I purpose to build a pit 20 feet long by 11 feet wide against a wall 4 feet 6 inches high, and to double-glaze it; in addition I shall have a stout canvas roller-blind to cover all, and this, by keeping the divisions between the sashes deeper than usual, will be kept a few inches from the glass. The entrance will be at the east end: at the west I have a brick wall. As it is at the further end of my little reserve-garden I do not want the trouble of any night fires. The roof will ventilate like an ordinary old-fashioned greenhouse, and under the front sill I shall have a line of ventilators 4 inches or 5 inches deep. Will this suit to keep a stock of standard Fuchsias for bedding, *Veronica speciosa* and *variegata*, *Hydrangeas*, *Rhododendrons*, *Roses*, *Tritomas*, *Genistas*, &c.? I fear the spring growth of the Fuchsia will get frosted. I think of leaving earth banks and cutting-out the pathway; if so, I shall

plant many of the bedders (half-hardy) in the banks to save potting, &c. On the front bank I shall plant-out *Calceolarias*, Parsley, *Vinca major variegata*, &c. In summer, as the sashes will be moveable, I can cover with tiffany, and get a very useful corner.

I often wonder *Veronica speciosa variegata* is not more used in bedding arrangements, it is a very pliant and very pretty variegated plant.

Is *Vinca major elegantissima* hardy? I have taken the trouble to pot and house about six dozen.—H. B.

[There is a great difficulty in meeting such cases where there is no one at home to give air or to throw a little covering on in a keen frosty afternoon. As respects the plants you mention, they would be safe in the pit, as the double glass would prevent sudden extremes inside. But after the plants began to grow in spring they would require more watching, and the canvas might want regulating before you returned. We think that for any particular thing your pit, 11 feet wide and 4½ feet at back, will be very flat, more especially if the front wall is high enough to enable you to give air by it. You will be likely to have damp and drippings from the glass. As you want no fires, that settles the question; but, approving of your double glass, we think a small brick stove in the centre at the back would save much nicety in covering, and save you from hurrying home. For instance: after a frosty night, a little fire in the morning would enable you to give a little air before leaving; if there was much sun it would secure safety, if not much there would be no harm, and the heated bricks would keep all safe until your return.

The *Vinca* is pretty hardy. We have not tried the *Veronica*. You must have a fine stock.]

### POINTS OF MERIT IN GRAPES.

I AM very pleased such an authority as Mr. Thomson, and several other correspondents, have commenced a discussion as to the relative merits the different points should bear in Grape-judging. I hope the *pro* and *con*. will be so well given by all who, like myself, like to see a good dish of Grapes, and the best to stand first at the exhibition, that a good basis may be formed for future Grape-growers and exhibitors. I saw the other day at a local show, Red—i.e., Black Hamburgs, supersede jet Black Hamburgs, because the berry and bunch were one size larger than the black ones: thus making size the premier quality. I then thought the Judges did not know their duty, but must suspend my opinion if Mr. Thomson is right with colour so low on the scale. It is very seldom in Hamburgs and Muscats but that good colour and flavour go together; but bad colour and indifferent flavour accompany each other often. From these premises imagination through the eye has to be pleased on the exhibition table, and the eye as well as palate on the dessert table. I would place their points thus:—Colour, 3 points; size and evenness of berry, 2 points; size and proportion of bunch, 1 point.

One of your correspondents would take the flavour test from Melons nearly away; but, as all gardeners of experience know it is harder to grow a good-flavoured Melon than a large, handsome one, the flavour test ought very much to predominate.—J. A., *Hants*.

In your Number of the 11th inst., three different individuals apparently well up in the art of Grape-growing, as well as that of Grape-judging, seem to differ so much in their opinion as to the best method of settling the vexed question raised by your worthy correspondent Mr. W. Thomson, that I fear after all that may be written on the subject much will have to be left to the discretion of the judges.

But, in order to satisfy exhibitors, I think the time has really come when Grapes must be "tasted," as well as "looked at," and I am sure that judges carefully selecting a few berries from each bunch of Grapes, such bunches would not be disfigured to any serious extent; and, therefore, it is only to be understood by exhibitors that flavour is to be an essential point with the judges, and the decision in most cases will be satisfactory.

All who do not think that a plea of necessity may be urged in favour of flavour being an essential point in judging fruits, such persons should study the decisions of the Fruit Committee of the Royal Horticultural Society, and they will find that flavour with the majority of the Committee is the most important point.

And if so in committee, why not at the regular shows or exhibitions?

If your correspondent "J. B. W." had asked why Melons, Apricots, Peaches, Plums, Apples, Pears, and other fruits that might be named, were invariably tested by flavour, and not Grapes, he would have been nigher the mark.—A LOOKER-ON.

### THE RIVINA LEVIS AND CALLICARPA PURPUREA AS DINNER-TABLE PLANTS.

The following description of a very beautiful dinner-table plant, which we so much admired at Shrubland Park, is kindly given by Mr. Blair's own pen.

"The *Rivina levis* to which you refer is a very pretty thing, and is an acquisition as an ornamental plant for dinner-table decoration. Its small white flowers are not showy, but the berries, which might be mistaken for Red Currants, hang in graceful bunches all over the plant. It is propagated by seeds, which are produced in abundance, or by cuttings in the usual way.

"Supposing cuttings to be rooted, or seeds sown in August or early in September, they will make good plants the following season. As soon as the young plants are 2 inches or 3 inches high, take off the top, and as they increase in size shift into larger pots. Pinch off the joints as they grow, and keep them near the glass in order to make bushy and compact plants. Syringe gently in the afternoons of fine days, and keep a moist atmosphere. They succeed in a pit or intermediate-house, and grow well in peat, loam, and sand. After the berries drop a few of the old plants may be cut down, stored away, and kept rather dry until February, when they may be turned out of their pots and repotted into smaller ones, in which they soon root freely. When ready they can get another shift into the size required."

That which attracted my attention at Hardwick House is, according to a letter just received from Mr. Fish, the *Calli-carpa purpurea*, and Mr. Fish kindly adds—"That seed of this beautiful plant may be sown at any time, and should be grown in a temperature of about 60°. The more light it has the more berries it will produce, and if kept clean the leaves are also pretty."

I have no doubt that by sowing at various times, as Mr. Fish does, plants of this may be had at almost any time fit for use, and in this plant we have beautiful fruit and foliage combined.

This is only one of the many plants which we "fished out of Mr. Fish's collection," and particulars of some others, perhaps, will be interesting when time permits.

The above-named will, I feel sure, stand in the foremost rank as fancy-fruit-bearing ornaments for decorating the dinner-table.—J. PERKINS, *Thornham Gardens, Suffolk*.

### DISTRESSED LANCASHIRE WORKINGMEN BOTANISTS.

I AM happy to say that my success has been beyond my most sanguine expectations. I can assure you I have had a busy time of it, but I never mind work if good is being done.

On Saturday the 15th inst. I paid a house-to-house visit to all the distressed botanists I could hear of; and I could "a tale unfold" that would draw a tear from many who rarely shed one.

I found all the botanists at home save one, and all the houses so clean that I could have eaten my dinner from the floor of them. I could tell you many anecdotes which would interest your readers.

In one house we found the father sitting reading, and the mother making two petticoats out of one that she had pulled off from herself to give her two eldest girls one each. To our question of "How do you find things now?" the father replied, "Well, thank God, I can get us something to eat, but we've not been able to buy any clothing for the last nine months; but I am thinking of trying to get our oldest girl into one of the sewing classes to get us a few clothes." When we told him I had some clothing tears started in the poor man's eyes, and several of the others shed tears when we told them we had some clothing for them. I may say that I never met with a more honest class in my life; for they that knew that we had some clothing to give away did not say they wanted things they did not want, but honestly told us what they were most in need of, and the kind donor had never a more grateful class of recipients.

One man with a wife and five children told us they did not want any clothing, but could do with something more to eat than they had; so we agreed to give them a little money in lieu of clothing.

I have received since I last wrote to THE JOURNAL OF HORTICULTURE from "A Clergyman's Widow," 2s.; from "Lex" for Ferns, 10s.; "Patelin," 10s.; from Lady Hawke, £1 10s.; from the Rev. B. B. Major, Rugeley, £1 1s. for Mosses; from Dr. Bull, Hereford, £1 12s. for Mosses; from Mrs. Ham Wood, Hoolo House, Chester, £3 for stockings, clogs, &c.; from Henry Dean, Esq., of Appleton House, Warrington, £1 for Ferns, Mosses, &c.; "W. P. C.," 16s.; "N. B.," 10s.; and "A Grub-catcher" sends his mite to Mr. Hague's fund, 5s. I have handed the last sum to John Kinder, of 47, Charles Street, Ashton-under-Lyne; and Michael Ward, of Mary Street, Dukinfield, Cheshire. They are two working men who collect butterflies, moths, &c., and are in great need at present. They desired me to say to "Grub-catcher" that they would be happy to make him a return or present of butterflies or moths if he would be kind enough to send his address. They would send him any of the northern things they have by them, or would be glad to supply to other persons anything they have with duplicates. These men have not studied botany and entomology for the sake of pence, but for the love of the sciences; and one of them told me he would very nearly as soon part with his bread as his specimens if it were not for his children. I know it to be a fact, that some of them have travelled hundreds of miles to procure what they have.

I have £5 in hand to buy clogs, stockings, &c., with for the distressed families, and I will try to execute my commission to-morrow in that respect.

I shall send the lady who sent me the clothing for these poor distressed botanists all the receipts from each family, and in the name of these humble but honest votaries of science, I have to thank all the ladies and gentlemen who have kindly taken or ordered quantities of Mosses and Ferns, and they will ever feel a debt of gratitude to those who have so generously sent donations for their relief.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

#### ENTOMOLOGICAL SOCIETY'S MEETING.

THE November Meeting of the Entomological Society was numerously attended, the chair being occupied by the President, F. Smith, Esq., of the British Museum. The exhibitions were numerous and interesting, and the donations to the library included the publications of the Royal Academy of Bavaria and Stettin, the Canadian Natural History Society, the Linnæan Society, Society of Arts, &c., together with Mr. Reading's "Catalogue of the Lepidopterous Insects of Devon," and Mr. Stainton's "Entomological Botany," reprinted from the "Zoologist."

General Sir J. B. Hearsey exhibited drawings and specimens illustrating the transformations of *Smerinthus denticulatus*, an Indian Moth belonging to the family Sphingidæ, the caterpillar of which is armed with a strong horn on the front of the head, in addition to the usual caudal appendage. The former horn is cast off at the last change of skin during the larva state. He also exhibited some stems of *Oelery*, the leaves of which had been infested by the mining grub of a small two-winged fly belonging to the genus *Tephritis*, of which an account of the transformations, with figures, had been published by Professor Westwood in Loudon's "Gardeners' Magazine."

An interesting collection of leaves of various trees and plants, carefully preserved, and showing the attacks of the larvæ of various species of Microlepidoptera and Diptera, which had been presented to the Oxford University Museum by Mr. S. Stone, of Brighthampton, was exhibited by Professor Westwood, who also made some comments on a paper upon the genus *Acentropus*, recently published by Mr. Newman, reiterating the grounds on which he had founded his opinion that the insect in question belongs to the order Lepidoptera; and referring to the report of his paper read at the British Association at Oxford, in which the transformations of the genus were proved to be those of the order Lepidoptera, and not of the Trichoptera, the distinctive character of which had been overlooked by Mr. Newman.

Mr. Stainton exhibited bred specimens of *Bactra uliginosa*, belonging to the family Tortricidæ, a species which differs from the majority of that family in being double-brooded, the summer brood differing considerably from the autumn one in the marking of the wings. The larvæ had fed on *Lythrum salicaria*. He

also made some remarks on a paper on the genus *Nepticula*, published by Herr von Heinemann, in which ten new species were described, and in which some interesting observations were made on the moulting of the larvæ; the short duration of the larva-state, especially in the summer; and the modification in the arrangement of the wing-veins, forming three sections in the genus.

Mr. F. Bond exhibited, on the part of Dr. Knaggs, some bred specimens of *Lithosia caniola*, together with a drawing of the larvæ. It was stated that the egg-state lasted ten days, and the larva-state ten months, during which time the insect changed its skin forty times! Also a remarkable specimen of the Death's-head Moth, *Acherontia atropos*, in which the wings on the left side were singularly crippled.

A monograph on the handsome species of Beetles forming the genus *Cataseopus*, belonging to the family Carabidæ, was read by W. W. Saunders, Esq., F.R.S., in which not fewer than thirty-five species were indicated, of which several brought from Sarawak, in Borneo, by Mr. Wallace, were described as new.

The injury committed upon Gooseberry and Currant trees by the larvæ of a species of Sawfly during the last two or three years, has attracted the attention of numerous observers, and specimens of the perfect insects, reared in Gloucestershire, were exhibited by the President, who considered them to belong to the *Nematus trimaculatus* of St. Fargean; the *Nematus ventricosus* of Vollenhoven's memoirs on the transformations of this family, translated in the "Zoologist," being regarded as a distinct species. In the instance in question, all the larvæ collected for observation proved to be females—a fact of some interest with reference to the economy of the species, and the possibility of its extirpation.

