing line might have been drawn between the two sections of the orchard, the trees which had been treated with ashes being forward and full in both leaf and blossom, and subsequently presenting a still more marked contrast as the autumn came on, and they were loaded with Apples, while the other trees remained barren. Exceedingly favourable results were also obtained when aged Peach and Plum trees were treated in a similar manner. Crude potash may also be used, but care must be taken that it is sufficiently diluted before it is applied.—*American Philosophical Society, Philadelphia.*

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 22.

I HAVE already called attention, in one of my papers, to the fact that amongst the few caterpillars to be found feeding late in the autumn, that of the Large Garden White (Pieris Brassicæ), is notable. Indeed, I have seen some of these so small towards the end of October, as to favour the supposition that they occasionally hybernate. Most of them certainly enter the pupa state before winter, and passing a garden the other day where many of these caterpillars had been feeding up, I saw a number already in the pupa state, and others about to change. I notice this comparatively trivial circumstance only to show that naturalists are constantly exposed to error through coming to hasty conclusions from imperfect observations. Upon a paling a short distance from the spot where the bulk of them had fed up, a number of larvæ were scattered about, in various positions, each one the prey of the larvæ of the parasitic fly, which is the peculiar foe of this species. There were very few, indeed, which had escaped and become pupæ. Now, the first impression of an observer would be this—"How extensively, in this instance, has the species been attacked by its parasitic enemy?" Yet further investigation proved that these were merely the stragglers. Plenty of healthy pupæ were to be found nearer the food plants; and though the fly had, possibly, made an attack upon a rather larger proportion of the caterpillars than usual, there were not so many sufferers as might be supposed. The caterpillar of Pieris Brassicæ, when thus affected, is smitten with a desire to wander; there is something wrong in its interior, and it cannot understand it; so that when it has ceased to eat it travels away from its food, making abortive attempts at last to undergo its transformation at some distant spot, and there it dies. I find on inquiry amongst my friends, that though very few of the spring brood of these caterpillars were to be seen, the autumn brood has been numerous in some districts in the south of England.

The history of the largest British Moth is so singular and interesting that it ought not to be passed over, though it would be a question for consideration whether it really does commit any ravages of importance. Yet as, whenever it is seen, either as moth or caterpillar, it is regarded by the uneducated (and sometimes by the educated) gardener with dislike, or even with dread, it has some claim to be noticed. The Death's Head Hawk Moth (Acherontia Atropos) appears on the wing in small numbers, in October and November, at a time when insect life is almost stagnating. Still the majority of the individuals come abroad as imagos in the summer, and this for some considerable period rendered the life history of the Death's Head rather a puzzle to us. However, thanks chiefly to the exertions of Mr. Newman, its economy has been elucidated, and proves to be rather peculiar in some of its details. The autumnal specimens of this Moth are mostly females, and though a few may live on through the winter, most of them die without making any provision for the continuance of the species. Those which continue in the pupa state until the year following emerge as moths in June and July, and deposit eggs in the usual way. There is only one general brood of the caterpillar of the Death's Head, and this occurs during July and August.

The Rev. J. G. Wood has given an amusing account of the consternation which pervaded a group of villagers just returning from church, when one of these Moths was discovered resting on the footpath. All drew back in amaze and fear, until a blacksmith, the sturdiest individual of the party, stepped forward, and with a sudden and dexterous spring brought his heavy heel down upon the luckless insect, and people breathed freely. Authors say that it is regarded with dislike on account of the shrill cry it makes, and the skull-like markings on its thorax, but in this case it does not seem to have been heard or closely scrutinised. Probably it shares the indiscriminate dislike with which too many people regard insects of any sort, the feeling being intensified in this instance by the size of the moth. The caterpillar, as is abundantly proved by the communications of entomologists and others to our journals during the last few years, is called in many districts a "locust," or "lokus," a singular designation, and in every way inappropriate. Though occurring in Potato fields, and on patches of Potatoes in gardens (and in some seasons rather plentifully in certain districts, especially in the midland counties), I am not inclined to believe that it does any notable amount of injury to this important vegetable. For instance, both in 1865 and 1869 there were many records of its occurrence, and yet there were no proofs that the Potato crop was diminished thereby. Certainly from the large size of this caterpillar, and the time it occupies in growing to maturity—about two months, I believe—a single caterpillar would consume a considerable quantity of leaves during its career, but I have yet to learn that in the particular season of the year when it is about, much harm, or any, in fact, is done to the Potato plants by the removal of a portion of their leaves, especially those near the ground, and which are already beginning to undergo decomposition. For these, it is said, the Death's Head caterpillar has in several instances shown a partiality. It is, at least, well ascertained that though this huge creature conceals itself sometimes during the day beneath the surface of the earth, it does not gnaw the tubers of the plant.

The caterpillar of which we are speaking, though most frequently discovered on the Potato, occasionally shows itself on allied plants. The Jasmine is established as one of its food plants, and also the Privet and the Thorn Apple, and it is found now and then on other species. As Rennie observes in his remarks on the species, since it appears to be decidedly indigenous, it no doubt fed upon the native species of Solanum and different Apocynæ before the introduction of the foreign species, the Potato and Jasmine, to which it now shows a preference. On the Continent, the Death's Head caterpillar occurs on fruit trees, such as the Mulberry and Pear. It is evident from the habits of the species, that were it necessary to keep it under, an examination of the plants by night with a lantern would be likely to be of more utility than searching for it in the daytime. Nor would it be impossible that this insect should so increase in numbers as to be harmful, but this circumstance is highly unfavourable to it—at the period when the Potatoes are dug up principally, it has gone into the pupa state. Many must be killed by the spade or fork, and others which are tossed on one side with the clods are exposed to the weather, and as it is not very hardy while in the pupa condition, probably most of the latter also perish. No doubt it is a very wise provision for the partial preservation of these pupæ from destruction, that the caterpillars when they have reached their maturity descend some depth below the surface, and thus are not only less likely to be unearthed by man or animals, but they also secure for themselves a measure of immunity from too much moisture and hard frost.

The caterpillar of the Death's Head Moth, like the rest of the Sphingine, is furnished with a horn above the tail, which in this instance is recurved in a way peculiar to the species. If it serves any purpose beyond that of ornamentation, it has not been as yet discovered. There are two varieties of this caterpillar, which differ from each other not only in colour but also in the character of the markings. The moths, however, produced from the typical form and the seemingly abnormal are exactly alike. If annoyed it attempts to drive off its enemy by uttering a peculiar sound, which has been compared to the snapping of electric sparks. There is not, though, anything of an electrical nature about the caterpillar; and though its powers of biting must be proportionate to the size of the jaws, I find no record of any instance of an individual having attempted to defend itself in that way when handled by an investigating biped. But, as I have repeatedly observed, some of the larger caterpillars are by far the most pacific, while such as those of the Buff-tip and Dagger Moths will repeatedly attempt to grip the finger if it is presented to them.

The moth is itself a predatory insect in our gardens, if not of our gardens, which it visits at the dusk of evening, seeking

honey not only from flowers, but from bee hives. The fact, long questioned by some, is undoubtedly well authenticated, that the Death's Head Moth, drawn to the hive as we may suppose by its sense of smell, does attempt to gain admission. If bees had the ability, they might inscribe upon their portals the motto, "All hope abandon, Death's Head Moths who enter here," for should one succeed in penetrating to the interior of the hive, it is dispatched by the stings of the revengeful Hymenopteron and embalmed, since it is too bulky to be removed. An instance was noted only last year where one was discovered in a hive. A correspondent of a scientific journal writes as follows:—"I was preparing to drive some bees located in a common straw hive, and on raising it from the floor-board just by the entrance, I found a very fine specimen of the Death's Head; the insect was quite fresh, and looked as though it had been killed in the most careful manner possible." Why this moth should thus visit bee hives, when many other species whose passion for sweets is as strong or stronger never approach hives at all, is not easy of explanation. Some assert that it does this, because it can intimidate the bees by means of the singular and plaintive cry which it has the power of uttering.

If you should happen to pass during the month of June some freshly-tarred paling, it is very probable you will find that it is studded over with specimens of the moth known as the common Swift (Hepialus Lupulinus), for it has a decided propensity for thus immolating itself. The flight of the species, as of its brethren, is wild and peculiar. Stainton observes that the caterpillar feeds on the roots of herbaceous plants generally; and Newman, in his recent work on moths, mentions the Dead Nettles (Ballots, Lamium) as its favourite pabulum; but it is also a feeder upon the roots of the Potato. I had myself often noted the occurrence of the moth on palings near Potato fields at Battersea, and wondered as to the reason of this, feeling assured that it could be accidental merely. The moths deposit eggs during the summer, and the larvæ, hatching shortly after, feed on until April, and might thus do a good deal of mischief were the species more abundant; at present, however, it is scarcely common enough to excite alarm. The larvæ, being subterranean, could not very well be sought out, but the moths might be easily destroyed by putting into effect against them some device suggested by their habit already noticed, of darting against a tarred paling, which is odorous and sticky.

It will be worth the while of anyone who should turn up a caterpillar of the Swift when he is digging Potatoes, to examine it, and notice how exactly its form is suited for the life it leads. The body is strong yet pliant, nearly colourless; the head provided with powerful muscles and glabrous; the segments which immediately follow the head are protected by horny plates. The legs are sixteen in number, as in the rest of the division of the Lepidoptera to which it belongs.—J. R. S. C.

HOW NOT TO HAVE NICE FLOWERS.

To begin with, beg seeds of all your friends who cultivate flowers; never mind what kind they are; it is not worth the trouble to remember; then when you put them in the ground, of course you cannot arrange them with any regard to height, colour, season of blooming, &c., but must sow them as you have gathered, promiscuously. Lay out your beds in the grass and dig them all of 2 inches deep, but certainly not over a foot. If this is done some wet day the sod will cut easier, and the soil will be in nice large lumps. Dig a hole about 6 inches deep and 2 in diameter among these lumps, pour in half an ounce of your most delicate flower seeds, and if they don't grow blame the one you got them of. If you happen to send to a seedsman for a few kinds, his reputation will be much enhanced by it.

Don't pay any more attention to them until you see other people's flowers in bloom, then pull out some of the largest weeds and wonder why you don't have any luck raising flowers. Don't dig around them for fear of disturbing the roots; don't thin out the plants, for you want to get the worth of your money; don't prune off any of the branches, for there won't be room for so many flowers. Don't pick any of the blossoms, but let them all go to seed, then sit down and say that a seedsman who sends seeds that won't grow ought to be compelled to send enough more to make it up.

Go right back to the friends you begged seeds of last year, and call them mean and stingy if they don't give you as many more. Of course, they can pay a good price for rare varieties, and then distribute them gratuitously with the greatest pleasure imaginable; in fact, you are rather favouring them by accepting. If you have summer bulbs, forget to remove them to the cellar until the ground is frozen up.

When you find farmers can raise Potatoes by planting a bushel in a hill, or excellent Corn without hoeing or cultivating, you will probably produce nice flowers from this sort of cultivation. I have been an eye-witness to several cases of this sort of floriculture.—Loretta E. Knapp (*Rural New-Yorker*).

GORHAMBURY.—No. 2.

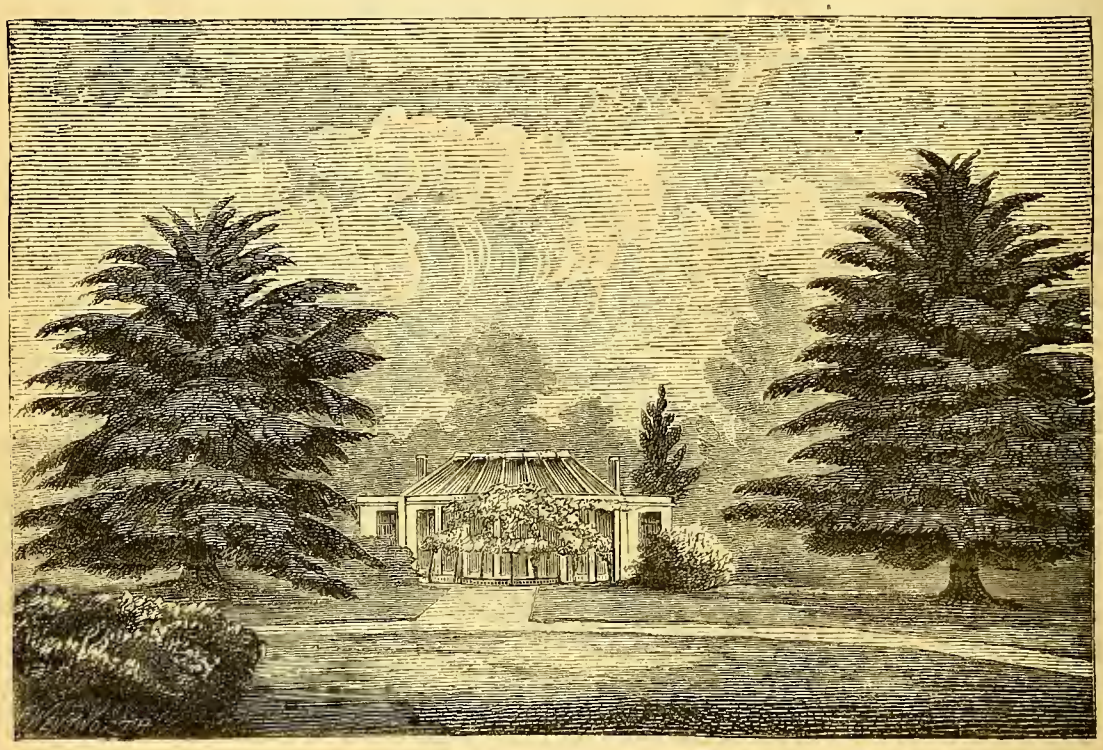
Leaving the flower garden, and directing our steps westward, we come to the conservatory. This used to have a dark roof, but it is now chiefly covered with glass. The tall upright windows and lofty parapet remain as before, the latter hiding the glass roof from view in the grounds. The plants usually met with in September were therein at the time of my visit, but the one which particularly struck my attention—although possibly as old as the building itself—is so far from being common that I am not aware of having seen it before. It is the Cissus antarctica, an evergreen climber, covering the back wall with a verdure equal to that of the Ivy, and like it, too, clinging to the walls by the same means. I do not know whether this Cissus flowers or not, but its lovely green foliage, a great deal smaller than that of the Ivy, seems to be well adapted for covering a dark wall, where Ficus repens will hardly endure the cold. Will any reader state his experience of the Cissus, which at Gorhambury covered a wall at least 60 feet long by 16 feet high? Near to this are several fine Cedars of Lebanon, some with fine clear stems, others branched to the ground. Amongst the former were several particularly fine-looking ones, said to be just sixty-two years old, and presenting a fine, clean, uniform-shaped bole. One, on measurement, was found to be upwards of 11 feet in circumference at 5 feet from the ground, where the bole was as smooth as a ship's mast and tall, with a leader still going upwards.

Following the easy curves of a walk in a south-westerly direction, and passing through a great extent of shrubbery, interspersed with some fine Oaks, we again emerge into the park for a short distance between the dressed grounds and the kitchen garden. Here a fine Oak attracts attention by its healthy appearance, length, and straightness of bole, which, at 5 feet from the ground, is upwards of 16 feet in circumference. Although we are now in the open park, and within less than 200 yards of the garden wall, we cannot see a vestige of it. A belt of trees and shrubbery surrounds it on all sides, serving to afford the shelter so much needed to all within. Externally this belt of trees and shrubbery presents the form of an irregular oval, with its longest diameter north and south, the kitchen garden proper, or that part of it enclosed within the walls, being almost a square, and with a central wall dividing it east and west into two compartments. From this latter a very large slip stretches away some distance to the south, and contains some cold pits as well as heated ones, and the usual appendages of what is called the framing ground. There are Melons and Cucumbers in abundance at the time I was there, as well as good stocks of fine healthy Chinese Primula, Cineraria, and herbaceous Calceolaria, for the whole of which Mr. Bogue, the gardener, is remarkable for having the best strains in the best form. We retrace our steps, and on entering the kitchen garden are attracted by a large breadth of ornamental Beet. This Beet Mr. Bogue has had for upwards of twenty years, having commenced to improve the old kind some years before that time, and he thinks it was as good both in colour of root and leaf twenty years ago as it is now; he therefore, with some justice, claims to be one of the originators of this ornament to the flower garden, though for many years it was simply called an improved Beet, or some such name, in the catalogue of Messrs. Osborn, of Fulham. Grown in a mass, as it was at Gorhambury, nothing could look more uniform, each individual plant being a counterpart of its fellow. Mr. Bogue, I may observe, also grows it in the flower garden, and in many other places, in all of which it looks well.

The forcing houses are against the north wall, with the sheds and other appurtenances behind them. An excellent crop of Black Hamburgh Grapes occupied one of these houses, the bunches of which, though not very large, had good-sized berries upon them, and by their firmness of touch, as well as by the healthy appearance of their foliage, gave token of keeping the usual time. Each bunch was firm and compact, well coloured, and just the size to show well on the dessert dish. Amongst them was a seedling black Grape, somewhat of the Lady Downe's shape, but of exquisite flavour, having a decidedly Muscat taste,

more so than I remember to have noticed in any other Grape partaking of that nature. I omitted to inquire of Mr. Bogue the history of this Grape, but I hope it is not destined to linger unnoticed in its present abode, as I believe it is as hardy as the Hamburgh, colours well, has round berries, and foliage of a healthy hue. The next house contained some of the best Muscats I have seen this year, there being scarcely a vestige of shanking or spot, from which causes in many places the crop is destroyed. Such a house of Muscats many a person would be proud of, and Mr. Bogue said they had been equally good last year, and for several years before that; thus showing that with careful and skilful management, and a judicious preparation of the border at first, this fruit may be grown without shanking. Neither the house nor the border is in any way remarkable, but both the Black Hamburgh and the Muscat of Alexandria were all that could be wished.

But lest the reader may think that I have overpraised the Grape culture, I will mention a fruit with which the results have been very different, that is the Peach. Mr. Bogue has failed to secure good Peaches from the walls after many years' trial, and frequent planting of new trees, until at length he has entirely abandoned growing them out of doors, and keeps some in houses as healthy and in as good bearing condition as could be wished. This difficulty in obtaining Peaches on the walls is not confined to Gorhambury, for we have heard of it in many places, but here it was plain enough. On the forma-



CONSERVATORY AT GORHAMBURY.

tion of the last Peach house, Mr. Bogue having a good space of south wall to spare, determined on one more effort. The soil was removed and fresh wrought in of the same kind as that used for the trees to grow in in the new house, but all in vain, for after a year or two they dwindled away, and there only remained some wretched-looking objects compared with those under glass and with some Apricot trees by which they were associated. The Apricot does remarkably well here, there being a wall of considerable length devoted entirely to those trees, from off which good crops had been gathered during the present season, and the same had been the case with Peaches in the houses, the latest one hanging still in fruit. On the other walls were excellent crops of Plums and Pears. Amongst the former I noticed as good, Pond's Seedling, Reine Claude de Bavay, Jefferson, Victoria, Golden Drop, Magnum Bonum, Kirk's Plum, Green Gage, and several others, the early ones having been gathered. Pears were also represented on espalier trees by the sides, as well as on the walls, while there were several open standards of Pears and of Apples in the west slip.

Extensive slips for the growth of fruit or vegetables surrounded the garden on all sides but the north, which might be called the back of the garden, and in these slips were crops of fruit good for the year, seeing that Apples and Pears are very scarce this season in most places; and although the crop here was not so heavy a one as that of last year, it must be pronounced a good average one. The Celery I saw in the kitchen garden was most excellent. Mr. Bogue has endeavoured to improve this important vegetable, and by selecting the best varieties has, in the course of years, succeeded in checking that tendency to run to seed which most kinds of Celery have when grown too early. Solidity of stalk and hardihood are also essential, and the quarters of this vegetable showed an evenness of growth, proving the uniformity and good qualities of the kinds grown. Mr. Bogue told me that he had not been so successful with winter Broccoli, the disasters of last season proving too much for all the sections of this numerous family, excepting a few of the very latest. Let us hope, however, that a winter like the last one will not often be repeated, and that the growth of this vegetable, checked as it has been by the dry weather in August and September up to the 22nd, will not partake of too much grossness after the autumn rains set in. This was the misfortune of last year, when mild growing autumn weather almost up to the time of severe frost, caused many of the winter crops to become quite 5 feet high, and as tender as a greenhouse plant. We are now led by our worthy cicerone to an open spot in the park, whence a good view of the surrounding country is to be obtained. Near here the former mansion of Gorhambury stood, the residence of the great Chancellor Bacon, and an old Oak is still pointed out as his favourite tree. The traces of that edifice have, however, been too completely obliterated to leave sufficient marks to judge of its character. Another building has also stood near at hand, but whether older or more recent than the one occupied by the great philosopher we are not able to say.

Great places like Gorhambury, however noble in themselves, are not always supplied with all the modern improvements so essential to comfort, and here an ample supply of water has been long felt a necessity. For many years a deep well and horse pump were the means of supplying the mansion, but the pump being at some distance, Lord Verulam determined to dig

another well of great depth in a more convenient place, which has been done, and fitted up with improved machinery. In such places rain water is prized, and Mr. Bogue has all that can be caught preserved in tanks, and only when these are empty does he resort to that from the well, as chalky water is injurious to most plants.—J. Robson.

VERSCHAFFELTIA SPLENDIDA.

The magnificent Palm here pourtrayed is a native of the Seychelle Islands, belonging to the dependencies of the Mauritius, and when first introduced to our gardens, in 1864, was known by the provisional name of Regelia majestica. The stem is slender and of somewhat quick growth; as it increases in size it sends down adventitious roots, which in the form of an inverted cone ultimately serve to support the tree after the manner of the genus Iriartea of the American continent, and

VERSCHAFFELTIA SPLENDIDA.

give to the plant a most singular and picturesque appearance. The stem is profusely clothed with very long black needle-like spines, which spread around it in a fanlike manner. The petiole is short, with the exception of the large, broad, sheathing base, which completely envelopes the stem, the latter portion being abundantly armed with long black spines, whilst the footstalk is only about 6 inches long and perfectly smooth. The leaves are entire, broad, somewhat serrate at the edges, and deeply bifid at the apex; they are of a rich bright green in colour, and in a plant of some 3 or 4 feet high the blade will measure from 3 to 4 feet in length and nearly as much across. One of the peculiar features of this plant is its broad entire leaves, which is one of the distinguishing characteristics of the genus.

Verschaffeltia splendida is the only true species in the genus, although we have another in our gardens which is at present recognised as a second species. I allude to V. melanochætes. This plant, although similar in habit in a young state, entirely differs in character with age, producing broadly pinnate fronds; and its seeds, moreover, which is a more certain indication, will entirely separate it from the species now under consideration. I shall now add a few remarks upon its cultivation.

Many gardeners do not like it, and say that it is difficult to grow. I can only tell them that no plant can be more easily grown into a fine specimen, and that those who fail to appreciate the beauties of this plant must indeed be extremely difficult to please. It is majestic in appearance, and so thoroughly tropical in aspect that it has never failed to strike me as one of the most superb introductions of recent years.

Referring to the culture of Verschaffeltia splendida one point must be thoroughly impressed upon my readers, and that is, it must have an abundant supply of heat and moisture to develope its beauties. All growers of Palms may accept this as a golden rule, that the more spiny the character of the particular

plant or plants under their charge, the greater the amount of water necessary. Having proved this to be the case, I am not an advocate of very large pots or tubs for these plants, but prefer using a pot in proportion to their size in a young state, and as they increase in growth confining them somewhat, supplying the deficiency by an extra supply of water. The soil I prefer for this plant is a mixture composed of about equal parts of good peat and loam, with sufficient silver or river sand to make the whole gritty, and not pressed too hard down into the pot, as I have found it, especially in the young state, grow more rapidly when potted rather loosely. In addition to its highly decorative character in the plant stove and the exhibition tent, I have frequently seen this plant used when young for table decoration with excellent effect; and where the artificial light does not proceed from gas, it can be done with less fear of injury to the specimen, which is always a matter of vital importance to the gardener.—Experto Crede.

[We are indebted to the kindness of M. Rothschild for the portrait of this Palm, which was published in M. Alphand's "Promenades de Paris." If a coloured portrait of this Palm is wished for, it may be referred to in the "Flore des Serres," where M. Van Houtte observes, "This Palm and Stevensonia seychellarum at present are the more majestic ornaments of our hothouses."—Eds.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

Continue to attend to previous directions and make all possible speed in carrying them out in suitable weather. See that a store of dusty earth is procured and kept convenient for protecting early Peas and Beans, for shaking among Lettuces, young Endive, late Radishes, and similar crops if we get much wet. Dry dusty loam, with a little dry lime rubbish, or old mortar pounded, sifted, and mixed together, will not only prevent the injurious effects of frost, cold rains, and canker, but will greatly improve the health, sturdiness, and luxuriance of the plants when the growing season once more arrives. Take advantage of frosty mornings to wheel manure on quarters where it will be wanted, and let all spare ground be trenched and ridged as soon as possible. *Endive* is blanched for salad and kitchen use by various means; the method I prefer is, after tying it up when perfectly dry, to cover with dry leaves as much as requires to be blanched at one time, throwing a little long litter over them to prevent their being blown about. *Celery*, *Cardoons*, and *Leeks* should be earthed-up in dry weather. *Broccoli*, *Borecole*, &c., the ground may still be hoed between the rows, also that between *Winter Spinach*, throwing it out to 16 inches apart.

FRUIT GARDEN.

Planting young trees and removing others should be proceeded with as expeditiously as possible, for the sooner this kind of work is finished for the season, the less trouble will be required in watering next spring and summer. Pruning and nailing should now be proceeded with every fine day, even although it should delay some other work which can be done with more comfort in bad weather than nailing; it is most important to get the latter done while the weather is mild. Nailing is a cold-enough job for even a warm winter's day, but to turn men out to it in very cold or wet weather, and to expect them to do a fair day's work, indicates bad management.

FLOWER GARDEN.

Now is a good time for taking-up and laying down Box edgings. This is also a good season for altering the surface of the flower garden. It is, perhaps, the best season of the year for laying down turf as far as regards facility and success. If the ground is newly made see that it is rendered perfectly solid before laying down the turf, so that there may be no giving way afterwards. When all is laid down it ought to be well beaten all over with the turf-beetle, which will close the edges of the turf, flatten-out the surface, and level down all irregularities. Follow-up the directions given, especially where neatness and order are required, bearing in mind the necessity of removing all leaves and rubbish to a convenient spot at some distance, to decompose as well as to destroy the eggs of insects. Dahlias temporarily placed heels upwards under cover to dry, should now be carefully stored away for the winter. See that coarse plants which may be encroaching upon their weaker neighbours are reduced so as to occupy their proper places. Gladioli may still be planted, but most kinds of bulbs are now better in the ground than out of it. For Gladioli choose a warm, thoroughly-drained situation, work the soil well by deep digging, and add plenty of rotten manure. Elevate the bed or patch a few inches above the general level, plant the bulbs 5 or 6 inches deep and 6 inches apart, and surround them with 1 inch of sand before covering with soil. Protect during winter against excessive wet and frost with a thick layer of sawdust, old tan, dry litter, and old carpet-thatched frames, or tarpaulin. The three last-named coverings must be removed during favourable weather, and the former coverings entirely cleared off when the plants appear. As tree leaves are always in request, either as fermenting material or for leaf soil, they should at this season be carefully collected. If they are required only as a manure, they may be stowed away in any bye place and left to decay; but if, as is generally the case, they are in demand as a cheap mode of furnishing bottom heat for forcing different kinds of vegetables, some pains should be taken to keep them dry. For this purpose they should be stacked-up in some back place, and after allowing time for them to settle, put on a coat of thatch to effectively secure them from rains. By these means they will be found in a fit state for use for some time to come. Should any surface soil of the pots of Auriculas assume a wet mossy appearance, it will be evident that the drainage is affected, and the sooner it is examined the better it will be for the health of the plants. Water must be given sparingly, and constant attention will be requisite to insure a finer bloom in spring. When I say constant attention, I do not mean that anything very laborious will be required—in fact, the success of all cultivators of florists' flowers depends more on their attention to details than to any hard work applied at intervals. Carnations and Picotees which have been placed in frames after potting must be gradually inured to the weather, for like other hardy plants of the Dianthus genus, they are extremely susceptible of confinement and consequent damp. As for Pinks and Pansies, the only attention they will require at present is to fasten them after the frost, and to keep them free from worms.

GREENHOUSE AND CONSERVATORY.

Chrysanthemums, in most instances, will be the chief feature of attraction here at present, and where they are largely grown, which they should be wherever there is a demand for flowers at this season, they make a fine display, and are worth every necessary attention to preserve them in beauty as long as possible. They are very impatient of a close rather warm atmosphere, and if the house contains plants requiring this treatment, the Chrysanthemums should, as far as practicable, be placed in the coolest part where air can be given freely on every favourable opportunity, for unless they can be rather freely exposed to air their foliage is soon attacked and disfigured by mildew, especially if the plants are bushy and well grown. See also that they are kept well watered at the root. Use fire heat only when absolutely necessary either to prevent the temperature from falling too low or to dry the atmosphere. If Geraniums, Cinerarias, and Calceolarias must be wintered in the same house with Heaths and other hardwooded plants, they should be kept as much as possible by themselves, as they will require a somewhat closer temperature than hardwooded plants. The bulbs of the various Japan Lilies should now be shaken out and repotted in pots of a size to correspond with their strength. This beautiful family of plants delights in a good holding fibrous loam with a portion of coarse, clean, sharp sand, and a good supply of charcoal intermixed; the pots to be well drained, and a good portion of rubbly charcoal laid over the drainage. The bulbs only require to be just covered, while the pots in the first place should be only two-thirds filled, for as the plants put forth abundance of roots for 2 or 3 inches up the stem, they may be considerably assisted by earthing-up in spring. Roses for early forcing should be pruned by this time, and placed where they will, at least, be safe from heavy rains. Where American and other shrubs are used for forcing, they should be taken up and potted without delay, placing them in a cool pit until they are wanted for forcing, or in a turf pit, where they can be protected from severe weather by straw mats, shutters, or other covering.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Cauliflowers.—As yet we have found the mode of protection described as given to banks and borders of plants in the open garden effectual, so that fine heads have been gathered, and none that received the protection have as yet suffered. Much,

we think, depends on the long litter placed between and well up the stems, which is not touched, and helps to keep the ground warm. The little that is laid over the top of the plant is lifted off in a fine day and replaced when the evening threatens to be frosty. We suffer least from the attacks of intruders when the plants thus stand in the open air instead of being taken up and put in earth pits.

Lettuces have also as yet stood well; but as it is advisable to be safe we emptied some space in frames, and filled it with Lettuces fit for use and approaching their best. Celery we covered for several days and nights when the weather was severe, but on a change uncovered at once that the heads might be kept green and hardy. A nice piece of Radishes out of doors has been kept well by placing a sprinkling of rough hay over them on frosty nights.

Put more roots of Rhubarb and Sea-kale in the *Mushroom house*. We earthed-up a second piece of a bed, spawned a third, and got a fourth piece in preparation, as we chiefly depend on many and small successions. The platform or shelf bed that we stated had become rather cold is now coming in nicely, the heat being restored by the manure that was placed on the ground beneath it, and where a bed will shortly be formed. Many such schemes must often be resorted to. We have a bed just now that has cooled too suddenly and is not yet spawned. If some simpler modes fail to restore a gentle heat we will mix some barrowloads of fresh horse droppings with the bed, and tread and beat it down afresh. This will give us all the heat we want, but with a loss of time. At this season of the year the easiest way of getting a mixture of droppinge and short litter sufficiently dry is to throw them into a compact heap and cover them with a little long litter. This will cause them to heat rather violently and so far lose a part of their fertilising powers, but then you get the material quickly in a suitable state of dryness. Some of the best Mushroom beds we ever had were made of tree leaves that had been collected damp, and placed in a heap until they heated so strongly as to destroy all spores of fungi, and send all slugs out of the way. All the outside of the heap not sufficiently heated to effect these objects was removed, and the central part chiefly taken and made into a bed from 12 to 15 inches deep. This, as the temperature moderates, will retain a mild heat a long time, and on being surfaced with 2 inches of droppings it was spawned, and, when there was no danger of overheating, from half an inch to an inch more of droppings was placed over it. The chief drawback to using leaves more freely for Mushroom beds is that they often contain the spores of many fungi which would thrive well in the mild heat of a Mushroom bed. Other manures, as a little green grass, would contain nitrogen; but they are apt to bring spores along with them, many of which would survive a high temperature, and would soon destroy the spawn of the cultivated Mushroom.

Cucumbers.—We have just, on the 25th, pulled out the plants from five lights in a pit, as we much wanted the room and though the Cucumber plants were vigorous and healthy, the fruit did not swell to our satisfaction, partly from deficient heat, but chiefly because the plants lay on the soil in which they grew. For all winter work the plants will thrive better when they are trained to a trellis a foot or more above the soil. When we used to have Cucumbers very early by dung heat alone, we found they did best thus free of the soil, even if the trellis was nothing better than a limewashed old hurdles laid across the bed. We have been rather uncertain what to do with Cucumbers lately, because our early-spring Cucumbers have continued to succeed so well in a small pit heated by hot water. We forced ourselves to destroy part and plant afresh. Another part is still producing so profusely that we have let it remain. The sort is Cox's Volunteer, a most prolific kind. We obtained stout plants to fill the space, but were rather afraid of them, as there was only a wooden division between them in a pit slightly heated and chiefly filled with Scarlet Geraniums in bloom. We could not well move the plants, so we put a mat in addition on the cold side of the wood division, tied some straw round the wall, and in the evening put a mat on the glass, and thus we have kept them all right, although the thermometer was not above 55° on the cold nights. In the proper pit, as we have not enough of heating power without making the pipes hotter than we like, we think that some of the success is owing to covering the glass in cold weather at night. Of course we make no reference to the Cucumber disease, for when it troubled us we adopted a similar treatment. We might have removed the young plants referred to from the comparatively cold pit into the warm one, but we were unwilling to do so until the latter was thoroughly cleared out, washed, and lime-and-sulphur-painted.

FRUIT GARDEN.

By turning over some of our beds we managed to get some Strawberry pots, where there was the slightest bottom heat, under glass. We cannot find space to tell how, how by clearing, &c., we prepared the five-light pit for the reception of Strawberry plants next week, leaving it a couple of days open to get frost, it being also an enemy to all insects. The Strawberry pots in beds on the hard soil kept well with the slight covering of litter, and we might have let them remain so, but by moving bedding plants from earth pits we obtained more room. We got under protection the most of the Strawberry plants that we do not intend moving on slowly.

ORNAMENTAL DEPARTMENT.

The chief work was having the last of the Calceolaria cuttings inserted in a cold pit, and getting the whole of the flower beds—unfrosted and frosted—cleared away, and moving against our will lots of bedding plants under Vines, because we felt we were scarcely sure with so many boxes of struck cuttings laid across earth pits under old rickety sashes. The little rough litter has hitherto kept all right, and the place thus occupied came in for the Strawberries.—R. F.

TRADE CATALOGUES RECEIVED.

James Dickson & Sons, Newton Nurseries, and 102, Eastgate Street, Chester.—*Catalogue of Forest Trees, Ornamental Trees, Shrubs, Evergreens, &c.*

Peter Lawson & Son, Edinburgh, and 20, Budge Row, Cannon Street, London, E.C.—*Catalogue of Forest Trees, Shrubs, &c.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

GORHAMBURY.—Through an accident on the machine last week, a portion of the references to the plan of the flower garden at this place "dropped out." These should read, "A A, Raised terrace walk, 20 feet wide; B B, Walks 10 feet wide; C C, Grass slopes; D D, Grass verges; E E, Grass plots; H, Mansion; G, Portico; 1—1, Geranium Mrs. Pollock; 2—2, Verbena Purple King."

POTTED PLANTS IN BEDROOMS (*S. H.*).—They are promotive of health. They purify the air. The carbonic acid they emit at night is too trifling to deserve consideration. We refer to growing healthy plants and those not having powerfully fragrant flowers.

COPROSMA BAUERIANA VARIEGATA (*J. A.*).—It is a greenhouse evergreen shrub of the Nat Ord. Cinchonaceæ. It is easily propagated by cuttings in gentle heat. It is a native of New Zealand. The directions given for cultivating Gardenias in the "Cottage Gardeners' Dictionary" are suitable to the Coprosma.

A CUPRESSUS (*A Lady, The Knoll*).—The plant referred to is the Cupressus torulosa, and we do not think it would train well over a window, and it has proved itself rather tender in many places. We think a variegated Ivy would suit you better. Pretty as the foliage of the Ampelopsis is in autumn, there is the litter of its falling leaves. Jasminum nudiflorum is a climbing evergreen of handsome growth, and produces a profusion of yellow flowers in winter and spring—in fine seasons a sheet of yellow; the flowers, however, are scentless. The common white Jasmine is very sweet, but it loses its leaves in winter, and does not grow so fast.

STRAWBERRIES FOR MAY EXHIBITION (*President*).—You should introduce your Strawberry pots about the middle of February, beginning with 45°, and rising gradually in a fortnight to 55°, and then to 60°. We should not think of repotting your plants in 48-sized pots now, but when you get your flower trusses up you might set each 48-pot in a 32-sized pot, with some good compost at the bottom. The Peas to come in the first week of May, should be sown in January, as they will not stand much forcing.

VINE FAILURE (*Subscriber, Co. Donegal*).—We cannot account for the Vines succeeding so badly. The want of artificial heat would not prevent the Vines growing freely. A little heat might be of advantage in maturing wood and fruit. With your preparations of soil, the Vines ought to have done well, if you have not overdone them with rich food. Sometimes the planting and watering afterwards will have great influence. A twelvemonth ago last spring, we saw Vines planted inside of a house having a very miserable appearance. It was said they were regularly watered, but though the surface soil was somewhat sodden for 3 inches down, where the roots commenced the soil was very dry. A good watering recovered them at once. We have no grounds for supposing that this is your case, but it may be looked to.

FERNS—HEATING A PIT (*Conifer*).—Purchase the "Fern Manual," price at our office 5*s*. "The British Ferns" are treated of more fully in a separate work, price 3*s*. 6*d*. at the office. You will see much about heating by flues in late numbers, and also in the present. We hardly know your purpose, otherwise we would advise you more definitely. If you merely want to save tender plants, then you cannot do better than run a flue through the pit, and place a stage for the plants over it, and we would have the stage so that we could raise and lower it at pleasure. If you wish the flue to act instead of hotbed manure, then it would be as well to take it along near the side, and return it on the other side. Lay rough slabs across 6 to 8 inches from the flue, fill the cavities between the slabs with clinkers, &c., and on this flooring place the soil. A simpler plan would be to surround the flue with open rubble, cover 3 inches or so with

the same, and then an inch of fine gravel, on which place the soil. In either case you must have upright drain tiles every 4 feet to let up heat, and moist heat when necessary.

Pears Shrivelling without Ripening (*A. F.*).—Madame Millet and Triomphe de la Pomologie are varieties which require extra warmth to enable them to perfect their fruit on the tree. If fruit is not so perfected it never ripens in the frnit-room. The juices have not been so elaborated as to accomplish by mere warmth the changes needed to form the sugar and the flavour. The requisites for ripening, and the chemical changes during the process, are fully detailed in Johnson's "Science and Practice of Gardening."

Sowing the Heps of Briars (*S. W.*).—The heps of the common Briar should be gathered in the autumn before severe frosts set in, stored in pots or pans, covered with sand in a cool place, and kept safe from the inroads of mice, which are very fond of them. They can be sown in rows in the following spring, much in the same way as haws, but not so thickly, about the end of March or beginning of April; and the rows should be well watered from time to time, especially if dry weather set in. If the season is favourable most of the seed will germinate; but it is better to leave the rows alone for a second season, both to strengthen the growth of those that have germinated and to give any seed that has lain dormant a chance of germinating. At the end of the second season transplant the young plants into rows about 3 feet apart, allowing 10 to 12 inches between the plants in the row, cut back freely so as to encourage growth from the base; and bud those that are sufficiently strong in the following autumn, budding low so as to make dwarfs. The advantage of using Briars raised from seed is, that by doing so it ensures a healthier growth, and more uniform growth, and the plants are not so liable to die off as many Briars transplanted from hedgerows are through having their roots injured. The plan is likely to succeed best where the soil is strong and not suited for the Manetti stock. The reason it is not oftener adopted is that it takes longer time than many nurserymen care to devote to it; but it would well repay the amateur who chose to devote his attention to it.

Jasmine not Flowering (*Idem*).—Is often a shy-blooming plant. It is better to thin-out and train-in the stems rather than to prune back too freely; and the soil—strong loam with a clay bottom—would induce a luxuriance of growth, which might very likely be advantageously checked by root-pruning. We are not usually an advocate for such severe measures, but if the Jasmine continued to be very shy-blooming we should try root-pruning one-half of the plant at a time, and thinning-out over-luxuriant growth so as to encourage the wood to ripen, only do not allow the plant to suffer from the want of water in dry summer weather.

Propagating Roses (*Ignorans*).—Tender Roses, Teas, Noisettes, and some of the Hybrid Perpetuals can be struck in spring, or grafted on Manetti stocks in heat, or budded. The wood that strikes the most readily is that which is taken from flowering shoots which have been slightly forced in pots. Teas and Hybrid Perpetuals procured from nurserymen now, may be kept in cool greenhouses or pits with plenty of air and light; and when they have done blooming in the spring cut off the flowering and other shoots before they start a second growth, leaving a small heel of the old wood, and strike them in a propagating pit with good bottom heat, taking care not to keep them too close. The soil used should be light and open, with plenty of silver sand, and a good moist top and bottom heat ought to be maintained, but giving more air than the generality of cuttings require. To avoid mildew, dust with a little flowers of sulphur if there is any sign of it. The end of February and all March is a good time for the operation. The young tender shoots may also be struck, but it requires the care and attention of an experienced propagator, and the Roses are apt to be very tender; in fact, it is our opinion that Roses grafted in heat on Manetti stocks never make quite such good plants as those budded in the open air; and in the same way, when striking Roses on their own roots, it is better to avoid too much heat. When struck, the young plants should be potted-off early, care being taken not to break the young white roots, plunging the pots in bottom heat, and giving air early in the mornings at first. Repot as soon as the roots are showing well round the pots and give plenty of air eventually. Care should be taken not to let the young roots suffer, either from too great bottom heat or from want of water.

Climbing Roses for an Arch (*Constant Subscriber*).—Four good Roses for covering an arch in an exposed situation are Général Jacqueminot, Gloire de Dijon, Sir Joseph Paxton, and Aimée Vibert. We should recommend them on the Manetti stock. Many other Hybrid Perpetuals as John Hopper, Madame Clémence Joigneaux, Boule de Neige, and Charles Lefebvre would cover an arch.

Netting—Manuring Roses (*Black Edge*).—We recommend Haythorn's hexagon Nottingham net, thick material, especially manufactured for protecting fruit trees; it is equally useful at the time the fruit is ripe, to protect it from the ravages of wasps. It is better stretched at least a foot in front of the trees, putting a coping either of wood, or better still of glass. The netting can be obtained of any London seedsmen, or direct from the manufacturer, Mr. Haythorn, Nottingham. The nets should be put on as soon as the first blossoms begin to open, and removed on fine days. The netting is equally good for Apples, Pears, and Plums as for Peaches, Nectarines, &c. You are quite right in applying the decayed manure to the roots of your Roses, as well as on the surface. The manure applied to the roots should be well incorporated with the soil, and not in lumps, and the manure on the surface should be longer and less decomposed, so as to act as a mulching during winter, and a protection against cold. If your soil is poor you have done right to manure the fruit trees, but as a general rule it is better to apply the manure at the surface to encourage surface-rooting. Four hardy Roses as climbers are Général Jacqueminot, John Hopper, Sir Joseph Paxton, and Felicité Perpetué. The above are not intended to cover a very large space. Of more tender Roses to cover a large wall, select Maréchal Niel, Céline Forestier, Gloire de Dijon, and Devoniensis.

Seedling Primula (*F. Holmes*).—The pips are large and well fimbriated; but they were too much bruised to judge of the colour. Why not send a plant to the Royal Horticultural Society's Floral Committee?

Vine Border Making (*J. H. G.*).—You will find the details in No. 542 of this Journal.

Orange Trees from Seed (*Inquirer*).—We are not surprised at your seedlings not having flowered at three years old from the pip. Your best plan would be to graft or inarch upon them scions of a fruitful tree and established variety, as the Tangerine, Mandarin, or Otaheite, if you wish to have a dwarf-growing kind. From the middle of March to the beginning of April is the best time to graft or inarch. If you wish to hasten the flowering of the seedling Orange trees, you should graft them, even if you place the scion on its own stock. On their own roots all seedlings are longer in flowering than on a foreign stock, and we have known seedling Orange trees not flower until they were nearly a dozen or more years old. On the other hand, we have known instances of their having flowered within six years. Hardwooded greenhouse plants of most kinds may be propagated by cuttings.

Dodder (*S. P.*).—We know of no mode of destroying Dodder without interfering with the plants it victimises. We should cut down the Lucerne patches close to the soil's surface as soon and as often as detected, and manure the patches with salt.

Camellia Leaves Browned (*G. E.*).—The leaves are browned by exposure to the direct rays of the sun, but are otherwise quite healthy. We do not think the plants are "out of condition," and all they require is slight shade from the commencement of new growth until the close of August, or if the weather is very clear, up to the end of September. Tiffany or other thin shading material answers perfectly.

Evergreen Shrubs (*C. H. H.*).—The kinds you name are mainly evergreen, and we presume you wish for such principally. Your list is on the whole good, and to it you may add besides, the common Aucuba, A. limbata, A. himalaica, A. longifolia, A. mascula maculata; Arbutus Andrachne, A. procera; Berberis japonica, B. Bealii; Buddlea globosa, which requires a warm situation or wall; Chamærops excelsa, a Palm of very distinct appearance; Cistus purpureus, C. ladaniferus, C. algeriensis, Colletia bictoniensis, Cotoneaster buxifolia, Cratægus Pyracantha, fine for a wall, or a sheltered position. Eleagnus japonicus variegatus, Escallonia macrantha, and E. glandulosa, require a warm situation or a wall along with the kind you name. Eurya latifolia variegata, Euonymus japonicus argenteus variegatus, E. japonicus latifolius aureus variegatus, E. radicans variegatus. Ilex or Holly—angustifolia, ciliata, crassifolia, and Fortunei, have small neat leaves; I. altaclerensis, Hodginsii, and Shepherdi, have fine broad leaves, and you will, of course, add the Gold and Silver-edged kinds. Osmanthus ilicifolius argenteus variegatus, Raphiolepis ovata, Skimmia japonica, Double Gorse, Vinca elegantissima, and Yucca recurva. Of American plants, besides Rhododendrons, Andromeda floribunda, Hardy Heaths, Kalmia latifolia, K. myrtifolia, K. glauca, Sedum latifolium, Pernettya mucronata, Menziesia polifolia, globosa or erecta. Of Coniferous trees of small growth, Abies excelsa var. Clanbrasiliana, compacta, elegans (dumosa), pumila, pygmæa, A. rubra cærulea, Cryptomeria japonica nana, Juniperus hibernica compressa, J. recurva densa, J. Sabina, and vars. tamariscifolia and variegata, Picea Fraseri Hudsonii, P. pectinata pygmæa, Pinus Strobus nana, P. sylvestris pumila, Taxus adpressa, T. baccata nana, Thuja plicata caucasica, T. glauca, and T. pygmæa.

Propagating Quick and Larch (*W. P.*).—Quicks are raised from the haws of the common Thorn placed in heaps, or in a pit in the ground, and covered with soil. After thus remaining for a year they are sown thickly broadcast in beds 4 feet wide, and the haws are covered about an inch deep with soil from the alleys. Care must be taken to prevent the attacks of mice. In the following autumn there will be some of the seedlings fit to draw and transplant in 4-feet beds. Plant five rows in each bed, the two outer lines 6 inches from the sides, and the others, of course, 9 inches apart. The seedlings should be about 3 inches from each other in the rows. Next autumn the remainder of the plants in the seed-bed may be taken up and transplanted as the strongest were in the previous year. In all their stages they should be kept clear of weeds. Quicks thrive best in rich deep soil. Larch seed requires to be sown in March in light sandy soil, and in autumn after they have cast their leaves the seedlings should be taken up and put out in lines a foot apart, and the plants about 3 inches asunder. Brown's "Forester" would suit you.

Manetti Rose Propagation for Stocks (*Old Subscriber*).—Cut one-year-old shoots into foot lengths, cutting right across, not in a sloping direction, immediately below a bud, but the top should be taken off with a gentle slope just above a bud. Remove all the buds except the uppermost two, and plant so that only the uppermost bud will be above ground. It is well to plant in the centre of a ridge, and the height may be about 8 inches. The cuttings may be inserted about 2 inches apart; but if they are to remain for budding where put in, they should be 6 inches apart, and in the August following the season in which they were inserted they will be fit to bud. The ridge should then be levelled, so as to expose the main stem of the cutting, and in this, at about 6 inches from the bottom, the bud should be inserted, the buds being put in directly after the removal of the soil. November is the time for planting the cuttings.

Planting English Iris (*Idem*).—Plant them about 3 inches deep, covering with light rich soil. They should have an open, sunny situation, and a light, well-drained soil.

Peas Dressed and Eaten with their Pods (*Cote House*).—They are the Pois sans parchemin of the French—that is, the Pea without any tough skin inside the shell. They are known in England as the Sugar Pea. Three hundred years ago Gerarde mentions them as "Pease whose cods are to be eaten with the Pease when they be young, as those of the young Kidney Bean." Any of the principal seedsmen who advertise in our columns could supply you.

Bedding Geranium and Verbena (*S. P. A.*).—Amy Hogg and Purple King will do very well together, but we would rather prefer Purple King and such a Geranium as Christine.

Ventilating a Long Frame (*A Novice*).—You will want a fair amount of top ventilation as well as the doors. Glazing with glass in grooves will only keep out wet when putty or packing with list or soft cord or india-rubber inside is used to keep the glass tight, and yet not too tight to prevent any expansion. We think you will need double the number of 3-inch pipes, unless you use some protection on the glass in the most severe weather.

Vines for a Cool Greenhouse (*A Subscriber, Dublin*).—For the six Vines for a cool greenhouse, we would advise one Buckland Sweetwater, one White Frontignan, one Muscat Hamburgh, one Black Champion, and two Black Hamburghs; also take the advice of the nurseryman you refer to. For the borders we would use but little of the sea sand. Of all the soils mentioned, we prefer the sod from the pasture field piled up some months before being used, so as to sweeten it; and if you fear that is too

rich, add lime rubbish, and some of your mountain soil. We hardly understand about Irish peat. If it is such as has been formed under water, and used as fuel, we would not use it at all in a Vine border.

HEATING (*D A.*).—There can be no difficulty in keeping out frost from a house 20 feet long by 14 feet wide, without going to the expense of a boiler and pipes, &c. We do not know the radiating stove of which you speak, but any stove will do if there is an outlet for the smoke. We kept the frost out of a lofty corridor, painted back wall, hipped roof, front glass to the ground some 10 feet in height, width of house 10 feet, and length about 40 feet, with a round stove of Brown & Green's, about 12 inches in diameter placed at one end, and plants were kept in bloom all the winter and spring. We have an old iron stove in the middle of a house 70 feet by 11 feet, and that has kept Scarlet Geraniums and other plants safe as yet. As the stove is very old, we have moved all such tender plants to-day for a couple of yards from the extreme end. For your half division, 20 feet, you might have less trouble with a small iron stove, the fire-box lined with firebrick. As you wish to study the greatest economy, we would have a brick stove, in the mode referred to at page 402. We should say the want of colour in the Grapes was more owing to bulk of crop than want of heat; however, a little heat would assist.

NAME OF FRUIT (*W. K., Angmering*).—Morris's Nonpareil Russet.

NAMES OF PLANTS (*F. H.*).—1, Leucopogon lanceolatus; 2, Hemerocallis fulva variegata; 3, Selaginella pubescens; 4, Pteris, apparently some form of P. aquilina, not typical however; 5, Blechnum occidentale; 6, Woodwardia radicans; 7, Gaultheria Shallon; 8, Platyloma rotundifolia. (*W. W. W.*).—Pelargonium echinatum, a very interesting as well as beautiful plant, the great wonder is that it should be so little known and appreciated. 1, Microlepia novæ-zelandiæ; 2, Pteris serrulata; 3, Pteris cretica albo-lineata; 4, Litobrochia pedata, in all probability, but very young, scarcely in character. We do not at all approve of your plan of using the refuse of your faggot-heap, unless, indeed, it be quite free from fungi, which is scarcely likely. In any case use it more in the place of a subsoil, and give it a good surfacing of some better material if you wish to utilise it for the purpose you name. We should certainly do this in preference to mixing uniformly. (*Rush*).—Nerine undulata. (*W. W.*).—The Palm bearing the Dates sold by grocers is the Phœnix dactylifera.

POULTRY, BEE, AND PIGEON CHRONICLE.

BIRMINGHAM POULTRY SHOW.

THE great annual reunion to which so many—may we not say all?—poultry fanciers look forward, manifests this year a marked superiority in many classes; and, indeed, as a whole, the quality of the birds is better than usual, though the number of entries is slightly less in the poultry classes through the Crystal Palace competition. The total number of poultry entries at the present Show is 2087, against 2125 last year, and it may be interesting to give the comparative numbers of the different breeds, which are as follows:—

	1870.		1871.
Dorkings	294	..	280
Cochins	323	..	261
Brahmas	261	..	346
Malays	27	..	16
Crêve-Cœurs	41	..	33
Houdans	58	..	42
La Flèche	8	..	10
Spanish	72	..	86
Hamburghs	195	..	105
Polish	63	..	58
Any variety	44	..	19
Game	342	..	382
Bantams	59	..	44
Game Bantams	115	..	109
Ducks	120	..	103
Geese	36	..	30
Turkeys	67	..	55

It will be seen that the decrease is pretty general throughout the classes, but especially in Hamburghs, which number little more than half of last year's entries, and "Any variety" are even less than half, the mistaken policy of cutting down the latter to only one class of three prizes thus bearing its legitimate fruit. Spanish show a small increase, but the only marked growth is in the case of Game and Brahmas. The increase in these latter is the most marked feature of the present Show.

In proceeding to go through the awards, we ought to remark that the light was unusually bad even for Birmingham, the day being dark and "muggy." Hence the Judges had to act under very unfavourable circumstances, and it is, perhaps, much easier to point out real mistakes with the aid of a catalogue than to avoid them without such a guide as the names of noted exhibitors afford. Yet to do so is, nevertheless, the duty of an impartial reporter, and we shall proceed to give our honest impressions of the Show.

DORKINGS.

Cocks.—First of all in the catalogue comes the cup cock, a grand heavy bird, and we were glad to see the honour once more awarded to light colour. The second-prize bird was of medium colour and large, with unusually good feet. Third came a very dark and big bird, one of the best in the class but for the very unsatisfactory state of one foot. Fourth was a small bird, and in our judgment much inferior to Mr. Wheatley's 13, one of the noted winners last year.

Cockerels.—The first prize went to a fine bird, not so large as several others, but with the best feet in the class. The second was a very poor bird, Silver-Grey in colour, and not large enough for a Grey Dorking. Third came a very excellent dark bird, shown in a very bad light, which in our opinion kept him from taking the second place. The fourth-prize bird was also very fine and large, but the fifth was not so good as the sixth, and both of these last we thought inferior to several others.

Hens were a fair lot, and both the first and second were really good pens and rightly placed. The third contained one grand hen, with another only poor. The fourth-prize birds were quite small for old Dorkings, and much worse than the fifth, which last were a bare average, and neither pen equal to No. 133.

Pullets.—The first-prize pair was good in every way, being large, dark, good in feet, and well matched. Second came a very poor pair indeed, only entered at two guineas. Those which were third were very much better, and good, but we thought the fourth should have had the second place. Fifth and sixth call for no remark.

Silver-Grey cocks were a fair class. The first prize was taken by a large but rather coarse bird, too dark for our fancy; the second very similar in both body and colour. The third and fourth-prize birds were the best in colour, but not so large. The fifth-prize bird was not pure either in the white or black, and several better birds could have been found for the honour. The first-prize *hens* were a very old but fine pair with long spurs. Second came a taking pair in the dark, but later in the day appearing very broken in colour, and one pullet had a very misshapen foot. The third prize went to a pair of pretty good old hens; fourth were pullets by no means pure in tint, red showing on the wings. This class was not so good as the cocks.

The *White Dorkings* were good, and the third-prize bird, though not large, was, perhaps, the best in carriage, and well deserved his place, though only entered at a guinea. The *hens* and *pullets* were not so good, and none but the prize pens could be called really good.

COCHINS.

Buff cocks were a good class. The first-prize was well put, Mr. Taylor winning with a grand real Lemon Cochin. Second a much darker, also very grand bird. Third of immense size and good colour, but not a good carriage. Fourth also rather clumsy, but sound in colour. Fifth had a slipped wing, or would have probably been third. The next two classes contained the "sensation blota" of the Show; and while knowing, as we do, how unpleasant it is both to the winners and the Judges to call in question the awards, we feel bound in simple justice to re-judge both classes, premising that we were borne out by all the Buff breeders present. The best bird in England, which won the Palace cup, and has had no equal for five seasons, was put sixth! The sixth prize should have been cup; second, a grand bird which will be better yet, in his place; the cup bird third; Mr. Tomlinson's, fourth; Mr. Taylor's fifth as he was; and Mrs. Allsopp's bird sixth. There were many really fine birds in this class besides; but the sixth-prize was so markedly superior that we cannot attempt to account for the mistake. *Hens* were little better, the first-prize birds being a comparatively worthless and mealy pair. Mr. Lacy's second-prize pen should have been first; Mr. Lloyd's fifth-prize pen second, his pen 377 third, putting the third-prize fourth. In the fifth-prize pen was far the best single hen in the class, or which we have seen for a long while, the other being very good, and the two only inferior to Mr. Lacy's pair. This was an excellent class.

The *pullets* were very fairly put, but as a class far from equal in shape to the hens. The fourth-prize were particularly narrow at the tail, and the sixth pen contained one very good bird with one as bad.

The first-prize *Partridge cock* was well placed, being a really good one. The second we did not like much, and the third was badly feathered. In *cockerels* Mr. Tudman took his old place with a bird hardly mature, but in faultless condition and with all the stuff in him of a good Cochin. Second, a good colour, but wanting in shape. Third, a better, rather, and deserving his place. In *hens* Mr. Tudman was first again with birds grand in size and shape, but not first-rate in marking by the modern standard. Second, well marked, but inferior in development. Third also very pretty pencilling, but wanting in size and good Cochin carriage. First-prize *pullets* beautifully coloured, and if one were rather better fea hered they would be very hard to beat. Second, both grand birds, but badly matched. Third, a fair average pen and no more: this class poor.

Whites.—The first-prize old cock was very old, rather heavy-looking, and by no means so good as the second-prize bird, except in colour, which was better. Third, a very good cock, but not good in style, in which the white cocks generally are falling off. In *cockerels* we thought Mr. Chase's pen, 511, the best in the class, certainly better than his first-prize. The second deserved his place, and the third was also good and well feathered. The three prizes in *hens* were also grand pens, with little to choose. *Pullets* were not nearly so good, and none really first-class, except the first-prize, all the rest being wanting in shape.

BRAHMAS.

In old *Dark cocks* the cup was secured by the Crystal Palace first-prize bird of Mr. Taylor. Second, a very good average bird. Third, a very light "washy" bird, scarcely able to stand, and inferior to at least four other birds in every way. The *cockerels* formed the largest class of any breed ever yet seen at any show, showing the amazing number of 105 entries. With so many birds, many really good, it may easily be believed judging was very difficult work, and it can, perhaps, scarcely be expected that any after-critic should altogether agree with the awards. The Crystal Palace cup bird was first, and rightly. The second, third, and fourth were all excellent birds evidently, or at least apparently, own brothers, as we believe they are. Fifth was rather showy, but valueless for breeding, and we liked the

sixth better, but the last two might in our judgment have been advantageously displaced by at least a dozen; still, our remark above must be kept in view.

Dark hens were pretty good, but to our mind quite wrongly placed; the first-prize Palace hens being here second, while they should, we think, have had their old place. We should also have placed the third second, and given the first third.

Dark pullets were another enormous entry of seventy-four pens. The Crystal Palace second-prize pen, much improved in condition, was here first, while the Palace cup pen was fourth. The second we did not much like, and think the fourth pen should have had that position. The third contained one of the Palace third birds, and another far inferior. Fifth, fair and no more, not quite so good as sixth in our opinion. There were numerous other good pairs, but the "highly commendeds," we confess, we could often not understand; but here, again, allowance must be made for the number of the class.

The first-prize *Light cock* was the same which won as a cockerel last year, small, but beautiful shape, hackle, and feather. Second, very large, fairly feathered, saddle well striped, but hackle too pale. Third lightly feathered, but good shape and very darkly marked. In *cockerels*, the first-prize was very large, fine shape and leg feather, saddle white, hackle poor. Second-prize darkest hackle in the class, saddle white, and leg feather moderate, but wings not sound and some black in them. The third prize went to a cockerel of very fine shape, also good in feather and colour, all but a little black on the wing. This was the heaviest-feathered bird in the class. The fourth-prize bird was also well feathered, hackle shady, saddle moderately wide. Pen 797 was one of the very best in the class, but shown very dirty; and the saddle was, while wide in front, narrow over the tail. This was the best Light-cockerel class seen for a long time.

Hens were very moderate. First-prize fine in shape, size, and colour, heavily feathered, and decidedly hocked, but not too much, nor tampered with. One had a coarse comb, and both were too narrow over the tail. The second-prize bird was good in size, colour moderate, feather middling, but shape poor. The third-prize pen had one fine bird, the other quite poor. The first-prize *pullets* had the best pair of cushions in the class, middling hackles, but poorly feathered. In the second-prize pen one was very fine in shape, size, and colour, the other, again, too narrow behind. The third pen contained one really beautiful bird—cushion, hackle, and feather all good, but her mate, again, a poor bird, and with a spotted back. The fourth-prize birds were of a nice colour, but small and narrow. This class was not equal in quality to the cocks, and disappointed us much.

MALAYS.

The *cocks* were very fine. The first-prize bird very stylish and hard in feather; the second-prize bird larger, but not so Malay in character. *Cockerels* only three! First, a very young almost black bird, in faultless condition. Second, a white. *Hens*, five pens again, and well judged, but in the three *pullets*, the second-prize was quite wrong, being low on the legs, and quite without Malay shoulders, the want of which was made up by a spreading tail.

FRENCH FOWLS.

Crêve-Cœur cocks were a good class and fairly judged, though we would prefer, perhaps, Mr. Sichel's second-prize pen. In the *hens* Mr. Wood was clearly first, but the others were very good, and this struck us as the finest of all the French classes. All the prize *Houdan cocks* were very fine and belonged to the usual names, but were not quite so large as some that have been seen. *Hens* were very fair, and we think we can see signs of their becoming a really handsome variety. We liked, perhaps, Mr. Wood's pen, 980, best of the lot. *La Flèche cocks* were in very good condition, but still few. The *hens* were fewer still, only numbering three pens. Both prizes were very good, but should have changed places.

SPANISH.

Old *cocks* were a small and middling class, bad spirits prevailing throughout. This class did not contain a single Bristol exhibitor, and placing pens was almost entirely a question of condition. The winners were well placed, though the second-prize bird was far the best in sterling value. *Cockerels* were numerous, but quality barely an average. The Palace cup-winner was here put sixth, the cup going to a bird which would be very good if given what the Yankees call "an eye-opener." The second and third were good birds, but the fourth and fifth very poor again, and the class generally was remarkable for the absence of any really first-class specimens. *Hens* again in bad condition, and none but the first and second prizes were really fit to be shown, even these by no means in order, and the present season seems by no means favourable to the faces of the birds, which were in reality good, but looked very middling indeed. It struck us that the faces of the *pullets* were getting smaller, and losing the smoothness which is so desirable. Only the first three prizes could be termed good, the first going to the Crystal Palace pen, and leaving no fault to be found with the judging. The Spanish classes, as a whole, greatly disappointed us, and judging must in a great degree have consisted rather in marking out bad pens than in ticking off the good. A change of weather may, we hope, bring better looks, especially to the "young ladies of the family."

HAMBURGHS.

Black Hamburghs, which here begin the list, were much better than at the Palace, both in number and condition. In *cocks* Mr. Beldon won with an old cock in fine feather, the others, being cockerels, also well shown. In *hens* Mr. Serjeantson took first in his usual style. Second were also in fine order, but third were hardly equal to pen 1108.

Gold-pencilled cocks were a well-filled class, Mr. Beldon being first with a very fine bird. The second and third were also of marked quality, but most of the others had far too much bronze in the tail. *Hens* a fair class, but the prize birds were easily distinguished from the rest. First-prize birds were small, but very accurately pencilled.

Silver-pencilled cocks were a small but really extraordinary class. There were but seven entries, and out of these we have no hesitation in saying that the three prizes (rightly placed) and the sole high commendation given, were the four best cocks ever shown together. The *hen* class contained a few very good pairs, the prize pens being superior in depth of colour, which, we may remark for the benefit of amateurs, is particularly essential to Birmingham winners, the light coming so directly down on the birds that many which appear a fine but colour elsewhere look but very washy at this Show.

Gold-spangled cocks were a good class, and abounded with smart and good combs, which used to be the exception. The best birds were to the front decidedly, all the winners being birds of the year.

Hens good, too, and awards correct. All the winners old birds, and the extra prize for the best Hamburgh hen went to this class.

Silver-spangled cocks were the best class ever seen at Birmingham. All the winners young birds again, and both they and the highly commended pens had wonderfully perfect tails. We were not quite sure about the third prize; but it was at best a ticklish matter, and not much to complain of.

Hens were a capital class and, as in Gold, the matrons took all the prizes. Awards were criticised, but we think them correct as the birds stood, though there is no doubt Mr. Beldon's third-prize will be in a few weeks better than the first. The singular fact may be noted, that except in first-prize Blacks, young cocks took *all* the Hamburgh prizes, while in the other sex all the winners in Pencils were pullets, and in the Spangles old hens.

POLISH.

Black Poland cocks, though few, were a beautiful class, and it was really hard to have only two prizes to give.

Hens were middling, and we must say were misjudged. The second prize should not have been in the list at all. The first prize should have been second, and first given to Mr. Shaw's pen, 1298. In *Golden cocks* first-prize was a grand bird for size and carriage, but his markings far too pale. Second smaller, but far better colour. The first-prize *hens* are the best we ever saw. Second, a nice pair of promising pullets. This breed still progresses. In *Silver cocks* first and second were both good, but third not enough colour. *Hens* were a nice class, the lacing being good all through. The same exhibitor took both prizes and won them fairly.

ANY VARIETY.

This class was remarkable for four rumpless pens shown by one exhibitor, and all quite different in character. First were a nice pair of Scotch Greys, second Andalusian, third Chamois Polish. In this class the legitimate result of the niggardly encouragement offered by the Committee was seen in only nineteen entries; many breeds, such as the now-increasingly-sought-for Leghorns, being quite unrepresented

GAME.

The first prize Black Red *cock* was very good in plumage, colour, and condition, and took the cup for the "best Red." The second should not have been in the list at all, having very scaly legs: he was a good bird otherwise, but this should have thrown him out. Third a grand bird in every way, and we should not be surprised if he turned his tail on the first. Fourth moderately good. Mr. Douglas's pen, 1390, ought in our opinion to have had the vacant second place. This was a fair class and no more. The young cocks, on the contrary, a first-rate class. First well won his position every way. Second a fine shape, but rather dull in colour. Third a good colour, but low on the leg, and with a forked tail. Fourth fine in colour and shape, but too much tail by far. Fifth a good bird, but shown rather too young. Many other really good birds. *Hens* a pretty good class. First a splendid bird, and clearly the best; but second and third also good. *Pullets* consisted of many capital birds, and the Judges again picked them out well. Second was perhaps a shade coarse, fourth rather slight, and fifth dull in colour, but the merits of all these birds quite outweighed the defects.

Brown Red cocks were not up to the Birmingham standard. First a fairly good bird, but far inferior to the same gentleman's pen, 1526—that is, so far as we could judge without handling, and supposing the latter to be as good as he looked. Second a splendid bird, both in carriage and colour. Third good all but his feet, which were too short in the toes. Fourth good in body and limbs, but carried his tail much too high. Fifth a fair bird. The same general remark as to quality applies to the *cockerels*, the good birds being the exceptions. Only the first-prize stood boldly out, being the Crystal Palace winner, which has changed owners, and nearly every breeder said this bird should have had the cup. Second rather too dark, but good in style, and particularly so in legs and feet. Third hardly ready for show, but undoubtedly good when he is. Fourth a nice bird, short in hack toes. Fifth again was too young to show well.

The *hens* were a capital class. The first was clearly before all the rest, having a most beautiful head and neck, and looking a lady all over. Second a nice hen, but tail a little too much up. Other prizes

also good. *Pullets* a fair lot. First-prize stylish, but too round in the back. Third had a stuck-up tail, which seems in fact rather creeping in. Fifth-prize ought to have been higher, and she and the second-prize ought to have settled the two first places between them perhaps.

Duckwing cocks were a fair class, and the winners were the same which took the three prizes at the Crystal Palace, but the Judges had judiciously made the alteration we suggested in our report of that show, the second there (**which had** changed hands), being now put first, and the first (we must in fairness say he was worse in condition) second, the third being third again. On a second inspection we adhere to an opinion there formed—that this last is the best of the three. *Cockerels* middling only, but the first prize went to a really capital bird. Second fine. Third and fourth fair birds only. *Hens* were few, only seven entries; but the first-prize bird really superb. *Pullets*, on the contrary, a first-rate class, which makes it the more remarkable that the same exhibitor (quite fairly) swept the whole prize list with three beautiful birds.

Blacks and Brassy-winged need little remark. We did not like the cock class, and failed to find any birds like those formerly seen. The winners were all Brassy-winged—that is, if black birds with a sort of grimy-red saddle can be so called, but we would fain see the colour more distinct. *Hens* a little better, but rather poor still.

In *Pile cocks* the Palace bird was again to the front, and secured both cup and medal for the best Game cock except Reds. The second prize was taken by the same exhibitor with a yellow-legged old cock (the same which was first here last year), the cup-winner being willow. Third also willow, and again the same as the Palace third, the second there being now left out in the cold, as we hinted he ought to be on that occasion. *Hens* were a good class. First a bird of last year, fine both in shape and colour; second and third good pullets, but not so well marked. All three ladies had yellow legs.

BANTAMS.

In *Gold-laced*, one entry being withdrawn left Mr. Leno both prizes. Both pens good. In *Silvers* the winners were too large but extra well marked, Mr. Crawys' pen being much smaller, but greatly wanting in depth of colour. *White* Bantams were good in quality and are improving. In *Blacks* the first-prize pen contained a very neat cock but very poor pullets, their heads and earlobes being far too dark. Second a scarcely equal cock, but infinitely better pullets. Third and fourth fair pens, but Mr. Draycott's pen 1769 ought to have had one of the first two prizes. In *Any variety* first were Japanese, the variety with that straight sword-like squirrel tail, which we confess not to admiring so well as the sickle. Second were frizzled, which we consider were far too large to find a place among Bantams at all, being as large as Silkies; but they looked rare if not rich, and this may be merely matter of opinion.

GAME BANTAMS.

The first-prize *Black Reds* were a good stylish pen well placed, though the second were little worse. Third rightly judged. Fourth as good in quality as any, but frightfully out of condition. 1817 was also a stylish pen. *Brown Reds* were middling, and the cock in the winning pen was too short in the head. The second-prize bird was much too large, and probably pen 1830 ought to have been first. In the "Any other variety" class, the first was a pen of Duckwings, capital in most respects, and well shown; but when examined fairly in the light, almost every feather on the breast was laced with brown. The defect could only be then seen, and apparently escaped the Judges. Second and third were good Piles. In *Red* cocks, some difference of judgment was expressed, but we thought the winner well placed, being Mr. Eaton's Palace bird, which was finer in the head than Mr. Entwisle's, but it was really hard judging between. Third was very good, and fourth fair, but the fifth was had every way, and a pen bearing the "Great Exhibition" number of 1851 ought to have taken his place. The next class, again, contained the Palace winner in his then post of honour, and we repeat our opinion that he is the best Duckwing, not to say Game Bantam—ever seen. Second was a good Pile, and third also a Pile, good on the whole, but rather too short in the hackle.

DUCKS.

We scarcely consider ourselves competent to judge of the exhibition merits of the remaining classes, and prefer only to give the weights. The first-prize Aylesburies were 17 lbs. 2 ozs.; second, 16 lbs. 12 ozs.; third, 15 lbs. 4 ozs. These it will be seen are actually going back since Mrs. Seamons withdrew. Rouens were much heavier, being 19 lbs. 5 ozs., 19 lbs. 1 oz., 18 lbs. 15 ozs., 18 lbs. 4 ozs., 18 lbs. 8 ozs., and 17 lbs. 10 ozs. respectively. The fifth-prize, it will be seen, was heavier than fourth, but hardly equal in plumage. The Ornamental Ducks were mostly beautifully shown, and among the many exquisite Mandarins and Carolinas we should despair of ourselves pointing out the best. It is a pity the handsome little creatures are so savage when penned up.

GEESE.

The first and second pairs of old white Geese each weighed 56 lbs. 9 ozs.; the young were 48 lbs. 6 ozs. and 44 lbs. The first old Greys reached the enormous weight of 60 lbs., the second 51 lbs. Young were 47 lbs. and 37 lbs. The great difference of nearly 10 lbs. between the first and second prizes in each case shows what good management can effect.

TURKEYS.

The winning Turkey cock was precisely the same weight as last year, 36¼ lbs., second was 32 lbs. 5 ozs. The best pair of hens reached the great weight of 38¾ lbs., or nearly 4 lbs. heavier than last show; second pair were 35½ lbs. Young cocks were 28 lbs. and 23¼ lbs. respectively, and young hens 28 lbs. 10 ozs. and 27 lbs. 2 ozs. The United States this time did not put in an appearance.

The following are the comparative weights of the prize Turkeys, Geese, and Ducks in 1870 and 1871:—

TURKEYS.

	1870. lb.	1871. lb. oz.		1870. lb.	1871. lb. oz.
Single cock, 1st prize ..	36¼	36 4	Single cock, 1871, 1st ..	24⅜	28 8
„ 2nd „ ..	35⅝	32 5	„ „ 2nd ..	23¾	23 4
Pair of hens, 1st „ ..	35	38 12	Pair of hens, 1871, 1st ..	31¼	28 10

Second-prize pair	18¼	19 1	Fifth-prize pair	17½	18 8
Third-prize pair.....	18⅜	18 15	Sixth-prize pair	17¼	17 10

Messrs. Hewett, Teebay, and Dixon judged the Brahmas, Spanish, Hamburghs, Ducks, Geese, and Turkeys; Messrs. J. H. Smith, R. Woods, and Edward Lowe the Game, and most of all the Game Bantams; and Mr. Baily, the Rev. G. F. Hodgson, and Captain Heaton the rest; but Captain Heaton was taken ill and had to retire about two o'clock.

As a whole, the show of poultry was to be remarked for its very superior quality, *Spanish* and *Dorkings*, however, being marked exceptions. The day being dull made judging difficult; but we repeat our remark of last year on the enormous waste of judging power caused by dividing the Judges into four threes. We were told on this occasion that next year this will not be repeated, but that six pairs of gentlemen will be substituted; we trust this will be the case, and that if not already contemplated our suggestion may even now receive attention. The last awards this year were later than ever, and fully one-third were not posted on the wall till past six o'clock. And lastly, after the perfect light of the Crystal Palace Show, the contrast of the "dark dens" at Birmingham was most painfully felt, and was freely remarked upon by nearly all the Judges and exhibitors who had visited both. We are fully persuaded that unless something be done to remedy this, and to give a far better light to the lower tiers, this great Show cannot hold its own, but must give way to the Crystal Palace, and this was the universal remark. We are convinced the time has come for this matter to receive the attention its importance requires. Few would wish this grand old Show to play "second fiddle" to any other; but whether it be by separating it from the cattle, or by other means, we believe it must now do so, unless some means can be devised of remedying the wretched light which we honestly believe is the chief cause of those "sensation blunders" in judging. While we point these out, we would wish our opinion of at least one cause of them to be remembered also—in justice to the gentlemen who have to act under such unfavourable conditions.

We have only to add that the Committee and officials were as courteous and anxious to oblige as ever, and to thank such of them as assisted us.

PIGEONS.

Many disinterested visitors to these great annual exhibitions have thought, as each successive year came round and showed an increase in the number of entries, as well as a marked improvement in the quality of the birds exhibited. "Now, surely, this must be the greatest height to which the culture of high-class stock can be brought, and hereafter these gigantic exhibitions must be on the wane." It may be, many lukewarm fanciers, too, have echoed the same sentiments, and have from time to time been expecting the retrograde movement to set in and drift us back to the original kind of stock from which hosts of beautiful birds have sprung. But no such downward course is yet to be. These great annual collections of stock, large, as they are, have still to grow and develope into greater achievements, for the competition or spirit of rivalry has hitherto been chiefly confined to fanciers, but in the dim future we fancy we can discern a still stronger spirit of rivalry growing up than fanciers even imagine, as to which shall be the largest and most important of our poultry and Pigeon shows. The great Crystal Palace Show is just of the past, the great Birmingham one is now the event of the period. The strength of the fancy has been put forth to meet both of them, the little summer shows, at which the dealer makes his harvest, are for a time partially forgotten, and the attention of their respective supporters directed to the great winter events, at any of which it is no

small achievement to record a victory, for most of the classes would form a little exhibition of themselves.

As an example that there is no lack of zeal on the part of fanciers, no backward movement yet, the following statistics of the number of Pigeons exhibited will show :—

	1864.	1865.	1866.	1867.	1868.	1869.	1870.	1871.
Pens	290	231	400	565	432	482	441	546

The accommodation for extra Pigeon classes has been judiciously provided for at Bingley Hall this year, by the erection of a gallery on the west side of the building, in continuation of and in character with the former portion on the east side.

Almond Tumblers.—As a class, this variety was the best that has been seen at Bingley Hall for some years. First were a neat little pair of birds; the same exhibitor also won third prize, and the latter pair, we think, should have been second on the prize list, for although young they are good Almond-feathered birds—rich, pure, and uniform in ground tint, and promise well to become the highest type of the Almond breed.

Carrier cocks (Black).—The first prize in this class was an easy victory for a grand bird, far superior in merit to his competitors. There were fourteen entries in this class.

Carrier hens (Black).—A smart stylish hen was first. In our opinion Mr. Fulton's highly-commended bird was the best bird in the class. Another excellent bird from the same loft was unnoticed in the awards. The birds in this class were good in quality, though few in number.

Carrier cocks (Dun).—A capital bird was first; a good bird second, but apparently it was suffering from wing disease. The two pens of Mr. William Siddons, sen., were of excellent quality, each of these birds was highly commended. Mr. Gordon's bird was a fine strapping bird for eighteen months, but was rather deficient in quality, yet it is a capital stock bird.

Carrier hens (Dun).—In this class the first prize was given to a very good hen, sound in colour, good in eye, bill, and carriage. She well merited her position. The second prize went to a good bird, but too coarse in head and rather down in hill. An unnoticed bird of Mr. Fulton's was to our mind far preferable to the second-prize bird.

Carrier cocks (Any other colour).—In this class there was little or no competition. Three birds only were entered.

Carrier hens (Any other colour).—In this class the prize list was headed by a very good Blue hen, perhaps the best of the colour that has lately come under notice. She has won, at various places, many prizes, and until fanciers receive more encouragement to breed for Blues we cannot hope for better birds. Mr. Fulton received a high commendation for a fair "Silver," and also a commendation for an average "Blue." The class was small from two simple reasons—viz., that there are few birds of the kind to be found, and so little pecuniary encouragement for fanciers to breed for them.

Carriers (Black) cock and hen hatched in 1871.—In this new class there was a capital muster of young birds. The silver cup probably caused the collection of twenty pens for the contest. An admirable pair of birds belonging to our veteran fancier, Mr. W. Siddons, sen., were soon dotted down as being in the race, and they ultimately, after close inspection, stood the ordeal, and were recorded victors, and indeed, they well merit the cup and prize which they have won. They are good-sized birds, raven black, straight and thick in bill, good in eye, narrow in skull, and are, besides, a perfectly matched pair in first-class condition. An uncommonly good pair were exhibited by Mr. G. Gordon, but they have not found favour with the Judges.

Carriers (Any other colour) cock and hen of 1871.—Twelve pens were brought together in this class. Both the winning pens were Blues of more than ordinary promise, and in time they will be most likely first-rate birds.

Pouter cocks (Red).—The first prize and cup were taken by a graceful bird in shape and carriage; colour and markings were also very good. He measured 19¾ inches by 7 inches in leg, and was truly a fine specimen. Mr. F. Gresham was second with a good bird in form and carriage, of great length, but of a poor colour. There were seven entries.

Pouter hens (Red).—First was a very stylish hen of symmetrical proportions and good carriage. An excellent bird, good in carriage, girth, and length of feather and leg was second, but she had two much "rose on the wing."

Pouter cocks (Blue).—First on the list was a good specimen, though rather too gay in markings. This bird wants a little more caressing in order that he may show himself and be more at home in a show pen.

Pouter hens (Blue).—A grand bird was first, but to our mind the second-prize bird was preferable.

Pouter cocks (Black).—First was a bird good in all points, and second an excellent specimen very little inferior to the former one.

Pouter hens (Black).—A splendid hen first, pressed closely by a very showy bird.

Pouter cocks (White).—In this class we find an entry of seventeen birds, most of which are first-class specimens, and several of them perfect models of the Pouter; pure, and possessing those graceful and elastic movements so characteristic of high-class stock. The foremost place was taken by a very fine showy bird, but a little too coarse in girth. A capital bird was second. The whole class was a meritorious one.

Pouter hens (White).—There are twelve pens of birds. The first prize went to a perfect gem, good in all points; the second prize to a very nice bird. This class is also very good.

Pouter cocks (Any other colour).—There were only four entries, all Yellows.

Pouter hens (Any other colour).—Seven entries. First prize and silver medal and second prize, both birds Yellows, and good in nearly all points.

The Pouters were subdivided into ten classes, and numbered seventy-six entries.

Barbs (Black).—Seven pens came in for competition in this class, all of which were good. The first and second-prize birds were rich in feather, heavily wattled, broad in skull, and good in eye. The class was a good one.

Barbs (Any other colour).—There were only four entries in this mixed class.

Barbs (Bred in 1871).—This new class drew forth only six entries.

Balds and Beards.—There were fourteen pens. The first prize went to a pretty little pair of Beards (Blue), good in head, compact and neat in form, beard well defined, but the colour was a little too dark. Second came a pair better than the above in colour, but of inferior head properties. Third a pretty pair of Balds.

Tumblers (Short-faced).—Both first and second-prize pairs were good Black Mottles.

Tumblers (Long-muffed).—In this class a handsome pair of Red Rosewings are first, a pair of the same variety second. Mr. H. Yardley showed a pair of Black Mottles and a pair of Blue Tumblers, either of which appeared far superior to the second-prize pair.

Tumblers (Any other variety).—First-prize a pretty pair of Red Mottles, good in colour and markings; second a pair of Silver Baldheads. Nine entries.

The following are the comparative sales last year and this:—

	Pens Sold.	£	s.	d.
1870	145	586	16	0
1871	155	569	2	0

[We must conclude our reports, for we have several, next week.—Eds.]

Dorking (Coloured, except Silver-Grey). — *Cocks.*—1 and Cup, Countess of Dartmouth, Patshull, Albrighton, Wolverhampton. 2, J. GEESE (White).—1, J. K. Fowler. 2, Rev. G Hustler, Stillingfleet, York *hc*, Lady G. Vernon, Droitwich; T. Statter, jun.; T. Harrison, jun., Gateacre. *c*, Lady G. Vernon, Droitwich; T. Statter, jun.; T. Harrison, jun., Gateacre.

GEESE (White) —*Goslings.*—1, J. K. Fowler. 2, J. Lycett, Stafford. *hc*, Rev. G. Hustler (2); J. K. Fowler.

GEESE (Grey and Mottled).—1, J. K. Fowler. 2, J. Lycett. *hc*, Lady D. W. Fitzwilliam, Wellingborough; W. Lort, King's Norton.

GEESE (Grey and Mottled).—*Goslings.*—1 and 2, J. K. Fowler. *hc*, T. Statter, jun.; E. Shaw, Oswestry; W. Tippler, Roxwell, Chelmsford; Hon. Mrs. Colvile, Lullington, Burton-on-Trent.

TURKEYS.—*Cocks.*—1 and 2, F. Lythall, Banbury. *hc*, Rev. N. J. Ridley, Newbury; Mrs. Parsons, Bridgnorth; F. E. Rawson, Thorpe.

TURKEYS.—*Cockerels.*—1, F. Lythall. 2, E. Kendrick, jun., Lichfield. *hc*, Lady E. Isham. Northampton; Mrs. Winterton, Hinckley; E. Kendrick, jun. (2); Hon. Mrs. Colvile (2); E. Shaw; Miss Winterton, Hinckley; T. Watson, Whiteacre, Coleshill; F. Lythall (2); Miss J. Milward, Newton St. Lee, Bristol; Hon. Mrs. Colvile; W. Tippler; W. Wykes, Welvey, Hinckley. *c*, W. Wykes.

TURKEYS.—*Hens.*—1, E. Leech, Rochdale. 2, F. E. Richardson, Bramshall, Uttoxeter. *hc*, Mrs. Parsons; F. E. Rawson; E. Kendrick, jun.; F. Lythall.

TURKEYS.—*Poults.*—1, E. Leech. 2, F. Lythall. *hc*, Lady E. Isham; Rev. G. Gilbert, Claxton, Norwich; Mrs. Winterton (2); T. Watson; Mrs. Wykes; E. Kendrick, jun.; W. Wykes. *c*, E. Kendrick, jun.

PIGEONS.

ALMOND TUMBLERS.—1 and 3, R. Fulton, Deptford, London. 2, J. Ford, Monkwell Street, London. *c*, E. Horner, Harewood, Leeds; J. Ford.

CARRIERS (Black).—*Cocks.*—1, R. Fulton. 2, E. Horner. *hc*, F. Smith, Selly Oak, Birmingham. *c*, T. Waddington, Feniscowles, Blackburn; W. Woolley, Bunbury, Tarporley.

CARRIERS (Black).—*Hens.*—1, E. Horner. 2, W. Woolley. *hc* and *c*, R. Fulton

CARRIERS (Dun).—*Cocks.*—1, R. Fulton. 2, E. Horner. *hc*, W. Siddons, sen. Aston, Birmingham.

CARRIERS (Dun).—*Hens.*—1, G. Gordon, Birmingham. 2, J. C. Ord, Lupus Street, London. *hc*, J. C. Ord.

CARRIERS (Any other colour).—*Cocks.*—Prize, R. Fulton. *hc*, J. Watts. *c*, W. Siddons, sen., Aston, Birmingham.

CARRIERS (Any other colour).—*Hens.*—Prize, J. Watts. *hc* and *c*, R. Fulton.

CARRIERS (Black).—*Cockerels or Pullets.*—1, 2, and Cup, W. Siddons, sen. *hc*, H. M. Maynard, Holmewood, Ryde, Isle of Wight; W. Siddons, sen. *c*, E. Horner, Harewood, Leeds.

CARRIERS (Any other colour).—*Cockerels and Pullets.*—1 and 2, W. Siddons, sen. *hc*, G. F. Whitehouse, King's Heath, Birmingham; J. Watts. *c*, H. Yardley.

POUTERS (Red).—*Cocks.*—1 and Cup, R. Fulton. 2, F. Gresham, Shefford.

POUTERS (Red).—*Hens.*—1, E. Horner. 2, W. R. Rose, Cransley Hall, Kettering. *hc*, J. Hawley, Bradford.

POUTERS (Blue).—*Cocks.*—1 and *hc*, F. Gresham. 2, R. Fulton.

POUTERS (Blue).—*Hens.*—1, F. Gresham. 2 and *c*, R. Fulton. *hc*, E. Horner,

POUTERS (Black).—*Cocks.*—1, R. Fulton. 2, F. Gresham. *hc*, E. T. Dew, Weston-super-Mare.

POUTERS (Black).—*Hens.*—1, R. Fulton. 2, E. Horner.

POUTERS (White).—*Cocks.*—1, F. Gresham. 2, Mrs. Ladd, Calne. *hc*, W. R. Rose. *c*, E. Horner; W. Harvey; R. Fulton.

POUTERS (White).—*Hens.*—1, F. W. Zurhorst, Dublin. 2, W. R. Rose. *hc*, R. Fulton. *c*, Mrs. Ladd.

POUTERS (Any other colour).—*Cocks.*—1 and 2, R. Fulton.

POUTERS (Any other colour).—*Hens.*—1, Medal, and 2, R. Fulton. *hc*, E. Horner. *c*, T. Waddington.

BARBS (Black).—1 and 2, R. Fulton. *hc*, F. Smith, Selly Oak, Birmingham. *c*, S. Shaw, Stainland, Halifax; H. M. Maynard.

BARBS (Any other colour).—1, T. Waddington. 2, R. Fulton. *c*, W. Harvey, Sheffield.

BARBS.—*Young.*—1 and Cup, F. Smith, Selly Oak, Birmingham. 2, T. Waddington. *hc*, P. H. Jones, Fulham. *c*, H. Yardley.

BALDS OR BEARDS.—1 and *hc*, W. J. Woodhouse, Lynn. 2, W. H. C. Oates, Besthorpe, Newark. 3, J. Fielding, jun., Rochdale.

TUMBLERS (Short-faced).—1, J. Fielding, jun. 2, R. Fulton. *hc*, J. Ford, London (2). *c*, J. Watts.

TUMBLERS (Long-muffed).—1, J. W. Edge, Birmingham. 2, H. Yardley. *hc*, H. Yardley (2); J. Watts.

TUMBLERS (Any other variety).—1, W. Harvey. 2, J. Percivall, Peckham, London. *hc*, E. Horner; J. Hawley. *c*, J. Thompson, Fern Hill, Bingley.

RUNTS.—1, T. D. Green, Saffron Walden. 2, R. Fulton. *hc*, S. A. Wyllie, East Moulsey (2).

JACOBINS.—1 and *c*, J. Thompson. 2, R. Fulton. *hc*, S. Shaw, Stainland, Halifax; E. Horner; P. H. Jones; W. E. Easten, Hull.

JACOBINS (Any other colour).—1, W. B. Van Haansbergen, Newcastle-on-Tyne. 2, T. Waddington. *hc*, F. Waitt, King's Heath, Birmingham; R. Fulton. *c*, J. Thompson.

FANTAILS (White).—1, Rev. W. Serjeantson. 2, W. B. Van Haansbergen. 3, J. F. Loveraidge, Newark. *hc*, H. Yardley. (The whole class highly commended).

FANTAILS (Any other colour).—1 and 2, H. Yardley. *hc*, F. H. Paget, Biratall, Leicester; W. B. Van Haansbergen; W. Choyce, Sibson, Atherstone.

TRUMPETERS (Mottled).—1, W. B. Van Haansbergen. 2, E. Horner. *hc*, T. Waddington; E. Horner.

TRUMPETERS (Any other colour).—1, W. H. C. Oates, Besthorpe, Newark. 2, P. H. Jones.

OWLS (Foreign).—1, J. Fielding, jun. 2, E. Horner. *hc*, T. Waddington; J. Fielding, jun.; P. H. Jones.

OWLS (English).—1, J. W. Edge, Birmingham. 2, C. Gamon, Chester. *hc*, C. Gamon; G. H. Gregory; P. H. Jones.

NUNS.—1, W. Bankes, Runcorn, Cheshire. 2, W. E. Easten, Hull. 3, H. Yardley. *hc*, J. Watts; W. Choyce.

TURBITS (Red or Yellow).—1 and 2, S. Shaw, Stainland, Halifax.

TURBITS (Any other colour).—1, R. Fulton. 2, W. Bankes. *hc*, O. E. Cresswell; W. Bankes; R. Fulton; F. H. Paget, Birstall, Leicester.

DRAGOONS (Blue).—1, 2, and Cup, W. H. Mitchell, Mosely, Birmingham. *hc*, F. Graham, Birkenhead.

DRAGOONS (Red or Yellow).—1 and 2, F. Graham. *hc*, J. Holland (2), Manchester; F. Graham.

DRAGOONS (Silver).—1, R. Fulton. 2, F. Graham. *hc*, H Allsop.

DRAGOONS (Any other colour).—1, G. H. Gregory. 2, F. Graham.

MAGPIES.—1, E. Horner. 2, J. B. Bowden, Blackburn. *hc*, P. H. Jones; J. B. Bowden.

ANTWERPS (Silver Dun).—1, H. Allsop. 2, J. W. Ludlow, Birmingham. *hc*, J. W. Ludlow; R. Brierley; W. Van Wart, Birmingham; H. P. Ryland, Erdington; C. F. Copeman.

ANTWERPS (Blue).—1, H. R. Wright, Birmingham. 2, W. Van Wart. *hc*, C. Gamon; H. R. Wright.

ANTWERPS (Red Chequered).—1, 2, and Cup, H. R. Wright. *hc*, J. Croxland; J. W. Ludlow.

ANTWERPS (Blue Chequered).—1 and 2, J. W. Ludlow. *hc*, W. Van Wart; J. W. Ludlow; C. Gamon; H. R. Wright; H. Yardley.

ARCHANGELS.—1, H. Yardley. 2, W. Harvey.

SWALLOWS.—1, W. Choyce. 2, F. H. Paget, Leicester. *hc*, W. C. Dawson, Otley; T. Waddington; E. Horner.

ANY OTHER VARIETY.—1, W. C. Dawson. Extra 1 and Cup, J. W. Ludlow. 2, F. Waitt, Birmingham. Extra 2, H. Yardley. 3, F. H. Paget. Extra 3, S. A. Wyllie. *hc*, H. Yardley; F. H. Paget; T. Waddington; J. W. Ludlow; A. Crosbie, Melrose.

JUDGES.—*Poultry:* Rev. G. F. Hodson, North Petherton, Bridgewater; Capt. Heaton, Worsley, Manchester; Mr. John Baily, Mount Street, Grosvenor Square, London; Mr. James Dickson, North Park, Clayton, Bradford; Mr. E. Hewitt, Sparkbrook, Birmingham; Mr. R. Teebay, Fulwood, near Preston; Mr. J. H. Smith, Skelton Grange, York; Mr. R. Woods, Osberton, Worksop; and Mr. Edward Lowe, Comberford, Tamworth. *Pigeons:* Mr. Harrison Weir, 9, Lyndhurst Road, Peckham, London; Mr. T. J. Cottle, Pulteney Villa, Cheltenham; Mr. E. L. Corker, Croydon; Mr. F. Esquilant, 4, Effra Road, Brixton, London, S.; Mr. T. J. Charlton, 62, Trafalgar Street, Bradford, Yorkshire; Mr. H. Child, Sherborne Road, Birmingham.

CAMBRIDGE POULTRY SHOW.—We are informed this is a great success. There are more than 700 entries.

OAKHAM POULTRY SHOW.

THE vastly improved arrangement of this year's Show is certainly worthy not only of all praise, but also of the large entry of first-rate specimens which was obtained. A building expressly erected since last year, admirably lighted from the roof, and capable of holding easily from a thousand to twelve hundred pens, has secured a firm position for future meetings of this Society. Although from the time fixed being midway between the great Shows of the Crystal Palace and Birmingham many persons doubted the success of the Oakham meeting, there was an entry of considerably beyond six hundred pens, the majority of which were excellent.

Perhaps years may elapse before so large and so praiseworthy a show of Grey *Dorking* hens may again take place in this district, and yet, strange to say, the Silver-Greys proved just as indifferent. The most notable, perhaps, of any varieties shown were the White *Cochins*. They were all that could be desired, and the Black Cochins were better than have been exhibited for many years. In *Game* fowls the chief merit lay among the Brown Reds, which were not only very perfect, but mostly exhibited in admirable condition. The Selling classes were exceedingly well filled, and a very brisk sale ensued; in fact, it is well known that these sale classes are not only most popular, but also by far the best paying of any to the committees of shows.

The *Pigeons* were mostly of a very high character, but any practised eye could discern, even at a glance, that many of the best pens were ailing very much from being overdone by almost continuous exhibition.

The attendance was satisfactory, and the pecuniary success of the Exhibition much better than heretofore.

DORKING (Coloured).—*Cock.*—1, J. Hornsby, Grantham. 2 C. Speed, Exton. *hc*, J. M. Wellington, Oakham; Mrs. G. Clarke, Sutton Marsh, Long Sutton; Henry Lingwood, Needham Market. *c*, R. Wood, Clapton, Thrapston; J. Stott, Healey, Rochdale; J. Smith, Shillinglee Park, Petworth; T. Briden, Cononby, Leeds. *Hens or Pullets.*—Cup and 1, L. Patton, Hillmore, Tauntcn. 2, J. Stott *hc*, G. Jackson, Langford; E. W. Southwood, Fakenham; R. Wood J. Tyler, jun., Loughborough; Henry Lingwood; C. Speed; J. Hornsby; Briden (2). *c*, J. Hornsby.

DORKING (Silver-Grey).—*Hens or Pullets.*—1 and 2, Marchioness of Exeter Burghley Park, Stamford.

DORKING (White).—*Cock.*—1, Miss E. Williams, Henllys, Berriew, Montgomery. 2, Marchioness of Exeter. *Hens or Pullets.*—1, O. E. Cresswell Bagshot. 2, Miss E. Williams. *hc* and *c*, Marchioness of Exeter.

SPANISH (Black).—1, J. Stephens, Walsall. 2, G. Hibbitt, Exton. *Chickens.*—Cup and 1, C. H Smith, Newport Pagnell. 2, E. Jackson, Finchfield, Wolverhampton. *hc*, W. Smallwood, Springfield, Wolverhampton; J. F. Dixon, Cotgrave, Nottingham *c*, J. F. Dixon; J. Stephens.

COCHINS (Cinnamon, Buff, or Partridge).—*Cock.*—1, J. M. Otter, Newark. 2, H. Lloyd, jun., Handsworth, Birmingham. *hc*, J. Sichel, Timperley; J. Stephens. *c*, R. B. Wood, Uttoxeter; Mrs. Woodcock, Leicester; T. M. Derry, Gedney, Wisbeach; J. Taylor, Sutton, near Ely. *Hens or Pullets.*—1, J. Sichel. 2, H. Lloyd, jun. *hc*, R. B. Wood; Henry Lingwood; J. Stephens. *c*, Mrs. Woodcock.

COCHINS (White or Black).—*Cock*—1, J. Sichel. 2, Mrs. A. Williamson, Syston. *hc*, H. H. Bletsoe, Barnwell, Oundle; Rev. C. H. Lucas, Edith Weston, Stamford (3). *Hens or Pullets.*—1 and Cup, A. Williamson. 2 and *c*, Rev. C. H. Lucas. *hc*, H. H. Bletsoe; J. Sichel.

BRAHMAS.—*Cock.*—1, J. Walker, Keele, Newcastle-under-Lyne. 2, Mrs. A. Williamson. *hc*, R. B. Wood; T. F. Ansdell, Cowley Mount, St. Helens; Mrs. A. Williamson. *c*, Hon. Mrs. A. B. Hamilton, Ridgmount, Woburn; R. B. Wood; J. S. Dew, St. Neots; L. Wren, Lowestoft. *Hens or Pullets.*—1, J. Sichel. 2, T. F. Ansdell. *hc*, R. B. Wood.

HOUDANS.—1, J. Sichel. 2, W. Dring, Faversham. *hc*, R. B. Wood; W. Cutlack, jun., Littleport.

CREVE-CŒURS.—Cup and 1, C. H. Smith, Radcliffe-on-Trent. 2, J. Sichel. *hc*. W. Dring; J. J. Malden, Biggleswade. *c*, J. M. Wellington.

HAMBURGHS (Silver-spangled).—1, J. B. Bly, Lowestoft. 2, W. Hughes, Oakham.

HAMBURGHS (Silver-pencilled).—1, J. Preston, Allerton, near Bradford. 2, H. Walker, Ashwell, Oakham.

HAMBURGHS (Gold-spangled).—1 and Cup, W. K. Tickner, Ipswich. 2, T. May, Wolverhampton. *hc*, L. Wren; T. Blakeman, Tettenhall, Wolverhampton. *c*, H. Hinckley, Radhourne; T. May.

HAMBURGHS (Gold-pencilled).—1, J. Preston. 2, G. Parker, Hopwell, near Derby. *c*, M. Brown.

GAME (Red and other dark colours).—*Cock.*—1, A. J. Fludyer, Ayston, Uppingham. 2, S. Matthew, Stowmarket. *hc*, J. Richardson, Loughborough. *c*, B. Jarvis, Mansfield; R. L. Healey, Hambleton, Oakham; J. Jeken, Eltham. *Hens or Pullets.*—1 and Cup, J. Tyler, jun. 2, R. H. Brown, Pellow Lane, Halifax. *hc*, A. Fetch, Melton Mowbray; W. Jones, Worcester; E. Brough, Leek. *c*, J. Jeken; E. Winwood; B. Jarvis; R. L. Healey, Hambleton.

GAME (White, Piles, and light colours).—*Cock.*—1, S. Matthew. 2, J. Jeken. *hc*, S. Deacon, jun., Oundle. *c*, G. Parker; B. Jarvis. *Hens and Pullets.*—1, S. Matthew. 2, E. Winwood.

BANTAMS (White, clean legs).—Prize, H. L. Bradshaw, Wakerley, Stamford. *c*, Messrs. S. & R. Mottram, Manchester.

BANTAMS (Black, clean legs).—Prize, W. H. Robinson, Long Lee, Keighley. *hc*, Mrs. G. Clarke; S. & R. Ashton. *c*, Mrs. G. Clarke; H. Draycott, Humberstone, near Leicester.

GAME BANTAMS.—*Cock*—1, W. B. Jeffries. 2, H. J. Nicholson, Millom. *hc*, E. Winwood; W. B. Jeffries; Bellingham & Gill, Burnley (2); F. H. Wright, Halifax; W. Adam, Ipswich. *c*, — Johnson, Newark; H. W Currie, Thetford. *Hens or Pullets.*—1 and Cup, Bellingham & Gill. 2, W. Adams. *hc*, E. Winwood; J. Smith; Mrs. H. C. Rogers, Newport Pagnell; H. Smith; W. B. Jeffries (2); J. Oldfield, Little Horton, Bradford; G. Todd. *c*, J. M. Wellington.

POLANDS.—1, G. W. Boothby, Leeds. 2, A. Almond, Oakham.

ANY OTHER DISTINCT VARIETY.—1, E. Fane, Grantham (Black Cochin). 2, Miss E. J. N. Hawker, Wycliffe, Tunbridge Wells (Silky Fowls).

TURKEYS.—*Cock.*—1, L. Patton. 2, M. Kew, Market Overton. *hc*, Miss E. Williams; J. H. L. Wingfield, Tickencote; Mrs. Berridge, Burley-on-the-Hill; W. Kirk, Wymondham; W. Hughes, Oakham. *Hens.*—1 and Cup, L. Patton. 2, G. R. Pearson, Grantham. *hc*, G. R. Pearson; M. Kew.

TURKEYS.—*Young Cocks.*—1, Mrs. J. Mayhew, Great Baddow. 2, T. M. Derry, Gedney, Wisbeach. *hc*, G. R. Pearson. *c*, G. R. Pearson; M. Kew. *Young Hens.*—1, M. Kew. 2, J. Mayhew. *hc*, G. R. Pearson (2); M. Kew.

DUCKS (White Aylesbury).—1 and Cup and 2, G. H. Finch, Burley-on-the-Hill, Oakham. *hc*, J. Hornsby. *c*, Mrs. Lowther, Barleythorpe, Oakham; M. Kew.

DUCKS (Rouen).—1, W. H. Robson, North Reston, Louth. 2, L. Patton. *hc*, W. Meanley, Walsall; J. White, Whitley Netherton, near Wakefield. *c*, W. H. Robson; G. R. Pearson; H. B. Smith, Broughton, Preston; L. Patton.

Ducks (Any other variety).—1, Rev. C. H. Lucas, The Rectory, Edith Weston, Stamford (Kasarka). 2, M. Leno (Mandarin). *hc*, M. Leno (Whistling); S. Deacon, jun., Oundle (Buenos Ayrean); H. B. Smith (Shell). *c*, H. E. Hardy, Ewerby, Sleaford (Buenos Ayrean); Rev. C. H. Lucas (Buenos Ayrean); H. B. Smith (Carolina).

Geese (White).—Prize and *hc*, N. Whitchurch, Melton Mowbray. *Goslings.*—Prize, T. M. Derry. *hc*, G. H. Finch.

Geese (Grey).—Prize and Cup, M. Kew. *hc*, W. Kirk. *c*, Rev. C. H. Lucas.

Selling Class.—*Cock or Cockerel.*—1 and Cup, E. Robinson, Kettering (Black Red Game). 2, J. Mills, Mount Ending, Healey, near Rochdale (Dark Brahma). *hc*, H. Lloyd, jun.; J. Tyler, jun.; F. J. Barlow, Oakham; R. B. Wood (3). *c*, J. Sichel; H. Lloyd, jun.; J. F. Dixon, Cotgrave, Nottingham; J. M. Wellington; R. L. Healey, Hambleton; H. H. Bletsoe.

Selling Class.—*Hens or Pullets.*—1, J. Sichel (Buff Cochins). 2, S. S. Mossop, Long Sutton (Silver-spangled Hamburgh). *hc*, J. Sichel; Miss E. J. N. Hawkes, Wycliffe, Tunbridge Wells. *c*, Lady Aveland, Normanton Park, Oakham; C. H. Smith, Newport Pagnell; J. F. Dixon; Rev. C. H. Lucas: T. M Derry; H. Yardley, Birmingham; Mrs. Woodcock; R. L. Healey; J. J. Malden, Biggleswade; W. Hughes, Oakham.

Miscellaneous Selling Class.—1, G. R. Pearson (Turkeys). 2, Mrs. Berridge (Pea Fowls). *hc*, Mrs. Berridge; G. R. Pearson.

PIGEONS.

Tumblers.—1 and *c*, E. Horner, Harewood, Leeds. 2 and *hc*, W. B. Van Haansbergen, Newcastle-on-Tyne.

Carriers.—*Cock.*—1 and 2, E. Walker, Leicester. *hc*, E. Horner; H. Yardley. *Hen.*—1, E. Walker. 2, H. Yardley. *hc*, E. Horner; E. Walker. *c*, E. Horner. *Young.*—1, E. Walker. 2, E. Horner, *hc*, E. Walker; J. Tyler, jun. *c*, E. Horner; L. Wren.

Pouters.—1, W. B. Van Haansbergen. 2, J. E. Palmer, Peterborough. *c*, T. J. Caparn, Newark; J. E. Palmer; E. Horner.

Jacobins.—1 and 2, E. Horner. *hc*, W. B. Van Haansbergen. *c*, J. E. Palmer; W. B. Van Haansbergen.

Fantails.—1, W. B. Van Haansbergen. 2, E. Horner. *hc*, J. Walker; W. B. Van Haansbergen. *c*, G. Jackson, Langford; H. Yardley.

Trumpeters.—1, W. B. Van Haansbergen. 2 and *hc*, W. Gamble, Thorpe Satchville, Melton. *c*, E. Horner.

Nuns.—1, E. Horner. 2, H. Yardley.

Turbits.—1, E. Horner. 2, W. B. Van Haansbergen.

Runts.—1, W. R. Van Haansbergen. 2, H. Yardley.

Any other Variety.—1, H. Yardley (Barbs). 2, H. Draycott (Red Swallows). *hc*, E. Horner; W. B. Van Haansbergen. *c*, J. E. Palmer, Peterborough; E. Walker; H. Yardley.

Gold Medal for classes in poultry, Mr. J. Sichel; ditto in Pigeons, Mr. E. Horner.

Mr. Hewitt, of Birmingham, and Mr. Tegetmeier, of London, were the Judges.

BARRHEAD POULTRY SHOW.

The fifteenth Annual Exhibition and competition took place on the 25th inst., when the following awards were made:—

Old Scotch Breed.—1, Mrs. Alston, Craighead, Hamilton. 2, J. Pollock West Walton. 3, J. Laird, Johnstone. *hc*, J. Meiklem, Hamilton. *c*, A. Small.

Spanish.—1, D. M'Beith, Bridge of Allan. 2, W. Wotherspoon, Paisley. 3, A. Robertson, Kilmarnock. *c*, J. Crawford, Beith; C. H. Johnstone, Barrhead.

Dorkings.—*except White.*—1 and *c*, Mrs. Alston. 2, J. Pollock. 3, T. Smillie, jun., Kilmarnock. *hc*, Z. H. Heys, Barrhead.

Game.—*Black-breasted and other Reds.*—1, D. Harley, Edinburgh. 2, G. Williamson, Johnstone. 3, J. M'Whirter, Barrhead. *hc*, J. Cochran, jun., Barrhead. *c*, R. Andrew, Barrhead. *Any other Colour.*—1, D. Harley, Edinburgh. 2, W. Neilson, Johnstone. 3, Z. H. Heys. *hc*, A. Hutchinson, Grahamston, Falkirk. *c*, J. Blair, Dollar.

Hamburghs.—*Golden-spangled.*—1, J. Crawford. 2, D. Picken, jun., Stewarton. 3, A. Robertson. *hc*, J. H. MacNab, Barrhead. *c*, J. Moodie, Paisley. *Golden-pencilled.*—1, W. Neilson. 2, Miss Muir, New Kilpatrick. 3 and *hc*, J. Smith, Stewarton. *c*, R. MacNab, Cardonald. *Silver-spangled.*—1, J. Moodie. 2 and 3, R. Mackie, Clerkhill, Stewarton. *hc*, D. Skeoch, Stewarton; A. Stirling, Grahamston. *Silver-pencilled.*—1, J. Nicholson, 2, R. Gilmour, Neilston. 3, J. Bacup, Paisley. *hc*, H. Arndale, Paisley.

Brahma Pootras.—1, A. Robertson. 2, G. Willison, Kilmarnock. 3, W. R. Farquhar, jun., Alexandria. *c*, T. Corbett, Barhead.

Cochins.—*Any Variety.*—1, G. Willison. 2 and 3, J. Pollock, Bushby.

Topped Polands.—1 and *hc*, W. Gibb, Wishaw. 2, A. Wylie, Johnstone. 3, J. Laird. *c*, C. Walker.

Any other Variety.—1 and 2, R. Mason, Springhill, Barrhead. 3 and *hc*, A. P. White, Paisley.

Cross Breeds.—1, T. Donnelly, Springhill, Barrhead. 2, J. Pollock, West Walton, Mearns. 3, W. Reid, Arthurlie Lodge, Barrhead. *hc*, J. Fulton, Beith. *c*, J. C. Shaw, Barrhead.

Bantams.—*Game.*—1, Gow & Walker, Kilbarchan. 2, J. Ynill, Barrhead. 3, Z. H. Heys. *Any other Variety.*—1, S. & R. Ashton, Mottram, Manchester. 2, D. Muir. 3 and *hc*, A. Robertson. *c*, A. Wylie.

Ducks.—*Aylesbury.*—1 and *hc*, Z. H. Heys. 2, J. Meiklem, Hamilton. 3, J. Campbell, Johnstone. *c*, A. Robertson. *Any other Variety.*—1, J. Pollock. 2 and 3, A. Robertson. *hc*, S. & R. Ashton. *c*, W. G. Mulligans, Belfast.

Selling Class.—1, Gow and Walker. 2, R. Leitch, Barrhead. 3, Mrs. Alston. *hc*, J. Bruce, Barrhead. *c*, W. Holme, Barrhead.

Judges.—Mr. Thomas M'Kean, Cowglen Cottage; Mr. Thomas Struthers, Larkhill; Mr. Thomas Raines, Bridgehangh, Stirling; Mr. John M'Innes, Broomlands, Paisley; Mr. John Sharp, Johnstone; Mr. John Paul, Govan Street, Glasgow.

KILMARNOCK ORNITHOLOGICAL ASSOCIATION'S SHOW.

The twentieth annual Exhibition took place at Kilmarnock on November 18th, and the result has been most satisfactory. In fact, the Show has attained such dimensions that increased accommodation and a larger staff of officials will be imperative next year. Poultry numbered 391 pens, Pigeons 251, and Canaries, &c. 204, while the quality of each class showed a decided improvement in every respect. We shall give a detailed report next week.

Spanish.—1 and Timepiece, H. Wilkinson, Earby. 2, A. Robertson. 3, A. Mollons, Standiford, Wolverhampton. 4, W. Paterson, Langholm. *First Sweepstakes for Pullets*, A. Mollons. *Second Sweepstakes for Pullets*, H. L Horne, Whiterigg, Airdrie. *hc*, J. W. Will, Errol; A. Garven, jun, Kilmarnock; A. Robertson, Kilmarnock; A. Walker; H. Paton, Kilmarnock; J. Crawford, Beith; J. Yuill, Chapelhall, Airdrie (2). *c*, H. Wilkinson.

Brahma Pootras.—1, H B. Smith, Broughton, Preston. 2, H. Wilkinson. 3, R. Brownlee, Kirkcaldy. 4, A. Robertson. *hc*, J. W. Will; R. Brownlee; G. Willison, Kilmarnock.

Cochin-Chinas.—1 and Timepiece, J. Pollock, Patna. 2 and 3, J. W. Will. 4, G. Furness, Rawtenstall. *hc*, J. Musgrave, Longtown.

Dorkings.—1 and Timepiece, Z. H. Heys, Barrhead. 2, J. Robertson. 3, T. Smellie, Moorfield, Kilmarnock. 4, H. Henderson. *hc*, T. Briden, Cononley, Leeds; A. Campbell, Largs; R. Watson, Newton, Ayr.

Scotch Greys.—1, J. Meiklem, Hamilton. 2 and 3, J. Alexander. 4, T. Wallace. *hc*, W. Lindsay, Busby, Glasgow; J. Laird, Johnstone.

Hamburghs.—*Golden-spangled.*—1, S. & R. Ashton, Mottram. Timepiece, J. Jardine, Kilmarnock. 2, H. Pickles, jun., Earby. 3, T. Bowlton, Hanford, Stoke-on-Trent. 4, A. Gibb, Ayr. *hc*, R. Dickson, Selkirk; A. Frisken, Irvine.

Hamburghs.—*Silver-spangled.*—1, J. W. Will. 2 and Timepiece for best Cock, Ashton & Booth, Broadbottom, Mottram. 3 and Timepiece for best Hen, H. Pickles, jun. 4, D. Skeoch, Stewarton. *hc*, S. Smith, Northowram, Halifax; Miss Boyce, Wolverhampton; C. Arrol, Paisley. *c*, J. Bruce, Barrhead.

Hamburghs.—*Silver-pencilled.*—1, J. Ashworth, Marsden Heights, Burnley. 2, T. Bowlton. 3, H. Pickles, jun. 4, J. Walker, Birstwith, Ripley.

Hamburghs.—*Golden-pencilled.*—1 and Timepiece, R. Dickson, Selkirk. 2, T. Bowlton. 3, J. Armstrong, Longtown. 4, J. Walker. *hc*, J. Wyllie, Darvel; J. Neil, Galston; R. Clark, Overton, Johnstone. *Disqualified*, H. Pickles, jun.

Game.—1, 3, and Timepiece, D. Harley, Edinburgh. 2, R. Clarke. 4, T. Mackie, Stewarton. *hc*, T. W. Mitchell, Perth; J. Wolfenden, Light Hasels, Littleborough; J. Robertson; A. Mackay, Whitletts, Ayr; W. Copeland, Ayr.

Game Bantams.—1 and Timepiece, J. Barlow, Monkwearmouth. 2, B. M. Knox, Kilbirnie. 3, A. Wilson. 4, T. C. & E. Newbitt, Epworth. *hc*, Bellingham & Gill, Burnley; T. Barker, Hill End, Burnley; D. Johnstone, jun., Dalry; T. Barker; S. Smith; J. W. Morris; G. Furness, Rawtenstall (2).

Bantams.—*Black or White.*—1 and Oil Painting, T. Waddington, Fenniscowles, Blackburn. 2, S. & R. Ashton. 3, H. L. Horne, Airdrie. 4 J. Currie, Kilmarnock. *hc*, J. W. Will. *Any other Variety.*—1 and 2, A. Robertson. 3, Master A. Frew, Kirkcaldy (Silver-laced). 4, J. Dunn, Galston. *hc*, W. Imrie, Kilwinning (Scotch Grey); J. D. S. Crawford, Kilbarchan (Gold-laced); Mrs. J. M. Proctor, Hull (Laced); Miss E. Robertson, Kilmarnock.

Topped Polands or Crève-Cœurs.—1 and Timepiece, H. Pickles, jun. 2, W. Bearpark, Ainderby Steeple. 3, W. A. Orr, Kilbirnie. 4, Z. H. Heys. *hc*, T. Millar, Stewarton; W. Linton, Selkirk.

Any other Variety.—1, T. Bowlton (Black Hamburghs). 2, R. M'M. Banks, Broomberry, Ayr. 3, Miss Drummond, Errol (Houdans). 4, W. Kerr, Milton, Kilmarnock (Black Hamburghs).

Ducks.—*Aylesbury*—1, A. Robertson, Kilmarnock. 2, J. W. Will. 3, W. J. Thompson. 4, W. G. Mulligan. *hc*, Z. H. Heys, Barrhead; W. J. Thompson, Woodhorn, Morpeth; D. M'Naught, Kilmaurs. *Rouen.*—1 and Timepiece, W. G. Mulligan, Springfield, Belfast. 2, J. Meiklem, Hamilton. 3, H. B. Smith. 4, W. J Thompson *Any other Variety.*—1, H. B. Smith. 2, Countess of Tankerville, Chillingham Castle (Shell). 3, Miss E. Robertson. 4, S. & R. Ashton (Mandarin).

Selling Class.—1, J. Rutherford (Coloured Dorkings). 2, J. Muir, Millport (Golden-spangled Hamburghs). 3, G. Willison. *hc*, Z. H. Heys (Crève-Cœurs); Countess of Tankerville (Guinea Fowl); T. Black, Stewarton (Gold-spangled Hamburghs); W. Jardin, Perceton, Irvine (Gold-spangled Hamburghs); A. Robertson (Gold-spangled Hamburghs). *c*, A. H. Banbury, Langton-on-Swale (Cochins).

PIGEONS.

Pouters.—*Black or Blue.*—1, 2, and Timepiece, W. Mushat, Kilmarnock. 3, J. Mitchell. 4, J. Mair. *vhc*, J. Butler, Glasgow. *Any other Colour.*—1, J. Sharp. 2, J Mair, Kilmarnock (Reds). 3, D. Munn, Kilmarnock (Splashed). 4, J. Mitchell, Glasgow. *vhc*, J. Frame. *hc*, T. Imrie, Ayr.

Carriers.—*Old.*—1, G. Brown, Kilmarnock. 2 and Timepiece, G. White, Paisley. 3, D. Lawrie. 4, J. M'Crae, Dalry. *hc*, A. Richmond, Kilmarnock; T. Waddington. *Young.*—1, D. Lawrie. 2, G. White. 3, J. G. Dunn. 4, A. Wardrop, Kilmarnock.

Tumblers.—*Short-faced.*—1 and Timepiece, Master J. Miller, Kilmarnock. 2, W. R. and H. O. Blenkinsop, Newcastle-on-Tyne. 3, Miss M. S. Millar, Kilmarnock. 4, Master A. Millar, jun., Kilmarnock. *hc*, J. & W. Towerson, Egremont. *Common.*—1, J. Sharp, Johnstone. 2, J. G. Dunn. 3, T. Imrie. 4, G. Brown.

Barbs.—1, J. Mair. 2, W. R. and H. O. Blenkinsop. 3, G. White. 4, J. Renshaw, Littleborough.

Trumpeters.—1, G. White. 2 and 4, T. Rule, Durham. 3, J. and W. Towerson. *hc*, Miss E. M. Beveridge, Ayr.

Fantails.—1 and Timepiece, J. Gault, Kilbirnie. 2, R. Young, Galston. 3, T. Wilson. 4, A. Smith, Broughty Ferry. *hc*, R. Dickie, Kilbirnie.

Jacobins.—1, R. Gibson, Kilmarnock. 2, T. Rule. 3, J. Frame. 4, T. Waddington. *hc*, W. Reid, Kilmarnock.

Turbits.—1, J. G. Dunn. 2, J. G. Orr. 3, T. Waddington. 4, J. & W. Towerson, Egremont.

Owls.—*English.*—1, J. Kemp. 2, R. & J. Anderson, Newcastle-on-Tyne. 3, J. Mair. 4, J. Kemp, Haslingden.

Nuns.—1 and 4, T. Imrie, Darvel. 2, H. Shields, Newmilns. 3, G. Gilchrist.

Common.—1, J. G. Orr. 2, J. M'Crae, Dalry. 3 and 4, D. Johnstone, jun. Dalry.

Any other Distinct Variety.—1 and Timepiece, T. Waddington. 2, T. Imrie (Swiss). 3, W. Reddihough, Colne, Lancashire (Dragoons). 4, A. Johnston, Bathgate (Frillbacks).

Selling Class.—1, J. Muir (Pouters). 2, D. M'Naught (Pontars). 3, R. M. Banks, Broomberry, Ayr. 4, T. Imrie.

CANARIES.

Clear Yellow.—*Cocks.*—1 and Timepiece, D. Dick, Kilmarnock. 2, W. Wright, Greenock. 3, J. M'Kendrick, Greenock. 4, W. Love, Kilbirnie. *Hens.*—1, M. Todd, Paisley. 2, J. M'Kane, Kilwinning. 3, D. Reid. 4, W. Hunter, Kilbirnie. *c*, R. Calderwood.

Clear Buff.—*Cocks.*—1 and 2, J. Dalziel, Paisley. 3, W. Love. 4, D. Holden. *Hens.*—1, R. Hannah, Girvan. 2, M. Adam, Ayr. 3, R. Houston, Kilbirnie. 4, W. Love, Kilbirnie.

Piebald Yellow.—*Cocks.*—1, H. Adair. 2, A. Borland, Galston. 3, J Allison, Paisley. 4, J. Glasgow, Beith. *hc*, W. Paul. *Hens.*—1, A. Borland. 2, A. Lyon. 3, J. Scoular, Kilmarnock. 4, A. Lyon.

Piebald Buff.—*Cocks.*—1, A. Kelly, Paisley. 2 R. Buntin, Kilmarnock. 3, J. Glasgow. 4, B. Benny, Kilmarnock. *hc*, A. Lyon, Crookedholm. *Hens.*—1 and Timepiece, W. Hunter, Kilbirnie. 2, A. Kelly. 3, A. Crawford, Johnstone. 4, D. Reid. *hc*, W. Campbell.

Dark.—1, D. Dick, Kilmarnock. 2, J. Ferguson, Kilmarnock. 3, W. Littlejohn, Overton, Kilmarnock. *hc*, R. Bryden.

Full.—1 and 3, W. Grieve, Kilmarnock. 2, J. Calderwood. *hc*, W. M'Cluckie, Kilmarnock.

Goldfinch Mules.—*Yellow.*—1, J. Baxter. 2, W. Littlejohn. *Buff.*—1, G. Goudie. 2 and 3, J. Baxter.

Goldfinches.—1, T. Conn. 2, T. Reive, Glasgow. 3, R. Gray.

Home or Foreign Birds.—1, W. Brown (Parrot). 2, J. M. Wilson, Kilmarnock (Grey Parrot). 3, J. Scoular (Parrot).

Judges.—*Poultry:* Mr. Richard Teebay, Fulwood, Preston. *Pigeons:* Mr. J. Wallace, Glasgow, and Mr. Mathew Stuart, Glasgow. *Canaries, &c.:* Mr. John Lyell, Wishaw, Mr. T. Fernie, Paisley, Mr. John Mair, Kilmarnock, and Mr. Charles Aird, Kilmarnock.

CAUTION TO PIGEON FANCIERS.

I write to draw the attention of fanciers to a very objectionable way of packing Pigeons for exhibition—that of a locked box with the key attached. The majority of fanciers here, if

they cannot go the exhibition, are sure to be waiting the arrival of the train, and, of course, find no cause for complaint. It was while waiting for mine a few days ago at one of the railway stations that I got a glimpse of the kind of treatment our pets receive at the hands of railway officials. Some boxes of the kind I have mentioned above were coolly unlocked, and the birds examined; nay, in one case they were taken out and handled by the boys, and were not put back until they compared the prices (which were foolishly written on outside labels) and discussed the merits of the birds. That they were not fanciers was very evident from their mode of handling them, and, although birds might not be lost, still they are very unsafe in such hands. I think the boxes must have been from the other side of the Tweed, and I can assure you that every fancier here would regret that anything should occur which might keep these fanciers from our exhibitions. Supposing the birds had escaped, who could trace the responsible party? Would the railway company be responsible if it were found out? These are questions for some one to answer who knows more of these things than I do, but I think the blame would be thrown on the unfortunate secretary, as is too often the case. Perhaps this may meet the eye of the offenders (and if I can it will go before their superiors also), and it may warn them to take care for the future.—A Glasgow Fancier.

Wilts County Poultry and Pigeon Show.—As in consequence of a misprint in one of your contemporaries some misapprehension seems to exist as to the dates of the entries closing for the above Show, would you kindly allow me to say that they have not closed, but do so on Friday, December 1st?—One of the Committee.

FEEDING BEES.

The other day I procured a bottle which, including the neck, stands 9¼ inches high, and, when nearly filled, it contained 6 lbs. 10 ozs. of syrup. I placed it on a stock of bees in a Woodbury hive, the hole in the crown board of which is less than 2 inches in diameter. I placed it on the hive at 1.25 in the afternoon, and am quite sure there was no leakage. I visited it at ten minutes to nine at night, and found that the bees had taken down 4¼ inches of the height of its full diameter, or rather more than half of the whole. I saw it again at half-past six the next morning, and there then remained about three-fourths of an inch of the neck filled, so that in seventeen hours the bees had taken down quite 6 lbs. of the syrup, and not one had to leave the main cluster in the hive to obtain it.

This experiment has quite satisfied me that bees may be fed as rapidly with a bottle as by any other means, if it is properly applied. It is quite true that a feeding bottle may stand for days, or even weeks, before it is emptied; but that is not the fault of the bottle, but rather of the bee-keeper, who ought to know better. I have seen bottles that have been put on when the perforated zinc has been gummed-up with propolis, and the bees inside starving for want of the food. I have seen many cases where the food has been crystallised, forming a coat of impervious hard-bake all over the canvas strainer tied over the bottle; and others, where the strainer has been too fine or the food too thick, the food has been sucked out until the strainer has become concave above the perforated zinc, and, as no air can get through, the bees have been tantalised with the food just out of their reach, and themselves on the point of starvation. I do not, however, recommend rapid feeding either with the bottle or by any other means, as there is no condition that I am aware of in which rapid feeding is not injurious; let the unprejudiced try experiments for themselves; but if they use the bottle, let them carefully avoid the blunders I have exposed.

My plan is to invert the bottle on to a plain tin shovel, like a little dustpan, set it on the perforated zinc, and steadily withdraw the shovel; thus there is no waste or mess, and the syrup is brought into actual contact with the zinc. Of course, if the zinc is too coarse, or the syrup too thin, or the hive unlevel, the syrup will escape, which may soon be detected by the bubbles of air rising too rapidly, and should be rectified.—*English Mechanic and World of Science.*

Enormous Egg.—Mr. Thornhill, of Crumpsall Green, near Manchester, recently found one of his Ducks dead upon her nest. She had been ailing for some months, and could neither eat nor lay. The body was opened, and there was taken from it an egg, which we have seen, and which measures 18¼ inches in its greater circumference, 15⅝ inches at the smaller circumference; and its capacity is 2¼ pints of water. It contained three yolks, and the shell weighed 8 ozs.—(*Manchester Guardian.*)

OUR LETTER BOX.

N.B.—Absence from home has compelled us to defer answering a number of questions till next week.

Crystal Palace Show.—We are informed that the second prize in Silver Dorkings was awarded to J. J. Waller, Esq., Mint House, Kendal also that his Silver-Grey Dorking cockerel was highly commended.

Injuries to Fowls at Shows (*R. B.*).—The loss of your Bantam's sickle feather is only one of many similar injuries. The difficulty is to know whether the injuries occur at the show or on the railway.

Antwerps Dying Rapidly (*Pinch Eye*).—There is a disease among Pigeons called "going light," which we believe to be consumption, and the disease in your birds appears to be "galloping consumption." There is no cure, as far as we know, for the disease in either form, whether in man or Pigeon.

Rabbit Show (*Bunny*).—We know of none near London.

Terrier's Hair Falling off (*Anthony*).—Try rubbing into the bare places ointment made of equal parts of flowers of sulphur and lard. Give the dog also thrice daily three grains of the sulphur.

REMARKS.

22nd.—Rather dull all day, and began to rain about 7 P.M.

23rd.—Foggy morning, continuing so all day, but increasing in evening, clear at midnight.

24th.—Foggy in morning, clearer after, and very much more clear than we have had it lately. Moonlight at night.

25th.—Not foggy, but a damp uncomfortable day, no sunshine. Snow at 10.30 A.M.

26th.—Fine morning, rather dull after, but very bright between one and two, rather less so in the afternoon, overcast at night.

27th.—Very fine morning, rather cloudy after, and a few rain-drops between one and two (heavy rain in the south of London about the same time). Fine night.

28th.—Fine in morning and so continued all day, not bright, but fair. Bright moonlight at night.

Atmosphere very damp throughout the week, temperature rather higher than during the previous fortnight, but still low for the season. Barometer rather high and very steady for November.—G. J. Symons.

COVENT GARDEN MARKET.—November 29.

Rough goods meet with a heavy sale at present, and the quantity coming precludes any advance. Foreign imports, owing to the settled weather, are also large.

From observations taken near London during forty-three years, the average day temperature of the week is 47.3°, and its night temperature 35.1°. The greatest heat was 63°, on the 11th, 1844; and the lowest cold 13°, on the 8th and 9th, 1867. The greatest fall of rain was 1.02 inch.

ELECTION OF THE ROSES.

[The following report is from the returning officer.—Eds.]

I SEND you the promised list of Roses which has been the result of the opinions of the following rosarians to whom I wrote asking them to send me the names of thirty-six Roses, stating out of the thirty-six which they considered the best twelve:—The Rev. S. R. Hole, Mr. George Paul, Mr. Benjamin Cant, Mr. May, Mr. Charles Turner, the Rev. H. H. Dombrain, Mr. Keynes, the Rev. P. M. Smythe, R. G. Baker, Esq., the Rev. J. B. Camm, Mr. C. J. Perry, Mr. Cranston, the Rev. C. H. Bulmer, the Rev. E. N. Pochin, and to this I have added my own list, which I wrote out previously to receiving any other, in order not to be influenced by the choice of others. The result is rather extraordinary from the number of Roses mentioned, especially those only mentioned once, to the number of thirty-eight for the second twenty-four.

The analysis shows there are only three Roses—Maréchal Niel, Baroness Rothschild, and Marie Baumann, named in every case for the first twelve; for though I stated Marie Baumann was omitted once, it has since been changed for Ferdinand de Lesseps, which had previously been put among the first twelve. Next comes Charles Lefebvre fourteen times in the first twelve, and once in the second; then Alfred Colomb and La France, each mentioned thirteen times among the first twelve, and twice among the second twenty-four; next comes John Hopper eight times first and seven second. These seven Roses are the only ones always mentioned by everyone. There were altogether 46 Roses named for the first twelve, and 111 named for the second twenty-four, or in all 116 Roses; as in the forty-six Roses three are not named in the twenty-four, because they are always placed among the first twelve; and two, Madame Furtado and Marquise de Ligneris, are named once in the first twelve, and not again in the other lists. It is also noteworthy that, although there are thus 116 Roses named, yet other writers in your Journal, when naming twelve, have named other Roses not contained in this list—namely, Madame Chirard by Mr. Radclyffe, and Princess Christian by Mr. W. Paul.

I shall not add many remarks, as the list speaks for itself. The first column A contains the number of times that a Rose is named among the first twelve; the second column B the number of times it is named among the second twenty-four; and the third column the total number of times it is named for the first thirty-six.

The new Roses most highly recommended by this list are Countess of Oxford, Mdlle. Eugénie Verdier, Marquise de Castellane, Edouard Morren, Emilie Hausburg, Louis Van Houtte, and Dupuy Jamain. Emilie Hausburg will, in my opinion, rank still higher when better known, as already it has been named six times among the first twelve, no other new Rose ranking so high, and some few omitted it from never having given it a trial.

I must return thanks to those rosarians who have so kindly responded to my call, and I feel sure the result will interest them as well as nearly all Rose-growers. It shows us what a wealth of good Roses we have, as I could name several more really good Roses not included in this list, as Monsieur de Montigny, Le Rhone, La Brillante, Lady Suffield, Duchess of Sutherland, Madame Knorr, Boule de Neige, Baronne de Noirmont, François Lacharme, Prince de Portia, and others; so that I do not think we should be wrong in saying there are at least 150 Roses which ought to be grown by everyone.

Names of Roses.	A	B	C
1. Maréchal Niel	15	0	15

CHRYSANTHEMUM CULTURE.

Those who are fortunate enough to possess a large glass house, which they can devote exclusively to the culture of the Chrysanthemum, will now, if they have properly managed their plants, have such a display of floral beauty as cannot be obtained from any other class of plants in the dreary month of November. In the neighbourhood of London, especially in the north and east, much encouragement is given to the Chrysanthemum. Societies have been formed, and the exhibitions are invariably held about the middle of November, as in ordinary seasons the flower is in full beauty at that time. This being a late season, however, forcing had to be resorted to in order to bring the blooms forward enough, which is unfortunate, as it spoils the character of the flower.

The head-quarters of the Chrysanthemum is Stoke Newington, and there is the oldest, and, perhaps, most flourishing of the societies. At its Exhibition prizes are offered for plants or flowers in all the classes except the Japanese. This class does not yet rise in popular estimation, and has no place with those who cannot look kindly on anything except what is called in garden language a florist's flower. For my part I confess to a great liking for the Japanese varieties. The colours are more brilliant and decided, and the peculiar shape and arrangement of the florets have a very distinct and quaint effect. A few stands of cut blooms, or collections of pot plants, would be admired by all, and be an object of wonder to some, if they were allowed a place on the exhibition-table. Another advantage attending this class is that the flowers do not require "dressing," whereas, before a stand of twenty-four incurved blooms can be placed on the exhibition-table, they must be subjected to many hours of tedious manipulation. This dressing is sometimes carried to excess, as witness the stands exhibited at South Kensington on November 1st. It was apparent to an ordinary observer that the centres of the flowers had been torn bodily out, and enough florets did not remain to hide the disfigurement.

Dressing cut blooms of Chrysanthemums is necessary to a certain extent, and winked at by all the societies, but it should not go further than removing a badly-formed floret or a few stamens which prevent the centre of the flower from closing over. If this is all that is done to the flowers, the most practised cannot say for certain that the flower has been dressed; but where the dressing is apparent to the ordinary looker-on it ought not to be allowed. Some varieties incurve naturally, and require no dressing, whilst others, which are to be seen in all the best stands, must be dressed. This delicate operation is performed by a pair of tweezers specially designed for the purpose.

There is also at the exhibitions a class provided for Anemone-flowered varieties, which are shown in single blooms, and the Anemone Pompons in trebles, and to these ought now to be added a class for Japanese, either as cut blooms or specimen plants in pots, or both. A few notes on the culture of Chrysanthemums may be useful to some of your readers—to a large class, perhaps—for there are very few who do not grow the Chrysanthemum, though it very seldom receives the attention to which its high value as a decorative plant entitles it. Those who have only limited means, and do not intend to grow for exhibition, should have a few of the best and most approved sorts only. Exhibitors will require to grow a large number of varieties, in order to be able to cut twenty-four distinct ones on a given day.

A noticeable fact with regard to this flower is that a variety may be worthless one season and of the best quality the next. One of our most successful exhibitors recently told me that he thought of discarding that magnificent variety Princess Teck, since with him it is worthless as an exhibition flower, whilst with me it has never failed to be first-class; and other flowers which I have seen very fine at exhibitions are invariably coarse with me. Any flower that has a tendency to coarseness should not be grown in such a rich compost as the finer flowers, and but little manure water should be given it.

If it is intended to grow specimen plants for exhibition, the cuttings should be inserted in November—one cutting in the centre of a 3-inch pot, in the case both of the large-flowered and Anemone sections. The pots should then be placed in a close pit near the glass for two or three weeks until the plants are established. If a very gentle bottom heat can be maintained the cuttings will strike out roots sooner, and when rooted they ought to have an ample supply of air on all favourable occasions. Should the plants be intended for cut blooms or small specimen plants only, February and March are the best months to propagate them in. If the cutting-pots are placed in a gentle hotbed they will form roots at once, and the lengthening days and increasing heat will tend to the formation of fine stocky plants, which will not require the same care as those struck before Christmas. When the cutting-pots are filled with roots the plants should be shifted into 6-inch pots, and again when well established change into 8½-inch pots, which are large enough for the Pompon section to flower in. The large-flowered varieties should be again shifted into 11-inch pots.

Those plants required for cut blooms should be grown from the first for this purpose. They should not be pinched at all, and each plant should be grown with a single shoot, and allowed to produce but very few flowers—from three to six on each plant—three plants being potted in an 11-inch pot, so that each potful may produce from nine to eighteen flowers. The Anemone-flowered varieties and the Japanese, when grown for the quality of their blooms alone, should be treated in the same manner as the large-flowered section, as ought the Anemone Pompons, except that 8½-inch pots will be sufficiently large to flower these last in. The compost in which I have found them succeed best is three parts turfy loam, one of rotted manure, and some pounded oyster shells, a 10-inch potful being added to each barrowload of the compost.

The plants will require the protection of cold frames or an airy pit until the end of April, and the lights ought to be entirely removed in fine weather, as the plants under glass are apt to become drawn. About the end of April they may stand out of doors in an airy position on a hard worm-proof bottom of ashes or some similar material. They ought to be carefully watered until the pots are well filled with roots, when abundant supplies ought to be given to them. The summer treatment consists in careful and unremitting attention to watering, and syringing or watering overhead in dry hot weather. The shoots should be pinched until the middle of June, and trained to sticks as they require it.

The training is a matter of taste; some prefer a pyramid form for Pompons, others train the shoots down until the plants present a flat upper surface slightly rounded towards the centre. This section may be trained into very pretty standards, with clean stems of 2½ to 3 feet high. The large-flowered varieties are generally trained in the form of dwarf bushes, each flower being supported by a neat stick painted green. I have also recently seen very handsome natural-looking specimens formed by training the plants to a centre shoot, and not stopping this or any of the side shoots. They then have the appearance of inverted pyramids, and make excellent back-ground plants.

A list of the best sorts to grow is desirable, and for this we must go back to those sent out before the establishment of the Messrs. Salter, at Hammersmith, was broken up. If there have been any good varieties sent out since then, I have not seen them except on pictures. I am alluding now to the large-flowered, incurved section. We must fall back on our friend, "D., *Deal's*," experience. Has he seen anything good during the last two seasons? There have been some good additions to the Japanese class. Magnum Bonum and Jane Salter are distinct and very good varieties; the latter, I think, the most pleasing flower yet raised in its class.

In adding a list of varieties I will place them in classes, and name only those flowers which I have grown and proved to be good.

Large-flowered for Cut Blooms.—Antonelli, Aurea multiflora, Bella Donna, Beethoven, Beverley, Blonde Beauty, Bronze Jardin des Plantes, Cassandra, Chernb, Donald Beaton, Duchess of Wellington, Eve, Empress of India, General Bainbrigge, Lady Slade, Golden Beverley, Guernsey Nugget, Her Majesty, Isabella Bott, Jardin des Plantes, John Salter, Lady Harding, Lady Talfourd, Le Grand, Lord Derby, Mr. Gladstone, Mrs. Cunningham, Mrs. G. Rundle, Mrs. Sharpe, Novelty, Pink

Perfection, Plutus, Prince of Wales, Prince Alfred, Princess Beatrice, Princess of Teck, Princess of Wales, Queen of England, Rev. J. Dix, Sir Stafford Carey, Venus, White Globe, and Yallow Perfection. The best for pots in this section are Annie Salter, Aurea Multiflora, Dr. Sharpe, Gloria Mundi, Her Majesty, Lady Harding, Empress of India, Mrs. G. Rundle, Prince of Wales, and Venus.

The best Pompons are Aurore Boréale, Bijou de l'Horticulture, Bob, Brilliant, Cedo Nulli, and its golden, lilac, and brown varieties; Drin Drin, Golden Aurore, La Vogue, Mdlle. Marthe, Miss Julis, Mrs. Dix, Saint Thaïs, Rose and White Trevenna, and Trophée.

Anemone Pompons for Cut Blooms.—Antonius, Astrea, Calliope, Eugéne Laujaulet, Fire Fly, Jean Hachette, Madame Chalonge, Madame Gramé, Madame Montels, Marie Stuart, Miss Nightingale, Mr. Astie, Mr. Wyness, Perle, Princess Dagmar, Queen of Anemones, Sidonie, and Zobeide.

Large-flowered Anemones.—Empress, Fair Margaret, Fleur de Marie, Gluck, King of Anemones, Lady Margaret, Louis Bonamy, Madame Godereau, Miss Margaret, Mrs. Pethers, Prince of Anemones, Queen Margaret, and Sunflower.

Japanese.—Comet, Dr. Masters, Grandiflorum, James Salter, Mandarin, Meteor, Prince Satsuma, Negro, Red Dragon, The Mikado, The Sultan, and Viceroy of Egypt.—J. Douglas.

SELECT PEACHES.

In an interesting article in your Journal of October 26th, the names of various Peaches are quoted. Having been successful in the cultivation of some varieties not there mentioned, my experience may not be without interest to some readers.

I entirely endorse Mr. Douglas's opinion of Early Beatrice; last summer mine were poor and watery. Hale's Early, grown in a neighbouring pot in a cool orchard house, ripened its fruit two or three days sooner, and, though small, was of delicious flavour. Early Rivers was very inferior in flavour as compared to last season. On the back of my orchard house is a twenty-five-year-old Royal George Peach with a moderate crop on it. Four Peaches, of course selected as the best, weighed as nearly as possible half a pound each, and measured 9¼ inches in circumference. Early Crawford is not so much grown as it should be; its flavour is good, if it is not allowed to become too ripe, and then it is apt to become mealy. Its appearance is most magnificent at dessert. I think the best late Peaches I had last season were the Malta; they were grown on a south wall without glass, and were therefore not ready till October, for I live amongst mountains, and therefore our sun is often clouded, and my garden is 450 feet above the sea. The above Peaches coloured well, and their flavour was excellent.

Albert Victor Nectarine is a very good late kind; I believe it is one of Mr. Rivers's seedlings. It is not equal to his Victoria. No Nectarine can ever surpass, nay equal that.—C. R.

POTATO TRIAL.

I entered upon my present situation in November last year; my employer told me that they could scarcely ever get a good eating Potato off the garden; and as my predecessor was an elderly man and had been there nearly thirty years, I thought he must either have used his own seed until it was tired of the soil or the soil was tired of it, or perhaps both. I determined, therefore, to try a fresh stock, and so collected twenty different kinds from various parts of the country. Now, although it has been such a wet season, some of these kinds have far exceeded my expectations both in quantity and quality. I send you a list of the kinds I have tried, with remarks regarding these points, and also with regard to the disease.

My soil is what I consider a good Potato soil, neither heavy nor light, but with a good deal of sand in it. Those kinds marked with an asterisk (*) are what I have selected as the best suited for our soil, but I regard the three best (in the order named) as Myatt's Prolific Ashleaf, Early May, and Lapstone Kidney.

I planted a half-peck of the American Early Rose, and the produce was nearly eight pecks all sound, and only three tubers have become diseased since they were lifted. Upon trying their quality when first taken up they were not eatable either boiled, steamed, or roasted; but since being stored they boil very mealy and dry beautifully white, with the exception of a slight tinge of pink in the middle. Flourball is an immense cropper both for size and quantity, but when cooked presents more the appearance of a wax than a flour ball, but it, like Early Rose, may improve by keeping, as remarked by one of your correspondents, until after Christmas. If I had to grow but one kind I should select the true Lapstone, as I consider that is not to be surpassed either for a second or late crop; and as most of us only want about three or four kinds, it would be a great boon to many if a few of the numerous readers of the Journal, and also Potato-growers from different localities, would enumerate but three or four sorts that are really suited to their soil. We should then all know what to grow without wasting so much time, seed, and ground.

—S. Taylor, *Sion Hill, Kidderminster.*

BERRIED HOLLY.

The profusion of berries upon the Holly this winter is very remarkable. Here, in Mid-Sussex, the common green Holly abounds in the hedgerows, and may be seen in thousands upon the wide-spread track of waste land known as "The Forest," ranging in size from the low-stunted bush to splendid specimens of perfect form and noble proportions. There is now a beautiful display of red berries, the branches of many trees being laden with their winter fruitage in such rich profusion as I have never seen equalled.

I suppose this abundance of Holly berries to be very general, as I lately saw some trees near Woking, in Surrey, very fruitful. I need not dilate upon the charming effect which the bright red berries have in contrast with the glossy deep-green foliage. Holly is too intimately associated with Christmas festivities not to be well known to old and young, and I would ask, Why it is not more frequently planted in large quantities in place of that sickly-looking plant the common Laurel? Here, at Oldlands, it grows in the woods by thousands, thriving equally well in deepest shade or brightest sunshine; no drip or crowding affects its health, its sturdy nature enabling it to flourish under circumstances and in situations such as would prove fatal to most other shrubs. Its growth may be somewhat stiff, but it can never be called ungraceful; and when, as now, it puts on its full, rich, winter magnificence of scarlet and green, it far surpasses all other shrubs in beauty.

There is a peculiarity of the Holly which I cannot understand; two trees, or a number of trees, may be frequently seen growing side by side, apparently equally vigorous, and very similar in every respect, with this exception—that some will be laden with berries, while others are totally barren. Why is this? Am I to suppose that there are male and female trees? If so, the only perceptible difference must be in the flowers, and these I have never examined closely.—Edward Luckhurst.

ORANGE TREES UNDER VINES.

Few persons are, I think, aware how well Oranges thrive under the shade of Vines if properly attended to. I have for several years grown the St. Michael and Tangerine Oranges in the cooler portion of a lean-to house. In this house there is in front a 6-feet border between the brick flue and the wall. In this the Vines are planted next the wall, which is built on arches, and in the same border next the flue are a row of Tangerine Oranges. There is a narrow strip behind the back flue, where are placed several large Orange trees in pots. A gentle heat is given during the cold months so as to keep out frost, and the trees are constantly examined for scale and rust.

Manure water is given nearly once a-week, and a little soot is laid on the top as a dressing. Several of the trees are well hung with fruit now turning yellow, while the leaves are of a fine dark green, and the growth of wood is very vigorous. On one Tangerine tree I ripened last year thirty-six nice Oranges. Oranges grown for dessert, of course, do not pay as a speculation, but the trees with their golden fruit are very handsome, and form a little cheerful winter garden.—J. C. Barnham, *Norwich.*

SCARCITY OF FRUIT AND THE REMEDY.

Nothing so fully proves the value and utility of a plentiful supply of fruit, especially Apples, as seasons of general scarcity like the present. In a prolific fruit year the demand for good produce is always equal to the supply, whilst a dearth of fruit is to many little short of a calamity. The population of the kingdom is growing apace. Cities and towns are expanding and sweeping away trees by thousands. How many trees, how many orchards, once flourishing in the immediate outskirts of fast-spreading towns have, within the last twenty years, been uprooted when in the plenitude of fruitfulness? How many tons of fruit have by this means been taken from the consumer? Were it, however, possible to put the loss in a tabulated form, we should be startled by its magnitude. This loss can only be met by a corresponding increase of trees. Has such increase been sufficient to restore the balance? Up to the present time results would seem to answer in the negative. Unquestionably large numbers of trees are every year planted; perhaps, indeed, so far as mere numbers go, more are now being put in than during any previous period. But where do we look for the great increase of planting, and what are the characters of the trees planted? On this point there can be little question that the places more than others where the regular planting of trees is a part of the yearly routine are in the grounds of the nobility and gentry; and the reason they are planted in greater numbers than in past times is explainable by the different class of trees now available, of which a given number go in infinitely less space than the ancient standard type. The free planting of trees of this special class in such places is a wise practice.

Early-bearing trees are naturally in favour with the gardener. He is, as a rule, of migratory habits. Anxious to see the fruits of his labours, he plants those which produce the soonest; and it cannot be denied that, in many instances, it is the only means he can adopt, as, before slower bearers are in anything like perfection, he probably may be gone. They also well serve the owner's purpose, for he, too, likes quick returns; besides, they give the extensive variety which is coveted.

This extensive planting, and the consequent plentiful supply, add, however, but little to the fruit resources of the nation. That they have an effect there can be no doubt, but it is almost solely negative, and a positive effect is better. In such places trees are sufficiently planted to give a fair supply in even a season of scarcity. This is as it should be. But on the other hand in a good season the surplus is immense. Where does it go to? In far too many instances, it is neither allowed to be sold nor given away. This is not as it should be. I remember that a great boast of a gentleman was that he gave his pigs a ton of Apples a-year. He, of course, had a perfect right to give the fruit to the swine, and a right even to boast about it, but the propriety of the deed is questionable. Large plantations of fruit trees have also been made by far-seeing judicious nurserymen for the purpose of realising profits by the sale of fruit. The returns have done credit to their judgment and skill in selection, but that the demand is still great is evidenced by the extreme prices obtained. Similar plantations are yet needed for the benefit of the consumer, and would leave a good margin of profit to the producer, taking into account the reduction in value from an increased supply.

Besides the loss of fruit by the encroachment of towns, the supply in country produce is diminished and diminishing. This, again, is not as it should be. Judging from the garden and orchard ground disposable in country parishes, it is surely reasonable to expect that nearly every village should grow sufficient fruit for its own consumption. This, however, is by no means the case, and the village populations are important competitors with the cities and towns for the productions of the great fruit-growing districts of our own and foreign countries.

Take a general glance at the character of the trees in the rural districts. As a rule they are scraggy and decrepid, fast falling into decay; and apparently there is scarcely anything to take their places. Many of these trees have in their best days produced half a ton of fruit each in good seasons. A few such are still to be seen, but they are rare, and each year are becoming more scarce. There appears to be little disposition to plant useful fruits in cottage gardens compared with what there was in years gone by. This is most probably traceable to the diminished number of freeholds.

While fully admitting the drawbacks of the principle so steadily carried out, there can be no doubt but that, in many instances, the purchasing of small holdings by capitalists and large landed proprietors to add to their estates has been of benefit to the districts. Decent dwellings have gradually taken the place of tumble-down hovels unfit for human habitation, and the sanitary measures adopted have tended to diminish dirt and increase morality. But there is such a thing as moral pauperism, and it is a question if it is not being fostered by the present state of things.

If landlords would but establish small farms on long leases, they would strike a deadly blow at the ugly pauper question, which is a growing evil. The pure labourer has nothing else to look forward to. He has not the means of helping himself out of it, however willing he may be to do so.

But fruit is the question, and buying-up of small holdings has tended to diminish it. When a tree shows signs of decay a landlord does not hesitate to plant another to take its place, but it is very different with the yearly tenant. Cottage tenants are, naturally, very reluctant to plant. However trifling the first cost of trees may be, the fact of their becoming the property of the landlord the moment they are in the ground, has a decidedly deterrent effect on the mind of the tenant. A yearly tenant argues thus: "I am not going to buy trees for my landlord, I may be gone soon and never see my money again." That fruit trees are valued is certain by the fact that a garden containing them is seldom long without a tenant. The fact also is very striking that, as soon as a man gets a piece of ground as his own, it hardly matters how small it may be, the first thing he does is to plant fruit trees.

Now, without assailing the law, but taking it as we find it, and without taking cognisance of any possible compensatory code, a suggestion may at any rate be ventured. Considering the growing scarcity of fruit in village gardens, and the cause that has mainly contributed to it, would it not be well if the landlords could see the expediency of furnishing a reasonable number of well-selected kinds of useful fruit trees to the gardens of their tenantry? The first cost to them would be a mere trifle, and even this would not be lost, as the annual rental would in time, with justice, be increased, and would even then be an advantage to the rentpayer. The extensive adoption of this plan would not only benefit those directly concerned, but would also confer an important advantage on the nation at large. Trees for this purpose should be of the old-fashioned standard type, requiring little or no trouble to keep in order. Let those possessing cultural knowledge plant bushes and pyramids to their heart's content; but for the inexperienced the old-fashioned standard orchard trees will, in the end, give the greatest amount of satisfaction.

The point to be kept in mind in selection is to plant as few kinds as possible. Early Codlin Apples as Domino and Lord Suffield, and later ones as Blenheim Pippin and Dumelow's Seedling, and Victoria Plums—such as these planted in duplicate would, over and over again, be of more real service than calling into requisition fifty or a hundred varieties.

The same with regard to dessert kinds. The best way to ensure profit is to select a very few of the very best, and of these plant largely. A hundred trees of Cox's Orange Pippin and Sturmer Pippin, for instance, would give a better return than planting the same number in as many or half as many varieties.

Limitation in selecting trees is not quite so much recognised generally as it should be. It is easy to err in planting too many sorts. It is well that this be impressed on young gardeners especially.

I would also call attention to another point. Many persons would plant trees who do not do so if they had a site whereon to plant. The point I conceive to be worth a thought is the advisability of planting fruit trees in and about shrubberies. Now that Beet and Kale are considered legitimate subjects for flower-garden ornamentation, surely fruit trees will not be voted incongruous as shrubbery decorative objects. Indeed, they cannot with much reason be objected to for this purpose, seeing they are prepared for and admitted into the conservatory for the sake of their floral effect. On the merits of their profuse and delicate tinted blossom alone, fruit trees are submitted as fit and proper subjects for extensive association with evergreen shrubs. Then there are the additional ornament, and, what is more to the point, the usefulness of the fruit. In the vicinity of large towns every

piece of ground is, in numberless instances, devoted to flower garden and shrubbery. The occupiers are large fruit-consumers. They have it all to buy, but most would prefer growing it. Shapely pyramids of Pears, Plums, and Apples, intermixed with shrubs, would give them fruit and flowers too, and could hardly offend the taste of even the most rigid æsthetic. Whether the "good and bad neighbour" theory has anything to do with it or not I cannot tell, but I observe that fruit trees, in common with deciduous trees generally, invariably flourish admirably amongst evergreen shrubs. The only really good crops of Apples I have this year seen were amongst shrubs, where the branches were literally bowed to the ground by the heavy tresses of excellent fruit. "Sheltered from frost," perhaps some may say. Well, if so, recognise its value. On this point alone the subject is worth consideration.

In reference to the devastation of fruit blossoms by spring frosts something may be done in plantations to lessen this by those who are able and yet do not pay attention to it, and that is the grouping of fruit trees among forest trees. It is quite common to see plantations of forest trees contiguous to country residences. The primary object of these is shelter. If in the centre of such plantations a place were planted with fruit trees, as an orchard, the shelter would be just the same, and the outward appearance would be just the same, while much valuable fruit might be drawn from the interior, especially in such seasons as this, when the blossom on exposed trees and orchards is killed by spring frosts. I have in my mind's eye a large wood on a gentleman's estate. Some years ago one of the workmen took a fancy to put in some grafts of Apples on the wild Crab stock growing about the wood. These trees eventually bore fruit, and what is more to the point, gave useful crops when the trees in the gardens were bare, in consequence of a lack of shelter, which was afforded to the trees in the wood. In my very limited travels this summer I have only seen one really well-laden orchard, and it was in a plantation surrounded and sheltered by Fir trees. My remark at the time, spontaneously uttered, was that "If I had a plantation of my own, but I never shall have, I should grub up some of the trees in the interior and plant fruit trees." On reflection I firmly adhere to that remark, feeling confident that if put into action I should often have plenty of fruit when I should otherwise have none at all.—J. W, *Lincoln.*

THE MADRESFIELD COURT GRAPE.

A most excellent Grape in some respects, being a good grower, of free habit, and a good setter, with large berries and good colour; but the most important quality it lacks—it will not keep after it is ripe more than three weeks or a month. I have tried it two years, last year in a late house, and this year in an early house. In the first, or early house, it was very fine and handsome, with very large berries of good flavour and good colour, but would not keep three weeks after it had become ripe. I kept one bunch four weeks, but it was not fit to send to table. That was in June. At present (November 1) I have some in a late house; they have been ripe since the end of September; now there is not a bunch fit for use. It is not so good as the Hamburgh as regards keeping qualities. I would earnestly advise anyone having a large demand in the autumn to plant a good number of it for its beauty and flavour. I am disappointed in it only in one respect—namely, that it was said to be a good late Grape.—J. Freeman, *Knowsley, Prescot.*—(*Florist and Pomologist.*)

ROYAL HORTICULTURAL SOCIETY.

December 6th.

Although the weather had been very cold for two or three days previously, there was, notwithstanding, a good show for this time of year, and especially was this the case with the fruit and vegetables. In the floral department the novelties were but few, and the certificates fewer still; yet as a whole this meeting, the last of the present year, afforded most encouraging prospects of what we may expect next season with the enlarged and more liberal schedule of awards which the Society has offered.

Of Tree Carnations there were no exhibitions in Classes 1 and 2.

In Class 3, for twenty-four Japanese and late Chrysanthemums, Mr. E. Rowe, gardener to Mrs. Lewis, Rochampton, was first with very good examples of John Salter, Lady Harding, Mrs. Halliburton, Princess of Wales, Venus, Nil Desperandum, Mr. Brunlees, Isabella Bott, Miss Mary Morgan, Yellow Perfection, Princess Beatrice, Nonpareil, Mr. Gladstone, Jardin des Plantes, Abbé Passaglia, and Lady Slade; of Japanese, Dr. Masters and Red Dragon, large. Second, came Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, with very fine blooms of Princess Teck, Pink Perfection, Miss Maréchaux, Mrs. Pethers (Anemone-flowered); and of Japanese kinds, Red Dragon, very fine in colour; Dr. Masters, Bronze Dragon, Grandiflorum, Magnum Bonum, and others. Mr. Goddard, gardener to H. Little, Esq., Cambridge Villa, Twickenham, who was third, had excellent examples of Red Dragon, Comet, The Daimio, and Aurantium (Japanese varieties), and good blooms of the incurved kinds. Mr. Hobbs, Lower Easton, Bristol, and Mr. George, gardener to Miss Nicholson, Putney Heath, also exhibited. Messrs. Jackson & Son, of Kingston, had a special certificate for a stand of twenty-four, shown not for competition. In this were remarkably fine examples of The Daimio, Red Indian, Aurantium, and Madame Godillot, Japanese kinds, and some large blooms of the incurved kinds, notably John Salter and Golden Beverley. Mr. Shrimpton, gardener to Mrs. A. Doxat, Putney Heath, had also a special certificate for some very large blooms, amongst which were the finest examples of Jardin des Plantes and Empress of India we have seen this year. John Salter and others were likewise very fine.

Class 4 was for the best collection of Hardy Evergreens bearing berries, exclusive of Hollies. Messrs. Standish & Co., of Ascot, were the only exhibitors, and took a first prize with beautifully grown little plants of varieties of Pernettya mucronata, P. pilosa, the cheerful Skimmia japonica, berry-bearing Aucubas grafted as half-standards, and Cotoneaster Simmondsii. Prizes were also offered for collections of nine Hollies and of six Box, but no exhibitors came forward.

Class 7 was for nine Hardy Evergreens of the Yew or Cypress tribe in 12-inch pots. Messrs. Standish had the first prize. Foremost amongst their collection were Taxus fastigiata aurea, a beautiful Golden Yew never browned by the sun; Cupressus Lawsoniana fragrans, finely furnished, and more glaucous than the type; and Retinospora lycopodioides, one of the handsomest of the new Japanese Conifers, and this one of the best specimens in the country. The others were Retinospora obtusa alba variegata, R. pisifera stricta, R. obtusa; Taxus coriacea, very distinct; and T. adpressa stricta.

Mr. George had an extra prize for a box of cut flowers, consisting of Cypripediums, Camellias, Azaleas, &c.

Prizes were offered for collections of hardy herbaceous plants, also for Endive and other Salading, but no one came forward to claim them. Mr. Meakes, gardener to R. Fowler, Esq., Petersham, sent a small collection, but as it was not entered it could not take a prize. Messrs. Carter & Co., High Holborn, offered prizes for collections of vegetables. There was only one exhibitor, Mr. Pragnell, Castle Gardens, Sherborne, who took the first prize with a large and very fine collection. His Carrots of various kinds, James's Keeping Onions, Hollow-crowned Parsnips, Salsafy, Scorzonera, Savoys, Kale, Cabbages, &c., were most praiseworthy.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. Crescuolo, Kay, & Co., of Gracechurch Street, sent fine specimens of Globe Tripoli Onions, grown in Italy. These imported Onions are said to be free from the strong disagreeable flavour of Onions when used in salads. Mr. P. J. Perry, of Banbury, sent some very fine specimens of the pure White Spanish Onion, which were much admired and commended. Messrs. Sutton & Sons, of Reading, sent roots of New Orange Naples Garlic, a remarkable new variety of a round regular form like an Onion, and not in the form of separate "cloves" as in the old sort, and of a peculiar orange colour. There was no information in regard to their culture, and as they were imported roots the Committee reserved an opinion till they had been grown in this country. Mr. William Jones, Kelvoy, Nenagh, Ireland, sent specimens of Leathercoat Potatoes as an example of the crop grown on the reclaimed lands of Ireland. A winter Radish from California, received from Mr. Robinson, was exhibited from the Society's garden at Chiswick. It is white and like the Teltaner Turnip in shape, very tender and succulent, and was considered useful for winter salad. It was awarded a first-class certificate. Mr. Sidney Ford, The Gardens, Leonardslee, Horsham, sent bulbs of Veitch's Red Globe Turnip, sound and succulent. Mr. Sage, The Gardens, Ashridge, sent roots of "Table d'Hôte" Potato, a long, small, deep-eyed variety, much used in Paris. Mr. Piccirillo, of Wigmore Street, sent heads of the Naples Champion Cauliflower, a variety very similar to Veitch's Autumn Giant. Mr. Parsons, The Gardens, Danesbury, sent six sorts of Celery for the Committee to distinguish their several merits. They were Grove White, Hooley's Conqueror, Williams's Matchless, Matchless White, Henderson's White, and Matchless Pink. Mr. Cadger, The Gardens, Luton Hoo, sent a quantity of fruit of Luton Hoo Cucumber, which were much commended as being excellent for the season of the year.

Mr. Young, gardener to Lionel Ames, Esq., The Hyde, St. Albans, sent a very fine dish of Marie Louise Pears.

Mr. G. Johnstone, gardener to Earl of Strathmore, Glamis Castle, N.B., sent two handsome Smooth Cayenne Pines, weighing in the aggregate 16 lbs. A special certificate was unanimously awarded. Mr. W. G. Pragnell, gardener to G. D. W. Digby, Esq., Sherborne Castle, also sent a Smooth-leaved Cayenne Pine, weighing 7 lbs., but it was a little defective in growth. Colonel Wallace, of Lochryan, Cairnryan, N.B., sent fruit of Golden Hamburgh Grape, with the following communication:—

"30th Nov., 1871.

"Sir,—I send you by post to-day in a small box some berries of Golden Hamburgh Grape, which I will be glad if you will show to your Fruit

Committee, and kindly let me know their opinion of. They have been ripe since the beginning of August, and so I fear may not carry very well; but I send them, as I think we always succeed in growing that Grape here very successfully both as to size and finish, and we sent them even finer than those to the International Show in Edinburgh in 1869. I attribute it to the borders being thoroughly aërated, and to there being no manure of any kind in them, as they are composed of ten parts rotted sods, one part of broken bones, and one part of lime rubbish, and nothing else whatever. The Vines are now bearing the fifth crop, and so they are, of course, at their best; but as the bones were broken very large, and there is no manure to be speedily exhausted, I expect they will remain equally good, if moderately cropped, for many years. We have grown White Tokay to 14, 16, 18, and 19 lbs., and never less than two bunches on a Vine. On one Vine this year we had the largest and smallest of these weights—14 lbs. and 19 lbs.

"Your obedient servant,
"WILLIAM S. F. A. WALLACE."

These, when they arrived, were large, handsome, and sound berries, but as they came some days before the meeting they had decayed considerably. Mr. A. Ingram, The Gardens, Alnwick Castle, sent bunches of Mrs. Pince, Lady Downe's, and a seedling. Mr. William Paul, of Waltham Cross, exhibited a bunch of his new Grape, Waltham Cross, in splendid condition. The bunch was very large, and the berries immense. This received a first-class certificate at a former meeting, and it was again much admired. E. Hubbard, Esq., exhibited a fruit of the Osage Orange, grown in the botanic garden at Parma. Messrs. Lane & Son, of Berkhampstead, sent a grand collection of Grapes, consisting of Alicante, Trebbiano, Gros Guillaume, Muscat of Alexandria, Bowood Muscat, Duchess of Buccleuch, Lady Downe's Muscat Hamburgh, Black Prince, Foster's Seedling, Frankenthal, and Black Hamburgh. The bunches were splendid specimens of high cultivation, and the collection received a special certificate.

From Messrs. Stuart & Mein, Kelso, came a quantity of Borecole, distinguished as Stuart & Mein's Extra Curled. This was as densely and beautifully curled as the finest curled Parsley. Unfortunately, it arrived too late to be submitted to the Committee.

FLORAL COMMITTEE.—W. Marshall, Esq., in the chair. Mr. Lee, florist, Arundel, sent blooms of several seedling tree Carnations, one of which, Mars, was a showy crimson scarlet. Mr. Clark, market gardener, Twickenham, exhibited a collection of Cyclamens raised from seed sown January 28th, and in very good bloom. Mr. Goddard, gardener to H. Little, Esq., Twickenham, also sent a collection of Cyclamens. Queen of Crimsons, rich deep crimson, had a first-class certificate.

A first-class certificate was also given to Mr. Green, gardener to W. Wilson Saunders, Esq., Hillfield, Reigate, for Argyroxiphium Douglasii, with silvery long-lanceolate leaves, an ornamental little plant from the Sandwich Islands. Yucca longifolia also came from the same exhibitor. Mr. Chambers, gardener to J. Lawrence, Esq., Beddington, sent flowers of Ipomæa cœlestina, large, and of a beautiful azure blue. Messrs. Standish & Co., of Ascot, sent a very graceful plant, Asparagus decumbens, with white and orange flowers, a native of the Cape of Good Hope, but long known in this country. It would be a pretty plant for table decoration.

Mr. Kerr, gardener to J. G. Shephard, Esq., Wickham Market, exhibited tree Carnations, and Messrs. Downie, Laird, & Laing a good white Chinese Primula, called New White. Mr. Rowe exhibited a fine white sport of Chrysanthemum Venus.

From Messrs. Veitch, of Chelsea, came several plants of a yellow-fruited Capsicum, called Yellow Gem. These were admirably grown on single stems of a foot or so high, and each had from eighteen to twenty-four fruit. A fine collection of hybrid Solanums, covered with berries, from Mr. Williams, of Holloway, had a special certificate. Mr. Williams also exhibited a variety of Lycaste Skinneri, with two flowers borne so closely together that they almost resembled a doubled flower.

Mr. Freeman, gardener to Sir J. Sebright, Bart., Beechwood, sent five fine cones of Picea nobilis from a tree fifty-eight years old. Models of Umpleby's hot-water circulator, and of Rendle and Burrow's system of glazing without putty, were also exhibited.

THE dates of the Committee Meetings and Shows for 1872 are January 17th, February 14th, March 6th and 20th, April 3rd and 17th, May 1st and 15th, June 5th and 19th, July 3rd and 17th, August 7th and 21st, September 4th and 18th, October 2nd, November 6th, and December 4th. The second May Show will last two days, and the first June Show three days.

CUT FLOWERS FOR TABLE DECORATION.

IT is said in the cookery-books:—

"If the woodcock had but the partridge's breast,
'T would then be the finest bird ever was drest;
Or the partridge had but the woodcock's thigh,
'T would sure be the finest bird ever did fly."

And so it is with the arrangement of flowers. The exhibitor of Roses is fain to add the graceful frond of the Maidenhair Fern to back the brilliant Rose-bud, notwithstanding "the veil of moss around it thrown;" but as the frond of the Maidenhair Fern bears no resemblance to the natural foliage of the Rose, if a pinnate leaf could be found equal to the Fern frond in gracefulness, it would be a very desirable acquisition for table decoration. For since Nature has generally supplied leaves of more or less beauty as a back or foil to flowers, we cannot greatly err in imitating so good an example in our artificial combinations. We have, moreover, in Nature a very notable example of this principle holding good, for we see in the fair colours of the rainbow that this glorious messenger rides upon or spans a dark cloud, and its beauteous tints are thereby enhanced in brilliancy. The leaves of the plant that I am about to recommend are not by any means tenacious of life, for if they are left out of water for a very short time they quail and dry up beyond all power of revival. It is a British plant, fond of rich soil and plenty of water; but when used for house decoration with flowers that are to stand in water, this failing of fondness for water becomes a virtue, and the leaves really enjoy the in-door life and the water so much, that after a week in a living-room I found that they had not only kept fresh, but had curled up to the light, and felt quite firm and crisp, unlike most leaves when kept a week in-doors. This is no other than one of the Cinquefoils, Potentilla anserina, the Goose Tansy of the older botanists and the Mossies of the north of Scotland. The leaves being silky on the under side, elegantly cut, and interruptedly pinnate, seem by Nature meant to adorn, and as the plant belongs to the Rosaceæ, the leaves fall in admirably with Roses and all the Rose tribe in table decoration. It is no matter which side of the leaf is seen, as the back is a silvery grey, and the face a light green. The foliage of this plant should be treated as an aquatic when in-doors, and it will then feel quite at home, and form a nest, or bed, or back for naked flowers, especially Roses, whose stems must of course be immersed in water.

So much for the wet medium in which to keep flowers, but there is also a dry one for a very elegant tribe of plants which are also extremely useful for table decoration—viz., the Grasses. These should be raised high enough to let their graceful curves and bends be seen to advantage, and should consist of mixed species, not, as we frequently see them, a bundle or sheaf all of one sort, and not only so, but caricatured and dyed red, blue, mauve, magenta, or some other unnatural colour—for it is just the unnatural arrangement of natural materials that is to be reprobated in ordinary house and table decorations.

Some may think the arrangement of flowers an easy matter, and of little importance; but if so, why are premiums offered at exhibitions for the best? and what becomes of the millions of nosegays that the Hebrew maidens manufacture in London, in what one might term the "button-hole" business, where a single Pelargonium leaf is the background, and any showy flower, however plain, in red or yellow, is very unnaturally mated to form the face? I have watched the craft at work, and have seen sprigs of Asparagus tied firmly and fast to a shabby truss of Tom Thumb Pelargonium flowers, to form a "posey knot" wild and disorderly. Now the flower of the Potentilla anserina has five golden petals, and is of nearly the same size as that of the wild Rose; indeed, it is as like a single Rose as it well can be; it is, therefore, in every way a meet companion for any of the members of the Rose tribe.

Those who admire Ferns have to sober down their ideas from gaudy flowers, for the flowerless Fern tribes expend all their energies on the fronds, and therefore they can afford to rise high in the leafy line. The Grasses, on the other hand, with a few notable exceptions, have inconspicuous flowers, but their habit and manner of flowering are exceedingly graceful, and they have no need of water to preserve their beauty when kept in-doors. This is no small recommendation to many parties, who are so peculiarly placed that they could not keep flowers in water; for I must not hide the fact that the water in which decaying flowers are kept becomes exceedingly offensive: hence the importance of dry flowers where there is any risk of flowers kept in water being neglected. The three Brizas—maxima, media, and minor—are, when in flower, very attractive, and may serve as examples of beauty in our native Grasses. When we see their hearts of chaff dangling in the meadow, we would gladly carry them home and admire their beauty for years to come, for they are veritable immortelles, and when enclosed in glass cases with stuffed birds they will last a lifetime. I mention these well-known species to show the sweet and cleanly character of Grasses when adopted for house decoration.

Let no one think, much less speak, lightly of cut flowers to make home look cheerful and happy. And this luxury is within the reach of thousands, wherever there is a roadside or hedge-bank or a common. I have used bushels of cut flowers, grown on purpose, to adorn the apartments of noblemen's

mansions, and I have carried a few cut flowers to the table by bedside of an invalid to cheer the dull surroundings of the sick-room by their lively looks and sweet odour; but it is on festive occasions that the decorations of the table rise in the esteem and play an important part in the merrymaking; and, like the music and the dancing, they are really part of the get-up, since the setting-out of the table on such occasions would be the talk of the guests for many years to come. It was only following the true spirit of merrymaking that made the Northern minstrel say—

"A Christmas gambol oft would cheer
The poor man's heart through half the year."

—Alex. Forsyth, *Salford.*—(*Florist and Pomologist.*)

TEA ROSES IN THE OPEN AIR.

As regards Tea Roses and Hybrid Perpetuals I do not think there is so much difference in their hardiness as many suppose, at least I do not find it so. Much, of course, depends on the soil and locality, yet I think more on the former than the latter. I have read with much interest the lists given from time to time in the Journal of the twelve best Roses, and, as I fully expected, the lists vary considerably, which, I think, may be accounted for as much by the soil on which they are grown, as the taste of the selector. Roses that do well with me are but poor in comparison in the gardens of some of my friends, and also, on the contrary, those which thrive well with others, in some instances I cannot induce even to grow. Take, for instance, that fine Rose Maréchal Niel, I have tried it on the Briar, on the Manetti, on Gloire de Dijon, and on its own roots, and it will not do. Some of the Hybrid Perpetuals serve me the same way. Lord Macaulay will not do with me, and I have seen it strong in other grounds. But what I wanted to say is that the few Tea Roses I have are in the most exposed position in my grounds, on the slope of a hill that has a north-east aspect, and no protection from the winds coming for miles and miles over the valley of the Medway, and I have not lost one from the cold or wet. I had one blown off close to the ground, but it did not break again, and that has been my only mishap. It was the Duchesse de Cazes, and had become a good-sized bush. I have Bougère, Souvenir d'Elise, Souvenir d'un Ami, Comte de Paris, Madame Willermoz, Madame Labonté, Ducheese de Cazes, President, with others, doing well, and seldom cut up by the frost; in fact, not so much so as my Hybrid Perpetuals, some of which I lost last winter, and others nearly so. I have a pillar of Céline Forestier, 6 feet high, in a most exposed position, and it only, as a rule, loses the tips of the shoots each winter. Gloire de Dijon does wonders, and is, I think, one of the hardiest Roses I have, and one of the most beautiful. My soil is a kind of loam on a dry subsoil, and I think the dryness of the roots helps much to my success with the Tea Roses. All the protection they have is a little rough stable straw shaken in between the branches. I am of opinion that Tea Roses in the south of England are much more easy of cultivation than is generally supposed, and I have just ordered a number of other varieties than those I now possess on purpose to test them, but I have no fear of the result. I do not think they will do well out-doors on wet clays, but on light or high land I think the grower will be very agreeably disappointed with them.

I shall not attempt to scrutinise the various lists of twelve Roses that have appeared, for, as I have said at the commencement of this, soil and situation have a great influence, but I may say some mentioned I shall not grow any longer, as they will not do well with me, while others not noticed have with me been fine. In the Rose it is so much a matter of taste.

I write the foregoing with the hope that other amateurs, as well as myself, will try the capabilities of the Tea Rose for out-door cultivation, and if they do I shall be pleased to learn from them their experience, as by such means we can help each other.—Harrison Weir, *Weirleigh, Kent.*

MANCHESTER BOTANIC GARDEN.

It is certainly much to be regretted that the term Botanic Garden is often given to a place widely different to what one would suppose it to be from its name. Sometimes a fashionable resort for those who care no more for plants than the colour of the flowers they bear, is unduly dignified by the name of "The Botanic Garden;" or it may be that some garden, once deserving that name, has through the force of circumstances, descended into the condition of a plot of ground devoted solely to the display of showy summer-flowering plants. There are, however, exceptions to this, and now and then we meet with a place where the legitimate purpose of cultivating a collection of plants having permanent botanical character and distinction about them is still pursued, whilst sufficient attention is paid to the more showy ornaments of the present time. In other words, Botany and Floriculture are united, and work pleasantly and well together; the mere sight-seers are delighted with the blaze of floral beauty, and the studious botanist has also a regard paid to his wants. Taking into consideration the many natural disadvantages it has to contend against, the Manchester Botanic Garden is one of the most successful of its kind, especially in the cultivation of potted and out-door bedding plants. Shrubs and trees, owing to the proximity of a large town, it is impossible to grow well, but all that it is possible to do in that way is done.

The site of the Manchester Botanic Garden is about a mile from that city, by the side of one of the many thoroughfares leading out to the south-west. The appearance of the imposing-looking gate and lodge, which strike the passer-by as being a likely entrance to some place of importance, is further enhanced by another gate (differing in detail but yet artistic) on the other side of the road, leading to the mansion of Sir Humphry de Trafford, Bart. Unfortunately the presence of houses on both sides destroys the quiet seclusion of the garden, and their rapid approach threatens at no distant day to swallow it up. Even now it is hemmed-in nearly on all sides, and the difficulty of growing good specimens of shrubs and trees is increasing every year. We fear that department of the garden will not be pleasing to those who reside where a purer atmosphere prevails, and before proceeding to details we must remark that everything is being done to mitigate an evil which no one deplores more than the worthy curator, Mr. Findlay. Indeed, the wonder is how he manages to present such a healthy collection of exotic plants under glass, and also to furnish such a rich display in the flower beds, which are both numerous and full-sized.

The garden is on that tract of land extending some miles to the south of Manchester, which is very dry, and consists chiefly of a black sandy soil, very productive and absorbent. On entering the garden, the first thing we see is a large and somewhat open grass plot. On this the Manchester horticultural shows are held. There is a peculiarly-constructed glass house of large size, some of its details certainly having an oriental rather than an English outline. This building, I believe, was originally intended as a conservatory, but owing to some cause has never been heated, and is now used to hold the horticultural shows in. Adjoining and leading out of it, the ground has been formed into a series of turf-covered stages for plants, much in the same way as at the London Botanic Society, Regent's Park. This, of course, at show time is covered with canvas, and with gravel paths between must look remarkably well. Even at the time of my visit Mr. Findlay had turned some of the circular stages to account by planting upon them Gladiolus and other showy plants, which were doing well, and showed to advantage. Fronting this was the flower garden proper—a series of beds laid out on grass, not crowded, yet ample in size as well as in number, and with the exception of Calceolarias, which in some places showed symptoms of disease, everything was in as promising a condition as could be wished. This geometrical garden was, of course, planted with the ordinary bedding plants, which by conventional usage are supposed to be best adapted for such purposes; and other beds scattered promiscuously over the ground, contained plants interesting to the lover of novelties as well as the studious botanist. The ground in this direction is bounded by a piece of ornamental water and some shrubbery, with some rustic-work, and only requires the shrubs to thrive better in order to look well.

Pursuing our walk to the left we come upon the range of plant houses, and here is ample scope for the lover of Cape and New Holland plants to indulge his tastes. It is a singular thing that so many fine plants of this class are omitted in private collections, as many of them possess beauty of foliage equal to that of some more recently introduced. Plant stoves are also to be seen, and two or three Orchid houses lower than those we have been in before. Mr. Findlay makes a great distinction between tropical and temperate Orchids, and although he by no means goes the fullest extent in cool treatment, on the other hand he considers that most of them require a warm temperature at the proper growing sea-

son; in fact, he thinks the difference between the hottest and coolest temperatures they are subjected to in a general way might be increased. We next follow him into some Fern houses, which are also mostly low structures, as best adapted for maintaining the required moisture. Here there was one small house devoted almost entirely to the cultivation of that class of Ferns requiring constant moisture, and amongst them were some choice specimens. On coming out we found ourselves near to a collection of herbaceous plants, which Mr. Findlay observed were but little looked at—a fact much to be regretted. The whole collection, in-door and out, was in a most praiseworthy condition for such a place, and if the shrubs were not all that could be desired, it was from causes beyond control. This is easily understood, and Mr. Findlay may justly claim a great amount of credit for the good condition of the plants in the houses, and also for that of the flower beds on the lawn.—J. Robson.

Royal Horticultural Society's Examination of Gardeners.—We have to remind young gardeners that the next examination in Fruit and Vegetable Culture and Floriculture is to be held in the Council Room, South Kensington, on the 12th inst., at 10 o'clock A.M. Those intending to compete should write at once to James Richards, Esq., Royal Horticultural Society, South Kensington.

A FEW WORDS ABOUT LILIES.

I wonder what the honest opinion now is about Lilium auratum? We were all taken by storm by it; but after all, was there not a little of the barbarian element in our admiration? Did not size captivate us more than beauty? and can it be true that, with all our civilisation, if you scratch the skin the old untutored nature comes out? When Bishop —— went out to Sierra Leone the natives crowded down to the beach to see their great preaching chief; what was their disgust, instead of seeing a tolerable-sized giant, to behold a diminutive dapper little man, whom we even should have called small! And this element of size is, I fear, far too much regarded amongst us. Big Pine Apples, big Potatoes, big bunches of Grapes with big berries; and so it runs through the gamut. "I have Celery that weighs I do not know how many pounds; Potatoes of which half a one is enough for a man's dinner," and so on. Yes, and in nine cases out of ten lose flavour to gain size. Not but that Lilium auratum is very beautiful, but can it be compared in beauty and elegance with L. lancifolium, which is beginning again to assert its position as the elder and better of the two? and it is mainly in reference to it that I have a word or two to say about Lilies.

There is unquestionably much confusion in the catalogues with regard to the nomenclature. Speciosum, by which name it is called in some, is, we are told, totally incorrect, and that it has never yet been introduced into Europe; while we find roseum, rubrum, cruentum, and a number of names applied to it. Desirous of unravelling some of this mystery if possible, I received through the kindness of the following firms bulbs of the different varieties in their possession—viz., Messrs. Carter and Sons, Holborn; Messrs. Sutton & Sons, Reading; Messrs. Veitch & Sons, Chelsea; and Messrs. W. Cutbush and Son, Highgate.

The impression that has forced itself on my mind is simply that it will be hopeless to determine now which is roseum and rubrum. Album is, of course, plain enough. Punctatum, which I believe when correct to be white with very pale pink spots, is also not difficult to determine, although sometimes it is called roseum, and the term punctatum does not appear with it; but beyond this all is confusion. The fact is, that large quantities have been raised from seed; that, like all seedlings, they vary somewhat in the marking; and that they have been placed indiscriminately under rubrum, roseum, or cruentum, according as they were more or less dark in their markings.

I feel a great affection for these Lilies. They are associated with pleasant thoughts of the first sight of them I had—dear me! how many years ago!—of the triumph I felt in the possession of a small bulb, and of the excitement connected with its growth and flowering. Ah! how very difficult to feel now as one did then! and what a very fine flower it would be that could excite the enthusiasm of those days! And so one feels in reading "At Last." Fine as are the descriptions of tropical scenery, one cannot help asking, What would Kingsley have written if he had visited Trinidad when he wrote "Alton Locke?". But to return to the Lilies. In beauty of marking they are quite equal to auratum; they excel in the contour of the flower, in the permanence of bloom, and in the delicacy of its perfume. Auratum is so strong that it is almost impossible to keep it in-doors, and in a room it is intolerable. It would ill become me to say a word on the tribe in general, but is it not a question whether auratum itself is not a natural hybrid between lancifolium and longiflorum? Again, can anyone grow Brownii? Everybody that I have ever met with speaks of it as almost hopeless. M. Jean Verschaffelt told me that there was some one in Germany who used to be able to do so, but he is dead, and his secret died with him. I may say that I have never seen L. auratum growing in greater perfection than amongst the Rhododendrons in the peaty light soil of Weybridge Heath, where I saw it last summer in the garden of George F. Wilson, Esq.; and the mention of his name leads me to say that he would confer a great favour on all admirers of the Lily if he would give in the Journal some popular notes on the flower. Mr. Baker has given a very elaborate synopsis in the pages of a contemporary, and most valuable it is; but the general lovers of the flower would like much, I am sure, some descriptive and cultural notes from one who loves and knows the tribe so well as Mr. Wilson.—D., *Deal.*

FLOWERING PLANTS FOR DECEMBER.

December—dreary, the fag-end of the year, midwinter, and a whole catalogue of dismal associations—has yet its cheerful aspects. Christmas, like May, is said to be merry, as we wish all our readers will be at that season. From a floral point of view, we are not by any means certain that December is the most dismal month of the year. November, and even October, are often greater floral blanks; we appreciate all evergreens more in December, especially those with berries, and in-doors there is a greater wealth of flowers.

We purpose to take a survey of the plants which occur to us as being in season at that time, with comments; and first we shall begin with stove flowers, as they present themselves to our mind's eye. One of the finest of all stove climbers for winter is Thunbergia Harrisii, a most chaste and grand flower, the colour a delicate blue, produced in large clusters; flowers all winter, and of the easiest culture: a cutting of September, 1870, planted out covers more than 50 feet of rafter with abundance of its racemose clusters. Next comes Passiflora kermesina, with clouds of crimson bloom on its elegant spray: the flowers make an elegant margin to a basket of cut flowers.

Ipomœa Horsfalliæ will be at its best in December, an immense grower and bloomer, producing heavy bunches of flower-buds at every joint, which open in succession; it also is crimson. The crop of Passiflora princeps will not be over until December; it is, perhaps the prince of Passion-Flowers. Bougainvillea glabra beats the Fuchsia as an accommodating plant: it blooms perpetually, or may be had perpetually in bloom. Our largest supply of it will be in December. A cutting of September twelvemonths is now an immense plant, and has literally bushels of bloom on it; it is one of the very best plants for cut flowers, as the flower-stalks can be cut any length. The last winter climber we shall mention is Manettia bicolor, a very elegant plant with a profusion of orange-scarlet flowers, after the style of a Cuphea or Libonia. This is really a very beautiful plant, and can be had in 6-inch pots. Staked with a few twigs of Birch, it is an elegant vase plant.

Of stove flowering plants for pot culture there are abundance. Gesnera elongata, an old and showy plant easily made into a specimen for a vase: small plants for furnishing can be easily propagated in spring, when the old plants should be well cut back: it is a woody plant. The various herbaceous Gesneras are now in perfection; we specially like the green-foliaged varieties. Thyrsacanthus rutilans, a noble plant for the centres of stands, should be grown in a moist cold pit in summer. Sericographis Ghiesbreghtiana, not so much grown as it deserves. Justicia formosa, which few new plants will equal when well done, can be made into a huge specimen or tiny plants for edging vases. Eranthemum pulchellum, of which the same may be repeated. Both have flowers of the richest colour. Libonia floribunda, not strictly a stove plant, but requires a warm place in winter. This, with a lot of other things, we intend growing all summer, planted out in a cold pit, potting them up in September. Cypripedium insigne and venustum, Calanthe Veitchii and vestita, may be all classed with ordinary stove plants for December. Begonia fuchsioides, Saundersii, and insignis, the last especially, are fine December plants, and should be grown in quantity: insignis is a most useful plant

for dinner-table decoration and housework. Epiphyllums of every shape, size, and variety can be had in perfection in December, and answer every purpose. Euphorbia jacquiniæflora is the prince of pot stove-plants for winter: we grow it in battalions of different sizes; it does for any sort of work. Specimens are elegant for the centres of vases, edged round with something, say Panicum variegatum, to contrast. It answers for edging small baskets by cutting the curved spikes and pegging them down. Its brilliant colour enlivens any place where it may be put; we also plant it out largely, which makes it show itself to advantage. It is by no means a shy plant, and will grow against the back wall of a conservatory or intermediate house if the roots be in well-drained soil. The Poinsettia is for December what scarlet Geraniums are for the flower garden in summer, and zonals for the conservatory. It can be started and grown in a cold pit in summer, and from the 1st of October and onwards in the stove. It is best propagated from the young wood in July and August. In September four or five cuttings may be put in 4-inch pots for dwarf plants. We have grown it from 6 inches to 16 feet high. For the decoration of staircases, halls, &c, large plants are invaluable; indeed, it can be used for any decorative purpose. It soon loses its leaves, however, in a cool conservatory. Heat is essential in winter.

Turning to greenhouse plants, we know of a large plant of Tacsonia Van-Volxemi, trained over a roof, which will be covered with blooms all December. We have it planted out-doors like a Vine, its head being trained to the rafter inside. We have it also inarched on the T. manicata for a stock, and also on its own roots inside. Hyemalis, Wilmoreana, and gracilis Heaths are easy of culture, and can be had in quantity for the conservatory, or single specimens for rooms: the first mentioned is really superb. For December there are other Heaths, but these are the best. They should not be crowded amongst other plants, nor do we care about them for cutting. Epacrises must be placed on a par with the Heaths just mentioned: they are all exceedingly bright and showy, but not well suited for cutting from: at least, we like to cut them as little as possible. The Camellia is in full force in December, even out of doors, in the south: any gardener with a lot of Camellia blooms in December will know well what to do with them. The Chinese Primula is perhaps the next plant we should mention as being of a staple character. Large plants, well bloomed, are exceedingly neat for small vases. Small plants in 4-inch pots are excellent for edging: these should be grown in battalions for various purposes.

Tree Carnations of different colours are a leading feature for December, and of easy culture. Large plants which have been well attended to out of doors on a sunny border, pinched and watered, lifted in October full of buds, make a fine display in winter; the blooms last a long time after being cut. Spring-struck plants grown in small pots are useful for mixing in stands in the conservatory. Cyclamens of sorts come-in in quantities for all purposes, like Primulas. Small seedling plants make neat edging-plants for small stands; and the pretty little Oxalis tricolor is, if possible, more showy for winter, but does not last so long. This is a plant which should also be grown in quantity, and managed along with the Cyclamens. Cinerarias early sown will be in bloom in quantity, in light airy houses, and are of great use as conservatory plants. The plant does not stand the heat of rooms, and the flowers soon fade when cut. Schizostylis coccinea will be at its best in December. This is an exceedingly easily-managed plant, and very showy, planted out in spring and lifted in October when the flower-spikes are up. Ours were not lifted until the month of November, and are now in a cool orchard house, waiting their turn of the conservatory in December. This plant can soon be got up in quantity from seed. Angelonia anguatifolia, another perpetual-blooming plant, with strong purple spikes of flowers, should be grown from cuttings in spring, planted out and lifted; it wants a dry airy house; it can also be had early from seed.

Mignonette, of which we cannot discover more than one sort, although we have sown several, only just wants to be mentioned, because it must never be forgotten for the winter. Trees trained umbrella-shaped in the usual way can be used in stands, with the surface dressed with smaller flowering plants, otherwise they are rather gawky. We have a plan for tree Mignonette, where the shoots are not tied down, but tied to wires which are made to radiate from the top of the centre stick, like a chimney-sweep's brush. The trees do not look so stiff, and the blooms are bristling outwards in a round head, like little standard trees. Roses of the Tea section will have a sprinkling of bloom, and even the Hybrid Perpetuals housed in October with the buds formed. Souvenir de la Malmaison, old though it is, is most useful in this way; also Madame Bosanquet and Gloire de Dijon. Heliotrope, with a little forcing, will, like Mignonette, be in in quantity, and never fails to be useful and admired. Neapolitan Violets are, like the Tree Carnations and the two last-named flowers, always in demand, and most appreciated in December. The bulk of them will be in cold pits and frames, but a few dozens are useful in pots for the conservatory, if the foliage be green and crisp, and the plants bristling with flowers. They are best potted-up in October. This is a moisture-loving plant, and we never had it in such fine condition as on the south coast, approaching the climate of Nice and Mentone—big fat blooms on stalks as long as a black-lead pencil.

Forced flowers still remain, which come in easily in December; and first of all is the White Indian Azalea, which contrasts so well with the scarlet Poinsettia. Hybrid Rhododendrons, especially Nobleanum, Persian Lilacs, Deutzias, Jasminum nudiflorum, Forsythia viridissima, Spiræa prunifolia, &c., all come in flower early in December with little forcing, if the plants be well prepared. Roman Hyacinths with almost no forcing, Dutch Hyacinths, Van Thol Tulips, and Narcissus also come in easily if potted in time, and plunged deep in sawdust in the open air in the full sun, care being taken not to over-force when taken under glass, as that will retard them more effectually than cold. A few Hotcia japonica and Lily of the Valley will come in about the end of the month.

We might still return and enumerate more plants of the various sections noticed which now occur to us, but enough are mentioned for the floral illustration of the month. We mention only one more, Luculia gratissima, a grand winter plant; we have it against a back wall, also as a tree planted out with Hydrangea-like leaves and blooms, and we mean to try it out of doors against a wall.—(*The Gardener.*)

ENTOMOLOGICAL SOCIETY'S MEETING.

The second meeting of this Society for the season was held on November 20th at Burlington House, the President, A. R. Wallace, Esq., being in the chair.

With reference to Professor Westwood's exhibition at the previous meeting of a number of specimens of Formica herculeana found in a perfectly uninjured condition in the proventriculus of a great black woodpecker, Picus martius, said to have been killed near Oxford, and brought to the physiological department of the new museum for dissection, Mr. Dunning remarked that (from information which he had received) several examples, presumably of foreign origin, of this bird were exposed for sale in the London markets at the precise time one was said to have occurred near Oxford. Professor Westwood said that he had received information from Mr. C. Robertson, the anatomical demonstrator at the Oxford Museum, that he had repeatedly seen the bird in the woods at Clovelly; and W. Jackson, Esq., F.L.S., who assisted in the dissection of the specimen, also stated positively that he had seen the bird creeping up the stump of a tree in another wood in Devonshire. As many as thirty instances of the occurrence of the bird in this country have been recorded, as stated in Mr. Gould's fine work on British birds now in course of publication. One of these is recorded to have been shot by the grandfather of the present Lord Derby, but doubt existed as to this fact, and no specimen indisputably shot in this country is known to occur in any English museum. Mr. Edward Sheppard could not reconcile the occurrence of a gigantic species of Ant, not hitherto actually known, although reputed, to be a British species, in the digestive canal of a bird, the origin of which was also open to doubt as a British species or specimen, with an idea of the former being a native insect. Professor Westwood stated that he was making further inquiries on the subject.

Mr. Frederick Bond exhibited some specimens of Lasiocampa Trifolii, a number of which of uniform small size and dark colours, had for several years past been taken in the caterpillar state in Romney Marsh, where no papilionaceous wild plant occurs, the larva feeding on grass growing in the shingle, the perfect insects from which thus seemed to constitute a distinct race; also specimens of Lithosia caniola, and some remarkable specimens of Clisiocampa castrensis, having the hind wings on one side marked like the fore wings. Mr. Stainton exhibited a specimen of Triphæna orbona (Agrotis comes) from the neighbourhood of Exeter.

Mr. McLachlan exhibited specimens of two American species of Dragon Flies, Libellula pulchella, *Drury*, and Plathemis trimaculata, *De Geer*, which, although belonging to different genera, were so much alike as to be easily mistaken for the same species. A long discussion took place as to the cause of this mimicry, as it is now the fashion to term such resemblances, some of the members considering that the smaller species put on the appearance of the larger in order to deceive birds, which would scarcely dare to attack the larger ones.

A letter was read from Mr. Miskin, of Brisbane, desiring to enter into correspondence with English entomologists, and to exchange specimens of Australian Lepidoptera and Coleoptera for English ones.

Mr. F. Smith exhibited some cocoons of Tiphia tarda, a sand Wasp of North America, received from Mr. Riley; they were double, consisting of an external thin pellicle and a hard internal oval cocoon. They had been found by Mr. Riley under cow dung, a situation in which the cocoons of the British species, T. femorata, had been found by Mr. Smith, who had no doubt that they fed on the larvæ of the dung Beetles, Aphodius, in the same manner as the larvæ of the allied genus Scolia fed on those of the genus of Beetles Oryctes.

Mr. Albert Müller stated that he had in the preceding summer detected a species of Thrips attacking the pods of the edible Pea, forming large white patches and preventing the growth of the seeds, as many as fifty or sixty of the larvæ feeding on a single pod.

Mr. McLachlan read some notes on the nomenclature of the two species of European Ant-lion Flies which had been confused together by Linnæus.

The President announced the publication of a further portion of the proposed catalogue of British insects, containing the Aculeate Hymenoptera by Mr. F. Smith.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 25.

DRAWING PLANS.

Fig. 50 is of too complicated a character to be defined in the same manner as the foregoing, the letters and figures required for reference being so numerous that they might lead to confusions in a limited space. If the figures previously given are well understood there will be no difficulty in finding the manner in which this plan is drawn. The means employed for transferring centres and lines from one side of the paper to correspond on the other have been already explained. The transferring of the designs to the ground will follow as a matter of course. The lines and dotted parts of *fig.* 50 indicate Box; *g*, gravel; B, beds; *c*, coloured materials or bulbs. — M. O'Donnell, *Gardener to E. Leeming, Esq., Spring Grove, Richmond.*

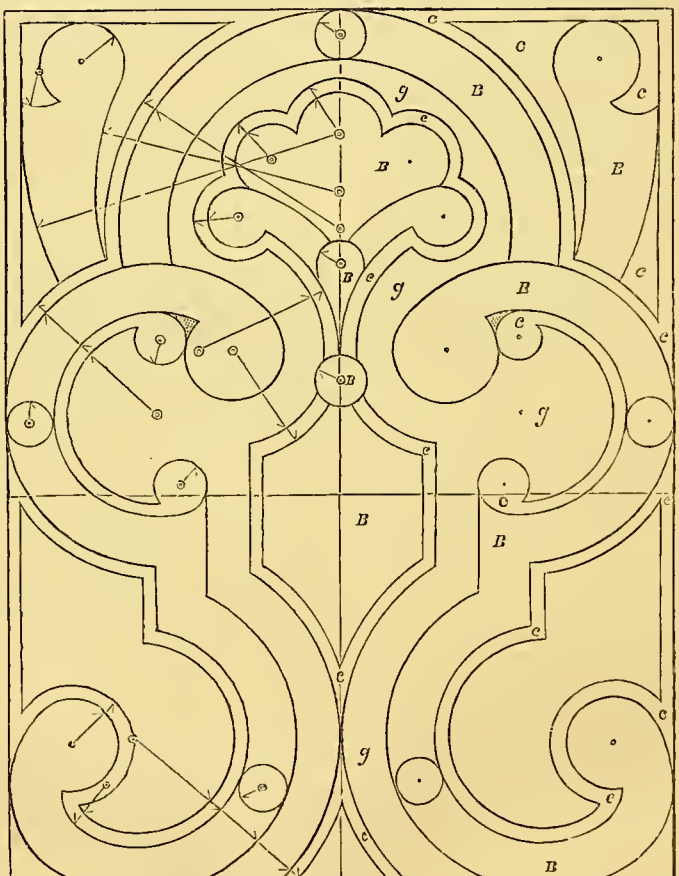

Fig. 50. Scale 24 feet to the inch.

VINE EYES ON TURF.

This mode was recommended by Mr. Thomson. Last February I put in eighteen eyes on pieces of turf, and started them in the Cucumber house. When about 6 inches long, to give them a fair trial, I built three brick pits about 3 feet square, in one of our Muscat houses, filling up with loam. I transferred my eighteen plants into these pits, placing six in each. They made excellent growth, although planted so thickly. This day I have taken all up save one in each pit; all three were admirable plants. In taking the others up I was quite delighted to see the roots more like ladies' fans than Vine roots, and that they were in the best possible condition. I should strongly advise my gardening friends to adopt the system, for which I have to tender my best thanks to Mr. Thomson. It is what I should term the common-sense principle.—R. Gilbert, *Burghley.*

A GARDENER'S HOLIDAY.—No. 3.

A very pleasant journey from Kelso by North British Railway brings you to Galashiels, celebrated for its woollen manufactures; from thence by a single line of rails to Clovenfords, which will very soon be equally celebrated for its Pine Apples and Grapes. It is here that Mr. William Thomson, late gardener at Dalkeith Park, has established himself. A wild out-of-the-way place it looks at first sight, but the air is pure, and the fine turfy loam with which the hillsides are covered is peculiarly adapted for Vine and Pine Apple growing. It resembles very much the loam which we procure from Wanstead and Epping, but is more friable.

Mr. Thomson's vineyard is close to Clovenfords railway station, and on getting out of the train you are at once struck by the large size and arrangement of the houses. I was conducted over every part of the establishment, and all the details of heating and ventilating were pointed out to me in the kindest manner.

The principal feature at present is three span-roofed vineries, each 200 feet by 24 feet. The first house I entered was almost exclusively devoted to Lady Downe's Grape. Here you are at once struck, not only by the strong short-jointed growth of the Vines, but also by their even appearance, not one seeming to be different from the other, when the varieties are the same, and their strength and vigour being astonishing; all through there does not seem to have been a single failure. The permanent Vines are planted between the hot-water pipes and the side walls, whilst a row which was bearing a fine crop of highly-coloured fruit is planted on the inside of the hot-water pipes. These will be removed as soon as the permanent Vines come into bearing. The middle house is planted with a mixed collection, the greater portion of them being Black Alicante. This is the true variety, and is easily distinguished by the leaves, which are very downy underneath, and by the stout short-jointed canes which it produces. I mention this because the Morocco, a very inferior Grape, is very often sent out as the true Alicante.

Dr. Hogg, in the "Fruit Manual," states that a very fine example of Morocco was named Alicante (Kempsey), hence the confusion, but he also states that it has no claim to the name. I saw a magnificent bunch of the true Alicante exhibited under the name of Kempsey at the International Fruit Show, October 4th. Gros Colman is also planted to a limited extent. It seems to be a very late sort, as the berries of Alicante were quite black when it was just showing signs of colouring. When quite ripe it is a good-flavoured sort, and serves well for market purposes, the berries being very large, quite black, and taking on a beautiful bloom. There are a few rods of Seacliff Black, which is worth growing as a variety. It resembles Black Prince, except that the bunches are more shouldered, more compact, and the berries are larger. It takes its name from Seacliff in the East Lothian. Burchardt's Prince [Aramon] Mr. Thomson thinks a desirable variety. It has large, well-shaped, tapering bunches, large jet black berries of good flavour, and keeps well. Madresfield Court Black is also grown in this house, with Mrs. Pince's Black Muscat close to it. The former Mr. Thomson considers one of the best new Grapes, an opinion which is being confirmed on all hands by the best Grape-growers in the country. The bunches of Mrs. Pince in this house were very poor, and wanting in finish; the berries did not seem to have set well. Mrs. Pince is sometimes good, and I grow it on its own roots, when the berries always set well; the bunches are also large, well-coloured, and the berries of good flavour, but it does not keep so well as Lady Downe's, the berries being so liable to shrivel.

The next is a Muscat house, the varieties being Tynningham Muscat and Muscat of Alexandria. The first is larger in berry, and ripens before the old Muscat. A new variety of which I had no previous knowledge, named Scott's Muscat, is very promising, and there is a large demand for young Vines of it. It was exhibited in Edinburgh, at the autumn exhibition of the Royal Caledonian Society, and obtained the highest award for flavour. These three varieties, and a plant or two of Trebbiano, are the only kinds grown in this house.

All through these vineries the same vigorous growth is noticeable, and is, no doubt, due to the fine turfy loam, this and a few crushed bones being all that the borders are composed of. Much of it is also due to the new system of raising young Vines, which Mr. Thomson has explained at length in the columns of this Journal (see vol. xx., page 61), and which at once commends itself to the notice of every intelligent cultivator. All the pot Vines are grown on the same system, and it is also worthy of note that both fruiting and planting canes were struck from eyes during the spring of this year. I am perfectly satisfied that all fruiting canes should be grown from eyes struck in the season of planting them. I have pursued this practice for the last seven years with invariable success, never failing to obtain a good crop of fruit, and that from plants which had no bottom heat from the time they started into growth. My plants were, of course, grown in pots from the first.

I was particularly pleased with the system of ventilation, all the side sashes opening simultaneously outwards by lever and screw, and they can, therefore, be fixed at any distance; even a child could move the whole length of 200 feet. The top is made to act upon the same principle. One thing more I must notice, and that is the watering of the inside borders. These are watered by an india-rubber pipe and hose in the following manner. At the highest end of each block of hot-water pipes is fixed an iron tank, which is filled from them with water of the same temperature. Part of the india-rubber tube is coiled into this warm tank, and the remaining portion carried down amongst the hot-water pipes, so that the cold water flowing through this tube is warmed to a considerable extent before it reaches the surface of the border. At the time of my visit they were giving the house water that was flowing through a rose fixed to the tube on the hot-water pipes, which still further warmed it before reaching the roots. There was an iron support to carry the rose, which was moved to a fresh position every ten minutes by the young man in charge, and who occupied himself with some other work while the house was being watered.

If the vineries contain some remarkable examples of skilful culture, one is equally astonished by what is to be seen in the fruiting Pine house. This is a lean-to, 150 feet by 12 feet, and contains such examples of Pines, mostly of the Smooth-leaved Cayenne variety, as are not to be seen in any other establishment in Britain. The Pine houses of T. N. Millar, Esq., of Bishop Stortford, under the care of Mr. Ward, are a sight not soon to be forgotten, but as the plants are grown in large pots 13 and 15 inches in diameter, and are allowed plenty of room to develope, under proper treatment one does not wonder that Cayennes are sometimes cut weighing 10lbs. each. Here at Clovenfords, 10-inch pots are the greatest size even for such robust-growing sorts as Charlotte Rothschild. There was ripening in these small pots fruit in plenty, which would weigh from 8 lbs. to 10 lbs. each. The pots used are rather different in construction from those usually employed, being almost as wide at the bottom as they are at the top. In the succession houses the young plants are all that can be desired, clean, and in sturdy, luxuriant health. No doubt, with the Pine Apples, as with the Vines, the rich, turfy, virgin loam is one reason of their success, but it is evident that to grow Pines in very large pots is sheer waste. There are plenty of places in England and Scotland where the loam is equally good, and equally well adapted for growing Pines as that obtained by Mr. Thomson. I shall certainly not use such large pots in future, and I thank Mr. Thomson for the lesson I obtained in Pine-growing from my visit to his establishment.

This attempt of Mr. Thomson at Clovenfords is a vast undertaking, but much more remains to be done, and let us hope that his efforts will meet with the success they deserve.—J. Douglas.

DRAUGHT OF FLUES TOO POWERFUL.

Since the cold weather has set in and the fires have had to be lighted, I have experienced some difficulty with the draught. I will preface my remarks by stating that, for economy's sake, I was obliged to content myself with a lean-to on the south side of the house. The fireplace is constructed at the extreme south-east side of the house, with the door and stokehole facing the south; whilst the flue runs along the south and west side, continued, with glazed pipes, about half way up the original south wall of the dwelling-house. As the greenhouse stands almost in the centre of the grounds, it would have presented an unseemly appearance if the chimney had been run up according to the usual manner—straight up for a short way above the greenhouse. Accordingly I deemed it less unsightly to run the flue into the chimneys of the dwelling-house, thus doing away with all obtrusion of a greenhouse chimney stack, and hence, I believe, arises the difficulty which I have hitherto been unable to cope with. As, of course, the chimney stack of the dwelling-house is carried much above the roof, it acts as a complete shaft to the greenhouse flue. Even if the one damper I have is only half way out, the fire roars out in an hour; in fact, it is impossible to keep in a slow fire during the whole of the night. Even if I put the damper in all but an inch, the house becomes full of smoke, whilst if the damper is much out, the fire roars up, and requires constant replenishing. The consequence is that the house partakes more of the temperature of the stove house and is rather injurious to Geranium and other cuttings, for which it was principally constructed. Another obstacle to the chimney being carried up in the ordinary way is that the chances are that the smoke would beat down into the drawing-room windows, to say nothing of how the house walls would be disfigured by the smoke whenever the wind blew from the south-west, a by-no-means unprevalent wind. Would you, therefore, assist me in solving the difficulty? I will only add that, as my tenure of the house (for I am only curate and not vicar) is precarious, I should not wish to incur any more expense than I could reasonably help.—Viridis.

[Your trouble is very different from other cases that have come before us—namely, want of draught. There seems to be no objection to the flue of the greenhouse going into the chimney of the dwelling-house. In some cases when we have advised such a course we have found it did not always answer unless a fire was kept in the fireplace in the room communicating with the chimney which received the flue from the greenhouse, as otherwise, by a back draught, the smoke would find its way down the chimney into the room. You seem to have no trouble in this respect, but from the great draught you cannot keep a slow fire, and you obtain far too much heat. We think you may manage what you want without any extra expense. More experiments with the damper would show you what was wanted. After your fire heated the flue a circular opening in the middle of the damper of 1½ inch in diameter, would very likely be sufficient to keep up a slow combustion. However, we place little value on a damper in a flue. We would place more dependance on banking-up the fire the last thing at night with

damp ashes, and more still on having close-fitting furnace and ashpit doors—the ashpit door being especially close-fitting. However high your chimney, there will be no such tearing draught, if no direct air, or the least possible amount, reach the fuel through the grate bars. One precaution more. In making up your fire for the last time under such circumstances, do not stir up or put the poker through the fire, rather take the shovel and beat down the fire to the bars—this will lessen the air passing—then put on what you want, and cover over with ashes. Lastly, do not suppose that you want a constant fire in a flue in a greenhouse unless the frost is keen and continuous. For several nights in winter, with merely a little frost, if the flue is properly heated, little more heat will be required, as the flue will retain its heat a long time.

We think that by acting on these hints you will manage the house at less expense, and we should be obliged if you will let us know how you get on, and what plan was the most successful. We say, Try the close ashpit door after the flue is becoming hot, and do not seek to keep a constant fire.—Eds.]

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 23.

The proverb that the most insignificant foes are sometimes most to be dreaded is rather hackneyed, yet it is true. The gardener meets with a constant proof of it in the injury and annoyance which the hosts of aphides, *alias* smotherflies, *alias* plant lice, *alias* blight—the last name being certainly the most vague—inflict upon him. There are many other species of insects whose ravages are a great deal more observable; there are some species which at times work much more mischief than the aphides ever do, but the latter are an ever-recurring pest, sparing few plants either in the kitchen or flower garden, frequent in their visits to conservatories, and from their small size and the tenacity with which they adhere to their various food-plants, and their ingenuity at concealing themselves, are not easily hunted out and destroyed. Has any poet ever sung the praises or dispraises of the aphis tribe? I find one notice regarding them in the "Insect-Hunters," couched in the peculiar Hiawathan metre in which that entomological poem is composed :—

"The noisome plant lice—
Smo'therflies the farmers call them—
Smothering all the growth of summer,
Crowd'ng till the shoots are hidden.
Leaves and buds concealed by numbers,
Anchored by their beaks sap-sucking,
Winged and wingless all together.
Their antennæ long and wavering,
Gradual taper to the summit.
All their wings are quite transparent
When they have them, and not folded;
All their feet are but two-jointed,
And their legs not formed for leaping."

Does some critic remark that this is but lame verse? Let it be remembered that it is written for beginners in entomology, and the description has at least this merit, which cannot be claimed for some very melodious poetical performances, that it is according to nature and fact. But it may be queried, What special end is subserved by these tiny insect hosts? They act not as scavengers, nor have they any particular beauty in their appearance, nor do they, like some species of coccus, yield any product important to man. (It is just possible, however, that aphides do some good after all, in the way of removing plants which are already diseased by accelerating their decay. They swarmed upon the Potato plants which were affected by the murrain, and hence were unjustly accused by some persons of being a cause, if not the principal, while they were only an effect). One of our most excellent of Scotch gardeners gives it as his opinion that Providence sends aphides to make gardeners more watchful, and also more patient, than they would otherwise be. Yet for all that he has no partiality for them, and has often declared to me that he greatly prefers honest caterpillars, which feed openly upon plants, to such sneaking fellows as aphides generally seem to be. But one of his puzzles is this, that he cannot find any allusion in Scripture o sot memorable an insect plague as the plant louse. His son, who attends evening classes, and is keeping himself up to the latest movements in science, has suggested to his parent that probably these insects did not occur in eastern climes at the time the Bible was written, the temperature not being congenial to them, but I don't think the old man received this solution with any favour.

But cannot aphides be turned to some account, for, though small, they are plentiful enough? My slight acquaintance with Sharpe Schemer, Esq., of this city, enables me to state that he was engaged some time ago in a series of experiments, with a view to the extraction of some peculiar dye from their carcases. He dropped this, however, and from his observations upon honeydew, and the relations existing between the ants and aphides, having come to the conclusion that aphides convert the juices of plants into sugar, he has now engaged in the promotion of a company, the "Aphis Sugar Company," capital £100,000, in 10,000 shares of £10 each, half to be paid on allotment, and the remainder when the first specimens of aphis sugar enter the market. Further particulars can be obtained at the temporary—very temporary—offices of the Company. As Mr. Schemer, however, was heard to remark the other day, that as soon as he had received all that seemed likely to be paid down on allotment he contemplated a journey to America, it is most likely that the second payment will not be called for in a hurry.

Two very troublesome species of the aphis genus are those known as A. Rapæ and Brassicæ. The former of these also bears the name of vulgaris, and is also, I believe, the vastator of some authors. A few entomologists doubt the distinctness of these two species, but I think it is unquestionable, though both may be found occasionally haunting the same plants. Some of the differences may be thus stated. In A. Rapæ, if it be examined by a hand-magnifier, it will be seen that the collar is brown, the abdominal tubes long; the iridescent wings have lightish brown nervures. A. Brassicæ has a black collar, the tubes are much shorter, and the wings, also iridescent, have stouter nervures, which are of a brownish black. The females of Brassicæ are also slightly mealy, the abdomen seeming larger than in Rapæ. The economy of both is very similar. Unlike many other aphides, they are most active towards the end of the summer. A. Rapæ is rarely noticed much before midsummer, and though we can hardly suppose that the first brood hatched from the eggs laid in the autumn is only then appearing, it is evident that their multiplication goes on but slowly for a certain time. I have not myself observed any males of the species in the spring or summer, and suspect that in both this and Brassicæ there is a succession of female broods until towards autumn, when the winged males appear. The "lords of the creation" in the domain of aphis life are not in request until the succession of broods has nearly reached its close. Brood after brood appears without the intervention of males, the wingless females producing their young alive, and these, if the weather is favourable, increase rapidly in size, and are soon able to be themselves parents. From September, on until nearly the end of November, we find A. Brassicæ abroad with a commingling, then, of all sizes, winged and wingless, feeding amicably together, and sheltering in the curled leaves of Cabbage and Broccoli plants when the weather is cold. The different species of aphis apparently stand cold better than do most other insects. Dry weather is much in their favour, there is no doubt.

Many years ago Mr. Curtis noted the fact that A. Brassicæ was partial to Swedish Turnips. Messrs. Hardy and Langland report that in 1870 it did much injury to these in the Border counties, confirming Mr. Curtis's observation. Only a few stragglers were seen at first, but they increased rapidly just as the plants were throwing off their outer leaves. The dry weather and mildew then kept back the young leaves, and as they slowly developed they were drained of their sap by the aphides, which now seemed to defy all attempts made to diminish their numbers. One man, indeed, tried the experiment of cutting off the tops and clearing them away; the plants sprouted again, and were none the worse, but others did not like to venture on so unusual an expedient. The later sowings suffered very little. At the same time that Aphis Brassicæ was infecting the Swedes, the white and yellow Turnips were furnishing food to crowds of Aphis Rapæ. A migration of the Turnip aphides was noticed by Mr. Hardy; this occurred at the end of September. Concerning this he says, "For more than a week during the calm and genial weather they rose in succession from Turnip fields along the valleys until they were almost incorporated with the air, so intensely crowded did they become. At night, or during dull days, they stuck to the threshold, to the grass by wall sides, or gathered upon hedges or trees. Many fell into the waters, or were swept from the grass on the brink. At length came some heavy showers of rain and hail, which cleared the air, and the insects mostly perished."