Mr. S. Stevens stated that the splendid insect described by Dr. Schaum at the September Meeting of the Society, under the name of *Scaritarchus midas*, had been published in August last by the Count de Castelnau under that of *Mouhotia gloriosa*.

Mr. G. R. Waterhouse read a paper upon certain British species of the genus *Quedius*, belonging to the family Staphylinidæ.

#### FORCING THE LILY OF THE VALLEY.

IN reply to "LILY OF THE VALLEY'S" inquiry, as to how long the plants are kept in the dark, I answer, Until they begin to show flower, which will be when the spikes are about 6 inches high. The inverted pots or boxes may then be removed, and, if dull weather, or if the plants occupy a shady situation, no further shading will be necessary; but, if bright sunny weather, and the plants are fully exposed, it will be proper to continue shading for a few hours every day—say from eleven A.M. to three P.M. for about a week longer.

The plants are thus gradually inured to full exposure to light. I need not remind "LILY OF THE VALLEY" that occasional waterings with tepid water are indispensable, as, when once fairly started into growth, they must on no account be allowed to become dry.

In my previous communication I recommended the second or third week in November as the best time to pot the tubers, and I still adhere to that opinion; but, in consequence of having been requested to have them in flower as early in December as possible, my first batch of tubers were potted on the 28th of October. After potting they were placed over the flue in a Vine-pit, every corner of which is at present full of bedding plants, and a little fire heat used occasionally to keep out frost and dissipate damp; the result of this treatment is, that they are now showing their flower-spikes, and, by the beginning of December, I expect they will be fully expanded.

I mention this merely to show that the Lily of the Valley can be had in flower prior even to Christmas; but I do not by any means recommend such practice to the attention of the amateur.

Of Crocuses, Snowdrops, and Hyacinths, it is unnecessary to speak, as these are not in demand here sooner than Christmas, or the beginning of the new year. A lot of each of the above were potted early in October, and the pots buried in a heap of half decomposed leaves, where they have since remained. On looking at them the other day I found they had pushed considerably, leading to the conclusion that the pots are now pretty well filled with roots, and ready to be introduced into a forcing-pit as occasion may require.—J. DUNN, Harrock Hall Gardens, near Wigan.

## CULTIVATION OF PEACH AND NECTARINE TREES.

HAVING cultivated the Peach and Nectarine for many years, in various soils and situations, with a success bordering upon perfection, I enter on the subject with no small degree of confidence. I commence with the border, one of the most essential points, and one too often mismanaged. Too frequently all that is thought necessary is to trench the borders to a good depth. The borders which I have prepared, and which have produced some of the most beautiful of fruit trees, were made in the following manner:—The width was 14 feet; less, I consider, will not do. In the bottom, through its whole width and length, was laid 15 inches of drainage, sloping considerably from the wall to the front, where ran a main drain to carry off superfluous moisture. The bottom under the drainage was perfectly smooth, in order to give the latter more effect. Where one end of the border is higher than the other, a cross drain must run from between each tree to the main drain in front, for effectual drainage is the greatest point; without it, it is impossible to grow fruit trees well.

The soil I have used is good friable loam, free from manure, not too light; indeed, a stiffish loam will be found to suit the fruit trees admirably, and in it they will flourish on the warm and comfortable bed of

drainage. The extreme depth of the soil for the border should not exceed 20 inches, and it should be allowed to settle thoroughly before the trees are planted. This is a point of no little importance, for if the trees are planted too soon, the settling of the border will cause them to be buried too deep.

I recommend early planting; for I have always found it best. When trees are had from the nursery in the autumn, and laid in until spring, as is sometimes the case, on their removal for their final planting they will be found to have made a mass of fibres, which, of course, must be injured and broken, and against this loss the tree has to struggle for the first summer, if, indeed, it survives it. I prefer half-standard trees, from 3½ feet to 4 feet high in the stem; and so strongly do I recommend this height, that I should rejoice to see dwarf Peaches, Nectarines, &c., banished altogether from gardens. It is a well-known fact that the finest fruit is produced towards the ground. This being the case, the principal object must be to well furnish the bottom of the wall with bearing wood of good quality, and keep it so at all times. Seeing that half-standard trees, trained star-form (*fig. 3*), afford the greatest facilities for this object, their decided superiority to the dwarf fan-trained trees must be apparent, as in the latter case the more a tree has grown the more old wood there is along the bottom of the wall.

When the border has well settled down, it is fit for planting. The trees should be placed so as to have 3 inches or 4 inches of their roots above the ground level, as shown in *figs. 1, 2, and 3*. I invariably make it a rule to keep the neck of the trees two courses of bricks above what is to be the ground level, and, after planting, litter is put around each tree, so that they are well mulched for the first summer, and continue so until the following spring. If the summer should prove dry, they will require frequent and copious waterings. The following spring, whatever little remains, as well as the soil, among the forks of the roots

will require levelling down to the ground line (*fig. 3*), in which state the roots for the future are to be left exposed. Trees planted in this way will be found to flourish much better than if their roots are wholly covered. I plant about 12 inches from the wall, it being advantageous to keep a reasonable distance to prevent the stem getting sunburnt, which it is more than probable may happen if it is set close to the wall. Twenty-four feet apart is little enough for trees on a ten-foot or twelve-foot wall, and I have had them cover the whole of that space in four years from the time of planting, and produce the most abundant crops. So plentiful indeed have I had them in the third year after planting, that I have sent fruit to the hall table by the garden sieveful. Six years ago I saw some trees in excellent condition, which I had thus planted fifteen years previously.

I prefer two-year-old headed plants, with five or six branches

(such as *fig. 1*). The head should be clean and healthy, not over gross; the stems should be quite clean, straight, and healthy. Hide-bound, canker, or knotty stocks, and trees with large scars or with wounds in the head, should be rejected as likely to gum or canker. The branches forming the head should be, as nearly as possible, of equal strength, as

*Fig 1*

when headed-back they will probably then break more regularly. A tree with one or two strong branches at one side, will, in all probability, become a one-sided tree.

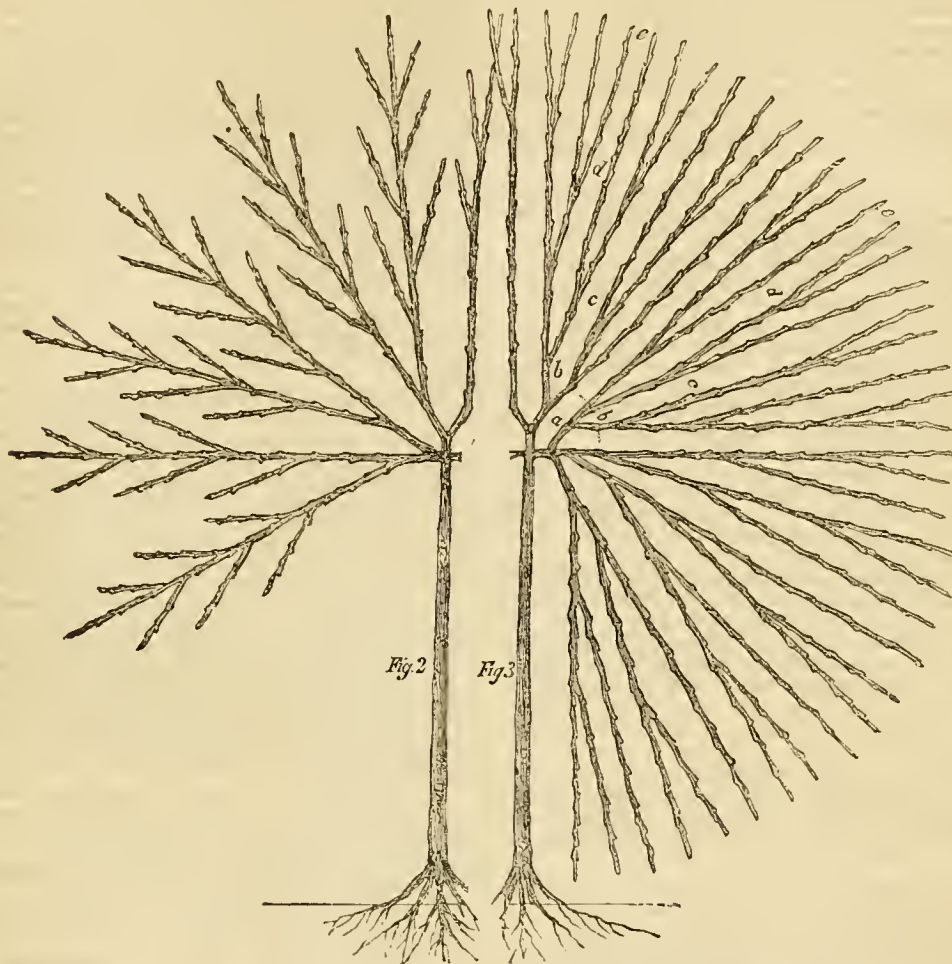

I will now explain my mode of pruning and training the Peach and Nectarine. *Fig. 1* shows a newly-planted tree, to be cut back to two or three eyes, where these appear most likely to break. Not more than two shoots must be allowed to push from each branch. As the loss of a branch would be irreparable, they should receive constant attention, and as soon as the shoots are long enough, they should be steadied by a loose shred, and this care must be continued through the season when requisite, using strong shreds, as the shoots will become of considerable weight. I have had them reach the top of the wall by autumn. All the laterals they produce must be allowed to remain, and the stronger ones tacked to the wall to prevent their

being broken by strong winds. The tree, after its season's growth, will have become such as is shown at *fig. 2*. Notwithstanding the size and strength of wood, it must be again cut back to three or four eyes, according to circumstances; and when the shoots break the following spring, select the two best shoots from each branch, and such as lay well to the wall. (These two first-year's prunings are shown at *a* and *b*, *fig. 3*). As vigorous shoots will, or ought, now to make their appearance, they will require extreme care in nailing, for they are easily broken off, and the loss of a branch now would be of the most material consequence. I recommend tacking loosely as soon as the branch is long enough, and to lay it close to the wall as soon after as possible.

The tree will now begin to acquire the form shown at *fig. 3*. Where the spring growth has attained 6 inches or 8 inches in length, the shoots are to be topped for the first time, as shown at *c*. In stopping, bear in mind that it must be done as soon as the young branches are of the required length, in the very soft

tissue of the points of the shoots, for if the latter are allowed to elongate, and are afterwards topped-back in the solid wood, they will not again break freely. In this system of training, this apparently simple point must never be forgotten. The shoots which now break out will be still more liable to break off than the first, if not carefully nailed to the wall. At this and the succeeding topplings, it is more than probable that more branches than are wanted will make their appearance; two or three more than necessary should be suffered to remain until those that are

required are secured, when they must be removed. The growth of the shoots will now be found so rapid as to require almost daily attention in nailing and training. Again, when this growth has attained from 10 to 15 or 18 inches, the shoots are to be topped. It is impossible to prescribe any special length, as much will depend on the strength of the shoots what direction they take, and the general formation of the tree; this topping takes place at *d*. The same care and attention as before must now be paid to the new shoots, and when they have grown an

equal length they are to be topped again (at *e*). Some trees will be more vigorous in growth than others; but many will require a fourth topping. This I have had to do frequently, and in the following spring had firm well-ripened wood, that cut more like a piece of Oak than what is generally seen as Peach wood, and the trees were well filled-in with bearing wood. Whilst these various topplings are going on, there are, of course, many vacancies in the trees, which I take for granted are filled up with weaker branches at full length, that the trees may be completely

furnished with fruit-bearing wood; and instances will also occur (as seen in *fig. 3*) where it will not be necessary to lay-in more than one shoot at the regular topplings of some of the branches, yet these vigorous branches will require to be topped to bring them into a bearing state. The Peach and Nectarine are the only trees which will submit to this system of summer pruning on the wall; the Apricot and others will not.—THOMAS HATCHER.—(*Gardeners' Magazine of Botany.*)

#### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

**BERBERIDOOPSIS CORALLINA** (Coral-flowered Berberidopsis).—*Nat. ord.*, Berberidæ. *Linn.*, Enneandria Monogynia. Native of the forests of Valdivia. "One of the most beautiful hardy shrubs introduced of late years into this country." It is interesting botanically also, "completely uniting the orders Berberidæ and Lardizabaleæ, and fully justifying their union into one order." Stalks, perianths, &c., of the flowers all scarlet.—(*Botanical Magazine*, *t.* 5343.)

**RITCHIEA POLYPETALA** (Many-petalled Ritchiea).—*Nat. ord.*,

Capparidæ. *Linn.*, Polyandria Monogynia. Stove shrub from Abeokuta in Western Africa. Flowers white.—(*Ibid.*, *t.* 5344.)

**ARISTOLOCHIA GIBERTII** (Gibert's Aristolochia).—*Nat. ord.*, Aristolochiæ. *Linn.*, Gynandria Hexandria. "A fine, free-growing, tropical climber." Native of woods at Assumption, in Paraguay. Flowered in September, but its leaves are its best ornament.—(*Ibid.*, *t.* 5345.)

**HIGGINIA REFULGENS** (Shining Higginsia).—*Nat. ord.*, Rubiacæ. *Linn.*, Tetrandria Monogynia. It has been called also

*Campylobotrys refulgens*. Believed to be from South America, introduced by Mr. Bull, nurseryman, King's Road, Chelsea. Flowers crimson.—(*Ibid.*, t. 5346.)

*PANÆTIA LESSONII* (Lesson's Panætia).—*Nat. ord.*, Compositæ. *Linn.*, *Syngenesia superflua*. This only species in the genus is a native of King George's Sound. Flowers yellow, retaining their colour when dry, and, consequently, belonging to what are popularly called "Everlastings." Imported by Mr. Thompson, of Ipswich.—(*Ibid.*, t. 5347.)

*OPHIOPOGON SPICATUS* (Purple-spiked Snakes-beard).—*Nat. ord.*, Ophiopogonæ. *Linn.*, *Hexandria Monogynia*. It has with the same specific name been included in the genera *Convallaria*, *Liriope*, and *Fluggæa*. It is really a liliaceous plant. Leaves long and grassy; flowers bright purple blue, in a long spike. Native of China and Japan. Bloomed in a cool greenhouse at Kew, in October.—(*Ibid.*, t. 5348.)

GOLD-BANDED LILY OF JAPAN (*Lilium auratum*).—This has already been noticed frequently in our columns.—(*Floral Mag.* pl. 121.)

WHITE-MARGINED CLARKIA.—A very pretty free-flowering variety of *Clarkia pulchella*. It has pink, white-margined petals, and was raised by Messrs. Carter, Seedsmen, High Holborn, at one of their Essex seed farms.—(*Ibid.*, pl. 122.)

GLADIOLUS MR. J. W. LANE, raised by Mr. Standish, of the Bagshot Nurseries, and is named after a very successful florist in Ireland. Colour bright crimson red.—(*Ibid.*, pl. 123.)

ACHIMENES MAUVE QUEEN.—The name announces the colour of the flower. It was raised by Mr. Parsons, gardener at Danesbury House, Welwyn, Herts, "who has done more for the improvement of this flower than any other English grower." It received a first-class certificate from the Floral Committee of the Royal Horticultural Society.—(*Ibid.*, pl. 124.)

RHODODENDRON PRINCESS ALICE.—A cross between *R. Edgworthii* and *R. ciliatum*. Exhibited by Messrs. Veitch & Son, of Exeter and Chelsea, receiving a first-class certificate from the Floral Committee of the Royal Horticultural Society. Flowers white.—(*Florist and Pomologist*, i, 161.)

LADY DOWNE'S GRAPE.—This member of the Black Hamburg family, has for some years had a high local reputation in Yorkshire, but it was not brought into general notice until adopted for exhibition by Mr. Hill, gardener to Ralph Sneyd, Esq., Keele Hall, Staffordshire. "A very valuable Grape; as a late-hanging variety, perhaps, unsurpassed by any other."—(*Ibid.*, i, 168.)

## NEW BOOK.

*Flora Capensis Medicæ Prodromus, Second Edition. Synopsis Filicum Africa Australis. Silva Capensis, Second Edition.* London: Ward & Co., Paternoster Row. Cape Town: W. Brittain.

THE above pamphlets are by Dr. L. Pappé, Colonial Botanist and Professor of Botany in the South African College, aided in that relating to the Ferns by the Hon. Rawson W. Rawson; and we welcome them not only on account of their merit as good contributions to our knowledge of plants and their whereabouts, but on account, also, of the information they give relative to the economic and medical uses of the vegetable products of the colony.

No one can so readily obtain information concerning the medical properties of the plants of a foreign land, as he who mixes with its inhabitants and seeks from them that desired information. Such information is the result of experience accumulated during ages, and handed down by that best impresser on the memory from generation to generation.

The "Prodromus" is a faithful record of the accumulated results of experience; for Dr. Pappé says in its preface, "There are Cape plants of unquestionable worth which I have not enumerated, because they are not actually employed by the inhabitants." That the experience of the natives has led to information not generally diffused in Europe, is testified by many of the pages we are now turning over. Thus it is stated of *Pelargonium scutatum*, that it is "the Kafir-sorrel (Kafir-zuring) of the colonists. The sap of its leaves is astringent and antiseptic, and of good service in aphthæ, sore-throat, &c. The juice of its petals produces a blue colour of the tint of Indigo, and may, according to Burchell, be used advantageously in painting. It is very common in many parts of the Eastern districts."

As another example we take *Arctopus echinatus*, on which Dr.

Pappé remarks:—"This plant, the Platdoorn or Ziekte-troost of the Boers, is one of those few indigenous remedies which, from the very establishment of the colony, have been constantly used by its inhabitants. At that early period, the European settlers, being often without their necessary stock of medicines, had to learn from their Hottentot neighbours, who held this plant in great esteem. It is demulcent and diuretic, and somewhat approaches the *Sarsaparilla*. The decoction of the root is the general form under which it is prescribed in lues, lepra, or cutaneous chronic eruptions of all kinds. It also furnishes a sort of resin, which is easily procurable by making incisions into the root while it is fresh. It has been shown from chemical experiments, that the root of this plant contains an alkaloid, which, combined with acids, assumes the form of neutral salts. Thus the *Arctopium sulphuricum* consist of small, scaly white crystals, which are astringent in taste, and which in half-grain doses, produce coagulation of the saliva within the mouth."

We will pass over the "Synopsis Filicum," because, although it contains good descriptions of 161 Ferns found in Southern Africa, yet there is nothing of particular interest except to the botanist; but this observation will not apply to the "Silva Capensis," containing as it does the descriptions of 102 trees and arborescent shrubs of South Africa, with the uses to which they are applied by the natives and colonists.

Dr. Pappé visited the primeval forests of the country and procured specimens of the woods of those trees and shrubs, forming the most complete collection hitherto made, and the specimens are now deposited in the Museum of Economic Botany at Kew.

As an example of the information, we extract, without need of selection, this note upon the uses of *Pteroxyylon utile*:—

"A tree, from 20 to 30 feet in height, and 2-4 feet in diameter. The leaves have some resemblance to those of *Acer pseudo-platanus*. The wood is handsome, takes a fine polish, is strong, durable, and somewhat like Mahogany. It is used for various kinds of furniture and agricultural utensils. Being little affected by moisture, it serves as a desirable material in the construction of bridges and mills. From the fact of its producing violent sneezing when sawn or otherwise worked at, it has received the name of Sneeze-wood. It is also said to ignite readily, even in its green state, and is the *Omtata* of the Kafirs. Common in the forests of the eastern districts. Fl. October."

In every instance, in all the pamphlets, a concise but efficient botanical description of each species precedes the notes relative to its uses, of which we would give more extracts relative to the trees if there were not an appendix, entitled "Contributions to the South African Economic Flora," from which we must make numerous excerpts.

"*I. Aberia caffra*.—A shrub or middling tree, and native of Caffraria Proper. The fruit (*Kei-apple*), having the size and appearance of a large Plum or small Apricot, is of a sourish taste but edible, and makes good preserve.

"*Adenogramma galioides*.—This little herb, the Mugge-grass (*Gnat-grass*), of the colonists, which during the wet season occurs abundantly, is regarded as superior fodder for cattle, which fatten when feeding upon it.

"*Asparagus larinicus*.—The young succulent shoots of this and several other wild species of *Asparagus* furnish a most excellent dish; they have an aromatic taste, and are preferred by many to the European kind cultivated occasionally in Cape gardens. The diuretic property of *Asparagus* is well known.

"*Aponogeton distachyon*.—The root of this water-plant (*Water-ninjas*; *Water-Onions*), when roasted, is very palatable, and somewhat resembles the Chestnut in taste. Its flowers, which are highly scented, are eaten as Spinach, and used as pickles.

"*Andropogon Ivaaraxusa*.—The creeping fibrous roots of this grass have a peculiar and rather ferulaceous smell. By the name of *Akirwanie* they are known to most colonists, and serve as a preventive against the destruction of wearing apparel, &c., by moths and other noxious vermin. This grass is also very healthy and nutritious food for all kinds of live stock.

"*Annesorhiza capensis*.—The Turnip-like root of this umbelliferous plant is very nutritious, and has been used for many years past as food by the natives and colonists, who call it *Anise-root* (*Anys-wortel*). It is much improved by cultivation, loses its acid taste, and becomes a very good vegetable.

"*Cucumis africanus*.—This species of *Cucumber* (*Thorn Cucumber*), which is easily recognised by its prickly coat, inhabits the more remote northern portion of the colony. It supplies horses and cattle with a welcome cooling food in those dry and

dreary regions, and has found its way into the gardens of the colonists, who use it in the form of pickles.

*Cyperus textilis*.—A Rush, 2 feet or 3 feet high, which grows in marshy localities and in the beds of rivulets. From it baskets and mats are manufactured by the natives, who call it Mat-rush (matjesgoed).

*Elegia nuda*.—This useful Reed (Thatching-reed; Dakriet), covers the sandy tracts of a great portion of the Colony. Not only does it fix the otherwise shifting sand, but supplies the farmers with a most excellent material for roofing their houses.

*Emex spinosus*.—The young leaves of this herb, which belongs to the Sorrel tribe, are used as Spinach. They make a tolerably good dish, and are slightly aperient. The colonial name is Dubbeltjes-blären.

*Ficinia filiformis*.—On account of its elasticity, this Sedge is extensively used for stuffing beds, mattresses, &c. It grows in dense tufts, and is common in many parts of the Colony.

*Gnidia oppositifolia*.—The bark of the stem and larger branches of this as of all other Thymelææ, being exceedingly tenacious, is converted by the natives into a kind of very strong cordage or rope. It is the Kanna-bast of Hottentots.

*Grubbia stricta*.—The big, bulky roots of this shrub, which grows on the mountains of the Stellenbosch, Tulbagh, Caledon, and Swellendam districts, furnishes superior charcoal. Its fruit, which has the size of a peppercorn, is exceedingly hard and almost bony.

*Hermas gigantea*.—The thick, white, woolly integument of the leaves of this plant, serves the natives for tinder, and the women prepare from it very curious little fancy articles. The plant which grows on the mountains near Tulbagh, in Du Toitskloof and on the Kaudeberg (Clanwilliam), is known as the Tinder-bush (Tondel-blad).

*Hibiscus Ludwigi*.—The stems of this Hibiscus furnish superior fibres of great toughness and strength, resembling Jute or Manilla Hemp, and well adapted for the manufacture of cords, ropes, and similar articles. This plant, which is common in the George, Uitenhage, and Katrier districts, and known there as Rose-touw, deserves cultivation.

*Hydnora africana*.—This interesting and extraordinary plant, which grows parasitically on the roots of Euphorbia Tirucalli and other succulent shrubs, is one of the numerous discoveries made by Thunberg, who mistook it first for a Fungus. Its fruit, which, like that of the Earth Nut, is subterranean, has the form, size, and taste of a Potato. It is of a reddish-brown tint, thoroughly mealy; and when fried under the embers, very palatable. Some wild animals, and particularly the porcupine (*Hystrix cristata*), are fond of this fruit, which is called Kannip or Kaupim by Hottentots, and Jackals-kost by the Dutch Colonists.

*Moraea edulis*.—The mealy bulbs, commonly known as Uintjes (bulbs), are nourishing and somewhat approach Chestnuts in taste. In collecting them, it is necessary to have them dug up by persons sufficiently acquainted with the plant, and I have had an opportunity of cautioning the public elsewhere (Prodromus fl. med. Cap. p. 37), against the obnoxious properties of *Homeria collina* (the Cape Tulip), the bulbs of which had in one fatal esse been eaten by mistake for those of this plant.

*Moraea polystachya*.—In the Eastern districts this species serves the same purpose as the preceding. Its young leaves, however, are said to be unwholesome to horned cattle.

*Mesembryanthemum edule*.—The antiseptic virtues of this valuable plant are too well known to require comment. The fruit (Hottentots' Fig) has a pleasant, sourish taste and is eaten either raw or preserved, and used as sweetmeats.

*Osteospermum pisiiferum*.—The bony kernels or seeds are enclosed with an oblong berry-like fruit, which, though small, is eaten by the natives and called by them Biedouw-besjes. They are of a sweet taste and palatable.

*Oxalis cornuta*.—A weed, common throughout a great portion of the Colony, where it is known as the Wild Sorrell (Wilde Zuring). On account of their acidity, the leaves, mixed with other vegetables, are used for culinary purposes. The bulbs, eaten raw, are pronounced to be a good vermifuge.

*Pelargonium peltatum*.—The juice of the petals produces a blue colour of the tint of indigo, and may be advantageously used for painting; while the sap of the leaves is astringent and antiseptic, and of good service in ulcerated sore throat. The vernacular name of this plant is Kafr Sorrell (Kaffer Zuring).