On the question as to the cause and extent of the migrations

which these insects perform every year more or less, we are hardly yet prepared to give thoroughly satisfactory answers. The opinion held by some that the swarms which pass through the air occasionally are made up of males only, which are either in search of females, or, having performed their customary office, are going out on a tour for recreation, has been rejected by Loudon and others. It has been pointed out that were this the case such a thing could not occur as the sudden appearance of hosts of juvenile aphides in spots where there had been none before, winged or wingless, until a migration brought a "flying party," who thereafter becoming parents proved that the wanderers must, in part at least, have been females. In reply to a communication made to "The Entomologist" this year, Mr. Walker, who is no mean authority in the matter, states his belief that the migrations of the aphis tribe do not carry them any great distance, and he thinks also they prefer peculiar states of the atmosphere for the purpose, when the sky assumes that appearance which is commonly termed "a blight." No doubt they pass at times from the fields to the adjacent gardens and *vice versâ*; but the evidence we have now before us leads us rather to doubt the stories told regarding their taking extensive journeys. Indeed, the very structure of an aphis, even in the winged condition, indicates that it is not adapted to travel very fast or far.

It is acknowledged by all practical men that the destruction of aphides which feed on low plants is no easy matter. With reference to Turnips, from the circumstance that the aphides especially haunt the lower leaves, fluid applications are generally deemed of little value, and as Professor Westwood points out, the removal of these by children, and their immediate destruction, is one of the best remedies. I do not know, however, whether the application of warm water, could it be obtained in sufficient abundance, might not be serviceable to Cabbages and Turnips in some instances. Though some persons have been incredulous, it has been proved that many plants thus infested have been greatly benefited by being immersed in water of from 120° to 150° Fahrenheit, which suffices to destroy the life of aphides. Books recommend "dusting" the plants with snuff, hellebore, lime, &c.; these are of partial utility, but not always easy of application. Tobacco, indeed, in several modes, dry, vaporised, or in solution, must be admitted to have its value. A solution of salt is also death to the plant lice.

I hope, in a future paper, when discussing other species of this tribe, to offer some further remarks on the transformations of aphides, and on their friends and foes in the insect world.—J. R. S. C.

SUCCESSIONS OF VEGETABLES.—No. 4.

CABBAGE.

Atkins's Matchless.—This is a small Cabbage, but one of the best; it turns in quickly, forming a good heart, and is of delicate flavour. With me it is the earliest variety, and very hardy. It is difficult to obtain true. Veitch's Improved is an excellent stock. Sow July 10th, and plant out on a warm border early in September, at 15 to 18 inches apart.

Cattell's Reliance.—An excellent, close-heading, and good Cabbage, being one of the best and earliest. It produces a fine crop of sprouts after the heads are cut. Sow July 10th, August 10th to 15th, and May 5th.

Williams's Early Nonsuch.—Dwarf, close, and early-hearting, of good flavour. Sow July 10th and August 10th to 15th.

Enfield Market.—A fine, large, good-hearting sort, and early. Sow August 10th to 15th, and April 10th to 15th.

Early Dwarf York or Barnes.—Early, dwarf, compact, hearting closely. Sow August 10th to 15th, and May 5th.

Wheeler's Cocoa Nut.—An early close-hearting Cabbage, the best flavoured of any. Sow July 10th, August 10th, and April 10th to 15th.

These are the best six Cabbages I have grown. The plants of the July sowings are pricked-off when large enough to handle, and are finally transplanted in the first or second week of September on a warm border with an east or west exposure, and which is sheltered from cutting winds. Atkins's Matchless, however, has a south border, and there it is fit for use a fortnight or three weeks before the others. The plants are hoed frequently, and earthed well up before winter. Atkins's Matchless will come into use at the end of April, sometimes a fortnight earlier, and as frequently later, for the time of the crop becoming fit for use is regulated by the weather. The July sowing will keep up a supply until the end of June.

The plants of the August sowings are pricked-off, when they have two or three rough leaves, into beds in an open situation but sheltered from winds, and there they remain through the winter. If the weather is mild, the best of them are planted after the middle of February, but if frosty or very wet not until the middle of March. A succession is planted about three weeks afterwards. The August sowings, planted in spring, come into use about the middle of June or a little later, and with successional plantings continue the supply until the close of July.

The April sowing, pricked-off and planted-out at the close of June, will come in during September, and the May sowing in November.

Except the first early crop, or that of Atkins's Matchless, I leave all the others for sprouts, consequently they are planted further apart than if the ground were intended to be cleared as soon as the crop is cut. Two feet apart every way is not too great a distance when the plants are allowed to remain for sprouts. The heads being cut when the sprouts are distinctly visible, the old leaves are cleared away, the soil stirred, and a dressing of two parts of guano to one of salt given between the rows. From the July sowing there are fine sprouts in August next year, and even in July; indeed, the sprouts follow the August-sown Cabbages, and will afford a succession of Coleworts up to Christmas, but I clear them off in November—manuring, and turning up the ground roughly for the winter. The August sowings, besides heads, produce fine sprouts from the end of the next August. I consider the small Cabbages, which are put forth after the hearted ones are cut, to be superior to a hearted Cabbage or Savoy, especially after they have had frost. Tastes will of course differ, but I have always found it desirable to have from the end of April until November a good stock, not only of Cabbages but also of sprouts. Cabbages, if not intended to remain for sprouts, may be planted much more closely, but to have good hearts a distance of 18 inches each way must be allowed between them.

Deep rich soil is necessary for the growth of Cabbages. They amply repay any waterings of liquid manure in dry weather.

For small gardens I recommend Atkins's Matchless and Little Pixie, a small but close-hearting, good-flavoured, early Cabbage. Sow July 10th, August 10th, and on April 5th for autumn. Both do well at 15 inches apart, and the same between the plants.

One ounce of seed of the kinds named is sufficient for a garden of two acres, and half an ounce for a garden of one acre.

Red Dutch Cabbage forms a fine close heart, and is the best for pickling, though any other close-hearted white sort is just as good, except in point of colour. Sow in the second week of August, prick-off when large enough, and plant out in March in good rich soil, at from 2 feet to 2½ feet apart, in rows 2½ feet from each other. Fine heads will be produced in the autumn.

Coleworts, or open-hearted Cabbages, are by some much esteemed.

Rosette Colewort.—Very hardy and dwarf, producing small dark green heads; very tender. Sow in the first week of June, July, and August, and when the plants are large enough to handle plant out at 1 foot apart in rich soil and in a sheltered position. They should be cut before they form close hearts, and are then the most tender of all autumn, winter, and spring Greens. The cuttings from the several sowings will form a succession from autumn until late in spring.

London Colewort is also an excellent sort, but not so hardy as the preceding. Sow in the second week of May and June. It will produce Coleworts from August to early winter.

Sandringham Sprouting is an improved Thousand-headed, in fact a sprouting Sugarloaf Cabbage. It hearts like any other sort from a sowing made in March or April, and whether the head be cut or not the stalk is clustered with compact little Cabbages throughout the winter. It is well, however, to cut the head, and the sprouts then grow larger and more rapidly.

It is hardly necessary to say that the soil between all the crops should be frequently stirred with the hoe, and some soil drawn to the stems, earthing well up, especially for those that are to stand the winter.—G. Abbey.

THE LAPSTONE POTATO.

Very wonderful was the account of the produce of the Lapstone recorded at page 400. But is it correct? I do not, of course, impugn the truth of the statement that a hundred Potatoes were dug up from one stock, but were they Lapstones? I ask this because it has come to be pretty well recognised that this is the best of all Potatoes for a gentleman's table. Many kinds go by the name which have no right to it whatever. The other day my neighbour Mr. Woodford, the Duke of Abercorn's gardener, told me he had seen such a fine crop of Lapstones at Lord St. Vincent's, and was good enough to promise me a few to look at and taste. They were unquestionably very

fine Potatoes, not Lapstones, but a very fine kind of Flake. And then it is said these hundred Potatoes were from a grain of seed; but Potatoes, like most other plants, do not come true to name from seed, so here, again, a doubt is thrown upon their being Lapstones. Fine as this Potato is, I have never seen it anything like the example stated in productiveness, and I should be glad to hear that it had gained in this point also. —D., *Deal.*

LATANIA BORBONICA.

The subject of the present illustration, although usually known by the above name, is, nevertheless, incorrectly so-called, and, in fact, does not belong to the genus Latania. Its more correct name is Livistonia chinensis, but as the former is better known amongst plant-growers, I have retained it in this place. It is a most beautiful object for decorative purposes, either in the stove, the greenhouse, the drawing-room, on the dinner-table, or in the open air during the summer months. Those who use it for the last purpose should endeavour to place it in such a position that it may be shaded during a part of the day from the direct rays of the sun, and if properly grouped I have no hesitation in saying that it will afford one of the most pleasing contrasts in the whole garden.

Latania borbonica.

The genus Livistonia, to which this plant properly belongs, is characterised by terminal fan-shaped leaves, divided into segments round the exterior, these segments being divided more or less deeply in the various species. The footstalks of the leaves are stiff and stout, having their edges armed with strong spines and their bases enveloped in a dense mass of coarse-netted fibre. The plant may be at once distinguished by its one-seeded fruit, whilst the genus Latania with which it is so commonly associated is three-seeded.

The plant is one which I would like to see grown to a greater extent than it hitherto has been; indeed, there are an immense number of Palms admirably adapted for the decoration of our apartments, halls, and corridors which are entirely neglected for a class of plants, which, as a rule, conduce but little towards beautifying a room. We are a progressive race, however, and I am pleased to see us awakening to the fact, that our houses are capable of being put in better order in this respect.

Livistonia borbonica is a plant within the reach of nearly everyone, as it can be purchased for a few shillings, and, therefore, no excuse can be made for neglecting its culture. Although a native of the East Indies, it may be grown either as a stove or greenhouse plant. In the former case, as a matter of course, it will increase in size much quicker, but should this not be desirable, then it will be best to grow it in the cool house. The soil I have used for it is a mixture of two parts peat, one of loam, and one of sand, and this I consider best when the plants are in the young state, because they will grow more quickly in it. As they increase in size, half loam and peat will be best, and if the plant has arrived at such a size that its rapid increase would be objectionable, then use nearly all loam. A liberal supply of water should be given, and avoid over-potting, as the plants can be used to much greater advantage in small pots.—Experto Crede.

[The name *Latania*, as was observed by the late Sir J. E. Smith, was barbarously constructed by Commerson from the French word *latte*, a lath, referring to its slim straight stem. *Borbonica* refers to the Isle of Bourbon, where it was first found. It was first introduced to Europe in 1816. M. Rothschild, of Paris, has obliged us with the portrait we now publish. It is one of the illustrations of "Les Promenades de Paris."—Eds.]

SUNFLOWERS.

Other countries have not been so backward as England in recognising the useful properties of the Sunflower. In the north-west provinces of India it is cultivated to a considerable extent, and with much success, in swampy districts; and it is asserted that the Sunflower plantations exercise a beneficial influence on the health of the neighbourhood, by tending to check the malarious fevers so prevalent in those parts. The Agri-Horticultural Society of the Punjaub, in a recent report, advocates the more general cultivation of the Sunflower for utilitarian purposes, and also enumerates some of the advantages which would attend it. We find that the flower leaves, removed without deranging the seeds, may be used as fodder

for cattle, and with great success; the stalks, when burnt, produce large quantities of potash; and the seeds, besides their use in feeding poultry, already mentioned, may be made to yield a large per-centage of oil.

In that practical country, the United States of America, where Sunflower cultivation is carried on to a considerable extent, principally on account of the value of the plant as an oil-producer, as much as 40 per cent. of oil is, on an average, obtained from the seed. After the process of expressing the oil, the refuse, under the name of "marc," is largely used as a fattening food for oxen, hogs, &c. More than this, the leaves also may be utilised; for, by parching and powdering them, and then mixing with bran, it is said that a food is produced to which cows are especially partial. Even if it had none of these useful qualities to recommend it, the excessive fondness of bees for the blossoms of the Sunflower would alone repay all owners of apiaries for the trouble of cultivation.—(*Food Journal.*)

VAN MONS.

Jean Baptiste Van Mons, one of the most distinguished pomologists of the present century, was born at Brussels on the 11th of November, 1765. From his earliest youth he showed a taste for gardening, and used to amuse himself in sowing and watching the growth of flowers and fruits. So ardently and successfully did he follow up the arts of cultivation and selection, that in the year 1815 his nursery at Brussels contained more than 80,000 fruit trees, most of them the result of his own sowings.

Van Mons.

About this time began those disappointments and crosses with which the career of Van Mons was chequered. In 1819 he received notice to quit his nursery of La Fidélité in the space of two months, because the ground he occupied was required for public purposes. This was, unfortunately, in the depth of winter, and Van Mons had only two days of the week at his disposal; he was, therefore, only able to collect grafts, mark the most valuable of his trees, and save, as nearly as possible, a twentieth of what he possessed. He conveyed the remains of his nursery to Louvain, where fresh vexations awaited him. In 1832, at the time of the siege of Antwerp, the ovens for the cooking of the soldiers' bread were set up in his garden, and a great part of the trees destroyed. Any other person would have been disheartened by these misfortunes, but not so Van Mons. He rented two other plots of ground, to which to remove his young plants, and congratulated himself on having had time to collect grafts from those he was forced to sacrifice. But the public good had not yet vented the whole of its severity upon him. In 1834 the engineers of the Government cast their eyes about, and fixing them on the nursery of Van Mons, decided that there was the most suitable spot for the erection of a gaswork. The gaswork was erected, and the engineers execrated. A year after this event he published the first volume of his work, "Arbres Fruitiers, leur Culture en Belgique et leur Propagation par la Grain, ou Pomonomie Belge experimentale et Raisonée." The second volume appeared in the following year.

Until 1842, when he died, Van Mons continued to cultivate the wreck of his nursery, but grief at the death of his second son and failing health prevented him from paying it the same attention as formerly. After his death the nursery was broken up, and the greater portion of the trees taken to Geest-St. Remy, where there is now an experimental garden of the Society Van Mons.

When we consider that Van Mons received but a moderate classical education, and at first only followed the vocation of an apothecary, the enumeration of his accomplishments, his works, and his honours will be the more striking. He made himself acquainted with the principal living languages, and with the science of physics. At twenty he published his first work, entitled "An Essay on the Principles of Antiphlogistic Chemistry." He was elected a corresponding member of the Institute of France, and like honours were heaped upon him by many other learned European societies. He was a Doctor of Medicine of the Faculty of Paris, occupied for fifteen years the professorial chair of Physics and Rural Economy at Louvain, and, last of all, was decorated with the Order of Leopold. His original works and translations are numerous, whilst the fact of his having produced 405 new varieties of Pears, and 200 more of different fruits, bears witness to the practical benefits he bestowed upon horticulture generally.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The presence of crops suitable as food for insects brings in the course of time a great number of such depredators about a garden. The invention of methods for their extirpation often taxes the ingenuity of a gardener to a considerable extent. There is, however, one substance not open to any objection, and it may now be used with advantage on land whence the crop has been removed—viz., lime. Ground cropped the preceding season with Carrots, Parsnips, or Potatoes, and found, as is frequently the case at this time, infested with insects, should have a good dressing of lime dug in, or, if that cannot be done, the soil should be turned up in ridges for the winter. Such an exposure will benefit the land if at all stiff, and cause the destruction of many insects. Birds are the natural enemies

of grubs; the services of a few rooks or seagulls, where they can be secured, would be found of no inconsiderable value. Surface-stirring amongst young growing crops of *Cauliflowers*, *Cabbages*, *Lettuces*, &c., must be as diligently followed-up now as in the summer when vegetation is more rapid; indeed, there is no season when these important operations can be neglected with impunity. Frequent pulverisation of the soil greatly checks the penetration of frost during winter, and the evaporation of moisture in summer. The ground must never be trodden on after the operation is completed. Continue to take up *Endive* and *Lettuce* on dry days, and store them in a dry airy shed; they will keep much better there than out of doors. If very severe frost comes on, protect *Celery*, *Parsley*, and late *Endive* for spring use. *Mint*, *Tarragon*, *Burnet*, *Basil*, &c., will require to be placed in a little heat to bring them on. Plant a quantity of the Early Ashleaf or some other good early *Potato* in small pots for turning out into a pit, or into larger pots, in January. The Mushroom-house will serve to sprout them. The first crop of forced *Rhubarb* and *Asparagus*, if growing under glass, should have a little air every fine day after they are started; the latter especially should be exposed to all the light possible. Keep up a mild steady heat, and prepare beds for second crops. *Sea-kale* should be kept dark and quite dry, as it is liable to damp-off. In cutting, leave the side shoots for a second crop; remember the more slowly it is forced the finer and more tender it will be. Give air on mild days to young *Cauliflowers* and *Lettuces* under glass. A sprinkling of soot now and then will keep out slugs and help to improve the growth.

FRUIT GARDEN.

Proceed with the pruning of Pears, Apples, Plums, and Cherries at all opportunities, taking those in the open quarters first, and afterwards the espaliers and wall trees. As soon as the quarters are done let the ground have a dressing of rotten cow dung or fresh loam, and afterwards dig it over for the winter. If the land is of a heavy nature leave it as rough as possible. Espaliers should be looked over after pruning, the stakes made good, and the trees securely tied to them. Where permanent iron-wire railing is used for espaliers, a coat of mineral black or anti-corrosion paint should be laid on it when the wire is dry before the trees are trained. Cherries, Gooseberries, and Currants have often their buds destroyed in severe weather by birds. Take the opportunity of a damp day, and dust the shoots with a mixture of dry soot and quicklime sufficiently to cover the buds. Two or three dustings during the winter will in a great measure prevent the ravages of these pests.

FLOWER GARDEN.

Beds of the choice kinds of Lilies and Cape bulbs should have a covering of sawdust or leaf mould to exclude frost. Roses may be planted wherever the ground will permit, and pruning the more hardy and common sorts may be commenced. Let the shrubbery borders after they are cleaned from leaves, &c., be forked over for the winter; the leaves and rubbish of each year should be preserved in a by place to rot, and should be spread over the ground for a dressing before they are forked over. Let the gravel walks be well rolled before frost comes on.

GREENHOUSE AND CONSERVATORY.

The conservatory should now be kept as gay as the limited number of plants in bloom at this season will permit. Remove Chrysanthemums as their flowers fade, so as to make room for other subjects. The earliest-started Camellias and Epacrises will be advancing into bloom, also the useful Erica hyemalis and Wilmoreana. Oranges and Daphnes should be introduced as they show bloom. Their fragrance is very desirable at this season. Neapolitan Violets, Mignonette, Cyclamen persicum, and the most forward of the Roman Narcissuses will assist in making the house agreeable till the more showy forced plants come into flower. Let the borders be frequently stirred and raked over to preserve a fresh appearance, and attend to the greatest cleanliness in every part. The night temperature may stand at 45°, and range up to 60° on sunny days. Let the ventilation be regular, avoiding currents of cold air. To obtain as much light as possible the climbers under the roof may again be reduced and tied closer together, washing the glass at the same time if necessary. Where stove plants are largely grown there will be a considerable number at this season which, after flowering and ripening their wood, will require to be wintered in a moderate and dry temperature. If the collection is extensive there should be a house devoted to this purpose; and as light is not essential to plants at rest, it might have a north aspect, where it would prove equally useful in the summer, either for retarding plants in bloom or for growing such tender-leaved plants as are injured by exposure to the direct rays of the sun. Where such accommodation does not exist, late vineries will answer for keeping Clerodendrons, Allamandas, Justicias, &c., while in a dormant state, as well as Hedychiums, Alpinias, Gesneras, and similar plants. The fire heat required to preserve the Grapes will generally prove sufficient, unless during frost, when a little extra heat should be put on to keep the thermometer at not less than 45°. The woody plants should be watered very sparingly, but the bulbous-rooted and herbaceous sorts may be allowed to get nearly dry. In the mixed greenhouse, see that the young stock of Heliotropes, Scarlet Pelargoniums, Persian Cyclamens, and other flowers grown especially for winter have light situations, and regular attention as regards watering. Let Ericas have close attention in watering if they stand unfortunately near flues or pipes that may become suddenly very dry. Keep up a quiet ventilation day and night if possible; let the air steal in moderately, and dispense with strong fires, or, indeed, fires of any kind when the temperature can be kept within proper limits.

FORCING-PIT.

This is a good time to introduce the following plants, provided, as before observed, they have received the necessary treatment during the summer—Rhododendrons, Azaleas, Persian Lilacs, Perpetual Roses, Sweet Briar, Moss and Provence Roses, Ledums, Kalmias, Anne Boleyn Pinks, Wallflowers, Sweet Williams, and Dutch bulbs. As soon as the more forward are moved into warmer houses or the conservatory, fill up the spare room with a fresh supply, so as to keep up a regular succession. If fire heat is employed be very moderate in its application to plants recently brought in.

PITS AND FRAMES.

If former directions have been carried out the plants in these structures will have a dwarf and robust growth, well fitted to bear deprivation of light for some time if severe weather should come. Damp has accumulated very much of late owing to the dense fogs with which we have been visited. It may be removed by giving air at the front and back on sunny days, but where the pits are heated with flues, a dry atmosphere may be obtained by putting on slight fires, and at the same time allowing a free circulation amongst the plants.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Protecting.—The very changeable character of the weather rendered protection all the more necessary, for sometimes an hour will do much harm, as in the case of the sharp frost a little before daybreak on the morning of the 2nd inst. after the mild evening of the 1st. Where neatness is not a special object, nothing is better than dry litter for keeping out frost. For efficiency and cleanliness combined, a clean open material to go over the glass or plants, and then a waterproof covering over all, will be the best means of protection. If made to fit closely, though a little expensive at first, nothing is better than light wooden shutters, painted, tarred, or pitched, and thoroughly dried previous to use.

We used to do much with straw frames neatly made, even when mats were not much above half of the present price, but employing the steam engine for threshing renders the straw not fit for making the best work. We do not think that a straw cover made with threshed straw is half so good and lasting as one made from drawn straw, and the heads of wheat then cut from the straw. Each straw then consisted of a number of perfect unbroken tubes. Threshed straw is more or less broken, and every tube becomes a receptacle for moisture, making each cover more heavy and unwieldy, and less useful as it becomes wet. We are sure that straw covers would be exceedingly useful if the straw could be drawn before it was threshed. Where many men are employed, making straw mats neatly gave plenty of work in wet weather. Straw mats are likewise very useful, and lasting too, if, when done with and dry, they can be put away where mice and rats will not burrow in them. We like good wheat straw better than reeds for covers. At first when we used to make covers we had three longitudinal pieces the length of the sash, placed so as to take in the width, and a piece across at each end, then cross pieces every 12 or 15 inches apart. The frame being reversed, the straw was packed neatly in, and then other cross pieces about 2 inches wide placed opposite the under ones, and nailed

to them. These cross pieces on the upper side we found to be disadvantageous, as the damp lodged against them, and the frame was made heavier.

For many years we made the under side of the frame as above described to keep the straw from the sash, but after packing with straw, on reversing the frame we merely put a cross piece of wood at each end, chiefly with the view of affording a hold in lifting, and took a string, firmly secured with tacks, across just above the lower cross piece. This made the cover lighter, and the rain passed off more freely. These strings can be made rather tighter if stout cord instead of tar string is used, and they may soon be run across with a small brush and tar to prevent their decaying. In fact, when there was an opportunity of well drying them previous to use, we often painted all the upper surface of the straw with warm tar, just having a little grease or oil in it to make it run freely. These made the covers almost waterproof, but they hardly lasted so long as those untarred, as the tar rendered the straw more brittle. We are now nearly out of such covers, but for protection we consider them second only to wooden shutters. We think some years ago we mentioned as a proof of their efficacy to convince one who could not believe in their utility, that in a low house, divided in the middle, the division that was required to be hottest was covered with these straw covers, one to every sash. There had been a sharp frost, and 3 inches of snow during the night. On the uncovered part the snow was all melted a little after ten o'clock. On the covered part the snow was not at all touched at that time, and to afford a little more light the covers were pulled down, and put on again in the afternoon with the snow lying on them. The glass beneath the covering was much warmer than the exposed glass, but the heat from the former could not pass through the straw to the snow. What will keep heat in will keep cold out.

The only drawback to the free use of such straw covers and wooden shutters, is the simple fact that there must be two men to carefully put them on and take them off, but the work can be done with great rapidity. Such covers with us usually lasted on an average three years, some much longer, with a little looking-over. Even if matting, calico, tarpaulin, or frigi domo is used, and where two men are available for the purpose, it is best when such covering is fastened to poles, so that in the case of pits and frames one man may move or roll the covering behind, and another in front. They are thus more easily dried and rolled up ready for use. All protecting material will be effectual in proportion to its dryness.

We write these details for the benefit of those who wish to know how to do things with the greatest present economy. Hot water might be cheaper in the end, but there are thousands who can stand much work, and a small present outlay, but who cannot make a large outlay at once. Even in the case of low pits and low houses heated by hot water, and where a high temperature is necessary, a little protection over the glass will often be found of great advantage, as wherever there is only a small amount of air shut in the changes from heat to cold, and from dampness to dryness, are more frequent than in larger houses, and not so uniform in either as when a little covering over the glass is used. Even a piece of calico strained or pulled tightly outside the glass makes a great difference on the internal atmosphere in a frosty night.

FRUIT GARDEN.

Fruits, especially Pears, are keeping rather worse than usual, chiefly owing to the dampness of the autumn. Apples, though on the whole smaller than usual, are keeping better, and are of good flavour. Used a little brisk fire every day in the late vinery to prevent damp, allowing the pipes to become somewhat cool before night, and then leaving the least amount of air on to prevent moist vapours collecting. In order to be sure we have taken a good many boxes of cuttings into the house. Pruned, nailed, and prepared sites for trees; the last can be done in the most frosty weather. Placed all the Strawberry plants in earth pits, so as to give them a little protection. This season we have taken out a trench at one end, deep enough to set a row of pots in up to the rims, packed them round with earth, and followed with another row, and so on. Round the ends, back, and front of this bed of pots in the earth pit, we left a breadth of about 6 inches, which we patted-down smooth, and then poured some tar along from the spout of an old pot, which neither rat nor mouse will care to pass while moist. Such a cordon of tar would not do in a heated building, but the fumes of the tar will do no harm in a cold earth pit. We might have kept the plants, as we have done, uninjured in beds in the open ground until now, but we feared lest one night of keen unexpected frost should injure the roots and the consequent crop if little or no protection were given. No better place can be found for such a purpose than an orchard house, but ours are at present too crowded to place them there. We have tried numerous plans, such as building the pots up like the roof of a span house, packing them layer above layer; but the buds are apt to turn to one side and the roots at times to become too dry, and even then the vermin would get at them. Whatever rest the crowns may have, the freeher and less injured the roots are when forcing is commenced the better chance is there for free blooming and free fruiting.

Insects attacking Strawberries.—From a leaf bed that afforded the slightest bottom heat we last week filled five lights of a pit nearly 6 feet wide, and which had been appropriated to Cucumbers, the pit being heated by hot water, though not enough for Cucumbers. A high temperature and a dry atmosphere soon bring on attacks of red spider on Strawberry plants. In low pits they are also liable to suffer when in bloom from too much humidity in the atmosphere, which clogs up the pollen and prevents free-setting. For the latter more dryness and more air are the best remedies, and at the worst times covering the glass at night to prevent condensation of moisture. Such an evil is seldom felt in large houses. In all cases, however, it is well to use preventives against the coming of insects. When the place is empty sulphur-smoking may be resorted to; but our chief reliance is washing the walls and woodwork with water as warm as it can be made—if containing some soap in solution all the better—and painting the walls with quicklime and sulphur. The part of the wall above the Strawberry pots we frequently paint over again with a solution of soft soap and sulphur in warm water. This adheres well, and as the sun plays on it slight fumes of sulphur will be emitted. In such small places where the air shut in is very limited it is better to place sulphur in water in evaporating pans than on a heating medium, be it flue or hot-water pipe. Before putting-in the plants most of the old leaves are removed, the pots are washed, and a little rich top-dressing given. Attention to these minor details will help to secure success, more especially if the rise of temperature is very gradual.

Cleanliness as a Preventive of Insects.—We have not had the opportunity of trying the efficacy of many insecticides, because we would rather prevent insects coming than kill them when they come, and run a risk of injuring the plants too. Whenever we change crops in pits, frames, and houses, we place great reliance on the free application of hot water, as hot as it can be used, if with soap in it all the better. A syringe is generally first used with a thick glove or a piece of cloth to protect the hand, whilst sending water not far from the boiling point into every crevice of the wall and woodwork, not using it quite so warm for the glass. The walls are then scrubbed, and a fresh application of the hot water made. In addition to this, if a pit or frame stands apart from others, we often put the lights on and burn some sulphur. This cannot be done unless the place contains no growing plants, and has no connection with others. It is true economy, as well as prudent, to do all this even when there has been little or no appearance of insects. Considerable practice has led us to the conclusion that it is better to prevent than to cure.

Temporary Stages for Strawberry Pots in Pits.—In building new pits we have several times alluded to the importance of leaving out a ledge of bricks an inch or so in width all round inside, so that by placing stout boards across one could either use the bottom of the pit or one or more platforms nearer the glass to accommodate dwarfer plants, unless in a span-roofed house or pit with glass at the sides as well as roof, and nothing to shade the plants.

Strawberry plants will not force well if placed at a great distance from the glass. From 12 to 15 inches from the glass to the top of the pot may be considered a good average distance for most kinds of Strawberries. The above mode will give a good base for easily forming a sloping stage. It is a good arrangement to have stages formed for the purpose to lift out when done with; but even with all advantage they require much storage room in summer when the pits are used for other purposes. As a makeshift we often lay bearers across, say old rafters or poles 2½ inches in diameter, and on these rest the shelves lengthwise. At times we have fastened a rail at the requisite height back and front for the cross-pieces to rest on, but we do not consider that necessary. The simplest plan is to take a line and measure the exact length from the front to the back wall where you wish the bearers to rest; and then, cutting the ends of these bearers a little diagonally, they will

rest at that place as firmly as a rock against the walls. Then, according to the number of shelves you place on these bearers, you will need as many wedge-like pieces of wood fixed on each bearer and fastened near the thin end with a small nail, so that when one side of the shelf rests on the cross bearer the other side will rest horizontally on the wide end of the wedge. The inexperienced will easily see how well the system will act by making a cross section of a bearer for themselves. When Strawberry-forcing is over and the space is wanted for something else than very dwarf plants, all that is necessary is to pull back the lights, remove the shelves to a place of safety, give an upward stroke with a mallet to each end of the cross bearers, remove them too with the wedges attached, and but little room will be wanted for storage for another season.

Let us add a few words of caution to inexperienced enthusiasts who intend to achieve great results by what they term a rush of forcing high temperature. Be assured that a gentle and gradual increase of temperature are the conditions of success. The plants, likewise, should never be quite dry, though they should be somewhat so rather than wet, until the flower buds and trusses appear, and anything like standing water in saucers or otherwise is the abomination of the plants. Avoid, also, as much as possible keeping the bud of the plant or even the collar of the plant wet.

ORNAMENTAL DEPARTMENT.

Most of the leaves of deciduous trees having now fallen, we swept and cleaned the most prominent part of the lawn. The sweepings are generally put in a heap to heat for present use. Dry leaves we like to keep dry for future use, so as not to waste much by fermenting. A heap of such leaves, with a little litter thrown over them to prevent the wind blowing them about, will keep out much rain if made in the slightest degree rounded and pyramidal. But for their blowing about few materials would be a better protection against frost.

Auriculas, Polyanthuses, Carnations, &c., require plenty of air, but in drizzly weather it is safest to tilt the sashes back and front instead of taking the glasses off. Mice must be looked after where Crocuses and Tulips are growing. We put the most forward Hyacinths in a mild hotbed. We gave plenty of air to Calceolaria cuttings in a cold pit to prevent anything like drawing upwards, and to keep them hardy, as they can be kept with much less care if they do not strike until after the shortest day is passed. Unlike other things, mere moisture will not injure them, but dryness is their abomination. Calceolarias, large-flowered for pot-blooming, and Cinerarias, will succeed best in a somewhat cool airy atmosphere. If kept 5° or 10° above freezing they will thrive better with a cool moist surface to stand on than with much other coaxing. The leaves soon suffer in a dry warm atmosphere. Cinerarias, Chrysanthemums, and Camellias will delight in clear weak manure water as the buds are swelling.

Where a great variety of softwooded and hardwooded plants must be kept in one house, success will greatly depend on keeping them in groups. Thus—florists' Pelargoniums will require more air than Scarlets, and the latter will do with less watering; Chinese Primulas cannot have too much light, and the watering should be given to sail round instead of coming against the collar of the plant; Cinerarias may have a damp bottom, and be kept closer than would suit the hardiest winter Heaths, which must have air to keep mildew from appearing, and then the Epacris—the Australian Heath—will stand a higher temperature and a closer atmosphere than Heaths. By thus grouping the plants we can, even by the regulation of air in a house 30 or 40 feet long, do something to make different climates in the same house. A breeze of air that would be the very life of Ericas would soon prove destructive to the finer Hoveas, Gompholobiums, Boronias, &c. The position of a plant in such a house, therefore, demands a great amount of consideration. The greatest acquaintance with the physical geography and the circumstances in which certain plants will thrive, will all be required to make even the best arrangement of plants in a small mixed house.—R. F.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Small Farms (*J. Taylor*).—Your communication is not suitable to our columns, wait until all the series has been published, and then if you like to write nothing but practical notes we may be able to spare space for them.

Maréchal Niel Rose (*L. G.*).—If, instead of putting Maréchal Niel into a pot, you were to plant it out in the border of the cold orchard house, and train it against the back wall, you would succeed with it better than in a pot. You can also have one in a pot for the conservatory heated with hot air. For planting in a house or a pot, Maréchal Niel does best either on the Manetti stock or on its own roots rather than on the Briar. Give plenty of well-rotted manure to the roots, as it is a strong feeder. Do not shorten the shoots in pruning, but thin out and encourage all the strong growth. Give plenty of air and water when growing, and syringe to keep down mildew, red spider, and green fly. A little guano water will be found most beneficial both for watering and syringing with. Have you tried Maréchal Niel against a south wall? We can see no reason why it should not succeed against a wall out of doors even in the north of Ireland.

Madame Sertet Rose (*J. H.*).—We have had no experience with this Rose. From flowers we have seen exhibited it seemed very similar to, if not identical with, Alba Rosea. We shall be glad of the opinion of Rose-growers who have tried it.

Chrysanthemums (*B. G.*)—The book is published by Messrs. Bradbury & Evans, Whitefriars, London. If you write to them they will give you full information. It ought to be advertised.

Animal Manures from Various Foods (*Agricola*).—We have seen in the Supplement to the "Agricultural Economist," exactly what you ask for. It gives in a tabular form the comparative fattening power of various foods and the fertilising power of the manures produced.

Greenhouse (*G. Robins*).—A house with its slope facing the west, but with little sun in winter, would do for flowering plants in general in summer, and would keep plants and grow Ferns and Mosses well in winter. We approve of the mode of using the gas air-stove, but you must be particular in joining the joints of the zinc pipes.

Cuttings of Evergreens (*W. B. A.*).—Except a small number of the commoner kinds, there are but few that will succeed in nursery rows without any protection. The common Laurel, however, will do well if the cuttings are taken off with a short heel—about 1 inch of the two-year-old wood. The Colchian Laurel will also succeed, as will the Portugal Laurel, Box of the various kinds, Privet, the Double Gorse, and Aucubas, but the last should have a sheltered situation. Hollies should be put in on the north or west of a hedge and covered with a close frame.

Cypripedium insigne Culture (*C. C.*).—It succeeds in a vinery or greenhouse, and should be potted in a mixture of two parts of turfy peat, and equal proportions of turfy loam, charcoal, and broken pots (crocks), with silver sand, affording more than a usual amount of drainage. It is necessary for the soil to be kept moist at all times, and when the plant is flowering water freely, and in summer sprinkle overhead and give shade from bright sun. The highest temperature from fire heat that you ought to have in your vinery is 40° at night, to 45° during the day. The Cypripedium will succeed in a greenhouse with a similar temperature, but the Stephanotis and Gardenia should not have less than 50°, though we have wintered both safely in a temperature of 40° to 45°, taking care to keep them dry. To induce the Begonias to flower well, you should give them a temperature of 50° to 55° from fire heat.

Hedaroma tulipiferum and Anthurium Scherzerianum to Bloom in August (*Wakefield*).—The flower-buds of the former will now be set, and in order to have it in bloom at the required time it will be necessary to keep the plant very cool, just avoiding injury from frost. When March is past place it in a cold pit, and retard the growth by placing it in a north aspect after May, by which means it may be kept back so as to bloom at the time required. The Anthurium should be grown in a brisk moist heat from January up to June, and then kept moderately dry for about six weeks, when it may again be encouraged with a good heat and plenty of moisture, and will most likely fulfil your requirements. It is a stove plant, and one of the finest-flowering ones. The Hedaroma is a fine greenhouse plant. The large Fuchsias will winter in a cellar, giving only sufficient water to prevent the wood shrivelling, should the air of the cellar be very dry.

Marantas in Winter (*M. W.*).—The Marantas should not be kept dry in winter like Caladiums, but should have the soil moist, and be sprinkled overhead once a-day. They will not, of course, require so much water as when they are growing freely; but, nevertheless, the soil must be so moist as to maintain the foliage in good condition. Alocasia metallica and A. zebrina also require to have sufficient moisture to keep the foliage fresh.

Bulbs to Flower at the End of March (*W. F. R.*).—Hyacinths, Narcissus, and Tulips potted at the close of last month we should place on a hard bottom, cover with fine ashes, or rather cocoa-nut refuse, about an inch deep, and place over them a frame to serve as a protection from wet. There they may remain until the middle of January, and then you may put them on the bed of leaves, made so high as to raise a gentle warmth, and with linings you may bring them into flower at the time you name. We should prefer moving them to a cool greenhouse in the middle of February. They all succeed under similar treatment.

Screen for Hotbeds (*R. J.*).—Arbor-Vitæ answers very well, and has an advantage over evergreen Privet, for it can be had as high as is wanted when first planted; but as you do not require a higher screen than 6 or 8 feet ultimately, we should plant evergreen Privet 2½ to 3 feet high, and 6 inches apart. If the ground is in good heart you need not give manure, though it may be mixed with the soil, and will assist the growth. The hedge you may cut as you like, but what you need with a screen 8 feet high we cannot comprehend, unless it is to shut out the view of the dung. Arbor-Vitæ should be planted 1 foot apart.

Caladiums in Winter (*T. R.*).—All Caladiums die down in winter, and should be kept dry, receiving only a gentle sprinkling from a syringe once or twice a-week. They would do better in a warm rather than a cool stove or intermediate house, but they will succeed in the warmest part of the latter. Marantas do not lose their leaves in winter, but should be kept moist, and have a gentle sprinkling overhead once a-day. The atmosphere in which they are growing is too cold and dry. Fittonias will start in growth again after losing their leaves, if kept only just moist. You can have all the works you name from our office for the sum named, and 6*d.* extra for postage.

Transparent Gage Plum and Figs in Orchard House (*An Amateur*).—With root-pruning and summer-pinching there can be no doubt that such Green Gage trees would be well stored with fruit buds. Are you quite certain you have no fruit buds now, as these buds will yet be small? However, after the treatment received, we have no doubt the trees will

bear out of doors the second season, and most likely the first season. If the small Figs are not larger than the largest Peas, let them alone. If larger than Mazagan Beans, and frost has access to them, the fruit will drop.

Chamber Over, or Rubble Round and Over Pipes for Bottom Heat (*York*).—We do not think there is much difference in practice, but we rather like the rubble best, and it is handiest and cheapest. Your proposed plan of covering the rubble with tiles (and if bedded in mortar all the better), is good. We generally use fine washed gravel for the surface. As to the pipes wasting and rusting where surrounded by rubble there can be no doubt, and so they would do in a shut-in chamber that you could not get at. How long they will stand the rusting process without wearing out we cannot say, but we know that some pipes covered over with rubble have been concealed and do their work after having been imbedded close on thirty years. Do you not think that five 4-inch pipes will be too much for a 5-feet bed? How about top heat in the house?

Lofty Glazed House (*A Subscriber*).—No doubt the house will be warmer with a double roof of glass. For Figs we should prefer the glass clear, but a slight green tint will do no harm. Would a little more heating power not do as well as the double roof? It is not easy to keep in all the heat at the top of a lofty house, but no doubt the double roof would keep the inner one much warmer, and especially if the space between them were nearly air-tight. We do not know of any powder that placed in vessels of small size would absorb the extra moisture of your fruit room. Quicklime will absorb a fourth of its own weight of moisture, and still remain a dry powder, but that would be useful chiefly for small places.

Boiler for Vinery (*A Subscriber*).—A common saddle-back boiler will do more than you require, but for one house we do not think you want any valves at all, though part of the pipes should be at the back and part in front, as when you do not want much heat you will use less firing. To do more justice to the roots of the Vines we should prefer planting them, as the roots are to be inside, 18 to 24 inches from the front wall, and have the under pipes a few inches from the wall. You need not, as you suppose, lose anything of the length of your roof by this mode of planting, as you can train the stems of the Vines to the front of the house before taking them up the rafter. When your Vines cover the roof, 3 feet apart, you will get no crop on the back wall. As you resolve to plant there likewise, we would plant them close to the wall, and have the pipes from 12 to 18 inches from it. With the two sets of Vines, we would plant in either case 6 feet apart, the back Vines to be trained down, the front ones up. Unless you are in a warm place you will not grow and ripen Oranges well, if they are kept in an unheated Orange house.

Heating a Small Lean-to (*Kettering*).—The cheapest way of heating such a house would be to have a small iron stove as often described, or, better still, a brick stove, with the pipe going through the glass roof or through the wall. It would be best to have a small flue passing beneath the pathway. A tile at bottom, and two bricks on edge 5 inches apart, so as to be covered with a 9 or 10-inch tile, would be amply sufficient if the tiles were placed close together at the joints. There is no neater nor better plan than this for small houses. The top of the flue should be in the centre of the pathway. You cannot heat a small place economically with hot water. The smaller the place the greater the waste.

Improving a Pasture Field (*D. C.*).—As you say the soil is shallow and upon the gravel, we do not suppose it wants draining; but if it does, let it be drained at once. The grass being coarse and rough, we would run a light harrow over it several times, which would tear up much of the moss and rough wiry grass. After doing this, give a dressing of manure or compost of a bulky kind—for instance, road scrapings, the parings of ditches, or soil of any kind, at the rate of from twenty to thirty one-horse cartloads per acre. The sooner this can be done the better, in order that frost may mellow any lumps that do not immediately pulverise. A good brushing in the spring will generally spread the mixture well, when the stones may be picked off and the roller passed over. It is a good practice to collect a large heap of rough earthy material in the summer and add some lime to it, which quickly decomposes the vegetable matter and forms a good compost for grass land. For thin poor land like yours we prefer such manure in large quantities to artificial manures, which are necessarily limited in bulk, and are of little service excepting in the season in which they are used.

Blood as a Manure (*J. L.*).—You may use blood for your Vine border in two ways—either by mixing it with eight parts of water and applying it in a liquid state; or, which is preferable, mix it with a quantity of spent frame manure, and spread the mixture 3 inches deep over the surface of the border. It would then be washed-in by the rains, or if necessary by water applied from a water-pot, using a coarse spreader. Apply it when the Vines are in active growth.

Vines for an Early Vinery (*Centurion*).—The following will suit you:—Three Black Hamburghs, one Muscat Hamburgh, one White Frontignan, one Buckland Sweetwater.

Pruning Young Vines (*E. P.*).—The canes should be cut back to three good plump eyes above the length required to reach the rafter or wires, or you will need 4-feet rods or canes to reach to within a foot of the glass, and three eyes beyond that. Of these two will form side shoots, on which you may allow a bunch each, and one the leading shoot. The Vines will be none the worse of bearing a bunch or two; in fact, we have some three-year-old Vines which in the second year were allowed to bear two, and this year half a dozen bunches each, and they are neither weaker in wood nor worse ripened than those that have not been permitted to bear. The main point is not to allow too heavy a crop. The pot Vines will, of course, render it less necessary to crop the permanent ones. The best covering for a Vine border is glass, but wooden shutters answer well, and so do straw mats over a coating of litter. Sheet iron, as represented in your sketch, will do to cover the heap of soil; but why cover it?

Soil of Faggot Heap (*J. A.*).—If the faggot heap is reduced to powder or soil, it is equal to leaf soil. It will not be peat, but decayed vegetable matter. It is an excellent dressing for beds of American plants, and useful for mixing with compost instead of leaf soil, but cannot be used in place of peat. It should be freed of the pieces of wood or sticks by sifting through a sieve.

Protecting Broccoli (*Idem*).—Tying the lower leaves loosely over the heads will not answer so well as laying down the plants, for in the former case only the head is protected, whilst it is the stem that is mostly destroyed. Lay them by all means, and without delay, and do not bring the leaves over the heart until the head is forming.

Storing Hotbed Materials (*An Amateur*).—Being short of horse manure for hotbeds, it will be an excellent plan to store the materials in a covered shed. Instead of throwing them in a heap, spread them out thinly so as to keep them from heating. The large bed you have made-up of three parts leaves and one part horse manure will be useful in March for mixing with fresh materials; indeed, just the thing to keep down violent heating, and for giving a steady, long-continued warmth. The horse manure, in consequence of its drying, will need watering when it is made into a hotbed.

Wintering Iresine Lindeni (*Idem*).—It would do better in a Cucumber frame kept constantly warm with fresh linings than in a sunny kitchen window, which has far too dry an atmosphere. The frame is just suitable provided you can exclude frost, but to do so the linings must be well kept-up in frosty weather, and the lights protected at night as well as by day if the frost is severe.

Wintering Geraniums in a Room (*Idem*).—Yours is the right plan of wintering them—that is, to give them plenty of air, and so keep them as sturdy as possible. Putting them out of doors every fine mild day for a couple of hours is quite right, and should be continued, only take care to protect them from cutting frosty currents. They will not be injured by a temperature of 35°, but we should not allow the air to fall much below 40°. Just give enough water to keep them fresh, but no more.

Protecting Peas (*Idem*).—When your newly-sown Peas are up, place some short sticks to them. Spruce branches without the leaves are the best thing you could use. In very severe weather you may employ full-foliaged spruce branches, but they must be removed whenever the temperature is above freezing.

Preparing Bones for Garden Use (*Ledbury*).—Sulphuric acid partly dissolves and partly crumbles the bones to which it is applied The process is fully detailed in "Manures for the Many," which you can have free by post from our office, if you enclose five postage stamps with your address. Bones so treated may be applied to Vine borders.

Insects (*B. & S.*).—The specimens of chrysalids sent as injurious to "Lettuce seed while yet in the pod," were all smashed in the post, but they are the immature states of a two-winged fly (Anthomyia lactucarum, *Bouché*), very closely resembling the common house fly. We can suggest no other mode of preventing their attacks than that of covering the heads of the plants with fine gauze bags.—I. O. W.

Names of Fruits (*D. R. K. B. M.*).—1, Norfolk Beefing; 2, Winter Greening; 3, Fearn's Pippin. The Potato is Lapstone. (*Alek Brown*).—7, Sykehouse Russet; 8, Surrey Flat Cap; 9, Golden Knob; 11, Margil. (*J. Rowland*).—Your Apple is the Cobham (*Jno. Green*).—3, Duc de Brabant Pear; 4, Belledge Pippin Apple; 5, Pearson's Plate Apple. We do not recognise the other two.

Names of Plants (*Sam or Tam*).—2, Nephrodium molle; 3, Adiantum hispidulum; 4, A. fulvum; 5, Asplenium attenuatum; 6, A. lineatum, var.; 7, Doryopteris pedata; 8, Asplenium flaccidum; 9, Probably Diplazium japonicum; 10, Asplenium filibelliforme; 11, Polypodium aureum. (*J. W. L.*).—1, Leucopogon Richei; 2, Not recognised; 3, Nerine pulchella; 4, Santolina pectinata. Santolina is a hardy border plant, but you are quite right in keeping Nos. 1 and 3 in the greenhouse. (*C.*).—The Fern is Cyrtomium falcatum, from Japan. The Conifer next week. (*Chas. Bennett*).—1, Gymnogramma, apparently G. Laucheana, but possibly one of the varieties of G. chrysophylla; 2, Microlepia novæ-zelandiæ; 3, Adiantum Capillus-Veneris; 4, Cheilanthes lendigera.

POULTRY, BEE, AND PIGEON CHRONICLE.

MOULTING FOWLS.

The moulting season is the most critical period of the year for old fowls; and yet in ninety-nine cases out of a hundred there is less care taken then than in the spring, when everything is in their favour. The idea seems to be, that now the young stock is out of harm's way, they can all shift for themselves.

Some have much more difficulty in moulting than others. Spanish are a long time naked. All the non-sitters feather more slowly than the others. It may be because they lay a greater number of eggs, and that the production of them causes more exhaustion of the system than the twenty-one days of the sitters. Certain it is, however, that moulting is an effort, and taxes the bird so much, that at such a time any old weakness or partially cured disease is sure to show itself again. Thus where roup has existed in a poultry yard, it always re-appears at moulting time.

Perhaps many readers have never considered the great drain upon the system of the fowl during this change of covering. Not only have the regular flesh-forming, life-giving processes of Nature to be fulfilled, but an entire new coat of feathers has also to be manufactured. These feathers consist not of flesh and blood alone, but of component parts of animal and mineral substances. These substances are assimilated from the food, and unless birds can obtain such food as contains the necessary qualities, the work drags, is prolonged, and the poor fowl droops and grows thinner in the vain endeavour to fulfil Nature's requirements, without the proper means to work with. I doubt if one person in twenty has ever given this a thought, and yet it is of the utmost importance to thorough and complete success in raising first-class stock.

Birds that have their full liberty and are well fed always moult well; but when they are kept in confinement, care and precaution are generally necessary. The effects of food may be proved by a fact. Quails are exceedingly fond of hemp seed. This is of a very heating nature, and if they are allowed to eat too much of it their plumage becomes nearly black. If they are fed entirely on it, their bodies are so heated that everything is dried up, and no nourishment is possible. The feathers, like plants, die for the lack of moisture. If proper food has this effect, then judicious feeding ought to assist. When birds are moulting they must have plenty of cooling food, and there is none so good as lettuce; if it has gone to seed and stalking so much the better. Sods of growing grass, and plenty of fresh earth with them, are also excellent.

A little treatment of this kind not only benefits the health of the fowl but shortens the period of moulting one-third. In addition to that, the growth of feathers is stronger and heavier, and the fowls are thus better able to stand the cold winter. The appearance of the fowl is also vastly better; the feathers are lustrous, and appear as if oiled; the bird takes on fat at once, and meets the cold weather with a vigorous health and strength which otherwise it might not have.

Sometimes a fowl will be seen while moulting to be continually pecking or scratching at one spot of its body. On examination it will be found that one or more feathers have failed in passing through the opening in the skin that is provided for the purpose. They keep on growing, but they grow beneath it. This causes much pain. It is common in the top-knots of Polands, but the remedy is a very easy one; take a stout needle and pass it under the quillend of the covered feather, then draw the feather from under the skin.

Not only is an abundance of warming nutritious food needed at this time, but a tonic of some kind may also be given. Stale bread sopped in old ale given two or three times a-week, is said to be beneficial; but perhaps one of the best things to use is one-half pound sulphate of iron (green vitriol), one ounce sulphuric acid, two gallons of water. Put a teaspoonful of this mixture to each pint of water in the drinking fountain, and keep it by them during the whole time of moulting.

One thing requires to be watched; they will sometimes, in a dissatisfied habit of body, begin to peck and eat each other's feathers. If a fowl does this it should at once be removed, as it will teach others the same habit.—(*American Stock Journal.*)

OVERWORKING THE JUDGES.

Permit me, as an old poultry fancier, to endorse most heartily the remarks which your reporter made at page 384 on the insufficiency of Judges at the Crystal Palace Show. It is most true that the work was "too arduous, the number of judges too small, and the awards made," as was well described in the Journal, "in failing light and other disadvantages, and with greater dispatch than advisable."

Were the Judges allowed more time, we should certainly hear fewer complaints, and read less severe criticisms afterwards in the leading poultry journals. Could we find a more palpable example of the effects of this haste than, for example, in the Light Brahma classes? There we beheld, to our amazement, cups awarded to a hen with vulture hocks, and a cockerel with a squirrel tail; prizes given to birds showing, as your reporter pointed out, a "tendency to white tails," while other old cocks, including the first and second-prize Southampton birds, were passed over for rivals seedy in health, dull in colour, or, as your reporter described one of them—a "bird we do not like in any way."—Brahma Pootra.

BIRMINGHAM POULTRY SHOW.

Little alteration has taken place in Bingley Hall since we last wrote on this subject. One of our humorous writers, recording the kind deeds of Toby Tosspot, speaks of some who "lose half man's natural estate of sun by borrowing too largely of the moon." Just so: the appearance of space, which has been diminished every year, has again been encroached upon by the erection of another gallery. The Hall has now galleries all round. That they were needed is evident from the fact that they are filled with goods and with buyers. If space were afforded we believe the four days of the Show would be a perfect fair. At present there are most things, from the cowhide of our relative across the Atlantic, to the composition for mending glass so strongly that the vessel cannot be broken again in the repaired part; there are foods so cunningly compounded by a master of the subject that it should cost nothing to fatten cattle, and the process should be a certainty; medicines that set sickness at defiance; gigantic roots that grow without reference to soil or manure; machines that so economise labour that, though all the cottages on the farm but two or three were vacant, yet men would not be wanted. Indeed, so much seems to be done to conquer everything that is antagonistic to the interest or the well-being of man, that it becomes a matter of surprise that poverty should still exist, or that man should not have everything he needs.

We do not wonder at these things. Although many visit these Shows determined to keep their pockets buttoned, it is by no means an easy task, especially if the visitor is blessed with the society of one of the fair sex. The man who visits this Show in such company is for the time invested with importance; he goes the round of the galleries, and is solicited at every step by vendors, and is, perhaps, coaxed by his better half. "Allow me, madame, to show you this washing machine, a child may manage it; it washes, wrings its own things, and positively costs but a few shillings." "Do, pray, come along," says Henry. "Well, but see, Mrs. Ruffdri is nearly worn out, and when she leaves off I don't see whom we shall get, unless we have Mrs. Uppish, and she eats and drinks so much, does so little work, and requires such extra pay, that I am sure this machine will be a great saving." Sooner or later Henry must buy it. His turn comes, for there are a chaff and turnip-cutter will save their cost in a month; for, says the vendor, "half the food is wasted, and the other half spoiled by the use of worn-out and antiquated machinery." Henry is sure of it. Better half says, "Do come along, do. You never go to a show but you buy something to economise labour, and I do not see you keep one man the less." "But," says Agricola, "I have never had such a machine as this." "No," says better half, "but you know there is an outhouse full of such things, and half of them have never been used." True, very true; but Henry *will* buy it. This goes on all day for several days. No wonder, then, if those who have goods to sell take standings, and thus from very small beginnings a monster Show has grown up.

In looking over the poultry that forms one part of this great Exhibition, it is impossible to avoid being struck with a great fact, that while there is an ebb and flow in those that make up the fancy classes, the breeds of practical utility, either as egg or meat producers, hold their own. Thus we find there were 280 pens of Dorkings, 261 of Cochins, 346 of Brahmas, 89 of French breeds, 86 of Spanish, 205 of Hamburghs, 58 of Polands, 382 of Game, 153 of Bantams, 103 of Ducks, 30 of Geese, 44 of Turkeys.

Seventy-seven pens of *Dorkings* were honourably mentioned by the Judges. The first-prize Dorking cock, belonging to the Countess of Dartmouth, was a bird of rare merit, and deservedly took an extra prize of ten guineas. Among the Silver-Greys there were more perfectly feathered birds than we have ever seen before. The White held their own, but no more. There was throughout these classes an entire absence of inferior birds, and the number of new names among the prizetakers was remarkable. We heard some remarks among the spectators that they seemed to make no progress, but we think it is unreasonable to expect increase upon increase. There must be, and there is, a limit. Having reached that, the aim must be not to lose ground.

We are bound to speak in very high terms of the *Cochin-China* classes. The silver-cup bird, belonging to Mr. W. Augustus Taylor, was a beautiful specimen of the bird of the year. We may notice here that in these, as in other classes, there was an absence of defects. This was especially true of the Grouse Cochins, where those disqualifying defects that help the Judges in their arduous tasks were not to be found. Weight, colour, and points were characteristic of every class.

The *Brahmas* were good, and some of them of great weight. Many were exquisite in colour, but in these, as in some of the Cochins, there is a tendency to breed vulture hocks. This is a mistake.

There was not only a good number of the *French* breeds shown, but they were birds of unusual merit. We must, however, except the La Flèche, which brought but ten pens into competition. This breed finds no favour, and it would seem advisable to distribute the money offered to them between the Crève-Cœurs and Houdans. Both these latter breeds have made great progress, and showed birds of large size and great beauty. We cannot help recollecting that only a few years since

the Brahmas and these breeds were confined to the Various class.

Spanish were good in quality, but not numerous. They do not make the progress they did years ago.

Hamburghs are up and doing, but in the Pencilled varieties the Golden still show better than the Silver. There were some unusually good Golden-spangled.

Polish fowls are decidedly looking up. We have not for a long time seen as many good Golden and Silver as at this Show.

It is unnecessary to make any mention of the *Game*. They formed magnificent classes. Some birds among them would by their weight have astonished the cockers of the last century. The Duckwings are still the weakest class.

Sebright *Bantams* will soon be things of the past. They brought but seven entries in two classes. The Black were excellent and the White good. The other varieties brought Cochins, Friesland, and Japanese. The Cochins were not so good as we have seen.

The Game Bantams were in themselves a show, and we thought a Duckwing cock one of the best birds we ever saw.

Ducks and *Geese*, with the exception of one class, were a continued but well-deserved triumph for Mr. Fowler. The same may almost be said of Mr. Lythall in *Turkeys*.

PIGEONS (*Concluded from page* 428.)

Runts.—Seven entries—viz., two pairs of Blues and five of Silvers. The winning pair were Blues of such size that they had scarcely room to turn in the pens. Their bulky forms likewise told well on the scales, the weight being 4 lbs. 6 ozs. The cock bird had unfortunately lost an eye, which loss with some Judges would have been a fatal objection, but the pair were worthy of their position. There were other good birds, but diminutive in comparison to the prizewinners.

Jacobins.—There were twenty-four pens of average merit; two were soon selected for severe criticism—namely, a handsome pair of Reds and a good pair of Yellows. The latter were chosen for the highest honours, though in our opinion Mr. Fulton's Reds were far preferable; they were perfect with the exception of a little blemish in the thigh of one bird. They were small, good in head, mane, and chain, sound in colour, compact in form, and in good condition. Mr. Thompson's Yellows, though very good, were larger, the cock foul in flight, and both birds somewhat out of condition; but in justice to the Judges we may state that there was a doubt as to the sex of the Reds, and this uncertainty might have influenced their awards. In the class for any other colour only seven pens were entered. The prize list was headed with a handsome pair of Whites of more than ordinary merit, good in the shape of the head and in general outline, clear white eye, hood and chain good. They were pure white, and did credit to the loft from which they came.

Fantails (White).—There were twenty-four pairs. It is proverbial that the Fantail classes are difficult to judge, for the worst pair in a class are often seen to the best advantage, whilst better pairs are crouching in corners of their pens. A very good pair was first. Second came a capital pair of birds, good in tail, make, and carriage. The hen showed to a disadvantage, as she is not quite through her moult, and when judged was bleeding from one of her half-developed tail feathers. A well-matched, unusually good pair came third. They had a full-feathered and expansive tail and carried it well, but were much soiled in appearance, otherwise they would doubtless have had a better place. Several other pens of good birds were shown, and among them a cock bird in a pen belonging to Mr. Yardley was noticeable as being of extraordinary merit. He had an immense tail, full-feathered, and well spread out into an almost circular form; he was otherwise good, but unfortunately was mated to a hen of the second order of Fans, so that pair were passed. The whole class was good.

Fantails (Any other colour).—Eight pens were exhibited—six pens of Blues and two of Blacks. An excellent pair of Blues were first. They were of a good pure colour, with regular and well-defined bars, good in tail and carriage, and without doubt the best pair shown. The same exhibitor also took the second prize with another pair of Blues, also good in colour and general characteristics, but they were ill-matched in eye, the hen having pearl and the cock red eyes.

Trumpeters (Mottled) were represented by six entries of capital Trumpeters, if not all proper Mottles. The first prize was awarded for a first-class pair of birds, good in feather, large, full in rose and well-feathered in leg. These birds well merited their position. The second prize was taken by a first-rate pair of birds, though scarcely entitled to be classed as Mottles. They were a perfect match, uniform black with mottled or sprinkled heads, good in every particular save their doubtful title as Mottles.

Trumpeters (Any other colour).—There were only three entries, but the quality of two pens amply compensated for the deficiency in numbers. First came a wonderful pair of Whites; second as wonderful a pair of Blacks. These two pairs were perfection, and one cannot help wondering at the marked improvement made of late years in the entries of this very attractive and prolific breed of Pigeons.

Owls (Foreign).—The first prize went to a splendid pair of birds, the second to a grand pair of Blues, pure and rich in colour, each pen remarkable (for coloured specimens) in head properties, and having, combined with other merits, the apparent vigour and vivacity of the larger kind. Mr. Fulton had an excellent pair of Whites, very short in head, very small in body, and very good in general characteristics. An unusually good pair of Blacks was exhibited by Mr. Joshua Fielding, jun. They possessed all the chief and essential features of the breed, but, as with most Blacks, they were of a bluish tinge. The jet black has yet to be obtained. The specimens were excellent.

Owls (English).—An admirable pair of Whites, that have won frequently, were first; though the cock bird does not show so well as formerly, yet that beautiful round head is still unchanged in either bird, but the cere around his eye has acquired a reddish tinge which is objectionable. There were ten entries in this class.

Nuns.—There were eighteen entries. All the prize birds were excellent, through to our mind a still more excellent pair belonging to Mr. E. T. Dew was passed over, we suppose, from the fact of being in a dark corner of the Show. The whole class was good. Three pairs of Yellows were shown, none of which found favour. Their tails were all of a faded washed-out colour.

Turbits (Red or Yellow).—In this class there was a good muster of birds (eighteen entries); though many of them seemed sadly out of condition, the quality of the birds was excellent. The first prize went to a handsome pair of Reds, the second to a pair of brilliant-coloured Yellows; in fact, rich and pure of colour, small and compact in form, but from having shell-crowns instead of peaks, they were destined for the second place. Mr. Horner showed a capital pair of Reds, but the hen, apparently about to lay, was quite out of form, and consequently showed to a disadvantage. Mr. F. Waitt also sent a first-class pair of Reds, but in rather a deplorable condition. Though they were very much soiled the colour was rich, and the line of marking distinct. Mr. O. E. Cresswell showed a very nice pair of Reds. The White class was good considering the disastrous season through which old birds have passed, and in which young ones have been reared.

Turbits (Any other colour).—Fifteen entries, among which were some splendid birds, the most conspicuous being the Blues that won the first prize—a really handsome pair, well matched, well frilled, good shape, good peak; sound, clear, and uniform colour, and in perfect health. The second prize went to a very pretty, neat, and compact pair of Silvers, well frilled and a good match. F. H. Paget, Esq., showed an excellent pair of Silvers. The class was good.

Dragoons (Blue).—This class was a large one, and owing to the diversity of opinion upon them, a difficult one to judge. The awards were not altogether in accord with our views. The first prize and silver cup went to a splendid, well-matched, and graceful pair of birds, which have been closely scrutinised many times and have always come off victorious. The same exhibitor took the second prize with a very handsome pair. The birds, ranged in a double tier, were either too high or too low to be properly seen.

Dragoons (Red or Yellow).—Thirteen entries. The first and second prizes were taken with two good pairs of Yellows. All the birds were too coarse and Carrier-like to be thoroughly good Dragoons.

Dragoons (Silver).—This class was unusually strong, Silvers being scarce and difficult to breed. There were, however, twelve pens of birds, most of which were very good, though too heavily warted to be satisfactory. The first-prize birds were good, though too heavy and coarse to be proper Dragoons. The same remark applies to the second-prize pen. These two pens were seen to advantage from their extra good condition. The bars of the second-prize pair are of too black a tint for Silvers. Mr. H. Allsop exhibited six good pairs, one of which should have been upon the prize list.

Dragoons (Any other colour).—Of these there were thirteen entries. Most of the birds were good, but many were out of plume and rather soiled.

Magpies.—Some excellent birds were shown. There were five pairs of Yellows, three of Blacks, and one of Reds.

Antwerps (Silver Dun).—This was a very large and excellent class, thirty-three pens appearing for competition. The fancy for this breed is extending every year, as the merits and value of the breed are more generally known. The first prize was taken by a very good pair of birds.

Antwerps (Blue).—There were seventeen entries, and the whole of the birds were good.

Antwerps (Red Chequered).—This was an excellent collection of thirteen entries. The first prize and silver cup went to a fine pair.

Antwerps (Blue Chequered).—There were twelve entries, all of good birds. The first prize went to a handsomely chequered and well-developed pair. The second prize was awarded to the same exhibitor for a pair infinitely superior in quality to that which won the first prize.

Archangels.—Of these there was a fair display.

Swallows.—Twelve pens of this kind formed the class, in which there were many very good birds.

Any other other New or Distinct Variety.—In this splendid class of various sorts it is usual to expect severe competition. This year there were thirty entries of beautiful pens of Pigeons. The first prize and silver cup were taken by an exquisite pair of delicately pencilled Brunettes, from a consignment of foreign Pigeons recently imported. A pair of handsome Ice Pigeons also took a first prize. A second prize

was awarded to a pair of very nice Ural Ice Pigeons, and a like award was made to a pretty pair of Satinettes.

SUMMARY OF POULTRY SALES.

1867...220 pens sold	£1,103	0*s.*	0*d.*
1868...203 pens sold	£1,004	0*s.*	0*d.*
1869...337 pens sold	£1,120	0*s.*	0*d.*
1870...300 pens sold	£1,043	5*s.*	0*d.*
1871...356 pens sold	£1,207	5*s.*	6*d.*

BRISTOL SHOW ENTRY FEES.

I HAVE been much pleased to see letters in your Journal directed against the large sum of £1 3*s.* being exacted for one pen of Pigeons; this being 6*d.* more than at Birmingham, while only two prizes are offered in a class. My advice to the Committee is to at once reduce the charge to 7*s.* 6*d.* for the first entry, and 5*s.* for every additional entry. I cannot see what they have offered for the extra charge. Take, for instance, cup No. 33; it is for Fantails any colour, Trumpeters any colour, English Owls any colour, Nuns and Turbits any colour. My reason for drawing attention to this is, that any young fancier who only keeps one of these varieties, may not notice that it is for the best pen in classes 79 to 83, as the Pigeon list does not say so, only the cup list.

The best plan is to say a cup for the best pen in so many classes. Some may say, All know better. I can assure you they do not. All old fanciers do, but many young ones do not. I know this makes the list look very attractive. My advice is, before fanciers enter only one or two pens, to count the cost. They will find it will not pay. As a young fancier and well-wisher of the Bristol Show, I now ask the Honorary Secretary and the six gentlemen upon the Committee to give the matter their most careful consideration, and hope they will come to the conclusion to reduce their entrance fees; and if so, I beg of my brother fanciers who have only sent one or two pens before, to send as many as they possibly can.—J. F. LOVERSIDGE, *Newark, Notts.*

I CONSIDER Mr. Cambridge's argument, in answer to "E.S.T." fails entirely to show that there is any advantage whatever to be expected from the £1 subscription fee. "E. S. T." may or may not be one of those who merely show for profit. If he is, I dare say he is not amongst those who are never disappointed. But be this as it may, the question appears to me to be this: What advantage do the Committee expect to gain from the £1 subscription? Surely the exhibitors who have only one or two pens, and they are many, will not give their support. The subscription applies very favourably to the large exhibitors and dealers, and will give the latter the chance of more than ever monopolising the prizes, as in the case of the Pigeon prizes at most of the shows lately. It is not that I look so much at the £1 as at the unjust way in which it is applied. If the Committee had adopted Mr. Sidgwick's plan and charged so much per pen, it would have been far more satisfactory, and would not have given an advantage to one which was a disadvantage to the other. Surely an entrance fee of 7*s.* 6*d.* per pen ought to support any show where there is so large a number of entries as at Bristol. And if I am rightly informed there was no loss, but a small balance on the last Show; and why not have continued the same rules as long as there was no loss? But the proof, I suppose, will be soon made evident; and if the Committee come out the gainers I shall be quite as pleased as though I had exhibited.—NON-EXHIBITOR.

I TRUST that you will spare me a small space to answer Mr. Cambridge's remarks upon a letter of mine on the Bristol entry fees, especially as he assumes that I am "one of those who look upon poultry shows merely as places to which they can send their birds with the hope of making a profit." This Mr. Cambridge assumes to be "evident." Well, I think that I can bring forward a little evidence the other way. Allow me to offer the following extracts from my poultry chronicle, a short record of the amount of prizes won, and of the amount of expenses incurred in showing, for the past four years; and surely if I began with a view to profit, I ought by this time to have moderated my views, at least during the past two years:—

Year.	Prizes. £ *s.* *d.*	Expenses. £ *s.* *d.*
1867	6 15 0	..... 7 12 10
1868	10 17 0	..... 19 2 9
1869	1 0 0	..... 7 2 2
1870	0 10 0	..... 13 5 10
Total....	£19 2 0	£47 3 7

I include in the expenses, of course, railway carriage; but as Mr. Cambridge will say that the committees are not benefited by that (although as surely I cannot include it in my profits), I have separated carriage and even payment for catalogues from the entry fees, and I find that entry fees amount to £29 17*s.* 6*d*, railway carriage and catalogues to £17 6*s.* 1*d.* I have thus to poultry shows paid more than £3 for every £2 received from them.

Mr. Cambridge goes on to say that at most of the five shows that have been held at Bristol the Committee have incurred considerable losses. Of course, I cannot tell what their expenses may be beyond the prize list, but I have seen it many times repeated, that the entries ought to pay the prizes, the admissions and sale of catalogues current expenses of the show, and the subscriptions to pay for cups. I have but one catalogue of Bristol by me, that for 1869, in which I find that Mr. Cambridge paid his expenses by his prizes; I am certainly did not. I see that the poultry entries numbered 1099, at 7*s.* 6*d*, the money prizes amounted to £293, the cups presented by the Committee to £73 10*s.* (other cups to the amount of £51, nine being presented by individuals), and the money saved in the first prizes, when cups were awarded, to £50. The account, therefore, will stand as follows:—

	£ *s.* *d.*
Entries 1099 at 7*s.* 6*d.*	412 2 6
Money prizes 293 0 0	
Committee cups 73 10 0	
366 10 0	
Less money where cups were awarded .. 50 0 0	
	316 10 0
Balance	95 12 6
	£412 2 6

So far, then, as entries and prizes, including cups, were concerned, the Committee had a surplus of £95 12*s.* 6*d.*, besides admissions, sale of catalogues, and 10 per cent. on sale of poultry, to provide for all other expenses. I certainly should not have expected that they would have found it necessary to increase the scale of entry, and I expect that they will find that the total amount received is very much less than under the old system, as there are many like myself, who, although not showing for profit, cannot afford to pay £1 6*s.* for the privilege of exhibiting one pen of birds.—E. S. T.

I THINK the different writers against the schedule of the Bristol Poultry Show are perfectly right in their objections. I for one intended to exhibit a few pens of poultry at the forthcoming Show, but when I saw that I should have to subscribe 20*s.*, besides paying entrance fees of 6*s.* for each pen, I gave up the idea. It is a pity that the committees of poultry shows do not hold out greater inducements to the exhibitors of French fowls; the present system of classifying gives no encouragement to fanciers (like myself), of such breeds. I would draw the attention of the different committees of English shows and that of exhibitors to the prize list now issued by the Grand National Poultry Show of Ireland, which does credit to the Committee in general, but especially to Mr. Zurhorst, the Chairman, who is well known as a fancier.—GEORGE A. STEPHENS.

LIGHT BRAHMAS.

MAY I crave a small space with regard to this subject, as my experience is not the same as that of your valued correspondent, Mr. L. Wright? I have been a breeder of Brahmas for some years. My first friends were the Light Brahmas, and excellent in all points I found them—good layers, hardy, and never despised when put on the table. Mine were white, and had well-marked black and white neck hackles, but, alas! they had single combs. At first this was no drawback, but an edict from the Judges went forth that Light Brahmas, as well as Dark, must have pea combs, and then my prizetaking ceased. Of course, when I found out the reason, I crossed with pea-combed birds from the two first yards of Light Brahmas in the kingdom, but I

found that when I obtained pea-combed chickens they either had no hackle worth the name or were cream-coloured, and frequently had white under feathers; for I venture to lay down as undeniable this trait in Light Brahmas—that if they are pure all the feathers underneath are of a darkish grey or slate colour, but if crossed with White Cochins, then they generally come white underneath. This I believe is an unfailing test, and I ask Judges when not satisfied as to the purity of a strain to make this one of their tests.

Your readers will now ask, "What does the writer want?" I ask Judges to declare that they will in future make no distinction between single and pea-combs in Light Brahmas; but that they will judge this class for colour, purity, size, and shape. For the last three years I have given up all my Light Brahmas, and do not feel inclined to breed them any more until this unfair favouritism of the pea-combed birds is relinquished, and a test as to purity of blood frequently made use of. The Dark Brahmas I still breed, and not always unsuccessfully, as Mr. Wright will testify.—F. P., *Yorkshire*.

DEALERS EXHIBITING.

I have come to the conclusion that exhibitions got up on the present system will not long be successful. Fanciers may buy the best birds dealers have at very high prices, and at the next show the same dealers beat them completely. I suggest to all secretaries and committees that, for the future welfare of their shows, dealers be restricted to exhibiting in the Selling class. Fanciers will then have a fair chance. If you refer to many shows of late, the prizetakers are confined to a few who really have no right to compete with amateur fanciers. I should be glad if any of your readers could make any further suggestion with the view of giving real fanciers a more open field amongst themselves.—John Ashworth, *Blackburn*.

A FEW WORDS ON POULTRY-KEEPING.

Thinking I am unusually successful in my management of fowls, and as I gained my knowledge from perusing your "Journal," I consider that I ought through it to inform other amateurs how to get a good many eggs from a small number of fowls. My poultry house consists of a wooden building with a slated roof, situated in a large garden, in an angle of a stone wall 12 feet high, and facing south-west; it is thus very warm. The roosting place is in the corner, and has about 8 square yards of floor; next to this is a small yard of about the same extent; both are covered-in and have a concrete floor. In the outer yard is a box containing about half a peck of sand, which is replenished about once a-month. The outer run wired-in consists of above 5 square yards, with ordinary soil for the floor. I never let the fowls out at any time, nor do I keep a cock, as I do not care to breed, my object being only to find sufficient eggs all the year round for my own house.

I bought four pullets, two Spangled Hamburghs and two Black Spanish, in October, 1870, and in February, 1871, they began to lay. I then killed off my other fowls. One of the Hamburghs died in August, thus I have only three hens at the present time. The following is the result:—

In March	79 eggs.	In July	66 eggs.
In April	68 eggs.	In August	23 eggs.
In May	84 eggs.	In September	36 eggs.
In June	71 eggs.	In October	50 eggs.

My system of feeding is as follows:—I feed twice a-day, at 9 A.M. and 2 P.M.; at each meal I throw down in the yard above a pound of paste made of barley flour or crushed oats mixed with kitchen scraps, also two or three handfuls of barley. At the same time I generally give them a four-tined forkfull of sods and with plenty of soil, which I dig up fresh out of the garden. I vary this with a supply of cabbage leaves, lettuces, or chickweed. About once a-month I break up very small about six oyster shells, which they soon pick up. If I find any food not eaten, I at once reduce the quantity. Half a stone of barley flour, or crushed oats, with the same quantity of barley, lasts one month, costing 1*s*. 3*d*., whereas the value of the eggs is at least 4*s*. I attribute my success principally to the warm roosting place, the green stuff, and sand bath, and also particularly to not over-feeding. On taking stock for the present month I have—November 1st, one egg; 2nd, two eggs; 3rd, three eggs; 4th, 0 eggs.—J. F. M.

Dublin National Poultry Show.—This Show is to be held on the 18th, 19th and 20th of January next, under the auspices of the Ornithological Society of Ireland. The working Committee comprise amongst them the same gentlemen who carried on the large Show of 1870. The advance made by all English shows has put Irish fanciers on their mettle. The best Judges in England will officiate; the poultry will be superintended by Mr. Shockley. When we mention this, and remember that at the last Show no loss nor death occurred, exhibitors will probably assist the Society. £550 are given in money, seventeen silver cups for poultry, fourteen for Pigeons, and £15 for cage birds. The entries close December 18th.

BIRMINGHAM FOR THE FUTURE.

In a communication I addressed to the Secretary before the entries closed, I explained my reasons for not entering, in the alterations the prize list contained, and my conviction that the Committee had taken measures this year that would lessen the entries. The catalogue proves I was correct; indeed, but for the wonderful entries in Brahmas (how these mongrels have held their ground!) the entries would have diminished very perceptibly. It would seem that Crêve-Cœurs and Houdans do not increase, whilst Malays have had a very great check. In this class the mistaken parsimony of the Committee certainly deterred me from entering four pens.

Birmingham, our old grandmother, it seems to me, should take warning from 1871. Some great alterations must be made if she is to remain at the top of the tree. Reverse the dates, and I fancy the Crystal Palace would have beaten her in entries, and I cannot but think that the London Show will in a few years outstrip her. What with darkness in the pens, and the utter disregard of friendly suggestions, I feel certain that without alteration Birmingham must soon resign "the pride of place." The treatment of the Variety class is shabby in the extreme, and this year it struck me that the prize list as regards poultry was very meagre compared to past years.—Joseph Hinton, *Warminster*.

PRIZE PIGEONS.

I heartily endorse the remarks of your correspondent with respect to the old diseased Carrier Pigeons shown at the Crystal Palace. I really could not see the least chance of a young exhibitor like myself ever attaining the honourable position of a prizewinner while such birds as the cup Black Carrier hen, diseased in her wing and eye, are to be specimens of high condition and perfect health as prescribed in the rules of the Show. The first-prize Dun Carrier cock was also diseased in the wing, his owner remarking to me that they were all a little bit queer at times.

Every bird that takes a prize should in my opinion be handled by the judge and the wing joints tried, also the eye well examined, as the grand object with most of our great exhibitors is to get their birds into the pens as short a time as possible previous to the judging, and whilst the sedative applied to the disease retains its effect; but an examination of the bird two or three days after tells the tale. I think a few exposures of this kind would put our shows in a more healthy position. The judges are, I believe, gentlemen of honour, and above all suspicion of the existing evils when they make their awards. Such a course would also give encouragement to young exhibitors.—An Old Subscriber.

AMALGAMATION OF COLUMBARIAN SOCIETIES.

The hint of "A Columbarian" (see page 404), is worth consideration, were it only from the fact that a great many of the best fanciers—fanciers in the truest sense of the word, who now never exhibit, would make an annual appearance at such a show as would practically be closed against all but the *élite* of the fancy. One of the great objects, as I think, of columbarian societies, is to oppose trickery and dishonest showing, and though it would be folly to expect to weed it out entirely, a single yearly show under the auspices of the amalgamated societies would do much for the fancy in that way, and bring to the fore many men who shrink from coming out at our ordinary shows, whose lofts contain the grandest specimens of their special fancy.

I would suggest here that at such an annual show, principally for birds of the year bred by the exhibitor, the prizes should be a gold and a silver medal, and that money prizes be not

offered. I shall be glad if there should follow some correspondence on the subject.—WEST RIDING.

AIRDRIE POULTRY SHOW.

THIS was held on the 2nd inst. There were upwards of 180 entries of poultry and Pigeons. The following is the list of awards :—

SPANISH.—1, G. F. Laing, Airdrie. 2, M. Clelland, Cambusnethan. 3, A. White, Motherwell. 4, J. Waddell, Airdrie Hill. *Chickens.*—1 and Medal, G. F. Laing. 2, J. Aitken, Losnhead. 3, A. Robertson, Kilmarnock. 4, J. Andrew, Clarkston.

DORKINGS.—1, Z. H. Heys, Farrhead. 2, J. Waddell. *Chickens.*—1, Z. H. Heys. 2 and 4, A. M'Donald, Easter Moffat. 3, J. Waddell.

GAME.—1 and 4, J. Waddell. 2, A. Mackie, Myvot. 3, Z. H. Heys. *Chickens.*—1 and Medal, J. Waddell. 2, R. Irving, Rockliffe, Carlisle, 3, Z. H. Heys. 4, J. Aitken.

BRAHMAS.—1, W. Good, Chapelhall. 2 and 4, E. Robinson, Airdrie. 3, J. Birch, Paillieston.

COCHINS.—1, J. Pollock, Bushby. 2, A. Crawford, Chapelhall. 3, J. Drinnan, Woodhall. 4, W. MacMillan, Bothwell.

SCOTCH GREYS—1, R. Gibb. 2, J. Meiklem, Hamilton. 3, J. Taylor, Johnstone. 4, J. Aitken, Johnstone.

HAMBURGHS.—*Golden-spangled.*—1 and Medal, F. Robinson. 2 and 4. M. Clelland. 3, T. Love, Chapelhall. *Silver-spangled.*—1, E. Robinson. 2, J. Aitchinson, Cambuslang. 3, J. Moodie, Paisley. *Golden-pencilled.*—1, J. Armstrong, Longtown, Cumberland. 2, M. Clelland. 3, H. Russel. 4, Beckmannan and D. Gibb. Motherwell. *Silver-pencilled.*—1, R. Crawford, Barrhead. 2, J. Pollock, Cumbuslang.

GAME BANTAMS.—1, J. Waddell. 2, G. Williamson. 3, R. T. Gemmell, Glasgow. 4, L. Douglas, Airdrie.

BANTAMS.—1, A. Robertson. 2, G. F. Laing. 3, W. Hardie. 4, W. Paterson.

TURKEYS.—1 and 3, E. Robinson. 2, G. F. Laing. 4, J. Gondie.

ANY OTHER VARIETY.—1, Z. H. Heys. 2, W. Gibb. 3, W. Linton, Selkirk. 4, A. Wylie, Johnstone.

DUCKS.—*Aylesbury.*—1, 2, and Medal, J. Meiklem. 3, Z. H. Heys. 4, J. Waddell. *Any other Variety.*—1, J. Waddell. 2, A. Robertson. 3, J. Meiklem. 4, G. F. Laing.

SELLING CLASS.—1, G. F. Laing. 2, J. Stevenson, Chapelhall. 3, Gow and Walker. 4, J. Wilson, Beith.

PIGEONS.

POUTERS.—*Blue* or *Black.*—1 and 2, J. Miller, Glasgow. 3, G. F. Laing. *Any other Variety.*—1 and 2, J. Miller. 3, E. Robinson.

FANTAILS.—1, R. Blair, Johnstone. 2, T. Imrie. 3, E. Robinson.

JACOBINS.—1, 2, and 3, E. Robinson.

TUMBLERS.—*Common.*—1, R. Blair. 2, H. B. Marshall, Motherwell. 3, W. Duguid, Motherwell.

ANY OTHER VARIETY.—1, A. Johnstone. 2, E. Robinson. 2, G. M'Adam.

JUDGES.—*Poultry:* Mr. J. Green; Mr. J. Hamilton; and Mr. G. Aitken. *Pigeons:* Mr. J. Sharp.

CANTERBURY (NEW ZEALAND) POULTRY AND CANARY SHOW.

I FIND from annually visiting this Exhibition that progress is very visible as regards better exhibits and better arrangements. I am a strict horticulturist here, therefore I do not interfere much with poultry matters, except in endeavouring to promote the success of such an exhibition in the province of Canterbury. I may, however, state my impression that if the poultry show were amalgamated with the dog show, the exhibition would be better in a financial point of view. I also find that new blood is being introduced very steadily but surely amongst our poultry—certainly at a very great expense—from the mother country especially; and I feel pleasure in stating that the Judges seem more capable than formerly, for we have had much less grumbling than there used to be. No doubt exhibitors take greater care in the selection of their birds for competition, and I may remark they meet with more civility from the Committee. Better pens, as well as in all respects better accommodation, have been provided, giving an appearance of neatness and care. Long may such an association prosper in a new country is the hope of one who is now an old settler in New Zealand.

I am able to write a few words about Canaries, for I was, when in England, a breeder of them. On this occasion (the fourth annual Show) the birds exhibited were of an excellence which far exceeded my expectations. They were nearly all young birds bred in the vicinity of Christchurch, and in number and quality far superior to those of other years. One fancier, Mr. T. Stapleton, who was a very old breeder of Canaries when in England, being afraid that some one would want to purchase his best cock bird, placed a card against the cage, fixing its price at £11 13s., and this he considered to be its full value to himself for breeding purposes this spring. I admit, being a fancier myself, that it is the best cock bird ever seen in Canterbury. As nearly as I can guess his length from head to tail was about 9 inches.

I am highly pleased that the Canary is becoming naturalised amongst us. Our native birds, though some of them are very pretty, I am sorry to say are mostly songless. I will do my utmost to cause the Canary, now it is one of ourselves, to fraternise with our native birds. If we can do nothing more, I hope some day we may be able to produce Mules similar to the Goldfinch and Linnet Mules at home, and that thus our woods and dells will resound with the warblings of birds—those having the Nightingale's song included. This aspiration may seem presumptuous in your mind, but it may be realised some day. Our native birds are very tame, the Canary we know all about, and what I have stated is not at all improbable. Canaries thrive and do well here. The following is a list of prizes awarded. —W. SWALE, *Avonside Botanic Garden, Canterbury, New Zealand.*

GAME.—*Black-breasted Red.*—1, 3, and Cup, presented by Mr. M'Callum also Cup, presented by Mr. G. Warner, A. Fraser. 2, D. J. M'Calmon. *hc*, W. James. *Brown-breasted and Ginger Red.*—Cup presented by Mr. J. G. Ruddenklan, 1st, 2nd, and 3rd, A. Fraser. *Duckwings.*—1 and Cup, presented by the Superintendent, G. A. Reade. 2 and *hc*, N. G. Glassford. *Any other Variety.*—2, D. J. M'Calmon (Blue Pile).

GAME.—*Single Cocks.*—*Black-breasted.*—1, A. Fraser. 2, W. James. 3, C. James. *Brown-breasted and Ginger Red.*—1, 2, and 3, A. Fraser. *Duckwings*—1, W. G. Walker 2, W. Calvert. 3, J. G. Ruddenklan. *Any other Variety.*—1, E. Deacon (White). 2, W. Calvert (Pile). 3, J. Hossack (Brchin Yellow). *hc*, G. Eares (White).

DORKINGS.—*Coloured.*—1 and Extra, presented by Mr. Sawtell, J. Hepworth. 2, H. Sawtell. 3, A. A. Fantham. *Chickens.*—1, C. Adkin.

SPANISH.—1 and Cup, presented by Mr. G. Warner, T. Stapleton. 2, A. Clark. 3, H. Sawtell.

COCHINS.—*Buff.*—1, 2, and Extra, T. Stapleton, presented by Mr. G. Gould. 3, E. H. Banks. *Any other Variety.*—2, E. Strange (Grouse).

BRAHMAS.—*Dark.*—Cup, presented by Messrs. Coates & Co., 1, 2, and 3, Wood Brothers. *Light.*—Cup presented by Mr. Wynn Williams, 1, 2, and 3, Mrs. R. W. Feroday.

HAMBURGHS.—*Golden-pencilled.*—2, T. Russell. *Silver-pencilled.*—1 and Extra, presented by Mr. G. Gould, H. Sawtell. 2, A. Todd. *Golden-spangled.*—1 and Extra, presented by Mr. G. Gould, T. Stapleton. 2, C. James. 3, W. Sneddon. *Silver-spangled.*—1 and 2, C. James.

POLISH.—*Golden.*—1, J. Fisher. 2, T. Abbott. *Silver.*—1, A. Fraser. 2 and 3, T. Williams.

CREVE-CŒUR.—1 and 2, Wood Bros. 3, W. N. Milton.

BARNDOORS.—1, R. P. Crosbie. 2, J. G. Palairet (Brahma and Dorking). 3, R. Bethell (Brahma and Dorking). *hc*, H. Sawtell.

GAME BANTAMS.—*Black-breasted Red.*—1, N. G. Glassford. 2 and *hc*, R. Kerr. 3, N. G. Glassford. *Duckwings.*—1, F. Biggs.

BANTAMS (Any other variety).—1, R. Kerr. 3, E. R. Deacon (White).

TURKEYS.—1, A. Fraser. 2, F. Pavitt (Buff).

GEESE.—1, Mrs. N. Gordon, Glassford.

DUCKS.—*Aylesbury.*—1, A. Fraser. 2 and 3, J. Hebden. *Rouen.*—1, G. Gould, 2, H. Sawtell. 3, J. Lane. *Any other Variety.*—1, J. Chegwidden.

PIGEONS.—*Carriers.*—1, T. Williams. *Tumblers.*—1 and 2, T. Williams. 3, F. Biggs. *Pouters.*—1, F. Biggs. 2, E. Strange. *Jacobins.*—1 and 2, T. Williams. *Fantails.*—1, G. Fletcher. 2, F. Biggs. 3, E. Strange. *Balds.*—1 and 2, T. Williams. *Beards*—1 and 2, T. Williams. *Nuns.*—1, T. Williams. 2, F. Biggs. *Owls.*—1, T. Williams. 2, F. Biggs. *Any other Variety*—1, E. Strange (White Trumpeter). Extra 1 and 3, F. Biggs (Turbits and Trumpeters).

CANARIES.—*Clear Yellow.*—1, 2, and *hc*, T. Stapleton Extra 2, J. Dunlop. *Clear Buff.*—1, J. Dunlop. *Yellow Variegated*—1, A. Wilson. 2, T. Stapleton. *Buff Variegated.*—1 and 2, T. Stapleton. *Mules.*—1, J. Dunlop (Linnet). *Any other Variety.*—1, E. Strange (Belgian). 2, G. Sadler (Goldfinch). Extra 2, J. Dunlop (Linnet).

AGGREGATE PRIZES.—A Silver Cup, presented by Mr. James Blake to the winner of prizes of the highest aggregate value in the poultry classes, A. Fraser. A Silver Medal, presented by Messrs. Peterson & Co. to the winner of prizes of the highest aggregate value in the Pigeon classes, T. Williams. A Silver Cup, presented by Mr. Sandstein to the winner of prizes of the highest aggregate value in the Canary classes, T. Stapleton.

JUDGES.—*Game and Game Bantams:* Messrs. Todd & Reese. *Dorkings, Brahmas, and Polish:* Messrs. T. Stapleton & W. Calvert. *Spanish, Cochins, Hamburghs, and Crève-Cœur:* Messrs. T. Williams and A. Fraser. *Barndoors:* Messrs. A. Fraser, T. Williams, & W. Calvert. *Turkeys, Geese, and Ducks:* Messrs. T. Williams, T. Stapleton, & W. Calvert. *Pigeons:* Messrs. Garrick & Bennett. *Canaries:* Messrs. R. D. Pirie & A. Clarke.

CHELTENHAM CANARY SHOW.

THIS was held on November 30th and December 1st. We must defer our comments until next week; but we can state that, though no official intimation is given as to who is the winner of the cup, the printed return shows that Mr. Ashton is winner by two points, and that Mr. W. Walter is second.

NORWICH.—*Clear Yellow.*—1, W. Walter, Winchester. 2 and 3, Bemrose and Orme, Derby. *hc*, Adams & Athersuch, Coventry; Bemrose & Orme; G. & J. Mackley, Norwich (2); Moore & Wynne, Northampton; W. Walter. *c*, E. Lulham, Brighton; Moore & Wynne; E. Mills, Sunderland. *Clear Buff.*—1 and *c*, W. Walter. 2 and *hc*, G. & J. Mackley. 3, Bemrose & Orme.

NORWICH.—*Evenly-marked Yellow.*—1, Adams & Athersuch. 2, Barwell and Golby, Northampton. Equal 3, Adams & Athersuch; Moore & Wynne. *hc*, Bemrose & Orme. *c*, E Lulham. *Evenly-marked Buff.*—1 and 2, Bemrose and Orme. Equal 3, Adams & Athersuch; Moore & Wynne. *hc*, S. Bunting, Derby. *c*, H. & J. Holloway, junrs., Stroud.

NORWICH.—*Ticked and Unevenly-marked Yellow.*—1, W. Walter. 2, Bemrose and Orme. 3, Smith & Preen. *hc*, Enoch & Chater. *c*, Moore & Wynne. *Ticked and Unevenly-marked Buff.*—1, J. Turner. 2, W. Walter. 3 and *hc*, Bemrose & Orme.

NORWICH.—*Yellow, with Clear Grey or Dark Crest.*—1, Moore & Wynne. 2, G. Mortimer, London. 3, Barwell & Golby. *hc*, J. Spence, Sunderland. *Buff, with Clear Grey or Dark Crest.*—1 and *c*, G. & J. Mackley. 2, E. Lulham. 3, S Tomes, Northampton.

NORWICH.—*Variegated Crested Yellow.*—1, Toon & Cleaver, Kettering. 2, S. Tomes. 3 and *hc*, Moore & Wynne. *c*, G. & J. Mackley. *Variegated Crested Buff*—1, W. Walter. 2, J. Mortimer, London. 3, G. & J. Mackley. *hc*, Barwell and Golby. *c*, J. Harrell, Sunderland; G. & J. Mackley.

BELGIAN.—*Clear and Ticked Yellow.*—1, H. Ashton, Polefield Hall, Prestwich. 2 and 3, J. Rutter, Sunderland. *hc*, W. Needles, Hull. *c*, S. Spinke, Chippenham. *Clear and Ticked Buff.*—1 and *hc*, J. Rutter. 2, J. N. Harrison, Belper. 3, J. Turner, Birmingham. *c*, Bemrose & Orme.

BELGIAN.—*Variegated Yellow.*—1, T. Turner. 2 and 3, J. Rutter. *hc*, T. Dove, Sutton, Mansfield. *c*, S. Brown, Handsworth. *Variegated Buff.*—1, S. Brown. 2, J. N. Harrison. 3, T. Dove. *hc*, J. Poole, Sutton-in-Ashfield.

COPPY.—*Yellow Manchester.*—1, M. Holroyd, Great Horton, Bradford. 2, H. Ashton. 3, L. Belk. *hc*, W. Walter. *Buff Manchester.*—1, H. Ashton. 2, Stephens & Leek, Middlesbrough. 3, — Fawcett Baildon, Leeds.

LIZARD.—*Golden-spangled.*—1 and 3, Smith & Preen, Coventry. 2, H. Ashton. *hc*, Rev. V. Ward, Hythe. *c*, R. Ritchie, Darlington. *Silver-spangled.*—1, H. Ashton. 2 and 3, Smith & Preen. *hc*, R. Ritchie. *c*, W. Jerram, Nottingham.

CINNAMON.—*Yellow*—1, C. Gayton, Northampton. 2, J. Harrell. 3, Barwell and Golby. *hc*, Toon & Cleaver. *c*, Moore & Wynne. *Buff.*—1, Barwell and Golby. 2 and *hc*, J. Tear, Northampton 3, S. Tomes. *c*, E. Mills.

CINNAMON.—*Variegated Yellow.*—1, J. Spencc. 2 and *hc*, Cox & Hillier. 3, M. Holroyd. *Variegated Buff.*—1 and 3, L. Belk. 2, M. Hoyroyd. *hc*, R. Hawman, Middlesbrough.

CLEAR GREEN.—1 and 2, Stephens & Leek. 3, G. Atkinson, Gateshead. *hc*, Holmes & Doyle, Nottingham.

ANY OTHER VARIETY.—1, E. Stansfield. 2, W. Walter. 3, T. Mann. *hc*, R. Hawman, Middlesbrough *c*, T. Swaine, Cheltenham.

MULES.

GOLDFINCH AND CANARY.—*Evenly-marked Yellow.*—1, H. Ashton. 2, E. Stansfield, Bradford. 3, Stephens & Leek. *hc*, M. Holroyd. *c*, L. Belk. *Evenly-marked Buff.*—1 and *c*, J. Baxter, Newcastle. 2, H. Ashton. Equal 3, W. Needles; L. Belk, Dewsbury. *hc*, W. Smith.

GOLDFINCH AND CANARY.—*Any other Class of Yellow.*—1 and *c*, H. Ashton. 2, E. Lulham. 3, E. Stansfield. *hc*, J. Baxter. *Any other Class of Buff.*—1, 3, and *hc*, H. Ashton. 2, Enoch & Chater, Coventry. *c*, E. Lulham.

GOLDFINCH AND CANARY. *Dark.*—1, *hc*, and *c*, E. Stansfield. 2, Stephens and Leek. 3, Cox & Hillier, Northampton.

LINNET AND CANARY.—1, J. Spence. 2 and 3, Stephens & Leek

ANY OTHER VARIETY.—1, E. Stansfield. 2 and *c*, H. Ashton (Bullfinch, Goldfinch, and Linnet). 3, A. Webster, jun., Kirkstall, Leeds (Bullfinch and Goldfinch). *hc*, T. Willsher (Siskin and Canary).

BRITISH BIRDS.

GOLDFINCH.—1, S. Bunting, Derby. 2, F. Woodward, Litchurch, Derby. 3, Stephens & Leek.

LINNETS.—1, A. Webster, jun. 2, Fairclough & Howe, Middlesbrough. 3, J. N. Harrison.

ANY OTHER VARIETY.—1, A. Webster, jun. (Mountain Finch). 2 and 3, Col. Tickell, Cheltenham (Starlings and Song Thrush). *hc*, T. Willsher, Chichester (Yellowhammer).

FOREIGN BIRDS.

PARROT.—1, J. S. Harrison. 2, W. Walter. 3, Mrs. Drayton, Cheltenham. *hc*, Col. Tickell, Cheltenham. *c*, G. Hodge.

COCKATOO.—1, W. Walter. 2, Col. Tickell.

PARAKEET.—1, Mrs. Drayton. 2, H. Ashton. 3, Capt. Acklom. *hc*, W. Walter. *c*, Miss M. Baksr.

ANY OTHER VARIETY.—1 and 2, W. Walter (Pintail Wydah and Madagascar). 3, Mrs. Drayton.

EXTRA CLASS.—1, Mrs. Stephenson, Cheltenham. 2, S. Tomes (Black Gold finch). 3, J. Baxter (Pied Lark).

SELLING CLASS.—1, G. Gayton. 2, Moore & Wynne. 3, G. & J. Mackley; W. Walter.

JUDGES.—Mr. W. A. Blakston, Sunderland, and Capt. Hawkins Fisher, Stroud.

KILMARNOCK ORNITHOLOGICAL ASSOCIATION'S SHOW.

(*From a Correspondent.*)

MUCH interest was excited among local fanciers from the fact that Mr. Teebay, the well-known English Judge, had been appointed Arbitrator. His decisions, after being severely scanned, were found, in the main, to be in harmony with the received opinions of the North, and gave general satisfaction.

Spanish.—This was allowed to be the best class in the Show, and judging from the time spent on it, Mr. Teebay must have found it nice work to adjust the winning cards. The prize birds merited their positions. Pen 32 was considered by good judges deserving of notice.

Brahmas.—No fewer than nineteen entries, all Dark. Quality on the whole very fair. Considerable diversity of opinion was expressed on the winning pen, which was entered at £2 and immediately claimed. The hen was of the close-pencil type, much inferior in marking to the one which stood next her in honour.

Cochins.—A very good class. Winners, large birds and fine in colour. The unnoticed pens of Messrs. Paton and Campbell were not in condition.

Dorkings.—A very fair class. The *Silver-Grey* cock in the winning pen beautiful in colour but very deficient in feet, while the second-prize hen was as near an approach to perfection as we have seen for years.

Scotch-Greys.—This breed, though pre-eminently national, appears to be falling off in quality and quantity. None deserve special notice with the exception of the winning pen, which contained a well-mixed hen.

Golden-spangled Hamburghs.—Hens on the whole not up to the mark. Both birds in the prize pen were tipped with white, and before a Scotch judge would have run a narrow risk of being left out in the cold. No. 89 contained a good cock badly mated, and No. 104 perhaps the best cock in the class. It is deserving of mention that Mr. Jardine, a local breeder, has carried off the timepiece in this class for three successive years.

Silver-spangled Hamburghs.—Scarcely a bad pair shown. The hen owned by Mr. Pickles, of Earby, was awarded the timepiece for the best *Hamburghs* in the Show, a decision acquiesced in by all.

Silver and Gold-pencilled Hamburghs.—*Silvers* were not numerous. But this drawback was more than balanced by the *Goldens*. A good deal of dressing of comb was observable, but the prize list showed that Scotch Judges are rather straight-laced on this point. Pen 147, containing a fine specimen of the "tailor's art," was instantly disqualified.

Game.—A good class, containing some splendid birds. The judging here gave eminent satisfaction.

Game Bantams.—No less than fifty-one pens. As was to be expected, many were indifferent and some positively bad. The timepiece cock in this class was a superb bird, though a severe critic might have objected to the colour of his saddle.

Black and White Bantams.—This class has shown a decided tendency for the last few years to merge its characteristics into those of the preceding class; the conceited carriage and trailing wing being conspicuous by their absence. The prize pens were good in other respects.

Bantams (Any other variety).—Sebrights, as usual, claimed the honours. The lacing and ground colour of Mr. Robertson's *Silvers* were simply unsurpassable.

Ducks.—The *Aylesbury*, though a good class, were fairly eclipsed by the *Rouen*, where the first, second, and third positions were barely secured by a neck.

Any other variety.—This class proved very attractive to the visitors, the beautiful plumage of the *Shells* and *Mandarins* exciting universal admiration.

PIGEONS.

The *Pouter* entries were not numerous, but of first-rate quality. The timepiece fell to a Blue cock, which showed a fine proportion of limb and feather. Pen No. 386 contained a stylish Mealy cock, imperfectly mated. *Carriers* formed a good class. The first prize went to a splendid pair of Duns, unfortunately not entered for the timepiece. No. 405 contained a hen, the best bird in her class. The young class showed a decided improvement on last year. The first place was gained by Mr. Laurie with a promising pair of Blacks. Short-faces formed a very fair class. Mr. Miller succeeded in carrying off the timepiece with a pair remarkable for skull and beak. In *Barbs* Mr. Yardley would undoubtedly have figured on the prize list, had not his birds been disqualified as both cocks. *Trumpeters* were the best ever shown in Kilmarnock. Mr. Rule's hen will be found hard to beat. *Jacobin* fanciers were delighted at the turn-out of their favourite variety, which they had well-nigh despaired of. A capital pair of Whites occupied No. 130. Much dissatisfaction was occasioned by the hurried manner in which the Judges discharged the latter half of their duty. The winning *Owls* were exceedingly foul, and in the other classes it was observable that a revision would have been more satisfactory, if not to the Judges, at least to the majority of the exhibitors.

CANARIES.

The Clean classes contained many good birds, but the Piebalds were very inferior in quality. The Buff cock in Class B was generally allowed to be a much superior bird to the Yellow cock which carried off the first honours. *Mules*, both Buff and Yellow, formed an extra good class, in fact the winning Buff cock could scarcely be equalled. On the whole, however, the Canary classes were not up to the standard of some preceding years.

[We published last week the list of the awards and the names of the Judges.—EDS.]

NEW BOOK.

Profitable and Ornamental Poultry. By H. PIPER. Groombridge & Sons, London, 1871.

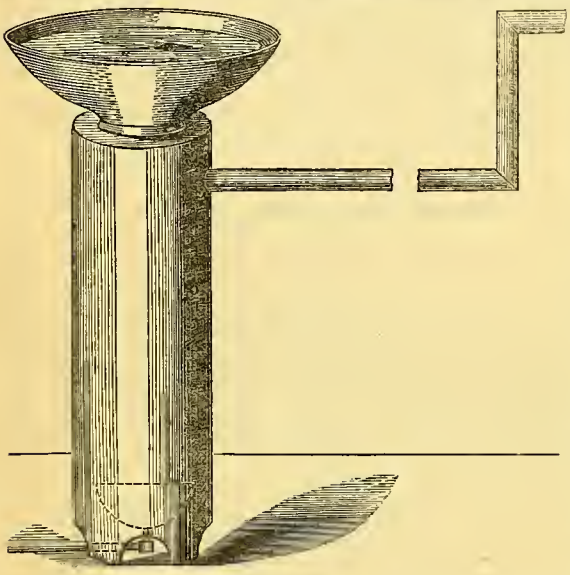
"SUCCESS," said somebody, who no doubt had himself been successful, "is the gauge of merit." That poultry have been successful during the last twenty years is undoubtedly true; the number of poultry shows and their vastness, as witness especially the recent Show at the Crystal Palace, prove it. Thus, the more in number the shows, and the greater the number of birds entered, prove the larger the number of possessors of poultry. Now-a-days in all neighbourhoods you find poultry-fanciers—in some neighbourhoods many. There were those who lamented the legal prohibition of cock-fighting, who themselves never saw or would see a fight, but because they thought that one very beautiful class of birds would become extinct. Yet what is the result? Instead of beautiful birds being disfigured, and made to resemble the first efforts of a school-boy in drawing a bird, Game cocks appear by hundreds in all their beauty of plumage at our shows. Certainly poultry as a fancy, and as producing exquisitely-shaped and plumaged birds, has been a wonderful success.

But there is another evidence of its success—viz., the number of books issued from the press as guides and instructors in the art of rearing, keeping, and exhibiting. The contrast, too, is very great between the poultry handbook or guide of twenty years since and that of the present time. It is quite certain that publishers, the most canny of men (if you doubt me, try them with a book which they think will not sell), would not go on issuing year after year new and attractively got-up works on fowls. The last new venture is the book at the head of this article. The true word in criticising it is to describe it as "pretty." The outside is "pretty," very pretty—blue and gold, and good taste outside. Within, excellent paper, pretty coloured plates, and clear pleasant reading type. As to the matter, there is nothing new, and our own two principal poultry writers, Messrs. Baily and L. Wright, are extensively quoted, so there can be nothing for us to condemn. Many of the coloured plates have the usual fault of the colours being too bright, as particularly in the Rouen drake and the Duck-winged Game cock, and they are on too small a scale to give more than an idea of what pencilled feathers are, as shown in the Gold-pencilled Hamburgh hen. The Golden and Silver-spangled Polish are the gems of the plates, and very pretty they are. The Black Polish are too green, as also the Black-breasted Red Bantam cock. The Malay, ugly rascal as we all know he is, has scarcely justice done him. The picture of the Turkey is again excellent. Some of the portraits are of birds which would not take a prize; others, again, are just what we wish to see in a pen.

The letter-press speaks of fowl-house and yard, of food, eggs, sitting, &c., but as there is nothing new, no remark is called for, save that all is well put together. Then the book proceeds with the breeds of fowls, Turkeys, Ducks, and Geese, with a final chapter on diseases. It is emphatically and especially a "pretty" book, and well suited as a present to a lady; and if the lady had no taste for poultry before she saw this pretty book, the pretty pictures, and the pretty reading, and the pretty outside, would, unless I greatly mistake, turn the lady into a poultry-fancier.—WILTSHIRE RECTOR.

HEATING A SMALL AVIARY.

I HAVE turned to the number of the Journal referred to in a letter from "A SUBSCRIBER" for further information on the subject of his query, as his last communication scarcely put me in possession of all the details. Of the merits or demerits of gas stoves and boilers I know nothing, nor have I had any experience in the heating of aviaries, and, therefore, am as much in the dark as "A SUBSCRIBER" himself on some points on which he seeks enlightenment. But I can reply confidently to the one question, as to whether it will be safe to put a heating apparatus in the compartment of the aviary occupied by the birds if a chimney be provided "to carry off the products of combustion?"—Perfectly safe, if that condition be complied with.