*Penicillaria Plukenetii*.—The Pogo-grass of Caffraria and

Natal, from the grain of which the natives prepare an intoxicating liquor or beer.

*Physalis pubescens*.—Although this plant, the Cape Gooseberry (Appel der Liefde), cannot in the strict meaning of the word, be called indigenous, being a native of South America, yet it has become so common in this country, that it is found now in most shady localities, where it grows perfectly wild. The round fruit, a fragrant, smooth, yellow berry, of the size of a Gooseberry or Cherry, is agreeably acid and sweet, and very palatable. It is eaten either raw, or made into a delicious marmalade.

*Polygala myrtifolia*.—The grey bark of this shrub is used by the Mahomedans (who call it Langelier) for a particular purpose. It is scraped off when fresh with a knife or piece of broken glass, mixed with water, and stirred about until it scums. With this saponaceous preparation they are in the habit of washing their dead before interment.

*Prionium palmita*.—The bases of the macerated old leaves yield an abundant supply of strong, coarse fibre, fit for the manufacture of brushes and brooms. The rest of the leaves abounds in a more elongated and finer thready substance available for a variety of economic purposes. The young rootlets of the Palmiet furnish a good dish for the dinner table.

*Rubus pinnatus*.—The fruit of the Bramble or Black berry bush (Braambosch) ripens in the month of January. It is equal in flavour and taste to that of Europe. The roots are astringent, and used in the form of decoction against chronic diarrhœa, &c.

*Sorghum saccharatum*.—This hardy grass, the African Sugarcane, which abounds more or less in saccharine juice, is extensively cultivated by the Kafirs and Fingoes, who call it Imphee. The young shoots in particular are very sweet, and therefore chewed by these natives, while the mature grains serve them for the preparation of flour. Amongst the colonial farmers this plant goes by the name of Zeet Stronk or Suiker riet.

*Stapelia pilifera*.—The stem of this plant, which grows in the dreary wastes of the Karroo, is fleshy and of the size and form of a Cucumber. It has an insipid, yet cool and watery taste, and is eaten by the natives, who call it Gvaap, for the purpose of quenching their thirst. Infused with spirits, this plant is said to be a useful remedy in piles.

*Suhria vittata*.—The whole of this handsome sea-weed is soluble in boiling water, and transformed into a gelatinous mass. In the shape of jelly or blanc-mange it is usefully employed in pulmonary complaints, as a demulcent and nutritive.

*Trachyandra revoluta*.—The flower-heads of this plant, which thrives abundantly in the deep sands near the seashore, furnish a kind of culinary vegetable, which somewhat resembles Asparagus, and is known as Hottentot's Cabbage (Hottentot's Kohl). When stewed and properly prepared, they make no contemptible dish."

In conclusion, we recommend these three cheap pamphlets, for they are only 1s. 6d. and 2s. each, to be bound in one volume and added to the library as "Contributions to the Flora of South Africa."

## THE POTATO, AND ITS LEADING VARIETIES.

It affords me much pleasure, after a careful and studied investigation, to lay before you the details of the respective merits of the collection of Potatoes, comprising between fifty and sixty distinct varieties, exhibited by me at the autumn Exhibition of the Royal Horticultural Society of Ireland, at which they were recommended a special prize by the Judges, which was afterwards confirmed by the Council; as also at the Meath Horticultural Society's Show, held at Kells, county Meath, August 26th. Of the earliness of many of the varieties I am at present unable to speak, in consequence of the delay encountered in procuring the seed, and thereby being precluded from subjecting them to the same trial as varieties I had in my possession early in January. So important a deficiency, I am aware, is much to be regretted, as the early maturity of so valuable an esculent is a point that should particularly engross the attention of those interested in its culture. It is only by careful attention, and subjecting the different varieties to the same treatment, that we can arrive at the desired information. I do not hold myself responsible for the identity of varieties of recent introduction, as I give the names as I received them, and merely lay before your readers a statement with regard to their respective merits from my own experience of them. In the event therefore, of any error having incautiously crept in, I shall be most happy to find it rectified.

—JOHN C. MORRIS, *Oaklands, Sandymount, Co. Dublin.*

*American Earlies.*—Fine, rough-skinned, white variety, resembling in appearance the Regent Kemp, remarkably dry and well-flavoured; very fine cropper, and large size, and free from disease; very early; a first class Potato.

*American Ladies.*—Handsome, smooth-skinned, white variety, with eyes well set, round shape, and flat; abundant cropper; medium dry, and fair flavour, not subject to disease; late.

*Apples.*—A well-known red variety, with deep-set eyes somewhat resembling in appearance the Irish Cup; medium dry, and weak-flavoured; very productive, and free from disease; late.

*Arrowsmith's Seedling.*—Handsome, round, flat, smooth-skinned white variety; with well-set eyes, diffused with purple blotching; fine cropper, attains a good size, and free from disease; a variety of recent introduction; late.

*Ashleaf Kidney.*—Fine, smooth-skinned, long, white variety; most productive, very dry, and free from disease; one of the earliest.

*Ballygawley Pinks.*—Round pink variety; with deep-set eyes; very productive, remarkably dry, and possessing fine flavour; free from disease; late.

*Birmingham Prizetaker.*—Long, smooth Kidney, very dry, well-flavoured, and most prolific; subject to disease; early.

*Blue Ferts.*—Handsome, flat, smooth-skinned white variety, in appearance resembling the Early Wellington; eyes well-set, around which are diffused purple streakings; fine cropper, and free from disease; early.

*Chapman's Early Ashleaf Kidney.*—Very like Golden Drop, but rounder; very dry, possessing fine flavour; free from disease; very early and good forcer.

*Cheshire Pink Eye.*—In appearance not unlike the last; remarkably dry and well-flavoured; medium sized and fair cropper; free from disease; early.

*Cumberland Bangor.*—Long white Kidney; very dry, and well-flavoured; most abundant cropper; and attains a large size; subject to disease; early; a good variety.

*Daintree's Seedling.*—Fine, rough, thin-skinned, round, white variety; good cropper; remarkably dry and well-flavoured; free from disease and very early; a capital variety.

*Dalmahoy's.*—Round, rough-skinned, white variety, remarkably dry; a fine-flavoured, heavy cropper; medium size, free from disease, and very early; a first-class Potato.

*Deane's Early Prolific Kidney.*—Rough-skinned white variety; shape nearly round; medium size, abundant cropper; dry, well-flavoured, and free from disease; early.

*Early Handsworth.*—Round, rough-skinned (better adapted for forcing than general culture); medium size, and cropper; very dry and well-flavoured, and perfectly free from disease; very early.

*Early Wellingtons.*—Handsome, round, flat, smooth-skinned variety; surface blotched with pink streaking, resembling Arrowsmith's Seedling; very prolific, possessing good flavour, and free from disease; early.

*Early Radicals.*—Rough-skinned round variety; white, with pink eye; medium dry, yet well-flavoured; abundant cropper, and free from disease; early.

*English Reds.*—Long smooth-skinned variety; with eyes well set; attains a large size, very productive; moderately dry; weak flavour; sound; late.

*Flounders.*—Flat, round, rough-skinned variety; very prolific; attaining a large size; very dry, well-flavoured, and free from disease; a first-rate variety for early field culture.

*Forty Fold.*—Rough, red variety, medium size; very prolific, dry, and free from disease; early.

*Flukes.*—Long, flat, smooth-skinned white Kidney; medium dry; very productive, attaining a large size, and free from disease; late.

*Golden Drop Kidney.*—Long, smooth-skinned yellow Kidney; medium size, dry, and well-flavoured; abundant cropper and free from disease; early.

*Glory of England.*—Long white Kidney; similar in shape to Cumberland Bangor; very dry, and fine-flavoured; fine cropper, and attains a remarkably large size; slightly subject to disease, and very early; a first-rate table Potato.

*Golden Seedling.*—Handsome, rough-skinned, round variety, with well-set eyes; abundant cropper; remarkably dry and well-flavoured; free from disease; a first-class early Potato.

*Haigh's Seedling.*—Handsome, rough-skinned, long kidney-shaped variety, with well-set eyes; very productive, remarkably dry, well-flavoured, and free from disease; a fine early variety.

*Harbury Kidney.*—Handsome, smooth-skinned, white variety;

very long, rounder than the old Ashleaf; a first-rate cropper, dry, well-flavoured, and free from disease; very early.

*Irish Blacks.*—Round, with deep-set eyes; remarkably dry, and possessed of good flavour; very productive, yet subject to disease; late.

*Irish Cups.*—Round, light red variety, rugged, with deep-set eyes; very productive, fine flavour, and free from disease; late. A variety nearly extinct.

*King, The.*—Round, rough-skinned, white variety; medium size; fair cropper, moderately dry, and flavour middling; free from disease; early.

*Lancashire Hero.*—Round white Kidney; medium-sized and cropper; very dry, remarkably well-flavoured and free from disease; early variety.

*Lemon White Blossom Kidney.*—White variety, similar in appearance to the Oxhorn Kidney; small size and cropper; dry and free from disease; early.

*Mona's Pride.*—An improvement on the old Ashleaf Kidney in appearance; attains a large size; good cropper; not altogether free from disease; medium dry, possessing a weak flavour; very early.

*Myatt's Ashleaf Kidney (Prolific).*—Round white variety, good cropper, and medium size; remarkably dry, well-flavoured, and free from disease; a variety well known in the London markets for its earliness.

*M' Mullen's.*—Round white variety, with deep-set eyes; similar in appearance to White Rocks; good cropper; dry and well-flavoured; free from disease; late.

*Norfolk Wonder.*—Handsome, smooth-skinned, white variety, with deep-set eyes; abundant cropper; very dry and well-flavoured; attains a large size; slightly subject to disease; late.

*Orkney Reds.*—Long, smooth-skinned, purple variety, with well-set eyes; fine cropper, remarkably dry; flavour similar to Irish Blacks, and free from disease; late.

*Oxhorn Kidney.*—Long, narrow, smooth-skinned, white Kidney; rugged shape; medium size and cropper; not very dry; early.

*Pheasant's Eye.*—A handsome, round, rough-skinned variety, with purple eye, inclined to grow long; medium dry, very prolific, and free from disease; early.

*Pink Eye, Kemp's.*—Rough-skinned white variety; shape long, resembling in appearance the Regent, with handsome pink eye; medium dry; fair flavour; abundant cropper, and free from disease; very early.

*Pink Eyes.*—Handsome, smooth-skinned, pink-eyed variety; with deep-set eyes; very dry; of colour, pale when boiled; possesses good flavour; fine cropper, subject to disease; early.

*Perkins' Seedling.*—Round, rough-skinned, white variety, with well-set eyes; in shape like the Regent Kemp; most prolific, very floury and well-flavoured; free from disease; a good late variety.

*Primroses.*—Pale red smooth-skinned variety, with well-set eyes; medium round, very dry, and possessed of fine flavour; a good cropper, and free from disease; late.

*Red Martins.*—Round rough-skinned dark red variety, with deep-set eyes, similar in shape to the Black Cup; good cropper, medium dry, and good flavour, and free from disease; late.

*Red Irish Roughs.*—Round, rough-skinned, dark red variety; with deep indented eyes; medium dry, and weak-flavoured; not productive; late.

*Red Rocks.*—Light red, rough-skinned variety, with deep-set eyes; round; in appearance like the White Rock; remarkably dry and well flavoured; not subject to disease; late.

*Rylott's Flourball.*—Round, smooth-skinned, white variety; remarkably dry and well-flavoured, abundant cropper; medium size and free from disease; early.

*Shaw's Early.*—Long, smooth-skinned white variety; most prolific; very dry, and well-flavoured; attains a large size, and free from disease; very early.

*Skerry Blues.*—Round blue variety, with deeply-set eyes; medium dry; weak-flavoured, remarkably productive; attains a large size; free from disease, and will keep well; late.

*Soden's Early Oxford.*—Round, rough-skinned white variety, with eyes well set; very dry, and possessed of fine flavour; free from disease; well known for its earliness.

*Walker's Earlies.*—Very fine, rough-skinned, long white variety; very dry, and fine-flavoured; very heavy cropper, and remarkable for attaining large size; free from disease; for early field culture is unequalled.

*Webb's Imperial Kidney.*—Handsome, smooth-skinned, white

Kidney; grows very long, and attains a remarkably large size; abundant cropper, medium dry, good flavour, and free from disease; early.

*Wonderful Red Kidney*.—Handsome, light red, smooth, thin-skinned variety, abundant cropper; medium dry, fair flavour, and free from disease; very early.

*White Kemp's*.—Rough-skinned round variety; good cropper; moderately dry, flavour weak; free from disease; early.

*York Regents*.—Fine rough-skinned variety, with well-set eyes; remarkably dry and well-flavoured; fine cropper, and free from disease; early.—(*Dublin Agricultural Review*.)