Aviary Gas Stove.

And with regard to the method of heating, I do not see any necessity for a complicated or expensive apparatus. A large room can be heated by simply inserting a common gas-burner in the mouth of an ordinary cast-iron rain-water pipe. We call them down-corners. The pipe must be placed with the lower end about a foot from the ground and inclined at an angle of about 45°, taking care that the heated air and products of combustion are conveyed outside the room into some receptacle not exposed to draughts, as any down-draughts will extinguish the light and cause unpleasant results. I have seen a roomy office heated in this way by a single burner (and a small burner too) attached to a pipe with a twist-about-every-way joint, and heated so rapidly that the gas, though turned on full at first, had soon to be reduced to a pressure so slight that it was difficult to imagine so small a flame could produce such results. The little gas stove of my Canary room is an adaptation of the same contrivance. A sheet-iron cylinder, about 2 feet high and 5 or 6 inches in diameter, perforated with four large holes at the bottom to admit of a continued supply of air, stands in a corner of the room over a common bat's-wing burner fastened on the floor. A stout tin chimney is inserted on one side of the top of the cylinder, and continued across the room to the opposite wall, through which it passes into an empty space under the roof of my house, where all noxious fumes are effectually dispersed. This is all the apparatus I have, and it does its work well, is quick in its action, and can be regulated to a nicety. Try it. The accompanying is a sketch of my "multum in parvo." The basin of water is to correct any dryness of the atmosphere. The chimney may be conveyed anywhere out of draughts.—W. A. BLAKSTON.

FOUL BROOD.

I HAVE been anxiously waiting for some of your correspondents taking the hint of "B. & W." relative to foul brood, but as no one appears to think the subject of sufficient interest, I conclude that the disease is not very prevalent with your scientific readers. I am sure if the reverse were the case we should have no lack of very interesting information. I have kept bees about ten years, have taken very great interest in them, and, notwithstanding many losses from various causes, I have never been disheartened until now, when the disease has attacked my stock, destroyed three good hives, and how many more it may take it is of course impossible for me to say.

I sent you a small piece of comb in August, asking at the same time your opinion and advice; a month later I examined my hives and found three of them suffering. I immediately took all the combs away, and joined the three lots of bees together, capturing the three queens, destroying two, and placing the third, an Italian, at the head. The three lots combined I put into a small cigar box, fitted with two pieces of perfectly new comb from an old-fashioned straw hive which had contained a swarm forty-eight hours, and they no more than half filled the box. I then took the queen from another black stock which was perfectly healthy, and placed the box over the hole in the top; the bees of the healthy hive ascended into the cigar box, and I then shook them out amongst the healthy combs. All this was done without losing a handful of bees. When I examined the two pieces of comb above mentioned, I found one full of honey, the other full of foul brood, the bees having carried the disease with them; some of the brood had escaped the infection, and had matured (the young bees being drones from worker cells), and this feature of the disease is, I think, very peculiar.

Of course I cannot expect the hive which now contains the bees to escape, but I intend making an inspection early in the spring, and if I find the disease, I shall have to take the combs away, and let the bees start life afresh.

When the disease first makes its appearance, it does not destroy the whole of the brood at once, but in each batch there are some cells that remain sealed, after the majority have hatched, and these sealed cells go on increasing, until by degrees the whole are closed. The bees will not leave them, as a bird will her young when they are dead, but will cling to the diseased brood although there is other comb in the hive free from taint. There is no unpleasant smell that I can detect, until long after the disease has spread through the combs; and so very unlike itself is the first appearance of the disease, that I recollect taking the trouble to pick the dead brood out of the cells with a pin, thinking they were merely chilled.

With regard to the cure of the disease, I do not think that anything would be gained by retaining the combs which contain the dead brood, even supposing the infection could be destroyed, because it would cost the bees more in time and labour to clean them than it would for them, with liberal feeding, to make new ones; but I think something might be done to disinfect the combs which are empty, and with that view I have kept fifteen, and shall be very glad if some one will make a suggestion for the purpose.—T., *Highgate, Middlesex.*

HEREWITH I send a piece of comb taken out of a strong stock. The stock is in a twenty-frame Woodbury hive, and was very full of bees all the season. I could only rob them of about 6 or 8 lbs. of honey owing to the poor season we have had in this county (Cheshire). The piece of comb I suspect to be foul-broody. I have had bees now for four seasons, and if this is foul brood I never have seen foul brood before. I first perceived it last spring in an Italian hive. The queen was an imported one twelve months ago; the box she came in emitted a strong and disagreeable smell not to be tolerated in the house, and I put it and the comb into the fire. I washed the box in several waters. All my stocks except one with combs are similar to the piece sent. Two stocks have dwindled entirely away. They do not smell so badly, but have not the fine aroma of a healthy stock.—JOHN ROBINSON.

[The comb sent for inspection exhibits undoubted signs of being badly affected with virulent foul brood. No doubt the infection was introduced into your apiary from the foul-broody condition of the comb which accompanied your Italian queen. Although you very judiciously burnt the comb as soon as you

perceived its diseased state, yet the queen and her bees must have carried the infection with them into the receptacle prepared for them. Your other pieces must have had access to the contents of this and of the other diseased stocks that have dwindled away. We have little faith in any remedial measures, particularly at this time of the year, short of absolute destruction of the bees, combs, and hives, or, if not of the hives, at least of all the bars and frames which may have been used by any much-affected colony. The hives, if too valuable to be sacrificed, must be scalded out with boiling water, scraped clean in every part or crevice, and well saturated with a concentrated solution of chloride of lime.

If you do not like to proceed to such extreme measures for the purpose of "stamping out" this dreadful malady, you can wait until April, keeping your stocks as strong as possible by judicious feeding if necessary until that time; then drive the bees out into empty hives—straw skeps or plain boxes are best—joining two or three stocks together. Give them some food, and in the course of a few days transfer them into clean frame hives, burning any comb that may have been built in the interior, and taking care to scald out and treat with chloride of lime the hives or boxes used for their temporary homes. You will then require to feed liberally until the season is sufficiently advanced for the bees to take ample care of themselves.

The chief objection to this plan is, that some of these infected hives you have now may perish during the winter or early spring, when they will be visited by hosts of robbers both from your own and neighbours' apiaries, thereby spreading the disease far and wide. Another objection is, that after all your trouble one or more of the expatriated colonies may convey some traces of the malady with them, either by means of honey with which they may have filled themselves prior to their exodus, or from actual contact with the disease, so that you may find that you will have taken all your trouble to no purpose. It seems a very hard measure to have to go thoroughly to the root of the evil and utterly destroy everything that has come in contact with this disease; but we are quite sure that it is the soundest and safest policy in the end, unless the bee-master has most abundant time and leisure for constant and unremitting attention and supervision. The late Mr. Woodbury certainly did succeed in eradicating foul brood from his apiary after it had established a firm footing, but very few apiarians would, like him, have the requisite time and leisure at their disposal, or, if they had, would be disposed to undertake the very considerable trouble that the experiment would involve.]

BEE-KEEPING IN CHESHIRE.

I HAVE been somewhat surprised that none of your bee-keeping readers have found time to give their experience of the past season, so acting on the friendly "provocative" of "B. & W." I forward an account of my doings for 1871.

May found me with eleven stocks, one having perished through loss of queen. Of these, three were in Woodbury hives, the rest in straw hives as described by me some time ago. The spring up to this time had been rather backward, cold winds and wet prevailing, but after May 3rd things looked brighter, and I observed honey glistening in the cells. On May 14th drones were visible, and breeding going on very fast. On the 16th I supered several, which took to their boxes at once. Towards the end of the month nearly all my stocks showed symptoms of swarming, though I did all I could to prevent it.

June was a most annoying month, though honey was plentiful, for the little rascals had made up their minds, and swarm after swarm issued from supered hives, though they had ample room and had stored a tolerable quantity of honey in the supers, so that by the middle of July I had fourteen swarms, and the honey season almost over. It generally ends with us about the 20th of July. I found that the honey in the supers, which were all removed, did not exceed 30 lbs.; and as I had no idea of giving a hundredweight or two of syrup to make a lot of weak stocks carry through the winter, I resolved to make my first trip to the heather, which was blooming finely on the ranks of the Dee, six miles away.

On August 5th I took eleven of the lightest hives, including a double swarm in one of Mr. Pettigrew's 16-inch hives, which issued at the end of June and had done little or nothing up to that time. I got them down very nicely, and for a month they did capitally. I brought them home on September 16th in fine condition (the Pettigrew hive weighed 50 lbs.), the average being 38 lbs. I obtained nine stocks of condemned bees for the trouble of driving, so that on the whole my trip to the heather was satisfactory.

Taking the whole year I find the general results to be good, for I have sold a few swarms and given one away. I have had about 125 lbs. of honey, maintained a unicomb hive, and at this date (November 27th) have fourteen very strong stocks, nearly all of which have had one or two stocks of bees added, and plenty of stores to last till spring.

I do not consider this district by any means first-rate for bees, and with almost the single exception of myself, the bee-keepers of our neighbourhood are content to do things in the old way, taking a hive or two when an unusually good season occurs and losing stock after stock through the want of attention in autumn. I am in hopes, however, of inducing a better state of things in time, as no one that I can hear of has taken any honey about here, and my results will set them thinking a little, I imagine.

Talking of results compels me to allude to the case of an old cottager on the hill to whom I took my bees. He commenced the year with three stocks, which had increased in September to thirteen, nine of which I drove for him. They all weighed well, so that he did wonderfully; but had he not lived in a good heather district of course all his swarms, as they were mostly late ones, would have come to grief, and so would have done harm instead of good.—WILLIAM BROUGHTON CARR, *Higher Bebington.*

OUR LETTER BOX.

OAKHAM SHOW.—"I obtained the second prize in the class for Game Bantams, best two hens or pullets.—JOSEPH OLDFIELD, *Bradford, Yorkshire.*"

CATCHING WILD PIGEONS ALIVE (*Columba*).—We know of no plan of doing this; there is, indeed, an old story of a man plagued with Wood Pigeons, who made small sugarloaf cones of stout brown paper, put some bird-lime inside, and some grains of corn at the point of the cone, and the birds trying to get at the corn became hoodwinked, and were so caught. We never tried the plan.

DORKINGS IN A GENERAL CLASS (*Surrey*).—Cuckoo Dorkings may and should be entered in a general Dorking class. They are as pure as any others, and are much prized in some parts of Surrey. You can enter in the Variety class any breed that has no class of its own. In a list where there is a class for Bantams of any other variety, Bantams must be entered in it. If there were no such class they would go in the "Any other variety."

MILK FOR FATTENING CHICKENS—PURIFYING ROOST HOUSE (*R. E. H.*).—Milk is better than water for fattening fowls. Your fowl house should not smell if your fowls are properly fed. See that the door is kept open all day, and ventilate it by removing bricks or boards immediately under the roof, that all vitiated air may be carried away, and that the draught may be above the roosting birds. Lime slaked on the floor will sweeten, but it should not be required in a well-kept house.

SILVER-PENCILLED HAMBURGH COCK'S TAIL (*J. W. W.*).—The entire tail of the Silver-pencilled Hamburgh cock should be black, save the silvering or edging of the sickle feathers.

SCOTCH GREYS, OR OLD SCOTCH BREED (*X. T.*).—The old Scotch Greys are the barndoor fowls of some parts of Scotland. They are somewhat akin to the Cuckoo of England, but they are smaller in size and bone, and lack the fifth claw. They are little kept or known in England, but are useful, hardy birds.

SCARCITY OF EGGS—FATTENING CHICKENS (*R. G.*)—Eggs have never been so scarce as they have been this year. Your fowls do not fatten because they have too much liberty. Shut them up in a small coop in a dark warm place, and they will then not only put on flesh, but in a fortnight they will fatten sufficiently for any useful purpose. They must not have food by them, but they must be fed three times per day.

BLACK RED GAME BANTAM PLUMAGE (*Far West*).—Any tinge of brown on the breast, or of white in the tail of a Game cock, Bantam or otherwise, is fatal to any hope of success if shown in a class for Black-breasted Reds. As the description implies, in such a class the breast must be black, and it is not so if there are brown feathers in it. If there be any difference in the colour of the legs you have no chance; unless the leg match you have no hope of success. If then, only one of the three hens has legs the same colour as the cock's, you must show her. A slim body is preferable, and a large comb is by no means an advantage. If it is possible to fulfil these conditions, join them with wings well clipped up to the body, and with hard feathers. If the class is for "Black-breasted and other Reds," you may show the cock in it; if not, you must show in Brown-breasted Reds. The white downy feathers do not much matter at the insertion of the tail; but if any of the tail feathers have white in them, it is a disqualification.

SEASONING FOWLS' FOOD (*C. M. S.*). — We are not friendly to any of these condiments. Good plain feeding has always answered our purpose. As in duty bound, we have tried experiments, and our belief is—that spices are injurious. Pullets well fed with good food will lay at this time of year if they are old enough. Whatever forces laying injures the fowl and lays the foundation of many diseases. It is with fowls as with human beings—the faster you live the sooner you wear out. The most useful food for hard weather is table and kitchen scraps, and in very hard weather, with snow on the ground, a little strong beer mixed with their food is often beneficial.

SELECTION OF STOCK (*Idem*).—To breed prize birds, select the parents carefully, hatch early (say March), and feed well from their entrance into life. Never let them go back; a chicken that has been checked is seldom a prizetaker in after-life.

DIARRHŒA IN FOWLS (*L. H. R.*).—Change your food. Give ground oats slaked with milk, and add some pounded chalk to it. Supply them plentifully with road grit.

AIDING MOULTING (*Lemon Buff*).—If your fowls have a good grass run, all they require to promote growth is to be fed well and regularly on ground oats. It is an advantage for growing cocks to have kitchen scraps. The great secret of rearing large and strong birds, is to feed them as well as possible from the first.

HOUDANS MOULTING SLOWLY (*X. Y. Z.*).—What age are your cocks, and how are they fed? The cock is longer than the hen in getting the new plumage, and the older they are the slower the progress. The reparative process is slower and weaker. We know nothing you can do, except to avoid heating and stimulating foods; they cause a feverish state of body, and the feathers, lacking moisture and nutriment, die away instead of growing into maturity. Fowls were never intended to take physic; they seldom injure their constitutions when they are young, and Nature is a better manager of these matters than we are. When fowls are properly judged, those who officiate should be able to make a right award, though the plumage should not be mature.

PENCILLED FEATHERS (*Amateur*).—You do not name the breed of your fowls. We presume from the feathers they are Brahmas. We prefer the feather No. 2 from the hen; but we like neither her long back nor her crooked breast. If you want a positive answer, we should, in spite of her faults, put her, being two years old, with the young cock. Either alter your perches or remove them, but fowls never do so well as when they perch.

COMPARATIVE WEIGHTS OF LIVE AND TRUSSED TURKEYS (*T. I. C.*).—Much would depend on the condition and fatness of the bird. A lean bird would lose much more in the trussing than a fat one; but as an average you may put it that a bird weighed alive and full, and afterwards weighed drawn and trussed, will be found to have lost a fourth, and sometimes a third of the weight.

LIGHT BRAHMAS DARKER (*Ignoramus*).—Your hen is cross-bred, and we do not advise you to breed from her at all if you wish for pure birds; but if you are careless of festher, it matters not which coloured cock you put her to. A Light Brahma cock should have dark flights, dark tail, striped hackle and saddle. Select the bird that comes nearest to this description

UNDUBBED GAME COCK (*W. H.*).—An undubbed Game cock, whether Bantam or otherwise, is disqualified.

ROUEN DUCK'S PLUMAGE (*G. A.*).—Rouen Ducks and drakes should be the exact representations of Wild Ducks and Mallards, differing only in size. No deviation, however trifling, should be admitted.

GOLDEN-PENCILLED HAMBURGH'S PLUMAGE (*Idem*).—The richer and fuller the colour of Golden-pencilled Hamburghs, the better they are; the "washed-out" plumage that seems akin to a dirty buff is inadmissible, but no richness of colour can be allowed to palliate a bad comb or mossy plumage.

PULLETS FOR WINTER LAYING (*Idem*).—Laying in the winter depends on the age of pullets. Hens do not lay in the winter. The best breeds we know for winter laying are the Brahmas and Cochins. Hatched in March or April, they naturally begin to lay in November and December.

GOLDEN-SPANGLED HAMBURGHS LIGHTER (*Hamburgh*).—It is by no means an uncommon thing for old Hamburghs to moult pale feathers, and even to show white spots in various parts of the body. You do not state their age. The production of feathers out of season is by no means favourable to colour or strength; thus in any bird, of whatever colour it may be, if you will pull out a patch of feathers on a certain spot repeatedly, they will at last come white; but that will not account for it in your case, the plumage was there destroyed at the natural season. All breeding hens at that period have the same broken plumage. It may be attributed partly to its brittle and worn-out condition. We do not believe the separation of the sexes would help you in the way of plumage.

GOLDEN-SPANGLED POLAND PLUMAGE (*H.*).—The feather you enclose is not such as should come from a Spangled bird. It is laced. In the earlier days of exhibitions such feathers would have disqualified, now they take prizes. Such marking is objectionable; if you can, replace it with spangles. A hay tail tipped with black is a very serious fault in a Golden-spangled Hamburgh cock.

SCURFY LEGGED FOWLS (*Amateur*).—There are two treatments. One is to keep the legs constantly wetted with oil, the other to rub sulphur ointment in very frequently, and to introduce it between the projecting scales with a feather. This disease has only been known of late years.

MALAYS' LEGS (*E. M.*).—There are very good Malays with white legs. Your fowl has incipient roup. Treat either with Bailey's pills, or try bread and ale for food, and doses of camphor, two pills each the size of a garden pea for a dose every twelve hours until relief is visible.

WEIGHT OF BANTAMS (*An Old Subscriber*).—The original weight of these birds was limited to 17 ozs. for the cock, 14 ozs. for the hen. Recent decisions have allowed an increase, and in the present day the Sebrights weigh at least 3 ozs. each more than that allowance. Till within the last ten years no Bantams were ever weighed but Sebrights. Black, White, and Game now outnumber them greatly, and they also come far closer to the limits of weight.

COCHIN COCKEREL PARALYSED (*Mrs. B.*).—We are afraid we cannot point out any cure. If the paralysis arise from an injury in the back, which is very possible, he will speedily recover, but if it be cramp he will not. We know nothing better than to give him a table-spoonful of castor oil every other day, and to give each night two pills of camphor the size of a garden pea. We have, however, small hope.

DEFECTIVE GAME BANTAMS (*W. Powell*).—It is never safe to breed from a faulty bird. A defect is always hereditary, and none more certainly so than a wry tail or a hump back.

BANTAM CATARRHED (*Game Bantam*).—Discontinue the fire in the fowl house; and if it has stone, brick, or wooden floor, cover it 6 inches deep in gravel or road grit. You may discontinue the pepper and substitute some bread and ale for barley at the midday meal. This is only necessary while they appear out of health.

GREY EGGS IN DEAD HEN (*M. H.*).—The grey-coloured eggs you mention are very common in old hens, but not in birds of the age you mention. All you complain of may be safely set down to Potato-feeding. It makes internal fat to such an extent it impedes the due action of the different organs. Thus, the liver, instead of being very dark, becomes of a pale buff colour, a fat liver, the celebrated "Foie gras;" the gall bladder no longer performs its functions, but disperses its contents at random. All the inside becomes yellow. Jaundice is the next symptom. The patient still makes a little fat, but loses flesh daily. All the Geese and Turkeys we get from Ireland are potato-fed. They are deficient in meat, and they have fat livers. Discontinue the Potatoes. Substitute good barley meal or Indian corn for them.

HOUDANS (*J. H.*).—You will do well to examine the list of Birmingham winners in our last number for an answer to your first question. Your cross is not one that we fancy, because sitters and non-sitters should not be put together. We should put the Brahma cock to the Houdan hen.

POULTRY CHRONICLE—POULTRY COMPANY (*S. Greenwood*).—No such "Chronicle" nor other serial devoted to poultry is published in England. The Company was a total failure. The work you mention is to be published in parts commencing with the next year.

SHOW AT EDINBURGH (*M. G. W.*).—There are several societies there; we believe all right.

TAKING SUPERS IN NOVEMBER (*H.*).—The objection to taking off supers so late as you mention is that the bees are apt to take down all the honey which is not sealed over, and often they will rifle and spoil the sealed honeycomb in the spring. In either case your honey harvest will be diminished. Of course it may happen that they are so well supplied below as not to be tempted to touch the honey in the supers. In this case the entire honey harvest above will be at the service of the bee-owner. We prefer to plunder in July, for another reason—to allow the bees to store up below for their own use as much of the later honey as possible, which is apt to be thin and poor.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

29th.—White frost in morning; fine day, sometimes very bright, clear evening, a few drops of rain at 10.30 P.M.

30th.—Fine morning, becoming more and more damp, till noon, rain the remainder of day and night. Strong wind at night.

1st.—Very fine till noon, then alternately fine and cloudy, clear evening and night.

2nd.—Beautiful morning, and till early afternoon, then rather dull.

3rd.—A little snow, either in the night or early morning, fine but frosty all day.

4th.—White frost in morning, fine but frosty all day, a few snow crystals at 11.30 A.M.

5th.—White frost in early morning, beautifully bright till 2 30, then getting rather dull and thick, slight fall of sleet at 8 P.M., but not a measurable quantity.

The dry cold weather which prevailed during November continues, and by its duration becomes remarkable. The total fall of rain in November (0.69 inch) was unusually small. Gale on north-east coast on the night of November 30th.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 6.

MARKETS very quiet, and no alteration worth notice, the frost not yet having any effect upon the supply. A considerable quantity of rough goods have gone over to-day for another market, in the expectation of better prices.

From observations taken near London during forty-three years, the average day temperature of the week is 45.9°, and its night temperature 33.5°. The greatest heat was 59°, on the 15th, 1868; and the lowest cold 7°, on the 16th, 1853. The greatest fall of rain was 0.87 inch.

SMALL FARMS—HOW THEY CAN BE MADE TO ANSWER.—No. 3.

By Rev. WILLIAM LEA, *Vicar of St. Peter's, Droitwich, and Hon. Canon of Worcester.*

PLUMS.—We will now pass on to the larger kinds of fruits, from bushes to trees, such as Plums, Apples, Pears, and Cherries, and I put Plums first of all in my list, because they produce a much earlier return than the others; indeed, so much so that it would pay a tenant to plant them on a fourteen-years lease, whereas the others if planted on the usual orchard stocks, are a landlord's improvement, and in most cases are planted for the benefit of the next generation. The Apple, Pear, and Cherry, on the usual orchard permanent stocks, do not become sensibly profitable till they are twelve or fifteen years old; whereas the Plum will produce a good return after six or seven years, and some sorts even earlier than this.

The most profitable way of planting Plums will be to put them in together with Currants or Gooseberries at intervals of 24 feet, which will take seventy-five trees to the acre, or even at intervals of 12 feet, which will take 300 trees to the acre. When the Gooseberries or Currants are wearing-out, which will be in fifteen or twenty years, the Plums will have covered the ground, and will bring an ample profit. I find that trees of the Pershore Egg Plum, which I planted in 1865, have this year produced on the average 30 lbs. weight of fruit each, which, at the rate of 5*s.* per pot of 90 lbs., is a return of 1*s.* 8*d.* each tree. The mention of this pot reminds me that in the midland counties all fruits and vegetables are sold wholesale by the "pot," as it is called. A pot is an oblong basket with a handle at each end, and without a lid. All the pots have these points in common, and being in such universal use, one would have supposed that they would have a still more important point in common—I mean a fixed and definite capacity; but this is not the case, there are pots and pots. This was one of the first lessons I learnt in farming; on going to buy some pots I was asked by the maker whether I wanted buyers' pots or sellers' pots, and on inquiring the difference, I was informed that buyers' pots were larger pots, and sellers' pots smaller pots, and that there was a difference of nearly a peck, or one-fifth, between them; and the different capacities of pots are so well known, that a remedy has been invented which is almost as bad as the disease. A certain conventional weight is required for a pot of every variety of fruit or vegetable; and if these weights were the same in different districts, there would only be the trouble of keeping the different weights in one's head. But this is not the case—the weights vary in different parts just as much as pots do; a pot of Potatoes is 95 lbs. in one place, while twenty miles away it is only 80 lbs. A pot of Plums varies even more than this—in one part it is 90 lbs, in another 72 lbs. The true remedy would be to buy and sell everything by weight, irrespective of these fictitious measures, which vary in every district. So much for pots. The question we have to consider is, What varieties of Plum will fill them soonest, and bring the best return to the planter?

Now, this question will be answered differently in different districts. In some it will be the Prune Damson, in others some other variety which has proved itself most congenial to the soil; but wherever the soil is strong and retentive the Pershore Egg Plum should form a considerable portion of every plantation. It is the hardiest of all Plums, the surest cropper, and the wood is tough, and the branches will bear an enormous weight of fruit without breaking. It is said to be a short-lived tree; but I know trees in full vigour which have been planted at least a quarter of a century. It brings a lower price than other Plums, but I think, in the long run, it will pay better than any other on the average. In fact Plums for market purposes may be divided into two classes—yellow or Egg Plums and coloured Plums; the latter in most years are worth nearly double the price of the former. Among coloured Plums the best are the Victoria, the Prince Englebert, Pond's Seedling, the Black Diamond, Belgian Purple, Kirke's Plum, Cox's Emperor, commonly called Jemmy Moor, Prince of Wales, Cluster Damson, Mitchelson's Damson, and the Belle de Louvain. The Victoria is a bright, large, pink Plum, an enormous cropper, always in demand, good for eating or cooking, still better, I am told, for bottling for use in the spring, but it has one most serious drawback—the wood is extremely brittle, and my trees break every year under the weight of fruit. This, perhaps, may be in part owing to their being what is technically termed "standards for orchards," and if I were to begin again I would have nothing but "half-standards" grafted about 3½ feet from the ground, and then I should prune back till the lower branches were strong enough to support the fruit. But notwithstanding this disadvantage, the Victoria should have a place in every plantation for its beauty and productiveness. I once saw long lines of this Plum alternating with Pond's Seedling; they were both ripe, and as the sun shone on their large pink fruit which hung the size of eggs from the boughs, I thought I never saw a more beautiful sight. The old Greek sailors never imagined anything finer in the gardens of the Hesperides.

Pond's Seedling has the reputation of being an uncertain cropper, but with me it always bears freely, and produces finer fruit than any of the thirty sorts I have in my plantation; its wood, too, is tough, and will bear a large crop without breaking. Prince Englebert is an excellent black Plum, and an abundant cropper. The Black Diamond possesses the last of these qualifications, but after all it is a monstrous abomination. Rivers's Early Prolific is in some places a profitable variety, and being the first in the market usually realises a high price to the grower, but I cannot speak much of it myself, as I have been unfortunate in my trees. The nurseryman from whom I bought them sent them on what I believe to be Almond stocks, and the result is that they have not made any growth in the six years, and I am now about to root them up and burn them.

This and other like experiences in buying trees lead

me to offer a word of advice to intending planters on this head. I know nothing more disappointing when a plantation has been made, than to find when your trees come into bearing at the end of three or four years, that the nurseryman has sent them on bad stocks, or sorts untrue to name. It has been my misfortune to find this to be the case on several occasions. When I began, I ordered trees from several nurserymen, and after waiting some years I found, to my disgust, that what ought to have been choice Pears, are in some cases nothing better than perry fruit, and Plums in like manner untrue to name. I should therefore recommend purchasers to visit the nurseries when the trees are in fruit, and select for themselves.

As I have mentioned the enemies of the Gooseberry, it may be as well to say a few words on the enemies of the Plum. The blackbird as usual is very mischievous, and in August and September the wasps and hornets are troublesome; but the most destructive of all enemies is the grub of the Cheimatobia brumata, or Winter Moth. This moth makes its appearance about the end of October, and continues on the trees till the end of the year. The male is a small-winged moth, the female a wingless abomination, not unlike a bug, but longer in the leg and lighter in colour. She lays about two hundred eggs, either round the buds of the Plum or Pear, or in the cracks of the bark. These eggs are hatched in April, and a small caterpillar appears which eats its way into the centre of the opening bud, and destroys all prospect of fruit. By the end of May it is full grown, and then lets itself down by a thread to the ground and buries itself in the soil, where it becomes a chrysalis. In this state it remains till the end October, when it emerges again in its winged state.

This grub is the Plum-grower's greatest enemy, and many plans have been attempted for its destruction, the most successful being the encouragement of small birds, and if they were sufficiently abundant I question if anything further would be required. In 1865 I bought some trees from the neighbourhood of the Vale of Evesham, which is the head-quarters of this Winter Moth, and on examining them in December I discovered that I had bought some moths with them, for I caught ten female Cheimatobias one morning, but since that year I have never seen a specimen of them, and I conclude that the small birds, which are plentiful, have completely extirpated them, but where they are not so abundant artificial means must be adopted. The fruit-farmers and their men turn out at night in November, with lanthorns, and kill the moths by hundreds on the stems of the trees. Hundreds more of the females are caught, as they climb the trees, in a mixture of tar and grease, with which the stems are smeared, and in some instances it is found necessary to pick the trees and destroy the caterpillars by hand; but all these means are troublesome and expensive, and I think would be unnecessary if a sufficient number of small birds could be induced to settle in the plantation.

(To be continued.)

GOLD AND SILVER FERNS.—No. 1.

I HAVE of late had several letters from Fern-growers, and all ask information respecting those species which are clothed with gold or silver farina. Now, as I am aware that the majority of the inquirers are readers of the Journal, I purpose saying a few words through its pages upon the management of these plants. The number of species coming under this heading is now somewhat numerous, and includes many plants that are veritable gems; still, there are many more known to science which have not yet been introduced into cultivation.

ADIANTUM.

This is a favourite genus with all growers of Ferns, and that deservedly, for the majority of the species are really beautiful, easily grown, and admirably adapted for combining with flowers either in bouquets or in vases. Two species only come under this heading: the first,

A. SULPHUREUM, is a native of Chili, and is usually considered difficult to cultivate, which I believe is due to the fact that most gardeners and amateurs keep it with their stove Ferns, whereas it will thrive only in a cool house. In such a situation I have grown this beautiful species to great perfection, the fronds being dense and about 9 inches in length. In a young barren state the pinnules of the tripinnate fronds are round, but when fertile the edges of the indusium give them the appearance of being somewhat serrate. The colour is bright green above, whilst the under side is clothed with a golden farina, and has a most beautiful appearance when grown as recommended above. The pinnæ, and indeed the whole fronds, form charming ornaments for a lady's hair.

A. SCABRUM.—This differs from the previous-named plant in its larger pinnules and somewhat more robust growth, as well as in the farinose substance, which is scattered over both the upper and under side, being of a waxy white instead of golden colour. It is an exceedingly pretty plant, a native of Chili, and succeeds best grown in a cool house as before described. As far as I am aware, it and the previously mentioned are the only two species known to be adorned in this manner.

CHEILANTHES.

This genus, taken as a whole, contains more really beautiful plants than any other with which I am acquainted. They are however, not generally well grown; in fact, they are usually stewed to death in hot moist stoves, while they mostly require a somewhat cool house. They enjoy moisture, but, like all the plants treated under the heading of this article, they will not suffer watering overhead with impunity. There are several species remarkable for the gold and silver covering of the under sides of the fronds, and most of them are furnished with a dense covering of scales on the under side. To grow them successfully, use a compost of peat and sand, with an equal quantity of sandstone, some of which should be broken fine, and the remainder disposed in pieces about the size of a walnut throughout the soil and upon the surface. Many of the species should be slightly elevated above the rim of the pot. Those species I shall refer to in this place are

C. ARGENTEA, known also in some gardens as PTERIS ARGENTEA, but by whatever name it is recognised, it cannot fail to be universally admired. This exquisite little plant seldom exceeds 6 or 8 inches in height. The fronds are triangular in shape, tripartite, bright green on the upper side, whilst below they are clothed with a pure white powder, to which the black marginal sori afford a beautiful contrast; and the jet black footstalks also add materially to the general elegance of the plant. It is a native of Siberia, and I have received specimens also from Japan. These latter, however, appear to be rather more robust in growth.

C. BORSIGIANA.—In general appearance this resembles the preceding, but it is taller, the fronds are larger, and the under side is clothed with a dense covering of pale golden yellow. It is one of the most beautiful little Ferns in cultivation, although through bad treatment it has obtained the character of being extremely difficult to cultivate. It is a native of Peru.

C. FARINOSA.—A noble-growing plant, yet so seldom does it receive suitable treatment that I have heard it condemned as worthless. When well grown it attains a height of from 18 to 24 inches. The fronds are somewhat triangular in a young state, becoming bipinnatifid as they increase in size; the upper surface is dark green, whilst below there is a dense covering of white farinose powder set off with a broad band of black marginal sori. I have found this plant succeed best when grown entirely in rough fibrous peat and sand, the pots well drained, and an abundant supply of water administered to the roots, but the syringe should never be used. The plant is a native of the East Indies, and requires the temperature of a stove.

C. PULVERACEA.—A plant similar in habit and general contour to C. farinosa, but less robust in growth, and its fronds less massive in appearance. It also differs from the last-named plant in having the upper side of the fronds dusted over with a white farinose powder in addition to that below. It should be treated like the preceding species, but special care must be taken to prevent its being watered overhead, or it will present a miserable appearance. Native of warm parts of Mexico.—EXPERTO CREDE.

LAXTON'S NEW PEAS.

BEING a neighbour of Mr. Laxton, and enjoying his friendship, I have on many occasions inspected his Peas. My opinion of William I. is very favourable; I think the same of Popular, which is, I believe, allied to Alpha, the latter being a very great favourite here. Superlative, however, throws all Peas that I know in the shade. I have read of the delight felt by plant-collectors in foreign countries when they met with some remarkable flower, and enjoyed the description of the pleasure they experienced, but even Mr. Fortune himself could not have felt more pleasure in one of these lucky finds than I did on first seeing Superlative Pea. With the other varieties I am not so well acquainted.

The arrangement of Mr. Laxton's crossed Peas, when they are seen growing, is a sight. They are not all mixed-up to-

gether, but plotted systematically. In No. 1 plot we see all the dwarfs, type Little Gem; No. 2 plot, type Veitch's Perfection; No. 3 plot, type Champion of England. Mr. Laxton's garden is full of interest to both the professional and amateur gardener.—R. GILBERT, *Burghley*.

SELECT GLADIOLUSES.

HAVING taken great delight for a good many years in growing the Gladiolus, all the remarks which have appeared in your Journal bearing on my favourites have been eagerly scanned to find something new regarding them.

Like many of your other correspondents, I have found Gladiolus cultivation very perplexing; indeed, some years ago I lost my entire collection. Shortly after that I had another garden, where they grew very well, but still not without many failures. From my experience, and the experience of others in the same locality as my first garden, I should say that in some soils they will not succeed at all; our subsoil was a cold heavy clay, and although deep digging and mixing sand and moss were resorted to, all would not do, and in similar soils no one should try any but the cheapest varieties, so that they could be renewed every year.

It was with much pleasure I read the reports of "D., *Deal*," and Mr. Douglas on some of the new varieties, and perhaps your readers might like to hear the experience of one living in a different locality. From some of the kinds named by "D." and Mr. Douglas as the best, proving with me only indifferent, we must conclude that certain varieties succeed much better in one locality than they do in another, notably Le Titien, James Veitch, Marie Dumortier, Reine Victoria, and Madame Basseville. All these I have grown, but I could never obtain from them a good spike.

Amongst last year's new kinds Aramis was with me very fine, and produced the largest spike I ever grew. It is a good variety, and when at its best there were fourteen blooms open, and the spike was fully 20 inches long. I do not know what length the spikes attain in the south, but here such a length is exceptional. Another cheap new variety was Colbert, tall, strong-growing, in the style of Horace Vernet, and not greatly inferior. Condé had a very showy spike, although the shape of the individual blooms was not all that could be wished. Horace Vernet is first-rate; of it I need not say more. Talisman is very good. Phèdre would be beautiful if it made a strong spike, but I fear it is delicate. Sir John Franklin was very good, but I failed in getting a long spike through the lower blooms failing too soon.

Of the varieties of the year before, Delicatissima carried off the palm: it is rightly named, because of the delicate tinge of lilac suffusing the white and the delicate streaks of the same colour; it has a strong-growing massive spike, and no one could wish for a finer variety. Armida is also a fine flower, but it did not equal the preceding. Of Elizabeth I did not think much. La Candeur I grew the first year it was sent out, and I consider it was nearly as good as that old variety John Bull. Rosa Bonheur was very fine, producing a long spike, and being new in colour—a lilac, instead of the common carmine or pink shades.

Of older varieties, Cornélie has a fine long spike, and is good in style, and Isabella is a fine white with a large dark carmine stain. Of La Favorite I had several very fine spikes; it is a strong grower, and a very distinct variety, the petals rather pointed, but altogether there are not many better. La Fiancée is the purest white grown, has a good spike, but is hardly so robust as could be wished. Le Poussin is a very good old variety, and, as I saw it exhibited this year, very large and handsome. Lord Raglan is an old favourite here, and often very good. MacMahon and Neptune are two very old varieties, but still so good that I had them in a stand of twelve, which took a first prize, despite a pretty strong competition. Michel Ange had the finest spike I exhibited; it produces a large spike and large blooms, and its colour is a beautiful contrast to the paper white under petals. It has a fault in the flowers not being at right angles to the stem, but growing upright; I had to put something behind each bloom to press it downwards, so as to meet the eye. The individual blooms on the same spike are likewise not all alike, some having only one segment white, others three, and one bloom had no white division; the blooms with three white divisions were the best. I am doubtful as to its constancy, for last year it was not nearly so fine as this; last year's bulb was imported, this year's was of the previous season's growth, but I am afraid that the same bulb's produce will never flower owing to the disease. Semiramis I have tried to grow for two years, but unsuccessfully; it is evidently a very shy variety; I must try it again, as I have seen it twice very fine. Thunberg is a very good sort, fine spike of a pleasing colour.

I had fine examples of many others named by "D." and Mr. Douglas, but I will give a list of those I think good and well worth growing, although some may be cheap old sorts. I have marked with an asterisk (*) those which are extra fine:—*Aramis, Colbert, Condé, *Horace Vernet, Sir J. Franklin, Talisman, Adanson, *Armida, Delicatissima (very fine), Orpheus, Rosa Bonheur, Argus, Cornélie, Diomède, Dr. Lindley, Eurydice, Homer, Horace, Isabella, *La Favorite, La Fiancée, Le Poussin, Lord Raglan, MacMahon, Madame Desportes, Madame de Vatry, Madame Furtado, Madame Vilmorin, *Maréchal Vaillant, *Mary Stuart, *Meyerbeer, Michel Ange (very fine), *M. A. Brongniart, *Legouvé, Mozart, Neptune, Princess Mary of Cambridge, Racine, Shakespere, Sir J. Paxton, Sir W. Hooker, Thomas Moore, Thunberg, Velleda, and *Virgile. —AYRSHIRE AMATEUR.

HARDY HEATHS.

IF the individual flower of the Heaths is of less size than that of the Pelargonium, Calceolaria, Verbena, and other plants used in massing, the number of the bells, their exquisite beauty, gracefulness, and diversity of colouring are ample compensations. No one would think much of a plant of Lobelia speciosa in a mixed border, but where a number of plants are required to form a line or mass, the individual flower is of little consequence; we judge them by the great mass of bloom produced, and the distinctness of colouring. Than the Heath there is no more profuse-flowering shrub, nor one which in my opinion is better suited for arrangements for effect. Taste, of course, differs, and I may be set down as having "very limited views" of what a massing plant should be, but those who form their ideas from seeing Heaths in a mixed arrangement have no conception of the effect produced by such plants when in a mass of as many square feet or yards as the individuals composing it cover square inches. Everybody knows the effect of the Heath on a moor. I am within easy distance of one of very many (too many, for some of the soil is fit for agricultural crops) square miles in extent, I believe the largest in these islands, and to produce an effect like that, but of course on a very much less scale, is the object of this paper. I may say that we have cultivated clumps of Heaths in varied forms and sizes, ranging in extent from a square rod to a quarter of an acre.

Very effective beds, nay, Heatheries, may be formed by selecting those hardy Heaths which bloom at the same time, and planting each separately in beds of almost any design, for design is not so material as the arrangement of the plants as to height, colour, and period of bloom.

Hardy Heaths are also extremely ornamental as bands or borderings to clumps of American plants—as Rhododendrons; and they have one other recommendation—they endure the smoky atmosphere of towns. Within three-quarters of a mile of the centre of one of our largest manufacturing towns, I have grown a collection amounting to upwards of fifty species and varieties of hardy Heaths.

They prefer a sandy peat soil well drained, but if the latter condition is secured the former is not imperative; for they will grow well in a soil containing vegetable matter, or such as may be found in most woods of some standing, where Foxgloves abound, mixed with an equal quantity of very sandy loam. They flourish in a humus soil, but are impatient of stagnant water, and if the site is low and wet—which is anything but good for them, as they delight in fresh air, and the cutting blast—put on a layer of stones as rough as possible, and about 6 inches deep, not raising them into a cone in the centre but with a gentle rise, and cover with from 6 to 9 inches of soil. To the soil may be added one part in four of stone, and if the soil is not sandy, add one part of sand to four of the compost. This may be used rough, but the surface should be fine and not rise more than 1 foot in 3. I know it is a practice to raise rockwork for these plants, and it is all very well to do so where there is an unlimited supply of water to prevent the plants dying from drought, which they are apt to do on rockwork. On low rockwork they succeed fairly, but on well-drained soil gently raised they do far better. Whatever soil be used let it be sandy, for silica is essential to the healthy growth of the plants and their profuse blooming.

The situation should be open. Shaded places answer for Ferns, but not for Heaths, and if there is a spot that is exposed to every breeze, there have the Heathery. Heaths like air, sun, and moisture, but will also live in shaded places, for I know several acres of Scotch Fir and Larch, where the ground is covered with a close carpet of Heath, but in the sunny open spots the bloom is best.

The best time to plant is, perhaps, February, but from October to March inclusive will answer. To give an immediate effect plant thickly; very little of the bare soil need be left, whilst the greatest distance apart should be equal to the height of each kind.

The after-treatment is very simple; all they want is to be kept clear of weeds, and to be pruned occasionally to preserve them in form, for however much irregularity of growth may break the monotony of the effect in a wild state, in a cultivated one irregularity of one form is not admitted. Pruning is best done just before the plants commence growth. If it can be afforded, top-dress with any grass-edging parings, thin turf reduced to soil, cocoa-nut refuse, old cow dung, or the short grass of the lawn. Half an inch deep of any of these materials applied in October will be sufficient for a year; it is then that they put out roots innumerable, and not only Heaths, but every kind of American plant. From my observation of the state of the roots, the end of September is the best time to remove this class of plants, but if they have been grown in sheltered positions, as they are in nurseries, with the view, no doubt, of obtaining a saleable plant in the least time, they are best removed in spring, when danger from sharp weather is past, and they can establish themselves before the return of severe weather.

Hardy Heaths look best in an arrangement of beds on grass, and may enter into geometrical or symmetrical combinations along with summer bedding plants, for I do not know by what law Heaths, and other profuse-flowering low shrubs, which are as effective by their foliage as their flowers, should be excluded from flower-garden arrangements. A few good beds of Heaths, if only for their light and elegant foliage, ought to be acceptable, as taking away or toning down those glaring masses of bloom for which our flower gardens are remarkable—or were, for thanks to the introduction of fine-foliaged plants, this dazzling brightness has been toned down considerably, and is now tolerable, which is more than could be said a few years ago.

The best arrangement of Heaths, is, perhaps, in the picturesque style, and associated with other shrubs not necessarily American, for they never look so well as with Furze (nothing makes a finer mass than the Double-flowered Furze, a mass of golden colour, and afterwards a mass of glaucous green, which will set-off bedding flowers better than nine-tenths of the plants used for the purpose), Andromeda, Cistus, and the like, and even with others they are well adapted for the most refined arrangements.

I shall not propose any particular mode of arrangement, for one cannot well be decided on without a knowledge of the ground, and it is best left to individual taste. I will now give a list of the best, freest, and most constant-flowering Heaths:—

Erica vulgaris alba, white.
flore-pleno, pale purple.
tomentosa, pale red.
argenteo-variegata, white variegated leaves.
aureo-variegata, gold variegated leaves.
Erica vulgaris coccinea, red.
Alportii, red.
rubra, reddish purple.
pallida, pale purple.
Hammondii, flesh.
stricta, reddish purple.
tenella, pale red.

These are all of very close stiff growth, and attain a height of from 1 to 3 feet. They usually flower towards the end of June, are a mass of bloom at the beginning of August, and the flowering is continued until the end of September. The variegated kinds are of lower growth, and form fine edgings to clumps of the other kinds. E. vulgaris stricta is of erect growth, and is suitable for dotting in the picturesque style.

Erica cinerea, pale purple or grey.
alba, white.
rubra, red.
carnea, flesh.
Erica cinerea atro-purpurea, purple.
rosea, rose.
coccinea, bright red.

These have all small flowers, and form a dense carpet about a foot high. They commence flowering in June, and continue in bloom up to September inclusive.

Erica Tetralix, pale flesh.
alba, white.
Erica Tetralix rubra, red.
carnea, flesh.

These are rather loose-growing plants, with graceful flowers from the early part of June until the end of August.

Erica vagans, pale red.
alba, white.
Erica vagans carnea, flesh.
rubra, deep red.

These are of rather straggling growth, but, nevertheless, form good masses about 1 to 1½ foot in height, flowering from July to October.

E. ciliaris, pale purple, of fine and neat habit, 1 foot high; July to September inclusive.

E. multiflora alba, white, and multiflora rubra, red. These are fine, and flower from July to November.

E. stricta, pale purple, of stiff erect growth, flowering from August to November; height, 2 feet.

E. Mackiana, reddish purple, flowering from June to September.

The preceding are summer-flowering kinds; they form very effective small or large groups, and are very hardy, except E. stricta, which is from South Europe, and in a moist soil the growth sometimes suffers from frost.

Erica carnea, flesh with purple, about 6 inches high, dense close growth, and covered with flowers from December to April. It is well adapted for edgings, forms a fine group, and may be effectively employed for winter and spring flower-garden decoration.

Erica herbacea, flesh.
alba, white.
carnea, deep flesh or pink.

These flower from December to April, and are similar to the preceding. The last-named does not flower until March.

Erica arborea, white. February to May. It is of tall growth, 4 to 5 feet, and requires a sheltered spot, but open.

Erica codonoides, pale rose, with larger flowers than E. arborea, of more slender growth. It grows 6 feet high or more in sheltered places, which it requires. February to April.

Erica australis, pale purple.
nana, pale purple and very dwarf.
rosea, rose.

These are of very close growth, and attain from 9 inches to a foot in height. They flower from March to June.

Erica scoparia, tall and slender, sometimes attaining from 4 to 6 feet in height.
nana, dwarf, about 1 foot to 1 foot 6 inches.
minima, attains to 2 or 3 feet.

All have greenish flowers in April and May.

Erica mediterranea, purple, 3 to 4 feet.
glauca, foliage glaucous.
hibernica, erect stiff habit.
nana, dwarf, but stiff habit.

Flower from February to May, and require sheltered places.

Menziesia polifolia, purplish red.
alba, white.
atro-purpurea, deep reddish purple.
pumila stricta alba, white.

The first three attain a height of 1½ to 2 feet, and produce their fine showy flowers in July and August, but the last attains a leaf-growth of not more than 9 inches, seldom that, and sends up very many spike-like flower-shoots 1 to 1½ foot high, or more, and on these are borne fine large white Lily-of-the-Valley-like bells. The effect is good from July to November; indeed whilst I write (November 2nd), the plants are conspicuous by their pure white flower-bells. It flowers more or less all the year round, and a mass of it is fine. I have it in patches of half a dozen, or a dozen, up to fifty, planted at about 2 feet apart in ordinary loamy soil on the margin of Rhododendron beds, not in a line, but as a mass next the grass, where it serves to break the outline of a plain figure of shrubs, and it has a good effect. Sandy well-drained soil is most suitable. Where common shrubs grow it will succeed, only it must have light to flower.—G. Abbey.

THE THIRTY-SIX BEST ROSES.

I have given the names of what I consider the best twelve Roses; I will now make the number thirty-six. I have left out some beautiful Roses because of their deficiency in growth or hardihood, or both—such as Louis Van Houtte (Lacharme), Marie Baumann, Marquise de Mortemart, Madame Furtado (the best specimen of an exhibition Rose), and Madame Vidot and Madame Rivers, the best Hybrid Perpetual light Roses. The above Roses are suited only to amateurs, or rich people who can afford to replace them from time to time. They are a paradox; they will win all hearts and break a good many. Marie Baumann is a most beautiful and perfect Rose, but at this place a miserable grower on the Manetti stock. I have for three years had twenty plants of this variety, which have become small by degrees and miserably less. Moreover, it has the

sad fault of turning its face to the antipodes. "*Se tenant bien*," or erect habit, is essential to constitute perfection in Roses, except lofty wall Roses.

The following Roses can be well recommended both for the garden and for exhibition. Making allowance for Tea Roses and Tea-scented Noisettes, they are hardy, free-blooming, free-growing, and an admirable set of Roses. In the case of duplicates and triplicates the reader may select which he likes without harm. They are placed from beginning to end in alternations of colour.

1, Maréchal Niel; 2, Pierre Notting; 3, Madame Chirard; 4, Charles Lefebvre; 5, William Griffiths; 6, Alfred Colomb; 7, Edouard Morren; 8, Perfection de Lyon; 9, Marguerite de St. Amand; 10, Madame Victor Verdier; 11, John Hopper; 12, Maurice Bernardin; 13, Gloire de Dijon in its globular form; 14, Marie Rady; 15, Devoniensis; 16, Prince Camille de Rohan, or Empéreur de Maroc; 17, Duchesse d'Orleans; 18, Dr. Andry; 19, Triomphe de Rennes; 20, Marquise de Castellane, a splendid Rose; 21, Duc de Cazes; 22, Elie Morel; 23, Maréchal Vaillant; 24, Souvenir d'Elise; 25, Leopold Premier, or Duchesse de Caylus; 26, Souvenir de Malmaison; 27, Madame Boll; 28, Céline Forestier; 29, Sénateur Vaisse, Lady Suffield, or Prince de Portis; 30, Madame Willermoz; 31, Felix Genero, or Madame Fillion; 32, Madame Boutin; 33, Abel Grand; 34, Gloire de Ducher, lake, a grand Rose; 35, Cécile de Chabrillant; 36, Rêve d'Or, choice and a real beauty, golden yellow with coppery centre.

Now, if the reader can bring these out well for the exhibition table he will have no occasion to be ashamed to meet the distinguished rosarians of England. There are other good Roses besides those named.—W. F. Radclyffe.

A GARDENER'S HOLIDAY.—No 4.

About one mile from Kelso is Floors Castle, the seat of the Duke of Roxburghe. A magnificent view of this noble mansion is obtained from the bridge in passing into the town. A new kitchen and flower garden, with very extensive ranges of forcing and plant houses, were laid out about thirteen years ago under the direction of Mr. Rose (now gardener to Her Majesty at Frogmore), a full description of which appeared in this Journal when Mr. Rose left the service of the Duke. The extent and arrangement of the houses, and principal features of the gardens, were detailed at that time.

The vineries, Peach houses, and principal plant houses are in one range, and consist of seven large span-roofed houses running north and south, connected with a long corridor at the north ends. The upright sashes are quite 6 feet high; such high upright sashes I do not think desirable, as they are not well adapted either for plant or fruit-growing. The Vines at Floors this year were making fine, strong, short-jointed wood. In previous years, when visiting at this place, I had remarked the heavy crops of Grapes in all the houses, but this season the crop was not so heavy. I learned that it was found necessary to undercrop the Vines this year, in order to recruit their energy from the exhausting effect of heavy cropping; and to improve them further some of the old canes were being removed and young ones trained up on the extension system. A very large number of Lady Downe's Grape is grown, which is everywhere held in much esteem as the best late-keeping variety. Black Hamburgh and Muscat of Alexandria are grown to the largest extent, the next best black being Black Muscat of Alexandria; and Foster's Seedling was stated to be the best white not Muscat-flavoured. I have always preferred the Buckland Sweetwater to this, because when well grown it has quite as good a flavour, and has a finer appearance on the dish than Foster's Seedling, which rarely finishes off well, the berries when ripe being more often of a green than a golden colour.

In passing through the large block of span-roofed houses, I noticed in one devoted to stove plants a very fine form of Anthurium Scherzerianum, the spathes of which were darker than usual, and peculiarly ribbed, which may to some extent be owing to the treatment. They were as large as any seen at the London exhibitions this year, and there are evidently many forms of this plant, some of them being far superior to the others. In another house was the best collection of Tree or Perpetual-flowering Carnations I have yet seen, and comprising many new and little-known varieties. These plants would supply a large quantity of cut flowers from October far into winter; probably Mr. Knight is cutting these flowers all the year round. Most of the plants were two years old, and seemed to grow very strongly. In such large houses these plants are, perhaps, the best, whereas in small houses cuttings struck in February and March are best adapted for supplying a succession of flowers the following winter. I noted the following as being valuable and distinct:—Beauty, scarlet flake; Comte de Derby, a large flower with a peculiar shade of bronze in its composition; Rembrandt, crimson maroon, a very fine flower; Brilliant, very dark, fine; Henshaw's Scarlet and Hector, scarlet flake. In front of the large block of houses is a terrace, at the base of which is the flower garden. This has been a very bad season for flowers in the north, and some of the more tender subjects have failed entirely. Conspicuous from the terrace, and forming the centre to two large beds, was an excellent strain of Beet; it was exceedingly effective, much more so than Perilla for ribbon work. I was informed that it was Dell's. Golden Gem has proved to be the best yellow bedding Calceolaria, and had been selected as the best out of a very large number of different sorts. Christine was the best rose-coloured Pelargonium for bedding. This variety seeds so freely in the south, that unless the pods are frequently picked off, the plants look unsightly; this objection is not urged against it here. Polemonium cæruleum variegatum was very effective in several combinations, and a very chaste and pleasing effect was produced by planting a bed with Purple King Verbena, and an edging of Mangles' Variegated Geranium, allowing the one colour to run into the other.

A substantial wall divides the flower from the kitchen garden, in which there are also fine ranges of houses, and some low span-roofed pits devoted to Melons. Of these a pit in three divisions contained Melons grown in three different ways: one set was trained to a trellis fixed about a foot from the glass; another was also trained to a wire trellis raised a foot or more above the surface of the bed, and at equal distances from it; the third set was merely trained over the surface of the ground, as is usual in ordinary dung frames. The largest crop was obtained from those trained over the surface of the bed without a trellis, the largest and best fruit being obtained from the trelliswork. In an adjoining house was a very good crop of the Currant Tomato. It was an instance of the combination of the ornamental and useful well worthy of imitation. The fruit was very beautiful as it hung from the trellis to which the plants were trained. I also noticed a vast improvement in the appearance of the Pines, they were planted out in beds instead of being grown and fruited in pots as was usual here. Smooth-leaved Cayenne and Queens were the principal sorts grown.

From Floors Castle it is but a short distance to Newton Don, the seat of Charles Balfour, Esq. The mansion is substantial and well built, commanding a very extensive view of the surrounding country. It boasts of a picturesque waterfall and extensive woods clothing to the summit precipitous banks, at the base of which an extensive stream abounding in trout glides rapidly onwards. Mr. Thom, the head gardener here, is a most worthy representative of the craft. The flower garden is not large, but it is laid out with great taste, and is beautifully kept, although Mr. Thom labours under difficulties. The soil is unsuitable, but this difficulty has been overcome by removing it to the depth of 18 inches, and replacing with suitable material. It is also overshadowed by surrounding trees, especially a row of Limes on the south side, so that the flowers are liable to decay from damp early in the autumn. A small flower garden in front of the mansion continues gay for weeks after the beauty of the other is past. The terrace wall in front of the mansion was planted with Roses and Tropæolums. I suggested to Mr. Thom that Clematis Jackmanni would be a good substitute for the Tropæolum, and I found he had already prepared plants of this type of Clematis for that purpose. This beautiful class of plants is now being extensively planted for covering low walls or old decayed stumps of trees; and as a new and striking feature in flower-garden work they are, as they deserve to be, the subjects of universal admiration.

In the kitchen garden there are some well-arranged mixed borders planted with Antirrhinums, Phloxes, Pentstemons, and the showiest of herbaceous plants, a class which has always found a place here. These are backed up by Dahlias and Hollyhocks, the borders being divided from the kitchen-garden quarters by rows of Sweet Peas. The heavy loam of this garden is peculiarly adapted for the Hollyhock, and I have never seen such spikes in England as those with which Mr. Thom used to carry off the principal prizes at Kelso fifteen years ago. I noticed one border which used to be devoted to the show Dahlias. It was now filled with Gladiolus and Carnations, both of which were doing well, the Gladiolus being a healthy

even lot. My first question was, Are these imported bulbs? "No, I have bought none for three years," and yet, strange to say, the soil is not what is generally considered suitable to this plant, being a somewhat heavy loam. The bed is raised considerably above the surrounding level, so that the bulbs have every chance of ripening well. The soil is also a good loam for Grapes and every description of stone fruit, the flavour of the Grapes being unsurpassed.—J. Douglas.

CALIFORNIAN CONIFERÆ.

Commencing in the southern part of the State, we meet in her littoral belt, a little north of San Diego, a small species of Pine, known to botanists as Pinus Torreyana. I have thus far not been able to learn its vernacular name.

The trees are small and few in number: they resemble most the so-called Digger Pine (P. Sabiniana) of our interior valleys. The leaves are in fives and pretty long.

The seeds are about as large as those of P. Coulterii. The locality mentioned is the only one known. It has not been tested long enough in our gardens to know what may be expected of it as an ornamental tree. In a practical point of view it is unimportant.

Going northwards and keeping close to the sea coast, we find at San Simeon Bay, at Monterey, and at a place a little south of Pescadero, the so-called Monterey Pine (P. insignis). The latter-named place is its most northern limit. It seems to occur only on the immediate coast, on bituminous slate. Monterey is the oldest seaport and the oldest point where botanists began their labours in California. Already, towards the close of the last century, it was visited by Menzies, an English botanist. Our species in question, being variable in the form of its cones, and the form of cones being one of the chief characters relied upon in a botanical description, gave rise to quite a number of synonymes.

In Captain Beechey's work we find it figured under the name P. Sinclarii. Later, it is again described by Loisleur, and called P. californica. Don described it even twice, calling it one time P. radiata and another time P. tuberculata. The name P. insignis, given to our species by Douglas, who visited Monterey in 1830 or 1832, is the one now generally used. The name cannot be considered as settled; for according to the laws of nomenclature adopted by botanists, it must retain its first name, P. Sinclarii.

This species attains a height of 80 to 125 feet, and a thickness of 2 to 4 feet. In old age its shape is very irregular and anything but beautiful. Its cones, three to five in a whorl, are persistent for many years. The leaves are in threes. Its timber is of little value when better can be had. In dry protected places it is pretty durable; but exposed to the vicissitudes of climate, it perishes soon. The tree, when young, is undoubtedly beautiful. It is extensively found in our gardens, and is known to every one as the Monterey Pine.

Mixed with the species just treated of we find another two-leaved one, P. muricata. The vernacular name in the southern portion of the State is Bishop Pine; in the northern, Pitch Pine. It occurs near San Luis Obispo at an altitude of 3,000 feet; near the Mission La Purissima, where it forms a small grove near Monterey, as just mentioned, sparingly; near Tomales Bay, scattered over hills; facing the ocean; near Point Arenas; also at the Albion River, extending northward to the Ten Mile River (Mendocino county). Its cones are in whorls of two to four, persistent for many years. Some trees, 2½ feet in diameter, had cones on the lower branches partially overgrown by the bark. In some trees we find a series of cones of twenty-five or thirty years. This species has not yet found its way into our gardens. When young it is beautiful, and apparently of a quick growth. The old tree is irregular in outline, mostly weather-beaten and unsightly. It attains a height of 50 to 80 feet. Its wood is fit for fuel only.

At the Albion River P. muricata is mixed with another two-leaved species of Pine, P. contorta, *Dougl.* (P. Bolanderi, *Parl*). It attains a height of 30 to 50 feet. On the upper drier portions of the so-called plains of that region it bears cones when it is about 5 feet high and 1 or 2 inches thick. The cones, several in a whorl, are also persistent for many years. Its small size and slender upright branches, its short and densely set bright green leaves, render it desirable for ornamental purposes. It evidently requires a sandy soil, whether wet or dry; it grows in both as its natural haunts. In the vicinity of Fort Bragg this species forms a perfect barrier and shelter against wind and drifting sand. Nature here hints at a remedy for us. This species used with the Monterey Pine and Cypress, would protect our city from drifting sand and fix the sand and soil. The people in that section of the country have no vernacular name for it. In any other point the tree is unimportant. It extends along the coast northward up to Alaska. On the sierras it occurs between 3,000 and 11,000 feet, descending, however, gradually to the north. This gradual descendance of all our trees on the sierras towards the north is readily explained; yes, it is self-evident. On the sierras, opposite Visalia, our big trees set in at 8,000 feet altitude. The Mariposa big tree is found to be 6,500, and the Calaveras 4,700 feet above the level of the ocean. On the sierras, P contorta or Twisted Pine grows on the banks of streams, on wet and moist flats, and in the higher portions of the mountains on moraines. Here it attains a height of 150 to 200 feet, and a thickness of 3 to 4 feet. Its outline is strictly cylindrical. Its wood is, owing to the frequent storms on the mountains, twisted, and therefore hard to split. It is principally used for building log houses and railway ties. The vernacular name applied is Tamarack. The application undoubtedly arose from the resemblance in form and habitat this species presents with our eastern Larch (Larix americana, Tamarack, Hackmatack) growing chiefly, if not exclusively, in swamps. The identity of the coast and mountain form is not altogether safely established.

Receding from the coast towards the east, we meet on dry hillsides a small tree, generally known as P. tuberculata. It attains a height of 20 to 40 feet, and a thickness of 10 to 20 inches. Its outline is conical. The leaves are in threes and the cones persistent. In gardens it does well, and as an ornamental tree is preferable to the Monterey Pine. I have not been able to learn its vernacular name. Being small and unsightly in its natural haunts, farmers never made any use of it, and therefore give it no vernacular name. It occurs on the coast mountains on the road to Santa Cruz, on the Oakland hills, on the mountains around Ukiah, on the Red Mountain, Humboldt county; also near Forest Hill, at Cape Horn, and further up near Alta in the dry slopes of the canon of the American river. In most cases this small tree forms a small grove by itself. After the trees have attained a height of 20 to 40 feet they die and decay.

Continuing our march eastward, we next meet, although sparingly at first, our well-known Yellow Pine (P. ponderosa). This species attains a height of 150 to 250 feet. Its form is cylindrical in outline. The branches are short and generally deflexed. The leaves are in threes and cones deciduous, falling every winter to the ground after they have opened (about the 1st of September) their scales to allow the seeds to be spread by the winds. In gardens it cannot be called an object of great beauty. But on the higher mountains, where it developes its full colossal growth, it is certainly a grand object to behold, and I can well see why Douglas called it ponderosa, the mighty. Generally speaking its timber is rather inferior, being too coarsely grained, and therefore subject to early decay. It must be mentioned, however, that there is considerable difference in the quality of the wood in different localities, yes, even in trees standing side by side. The timber from Truckee, so called Truckee Pine, belongs entirely to this species. The species in question is one of the most widely distributed trees of the western coast of North America. It grows on all higher and drier points of the coast ranges, and it descends even into their dry gravelly valleys, as is the case a little north of Ukiah, Mendocino county. It occurs on the Sierras from 1,500 to 9,000 feet, in great abundance; in fact, it is the principal component of that mighty belt of timber extending from south to north along the western slope of the sierras, between 2,000 to 7,000 feet, a belt of timber whose equal cannot anywhere elee be found. It extends from the Colorado north throughout the Rocky Mountains, and occurs also in the higher mountain ranges of the Great Basin. Its northern limit is unknown. This immense diffusion over so large a territory, exhibiting so many different expositions and climatic differences, must naturally cause a great variation in form and size of the tree and in the quality of its timber. Its very botanical history proves this assertion, for there are few trees that have more synonymes than the one in question. Besides the name above given there are the following synonymes: P. Engelmanni, P. brachyptera, P. Benthamii, P. deflexa, and P. Jeffreyi. The cones of trees in a dense forest are usually small, while those of isolated trees standing in alpine meadows or on bare rocky slopes of mountains, or on wide sandy plains

(Mono Lake), are from four to six times larger. This larger size of the cone is perhaps due to the intense reaction of the atmosphere caused by bare rocks, wet meadows, and dry sand. Considering the quick radiation of heat in such localities towards evening and shortly after sunset, which cools the air and causes a heavy dewfall, we may be able to understand this phenomenon.

Ascending the highest points of the Coast Ranges, we meet the well-known Sugar Pine, P. Lambertiana. But the Sugar Pine of the coast ranges is not that colossal structure of the higher or rather middle sierras. Its beauty, size, and length of cones are inferior. This tree yields an excellent timber, and attains a height of 150 to 200 feet. The outline is cylindrical, the branches are short, dense, and much divided into spray. A characteristic exception, make the topmost branches, which spread in a loose irregular manner, almost horizontally. These are the cone-bearing branches, which attract the attention of everybody by their clusters of pendulous cones, 15 to 18 inches long. The cones open about September to emit their seeds, and fall then themselves during winter to the ground. This noble tree has its leaves in fives; they are comparatively short and of a glaucous green colour. It ranges throughout the entire length of the sierras north to the Columbia river between 4,000 to 10,000 feet. I have not yet observed it in any of our gardens. The resinous matter exuding from burnt spots of the trunk hardens into a whitish mass, sweet as sugar.

Descending into the more easterly valleys of the coast ranges we meet a very peculiar Pine, the Digger Pine (P. Sabiniana). This species attains the height of 40 to 60 feet and a thickness of 2 to 3 feet. Its outline is irregular; the trunk is generally low. Its branches are characterised by a few main leaders and by the paucity of their spray. The foliage is light and quite glaucous green. The leaves are in threes and the cones persistent, although not to the extent of some other species. The seed is the largest of all our Pines. The testa of its seed is very hard and bony. This species occurs in the driest portions of valleys and hillsides, even up to 4,000 feet of the sierras. It forms very seldom small groves. On account of its irregular form it is not a desirable tree for gardens. Its wood is useless except for fuel.

In similar localities we find growing with the Digger Pine, although less frequently, another Pine, P. Coulteri. This species attains the height of 30 to 50 feet, and a thickness of 2 to 3 feet. It has a broad oval outline. The branches and branchlets are thick and clumsy and few in number. The leaves are very long, bright green, and in threes. The cone is the largest produced by our Pines. It occurs at Pass Tejon, on the Santa Lucia mountains, and at Mount Diablo. In our gardens it does well.—(*Professor Bolander in California Horticulturist*)

DRAUGHT OF FLUE TOO POWERFUL.

If your correspondent "Viridis" banks up his fire with a mixture of sawdust and coal dust, using a larger proportion of the former than of the latter, he will be able to maintain a slow fire for a considerable time. The above fuel can be used in quantity, and yields comparatively little heat, so that there is no risk of scorching the plants with it. It will keep up a smouldering fire for nine or ten hours, and is occasionally very useful to deaden the fire. "Viridis" had, however, better take your advice and look to the draught from his ashpit door. It is surprising how little air a greenhouse fire often requires, an opening the size of a fourpenny-piece is frequently sufficient, as in the improved Arnott stove. I am the fortunate possessor of a flue with a tearing draught, but can always regulate it to a nicety by means of the ventilator in the ashpit door. A small pin is so fixed that the ventilator cannot be entirely closed by one-eighth of an inch, and this small opening admits air in sufficient quantity after the fire has burned up well. A few days ago, on looking at the fire for the last time at night, I found it roaring furiously, the door, &c., red hot, and soon discovered that the stopping round the door had fallen down and that air was admitted freely. I had no sawdust handy, so I smothered the fire with ashes.

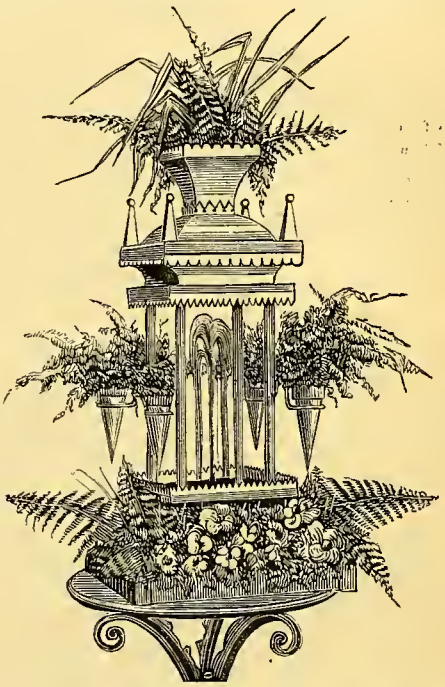
Many amateurs take much more trouble than is necessary with their greenhouse fires. I cannot now help smiling at my own care some years back. I used carefully to make up the fire between 10 and 11 P.M., visiting it again the next morning at 6 o'clock. For some time past I have banked up at 8.30 P.M., and not troubled myself about the greenhouse until a comfortable hour the next morning, feeling sure that though the fire might have burned out hours before daybreak there would be heat enough in the flue to exclude the frost, however severe.

In conclusion, I will just add that a continuous small fire can be more easily kept up if the furnace be not too large, as the fuel will lie in a compact mass.—John Marshall.

[We are very much obliged by your note. It is a great mistake to think that such "simple" information is not valuable; all success is secured by a knowledge of small facts.—Eds.]

SELF-ACTING PORTABLE FOUNTAIN.

My new portable table fountain will play from one to three hours, according to size. The top part acts as a cistern, and when the water has run out I unscrew the jet, screw it into the cistern and reverse, both top and bottom being alike. The



whole operation can be performed in half a minute without spilling one drop. The flower-vases are moveable for reversing. The idea is entirely original, as far as I know. I have never seen anything of the kind before. I took my idea from an hour-glass.—T. Wood.—(*English Mechanic and World of Science.*)

ROYAL HORTICULTURAL SOCIETY.

Report to the Council on the Permanent Exhibitions, and International Competition, 1871.

As regards the permanent exhibitions in the arcades of the Royal Horticultural Society, we have to report, that the display made by the several exhibitors has been examined by us on the first meeting day of each month, according to the conditions of the Society's Schedule, and speaking in general terms we may *state* that the exhibitions have been well kept up from the beginning to the end of the season. Mr. W. Paul, who has in our opinion earned the first place, had in the beginning of May a magnificent display of pot Roses, such as were probably never brought together before by one exhibitor, and we have proposed to mark their excellence by the special award of a gold medal. Mr. Paul also made an excellent display of cut Roses in May, June, July, August, and September, those in July being considered especially good; and these were supplemented by ornamental evergreens, and in their respective seasons by Lilies, Pelargoniums, Hollyhocks, Asters, &c.; while in September the collection contained some excellent pot Vines.

Messrs. Lane & Son occupy the next place, their exhibition being of a more miscellaneous character, made up in the main of fine specimens of hardy evergreens, enlivened in May and June by Rhododendrons and Azaleas, of which they had a good display. Later on we found a good collection of Ivies, and in September several very interesting Conifers bearing fructification.

Almost on an equality with this was the display made by Messrs Standish & Co., in which a more decided attempt at effective arrange-

ment has been fairly successful, and has been estimated in the award. This exhibition was made up of a miscellaneous background of evergreens, varied from month to month in the more prominent parts by groups or specimens of flowering plants, amongst which we may particularly mention Eucharis grandiflora, Anthurium, Bouvardias, and towards the close of the exhibition, Gladioli. A handsome bush of Skimmia oblata attracted a good deal of notice, and some of the novelties among Coniferæ received much attention from the foreign Jurors associated with us.

Mr. Wills's exhibition was of a different character altogether, consisting mainly of the class known as furnishing plants, and its chief merit consisted in the arrangement, which was the most tasteful and effective in the whole exhibition, though of much less extent than those previously adverted to. As part of this arrangement he had a revolving stand, which we consider deserving of special mention and approbation.

Messrs. Paul & Son's exhibition consisted mainly of Hollies, Conifers, and other evergreens, and was generally set off by cut Roses, and in September by a group of Vallotas.

Messrs. Kelway & Son showed only Gladioli, but they were of so much merit that we have proposed to award to them a Silver Flora Medal.

Deducting the cost of the medals, we understand that we are to allot £243 between the exhibitors, according to the total number of marks obtained, and, based on this understanding, we have made our awards as follows:—

Mr. W. Paul	285 marks	..	£72	10	0	and Gold Medal.
Messrs. Lane & Son	243 ,,	..	62	0	0	
Messrs. Standish & Co.	228 ,,	..	58	0	0	
Mr. Wills	98 ,,	..	25	0	0	
Messrs. Paul & Son	61 ,,	..	15	0	0	
Messrs. Kelway & Son	40 ,,	..	10	0	0	and Silver Medal.

Thomas Moore, *Reporter*.
Robert Hogg.
Maxwell T. Masters.

INTERNATIONAL EXHIBITION, 1871.

In the case of the international competitions it was ascertained that previously to the organisation of the Jury, to which we were appointed to act as Secretaries, certain foreign novelties had been exhibited at the meetings of the Society, and with a view to completeness we have here included the awards made to these subjects by the Floral Committee. Subsequently the awards have been made by an International Jury constituted in accordance with paragraph 4 of the annexed printed paper, which formed the instructions under which we have acted.

[Horticultural Department of London International Exhibition, 1871.

1. By a Minute of Council, dated April 6th, 1870, the following gentlemen were appointed, with the sanction of Her Majesty's Commissioners for the International Exhibition, to act as Permanent Secretaries of the Horticultural Section of the London International Exhibition, the management of which is vested in the hands of the Society—namely,

Dr. Hogg, F.L.S., for the Fruit Department.

Dr. Masters, F.R.S., for the Foreign division of the Floral Department.

T. Moore, Esq., F.L.S., for the Home division of the Floral Department.

These gentlemen have been accordingly deputed to carry out all the necessary arrangements, and to conduct all correspondence relating thereto.

2. Foreign Horticulturists may enter and exhibit novelties or any other objects of interest at any meetings of the Fruit or Floral Committee.

3. Such Foreign Horticulturists as may be accredited to represent their respective countries at the London Exhibition, or who may attend in the capacity of distinguished visitors, will be installed *pro tem.* as members of the Scientific Fruit or Floral Committee, and will be invited to join in their deliberations, conforming at the same time to the general regulations of the respective Committees, which require that members should retire while subjects in which they are personally interested are being adjudicated upon.

4. The Secretaries will form, *ex officio*, the nucleus of an International Jury for the adjudication of all Foreign novelties exhibited in this department; and in order that nothing of importance may be overlooked, or may fail to receive full consideration, they will at each meeting during the season (May to October) invite the assistance of such members (Home or Foreign) of the Fruit and Floral Committees respectively as may be known to be authorities on the merits of the particular classes of flowers or fruits to be exhibited.

5. The Permanent Exhibitions will be judged in the manner already indicated, so far as the conditions will admit. They will be examined at the first meeting in each month (May to October), and marks will be recorded at each examination in favour of the meritorious features of each competing exhibition, which marks will be summed up at the end of the season, and the rewards distributed accordingly. In addition to this, a medal may also be awarded to any exhibitor for any specially meritorious display noted during the season.

6. The awards made to novelties shown by Foreign exhibitors will consist of the usual certificates (First and Second-class) granted by the Society for similar subjects.

7. When Foreigners exhibit in the classes defined in the Society's Schedule, they must conform to the general regulations, but those who compete successfully may, if they desire it, on notification to the Secretary, obtain Medals instead of the Money Prizes.

8. The Prizes awarded for the Permanent Exhibitions, as well as those to foreigners for Special Exhibitions, *hors de concours*, such as (1) Groups of New Plants, Orchids, Palms, Apples, Pears, or any similar prominent subjects; (2) Miscellaneous or mixed Groups of Plants, Flowers, or Fruits; or (3) Remarkable Individual Specimens, will consist of Medals. Those who may desire to commute the Medals for Money or Articles of Value, must notify the same to the respective Secretaries before the close of the season.

9. In forwarding objects for exhibition (especially flowers or perishable fruits), when they are not accompanied by a person in charge, exhibitors are advised to take especial care to forward the bill of lading in due time to the Assistant-Secretary, James Richards, at the Society's Offices, South Kensington, as in default of the receipt of this document delay has already in some cases taken place in the delivery of perishable objects sent for exhibition.

10. In all other respects, and in so far as they apply, foreigners will be guided by the general regulations of the Society's Exhibitions, as printed in the Schedules. By Order of the Council,

Henry Y. D. Scott, C.B., Lieut.-Col. R.E.,
Secretary to the Royal Horticultural Society, and to Her Majesty's Commissioners of the Exhibition of 1851.]

The awards made on the respective days of meeting have been as follows:—

April 19th.

Silver Flora Medal to M. Van Houtte, Ghent, for a fine group of new Indian Azaleas.
First-class Certificates to the same for Azalea Comtesse de Beaufort.
Azalea President Ghellinck de Walle.
Azalea George Loddiges.
Azalea Alice.
Azalea Marquis of Lorne.
(The certificates awarded by Floral Committee.)

May 3rd.

Silver Floral Medal to M. Dallière, Ghent, for group of Palms and other plants.
Second-class Certificate to the same for Azalea La Reine.
(Awarded by Floral Committee.)

June 7th.

Silver Flora Medal to M. A. Dallière, Ghent, for a group of twelve Palms.
for pair of pyramidal Bays.
Bronze Medal to M. Linden, Brussels, for group of Japanese Acers.
First-class Certificate to the same for
Xanthosoma Lindeni.
Dracæna lutescens striata.
Acer palmatum crispum.
Acer palmatum roseo-dissectum.
To M. L. Jacob-Makoy & Co., Liege, for
Lycopodium dichotomum.
Lycopodium mandioccanum.
Lycopodium taxifolium.
Tillandsia Morreniana, subsequently published as T. staticeflora.
Second-class Certificate to M. Linden for Epidendrum paniculatum.

June 21st.

First-class Certificate to M. Linden for Verschaffeltia melanochætes.
Thrinax elegantissima.
Calamus sp. Menado.

July 5th.

Silver Flora Medal to M. Linden, Brussels, for
Collection of Orchids.
Collection of Dioscoreas (new).
Collection of Marantas (new).
To M. A. Dallière, Ghent, for Collection of finely grown Marantas.
Bronze Medal to M. A. Dallière, for Collection of greenhouse plants.
To M. Jos. Hermans, Herenthals, for cut Roses.
First-class Certificate to M. Linden for
Alloplectus vittatus.
Dioscorea chrysophylla.
Dioscorea prismatica.
Dioscorea Eldorado.
Dioscorea meleagris.
Dieffenbachia imperialis.
Maranta Mezellii.
Maranta Wallisii discolor.
Epidendrum Frederici-Gulielmi.
Second-class Certificate to the same for Aralia japonica aureo-reticulata.

July 19th.

Silver Flora Medal to Mr. Wendland, Herrenhausen, for Æchmea Mariæ Reginæ.
To M. Jean Verschaffelt, Ghent, for Group of twelve Agaves.
Twelve standard Orange trees.
First-class Certificate to M. Wendland for Æchmea Mariæ Reginæ.
To M. Jacob-Makoy & Co., Liege, for Tillandsia complanata.
To M. J. Verschaffelt, Ghent, for
Zamia sp. nov. New Caledonia.
Dicksonia sp. St. Catherine's.
Encephalartos Vroomii.
Agave sp. nov.
Agave Regelii macrodonta.
Agave Mescal fol. variegatis.
Agave elegantissima.

September 6th.

First-class Certificate to M. J. Verschaffelt for
Agave Celsiana albida.
Agave Toneliana.
Agave Mescal nigrispinis.
Agave dealbata compacta.
Second-class Certificate to the same for Agave dealbata compacta angustifolia.

The following foreigners of distinction have assisted in making these awards:—

Dr. Regel	M. Wolkenstein	M. Glover
Prof. Koch	M. Linden	M. Doucet
Prof. Morren		

And the services of the following members of the Floral Committee, in addition to the Secretaries, have been rendered:—

Mr. H. J. Veitch	Mr. J. Fraser	Mr. C. Pilcher
Mr. W. B. Kelloch	Mr. J. Standish	Mr. C. Penny
Mr. W. Bull	Mr. C. Green	Mr. F. P. Smith
Mr. C. Lee		

Thomas Moore, *Reporter*.

Pomological Report.

Although it was late in the season before it was decided upon to hold an International Fruit Show, the success which attended that which took place on the 4th of October exceeded the most sanguine

expectations. If a longer notice had been given, and more time afforded to have communicated with the fruit-growers of other countries, the exhibition would, no doubt, have been much more extensive than it was; but even with the short notice no less than upwards of 1500 dishes of fruit were exhibited. From almost all parts of the southern counties of England collections more or less meritorious were produced, and notably among these were upwards of one hundred varieties of Apples from Messrs. Lucombe, Pince, & Co., of Exeter; 130 varieties from the gardens of W. Egerton Hubbard, Esq., of Leonardslee, Horsham; 171 varieties from Mr. Wm. Paul, of Waltham Cross; and very considerable collections from the gardens of H. Allsop, Esq., Hindlip Hall, Worcester; Richard Webb, Esq., Culham House, Reading; Alfred Smee, Esq., F.R.S., Carshalton; J. H. Houblon, Esq., Hallingbury Place, Bishop Stortford; H.R.H. The Prince of Wales, at Sandringham; D. W. Digby, Esq., Sherborne Castle; Messrs. Rivers, of Sawbridgeworth; Messrs. J. & C. Lee, of Hammersmith; and many others whose collections were not so numerous.

In Pears the Exhibition was equally rich; the same exhibitors being found in this class of fruit as in the Apples, with the addition of very choice specimens from the gardens of Lord Eversley, at Heckfield; E. P. Shirley, Esq., Lower Eatington Park, Stratford-on-Avon; and William Thompson, Esq., Ilford.

The only foreign exhibitors were Messrs. Baltet, of Troyes, who contributed much towards the interest of the Exhibition, both in the quantity and quality of the Apples and Pears they exposed. Of Apples there were 150 varieties, and of Pears upwards of 300; and these were, without doubt, the finest contributions to the Show of that description of fruit.

In Grapes the Exhibition was such as never to have been equalled on any previous occasion. The collections of Messrs. Lane & Son, of Berkhampstead; of Mr. Meredith, of Garston; of the gardens of the Society at Chiswick, together with the minor exhibitions from the gardens of Lord Bagot, Blithefield, and other private gardens, combined to illustrate Grape-growing as practised in this country in a manner which cannot be surpassed, and is rarely equalled.

From the gardens of Lord Carrington, Wycombe Abbey, there came a Smooth-leaved Cayenne Pine, weighing 9¾ lbs., from a plant nineteen months old; and Mr. Terry, of Peterborough House, Fulham, sent three Queen Pines, weighing respectively 4 lbs. 6 ozs., 4 lbs. 11 ozs., and 5 lbs.; while from Earl Vane's garden at Wynyard Park there was a fine specimen of the same variety which weighed 5 lbs. 13 ozs.

The awards which were made on this occasion were:—

Class 1.—The most complete Collection of Apples, three Fruits of each Variety.—1st, William Paul, Paul's Nurseries, Waltham Cross, gold medal. 2nd, Messrs. Baltet Frères, Horticulteurs, Faubourg Croncels 14, Troyes, France, silver gilt medal. Extra, Mr. C. Chaff, Wallington, Carshalton, Surrey.

Class 2.—Collection of Dessert Apples, three Fruits of each Variety.—1st, Mr. C. Chaff, silver gilt medal. 2nd, Mr. R. Webb, Culham House, Calcot, Reading, large silver medal.

Class 3.—Collection of Culinary Apples, three Fruits of each Variety.—1st, Mr. S. Ford, gardener to W. E. Hubbard, Esq., Leonardslee, Horsham, Sussex, silver gilt medal. 2nd, Mr. C. Chaff, large silver medal.

Class 4.—The most Complete Collection of Pears, three Fruits of each Variety.—1st, Messrs. Baltet Frères, Troyes, France, gold medal. 2nd, Mr. C. Chaff, silver gilt medal. Extra, Mr. E. Spivey, The Gardens, Hallingbury Place, Bishop Stortford, Essex.

Class 5.—Collection of Dessert Pears, three Fruits of each Variety.—1st, Messrs. Baltet Frères, Troyes, France, silver gilt medal. 2nd, Mr. A. Moffat, gardener to H. Allsop, Esq., Hindlip Hall, Worcester, large silver medal.

Class 6.—Collection of Kitchen Pears, three Fruits of each Variety.—1st, Messrs. Baltet Frères, Troyes, large silver medal. 2nd, Mr. W. Earley, The Gardens, Valentines, Ilford, Essex, bronze medal.

Class 7.—Collection of Grapes, two Bunches of each Variety.—1st, Messrs. H. Lane & Son, gold medal. 2nd, Mr. J. Meredith, silver gilt medal.

Class 8.—The Largest Bunch of Grapes.—1st, Mr. T. Bannerman, silver medal. 2nd, Mr. P. F. Le Sueur, bronze medal,

Class 9.—Collection of Oranges, Lemons, Citrons, Limes, &c.

Class 10.—Miscellaneous Fruit, not mentioned in either of the above. Extra Prizes.—Mr. W. G. Pragnell, Castle Gardens, Sherborne, Dorset, Collection of Fruit. Mr. W. Jones, gardener to Earl Vane, Wynyard Park, Co. Durham, one Queen Pine Apple. Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, Bucks, one Smooth Cayenne Pine. Mr. T. Jack, gardener to the Duke of Cleveland, Battle Abbey, Sussex, eight dishes of Peaches. Mr. A. Moffatt, three Melons.

Robert Hogg.

FRENCH DESCRIPTIONS OF ROSES.

I find that Mr. A. Kent has disputed the correctness of the translation which I have always given of the words "*belle tenue;*" and although I felt convinced that my version of it was correct and as likely to be so as Mr. Kent's, yet I thought it better to be on the safe side. I therefore wrote to my friend M. Guillot fils, of Lyons, to know what he meant by it. Here are his words—"*L'explication que nous donnons à nos Roses, au mot belle tenue, cela veux dire que le pédoncule est ferme, et que la fleur se tient drôite.*" I hope Mr. Kent will not be offended if I protest against endeavouring to retain the French expression "remontant" instead of Hybrid Perpetual. Granting that the latter is an unfortunate one, it is too late now to alter. "Fancy," as a good rosarian wrote to me, "saying to one's garden boy, 'Jack, water those remontants.'" Many abortive attempts have been made to alter existing names, but custom is too strong, and Hybrid Perpetual will remain to the end. —D., *Deal.*

BEST ROSES IN IRELAND.

I have read with interest the various notices of Roses in your Journal for the past season, and remarked with surprise the comparatively low position and small attention given to Fisher Holmes, which I can only account for by suitability, or the contrary, of the soil it is grown in. La France, Marie Baumann, Baroness Rothschild, and others have blown peculiarly well amongst a considerable lot of healthy and luxuriant plants here; but Fisher Holmes, for beauty of shape, colour, richness, and consistence of petals, has far exceeded all others, not only in my estimation, but in that of the best growers of this district. In fact, all admit it to be about the best Rose they know. The soil here is a warm sandy loam.—Samuel Riall, *Annerville, Clonmel.*

CUT FLOWERS IN WATER.

In an article, taken from the "Florist and Pomologist," in last week's Journal, Mr. Forsyth refers to the unpleasant smell from water in which cut flowers have stood for some time. Now this great objection to cut flowers so preserved in invalids' rooms may be obviated by putting a small teaspoonful of sulphate of iron (copperas) in every pint of water. The only effect this will have is a beneficial one on bloom and foliage. A few drops of Condy's disinfectant fluid, or a few grains of permanganate of potass, will answer the same purpose, used in the same manner.—Far West.

ICE STORING.

Sufficient ice in good clear condition was secured last week to last the whole season. It is seldom that we can collect ice clean enough for putting in water or wine, as we have only ponds of small size. Most of the country ice will not bear comparison with Wenham Lake, ice nor will it stand exposure so long, as the blocks are much smaller. For consolidating such things as butter in summer, ice is very advantageous, but neither vegetables, meat, nor fish can be long kept fresh by ice without deteriorating in flavour.

Most people now have ice-preservers. Some are made of wood inlaid with cork, and have a double top, with a tap at bottom to let off what water collects. I think nothing better than a double box or barrel, with an empty space of some 2 inches between the two vessels made air and water-tight. In such vessels ice will keep a long time, and be most useful for cooling wine and other things. In all cases where the ice is not pure enough to be used in lumps, it is a good plan to have a vessel of tin or zinc—I prefer the latter as being free from rusting—and place it near the centre of the tub with a small pipe passing from near the bottom through the tub, and furnished with a small tap outside for drawing off the iced water.

In storing the ice last week I did not pound it so much as is usually done, because I have often found that if there is just enough of well-broken ice to pack the larger pieces firmly, without leaving air-spaces between them, it keeps as well as when a double or treble pounding has been given. Collecting the ice clean is of more importance than extra pounding, as every bit of wood, mud, or litter acts as an air-holder.

For many years I have never used anything for covering the sides of the ice-well, or the surface of the ice when the house is nearly full. I object to straw, chiefly because as soon as it gets damp, vapour is given off, which tends to melt the ice. If we had to open the ice-house several times a-day instead of for large quantities two or three times a-week, then a dry straw covering on the surface often renewed—especially if there were a small air-pipe above the covering to allow any moist vapour to escape—would be an advantage.

Ice will keep all the better if placed together in good large quantities, say from fifty to a hundred loads or more, as a few loads will melt away sooner in proportion. We would have little faith in an ice-heap out of doors, however well protected, that did not contain from twenty to thirty loads. Whether in heaps out of doors or in a house, it will keep all the better if exposed to severe frost before being covered over or shut up. For a covering out of doors nothing is better than dry tree leaves put on at different times, so that they may not become damp, and heat. I remember a case of an ice-heap carefully

made that melted away from being covered over with oat straw to a depth of 18 inches. The straw had been imperfectly threshed, and mice and rats so hunted after the grain left, that the rains penetrating by the holes, made the covering damp, set it heating, and the ice soon disappeared. Even when heating does not take place, ice-stacks out of doors are liable to have rat-holes made in the covering, through which the warm air obtains rather too free an entrance. I believe that the heating of the covering is the chief reason why farmers who have tried ice-heaps for various purposes, have so often failed. The covering should be dry and put on twice or thrice instead of all at once. From 24 inches of dry straw or leaves ought to keep out any heat of our summers.

Not choosing the position either on a mound or a steep incline, so that no water can stand near the ice-heap, is another cause of failure. When once double walls and double roofs, with a space of confined air between them, come to be rightly valued as non-conductors of heat, it will be quite as common to see an ice-house above as below the general surface of the ground.—R. F.

PHŒNIX DACTYLIFERA—THE DATE PALM.

I wish to draw the particular attention of both amateurs and gardeners to the merits of this plant, as it is an excellent subject for decorative purposes, independently of the immense benefit which man derives from it.

The genus Phœnix is distributed over northern Africa and tropical Asia, although one or two species seem to have strayed from their original home, being found in south-eastern Africa. All the species have long pinnate foliage, the lower pinnæ in some of the species being reduced to mere stout spines. Some have tall and stout stems, whilst others are dwarf, and in some instances stemless. The plant under consideration belongs to the arborescent section, and although numerous varieties are distinguished by the Arabs, and each named after some peculiarity, in every case it is a tall handsome tree, attaining a height of from 50 to 80 feet, bearing an immense quantity of nutritious fruit, and yielding most of the articles of life necessary to the Arabs and their domestic animals.

Phœnix dactylifera—the Date Palm.

I have remarked that stating the height which Palms and various other tropical trees attain, often has the effect of deterring many from commencing their culture. This is because they imagine they cannot accommodate them, quite forgetting that under cultivation it frequently takes very many years before the plants reach their greatest altitude. And so it is in this case; when about three years old the Date Palm is an elegant plant for the dinner-table, and the remarks it excites among the guests upon its products and their application might conduce considerably to the entertainment of a number of intelligent persons. Then for an amateur who desires a good window plant, here is Phœnix dactylifera, which will grow and thrive in a sitting-room, and will always have a cheerful effect. As it increases in size our fair readers may wish to have it removed for something smaller, but it by no means follows that the plant must be discarded. It will form a magnificent ornament for the hall or the landing upon the top of the staircase during the winter months, and in summer it may be planted, or rather plunged, out of doors in the garden, either as a single specimen on the lawn, or as the centre of a group of broad-foliaged plants, in which positions it will be at home, and very much enhance the tropical appearance of the summer garden. I must, nevertheless, not ignore its beauties as an in-door plant, for if grown in a stove it affords a pleasing contrast to other subjects—those having gay flowers, or those whose chief attraction is the ornamental character of their leaves—and when well grown it is a telling plant either in a collection of Palms or a mixed collection of stove and greenhouse plants.

Much more could be said respecting this most interesting Palm, but I must conclude this brief summary with a few remarks upon its cultivation, and this to anyone having a little acquaintance with plants will be found of the simplest character. The soil I prefer for potting is half loam and peat, with a liberal allowance of sand, and if a little fine cocoa-nut fibre refuse can be added it will materially encourage the roots. Soil such as that described, good drainage, plenty of water, and stove heat, are the leading features of the system I adopt with Date Palms until they are about three years old, at which time they should have assumed their normal state, and be neat little plants, with several of their distinct-looking pinnate leaves fully developed. Some may then be gradually inured to the temperature of the greenhouse, and when this is effected they may be used for window decoration, or any other purpose, in a low temperature, as the taste of the owner may dictate. The others, if required for stove decoration, or if it is essential that they should be grown quickly, may be kept in the hothouse, supplied with an abundance of water, and repotted from time to time as may be necessary.

I have found that as the plants increase in size it is beneficial

to decrease the quantity of peat, and substitute loam for it. For old plants about one part of peat mixed with three of loam forms a very good and nutritious compost, in which not only the subject of the present paper, Phœnix dactylifera, but the other species of the genus in cultivation, will be found to flourish.—Experto Crede.

A GOOSEBERRY DISEASE.

Æcidium (Persoon), a genus of plants belonging to the natural family of Fungi, or the Mushroom tribe, and to the class Cryptogamia of Linnæus. This Fungus consists of small membranous sacs or protuberances, which are found parasitic on the leaves, bark, fruit, &c., of several plants; such as the Fir, Violet, Berberry, Hawthorn, Primrose, Nettle, &c. The membrane forming the sac has received the name of peridium. It pierces the bark or epidermis of the leaves, and encloses very minute dust-like seeds or sporules, which are ultimately discharged by an opening in its side or summit. In consequence of the seeds being contained in a membrane, the genus has been referred to a division of Fungi that has been denominated Angiocarpi. There are upwards of thirty known species of the genus, and they receive their names from the plants on which they are found. Link has divided this genus into three sub-genera, the Æcidium properly so called, the Rœstelia, and Peridermium. The Æ. cancellatum here represented belongs to the second of those divisions. It is often found on the leaves of Pear trees. To the third division belongs the Æ. pini, remarkable for being the largest species, and for growing not upon the leaves but upon the bark of the Pine tree. They vary in colour. The species that grow on the Gooseberry and Berberry leaves are red; that found on the Scotch Fir is yellow, and that on the Meadow Rue bright orange. The Æcidia cause considerable deformities in the plants on which they grow, and some of them are decidedly injurious and poisonous. The Gooseberry Æcidium is said frequently to destroy the young fruit of that plant, which we are quite satisfied to believe; the species found on the Berberry has been stated, though perhaps erroneously, to be hurtful to corn growing near it; but as some of our horticultural friends may be desirous to know how to subdue this pest, and eradicate it from their Gooseberry plantations, I will give my experience on this point, and how I have gained a perfect cure. In 1868 and 1869, about one-third of the fruit here (Mouswald Gardens, Dumfries, seat of Sir James J. Reid) become blotched very much by this fungus. I give the ground amongst the bushes a liberal dressing with lime in the autumn, and syringed them over with a compound of alum 1 drachm, tobacco essence 2 ditto, flowers of sulphur ½ oz., common salt ¾ oz., all mixed in 3 gallons of rain water; this was done twice before the expanding of the leaf, and again as soon as the fruit appeared fairly set. This first destroyed the mycelium in the soil, and the syringing cleared the bark of its sporules; and my Gooseberry bushes are now free from all trace of fungus. — John Graham (in *The Gardener*).

Æcidium cancellatum,—*a*, a berry upon which it is seen growing in its natural size; *b*, leaf cut showing the part where the peridia are magnified; *c*, a full-sized leaf affected as the berry, appearing like a drop of red paint at a distance.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The Celery ground will answer well for a new plantation of *Asparagus;* the soil should be ridged-up to mellow as the Celery roots are taken up. The best policy with *Lettuces* for the supply next spring, is to allow them to freeze tolerably firm before covering them up. A very light screen of straw should be shaken over them at first, and when this is frozen add a little more, the object being to keep them frozen as long as possible. Above all, do not uncover them when a thaw arrives, but let them remain until completely thawed. These remarks will bear equally on all other tender vegetables. The tool-house should always be in good order, and the tools clean and in good repair. Those with long handles should be hung upon the highest hooks or pegs, the others at convenient distances, finishing with the water-pots and other small-handled tools on the lowest hooks. Every tool or utensil should have its place and be put away clean when done with.

FRUIT GARDEN.

It may appear somewhat early to offer advice with regard to preparations for spring, but such is the pressure then that anything which can be done now to forward work should not be deferred. If it can be avoided let no alterations, planting, &c., interfere with the ordinary work at that busy season. All the pruning, excepting of Figs and Apricots, and most of the nailing of wall trees, as well as the training of espaliers, should be finished if possible by New Year's-day, and the same may be said of bush fruit. Making borders or stations for fruit trees should be autumn work; indeed, where new soil is to be introduced, September or October is the most fitting time, as the best of soils may be seriously injured by moving them in a wet state.

FLOWER GARDEN.

In favourable weather transplanting shrubs, trees, &c., should be carried on. See that all the principal and choice plants in this department have sufficient scope to develope their true character. There are few situations in a garden more interesting than a well-arranged shrubbery, where every plant from the largest to the smallest had sufficient room to form a perfect specimen. Collections of shrubbery plants appear to be much less attended to than their true merits entitle them to. Little can be done now except by way of preparation. Should the present frosty weather continue it will afford an opportunity of having all the compost heaps thoroughly frozen. By repeatedly taking off the encrusted surface and piling it up every morning, many of the insects and their eggs will be destroyed. It will also be a good time to cut turf sods, peat, &c., and to lay in a

good stock of soils most essential for the growth of various plants and flowers. If leaden pegs are used for layering Carnations (and these we should always recommend in preference to Bracken or Fern), a fresh stock may be prepared and the old ones cleaned and straightened. If the florist can mend his own hand-lights and shades, this ought now to be done, and the metallic wire which has been used for attaching the stems of Carnations or Tulips to their supports, should be made ready for use and stored away in its place till the returning season renders it necessary. Rabbits during severe weather will be apt to attack Carnations and Pinks; it would be worth while to try the plan of dipping small square pieces of cloth into brimstone, tying them to sticks, and inserting the sticks in the ground round the beds.

GREENHOUSE AND CONSERVATORY.

Camellias now swelling their flower buds will require a liberal supply of water. When they are planted out in the open border of a conservatory, regard should be paid to their state of moisture. If any signs of overdryness be apparent, get the soil forked-up as deeply as the situation of the roots will permit, and give them a good soaking of soft or rain water. Two or three of such applications at short intervals will do no harm, provided the flower buds are fast swelling. The same kind of treatment may be given to many plants in similar circumstances. In the greenhouse a free admission of air at all times, if the weather is favourable, will be advantageous, at the same time care should be taken to prevent as much as possible strong currents of dry cold winds from passing through the house, as they are invariably injurious to vegetation. A few of the earliest and strongest Calceolarias, Cinerarias, and Geraniums used for forcing may now have their final shift, giving either 6 or 8-inch pots according to the size of the plants. After potting, let the shoots of the Geraniums be carefully pegged down as near as possible to the rim of the pot without breaking. They will require to be sparingly watered for a time, and placed as near the glass as possible. The general collection of Geraniums should now be stopped-back for the last time, unless required to flower very late in the season. Azaleas which set their buds early, will soon come into flower if placed in a warm, moist temperature, and some of the early-blooming Rhododendrons require very little forcing to bring them into bloom at any time after this season. When, therefore, there is a good stock of these, and of Ghent and other hardy Azaleas well set for bloom, a portion of the plants should be placed in heat at intervals of about three weeks, and as they are very showy and last long in bloom, they will be invaluable. Winter-blooming plants in borders, such as Acacias and Luculias, must be well supplied with water at the roots, but plants which are a trest, especially deciduous plants, and such as are scarcely hardy in the temperature of the conservatory, cannot be kept too dry at the roots just now. Remove decaying leaves daily, and re-arrange the plants in bloom frequently.

COLD FRAMES.

These afford the best accommodation for the culture of all greenhouse plants in summer, but unless furnished with pipes, so that a little heat may be had to dry the atmosphere occasionally, and also to exclude frost, they are not fit quarters for many plants in winter. Plants which are impatient of damp will not bear being covered and shut up in severe weather, as must be done to exclude frost; and although, in mild winters, most greenhouse plants may with care be wintered in cold frames, still such plants as Boronias, Leschenaultias, Gompholobiums, &c., should be removed to safer quarters at once. Water cautiously, keeping rather on the dry side, but not to excess.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

LITTLE has been done except wheeling-out manure, and laying it down in lines. A good rubbish-heap supplies valuable manure, and should contain a large amount of litter and short grass to make it heat well, with earth to absorb the fertilising gases. A little salt is a good addition, and a little lime accelerates decomposition. It is always advisable to have several rubbish-heaps, and to cover the oldest one with soil; then leave it for some time before using it. We are careful of placing in it any plants or seeds which are likely to resist the influence of the heat and disseminate themselves as noxious weeds. Thus managed a good rubbish-heap is much better than manure taken from an open exposed yard.

Protection.—As regards protection, where there was no heat to cause growth, we did not uncover even in the coldest, dullest days. In some cases where litter was scarce, we broke the surface with a light fork night and morning to prevent radiation. When there was the likelihood of sunlight, frames with a little heat below them were partly uncovered, and a little air given at the top to dissipate condensed moisture. Protected hardy plants where there is no artificial heat, should not be exposed to the sun when the temperature is from 6° to 10° below the freezing point on the north side of a wall.

Cleaning Glass.—At no time when the weather is favourable is clean glass more important than now. If the water is heated a little the cleansing will be done all the more easily, using cloths and brushes. If anything interrupts it is well to wash the inside of the glass in preference to the outside, which can be cleaned down without taking off the sashes. Great care should also be taken not to break any glass now, and also to keep it clean, as much of the success of early crops depends on the transparency of the glass.

FRUIT GARDEN.

Preparations may be made for all kinds of planting where the ground is not too hard, but planting itself cannot be safely ventured upon in such frosty weather. Thinning and pruning may be freely proceeded with, but if any large branches are cut off it is well to daub the cut parts with clay or paint to keep out the wet and prevent decay. Dwarf trees may also be mulched to keep the roots near the surface, and root-pruning and replanting will thus be rendered almost unnecessary.

ORNAMENTAL DEPARTMENT.

Looked over and tied Azaleas and other plants. We do not like to see plants with more sticks than are absolutely necessary, and with a little looping and a ring of wire at the base, it is seldom that more than one stick is required. The right way is to conceal as much of the supports as you possibly can. Many plants in pits ought to be in houses, but we prefer that those which are in the pits should become somewhat dry instead of being exposed much to the air in such weather. Poinsettias and Euphorbias are in their glory, and Camellias opening well. Scarlet Geraniums, doubles and singles, have as yet yielded a fine mass of flowers. To have them at all good in the dark months, whether the plants are in 4, 6, or 10-inch pots, they should not be allowed to bloom much in summer and early autumn. Brought in plenty of soil for potting, so that it might become mellow, as much of the future health of plants and their freedom from insects will depend on the warmth of the soil used for potting. When the frost goes, the harvesting heaps of good soil might be proceeded with. We find that by building in narrow stacks we can always have the soil dry, when it is an easy matter to damp it if too dry. If there is a deficiency of good fibrous soil, it is a good plan to char turf at once on an iron plate or over a fire, and then expose it to sweeten well before using.

We would again remind our readers that it is better to cover a little, or even to let houses and pits get 5° to 10° lower in temperature in this severe weather, than give too much fire heat. Of course the plants must be kept safe, and except in the case of those blooming or swelling their buds, a comparative state of rest will be best, and if they are closer than usual, should be kept cooler. We are often surprised to see so large an amount of air admitted in cold weather, as we believe that less air and less artificial heat would be better for the plants, and they would be more able to endure and benefit by a bright sun. Looked over Achimenes, Gesneras, Gloxinias, Caladiums, &c., laid down in a dormant state. Now is a good time to place hardy shrubs, Roses, &c., in a gentle bottom heat, beginning with but little top heat.—R. F.

TRADE CATALOGUES RECEIVED.

Joseph Schwartz (late J. B. Guillot père), Rue du Repos 43, à la Guillotière, Lyon.—*Catalogue of Roses*, 1871-2.

Martin & Son, Cottingham, and 7, Market Place, Hull.—*Catalogue of Forest, Fruit, and Ornamental Trees, Shrubs, &c.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

ROSES ON THEIR OWN ROOTS (*E. T. H.*).—Roses on their own roots require great care for three years till their roots are strong. You will see select lists of thirty-six Roses in last and this week's Journal. From those lists you can select with safety. The easiest way to obtain Roses on their own roots is to buy them on the Manetti stock and cover the

point of union 2 or 3 inches with soil. They will require to be mulched in winter and summer to defend the young rootlets. In addition to those in my list, if you need more you may buy of *Tea Roses*—Adam, Souvenir d'un Ami, Madame Margottin, Adrienne Christophle, Madame Trifle, Marie Sisley, Madame Hippolyte Jamain, and Sombreuil. *Hybrid Perpetuals*—Souvenir de Dr. Jamain, John Keynes, Fisher Holmes, Madame Clémence Joigneaux, Baronne Prevost, Comte de Nanteuil, Duke of Wellington, Baroness Rothschild, Gloire de Vitry, Baron Adolphe de Rothschild, Madame Charles Verdier, Madame Charles Wood, Madame Knerr, Madame Jacquier, Comtesse d'Oxford, and Dupuy Jamain. *Bourbons*—Acidalie, Baron Gonella, Sir J. Paxton. The thirty-six named, and these, are all good growers and free bloomers.—W. F. Radclyffe.

Diseased Horse Chestnut (*W. Hartnup*).—The only remedy we can suggest for your tree is to scrape off all diseased bark and coat the injured parts with a mixture of slacked lime and soot of the consistency of thick paint. A mixture of tar and train oil has been recommended to destroy the larvæ of insects in forest trees. We would use Stockholm tar, as gas tar is injurious if not fatal to plant life.

Small Fruits for Wet Ground (*An Old Subscriber*).—Black Currants and Raspberries are the most suitable fruits for such ground. Celery would be the best vegetable.

Propagating Vines (*St. Asaph*).—If you have a glass frame and can make a hotbed of leaves and stable manure so as to obtain a gentle bottom heat, that would be the best place to start your Vine eyes. If you have not a frame you should raise them in the greenhouse; better plants are obtained from single eyes than from cuttings.

Syringing Azaleas (*Julia*).—At this season, or from the time the buds are set until after flowering, it is not desirable to syringe Azaleas, though syringing may occasionally be practised to free the leaves from dust. The plants should be supplied with water when the soil is dry, before the foliage becomes limp, and then enough should be given to show itself at the drainage.

Old Garden-wall Pointing (*G. R.*).—The best thing you could do would be to have all the loose old mortar picked out, and to repoint, filling up the face of the bricks, where broken, with Portland cement. Damp the brickwork or joints before pointing, which must be done in mild weather. Two parts of sand, one of lime, and one of Portland cement make a very good pointing material. The lime and sand should be made into mortar in the usual way, and the cement added and wrought up as required for use. To preserve the wall from destruction by nailing after the pointing, it would be well to have it wired, so as to dispense with nails and shreds.

Cosmos bipinnatus atro-purpureus not Flowering (*M. E.*).—The cause is probably the dull, wet, cold summer, and yet we do not remember seeing these plants in better foliage. Your treatment was quite right. The seeds require to be sown, and the seedlings forwarded, in gentle heat, and planted out in summer.

Pegging-down Gorse (*J. N. P., of York*).—The clump of Gorse having grown very tall and straggling you may peg down the shoots, layering them in the soil, and they will root if not very old. If they are old, and there is any difficulty in layering them, we should cut the plant down to within 6 inches of the ground, and it will push again strongly from the root. This is the way we treat ours, raised from seed and young shoots, and we have a fine dense mass in a year or two. The best time to cut Gorse is just after cold weather in March and up to April. Have you tried the double-flowered Gorse planted out from pots? We plant out ours at from 3 to 4 feet apart, and they meet in about three years; rabbits do not touch them. We plant in February or March.

Poinsettia pulcherrima Bracts Imperfect (*A Limerick Gardener*).—We presume they are twisted and curled—very often a result of bringing the plants forward too rapidly, and not affording sufficient air, with a light position, a moderate degree of moisture, and a temperature of 50° to 55° at night. If you have a little patience we think your plants will do better than you anticipate.

Cottage Gardeners' Society Rules (*T. T.*).—If you enclose four postage stamps with your address, and order No. 538 of this Journal to be sent, you will find a detail of rules, &c. A small stove with a funnel would warm your aviary.

Morris's Nonpareil Russet.—"W. K." wishes to know where he can procure trees of this Apple.

The Best Roses (*G. S., Rosarian, &c.*).—Several correspondents have written to inquire what is implied by the descriptive word "best," and we can perceive no difficulty in explaining it. The desirable qualities in a Rose are vigorous growth, free and successive production of flowers in the plant; fine form, size, fragrance, colour, and strength of petal in the flowers. Those Roses which possess all or the most of these qualities in the highest degree are "the best." Mr. Peach's list combining the testimony of many rosarians in widely-separated localities is by much the most reliable, for flowers commended by all these rosarians may most justly be expected to succeed in the garden of an intending purchaser. A great mistake is made by an amateur who concludes because a Rose is excellent in his garden that it will be equally excellent everywhere. We have seen Julee Margottin in Devonshire unsurpassable by any variety, and in a lighter soil in the east of England we have known it a miserable object which no culture would invigorate.

Seedling Geranium (*J. H. B.*).—Your seedling having the foliage of Golden Chain and double crimson-scarlet flowers is worth preserving and testing. We know of none like it.

Covering an Outside Vine Border (*J. Booth*).—As a rule we do not approve of covering outside Vine borders with glass; but in your case, if you had moveable lights to take off in summer, the enclosed space, if heated, would be useful for wintering bedding plants. More attention will be necessary in watering the Vines. Your Grapes are affected by mildew; this ought to be destroyed at an early stage of its development by painting the hot-water pipes or flue with flowers of sulphur, brought with water to the consistency of paint, taking care not to overheat the flue or pipes. When the disease has made much progress dust the bunches with sulphur, but we think then the cure is as bad as the disease.

Pruning Fruit Trees—Planting Asparagus, &c. (*A constant Reader*).—Your trained fruit trees newly planted should be pruned in spring as soon as the buds begin to move. Cut the young shoots back to two-thirds of their length; any weakly trees may be pruned-in closer. For a north-east aspect Morello Cherries would be the best, and only the hardy sorts of Pears and Plums. The beginning of April, generally speaking, is the best time to plant Asparagus, Sea-kale, and Globe Artichokes. They require light rich soil, well trenched, and thoroughly drained. Asparagus requires a large quantity of stable manure; as much ought to be trenched in as would cover the ground to the depth of 9 inches. If the ground will admit of it, trench it 3 feet deep, placing a good layer of manure at the bottom of the trench. Lay the ground out in 4-feet beds, with 2-feet alleys between. Plant in April one-year-old plants, at a distance of 18 inches from plant to plant. For Sea-kale the soil ought to be light and rich, but it does not require so much manure as Asparagus, nor does the ground require to be so deeply trenched. Plant in rows 20 inches apart, and 12 inches between the plants March is a good month to plant in; one-year-old plants are the best. Globe Artichokes are propagated by suckers, taken off with a portion of roots attached. Plant them 3 feet between the rows, and 2 feet apart in the rows. They are rather tender, and some rough litter should be placed round them as a protection in winter.

Saddle Boiler's Heating Power (*W. M.*).—The boiler 20 inches long, 16 wide, and 14 deep, would heat from 150 to 200 feet of 4-inch piping, but we would never heat pipes to near the boiling point. You had better have mere piping, and never keep the pipes above 170°. The proposed boiler will do all you require, if well set and well managed.

Stove for Orangery (*R. D. Long*).—We have used open charcoal stoves in emergencies, but always to the injury of everything at all tender. Why not have an iron or brick stove, shut up in the usual manner, with a pipe to take off the fumes, and then you may burn charcoal, coke, or cinders with safety?

Heating Pits (*Camjee*).—Much has been said in recent numbers, and also in the present on the subject. If we knew exactly what you wanted it for, we could advise better. In a small pit, a stove fed from the outside would keep out frost, and be cheaper than a flue. It will be an advantage if you can take the flue into the chimney of the greenhouse. All books with coloured plates are costly.

Boiler for 2000 Feet of Piping (*A. B.*).—As you find a saddle-back boiler answer so well, we would take that as a hint, and for the 2000 feet of piping have one of wrought iron 5 feet long. If you want much more piping heated the boiler should be larger. If you do not want all the 2000 feet well heated at once, then a 4 or a 4½-feet boiler might be sufficient—we should say 5 feet. Smaller boilers, up to 3 feet in length, we prefer to be of cast iron; when about 5 feet long we prefer wrought iron.

Pit and Flue (*B., Knowle*).—If you want your pit for propagating, the arrangement with sand over the flue would be best, with the side of the flue next the pathway. If for strong plants, the other would be best, without ashes between the flues. For such a narrow house—7 feet wide—for growing plants, we should have a pathway in the middle, a platform on each side, and a 6-inch-wide flue beneath the centre of the pathway. That would be quite sufficient to keep out frost. We are saying this in the belief that you can walk through your pit. If not, then the arrangement of a flue round close to the sides, with a floor all over them, would be better. If so, a flue 5 inches wide, inside measure, would enable you to keep up what heat you wanted. Merely to keep out frost, a flue 5 inches wide inside, once through the house, would be sufficient, but it is always well to have the command of heat, whether it be wanted often or not. For general purposes, the larger and wider the flue the less will it require to be heated. A flue retains heat so long, that, except in severe continuous frosts, a constant fire will not be required.

Heating a Boiler by an Oven (*Amateur*).—If you have a boiler in your kitchen range you could heat your house better from that than from your oven. We presume you made the hole in the oven close to the top; if not, it should be as near the top as possible, and a 2-inch pipe would not be too large. Even that would not do well, unless you had another hole and pipe entering close to the bottom of the oven; and whilst the upper pipe was turned upwards at the point, the lower one should be turned downwards. We should then expect a free circulation of air from the oven, the cold air of the house going in at the bottom of the oven, and the hot air going out at the top. That air will be dry. In similar cases we have seen every purpose answered by taking out part of the wall opposite the kitchen range, and fixing an iron plate 30 inches or so square. In all such cases the heat will be dry. When heat is wanted in the oven and not in the house, plug up the pipes on the greenhouse side. Let us know the result.

Utilising Sashes (*Subscriber*).—To make a small house of your sashes you will require a plate for the back and front wall; the back wall 7½ feet in height, and the front one 3 feet; a narrow walk at back, and a platform in front. We would, under the circumstances, plant the Vines against the back wall and train downwards. When once the Vines reach to the roof you could have four or five shelves against the back wall in winter. The rafters should be 3½ inches by 2 inches to support the sashes. We would have ventilators in the front and back wall. A small flue along the front would keep all secure. We would have no front sashes, but if you raised the walls higher they would be necessary: in that case the house also should be wider to be at all economical.

Newtown Pippin (*South Wales*).—You can obtain a tree of this variety of Apple from any of the large nurserymen who advertise in our columns.

Ferns not Growing (*A Lover of Ferns*).—We are surprised you cannot make these plants flourish in a stove heated with hot water. Of course your plants are in pots, though you do not say so. The compost should be three parts fibrous peat full of fine white sand, one part light turfy loam, one part sandstone broken up rather small, and half a part of silver sand, the peat and loam broken up small, and the whole well mixed. The pots must be well drained. If the Ferns are growing in soil of this description they will not require to be repotted till the beginning of March; at that time remove from the roots any compost that comes away freely, and place them in pots of sufficient size to admit the fingers all round. Pot rather firmly, keep the soil in a healthy state of moisture, giving a good supply of water when it is required. Sprinkle the floors, walls, and other surfaces with water morning and evening, and in very hot weather the plants may be lightly sprinkled overhead morning and evening, except Gymnogrammas, Nothochlænas, and Cheilanthes. Maintain a temperature of 60° to 65° at night from April to October, and 55° to 60° from October to April, allowing a rise in summer to 75° and 80°, and to 65° or 70° in winter. Shade from sun from March to October.

ANTHURIUM SCHERZERIANUM CULTURE (*S. T.*).—It should be grown in the warmest part of the stove. Use for it a compost of two parts fibrous peat, one part fibrous loam, half a part lump charcoal, and a like quantity of silver sand, just potting so as to cover the roots, and surfacing with sphagnum. The plant requires moisture both at the roots and in the atmosphere.

LILIUM GIGANTEUM CULTURE (*Idem*).—We presume you grow it in pots in a greenhouse or conservatory. It ought now to be kept rather dry and safe from frost. In February pot it and encourage it with plenty of moisture, shifting into larger pots in May. Continue to give water abundantly up to August, then place it out of doors in an open situation and keep it dry, returning it to the protection of a pit or house in winter, and keeping it moderately dry. It will flower when strong enough. It will thrive well in soil consisting of two parts fibrous loam and one part leaf soil or well-rotted manure, with a free admixture of sand.

LIQUID MANURE FOR AZALEAS (*George*).—Indian Azaleas may safely have liquid manure when they are swelling the buds. There is no better manure for this purpose than one pack of sheeps' droppings to thirty gallons of water. Stir well up before use, and apply the liquid at every alternate watering, taking care that it is at the same temperature as the air of the house. An ounce of guano to a gallon of water is also a good application; so is a peck of soot to twenty gallons of water.

CHRYSANTHEMUMS AFTER FLOWERING (*B. B.*).—We should cut away the old stems, place the plants in a cold frame, and insert cuttings from them singly in small pots. They will root well in the house in which the plants have flowered. Choose for cuttings the stiff shoots that come from the base and are 3 to 5 inches long. The old plants will afford a number of cuttings from now up to April, and when you have as many as you require you may turn out the plants into the open borders. The cuttings will form better plants than old plants retained for another year.

PRIMULAS WITH SHORT FLOWER-STEMS (*St. Honoré*).—Your fine plants with numerous trusses only need a temperature of 45°, and weak liquid manure once a-week, to make them all that could be desired. We have a practical illustration of this in about a hundred plants in 7-inch pots on the shelves of a Peach-house, where they have grown well and are covered with flowers, but these are lost in the foliage. In a greenhouse we have twice that number of plants, and they are far more effective from having much longer flower-stems, and the difference in temperature is only 5°.

OXALIS CULTURE (*E. H.*).—You do not say what varieties you cultivate, but we presume they are the ordinary greenhouse kinds, as O. Bowsi, floribunda, rubella, speciosa, &c. If so, place several bulbs in pots 6 or 7 inches in diameter, well drained, using two parts light turfy loam and one part leaf soil, with a free admixture of sharp sand. They require to be kept near the glass, and to have an abundant supply of water when growing, with slight shade from bright sun. The kinds rest at different times, and ought at those periods to be kept dry, but not dust-dry, therefore water occasionally. Repot when they begin to grow.

STOCKS FOR PYRAMID PLUMS (*Amateur*).—Plums are not successfully grafted, but are best budded—the general practice. The Brussels stock is most commonly used; but for your purpose the Mussel is preferable, especially for strong-growing kinds, as Golden Gage, Magnum Bonum, and Victoria.

PRUNING CUPRESSUS AND ARBOR VITÆ (*Idem*).—You may cut them in as much as you like, removing the strong growths in April. The upper part will need to be the most restrained, and there you should leave the weaker growths, as well as in other parts of the trees. They are kept in bounds as easily as the Yew, and form quite as handsome bushes. The pruning should be done with a knife.

PEACHES UNDER GLASS (*Idem*).—Three good sorts are Noblesse, Grosse Mignonne, and Malta. Barrington is also excellent. We presume they are to be planted out.

PICEA NOBILIS.—The cones shown before the Floral Committee on the 6th inst. by Mr. Freeman were from a tree 58 feet high, not fifty-eight years old.

NAMES OF FRUITS (*T. V.*).—1, Alfriston; 2, Scarlet Leadington; 3, Surrey Flat Cap; 4, Beauty of Kent; 5, Sir William Gibbons'; 6, Dutch Mignonne; 7 and 9, Dumelow's Seedling; 10, Ross Nonpareil.

NAMES OF PLANTS (*C.*).—Biota orientalis, also called Thuja orientalis. (*G. B.*).—1, Eupatorium glabratum; 2, Duranta Baumgartii. Its flowers are by no means attractive, and are, we believe, very rarely produced. Its foliage is its chief attraction. (*J. J. D.*).—1, Polystichum angulare, var. proliferum; 2, P. angulare, typical state; 3, P. aculeatum, in a young condition. (*E. S.*).—1. Pteris semipinnata; 2, Asplenium flabelliforme; 3, Polypodium vacciniifolium. The Fungus is a species of Clavaria.

POULTRY, BEE, AND PIGEON CHRONICLE.

CAMBRIDGE POULTRY SHOW.

IN spite of the great number of long-established poultry shows now taking place almost daily, the Cambridge Poultry Exhibition, though a first attempt, proved a most successful one. More than seven hundred pens were entered, chiefly from the most renowned of our poultry yards.

Game were so good throughout, that they appeared to excite more public interest than any other division of the Show. A remarkably fine pen of Brown Reds were the cup-winners, very closely pressed, however, by another pen of the same colour, exhibited by Mr. J. Fletcher, of Manchester. By some neglect in the entries, Mr. Mathews's birds were entirely thrown out of competition. In both *Cochins* and *Dorkings* the chicken classes were very far preferable to the adults, most of the old birds having as yet scarcely recovered from their moult. *Brahmas* throughout formed a strong feature of the Show, the dark-feathered, as a whole, being the most praiseworthy of the two breeds; nevertheless, in an open class for Brahma chickens of any colour, and with a very good entry, a really good pen of Light ones were the winners. As generally of late, the entry of *Spanish* fowls was very limited, but all the winning pens of this breed were much better than those exhibited at even the largest of our recent shows. The Game *Bantams* were not only of great merit, but there was an unusually large entry. In the Selling classes were to be found many pens of unexceptionable quality, and as the Show was well attended by a large number of anxious purchasers, a very fair proportion of the pens in each of the Selling classes changed hands.

We never remember seeing so many pens of Carrier *Pigeons* all in such high condition at any show, and among so many and all good, great must have been the difficulty of judging. Almonds and Ponters were also very fine, and the Dragoons and Antwerps well deserve our favourable mention.

DORKINGS.—1, R. Wood, Clapton, Thrapstone. 2, Mrs. G. Clarke, Sutton Marsh, Long Sutton. 3, Henry Lingwood, Barking, Needham Market. *Chickens.*—1, F. Parlett, Great Baddow. 2, Rev. E. Bartrum, Great Berkhampstead. 3, R. Wood. *hc*, A. Darby, Bridgnorth; J. Watts, King's Heath, Birmingham.

COCHIN-CHINA (Cinnamon or Buff).—1 and Cup, H. Lloyd, jun., Handsworth. 2, Henry Lingwood. 3, J. K. Fowler, Aylesbury. *c*, E. R. Gray, Kensington.

COCHIN-CHINA (Any other variety).—1, C. Howard, Peckham. 2, H. Lloyd. 3, P. H. Jones, Fulham. *hc*, Horace Lingwood, Creeting, Needham Market; J. K. Fowler. *c*, Rev. C. H. Lucas, Edith Weston, Stamford.

COCHIN-CHINA (Any colour).—*Chickens.*—1, J. Long, Plymouth. 2, Horace Lingwood. 3, Henry Lingwood. *hc*, H. Lloyd, jun. *c*, A. Cole, Colchester; J. K. Fowler.

BRAHMA POOTRA (Light).—1, H. Dowsett, Pleshey, Chelmsford. 2, M. Leno, Markvate Street. 3, J. Long. *hc*, J. Moore, Rothwell, Northampton.

BRAHMA POOTRA (Dark).—1 and Cup, T. F. Ansdell, Cowley Mount, St. Helen's. 2, W. Adams, St. Clement's, Ipswich. 3, J. Watts. *hc*, T. Norfolk, Bury St. Edmunds; W. Stevens, Northampton; J. H. Cuff, Holloway; Horace Lingwood. *c*, W. Cutlack, jun., Littleport; F. R. Coales, Longstanton.

BRAHMA POOTRA (Any variety).—*Chickens.*—1, P. Haines, Palgrave, Diss. 2, Dr. Holmes, Whitecotes, Chesterfield. 3, J. Watts. *hc*, Rev. J. D. Peake, Laleham; J. Bloodworth, Cheltenham; B. S. Lowndes. *c*, T. F. Upsher, Sutton, Isle of Ely.

GAME (Black or Brown Red).—1 and Cup, A. Fludyer, Uppingham. 2, J. Fletcher, Stonecliough, Manchester. 3, W. Boyes, Beverley. *hc*, J. Fletcher; A. C. Swain, Buckingham; R. Postle, Gazeley, Newmarket. *c*, H. E. Martin, Sculthorpe, Fakenham; S. Matthew, Stowmarket; R. Hall, Cambridge.

GAME (Any other variety).—1 and 3, R. Hall. 2, E. Winwood, Worcester. *hc*, J. Fletcher; W. Bullen, Cambridge (2).

GAME (Any colour).—*Chickens.*—1, H. E. Martin. 2 and *hc*, J. Fletcher. 3, R. Hall. *c*, Hon. Mrs. Paget, Hoxne, Scole.

HAMBURGHS (Gold-spangled).—1 and 2, L. Wren, Lowestoft. 3, S. & R. Ashton, Mottram. *hc*, C. Plimley, Wolverhampton; T. Love, Kingsthorpe. *c*, W. K. Tickner, Ipswich; J. Watts; T. Walker, jun., Denton, Manchester.

HAMBURGHS (Silver-spangled).—1 and Cup, Ashton & Booth, Broadbottom, Mottram. 2 and *hc*, J. B. Bly, Lowestoft. 3, A. Ainslie.

HAMBURGHS (Gold-pencilled).—1, W. K. Tickner. 2, R. R. Parker, Ipswich. 3, J. Walker, Birstwith. *hc*, A. Cole, Long Sutton; C. W. Gibbs, Sutton Bridge.

HAMBURGHS (Silver-pencilled).—1, J. Walker. 2, N. H. Scott, Northampton. 3, W. Mansfield, Cambridge.

SPANISH.—1, Nichols Bros., Camberwell. 2, H. Brown, Putney Heath. 3, H. F. Cooper. *hc*, Burch & Boulter, Sheffield. *c*, W. R. Bull, Newport Pagnell.

FRENCH.—1, J. J. Malden, Biggleswade. 2, W. Dring, Faversham. 3, J. K. Fowler. *hc*, J. S. Price, Potter's Bar; E. Pritchard, Tettenhall; Mrs. J. Cross, Appleby Vicarage, Brigg; C. H. Smith, Radcliffe-on-Trent; W. O. Quibel, Newark. *c*, W. Burrows, Diss; W. Cutlack, Littleport.

ANY OTHER VARIETY EXCEPT BANTAMS.—1, W. K. Patrick, West Winch, Lynn. 2, R. Wilkinson, Guildford. 3, T. Walker. *hc*, Miss E. J. N. Hawker, Tunbridge Wells; G. Boothby, Louth; Miss Mill, Rickmansworth; P. H. Jones.

GAME BANTAMS (Black or Brown Red).—1, W. B. Jeffries, Ipswich. 2, Hon. Mrs. Paget. 3, T. Sharples, Forest Bank, Rawtenstall. *hc*, C. H. Webb, Chelmsford (2); H. L. Cocksedge, Woolpit, Suffolk; T. Barker, Burnley; W. B. Jeffries, Ipswich; Bellingham & Gill, Burnley; J. Eaton, Farnsfield. *c*, G. B. Francis; H. C. Hill.

GAME BANTAMS (Any other variety).—1, J. Eaton. 2, Bellingham & Gill. 3, T. Sharples. *hc*, Rev. F. Cooper, Ampney Crucis; T. Barker; Bellingham and Gill; A. Ainslie.

BANTAMS (Any other variety).—1 and Cup, B. S. Lowndes, Stony Stratford. 2, M. Leno. 3, C. Reed, Cambridge. *hc*, J. Bloodworth; C. Read (2); M. Leno B. S. Lowndes. *c*, C. Reed (2).

SELLING CLASS.—*Cock.*—1, W. K. Patrick. 2, Miss Mill. 3, F. A. Cole. *hc*, Rev. C. H. Lucas (2); H. Lloyd, jun.; C. Bayes, Kettering; W. King, jun., Cambridge; A. Darby, Bridgnorth; F. Parlett; A. C. Swain; C. Howard; P. H. Jones. *c*, Mrs. F. Stevens; H. L. Cocksedge; W. Mansfield, Cambridge; J. S. Price; W. Burrows; W. K. Patrick; H. P. Moore, Langley Lodge, Chippenham (2); Dr. Campbell, Brentwood; J. J. Maldeu; R. Hall (2); W. Burch; H. Dowsett; T. M. Derry, Gedney.

SELLING CLASS.—*Hens or Pullets.*—1, P. Passmore, Northampton. 2, H. Griss, Ipswich. 3, C. Bayes. *hc*, Rev. C. H. Lucas (2); W. K. Patrick; T. M. Derry; T. Boulter; H. Dowsett. *c*, J. Walker; Lord G. Manners; H. Lloyd, jun.; W. King, jun.; W. Mansfield; R. Hall; A. H. Moyes (2); T. Love, Kingsthorpe; J. F. Loversidge, Newark; J. B. Lakeman, Ipswich; O. W. Hoare, Woolaton, Southampton; Rev. F. Tearle (2); C. Howard; Nichols Bros.

DUCKS.—1 and 2, J. K. Fowler. 3, Rev. J. Richardson, Sandy Rectory. *hc*, T. F. Upsher; W. Burrows; J. King, jun. (2); U. Marshall, Cambridge; H. Dowsett; Miss Mill; C. Thurnall, Whittlesford (2). *c*, W. H. Baker (2); W. King.

PIGEONS.

CARRIERS.—*Cock.*—1 and Cup, E. Walker. 2, W. Massey. 3, H. M. Maynard, Holmewood, Ryde. *hc*, F. W. Metcalfe, Cambridge; W. Woolley. *c*, L. Wren; C. Minson.

CARRIERS.—*Hen.*—1, Cup, and 3, F. W. Metcalfe. 2, E. Walker. *hc*, J. Baker; F. W. Metcalfe; H. M. Maynard; W. Woolley. *Disqualified*, E. Walker (beak wattle cut).

CARRIERS.—*Young.*—1, E. Walker. 2 and 3, F. W. Metcalfe. *c*, J. Baker; F. W. Metcalfe; R. Hall; W. Massey, Spalding; H. M. Maynard.

POUTERS.—*Cock.*—1 and 3, F. Gresham, Shefford. 2, Spence & Styles, Kettering. *vhc*, P. H. Jones. *hc*, G. H. Gregory; J. E. Palmer, Peterborough; T. Adams; T. Rule; G. Sturgess, Leicester (2); P. H. Jones. *c*, J. Barbor, Kettering; T. Adams; W. Nottage; W. B. Van Haansbergen, Newcastle-on-Tyne; P. H. Jones.

POUTERS.—*Hen.*—1 and 3, F. Gresham. 2, G. Sturgess. *hc*, J. E. Palmer; W. Nottage, Northampton.

TUMBLERS.—*Almond.*—1, 2, 3, and Cup, J. Braid, Cambridge. *Any other Variety.*—1 and 3, W. J. Woodhouse. 2, R. Minnitt. *hc*, W. J. Woodhouse; J. Watts; W. B. Van Haansbergen.

BARBS.—1 and Cup, W. B. Van Haansbergen. 2, J. & C. Ballen. 3, H. M. Maynard. *c*, R. Hall; P. H. Jones.

JACOBINS.—1, W. Massey. 2, J. Thompson, Bingley. 3, T. Adams, Northampton. *hc*, F. Wait; W. B. Van Haansbergen. *c*, J. Thompson; W. Bishop, Dorchester.

FANTAILS.—1, W. B. Van Haansbergen. 2, J. T. Cater, Colchester. 3, J. Walker. *hc*, J. Walker, Newark; J. F. Loversidge. *c*, H. Yardley, Birmingham.

TURBITS.—1, E. T. Dew, Weston-super-Mare. 2, G. South, London. 3, W. and J. Cutler. *c*, W. Goddard, Stanhope Street, London; P. H. Jones.

DRAGOONS.—1, G. South. 2, W. Bishop. 3, P. H. Jones. *hc*, W. Massey; H. Yardley. *c*, F. Graham, Birkenhead; G. H. Gregory.

ANTWERPS (For flying purposes).—1, J. J. Sparrow, London. 2, Spence and Styles. 3, T. King. *hc*, J. J. Sparrow (2); J. W. Collinson, Halifax. *c*, J. S. Dew; F. Harwood, jun., Colchester (2); F. W. Metcalfe.

ANY OTHER VARIETY.—1, W. Goddard. 2, J. S. Price. 3, J. & C. Bullen. *hc*, J. S. Price; C. Norman; W. Gamble, Thorpe Satchville, Melton Mowbray. *c*, W. Gamble; G. H. Gregory (2); W. Bishop; J. Watts; T. Rule; W. B. Van Haansbergen; H. Yardley.

SELLING CLASS.—*Single Cock or Pair.*—1, W. Nottage. 2, F. Waitt, King's Heath, Birmingham. 3, T. Rule, Durham. *hc*, J. Braid, Cambridge; C. Norman, Westerfield, Ipswich (2); J. Barber, Kettering; J. T. Cater (2); J. Thompson; J. E. Palmer. *c*, J. S. Price; F. Graham; J. T. Cater; H. Thurlow, Burnham Market, Lynn.

Members' Cup for the best pen of Carriers—F. W. Metcalfe.

Members' Cup for the best pen of Tumblers—J. Braid.

Prize for the best pen of Pigeons exhibited by any member—F. W. Metcalfe.

RABBITS.—*Lop-eared.*—1 and Cup, H. Thurlow. 2, Lewin & Robinson. 3, H. Cawood, Thorne, Doncaster. *hc*, J. E. Palmer; C. King; J. Quick. *c*, T. E. Terry, Shawfield, Tong; R. Hall; Mrs. Passingham, Milton; J. W. B. Rooke; J. A. Clough; J. Quick. *Any other Variety.*—1, W. Cory, Northampton. 2, A. B. Simpson, Trumpington. 3, J. Allen, Ampthill. *hc*, T. E. Terry; W. W. Robinson, Cambridge; A. H. Easten, Hull. *c*, T. Adams.

The Judges were Mr. Edward Hewitt, of Birmingham, and Mr. Tegetmeier, of London.

DORKING POULTRY SHOW.

THE twelfth annual Show of Dorkings, Ducks, Geese, and Turkeys took place on the 7th inst. The awards were as follow:—

DORKINGS.—*Coloured.*—1 M. Putney, Dorking. 2, J. Smith, Shillinglee Park, Petworth. 3, F. Parlett. *hc*, H. Humphrey, Ashington; W. H. Robson, North Reston, Louth. *c*, Miss A. Brassey, Normanhurst Court, Battle. *Chickens.*—1, Mrs. Wheatley, Ingatestone. 2, J. Clift, Dorking. 3, Rev. E. Bartrum, Great Berkhampstead. *hc*, Miss A. Brassey; G. Ellis, Ashcroft, Betchworth; H. S. Fraser, Headley, Petersfield; H. Humphrey; M. Putney. *c*, W. B. Boxall, Strathfieldsaye; H. S. Fraser; H. Humphrey.

DORKING (Coloured).—*Cockerel.*—1, Rev. E. Bartrum. 2, J. Clift. *hc*, J. Clift; G. Cubitt, M.P., Denbies, Dorking; Mrs. Meek, Brantridge Park, Balcombe; M. Putney; Mrs. Wheatley. *Pullets.*—1, Mrs. Wheatley. 2, W. B. Boxall. *hc*, Miss A. Brassey; Mrs. Meek; Miss J. Millward, Newton St. Loe, Bristol; M. Putney. *c*, H. Humphrey.

OPEN TO MEMBERS.

DORKINGS.—*Coloured.*—1 and Extra, M. Putney. 2 and Extra, W. Fell, Westcott. 3 and Extra, E. May, Dorking. *hc*, H. Mills. *Chickens.*—1, J. Clift. 2, W. Fell. 3, M. Putney. *hc*, M. Putney; J. Wood, Westcott. *c*, J. Clift; J. Constable, Leatherhead; G. Ellis, Ashcroft, Betchworth; T. H. Perks.

DORKINGS.—*Coloured.*—*Hens.*—1, G. Cubitt, M.P. 2, J. R. Corbett, Betchworth. *hc*, J. Clift; T. H. Perks; M. Putney. *c*, G. Hine; M. Putney; J. Wood. *Pullets.*—1, J. Clift. 2, W. Fell. *hc*, G. Ellis; H. Mills; M. Putney. *c*, D. B. Green.

DORKINGS.—*Coloured.*—*Cock.*—1, M. Putney. 2, E. T. Bennett, Betchworth. *Cockerel.*—1, J. Clift. 2, J. Wood. *hc*, M. Putney (2). *c*, J. Clift; W. Fell.

DORKINGS.—*Blue-speckled.*—1, Mrs. Mayo, Dorking. 2, G. A. Fuller, Dorking. 3, G. Hine, Westcott. *c*, W. Philps. *Chickens.*—1, G. Hine. 2, Mrs. Mayo. 3, W. Messenger, Wonersh, Guildford. *hc*, W. Griffin, Westcott. *c*, R. Eldridge, Westcott; W. Philps; J. Young, Dorking.

DORKINGS.—*Blue-speckled.*—*Cock.*—Prize, J. Rowe, Dorking. *hc*, R. Gamon, Westcott; Mrs. Mayo. *Hens or Pullets.*—Prize, J. Young. *hc*, G. Hine; Mrs. Ramsey, Shere.

DORKINGS.—*White.*—1, G. Cubitt, M.P. 2, W. Attlee. 3, Lady M. Legge. *c*, W. Attlee; W. F. Watson, Henfold, Capel. *Chickens.*—1, J. Attlee. 2, R. Wood, Betchworth. 3, C. Maw, Dorking.

DORKINGS.—*White.*—*Cock.*—Prize, H. Mills. *hc*, J. Attlee. *Hens or Pullets.*—1, W. F. Watson. 2, J. Attlee. *hc*, G. Hine.

DUCKS.—*Aylesbury.*—1, J. B. Nicholls. 2, W. F. Watson. *Any Breed.*—1 and Extra, G. Hine. 2, Extra, and *hc*, J. R. Corbett. 3 and Extra, Mrs. J. Sturgess, Leatherhead.

GEESE.—1 and Extra, J. Wood. 2 and Extra, Mrs. J. Sturgess. 3 and Extra, W. F. Watson. *hc*, W. Messenger. *c*, W. Attlee. *Goslings.*—1, Mrs. J. Sturgess. 2, G. Hine. *hc*, W. Messenger, Wonersh, Guildford. *c*, W. Attlee; H. Lainson, Reigate.

TURKEYS.—1, Sir R. A. Glass, Ashurst, Dorking. 2, W. F. Watson. *hc*, J. Constable; W. Messenger.

JUDGE.—Mr. Matthew Hedley, Redhill.

EDINBURGH POULTRY SHOW.

THIS was held on the 6th, 7th, and 8th inst. It should be considered whether more light could not be admitted to that portion of the building where the poultry is exhibited, so that the birds in the centre pens may be better seen by spectators. The pens were most injudiciously placed in tiers of three, the lowest being nearly on the ground; the birds in them could be seen with difficulty. The pens were also too small.

SPANISH.—*Cockerel.*—1, A. Shepherd. 2, R. Dickie. 3, Mrs. Gracie. *hc*, J. W. Will; Mrs. Gracie; W. Paterson. *Pullets.*—1, W. Paterson. 2, A. Shepherd. 3, W. Rutherford. *Cock.*—Cup, R. Waugh. 2, A. Shepherd. 3, Master A. Ridpeth. *Hen.*—1, A. Shepherd. 2, Mrs. Gracie. 3, W. Rutherford.

DORKINGS.—*Coloured.*—*Cockerels.*—1, Mrs. M'Donald. 2, D. Gellatly. 3, J. Robb. *hc*, T. Raines; L. M'Donald; A. Haggart; J. Rutherford. *c*, A. Haggart. *Pullets.*—1, J. Fetheringham. 2, Mrs. Morrison. 3, D. Gellatly. *hc*, A. Haggart; Mrs. Chalmers. *c*, D. Gellatly. *Cock.*—Cup, D. Gellatly. 2, J. Gibson. 3, J. W. Will. *hc*, D. Annan. *c*, A. Haggart. *Hens.*—1, A. Haggart. 2, D. Gellatly. 3, T. Briden. *hc*, Miss H. R. Lind. *c*, A. Shepherd.

DORKINGS.—*Silver.*—*Cockerels.*—1, J. Curror. 2, D. Forrester. 3, Lady G. Montgomery. *hc*, T. Raines; G. F. Lyon; W. Leslie. *Pullets.*—1, J. Cunningham. 2 and 3, J. Curror. *hc*, A. M. Sanderson; W. Meff. *c*, Lady G. Montgomery. *Cocks.*—1, — Chalmers. 2, Sir J. D. Wauchope, Bart. 3, Lady Baird. *Hens.*—1, T. Raines. 2, W. Meff. 3, D. Annan. *hc*, Lady G. Montgomery; Lady Baird.

COCHINS.—*Cockerel.*—1, R. Williamson. 2, J. Sichel. 3, J. W. Will. *hc*, R. Boyle; W. Fraser. *Pullets.*—1, J. W. Will. 2, H. White. 3, C. Sidgwick. *hc*, Mrs. Oswald; J. Sichel. *Cock.*—1, C. Sidgwick. 2, J. Sichel. 3, J. W. Will. *Hens*—Cup, J. Sichel (White). 2, J. W. Will. 3, C. Sidgwick. *hc*, J. Sichel; W. Meff.

BRAHMAS.—*Cockerels.*—1 and 3, Mrs. Gillison. 2, R. Brownlie. *hc*, T. Raines; Mrs. Harvey; J. Stuart. *c*, J. W. Will. *Pullets.*—1 and 2, J. Stuart. 3, J. W. Will. *hc*, J. W. Will; Mrs. Gillison; J. Stuart (2). *c*, T. Raines. *Cocks.*—1, R. Brownlie. 2, Mrs. Gillison. 3, Lady Baird. *Hens.*—1, J. Sichel. 2, T. Raines. 3, J. W. Will. *hc*, Commander G. F. Lyon.

GAME.—*Black and other Reds.*—*Cockerel.*—1, T. W. Mitchell. 2, R. Stewart. 3, J. Scott. *hc*, D. Harley; J. Rooch. *Pullets.*—1, D. Harley. 2, C. Jamieson. 3, T. W. Mitchell. *hc*, J. Scott; J. Wishart; J. W. Will; H. Archibald. *c*, D. Harley; J. Blair. *Cocks.*—1, A. Stephens. 2, J. W. Will. 3, A. S. Brewster. *Hens.*—1, D. Harley. 2, J. W. Will. 3, J. Aadersoa. *hc*, D. Harley.

GAME.—*Any other Colour.*—*Cockerels.*—1, D. Harley. 2, W. Scott. 3, J. Blair. *Pullets.*—1, J. Lyall. 2, A. Milne. 3, D. Harley. *hc*, A. S. Brewster. *Cocks.*—1 and Cup, D. Harley. 2, J. Anderson. 3, A. Milne. *Hens.*—1 and 3, D. Harley. 2, H. Goodal. *hc*, J. W. Will.

HAMBURGHS.—*Spangled.*—*Cock.*—1 and Medal, W. R. Park. 2, Mrs. Brown. 3, J. Watson. *hc*, W. M'Intosh. *Hens.*—1, S. & R. Ashton. 2, J. W. Will. 3, J. W. Blakey. *hc*, D. Annan; R. Dickson.

HAMBURGHS.—*Pencilled.*—*Cock.*—1, J. Kerr. 2, D. Cheyne. 3, A. Pratt. *hc*, L. M'Donald; J. W. Will; W. R. Park. *c*, A. B. Cranston. *Hens.*—1, R. Dickson. 2, W. R. Park. 3 and *hc*, J. Walker.

BANTAMS.—*Game.*—*Cock.*—Cup, J. Barlow. 2, G. Hall. 3, G. Todd. *hc*, G. M'Millan; G. Bell; J. Scott; E. & J. T. Hudson (2); G. Dowie; T. C. & E. Newbitt (2); R. Brownlie. *c*, F. L. Roy; R. Brownlie. *Hens.*—1, J. W. Will. 2, G. Todd. 3, G. Hall. *hc*, J. W. Will; J. Archibald; Bellingham & Gill; Miss R. C. Frew. *c*, G. Dowie.

BANTAMS.—*Any other Variety.*—*Cock.*—1, J. W. Will. 2, T. Watson. 3, J. Sichel. *hc*, A. Johnston; W. Rutherford (2); S. & R. Ashton. *Hens.*—1, Miss P. P. Frew. 2, T. Watson. 3, S. & R. Ashton. *hc*, J. W. Will; J. Sichel.

SCOTCH GREYS.—1, W. Coke. 2, W. Gibb. 3, D. Waldie. *hc*, T. Lawrie.

ANY OTHER VARIETY.—1 and Cup, J. Sichel (Crève-Cœur). 2, C. Sidgwick (Black Hamburgh). 3, W. R. Park (Crève-Cœur). *hc*, Mrs. Cross; Miss Drummond; J. Sichel.

DUCKS.—*Aylesbury.*—1 and Cup, E. Leech. 2, J. W. Will. 3, Commander G. F. Lyon. *hc*, Commander G. F. Lyon; J. W. Will; W. Rutherford. *c*, J. Fotheringham.

DUCKS.—*Rouen.*—1, W. Rutherford. 2, H. Stephenson. 3, E. Leech. *hc*, W. Thomson; J. Thomson.

DUCKS.—*Any other Variety.*—1, W. Burns. 2, T. Clarkson. 3, H. B. Smith. *hc*, H. B. Smith; S. & R. Ashton; S. H. Stott. *c*, J. J. Maldeo.

TURKEYS.—*Norfolk.*—*Young.*—1, J. Wilson. 2, Miss M. R. Melrose. 3, Duke of Buccleuch. *Old*—1 and 2, J. Wilson. 3, Duke of Buccleuch.

TURKEYS.—*Any other Variety.*—*Young.*—1, E. Leach. 2, Lady G. Montgomery. 3, Mrs. Somerville. *Old.*—1 and Cup, E. Leech. Lady G. Montgomery. 3, T. L. M. Cartwright.

GEESE.—1, S. H. Stott. 2, E. Leech. 3, H. Stepheason.

Mr. Teebay was the Judge.

HYDE POULTRY SHOW.

CONSIDERING that none of the acting Committee had previously been engaged in the management of a poultry show, the general arrangements of the Hyde Show were very creditable. Messrs. Turner's pens were engaged for the occasion, and so far as the Concert Room is suited for the purpose, the position of the pens could not have been improved.

Strange to say, *Dorkings* were a very limited entry, though the prize birds were very good, and yet more singular, only a solitary entry was made in the class for *Cochins*. Mr. Ansdell took both prizes for *Brahmas* with his well-known Dark birds, but there were many excellent pens of this breed shown, even in the Selling classes. A few good *Game* fowls were exhibited, but the cream of the Show were the *Hamburghs*. In Black Hamburghs it is very questionable if such good pens were ever seen side by side at any show. The Spangled, also, of both colours were quite equal to the reputation of the breeders of Hamburghs in this district; the "spangling" of the majority of those shown was such as once seen could never be forgotten. Mr. Peter Unsworth contributed much to the general attractions of this first Show, by the entry of several pens of very excellent *Polands*. The *Ducks* were particularly good, and the winning *Geese* and *Turkeys* were pens from the noted yard of Mr. Leech, of Rochdale.

The music gallery formed a very good position for the display of a large and excellent collection of *Pigeons*, but a side light from each direction rendered somewhat obscure this division of the Show. Few of the visitors anticipated seeing so perfect a collection of Pigeons, supported by many of the most distinguished breeders in the kingdom. No committee could devote more willing and earnest attention to the well-doing of the birds under their care, and no doubt annual and successful meetings will be the result.

DORKINGS.—1 and *hc*, W. H. King, Moss Mills, Rochdale. 2, E. Smith, Pass mans, Rochdale.

COCHIN-CHINAS.—1, J. Railton, Manchester. 2, No competition.

BRAHMA POOTRAS.—1 and 2, T. F. Ansdell, St. Helens (Dark). *c*, J. Finchett, jun., Chester (Dark); J. Railton (Dark); G. B. Goodfellow, Hyde (Dark).

GAME.—*Black or Brown Red.*—1, J. Jones, Nantwich. 2, J. Frith, Chatsworth. *Any other Variety.*—1, C. Travis, Thurgoland, Sheffield. 2, J. Frith. *c*, G. Frith.

HAMBURGHS.—*Gold-spangled.*—1 and 2, J. Buckley, Taunton. Ashton-under-Lyne. *hc*, W. A. Hyde, Hurst, Ashton-under-Lyne. *c*, S. & R. Ashton, Mottram; N. Marlow, Denton. *Silver-spangled.*—1 and 2, Ashton & Booth, Broadbottom, Mottram. *Gold-pencilled.*—1, Ashton & Booth. 2, S. & R. Ashton. *c*, R. Pickles, Edenfield, Bury. *Silver-pencilled.*—1, G. Furness, Rawtenstall. 2, Ashton and Booth. *c*, E. Siddall, Rawtenstall.

FRENCH.—*Any Variety.*—1, C. H. Smith, Radcliffe-on-Trent (Crève-Cœur). 2 and *c*, G. W. Hibbert, Manchester (Crève-Cœur). *hc*, J. Railton.

POLANDS.—*Any Variety.*—1, 2, and *c*, P. Unsworth, Newton-le-Willows.

ANY OTHER VARIETY EXCEPT BANTAMS.—1, H. Hoyle, Lumb, Newchurch, (Black Hamburghs). 2, N. Marlow (Black Hamburghs). *hc*, Stott & Booth, Huntley Brook, Bury (Black Hamburgh).

GAME BANTAMS.—1, G. Furness. 2, Rev. F. Cooper, Ampney Crucis, Cirencester. *hc*, J. Frith (3).

BANTAMS.—*Any other Variety except Game.*—1, S. & R. Ashton. 2, J. R. Jessop, Hull. *hc*, R. Brown, Cheadle Hulme, Stockport. *c*, S. & R. Ashton.

DUCKS.—*Aylesbury.*—1, E. Leech, Rochdale. 2, J. Fogg, Reddish, Stockport. *Rouen.*—1 and *hc*, P. Unsworth. 2, A. Haslam. Hindley, Wigan. *c*, E. Leach. *Any other Variety.*—1, S. & R. Ashton (Mandarin). 2, No competition.

GEESE.—1, E. Leech. 2, W. Hibbert.

TURKEYS.—1, E. Leech. 2, E. Ryder, Hyde.

SELLING CLASS.—1, G. B. Goodfellow (Dark Brahma). 2, K. Dawson, Shaw, Oldham (Black Hamburghs). *hc*, C. Travis (Game); A. Haslam (Brown Red Game). *c*, G. W. Hibbert (Houdan); J. Frith; G. Fletcher (Buff Cochin); E. Smith (Dorking); J. Booth (Black Red Game).

PIGEONS.

CARRIER.—*Cock.*—1, H. Yardley, Birmingham. 2, E. C. Stretch, Ormskirk. *Hen.*—1, B. Consterdine, Littleborough. 2, E. C. Stretch.

POUTER.—*Cock.*—1 and 2, W. T. Richardson, Oldham. *Hen.*—1 and 2, W. T. Richardson. *hc*, H. Yardley.

TUMBLERS.—*Almond.*—1, J. Fielding, jun., Rochdale. 2, W. A. Hyde. *Any other Variety.*—1, J. Fielding. 2, A. Ashton, Parkfield, Middleton. *hc*, R. G. Teebay, Ormskirk.

RENTS.—1 and *hc*, W. Taylor. 2, H. Yardley.

JACOBINS.—1, F. Waitt. 2, H. Yardley.

BARBS.—, H. Yardley. 2, E. C. Stretch. *hc*, H. Smith. *c*, Mrs. Hunt.

FANTAILS.—1, H. Yardley. 2, A. Ashton.

DRAGOONS.—1, F. Graham, Birkenhead. 2, P. Unsworth. *hc*, A. Ashton; J. Holden, Heaton Norris; J. Westwood, Bredbury; T. J. Caparn; F. Graham. *c*, J. Chatterton; Mrs. Hunt.

ANTWERPS.—1 and *hc*, W. J. W. Pass, Bury. 2, J. T. Cook, Denton. *hc*, R. Brierley, Fishpool, Lancashire.

ANY OTHER DISTINCT VARIETY.—1, H. Yardley. 2, J. Fielding. *hc*, A. Ashton; H. Eaton, Manchester.

SELLING CLASS.—1, B. Consterdine. 2, T. Moore, Birkenhead.

LOCAL CLASSES.

GAME.—*Cock.*—1, W. Warburton. 2, J. Arrandale. *Hen.*—1, W. Warburton. 2, J. Arrandale.

HAMBURGHS.—*Gold or Silver-spangled.*—1, Ashton & Booth. 2, T. Walker, jun. *hc*, S. & R. Ashton. *Gold or Silver-pencilled.*—1, S. & R. Ashton. 2, Ashton & Booth.

BANTAMS.—1, Ashton & Booth. 2, S. & R. Ashton. *hc*, J. H. Howe. *c*, H. Hague, Hyde.

ANY OTHER VARIETY EXCEPT BANTAMS.—1, T. Walker, jun. (Black Hamburgh). 2, E. Ryder. *c*, C. B. Cooke (Dark Brahmas).

CROSS-BRED.—1, W. W. Cooke. 2, Ashton & Booth.

DUCKS.—*Any Variety.*—1, G. B. Goodfellow. 2, S. & R. Ashton. *hc*, H. Smith.

PIGEONS.

CARRIER.—*Cock.*—1, W. A. Hyde. 2, J. Ainsworth, Hyde. *hc*, G. B. Goodfellow. *Hen.*—1, J. Ainsworth. 2, W. A. Hyde.

DRAGOONS.—1, G. W. Hibbert. 2, T. Wardle.

ANY OTHER VARIETY.—1, J. Armitage (Blue English Owl). 2, J. Swan (Owl).

CROSS-BRED.—*Cock.*—1, J. Smith, Hyde. 2, J. Ainsworth. *Hen.*—1, J. Smith. 2, J. Ainsworth.

Mr. Edward Hewitt, of Birmingham, was the Judge.

YORK POULTRY SHOW.

THE fifteenth annual Exhibition of poultry and Pigeons was held in connection with the Yorkshire Agricultural Society, on the 5th, 6th, and 7th inst., and proved another success both as respects the quality and number of the birds and the amount of the receipts.

Dorkings numbered over thirty pens, and were good, the prizes going mostly to young birds. *Spanish* were very good, and the winning birds were much admired. *Cochins* and *Brahmas* were very fairly represented, but we did not consider the *Hamburghs* quite up to a Yorkshire competition. *Game* and *Polish* formed good classes, and that for Any other variety was well filled, chiefly with the French breeds; a good pen of Crêve-Cœurs were first.

PIGEONS.

THE show of Pigeons was beyond all comparison the best for the last five years, numbering 198.

The Carrier cocks were a good class of twelve entries, and the prize birds rightly placed. The Carrier hens numbered seven entries; they were a rather coarse lot with the exception of the first-prize Black hen, which was very fine. Of Carriers hatched in 1871 there were only six entries. I think exhibitors should support this class better. The first prize was won by a very fine Black cock; the second by a very good Dun.

Of Pouter cocks there were nine entries. The first prize went to a very good White cock; the second to a very inferior Blue cock. For Pouter hens the first prize and cup were given to a Red hen, good in limb and feather, but bad in colour, and inferior in crop. The second-prize Red hen was by far the best in the class; she certainly should have been first; her colour was very fine; she had great length of feather, good shape, and a grand crop. Two good Blue hens were shown.

The Almond Tumblers were easily judged. The first-prize pair was fine in colour and shape; the second-prize pair good in head and beak, but not so rich in colour as the first-prize pair. For Short-faced Tumblers, a pair of fine Black Mottles were first; and the second prize went to an odd-coloured pair, the cock being red and white, and the hen yellow and white. These birds were the best in head and beak, but I could not see their claim to the prize, not being of the same colours.

Of Fantails there were fifteen entries. This was a very fine class; I think the Judges could have given the prizes twice over. In the first-prize pair the cock was very fine, the hen rather out of condition; the second-prize pair was very good. I considered the best pair in the Show was Pen 602, which was overlooked.

Of Trumpeters there were only six entries, but the birds were of excellent quality. The first prize went to a remarkably fine pair, very large in rose and hood, and with capital feet. The highly-commended Blacks shown by Mr. Haansbergen should have had the second prize; the hen is the best I have seen.

Of Barbs eight pens were shown. The first prize and cup went to a pair of Blacks which really were perfect. The second-prize pair were very good Blacks.

Jacobins were an excellent class, numbering seventeen pens. The first prize went to Reds, the second to Whites. The best pair in the class was passed over, a pair of Yellows, good in hood and chain, rich in colour, and small. The Reds should have given way to the Yellows.

Of Turbits there were eighteen entries. The first prize went to Reds, the second to Blues, but the best pair was overlooked, Pen 649, a pair of Yellows. These birds should have been first, and the first-prize Reds second.

There were ten entries of Owls; the first-prize pair Whites, the second Blues. This class was good in quality and rightly judged.

Nuns, eight pens, were good. The first prize went to Black-headed, the second to Yellow-headed. The highly-commended pair, No. 666, was very fine—clean marked and with capital hoods; they should have had a place.

Antwerps numbered twenty-two pens. The first-prize pair were Silver Duns, the second Blue-chequered. Several other excellent pens were highly commended. I thought Pen 680 should have been second. They were short-faced and had well-shaped heads. Another pair shown was also equal to either of the prize pens.

In the class for any New or Distinct Variety there were fourteen pens. The first prize went to a pair of fine Ice Pigeons, which were claimed at £5; the second to a pair of White Dragoons. Pen 697 should have been placed second. They were a pair of grand Black Priests. Several other pens of excellent birds were shown, one being a splendid pair of Red Magpies, rich in colour and markings.

In the Selling Class there were twenty-three pens, but most of them very poor, and some of the winning pens were hardly worthy of notice.

The birds were well looked after, and had a plentiful supply of good food and clean water.—J. W. R., *York.*

RABBITS.

PERHAPS in no other place have admirers of these pets seen such a collection either as to number or value. Too much praise cannot be given to those on the Committee for their untiring efforts to insure success, and this was, indeed, the reward for their zeal. York now stands foremost in its show of Rabbits, and I feel assured other places will more patronise these interesting animals.

Of the Lops, the Grey Self-coloured eleven-months-old doe, justly the winner of the silver cup, had ears 23 inches by 5 inches, and Mr. Boyle's Sooty Fawn buck, seven months and a half old, was good in all points, and had ears 22¾ inches by 5½. In the class for Yellow and White Mr. Terry again stood first with a doe, ears 23¼ inches by 5⅝, and was closely followed in position by a beautiful young doe (seven months) of Messrs. Lewin & Robinson, ears 22¼ inches by 5½. In the Tortoiseshell Mr. Terry again won the first prize with a buck well found, ears 22½ inches by 5; and next in position was a seven-months-old doe, with ears 22¼ inches by 5¼, also a good specimen. In the Black and White class Mr. C. King stood first with a nine-months-old doe well marked, ears 21⅝ inches by 4¾; and Mr. T. Irving's buck, with ears 21¼ inches by 5, entitled him to the second position. The Blue and White are evidently scarce, as only one entry was made, and that a fair specimen, four months old, well marked, but rather short in ear (18¼), yet by no means unworthy the second prize awarded. The Grey and White class was good (seven entries), and Mr. J. Boyle's buck, seventeen weeks old, with ears 21¼ by 5 inches, is evidently a good specimen of a Lop, as his first position proves. Mr. Terry's buck, with ears 22 by 5 inches, was a well-formed animal, yet rather of an undecided shade for a Grey.

To speak of the Lops as a whole, we must in justice say they were very good, and it is not often that thirty-three Lops of such value, and possessing such points of excellence, are found. The longest-eared Rabbit in the Show had ears 23 inches by 5, a size not always to be met with, especially during the winter season, as December and June weather produce in all probability some slightly different results in this respect when the ears are measured, though the Rabbits were in a nice warm corner of the building, forming three sides of a square, with a fire in the centre.

The Himalayan next claim our notice, and to speak of them as a class (twelve entries), they were not quite equal to what I have seen; the want of equality of shade in the extremities was what we most complain of; in point of size I find no fault, as some of them were rather large for this variety; the ears and nose were of the right shade, but the feet rather too light in most specimens. Mr. W. H. Tomlinson's first-prize doe was an excellent Rabbit, as was also Mr. H. Cawood's six-months-old buck as second. Next comes the showy Angora in goodly numbers (twenty-two entries), and, perhaps, a better class is seldom seen. The large lamb-like doe of Mr. W. Whitworth was as good a specimen as we ever remember seeing, white and clean, with her wool evidently well cared for; Mr. C. Anton's buck, a fitting companion, was in the next pen as second prize, and perhaps a finer or more perfect pair are rarely seen. The pretty little Dutch (fourteen entries) were also good as a class. Some presented rather too much white around the neck, and too little about the feet, yet some almost perfect pens were found. A Blue and White buck was the fortunate first-prize winner, and Mr. S. G. Hudson's "wee" Grey and White buck was a worthy second-prize. The Silver-Greys (nine entries) were good with one or two exceptions. For equality of silvering, which we prefer, the prizetakers were what a Silver-Grey or Chinchilla should be. In the Any other variety class (thirteen entries) the large Patagonian, or "Ram Rabbit," buck, with his broad bull-dog-looking head, was entitled to the first position, and it is rare we meet with so good a specimen, as they are scarce, and Mr. J. Boyle's Belgian Hare Rabbit buck was a deserving second prize; with a pretty "silver cream" of Mr. S. G. Hudson as highly commended, and a Polish buck of Mr. C. King's, were novelties in the class, and both were good specimens. The Selling class (fourteen entries) presented some good Rabbits; Mr. Wharton's Sooty Fawn doe, with ears 21⅜ inches by 5, was a fitting first prize. This, a Silver-Grey as second, and a Yellow

and White Lop as highly-commended, ears 20¾ by 4½, formed a trio not always to be seen in a selling class.

The pens were roomy, and well supplied with hay, oats, and swedes, and a sort of well-to-do air seemed evident from the abundant supply of food and care bestowed upon the whole.

Mr. Millington judged the Lops, and Mr. C. Rayson the fancy varieties.—CHARLES RAYSON.

DORKINGS.—1, R. W. Richardson, Meaux Abbey, Beverley. 2, J. Newall, York. 3, J. Stott, Healey, Rochdale. 4, Miss Simpson, Rawcliffe, York.

SPANISH.—1, R. Smith, Norton, Malton. 2, H. Wilkinson, Earby, Skipton. *Chickens.*—1 and 2, J. Thresh, Bradford.

COCHIN-CHINA.—*Yellow or Buff.*—1, H. Mason, Drighlington, Leeds. 2, G. Speedy, Whitby. 3, C. Sidgwick, Ryddlesden, Keighley. 4, D. Ibeston, Whitby, *Any other Colour.*—1, T. Stretch, Ormskirk. 2, R. L. Story, Wensley, Bedale. 3, Miss J. Boulton, Beverley. 4, G. Calvert, Darlington.

BRAHMA POOTRA.—1, E. Corney, Whitby. 2, J. T. Travis, Rochdale.

GAME.—*Black-breasted or other Reds.*—1, G. Sutton, Bootham, York. 2, J. Watson, Knaresborough. *Duckwings.*—1, W. Fell, Adwalton, Leeds. 2, H. Mason. *Any other Variety.*—1, F. Sales, Crowle. 2, J. Smith, jun., Norton. *Chickens.*—1, G. S. Thompson, York. 2, G. Sutton, York.

HAMBURGHS.—*Golden-pencilled.*—1, J. Walker, Birstwith, Ripley. 2, W. Clayton, Keighley. 3, Pennington & Kidson, Thirsk. *Silver-pencilled.*—1, J. Walker, Birstwith. 2, H. Smith, Merton Banks, Keighley. 3, T. H. Readman, Whitby. *Golden-spangled.*—1, J. Rollinson, Lindley, Otley. 2, J. Walker. 3, W. Bearpark, Ainderby Steeple. *Silver-spangled* —1, G. Huby, Banninghrough, York. 2, Creekes & Beeth, Sheffield. 3, G. Holmes, Great Driffield.

POLISH.—1, W. Silveater, Sheffield. 2, G. Speedy, Whitby.

BANTAMS.—*Game.*—1, J. Rollinson. 2, W. Adams, Ipswich. 3, R. Bradley, Green End, Earby. *Laced* —1. F. Powell, Knaresbrough. *Any other Colour.*—1 and 2, G. Holmes, Great Driffield.

ANY OTHER VARIETY.—1, Mrs. E. Cross, Appleby, Brigg (French). 2, H. Chawner, jun., Uttexeter (White Leghorns).

TURKEYS.—1, J. Sterry, Tame Bridge, Stokesley. 2, H. R. W. Hart, Dunnington Lodge, York. *Poults.*—1, T. M. Derry, Gedney. 2, A. Reynolds, Morr Monkton, York.

GEESE.—1 and 2, G. Hustler, Stillingfleet, York.

DUCKS.—*Aylesbury.*—1, J. Sterry, 2, W. Stonehouse, Whithy. *Rouen.*—1, R. W. Richardson. 2, R. Gladstone, jun, Court Hey, Liverpool. *Any other Variety.*—1, R. W. Richardson. 2, S. Barn, Whitby.

SELLING CLASS.—1, H. Dale, Northallerton. 2, G. S. Thompson. 3, H. Judson.

PIGEONS.

CARRIERS.—*Cock.*—1, E. Horner, Harewood, Leeds. 2, J. Stanley, Blackburn. *Hen.*—1, J. Stanley. 2, E. Horner. *Chickens.*—1, E. Horner. 2, W. Campey. Beverley.

POUTERS.—*Cock.*—1 and 2, J. Hawley, Bradford. *Hen.*—1 and Cup, J. Hawley. 2, E. Horner.

TUMBLERS.—*Almond.*—1, E. Horner. 2, H. Adams, Beverley. *Any other variety, Short-faced.*—1, J. Fielding, jun., Rochdale. 2, H. Adams.

FANTAILS.—1, G. Fletcher, Acomb Landing, York. 2, J. F. Leversidge, Newark.

TRUMPETERS.—1 and 2, E. Horner.

BARBS.—1 and Cup, W. B. Van Haanshergen, Newcastle-on-Tyne. 2, J. Stanley, Blackburn.

JACOBINS.—1, R. G. Sanders, Leven, Beverley. 2, W. B. Van Haanshergen.

TURBITS.—1, J. T. Lishman, Girlington, Bradford. 2, W. Bearpark.

OWLS.—1, J. Fielding, jun. 2, J. Stanley.

NUNS —1, R. W. Richardson. 2, E. Horner.

ANTWERPS.—1, J. Stanley. 2, F. Woodhouse, Blackburn.

ANY OTHER VARIETY.—1, W. C. Dawson, Weston Hall, Otley. 2, J. G. Dunn, Newcastle-on-Tyne.

SELLING CLASS.—1, E. Horner. 2, J. Cundale, Copt Hewick, Ripen. 3, R. W. Richardson.

RABBITS.

LOP-EARED.—*Self-coloured.*—1 and Plate, T. E. Terry. Shawfield, Tong, Leeds. 2, J. Beyle, jun., Blackburn. *hc*, H. E. Gilbert, Rugby. *c*, J. Tring, Blackburn. *Yellow and White.*—1, T. E. Terry. 2, Lewin & Robinson, Kettering. *hc*, H. Cawood, Thorne, Doncaster. *c*, F. S. Arkwright, Sutton Scarsdale, Chesterfield. *Tortoiseshell* —1, T. E. Terry. 2, Lewin & Robinson. *hc*, C. King, St. John's Wood, London. *Black and White.*—1, C. King. 2, J. Irving, Blackburn. *hc*, Lewin & Robinson. *c*, A. L. Pearce, Thorne. *Blue and White* —2, W. Denkin, Driffield. *Grey and White.*—1, J. Beyle, jun. 2 and *c*, T. E. Terry. *hc*. A. H. Easten, Hull; J. G. A. Hillyard, York.

HIMALAYAN.—1, W. H. Tomlinson, Newark-on-Trent. 2, H. Cawood, Thorne. *hc*, Miss M. E. Boulton, Beverley. *c*, W. Whitworth, jun., Manchester; H. Myton, York.

ANGORA.—1 and Plate, W. Whitworth. 2, C. Anton, York. *hc*, J. Boyle, jun. *c*, T. E. Terry; G. T. Linfoot, York; G. Robinson, York.

DUTCH.—1, J. Boyle, jun. 2, S. G. Hudson, Hull. *hc*, W. Whitworth. *c*, W. Denkin; W. Merhey, Northampton.

SILVER-GREY.—1 and *hc*, T. E. Terry. 2, J. Beyle, jun. *c*, S. G. Hudson.

ANY OTHER VARIETY.—1, W. Whitworth. 2, J. Beyle, jun. *hc*, S. G. Hudson. *c*, C. King.

SELLING CLASS.—1, T. Wharton, York. 2, J. Beyle, jun. *hc*, T. E. Terry. *c*, A. Cattley, Barnsbury, London.

JUDGES.—*Poultry and Pigeons:* Mr. Teebay, Fulwood, Preston; Mr. W. Maesey, Spalding; and Mr. H. Brown, Walkley, Sheffield. *Rabbits:* Mr. C. Rayson, Ivy Lodge, Didsbury; and Mr. M. Millington, York.

TREDEGAR POULTRY SHOW.

THIS Show was held at Newport on the 12th and 13th inst. Although a slight reduction in the prize list had taken place, the number of entries was about the same as last year.

In the first section of the Show *Game*, *Dorkings*, and *Spanish* competed for the cup, which was won by a pen of adult Brown Red Game, the Duckwings running them closely for it.

The *Dorkings* were of only moderate quality, but the Buff *Cochins* were very large and true to colour, although several of the adult birds were scarcely in dry feather. Light *Brahmas* were greatly improved in both classes, as regards marking of tail, hackle, and size.

The cup for the second section went to a large well-marked pen of adult *Brahmas;* the young of this variety were also worthy of note.

Unfortunately many pens were empty, owing to the birds being too late for competition, and this remark applies particularly to the *Hamburgh* classes. In Pencilled, of both colours, only the winners were worthy of notice; but there were many excellent pens among the Gold, Silver, and Spangled. Of the *Polands*, the first were an extraordinary pen of Golden, to which the cup for this section was given, and the second a pair of White-crested Black of rare quality. The *French* class was very good. Crêve-Cœurs were first and third, and Houdans second. Game *Bantams* were badly placed as to light, were with difficulty judged, and our remarks must in consequence be limited. Blacks were good, and the Whites even better; but the gems of this section were a pair of Silver Sebrights, the name for once suggesting the true colour of the birds. In the Variety classes were Black Hamburghs, Sultans, and White Dorkings.

Both the Ronen and Aylesbury *Ducks* were good, but this applies to quality rather than to size.

The weight of the first-prize pair of *Geese* was 40 lbs., that of the *Turkeys* 41 lbs., and of the second-prize birds 38½ and 34 lbs. respectively.

There was a good display of *Pigeons*, the Pouter and Fantail classes being very good, although, owing to the use of small wickerwork pens, the latter were very difficult to see. The whole class was commended. There were no less than thirty-two entries in the Variety class; and many more prizes could have been well won. We should advise a reconstruction of the schedule for Pigeons for another season.

GAME (Black or Brown-breasted Reds).—Cup, J. W. Jones, Malpas, Newport 2, G. S. Cole, Llanelly. *hc*, W. Dunning, Newport, Salop. *c*, C. H. Myers, Crynant, Glamorganshire; H. Horten, Colwall, Malvern; J. Davies, Cwmpark, Treorky, Pontypridd.

GAME (Any other variety).—1, H. C. & W. J. Mason, Drighlington. 2, J. P. Moses, Llandaff. *Chickens.*—1, J. W. Jones. 2, Rev. C. T. Salisbury, Tredunnoc Rectory, Newport.

Polish.—1, G. Boothby, Louth.

Crève-Cœur.—1, W. Dring, Faversham. *hc*, T. G. Ledger. *c*, Rev. H. H. Dombrain, Westwell Vicarage, Ashford.

Houdan.—1, W. O. Quibell, Newark. *hc*, J. Marten. Chilham. *c*, W. Dring. *Chickens.*—1 and *hc*, W. O. Quibell. 2, W. Dring. *c*, Hills & Co., Brighton.

Bantams.—*Game.*—1, W. S. Marsh, jun. 2, H. Lowe, Chartham. 3, Rev. F. T. Scott. *c*, Rev. F. Cooper; W. White, Canterbury; H. H. Stickings. *Any variety.*—1, Mrs. Lee, Penshurst. 2, W. White.

Ducks.—*Aylesbury.*—1 and 2, G. W. Greenhill, Ashford. *hc*, W. Young. *c*, C. S. Hardy (2). *Rouen.*—1, J. Austen, Denton, Canterbury. 2, F. Cheesman. *hc*, F. E. Arter. *c*, J. Austen (2); W. F. Harvey; G. W. Greenhill.

Geese.—1, Mrs. Lee. 2, J. B. Plumptre. *hc*, W. H. Mold; Mrs. Powell. *c*, W. H. James; Mrs. Brassey.

Turkeys.—1, A. Warde, West Farleigh. 2, C. J. Plumptre. *hc*, Mrs. Brassey; Mrs. Deedes, Sandling Park, Hythe. *c*, H. Andrews. *Poults.*—1 and 2, C. J. Plumptre. *vhc*, A. Warde (2); H. Andrews, Great Chart, Ashford. *hc*, Mrs. Harvey.

Any other Variety.—1, Mrs. Brassey. 2, Mrs. Bacon, River, Dover. *hc*, R. S. S. Woodgate; W. F. Harvey, Thruxted, Chartham; Miss Hales.

Pigeons.—*Carriers.*—1, G. Wise. 2, J. Bowes, Herne Bay. *Pouters.*—Prize, J. Bowes. *Tumblers.*—Prize, J. Bowes. *Fantails.*—Prize, G. W. Greenhill, Ashford. *Any other Variety.*—1 and 3, J. Bowes. 2, W. S. Marsh, jun. *c*, W. P. Forth, Ashford.

DEVIZES POULTRY SHOW.

We must defer our remarks on this Show, held on the 12th and 13th inst., until next week. The following is the prize list :—

Dorkings.—*Coloured.*—1 and 2, J. Martin. 3, C. Cork. *hc*, M. Putney; Lieut.-Col. Lane. *Silver-Grey.*—1, O. E. Cresswell. 2, W. E. George. 3, Mrs. C. Smith. *Any other Variety.*—1 and *hc*, Mrs. Hayne. 2, O. F. Cresswell. 3, Miss E. Williams. *c*, W. May; F. F. Fowler.

Spanish.—1, Mrs. Allsop. 2, Miss E. Browne. 2, W. Paraley. *hc*, E. Gill; H. F. Cooper; Mrs. Allsop.

Cochins.—*Cinnamon and Buff.*—1, H. Lloyd, jun. 2, Mrs. Allsop. 3, D. Young. *hc*, E. R. Gray; J. K. Fowler; H. D. Dent; J. Sichel. *Partridge.*—1, Horace Lingwood. 2, J. K. Fowler. 3, Miss Allsop. *Any other Variety.*—1 and 2, J. Sichel. 3 and *c*, R. S. S. Woodgate.

Brahmas.—*Dark.*—1, T. F. Ansell. 2, J. Watts. 3, E. Pritchard. *hc*, J. Walker; J. H. Cuff; Horace Lingwood; W. E. George; J. S. Tainton. *c*, W. E. George. *Light.*—1, J. R. Rodbard. 2, W. E. George. 3, Mrs. T. Turner. *hc*, W. Hanks; H. M. Maynard; W. E. George.

Game.—*Black-breasted Reds.*—1 and 3, W. H. Stagg. 2, S. Matthew. *hc*, P. P. Cother. *Brown-breasted Reds.*—1, S. Matthew. *Any other Variety.*—1, S. Matthew. 2, G. S. Sainsbury. 3, F. Bailey. *Any Variety.*—1, W. H. Stagg (Black Reds). 2, H. Brown. 3, W. H. Stagg (Black Reds).

Hamburghs.—*Gold-pencilled.*—1, W. Speakman. 2, H. Pickles, jun. 3, Capt. F. G. Coleridge. *c*, Rev. F. Goddard. *Silver-pencilled.*—1, H. Pickles, jun. 2, W. B. Payne. 3, C. H. Mayo. *Gold-spangled.*—1, H. Pickles, jun. 2, Lady Vivian. *Silver-spangled.*—1, Mrs. Allsop. 2, H. Pickles, jun. 3, G. Slade.

Polands.—1, J. Hinton. 2, G. W. Boothby. 3, P. H. Jones.

Houdans.—1, J. Sichel. 2, W. Dring. 3, Hills & Co. *hc*, M. H. Sturt; J. K. Fowler.

French.—*Any other Variety.*—1, J. Sichel. 2, C. H. Smith (Crève-Cœur). 3, Rev. N. J. Ridley (La Flèche). *hc*, Rev. N. J. Ridley (Crève-Cœur); — Dring (Crève-Cœur); H. Wyndham (Crève-Cœur); J. K. Fowler; J. J. Malden (Crève-Cœur).

Malays.—1, W. B. Payne. 2, Rev. N. J. Ridley. 3, J. Hinton.

Any other Variety.—1, Rev. W. Serjeantson (Black Hamburghs). 2, Wildey and Smith. 3, M. H. Sturt (Leghorns). *hc*, R. C. Forster (Black Minorcas); C. F. Wilson (Black Hamburghs); T. Bush (Black Hamburghs); Wildey & Smith (Andalusian).

Game Bantams.—*Black-breasted and other Reds.*—1, Rev. E. S Tiddeman. 2, Bellingham & Gill. 3, O. E. Cresswell. *hc*, C. H. Amea; Rev. F. Cooper. *c*, C. H. Webb. *Any other Variety.*—1, Bellingham & Gill. 2 and 3, Rev. F Cooper. *Any Variety.*—1, C. H Webb. 2, Ashley and Maitland. *hc*, Bellingham & Gill.

Bantams.—*Gold or Silver-laced.*—1 and 2, M. Leno. 3, J. Watts. *hc*, J. R. Jessop; G. W. Boothby. *c*, F. Hedding. *Any other variety.*—1, J. Sichel. 2, J. Watts. 3, T. Bush (Cuckoo). *hc*, Rev. W. Serjeantson. *c*, G. Francis (Black); J. Whitehead; S. & R. Ashton; W. Bishop.

Ducks.—*Aylesbury.*—1 and 2, J. K. Fowler. 3, G. Hanks. *hc*, R. C. Forster. *Rouen.*—1, H. Hoit. 2, E. Burton. 3, J. K. Fowler. *hc*, W. Stephens. *c*, J. H. Fry; G. M. Hulbert; J. K. Fowler. *Black East Indian.*—1, G. S. Sainsbury. 2, S. Burn. 3, F. Pitts, jun. *hc*, Mrs. Hayne (2); S. Burn; G. S. Sainsbury; W. E. George. *c*, F. Stratton; G. S. Sainsbury. *Any other variety.*—1, 2, and 3, M. Leno (Mandarin, Carolina, and Viduata Whistling Ducks). *hc*, W. Binns (Mandarin); S. & R. Ashton (Mandarin).

Turkeys.—1, Rev. N. J. Ridley. 2, Mrs. Dunn.

Geese.—1 and *hc*, J. K. Fowler. 2, M. Kew. 3, R. J. Spackman.

Selling Class.—1, J. Watts. 2, Rev. J. D. Heysted (Light Brahmas). 3, H. Lloyd, jun. *hc*, Mrs. Dunn (Dorkings); W. Hanks (Light Brahmas and Spanish); H. M. Maynard. *c*, H. H. Thompson; W. Beaven (Game); Miss E. Williams.

PIGEONS.

Carriers.—*Cocks.*—1, H. Yardley. 2, H. M. Maynard. *hc*, H. M. Maynard; C. Cork. *Hens.*—1, H. M. Maynard. 2, P. Wise. 3, W. B. Ford.

Pouters (White).—*Cocks.*—1, Mrs. Ladd. 2, A. Heath; Mrs. Ladd (3). *Hens.*—1 and 2, A. Heath. (Any other colour).—*Cocks.*—1, E. T. Dew. 2, G. Gregory. *Hens.*—1, F. T. Dew. 2, Miss J. Millward.

Tumblers.—*Almond.*—1, E. T. Dew. *Any other variety.*—1, S. Stephens, jun. 2, H. O. Crane. *c*, J. E. Combley.

Owls.—1, P. H. Jones. 2, H. Yardley. *hc*, G. H. Gregory; J. Watts.

Barbs.—1, H. Yardley. 2, H. M. Maynard.

Fantails.—1, Miss J. Millward. 2, H. M. Maynard. *hc*, H. Yardley. *c*, P. H. Jones.

Jacobins.—1, Mrs. A. Vigor. 2, Miss J. Millward. *hc*, F. Waitt (2).

Nuns.—1, F. Waitt. 2, H. Yardley. *hc*, F. Hedding; J. Watts.

Antwerps.—1 and 2, H. Yardley. *hc*, W. E. George (2). *c*, P. Wise; J. E. Combley.

Trumpeters.—1, P. H. Jones. 2, W. Masland.

Runts.—1, H. Yardley. 2, Mrs. J. Clark. *hc*, Mrs. J. Clark (2); W. Masland.

Any other Variety.—1, H. Yardley. 2, W. E. Stephens. *hc*, G. H. Gregory; F. Hedding; O. E. Cresswell; H. Yardley; F. Pittis, jun.

Selling Class.—1, F. Waitt. 2, W. E. Stephens. *hc*, W. J. Keall; C. Jarvis; C. Cork (2). *c*, P. H. Jones; J. Watts.

Judges.—Mr. E. Hewitt, Eden Cottage, Sparkbrook, Birmingham, and Mr. R. Teebay, Fulwood, Preston.

BERWICK AND BORDER ORNITHOLOGICAL ASSOCIATION.—December 6th and 7th.

There were sixty-one exhibitors; the number of birds competing was 273, besides a goodly number offered for sale only, and others only for exhibition. The birds were arranged on five tables running through the hall, in cages nearly all uniform. The following is the prize list :—

Belgian.—*Clear or Ticked Yellow.*—1 and 3, J. Rutter, Sunderland. 2, W. Bulmer, Stockton. *vhc*, W. Bulmer; Wallace & Beloe, Hide Hill; G. Norris, Castlegate. *Clear or Ticked Buff.*—1 and 2, J. Rutter. 3 and *vhc*, W. Bulmer. *c*, G. Norris. *Varicgated or Unevenly-marked.*—1 and 2, J. Rutter. 3, W. Bulmer. *c*, J. B. Gilchrist.

Glasgow Don.—*Clear Yellow.*—1 and 3, R. Forsythe, Edinburgh. 2, Wallace and Beloe. *vhc*, C. Lugton, Hillhurn, Ayton. *c*, J. Eagle. *Clear Buff.*—1, R. Forsythe. 2, Wallace & Beloe. 3, R. Aird, Edinburgh. *vhc*, C. Luton. *c*, J. Eagle. *Flecked.*—1 and 2, R. Forsythe. 3, G. Lobban. *vhc*, J. Eagle. *hc* and *c*, Wallace & Beloe.

Norwich.—*Clear or Ticked Jonque.*—1, 3, and *hc*, Adams & Athersuch, Coventry. 2, G. Gayton, Northampton. *vhc*, Barwell & Golby; Moore and Wynne, Northampton; G. & J. Mackley, Norwich. *Clear or Ticked Buff.*—1 and 2, G. & J. Mackley. 3, Wallace & Beloe. *vhc*, Adams & Athersuch; Moore and Wynne; G. J. Barnesby, Derby; J. Cleminson, Darlington.

Norwich.—*Evenly-marked Yellow.*—1 and 2, Adams & Athersuch. 3, Wallace and Beloe. *vhc*, Barwell & Golby; Moore & Wynne. *hc*, R. Hawman, Middlesbrough. *Evenly-marked Buff.*—1 and *hc*, Adams & Athersuch. 2, Wallace and Beloe. 3, Moore & Wynne. *vhc*, Swan & Medd, Scarborough; W. & C. Burniston, Middlesbrough.

Norwich.—*Uncevenly-marked Jonque or Buff.*—1, W. Yonng, Belford. 2 and 3, Adams & Athersuch. *hc*, Barwell & Golby; Moore & Wynne; G. J. Barnesby. *c*, J. Cleminson.

Norwich.—*Evenly-marked Jonque or Buff, with Crest.*—1, S. Tomea, Northampton. 2, Wallace & Beloe. 3, Adams & Athersuch. *vhc*, J. Hurrell, Sunderland; J. Spence, Sunderland; G. & J. Mackley.

Norwich.—*Clear Jonque or Buff, with Dark Grey, or Clear Crest.*—1, G. and J. Mackley. 2, W. Bulmer. 3 and *hc*, Wallace & Beloe. *vhc*, Moore & Wynne; S. Tomea.

Norwich.—*Any other Variety of Crested.*—1, J. Hurrell. 2, W. Watson, jun., Darlington. 3, J. Rutter. *vhc*, M. King, Scarborough; G. & J. Mackley.

Cinnamon.—*Jonque.*—1, Wallace & Beloe. 2, Fairclough & Howe, Middlesbrough. 3, Barwell & Golby. *vhc*, Moore & Wynne; S. Tomes; Wallace and Beloe. *Buff.*—1, S. Tomes. 2, Barwell & Golby. 3, E. Mills, Sunderland. *vhc*, Moore & Wynne. *c*, Wallace & Beloe. *Evenly-marked* (Any variety).—1, J. Spence. 2, L. Belk, Dewsbury. 3, Wallace & Beloe. *hc*, L. Belk; G. Cox, Northampton.

Any other Variety.—1, J. Taylor, Middlesbrough. 2, J. B. Gilchrist. 3, Stephens & Leek, Middlesbrough. *vhc*, Stephens & Leek; T. Tenniswood, Middlesbrough; R. Hawman.

Goldfinch Mules.—*Marked or Variegated.*—1, L. Belk. 2, Stephens and Leek. 3, R. Paxton, Belford. *vhc*, Wallace & Beloe. *c*, T. Allenby, Durham; W. & C. Burniston. *Dark Jonque.*—1, Moore & Wyone. 2, J. Taylor. 3, Stephens & Leek. *c*, T. Tenniswood; Wallace & Beloe. *Dark Mealy.*—1, G. Fox. 2, Wallace & Beloe. 3, S. Tomes. *vhc*, Fairclough & Howe. *hc*, Wallace and Beloe.

Selling Class.—1, G. Gayton. 2, J. Eagle. 3, J. Cleminson. *hc*, G. Gayton; R. Forsythe; Wallace & Beloe.

Goldfinch.—1, J. Taylor. 2, Stephens & Leek. 3, T. Tenniswood, Middlesbrough.

British Birds.—*Any other Variety.*—1 and *vhc*, W. & C. Burniston. 2, J. Roper. 3, G. Cox. *c*, R. Stevens.

Foreign Birds.—*Any variety.*—1, W. L. Beloe (Golden Pheasants). 2, 3, and *c*, Wallace & Beloe (Golden Pheasant, African Love Birds, and Bishop Birds).

DISTRICT PRIZES.

Clear or Ticked.—*Any Breed.*—1, P. Farrell. 2, W. Grieve. 3, J. Teague, Woolmarket. *vhc*, W. Headsmith. *hc*, P. Farrell; J. Teague.

Evenly-marked.—*Any breed except Norwich.*—1, J. R. Nisbet, Spittal. 2, T. Robertson, Berwick. 3, P. Farrel.

The Judges were Mr. Thomas Clark, Sunderland, and Mr. Henry M'Dougall, Edinburgh.

Kendal Poultry and Pigeon Show.—The prize list is rich, there being thirty-nine silver cups in addition to the prizes, the first of which is two sovereigns. The entrance fees are small.

Weight of Runts at Birmingham.—I do not know if all the Runts were weighed, but I was surprised this morning on

weighing the two highly commended pens to find that one pair weighed 4¼ lbs., and the other 4¼ lbs. I know the Blues weighed 4 lbs. 6 ozs. when they went to the Crystal Palace, before I sold them.—S. A. W.

ROYAL DUBLIN SOCIETY'S POULTRY SHOW.

This Society's winter Show opened on the 5th inst., and was continued on the following two days. There were upwards of four hundred entries of poultry and Pigeons. The following awards were made:—

Dorkings (Silver-Grey).—1, Miss De Courcy Drevar, Blackrock. 2, R. P. Williams, Clontarf. Third, S. Mowbray, Mountrath. *hc*, J. C. Cooper, Limerick. *c*, W. G. Mulligan, Belfast. *Chickens*.—1, Mrs. Warburton, Kill, Naas. 2, Capt. Downman, Kingstown. *hc*, Mrs. Warburton; Hon. J. Massy, Limerick.

Dorkings (Any other variety).—1, Mrs. Warburton. 2, G. A. Stephens, Dublin. 3, G. A. Perrin, Loughlinstown, Co. Dublin. *Chickens*.—1, A. Stephens. 2, W. G. Mulligan.

Spanish.—1, Miss De Courcy Drevar. *hc*, W. G. Mulligan, *c*, T. A. Bond, Londonderry. *Chickens*.—2, W. G. Mulligan. *hc*, J. Barlow, Chapelizod.

Brahma Pootras.—1, G. A. Stephens. 2, Hon. J. Massy. *hc*, Capt. Downman. *c*, Mrs. Warburton; R. Dore, Dublin. *Chickens*.—1, G. A. Stephens. 2, L. F. Perrin. *c*, Capt. Downman.

Cochin-Chinas.—1, W. H. Perrin, Chantilly, Co. Dublin. 2, J. K. Milner, Cherbury, Co. Dublin. *hc*, L. Stonie, M.D., Dublin. *c*, F. W. Zurhorst, Dublin. *Chickens*.—1 and 2, W. H. Perrin. *hc*, Miss L. Warburton, Kill, Co. Kildare. *c*, J. C. Cooper.

Game.—1 and 2, G. A. Perrin. *Chickens*.—1 and 2, G. A. Perrin.

Hamburghs (Pencilled).—2, L. Stonie, M.D. *hc*, R. P. Williams.

Hamburghs (Spangled).—1, S. Mowbray. 2, G. A. Perrin. *hc*, Capt. Downman.

Polands (White or Black-crested).—1, Miss De Courcy Drevar. 2, R. P. Williams. *hc*, J. K. Milner. *c*, W. G. Mulligan.

La Fleche.—1 and *hc*, G. A. Stephens. 2, Capt. Downman.

Houdans.—1 and *c*, J. C. Cooper. 2, G. A. Stephens.

Creve-Cœurs.—1, G. A. Stephens. 2, Hon. J. Massy. *c*, E. J. Poer, Limerick.

SINGLE COCKS.

Dorking.—1, Mrs. Warburton. 2, J. C. Cooper. *c*, Mrs. M. Ashton, Phœnix Park, Dublin.

Spanish.—1, W. G. Mulligan. 2, Miss De Courcy Drevar.

Cochin-China.—1, J. K. Milner. 2, W. H. Perrin.

Brahma Pootra.—1 and 2, Mrs. Warburton. *c*, R. P. Williams.

La Fleche.—1 and *hc*, G. A. Stephens. 2, E. J. Poer. *c*, A. Field, Blackrock.

Houdan.—1, G. A. Stephens. 2, J. C. Cooper.

Creve-Cœur.—1, Hon. J. Massy. 2 and *hc*, E. J. Poer.

Game.—1, 2, and *hc*, G. A. Perrin.

Any Variety not Previously Mentioned.—1, S. Mowbray. 2, Hon. J. Massy. *c*, R. P. Williams.

Game Bantams.—1 and *hc*, G. A. Perrin. 2, W. G. Mulligan.

Any other Variety.—1, E. J. Poer. 2 T. A. Bond, Londonderry.

Fat Fowls.—*hc*, A. Field. *c*, Miss L. King, Geashill.

PIGEONS.

Carriers.—1, J. M'Donnell, Upper Rathmines. 2, R. W. Smith, Cahir.

Pouters.—*hc*, E. A. Seale. *c*, F. W. Zurhorst.

Owls.—1 and *hc*, J. Dowling, Cork. 2, J. M'Donnell. *c*, H. L. Tivy, Cork.

Tumblers.—1 and *hc*, E. A. Seale. 2, J. Dowling.

Barbs.—1 and 2, J. Dowling. *hc*, R. W. Smith.

Trumpeters.—1, J. Dowling. 2, H. L. Tivy.

Fantails.—1 and 2, E. A. Seale.

Turbits.—1, E. A. Seale. *c*, J. K. Milner.

Jacobins.—1, R. W. Smith. 2, E. A. Seale. *c*, J. Dowling.

Nuns.—1 and *hc*, J. Dowling. 2, E. A. Seale.

Homing.—1, G. M. Caparn, Beggar's Bush. 2, F. W. Zurhorst. *hc*, J. Dowling.

Judges:—Mr. E. Hutton, Pudsey, and Mr. C. F. Staunton, Cappagh, Clondalkin.

THE SECOND CAT SHOW AT THE CRYSTAL PALACE.

Another cat show at the Crystal Palace, and another success. The entries were about two-thirds more than at the first show, an comprised, of course, a far greater variety of form and colour, and the exhibition was therefore far more interesting. Looking over the list of the exhibitors, we find nearly as many, if not quite as many, gentlemen as ladies, besides here and there a Master "So-and-so." It was said when a cat show was first announced that all the "old ladies" would be sending their pets, but the result proves that men are as fond of cats as the gentler sex. The Earl of Hopetoun sent no less than seven fine specimens, amongst which were some half-bred wild cats. But, perhaps, the most attractive animal of the Show, or, at least, the most scarce, was a real tortoiseshell he-cat—red, yellow, and black, with no white. Almost everyone knows that the existence of such is denied, yet at the Crystal Palace Show there was one, and rare as it is supposed to be, the price of £10 only was marked on it. Most of the other classes contained fine specimens of their kind, the Tortoiseshell and White being very rich in colour and beautifully marked. The Tabbies varied much in their black and brown tracings, some being very dark, while in others the lines had almost disappeared, and the fur presented more the appearance of that of a rabbit, or Chinchilla squirrel.

Then the White cats were a charming variety, one in particular being extremely beautiful, the eye having a deep ultramarine hue. This was a short-haired cat. At the last Show, a long-haired one possessed the same fine quality of colour in the eye. Grand-looking cats were the half-bred wild sent by the Zoological Society, Regent's Park, and they showed evident traces of their origin; but the two largest in the Show were those sent by Miss Amos and Miss Hawthorn, both of which weighed 21 lbs., and were awarded equal first prizes. The heaviest long-haired cat, though looking much larger, weighed but 18¾ lbs., and was beautiful in colour.

But where so many were good it is difficult to individualise, and we feel it was a Show that ought to be seen more than described, the universal opinion being, that there was an air of elegance and refinement about it that was not to be found in many other shows of our domestic animals. And, indeed, what animal is more domestic than the cat? and it is well, therefore, that this animal should have its admirers, and care and attention bestowed on it, for if we try for beauty in our out-door animals, why not still more for beauty in those that sit by us at our own fireside? There is now but little doubt that cat shows will become as permanent as poultry shows, and if we may form any criterion from those held at the Crystal Palace, will receive a greater amount of support from the public than almost any other kind of show, as we find that nearly 20,000 persons visited this second Show at the Crystal Palace, although then the weather was very severe, and, therefore, prevented many from being present. We mention this merely to show that the domestic cat has many friends, and we are of opinion they will now rapidly increase, nor should we be surprised to find the next Show numbering two or three times as many specimens and of still finer quality, and attracting many more visitors.

The Judges on this occasion were the Lady Mildred Beresford Hope, the Lady Dorothy Nevill, the Rev. J. Cumming Macdone, Harrison Weir, Esq., F.R.H.S., and John Jenner Weir, Esq., F.L.S.

LARGE OR SMALL HIVES.

My experience in keeping bees in large and reasonably small hives may be of service to some of your readers similarly situated to myself.

The first things to be considered are situation and the nature of the surrounding country. I keep my bees six miles from London, on the Surrey side, which I must confess is not at all a promising locality; and it is a fact that many of my neighbours who have attempted to keep bees have been obliged to give them up, as they have never been able to obtain a drop of honey. But I account for my success in this way:—There are two seasons at which the bees obtain the most honey. The first is the spring, when all the fruit and garden trees are in full bloom; and the second about July, when the limes are fully out. I always rely upon these two seasons for obtaining most of my honey. Now I have kept bees both in large and small hives, and I certainly give the preference to a smaller hive, for while I have always succeeded tolerably with the latter, I find I do not succeed so well with the larger hives.

In a large hive I have never yet succeeded in getting the bees to work a super, although to all appearance very strong in numbers, therefore, without driving the bees, I can obtain no honey from them. With a smaller hive, on the contrary, I can always get the bees to work a super, and what is very essential they can fill a small hive with comb so much more quickly than a larger one. I may state that I usually keep one large hive and add all the late swarms to it, but I find I cannot do much with them. This may, perhaps, be owing to the make-up, but I do not lose many bees during these operations. As a proof of the above, I have had 35 lbs. of honey from four small hives, and I have left the hives quite strong enough to pass through the winter, but I have had to drive a large hive, which only yielded about 25 lbs.—Carolus, *Tooting*.

[We are right glad to receive such notices of practical experience as yours. With regard to a preference for large or small hives, it is a question which must depend for its answer upon two things: first, the size of the swarms put into them; secondly, the nature of the honey pasturage in the vicinity. To put small swarms into big hives is, of course, an absurdity; similarly it is absurd to put a swarm, however large, into a big hive if the honey-producing power of the surrounding district is small. Circumstances can alone decide what is fitting in each case. At the same time, given a fine pasturage and a full-sized swarm, and we unhesitatingly say use a large hive. But it must be borne in mind that a supered hive is often virtually a big hive.—Eds.]

WINTERING BEES.

Our American bee friends are trying curious experiments with their favourites, which seem to thrive in that continent wonderfully. Among others is a new mode of wintering, which is confidently recommended by a gentleman of the name of Hosmer. Mr. Hosmer finds that when colonies are wintered in a warm place it is not necessary to have a large number of bees in a hive. A quart, he says, will be sufficient for the safety of any queen. The theory is that the old bees which have consumed honey all the winter die soon after they first fly in the spring, and have had their winter's hoard for nothing, while younger bees have a lease of life before them and are full of

vigour for the important work of assisting in the breeding operations of the hive early in the spring. Consequently he would encourage late breeding, and prefers a number of what we should call weak hives. "Mr. Hosmer rears surplus queens in small boxes, and then, about the season of the year that we are accustomed to unite our weak colonies to make all strong for the winter, he divides his strong ones, so that with each queen he has only a moderate supply of bees, and honey in proportion."

Now, however contrary this may be to our ordinary notions of safe management of bees, I am persuaded there is something in it which deserves consideration. Of course such treatment would be fatal to all hives left out all the winter on their stances. Some would starve to death of hunger and others of cold. But if a different mode of wintering bees were adopted—supposing it possible for us to stow them away in dry lofts in total darkness from the middle of November to the middle or end of February—I cannot but believe this treatment would be found beneficial; especially if we could contrive to get rid of all summer-bred bees and encourage late breeding in autumn. From the greater and more continued severity of their winters in America they appear commonly to stow away their hives in dark and warm places, as they do in the colder regions of Europe.

It might be well to give this plan a trial; and especially in cases where hives are known to be weak both in bees and honey, and I fear there are many such this year. Skeps half full of comb would winter particularly well in this way. I should advise their being suspended from a beam with the floor board hung beneath them and sloping in one direction, so as to carry off any bees which happened to die during the winter. It is absolutely necessary they should be in total darkness. The floor-board should touch the hive on one side so as to permit any live bees to crawl back again if they happened to fall down accidentally. Of course the hives so treated must have enough honey or bee-food to support the bees during their incarceration, little as may be the quantity required.

Some of your readers will recollect an experiment as to burying bees in the ground, which was largely tried some twenty years ago. The results were duly chronicled in your pages. It was a complete failure, and settled for ever this mode of wintering. In almost every case the bees died of damp and dysentery. It is, however, quite a different thing to stow them away in dry lofts or cellars. Will any of your apiarian readers try the experiment on a small scale, and report the issue? I would not recommend any strong stocks to be so treated, because the natural warmth of the hive in such cases would tempt the bees to activity: they would therefore become restless and uneasy, and more disposed to crawl out. Strong stocks are best left to themselves on their summer stances.—B. & W.

OUR LETTER BOX.

Scottish Columbarian Association's Show (*Capt. D. and others*).—You are all quite justified in mentioning the prizes offered as "most handsome." We were amused by the doubt as to its "promoters" being trustworthy. We can say unreservedly, Perfectly so.

Grasses for Poultry Run (*A. A.*).—On your light soil the following mixture and quantities are for an acre:—Alopecurus pratensis, 2 lbs.; Dactylis glomerata, 5 lbs.; Festuca duriuscula, 2 lbs.; F. pratensis, 3 lbs.; F. rubra, 1½ lb.; Lolium italicum, 7 lbs.; L. perenne, 10 lbs; Phlenm pratense, 1 lb.; Poa nemoralis sempervirens, 1½ lb.; P. pratensis, 1½ lb.; Medicago lupulina, 1 lb.; Trifolium pratense, 1 lb.; T. pratense perenne, 2½ lbs.; and T. repens, 6 lbs.

Woodbury Hive (*Yours*).—If you enclose five postage stamps with your address, and order "Bee-keeping for the Many" to be sent, you will have it post free. It contains a description of the Woodbury and other hives, and how to manage bees.

Fallen Combs (*H. Jenner*).—It would not be safe to attempt transforring the combs and bees into a bar box at this time of the year, and unless the combs are so fallen down and jammed together as to block up the lower portion of the hives, we think it would be better to defer any attempt to rectify the evil until mild weather in March or April. If, however, the combs are badly massed together, you can turn each hive, with its board, upside-down in a bucket, and having removed the board, adjust the combs in position as well as you can at the proper distance apart. Put in half-inch slips of wood between each comb to keep them in place, and two long pieces of the proper thickness may be placed across the bottom of the combs. The board may then be put on, and the hive carefully reversed to its proper position. This may be done on any mild day, or in a warm room, and if the wooden slips are prepared previously, but little time need be occupied in the operation, unless the combs have been much fastened together. We should prefer this plan to that of transferring the contents of the hives into small supers.

Washing Pigeons for Showing, &c. (*H. J. R. S.*).—Pigeons best clean themselves; they are great washers, and struggle and fight with each other for the bath. They always bathe in the morning, and a shallow pan placed in a gleam of sun in winter, and a few drops of hot water to take the chill off, will induce them to wash in a moment. Ours are doing so this frosty morning. A little hempseed warms Pigeons for a journey to a show this cold weather, and on returning home this and good beans are now best. Fowls are dusting birds, and will not wash themselves. The best plan is to wash their heads and legs, then put them in a room thickly covered with clean straw, throw a few handfuls of wheat in the straw, scattering the grain thinly, and the birds in searching and scratching for the wheat will clean themselves beautifully.

Weaver Birds (*Edith*).—They are apparently a pair of yellow Bishops in bird-dealers' language—African Weaver birds, of which there are many sorts. Most of them eat insects. Procure some German paste from Hawkins's, 6, Bear Street, Leicester Square, or any other dealer, and give a little now and then for a treat if the birds eat it. Canary and millet seed are the proper staple food; hemp only occasionally for a treat—no rape. Moulting begins in January, and ends in July. Supply bits of hay, dry grass, &c., and see if they twine them in the cage wires. They have no song. Give green food only occasionally. Try a watercress now and then, and hard-boiled yolk of egg, and stale bread crumbs occasionally, but a bath often in a sunny day. They will live with other birds well enough, but probably require more warmth than Canaries. We should keep the Canaries in one cage, and some foreign Finches and the Weavers in another. They are rendered tame by being kept in a room frequented by the family. If yours mope they may be moulting.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

6th.—Thick in early morning, very dark at 8.30 A.M., bright at noon, and a fine day on the whole.

7th.—Frosty and dull in morning, bright at 1 P.M., rapidly changing; very dark with snow at 6 P.M., cold northerly wind.

8th.—Very sharp frost with thick white fog in the morning, occasionally bright between 11 and 2, then dull (though fair) all day.

9th.—Very dull and cold all day, frequent slight falls of snow.

10th.—Still frosty but not so intense, fair all day but no sunshine.

11th.—Morning dark, very bright at noon, slight rain about 2 P.M., dull after.

12th.—Apparently fine above the fog in the morning and occasionally bright about noon, but very thick, damp, and uncomfortable in the afternoon, rather better in the evening.

The temperature of the week has been unusually low, even for December. The height of the barometer also is equally noteworthy.—G. J. Symons.

COVENT GARDEN MARKET.—December 13.

We have no alteration to report. Owing to unfortunate influences at work, which have a great bearing upon the movements in our markets for best goods, prices are likely to recede.

From observations taken near London during forty-three years, the average day temperature of the week is 43.8°, and its night temperature 31.4°. The greatest heat was 58°, on the 25th, 1827; and the lowest cold 4°, on the 24th, 1860. The greatest fall of rain was 1.13 inch.

THE RISE AND PROGRESS OF THE BEDDING GERANIUM.

WERE any individual to write an account of the rise and progress of some of the plants that supply our daily wants, many very interesting facts would be revealed, and all controversy which at present exists as to the origin of several of them set at rest. The Wheat, for instance, has by some been asserted to have come from Ægilops cylindrica, but the origin of this and some other plants is far from being clearly defined, as the transmutation of the wild plants to which their parentage is ascribed, is so slow that a human life is but a fraction of the time sufficient to render the difference very perceptible. Certainly there are cases where a marked improvement has taken place within a very few years, but this generally occurs in plants devoted to ornament rather than to use, and it will readily be admitted that the Geranium is one of these. A cursory review of its progress will not be without interest, and I intend to give a few of the leading features of the plant, its history, and the position it has taken in the ornamental department of gardening.

Although botanical catalogues assign a rather remote date to the time when the Scarlet Geranium made its first appearance in this country, it is likely that for many years its cultivation was limited to very few plants. Kept in a small pot, as was the custom at that time, it afforded but few cuttings, and even these were not propagated to the same extent as now. The first quarter of the present century, most likely, passed before any great progress was made in the cultivation of this important plant. It had, certainly, found its way into most greenhouses, but the varieties were, if I remember rightly, very few, as I cannot recall any prior to 1826, but the old Horseshoe-leaved Geranium, the flower of which was a dull red rather than a bright scarlet, and the petals narrow and windmill-like. This old Scarlet was very soon followed by one under the equivocal title of "The White Scarlet," a horseshoe variety with blooms of a dull white colour. This certainly was not uncommon before the year 1832; and coeval with it were a gold and a silver-edged variety which I remember to have seen in the cottage windows. They were slow growers, and of course their multiplication was correspondingly slow, though they certainly were to be had. I confess having no recollection of seeing any of the Ivy-leaved class at that time, nor for many years afterwards, although it is likely enough they were in cultivation.

But an important future was now in store for the Scarlets; both a red and a white were to be had, and the purpose of garden decoration to which they were destined to be put was by degrees developed. My first experience of them as applied to that use was, singularly enough, a successful feat in cultivation under circumstances at the time unexpected. A large plant of the old Horseshoe variety had been planted against the back wall of a plant house, and the soil being favourable, it quickly reached the top, and flowered most abundantly. As it bid fair to outgrow everything else it was much cut-in, furnishing a full wheelbarrow-load of shoots and stalks. This was towards the end of May, when some flower beds on the lawn were being planted with French Marigolds, Asters, Ten-week Stocks, and such other annuals as were to be had at that time. It was thought that some of the shoots of the Geraniums that were cut down might be stuck into one of the least promising of these beds. Accordingly a quantity of the shoots were put in, and as might be expected now, but hardly so then, they almost every one grew, and by the 1st of September were fine healthy plants in full flower, the annuals having been removed as the Geraniums progressed.

This lesson was not lost on those who witnessed it, and striking cuttings out of doors became somewhat the order of the day in that district. I recollect one who had the reputation of being a good gardener as well as the best botanist in that neighbourhood—for botany was more associated with gardening then than it is now—attempting to propagate out of doors the whole of his New Holland plants, of which he had a good collection; but hardwooded plants, of course, refused to grow on the same terms as succulent Geraniums, and disappointment was the result. Cuttings of the latter plant were, for some years afterwards, always placed in the full sun when it was intended to propagate them; and although the case I allude to took place in 1829, the mode of propagating them discovered by accident has not been much improved upon. Great quantities of cuttings are not at the present day generally put in during May, but the chief points of the practice are still the same. It must not be inferred that inserting cuttings in the open ground every May was the only plan adopted; on the contrary, I am not sure that I have ever seen that process repeated, for the very good reason that cuttings at that time are not plentiful.

The plan of taking up the plants in autumn, and wintering them in some cool vinery or similar place, was certainly practised as early as 1830, but how much earlier I am not able to say. I remember perfectly well having to plant in 1831, a circular bed of Geraniums which had occupied the same position the year before, and were tall and rather unwieldy plants. The bed they were put into was surrounded by wire basketwork about 15 inches high, so that the unruly growth of the Geranium was carefully kept in bounds, and a good show of flowers, both early and late, was the result, the old plants invariably blooming earliest. This mode of treating the Scarlet Geranium was common for some years, the plan of striking a large number of cuttings in summer and keeping them in a limited space till the following spring not being fully understood for some years after. At the same time it ought to be observed that the planting-out of the greenhouse varieties of the Pelargonium was as much practised as that of the Scarlets, and some favourite kinds of that time still retain a place. My memory seems to rest on Moore's Victory as one of the most popular about 1831, both in-doors and out, while amongst the White-flowered section with dark blotches, old Macranthon held the sway for some years, but this

section being akin to the one immediately under notice, further remarks about it are unnecessary.

Returning, therefore, to the Scarlet section, I believe the first improvement on the old Horseshoe-leaved was called Waterloo, a favourite name in those days, and a very appropriate one too. The Brighton Hero which followed this, a variety having a less distinct horseshoe marking and a much brighter flower, attained a rather respectable position, being for some years the favourite bedding plant. Eventually, however, it was superseded by others of its class, of which one called Sol became common about 1836, soon after which time the importance of scarlet Geraniums as ornaments to the flower garden were fully acknowledged. Now there arose a host of aspirants to distinction, and the class became divided into two sections: one tall, with foliage more or less downy, was represented by the Emperor, or Smith's Emperor, a tall, strong-growing plant with heads of flowers of large size; the other was shorter, with leaves more or less shining, and was ushered in by such names as the Huntsman and Frogmore Scarlet. The latter differed but little from Tom Thumb, which followed it some years afterwards; and whether a spurious Tom Thumb made its appearance or not I cannot say, but for some two or three years after the last-named kind came out, I could not see any difference between the Tom Thumb I had and the Frogmore. I believe the late Mr. Beaton never could make anything out of Tom Thumb, and I do not think it was ever a favourite of his. Nevertheless it must be admitted that Tom Thumb reigned supreme in the class of scarlet Geraniums used for bedding purposes for a much longer period than any had done before or has done since. The plant had a good habit, and was easy of culture, reasons which tended to prolong Tom Thumb's popularity for some time after his rivals had fairly eclipsed him in the contest for floral honours. Even now the name is often brought up in connection with scarlet Geraniums, although it may fairly be regarded as having ceased to be the champion for some eight or ten years. Its decline was accelerated in a great measure by the late Mr. Beaton introducing the class of bedding Geraniums now known as the Nosegay section; and to one of these the hero of several years had to succumb. Stella beat Tom Thumb, and I believe I am speaking within bounds when I say that from 1863 to 1869 Stella was more grown than any other variety. Tom Thumb in the meantime declined, but regal honours are at best but fleeting, and Stella has had its day. Having during the last few weeks seen several flower gardens, I had the opportunity of noticing those flowers which appeared the most popular, and asked a friend who had travelled much about, which was the best at the present day, and he unhesitatingly said Waltham Seedling, which beats Stella as Stella did all that came before it—an opinion in which I fully concur. I do not pronounce this opinion on the experience of one season or a small quantity of plants, but upon that of three or four years, and rather an extensive cultivation of it and others. I do not, however, deny merit to other kinds, some of which may possibly do as well elsewhere as Waltham Seedling has done where I have noticed it.

From the advent of Tom Thumb, about 1842, until the present time many and very important members of this family have made their appearance, and one amongst the number as old as Tom Thumb is still popular. It represents a section which, strange to say, has not been improved upon since, and that is Mangles' Variegated. This fast-growing and convenient plant ought certainly to have undergone some transformation during the thirty years it has been known to gardeners, yet there it is, still unchanged both in flower and foliage. Fortunately its constitution does not seem impaired, as it grows as well as before. It has done good service in its time, and although some enthusiastic growers have promised to change its somewhat dull white garb into a bright yellow one, it has not yet been done. I am not particularly fond of the yellow section; a clear, good, white edging being in my opinion of more importance in the flower garden.

But returning to the Scarlet class. I believe I am right in asserting that Tom Thumb was the all-important one twenty years ago, but which is the one now? I have put Stella as Tom Thumb's successor, and Waltham Seedling as superseding Stella, basing my opinion on the general approval the public has given to these varieties, and not on that of individual growers, however high their judgment might stand.

Next to the Scarlets in point of utility are the Pink-flowered kinds, and I do not recollect any of merit before 1846 or 1847, when, I think, Lucia roses made its appearance, and was succeeded by one or two others. By means of these a respectable appearance was kept up for some years until Christine came out, and though many faults have been found with this variety, it is, nevertheless, more grown at the present day than any other of the same colour. There have been produced during the last few years many rivals to it, of which Wiltshire Lass, Rose Rendatler, Beauté de Suresnes, Helen Lindsay, Blue Bell, and others have all had their admirers, including, also, some of the Nosegay class, of which Pink Stella may be regarded the type; but I would rather that some one else elected a principal to this class than take the responsibility of doing so myself. If called upon to give an opinion, I would say that Blue Bell is about as showy as any, the pink tint partaking a little, though not much, of a blue colour, and not nearly so much as I hope to see in the Geranium hereafter.