### BALANCE OF BIRDS.

HAVING had an opportunity of reading most that has been said about small birds, I have no hesitation in saying that Mr. Robson, in the Number for October 7th, expresses more good, sound reasoning than anything said by any one I have read before, and which I think no one will deny that lives in a well-wooded country as I do; and as to how far he is right in the balance he has pointed out I think I can bear testimony from eight years' experience.

I will begin by stating that the estate where I am gardener is about 5000 acres, in a ring fence, with a walled kitchen garden of two acres in almost the midst of it. There are splendid timber trees all over the estate, immense game covers, woods, Ash-beds, and great hedgerows, even close up to the garden, and eight years ago there was no gamekeeper on the estate, nor for some years before—only some men that worked in the woods and about the place to look after the game at certain times. Consequently, there was no vermin-killer, and then and for three years afterwards, all around me there were lots of owls, white and grey, likewise hawks of three different sorts, stoats, weasels, and fitchets, and a cat or two at every cottage and farmhouse, and I always had three cats about the place, and sometimes more.

The white owls were very tame, and would come out in early evening and skim over the garden and all the adjoining fields, and up all the old hedgerows. They would come within 20 yards of me, and hunt all the place over like so many terrier dogs after the mice; and the consequence was, I had no trouble in those days to net anything but the Cherries, and by being up by break of day for a few mornings to knock over a stray jay or two among the Peas, I managed pretty well. I would rather have ten jays than three tomits.

Now, mark the difference. There has been a gamekeeper for these last five years, and there has been a regular war going on against my above-named friends. I cannot even keep a cat, neither have I seen but one cat in the parish for these two years, and I had but a glimpse of that one, for she was no more the next day. Well, the consequence is, that the small birds have had it all their own way for four years out of the five: therefore, the balance is lost, and to such an extent, that I cannot keep anything in the shape of fruit or Peas without nets, and hardly with, though I stand in the garden with a gun all day into the bargain; besides my Gooseberry trees were subdivided to such an extent, that I was obliged this year to grub-up thirty-five trees, and all the others were sadly damaged.

My worthy employer has been all for the protection of the small birds, but he began last year to see that it was being carried too far, and I got him in the humour to begin to restore the balance again, and we set to it in right good earnest. Early last spring we destroyed the blackbirds by hundreds, by taking all the eggs and young ones about the garden and shrubbery, and trapped, and shot, and caught in the nets all through the summer, and served the tomits the same; and up to the day that all the Currants, Gooseberries, and Peas were gone, the birds did not seem to be one whit thinner. There is a heavy load of berries on the Hawthorn this time, and we shall wage war against the blackbirds if it come hard weather.

No doubt I shall be called a most cruel fellow, but I cannot help myself. Only imagine having to net every row of Peas that is to be grown for a large family, and the destruction of nets, as the nets must be pegged down to the ground, up each side of the row, and that part is all rotten before the season is over; besides the time it takes to net and unnet every day to gather the pods. Then, all the finest and best of the fruit on the standard trees and others, which we cannot net, are spoiled by the tomits.

I had an excellent row of Champion of England Pea, not

15 yards from my cottage door this season. As my cottage is in the garden, they were not netted, as I had not a net out of use. They were attacked one Sunday afternoon, and I was obliged to sit at my cottage door, and every ten minutes or so get up and throw handfuls of gravel or soil into the Peas till the birds were gone to roost, or they would have entirely spoiled the crop before night.

Only picture to yourself, also, from forty to sixty blackbirds amongst the Gooseberries and Currants; and as my employer walked through the bushes, they would fly up two or three at a time, and just skim over the wall. He shot them just going over, but never more than one at a time. He would kill six or seven every day for weeks, but you could see no difference in the number, and they became so bold that they would all come back in ten minutes after the discharge of the gun; and I have seen them fly straight across the garden at an Orleans Plum tree against the wall, and twist off a Plum in a moment, just rise over the same wall, skim the top, and down into an old hedgerow with the Plum in their beak, or rather the beak in the Plum. I could not keep a red Plum without netting. Green Gages they did not touch.

In losing the white owls, I am overrun with field mice, and I may here add, that I have been attacked with caterpillars as usual, and I see no other way of proceeding than by thinning the birds or having the garden netted over from wall to wall.—WORCESTER.

[There is no doubt that those who destroy owls and hawks act most erroneously, for these birds of prey benefit an estate much more by destroying small marauders, and keeping the balance of animal life corrected, than they do harm to the estate by killing its game. So far we coincide with our worthy correspondent; but we venture to suggest that the old Saxon love for the exhibition of expertness in hitting a mark, and bringing down the quarry by a skilled shot, gives the casting vote in favour of the gun. We say this, because no one can deny that every small bird killed deprives the neighbourhood of a destroyer of caterpillars, aphides, &c., during the season of nestlings; nor can any one deny that two or three old women would scare away all the birds from the largest kitchen garden that ever was enclosed within four walls. They would not cost much more than do the powder, the shot, and the time of a skilled workman; and we will add, never do we sanction the discharge of shot among fruit trees.—EDS.]

### THE HOUSE-SPARROW (*PASSER DOMESTICUS*).

IN commencing my defence of this useful bird to the farmer and gardener, I will say with Barry Cornwall—

"Long live  
The household sparrow! may he thrive for ever;  
Long may he live; and he who aims to kill  
Our small companion, let him think how he  
Would feel if great men spurned him from their hearths."

The sparrow, like the redbreast, is one of man's companions: it seeks out his habitation, and unites its fortune with his. From the north of Scotland to the African Continent, from the one side of the Himalayan Mountains to the other, he is found. To the storm-tossed mariner a symbol of land, and to the lost pedestrian wanderer a token of the habitation of man.

Though the sparrow neither attracts our notice by the sweetness of its song nor the beauty of its plumage, it is of the greatest use to the cultivator of the soil. If he was not so, he, like his black persecuted neighbour the rook, would not be so generally distributed over most parts of the world. Nor is he less abundant in great cities than about the rural homes of our cultivated districts. That sparrows do eat grain, and at times to a considerable extent, no true naturalist will deny; but we never, as yet, heard of a farmer or a gardener being ruined by them, as some of their enemies have endeavoured to assert; but it is well known that whole fields of grass and grain, as well as root and garden crops, have been destroyed by various species of insects which form the sparrow's chief food. Of these I may name the large cabbage butterfly (*Pieris brassicae*), the green-veined white (*P. napi*), the small garden white (*P. rapæ*), the cockchafer or Maybug (*Melolontha vulgaris*), which of itself has been known to destroy whole fields of pasture and garden lawns in its grub state, eating away the young fibres so effectually that the turf could be rolled up, as if it had been cut with some instrument. Again: the wheat-midge, gnat, or fly (*Cecidomyia tritici*); the green fly

or plant lice (Aphidæ); the black caterpillar, black canker, or nigger (*Athalia centifoliæ*); the turnip fly or beetle (*Maitica nemorum*). Nor are we exempt from the possibility of an importation of that dreaded and far-famed insect known to our American friends as the "Hessian fly," to lay waste our fields of corn, as in the vast valleys of the Ohio and Mississippi, or those dreaded locusts which have in all ages been ranked amongst the most dreadful of human calamities.

That sparrows are the wholesale destroyers of our crops which some writers represent them to be is far from being correct. Let such watch them during the season of incubation, when they are most voracious, and no better locality for such can be selected than a farmyard, surrounded with hedgerows, stretching away towards a wood side. The sparrow will be seen to fly out of its nests with a rapid and bounding flight, and after scouring the hedges, he returns with a caterpillar, or some other insect, in his bill, and is welcomed home with a chorus of sweet chirrupings; and so on for many a long hour in the bright days of spring and summer, when there is not an atom of grain for him to devour—watching over the comforts of his offspring till they are able to fly and provide for themselves with a zeal and affection that would put many a Christian to the blush.

A single pair of sparrows having young to maintain will destroy, by my own observations, upwards of four thousand caterpillars and other insects in one week; and Mr. Abbey, one of our best writers on the subject, has shown in *THE JOURNAL OF HORTICULTURE*, "That a nest of sparrows is fed forty times in an hour; and presuming that one bird is fed, or one caterpillar taken at one time, we shall have, for sixteen hours for a working day, a grand total of 640; but as sparrows often take four and five caterpillars at a time, that estimate is considerably below the approximate amount. However, we will be content with the smaller number, and when we multiply the daily consumption by the period that transpires between hatching and leaving the nests (fifteen, and from that to twenty days), we have 9600, the amount of caterpillars destroyed by a pair of sparrows."

The house-sparrow will rear three broods of young in one season, and each brood consisting of five to six individuals, so that the period of their insect-destroying and the number of their young induce me to believe that even the above calculation is very far below the amount of good they do in this respect. In France, the extermination of this bird has been carried to such an extent that caterpillars have increased so alarmingly that Government has been compelled to legislate for the preservation of these useful birds. Bewick, in his "British Birds," endorses my calculation that a single pair of sparrows during the time they are rearing their young will destroy four thousand caterpillars weekly, besides the butterflies and other winged insects, each of which, if not destroyed, would produce several hundreds of caterpillars the following season. The late Bishop of Norwich found that sparrows fed their young thirty-six times in an hour, and calculating fourteen hours to a day during summer, will give 3500 times per week; and another authority of equal credit calculated the destruction of caterpillars at 3400 per week. These calculations have all been made by close observers and for scientific purposes. They are not the haphazard ravings of ignorance and prejudice.

Now, what would these 9600 caterpillars destroy in that time of the food of man, supposing that only 3000, little more than one-third of these, arrived to the state of perfect butterflies and moths, and lay their eggs? Why we should be overwhelmed with a far more serious pest than the poor house-sparrow is accused of being, which we could neither shoot, trap, nor poison. Who, I ask, has not observed the persecuted sparrows dart upon that all-destroying pest of our Cabbages, &c., the common white butterfly, while seeking a favourite spot to lay her eggs, which are to produce voracious caterpillars by thousands? Watch them again in a field of Beans, clearing that important crop of aphides, a race of insects that perplex naturalists by their angularities, and the facility with which they increase their vast numbers, and their destructive properties to plants, of which we have this last year had painful experience—

"These insect pests, powerful though small,  
Blighting at once the green leaf and the grain."—(Graham.)

Again, who has not observed them pulling the thatch out of the roof of cottages and outbuildings during winter? What is this for? Not for mere wanton mischief, as is generally supposed, but for the myriads of flies (*musca*) which are quartered there for the winter, to issue forth in the spring to annoy us or our

cattle, or to pollute our food, and otherwise to become an intolerable nuisance. The sparrow frequently attempts the capture of insects on the wing, but with poor success. Nature never intended him to catch flies in this way, though the hunting of butterflies by sparrows trained for the purpose, is said to be one of the royal sports of Persia. It is not only on insects that the sparrow feeds. I have watched them devouring snails and slugs (*Helix* and *Limax*), which are well known to be wholesale destroyers of vegetable life in its young state. It is quite amusing to watch them hammering away at the shell of *Helix virgata* and *rufescens*, which in some fields may absolutely be collected by bushels, particularly in the chalk counties of Kent and Dorset. If the mollusc is too large, they will place one foot on it, and tear it to pieces with their bill; if small, it is devoured whole. In this way thousands of these pests are devoured unknown to man.

No sooner do the leaves of the Hawthorn appear than the sparrows may be seen hunting the hedgerows for insects, even before they have young. I have for hours watched them in large Rose-quarters, in company with other birds, in nurseries and gardens clear the young shoots of every aphid. I have watched them examine every crevice of a wall, clinging to its face like the "wall creeper," devouring spiders and other insects. A long series of observations enables me to assert that the sparrow prefers insect food to all other, when he can procure it. In fact, their summer haunts are chosen with reference to a supply of such food.

To accuse the sparrow of nibbling off the buds of trees, &c., for food, is a most mistaken idea; they do nothing of the sort. They are also accused of plucking off the flowers of Auriculas, Polyanthuses, and even of dieting upon the petals of the Dahlia. They might as well be accused of dining off the hind-quarters of a hippopotamus or rhinoceros.

Has it never occurred to these persons who thus accuse them that it is insects they are in search of, particularly that destructive pest the common earwig (*Forficula auricularia*), that insect of unconquerable dislike in all countries and through all ages, from the absurd idea of its insinuating itself into persons' ears, though unsupported by a single fact? What I have already advanced is with reference to the rustic sparrow. The city-bred gentlemen are differently situated; they are obliged to pick up all the nutritious particles from the streets, roads, yards, and dunghills—no part of the crowded city seems to daunt them. In the railway station, with its snorting, puffing engines, as they dash through with a velocity that makes the earth tremble, you find the sparrow at home. In the Zoological Gardens you may observe him feeding with the majestic eagle, and splashing merrily about in his bath; you may find him in company with the elephant, rhinoceros, hippopotamus, or the wild swine, skipping about with utter indifference; visit the crowded markets, especially where vegetables are sold, there you find the sparrow. Who has not observed him hopping about the streets, even under the very feet of the horses as they stand in the cabs for hire? How frequently may he be observed pouncing upon the piece of bread which lies on the pavement within a yard or two of you as you walk along, and carry it off to its mate seated on a window-sill or roof of a house. Indeed, nothing can exceed the self-complaisance of the town-bred sparrow. You see him build his nest and rear up his young amongst the richest tracery of a church roof or window; within the very coronet or escutcheon set up over gate of hall or palace; he would build in the Queen's crown itself if it were placed conveniently for his purpose.