White-flowering Geraniums of the Zonal section have never yet, in my opinion, reached the same degree of perfection that the Scarlet have. The White, if deserving the name, is, in all the varieties I have seen, a dirty one, a stain of pink or some other hue pervading almost every petal; and, indeed, for beauty of flower coupled with good foliage, there has none of the so-called Whites of the Zonal section come up to the White-flowered Ivy-leaved. The shining foliage of the latter shows-up the flower to advantage; but as that section may be spoken of separately, and may, perhaps, be thought an unfair rival to the class now under discussion, it need not be put in comparison with it. I must say that if a good white-flowered kind could be obtained, without that very dark zone which most of them have—in fact, if a good white flower could be put upon a Tom-Thumb foliage—the appearance would be much improved. Still I am not sure they would ever become very popular, for as foliage now-a-days has in a great measure taken the place of white flowers, this class is not so much wanted. Nevertheless, I may inform those interested in such matters, that white-flowered Zonal Geraniums have been known for considerably more than forty years, but the section was never considered of much importance, and I have no remembrance of the first-named variety. Amongst those we have grown here I can see very little, if any difference, and yet they rejoice in such names as Ave Marie, White Perfection, Ethel, Purity, Virgo Marie, Madame Vaucher, and some more; all of these have a dark horseshoe marking, or a stain of some other colour in the flowers, and when they decay the appearance they present is more objectionable than that of any other Geranium.

It is needless to mention the other flowering varieties of this family; rather let me explain what is wanted than repeat what we possess. We want a class with more blue in the flower, and I imagine this is more likely to be obtained through the pink section, of which Wiltshire Lass and Blue Bell are the types, than through the darker-coloured varieties, as Magenta, Celestial, Enchantress, and others. In these, I think the crimson predominates too much, but of that experienced hybridists will be better able to judge. There is one other class it would be wrong not to mention here, and that is those having the tips of the petals of a paler hue than the remainder of the flower. The lively appearance these flowers present, at least the few of them that I am acquainted with, seems to promise a useful future for them; but my knowledge is limited to two varieties, having only grown in any quantity Eugénie Mezard and Rosy Circle, both light-coloured. I think light ones will be best, as anything that tends to soften the brilliant hue of the scarlet must be detrimental to its effect unless it be close to the observer.

Of the class of salmon and dull red colours, I find that Mr. Fish still grows Rubens, a variety some sixteen or seventeen years old, and yet good. I hardly know how much further back to go for one of this colour, as it did not become popular until that time, since which there has been no lack of varieties. One of my greatest favourites for some years was Indian Yellow, also another of poor Beaton's, but Hector, Mrs. Longman, Striking, and some others, although not properly salmon colour, are all good in their way; whilst amongst the rose-tinted class I also find Mr. Fish has returned to old Trentham Rose, after having tried many more recent kinds. I myself hardly know which to give the preference to in this class, as they seem to merge into the darker hue so imperceptibly. When such as Duchess of Sutherland, Dr. Kirkland, and others put forth their claims, I must leave somebody else to choose one from amongst them, none having of late years appeared so pre-eminently popular in this way as Stella and Tom Thumb were among the Scarlets.

We now take a glance at another section of the great Geranium family, and one which somehow has made less progress than the other—namely, the Silver-edged class. Specimens of this were in cultivation more than forty years ago, and no great improvement was made for some fifteen or sixteen years, during which time the plant was little used for bedding purposes. One called Jackson's Variegated became known about 1848, or before, and with an older one did duty where Mangles', which dates back to about 1843, was thought unsuitable. The colour of the flower of these old white variegated kinds was not very good, and a good scarlet and a plant of better habit was much desired in 1850 or 1851. These qualities were presented to us in Flower of the Day, a variety still in cultivation, but considerable improvements have been made since then. Flower of the Day was in great demand at the time, and, perhaps, next to Golden Chain and Mrs. Pollock, was more grown than any of the leaf-class; but rivals to Flower of the Day were soon forthcoming. Osborn's Brilliant surpassed it by many degrees in the brilliancy and abundance of its flowers; in fact, I believe I am speaking within bounds when I say that Brilliant has never been exceeded for abundant blooming. It is also one that Mr. Fish recommended to a great extent. As a bloomer, Brilliant occupied a higher position then than it at present does, for its foliage is hardly white enough, but the habit is dwarf, while at the same time it is a free grower, and a greater number of cuttings of Brilliant can be put into a box, pot, or pan than there can of any other kind I know, and they invariably do well. Where a good white-edged variety is wanted to look well without flower, Bijou, Flower of the Spring, Shottesham Pet, Silver Star, Queen of Queens, and others, stand higher; but I confess to not being able to discern all the differences that are made in this class.

A sort widely different remains to be noticed, and that is the white-edged Oak-leaved, called, I think, Lady Plymouth. This is certainly so much different from the others, that I do not know I am justified in including it with them. I regard the Silver-edged Geraniums of vastly more importance than the Golden or Tricolors, or by whatever other name, such as Mrs. Pollock, Lady Cullum, and others are styled, unless they have to be examined close under the nose of the inspector, as at the distance of 20 yards the white-edged ones have a finer appearance, besides being much better grown in general, and more easily kept through the winter.

I now come to the Ivy-leaved section, a very distinct class, one I think capable of much further improvement, and from which I think it possible the coveted blue tints might be obtained as soon as from the Zonal. I cannot precisely say when this became common as a bedder, but it was known in plant-houses long before anyone attempted to propagate it in sufficient numbers to make a bed. There seems to be a greater liability in some of the varieties to this sporting than there is in the others, not in the foliage, but in the flower, a crimson becoming a pink, and *vice versâ*. The white, I think, is more fixed, and is a greater acquisition to the garden, as the display of flower on a bright sunny day, combined with the shining green leaf, produces a very showy effect. I think much improvement may be made in the variegated class. The sort called Golden possesses but little of that colour, and the tendency of the white-edged one, L'Elégante, to assume a bronzy hue in hot weather, is a defect rather than an advantage. Duke of Edinburgh is better, but I still think improvement may be made alike in foliage as in flower. I hope to see some of the hues of the Petunia exemplified, and after that by degrees a better lilac, lavender, and eventually a blue; but this is conjectural.

There is one more class which I ought to include in this sketch of the family, and that is the Golden-coated section. I confess entering on this part of the subject with much reluctance, for the twofold reason that I am no particular admirer of them, and because I am not sufficiently versed in them to say much about the respective merits of the kinds most in use. The Golden-edged Geranium claims a much higher antiquity than is often supposed. I certainly saw it before 1826, but for very many years it was confined to the collections of the curious, and certainly did not make its appearance out-doors until some time after the white-edged ones had been so employed. I am not sure but that the gardening world is not in a great measure indebted to Mr. Beaton for calling attention to the Golden Geranium as a fit and proper plant for bedding purposes. However this may be, I do not believe it has been so employed for more than twenty years, or, perhaps, so much. Golden Chain, the origin of which I cannot give, was the kind first in fashion. This was followed by Golden Circle, Cloth of Gold, Golden Fleece, and some others, until Mrs. Pollock made its appearance, giving altogether a new feature to the case, by supplying a third colour to the leaf. Of the popularity of Mrs. Pollock it is needless to speak, as it exists still, and, although the names of its rivals are legion, continues to retain its place. The importance of some other fine-coloured ones is that they are badly grown, of bad habit, or it may be miffy, or in some other way deficient in the qualities which are necessary for a plant to make way in the world, otherwise such varieties as Lady Cullum, Florence, Louisa Smith, Sophia Dumaresque, and Edwina Fitzpatrick, would be popular enough. When it is known that perhaps as many growers lose these kinds as propagate them, enough has been said. Mrs. Pollock is certainly better to manage than some of them. There is another class that may be carved out of this family which really do pretty well, and these are those having less pretensions to foliage display, but a more robust growth and tolerably good flowering qualifications, as Perilla, Refulgens, and Her Majesty. But the task of deciding on the respective merits of those which only lay claim to foliage attractions I must leave to some one else, since, having before said I prefer the Silver-edged class for bedding purposes, I fear I could not be held as impartial if I gave credit to individuals in a class which I have already condemned as a whole.

Having extended this paper to a greater length than was expected, I must sum up in few words what I have to say on the merits and demerits of Geraniums planted out in beds. In my opinion a single inspection is by no means sufficient to entitle a plant either to commendation or the reverse, but let it be watched the whole summer and its character duly chronicled—from the middle of June to the middle of October—and if this were done once a-week with each aspirant to bedding honours, it would be more easy at the end of the season to arrive at a conclusion as to the merits and shortcomings of each than to do so on one particular inspection. It is for this reason that I do not pay so much regard to the otherwise valuable remarks of the censors of the display at Chiswick. Seeing the whole at one time is not enough, unless there is a very great number of plants—say fifty at least of each kind—and even then the report would not meet all the requirements I hold necessary, as circumstances may have delayed the due flowering of one kind and improved that of another. A more prolonged observation of their qualifications is necessary to insure a just character. Neither is the appearance which plants in quantity make in a bed always to be depended upon. Nothing can be more fallacious than to go into ecstacies about the appearance which certain beds present at the end of August after a fortnight or more of fine dry weather. All Geraniums are then in their prime, and the very shyest bloomers are generally gay; but before a too hasty judgment is given, an inquiry into the past and a close inspection should be made, for it may very likely happen that the one the gardener of the place esteems most has fewest flowers upon it, and for a very good reason—the plants have been severely mutilated to supply cuttings, whence the paucity of flowers.

An instance of this occurred here during the present season. In a long ribbon border we have are two rows of Stella Geranium 350 feet long, or upwards. We wanted cuttings of these, but they were, unfortunately, taken off about one-half of the length instead of being cut from the whole of it. This occurred about the 1st of September, and although there are still plenty of plants left where the cuttings were taken off, it is easy to tell to an inch, by looking at one end, how far the cuttings had been taken by the smaller quantity of flowers. Now this is the same on beds; a good favourite kind is of necessity mutilated, and towards the end of the season shows it, but to condemn it for this would be wrong. It is advisable, therefore, on the part of those who would be judges, to make themselves thoroughly acquainted, not only with the treatment the plant has received during the season, but also the appearance it has presented at certain portions of it, as the good appearance very often presented in August and September ought not to be a sufficient guarantee that they have been in the same gay condition for months before that time.

This observation, though made here in reference to Geraniums, is also applicable to many other plants, and especially to such as Verbenas, on which there is the greatest mass of bloom. Few plants, indeed, continue to furnish that profusion of bloom that is often seen at one particular time for more than four months in the year, and it is the grower's duty to ascertain whether he would rather have them all in a fortnight,

or have them spread over the greater space of time indicated. —J. Robson.

SUCCESSIONS OF VEGETABLES.—No. 5.

SAVOYS.

Early Dwarf Ulm.—This heads quickly, forms very close hearts, and is of fine flavour. Sow 5th and 10th of March, and April 10th.

Dwarf Green Curled.—This likewise heads quickly, forms a good but not large heart, and is hardy. Sow in the middle of March and the third week of April.

Drumhead or Globe.—Heads very large, firm, and good, but not so hardy as the Green Curled. Sow in the second week of March and third week of April.

Feather-stemmed or Sprouting.—Habit of the Brussels Sprouts, the stems being covered with compact, small, Savoy heads, which are delicious. Sow in the third week of March.

Savoys require deep, rich, well-manured soil and an open situation. The seeds should be sown rather thinly, in order to produce sturdy plants, which should be pricked off when they have formed the second or third rough leaf, and be planted out while the stem is short. Plant in rows 2 feet apart, and the same distance from plant to plant. Early Dwarf Ulm should be planted 18 inches apart every way, and is the best kind for small gardens. Stir the ground frequently with the hoe, and earth up the plants when they are established.

The first sowing of Early Ulm will be fit for use early in September, and the first sowing of Green Curled and Drumhead from the end of that month up to Christmas. The second sowing of Early Ulm will come into use early in October, and the late sowing of Green Curled and Drumhead from the beginning of November until the warmth of spring causes the plants to start for flower. The Feather-stemmed Savoys come-in in October, but are the better of frost, and continue to yield delicious sprouts until late in spring.

BRUSSELS SPROUTS.

Scrymger's Giant.—Habit robust; height about 2 feet; sprouts firm and close, thickly set on the stem, and excellent. I do not consider it necessary to grow any but this variety.

Imported.—When the stock is good these form firm compact heads, but not so large as the former.

Roseberry.—Habit tall; sprouts firm, close, and abundantly produced.

The first sowing should be made in the first week of March under a south wall, and another sowing the second week of April. Prick-off when they can well be handled, and plant-out, before they become drawn, in good, deep, rich soil, allowing 2 feet between the plants every way. The ground should be well hoed and the stems earthed-up. Liquid manure may be applied between the rows to any extent in hot dry weather in August and the early part of September. When the heads begin to form on the stem, the centre or top sprout may be pinched out. This will encourage the growth of the side sprouts. The first sowing will come into use at the end of September, and afford a supply up to Christmas; and the second sowing will afford sprouts from the early part of November up to April.

Dalmeny Sprouts.—A hybrid between Cabbage and Brussels Sprouts. The stems are clustered with small Cabbages, or rather Colewort-like sprouts, which are very tender, and in flavour superior to Brussels Sprouts.

Albert Sprouts.—A hybrid between the Savoy and Brussels Sprouts. The stems are clustered with hearting, miniature Savoy-like sprouts, which are very good, especially after frost.

These Sprouts should be sown the second week in April, and should be treated the same as Brussels Sprouts. They are in use from October to April.

BORECOLE OR KALE.

Cottagers' Kale.—Tall-growing and robust; the stem surrounded with a great number of sprouts that are of good flavour. This kind is apt to sport much—at least a packet of seed produces a number of forms. I do not consider it desirable to plant any but the green-leaved plants. I do not plant any with the midribs of the leaves and stems of a reddish purple, for they are not at all equal to the green in flavour and amount of produce. Sow March 5th to 10th, and April 15th.

Dwarf Green Curled.—This is, undoubtedly, the hardiest and best.

Veitch's Dwarf Late Curled.—This is an excellent stock, and comes in late, being in good condition late in spring. Finely curled, very leafy, and hardy. Sow March 10th and April 15th.

Jerusalem.—A late or spring kind; sprouts thick and purple, which when 6 or 8 inches long are very tender and good. Sow April 15th.

Asparagus.—A spring kind, producing long sprouts or shoots, which when about the length of Asparagus shoots are very tender and good. Sow April 15th.

Melville's Variegated or Garnishing.—Habit of the Dwarf Curled. Heads various-coloured, transparent white or various shades of red, fringed with green or white. Sow April 15th.

Borecoles require the same treatment as Brussels Sprouts, but Cottagers' Kale should be planted 2½ feet apart, and the others 2 feet. The earliest sowings will come into use after the first frosts in October, and continue good until April, for after the heads are taken off a great number of side shoots will be produced. Of Cottagers' Kale the heads should not be cut until February. The second sowing will be in fine condition by Christmas, and will continue in use up to April or May.

The first sowings of Savoys, Brussels Sprouts, and Borecoles ought to be planted out from the 15th to the end of June, and the second sowing from the 10th to the 21st of July. Plants may be put in afterwards, but they will be of less growth, and not unfrequently occupy ground unprofitably.—G. Abbey.

GOLD AND SILVER FERNS.—No. 2.

In resuming my remarks upon these, I must impress upon my readers the necessity of keeping the fronds dry, or at least the syringe must never be used, otherwise they will present a wo-begone appearance.

NOTHOCHLÆNA.

In my former article I named a few species of the genus Cheilanthes, and I now wish to draw attention to a few equally beautiful plants which belong to its near neighbour Nothochlæna; and as my remarks upon the treatment necessary for Cheilanthes are equally applicable to Nothochlæna, it is unnecessary to recapitulate here.

N. trichomanoides is a beautiful species, which should either be grown in a basket or be planted in a recess in the fernery about level with the eye, as it is of pendulous growth. The fronds are from 12 to 18 inches in length, pinnate, with the pinnæ roundish and dark green above, whilst their under side is clothed with white stellate scales. These change with age to a reddish brown, and are in addition dusted over with a mealy powder. The sori are black, and form a marginal band round each pinna. This very beautiful plant is, as far as I am aware, peculiar to Jamaica.

N. rufa.—Another elegant species, similar in general appearance to the preceding, but the pinnæ are smaller and toothed at the edges; they are light bright green on the upper side, and the under surface is densely clothed with long, white, woolly scales. It is a native of Peru and Mexico.

N. lævis.—An erect-growing plant, attaining a height of about 12 inches. The fronds are pinnate; the pinnæ entire, roundish or somewhat cordate, dull green above, thickly covered with long, pure white, silky hairs, which become brown with age. A somewhat rare species, which should be grown in a cool house. Native of temperate parts of Mexico.

N. lanuginosa.—This most beautiful species is a native of Madeira, but still somewhat rare in cultivation. The fronds are erect, about 8 inches high, bipinnate, dark green on the upper side, whilst below they are wholly covered with very long, pure white, woolly hairs, which are very conspicuous beyond the margin. It must be kept in a cool house and not be watered overhead, although it enjoys a copious supply at the roots with good drainage.

N. Eckloniana.—An extremely rare species, and one of the handsomest in the genus. Fronds tripinnate, when well grown a foot high, produced from a creeping rhizome. When young they are clothed on the under side with a profusion of very long silky hairs, which ultimately turn brown. It must be grown in a cool house. Moist heat will soon destroy it. Native of South Africa.

N. canariensis.—This is a superb plant, and from the numerous specimens I have received from Teneriffe and the adjacent islands it would appear to be by no means rare. Its usual height is about 18 inches. The fronds are ovate-lanceolate in shape and bipinnate; the pinnules blunt, their upper side deep green, whilst the footstalks and under side are heavily clothed with long dense golden red scales, which in old fronds become of a deep reddish brown. Its great beauty and distinctness should secure it a place in every cool fernery, but it must never be syringed.

N. sinuata.—A species nearly allied to N. lævis, and by some considered synonymous, but sufficiently distinct in cultivation to warrant a separate name. The fronds are from 12 to 20 inches long and pinnate; the pinnæ somewhat oblong and deeply lobed at the edges. The upper side is bright deep green, and the under surface clothed with white and fawn-coloured woolly

hairs. It comes from warm parts of Mexico, and in winter should be placed in the stove.

N. FLAVENS.—An elegant plant, perhaps better known as N. chrysophylla, but as the true N. chrysophylla is not yet in cultivation, the name is erroneous. Strictly speaking, I prefer placing it in the genus Cincinalis, but have retained it here for the sake of uniformity. The fronds are tripinnate, 9 or 10 inches high, supported upon slender black footstalks; pinnæ distant, somewhat cordate, deep green above, covered below with a rich golden farinose powder. It requires stove heat, but should never be syringed. Native of South America.

N. NIVEA.—This is another most elegant species, similar in habit to the preceding, and, like it, should be placed in the genus Cincinalis. It differs from N. flavens in having the under side of the pinnæ covered with a snow-white farinose powder, making it a superb companion for the last-named kind, as it requires exactly the same treatment. It comes from South America.

GYMNOGRAMMA.

This is the best known, and consequently the most popular genus of Gold and Silver Ferns. The species here named are similar in general culture, therefore I shall not attempt to describe each separately. They grow from 12 to 30 inches high, in some instances more, with elegant bipinnate fronds. The kinds I name all require stove heat; some of them are rather delicate during winter, and require to be carefully kept from dampness upon the fronds. The soil which I prefer for them is peat and sand, with just a sprinkling of light loam. Although potted in such compost they require frequent and careful watering, therefore drain the pots well that no stagnant water may remain about the roots; above all, never use the syringe, otherwise the appearance of these usually beautiful plants will be utterly spoiled, through the farinose powder with which the under sides of their fronds are covered becoming splashed and dashed over the whole surface, and it is this brilliant powder which is their great attraction.

The following are the most attractive kinds in cultivation. G. calomelanos, silver. G. Pearcei, silver. G. peruviana argyrophylla, silvery on both surfaces. G. pulchella, silvery. G. tartarea, silvery white. G. Wettenhalliana, silvery white on both surfaces, with tasselled fronds. G. chrysophylla, rich gold. G. chrysophylla Parsonsii, rich golden, with tasselled fronds. G. Parsonaii gigantea, a very large and grand form of the preceding. G. Laucheana, a larger and freer-growing plant than G. chrysophylla. G. L'Herminieri, a somewhat rare plant, light golden yellow, very beautiful. G. sulphurea, an elegant small-growing species, delicately dusted with sulphur yellow.

ONYCHIUM.

O. AURATUM.—This belongs to a small genus, and is far too little known. It is a stove plant with much-divided fronds, the segments being narrow and very graceful. The upper side of the fronds is bright green, and the fruiting fronds are of a golden yellow on the under side; this arises from the indusium being of that colour, and as it is very large in proportion to the size of the pinnules, it nearly covers the entire under surface with its rich colour. It is a good exhibition plant, and is well adapted for cutting. It succeeds best in a mixture of about equal parts of loam, peat, and sand. Native of the Malay Archipelago.

CYATHEA.

C. DEALBATA.—With this plant, the Silver Tree Fern of New Zealand, I shall draw my brief remarks to a close. It is undoubtedly the most beautiful species of the whole family of Cyathea, forming a fine stem, which supports a large feathery head of fronds, which are bright green above and silvery white below. It grows admirably in a cool house, and I have little doubt but in some sheltered dells in the southern and south-western counties it would stand in the open air. For soil it requires peat and loam in about equal parts, with a liberal addition of river sand, and it will bear the syringe to be used upon it, as the beauty of the under part of the fronds is not easily removed.—EXPERTO CREDE.

LATE RIVERS PLUM.

THE culture of a numerous collection of young fruit trees is a work of much interest. The vigour and habit of a pyramidal Late Rivers Plum, planted last autumn, are so good as to be worthy of mention. This tree when it came into my hands was already well furnished with shoots, and when these were shortened for planting it measured nearly 6 feet high. It is now a picture of health, being nearly 12 feet high and 9 feet in diameter at its base; all the leading shoots from the base upwards bristle with stout little laterals, and the leading shoot of nearly 6 feet is as well furnished. I have not seen enough of the fruit to enable me to form an opinion, but I believe it is a valuable late kind. Certainly the growth of this tree greatly surpasses that of several other varieties of Plum planted near it in precisely similar soil, and attended to during the season with equal care.—EDWARD LUCKHURST.

ELECTION OF THE ROSES—GLADIOLUS FAILURES.

MANY thanks for giving us the result of the Rose poll. I quite concur with the eminent rosarians who have placed the first eight in the positions they hold; yet I rather wonder that Princess Christian is unmentioned. I think I should have voted some of my favourite Teas into a higher position. I sought in vain for Madame Falcot, Rubens, and Moiret. In some letters which I have seen in the Journal the following remarks have been made and questions asked. First I am glad to say that on the Manetti stock Louis Van Houtte has with me shown no want of vigour; on the contrary, it has been quite as strong as any other dark Rose I have except Pierre Notting. Marie Baumann has not been so strong as Alfred Colomb, but on the Manetti stock has done well; it has failed entirely on the Briar, while Alfred Colomb has been best on that stock. I find Madame Margottin very vigorous both on the Briar and Manetti; I think it a first-rate Tea. With regard to Homère, I consider it as hardy as Gloire de Dijon, and very vigorous on both stocks; it should, however, be disbudded if good flowers are wished for.

A correspondent some weeks ago mentioned L'Enfant Trouvé and Madame William as identical; now I grant that the flowers are very similar, but the wood and habit are very dissimilar. L'Enfant Trouvé has weak wood more like Narcisse, and creeps along the ground; Madame William is much more vigorous, and throws up its trusses well over the foliage.

I have this year seven hundred Teas in the open ground; if they stand the winter we seem likely to have there will no longer be any question as to hardiness.

Last year I spoke in favour of Early Rose Potato. This year I must retract all I said. This wet season it is useless—much diseased, and the sound tubers unestable.

I have this autumn, during the first and second weeks of September, picked dishes of Strawberries, second crop, from Vicomtesse Héricart de Thury.

Will Mr. Dombrain, Mr. Douglas, or some other grower of the Gladiolus, tell me whether bulbs which have not succeeded this season will be of any use next? I bought a hundred bulbs from one of our greatest English growers; I treated them most liberally, and gave them all the attention I could, but I had not a decent spike in the lot. I blamed the bulbs, the vendor blamed the soil. I have taken great pains in preparing a bed for this year; now what I want to know is, If the bulbs were ever good, will they recover; and may I expect good spikes this year?—STIFF SOIL, *Somerset*.

LAPAGERIA ALBA.

ON referring to some of the back numbers of this Journal, I noticed the directions given to a correspondent, "T. H.," for sowing the seed of Lapageria alba (see vol. xx., page 168). I trust he has been successful in his attempts to increase the stock of that truly beautiful plant, at present so small as compared to that of the rose-coloured Lapageria.

We have two plants which, after flowering profusely in the autumn of 1870, set one pod of seed each. These ripened early last summer, and there were eighty-three seeds in each pod. The first lot of seeds was sown on the 2nd of June, in a pan, which I thought more convenient than single pots on account of the less space it would occupy. The first signs of germination were noticed at the end of a month, and in a few days upwards of fifty seedlings were to be seen. On June 19th the produce of the other pod was sown in a similar manner, but only fifteen seeds germinated. As soon as the seedlings were large enough to handle they were placed in small pots, and are now nice little plants, many of them breaking from the base, all that is now required being time and the patience requisite to test their qualities.

Those who are fortunate enough to possess this lovely gem will be amply repaid for bestowing on it a little extra care and

attention, because during the autumn months its milk-white wax-like flowers can scarcely be surpassed in richness and beauty.

The manner in which we grow the white Lapagerias is very simple. They are placed on a stage in an early vinery, strong string is attached to the pots and carried to the roof, up which the young shoots twine with great rapidity. No tying is needed, for they naturally support themselves, and if permitted would soon form a mass at the top; this, of course, is prevented in order to give the growths every chance of ripening. As soon as any signs of flowering appear the shoots are taken down and regulated on a trellis, which may be of any shape according to taste, the result being a profusion of flowers for the decoration of the conservatory, and lasting a considerable time.

In the same manner are grown a few plants of Lapageria rosea. I have no doubt that by planting it and the white kind together a grand effect would be obtained when both were in flower. During the growing season of the Lapageria it is important to give plenty of water, and if care be exercised to secure good drainage, it will endure any amount. Perhaps its worst enemy is the slug; therefore, a good look-out should be kept to prevent the ravages of this destroyer, for when the young shoots are just emerging from the soil, slugs will often eat them off as fast as they appear.—C. J. W., *The Gardens, Ferniehurst.*

ELECTION OF ROSES.

[Not being by ballot, we publish the vote-papers.]

I have been asked to publish the lists sent by each of the different electors with regard to the election of Roses which appeared in your Journal of the 7th of December. I did not send them before, as I thought they would occupy too much space, and the analysis arrived at by simple arithmetical figures was, after all, the most important part. As, however, nearly all Rose-growers have their favourites, they will be glad to know which of the electors have supported their candidates. I have made two mistakes. Baron Haussman was twice mentioned instead of once, and I have put down in the list of names only once named both Lælia and Louise Peyronny. I did so from copying out the lists accurately, though strictly speaking we must consider them as identical, and consequently will give Lælia two votes.

On looking over the lists I find I am the only one naming Henri Ledechanx among the second twenty-four. This has a little surprised me, though I believe it partly because in some of the lists it was spoken of as a beautiful button-hole Rose, and many amateurs would not go to the trouble of buying and testing a button-hole Rose. With me the colour was very perfect—a true deep pink, a brighter colour than the old Jules Margottin, and a better-shaped Rose. I shall be glad to know what Rose-growers think of it after another year's trial.

Will some one else kindly give their experience with regard to Madame Chirard? as no one seems to mention it besides Mr. Radclyffe. Marie Baumann undoubtedly holds down its head, which does not make it look so well when growing on the tree, but I know no Rose to equal it when picked and put into a specimen glass on the drawing-room table; for, lovely though Madame Furtado may be, it cannot in my mind compare with Marie Baumann, and, given ten trees of each kind, I would guarantee to cut ten times as many good blooms from Marie Baumann. With me this year it has made shoots 3 or 4 feet long from the ground, even where cut down by the frost.

Mr. Baker, in sending his list of Roses to me, said he certainly would put Paul Verdier into the first twelve if it had been a Hybrid Perpetual. Has it ever been known to bloom a second time yet? and if not, why is its name still retained among the Hybrid Perpetuals?

I quite agree with Mr. Dombrain, we do not want the name "Remontant;" it is no improvement on the old one, or rather that which we have.

We are threatened with a great inundation of Roses next year. Does anyone know anything about them? If I might suggest a hint to hybridisers, we want to cross Roses of opposite habits not too nearly allied in blood, as Charles Lefebvre with La France, Alfred Colomb with Baroness Rothschild—to take the best Roses, in short, of distinct types. We still want a white Alfred Colomb.—C. P. Peach.

LARKFIELD RIVAL PELARGONIUM.

Some months ago I contributed to the Journal a short list of Show Pelargoniums adapted for forcing, and I specially noticed the usefulness of Larkfield Rival for the purpose. Further experience confirms my opinion of its merits, and leads me to the conclusion that it is the best forcing variety of Pelargonium that I have ever grown or seen. I considered it so manageable that I determined to attempt flowering it at Christmas. I accordingly ripened plants of this and other varieties, and cut them down the first week in June. I grew them in the open air during the summer months. Larkfield Rival and Crimson King are now in beautiful bloom. The latter, though not bright even when at its best, is more than usually dingy now, and is by no means a striking object in the depth of winter, but far otherwise is the former. Its glistening white is more than usually clear, and the delicate touches of pink in the upper petals add to its attractiveness. On entering the house it is the plant of all others that catches the eye of every visitor.

The above facts are tolerably conclusive evidence of the value of Larkfield Rival as a winter-blooming plant for greenhouse and conservatory decoration. So far from its having a drawn and unnatural appearance, it is more than usually sturdy. The flowers, to the number of four, five, or six on each truss, are borne on stout stems not more than 4 inches in length, and rest just over the foliage. From a florist's point of view it possesses little merit, perhaps, and this is why it may not appear in trade lists; but if it is wanting in circular outline, it is not so in general effect and usefulness, qualities which, to the majority of gardeners, are of equal, if not of greater importance than outline. I found the plant here upwards of six years ago, and confess I thought little of it. Since that time the addition of other varieties has rendered occasional weedings necessary, but now I would sooner part with any Pelargonium on the place than with this. Grown in quantity for early blooming few plants are more easy to flower and could be more useful, and where cut flowers are in great request few would be more admired in winter and spring. No doubt there are other varieties amenable to the same treatment—ripening and cutting down early—and which would be useful for winter flowering. It is not exactly forcing, but simply taking advantage of their natural precocity and indulging them accordingly.—J. W., *Lincoln.*

CELERY RUNNING TO SEED.

On the 28th of February I sowed four pans of Celery in good rich compoet, and placed them in a small frame with very mild heat. They were —No. 1, Cole's Incomparable; 2, Cole's Crystal White; 3, Cole's Defiance; 4, Ivery's Nonsuch. The four lots were pricked into boxes on April 26th, again pricked-out into beds June 6th, and finally planted-out, Nos. 1, 2, and 3, July 6th, and No. 4 July 15th. In all the stages, from the first sowing to the final planting-out, they were treated with old stable manure, mainly from a Cucumber frame, and fowls' dung, had occasional waterings of liquid manure in the earlier stages, but nothing after the final planting-out, at which time they were all fine and apparently healthy plants.

No. 1 turned out beautifully solid and crisp, and was gathered from the middle of September to the middle of November. Nos. 2, 3, and 4 are all gone to seed, or, when they have not actually seeded, are mere hollow canes. The lots are side by side in the same ground, and I know of no difference in their treatment from first to last.—Subscriber, *Cartmel.*

[We should say that the fowls'-dung liquid manure when the plants were young would be apt to accelerate the seeding process; but the chief cause of failure we consider to be not so much such watering in the earlier stages, "but nothing after the final planting-out in July." In the hot weather the plants would have required a good many drenchings after that. In the current volume the causes of Celery bolting have been frequently referred to. Bear in mind that Celery is a ditch plant, and you may never be so disappointed again. We have not seen a run head yet.]

Weeks' Pocket Book and Diary.—Messrs. John Weeks and Co., of Chelsea, have again issued their annual Pocket Book

and Diary, which for all gardeners will be found a very useful pocket companion. Messrs. Weeks say, "Not merely as a trade announcement do we circulate amongst gardeners our annual Pocket Book and Diary, but especially with a view to promote the habit of keeping a daily record, or garden memoranda, of sowing, planting, treatment, temperature, changes, and notes of general information, giving practical results from past experience, which can hardly fail to serve as a useful reference for future operations, and thereby reduce to method and order that which too frequently has been carried out by the 'rule of thumb.'"

WINTERING GERANIUMS—SANTOLINA INCANA.

Thinking it might be useful to some of your readers who have Geraniums to keep and have not the best of convenience for the purpose, I write to mention the following circumstance.

To the south-east of the grounds here is the river Dysyni, near which we have a pretty cottage, with a verandah running round three sides, supported by rustic pillars. Under the verandah, which of course is quite open at the sides, we plunged some Trentham Rose and Tom Thumb Geraniums in pots. For the last six weeks they have had no water, and though so near the river, where the air is generally much colder and moister than on the higher ground (we have had 12° of frost), yet the Geraniums are quite as fresh as in September, thus showing that if kept dry they will endure a much greater degree of cold than if kept constantly saturated with water.

I can endorse what Mr. Luckhurst says of Santolina incana (page 313), except as to its being perfectly hardy. In Montgomeryshire, in the Severn Valley, I planted several plants on a rockery, but they quite succumbed to the severe winter of 1870-71, when we had 34° of frost. I may mention that the rockery was in an exposed position, and that plants in a cold frame with a little covering passed the winter safely.—George Cooke, *The Gardens, Peniarth, North Wales.*

DESTROYING AMERICAN BLIGHT, MOSS, AND SCALE.

Where American Blight exists on trees I recommend as the simplest remedy thoroughly coating them with fresh limewash, by means of a brush or an old syringe. At this season, and in a frost, the insects go down into the ground. Baring the roots and watering with ammoniacal liquor, or, what I have found as good, dusting all over with a layer of fresh lime and soot, will to a considerable extent destroy the insects. Simplest remedies are often the best. Turpentine, oil, and other liquors will kill the insect when they fairly reach it, but they often more or less injure the wood. Even if none of the insects appear on the trees now, if they do so in summer they will leave their eggs and young behind, and these may be found on turning up a piece of loose bark in the knots, where they are fond of congregating. The safest application I have used is fresh limewash, which, applied now, and again before the buds swell in the spring, will generally destroy the insects without injuring the trees. I have applied it to the bole of a tree and some of the larger branches in the summer, and found that the insects were almost destroyed. The powder of the lime, even when it has become mild, annoys the insects, as it rolls and falls about them. The limewash will also prevent the birds from picking the buds. The whiteness seems to deter as well as the mere action of the lime, for the caustic alkali ere long becomes no better than so much chalk.

For destroying moss on trees nothing is better than a good application of limewash made with salt water. It is tedious to use a brush, but a good barrel of fresh limewash may be quickly made by powdering the lime, passing it through a fine sieve, and then pouring water on it through the sieve, or a rough canvas bag that will let no large pieces of lime pass through. Then syringe the trees all over with the thickest wash by using the jet of a syringe. This also will help to scare birds, and all will be mild and sweet enough before the buds swell.

I find some of my friends have their trees so much affected with scale that the bark cannot be cleaned. Anything in the way of a paint that will smother the scale will be of advantage, as clay and lime paint; but one of the simplest and best remedies I have found is syringing or engining the trees with water at from 160° to 180° in a continued frost. The shoots will soon be encrusted in ice if a proper time be chosen; and if this ice coating remain, a large portion of the bark that is loose, and the clinging insects, will come away; there will thus be a chance of the bark becoming clean and healthy.—R. F.

FRENCH DESCRIPTIONS OF ROSES.

I can assure "D., *Deal*," that I never take offence at any impartial and candid *critique* on my contributions, but if I find any such to contain a misquotation or misapprehension of my meaning I claim a right to reply. The phrase to which I took exception was "*se tenant bien*," see page 333, not "*belle tenue.*" I am, however, willing to pass over this trifling difference. I was induced to believe that "erect" was not the meaning intended by the French Rose-growers from finding that the result did not tally with the description.

In reply to "D., *Deal's*," protest against the retention of "Remontant" in preference to Perpetual, I beg to differ from him *in toto*. I see nothing more ridiculous in telling Jack to water those Remontants than in directing the same useful individual to water the Perpetuals. It is far more probable that in actual requests of this kind neither word would be used. The protest is equally applicable to *depôt*, *prestige*, *souvenir*, *critique*, and many other useful words of daily occurrence, which are now as much at home with us as Perpetual, which at best is only a clumsy and floundering attempt at translation of a word for which we have not an exact equivalent. I am strongly inclined to believe, therefore, that the word Perpetual, as applied to the most important section of Roses, is as much "doomed" as the Briar upon which they formerly used to be much more grown than at present.—A. H. Kent.

CONSEQUENCES OF EXPOSING PLANTS TO SMOKE.

At a recent meeting of the Warrington Literary and Philosophical Society, Mr. E. Green, head gardener at Bank Hall, read the following notes on vegetable life in and about Warrington:—

The few remarks I am about to lay before this meeting will, no doubt, give rise to some differences of opinion as to whether I am correct or not in my observations. Let me say I have strictly confined myself to what has come under my personal notice with regard to the destruction of trees, shrubs, and plants by smoke and chemical vapours, and also in regard to certain plants that will not grow—I believe from natural causes.

I have lived in Warrington for twenty-five years; most of that time I have been employed on the grounds at Bank Hall, and I have paid considerable attention to the decay of vegetable life. Among the evergreens that are most severely injured by smoke, &c., are the Conifers. The Scotch Fir (Pinus sylvestris) has long since disappeared with us. So has the Spruce (Abies excelsa). About two years ago we planted one hundred young healthy plants; there are only a few now alive, and these are sickly. I have seen nice plants in other parts of the town gradually dying. The Arbor-Vitæs (Thuja occidentalis and Thuja Warreana), the Saviu (Juniperus Sabina), Lavender (Lavandula spica), Rosemary (Rosmarinus officinalis), Laurustinus (Viburnum Tinus), and Cotoneaster microphylla are among the plants that fifteen or twenty years ago flourished well with us but have now disappeared.

Among the plants that just exist are the Yew (Taxus baccata), several varieties of Heaths, the Sweet Bay (Laurus nobilis), Common Laurel (Cerasus Laurocerasus), and Portugal Laurel (Corasus lusitanica). The Cedrus Deodara and Araucaria imbricata we have not tried here, but I have seen them in the town, very meagre specimens; at the cemetery they grow tolerably well. The common Holly (Ilex Aquifolium), has grown very well till within the last three or four years, the tips of the plants are now dying. The Evergreen Oak (Quercus Ilex latifolia), has so far stood pretty well; so has the Box (Buxus sempervirens). Among the evergreens that flourish best is the Rhododendron; the plants here are healthy, flower freely, and grow to a large size, the only complaint is the foliage is very dirty. The Aucuba japonica is more vigorous than the Rhododendron, and grows almost under any treatment with us, but the very best of all is the Ivy, particularly the Irish Ivy (Hedera canariensis); this does not appear to be damaged in the least, beyond being dirty.

Among the deciduous trees and shrubs suffering most are the Mountain Ash (Pyrus Aucuparia), Service (Pyrus Sorbus), Beech (Fagus sylvatica), Hornbeam (Carpinus Betulus), Wych Elm (Ulmus montana), and several other large-leaved Elms. The Sycamore (Acer campestre), and the variegated Sycamore

have suffered very severely the last two or three years. During the present year the leaves have been three times suddenly destroyed, and the result has been that the trees put forth fresh, but very puny ones; the trees will certainly die before long if they continue to suffer the loss of foliage. The Birch (Betula alba), Poplar, and the Lombardy Poplar (P. fastigiata), are now suffering to some extent in various parts of the town. The Ash (Fraxinus excelsior), till two or three years ago was among the trees least affected here. The late Mr. Rothwell placed this tree among those most easily affected by chemical vapours; as it here stood so well the dense smoke for many years and now is so much affected, tends to show that though it will not stand these vapours yet it will stand black smoke pretty well. The Horse Chestnut (Æsculus Hippocastanum) a few years ago grew well and flowered profusely, but is now suffering severely.

I may remark that the fact of some sorts of trees, now sinking so rapidly, being able to resist the effects of smoke a few years ago, is a sign that there must be something in the atmosphere that there was not formerly, for some trees that showed little or no signs of decay through dense smoke are rapidly giving way. While the large Elms suffer, the common English Elm (Ulmus campestris) has so far proved to be one of the very best growing trees in a smoky atmosphere, retaining its foliage much longer than any other old-established tree that we are acquainted with. We have two years ago planted several Plane trees (Platanus occidentalis), and so far they appear to be the very best trees to suit this locality. The Common Oak (Quercus Robur) stands as well here as in the country. One that grew close to my cottage was cut down this spring, that was a good specimen of early-foliaged trees. We have two or three Turkish Oaks growing well. Among the others that stand well is the Tulip tree (Liriodendron tulipifera), common Laburnum (Cytisus Laburnum), and Lilac (Syringa vulgaris). The Mulberry (Morus nigra) keeps its foliage well. The Walnut (Juglans nigra) we have not got, but in Orford Lane it grows well. The Hawthorn (Cratægus Oxyacantha) and Elder (Sambucus nigra) are the very best of all trees or shrubs to withstand deleterious vapours. They grow near Widnes better than any other trees. I saw stunted plants of Elder, where the garden at West Bank formerly was, alive when there was scarcely a leaf of any other remaining plant to be seen.

I do not think it necessary to dwell on fruit trees beyond stating that the Red and White Currant trees have nearly succumbed. Black ones still grow. Gooseberries are getting worse; so are Apple trees; but Pear trees still grow well, only the fruit is dirty.

In softwooded flowering plants, though some of them grow very well, yet the flowers are unsatisfactory, with very few exceptions, among which are the Dahlia, Stocks, Pansies, Mignonette, Nasturtium, Lobelia, Ageratum, Pentstemon, Antirrhinum, and a few others. For the last few years I have paid some attention to variegated and fine-foliaged plants in the flower garden, and found this to be the best course to take to get a good display of colour, which is a fine substitute for flowers in a town atmosphere.

The Rose we used to grow well, but now it is very inferior. The Scotch Rose we have been compelled to destroy, it was so bad. The Chrysanthemum is also very inferior to what it was a few years ago. I may mention there is some variation under peculiar circumstances. For instance, a Laurustinus might be found somewhere in town, but not very healthy nor yet flowering freely, and even that in some dry place, or it might be a Yew tree in some screened or sheltered spot, but the notes I have given are from careful observations, and will apply to a large majority of plants in Warrington. If we get a little outside we find some improvement. As a sample we might take a walk from Bank Quay through Orford to the cemetery. At Orford we see the Fir has made very fair growth for a few years, but on inspection we find the growth has become more retarded every year. The same remarks will apply to the same trees at the cemetery, more particularly those on the Warrington side.

I will now for a few moments draw your attention to the general appearance of forest trees within a few miles of Warrington. Leaving that desolate place Widnes, and passing to Bold Heath, there we find trees in fair condition, but as we near St. Helen's Junction they are again bad. In this locality is a group of promising trees cut off in their prime. Near Earlestown is another group, healthy on the east side but injured on the west. At Bewsey the woods look pretty well, but between there and Earlestown they are very bad. Near Newton Bridge, in the valley round the lake, the trees look well; so they do at Kenyon. Crossing the moss through Rixton, High Leigh, Lymm, Grappenhall, Appleton, Walton, and Daresbury, trees look well on the average. So they do on the east side of Norton; but on the west, near Runcorn and Widnes they are severely injured, whilst at Widnes, St. Helen's, and Newton we find a very large number of trees entirely destroyed by chemical vapours. We also find some trees in other parts not looking healthy, but many of them never were anything but stunted or starved, through the unsuitability of soils or subsoils, or perhaps the trees were never properly planted, or the ground properly prepared. But when trees that once were vigorous become gradually destroyed, their leaves being injured from time to time, then we feel sure some chemical agent is at work; nevertheless, we ought always to be cautious in our judgment. Sometimes premature decay is laid to the charge of smoke when something else is the cause of it. I have seen a little of this. On one occasion there was pointed out to me a lot of young Firs, in which a few were dead. The dead Firs were not all together, but were intermixed with the healthy ones; they were diseased at the roots. I noticed that live branches of the trees around them were intermixed with those of the dead ones. All were of one variety. Had this been the effect of chemical vapour some portion of the adjoining trees would have been discoloured, while the other part which the vapour did not pass over and fall upon would have remained green. The sulphurous gas, or whatever it may be, passes over in a body, very often in a direct line, injuring only that plant, or portion of plant, on which it falls. Plants affected by smoke only gradually decline, when by deleterious gas the destruction is much quicker.

We must bear in mind there are natural causes even in Warrington, through which certain plants will not grow; it may be soil, subsoil, or air. This we find to be the case with Ferns. I have paid some attention to the growth of these plants. It is remarkable that some of the Ferns that grow within a short distance of town, I have not been able to establish in Bank Hall grounds, while others have grown successfully, and this experiment was tried nearly twenty years ago, before our atmosphere was so bad; so the success or failure was from natural causes. The following Ferns grow well with us:—Pteris aquilina, long established in Bank Hall gardens; most likely brought in among the peat used for planting Rhododendrons; Lastrea Filix-mas, L. dilatata, and Athyrium Filix-fœmina, all found with a short distance from town on every side, in some places very abundant, more particularly in Dallam and Burton Wood. Many varieties of these Ferns grow vigorously. Osmunda regalis is found at Dallam, Risley, and Appleton, in moderate quantities. A short time ago there was at Bold Heath an old marshy piece of land brought under cultivation by lowering the slope or bank of the marsh and digging and planting with Potatoes, wherein came several young plants of Osmunda, no trace of any old plant being seen, so I think we may conclude the spores must have long lain dormant, and when brought to the action of the air they vegetated. Among those that grow moderately is Polystichum aculeatum, found in Bewsey; P. lobatum; Lastrea Oreopteris, found at Appleton, Penketh Common, Belman's Lane; Lastrea Thelypteris, Knutsford Marsh; and Lomaria Spicant, in the outskirts of the town. Onoclea sensibilis (American Fern), formerly grew behind Orford Hall, but is now eradicated. Among those that grew a few years and then died were Polypodium Dryopteris (I believe there is a plant of this kind growing near the Water Works, but I have not seen it), Polypodium Phegopteris, P. calcareum (not local here), Cystopteris fragilis, Lastrea rigida (chiefly mountain Ferns), Scolopendrium vulgare (Burton Wood), &c. Among those that live only two or three years are Asplenium Adiantum-nigrum (Winwick), A. Trichomanes (Appleton Park), A. Ruta-muraria (Penketh and Stockton Heath), Polypodium vulgare (very common), Asplenium lanceolatum, A. viride, Allosorus crispus, Ceterach officinarum. I have not seen these last four growing anywhere about here. The last I name is Ophioglossum vulgatum, found on the river bank below Atherton's Quay. I have taken great pains with this plant, and tried it on its own soil, even taken up with a large lump of earth, but in no way could I succeed. I have tried almost every British Fern, but many of them without success. We have still a few in pots that we have kept for many years in the frames, growing only moderately.

Some time ago we prepared a piece of land for bog plants collected on Risley, Woolston, and Rixton Moss; Heaths and a few others prospered for a few years, but the Sweet Gale (Myrica Gale) we could not get established. Though we do suffer, and suffer severely, from smoke and deleterious gas, we

must bear in mind that there are natural difficulties also to contend with, and that we should endeavour as far as we are able to pay attention to these obstacles, and try to grow in and around our town such trees as will grow best under the circumstances in which we are placed.

Mr. Paterson said no doubt a general opinion prevailed that it was to the smoke and chemical vapours in the neighbourhood the decay of vegetation was largely owing, but there were other causes in operation which would go far to explain the phenomena. For instance, the Fir was frequently found in a state of decay under circumstances that might be considered favourable to its growth, and which it was impossible to explain from any cause referred to. There was also another plant very susceptible to smoke—the Laurustinus. It was extremely sensitive to smoke and chemical vapours, and yet it grew vigorously in the immediate neighbourhood. In the case of Ferns there was a difficulty in associating the alpine with the common Ferns of the neighbourhood, inasmuch as they required a drier atmosphere. The failure in growing them was not, therefore, to be ascribed to smoke, but was due entirely to the altered condition under which these plants required to be treated.

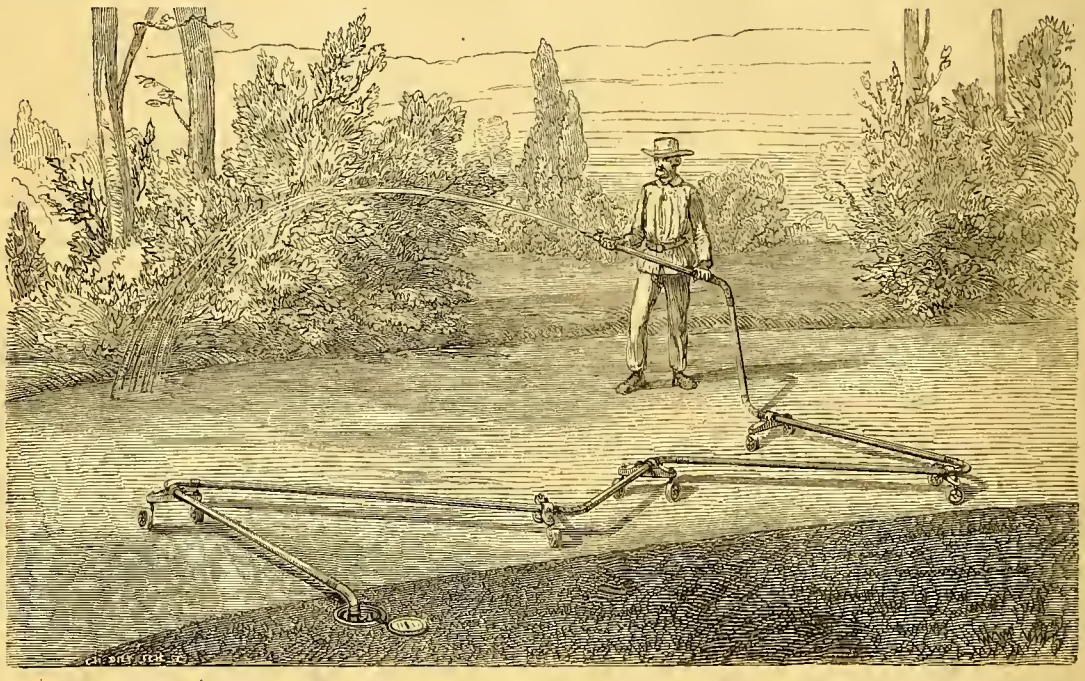
The Rev. J. B. Johnstone said, that when recently in Scotland, he observed several Larch trees had died in certain districts which were free from smoke and chemical vapours. No one could give the reason for it, and the curious thing was that trees of greater size formerly flourished on the spots.

Mr. Green, in replying to the remarks of the various speakers, gave the results of his observations on various forest trees in the Bewsey Valley, and said that he invariably found that the trees commenced to die from the west side.

"LES PROMENADES DE PARIS."

Bois de Boulogne, Bois de Vincennes, Parcs, Squares, Boulevards. Par A. Alphand. Paris: J Rothschild.

This splendid work is the substance, of which one with a somewhat similar title recently published in English is merely the shadow. All that talent in engineering skill combined with artistic ability and enterprise can effect, unite in making this



Watering Apparatus.

volume of M. Alphand the most complete, useful, and elegant which has ever been produced on what we in this country are accustomed to call Landscape Gardening and Groundwork. No one could have been better qualified than M. Alphand for the execution of such a production. His experience is that which few men have had the opportunity of gaining, for throughout the whole of the extensive works which have for so many years been going on in the construction of modern Paris, M. Alphand has been chief engineer, and most ably has he given to the world the result of his vast experience in this remarkable book.

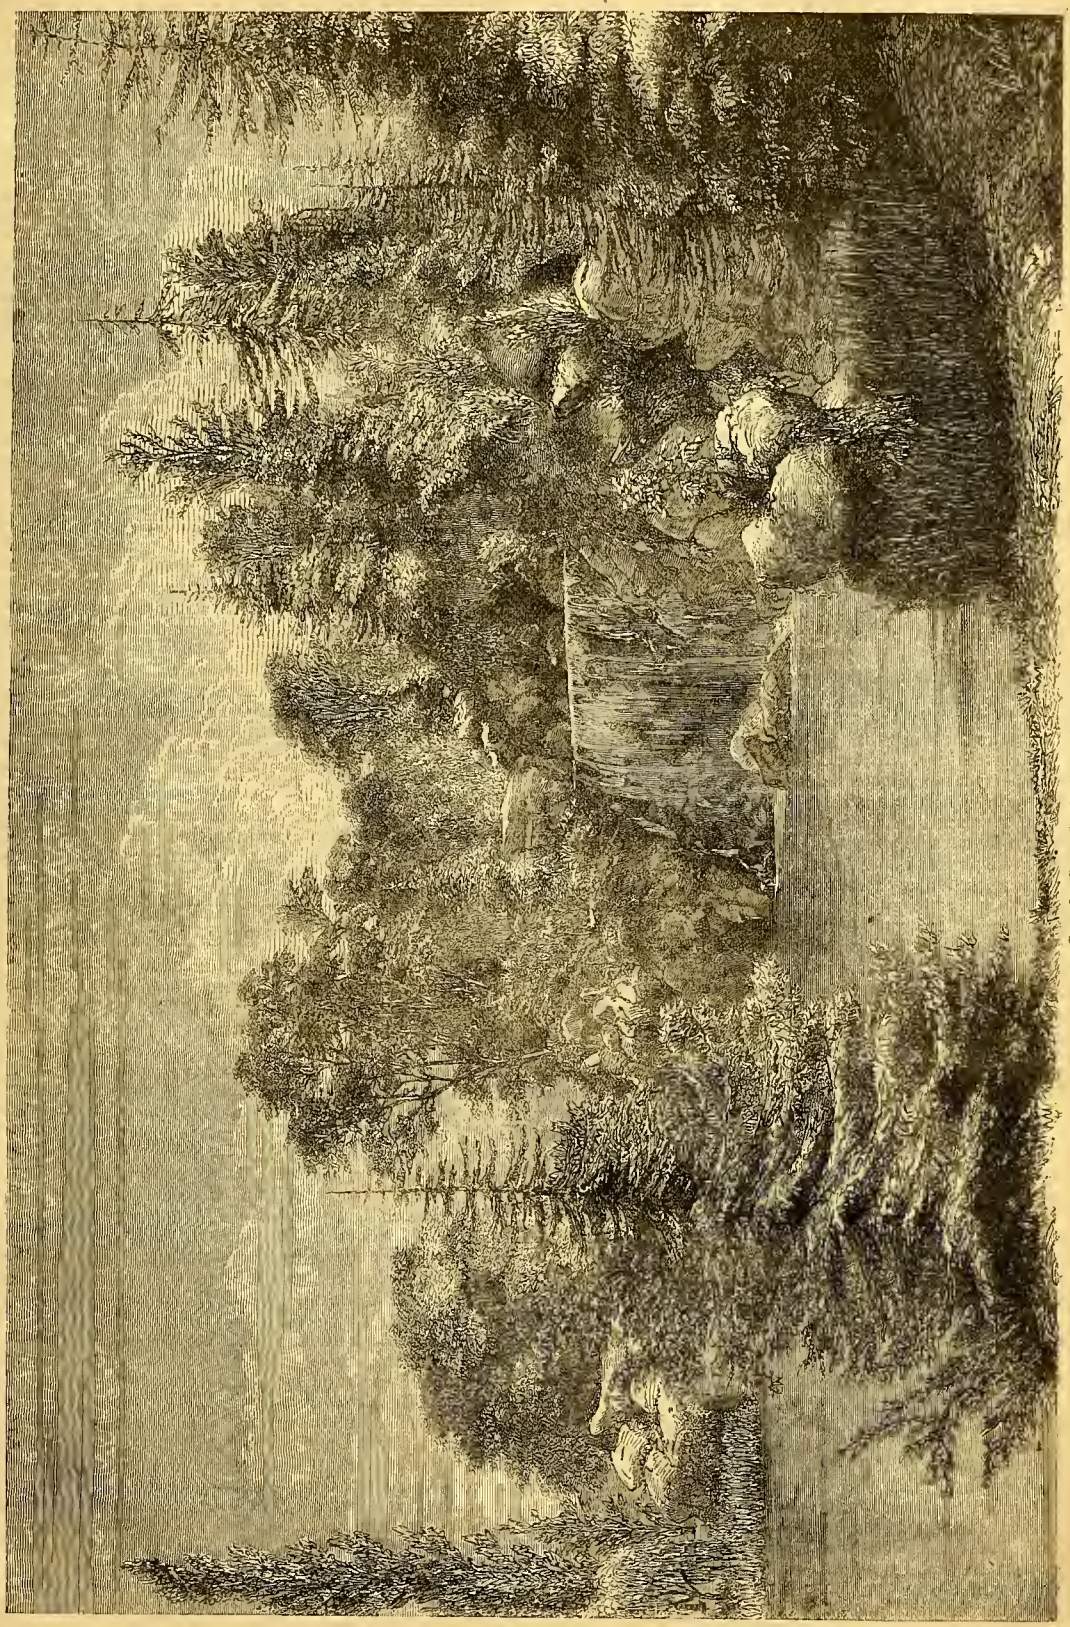
The work is essentially a *livre de luxe*, printed on paper akin in quality and substance to cardboard, and illustrated both by wood engravings and chromo-lithographs in the highest style of French art. We have recently given in our pages examples of these woodcuts, which were liberally placed at our disposal by M. Rothschild. The portraits of Palms with which our pages have lately been interspersed are taken from the sheets now before us, and we shall be enabled, through M. Rothschild's kindness, to furnish our readers with a variety of illustrations from which they will be enabled to form a slight, though very slight, idea of the quality and importance of "Les Promenades de Paris."

The first section is devoted to the Bois de Boulogne, and the first chapter of the section treats of the general description of the Bois and the works which have already been completed there; and what renders the information which is given so valuable is, that the details of the works are all illustrated and the entire cost of them is given. The third chapter treats of the roads and walks, of which every particular is furnished of the drains, the tanks, the ballast, the gravelling, and even to the edgings. In Chapter IV. we have a full account of the arrangements for supplying the Bois with water, in which the underground arrangements for conducting it and the hydrants are fully explained and illustrated. The figure which is here given represents the mode by which the roads and walks of the Bois are watered. M. Alphand says that formerly this operation was performed by means of water-barrels drawn by horses, and containing one cubic metre of water, which was discharged through a pipe behind pierced with holes; but since the introduction of the "lance," which is represented in the figure, the cost of watering has been reduced from 210,000 francs for six months' watering to 55,000 francs per annum.

Chapter V. treats of the lakes, sheets of water, rivulets, and cascades. The most important of the latter is the "Grande Cascade de Longchamps," of which we furnish an artistic representation taken from the original work. The waters which supply this cascade, reserved during twenty-four hours in the reservoir, are discharged at the fashionable hour of promenade in a

sheet 12 feet wide, and with a fall of 24 feet into a basin. Two lateral falls accompany the principal one, and the total delivery of water is 3000 metres cube per hour, or 800 litres every second.

We shall have occasion frequently to allude to this admirable work, but we shall at present merely content ourselves with explaining to our readers its style. It is in large folio,



Grande Cascade de Longchamps

printed on the finest paper, illustrated with hundreds of woodcuts, engravings on steel, and chromo-lithographs. It is published in parts, of which fifty-four out of the sixty-five, which will complete the whole in 1872, have already appeared. Each part costs 4s., but as a great number of the copies were destroyed in the fire at the Hotel de Ville, the price of £13 to subscribers for the whole work will be raised to £16 when it is completed. Up to the present time the Bois de Boulogne and the Bois de Vincennes are complete. There now remains Paris proper to be illustrated and described.

To all owners of estates, country residents, landscape gardeners, architects, and amateur horticulturists this work is an invaluable boon, and it ought to find a place in every public library.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Proceed with manuring and trenching, which are the principal operations at this season. Sifted coal ashes are excellent for the back walks as bearing the winter traffic well, and being always pleasant to walk upon; a coating may now be put on if they are in bad condition. *Beans* advancing should have the surface soil stirred, and the earth drawn over them. *Peas* sown on a warm border will now be peeping up; the surface soil should be stirred about them, and a covering of decomposed leaf mould laid immediately over the rows. If cutting winds prevail some branches of Spruce Fir or Birch on the windward side will be useful.

FRUIT GARDEN.

Pruning and nailing wall trees should be carried on with the utmost dispatch at every favourable opportunity. Trees infested with scale should be loosened from the wall entirely, the bark well scraped, and painted with a mixture of soft soap, cow dung, and lime, taking care to well work the composition into the crevices of the bark. If planting young trees or removing others has still to be done, attend to it at once. Let Gooseberry and Currant bushes be pruned on frosty mornings, or when the ground is in a dry state, so that it will bear to be trodden upon without injury. After pruning give the ground among the Gooseberry trees a good dressing of lime, which is useful as a preventive of their great enemy the caterpillar. Also wheel the manure necessary for the other small fruit bushes whenever a favourable opportunity occurs, and dig the ground that it may look clean and fresh. Where the Raspberry grub is troublesome, give a dressing of gas lime before digging the ground, taking care to apply it regularly about the base of the plants. The ground among fruit bushes should be dug very lightly, especially in the case of Raspberries, which have their roots near the surface, and it is better in all cases to dispense with digging, where it cannot be done without injuring the strong roots. The pruning of orchard trees of large size is much neglected in many places, the head being allowed to get so thick of wood that fruit cannot be expected save from the points of the outside shoots; and except when the crop is accidentally thinned to something considerably below an average, the fruit is small and of indifferent quality. Dry frosty weather offers an opportunity for properly thinning the heads of trees, as men can work at this with comfort when it is too cold for nailing. Cut out all branches which cross the others, and dead pieces, leaving the shoots sufficiently far apart that light and air may have free play among those left when the foliage is on. In removing large branches care should be used to make close clean cuts, and if the wood is coated with strong thick paint, this will help to prevent decay setting in before the wound is healed over.

FLOWER GARDEN.

Flower borders should now be top-dressed with some well-prepared compost, which should be forked in and the surface of the borders left as rough as possible. This will give them a fresh appearance during winter, and will be of great service in stiff soils, for the soil will be pulverised by the frosts of winter. From about standard Roses, which, by the weakness of the shoots and the paucity of their bloom this season, are showing symptoms of decay, the surface soil should be taken off down to the roots, and all suckers removed, after which a thick coat of well-decayed dung should be placed round them, and covered with soil. This applies with still greater force to those standards planted out in turf, in which case, taking it for granted that the turf is not nearer the stem than 18 inches, the soil should be removed as in the former case, and a good dressing of strong compost applied. If this be covered with flints or white pebbles, the unsightly appearance of the soil upon the turf will be obviated.

GREENHOUSE AND CONSERVATORY.

Many failures in plant-growing, and the sickly and drawn character of the inmates of greenhouses, may be fairly traced to the attempt to maintain a degree of artificial warmth incompatible with the amount of light. Heat as well as atmospheric moisture should at all times be regulated strictly in accordance with the amount of light. No prescribed temperature, even if stated by the most experienced, will answer well without some modifications founded on the character of the weather. For instance, a general temperature of 55° by day may be recommended for the conservatory through December, supposing it to be what a house of the kind ought to be—namely, filled with Camellias in flower, hybrid Roses, and a host of other gay subjects. This recommendation will be very suitable whilst the weather continues open, but if frost suddenly sets in the attempt to keep up even this moderate temperature will, from the construction of most houses, soon produce bad effects, provided the frost continues, more especially if accompanied by a dull and lowering sky. In such cases the experienced gardener will allow only the minimum amount of heat, and be content with an average of 45°. The attempt to maintain an unnatural degree of heat will, of course, require the assistance of a corresponding amount of atmospheric moisture, and this under ordinary circumstances will have a tendency to produce drip.

STOVE.

Some of the early-ripened tall Cacti may now be introduced either into the stove or the forcing pit, and receive a liberal watering to commence with. If, however, the blossom-buds are not well matured it is of little use forcing them. Do not encourage any fresh growth among stove plants at this period, rather aim at that kind of routine management which will serve to consolidate the growth already made, and to properly develope the blossoms of late-flowering plants. Great caution will be necessary during the next month to provide against drip. Many plants, such as Orchids, will make late growths in spite of system, and these, although not encouraged by improper temperatures, will be liable to decay if condensed vapour or drip be permitted to lodge in them. Where the heating apparatus is sufficient for the purpose (as it should be in all cases) a very free circulation of air may be encouraged, not only by day but also by night when the weather will permit. This is the best corrective after all to drip and the condensation of moisture.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

We laid a leaf over some young heads of Cauliflower to keep them from being stained by the litter. As the thaw has set heaps of leaves heating, we shall at the beginning of the week be preparing beds for Cucumbers, Carrots, Radishes, early Onions, Potatoes, &c., so as to get a little in advance. Now is the time for washing glass, cleaning houses, washing plants, tying mats, making tallies, sticks, and stakes of all kinds. Labled most of our forced Strawberry pots, to prevent confusion on the plants being again transplanted. Leaves that are heating require no turning, and plants must not be plunged in too great heat, or else they will be destroyed. For all delicate purposes, such as Cucumber beds, the leaves should be allowed to heat well before using them, so as to destroy all molluscs and spores that might be amongst them. We find a good plan to keep snails and slugs out of moss is to soak it in a barrel of very warm water, with a spadeful of quicklime well worked through it.

Laid-in a stock of Rhubarb, Sea-kale, and Asparagus roots for succession; these ought all to be kept well secured and damp. For out-door forcing nothing is better than an old barrel. A barrel set over a huge Rhubarb stool with the bottom end uppermost, and surrounded with a mound of leaves or litter, would yield a good many gatherings of early Rhubarb. Such a barrel bored with holes half an inch or a little more in diameter, in rings 6 inches apart, would hold a great number of roots of Dandelion or Chicory; the top of the plant is left outside the barrel, and the bulk of the roots inside, packed in damp earth layer above layer. This if placed in a dark cellar would furnish many a salad for the winter months.

As the weather became mild we took the opportunity of examining beds in the Mushroom house, and brought in material for making another bed. We could not do this during the severe

frost, as we feared admitting the frosty air. The sudden admission of cold air will stop the swelling of the very young Mushrooms, and in unfavourable weather it is well to cover a bearing bed previously to opening the house.

FRUIT GARDEN.

Preparing houses, and gently bringing on Strawberry plants in pots, have been the chief objects of our attention. Before much wet comes, the ground will be in good condition for planting. In all forcing the temperature should be raised very gradually, and the atmosphere of the house should be damper than usual until the buds break freely. One ought never to go to a fire or a furnace without previously noting the outside temperature, and not merely noting the temperature of the house, but also that of the pipe or flue. With such attention there will be little necessity for opening furnace doors to keep down draught and overheating. In order to avoid having sun heat meeting with strong fire heat, let the furnace get low as the sun promises to be bright. Tender plants are apt to be scalded or burned by neglecting to attend to this, and the admission of more air will often add to the evil, especially if the air is at all dry and frosty. Damping the floors and beds, and reducing fire heat are the chief means of safety, or even a slight shading for a short time, until the fair balance is restored.

ORNAMENTAL DEPARTMENT.

Walks should now be kept clean. The present is a good time for transplanting large trees, and also for planting in general. We would have preferred the end of October or the beginning of November for this, but we could not do it then. Planting too deep should be avoided. The collar of the plant—that is, the point whence roots descend and the stem ascends, should not be deeper than it stood before. Thousands of young trees are killed every year merely from sinking the stem of the plant from 2 to 4 or more inches deeper in the ground. The plant is thus made firm more easily, and so there is the temptation to indulge in it. Another cause of failure, is having the plants taken up and the roots exposed in dry frosty weather.

Pruning forest, fruit, and ornamental trees can often be best done in frosty weather, as then all branches can be taken away with less trouble. We have never observed that trees at all hardy felt pruning and cutting more in frosty weather than in mild weather, if all large cuts had the wound smeared over to prevent the damp penetrating.

Plants in cold pits and frames would be better where a little dry heat could be given them. Calceolarias, we think, do best in a cold pit or frame without any artificial heat. Once this winter our Calceolarias were covered up for about a week, and they did not seem to feel it at all. The first put in are lengthening a little; the last put in during November, after being exposed to much frost, are not yet moving. These cuttings have each about 1½ inch space, and therefore we do not want them even to root much until the days grow longer. A good deal of damp does them no harm. They had no air when shut up in the frosty weather. Other plants, as Scarlet Geraniums, though mostly covered up, had in the middle of the day a little air at the back to let out any damp. The moist atmosphere, and moist standing ground that would cause a Geranium to damp and shed its leaves, are the delight of Cinerarias and Calceolarias. When either of these begin to open their blooms the atmosphere should be somewhat dry, but at all times they prefer a moist cool bottom. One reason why Chrysanthemums often bloom better out of doors than they do when sheltered under glass, is because the air is more dry, and they are apt to suffer from dryness at the roots. We have often remarked how vigorously Chrysanthemums swell and open their blooms on misty mornings and evenings, and on very dewy nights. When under glass, before the blooms open, a free use of the syringe greatly helps them. Those who have only one glass plant house will see the importance of placing their plants in family groups, instead of distributing them regularly over the house. It would then be possible to vary the treatment considerably.

Florists' flowers in cold pits, as Auriculas, Carnations, Calceolarias, and Geraniums, had plenty of air after the change of the weather. On a sunny day we were glad to pull the sashes off; but in these dull, drizzling days, when air is even more wanted than when the sun shines, we gave a thorough circulation of air, and kept the damp out by raising the sashes back and front. This is a good plan in changeable weather, and when the plants must be left for some hours to themselves. A brisk shower of ten minutes might occasion an endless amount of trouble for months afterwards. With the exception of those alluded to, the majority of plants in cold pits can scarcely be kept too dry, so long as they are moist enough to be safe. Where no fire heat can be given to correct any excess of moisture in the earth or air, all watering in winter should be done with great care. In places where the intention is merely to keep plants alive, no water should be spilled, and it will often be wiser to allow the temperature to get lower than to use much more water.

In watering plants where fire heat is given, so as to keep an average temperature in cold weather of 45°, the water used should rarely be below 60°, and be given, when needed, as early in the forenoon as possible, that the plants may part with any extra moisture before night. Even in such houses the less the water is spilt the better. It is a very different affair in summer, when watering the floors and platforms does so much to improve the atmosphere of the house. All the varieties of the yellow-flowering Cytisus require plenty of water, and especially if at all underpotted, when opening their blooms.

Such plants in a stove house as Poinsettias, Euphorbias, and Justicias, either showing for bloom or in bloom, require also plenty of water, 70° in temperature. In such a house the spilling of a little water is of less consequence, as moisture will be required to prevent the atmosphere becoming too dry, and that which rises from the floor or pot is quite as healthy or more so than that which steams from evaporating troughs. We would sooner keep such a house ranging from 58° to 63°, than ranging from 70° to 75°, as a rise from sun heat is less to be regarded. With less fire heat the plants do better, less watering is necessary, and less moist vapour is required in the atmosphere. Mosses and Ferns should be kept tolerably moist, and the stove varieties thrive better during cold weather in a moderate than in a high temperature.—R. F.

TRADE CATALOGUES RECEIVED.

J. Carter, Dunnett, & Beale, 237 and 238, High Holborn, London, W.C.—*Gardeners' and Farmers' Vade-Mecum*, 1872, *with numerous illustrations.*

R. Bradley & Sons, Halam, near Southwell, Notts, and Rainworth, near Mansfield, Notts.—*Catalogue of Nursery Stock.*—*Trade List of Nursery Stock.*—*Abridged List of Roses.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*Q. Q.*).—The "Vine Manual." You can have it from our office if you enclose 2*s.* 7½*d.* with your address.

Marking Labels (*A Subscriber, Lanarkshire*).—The short-hand inscribing is almost as difficult as common figures, more difficult to remember, and the marks are so much alike as to cause numerous mistakes. Earthenware labels written on with a pointed piece of soft lead are very desirable, and easily renewed.

Nurserymen's Catalogues (*Rev. P. D.*).—We cannot recommend, much less review these, for they are published in legions; but to your query, "Is Messrs. Carter's 'Gardeners' and Farmers' Vade-Mecum' useful?" we can reply safely it is very useful.

Keeping Pears (*D. F. J K.*).—The specimen sent is Passe Colmar, and is just ripening. It is hardly time yet for them to be quite ripe; but the maturity may be hastened by keeping them in a warmer, but not a drier apartment Do not expose them too much to light. The specimen that you sent was delicious in flavour, and this was due, no doubt, to its having been "for the last week on the dining-room chimney-piece."

Self-acting Fountain (*J. K.*).—We cannot tell where it can be obtained. If advertised it would sell well.

Fungus (*J. J. Chater*).—Your Peziza is a new species, and at present undescribed. Its nearest ally is P. melaloma, from which it differs, in having no black fringe round the margin of the cup, and in other characters. We have seen the same plant before.

Vine in Ground Vinery—Pears for West of Ireland (*Far West*).—The Black Hamburgh Vine planted against a south wall will do well to train under a ground vinery placed at right angles to the wall. Shorten the shoot now, but do not transplant. A Peach tree will do in a ground vinery if trained as a horizontal cordon. It must be kept free from red spider by syringing during summer. Pears for cordons—Madame Treyve, Beurré d'Amanlis, Beurré Hardy, Beurré Superfin, Fondante d'Automne, Gansel's Bergamot, Louise Bonne of Jersey, Beurré Bosc, Marie Louise, Easter Beurré, Bergamotte Esperen, and Doyenné du Comice. Apricots would do well on your west wall.

Planting Vines &c. (*A Subscriber*).—Plant all your Vines in the front of your inside vinery border. Without artificial heat the Oranges and Lemons would not ripen to be of any use, especially as they would have no sun after midday. Murray (medium size), and Victoria (large), are excellent Nectarines for orchard houses, and of first-rate flavour. Of the Vines you name, White Frontignan, Black Hamburgh, Buckland Sweetwater, and Trentham Black would do best in the early house; Lady Downe's, White Tokay, Muscat of Alexandria, and Alicante for the late house, but they require in most seasons artificial heat to ripen them. We do not think you will have sufficient ventilation at the top of your vinery; you should have all the top lights made to slide. In some cheap houses short top lights are made to lift-up with hinges. No doubt fruit trees planted amongst shrubs would to a large extent be protected from frosts when in blossom. Either standards or pyramids might be planted, and space allowed for their development.

Lawn Levelling (*Black Edge*).—The best and cheapest plan would be to remove the turf from the uneven part, level the soil, and then relay the turf. You could certainly level it by putting on soil and sowing with grass seeds, but it would have a patchy appearance for years, and considering the cost of seed and bringing soil you would find it unsatisfactory. By taking up the turf, levelling, and relaying, the difference would not be great after a few mowings. The best place to get bone dust is of the agricultural manure dealers.

Mulching Border Bulbs (*Idem*).—Cocoa-nut refuse is the best material, and has an advantage over tan in being an excellent dressing for the soil. It may, however, be costly from carriage, but it is superior in appearance to stable dung, which has a very bad effect, and, indeed, is not tolerable unless covered over with soil. The bulbs you have yet to plant may be covered only an inch deep, mulching them with cocoa-nut refuse. Write to Messrs. Barsham & Co., Kingston, and ask for terms, stating the quantity required, and the place where it should be delivered. A good covering is 1½ to 2 inches, but we have put it on 3 inches thick, and not found it too much, as we practise shallow rather than deep planting, though the shallow planting compels us to mulch in order to protect from frost.

Gymnogramma (*M. S. B.*).—A temperature of 70° if maintained by night and day is too high; 55° to 60° at night is quite sufficient at this season, and 60° to 65° by day, with a rise from sun heat to 70° to 75°. The cause of the fronds being long is no doubt owing to the high temperature. To do well they should not be more than 2 feet from the glass, and the soil sufficiently moist to keep the fronds fresh. They should not be syringed overhead, but a moist atmosphere should be kept up by sprinkling the floors and walls. When growing they should have abundant waterings. The Adiantum farleyense is suffering from the great heat, and probably dry atmosphere. Keep it cooler and moister. The Poinsettias have cast their bracts from having been brought forward too quickly by the great heat. Afford more moisture, and lower the temperature to 55° or 60° at night, sufficient for nine-tenths of stove plants in the dull winter months. We could not account for the insect eating the Orchid flowers. Have you crickets, cockroaches, or slugs? Search at night with a lantern.

Fern Pillar (*Conifer*).—Any of the dwarf greenhouse Ferns described in the "Fern Manual" would do. We should prefer Isolepis gracilis to flowers, but it is a matter of taste.

Ferns for Window Fernery (*A Subscriber*).—You do not say whether your fernery will be heated or not, but we shall name Ferns that require frost to be kept out. You will not require nearly so many Ferns as you name, and only small kinds will be suitable. For the upper part of the rockwork:—Adiantum Capillus-Veneris; Asplenium Adiantum-nigrum, A. fontanum, A. Trichomanes; Blechnum Spicant, Cystopteris Dickieana, C. fragilis; Polypodium vulgare, P. vulgare cambricum, P. alpestre; Adiantum assimile, A. setulosum; Asplenium flabellifolium, A. monanthemum; Davallia canariensis, D. dissecta, D. novæ-zælandiæ; Drynaria pustulata, Hypolepis repens; Lomaria alpina, L. blechnoides; Microlepia hirsuta angusta; Nephrolepis lingua, N. rupestris; Platycerium alcicorne, Platytema rotundifolium; Pteris cretica albo-lineata, P. scaberula, P. serrulata cristata; Nephrolepis tuberosa, and N. lingua corymbifera. For the lower part the above-named are suitable, as well as the following:—Asplenium marinum, Athyrium Filix-fœmina varieties, Lastrea Filix-mas cristata, Polystichum angulare proliferum, Scolopendriums, Acrostichum palmatum, Adiantums various, Asplenums, Cheilanthes elegans, Cyrtomium falcatum; Doodia aspera, D. media, rupestris; Doryopteris palmata; Gymnogramma tartarea, G. ochracea; Lastrea acuminata, L. glabella, L. decomposita; Lomaria gibba, Lygodium scandens, and L. palmatum—the last two are climbers, let them form the sides of the entrance—Mohria thurifera, Nephrodium molle corymbiferum, Onychium japonicum, Polypodium pectinatum, Pteris umbrosa, P. crispa, and P. serrulata variegata. Few Ferns that will grow by the side of the dripping water. In a similar fernery as a last resource, had the pockets filled some with the common Liverwort Marchantia, others with Isolepis gracilis, and some with Cyperus alternifolius variegatus. At the base, where the spray of the falling water will reach, we have Trichomanes radicans on raised rockwork, Hymenophyllum tunbridgense, and H. unilaterale (Wilsoni), and they thrive well. Useful for filling any small crevices is Selaginella denticulata, but it must be kept within bounds, S. apoda, S. formosa, S. pubescens, and S. Wildenovi are also useful.

Planting Potatoes (*St. Edmond*).—The sets should be planted on their ends, eyes uppermost, in shallow boxes without soil one tier deep. Place them in a room with a temperature of 45° to 50°, and let them remain there until they have sprouted to the length of half or three-quarters of an inch. They should then be removed for a few days into a cooler spot to harden, and be planted during the first mild weather after the middle of February, though, should the ground then be wet and cold, it is well not to plant until the early part of March. Take out a trench about 6 inches deep, and line it with a 2-inch layer of well-rotted stable manure, place the sets upon it at the distance of from 10 inches to a foot, and cover them with soil to the depth of 4 inches. When the haulms appear protect them with spruce branches in frosty weather, but remove these in mild weather. Loosen the soil with a hoe when the Potatoes are well above ground, and earth them up when they are 2 inches high. The best early kind is Ashleaf, but Myatt's Prolific is a better cropper and only a few days later. The crop will be in at the close of May or early in June according to the season. The "Garden Manual" contains the information you want. It may be had from our office for twenty stamps.

Ampelopsis tricuspidata (*Rathgar*).—It is also known as A. Veitchi, and is a miniature-foliaged Virginian Creeper, equal to Ivy. It is quite hardy, and may be planted at any time; it is generally grown in pots. We consider that from the present time up to the close of March is the best time to plant. You can procure it from any of the principal nurserymen advertising in our columns. We cannot recommend dealers.

Adhesive Gravel Walk (*D. B.*).—Cover the walk with half an inch of gravel, rake it evenly, roll it well, and your walk will be firm and dry. Very loamy gravel will do well for walks in dry weather and these not much used, but in winter it clogs the feet. The right sort of gravel is small pebbles with just enough loamy matter to make them firm. The path is, however, better loose and without a surface in wet weather.

Frame for Cucumbers (*Cucumis*).—For growing Cucumbers the old-fashioned wood frame of two or three lights, and "set upon a heap" of sweetened fermenting materials is, in our opinion, better than pits; in fact, though we have heated pits, we prefer to grow our summer supply in frames on dung beds.

Plants for a Small Greenhouse (*Manchester*).—We think that Camellias, Fuchsias, and Lilies would suit you best, as most fine-foliaged plants require a considerable degree of heat, while you give very little. If we knew the size of the house and what you could now grow in it, we should be better able to advise you.

Lilium giganteum Sowing (*A. A.*).—Sow the seed now in well-drained pans, and fill with a compost of two parts fibrous loam, and one part leaf soil, and also one of sandy peat, with a sixth of silver sand. Scatter the seed evenly, and cover it a quarter an inch of fine soil. Stand the pans in a house where there is a warm greenhouse or a gentle hotbed, and keep the earth moist. Let them remain until they can well be handled, and then place them carefully in small pots. We prefer to sow the seeds of all bulbous plants as soon as ripe, and to place them in a house with warmth of from 5° to 10° above their proper temperature. We find they germinate much more speedily in autumn than at any other time.

Glazed Covering of Wall Trees (——).—If the Vine stem has been covered-up we do not think it is likely to be injured. The roots, however, would be all the safer if frost were kept out of the ground by a covering of litter, &c. There is always a little trouble with Vines thus taken out of the house and then put back at once in stove heat. It is much better if the Vine can be brought on a little in a lower temperature. All you can do is, when you take the Vine in to keep it close to the front, and give a little air there to keep it cooler than the rest of the house. We would put the lights against the wall when the buds begin to swell, and remove them as the fruit is towards ripening.

Vines in Inside Borders (*C. C.*).—In this case it is quite possible to have soil too dry. If the surface is dust dry now, it would be well to scrape off the driest portion, and if the soil is also dry beneath loosen it a little with the point of a stick, and apply enough of water at about 60° to make the soil moist, but not wet. After Christmas you may add the rich top-dressing, and give a very moderate watering, watering more freely in February with water slightly heated. This will induce a free action of the roots before the swelling of the buds, which begins about the middle or end of March. Pigeon's dung will do for surface compost, but neither that nor guano should be used freely at one time. We do not know the size of the inside border, but for four Vines we should think a bushel of poultry dung would be enough at a time, and about one-sixth part of a bushel of guano. Both are dangerous when in excess. It is as well that the hot pipes should not touch the ground. Unless it could be easily done we would not move the little stage out of the house in summer. You would have more reflected light if you allowed it to remain and painted it with limewash.

Boiler Unmanageable (*M. D.*).—In such a case as yours, you cannot empty the border except by inserting a screw 1-inch pipe at the bottom, furnished with a plug or tap to take the water out, while you supply fresh water to the pipes above. This will to a great extent clean the boiler. The furring of the boiler and pipes will to a considerable extent be prevented by placing an ounce of powdered sal ammoniac now and then in the water after powdering it. The upright continuation of the 4-inch pipe furnished with a plug, is no doubt intended as a means of filling the pipes and boiler. The small hole in the upper pipe near the farther end is, no doubt, intended for letting air out, and should be at the highest level of the pipe. A yard or two of gas piping half an inch in diameter, with the end left open, would allow all air to escape, and thus you would not need a peg there. Whilst it remains you must move it often, or air may accumulate and stop the circulation of the water.

Roses for Exhibiting (*A Subscriber*).—There is, we fear, no royal road to make Roses fit for exhibition by a particular week, as so much depends upon the character of the season in the months of April and May. The flowering may be retarded by late pruning, about the middle of March, in your situation, Somersetshire, but the spring months even then in Somersetshire are often so warm, it would be difficult to insure the best blooms so late as the last week in June. A few of the strongest-habited kinds removed both in November and in the spring, might give good blooms for exhibition, but as a general rule few Roses would stand the double removal. You might, however, by retarding the flowering by lifting Roses in October and planting again in good compost, with a winter's mulching, have very good blooms. We do not think lime adds to the brilliancy of the Rose; it is good to add to some vegetable soils to hasten decomposition. The soil which generally seems to give most brilliancy of colouring to Roses is one that has a fair proportion of ferruginous clay. Old lime rubble is a very good material to mix with heavy clay, especially if wet and tenacious. Roses on the Manetti stock ought to have all the wood more than two years old entirely removed. Two-year-old wood ought to be close-pruned, and the wood of the previous season left rather longer. If Roses on the Manetti stock are treated in this way they will push every year fresh wood from the ground. It is this habit which should be encouraged by entirely removing all old wood above the young shoots at the base. Be it remembered that nearly every Rose planted sufficiently deep on the Manetti stock is soon established on its own roots as well, and it is this which induces it to throw out shoots from the ground line.

Pæonia Moutan Transplanted (*An Old Subscriber*).—These plants will not require any water between now and March, when, if the weather be very dry, you may give a good watering, though we should not do this to any extent until the ground becomes warm and the plants from growing need a liberal supply of water. Heavy supplies of water early in spring, by rendering the soil wet and cold, often prevent recently transplanted shrubs from rooting well and making a good growth. Mulch the plants to the depth of 4 inches with some partially decayed leaves around and beyond where the balls extend. When the plants begin to grow, cut away the old branches and encourage young shoots from the base, watering copiously when the growth has well started.

Select Cyclamens (*Cyclamen*).—C. Atkinsi and vars. carneum and roseum, C. coum and vars. album and carneum, and C. græcum are all hardy and flower in winter and spring, requiring only a well-drained soil, shelter from cutting winds, and a slight shade in summer. They are fine subjects for pot or pan culture. C. europæum is also hardy, flowers early in autumn, and the flowers are sweet-scented. C. hederæfolium and its white variety flower in autumn and are quite hardy. C. vernum is also hardy, flowers late in winter or early in spring, and is a pale red variety of C. coum. C. repandum is the last to flower in spring, just as C. europæum is the first in autumn, having bright red flowers in April. It is also hardy, and needs a wall-drained spot and shade from bright sun. C. macrophyllum, C. nobile, and C. persicum vars. album, delicatum,

grandiflorum, odoratum, roseum, roseum coccineum, rubrum grandiflorum, rubrum coccineum, striatum, marginatum, pulcherrimum, and Fairy are all good and suitable for pot culture in the greenhouse. Seeds of the best strains of C. persicum may be had of most of the principal seedsmen, and a packet will produce upwards of half a hundred plants, and more than a dozen varieties, some with beautifully marbled foliage. Seed sown early in spring and forwarded in heat will flower finely in the following winter. Mr. Atkins is perhaps the best cultivator of the genus.

Phœnix dactylifera (*A Constant Subscriber*).—Apply to any of the principal nurserymen who advertise in our columns, and state what you need.

Select Chrysanthemums, Fuchsias, and Stove Plants (*M. H. B. L.*). —*Large-flowering Chrysanthemums.*—Ondine, Miss Hope, Beauty of Stoke, Meyerbeer, Princess Louise, and White Eve. *Pompons.*—James Forsyth, Madge Wildfire, The Little Gem, White Treveona, Fairest of the Fair, and Lizzie Helmes. *Anemone-flowered.*—Emperor, Marguerite de York, King of Anemones, Princess Thyra, Miss Margaret, and Marguerite d'Anjou. *Fuchsias.*—Avalanche, Blue Boy, Striata Perfecta, Formosa, Sultan, and Catherine Parr. *Stove Plants.*—Æschynanthus splendens, Allamanda grandiflora, A. nobilis; Alocasia metallica, A. macrorhiza variegata; Ananassa sativa variegata, Anthurium Scherzerianum, Aphelandra aurantiaca, Roezlii, Ardisia crispa elegans, Areca Verschaffelti, Bougainvillea glabra, Burchellia capensis, Clerodendron Balfourii, Cissus discolor, Cochliostema Jacobianum; Croton variegatum longifolium, C. irregulare, C. pictum; Dalechampia Roezliana rosea, Dieffenbachia Pearcei, Dipladenia amabilis; Dracæna stricta, D. ferrea, D. regina; Eranthemum pulchellum, Eucharis amazonica, Euphorbia jacquiniæflora, Franciscea confertiflora; Gardenia citriodora, G. radicans major; Gesnera exoniensis, Gymnostachyum Pearcei, Heya bella, Imantophyllum miniatum; Ixora acuminata, I. javanica floribunda; Lasiandra macrantha floribunda; Maranta illustris, M. rosea-picta; Medinilla magnifica, Pandanus elegantissimus, Pentas carnea, Poinsettia pulcherrima, Rondeletia speciosa major, Stephanotis floribunda, Thyrsacanthus rutilans, Tillandsia splendens, Torenia pulcherrima, and Vinca alba. We have named a few of both flowering and variegated, or fine-foliaged, plants. See them at the nursery, and select such as you like best.

Worms in Cricket Field (*Hon. Sec.*).—Worms may be destroyed by watering with lime water, mixing 25 lbs. of fresh lime in seventy gallons of water. Stir well up, and allow the liquid to stand two days and then water with the clear lime water, which will bring the worms to the surface, when they may be swept off. Roll the ground a day previous to the application. We question the propriety of destroying the worms. Worms assist the passage of rain through the soil by their holes, and to have a wet surface in a cricket field is worse by far than wormcasts. What is wanted is a dry surface, firm, and clothed with short herbage. Draining is the means of securing the first, rolling the second, and dressing with bone dust the third. Another essential is grazing by sheep.

Names of Plants (*H. C.*).—Cotoneaster nummularia. (*Colney Hatch*) —Callistemon lanceolatus, native of Australia; a frequent greenhouse plant. (*Quercus*).—1, Pernettya mucronata; 2, Gaultheria antipoda; 3, Garrya elliptica. (*J. W. L.*).—Has been answered already. His plants are—I, Nerine pulchella; 3, Leucopogon Richei; 7 (or 4), Santolina pectinata. No. 2 is utterly unintelligible in its present condition, and presents no character to define even the natural order to which it belongs. In aspect it almost imitates a Tamarisk. No. I is a Cape bulb, succeeding in a greenhouse if planted in loamy soil. 3 Is an Australian shrub, also succeeding in a greenhouse; soil, chiefly peat and silver sand with a little loam or leaf mould. 4, A hardy border plant.

POULTRY, BEE, AND PIGEON CHRONICLE.

WILTS COUNTY POULTRY AND PIGEON SHOW.

Some months since a few spirited fanciers met at Devizes, and determined to endeavour to get up a county show. Nine years ago there was a show of poultry at Devizes, also one the year before that date (Pigeons had not then become, a rule, exhibition birds); but though the shows were both good, yet, being limited to one town, they faded away. Some of those who tried then were determined to try yet again, and it was wisely judged to call it a county show. In the north of England towns, where every third man is a fancier, town shows do well, but in the south and west it is not so; hence it is wise to extend the area. Besides, county sounds superior to town. The county member considers himself a much grander man than the borough member, and the county magistrate than the borough magistrate. So, taking human nature as it is, it was well to try a county show, and, as somebody says, "there's a deal of human nature in all of us." Everything county goes down better than town. "Gweat hore this cock-a-doodle show; but I must go, you see, for it's a county affair," says Mr. Magnificent Swell. Then, again, there are those who will give if it in some degree comes home to them, and a Wilts county show comes home to every Wiltshire man, for it seems in some way to belong to him. Make a show co-extensive with a shire, and you get more subscriptions and more company. Givers and workers set a thing going and carry it on. One says "I can give;" another, "I can but give little, but I can work." By rights county shows ought to be like gypsies—wanderers—this year at one town, that at another; but then in all towns you cannot find men understanding shows and willing and able to work.

I hoped for open weather, and to be able to drive to Devizes; but frost—frost—frost. "Can't drive!" "Horrid bad weather for Devizes Show!" I kept muttering; all the ladies skating with, or looking on at, gentlemen skating. That feminine skating is becoming almost universal. Well, I remember when it wasn't thought the thing. However, these are the days of strong-minded women, so making them strong ankle-women may be a proper counter-attraction, and the world will get on better. But enough. Still it is odd to see old ladies have the face to begin to learn to skate—yes, bewigged old ladies. (N.B.—If any such read this, I beg to say I am not a bewigged old gentleman.) Monday, thaw, but the glass firm, and the ladies skating inch deep in water, such their perseverance. Tuesday, regular thaw, no skating at all for anybody, and so for a change people are likely to go to the Show. Tuesday noon, I stood in the fine open market-place of our fine old county town. Not a bad day for the time of the year. In a few minutes I was inside the Corn Exchange, where it so chanced I had never been before. I find a long well-proportioned building lighted from the top, and the light admirable—better inside than out, as there was within no mist. Mr. Billett's well-known pens were ranged as usual, and now that the open-wire backs have canvas drawn tightly along they are in every way excellent.

Before speaking of each class separately I will give in a general way an idea of the excellency or the reverse of the classes. The Coloured Dorkings were good; the White Cochins very good; Buff Cochins good; but the Hamburghs of all varieties were, though numerous, very indifferent—indeed they were a disappointment, as if it had been thought by great Hamburgh breeders, "Anything will do so far south as Wiltshire." Among the Game class, which contained some very excellent birds, there were shown many with a strong tendency to "duckfootedness." The Houdans were very good and numerous. The Game Bantams had many of them been overshown. The Sebrights were an agreeable surprise in numbers and excellence; clearly they must not be talked of as "things of the past." The Geese and Turkeys were good; but the pride of the whole Show were the Black Ducks, of which there were sixteen pens, and on many of the birds was a bloom very rarely seen. The order at Birmingham was reversed. Mr. Pettis's Ducks, there first, were here third; and Mr. Sainsbury's, there second, were here first. But the winning birds were all wonderfully excellent; the distance of the journey made probably the difference.

In regard to the Pigeons, Committees have to learn that cups, however sparingly offered alone (of course I mean any plate-prize), bring numbers and excellence. Even dividing the classes into cocks and hens is not sufficient. Thus, in the Coloured Pouter classes only four birds appeared. Well-off fanciers like a piece of plate, be it cup, or, better still, some useful or ornamental bit of plate to keep and show. Towards the golden sovereign they seem to feel with Bassanio in the "Merchant of Venice"—

> "Thou gaudy gold,
> Hard food for Midas, I will none of thee."

And towards the ten-shillings they likewise feel with the same gentleman—

> "Nor none of thee, thou pale and common drudge
> 'Tween man and man."

A cup or other plate-prize for the best pen of Pigeons, or for the most points in birds shown by one exhibitor, would have brought together many more excellent birds. As it was, the Carrier class was very good, and the White Pouters generally good.

Now to take the classes in order.

Dorkings (Coloured), eight entries, and five good enough to be noticed. Mr. Martin was first of course, and second too. The Silver-Greys, good, old-fashioned, beautifully coloured birds, showed four pens only; would there were more! The White were equal in number to the Coloured, and were so good that six out of the eight pens were noticed.

Spanish.—Devizes is near enough to Bristol to be sure to have a good show of these, so there were thirteen pens; yet Bristol did not come in first nor yet second, but a Worcestershire lady, Mrs. Allsopp, took the first prize, and a Somerset lady the second. I hope and expect to see better birds at the Bristol Show.

Cochins.—How seldom one sees these birds save at shows! A dozen pens of Cinnamon and Buff, and nearly all good, as one test will show—Miss Milward's birds were there and not noticed, although seven were noticed. Mrs. Allsop's second-prize deserves a special word of praise. The five pens of Partridge Cochins were up to the average, while the White Cochins were much above the average. Mr. Sichel's first and second-prize birds were extremely good, and shown in perfect condition. His labour met a just reward.

Brahmas.—I have said how rarely one sees Cochins except at a show, yet Brahmas or crosses are in almost every farm and inn-yard. This may make their old staunch friends rejoice. Here were seventeen pens of Dark, and fifteen of Light, the latter being the better class. Yet many of the Light showed two faults—one a largeness and looseness of comb and the want of size, evidently not having been bred early enough in the year. Another fault must be noticed, a sandy tinge over the plumage. All these faults must be corrected. The first-prize Light were not so clean as they might have been.

Game.—Black-breasted Reds were headed by Mr. Stagg's first pen. One of the Judges remarked to me that he could have stood for hours admiring the cock bird. There was shown in him a properly-made tail, sickle feathers narrow, not broad, and the tail close and rather drooping; his true of some of the others. Strange only one pen of Brown-breasted Reds, Mr. Matthew's. The Duckwings were more numerous. I specially admired Mr. G. S. Sainsbury's second-prize pen. The Game cock class had good birds in it.

Hamburghs.—All the four varieties, numbering thirty pens, a sad disappointment. A pen in the Selling class was as good or better than any of the thirty.

Polish.—"To be quite in the fashion," remarked a lady near me, "they should lower their chignons." Mr. Hinton's excellent Silvers were first; Mr. Boothby, the plucky and persevering breeder of the Golden, second. I particularly admired his cock bird. The exhibitors of Polish confer a special benefit upon the public, as no birds look so beautiful in the show pen.

Houdans.—Very good.

Any other French Variety.—Fair. Diabolical-looking Crève-Cœurs in abundance, and one pen of La Flèche, another French imp of unprepossessing appearance.

Malays.—The hens hardly large enough to match their mates. Seven pens of them. Messrs. Payne, Brooke, and Hinton, winners in their order. This gave my friend, Mr. Hinton, *pain* he could hardly *brook*, but I *hint on*, that with a larger hen and no white in his cock's tail, pleasure awaits him in the future.

Any other Breed not mentioned.—The Black Hamburghs of Mr. Serjeantson most deservedly took the first prize; seldom have I seen such excellent birds, and from the low price he put on them (£4), they are doubtless no longer his. They were the cheapest birds in the Show, and among the very best. Two pens of Andalusians, pretty birds not enough bred, one took second; and Leghorns, a new class, and pretty withal, third.

Bantams.—Game a middling lot. First-prize cock a gamey bird, and the second hen good, but throughout, the hens too dark in colour. The first-prize single cock was the best bird of all the Game Bantams shown. The Sebrights were excellent, five pens Silver and three Gold. Some of the Silvers too Golden, but the whole class very good and more numerous than usual. Among the "Any variety" Bantams, a neat pen of Pekins were first. They were clean, but many in this class were badly shown.

Ducks (Aylesbury).—Few pens, but good, of course. Mr. Fowler first with splendid birds, quiet and calm in apparent conscious superiority.

Rouen Ducks numerous and not very good. Black East Indian Ducks *the* class of the Show. They were a grand lot; such colour, and such a bloom on them! Looking down through the top of the pens, nothing in the Duck kind could be more beautiful, and great must have been the care and pains of their breeders. Ducks (any variety), lovely Mandarins and Carolinas.

Turkeys and Geese.—Excellent both, and sadly tempting from their size and the nearness to Christmas.

The *Selling Class.*—A large one, hence beneficial to the Committee, but, as a good fancier remarked to me, "they ought to be killed at the door and not admitted." A useful though not ornamental class, certainly.

PIGEONS.

Carrier Cocks.—This a good class, containing, as of the hens likewise, some splendid Black birds—birds raven black, a great contrast to others of the smoky tint. The second-prize ought, perhaps, to have been first. He is a showy stylish bird. Hens much like the cocks in excellence.

Pouters (White).—Owing to two near resident fanciers, Mrs. Ladd and Mr. Heath, of Calne, this was a very good class.

Pouters (Any other colour).—Only four entries. Mr. Dew's Black-pied cock bird deservedly stood first.

Tumblers (Almond).—Only one entry. Cock bird good, but wattle on beak coarse.

Tumblers (Any other variety).—A fair pair of Kites first; one head and beak good. A nice pair of Blue Beards second. A pair of well-shaped old-fashioned English Tumblers, red in colour, and neat in shape, were most deservedly commended, and ought to have been sold, being priced very low.

Owls.—A good class, Whites being first.

Barbs.—Few, and all Black. The second-prize cock has a good broad head.

Fantails.—A nice class, Miss Milward's first having excellent tails.

Jacobins.—A large class. Reds first.

Nuns.—These were good, though few.

Antwerps, now being known as the real Carrier Pigeons, were regarded with much interest. They were of very varied shape and feather.

Trumpeters.—Only four pens, but Mr. P. H. Jones's Blacks were much admired.

Runts.—An unusually large number, in proportion to the other classes, made their appearance. Eight pens in all, mostly Blue, but two pens White. The first-prize birds were not paired, and some therefore took them for two cocks, so fiercely did they fight, but I believe it was not so.

Any other New or Distinct Variety.—Mr. Yardley's Satinettes were by right of beauty first. This variety of Turbit is singularly beautiful in feather, and when handled, the tail expanded, and the round spots shown, a more lovely bird can scarcely be imagined. This was, as it always is, a very pretty and interesting class, and deserved the extensive notice by the Judges and visitors which it received.

Selling Class.—Eighteen pens of mixed value. The pair of Red Short-faces which were first were very pretty sound-coloured birds.

Of dead poultry there was only one entry. This was a pity, because the increase of weight in poultry is a food question, and as Dean Swift remarked, "A man who makes two blades of grass grow where one only grew before, is a benefactor to his country;" so that man, in these times of dear beef and mutton, is also a public benefactor who teaches us or shows us how a lean fowl can become food-supplying. There was no class for eggs, which was a pity, as it is usually well filled, and baskets of snow-white eggs nestling in green moss are very pretty to look at.

Such was the first Wilts County Show, and on the whole I was very pleased with it. There were 450 pens, and next year no doubt there will be more of both poultry and Pigeons, especially the latter. The management was excellent; the Committee few in number and good workers; the food supplied to the birds was of good sound character; the railway arrangements of the best; and I believe every catalogue promised was dispatched by the first day's post. I should like in future for the Pouters to have a little block each to stand on, as they look better and show better.

I never enjoyed a show more thoroughly both by daylight and gaslight, for it was kept open at a reduced price for two hours in the evening for the artisan class. I wandered round and round, chatting now with old friends, then with new acquaintances; instructing poultry-ignorant ladies (this a very pleasing task), examining this bird and that bird, until six o'clock reminded me of a certain snug dinner at "The Bear Hotel," a famous hostelry known all over Wiltshire, and where the Bear Club, connected with the Bear charities, meets every year, some great man in the county presiding. There, too, at the Bear, Sir Thomas Lawrence was born, and first exercised his boyish pencil. Well, there we, too few for so extensive a dinner, sat down, and ate, and drank, and chatted, talked poultry and Pigeon talk, talked over the Show, and fanciers, and birds, and sipped in moderate quantities dry liver-suiting sherry. By the way, Black Ducks came very often on the table. What enthusiasts their fanciers are! but then at this Show they, the Black Ducks, were the greatest feature. We wanted another specially at that dinner, but whom sickness hindered being present; he would have brought Black-breasted Reds into the conversation I well know. However, not forgetting the absent but regretting them, we chatted on until the more distant-living had to be up and away, for the "Time approaches, Tam maun ride," and so away into the dark rode one far off to Salisbury Plain. Just when leaving, a kindly new acquaintance and resident said, "Had I seen the unfinished picture of Shakespear, by Lawrence, that was in the house?" "No, I had not." So following my guide, he candle in hand, down steps and up steps, along a corridor and up a landing, I was shown the picture by the boy artist, for which a heavy sum had been offered and refused. It was like the statue of the immortal bard in Westminster Abbey, a full length and nearly full size, but with little save its history to mark its value. Then to bed, and on the morrow home, to home duties, and scenes, and faces, but with a pleasant remembrance of Devizes Show, flavouring, as it were, the following days of the week.—WILTSHIRE RECTOR.

OVERWORKING THE JUDGES.

I AM pleased to hear the Committee of the Portsmouth Show have taken the hint with reference to the judging, and have secured the services of Messrs. Hewitt and Tegetmeier, instead of, as in former years, only one Judge for poultry. The Portsmouth Show in three years has doubled itself in magnitude; and when it is considered that several additional classes have been formed, and all classes are to have a third prize, I think it may naturally be expected to increase very much more. Amongst the alterations in the classes I notice Light Brahmas are to have two classes—one for old and another for young birds, and a five-guinea cup to each. The Game Bantams have been divided into two classes; Black Reds to be shown by themselves.—REDLEAF.

LEEDS POULTRY SHOW.

THIS Show was held on the 12th, 13th, and 14th inst. The following is the prize list:—

GAME.—*Any Description.—Cock.*—1, W. Spencer, Haworth: 2, A. Haslam Hindle. 3, H. M. Julian, Hull.

GAME.—*Black-breasted Red.*—1, H. M. Julian. 2, T. Mason, Green Ayre, Lancaster. 3, J. Firth, Chatsworth. *Chickens.*—1, W. Fell, Adwalton. 2, W. Spencer. 3, J. C. Coupe, Doncaster.

GAME.—*Brown-breasted and other Red, except Black-breasted.*—1, F. Sales, Crowle. 2, J. Watson, Knaresbrough. 3, T. Mason. *Chickens.*—1, F. Sales. 2, W. Pervis, Nantwich. 3, R. H. Brown, Halifax.

GAME.—*Duckwings.*—1, H. C. & W. J. Mason, Drighlington. 2, Winwood and Cutler, Worcester. 3, W. J. Cope, Barnsley. *Chickens.*—1, J. Pickles, Mytholmroyd. 2, W. Fell, Adwalton. 3, H. Jowett, Shipley.

GAME.—*Any other Variety.*—1, T. Mason. 2, F. Sales. 3, J. Firth. *Chickens.*—1, R. Walker, Gomersal. 2, A. G. Wilding, Montford, Burnley. 3, J. C. Yates, Bentley, Doncaster.

DORKINGS.—Cup and 1, J. White, Northallerton. 2, R. W. Richardson, Beverley. 3, T. Briden, Cononley, Leeds. *Chickens.*—1, R. W. Richardson. 2, T. E. Kell, Wetherby. 3, F. S. Arkwright, Chesterfield.

SPANISH.—1, H. Wilkinson, Skipton. 2, Burch & Boulter, Sheffield. 3, W. and F. Pickard, Leeds. *Chickens.*—Cup and 1, H. Beldon, Goitstock. 2, J. Thresh, Bradford. 3, Hon. Miss D. Pennant, Penrhyn Castle, Bangor.

COCHIN-CHINA.—Cup, 1, and 2, W. A. Taylor, Manchester. 3, H. Lacy, Hebden Bridge. *Chickens.*—1 and 2, W. A. Taylor. 3, T. Stretch, Ormskirk.

BRAHMA POOTRA.—Cup and 1, W. A. Taylor. 2, T. F. Ansdell, St. Helen's. 3, Hon. Miss D. Pennant. *Chickens.*—1, F. S. Arkwright, Sutton Scarsdale. 2, H. Beldon. 3, Dr. Holmes, Chesterfield.

HAMBURGHS.—*Gold-pencilled.*—1, W. W. Tickner, Ipswich. 2, H. Beldon. 3, H. Pickles, jun., Earby. *Chickens.*—1, H. Beldon. 2, J. Walker, Birstwith, Ripley. 3, J. Rollinson, Lindley, Otley.

HAMBURGHS.—*Silver-pencilled.*—1 and 3, H. Beldon. 2, H. Pickles, jun. *Chickens.*—1, H. Smith, Keighley. 2, H. Pickles, jun. 3, H. Beldon.
HAMBURGHS.—*Gold-spangled.*—1, H. Beldon. 2, J. Newton, Silsden. 3, T. Walker. *Chickens.*—1, H. Beldon. 2, J. Ogden, Manchester. 3, T. Walker.
HAMBURGHS.—*Silver-spangled.*—Cup, 1, and 2, H. Beldon. 3, Ashton and Booth, Mottram. *Chickens.*—1, H. Beldon. 2, H. Pickles, jun. 3, Ashton and Booth.
HAMBURGHS.—*Black.*—1, H. Beldon. 2 and 3, T. Walker. *Chickens.*—1, T. Walker. 2, H. Beldon. 3, J. Statter, New Brighton, Cheshire.
POLANDS.—1 and 2, H. Beldon. 3, W. Silvester. Sheffield. *Chickens.*—1, J. Bowker. Shipley. 2, H. Beldon. 3, J. Battye, Holmfirth.
FARMYARD CROSS, OR ANY OTHER VARIETY.—1, Mrs. J. Cross, Appleby Vicarage, Brigg. 2, J. Railton, Manchester. 3, J. Dearden, Hebden Bridge.
SELLING CLASS.—1, J. Blackburn, Ackworth. 2, J. J. Booth, Highfield, Silsden. 3, J. Mills, Healey, Rochdale.
BANTAMS.—*Black.*—1, H. Beldon. 2, J. Riley, Guisely. 3, C. Sedgwick, Skipton. *White.*—1, F. Tearle, Gazeley Vicarage, Newmarket. 2, Winwood and Cutler, Worcester. 3, S. & R. Ashton, Mottram. *Game.*—Cup and 1, G. Hall, Kendal. 2, J. Crossland, jun., Wakefield. 3, Bellingham & Gill, Burnley. *Any other Variety.*—1, E. Walton, Rawtenstall. 2, J. Walker, Halifax. 3, H. Beldon.
TURKEYS.—1, J. B. Braithwaite, North Otterington. 2, F. E. Rawson, Thorpe. 3, B. H. Brookshank, Rotherham.
GEESE.—*White.*—1, Rev G. Hustler, York. 2, F. Leech, Rochdale. 3, J. B. Braithwaite. *Grey and Mottled.*—1, E. Leech. 2, W. Fieldhouse, Leeds.
DUCKS.—*Aylesbury.*—1 and 3, E. Leech. 2, H. Frankland, Church. *Rouen.*—1, J. White, Wakefield. 2, J. Newton. 3, R. Gladstone, jun., Broadgreen, Liverpool. *Any other Variety.*—1, R. W. Richardson. 2, W. Binns, Pudsey. 3, H. B. Smith, Preston.

PIGEONS.

CARRIERS.—*Cock.*—1, E. Horner, Harewood. 2, J. Thompson, Bingley. *Hen.*—1 and 2, E. Horner.
POUTERS.—1 and 2, E. Horner.
TUMBLERS.—*Short-faced.*—1, E. Horner. 2, H. Adams. *Any other Variety.*—1, J. Hawley. 2, R. G. Teebay, Ormskirk.
OWLS.—1, E. Horner. 2, R. W. Richardson, Meaux Abbey, Beverley.
FANTAILS.—1, W. C. Dawson, Otley. 2, H. Yardley, Birmingham.
BARBS.—1, E. Horner. 2, R. W. Richardson.
TURBITS.—1, J. T. Lishman. 2, E. Horner.
JACOBINS.—Cup and 1, J. Thompson, Fearnhill, Bingley. 2, E. Horner.
TRUMPETERS.—1 and 2, E. Horner.
NUNS.—1, R. W. Richardson. 2, O. A. Young, Driffield.
DRAGOONS.—1, E. Horner 2, H. Adams.
ANTWERPS.—1, H. R. Wright, Hockley, Birmingham. 2, R. Smith, Hull.
MAGPIES.—1, E. Horner. 2, W. C. Dawson, Otley.
ANY OTHER VARIETY.—1, E. Horner. 2, W. C. Dawson.
SELLING CLASS.—1, G. Lister, Harewood. 2, D. Reddihough, jun., Bradford.

RABBITS.—*Yellow and White, and Tortoiseshell.*—1, Sewin & Robinson, Kettering. *Black and White.*—1, A. S. Peace, Thorne. 2, J. Irving, Blackburn. *Self-coloured.*—Cup and 1, T. E. Terry, Tong. 2, J. Irving, Bradford. *Grey and White.*—1, A. H. Easten, Hull. 2, J. Irvin, Blackburn. *Selling Class.*—1, T. E. Terry. 2, J. Railton, Manchester.

JUDGES.—*Poultry:* Mr. James Dixon, North Park, Clayton, Bradford; Mr. Thomas Dodds, Wakefield. *Pigeons and Rabbits:* Mr. F. Esquilant, Effra Road, Brixton, London.

CARRON, STENHOUSEMUIR, AND LARBERT POULTRY SHOW.

THIS was held in the Drill Hall, Stenhousemuir, on December 9th, when the following awards were made:—

SPANISH.—1 and Special, Miss Rae, Glasgow. 2, W. C. Hardie, Carron. 3, J. Young, Motherwell. *hc* and c, D. MacBeath, Bridge of Allan.
DORKINGS.—1, J. Weir, Rosehill. 2, — Meiklejohn. 3, Mrs. Neilson, Carron Mains. *hc*, S. Bell, Castleton, Plean. c, J. Turnhull, Carnock; Rev. F. MacPherson, Larbert.
DORKINGS.—*Silver-Grey.*—1, J. Malcolm, Langton. 2, W. Weir. 3, A. Archibald, East Plean. *hc*, Mrs. Neilson. c, Capt. Brown, Kilsyth. *Chickens.*—1, R. Duncan, Whins of Milton. 2, J. Malcolm. 3, S. Bell. *hc*, J. Fotheringham, Galamuir. c, S. Bell; J. Turnhull, Carnock; Capt. Brown, Kilsyth.
COCHIN-CHINAS OR BRAHMAS.—1, W. Weir, Inches. 2 and 3, J. W. Will, Errol. *hc*, H. Wyse, Bishophriggs. c, R. Williamson, Grangemouth (2); Mrs. Graham, Airth
HAMBURGHS.—1 and 2, H. Russell, Clackmannan. 3, J. W. Will. c, J. Carswell, Uplaw Moor.
GAME.—1, W. Bruce, Falkirk. 2 and *hc*, J. W. Blakey, Stirling. 3, A. Hutchison. c, D. Duncan, Carron.
BANTAMS —1, R. Gemmell, Glasgow. 2, S. Brown, Glasgow. 3 and c, J. W. Will. *hc*, Miss J. M. Frew, Sinclairtown, Kirkcaldy.
ANY OTHER VARIETY.—1, A. Wylie, Johnstone. 2, A. Binnie, Grahamston. 3, R. Williamson, Grangemouth. *hc*, T. Tough, Torwood.
DUCKS.—1, — Harper. 2, J. W. Will. 3, R. Macvey, jun. *hc*, S. Bell. c, C. Laird; T. Tough.
TURKEYS —1, W. Weir. 2, R. Campbell. 3, J. Webster, Carronside. *hc*, C. Laird. c, Miss Meikle.

PIGEONS.—*Pouters.*—1, J. Murdoch. 2, T. Park, Westerton. *hc*, J. Duncan, Carron. *Fantails.*—1, J. Murdoch. 2 and *hc*, H. Y. Hardie, Carron. *Tumblers.*—1, A. Johnstone, Bathgate. 2, Mrs. Ferguson, Larbert. *Any other Variety.*—1, A. Johnstone. 2 and *hc*, J. Weir.

CANARIES.

YELLOW.—*Cocks.*—1, R. Stewart, Perth. 2, J. Meldrum, Glasgow. 3, J. Smith, Perth *Hens.*—1, D. Duncan. 2, W. Muirhead, Alloa. 3, J. Halley, Carron.
BUFF.—*Cocks.*—1, J. Dalziel, Paisley. 2, W. Mochrie, Lanark. 3, J. Smith, Coatbridge. *Hens.*—1, T. Scott, Carluke. 3, W. Alexander, Edinburgh. 3, J. Ritchie, Renton.
PIEBALD (Yellow).—*Cocks.*—1, T. Scott. 2, J. Hogg, Oakley. 3, J. Pender. *Hens.*—1, J. Mullion, Perth. 2, J. Halley. 3, C. Smith, Leith.
PIEBALD (Buff).—*Cocks.*—1 and 2, T. Scott. 3, G. Ritchie. *Hens.*—1, J. Lyle, Wishaw. 2, A. Crawford, Johnstone. 3, J. M'Craw, Edinburgh.

JUDGES.—*Poultry:* Mr. T. Raines, Bridgehaugh, Stirling; and Mr. Morrison, Glasgow. *Canaries:* Mr. Brown, Glasgow; Mr. G. Binnie, Perth; Mr. J. Morrison, Bainsford; and Mr. T. Stirling, Carron.

SCOTTISH COLUMBARIAN ASSOCIATION.—We think most Pigeon fanciers will enter the lists and contend on the 28th for the twenty gold medals and the liberal money prizes offered by this Association. The Exhibition will be in the Music Hall, George Street, Edinburgh.

NORFOLK AND EASTERN COUNTIES POULTRY SHOW.—This, to be held at Norwich on the 17th and 18th of January, has a liberal prize list, besides cups, and low entrance fees; but we must protest against all varieties of Dorkings being included in one class and all the varieties of Hamburghs in another. This is quite absurd. Setters and Pointers might as well be exhibited in one class.

NORTHERN COUNTIES COLUMBARIAN SOCIETY.

THANKS to the usual liberality of Messrs. Jennison, of Bell Vue, Manchester, this Society held its annual Show on the 9th inst. in one of their spacious and well-lighted rooms. The arrangements were excellent, the three hundred hee-hive pens being placed in double rows, and between the rows were placed hothouse plants, which gave the Show a very pleasing character. The Judges gave general satisfaction, and stated that they never judged or witnessed a better Show.

The Carrier cocks and hens were all grand, stylish young birds. Pouters, excepting the prize birds, were poor. Out of Mr. J. Fielding's fine loft of birds, we thought he might have sent something better in Short-faced birds than he did. Very superior Black African Owls were shown by the President, and deservedly took the first prize. There was a grand array of English Owls and Turbits of all varieties. When we state the entries for Jacobins numbered thirty pens, and the two old exhibitors, Messrs. Royds and Ridpeth, put forth the full strength of their lofts, the Judges may be believed when saying such a show of Jacobins was never seen together before. Among the Barbs of Captain Heaton and Mr. J. Firth, there was not a bad bird in any of the classes, and Capt. Heaton's champion pair were conspicuous for their splendid condition. Unfortunately Mr. J. Holland, although he had made many entries, could not show any of his marvellous Dragoons, owing to family affliction; but there were many splendid birds exhibited.

Fantails, although not numerous, were of great merit, and there were some very pretty Long-faced Balds, Beards, and Mottled Tumblers exhibited. The Long and Short-faced Antwerps were as good as can be found in the country, and were a show in themselves. Of Trumpeters, such a lot is rarely seen together. There were some good birds in the Variety classes. The birds shown in the collections of six were exhibited in the large mahogany cages belonging to the Society; they were numerous, and many of very great merit. We may add that at this Society's Exhibitions the competition is not for money prizes.

CARRIERS.—*Cocks.*—1, J. Chadwick, Bolton. 2, T. H. Ridpeth, Handford. *Hens.*—1, T. H. Ridpeth. 2, J. Chadwick.
POUTERS.—1 and 2, T. H. Ridpeth.
TUMBLERS (Short-faced).—*Almonds.*—1, J. Fielding, jun., Rochdale. *Mottles.*—1, J. Fielding, jun. *Balds.*—1, J. Fielding, jun. *Beards.*—1, J. Fielding, jun.
TUMBLERS (Long-faced).—*Balds.*—1 and 2, W. R. Haycraft, Manchester. *Beards.*—1 and 2, R. Marshall, Manchester. *Mottles.*—1, R. Marshall. *Any other Variety.*—1, F. Hughes, Stockport.
OWLS.—*Foreign.*—A. Mangnall, Lower Broughton. 2, J. Fielding, jun. *Young.*—1, J. Fielding, jun.
OWLS.—*English.*—*Blue.*—1, J. Chadwick. 2, A. Mangnall. *Silver.*—1, J. Chadwick. 2, A. Mangnall. *Cock.*—1, F. Mangnall, Styal. 2, W. Gamon, Chester. *Hen.*—1, F. Mangnall. *Young.*—1, A. Mangnall. 2, W. Justice, Salford.
TURBITS.—*Blue or Silver.*—1 and 2, F. Mangnall. *Any other Colour.*—1, J. B. Pinder, Harpurhey. 2, F. Mangnall. *Cock.*—1, J. Fielding, jun. 2, F. Mangnall. *Hen.*—1, T. H. Ridpeth. 2, J. B. Pinder. *Young.*—1, J. B. Pinder.
JACOBINS.—*Yellow.*—1 and 2, E. E. M. Royds, Rochdale. *Red.*—1 and 2, T. H. Ridpeth. *Black*—1 and 2, E. E. M. Royds. *Young.*—1 and 2, T. H. Ridpeth. *Cock.*—1, E. E. M. Royds. 2, T. H. Ridpeth. *Hen.*—1, T. H. Ridpeth. 2, E. E. M. Royds.
BARBS.—*Black.*—1, H. Heaton, Worsley. 2, J. Firth, Dewsbury. *Any other Colour.*—1, J. Firth. 2, W. Justice. *Cock.*—1 and 2, H. Heaton. *Hen.*—1, H. Heaton. 2, J. Firth. *Young*—1, J. Firth. 2, J. Heaton.
DRAGOONS.—*Blue or Silver.*—1, W. Whitworth, Rusholme. 2, A. Jackson, Bolton. *Cock or Hen.*—1, W. Gamon. *Any other Colour.*—1, A. Jackson 2, T. H. Ridpeth. *Cock or Hen.*—1, W. Gamon. 2, T. H. Ridpeth. *Young.*—1, T. H. Ridpeth. 2, A. Jackson.
FANTAILS.—1, F. Mangnall. 2, T. H. Ridpeth. *Cock or Hen.*—1, F. Mangnall.
ANTWERPS (Short-faced).—*Red or Blue-chequered.*—1 and 2, J. Wright, Manchester *Silver Dun.*—1, W. Justice. 2, R. Marshall. *Any other Colour.*—1, W. Gamon. 2, W. Justice. *Young.*—1, W. Justice. 2, W. Gamon. *Cock.*—1, J. Wright. 2, W. Justice. *Hen.*—1, R. Marshall.
ANTWERPS (Long-faced).—*Red or Blue-chequered.*—1, W. Justice. 2, R. Marshall. *Silver Dun.*—1, J. Wright. 2, W. Justice. *Any other Colour.*—1, P. McDonald. 2, R. Marshall. *Young Hen.*—1 and 2, W. Justice. *Cock.*—1, W. Justice. 2, R. Marshall. *Hen.*—1 and 2, W. Justice.
TRUMPETERS.—1 and 2, J. Firth. *Young.*—1 and 2, J. Firth. *Cock or Hen.*—1, J. Firth. 2, T. H. Ridpeth.
ANY OTHER VARIETY.—1, E. Slack, Lower Broughton. 2, T. H. Ridpeth. *Single Bird.*—1, T. H. Ridpeth. 2, E. E. M. Royds.
COLLECTIONS OF NOT LESS THAN SIX BIRDS.—1 and 2, F. Mangnall.

JUDGES.—Mr. Peter Eden, Salford; Mr. W. Cannan, Bradford; and Mr. R. Chadwick, Oldham.

NORTHERN (NEWCASTLE) COLUMBARIAN SOCIETY.

(*From a Correspondent.*)

THIS very interesting competitive Exhibition for young Pigeons was held on the 13th and 14th in a very commodious sale-room, owned by Mr. S. Joel, Pilgrim Street, Newcastle-upon-Tyne, under the auspices of the above recently-formed Society. This being their first Exhibition, it was considered highly successful, and although the Society is in its infancy, it was remarkable for the number of birds of this year's breeding shown. The birds were exhibited singly, and numbered 271 pens in twenty-nine classes; the prize money amounted to about £20. In addition to this amount there were fifteen silver challenge cups ranging from two to four guineas each. To Mr. T. Rule, Durham'

Mr. W. B. Van Haansbergen, and Messrs. Blenkinsop, Newcastle, the Society owes its origin.

First on the list came Pouters. There were only three entries. Mr. N. Dunn, Newcastle, took the cup with a very fine bird. Black Carriers numbered eleven entries. Mr. Guthrie took the cup with a very fine cock bird, also first prize with a splendid hen; the pair were claimed for £5. Of Carriers, Any other colour, there were five entries, Mr. J. G. Dunn, Newcastle-on-Tyne, winning in a canter with a splendid Dun bird—in fact one of the finest young Carriers, fanciers say, that has been shown this year, and it was claimed for £5 5s.; it was the general opinion that this bird should have had the Carrier cup, but the bird being so young the sex could not be determined. In both Carrier classes adult birds were shown.

Of Barbs, in both classes, there were nineteen entries, and most of them were good. Mr. Joseph Firth won the cup with a splendid bird. In Short-faced Almonds, Messrs. Blenkinsop took the cup with a magnificent bird, in fact one of the finest young birds I have seen this year. Short-faced, Any other colour, twelve entries, and Mr. H. Adams had no easy victory for the cup. Messrs. Blenkinsop ran a close race with him.

Trumpeters, Mottled, eight entries. In this class evidently there was a grand mistake, pens 71 and 72, shown by Mr. T. Rule, of Durham, were passed by unnoticed; but I have not the slightest hesitation in saying that scores can bear me out—that these two pens were, without exception, the finest birds I ever saw (to be young ones), and should have been awarded the cup and first prize. Other birds in this class were very moderate. Trumpeters, Self-colour, had seven entries. Mr. T. Rule showed two pens of Blacks, decidedly the best birds, and they ought to have been placed first and second, but, as in the previous class, were passed unnoticed, and the awards went to birds of no merit.

Jacobins, Red, twenty-seven entries. Mr. Rule took the cup with a really good bird, while his little Red hen, decidedly the best Jacobin in the Show, was passed unnoticed. In this class Mr. Rule should have stood—pen 90, cup, and 91, first prize. Of Black Jacobins there were nine entries. Mr. T. Waddington only obtained a second prize, but undoubtedly should have stood first, Mr. Royds' bird being coarse. Jacobins, Any other colour, eighteen entries, Mr. W. B. Van Haansbergen winning with one of the Whites, for which he is renowned; H. J. Nalder pressing him very closely with a splendid Yellow. Mr. E. E. M. Royds showed in the Jacobin classes several old birds, which were admitted by telegram, but not before Mr. Jones had judged them; in any case none of them had a chance, young birds clearly beating them.

Next came Point-headed Turbits, with twenty-eight entries, and the best class in the Show. A most difficult class to judge, there being some very young birds shown, and after the Judge's patience had been well tried for upwards of an hour, he awarded Mr. J. G. Dunn's Red bird first prize, this bird being the youngest in the Show, and only a little over eight weeks old. It was put up by auction, and brought 25s.

Of Shell-crowned Turbits there were thirteen entries, Mr. O. E. Cresswell taking the cup against Mr. J. G. Dunn's Red bird in the previous class; the cup bird was sold for £4 5s. Nuns, Black, eight entries, Mr. R. W. Richardson, Beverley, taking the cup and first prize. Of Nuns, Any other colour, there were four entries. Mr. W. B. Van Haansbergen had all his own way in this class.

Of Fantails, White, there were twelve entries. Mr. J. F. Loversidge, Newark-on-Trent, took the cup and first prize easily. English Owls, eight entries. Mr. T. Waddington had an easy victory for the cup.

In Magpies Mr. T. Waddington had an easy victory for the cup. In Swallows there were two entries.

Of Dragoons the entries numbered twenty-six, and most of them were really first-class birds. This was a most difficult class to judge, and after a great deal of time had been spent, the cup went to Mr. T. Waddington, who well deserved it, the bird being a splendid Blue with fine carriage and good head, but his greatest point of excellence was his narrow black bars, which are so much admired. Antwerps were a good class, and Mr. W. H. Mitchell swept off the prizes. Of Long-faced Tumblers there were thirteen entries of moderate birds; of Baldheads, seven entries; of Beards, twenty; in the Variety class, seven entries.—FAIRPLAY.

POUTERS.—*Red or Blue.*—Cup, N. Dunn, Newcastle. 1, J. Towerson, Egremont. 2, J. Guthrie, Hexham.

CARRIERS.—*Black.*—Cup and 1, J. Guthrie. 2, J. G. Dunn, Newcastle. *hc*, J. Watts. *c*, J. G. Dunn; C. Vaux, Boldon. *Any other Colour.*—1, J. G. Dunn. 2 and *hc*, J. Watts. *c*, J. Towerson.

BARBS.—*Black.*—1 and 2, R. W. Richardson, Meanx Abbey, Beverley. *hc*, J. Firth, Dewsbury. *c*, J. Firth; W. R. & H. O. Blenkinsop, Newcastle. *Any other Colour.*—1 and Cup, J. Firth. 2, W. R. & H. O. Blenkinsop. *c*, R. W. Richardson.

TUMBLERS (Short-faced).—*Almond.*—Cup and 2, W. R. & H. O. Blenkinsop. 1, H. Adams. *hc*, C. Vaux. *c*, W. B. Van Haansbergen, Newcastle; H. Adams. *Any other Colour.*—1, H. Adams. 2 and *hc*, W. R. & H. O. Blenkinsop. *c*, J. Watts (2); T. Gallon.

OWLS.—*Foreign.*—Cup, J. Towerson. 1, R. W. Richardson. *English.*—Cup, T. Waddington. 1 and 2, J. Watts. *hc*, T. W. Kilburn. *c*, T. Gallon.

TRUMPETERS.—*Mottled.*—1, W. B. Van Haansbergen. 2, J. Firth. *c*, J. Firth; W. B. Van Haansbergen. *Self-colour.*—Cup, W. B. Van Haansbergen. 1, J. Firth. 2, W. R. & H. O. Blenkinsop.

JACOBINS.—*Red.*—Cup, T. Rule. 1, 2, and *hc*, W. E. Easten, Hull. *c*, R. W. Richardson; W. E. Easten; H. F. Nalder, Croydon; E. E. M. Royds, Rochdale. *Black.*—1, E. E. M. Royds. 2, T. Waddington, Feniscowles, Blackburn. *c*, H. F. Nalder. *Any other Colour.*—1, W. B. Van Haansbergen. 2, H. Nalder. *c*, W. B. Van Haansbergen; W. R. & H. O. Blenkinsop.

TURBITS.—*Point-headed.*—1, J. G. Dunn. 2, W. E. Easten. *vhc*, O. E. Cresswell, Early Wood, Bagshot. *hc*, T. Gallon, Felling, Gateshead. *c*, J. G. Dunn; W. E. Easten (3); W. B. Van Haansbergen; O. E. Cresswell. *Shell-crested or Plain-headed.*—Cup, O. E. Cresswell. 1, W. B. Van Haansbergen. 2, H. F. Nalder. *c*, J. Watts; O. E. Cresswell.

NUNS.—*Black.*—Cup, 1, and *c*, R. W. Richardson. 2, W. E. Easten. *Any other Colour.*—1, W. B. Van Haansbergen. 2, N. Dunn.

FANTAILS.—*White.*—Cup, 1, 2, and *hc*, J. F. Loversidge, Newark. *c*, H. Adams; Newark; T. Gallon.

MAGPIES.—Cup, T. Waddington. 1, J. Watts. 2, J. Towerson.

SWALLOWS.—1 and 2, J. Watts.

DRAGOONS.—Cup and 1, T. Waddington. 2, J. Watts. *hc*, R. W. Richardson; W. H. Mitchell (2). *c*, R. W. Richardson (2); J. Watts; W. H. Mitchell; W. R. and H. O. Blenkinsop.

ANTWERPS.—Cup, 1, 2, and *hc*, W. H. Mitchell, Moseley, Birmingham. *c*, J. G. Dunn (2).

TUMBLERS.—*Long-faced.*—1, J. Watts. 2, H. Adams. *c*, J. Guthrie (2); T. Gallon (2).

BALDHEADS.—1 and 2, J. W. H. Thorpe. *hc*, W. R. & H. O. Blenkinsop. *c*, J. Watts.

BEARDS.—1, J. W. H. Thorpe.

ANY OTHER VARIETY.—1 and 2, J. Watts (Dentilettes). *c*, T. Rule, Durham (Letz); T. Waddington (Porcelain).

Mr. P. H. Jones, of London, was Judge.

THE DRAGOON PIGEON.

IN your correspondent's criticism of the pair of Silver Dragoons with which I took the second prize at Birmingham, he says the bars were of too black a tint; now I maintain that they cannot be too black, and I should be only too glad to meet with a pair having jet black bars and as good in other points as my own. They were second at the Crystal Palace, competing in the same class with Blues, and second at Bingley Hall. They were so placed by different Judges; and I am sure if, as your correspondent says, they were too black in bar, they would not have been amongst the prizewinners. I should be glad to hear the opinions of other fanciers of Silver Dragoons as to this point. I sincerely wish we could come to some more definite standard of a Dragoon. It is very disheartening to hear so many differences of opinion. Some tell you your birds are not stout enough in bill, others that they are too stout. For myself I would not give room to a spindle-beaked bird, such as many of the Birmingham fanciers have. Calling on one when in that town during the show week, he bragged to me that he had bred birds this year with beaks as thin as a bodkin.—FRANK GRAHAM.

CHELTENHAM CANARY SHOW.

"GOOD-BYE—pleasant journey—be sure and send a catalogue." The valediction, benediction, and supplication of three shivering members of the fancy, as I slowly steamed out of the apology which does duty for a station at Sunderland, on a nasty, wet, sloppy night in November. The weather could not make up its mind as to which was most desirable—to snow, rain, or freeze, and so it did all three by turns. I went my way, out into the black, murky night, and they theirs, back to their own fireside. One, a good man and true, who has learned the first lesson in exhibiting—the art of seeing yourself beaten without grumbling, and a belief in the possibility of there being as good fish in the sea as ever came out of it; another, with hope strongly developed in his cerebral formation, and who always comes up to the mark smiling; the third, trembling in mortal agony lest by any chance there should be found better birds than his own, and meditating taking a "turn round by Brussels, Antwerp, Ghent, and there away," to see if haply he might "pick up anything good."

Engagements at home have prevented my attending so many shows as last year. Old friends at Hatfield and Scarborough, and new ones at North Ormesby and Guisborough, I was reluctantly obliged to disappoint, and with the exceptions of Whitby and Hartlepool, I had not seen any of the great gatherings of the season. Week after week I have opened the Journal anticipating something more than a bare return of awards, and longing to hear the opinions of men well qualified to judge of the progress made in the breeding of the bird, the name of whose admirers is now legion, and I do not know whether my disappointment or my wish to see for myself has been the greater. "WILTSHIRE RECTOR'S" observation that the field is not large, often presented itself to my mind very forcibly, but I wished that, contracted though it may be, other husbandmen would take as much pleasure in cultivating it as I. If the space be somewhat circumscribed, we must just do as Mr. Wright recommends for poultry in confinement, dig deep and turn up fresh soil in which we can scratch.

I travelled to Cheltenham in company with a grizzly bear. But it was, withal, a good-natured bear. I found it curled-up in a corner of a carriage at Normanton, with the cleverest arrangement of foot-warmers and cushions I ever saw. I had to climb over the barricade when I entered the carriage, and I think I awoke the bear, which on emerging from its skin assumed the appearance of a bear and seal mule, and a jelly specimen it was. It had a spare portmanteau, and with it and my share of the cushions, built me a barricade and a den, after which it crawled under its skin and hybernated. And how it did snore! Anxious guards and inquisitive porters, who always wanted to examine our tickets when there seemed to be no necessity, made no impression on Ursus Major.

"Be sure and send a catalogue." I knew it would be a large one, for such a schedule has not appeared for some years. I estimated the probable number of entries at five hundred, and was agreeably sur-

prised to find that they had reached nearly six hundred *bonâ-fide* entries. But my heart made one or two unmistakeable jumps when I entered the Assembly Rooms and took in at a glance the difficult nature of the task set before me and my colleague, Capt. Hawkins Fisher. The great room may be, and, I understand, really is the finest floor in Europe for dancing purposes, but as the votaries of Terpsichore do not require strong sunlight for the celebration of their revels, the room appears to have been constructed without any recognition of its necessity. True, one end of it is almost entirely of glass, but being a long, oblong-shaped room, the direct rays do not penetrate far, and the shade from the ceiling is soon perceptible. The consequence was, we had every cage to lift and arrange facing the light, in some rough approximation to order of merit before we could arrive at definite conclusions. At first it was easy enough, but at last it was as though I was running a race against time or picking up the hundred eggs a yard apart, singly, and returning with each one to the basket. And I weigh fourteen-seven! However, I was ably seconded by my coadjutor, an enthusiastic ornithologist, whose infinite acquaintance with hybrids and British and foreign birds relieved me of much of the responsibility in these classes.

But, work as hard as we could, to get through in a short November day was impossible, and a portion of the judging still remained to be done on Friday morning. Visitors took everything in good part; it was a first Show, successful in point of numbers beyond all precedent, conducted with a manifest desire to have everything done as it ought to be done, and I never heard a single grumble at delay in the issue of the award of prizes. A great portion of the judging, too, and especially of the Belgians, being done in public, excited a deal of interest, and nothing but admiration of the spectacle and patient waiting for the completion of every detail seemed to occupy the mind of every visitor. Many who came for the day remained in the town all night to see "the end of it," in any class in which they took a peculiar interest. Surely their patient waiting and enthusiasm are a quiet reproof to some who are subject to fits if they do not receive a catalogue and award of prizes by first post—or sooner.

The Clear Norwich classes made a fine show; Messrs. Adams and Athersuch, Bemrose & Orme, G. & J. Mackley, Moore & Wynne, and W. Walter making the running at a "hot" pace. It *was* hot. Colour and quality were prominent in all, but the struggle at the finish lay between the Derby confederacy and Mr. Walter, the latter taking first in Jonques and Mealies with birds of exceptional quality of feather. The Derby birds were grand in colour, but not so soft and silky in texture as I like to see them. Mr. Bemrose called my attention to one of his Buffs, No. 49, I think, which he said was one of the warmest birds he had seen for a long time. It certainly was a bird of rare colour, but—my view may be extreme—too warm. It wanted more frosting.

The Evenly-Marked Norwich were a show in themselves. Frequenters of Canary shows know what is the average run of so-called Evenly-Marked birds usually staged. One or two, perhaps, come up to the standard. I do not mean the standard of perfection, but the simple standard which is included in the definition Evenly-Marked. And on this point allow me to say, in passing, that there seems to be a misunderstanding as to what constitutes an Evenly-Marked bird. Indeed, my attention was directed to one, No. 94, first prize, Class 4, which a friend thought was not an Evenly-Marked bird at all, because one eye was more heavily marked than the other. To set this question at rest, let me say that evenness of marking is, primarily, a question of locality, and not of absolute exactness of marking in that locality. I have, in an earlier number, enunciated this theory at length. Suffice it to say here, that eye marks, wing marks, and tail marks, marks which can be repeated in duplicate, constitute even marks, and the fact of any one or other of these marks being unequal to its fellow, in no way alters the fact of the bird being evenly marked. Positive exactness is seldom or never found, and a close approximation to it not frequently. The wording of the Crystal Palace schedule for last year was intended to meet this difficulty, at least I could understand it in no other way. The description there was "Best Marked or Variegated," allowing a wide discretionary power to the Judge; and seeing that birds of great merit, otherwise marked than evenly, and which at the same time cannot be considered as Ticked or Unevenly-Marked (as understood by the fancy), can by this wording find their way into competition with the Evenly-Marked specimens, I am inclined to view this description, "Best Marked or Variegated," as preferable to the more rigidly exacting one, "Evenly-Marked," which excludes many a superb specimen which is both evenly and otherwise marked.

At Cheltenham there were more than a dozen *bonâ-fide* Evenly-Marked birds among the Jonques, not to mention the Mealies, without counting those which, though nicely marked, either had too much of it or were capped and otherwise variegated. The competition was very close, and the first prize fell to a bird of Messrs. Adams and Athersuch's, very beautifully marked on the wings, and very evenly, though rather heavily, on the eyes. Barwell & Golby, and Moore and Wynne were close behind, with Messrs. Adams & Co. equal third. No. 71 in this class, Bemrose & Orme, was very fine, and by the dull light of a November afternoon looked so grand, that I was at one time afraid I had made a mistake and had come to a decision too hastily. But a closer inspection in the morning confirmed my opinion. The standard of excellence is somewhat arbitrary. Some judges like four and others five, six, or seven dark feathers in each wing. Some like half the wing dark; and from an almost unintelligible heap of jargon and incongruous nonsense in a schedule before me, I learn that "the flights, or first nine feathers, white, and the secondaries dark, are the most perfect wing-marks." To my eye if the primaries (which by the way are *never* nine in number), alone are light, the bird would be too heavily marked, and, *cæteris paribus*, would not win against one with a much lighter wing.

No. 94, in the Evenly-Marked Buffs (Bemrose & Orme), I have adverted to. He was in the perfection of condition, and could afford to give away any trifling irregularity and still win with something in hand. The other winners, Bemrose & Orme, second, with Moore and Wynne and Adams & Co. dead heat for the third place, were gems of birds. Where to draw the line between highly commended and commended was a difficult task.

Ticked birds were wonders, the most remarkable being 156 (J. Turner), a heavily-marked Buff, which I am given to understand has been in the crucible and submitted to all kinds of searching tests without anything "coming off." I was much amused at a remark I overheard while examining this bird and a Lizard; extraordinary opinions were being hazarded pretty freely, but everybody was silenced by a jolly old fellow who hailed from Birmingham or "thereaway" saying, "He have got a better receipt nor most of you!" I have not heard anything so rich since Mr. Jones, who has the care of Mr. Ashton's birds, lectured a delinquent on the sin of painting and staining, and wound up with a grand chaffing peroration, "It's all along o' you not using fast colours!"

Jonque Crests were nothing extra, but such a fine lot of Buffs I do not remember ever to have seen. It was a very near thing at the finish, but all told, the best bird stood first. Nearly a score were mentioned, and almost any one of the score could have won under ordinary circumstances, if not opposed by such an exceptional array.—
—W. A. Blakston.

(To be continued.)

QUEENS LEAVING THEIR HIVE.

Queens will leave the hive at other times than with a first swarm or to meet the drone. I took brood, larvæ, and eggs from the queen I received from you, and placed them in an empty hive with two frames of honey taken from other stocks. I then removed a strong stock of blacks some 15 or 20 yards distant, and placed the new hive on its stand. On the ninth day afterwards I examined, but found no queen-cells started. I tried again with the same result, but found eggs and brood in all stages. I also found the black queen in the nucleus, and upon examining the hive I removed I found queen-cells destroyed and a young queen just hatched. She had evidently left and returned to the old stand. Can anyone report a similar case?—R. W. Harrison.—(*The Bee-keeper, New York.*)

UNSEASONABLE DRONES.

On examining one of my stocks to-day I found three dead drones and four dead young bees. There were also some white larvæ. They seem to have been taken out of the cells by the bees. Have I any cause for alarm?—Baron.

[It is difficult to assign a reason for the presence of drones and young bees in your hive without further information. You do not say if your stock has an old or a young queen, or whether she was raised artificially or not. Your hive may have lost its queen late in the autumn, and her successor in her matrimonial flights failing to meet a drone in due time, consequently commenced her career as a drone-breeder. Or the old queen may have become worn-out with age or accident, which would cause her to deposit drone eggs as well as those of workers. Or the bees may have been aware of her increasing incapacity, and have allowed the drones, which would otherwise have been killed in autumn, to live to provide for her successor in case of her death. We think you have some cause to fear that all is not right within your hive.—Eds.]

Wolverhampton Show of Poultry and Pigeons.—The prize list is liberal. In fifteen classes the first prizes are £3 or £3 3*s*., instead of £2 as formerly. In classes for Light Brahmas the first prizes are £5 5*s*. (cups). There are also several extra prizes in addition to the above. The prizes for Pigeons also are increased, while the entry-fee is lowered. Homing Antwerps are a new class.

OUR LETTER BOX.

West of England, Plymouth, Newcastle Poultry, Watford, and other Shows (*L., Ames, &c.*).—We have not reported these Shows, because, if a committee does not advertise an exhibition in our columns, we conclude it is local, and not of general interest.

Dublin Society's Report (*E. A. S.*)—It was put in as a matter of favour. The Society does not advertise, and we can spare no more space.

POULTRY FOR USE (*Ignoramus*).—Keep a Dorking cock, Brahma pullets, and Rouen Ducks. If you enclose seven postage stamps with your address, ordering "The Poultry-book for the Many," you will have it sent post-free from our office.

PREPARING SPANISH FOWLS FOR EXHIBITING (*Inquirer*).—There can be no doubt that it is for the advantage of Spanish fowls to be kept some days in the dark before being shown. Soft food and white peas are favourite foods at such a time.

INDICATION (*A. B. G.*).—No, but it is a sign that if she does lay the eggs will be fertile.

COCHIN'S HACKLE CURLING (*E. H.*).—It is a great disadvantage, if not a disqualification. We have seen several cases of it, and know no remedy. We believe all these vageries, and we know of many of them, arise either from distant crosses, or, in other instances, from in-and-in breeding.

CROSS-BREEDING (*E. H. R.*).—Our opinion is an old one. We are not friendly to crosses for useful purposes. To keep good layers, we should keep pullets and dispose of them after the first year. If we wanted a cross for eggs only, we should think that you mention a good one.

TELLING THE AGE OF POULTRY (*T. G.*).—The scales of the legs are only marks of age when their wearer is very old, but they are no criterion between a young hen and one a year or eighteen months old. A very practised eye can up to seven or eight months detect the difference by looking at the flesh. It is mere assumption for any man to profess unerring judgment as to age of hens. No one can tell the difference between birds of fourteen or twenty months. The difference between a pullet and a hen ceases as soon as the former has eat and reared her chickens, and those who buy and kill young poultry for a livelihood are frequently deceived by buying fattened hens for chickens, the daily experience of thirty or forty years notwithstanding.

GAME FOWLS (*Far West*).—It is impossible you can show your birds as Black Reds. They are very strict in colour, and no deviation can be allowed, but there is some latitude in Brown Reds. As a rule, a prize list is thus worded, "Black-breasted and other Reds;" that would suit your case. Your chickens would have died on the flagstones. Fire is not good for poultry. Warmth must be conveyed through food. The boarded floor is bad for the chickens, unless it is covered some inches thick with dust, sand, or road grit. There is nothing unusual in chickens at this time of year. They will soon want fresh air, and when they begin to droop, try to find an outhouse or shed with an earthen floor, where the hen can be put, and where they will be sheltered from wind, rain, and draught, while they can run out if they like.

FOWLS DYING (*J. Railton*).—Your fowls are dying from cold, and from cayenne. We advise you to discontinue the stove and the pepper. Neither are necessary. Assimilate your food as much as possible to that of birds in a state of nature, and provide them with things they do not come in contact with. Feed in the morning on slaked oatmeal mixed with cold water; midday with the scraps and some whole corn; evening with slaked oatmeal, or ground oats still better. The spots and pimples would suggest poison, were it not for the fact you have been giving cayenne. In the inflamed state of the œsophagus that you have described, a grain of cayenne if lodged would form an irritant that would account for pimples or irritation. Feed on ground oats mixed with water, allow only a little water three times per day (none by them), and give two pills of camphor, each the size of a pea, night and morning.

DUCKS' EGGS (*St. Edmunds*).—If from young Ducks, probably within a month; if from older, double that time or longer. Weather will have some influence; the colder it is the longer you will have to wait.

DUCKWINGED BANTAMS (*A. M.*).—We have Duckwinged Bantams now in confinement that have been in the same place at least eighteen months. Eight birds in perfect health in a space 5 yards by 2, with a roomy sentry-box to roost in. All our Game cocks are dubbed. The dark leaden appearance of the comb is from cold or indigestion. A dose of castor oil will probably remove both.

WEIGHT OF LIGHT BRAHMAS (*A. A.*).—Cock, 8 lbs., pullets, 6 to 7 lbs. Some are larger, but the foregoing is a good average at seven months.

FOWLS IN A HOUSE (*Houdan*).—Your arrangements are bad, the flue is an evil. Pheasants, Partridges, and Grouse know no disease, make no smell, yet they roost in the open air, but they are wise in their generation, they do not choose a brick to squat upon for the night. The brick floor is very bad, the interstices absorb all that is liquid, and, as a rule, that which is liquid is the most offensive. In a space as small as that you mention, the most scrupulous cleanliness is necessary to prevent foul smells. If you cannot take up the run of bricks, cover them with 3 or 4 inches of sand, gravel, or grit. Green food is good; let none be thrown in the house, but all in the front. The ground should be scraped, or raked, or swept hard with a birch-broom every morning. Discontinue wheat. Feed on ground oats or oatmeal every morning, Indian corn midday, and ground oats in the evening. Nothing must be given in the house. All should be given outside, and the surface swept so hard and clean every morning that there shall be no appearance of its being used. Disinfect the house and run with one of the many disinfectants now in use.

PURCHASING POULTRY PENS (*X. Y. Z.*).—Your Committee will find on application that those who lend pens on hire are the makers also, and will readily sell them.

COLCHESTER SHOW (*J. G. Dunn*).—Turbits, G. South.

DUBLIN POULTRY SHOW.—In the class for Any variety of Bantam except Game, the first prize was awarded to Mr. G. A. Stephens, and the second to Mr. W. M. A. Wright.

TREDEGAR SHOW.—In White Bantams at the Tredegar Show the first prize was awarded to the Rev. F. Tearle's birds, and the second to those of Messrs. S. & R. Ashton; and in Blacks both Messrs. Mayo and Draycott were highly commended.

PRESERVING BIRDS' NESTS (*Rush*).—Soak them in a tanner's tanpit for a few hours.

SEA LAVENDER FOR BEES (*E. H. R.*).—We have no acquaintance with sea lavender as a pasturage for bees. Can any of our readers give their experience of it?

BEES WEAK (*A Subscriber*).—We fear your bees by this time are dead. A great mortality has already set in amongst our own bees, even where they had plenty of food, especially among those which were weak in numbers. It is, moreover, a bad time to feed, and great harm may be done in this way by inducing them to bestir themselves, except on the warmest of sunny days. If you do feed, use a syrup of loaf sugar, and put a tea-spoonful of gin or brandy to every 2 lbs. of food. Watch your opportunities and give a little at a time. Beware, especially, of flooding the hive with bee-food; nothing is more conducive to dysentery than this, and owing to the long-continued bouts of cold weather which seem normal this winter, dysentery is likely to be very prevalent. In fact, we have lost several hives owing to it already. If your bees are still in the greenhouse they ought to be warm enough, but you might cover them over with some woollen material during intense frost.

REMARKS.

13th.—Extremely damp and dull all day, though no rain fell.

14th.—Beautiful soft air, but rather damp all day, a very slight shower in evening.

15th.—A fine day but no drying-up of the mud, rather foggy about 6 P.M. clearer afterwards.

16th.—A very mild but damp dull day.

17th.—Very foggy and damp in morning, clearer at noon; at 1 P.M. the sun tried to shine through the mist and probably succeeded where was less smoke; rather thick in the afternoon, clear at night.

18th.—Rather windy in the morning, but still damp and dull. The wind increased during the day and was strong at night.

19th.—Much wind during the past night, which ceased in the morning, and was followed by a rather dull day, except a short time before sunset, when it was bright for a short time, rain at night.

A most marked change in temperature from last week, the mean of the morning observations 12° higher; max. in air, 10°; min. at 4 feet above ground, 13.7°; max. in sun at 4 feet, 12°; and the min. on grass, 9.8°. The difference on grass would have been more equal to the others but for this low reading of the first day caused by the cold of the previous day, and the frost still lingering in the ground.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 20.

BUSINESS transactions are limited, and there is very little improvement to be noticed in any department. The wholesale trade is languid, and country orders are confined to immediate wants. Prices have been scarcely maintained in rough goods, which continue abundant. Pears comprise Glou Morceau, Winter Nelis, Jean de Witte, and Chaumontel. Apples consist of Newtown Pippin, Ribston Pippin, Blenheim Pippin, Nonpareil, and others.

POULTRY MARKET.—DECEMBER 20.

THE market is all confusion preparing for Christmas. Tons of provisions are coming in that will not be unpacked. Under the circumstances quotations would be jumps in the dark, and we must defer our notice till next week.

WEEKLY CALENDAR.

Day of Month	Day of Week.	DEC. 28—JAN. 3, 1872.	Average Temperature near London.			Rain in 43 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during forty-three years, the average day temperature of the week is 43.0°, and its night temperature 30 8°. The greatest heat was 58°, on the 28th, 1855; and the lowest cold 2° below zero, on the 2nd, 1867. The greatest fall of rain was 0.62 inch.

SMALL FARMS—HOW THEY CAN BE MADE TO ANSWER.—No. 4.

By Rev. William Lea, *Vicar of St. Peter's, Droitwich, and Hon. Canon of Worcester.*

APPLES, PEARS, AND CHERRIES.—I put these three favourite fruits together, because if they are planted on common orchard stocks it is at least fifteen years before they become profitable; so, if they are planted on a fruit farm, it should be at the expense of the landlord and not of the tenant. But Apples on the English Paradise stock, and Pears on the Quince, and Cherries on the Mahaleb, will come much earlier into bearing, and will, if the farm is within reach of a good market, prove a profitable crop. We will, therefore, dismiss the consideration of orchard stocks, and see what may be done with Apples on the Paradise stock.

If Apples are planted in this form it should be as "bushes," and the pruning should be of the simplest kind, just shortening shoots which are too rampant, and cutting out those which cross. Treated in this fashion, the tree at six years old may produce, say, one-third of a pot of fruit, the price of which will vary from 2*s.* 6*d.* in a good season to 6*s.* or 7*s.* in a bad one. I do not think, therefore, that the Apple, as a rule, will be so profitable a crop as the Plum; but if, instead of growing the common sorts, a man will go-in for the choicer varieties of large or table fruit, such as would be appreciated in Covent Garden, and could be sold by the dozen, he would obtain a better return. From my own experience I should say that the surest way of obtaining fine fruit is to grow Apples on the French system of single or double cordons. This is easily done, and at a very slight expense; you only want a training ground and a line of wires to fasten your trees to when they are trained. The way to set about it is this—First put up two posts in any part of your ground which is convenient, and nail a common deal batten to them at 15 or 18 inches from the ground. This is your training ground. Then purchase some "maidens" on English Paradise stocks, and bend them into shape by tying them down to the batten; in one season they will acquire the proper form, and be fit to transplant to your wire, along which they are to make a permanent cordon.

The French grow two varieties of cordon, the single and the double. In the single cordon the trees are planted about 9 feet apart, and when the head of the shoot of one reaches the tail of the next, it is grafted into it, so that the sap is passed on from one to another throughout the whole line. The theory is that a vigorous grower should be planted next to a weaklier one, and thus the want of stamina of the one replenished from the redundancy of the other; but I cannot say how this will answer from my own experience, as my trees have not yet caught each other. All I can say is that cordons form a very pretty edging, and that they produce finer fruit than can be obtained in any other manner, both Apples and Pears. Of the two I think Apples succeed better than Pears, and if Pears are planted they should be higher from the ground than Apples, say 20 instead of 12 or 15 inches, as the blossom is earlier, and more liable to be cut off by the frost. I do not recommend this mode of growing fruit, except where fine fruit in small quantities is desired; as I intimated above, it is for the London market and not for the Black Country. In the first, such fruit is sold by the dozen, in the latter by the pot.

Such varieties as the White Transparent, Calville Blanche, Cox's Pomona, Ecklinville Seedling, Oslin, Irish Peach, Kerry Pippin, Brabant Bellefleur, and the Reinette du Canada answer well as cordons, and produce enormous fruit, but of course the number is limited, and a dozen or a dozen and a half are quite as many as one cordon can do justice to. This will settle the question where quantity and not quality is desired. If grown as bushes the following sorts may be added to those which are named above:—Cox's Orange Pippin, the best of dessert Apples; the Joaneting, Hawthornden, Duchess of Oldenburg, Emperor Alexander, Small's Admirable, Blenheim Orange, Cellini, Wick Pearmain, Dumelow's Seedling, Brabant Bellefleur, and Lord Suffield, which from coming in early is always in demand, and last, but not least in value, where it will grow, the Sturmer Pippin, which will keep till Apples come in again, if this be considered an advantage; add to these, if the fruit is intended for the markets of the North, anything that shines or has a red cheek.

In the same way in growing Pears, your choice of sorts must depend on the market for which they are intended. If for Covent Garden Market, fine fruit which will come in between late Grapes and early Strawberries from December to Easter, will be the most profitable to grow; if for the north, the earliest you can get—the quality is immaterial, provided it is called a Pear.

On one occasion I happened to be in London, and having a morning to spare I went to Covent Garden, and amused myself by looking at the fruit and chatting with the salesmen, who were willing enough to give me information when they found I knew something of their subject. From what they told me I discovered that there are certain stock varieties which usage has made fashionable in the market, and which their West-end customers demand; and that many of the best Pears are not known there by name. To my inquiries, "What they thought of the Joséphine de Malines or the Doyenné du Comice?" I was told by several, "We never heard of them." It was the same with the Beurré Superfin, Fondante d'Automne, Winter Nelis, Bergamotte Esperen, and other first-class varieties. Pears, as they know them, come in in the following rotation:—Bon Chrêtien, Louise Bonne of Jersey, Beurré Diel, Duchesse d'Angoulême, Marie Louise, Chaumontel from Jersey, Glou Morçeau of which there were then (November) splendid specimens from France, Vicar of Winkfield under the name of the "Curate," Easter Beurré, and Beurré de Rance. These later sorts carry them on till the hothouse produce begins, and on this account I should imagine that they would be the most profitable to grow.

I hardly know how far to recommend the Pear as a staple for a small fruit farm; the fruit of the later sorts

requires to be carefully stored, it is not more than an every-other-year crop. It is subject to the disadvantage of not being saleable except when ripe, and when ripe it must be eaten to the moment, or it is gone; but if any one should be induced by what has been said to make a plantation, I will add a little more advice from my own experience. You may grow early Pears as pyramids, but not the larger and later sorts, for if you do the equinoctials will probably blow down at least one-half of your crop. These heavy Pears should be grown in a spot well sheltered from the West, as bushes or as espaliers, or, if you like, as cordons; they will require careful watching for a month before they are gathered, otherwise you will have a visit from a family of tomtits, who will just make one small incision near the stalk in the finest fruits, thus ruining them as effectually as the blackbird with his larger mandible and more vigorous thrusts. Above all, before you plant Pears make sure that your ground is perfectly dry, and is not subject to the influence of late frosts, or year after year you will be disappointed of a crop. The Apple and the Plum, which blossom later, will succeed where the Pear will fail.

I have already named the best varieties of Pear, out of the thousand sorts which have been raised and thought worthy of being named; there are many others of undoubted excellence, but I do not think that there are any to beat the sorts above mentioned in their season. A small fruit farmer does not require many sorts. Two or three varieties will be quite sufficient for his purpose, if he seeks for quality—Louise Bonne, Beurré Diel, and Easter Beurré; if for the northern markets, the Green Chisel, or any very early variety which succeeds in the district, Summer Doyenné, and the Bon Chrêtien, which last is one of the best of all Pears.

With regard to Cherries, I doubt if it would pay at all to grow them for market purposes on the Mahaleb stock. They must be planted for orchards on the wild Cherry stock; but unless the soil is good, notwithstanding the old adage, that "a Cherry tree will buy a horse before a Pear will buy the saddle," they will be some years before they come into profitable bearing. A man who plants a Cherry orchard when he is turned fifty, must do it for the benefit of his successors, and they will have good cause to thank him, for the produce of an orchard at thirty years of age will average something like 20*s.* per tree, which, taking seventy-five trees to the acre, will give an abundant return.

Out of the many varieties which appear upon the lists, I believe none are more profitable than the Early Black, the Bigarreau, and the Waterloo; but this, again, is a matter of soil and climate, and as in all other fruits, the first thing to be done is to ascertain what sorts flourish best in the neighbouring fields; but if Cherries are planted it should be in considerable quantities, as from the moment they begin to colour till they are gathered, they will require to be protected from the depredations of birds. Here, again, blackbirds are notable offenders. So, too, are starlings and jays if there are any in the country, and even sober-minded rooks are not above the temptation.

(To be continued.)

NOTES ON THE LILIES.

Your well-known correspondent "D.," of Deal, suggests (page 440), that I should give a few notes on Lilies. If I could help anyone who has but lately taken up my favourite flower I should be only too glad to do so.

I must begin by saying that we have all a great deal to learn in Lily-growing. For instance, why do three out of a dozen L. auratum bulbs—all to every appearance equally sound, equally fresh, and of the same age and size—rot or break-up into small bulbs, while the other nine, apparently identical, planted in the same situation and in the same soil, and having the same watering, grow strongly and well? I have seen this over and over again, both in sun and shade, in pots under cold glass, and in open borders. We have tried a great many experiments, and are trying many for next season, but this is still a mystery here. Wireworm will not account for it. A number of L. auratum bulbs, planted in deep peat among dwarf Rhododendrons, or making a small jungle for themselves, have succeeded best here. This season, however, some have been attacked for the first time with a brown spot, in some cases showing itself on the leaves, in others on the flower-buds, which seemed to destroy the vigour of the plant for a time. We had a great many L. auratums attacked in this way in a bed enclosed by Beard's glass walls. The disease seemed suddenly to have worn itself out, and the stems looked better and the flowers came out—after a fashion. I took specimens of the diseased leaves and flower-buds to a meeting of the Royal Horticultural Society's Scientific Committee one day, when there were several foreign authorities present, including M. Linden, but the disease appeared to be unknown to all. In most cases the bulbs were healthy and continued to be so. I have seen L. auratum show beautifully in a root bed in a friend's garden, all the better for being rather dwarf, which was owing, probably, to the bulbs not being large.

"D.," of Deal, speaks of the difficulty of growing L. Browni. I have bought bulbs from Van Houtte, and from Turner of Slough, but cannot as yet get anything like the strength and vigour of the Longiflorum varieties. I believe Major Trevor Clarke grows this Lily without difficulty, and with a little artificial heat. He gave me a bulb last season with its shoot 2 inches above the pot, which flowered in course of time well, and the bulb has besides greatly increased in size, producing two promising baby bulbs on the stem, so I hope to do still better with it this season. I have some L. Browni planted in a large rootwork, the soil of which is composed of two parts fibrous peat and one part of loam, and I fancy this position will suit it. The only other Lilies I have got on badly with are Tenuifolium and its allied Lily Buschianum, and Szovitsianum, which bloom well with us one year, but do not keep healthy. I am trying them in the rootwork sheltered but facing north. Ours is a hot country in summer.

I believe with "D.," of Deal, that L. auratum is probably a hybrid. There would hardly be such endless varieties of colour and form if it were not so. I agree with him, too, that its social position should not be above L. speciosum, though when really well grown it is a grand flower. Who that saw the wonderful tub with its some 130 flowers standing about 10 feet high, that was shown a couple of years ago at South Kensington, could ever think otherwise? Everybody coming into the room seemed inclined instinctively to say, "Oh!" and to take off their hats to it. The overpowering perfume was no joke to the Committee, who must have thought of the Upas tree.

I am afraid we must unlearn "lancifolium." I have kicked against changes in nomenclature as hard as anybody, but the scientific authorities will have their way sooner or later. The changes are not only with us. To a young but high scientific authority I was groaning over the alterations the British Museum is making in the names of shells, instancing that I had found my old friend Rostellaria set down as Fusus, which everybody was familiar with as the name of a very different shell. I got no sympathy. My friend said, "I take the other view;" and then completed my dismay by saying that in his science they were taking away about the only Latin name of a beetle I knew, the Blatta orientalis (cockroach), and giving the name Blatta to an out-of-door bug. A universal language is of course most desirable, and if the only way to arrive at this is to go back to the original name, I suppose we must submit. I believe the name lancifolium was previously given to another Lily not now in cultivation.

The Lilies with us which give no trouble are the speciosum varieties, the tigrinum, and the longiflorum, some of the canadense type, and Leichtlinii. This last is a very beautiful, graceful, and most satisfactory Lily. You have lately had the best of twelve Roses; if you had the best of four Lilies I should give in L. Leichtlinii as one. It is difficult for many new growers to realise how thoroughly hardy the great majority of Lilies are. I have this season given away many bulbs, and am almost always asked whether it would not be safer to keep them in the greenhouse through the winter. Why I believe both L. speciosum and auratum show best in a sheltered place is, that though they will stand a fair amount of rain, yet if exposed to dritting rain in large drops accompanied by high wind, the pollen gets smeared over the petals.

In an old-fashioned garden at Wandsworth, where there was a small lawn leading from the principal one, enclosed by tall shrubs and sheltered from all winds, I planted a bed of many sorts of Lilies. They seemed perfectly happy, and I showed flowers from this bed at South Kensington after a week of wet and stormy weather. Of course a few of the old flowers were damaged, but most were perfect.

I have seen L. speciosum growing perfectly in an exposed garden near Rochdale. The lady of the house looked after the bed herself, but if I remember rightly no protection was given in winter, though the climate is cold and damp. L. longiflorum we find to bloom best in a bed of dwarf shrubs. It comes up so early before the frosts are over, that it often gets cut by the

cold wind. We had as strong growth this unfavourable season in a Rhododendron bed as in pots in the orchard house.

I do not believe in mixing dung with Lily compost, unless, indeed, it is so old that it has ceased to be dung; but where the bulbs are very strong and planted very close together, a top-dressing of old dung seems to be only beneficial. I have been told that L. tigrinum Fortunei will stand and thrives upon a strong dose of dung, but I have not yet tried this treatment.

If these are the sort of notes you care to have I may, perhaps, send a few more, or I shall be happy to answer questions. If many growers would give us their experience we should soon get more facts to work by.—George F. Wilson.

FORCING VEGETABLES.—No. 4.

THE PEA.

Hitherto comparatively few gardeners have attempted to produce this vegetable to any extent, much before the season in which it comes to perfection in the open ground. Doubtless the chief reason was the want of a dwarf-growing prolific sort, as the tall rambling habit of most varieties requires more room than can conveniently be spared in the forcing department at that time of the year. Now this objection has, in a great measure, been overcome by the introduction of such dwarf-growing sorts as Tom Thumb, or what some call Beck's Gem, McLean's Little Gem, and another kind called Multum-in-Parvo, a dwarf-growing productive variety, not one of which sorts exceeds 18 inches high. I have grown them all, and if I have been supplied with the true varieties, I, notwithstanding, have been unable to discover any material difference between them. The pods are produced plentifully enough, but the peas within are few and very small.

For forcing, however, these dwarf-growing sorts are far preferable to any of the tall-growing ones, the best of which was Bishop's Dwarf Longpod, the only kind used for forcing years ago. But I find from experience that of all the vegetables which admit of forcing, the Pea is the least profitable, not only from the large space required for a succession of crops to grow in, but also because it takes a long time to bring it to perfection. Still these difficulties should not deter us when we remember how delicious is a dish of Peas, and how admired and valuable they would be if placed upon the table at a season of the year when vegetables naturally grown are scarce.

The treatment required to force the Pea successfully is not a difficult one for a beginner to learn. The principal point to observe is that the plants are grown at starting in a moderate temperature of about 45°, with a gradual rise to 60° up to and during the time that they are in flower. Afterwards an increase of 5° or 10° will suit them until the crop is fit to be gathered. Air is very important, and should be plentifully given up to the setting of the fruit, but after this a slight diminution of the afternoon and night air will help to swell the pods perfectly. While the plants are growing water should be given sparingly and judiciously, or else they are apt to run too much to straw; but from the beginning of the blooming and onward to the swelling of the pea, it must be given plentifully. Like any other plant grown in an artificial temperature, they will succeed the better if the water can be applied in a chilled state.

The transplanting is another very important part in the cultivation of Peas under glass. This should be particularly attended to, as it prevents them from running too much to straw, and if in the case of the plants blossoming freely, the tops of the shoots are pinched off, their tendency to grow to straw will be reduced, and additional sustenance will be added towards the formation of pods. Syringing overhead once a-day while they are growing assists them, but it should be discontinued after the fruit is set, and a moist atmosphere supplied instead. It matters little what structure the Peas are grown in, so long as the above conditions are attended to. I have grown them in pigeon-holed pits, and on the borders of a Peach house, by placing about 8 inches depth of soil on the border, not in the border, and planting them in it. They may also be grown in pots, and transferred from one house to another as occasion may require. Orchard houses are very suitable places in which to bring forward a crop of Peas, and I have found them do better there than in any other structure I have tried. In these there is more room for their natural habits to become developed; but in whatever structure they are grown, if planted out, they should first be sown in pans or boxes, and when about 2 inches high planted out about an inch from plant to plant in the rows, which ought not to be less than 2 feet from one other. Remove as much earth with the roots as possible, so as to cause the plants little check, and reduce the necessity for shading on any but very bright days. Avoid giving the Pea a very rich soil. A fresh loamy soil not too light will suit admirably. From three to five months, according to the season and the treatment they receive, will elapse between the time of sowing and fruiting.—Thomas Record.

OLD PEARS WITH NEW NAMES.

Some time early in November I received two or three Pears from Glastonbury of a large size, covered with russet, and of a texture and flavour remarkably fine, the latter with a smack of aniseed very agreeable. These I found had been submitted to Mr. Cramb and some nurserymen, who pronounced them to be the Brown Beurré.

A few days afterwards my son brought from the neighbourhood of Bristol, from the garden of a friend to whom I had presented a tree some ten years since, an equally fine specimen of the Pear received from Glastonbury. This tree had a label with the name on it as sent from here, and this was one long since known to me and forgotten—the Esperione. This was a clue, and I at once went to my preserve—my plantation of stock trees, and there I found the tree, which had borne some fruit. In my fruit-room I found them to be the same Pear, but much inferior in size to those from the west. About the middle of the month I received from another part of Somersetshire two or three specimens of the same Pear, but this time with a name. On examination I found them much inferior in size and flavour to those I have mentioned, owing, probably, to stock, or site, or soil, but evidently the same Pear.

Now I fully believe that unless I had recognised these Pears we should have had two new sorts added to our collections, for the Fruit Committee, not knowing the first mentioned, would have given it a certificate, and probably the second also, thus benefiting the pockets of the growers. I mention these unknown Pears because I feel assured there are hundreds of French and Belgian Pears that have lost their names and have had local names attached to them, as is doubtless the case with Wheeler's Brockworth Park Pear. The history of this showy Pear seems to be this. In 1870 Mr. Wheeler saw it growing against a wall at Brockworth Park, and sent it to the Fruit Committee. It proved very handsome and good, and had a first-class certificate. In 1871 it was not so good. Now, although it could not be proved to be a seedling, it is now called Wheeler's Brockworth Park. This is not pomologically correct; it might have been called temporarily a foundling till its true name is found, which it assuredly will be.

This naming of unknown fruits used to be very common, but Thompson spoilt the trade in guinea and half-guinea quasi new fruits when he published his "Catalogue of the Horticultural Society," and I quite thought the practice was entirely out of date till my attention was called to it recently. No fruit should be called a seedling or named as such till its origin can be fully proved. There is a sort of assurance in a man placing his name to a fruit unless it can be proved to be a seedling. Mr. Wheeler is not to be blamed for introducing a Pear unknown to him but of good quality, but he is not blameless for attaching his name to it as if it were a seedling. If I had bought a tree at one guinea, I should hold him responsible for that sum when its true name was discovered.

It is curious to observe the change in some Pears brought on by the soft mild climate of the west of England. Some sorts are much improved both in size and flavour, and others are to a certain extent the contrary; so that my axiom is good—Try and try again before any kind is fixed upon for extensive cultivation.—T. R.

AUTUMN-BLOOMING DAFFODIL.

In your number of August 31st (page 164) is an interesting article on autumn-flowering Crocuses. Will you allow me to call your attention to an old-fashioned autumn flower, which would, I believe, at the present time be a most valuable addition to our flower gardens—I mean the autumn-flowering Daffodil? I have repeatedly asked for it at seed-shops, but it seems unknown; and the only work I know of in which it is mentioned is Parkinson's "Garden of Pleasaunt Flowers," date 1689, under the name Narcissus autumnalis major.

I have seen the flower twice: first, some years since in a garden at Ipswich, the owner of which did not know the name of the flower, and again about two years ago in an old garden at Bexley Heath. On both occasions I procured roots; the first time I bought, the next I begged them, but I am sorry to

say in both cases I lost them, I imagine from the same cause —moving the bulbs while in blossom. The flower is a golden yellow, somewhat softer than the spring Daffodil, about 6 inches in height, growing amongst long, narrow, green leaves, which are of a deeper green and firmer than its spring cousin. The root is bulbous, very like in appearance the spring Daffodil. It was early in December of 1869 that I procured the root from Bexley Heath. I made a drawing of the flower and showed it to a nurseryman in this neighbourhood, but he was unacquainted with it. I think if you could succeed in drawing attention to it and reintroducing it again, all lovers of gardens would be grateful.—Harriett Jabot.

[We do not know the flower which you identify with Parkinson's Narcissus autumnalis major, but his Narcissus autumnalis minor is that known as Narcissus serotinus. This blooms in the autumn, as do two other species, N. elegans and viridiflorum.—Eds.]

MADRESFIELD COURT GRAPE.

Mr. Freeman's remarks on this Grape (see page 437), are very important, and from his character and experience are worthy of every respect. His plain matter-of-fact statement that "it will not keep more than three weeks or a month, and not so well as the Black Hamburgh," will no doubt be read by many with feelings of disappointment. There is no doubt that this Grape is being planted extensively on account of its reputed excellence of flavour and easy culture, but especially for its late-keeping properties. The sooner its late-keeping properties are placed beyond dispute the better. By Mr. Freeman's account it is not a late-keeper; by another account, for which Messrs. Lane are responsible, it is. In the latest published list of the great Grape-growers of Great Berkhampstead occurs the following in reference to Madresfield Court—"As a late Grape it is especially valuable, it having been proved that it will hang for months after ripening without shrivelling." Proved by whom? Statements so opposite by recognised authorities are most perplexing. The other day a grower decided to plant a large house principally with it on account of its late-keeping properties. To him the question is of great importance and to many others. Further information is, therefore, anxiously awaited.—J. W.

HORTICULTURAL and COTTAGERS' SOCIETIES.

There are few things more enjoyable to the lovers of gardening than a good horticultural exhibition—not a mere flower show, but a collection of flowers, fruits, and vegetables in as high a state of excellence as the skill or means of the respective exhibitors can effect.

The organisation of a society for the promotion of horticulture is by no means an easy matter, as many who read and contribute to the Journal very well know. Many a society has been formed, held a brilliant exhibition or two, and collapsed. This downfall was owing, perhaps, to the want of energy on the part of the committee, but more probably to a lack of funds, and in some instances to the effects of the two evils combined. How little does it occur to the public as they enjoy the gay scene of an exhibition-day, to reflect upon the labour implied in its details. Nor is this altogether to be wondered at, for who that sees a certain worthy secretary in all the glory of his proud position and white waistcoat, complacently surveying the results of his toil, could possibly picture him groaning under the weight of office, or lamenting that he had ever been induced to undertake its duties?

For a horticultural society to be really successful three things are necessary—a good working committee, an energetic and able secretary, and, above all, a liberal paid-up subscription list. The society will then have plenty of "go" in it, and with a popular prize schedule there need be no fear of failure, which may happen sometimes, indeed, from other causes, but I think generally from the absence of some of these conditions.

In arranging the prize list it is well to offer the leading prizes for collections of vegetables, fruits, and flowers, such prizes being best adapted for bringing together those plants in the production of which a gardener's skill is strongly tested. It may be thought that this is sufficiently regarded in the usual premiums for a few large specimens, but I would also offer other prizes for collections of small healthy plants developed enough to convey a clear idea of their true character, and thus encourage the culture of those plants most in request for decorative purposes. Moreover, the large number of varieties which would probably thus be exhibited, would serve to convey instruction as well as amusement. To many a man serving in a small place, and with but few chances of observation, the "show day" is the principal holiday of the year. A sensible, earnest man in this position, would be glad to avail himself of the opportunity of acquiring a greater knowledge of new varieties of plants worthy of cultivation.

It is unnecessary to enter upon the usual premiums for single specimens or dishes, farther than to notice the prize for single specimens of pot plants as a very desirable one, likely to develope taste and skill in the culture of such plants by those not having space for collections, and to bring together a number of fine plants which would otherwise be lost to the exhibition. With the prizes for garden produce it would be well to offer a few others for models or plans of garden structures, designs for flower gardens plain and coloured, and any other object worthy of the attention and study of young men in their leisure hours.

All these things are, I think, such as rightly come within the scope of a horticultural society, as they contribute to its usefulness, and serve to foster the intelligence of the class for whose benefit such societies are principally formed. In this, as in all other undertakings, it is better to do a few things well than to attempt matters beyond the strength or funds of the society, for after all it is a mere question of money.

It is, doubtless, right to offer prizes for cottagers' productions, yet unless there is abundance of funds to do this well, it is best not to attempt it. In any case I am inclined to question whether the cottager does not gain most good when exhibiting the pet productions of his garden at one of the excellent cottage garden societies now common to most villages. The aim and end of a cottagers' society should be the promotion of industry, intelligence, frugality, and sobriety. In all these qualities, to take the class generally, there is much need for improvement. Anything tending to correct the spirit of selfishness is surely a legitimate object for such a society. To see a gang of labourers of the genus navvy employed upon a job of piecework is a sight to set one thinking. They will frequently work so hard as to break down the weak men, and the unsteady hands of the stronger show but too plainly that they have tried Nature too severely. If this high-pressure speed were for the good of the wives and children, or to add to home comforts, one could not blame them; but in by far too many instances its object is only to obtain a little extra money to gratify the greed for drink, and the pay-night not unfrequently ends with an empty exchequer. I have heard from reliable sources of poor wretches having partly stripped their already too-scantily-clothed persons to sell the garments for drink, and these men often have children depending on them for all they want—for everything. Let it not be thought that I am quoting an extremely bad and solitary case, and thus condemning an entire class from the failing of a few. I am acquainted with many whose lives must be a curse to themselves, and those depending on their exertions for subsistence. Surely it is worth while encouraging the praiseworthy lives of those honest sturdy men, of whom it has been most justly said that they are the pith and marrow of the nation, at the same time not forgetting those whose lives are so faulty and full of error, but to hold out inducements likely to draw them on to better things.

The prizes for cottage-garden produce should embrace the most useful kinds of vegetables and fruit suited for limited spaces, and for maintaining as good a succession as possible throughout the year. By giving a select list of such things, taking care only to name well-established sorts, the very prize list would be made to convey instruction. It is also, doubtless, a good thing to offer premiums as sort of champion prize for the best garden, neatness and culture being the test points. There are also home-made garments, wine, bread, miscellaneous articles of furniture made by the cottager, and, in fact, anything tending to increase the home comforts, or to develope intelligence and sobriety. Poultry and pig-keeping, too, should be encouraged. Many of the labourers working in the garden here keep poultry, and their wives make considerable sums of money by the sale of the chickens for which Sussex is so famous.—Edward Luckhurst.

Christmas at the Crystal Palace.—The preparations for Christmas and the new year at the Crystal Palace are more than usually good. Among a multitude of other seasonable attractions a Christmas Tree, 80 feet high, is raised in the northern nave, and has been beautifully decorated by Mr. Wilson, the Company's naturalist; round the base, which is formed of roots of trees, live birds and animals are arranged,

as well as dead specimens in natural history; the branches are touched with snow with beautiful effect. The aquarium with its thousands of living ocean creatures is a marvellous exhibition, and it alone would be worthy of a visit.

SOME ROSES THAT HAVE BEEN INQUIRED ABOUT.

Mr. Peach has asked for the experience of Rose-growers of some kinds named by him at page 486. I subjoin mine.

Paul Verdier.—It was asserted some time ago by a contributor to these pages, that this Rose will bloom sometimes in the autumn if budded on the Briar, although it does not on the Manetti. Wishing to put this to the proof, I budded two Briars with it some time in the summer of 1869, and three more in the summer of 1870. The first two, after yielding very fine flowers in the summer following that in which they were budded, also produced flower-buds late in the autumn of the same year, but these did not expand, from the wet and cold prevailing at the time. Last season—that is, in the present year, flower-buds were again produced in the autumn much earlier than last year, and expanded beautifully. Of the other three, two produced flower-buds too late to open, the other plant met with an accident that it will take another season to repair. Paul Verdier is thus proved to be remontant, but that it possesses this quality in a much less degree than most other fine varieties is quite manifest. Still, that it should be so, budded on the Briar, and not on the Manetti, is a phenomenon beyond my power to explain. It is a magnificent Rose.

Marie Baumann.—Its habit is not all that can be desired. Here its growth is moderately vigorous, far better than such Roses as Madame Furtado or Madame Vidot, which are too feeble to be grown at all on light soils. It is also worthy of remark that Marie Baumann is very constant, yielding every season a full proportion of good blooms. Its drooping habit is certainly objectionable, but we forget that in looking upon the unrivalled beauty of the expanded flower.

Henri Ledechaux.—Its colour, as Mr. Peach correctly describes it, is a true deep pink, quite brilliant when first expanded. Its size, if not quite so large as is now generally sought after (whether rightly is quite another question), is certainly beyond the dimensions of what are usually considered button-hole flowers. Its growth thus far is very unsatisfactory, and another season must pass before its merits can be fairly decided upon.

Logomachy.—This is not the name of a Rose, but a strife about words. Mr. Peach will at least allow that "remontant" expresses very nearly the property that the class of Roses to which it is applied possesses, while "perpetual" certainly does not. I use the word remontant instead of perpetual not as a final, but as a truer designation of the quality which is generally understood to be implied. If a more appropriate English word than "perpetual" can be found, let it be employed; if not, there is no violation of the laws of language in borrowing from another tongue a word to express what we have no equivalent term for in our own. I, therefore, will be no party to perpetrating so glaring an abuse of terms as that now under notice.

Election of Roses.—I give my suffrage for the following as the best twelve Roses suitable for exhibition, so far as they are the best I have been able to grow in the light soil of this garden. 1, Maréchal Niel; 2, Gloire de Dijon; 3, Devoniensis; 4, Charles Lefebvre; 5, Baroness de Rothschild; 6, Alfred Colomb; 7, Marie Baumann; 8, La France; 9, Pierre Notting; 10, John Hopper; 11, Madame Victor Verdier; 12, Comtesse de Chabrillant.

Of newer kinds Marquise de Castellane promises to take a first place, and another season will, doubtless, assign it such. Marquise de Mortemart is unquestionably a fine variety, but its growth very unsatisfactory. Perfection de Lyon was remarkably good this year. Comtesse d'Oxford produced deformed flowers.

As several others besides those named by Mr. Peach have recorded their votes, and notably Mr. W. Paul and Mr. Radclyffe, whose decisions are of much weight, the arithmetical state of the poll for the best twelve might be re-declared, or if needful the final close issued.—A. H. Kent.

FRENCH HORTICULTURISTS' RELIEF FUND.

As the account is now about to be closed, it is requested that any nurseryman or seedsman who undertook to receive subscriptions will be kind enough, if they have received any, to forward them to the Treasurer, George F. Wilson, Esq., care of J. Richards, Esq., Royal Horticultural Society, South Kensington, or to the Hon. Secretary, the Rev. H. Honeywood Dombrain, Westwell Vicarage, Ashford, Kent. Sum not previously acknowledged, collected by Rev. W. Middleton, Heybridge, Devon, £2 6s.

CULTURE OF THE FUCHSIA.

Perhaps there are few flowers so universally cultivated, or more generally useful for decorative purposes, than the cultivated varieties of the Fuchsia. It is grown by the cottager, and is one of the very best window plants, as it yields its pendant and graceful clusters of scarlet and white drops under very unfavourable circumstances. Indispensable as a window plant, it is never out of place in any garden, however large or limited in extent, whether planted out as a border plant, or grown in pots for greenhouse and conservatory decoration. The Fuchsia is neither so universally nor so well grown as it used to be fifteen years ago. More recently introduced plants receive more attention, and hordes of "bedding stuff" occupy the available space once devoted to this plant. Amongst hardy varieties useful as border plants, Thomsonii, Riccartonii, and globosa have long been favourites in old-fashioned gardens. The two first-named sorts are hardy enough to stand our severest winters without protection. The old shoots are generally killed to the ground in winter, a fresh lot being thrown up from the stool, which branch out freely and flower abundantly during the summer and autumn months. Globosa is a very distinct and comparatively hardy sort; the flower-buds previous to the opening of the flower are nearly globular.

These hardy sorts are easily cultivated, and form an interesting feature in the best-arranged flower gardens. They are propagated by division and from cuttings. In spring, when the young shoots have grown 3 or 4 inches, lift the plant and divide it with a trowel, but if a large increase of the stock is desired, the shoots must be slipped off and inserted as cuttings, a dozen of them in a 6-inch pot. A bed composed entirely of the variety Thomsonii, or of the more robust Riccartonii, is a very beautiful feature in the flower garden. The plants should stand 2 feet apart each way; they require very little attention, and being of sturdy growth seldom require sticks. When the shoots are cut down by frost the bed should have a dressing of rotted frame manure, as in the event of severe frost it will keep all right, and act as a fertiliser at the same time. I have also seen the above varieties introduced in positions in the front row of shrubbery borders, where they have been left in the same position for a decade at least without being disturbed.

The pot culture of the Fuchsia is very generally understood amongst gardeners, but to many readers of the Journal a few practical hints may be useful. The Fuchsia is a gross feeder, and grows rapidly, so that handsome specimens may be formed from cuttings struck the same season. The very large specimens seen at exhibitions are formed from old plants. At the present time all the plants should be at rest. When all the leaves have fallen, and the plants are quite dry at the roots, they should be pruned, cutting them in rather close. About the first or second week in January the plants should be placed in heat—not a very high temperature, as it would cause the plants to break irregularly; 45° at night will be sufficient, with a slight rise by day. I generally contrive to introduce them to a vinery started at that time, as the same treatment required for the Vines is that best adapted for the Fuchsias. They should be syringed overhead twice a-day, and will soon start into growth.

When the young shoots are an inch long take off as many as are required for cuttings. These may be inserted in 5-inch pots, a dozen in a pot, in a compost of equal parts loam, leaf mould, and sand. The pots should be plunged in a gentle bottom heat, and the temperature of the house should be a few degrees higher than that in which the plants were growing. If the atmosphere of the house or pit be dry, place a bell-glass over them. Under proper treatment they will soon form roots, and as soon as they commence to grow pot them off singly into 3-inch pots, still keeping the plants in a growing temperature—55° at night will be best at this time; indeed, the whole secret of success consists in maintaining a moist atmosphere with a night temperature of from 55° to 60°, with a rise of 10° by day from sun heat, and repotting the plants as they require it. The size of pots should be in the following ratio—5, 7, 9, and 11½-inch, and the plants will require repotting at intervals of a month.

The best compost to grow them in is one of two parts turfy oam, one of leaf mould, and one of decomposed manure with a liberal proportion of silver sand, as the Fuchsia delights in an open porous compost. During the whole period of their growth the plants should be kept near the glass, and syringed daily to prevent red spider from appearing on the leaves. Any sudden check such as an arid atmosphere, dryness at the roots, or an attack of red spider will cause the leaves to fall off in great numbers and sadly disfigure the plants.

Then as to training, which is a matter of taste, some prefer the pyramid, others the bush form; both systems if the plants are well managed will obtain admirers. The pyramid form does not require so much work as the other; a stout stick should be placed to the leading shoot, and a system of timely pinching is all that is required. Some of the varieties are naturally of a short-jointed, compact, sturdy growth, others are of a more straggling habit, and will require more attention as to stopping. Where this loose-growing habit is apparent, the leading shoot must be stopped three or four times, which will cause the plants to break more regularly. Where the plant is of a bushy habit, the leading shoot will not require to be stopped until it has grown to the required height. The side shoots must be repeatedly stopped until the plant is of the desired size, when it may be allowed to flower.

Plants to be grown in the bush form should have the leading shoot stopped when the plant is 6 inches. A high number of lateral shoots will form, which should be stopped at the third oint. The shoots will require two more stoppings, and they should receive their final one about six or seven weeks before the plants are required to be in flower. Under this system a large number of sticks are required for each plant: a well-brown specimen will take a hundred, as one is required for each shoot. The sticks should be slender, painted green, and hidden by the foliage as much as possible.

If the plants are intended for exhibition they must be large, but for general decorative purposes plants grown in 7 and 9-inch pots are the most useful. Fuchsias are grown and flowered in all sorts of houses, and sometimes in very unfavourable circumstances; but a light airy span-roofed house running north and south is the best both to grow and flower them in. A very thin shading should be used to break the force of the sun's rays in hot weather. The plants also delight in a rather moist atmosphere: even when in flower a dry atmosphere should be avoided, especially if combined with draughts, as this will cause the yet unexpanded flower drops to fall off.

The varieties of this plant are so well known that to give lists of them would only occupy a valuable space. Good-habited free-flowering sorts should be grown, and the single-corollaed sorts are to be preferred to the double, some of which are only so many monstrosities.—J. Douglas.

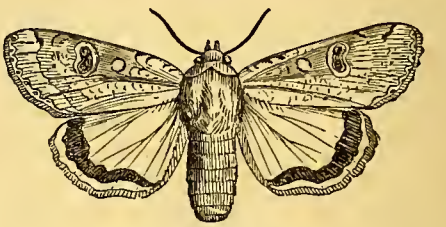
DRAUGHT OF FLUE TOO POWERFUL.

Having been placed in a similar position to your correspondent, "Viridis," with the fire of my little greenhouse, till my patience had given up to despair, I consulted your experience, and I have ever since had reason to be thankful for your advice. If "Viridis" do but follow your instructions and pay the same attention to the ashpit-door as he seems to have done to the damper, I am quite certain he will not require the services of the latter at all.

Being only an amateur I required much guiding, and although I could build my greenhouse and construct the flue and fire-box, I was brought to a standstill. When my fire is burnt-up I place, in the absence of an ashpit-door, a sheet of iron with two slits near the bottom 1½ inch long, and half an inch wide, by which I can regulate the combustion to a nicety. It will burn from eight at night till ten the next morning. It burns tan and cinders from the house. One thing I consider very essential—I keep all dust and small ashes from under the furnace as directed by Mr. Keane some time back.—T. Sedoley.

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 24.

There are many species of moths which enter houses of their own free-will, and none more frequently, perhaps, than the Large Yellow Underwing (Tryphæna pronuba). This species is also now and then to be seen resting during the day on palings or the sides of windows, where it draws itself up closely, and so frequently harmonises in colour with the object on which it reposes that the unobservant pass it by. Pronuba has also a partiality for places of public assembly, drawn hither by the fascination of the lights, or, perhaps (shall we say?), from some liking for the society of the human kind. I have seen one of these occasion quite a commotion in a church by its wild gyrations from pew to pew, all the while carefully avoiding a catastrophe which would soon have befallen other moths of feebler frame and less rapid wing—viz., destruction by the flames of the gas-jets. Like other moths of the genus, too, Tryphæna pronuba has strong legs, and will sometimes run with great rapidity, which renders its chase rather difficult, for you have marked its settling, as you think in one particular spot, and you keep your eye on that spot, yet shortly after you see the moth taking an aërial excursion from quite a different



Tryphæna pronuba.

point. This moth comes to sugar, when spread upon trees as a bait, though not so eagerly as do some of its brethren, and it often haunts grassy meadows, being, probably, attracted thither by the scent of certain flowers, or it may have been nurtured to maturity on some weedy bank in the vicinity.

The fore wings of this handsome, though common, moth (which is usually on the wing during July and August), very much vary in colour and markings, the general hue being some shade of brown; in almost all specimens what are called the discordal spots are clearly defined; there are also several transverse lines of differing intensity in colour. The hind wings, however, show scarcely any variation, being of an orange-yellow colour, with a narrow black border.

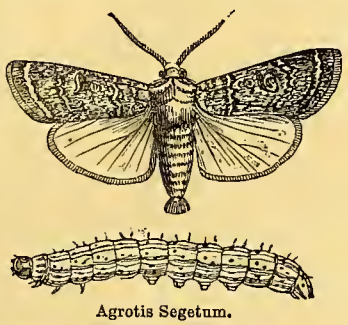
With the caterpillar producing this moth some persons make acquaintance in rather a singular way—that is to say, they eat it; for owing to its mode of life it is occasionally boiled with some Cabbage, in the heart of which it had been feeding, and being brought to table it is mashed up and eaten as "greens" without being remarked. This caterpillar, however, is an external feeder also at times, taking as its right not only the Brassicaceous plants in the kitchen garden, but many others with succulent leaves. It does not seem to discontinue feeding during the winter, and is not uncommonly disinterred by the gardener at this season. For, as Mr. Newman observes, "it conceals itself almost entirely during the day beneath the surface of the ground, emerging at night;" and he also adds concerning it, "I have frequently found it hidden at the roots of Lettuces, and it is brought to light when they are pulled up for the table; when thus exposed it rolls itself into a very compact ring."

A decided family likeness is observable amongst the caterpillars belonging to that section of the Noctuæ in which T. pronuba is included. There are numerous lines and stripes of dark brown, some of which are occasionally wanting, but when present they are arranged according to a regular pattern; the ground colour is often an unpleasant shade of green, at other times a brown, which renders the markings scarcely distinguishable. The body of the caterpillar is stout and velvety both to the eye and the touch. Comparing the head with the body, it seems small in proportion; it is shining and reddish brown. The eggs of this species hatch towards the end of the summer, and the caterpillars do not attain their full proportions until the following spring or the early summer. They form a cell to undergo pupation beneath the surface of the earth. I know no way of dealing with this species except by the destruction of the moth, pupa, or caterpillar whenever either is seen.

A closely-allied species, the Lesser Broad-bordered Yellow Underwing—a rather long name, which leads us to take refuge gladly in the much briefer Latin, Tryphæna ianthina. This, though not particularly common, does occasionally a little mischief in the flower garden. It is stated to be partial to the Polyanthus, sometimes feeding on the roots beneath, sometimes eating into the crown of the plant, and at other times devouring the leaves. It will also attack a variety of other plants, but keeps itself carefully out of view in the daytime. This

caterpillar is brown in colour like that of T. pronuba, resembling it in appearance, but marked with some conspicuous black spots. The moth is exceedingly beautiful, and the insect-hunter looks upon it as one of the choicer ornaments of his collection; it flies in July. The caterpillar feeds from autumn to spring. I have taken this species in Surrey; more frequently, however, in Kent, especially in the lanes about Greenhithe, where the moth flies out briskly from the hedges when aroused by the beating-stick of the entomologist. Yet it is not easily secured, for it can rarely be netted on the instant, and darting some distance along the road, it generally enters the hedge on the same side again. You approach, having marked the spot, as you suppose, thinking that the net may be easily clapped over it, but you fail to find it, and the reason is, that after entering the hedgerow it moves along amongst the leaves, which throws the observer out of his calculation. In the district to which I am referring gardens are not numerous, the country being well wooded, and I have no doubt that the caterpillars there feed upon Chickweed, perhaps Nettles, and other low-growing plants.

Judging from the abundance of Turnips in the market at present, I should surmise that on the whole they have not suffered much from the attacks of insect enemies, though in some quarters they have complained of the Turnip fly or beetle. There are two lepidopterous larvæ, however, which in some seasons make sad ravages amongst our Turnip crops, and, indeed, every season they do a certain amount of damage. From its great partiality for Turnips, one of these (Agrotis Segetum) bears the name of the Turnip Moth. Besides the Turnip, however, the caterpillar attacks a number of other plants in the kitchen garden, as, for instance, the Radish, the Carrot, and Cabbages of various sorts. Now and then a party of the moths will visit the flower beds, and depositing eggs there, the natural result is that an active colony of caterpillars is at work there shortly after, both above and below the ground. Mr. Newman draws a dismal picture of the mischief they will do in a bed of that attractive flower—the China Aster. He says, "Often the leaves of a plant here and there will be found withering and curling up, and you become aware that it is dying, and can't tell why; just examine the stem where it enters the ground, and you will find it completely decorticated; the rind has been gnawned off all round, and the circulation of the sap being prevented, life is destroyed. You pull up the Aster to find the enemy, but fail; his depredations are committed in the night, and before daybreak he has wandered far away." Whatever food the young caterpillars select, they appear to prefer to feed above the surface at first, going deeper as they get larger: hence it is that some gardeners have gone forth with lanterns, not like Diogenes to find an honest man, but to detect dishonest depredators of the caterpillar sort, and many young fellows of the species Segetum have paid dearly for their midnight excursion. The process of searching, is, however, tedious, and after a day's hard work in the summer the gardener cannot be expected to take much interest in a hunt of this sort, which must be carried out in an uncomfortable stooping position.



Agrotis Segetum.

We find that the caterpillars feed on throughout the winter with scarcely any intermission, and from August onwards they are diligently engaged in feeding underground on the Turnip bulb, several being found very often burrowing into the same Turnip. The rapidity with which one of these caterpillars will make its way into the earth is very remarkable. The ground colour is a dull brown usually, there are some indistinct stripes, and a series of well-defined circular spots on all the segments after the second. The second segment is notable for having on its back a dark plate, which, doubtless, assists the caterpillar in its mining operations. A minute examination, however, of this caterpillar hardly affords any very marked distinction by which we can separate it from its congener, A. exclamationis, also injurious to Turnip crops. It has been noticed as a curious fact in the history of this species, that while the greater part of the brood continue in the caterpillar state until the spring, a few become mature in October and appear as moths, but do not live long, nor do they attempt to continue their species. Mr. Newman regards this as a case somewhat analogous to the autumnal production of drones in bee hives; in both cases there is an apparent waste in Nature, but had we a deeper insight we should probably be able to explain this and several other instances, wherein we in our wisdom should be tempted to fancy we could improve upon the economy of a species.

The Turnip Moth was particularly injurious to the crops in 1863-64, at which time it was shown by entomologists that farmers and others have by their injudicious destruction of birds preying upon the Turnip caterpillar and various "grubs" of similar habit, been the chief cause of the multiplication of these insect enemies. The rook and the partridge stand foremost in the list of the devourers of the Turnip grub. The rooks, doubtless, obtain most, because they strike at the caterpillar in its retreat and drag it to the surface; the partridges hunt by scratching, and pick up smaller numbers. Many expedients have been tried by gardeners to keep the species under, such as digging between the plants, which, it will be found, usually is, in fact, doing an injury to remedy another; others have tried the application of different solids and fluids, such as lime, soot, sawdust, ashes, and the refuse liquor from gasworks; these are mostly, as Mr. Newman observes, "uncertain and unsatisfactory." However, this and the equally troublesome species of which I am next to speak have been in some cases destroyed very successfully by watering the plants with strong lime water.

The Heart-and-Dart Moth has been so named because it bears upon the fore wings markings supposed to resemble the objects in question; but really it might be thus designated from the rapidity with which a caterpillar of the species will "dart" to the "heart" of a tempting Turnip, Parsnip, or Carrot. Why the older entomologists called it Agrotis exclamationis is not positively known, unless, indeed, it was because it has forced many a bitter exclamation of disgust from the horticulturist or agriculturist, for the species is a plague at times in the fields as well as in gardens. Just about this time also, on a mild night, caterpillars of the Heart-and-Dart may be detected banqueting on the leaves or heads of any greens which the autumnal frosts have as yet spared. The young caterpillars also feed externally on various vegetables in the garden and on weeds in waste places: they emerge from the egg in June.

Like A. Segetum, the species remains in the larval state until the spring. The adult caterpillar forms a cocoon of earth several inches beneath the surface, and is frequently dislodged by the spade or hoe. Probably, as we find in some other species, the disturbance does little harm to the pupa, unless, indeed, it should be actually wounded, and left in so exposed a position as to be an easy prey to birds, for there are many which will devour a pupa quite as eagerly as they would a caterpillar. Another rather singular foe to the caterpillar of Agrotis exclamationis is the common rove beetle (Staphylinus olens). Mr. Moncrieff observed one evening a party of these beetles journeying towards their retreats, and each was dragging along a caterpillar, which, on examination, was found to belong to this species. They had all been disabled, but not killed. Afterwards this gentleman found a quantity of larva skins lying near the holes of the beetles.—J. R. S. C.

MRS. PINCE BLACK MUSCAT GRAPE.

After reading the description of the above Grape in the "Gardeners' Year Book" for 1866, I at once ordered it direct from the Messrs. Pince, of Exeter. In 1868 a vinery was erected here on Beard's principle, and in the month of June I planted twenty Vines, ten of them being Mrs. Pince. In 1869 I had only a few bunches, and last year also it did not set well. I had five bunches on each Vine, a good many small berries, but the most of them shrivelled by the 1st of November. This year I have ten bunches on each Vine, and not a small berry in the hundred bunches. I have grown the most of the old Grapes as well as the new which have been sent out during these last twenty years, and I have no hesitation in saying that Mrs. Pince, in my estimation, is the best late black Grape in cultivation. I herewith send for your inspection a fair average bunch, likewise a bunch of Alicante grown in the same house.—A Donaldson, *Latimers*.

[The bunches of Grapes as sent by Mr. Donaldson indicate not only that he knows how to grow, but how to pack them.

There are many men who cannot do either as they ought to be done, and among these are they who hastily set themselves up as censors of other men and things, solely on their own experience of them. It will be in the recollection of many that Mrs. Pince was one of the new Grapes of the time, which those wiseacres so well abused, on the ground, we take it, that they and some others failed to grow it as Mr. Pince did, and as Mr. Donaldson does now. The bunch before us measures 14 inches long, 9 inches across the shoulder, and weighs 3 lbs. 2 ozs., while the flavour is all that can be desired. The bunch of Black Alicante weighed 4 lbs. 14 ozs., and both colour and flavour were unexceptionable. Some of the other best-abused grapes, such as Muscat Champion, Royal Ascot, and Golden Champion, we have no doubt will, in the hands of such cultivators as Mr. Donaldson, ere long force their detractors to abandon the ill-timed and hasty conclusions they formed and attempted to impress upon others.]

GLADIOLUS FAILURES—ROSES.

In answer to your Somerset correspondent referring to the failure of his Gladiolus (page 485). If the signature appended to his paper is at all descriptive of the nature of his soil, then it is an unsuitable one for the Gladiolus. I very much fear if his roots did not throw-up any good spikes last season, there will be no improvement in the ensuing one. His ground might be improved by using stable manure and road scrapings which have been exposed to the direct influence of frost during winter. I would also suggest spreading 6 inches of gravel over the surface, and stir up the ground to the depth of 2 feet. The soil here is very light and stony, resting on a gravel subsoil, and is of a similar nature to that of the Messrs. Stuart & Mien, of Kelso, N.B. If the roots were sound and healthy when bought-in last year, there would be no reason to blame the English house that supplied them.—J. Douglas.

In reference to the query put by "Stiff Soil" as to his bulb, he is, unfortunately, as many querists are, not sufficiently explicit, and no lawyer will give his opinion unless he knows the whole case. He says that he obtained a hundred bulbs from one of our greatest English growers, and that he had not one decent spike. Very likely; but will he say in what condition he received the bulbs? Were these clear and bright in the flesh, or had they darkish spots over them? If he can certify to the latter, then he ought to claim some compensation. And then in what condition are the bulbs now? Have they this spot on them or not? If they have, they are not worth a dump; if they have not, there is still hope for them. Now, if "Stiff Soil" will send me a bulb, a fair average sample of his lot, I will with pleasure give him my diagnosis of it, and return the patient.

I once used to think it was some use trying to save diseased bulbs, but am now fully persuaded it is useless to try and do so. When going with Mons. Souchet (whom all lovers of this beautiful flower will be truly sorry to hear is now "*toujours très malade*"), through his grounds, I have seen him when coming to a plant in full bloom, which displayed that rustiness of foliage too surely indicative of disease, pluck it up at once and cast it away. This will show the opinion of the most experienced grower of the flower that we have as to a diseased bulb recovering itself. But after all, "Stiff Soil's" may not be diseased, and if only puny and weak, there may be hope for them yet. "The dealer laid it to the soil." Perhaps; but very likely some wonderful manure might have put it right. If, however, "Stiff Soil" really indicates the nature of the ground he has to deal with, it is not a favourable one for the Gladiolus, and he had much better try to lighten it, for few bulbs like a stiff soil, and the Gladiolus, I think, particularly dislikes it. I should imagine well-decomposed leaf mould would tend to do this; and in a stiff soil I should be inclined to mix thoroughly well-rotted manure with the leaf mould, dig it in, and then when planting the bulbs, remove the soil from each spot where the bulb is to go, and put in sand and leaf mould, so as not to allow the bulbs to come in contact with the manure. The one great drawback to the growth of this lovely flower is the tendency to disease, for which, unhappily, there seems to be no remedy or preventive.

As to Roses. My reason for excluding Princess Christian is that there is not enough of it; and so of the very beautiful Teas he mentions. Lovely in the bud, woe to him who trusts to them in a show stand. They are seen to open and show the eye—as bad as showing the white feather.

With regard to the difference between "*se tenant bien*" and "*belle tenue*," there is really none, except in the form of expression. If possible, the former more decisively means stiff, erect, and is what one might often hear applied to the Cent Gardes of the Second Empire—"*Comment ils se tient bien.*" I think Mr. Kent hardly estimates aright the force of fixed names and the difficulty of changing them. If he and I never have a headache until we see Remontants taking the place of Hybrid Perpetuals we shall do well. An attempt was made to change the absurdly arbitrary terms of show and fancy Dahlias, but it never got beyond an attempt. Shanghais was no doubt the proper name to apply to the Brahma fowl; it was tried, but the absurdly wrong one remains, and the Brahma, which has no more to do with the Brahma Pootra river than with the Orinoco, holds its own. And so with the Hybrid Perpetual; the term will outlive Mr. Kent and myself too.—D., *Deal.*

HEATING BY IRON STOVES.

I have a lean-to greenhouse facing the south, about 17 feet by 11 feet, and at present it is heated by an iron stove, about 8 inches square in the narrowest part, attached to a 5-inch metal pipe, which is placed at the end opposite the door. Within the structure the flue runs for about 4 feet straight along the end of the building, and then turns at right angles with a rise of about 18 inches in 12 feet, and with another elbow through the roof, which it tops by at least 4 feet. This arrangement has never been satisfactory, for when the wind was to the north of west or east the stove used to smoke, no matter how strong the wind was. I have since attached to the end of the flue one of the patent screw ventilators, and find that when there is any wind it does its work well, but when there is a calm or very little wind, which is generally the case with severe frosts here, it is necessary to heat the flue before the draught sets in. This makes a great smoke, from which I am sorry to say the plants suffer. I enclose a rough plan of the arrangement of the flue as it now is.

I am thinking if the stove were sunk in the ground, and a portion of it entered under the end wall, with an elbow joint so as to make the stove face the east side instead of the south, and to be fed from the outside instead of inside, I might so stop the smoking. Or if I were to place the stove as last mentioned, and run the flue under the centre walk, with an elbow at the end, and another at the back wall. This I am afraid would necessitate cutting the metal pipes. At present the flue is set on brackets fixed to the back wall, which is a boundary wall. As I have only a limited interest in the place, I do not wish to go to much expense.—J. W. B.

[There can be no doubt that a greenhouse 17 feet by 11 can be heated by an iron stove; but we do not think you will escape being smoked, or be thoroughly successful by your present or proposed plans. During the last two winters we kept a lofty place double the size of yours, temperate, by having a round stove inside at one end. It was about 13 inches in diameter, 30 inches in height, lined with fire-brick about 7 inches through, and the fire was placed inside. We have no faith in iron stoves for plants, but as mere makeshifts, unless the fire-box stands in the middle, leaving 1½ to 2 inches all round between the fire-box and the outside of the stove, or unless the fire-box is lined with fire-brick. In either case the sides of the stove opposite the fire will never get anything like red hot, as iron when so heated exerts a deteriorating influence on the atmosphere of the house, and this would be apt to injure plants in severe weather.

If you had been an older subscriber you might have seen that the chief error in your present plan is not so much having the stove at one end of the house, but in taking the flue straight from it for about 4 feet on the level, then by a right-angle bend along the back wall with a rise of 18 inches in 12 feet, and thence out through the roof and 4 feet above it. The error consists in the 4-feet horizontal. If you only had a level of 12 to 18 or even 24 inches, and then rose at once as nearly perpendicularly as possible, we should wonder if you were much troubled with smoking. We need not enter into the causes, the fact we have proved over and over again, that no iron stove in a house, nor any mere stove will work well unless the horizontal pipe that issues from it is short instead of long. The quantity of piping, too, is based on a misconception of the theory of heating by such stoves, as if the pipes and not the stove were to be the means of heating. Now it is best to make the latter the chief heating medium, and it would do all you require in such a small house if you merely had 18 inches or

24 of level piping, and raised the piping from that elbow right through the roof of the house. When once the stove was heated it would keep the heat a long time, if the feeding-door were shut, and there were a slit an inch long and from one-eighth to a quarter of an inch wide in the ash-pit door, to support a slow combustion. With this we would be perfectly satisfied, and all the more so if the stove were placed in the centre of the house. Truly, if you wished to utilise your piping against the back wall, you could do so, but you must give up the 4-feet of a horizontal pipe, and be content with 12 or 18 inches. Then you may raise on an incline against the back wall if you like, and the steeper the incline the better the draught. Your stove might even stand against the back wall, and then give enough of heat.

Your second plan of moving the stove from the end of the house partly into the wall, and a little sunk in the ground so as to be fed from the outside, would answer better, since the return smoke would be kept out of the house. Unless, however, the stove was sunk a great deal, the long horizontal pipe from it would be objectionable so far as free draught was concerned. If your first elbow pipe from the stove was only a foot long, and the upright pipe rose from it at once, this plan would answer admirably, as you would be saved from all smoke and ashes in the house. The latter is always troublesome, unless they are damped before clearing out the fire-place.

Your proposed plan, No. 3, is to have the stove sunk, fed from the outside, and your present 5-inch iron pipes taken horizontally from it beneath the level of the floor across the farther end, and thence up as a chimney against the back wall. Such a plan we have never tried. We fear that you would be smoked out of your stokehole. We should have no faith in its answering at all unless the smoke-orifice of your stove was some 24 to 30 inches below the level of the bottom of the pipe that went beneath the floor, and these were connected with two short elbows and an upright. Even then we should be doubtful as to iron pipes, and more especially if they could not be easily cleaned at the junctions. A small flue beneath the floor, with the furnace-bars 2 feet below the level of the bottom of the flue, would answer well. Meanwhile, as you do not wish to incur much expense, shorten to one-third the length of your present horizontal pipe, and rise upright at once, then you may continue against the back wall if you like. The short horizontal piping is the secret in all stoves when the piping goes from the top. There is little trouble as to draught, but the draught is not so easily and thoroughly regulated from the ash-pit door as when the outlet is on the side.]

ENTOMOLOGICAL SOCIETY'S MEETING.

The December meeting of this Society was held on the 4th inst., the President, A. R. Wallace, Esq., in the chair. Among the donations to the Society's library received since the last meeting, were the publications of the Entomological Societies of France, Switzerland, and Italy, and various periodicals devoted to the subject. Mr. S. Stevens exhibited, on behalf of Mr. Shearwood, a remarkable dark variety of Argynnis aglaia (closely resembling that figured by Curtis), taken near Teignmouth. Mr. F. Bond exhibited some curious varieties and malformations in specimens in Pieris Rapæ, Cheimatobia brumela, and other Moths. Mr. Ianson exhibited a collection of insects, chiefly Coleoptera, from the diamond fields of South Africa; the species were of the ordinary Southern African forms. Mr. Higgins exhibited specimens of Scarites Schrœteri, a very fine Australian species, and also of Tetracha crucigera, *McLeay*, one of the Cicindelidæ, from the neighbourhood of Sydney.

Professor Westwood exhibited a series of drawings and specimens illustrating a species of Butterfly (Papilio Thersander of Fabricius), proving that the figures of that species (affirmed by Donovan to have been copied from the famous collection of drawings made by Mr. Jones, of Chelsea, so often referred to by Fabricius), were made up by Donovan from a mutilated drawing, apparently gnawed by mice, of Jones's insect from Africa, completed from the Indian Charaxes Fabius! A discussion ensued concerning the right of named figures of insects by the older authors to be regarded in questions of priority. Here, however, the question was hardly applicable, because the Fabrician description was sufficiently precise, and the only difficulty arose from Donovan's want of truthfulness in manufacturing a figure, which he affirmed to be a true copy, from the original drawing from which the species had been described.

With reference to the liability of the larger Dragon Flies to be eaten by birds, Mr. Albert Muller stated that Mr. Natterer had mentioned that some of the Falconidæ in Brazil fed on Dragon Flies, thus disproving the fanciful ground for the mimicry of the two species of Dragon Flies from North America, exhibited at the last meeting of the Society by Mr. McLachlan. A paper was read by Major F. Parry on the generic nomenclature of Lissapterus Howittanus, one of the Lucanidæ, from New Holland; and some synonymical notes on various species of Lepidoptera by Mr. Kirby, in which it was endeavoured to be proved that Colias Hyale ought to retain the specific name of P. croceus of Fourcroy.

NEW BOOK.

Elements of Agricultural Chemistry and Geology. By James F. W. Johnston, M.A., F.R.S., &c. *Ninth Edition. Revised and Edited by* G. T. Atkinson, B.A., &c. W. Blackwood and Sons, Edinburgh and London.

No manufacture but is promoted by an appropriate combined knowledge of practice and science in the manufacturer. Agriculture is a manufacture of certain crops and live stock, and no manufacturer has ever been more benefited by "practice with science," than has the agriculturist. The science most useful to him is a knowledge of chemistry and geology. To that knowledge the book before us is one of the best of aids. We remember one old gentleman, whose mental power may be judged by his always beginning harvest on the 25th of July, "because his father did." The same bigot in the things-that-were, would not believe that underdraining was the cause of corn being more productive and ripening earlier than on adjoining land undrained. "Leave the water in the land," he argued, "it's wanted in summer and keeps out the rain in winter." If it had not been for chemistry those reasons of the olden time would have prevailed.

A mere practical farmer is like a blind man who passes our office. When unled he goes fumbling and shuffling along, and always slowly, on the same side that he has been accustomed to—and cannot surmount any unusual obstacle—that's practice; but when he is led by his wife he steps out confidently, makes short cuts, and goes ways he never knew of before—that is how science guides practice. The book which has led to this notice needs no better evidence than that this is the ninth edition of it. It is a thoroughly good book, and imparts sound useful knowledge upon every practice of crop-culture and stock-feeding.

BOWOOD.—No. 1.

The Seat of the Marquis of Lansdowne.