A pair, some few years ago, built in the mouth of the stone lion on the Duke of Northumberland's house in Charing Cross, London. A pair built in the "bunts" of the main and mizen topsails of the "Great Britain" ship while it was lying for repairs in the Sandown graving-dock. A pair built upon the furlled sail of the "Aurora," of Belfast, which was destroyed on the ship's route to Glasgow. A pair built under the slings of the foreyard of the ship "Ann," of Shields, just before leaving port, and sailed out to sea, coming down on the deck to feed on the crumbs which were spread for them by the sailors. The sparrow, in fact, suits himself to any spot or place, using any material he can find to line his little abode; he is alike at home under the roof of the poor man's cottage as he is hid in the ornamental carvings of Her Most Gracious Majesty's palace—

"At home, abroad, wherever seen or heard,  
Still is the sparrow just the same self bird."

In Tartary, Thibet, and in China he is, perhaps, more im-

udent than in Europe, for we are well informed that his nest and his brood are always religiously respected, and he enters every house quite at his ease, and picks up whatever he can from the food of the family. Would that this example were to some extent followed by his enemies in this country! It has been the fashion of most writers on the history and habits of this bird to brand it as an ugly and vulgar-looking bird; this is really not the case. Let us take, for example, a rustic cock sparrow, examine his plumage, and for a moment consider how much there is in that compact little frame which would baffle the power of the wisest man to explain, and you will not pronounce him ugly—

“He who feels contempt  
For any living thing, hath faculties  
That he hath never used, that thought with him  
Is in its infancy.”—(*Wordsworth.*)

In South America, the sparrows were persecuted with such unremitting perseverance that insects increased to such a degree that many cultivated lands were so ravaged that it became quite impossible to raise any crops upon them. Naturalists are acquainted with the results of the destruction of sparrows in one of the Wheat-growing districts of the Baltic, and where it was afterwards found advisable to import sparrows, to replace those destroyed, in order to keep a check on the insect pests. The same occurred in a division of Prussia. The farmers were much annoyed by sparrows, and sought to eradicate them by a kind of poll-tax. The authorities allowed part of the imposts to be paid in sparrows' heads. They succeeded, but what was the consequence? In two seasons they were obliged to apply to the neighbouring countries for a supply of sparrows, for their crops were nearly consumed by flights of insects which the sparrows would have devoured; so dangerous is it to act against the decrees of nature. Providence is wiser than man. I know a gentleman in East Kent, a large landed proprietor. He laid a wager of £1000 that he would destroy every sparrow in his parish. In this he succeeded only the night before the time expired; he, therefore, won his bet, but he lost double and treble the succeeding years by the damage done to his crops by the ravages of insects. Man is justified in protecting his crops, but in this he should act with caution; for let those “societies,” sparrow clubs, &c., or whatever their local name may be, for killing sparrows, beware, lest when they find their crops in the jaws of a more deadly enemy, which they can neither shoot, trap, nor poison, they may wish that they had paused in their work of destruction, and left a few of their poor enemies the sparrows to rid them of the pest.—OMEGA, in *Scottish Farmer.*

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

EVERY opportunity of favourable weather should be promptly employed in carrying out whatever digging, trenching, and draining have been marked out for completion during the winter months. Deferred until a late period, severe weather may set in, and thus the operations may be retarded to the loss of the ameliorating influence of frost and other advantages. *Asparagus*, if new beds are to be made, trench deeply, and apply manure unsparingly; for it is better to enrich the ground well at first than to trust to subsequent top-dressings. Now is the time to see about getting ready for spring planting. *Cauliflowers*, the plants under hand-lights to have the soil occasionally stirred about them, and abundance of air to be given in favourable weather. *Herb-beds*, if they are not yet cleaned and done-up for the winter, they should be attended to without delay. A slight coat of very rotten dung to be laid on them for the double purpose of protecting the roots from severe frost and to enrich the soil. All wood ashes and soot to be preserved with care; both are valuable as manures. As the labour can possibly be better spared at this than at the spring season, and as an advantage attends the practice, wheel on the manure to the land, and dig it in; throw up the unbroken spits of soil to be pulverised by the frost. The land which should be manured most particularly is that intended for Peas, Beans, Cabbage, Onions. Do not manure the division intended for Potatoes unless the soil is extremely poor.

### FLOWER GARDEN.

We again urge the necessity of getting all intended alterations and improvements commenced or brought to a close as speedily as possible. Now is a fine time for taking-up and laying-down

Box-edgings. This is also a good season for altering the surface of the flower garden, and for laying down turf. If the ground is newly made, see that it is rendered perfectly solid before laying down the turf, so that there may be no giving way afterwards; when all laid down, to be well beaten all over with the turf-beater, which will close the edges of the turf; flatten-out the surface, and level-down all irregularities. Rustic baskets and vases planted last summer should now have the soil taken out of them in order to keep them from being injured by frost. *Fuchsias* and other half-hardy plants that have been killed down will now require to have their roots mulched to keep the frost from injuring them. Where shrubberies are too thick take up some of the best specimens, and transplant them, or cut-down inferior sorts to give more room, light, and air to the others. Continue to sweep, roll, and clean lawns, walks, &c. Annuals and herbaceous plants killed down by frost should now have their stems cut down and taken to the rubbish-heap; the most choice kinds to be labelled to prevent them from being destroyed when digging the borders. Seeds not yet collected to be gathered on a dry day.

### FRUIT GARDEN.

The planting of young fruit trees, and transplanting or raising those of larger growth, to be vigorously prosecuted, as the season is very favourable, and the earlier these operations are performed the greater the success. Fig trees to be protected: the best plan is to loosen them entirely from the wall, to tie the branches closely together, and to wind thick haybands round them from bottom to top. Let all superfluous nails be drawn from wall trees, and proceed on every favourable opportunity with pruning and nailing, except, perhaps, in the case of south walls, which had better remain till the end of January, as the buds are apt to become unseasonably excited.

### GREENHOUSE AND CONSERVATORY.

The *Geraniums* intended for early blooming should now be stopped and plenty of room afforded them. Let them be tied-out, and as soon as they begin to break let them be repotted and their growth slightly encouraged, always keeping them near the glass. Give abundance of air on all mild days to keep the plants from growing.

### STOVE.

Keep the temperature rather low than otherwise that no new growth may be promoted. Much more injury is likely to result from a high temperature at this season than is generally supposed. Sixty degrees of fire heat is ample for all stove plants. Continue to look sharply after mealy bug, scale, and other insects. This is the season more especially when stove plants can be got thoroughly clean.

### FORCING-PIT.

Get in all kinds of Dutch bulbs, American and other flowering shrubs, *Lilies of the Valley*, *Heliotropes*, *Pinks*, *Roses*, *Double Roman Narcissus*, *Crocuses*, *Neapolitan Violets*, *Mignonette*, and *Cyclamens* to begin with in gentle heat, as many of these bloom early without much forcing. Keep down the green fly by occasional fumigations of tobacco.

### PITS AND FRAMES.

As the nights are now cold, the lights should be closed at night, and the frames well covered with mats and litter if required, avoiding fire heat until it is absolutely necessary. Look carefully over plants requiring water every fine day, but avoid watering at this season in dull weather. In a cold pit, should now be safely stored such plants as will furnish the forcing-pit in succession, such as good bloom-showing plants of *Rhododendrons*, *Kalmias*, *Belgian Azaleas*, *Sedums*, &c., to be selected and lifted with good balls and potted for the purpose of being taken care of in this useful structure. W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

SECURED vegetables as mentioned last week. Covered over Sea-kale plants with a little ashes in the form of long cones; planted the *Asparagus-bed*; earthed-up *Mushroom-bed*; gave protection to *Radishes* out of doors; packed-up roots in sheds; wheeled rotten leaves over *Asparagus-beds* on frosty mornings, &c.; gathered a lot more of *Capsicums* and *Chilis* for cayenne pepper. These have ripened more slowly than usual this season, which I attribute partly to planting them out in a bed under glass, instead of keeping them in pots, and where much heat

could not be given them. The fruit was finer than usual, but the luxuriance given to the plants made it ripen slower. Much of the quality of the pepper depends on the bright red of the skin. I find the seeds are but little used, as they would detract from the colour—so much are we in everything the slaves of appearances. Even lovers of pickles must have them green, though well knowing that no *artiste* can make them so without spoiling them with copper, or something else as deadly.

#### FRUIT GARDEN.

In frosty mornings rotten dung and leaves were wheeled between the rows of Strawberries, and a little used for surfacing dwarf Apple and Pear trees. Not many years ago, I found at one time men making tallies on a hard frosty day, and not long afterwards they were wheeling manure and soil with the wheel of the barrow almost out of sight in mud, and of course there was a constant standing dish of grumble that half enough of men were not allowed for the place. The making walks, &c., right after such work, would take up about as many men and as much time as doing the work altogether would have required in frosty, or even in dry weather. Timing work will often be the means of avoiding making work. Doing a job in such a way as not to make another, is what distinguishes chiefly the intelligent thoughtful workman from the careless, slovenly, six-o'clock practitioner. Cleared, pruned, and fastened-up Raspberries. After trying many modes, find no plan better than growing them in rows 4 feet or 5 feet apart, and fastening them to a couple of slight rails an inch in diameter, fastened to posts in the row. Syringing Cherries and other trees with soapsuds, holding a little salt in solution, which, in addition to being unpleasant to insects, helps to remove mosses and lichens from the trees and walls. Commenced pruning Pears, &c. Orchard trees in pots, we have not had time to wash and secure the pots from frost, but the latter has not been severe enough to touch them. Syringed them, however, several times with water about 160°, holding soap in solution, and even after that found some of the black beetle creeping on the pots. Will, if possible, give all the soil in the house a watering with hot water, and will remove all surface soil from the pots. We have a vast deal more faith in prevention than in cure.

Stripped most of the leaves off the Figs in the Fig-house, and all the smaller fruit, leaving only the larger to ripen. The bed is chiefly filled below with large Begonias, and will soon be occupied with other things. The soil, though dry, we will not water for a month or six weeks to come. The plants had been originally grown in pots, but have now been turned out for a number of years in a shallow bed, and are allowed to fill the space in a rough manner, there being several longitudinal rods along the house, just to tie down a branch to that comes too near the glass. Looked at now, or shortly, there is roughness instead of symmetry, and wildness instead of training. Well, our advantage is, that we save all the time it would take to make them look nice and neat, and the expense of a trellis; and when the plants are full of fruit people think more about that than any training and tying. Our only secret is, plenty of rich manure water when growing and swelling, and dryness when at rest. The great thing is to give a little water by degrees before the young fruit get much larger than Peas, or they would drop off, and a deluging then would have much the same effect.

The Vines in the houses attended to as last week; all houses crammed where fruit is not hanging. In a narrow pit shut up, and filled with the latest bedding plants in pots, the Vines have been cleaned and painted, and the temperature raised from 43° to 48°, the roots of the Vines, which were very dry, being moistened with warm water about 90°. This will bring them along gradually. The Vine-border outside of houses covered with stubble, and not much of that, is still 50°, 3 inches below the surface. A few Strawberries will be placed on a shelf at the back of the Vine-pit. The Fig trees out of doors, which, on the whole, did pretty well, have had the whole of the fruit left larger than a Pea stripped-off, or, rather, cut neatly off, and the trees thatched with Laurel branches, either tied against them, or nailed to the wall by passing the nail through the branch. I tried this plan last year, and it answered perfectly. It is a mere chance to be sure of them without some help here. Formerly I used to unnailed the trees, and fasten them close together in bundles, and stuffed some straw about them, fastening a mat or something of that kind over them. The objections to that plan were, that the unpacking them was apt to be too long

delayed, and the trees needed protection afterwards, either from bright sun or frost; and again, from being so busy at that time in spring, the laying-out and nailing the branches were apt to knock off a number of the fruit. By merely placing the Laurel branches against the trees, there is no unnauling wanted. They will be sufficient protection against a common frost. Additional protection can be given if we come near to zero. The air and light, too, will permeate among the young fruit, giving it a hardy green appearance, that will suffer nothing when the branches are removed by degrees. Swept leaves from Apricot trees; some, however, are rather green yet. Dwarf Pears, &c., are ripe, as they ought to be, and most other things under cover. Tomatoes are making their appearance; but they look after insects now, but will go to the buds as soon as these fail.