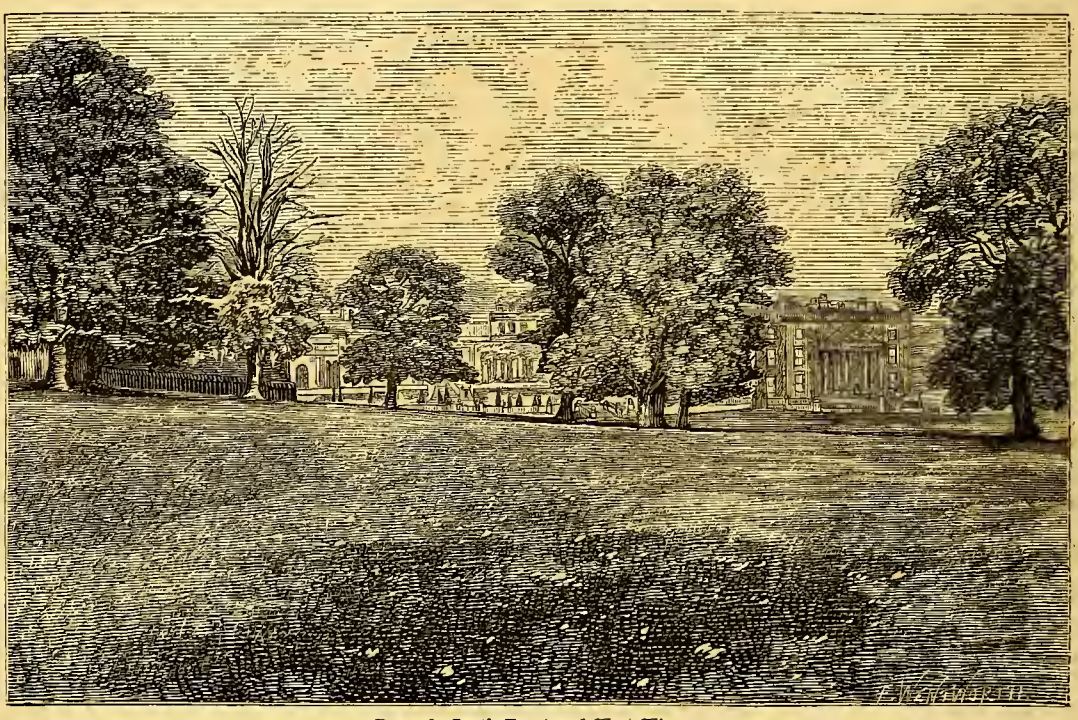
About two miles from the little town of Calne, ninety-eight miles from London by rail, and about twelve miles from Bath by road, is Bowood, the gardens of which stand in the foremost rank. When the frost crisps the grass, when the mists of the winter morning render distant views impossible, when the flower garden is tenantless, when there is nothing but the green turf and the leafless trees, and the evergreens less cheerful-looking than in spring and summer—that surely is not the time to see a garden. It is not the time to see a garden at its best; but if a garden is fair to the eye then, how much fairer must it be when Nature puts on her gayest attire, when the many-hued flowers give colour to the landscape, when the Thorn and the Apple tree are in blossom, or, later still, when the dazzling scarlet of the Geranium is relieved by many a broad acre of green sward. We have seen Bowood in its summer pride, and we saw it, too, but a few days ago in its winter garb, and as in summer so in winter, we admired it still. But before entering into other details let us give a short sketch of its history so far as certainly known, for there is much of its history which is dim in the far past.

In Anglo-Saxon times Caune, now spelt Calne, and its adjacent forest of Pewisham, were all royal demesne. This forest was of no mean extent, for it covered the entire surface between Calne, Chippenham, Laycock, and Devizes. When James I. ascended the throne he disafforested the whole, and granted one-half to the Devonshire Careys, and the other half, which included Bowood, to the ancestors of Baron Audley. During the Protectorate it was resumed as public property, but Charles II. re-granted it to Sir Orlando Bridgman, the licentious son of the Lord Keeper, who bore the same names. Ruined by extravagance, his creditors sold it to Lord Shelburne, from whom the Marquises of Lansdowne are descended.

The mansion was probably partly erected by Sir Orlando Bridgman, but the chief portion was erected by John Earl of Shelburne, from designs furnished by Mr. Adams, the architect. A wing 300 feet in length was added by the first Marquis of Lansdowne. Thus the mansion by degrees has become so very extensive, and is of such various styles of architecture, that a countryman once inquired at the lodge, "In which of them houses Lord Lansdowne lived!"

The mansion is partly built in the Grecian, partly in the Italian style of architecture, and is situated on the side of rising ground, that ascends towards the back and descends to a lake in front, which is said to have been formed by damming back a rivulet which flowed in the bottom of the valley. This lake is upwards of a mile in length, and the irregularity of its outline, its broad expanse of water, and its accompaniments of trees and shrubs, combine to make it one of the great features of the place. It has been supposed that the lake as well as much of the planting of the park was the work of the celebrated "Capability Brown," who formed lakes at Blenheim and other places in a similar manner. The principal front of the mansion faces the south, and comprises the main portion of the building, with the Grecian portico; whilst extending westward is a wing 100 yards long in the Italian style, containing the library, orangery, and offices. A view of the south front of the mansion, taken from the park is given in the accompanying engraving.

In front of the west wing just noticed are the terrace gardens, These extend the whole length of the west wing, and are on two levels, the upper terrace being 8 feet higher than the lower one, and divided from it by a wall surmounted by open work in dressed freestone; with vases at the top, which are filled with Geraniums and other plants in summer. The width of this terrace is about 60 feet, and it is laid out in geometrical beds, grouped very effectively round two marble fountains, one towards each end of the terrace. Each bed has a dressed-stone edging 4 inches high and 3 inches wide, next there is a 3-inch space which is filled with white spar in summer, and then a low Box-edging clipped square at top. Cypresses and Irish Yews kept in a strictly upright form are planted at intervals suitable to the design, which, though far from being so complicated as many others, and much more elegant, could not be adequately described without an engraving. We now come to the lower terrace, to which we descend by a broad walk and flight of



Bowood—South Front and West Wing.

steps. This fills up the space between the upper terrace and the park, the two terraces being equal in width to the depth of the main body of the building from the line of the west wing. On each side of the walk leading down to this terrace is a bronze stag. The upper terrace, it is believed, was formed in 1810 or 1811, and the lower one in 1851, when Mr. Spencer was the gardener. This is separated from the park by a low freestone balustraded wall, covered with Ivy and surmounted with vases; and at the west end is an architectural wall with a flight of steps leading down to the garden, and dense masses of Laurustinus, Phillyrea, and other shrubs closely cut-in, on each side of a fountain. The retaining wall is likewise surmounted by vases, and is of a bold architectural design, furnished, we believe, by Mr. Kennedy, of Glasgow. This garden forms one of the most beautiful features of Bowood; even in winter with the beds empty and with nothing but its upright Cypresses, its dark Irish Yews, its close-shaven green turf, its architectural surroundings, and its background of massive trees, it has a noble and impressive appearance, but how much more attractive must it be when the beds are all aglow with the liveliest colours! This terrace, like the upper one, dotted, as we have already said, with Cypresses and Yews, was laid out by Mr. Spencer, and the beds set in turf and a framework of bright-coloured gravel are extremely neat. A good idea of the general appearance of this portion of the garden will be obtained from the accompanying engraving, but the outlines of the beds would require, and well deserve, a separate representation, and to give a just conception of their effect in summer the aid of the colourist would also be necessary.

In front of the east wing of the house is a croquet ground and a small flower garden in Box with a raised bed, in the centre of which are three boys supporting a terra-cotta basket of fruit. Round these is a 5-feet bed surrounded by a low Ivy-covered wall, with scroll beds representing the Prince of Wales's feathers.

After all it is in the extensive pleasure grounds and the still more extensive park that we must look for the chief beauties of Bowood. It is not in gay parterres, not in acres of bedding plants, not in miles of ribbon-borders, in thousands of Geraniums, in hundreds of Verbenas, and in multitudes of the other flowers which furnish the materials of what is called "bedding-out"—not in all these that Bowood claims its high position among the seats of our English nobility. Its undulating surface, its wood, its water—these are its charms. Here soft-green turf, there a rough tangle; here the Pines of America, there the Oak, and the Beech, and the Fir, the trees of our native land. And then there are long glades affording glimpses of the far-off hills, and steep banks densely clothed with grey lichen-covered wood-growth, with lofty trees springing from the midst. Again, we say, it is in these that the beauty of Bowood consists.

But while thus descanting on what Nature and the hand of the planter have done—and the skill of the planter has done much—we have forgotten to notice one of the main features of the place, the waterfall at the head of the lake. One might well suppose this to be a work of Nature, so well is the deception

carried out, but it is merely the waste water of the lake carried over an artificial rockwork, constituting the dam by which the lake was formed. The water falls a height of between 20 and 30 feet, dancing from rock to rock in four stages, and the fall, though by no means so lofty as others where the natural formation of the ground is more hilly, is still of sufficient importance both in height and body of water to lift it above those toy devices which are so often and so justly held up to ridicule. The rockwork is partially covered with Ivy, and at its sides are Portugal Laurels and Pinuses. Near this point the winding walks are skirted by plantations of Laurels and Rhododendrons, which serve to conceal the boundary of the pleasure grounds, if boundary it can be called, for the view so merges into that of the park and plantations, that a boundary is nowhere apparent. The Rhododendrons, chiefly varieties of the ponticum race, were cut back three years ago, and have now made vigorous shoots.

Passing close by the lower side of the waterfall and through a grotto and rockery we reach the other side of the lake's head The next prominent object is a Doric temple from which we gain a view across the lake of the east front of the mansion. At the back of the mount on which this temple summer-house is situated is a winding walk, with a bank on the other side planted with Scotch Firs, Weymouth Pines, Beeches, and other trees and shrubs. Near this point is a noble specimen of Pinus Pinaster, which may be estimated at 100 feet high, and at a little distance off the red shoots of a clump of the Dogwood (Cornus sanguinea), lighted-up the duller hues of the evergreens. Pausing now and then to admire the old Beeches, generally branching not more than the height of a man from the ground, but throwing their spreading arms over a wide diameter, eventually we come to a Laurel-skirted walk leading to the pinetum. This was planted about 1850, and covers several acres out of the seventy or eighty of kept pleasure ground, and of which about fifty acres are under the scythe, or rather the mowing-machine.

Lower Terrace Garden at Bowood.

The pinetum is one of the most notable features of Bowood, and contains a very complete collection of the finest Conifers from all parts of the globe. It is true we did not notice the new introductions from Japan, such as the Sciadopitys, the Retinosporas and others, but no doubt they had a place elsewhere. Of the giant American Pinuses, however, there were many noble specimens. Cupressus macrocarpa could not be less than 30 feet high; Wellingtonia gigantea was probably as tall, and from the thickness of its stem both here and at other places it seems likely to attain as great dimensions, at least in girth, as it has done in the Californian groves. Of Abies Douglasii the tall spar at Kew must be familiar to many of the readers of this Journal, and the trees of it at Bowood outside the pinetum proper, some of them from 50 to 60 feet in height, have the same erect towering habit. It is, indeed, a noble tree, especially when so well furnished with branches as the specimens here. It is found, however, that when high winds come while the branches are laden with snow, disastrous breakages sometimes occur. Araucarias are represented by specimens 25 feet high; Pinus insignis, which is tender in some places, has attained a height of from 40 to 50 feet; of Picea Nordmanniana there are several handsome trees, one of which is 18 feet high; and so there are of Picea Pinsapo, Cupressus Lawsoniana, Picea nobilis, P. cephalonica, Taxodium sempervirens, of which the branches cover circle 30 feet in diameter; Cedrus atlantica, remarkable for its glaucous hue; Abies orientalis, a beautiful lawn tree; Juniperus recurva, J. communis; the Savin (J. Sabina); J. pendula, J. virginiana; Abies Menziesii, Pinus excelsa, Pinus Pinea, Abies canadensis, and many others, not to mention majestic Cedars of Lebanon in various parts of the grounds. It must be added that to every tree in the pinetum is placed in the ground near it an iron label with the name, height, and native country of the tree printed, and protected from the weather by glass—such labels as were in use at Chiswick some years ago. The grass of the pinetum is beautifully kept, and even at this season, when falling leaves cause many a struggle in the gardener's mind between considerations of economy and appearance, there was nothing that could offend the eye of the most fastidious, and all the walks were as clean and bright as they could have been in summer. Here we must take our leave of Bowood for the present week, deferring to another the notice of the kitchen garden and hothouses.

NOTES AND GLEANINGS.

The Royal Horticultural Society's Provincial Show at Birmingham will open on the 25th of June and continue until the 29th.

—— Losses of the French Nurserymen during the War.—From statistics which have been furnished us by the Rev. H. H. Dombrain, the Secretary to the French Horticulturists'

Relief Fund, we find that in the Department of the Seine alone the number of sufferers amounts to 555, and their total loss in structures and other requisites for carrying on their business, and of plants, is estimated at 2,626,330 francs, or in round numbers £105,000.

—— The death is announced on October 10th, in Nicaragua, of fever, of Dr. Berthold Seemann, one of our most enterprising travellers and naturalists. Born in Hanover in 1825, Dr. Seemann was, in 1846, appointed naturalist to H.M.S. Herald, in its survey of the Pacific, during which voyage he had the opportunity of exploring, more thoroughly than almost any other European, the Pacific countries of South America and the Isthmus of Panama. In the same vessel he subsequently visited the Arctic regions, and the "Narrative of the Voyage of H.M.S. Herald," by Sir John Richardson and Dr. Seemann, is an important contribution to the natural history of previously little-known regions, the portion contributed by the latter comprising an account of the flora of Western Eskimoland, North-western Mexico, the Isthmus of Panama, and the island of Hong-Kong. In 1860 he was sent by the English Government to the Fiji Islands, then lately acquired, and on his return published two works, one containing a narrative of his mission, the other, under the title of "Flora Vitiensis," a history of the vegetable productions of the islands. Since 1864, he has been greatly interested in the mining capabilities and other resources of the various states of Central America, and has spent much of his time there in the interest of different trading communities, and in promoting the route across the Isthmus. Dr. Seemann is the author of several popular botanical works in German and English, and has been since its foundation, editor of the *Journal of Botany*.

—— The Government is advertising the appointment, by open competition, of a Clerk to the Curator of the Royal Gardens at Kew, and of a second assistant in the Herbarium. The salaries commence at £100 and £60 respectively, and the specified age is in one case from twenty to thirty, and the other from eighteen to thirty. The examinations will take place on January 16th.—(*Nature.*)

WORK FOR THE WEEK.

KITCHEN GARDEN.

The young plants of *Cauliflowers* in frames must be protected from severe frost by covering the lights with mats, and if there are any in the open borders, protect them with arched sticks and mats. Lay a coating of long dung over ridges of the *Celery* required for use, to preserve it from frost. Plant a few *Garlics* and *Shallots* on a ridge, and put a sprinkling of wood ashes in the drills to keep off the grubs. Ground intended for *Onions* should be got in good condition for the March sowing. Pond mud or the scrapings and sides of ditches put on the surface of the ground to the depth of 4 or 5 inches, left to meliorate by the frost, and pointed-in a week or two before sowing, is the best of all composts for Onions. Wood ashes should be sprinkled upon the surface at the time of sowing, and raked-in with the seed, when the process is complete, with the exception of the hoeing and weeding afterwards.

FRUIT GARDEN.

Push forward pruning, nailing, tying espalier trees, and such-like tedious operations as fast as the weather and circumstances will admit. Make a point of every week regularly examining all the choicer kinds of fruit, as the finest Pears are almost worthless if allowed to get over-ripe before being used, and the same is the case with many varieties of Apples. All decaying fruit should be removed, and any of the choicer kinds of Pears that do not appear to ripen properly in the fruit room, should be removed to a warm, dry room for a few days.

FLOWER GARDEN.

Trim up shrubbery borders for the winter, and at the same time prepare places intended next summer for Hollyhocks, Dahlias, &c., by deep digging, and working in plenty of good rotten manure. Reduce all coarse-growing plants by pruning, to prevent them injuring others more valuable. Valuable plants, as Variegated Hollies, and Rhododendrons, and what are called American plants, if not growing as freely as is desirable, would be benefited by the application of a top-dressing of decayed manure or decayed leaf soil, covered with a little fine soil, and worked into the ground round the ball towards the extremities of the roots. American and other plants not growing satisfactorily should be taken up, the ground well prepared by a liberal addition of peat or leaf soil, and replanted.

GREENHOUSE AND CONSERVATORY.

Valuable pot specimens of hardwooded plants may, perhaps, have to be wintered in the conservatory, for many of these are impatient of fire heat and a confined atmosphere, and ought, therefore, to be kept as much out of the way of its influence as circumstances permit. They should be placed near the glass and turned partly round every week, so that portions of them may be equally exposed to the light; fresh air should be admitted on every favourable opportunity, but cutting winds carefully guarded against. Use no more fire heat than may be indispensable, and be careful to counteract its drying effect on the atmosphere either by means of evaporating pans, or by sprinkling the borders. It is in many cases a very difficult matter to maintain a sufficiently moist atmosphere without producing drip, as the moisture in the house gets condensed upon the glass, and unless provision is made by means of inside gutters and pipes to catch the condensed moisture and carry it off, it is nearly impossible in frosty weather to preserve the beauty of flower for any length of time. In cases where there is no provision made against the condensed moisture falling upon the plants, the temperature should be kept as low as may be consistent with safety, avoiding moisture in the atmosphere as far as possible wherever the glass is affected by frost.

STOVE.

If there is any prospect of a scarcity of bloom next May, a portion of Achimenes and Gloxinias which have been longest at rest, and a few Clerodendrons and Allamandas, should be repotted at once, and placed in a warm part of the stove; a few plants of Echites splendens, and Dipladenia crassinoda, may also be started, but unless their wood is well ripened wood, and they have been some time at rest, there will be nothing gained by attempting to start them into growth at present. A gentle bottom heat of about 80° or 85° will be of great service to such plants by inducing a healthy root action, and if this can be secured, there will be little doubt about obtaining free vigorous growth. Let Ixoras and other hardwooded plants that have made sufficient growth be kept rather dry at the root, in order to check their growth and induce a tendency to form bloom. We are careful not to allow the balls to become so dry as to endanger the foliage. Be sparing in the use of fire heat save in the case of plants being forced into flower or growth. It is in every sense good policy to have a separate house or compartment for these, as it saves fuel, avoids overdriving the whole collection for the sake of a small portion, and insures a more satisfactory result than can be obtained where there is but one house for the whole collection of stove plants. Keep a moderate heat of from 50° to 60°; and give plenty of air. Stephanotis, Allamandas, &c., may be potted and trained preparatory to starting after Christmas, and the staking of all specimen plants must be proceeded with as fast as possible.

FORCING PIT.

This is a good time at which to introduce a considerable number of plants for general forcing purposes. Rhododendrons, Azaleas, Persian Lilacs, Moss and Provence Roses, Sweet Briars, Honeysuckles, Kalmias, Daphnes, Rhodoras, the more advanced Hyacinths, Narcissus, Tulips, &c., may now be started. A sweet bottom heat of 80° max., and a temperature of 65°, will be necessary whatever the structure. One thing may be here observed—that is, that it is vain to introduce anything unless properly set for bloom. This points to the necessity of a special summer's training as suggested long since.

COLD PITS.

Plants that have been excluded from the light and air for a few days must not be too suddenly exposed, especially to cold northerly winds, but should be very gradually inured to free exposure. Take advantage, however, of mild days to give air freely, and keep the plants very sparingly supplied with water at the roots, so as to prevent weak sappy growth. Look frequently over anything subject to the attacks of mildew, apply sulphur the moment this pest is perceived, and see that everything is perfectly free from insects.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Little could be done this week, on account of the weather, except trenching. Now is the time for tree-planting, if done immediately after the hole is made, as the moisture has not yet affected the soil beneath, which for packing the fibrous roots in should be dry. We have frequently noticed how much better trees thrive when planted in moderately dry than in wet cloggy soil.

Collecting Leaves.—We could do little of this during windy days. Leaves raked up wet are just as good as any for present purposes, or for being placed in heaps to decompose into leaf mould. For future use they cannot be brought home too dry. A covered shed is a good place for them, but they will keep well for years if placed in a well-rounded heap, and a little litter thrown over them to prevent the wind acting on them. On such a heap of dry leaves it is rarely that the heaviest rains will penetrate more than 1 or 2 inches. We have found heaps collected two years previously almost as fresh as on the day they were gathered, which was entirely owing to their dryness. When we wanted them to heat and decompose we watered them. Leaves need no preparation for hotbeds, except throwing them together to heat. A correspondent informs us that he used leaves among which were many bits of wood and much long grass, and that his plants suffered from the fumes. We can hardly conceive it to be possible at this season, as there can be little of such rank grass now after the frost. If it is yet somewhat long it must be rather grey or whitish in its tint, and in such circumstances along with leaves we have never found it give out unhealthy fumes. Of course it is well to use a little precaution, and the simplest one is to cover the bed with soil or more sweet, rotten material, and to observe if the condensed drops on the glass or sashbars are clear as a dewdrop. If so, there can be no danger, but there will be if they are yellowish or brownish in colour.

Fungi spores will seldom appear if a bed of rather hot rank dung is placed beneath the leaves, and the latter allowed to become very warm, and then to cool before using them. Another correspondent wishes to know how to turn a heap of green dung and another of leaves into a heap of sweet material, losing as little as possible of heat and bulk. It is next to impossible to obtain both objects; mixing dung and leaves together at once, is the best means for getting a heap by various turnings uniformly sweet. True, but no plan could be better for diminishing bulk, as the leaves will be half decomposed before the horse dung is sweet. If one uniform heap must be made, it is best to heat and turn the rank dung two or three times before the leaves and dung are mingled together. If we wished to make the most of both, and to keep up as much bulk as possible, we would give the dung one or two turnings, with as much watering as would insure rapid heating; and when that was hot, but not sweet, we would line the bottom of the bed with it, and top it with hot leaves from the heating leaf heap. This would make the most lasting bed for temporary purposes. For a lasting Cucumber bed, instead of a layer of each, we would have several thin layers of each, and a heavier one of hot leaves to finish with. Beds thus made in January have retained a fair heat in the following November.

Discard all soil that seems to have any spawn running in it. It may be purified by having boiling water poured over it, or by being placed as a covering over burning and charring material. In each case the soil requires to be well aërated before use, so that on the whole it is best to examine and get rid of such pieces as can be seen. We are sorry to confess that we really do not know what amount of heat will kill the spores and spawn of fungi. A correspondent remarks that it would be useful to know the amount of heat and cold beyond which even the spawn of the Mushroom would not live, but here our experience fails us. A friend of ours often waters his Mushroom beds with water as near the boiling point as possible, and he gathers fine crops. He says that even pin-head Mushrooms are not injured. A neighbour of his followed his plan but he got no Mushrooms. We know that when placed in a bed spawn is easily injured by heat, but when fairly run it will stand more. We have poured very warm water down at the back and front of a Mushroom bed to dislodge and kill woodlice, but we have never used it so warm over the bed. If poured hot on a bed, however, it would be much cooled before it passed through the earth.

Asparagus.—The dull foggy weather has been against the colour of Asparagus in a common hotbed frame. Though we have washed the glass and kept it clean, the shoots are not so bright green as we wish to see them. We have had them grown almost as green in a dark place, and then placed with the base of the shoots in damp moss in a house of medium temperature for a few days. The want of the bright green tint is a great one, though the shoots may be crisp and sweet.

Cucumbers.—We have cleared out at length those we planted in a pit in the beginning of the year, as the walls, &c., sadly wanted cleaning, and the young plants were getting injured from want of heat. Five lights will thus be fresh planted with stout plants, and all are put in pots, as stated last season. Three lights are now bearing nicely, but of course if we fruit them heavily now, we cannot expect the plants to last so long. The object in planting in pots is to get great quantities of fruit and comparatively small foliage. In a place from 5 to 6 feet in width, leaves like parasols or small umbrellas are of no use when plenty of fruit is wanted.

FRUIT DEPARTMENT.

The weather has been bad for bringing on early Strawberries —scarcely a blink of sun to cheer them. An experienced gardener used to say that it was little use putting many good pots in until about Christmas time. Put a good many into an old bed where you can just detect the least bottom heat, to bring them on gradually. They must, however, at this early period, be left only a little time in a bed where there is much heat below them, as this tends to make them grow too much to leaf, and not enough in the flower-truss. Many a flower-bud becomes blind altogether from the stimulus so applied. It is useful in moderation, and almost essential where successions are to be kept in a house of a rising temperature; but where room can be afforded there is no safer or better plan than placing the pots on the shelves where they are to fruit, and increasing the heat very gradually.

Fruit-rooms, &c.—Looked over fruit-room and late Grapes nipped out a few fading berries from the latter, and gave a brisk fire during the day with air back and front—very little heat at night, and a little air at back unless when very cold and frosty. Made preparations for forcing Peach and other houses, but we find where frost is kept out the trees come on early very fairly of their own accord, without commencing regular forcing so very early. For planting, &c., see previous numbers.

ORNAMENTAL DEPARTMENT.

All plants growing, flowering, and coming into flower should be kept scrupulously clean. Much may be done by keeping them from the dust of the room when swept, much more by washing them frequently. This is easiest done in the case of small plants suitable for a window, by placing a cloth over the soil of the pot, spreading the fingers of the left hand over it, and then with the other hand holding the pot, reversing the head of the plant in a bucket of water, and drawing the leaves, &c., backwards and forwards in the water. The leaves should be gently sponged afterwards, and the process then repeated in a fresh pail of clean water. Two pails of water might thus do for a number of plants. In frosty weather when much air cannot be given, slight frequent damping of the foliage will counteract the dry heat of the room. This damping of the foliage will often be more important than frequent watering at the root. Plants kept too damp now are apt to make spongy watery growth. As long as there is no sign of the leaves being distressed it is advisable not to water, but water sufficiently so as to moisten all the soil when you do give it. As a general rule let the whole of the roots be moistened, and give no more until they again become dry. Giving a little drop on the surface is always deceptive. When doubtful, turn the ball carefully out, and see what like it is. If the pot is clean and dry at potting time the ball can be turned out and replaced unbroken. If you are not sure of that, insert a stick or your finger by the side of the pot, and see what state the soil is in 2 or 3 inches from the surface; and if you think that such is the case give the pot a sharp ring to test its soundness as in buying a porcelain vessel. Should the sound be clear the earth wants watering, but if it be dull it does not.

Water in Saucers.—As a general rule it is well to have saucers for plants in windows, and to throw out the water that collects in the saucers. If you have Cinerarias or Calceolarias in your windows a little damp moss in the bottom of the saucer will do good, and help to keep a moister atmosphere about them. As regards plants in general, though the bottom of the pot should not be in water, yet in cold frosty weather when the strong fires are apt to dry the air of the room too much for your window plants, if you put three pieces of stone, or even of cork, all the same height in the saucer, set the pot level on these pieces, and then put water in the saucer so as not quite reach to the bottom of the pot, you would find vapour to rise insensibly from that water, and enable the green foliage to resist the dry air of the room all the better. In mild weather with smaller fires this would be less necessary. Keep in mind, also, that when a plant is growing freely it must have light.

Bulbs.—Put a number of well-rooted bulbs, such as Lily of the Valley, into a mild hotbed to bring them sooner into bloom. It is no use doing anything of this sort until the pots are full of roots. We often help this a little by placing the fresh-

potted bulbs in a little heat to draw the roots down, whilst the tops of the pots are help cool. We also often assist the free rising of the flower-stem by means of funnels of paper, or even a pot of smaller size placed over the other containing the bulb. Window gardeners who possess no hotbed, and who yet wish to have early bulbs, as Snowdrops, Crocus, Hyacinths, and Tulips, in their window, should pot the bulbs early, and place them in any dark place where the roots will be encouraged to develope themselves before the flower-stem. A dark closet or cellar is the proper place, and the pots will be all the better if plunged in either sand, ashes, or moss, and covered with a little of the same material. When the pots are full of roots they may be brought to the window as the tops are beginning to show. These if covered up will have a yellowish tinge, and should not be fully exposed to the light until they become somewhat green. If wanted early, the pot or funnel over them will help both processes, and the rooting may be hastened by some weeks in this manner. The pots are set on as above, not in saucers, and as thickly as they can stand, with a little moss or sawdust stuffed in between them, and whilst no water is given to the pots, warm water about 90° is poured on the moss or sawdust, and extra heat thus supplied to the bottom of the pot. We found we could gain as much as three weeks in full rooting by this process, and by continuing it the flowering was also earlier. We also found a good plan for getting early bloom without the help of a hotbed was to place a 5-inch pot into a 6-inch pot, fill the bottom of the large pot with moss, and the space between the pots with moss or sawdust, and then water between with water at from 90° to 100°. Allow the flat or saucer, which even then is a little distance from the bottom of the inside pot, to remain full. Each pot thus has a hotbed for itself. Where room is an object, the outer pot should be dispensed with as the bulb comes into flower, taking care, however, that no violent check is experienced. In watering the temperature should never be colder than the heat of the room, say from 60° to 65°.—R. F.

TRADE CATALOGUES RECEIVED.

Dickson & Co, 1, Waterloo Place, Edinburgh.—*Catalogue of Forest and Ornamental Trees and Shrubs, Conifers, Rhododendrons, &c.—Descriptive List of Gladioli.*

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, N.—*Descriptive Catalogue of Flower, Vegetable, and Agricultural Seeds*, 1872.

J. Wheeler & Son, Gloucester, and 59, Mark Lane, London.—*Wheeler & Son's Little Book, or Select Seed List for* 1872.

Sutton & Sons, Reading.—*Suttons' Amateur's Guide and Spring Catalogue for* 1872.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Address (*A. Crickett*).—Mr. West died two years since.

Exchange Column (*C. F. H., Dorset*).—We are willing to insert exchange advertisements not exceeding two lines for 1s. It is not our fault that so few have availed themselves of this facility, which, on looking back, you will find we offered long ago.

Anti-cloche (*An Old Lover of Horticulture*).—We can only insert it as an advertisement, for which the charge would be heavy.

Roses for a Trellis (*H. H.*).—Gloire de Dijon, yellow; Boule de Neige, white; Alfred Colomb, red; John Hopper, rose; and Abel Grand, pink.

Apples and Pears for Espaliers (*A Subscriber, Ireland*.—Apple trees should be worked on the Paradise, and Pears on the Quince stock. Some varieties of Pears do not succeed on the Quince, but may be worked on the Pear. Trees three years old from the graft, specially trained, would be the best to plant. Horizontal-trained wall trees as sold in the nurseries, will answer your purpose. It will be best to train your Vine in through a hole in the brickwork at the base of the wall. The mulching which the border should receive in winter will cover that part of the stem exposed. The trellis to which the Vinee are trained should be 15 inches from the glass.

Temperature for Tree Carnations (*H. C.*).—To ensure the flowering at this period of the year they require a temperature of 50° at night and 5° higher in the day, admitting air freely with an advance from sun heat. Give them abundance of air and light, and keep them near the glass.

Variegated Holly Propagating (*Idem*).—The variegated kinds are raised by grafting on stocks of the common or green Holly, and the best time to do this is in March. They may also be raised from cuttings of the ripened summer shoots, put in during November on a north border, and covered with a hand-glass.

Repotting Pelargoniums (*Idem*).—It should be done at once, not giving a large shift, as you wish them to flower early; but if they are already in good-sized pots, we should not advise their being repotted.

Mulching Newly-planted Fruit Trees (*F. J.*).—Two to 3 inches of stable litter is not too much to put about newly-planted fruit trees. It may be put all over the ground, or in a circle of about 3 feet around each. If put over the whole surface it could be pointed-in during the spring, and would be a means of enriching the soil. Prune newly-planted pyramids, bushes, &c., very little, merely taking off the irregular or unnecessary growths, which is all these trees require at the winter trimming. The principal pruning should be done in summer. It is better to prune at planting than in spring.

Sutton's Order List (*Jeff*).—Your note is an advertisement. We have seen their list, and agree with you ,that it is one of the most useful published.

Weeping Trees (*B. A.*).—There is no known system of "raising" weeping trees, nor can we account for some trees producing their shoots pendulously, whilst others grow erect. Some are species and others sports, but none that we are aware of have been raised from seed, nor a pendulous habit induced by any forethought of man. Weeping trees are propagated by grafting on stocks of kindred species at the height of stem required. The sprig of shrub enclosed to us in flower is the Strawberry tree, Arbutus Unedo.

Orange Tree Leaves Browned (*J. D.*).—The leaves enclosed to us are very badly browned, which we think may be owing to dressing with some compound, or perhaps to their being constantly wet from syringing or drip from the roof. The cause of falling is probably due to potting at this season, which has occasioned a check, and brought on the affection you complain of. It would be well to give the plant the benefit of a mild bottom heat of 55° to 70°, so as to induce a good root action, and if that is done we think the foliage would be better. It is evidently the Mandarin Orange (Citrus nobilis).

Roses in Pots (*P. Paget*).—The Roses in the coolest part of the conservatory should be kept rather dry until the early part of February, and pruned. If not already potted do it now, and defer pruning a fortnight. Hyacinths coming into flower would be benefited by the application of weak liquid manure.

Rose (*J. Carr*).—We do not know Madame Barriott. There is one named Madame Barillet.

Twenty-four Dwarf Roses (*M. A. B.*).—Alfred Colomb, Charles Lefebvre, Marie Baumann, Baroness Rothschild, La France, Gloire de Dijon, Cécile de Chabrillant, Duke of Edinburgh, Marguerite de St. Amand, Dr. Andry, Sénateur Vaisse, John Hopper, Abel Grand, Emilie Hausburg, Victor Verdier, Monsieur Noman, Pierre Notting, Mdlle Eugénie Verdier, Countess of Oxford, Duchesse de Caylus, Marquise de Castellane, Edonard Morren, Xavier Olibo, Mdlle. Marie Rady. Add to these as Teas—Souvenir d'un Ami, Madame Willermoz, Belle Lyonnaise, Souvenir d Elise.

Epiphyllums for Grafting on Pereskia Stocks (*W. W.*).—E. truncatum var. Ruckerianum, tricolor, violaceum Snowii, salmoneum marginatum, roseum amabile, Russellianum, magnificum, albo-lateritia, albo-violaceum, purpureum, Bridgesii, aurantiacum, and E. speciosum superbum.

Iron Stakes for Roses (*Clyde*).—Iron, from their durability, are superior to wood stakes, and are not injurious to the roots. You may fruit pot Vines the year after being raised from the eye, but additional care is necessary to do so with the apparatus you name. The canes should be strong and well ripened.

Culture of Heaths (*Amateur*).—The culture of Cape Heaths has been treated of repeatedly in our previous volumes, but some hints will shortly be given on their culture and varieties.

Select Plants (*A Beginner*).—Three *Heaths* to flower in October or November are Erica colorans, E. sebuscula, and E. caffra. Twelve *Greenhouse Ferns* are Adiantum cuneatum, Lomaria gibba, Asplenium dimorphum, Cheilanthes elegans, Davallia pyxidata, Gleichenia dicarpa, Neuropteris australasica, Nephrolepis tuberosa, Pteris scaberula, Adiantum cuiphureum, Asplenium Veitchianum, and Lomaria Belli. Six *Show Pelargoniums*—Charles Turner, Claribel, Cycle, Emperor, Maid of Honour, and Troubadour. Six *Fancy*—East Lynn, Fanny Gair, Princess Teck, Marmion, Formosa, and Pink Perfection. Six *Stove Ferns*—Adiantum farleyense, Asplenium præmorsum, Gymnogramma Laucheana, G. Wettenhalliana, Polypodium appendiculatum, and Davallia polyantha. Six *Achimenes*—Ambroise Verschaffelt, Rollinsoni, Multiflora major, Marguerite, Porpurea Magnifica, and Sir Treherne Thomas. Six *Fine-foliaged Plants Suitable for Table*—Croton angustifolium, Maranta roseo-picta, Myrtus microphylla, Dracæna regina, D. Chelsoni, and Terminalia elegans.

Cyclamens (*Cyclamen*).—You must apply to any of the leading florists who advertise in our columns.

Peas of Moderate Height (*George Yardley*).—1st, Early—Dickson's First and Best, Kentish Invicta. 2nd, Midseason and Main—Princess Royal, and Maclean's Premier. 3rd, Late—Yorkshire Hero, and Dwarf Branching. They do not exceed 4 feet in height.

Mrs. Pollock Geranium Leaves Browned (*S. Hiscoe*).—The leaves sent appear to have suffered from cold and damp, and we consider these to be the causes of their present condition. They should have a temperature of 45° to 50° at night to keep the leaves in good condition, with no more water than is sufficient to keep the leaves from becoming limp or flagging. One watering at a time should be sufficient, without going over twice at an interval of half an hour. Admit air moderately, avoiding cold cutting currents.

Tulips not Flowering (*A Constant Subscriber*).—It is not difficult to have Tulips in flower at Christmas, but it is necessary that they be potted early and placed on a gentle hotbed, with very little top heat after they have been on a cold bottom for a month. Early in November they should be put in a house with a temperature of 45°, increasing to 50° to 55° at night at the close of that month, and should be near the glass to keep them from drawing. Another essential is to choose the early kinds, as Duc Van Thol, Pottebakker, &c.

Tulips Out-doors (*Idem*).—Tulips do not increase in size of bulb from year to year, and seldom improve in size or blooming qualities on those imported. Of course they continue to attain a full flowering size, and give a number of offsets that in course of two or three years come to a flowering state; in that way they improve.

Cotton Waste Hotbed (*E. W.*).—It is formed in the same way as a bed of dung, but being of a greater heat-giving nature it is not necessary to make it so high. It is best used in a brick pit, though one with sides of boards will answer well. We have made the outside of stable litter, and then filled up the centre with the waste. Four feet high at back and

3 feet in front forms a good hotbed. It will need to be slightly moistened, but not made very wet.

Chrysanthemums from Suckers (*Idem*).—We prefer taking good, strong, short cuttings with some roots, placing them singly in small pots, and putting these in any house with a gentle heat. They make the best plants, and have single stems. You may also divide the old plants as you propose, retaining three or more of the best shoots, and removing the weakest. Take away most of the old soil, reduce them considerably, and put in pots that will hold the roots, which should be cut in considerably. Place them in a cold frame until established, and then harden off.

Cineraria Leaves Curling (*Berra*).—Are you sure that there are no insects on the leaves? Examine them carefully, and if you find any trace of thrips or aphis, fumigate with tobacco. See that the plants are not subjected to cold cutting currents of air, and keep them near the glass in an airy structure, standing on a cool bottom, and in a temperature of from 40° to 45°, if young, or if advanced to a flowering state, of from 45° to 50°.

Silver or White-foliaged Plants for Bedding (*Longlands*).—Achillea ægyptiaca, Arabis alpina argentea, Antennaria tomentosa, Centaurea argentea plumosa, Centaurea ragusina, Cerastium tomentosum, Cineraria maritima, Dactylis glomerata variegata, Euonymus radicans variagatus, Gnaphalium lanatum, Poa trivialis argentea elegans, Santolina incana, and Senecio argentea. You may obtain seed of the Cineraria and Cerastium, which sown now will be in good order for planting out in May.

Ferns Importing from Demerara (*Amateur*).—We could not name the Ferns that are worth importing from Demerara, but we should consider most if not all to be desirable. They should be packed in Wardian cases for transit by sailing vessel, and will need to have air and water on the voyage. You might also arrange to have Orchids sent you, packing them in boxes of moss no more than moist.

Red Celery (*L. W.*).—Coles's Defiance Dwarf Red Celery is a good and high-coloured kind, but this latter we do not consider any advantage, but rather the reverse. Any of them are red enough even with the best blanching, and no deep-red Celery is good for anything—*i.e.*, if it be red after earthing-up. Do not earth-up and tie the leaves together, and it will be red and useless. The merit of Celery consists in its being solid, crisp, sweet, and of a nutty flavour.

Shrubs for Lawn (*E. B.*).—Portugal Laurel, Chamærops excelsa, Hollies (Ilex), altaclarensis, Aquifolium flava, Aquifolium pendula, Hodginsi, Gold and Silver-variegated Laurustinus, Magnolia grandiflora, Exmouth var. Quercus Ilex, Q. Fordi, Q. austriaca. Abies Clanbrasiliana, A. pygmæa, A. compacta, A. elegans, and A. pumila are dwarf varieties of Norway Spruce (A. excelsa); Cedrus Deodara, C. atlantica; Cupressus Lawsoniana; Juniperus chinensis; Picea nobilis, P. Pinsapo, P. grandis, P. Nordmanniana; Pinus Cembra, P. excelsa; Retinospora pisifera; Taxus adpressa, T. elegantissima, T. fastigiata; Thujopsis borealis; Thuja plicata, T. orientalis, and vars. aurea and stricta; and Wellingtonia gigantea. Thorns double scarlet, pink, and white, are fine lawn trees. Also have standard Rhododendrons, and Kalmia latifolia. Plant after the ground is in good order early in March, a preferable time to now.

Stove in Hothouse (*A. C. C.*).—We cannot advise you to do as you propose. You had better, if you can be supplied with gas have a Shrewsbury's hot-water apparatus. We have known outside blinds quite sufficient to compensate for a slightly deficient heat inside.

Heating by Hot Water (*A. J. T.*).—Your arrangement of heating seems to be a singular one—taking the pipes round what looks like a number of beds. Nothing is more settled as to heating than this, that the flow-pipe should go from near the top of the boiler, and the return-pipe come in near the bottom of it. As to your particular question, there can be no doubt that you can heat as far as A B separately by the junction 2 furnished with a valve; but to do this you must also have a valve under command at 3, to prevent the flow going its usual course. When you wish the heat to go round as hitherto, you have only to open the valve 3, and shut the valve in the junction 2. To be thoroughly under control, you want therefore the valves at 2 and 3 instead of 1.

Heating by Flue &c. (*Midland Counties*).—There can be no doubt that a flue would heat a small vinery 32 by 20 feet; but if you contemplated anything like forcing you had better have the flue all round, or round three sides, to avoid doorways, and have it above ground. A flue 15 inches high and 9 inches wide would do, though we recommend flues beneath the floor level for small greenhouses. We look upon such a contrivance merely as one of the neatest for keeping out frost in winter. If you merely wished to help your Vines a little, and keep Lady Downe's for a good while in winter, then a flue all round under the pathway—say two bricks-on-side deep, 5 inches wide inside measure, and covered securely with a 9 or 10-inch tile, would answer well, and all the better if the floor were tiled for the pathway, so as to leave a slope open at the sides of the flue. As stated already, if you contemplate forwarding the Vines much, have your flue above ground instead of beneath the floor. As to your next question, much of the success will depend on sinking the furnace. The fire-bars of your furnace should be 2 feet below the bottom of the flue. Sixteen-ounce glass would do very well for sides and ends. Twenty-one-ounce would be more secure against wind and hail. Strange though it seem, it is no less true, that in one case even on a roof, 16-oz. was safer from hail than 21-oz. The latter resisted and was cracked, the other yielded and rebounded to the hail; but on the whole we would prefer 21-oz. or 28-oz. for roofs. Have nothing to do with coal ashes for a Vine border.

Names of Plants (*Walton*).—1, Zygopetalum Mackayi; 2, L. crinitum. (*Jno. B. Blennerhassett*).—Your Fern is Asplenium marinum, the Sea Spleenwort. We should suppose it worth your while to attempt to turn your discovery to profit—indeed, feel inclined to hope you will be good enough not to run any risk of destroying, or, indeed, despoiling it in the locality you name. Fern-hunters too often prove themselves nuisances by exterminating rarities, or so hacking their rhizomes, &c., as to soon eradicate them. We look on the plundering of a Fern in a locality where it is confessedly seldom seen as an act somewhat akin to sacrilege. A. marinum is not such a scarcity elsewhere, and not of great value. (*A Ten-years Subscriber*).—1, Oncidium, not yet identified; 2, Maxillaria picta; 3, Epidendrum ciliare. (*W. F.*).—Some Myrtle, and in all probability a form of the common Myrtle (Myrtus communis), a trifle narrower than usual in its foliage.

POULTRY, BEE, AND PIGEON CHRONICLE.

FRAUDULENTLY CHANGING CLAIMED BIRDS.

I wish to direct your attention to a very disagreeable fact connected with the late poultry exhibitions, which I think might, with advantage, be commented on by the Editors. I allude to the theft of valuable birds. That the poultry and Pigeons which have disappeared so mysteriously during the last twelve months were stolen from exhibitions, for the most part probably during "packing-up time," I have no doubt. Every one must acknowledge that such thefts, unless strong and prompt preventive measures be taken, will speedily bring fowl-fancying into such ill repute as to make all right-thinking persons recoil with horror from a pursuit so intimately connected with fraud. I could write a little volume (I mean a large volume) upon the varieties of fraudulent practices in which "the fancy" indulge; but having no wish to overtax your patience, I will simply give one instance of roguery, of which I was the victim. At the same time I enclose for your perusal two letters, one from our most esteemed Judge, the other from an exhibitor of the highest integrity, both sufficiently corroborative, I fear, of the unpleasant statements with which I have felt it my duty to furnish you.

This month, a year ago, at one of the most important poultry shows held during the season, I claimed a pen of Colonred Dorking pullets at eight guineas. After the show was over two old hens were forwarded to me in place of the birds I had claimed. Unless much mistaken, I had observed these hens (one of them even then in a dying state) unnoticed in the Selling class. Having ascertained from the Secretary that Mr. Hewitt was one of the Judges of the Dorkings, I at once wrote to that gentleman, asking to be allowed to forward to him the birds which I had received from the show, that he might substantiate my assertion that they had not constituted the pen which I had claimed, and to which the third prize had been awarded in the pullet class. Mr. Hewitt, in reply, sent me a very kind letter, but in it he juetly observed that he could not undertake to arbitrate in matters of dispute between vendors and purchasers.

So kind, however, was his letter, that I ventured to write to him again for his assistance to this effect:—"I want very good Dorkings. I am a fair judge of a fowl for an amateur, but I never can obtain good birds; for if on the one hand I ask would-be vendors of certain prizewinners to send on approval, they shirk out of it; and if on the other hand I claim a pen of birds at a poultry show, they are stolen. What can I do?" In conclusion, the following quotation from Shakespeare expresses my humble opinion in relation to "the fancy," and it might, I think, be advantageously adopted as a motto by ardent amateurs generally:—

> "Because I will not do them
> The wrong to mistrust any, I will do myself
> The right to trust none."
>
> —(*Much Ado about Nothing*, Act i. Sc. 1.)

—H. Seymour Fraser, *Headley, near Petersfield.*

Mr. Hewitt's letter was as follows:—

"I really am sorry to find complaints so very general, as they evidently are becoming, respecting the identity of 'claimed' fowls, as it must at least compromise the honour and credit of some one or more parties. It seems at first blush incredible, but it is nevertheless a fact, that since your affair no less than three parties have written to me for advice to this effect, 'What can they do?' One says, he 'claimed a pen of birds more than a month ago. They went back, and he says he can prove that the birds he has got were bought and sent on direct to him from a dealer, and never shown at all. I advised this applicant to 'take the case to the County Court, and prove it to conviction, if certain that it is so.' The other cases are both alike. They saw the birds at the time, bought them, and, as one expresses it 'they aint them.' I really do not myself know how to advise, but this I well know, such mean actions will help a good deal to break up the fancy among many of its most creditable and most-to-be-valued supporters. Again, I cannot help thinking that at least some of these cases are beyond question facts, and I grieve to find it so.—Edward Hewitt."

[It is very disheartening, but not to be wondered at, that villains mingle with true-hearted poultry fanciers. Not only would we sue for compensation if the birds we bought were not sent, but others in their place; but we would indict the vendor for felony—it being undoubtedly a larceny. One poultry changer suffering six months imprisonment with hard labour would have a most wholesome effect. We advise all committees to give notice that they will not deliver claimed birds to anyone who has not a written order from the purchaser. In future, when purchasing at a show, we shall give notice in writing to

the committee not to deliver what we have purchased to anyone but the bearer of half a card, the counter half of which we shall give to the secretary.—Eds.]

NORWICH POULTRY SHOW.

There is a slight error in your columns last week in alluding to the Norwich Poultry Show. A protest is made against Hamburghs of all varieties being included in one class. This is not the case, but it is precisely like the Dublin and many other important schedules—having a class for Gold or Silver-pencilled, and a class for Gold or Silver-spangled. It would doubtless be far better to have four classes, dividing the Gold and Silver; but these classes in the eastern counties are generally very badly represented. It would be indeed bad policy to offer liberal prizes for any variety or breed for which there is little or no competition. As regards Dorkings, these are sparingly exhibited in this district. If fanciers of these varieties are desirous of increasing the number of classes, I should recommend them to exhibit more liberally to induce those who have the framing of prize lists to comply with their wishes, and who would gladly provide for all varieties likely to receive support. I can only add, that I will willingly instruct the Judges to award additional prizes in any class for deserving specimens. —Wm. Groom, *Ipswich, General Manager.*

MAIDSTONE POULTRY SHOW.

This was held on the 20th and 21st, and obtained a complete success, which was due to a most energetic Secretary and a few hard-working Committeemen. This year the Show was confined to the county, and it will most likely in future be thrown open. Nearly 420 pens of unusually good birds were exhibited. *Dorkings* headed the list. Coloured and Silver-Grey were good. Then came the *Cochins*. Among the Whites were the cream of the year, and the Judge ordered "A very good class" to be added to the prize list of this class. *Brahmas*, too, were well represented. Mr. Knight won the £15 15s. cup for Brahma chickens with the bird he was third with at the Palace —a grand cockerel indeed. Why Mr. Dring's birds, which took Southampton by storm, were not second remains to be proved. *Hamburghs* were well represented, especially the Golden-pencilled variety. *Polands* were, in every case save one, sent with two hens, which was a disqualification, and this one pen was so poor that no prize could be awarded. Then came the *French*. The second-prize Houdans should have been first, but both classes were good. The *Variety* class had good La Flèche, Silkies, and Andalusians. There was a large Game *Bantam* class with some good birds. Mrs. Dring had a pretty pen, which well deserved a high commendation. Good Aylesbury, Rouen, and Black *Ducks* put in a strong appearance, and very large Selling classes wound up the lot.

The *Pigeons* were few but good. A lovely pair of Barbs was first in the Variety class; and a very neat pair of Antwerps won the extra prize given by "Albus," a gentleman who need not conceal his name.

Dorkings.—*Coloured.*—1, R. Cheeseman, Westwell, Ashford. 2, W. Haynes. Maidstone. 3, Dr. Jepson, Stone. *Chickens.*— 1 and Cup, G. W. Greenhill, Ashford. 2, W. S. Marsh, jun., Deal. 3, W. Reeves, Crittenden. *hc*, E. J. W. Stratford, Maidstone.

Dorkings.—*Silver-Grey.*—1, G. W. Greenhill. 2, Rev. T. E. Cato, Wye Vicarage. 3, F. Cheeseman. *Chickens.*—1 and 2, Rev. T. E. Cato. 3 and *hc*, F. Cheeseman.

Cochins.—*White.*—1 and Cup, R. S. S. Woodgate, Pembury, Tunbridge Wells. 2, Miss Hales, Canterbury. *hc*, R. S. S. Woodgate (2); Miss Hales. *c*, R. S. S. Woodgate. *Any other Variety.*—1, W. Jacob, Shepherdswell. 2, E. Hook, Chatham.

Spanish.—*Black.*—1, J. Francis, Hildenboro, Tunbridge Wells. 2 and 3, E. J. W. Stratford. *Chickens.*—1 and Cup, E. J. W. Stratford. 2, J. Francis. 3, Rev. P. H. Moneypenny, Hallow Vicarage, Tunbridge Wells.

Brahmas.—*Dark.*—1, Cup, and 2, W. Jacob. 3, H. Kennett, Wincheap, Canterbury. *c*, E. J. W. Stratford. *Chickens.*—1 and Cup, Rev. J. G. B. Knight, Wrotham, Sevenoaks. 2, W. Jacob. 3, E. J. W. Stratford. *hc*, Mrs. Jenner, Preston Vicarage, Sandwich; J. K. Parton, Maidstone; T. Goodwin, Thornhills, Maidstone; E. J. W. Stratford (2). *c*, W. Dring, Faversham.

Brahmas.—*Light.*—1 and 2, Rev. F. T. Scott. 3, H. Mitchell. *Chickens.*—1, H. Mitchell, Sydenham. 2, G. Mills, Dover. 3, Rev. F. T. Scott, Sibertswold Vicarage. *hc*, Rev. F. T. Scott. *c*, Rev. F. T. Scott; Miss Hales; Mrs. H. Brassey, Preston Hall, Aylesford.

Game.—*Black-breasted and other Reds.*—1 and Cup, G. Braham, Ashford. 2, J. Jekin, Eltham. 3, J. G. Ledger, Folkestone. *hc*, W. Foster, Deal; J. Jekin. *Chickens.*—1 and 2, J. Jekin. 3, W. Foster. *hc*, J. A. Harms, Ashford.

Game.—*Any other Variety.*—1, E. Rice, Danecourt, Sandwich. 2 and 3, J. Jekin. *c*, W. Foster; T. Griffin, Broadmead Manor, Folkestone. *Cocks.*—1, W. Foster. 2, J. Jekin. *hc*, G. Braham.

Hamburghs.—*Golden-spangled.*—1, W. Taylor, Maidstone. 2, H. Saker, Maidstone. *Silver-spangled.*—1, H. H. Stickings, Ashford. 2, Miss L. Derman, Ashford. *hc*, W. Taylor (2). *Golden-pencilled.*—1 and 2, R. S. S. Woodgate. *hc*, J. Chapman, Ashford; G. Mills. *Silver-pencilled.*—1, J. Chapman. 2, B. Norton, Town Malling.

Creve-Cœurs.—1 and 2, W. Dring.

Houdans.—1 and 3, E. J. W. Stratford. 2, W. Dring. *c*, E. J. W. Stratford; W. Dring.

Any other Variety.—1, Mrs. S. E. Bacon, River, Dover. 2, Miss Hales. 3, G. Springett, East Farleigh. *hc*, R. S. S. Woodgate; Misses Mansell, Wrotham; E. J. W. Stratford.

Game Bantams.—1, W. S. Marsh, jun. 2, E. F. Wells. 3, A. J. B. B. Hope, M.P., Bedgebury Park. *hc*, E. J. W. Stratford. *c*, T. W. R. Hore, Tunbridge; J. Burch, Canterbury.

Bantams.—*Any variety, excepting Game.*—1, Master G. Ramsden, Ashurst. 2, J. S. Crundwell. *c*, Miss E. J. N. Hawker, Wycliffe, Tunbridge Wells.

Ducks.—*Aylesbury.*—1 and 2, W. Jacob. *hc*, G. W. Greenhill. *Rouen.*—1, F. Cheeseman. 2, F. E. Arter, Barham, Canterbury. *hc*, W. Jacob. *c*, C. Ratcliffe, Womenswould, Canterbury; W. S. Holding, Yalding. *Any other Variety.*—1, R. S. S. Woodgate. 2, A. J. B. B. Hope, M.P. *hc*, Major Archer, Tunbridge.

Geese.—1, E. J. W. Stratford. 2, Mrs. Powell, East Lenham. *hc*, H. White, Wateringbury; Mrs. Powell; A. J. B. B. Hope, M.P.

Turkeys.—1 and 2, A. Warde, Tutsham. *hc*, G. Springett; E. J. W. Stratford. *c*, A. J. B. B. Hope, M.P. (2).

PIGEONS.

Carriers.—1, G. H. Nutt, Maidstone. 2, W. S. Marsh, jun. *c*, W. S. Marsh, jun.; G. H. Nutt; E. J. W. Stratford.

Pouters.—1, W. Wells. 2, A. Watkins, jun.

Fantails.—1, G. Mills. 2, Mrs. J. Viner.

Tumblers.—1, R. S. S. Woodgate.

Any other Variety.—1, W. S. Marsh, jun. 2 and 3, Miss Hales. Extra 8, G. H. Nutt. Extra prize given by the Judge, G. H. Nutt. *hc*, E. J. W. Stratford; G. H. Nutt. *c*, T. H. Spencer, Maidstone.

Selling Class.—*Cock.*—1, G. W. Greenhill. 2, Mrs. W. M. Cheere, Aylesford. 3, C. Terrill, Maidstone. Extra 3, Rev. F. T. Scott. *hc*, A. Rigg, Wrotham Hill Park (2); C. Brown, Charing; Mrs. W. M. Cheere; W. Foster; —Jeken; E. J. W. Stratford (2). *Hens.*—1, Rev. F. T. Scott. 2, R. Cheeseman. 3, E. J. W. Stratford. *hc*, A. Rigg; W. Foster; S. Hubbard; E. J. W. Stratford. *c*, W. Dring.

BARTON AND NORTH LINCOLNSHIRE POULTRY SHOW.

The fourth Annual Exhibition was held at the Volunteers' Hall, Barton-on-Humber, on Wednesday, December 20th. There were upwards of 200 entries in the All-England classes besides a fair sprinkling in the Local classes, which were for farmers only, and confined to North Lincolnshire. A department for dead poultry dressed for the spit was also provided. This latter department was unsatisfactory in its results, as it has ever been. The Show altogether was a great success. The specimens were of the highest order of merit in the open classes, especially *Dorkings*, *Brahmas*, and *Game*. *Game Bantams* and *Bantams* of any other variety were especially good, and obtained the highest praise. *Pigeons* were a good Show; Mr. Yardley, Birmingham, and Mr. Hairsine, Hull, had some beautiful specimens, and with Mr. W. G. Waters of Elsham, and Mr. W. Beecroft a new exhibitor, pretty evenly divided the honours.

Spanish.—J. H. Yardley, Birmingham. 2, R. Cograve, Hessle.

Dorkings.—1, Lieut.-Col. Eyre, Newark. 2, H. Smith, Brigg.

Brahma Pootra.—1, Dr. Holmes, Chesterfield. 2, E. Corney, Whithy.

Cochin-China.—1, J. Brown, Hull. 2, J. Johnstone, Newark.

Game.—*Black-breasted or other Reds.*—1, F. Sales, Crowle. 2, H. E. Martin, Scunthorpe, Fakenham. *Any other Variety.*—1, F. Sales. 2, J. B. Hepworth, Hatfield. *Cock.*—2, T. Ward, Goxhill.

Hamburghs.—*Golden-spangled.*—1, W. Beecroft, Hull. 2, Master F. Astley, Elsham Hall. *Silver-spangled.*—1, W. G. Waters, Elsham. 2, Master F. Astley. *Golden-pencilled.*—2, G. W. Canty. *Silver-pencilled.*—2, R. E. Stringer, Brigg.

Game Bantams.—1, —Robson, Hull. 2, Rev. F. Cooper, Ampney. *hc*, —Hudson, Epworth; J. C. Meggit, Barton; Miss Wells, Winterton. *Any other Variety.*—2, W. G. Waters.

Any other Variety.—1, Mrs. J. Cross. 2, H. J. Tomlinson, Barton. *hc*, J. Wicks, Appleby. *Cock.*—2, J. Naimby, Brigg. *hc*, Lieut.-Col. Eyre. *Hen.*—1, Mrs. J. Cross. 2, F. Sales.

Selling Class.—1, F. Sales. 2, W. Beecroft.

Ducks.—*Aylesbury.*—1, H. Lawson, Hull. 2, R. Robinson, Goxhill. *Rouen.*—1, W. Yonhill, Goxhill. 2, Miss Wright, Broughton. *Any other Variety.*—1, H. B. Hardy, Ewerdy Manor. 2, Miss Wright.

Pigeons.—*Carriers.*—1, H. Yardley. 2, J. Hairsine, Hull. *Pouters.*—1, W. Beecroft. 2, H. Yardley. *Tumblers.*—1, H. Yardley. 2, W. G. Waters. *Fantails.*—1, J. Hairsine. 2, H. Yardley. *Jacobins.*—1, J. Hairsine. 2, H. Yardley. *Turbits.*—1, H. Lawson. 2, H. Yardley. *Antwerps.*—1 and 2, J. Hairsine. *hc*, H. Yardley. *Trumpeters.*—1, H. Yardley. 2, W. Beecroft. *Barbs.*—1, H. Yardley. 2, H. Lawson. *Any other Variety.*—1, H. Yardley. 2, W. G. Waters.

Cage Birds.—*Canary.*—1 and 2, T. S. Petch, Hull. *Any other Variety.*—1, J. Clarke, Doncaster. 2, T. Britton. *Linnet.*—2, J. Bacon. *Any other Variety.*—1, T. S. Petch. 2, J. Fox.

Rabbits.—*Lop-eared Buck.*—1, J. Fletcher, Hull. 2, P. Ashton. *Lop-eared Doe.*—1 and 2, J. Fletcher. *Pair Lop-eared*—1, P. Ashton. 2, H. J. Tomlinson. *Any other Variety.*—1, E. Walker. 2, T. McLellan.

The Judges were Mr. Edwin Newbitt, London House, Epworth, Bawtry, and Mr. George Pashby, Charlotte Street, Hull.

GUERNSEY POULTRY SHOW.

An Exhibition of poultry took place at the Militia Crescent on Wednesday and Thursday, the 20th and 21st inst. The Show was open to the United Kingdom and Channel Islands, but in consequence of the short notice given of the Exhibition, poultry-fanciers in England did not exhibit, consequently the Channel Islands had it all to themselves. There were upwards of two hundred pens of poultry, sixty of Pigeons, as well as several pens of Turkeys, Geese, and Ducks. On the whole, considering that this was the first Show of such a kind in the Island, it may be looked upon as most successful, and we beg now to attach a small summary of the Show. The *Spanish* were nothing remarkable. Mr. L. S. Robin, of Jersey, took the first prize with a fair pen; Mr. Ralfe, of Guernsey, a second. *Andalusians* were also very fair, Mr. Hutton carrying off the first prize in the class with a very neat pen; the cock was a particularly nice bird. Mr. Spencer, of the Castle, Guernsey, was awarded the first prize in the *Dorking* class, and a rare pen they were; the Rev. T. Bell, also of Guernsey, taking the first and second for chickens of 1871, two excellent pens of birds, and fit to exhibit at any show. The *Game* classes were very strong, and this splendid breed was nobly represented. Mr. Voisin, of Jersey, took the first prize for Black Reds over one year, closely pressed by Mr. Hutcheson, of Guernsey, who was awarded the second prize. Both had excellent specimens. In chickens of this year, Mr. Davey, of Guernsey, carried off both first and second prizes with two first-class pens. In Brown Reds over one year Lieut-Col. Guerin, of Guernsey, received the first prize, and Colonel Bell, also of Guernsey, took the first prize with chickens, and the silver cup for the best pen of poultry in the Exhibition.

The Judge in awarding the prize remarked that it was a splendid pen of birds. The *Houdans* were admirably represented, Mr. Bronard, of Guernsey, being first, and Mr. De Faye, of Jersey, second. Messrs. Le Mottée, Kinnersley, Guerin, and Bell were commended; although we must add pen 108, Mr. Dobrée's birds were very fine specimens. As for the rest of the Exhibition there is little to add with reference to it, except that in the *Selling Class*, Mr. Carré, of Guernsey, exhibited some remarkably nice birds, as also the Rev. T. Bell. The *Pigeons* were also very good.

SPANISH.—*Black.*—1, L. S. Roblu, Jersey. 2, W. V. Ralls, Cätel. *c*, G. De Faye, Jersey; E. C. Musson.
MINORCAS.—2, G. De Faye.
ANDALUSIANS.—1, T. B. Hatton, Candie. 2, W. H. Tozer, St. Sampson's. *hc*, E. Tomkins, Jersey. *c*, S. Bishop, Rohais.
DORKINGS.—1, H. Spencer, The Castle. 2, Rev. T. Bell, The Vale. *Chickens* —1 and 2, Rev. T. Bell.
CUCKOO.—3, T. B. Le Page. *Chickens.*—2, A. Helyar, Croûtes.
COCHINS.—*Buff.*—1, E. L. Vos, Nashville. *Chickens.*—1, J. Downing, Jersey. 2, J. De Gruchy, jun., Jersey. *Partridge.*—1, W. T. Kinnersley. 2, L. S. Robin. *Chickens.*—1 and 2, Miss E. Tupper, Les Cotils. *hc*, W. T. Kinnersley.
BRAHMAS.—*Dark.*—1, L. S. Robin. 2, Miss C. B. Carey, Candie. *Chickens.*—1 and 2, E. Messervy, Jersey. *Light.*—1, T. W. Cluett. *Chickens.*—1, E. Guerin. 2, J. De Gruchy, jun.
GAME.—*Black Red.*—1, J. Voisin, Jersey. 2, F. P. Hutcheson. *hc*, J. Davey, Gravées. *c*, J. Downing; Col. Miller, Kilburn. *Chickens.*—1 and 2, J. Davey. *c*, F. P. Hutcheson; Dr. C. Crewe; Dr. Sheppard. *Brown Red.*—1, Lieut.-Col. Guerin. *Duckwing.*—1, G. W. Wood. 2, Lieut. Col. J. Guerin. *Chickens.*—1, J. Davey. 2, W. Hancock. *Pile.*—1, J. H. Carré. 2, S. Cooper. *hc*, G. Rose; G. Warr.
BEST PEN OF FOWLS IN EXHIBITION.—1 and Cup, Col. W. Bell. 2, J. Hamley, St. Sampson's.
MALAYS.—1, J. Dowaine, Jersey. 2, J. Le Rossignol. *hc*, Col. Miller.
HAMBURGHS.—*Pencilled.*—1, J. De Gruchy, jun. *Chickens.*—1 and 2, J. De Gruchy, jun. *c*, E. Tomkins, Jersey. *Spangled.*—2, G. De Faye. *Chickens.*—1, A. Sheppard. 2, G. De Faye.
POLANDS.—*Silver-spangled.*—1 and 2, F. Alban, Vrangue. *c*, J. Carré; J. Le Rossigool. *Golden-spangled.*—1, J. Le Rossignol. 2, J. Downing. *White-Crested Black.*—1, F. Alban. 2, G. De Faye.
HOUDANS.—1, — Brouard, Millbrook. 2, G. De Faye. *vhc*, J. Le Mottée, Vauquiedor. *hc*, W. J. Kinnersley; L. S. Robin. *c*, Col. Bell, Swissville. Lieut.-Col. Guerin.
CREVE-CŒUR.—1, L. S. Robin. 2, G. De Faye. *hc*, Miss E. Tupper. *c*, Col. Bell.
LA FLECHE.—1, L. S. Robin. 2, G. De Faye.
ANY OTHER VARIETY.—1, L. S. Robin. 2, W. T. Kinnersley.
GAME BANTAMS.—1 and 2, N. Abercrombie, Jersey. *hc*, N. Abercrombie; J. Le Bass, Jersey. *c*, J. Le Rossignol. *Any other Variety.*—1. J. B. Carey, St. Helens.
TURKEYS.—1, H. Spencer. 2, Rev. T. Bell.
GEESE.—1, J. Talbot. 2, T. B. Falls.
DUCKS.—*Aylesbury.*—1, F. Gosselin, Springfield. 2 and *c*, G. Payne, Coutanchez. *Rouen.*—1, J. L. Hocart. 2, Mrs. H. Hubert. *Any other Variety.*—1, J. Le Rossignol. 2, Miss C. B. Carey. *hc*, Miss L. R. Hocart. *c*, J. B. Carey.
GUINEA FOWLS.—1, E. L. Vos.
SELLING CLASS FOR GAME.—*Cock or Cockerel.*—1 and 2, J. A. Carré, Hauteville. *hc*, G. Balsam; Dr. Crewe. 3, F. Gosselin. *Hens or Pullets.*—1, J. A. Carré. 2, Rev. T. Bell. *vhc*, W. V. Ralls. *hc*, J. B. Carey; E. Messervy. *c*, Dr. Crewe; J. De Gruchy, jun.; Mrs. Elliott.
SELLING CLASS.—1, E. Messervy. 2, Rev. T. Bell. *hc*, Col. Fannce; Rev. T. Bell; J. D. B. Dobrée. *c*, W. A. Hendy.
PHEASANTS.—1, G. De Jersey. 2, Mrs. Rogers, Les Godaines.

PIGEONS.

POUTERS.—1, G. H. Vos. 2, J. Le Rossignol.
TUMBLERS.—1, J. A. De La Mare. 2, Col. Gordon.
BARBS.—1, J. Le Rossignol. 2. J. H. Hardy.
JACOBINS.—1, J. De La Mare. 2, W. James.
FANTAILS.—1, D. De Mouilpied.
OWLS.—1, J. A. De La Mare. 2, J. M. Reilly. *c*, Miss E. Tupper; J. Hardy; J. Le Rossignol.
CARRIERS.—1, J. A. De La Mare. 2, J. E. Paint.
TRUMPETERS.—1 and 2, P. J. De Carteret, Jersey.
ANTWERPS.—1, H. A. Chick. 2, W. Ferguson.
RUNTS.—1, 2, and *c*, Lieut.-Col. Guerin. *c*, Mrs. Kinnersley.
ANY OTHER VARIETY.—1, E. Cadie (Blue Swallows). 2, J. L. Cadie (Suabians).

CAGE BIRDS.

CANARIES.—*Belgian.*—1, Mrs. Pirie. 2, J. Hennessy. *Any other Variety.*—2, Miss Layard. *Cock.*—1, Miss Layard. 2, Mrs. Pirie. 3, J. Hennessy.
GOLDFINCHES.—1, Mrs. Ramos. 2, Lady Carey, The Cottage.
LINNETS.—1, Mrs. Hutton, Candie. 2, Mrs. Randell.
MULES.—1, G. Cochrane. 2, Miss Layard.
PARROTS.—1, Miss M. Le Messurier. 2, — Brand.
COCKATOO.—1, Capt. Lenfestey. 2, Mrs. De Grellier.
FOREIGN.—1, Mrs. Pirie. 2. Mrs. Ramos (Cardinal).
BRITISH.—1, Mrs. Ramos (Bullfinch). 2, Mrs. Reilly (Redpoles.)

Mr. Jones, of Fulham was the Judge.

SCOTTISH METROPOLITAN POULTRY SHOW.

THIS, the first Scottish Metropolitan Poultry Show, was held on Saturday, Monday, and Tuesday last in a commodious hall on the grounds of the Royal Gymnasium, Edinburgh. The arrangements and fittings in every part of the hall were of the most complete description, the pens for the various classes of birds having been excellently arranged at a proper elevation, so that they could be inspected without the least difficulty. The decorations around the hall were of tasteful designs, interspersed with several appropriate mottoes. Everything, indeed, betokened that the utmost care had been taken for the comfort of the birds. That the entries numbered upwards of eight hundred on this the first occasion of such an Exhibition is not a little remarkable, and shows that a very great amount of interest attaches to exhibitions of this description. We may state that the general arrangements were made under the able superintendence of Mr. J. M. D. Brown, while Mr. George Billett, of Southampton, attended to the "naturalist" department, and it is not too much to say that both gentlemen performed their duties in the most satisfactory manner. We may also state that the prizes amounted to £400, and, although it is usual in such cases elsewhere when a bird is awarded a first prize, should it be a cup with money added, the money is withheld and only the cup given, at this Exhibition the winner of the first prize takes both cup and money. The cups and medals were furnished by Messrs. Hamilton & Inches, jewellers, Edinburgh, and were greatly admired, being of solid silver. The Show, as a whole, was truly excellent, and seldom, if ever, has such a fine selection of birds been brought together. It would be impossible to enter into the merits of all the prize birds, and we must content ourselves by alluding to only a few of the principal pens. A very fine specimen of the Coloured cockerel *Dorkings*, the property of Messrs. Gunson & Jefferson, Whitehaven, obtained the first prize in that class. In the class for pullets Mr. D. Gellatly, Meigle, carried off the first prize with a pair of finely-marked specimens. Mr. Will was first with a Coloured cock in Class 3, and Mr. D. Gellatly, Meigle, was again to the fore in Class 4. For the Silver Dorking cockerels Mr. Raines, Stirling, obtained the first award with a specimen having high general qualities. Mr. Will's *Cochin* was deservedly awarded the first prize in that class. The *Game* birds were, however, by far the most attractive portion of the Exhibition, and they were truly a fine lot throughout. Mr. Fletcher took the first prize with a very finely-shaped and beautifully-marked cock. Mr. Fletcher again led the way with a very pretty pen of pullets. Mr. Harley, Edinburgh, was first in the hen class with a hen of beautiful shape and of almost faultless colour. The show of *Ducks* was rather above what is commonly seen at even the best shows. They are large heavy birds. The Shelldrakes, Carolinas, Muscovies, and other fancy Ducks, were most attractive, and elicited general marks of attention, as also did the Golden *Pheasants*. The classes of *Bantams* were also very interesting, being divided into seventy-eight pens, and from their neat and sprightly air commanded a very large share of attention.

DORKINGS (Coloured).—*Cockerel.*—1, Gunson & Jefferson. 2, D. Gellatly. 3, J. Fotheringham. *Pullets.*—1, D. Gellatly. 2, J. Fotheringham. 3, J. Glessall. *hc*, Rev. E. Bartrum; Mrs. M'Donald; T. Raines; J. H. Wilson. *Cock.*—1 and Cup, J. W. Will. 2, Gunson & Jefferson. 3, J. Gibson. *hc*, H. Beldon; T. Raines. *Hens.*—1 and Cup, D. Gellatly. 2, W. H. & G. A. Perrin. 3, Hon. J. Massey. *hc*, A. Haggart; W. W. Ruttlidge; J. White; J. W. Will.
DORKINGS (Silver-Grey).—*Cockerel.*—1, T. Raines. 2, J. H. Macnab. 3, J. Curror. *hc*, D. Hardie; Earl of Haddington; T. Raines. *Pullets.*—1, J. Turnbull. 2, R. Smalley. 3, J. Cunningham. *hc*, Capt. Downman; R. Smalley; A. M. Sanderson. *Cock.*—1, J. H. Macnab. 2, J. Turnbull. 3, J. Curror. *Hens.*—1, J. H. Macoab. 2, D. Annan. 3, W. W. Ruttlidge. *hc*. W. Christie; T. Raines.
COCHINS (Cinnamon and Buff).—*Cockerel.*—1 and Cup, J. W. Will. 2, J. Sichel. 3, J. Pollock. *hc*, H. Lloyd, jun.; E. Leech. *Pullets.*—1, E. Fearon. 2, J. Sichel. 3, H. White. *hc*, Brown & Fleming; Capt. Downman; W. H. & G. A. Perrin; J. W. Will. *Cock.*—1, H. Lloyd, jun. 2, H. Lacy. 3, J. Sichel. *hc*, H Tomlinson. *Hens.*—1 and 2, H. Lacy. 3, Mrs. Wilkin. *hc*, H. Lloyd jun.
COCHINS (Any other variety).—*Cockerel or Cock.*—1, H. Lacy (Partridge). 2, J. Sichel (White). 3, H. Lloyd, jun. (Partridge). *hc*, E. Fearon (White). *c*, E. Leech. *Pullets or Hens.*—1, J. Sichel (White). 2, R. Smalley (White). 3, E. Fearon (White). *hc*, J. W. Will.
BRAHMAS (Dark).—*Cockerel.*—1, Hon. Mrs. A. B. Hamilton. 2, Mrs. Gillison. 3, R. Brownlie. *hc*, D. Annan; P. Campbell; R. Brownlie; Mrs. Gillison; Mrs. Wilkin. *Pullets.*—1 and Cup, H. Lacy. 2, Mrs. Gillison. 3, J. W. Will. *hc*, R. Brownlie; T. Raines; H. S. G. Stephenson. *c*, H. Lacy; H. B. Smith. *Cock.*—1 and Cup, T. F. Ansdell. 2, H. Lacy. 3, R. Brownlie. *hc*, J. Cowman. *Hens.*—1 and 3, H. Lacy. 2, T. F. Ansdell. *hc*, E. Leech; W. G. Mulligan; T. Raines; J. Sichel. *c*, J. Riddell.
BRAHMAS (Light).—*Cockerel or Cock.*—1, J. R. Rodbard. 2, Capt. Downman. 3, Mrs. Harvey. *hc*, Hon. R. B. Hamilton. *Pullets or Hens.*—1, J. R. Rodbard. 2, J. Beech. 3, J. Pares.
SPANISH.—*Cockerel.*—1 and Cup, H. Beldon. 2, W. Paterson. 3, A. Shepherd. *hc*, A. Glendinning; Hon. Miss D. Pennant; J. Thresh; Miss Wilson; J. Walker. *Pullets.*—1, Boulton & Gliddon. 2, Hon. Miss D. Pennant. 3, J. Walker. *hc*, A. C. Mollons; J. Thresh. *Cock.*—1, Hon. Miss D. Pennant. 2, Mrs. H. Lane. 3, R. Waugh. *Hens.*—1 and Cup, J. Thresh. 2, H. Beldon. 3, Hon. Miss D. Pennant. *hc*, R. Somerville (2); J. H. Wilson.
FRENCH FOWLS.—*Cockerel or Cock.*—1, W. R. Park. 2 and 3, J. Sichel. *hc*, W. O. Quibell. *Pullets or Hens.*—1, W. R. Park. 2, J. Sichel. 3, J. J. Malden.
HAMBURGHS (Golden-spangled).—*Cockerel or Cock.*—1, S. & R. Ashton. 2, H. Beldon. 3, W. A. Hyde. *hc*, R. Dickson; E. T. Gardom; J. W. Will. *Pullets or Hens.*—1 and Cup, J. Rollinson. 2, H. Beldon. 3, E. T. Gardom. *hc*, R. Dickson.
HAMBURGHS (Silver-spangled).—*Cockerel or Cock.*—1 and Cup, Ashton and Booth. 2, H. Beldon. 3, W. M'Intosh. *hc*, J. M. Campbell; R. Mackie; W. R. Park. *c*, Miss Wilson. *Pullets or Hens.*—1, Ashton & Booth. 2, H. Adams. 3, W. R. Park. *hc*, R. Cunningham.
HAMBURGHS (Golden-pencilled).—*Cockerel or Cock.*—1, J. Walker. 2, H. Beldon. 3, R. Dickson. *hc*, J. Armstrong; J. W. Will. *Pullets or Hens.*—1 and Cup, H. Beldon. 2, W. R. Park. 3, J. Walker.
HAMBURGHS (Silver-pencilled).—*Cockerel or Cock.*—1 and Cup, W. M. Mann. 2, H. Beldon. 3, Countess of Tankerville. *Pullets or Hens.*—1, H. Beldon. 2, W. M. Mann. 3, Countess of Tankerville.
HAMBURGHS (Black).—*Cockerel or Cock.*—1, Rev. W. Serjeantson. 2, H. Beldon. 3, C. Parsons. *hc*, Miss Wilson. *Pullets or Hens.*—1, C. Sidgwick. 2, Rev. W. Serjeantson. 3, H. Beldon.
GAME (Black-breasted Reds).—*Cockerel.*—1 and 3, J. Fletcher. 2, J. Forsyth. *hc*, W. Pearsun. *Pullet.*—1, J. Fletcher. 2, W. H. L. Clare. 3, D. Harley. *hc*, C. W. Brierley. *Cock.*—1 and Cup, J. Fletcher. 2, J. H. Wilson. 3, W. H. and G. A. Perrin. *hc*, J. Dick; J. Forsyth; J. Fletcher. *Hen.*—1 and Cup, D. Harley. 2, J. H. Wilson. 3, J. Fletcher. *hc*, J. Forsyth; D. Harley.
GAME (Brown and other Reds, except Black-breasted).—*Cockerel.*—1, J. Wood. 2, E. Aykroyd. 3, C. W. Brierley. *vhc*, E. Mann. *Pullet.*—1, W. Bearpark. 2, J. Fletcher. 3, J. Wood. *c*, C. W. Brierley. *Cock.*—1 and Cup, E. Aykroyd. 2, C. W. Brierley. 3, J. Fletcher. *hc*, J. H. Wilson. *Hen.*—1 and Cup, C. W. Brierley. 2, J. Wood. 3, H. M. Julian. *hc*, E. Mann.
GAME (Any other variety).—*Cockerel.*—1, C. W. Brierley. 2 and 3, D. Harley (Duckwing). *vhc*, W. Nelson. *Pullet.*—1, E. Aykruyd (Duckwing). 2, C. W. Brierley. 3, J. Fletcher. *vhc*, A. S. Brewster (Duckwing). *Cock.*—1, 2, and Cup, C. W. Brierley. 3, H. M. Julian (Duckwing). *vhc*, J. Fletcher. *hc*, J. Fletcher; D. Harley (Duckwing); J. W. Will. *Hen.*—1 and Cup, C. W. Brierley. 2 and 3, D. Harley (Duckwing). *hc*, H. M. Julian (Duckwing).
POLISH.—1, 2, and Cup, H. Beldon. 3, G. W. Boothby. *hc*, Parsons & Wilson (Golden); W. Silvester (Golden); A. Wylie (Silver); T. Waddington.
ANY OTHER VARIETY.—1, J. Bell (White Dorking). 2, W. Gibb (Scotch Grey). 3, R. Loft (Sultan). *hc*, W. B. Mackay; J. Schiel (Sultan); D. Waldie (Scotch Grey).
DUCKS (White Aylesbury). — 1, H. S. G. Stephenson. 2, E. Leech. 3, A. Robertson.
DUCKS.—*Rouen.*—1 and Cup, A. Dickinson. 2, D. Hardie. 3, G. W. Mulligan. *vhc*, H. B. Smith. *Any other variety.*—1, C. W. Brierley. 2, W. Binns (Mandarin). 3, H. S. G. Stephenson (Carolina). *hc*, H. B. Smith (Fancy).
GEESE.—1, Rev. G. Hustler. 2, E. Leech. 3, D. Hardie.
TURKEYS.—1 and Cup, Mrs. Houldsworth. 2, Earl of Haddington. 3, Miss Stenhouse.
GAME BANTAMS (Black-breasted Reds).—1 and Cup, G. Hall. 2, J. W. Morris

3, G. Maples, jun. *hc*, J. Gow & Walker; H. J. Nicolson; W. Robinson; T. Raines; T. Sharples; J. W. Will.

GAME BANTAMS (Brown-breasted Reds).—1, J. Dick. 2, G. Hall. 3, Miss J. M. Frew.

GAME BANTAMS (Any other variety).—1 and Cup, G. Hall (Duckwing). 2, Rev. F. Cooper (Duckwing). 3, J. Gew & Walker (Pile). *hc*, G. M'Millan. *Cock.*—1, J. W. Morris. 2, J. Clark. 3, D. Hardie. *hc*, J. M. Campbell; Miss Wilson.

BANTAMS (Any other variety except Game).—1 and Cup, W. H. Robinson (Black). 2, J. Sickel (Pekin). 3, Master A. Frew (Silver-laced Sebrights). 4, Countess of Tankerville (White Frizzled Japanese). 5, C. Reed (White Rose-comb). *hc*, H. Beldon; G. W. Boothby (Silver-laced); T. Waddington (Black); C. Reed (Black Rose-comb).

SELLING CLASS.—*Cock or Cockerel.*—1, J. Sichel (Buff Cochin). 2, C. W. Brierley. 3, J. Clark (Dorking). 4, C. Sidgwick (Cochin). *hc*, E. Fearon; P. Gray; J. Clark (Dorking); Capt. G. F. Lyon, R.N.; W. Linton; J. Mansell (Spanish); T. Mason (Game); W. R. Park (Crève-Cœur); J. Oldfield; Mrs. T. S. Thomson (Brahma); J. H. Wilson (Dorking); J. W. Will; A. Robertson (Spanish). *Hens or Pullets.*—1, C. W. Brierley. 2, A. Robertson (Spanish). 3, W. Grice (Game). 4, J. J. Waller (Dorking). *hc*, J. Chapman (Scotch Grey); E. Fearon; Capt. G. F. Lyon, R.N.; W. W. Rattlidge (Dorking); J. Sichel (Buff Cochin); Mrs. Wilkin (Brahma).

PHEASANTS.—1, J. F. Dewar (Gold). 2, Countess of Tankerville (Gold).

The Judges were Mr. Richard Teebay, Fulwood, near Preston, and Mr. John Douglas, The Aviaries, Clumber, Worksop.

DURHAM POULTRY SHOW.

THIS was held on the 20th and 21st inst., when the following awards were made:—

COCHIN-CHINAS (Cinnamon and Buff).—1, C. Sidgwick, Keighley. 2, T. H. Redman, Whitby. *Chickens.*—Cup, 1, and 2. G. H. Procter, Durham.

COCHIN-CHINAS (Any other variety).—1, G. Calvert, Darlington. 2, J. Bell, Thirsk. *Chickens.*—1, C. Sidgwick. 2, G. H. Procter.

BRAHMA POOTRA.—1, R. Shield, Swalwell. 2, Mrs. Wilkinson, Buckledale, Frosterly. *Chickens.*—1, T. Rutherford, Durham. 2, J. Stalker, Bedlington.

BRAHMA POOTRA.—*Chickens.*—1 and Medal, T. Rutherford. 2, J. N. Lawson, Ryhope.

DORKING.—1, J. White, Warlaby, Northallerton. 2, J. T. Proud, Bishop Auckland. *Chickens.*—1, J. White. 2, W. Swann, Bedlington.

SPANISH.—1, H. Wilkinson, Earby, Skipton, York. 2, G. Holmes, Driffield. *Chickens.*—1, H. Wilkinson. 2, J. Thresh.

POLAND.—1, G. Speedy, Whitby. 2, J. T. Proud. *Chickens.*—1, Buglass and Williamson, Carrville, Durham. 2, G. W. Boothby, Louth.

GAME (Black-breasted and other Reds).—1, J. Gibson, Stanhope. 2, T. Robson, Bishop Auckland. *Chickens.*—1, J. Watson, Knaresbrough. 2, R. Sharp, Blyth.

GAME (Any other variety).—1, L. Casson, Ulverstone. 2, J. Gibson. *Chickens.*—1, H. Martin. 2, L. Casson, Ulverstone.

HAMBURGHS (Golden-spangled).—1, G. & J. Duckworth, Church. 2, G. Speedy, Whitby. *Chickens.*—1, H. Pickles, jun., Earby, Skipton. 2, W. Whitfield, Fence Houses.

HAMBURGHS (Silver-spangled).—1 and 2, H. Pickles, jun. *Chickens.*—1 and 2, H. Pickles, jun.

HAMBURGHS (Golden-pencilled).—1, T. H. Redman, Whitby. 2, G. Holmes. *Chickens.*—1, J. Webster, Whitby. 2, H. Pickles, jun.

HAMBURGHS (Silver-pencilled).—1 and 2, H. Pickles, jun. *Chickens.*—1, J. Walker, Birstwith, Ripley, Leeds. 2, W. M. Mason, Kendal.

GAME BANTAM (Black Reds).—1 and Cup, G. Hall, Kendal. 2, W. Dixon, Sunderland. 3, W. Adams, Ipswich.

BANTAM (Game).—1, G. Hall. 2, G. Todd, Sunderland. 3, W. Adams.

BANTAM (Any other variety except Game).—1, T. Waddington, Feniscowles, Blackburn. 2, S. & R. Ashton, Mottram.

ANY OTHER VARIETY.—1, J. Elgar, Newark. 2, R. Hawkins, Seaham Harbour.

DUCKS (Rouen).—1, H. Simpson, Pyclose, Frosterley. 2, R. Gladstone, jun., Liverpool. (Aylesbury).—1, W. Stonehouse, Whitby. 2, T. P. Carver, Langthorpe, Boroughbridge. (Any other Variety).—1, J. J. Waller, Kendal. 2, J. A. Smith, Durham.

SELLING CLASS.—1, G. H. Procter, Durham. 2, J. P. Fawcett, Whitby.

PIGEONS.

CARRIERS (Black).—*Cocks.*—Medal, H. Yardley, Birmingham. 2, A. Brown, Durham. *Hens.*—1, T. Waddington, Feniscowles, Blackburn. 2, T. Sanderson, Stanhope.

CARRIERS (Any other colour).—1, G. W. Lilburn, Sunderland. 2, E. C. Stretch Ormskirk, N.B.

POUTERS (Blue).—*Cocks.*—Medal, T. Rule, Durham. 2, E. T. Dew, Weston-super-Mare. *Hens.*—1, E. T. Dew. 2, W. Rowell, Clough Dean, Barnopfield.

POUTERS (Any other colour).—1, A. Frame, Lark Hall, Lanarkshire. 2, G. J. Taylor, Fartown, Huddersfield.

TUMBLERS (Almonds).—*Cocks.*—Medal, J. M. Brsid, Cambridge. 2, J. Fielding, jun., Rochdale. *Hens.*—1, E. T. Dew. 2, J. Ford, London.

TUMBLERS (Any other colour).—1, G. J. Taylor. 2, W. R. & H. O. Blenkinsop, Newcastle.

BARBS.—*Cocks.*—Medal, T. Waddington. 2, W. E. Easten, Hull. *Hens.*—1, T. Waddington. 2 G. J. Taylor.

TRUMPETERS (Mottled).—Medal, T. Rule. 2, G. W. Lilburn, Sunderland. (Any other colour).—1, W. H. C. Oates, Bestborpe, Newark. 2, T. Rule.

FANTAILS (White).—Medal, J. Gault, Kilbirnie. 2, J. Walker, Newark. (Any other colour).—1, H. Yardley. 2, T. Rule.

JACOBINS (Red).—1, W. Massey, Spalding. 2, T. Rule. (Any other colour).—Medal, G. Roper, Croydon. 2, R. G. Sanders, Leven, Beverley.

TURBITS (Blue).—1, J. G. Dunn, Newcastle. (Any other colour).—Medal and 2, W. Croft, Killinghall, Ripley.

OWLS (Foreign).—Medal, J. Stanley, Blackburn. 2, J. Fielding, jun. (English).—1, J. Chadwick, Bolton. 2, J. Thresh, Bradford.

TUMBLERS (Long-faced).—1, E. C. Stretch. 2, R. G. Teebay, Latham, Ormskirk.

BALDS OR BEARDS.—1, W. H. C. Oates. 2, J. Donkin, Newcastle.

NUNS.—1, W. Bearpark, Northallerton. 2, W. Croft.

MAGPIES.—1, W. Kitchen. 2, W. C. Dawson.

DRAGOONS.—1, F. Graham, South Birkenhead. 2, W. Reddihough, Kelbrook Colne.

ANTWERPS.—1, H. Yardley. 2, W. H. Mitchell, Moseley, Birmingham.

ANY OTHER VARIETY.—Medal, T. Waddington. 2, W. C. Dawson.

SELLING CLASS.—1, R. Anderson, Newcastle. 2, A. Frame. 3, J. Cundle, Copt Hewick, Ripon. 4, W. R. & H. O. Blenkinsop. c, M. Ord.

JUDGES.—*Poultry:* Mr. R. Teebay, Fulwood, Preston. *Pigeons:* Mr. E. L. Corker, Croydon.

NORTHERN COLUMBARIAN SOCIETY'S SHOW.

I CLAIM the right of reply to your anonymous correspondent, "FAIRPLAY," because many of the statements made in his account of the Northern Columbarian Society's Show of Pigeons at Newcastle-on-Tyne are untrue, and calculated to damage the interests of the Society and to stultify the Judge, Mr. P. H. Jones, besides condemning the birds of several exhibitors unjustly. If "FAIRPLAY" had tried, he could not have written a letter more calculated to hurt our Society, but I have not the slightest hesitation in saying, that whoever he is, he has no knowledge of the subject which he professes to criticise. I will take "FAIRPLAY'S" statements *seriatim*. Firstly, he says that Mr. T. Rule, myself, and Mr. Blenkinsop were the originators of our Society; this is incorrect. Mr. Rule had nothing to do with the formation of our Society, and was not elected a member until the 3rd March, 1871; the Society was formed on 28th January, by Messrs. T. W. Kilburn, J. Pringle, N. Dunn, H. O. Blenkinsop, W. R. Blenkinsop, and myself. Now I must enter upon a subject which I would willingly have avoided, but cannot in justice to Mr. Jones. "FAIRPLAY" says that Mr. Rule's Trumpeters were the best in the Exhibition, and ought to have won the cup, first, and second prizes instead of being passed over. Now they were not passed over; all four pens were ticketed "Disqualified, trimmed," having been clipped in front of the crest to make that look larger and better-formed. I am very sorry to have to state this, and had passed it over in my account to you, but as you published "FAIRPLAY'S" statement, you must in fairness publish mine. In case "FAIRPLAY" may say that the "trimmed cards" were not up when he wrote his criticism, I beg to say they were up, because "FAIRPLAY" alludes to the sale by auction of some birds which did not take place until long after the cards were put up.

As to "FAIRPLAY'S" statement that my Trumpeters were of no merit, I beg to say that the cup bird was good enough to beat Mr. P. H. Jones's celebrated pair of Blacks at the open Show at Newcastle.

Now as to the Jacobins. "FAIRPLAY" calls Mr. Royds' Black a coarse bird and inferior to Mr. Waddington's. This is not the case. Mr. Royds' bird is one of the best Black Jacks in the fancy, and Mr. Waddington's, though a good bird is short in frill, and cut very low, low enough for a Baldhead Tumbler. In Red Jacks, "FAIRPLAY" says Mr. Rule's Red hen ought to have had the first prize. Very likely she ought, but she happened to have been trimmed the same as the Trumpeters, and had the trimmed card fixed on her pen instead. In the Carrier classes, "FAIRPLAY" says the Dun bird winning first ought to have had the cup, and was so young that its sex could not be ascertained. How does he know this? The bird is entered by its owner as a cock, and I suppose he ought to know. What "FAIRPLAY" means when he states "That Mr. E. E. M. Royds showed in the Jacobin classes several old birds which were admitted by telegram," I am at a loss to know. He says further, "but not before Mr. Jones had judged them; in any case none of them had a chance, the young birds clearly beating them." Now Mr. Royds' brother accompanied his birds, and under my direction he took out all his old birds (brought in mistake), and they were not put back until long after the judging was finished, and were ticketed "not for competition." Whether they were better or worse than the young birds shown has nothing to do with the subject under discussion, only I should not like to have to compete with young birds against them.—W. B. VAN HAANSBERGEN, *Hon. Sec. Northern Columbarian Society.*

[We readily insert the foregoing, and we shall decline inserting any reply.—EDS.]

BEES NOT FRUIT-ROBBERS—LIGURIANS.

I HAVE read with interest the accounts of "J. R. S. C.," on the predatory insects of our gardens, and I much regret to find him placing the honey bee amongst these. I do not know where he obtained the information of bees attacking and destroying fruit, but I can testify, after considerable experience with bees, that I never yet knew them to attack sound fruit. I have seen them by the thousand on damaged Strawberries, but I never yet saw them meddle with fresh ones. I have seen them on Peaches, Pears, Plums, &c., but they appeared to act merely as scavengers in this respect, and it was only after the skin had been broken by some other insect, such as earwigs and beetles, that they ever interfered with them. Nay, I have even presented fresh fruit to them, and they always refused it, but fruit in a half-decomposed state they appeared to eat greedily. I hope, therefore, before waging war against our favourites, he will satisfy himself and others that they are really the depredators in the first instance.

As to their destroying flowers by boring a hole in the right position to enable them to rifle the flower of its treasures, although I have heard it mooted before, I must also give my evidence in this respect rather contrary to that of your correspondent. I may mention, however, that I have not hitherto paid due attention farther than I invariably find the common or black bee getting access to the honey in the blossom of the bean through a hole at the base of the flower previously made, as I suppose, either by some insect, or, perhaps, a bee that had visited the flower before. But it is very different with the Ligurian bee, for whilst the black gets access to the honey at the base of the flower, the Ligurian invariably enters at the mouth of the blossom. So mark the difference in this respect

between the two varieties. Some writers affirm there is no difference but that of colour between the two species, the palm of superiority resting with the black bee, and Mr. Pettigrew in his "Handy Book of Bees," clings to this opinion. I have, however, been already found fault with in pointing out his errors, and it might be conjectured that I would leave that gentleman alone, and cease to doubt the accuracy of his statement. So I would were I as ignorant as the author of the "Handy Book" is about the Italian bee. I say "ignorant," because he asks questions on the Italian bee, and replies to them all in the negative, not one of which answers is in accordance with the facts.

Before giving my experience of Ligurian bees, I will review Mr. Pettigrew's chapter on that insect. He is bold enough to assert that his book is for the guidance of "inexperienced bee-keepers," but I must confess that it is only an attempt of the blind to lead the blind, particularly in this chapter. Had he stated his experience of these insects, we would have been able to detect why he has given them such a bad character; but as he has not done this, it keeps us entirely in the dark as to whether he ever possessed an Italian bee. It must be patent to everyone who reads the chapter, that his object has not been so much to make known the qualities of these bees, as it has been to ridicule the English.

Mr. Pettigrew's first question on the Ligurian bees is, Do they fly faster? I will not here endeavour to state how much faster they do fly, but it is sufficient to say that their motions when working are in the ratio of five to three of the blacks, and in a race of a thousand yards they are faster by about a quarter of a minute. His second question, Do they carry heavier loads? may not be far wrong, but they carry equal to the blacks. As to his third question, Do they lay more eggs? In the case of four hives, of which two were Ligurians and two blacks, the latter having the advantage in numbers, the former laid, on an average, two to three hundred eggs more daily, beginning earlier and continuing longer in the season. His fourth question, Do their eggs become perfect bees sooner? may not be faulty. His fifth and sixth questions may be answered thus. When honey is to be had, not only are the Ligurians earlier at work in the morning, but they are also later at work at night. This year, when we took our bees to the heather, there were fourteen blacks to one Italian, and whenever they were let free we started "o'er the moor amang the heather," for nearly a mile, and there saw hundreds of Ligurian bees long before a black was visible; in fact, we never saw any of the latter until we were half way on the road home. On a visit to our bees some time after, we took a roundabout tour, and nearly lost our way, and the thing that showed us our course when several miles distant, was the Ligurian bees in great numbers unaccompanied by a single black one. The Ligurians are also the first to find out any new flower or concealed honey. His seventh question, as to whether they gather more honey, I can answer thus—not only do they gather more honey, but they produce it far finer, and more highly flavoured. Wherever these bees have been introduced they give the same satisfaction, and this year, in the month of May, I had letters from different parties reporting that the Ligurians were, on an average, 10 lbs. heavier than the blacks. His eighth question regarding their rate of breeding is soon disposed of, for as they lay more eggs they must breed faster; whilst his ninth question with regard to their swarming more, is absurd. They not only swarm more, but their swarms are larger in proportion. When he compares the wasp to the excellency of the bee, we can only exclaim that he is a man preferring colour to symmetry and usefulness. I hope, therefore, for the benefit of your readers and of his own honour, he will give us an account of his experience with the Ligurian bee. We shall then be able to understand why he has given them a character they do not deserve.

Though the sting of the bee is so dreaded by many, I believe imagination has much to do with the pain and evil that follows in some persons. There are several instances which have come under my observation, that make me often believe people are sometimes more benefited by a sting than otherwise. I have found in hot sultry weather, when it was difficult to move about without oppression, that a smart sting or two caused me perspire more freely, and to feel much lighter afterwards. There is also another fact that may be of some importance, and that is, in two different cases of vaccination, where the patients had been stung, the lymph had no effect, whilst those vaccinated at the same time, but not stung, did well. I have also known persons suffering from sores which, although painful at the time, invariably when stung healed soon after.

It is but a short time since I doubted the accuracy of the statement that two queens would exist for some months together in one hive. I was not long, however, in being convinced of the fact, as several instances came under my notice; but since they were all much alike, and all support the theory advanced by your esteemed correspondent, "R. S."—viz., that aged queens may be tolerated in a hive, I will mention but one of them. This will not only prove the existence of two queens, but will give evidence of several other facts at the same time.

The hive in the present case was that of an imported queen in the summer of 1867. During the month of August, 1870, I put this queen and her bees into an empty hive, and in consequence of a little feeding, and their own industry, it was soon in a fit state to stand the winter. From the abundance of brood and young bees which there were in a month, I felt no anxiety about my beautiful and prolific queen, nor was I at all alarmed in February, when hundreds of young bees sported on and around the hive. Perhaps I was not a little vain, when in the month of March, many drones made their appearance, for as I was sure this was not a case of drone-breeding, I anxiously looked for an early swarm of pure Italians, having no doubt but that they were so. I had satisfied myself a few days before that my queen was alive, and, though aged, able to lay the numerous eggs which produced such lovely-coloured bees. By this time I had determined how many almost-yellow queens I was to have from this stock alone, but "the best-laid schemes o' mice and men gang aft aglee," and one day came from the hive a rush of bees, that did not possess such fine markings as they ought. I was apprehensive, but why? Had I not just the other day seen both queen and workers? And what need was there to surmise when I could see no signs of hybrids? It was not possible after September to have a case of pure fertilisation when there were no pure drones, these having been all destroyed long before the middle of August. So I allowed matters to go on, believing that I must have been deceived with the colour of the last relay of young bees, and not until one day in the beginning of May was I made fully aware of the fact that two queens had been living together for nearly a year. On taking a look round my hives I picked up a beautifully marked queen that had been thrown out of the hive. This I knew to be my favourite one, but her shell only remained, as the inside had been thoroughly cleaned out by insects. My first act after finding her was to examine the hive and see what was the result, when to my astonishment I found another dead queen, with her head in an empty queen cell. This one I subjected to *post mortem* examination, and found her perfectly fertilised. From the appearance of the hive it was clear that the colony was divided, because the one side of the hive contained worker brood and eggs, whilst the other side had mostly drone brood with a few worker brood. How both queens came to grief at the same time we can only conjecture.

My next object was to raise a young queen, and to be certain that what I was going to raise should be pure, I removed all worker eggs, and inserted a frame of comb of undoubted purity from another hive. Meanwhile the bees had already commenced to raise a number of queen cells containing drone eggs. What a pity Mr. Pettigrew had not a chance like this! It would surely have satisfied him and refuted the absurd idea that drone eggs are capable of being transformed into queens. One of these was rather singular in its construction; instead of being hung in its usual vertical way, it was nearly 2 inches long, and extended in a horizontal manner. Notwithstanding this extravagance its occupant, as well as those of the rest, emerged from the cell at the usual time as perfect drones. As I had not a chance of entering into this subject when it was last discussed by our deeply-lamented friend "A Devonshire Bee-keeper," I may, perhaps, be allowed now to express my opinion on the matter.

I say that no person who understands the nature and anatomy of the honey bee, will advance the theory that queens can be raised from drone eggs. Mr. Woodbury, in his last letter, very wisely showed where a mistake might arise with those who did not fully understand the nature of the hive and its occupants—viz., that of the transitionary cells, where a worker egg might be placed in the midst of the drone ones. There is, however, another case in which the ignorant, or even some with considerable knowledge may be deceived, and it is that of the hermaphrodite bees being raised in queen-cells; the resemblance that many of these bees bear to the true worker in many cases, perhaps, deceiving the apiarian. I have myself seen these hermaphrodites transformed into queens, and but for some slight part of the male, such as the antennæ, or leg being pro-

minent, I would have remained ignorant of their not being true queens. The hermaphrodite bees, in many instances, approach so nearly to the one sex, that not only is the bee-keeper sometimes cheated, but the insects themselves are in doubt. The description of one hive that produced nothing but these compound bees may be of interest. They were produced in prodigious numbers, and varied from the appearance of a perfect drone to that of a worker. These singular bees carried pollen in large pellets in the ordinary way, but I am not aware that any of the pollen was ever stored inside of the hive; it appeared either to be dropped on the board or around the hive, and was lying there in great quantities. Their hum was also of a peculiar sound. I fully intended to have secured this queen for examination, but the owner, before I was aware, crushed it between his finger and thumb.

I have, however, found queens with an ulcer on one side of the spermatheca bag, and I doubt not but it is through some defect of this kind that these bees are produced. Fertile workers, on the other hand I believe, are raised in consequence of the bees supplying the larvæ when too far advanced with royal food. These fertile workers are a great annoyance to the bee-keeper, as they bring many a hive to ruin and dispel his hopes. They kill the fertilised queen, and the eggs put into a hive which they occupy are invariably destroyed.

I will describe the case of one that came under my observation this autumn. A friend brought me a hive of black bees for the purpose of being ligurianised by introducing some eggs; this I did from a healthy hive and with a pure queen. The bees of the black hive commenced at once and raised two queen cells, but in consequence of its being affected with foul brood none of the queens hatched, and only two of those in worker cells came out. One of these cells was a little convex, and had almost the appearance of a drone cell; and although I gave this hive a piece of brood comb every third day for nearly a fortnight, every egg and grub was always removed, and in exactly four weeks from the hatching of the fertile worker, young Italian drones were hatched.—A Lanarkshire Bee-keeper.

LARGE AND SMALL HIVES—WINTERING BEES.

The size, form, and material of bee-domiciles, and the wintering of bees, are, and ever have been, fertile themes of discussion amongst apiarians, so that even practical bee-keepers, sometimes, of no small experience, are apt to get perplexed amidst the many discordant opinions and distracting theories which have from time to time been propounded on these subjects.

In regard to whether large or small hives are best suited to the successful and economic cultivation of the bee, it is refreshing to read such sound remarks as are appended to an article on this head in last number by the Editors. Yes. "Circumstances can alone decide what is fitting in each case." The experienced cultivator well knows that a propitious season, a rich pasturage, a strong and vigorous colony, are the real elements of prosperity, and according to the character of these must we be guided by the size of domicile used. Independently of these, it is a complete fallacy to suppose that bees can be forced, as it were, to augment their sweets according to the mere whim, crotchet, or caprice of their owners. In ordinary localities we must avoid extremes, both being equally unsuitable, if not injurious. A hive too small is certainly far more damaging to prosperity than one too large. In the former case there is insufficient space for breeding, and, consequently, for storage of honey. In the latter, on the other hand, the capacity of the hive being beyond the necessity of the case, it is generally unfilled with comb, and when filled, exceptionally, we rarely get that purest of honey which is stored in supers.

I have tried both extremes, and find a medium is best. I shall not say what that medium is, because each locality must determine that according to the elements of the prosperity I have already indicated. I more than once wintered bees in small hives, and found the results in every case most prejudicial. The swarms emanating from these were most diminutive, and the honey collected was, from inadequate numbers, as well as inadequate space, necessarily very small. As a general rule, I might remark, that any hive which can be filled with comb in two or three weeks in summer, by a swarm of 4 lbs. or 5 lbs. weight, may be considered a suitable-sized domicile for an ordinary good locality. Circumstances, however, vary so much that experience is alone the safest guide.

I must reserve my remarks on "wintering of bees," referred to by "B. & W.," till a future occasion.—J. Lowe.

OUR LETTER BOX.

Our Reports.—A bookseller writes thus to us, "I should add several subscribers to my list if you could give a good and impartial critical report of all the principal shows in each county. There are complaints that the reports are written for the great breeders, and when an amateur wins he is quite ignored."

[Of unjust charges the above is among the superlative. Our reports are usually written by men who are the best judges, and as far as we know, unbiassed. When correspondents favour us with reports we omit all that we think exaggerated. It is quite impossible to notice every successful exhibitor, except in the prize list.]

Preserving Bird Nets (*Rush*).—This was printed "birds' nests" on page 500.

Leeds Poultry Show.—For Dorking chickens the second prize, we are informed, was awarded to Mr. J. White, Warlaby, and not to Mr. Kell, of Wetherby.

Northern Columbarian Society's Show.—We have received several letters replying to "Fairplay's" criticisms, but we cannot insert them. It would be a mere contest of opinions. Mr. Justice, Salford, we are informed, took the second prizes for Black and Any other coloured Jacobins.

Tredegar Poultry Show.—Mr. Thomas May, Wolverhampton, informs us that he gained the second prize for Golden-spangled Hamburghs.

Plymouth Poultry Show (*Westernman*).—We are obliged by the details you send us. Such proceedings must put an end to the exhibition. No wonder it was unsuccessful. We shall make further inquiries and warn exhibitors in time.

Durham Show (*J. F. B.*).—You are not the only one who has written to complain of the judging. Representations should be made to the Committee.

Matching Jacobins (*Captain*).—We have seen very good coloured Jacobins bred from Blacks crossed by Reds, and their progeny, if two be mated of the same colour, throwing back the other colour. Black and yellow are not so good to cross; these colours often produce a kind of strawberry colour not at all worth having.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

20th.—Deep roseate sky at sunrise, overcast by 9 A.M., rain at 10 A.M., and at intervals all day; fine evening.

21st.—Fine morning, but soon clouded over, slight rain between 1 and 2 P.M., and at intervals afterwards.

22nd.—Overcast, dark and foggy, wetting mist but no rain, fine at night.

23rd.—Dark and foggy morning, clearer after noon, but overcast throughout.

24th.—Fine morning, with bright sunshine about noon, lunar halo from 7.55 to 8.20 P.M.

25th.—Fair but overcast in the forenoon, slight rain began about 4 P.M., and continued at intervals till 9 P.M., fair till 10 P.M., and steady rain till midnight.

26th.—Heavy rain until 5 A.M., slight until 7.30 A.M., fair till evening, sharp shower at 7 P.M.; a damp muggy day.

Owing to the generally overcast state of the sky, and the great dampness of the atmosphere, the temperature this week has been singularly uniform, and though rather less than in the previous week, is still nearly 4° warmer than usual.—G. J. Symons.

COVENT GARDEN MARKET.—December 27.

With the exception of the influence of Christmas on the demand here we have nothing to report worth notice. The supply of everything but Apples and Pears is ample, the importations having been moderate from the Continent lately, and confined to Glou Morceau and Easter Bourré Pears. Potato trade heavy, with large stocks of inferior descriptions.