#### ORNAMENTAL GARDENING.

The frost having gone, commenced in the middle of the week to give the lawn the last mowing, rolling it previously. Have got the greater part of the dead flowers removed from beds and borders, and found the quantity more than usual, as the whole were so densely packed and so vigorous before the frost came. The leaves are not yet all down, and until that is the case it will be sweep, sweep, and sweep again. As soon as possible beds will be dug, borders ditto, herbaceous plants regulated, &c. Pretty well finished putting away in the faggot style lots of Scarlet Geraniums, &c. They had stood so long under cover and so thickly that the leaves were getting all faded and yellow, but that made them all the easier to come off, and as the roots and stems were all sound, that was all we cared about. A few of these were potted separately; but most of them were put, a dozen or a score, like a faggot in a pot. We must, however, here give a little minutiae. The soil used was just moist enough, light sandy loam and leaf mould. The roots were getting rather dry; each lot of plants as dressed was set for five minutes in a pail as deep as to cover the roots and 2 inches or 3 inches of the stem, the water about 60°. This was to distend the roots, and the soil being packed firmly about them, no water will be given for a good time to come. A lot of these were put in a cold pit with a layer of tree leaves a little warm below them, and we believe that in moderation as to dryness the fresh roots will run sooner than in soil saturated with moisture. Others were placed beneath the stage in a vinery, the stage being filled with plants in pots. Those below the stage, if much fire heat should be used to keep out frost, will have a slight syringe during the day to keep the stems from shrivelling. We should do much the same if the plants were kept in stable, garret, or byre, and in all such places may such plants be kept, and best in summer young plants that received the kindest treatment. We saw a lot last year in a garret that would have been first-rate if the frost had not nipped the stems. A woman's apron would pretty well have saved them. Another lot in an airy cellar would have been first-rate, but a girl, who must be doing something, soaked them with water, and they could not help themselves, and were obliged to rot. Had they remained as packed until the middle of March, and then got light on fine days, they would have been first-rate in the beginning of May. They will be all the better if they make not a single leaf during the winter.

I was delighted with our friend Mr. Beaton's account of the celerity with which Mrs. Bird pitches in her Calceolaria cuttings; but what do you think? my men and boys will not take it in that the lady's plan is any improvement on theirs, and do not believe it is managed a bit quicker, even than they did them, as the lady could only use one hand when dropping the cuttings, whilst they would fasten the cutting with one stroke of the dibber with the other. We have, years ago, also done a great many by one of the dropping-modes. The holes were made from top to bottom of the bed, or a slit of equal depth; a handful of cuttings with the bottom ends are then held in the left hand, and as fast as the right hand can go down goes the cutting, and before the thumb and forefinger leave it, the soil is pressed to it with one move; or if only a few cuttings are held in the right hand, the left hand follows, and does this firming work, and then all the cuttings stand upright, which my men rather doubt will not be the case in the mere dropping-mode of Mrs. Bird. However, I am at present inclined to give the palm of victory to the lady; and one thing I am sure of, that some who make such a fuss about a few Calceolarias will have their eyes opened when they see such beds. Of our first batch I do not see one wrong; the only thing I regret is that they are

beginning to root, and I would have liked better if that had not taken place until after the new year.

House plants, bulbs, &c., much the same as last week.—R. F.

### TRADE CATALOGUES RECEIVED.

J. Scott, Merriott Nurseries, Crowkerne.—*Descriptive Catalogue of Fruit Trees.*

Carey Tyso, Wallingford, Berks.—*Descriptive Catalogue of Flower Roots, Plants, &c., for 1862-3.*

### TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

GLADIOLUS (*W. H. Box*).—The accent is on the second syllable, and the *o* is not uttered at all, but the name is pronounced as if spelt Gladiulus.

BOOKS (*W. G. H. C.*).—Dr. Lindley's "Vegetable Kingdom" does not contain anything about plant-culture. The other book you mention, McIntosh's "Book of the Garden," is very copious on all subjects connected with gardening. It is in two volumes, price £7. *6d.* In addition for a good gardener's library, we recommend Thompson's "Gardener's Assistant," "The Cottage Gardener's Dictionary," Lindley's "Theory of Horticulture," and Johnson's "Science and Practice of Gardening."

WATER FOR AQUARIUM (*Rusticus*).—Rain water, conveyed from the roofs of buildings in the country, entirely uncontaminated by soot, would be very well for an aquarium. Even a slight impregnation with soot would be no objection if the water were quite pellucid, and plants only placed in the aquarium. It would be injurious to fish and water insects.

WEEKLY CALENDAR (*L. R. W. L.*).—The temperatures in the table at the head of the first page usually show in whole degrees the highest and lowest of the thermometer during each day, as "33-13." If a fraction of a degree is stated, as "35°.3," which rarely happens except when averages are given, so many degrees, and so many tenths of a degree, are indicated: thus, in the instance given, the temperature indicated is 35° and three-tenths of a degree.

EXCELLENT MODE OF SHOWING A FLOWER-GARDEN PLAN (*M. D.*).—Capital. Six or 7 square inches of green paper, full of flower-beds, with the names of the plants under them. The shape of each bed is cut out of paper of the same colour as the flowers, the edgings the same way. The green paper represents the lawn, and with this way of marking the beds on it one can see the effect with half an eye at once. The letter was in three lines on the back of the green paper, and our answer is, The garden will, indeed, be a most effective composition.

CINERARIA FLOWERS NOT OPENING (*Wm. M. Jun.*).—We suspect you have repotted your Cinerarias into rather large pots, and rather late. When once the pots are crammed with roots, and plenty of air is given, and the plants are sufficiently supplied with water, we think you will have no want of flower-trusses.

CUTTING A VINE SHOOT (*J. G. D.*).—If you had stopped the shoot, now 17 feet long, and allowed laterals to grow, the lower part of your rod would have been stronger. Now, you should not have more than 5 feet for next year. It would most likely bear a heavy crop if you let it; but it would be injured for the future.

LAPAGERIA ROSEA (*Mrs. W. S.*).—Very full directions have been given for the culture of this beautiful plant in No. 575 of this Journal, which you can have free by post for 4d. It will do well in your cool conservatory, and the chief care it requires is abundance of drainage to prevent stagnant water, good health soil mixed with a little fibry loam, and never to want for water. The roots do not naturally run deep, and, therefore, moisture is indispensable. If one end of the house is warmer than another, we would place it there.

LIQUID MANURES OF SHEEP'S AND PIGEONS' DUNG (*A Seven-months Subscriber*).—Use them both, but weak and alternately, and alternately with clear water; but use them in none of the cases mentioned until the plants are knotted for bloom. In the case of Begonias, use it chiefly after the sun has gained power and they are growing freely late in the spring.

PROPAGATING INDIAN AZALEAS (*Ignoramus*).—"Buy Greenhouses for the Many," "In-door Gardening for the Many," and "Window-Gardening for the Many," they will give you all the information you mention. You need not be particular as to the time of propagating Azalea indica. You may proceed now or as soon as the days begin to lengthen. Select a number of small shoots of last season that have no flower-buds, greenish but firm at their base, and from 2½ inches to 3 inches in length. Cut them across at the base, and remove a few of the larger bottom leaves, and then insert in silver sand, in pots well drained, and a layer of sandy peat below the sand. Water well, and when the cuttings are dry cover with a bell-glass. Allow these to stand for a month in a shady part of the greenhouse, or if not shady, have a piece of paper to put over the glass in bright sunshine; ease the glass a

little to admit air in mild nights. In a month plunge the pot in a mild hot-bed and attend to air at night. Water when necessary, and shade in bright sunshine, and as soon as struck pot off and keep close for a time, until the young plants are growing freely.

STOKERIA CTANEA (*Rusticus Expectans*).—This plant was introduced from Carolina nearly a hundred years ago, and produces blue composite flowers. The flowers are too thin to suit a florist's fancy, who must have a Cineraria like a perfect circle. We are not aware of the plant standing out during the winter; but think that young plants would stand secure in a dry cold pit. In general seasons we should expect it to bloom out of doors in the autumn. If it bloomed freely in winter it might be desirable for that purpose, grown as you have done, or potted late on purpose. We think you would have had flowers but for the extra luxuriance. As far as we recollect the notched leaves are as singular and even more worthy of admiration than the flowers.

VARIOUS (*Westmoreland*).—We do not know the Pear you have sent. It must be some local sort, and it is one we should not think anything of in the south for its flavour. We see no reason why the tar of wood should not answer quite as well for making waxes and floors as gas tar. All tar when boiled becomes hard, and this would be so deleterious to vegetable life as coal tar. If you train up the Cottonaster microphylla, you may get it 6 feet high in soil where it thrives. We have seen it against a wall much higher than that; but you need not despair of speedily getting a hedge 3 feet high.

PHLOXES (*M. F.*).—On the supposition the Phloxes were planted out after being the four years in pots, you have left them two years too many unremoved; and if they were established plants from old stools, you had left them three years too long. The best bloom which the best management can get out of the best kinds of Phloxes is, when the plants are old and on the spot to lift the old plants any time from the end of October to the beginning of March, and take four lumps from the outside of each ball or stool; or first quarter the stool and then take the outside of each quarter, where the roots are soft, free, and fleshy, and where no wry old "bottoms" are met with; to plant the young stock in fresh places, and no place was ever yet made for a Phlox of the present race so good as a Rhododendron-bed—that is, for a fine bloom; but the plants will grow in any soil, even in the very worst. It depends on whether the old plants were properly done or not, if the new plants flower best the first season or the second year after planting. Some renew their Phloxes every year, in February, but we always keep a certain portion of our stock two years for two reasons—in order to have taller and bigger plants, which must overtop our Rhododendrons before the flowers could be seen; and, secondly, to make people, who see them from a distance, believe the Rhododendrons themselves are in full bloom in all the shade of the two families. But for the borders we renew our Phloxes every year, and give each lump or plant a large spadeful of very rich light compost.

GARDENERS' RHEUMATISM.—The way I have treated rheumatism for a long time is this. As soon as I find it coming on I get some spirits of turpentine and rub well into the painful part. I then get some old piece of cloth, as an old shirt or the like, and put it six or eight times double, then dip it in a bowl of cold spring water, squeeze it just so that it does not run about from the cloth, put that cold on the part, and as soon as it begins to get nearly dry or uncomfortable, wet it again. I take some cold water to bed with me and follow it up night and day till well, and apply the turpentine once a-day, twice a-day, or once in two days, according as the pain is. When the pain ceases I leave off the turpentine. This is the best remedy I ever tried. No one told me this, neither could I ever get any one to try it; every one seems afraid, and many have said I should have my sinews drawn up and lots of other calamities, but instead, it has done wonders for me. Turpentine eases the pain almost immediately, and the wet cloth brings down the swelling by evaporation. If the patient cannot bear the cold, the cloth may be just held before the fire to take the chill off.—WORCESTER.

HEATING A PIT (*An Amateur*).—The other week you would see much on heating such a pit by a fire, and there seems nothing we can add to it. You must have a chamber of some kind over the fire or round it, or the heated air will not get out freely for top heat. Neither should the cocoa-nut fibre touch the fire. There is no doubt that otherwise your plan will answer. The fire will be much cheaper than an Aroott's stove with boiler and pipes. The cheapest of all would be an Arnott's stove alone, placed at one end, where the furnace is proposed to be. This placed low enough so as to have a chamber and openings into it, would be the simplest if you could do it. (See page 632.) Such slopes do not work well with much length of horizontal pipe; and, therefore, the smoke had better be conveyed in a rising direction to the back wall. We do not think these simple stoves, or kiln-gases, have ever had full justice done to them. If you do not understand their simplicity you had better stick to the flue. For such a place as yours, we would go 4 feet brick on bed—that is, lay the brick on its flat side, 4½ inches, the rest brick on edge—that is, 2½ inches wide. For such a fire two bricks on the side or edge would be sufficient, and 7 inches wide outside would be enough, so that a foot tile would cover all. We plaster none inside, a little outside if you like. Portland cement pipes would do 6 feet from the furnace. You have missed details about flues.

PROPAGATING HEN-AND-CHICKEN DAISIES BY SEED (*C. D.*).—The condition called hen-and-chicken in the flowers of Composites being not in the nature of sports, nor yet in that of a step towards donbleness, but a further development of flowers through the scales of the involucrem, and not through any portion of the florets, we have every reason to believe that a Hen-and-Chicken Daisy will reproduce itself at some certain rate per cent. But the case has never been tested as far as we know. All deviations from the normal type come more true from seeds in Composites than in any order of plants, as far as our observation extends.

LITTLE DOT GERANIUM (*J. B. Fremde*).—Your Geranium Little Dot is the most dwarf, the best horseshoe mark, and the most profuse bloomer we have seen of the breed of Luca Rosea, and we would recommend it as a distinct kind for edging large beds with. As you have proved it under the shade of a large tree, we should like to see a bed of it under one of the Yew trees at Hampton Court.

GRAPE (*John Ferme*).—We do not know whether the Abbe and Black Monukka Grapes are to be had of the nurserymen; at least, we do not know of any who have got them. If you are a Fellow of the Royal Horticultural Society, you could procure some cuttings of both. The Hushsee is not the same as the Abbe of Dr. Hogg's "Fruit Manual," but is a long dull red Grape, in shape like a long, narrow Filbert, and with no particular merit to recommend it.

MANURE FOR AZALEAS (*An Old Subscriber*).—Manure is not only not good, but is actual poison to Azaleas, Rhododendrons, and Heath. Never think of such a thing, nor of giving them manure water.

HEATING FROM A CISTERN (*R. L.*).—Your cistern (not tank), is a general reservoir, whence the heated water is to proceed and be regulated. If so, then all your proposals are wrong. The most simple thing for you to do so, is to have your cistern, or tank—say 18 inches by 18 inches—larger if you like—raised 18 inches above your highest pipe for top heat, which will be 36 inches or 42 inches above the highest pipe likely for bottom heat. Place the top of your boiler lower than the lowest pipe. Take the flow-pipe from the boiler into the cistern by a hole in the centre of its bottom. According to your plan of heating each side of your house separately, and to have top heat and bottom heat at will, you will require four more holes in the bottom of your cistern for pipes to be placed in them. One for each side for bottom heat, one for each side for top heat. These pipes you supply with plugs or valves, to open, shut, or regulate at will, and at first they will need a little attention. After this you have nothing more to do with this cistern or tank. All your returns will communicate with the bottom of the boiler by means of a single or double T-piece. Now, supposing that the cistern is at the end of the house, settle upon the level for your top and bottom heat; only from that level, in a length of 40 feet we would let the flow-pipe gradually rise from 2 inches to 3 inches to the extreme end, and fasten a small open gas-pipe on the circular bend  $\curvearrowright$  there. Of course, then the return-pipe would slope backwards in the same way until it descended to join the boiler. No air will thus accumulate; and so long as you keep the cistern supplied, and apply heat, there must be circulation. Some plans were given some time ago by Mr. Fish, showing how many places might be heated from such a cistern. The above is the simplest you can try.

FORCING LILIES OF THE VALLEY (*Idem*).—That was an excellent suggestion about forcing the Lily of the Valley for Christmas. The reason for covering them to keep them in the dark at the first going-off, is the grand secret of all about forcing them and many bulbs, and you have been doing the very same thing all your life without knowing it. You put so much covering over the Asparagus-bed every year, and it was only a year or two back since you had long chimney-pots over your Rhubarb. Why did you do that, and how long did you keep the covering on? Spent hops, or cocoon-fibre refuse, 6 inches deep, over a Hyacinth or over Lily of the Valley, will cause the flower-stem to push up 6 inches before the flower-buds will be more forward than when you could first see them; then the bloom is obtained on a good stalk, instead of coming dumplings as they would so early without the covering. Watch till the flower-stalks are long enough to your liking—they will be as white and blanched as can be; but, in a few days, the light and the heat will give the proper colour. Those who force bulbs for market do them just the same way—keep them covered in the dark until the flower-stalks are as long as they want them: that is the rule, and not how many days or weeks. You will see another answer in our columns to-day.

NAME OF FRUITS (*A. B. C.*).—Marie Louise Pear, undoubtedly. (*A. C.*).—Apples.—1, Albiston; 2, Yorkshire Greening; 3, Hanwell Souring; 4, Mère de Ménage; "1 small" Dutch Mignonne; "3 small" Court-Pendu-Plat; "2 small" unknown, frightfully acid, good for Apple Jelly probably. Do you know anything about it? "4 small" Golden Harvey. Pears.—1, Beauté de Rance; 2, Passe Colmar. (*P. Lang*).—We have paid 1s. 4d. for the carriage of the fruit you have sent to be named. We do not take cognizance of any fruit that is so sent, and beg that you will forward us that amount.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.  
 DECEMBER 9th, 10th, 11th, and 12th. CRYSTAL PALACE. (Poultry, Pigeons, and Rabbits.) Entries close November 8th. *Sec.*, W. Houghton.  
 DECEMBER 16th and 17th. LOAN TREDEGAR'S, Newport, Monmouthshire. *Sec.*, Mr. J. G. Palling, Newport.  
 DECEMBER 26th. HECKMONDWAYKE. *Sec.*, Mr. J. Thornton. Entries close December 20th.  
 DECEMBER 29th, 30th, and 31st. MANCHESTER.  
 JANUARY 1st, 2nd, and 3rd. GLASGOW. (Pigeons and Canaries.) *Sec.*, Mr. T. Buchanan. Entries close December 22nd.  
 JANUARY 6th, 7th, and 8th. KENDAL. *Secs.*, George C. Whitwell, and T. Wilson.  
 JANUARY 13th and 14th. GLOUCESTER ORNITHOLOGICAL. *Sec.*, Mr. G. Cummings, 89, Southgate Street.  
 JANUARY 21st and 22nd. LIVERPOOL. *Sec.*, J. T. Lawrence, 3, Cook Street. Entries close January 5th.

### POULTRY IN FROSTY WEATHER.

THERE is something exhilarating in a frost. When the early morning breaks on the earth covered with rime, and the hard ground seems to spurn the foot that treads on it, and the sun rises like a disk of burning copper, there is something cheerful about it. Nature has donned her masquerade dress of white. Your horse cannot contain himself; and the steady old friend for some months past, content to shake his head, or whisk his tail, as the only answer to what a granddaughter of our's calls a "good cut o' the whip," now seeks to devour space, and to try conclusions with your strength or that of your reins. In like manner your tried friend, the old dog, gambols, and, in the gleesomeness of his feelings, he picks up a shred of cloth in the field, and shakes and tosses it for very wantonness. Your eldest boy seeks his skates; his sisters look out their warm clothing, the stout boots, and they accompany their brother on mysterious excursions to old gravel-pits, lonely ponds and such places, and return glowing with health, although curt and uncommunicative

on the whereabouts of their rambles, and it is not till the frost has broken up you learn that "Emily slides well," and "Adela can skate a little."

The appearance of real winter is then a holiday to many, but (ah! those *buts*) not to all. It is none to the poultry. Water is frozen, the ground is so hard they cannot scratch; there is not an animal of any kind on its surface, and they must depend on their owner for everything they want. See they lack nothing. First, they must have water. Few people have any idea of the suffering caused to birds by the lack of water. Their power of maintaining life on the smallest possible quantity of food is wonderful, provided they have water; but a practised eye can tell in a dead fowl or Pigeon whether it suffered or not from thirst. The skin becomes hard, dry, and red; the flesh contracts, as it were, and becomes brown, and the whole body looks as if it had been suddenly shrivelled and dried-up. You must bear in mind they require more food and better than they do in milder weather, and, if you can, let them have a greater variety. They want substitutes for the worms and insects. Now, the scraps of meat and fat from the table should go to the fowls. Save the drainings of all the glasses, pour them together, and sweep all the crumbs and odd corners of bread into it. Feed the birds often, and, if there is snow, sweep a place clean, and feed there. Never feed any kind of birds in such manner that they shall pick up snow with their food: it is strong medicine to them. The Lark that fattens in two days on the white hear-frost becomes a wretched skeleton after two days' snow. The wild Duck that has cautiously crept into the stubble every evening, and laid hidden in the sedge or rushes all day till it has become plump and lazy, loses all the moment the melted snow has poisoned the water—it is then literally only skin and bone. Everything that depends on itself for food becomes thin during a frost. This has to be guarded against. Be careful, then, to keep them supplied with water. Feed often, and give more stimulating food than in milder weather. Do not let them have snow mixed with their food. Provide them with ashes—wood ashes are the best—in which they may scratch and take their bath.

Yet if this seasonable weather gives some extra work to the amateur, it has its favourable side. It is healthy for the fowls; it is dry, and it purifies everything. It searches out the nooks and corners, nothing escapes it; unpleasant odours disappear, and other works being stopped by frost, all these jobs in poultry-houses should be done. In hot weather many are put off; they can be better done when it is cold, or in the winter. Let them be done now. Save whitewashing or painting, this is the time for poultry-house work.

### LEEDS AND WEST RIDING HORTICULTURAL AND POULTRY SOCIETY.

WE have received a letter from Mr. J. Wade, charging the Secretary with false statements in his letter which we published on the 11th inst., but it does nothing else, and we decline to publish it, for it leaves uncontradicted the glaring fact that the *Committee have not paid the prizes awarded by the Judges!*

It is no defence saying that the entrance and admission money did not amount to enough to meet the expenses, for the Committee are bound in honour to pay the prizes which, in their prospectus, they offered without any such reservation.

Mr. Holdsworth informs us that he resigned the Secretaryship because he was not able to attend the meetings regularly.

We now leave the subject, regretting that such a number of Yorkshiremen can be found in Leeds to act so unjustly, and who would be ready enough to condemn such conduct in any other committee.

### JUDGES AT THE NEXT BIRMINGHAM POULTRY SHOW.

I WAS glad to find the question I asked respecting this important matter in your last Number was answered by Mr. Hewitt in the same. His explanation to me appears to be most substantial; but all this correspondence, unfortunately, I do not think will remedy the evil of the exhibitors being deprived of his valuable services. Unfortunately, the poultry by the Council is considered of very small importance in connection with the Show, and hence it is that this important arrangement, the appointing of judges, should be left for one only to decide.

The poultry is, no doubt, the backbone of that Exhibition. It commenced with poultry; it was poultry that made that Show what it is; and if the Council do not more carefully study the interest of exhibitors, it will be poultry that will finish it. Practical influence must be used to settle this important matter, and I suggest that a meeting of exhibitors be called to meet at the Queen's Hotel, Birmingham, on the Tuesday of the Show week. Mr. Hewitt, I dare say, will be courteous enough to attend; and if some influential exhibitor will do this through the medium of your paper, or otherwise, it would be the time to get a stronger muster together than any other that could be appointed. I am convinced it would be largely attended. I am in the habit of meeting weekly a large number of poultry exhibitors, and I know the feeling upon this point. This unfair system of appointing Judges to emanate from our mother Show, proves to me the importance of a poultry club. This also might be discussed at the meeting.—AN OLD EXHIBITOR.

### SALE OF THE LATE MR. BULT'S POWTERS.

ON Tuesday last, November 18th, Mr. Stevens submitted the entire stock of the late Mr. Bult to public competition. The reputation of this strain of birds attracted buyers from almost all parts of England, and the result was a very spirited competition, and a most satisfactory sale.

The birds were seventy in number, and in such capital condition as to reflect great credit on those in whose charge they had remained since the lamented death of their late owner.

They comprised Blue, Black, Red, and Yellow Pies, as well as the White and Mealy varieties. Four of the old birds—a White, a Red, a Blue, and a Black Pied realised five guineas each; seven others went at between £4 and £5 each; and the average of the remainder may be estimated from the fact that the seventy birds, old and young, produced upwards of £180.

Some of the best of the old birds did not produce as much money as might have been anticipated from their very superior character; several of them in private hands would readily realise £10 each, but the deficiency in their value was fully made up by the extraordinary prices of the second and third-rate birds, many of which went at from twice to thrice their value. When we state that two hens of no very remarkable character or length of limb, one a Black Mottle and the other a Mealy, produced over £3; the Pouter-fanciers amongst our readers will readily see that the inferior birds were well sold. We can only attribute these prices to the desire to possess some birds of Mr. Bult's strain, and the fact that this was the final sale of his stock.

The best of the strain remain in the hands of the members of the Philopisteron Society, of which Mr. Bult was Chairman. Two of the members alone expended upwards of £100 in the purchase of the most desirable birds. Few events have caused greater interest amongst Pigeon-fanciers for many years than this sale, and the general attendance of gentlemen from all parts of the kingdom, must be, to the members of Mr. Bult's family, a gratifying tribute of respect to his memory.

### MR. TATE AGAIN!

SOME time since I wrote to a man named G. R. Tate, at Driffield, for a white-legged Game Bantam cock. He sent me two to choose from, first demanding payment. Fortunately, I refused to pay for them until I saw them. One I liked and retained, sending the other back with post-office order for his price, paying also carriage both ways. Mr. Tate wished for a willow-legged pullet, and as I had some very good ones I sent him one, stating the price in money, or that I would exchange it for a cock. After several excuses and delays, and much correspondence had passed, I wrote to him peremptorily demanding the bird back again. Finding I was in earnest, he writes to inform me that he cannot send the bird back, as he has "sold it!" With this cool communication, he forwards to me a miserable little Bantam cock, with white wings and splashed breast, not worth the 2s. 9d. carriage, and tells me I can have it by paying him 7s. 6d. more than the price I asked for my pullet!

You are at liberty to make any use of this communication, and I will take the responsibility; and if your readers are made aware of the facts, perhaps the man may not succeed in taking-in another.—T. C. HOSE, Harpenden, Herts.

### HONEY HARVEST ON THE YORKSHIRE MOORS.

My four hives together do not reach 40 lbs. in weight, so that I am feeding as fast as possible before the frost sets in. They were sent to the moors, but were lighter on their return than when sent off, having cost me at least 15s.—J. C., Mill Bridge near Leeds.

### BEEES AND BEE-HIVES IN THE INTERNATIONAL EXHIBITION. (Continued from page 581.)

PETTITT, W. J., Dover, No. 2162, shows one of Major Munn's bar-frame hives, of which we give an engraving. It is stated

that "each comb can be lifted out and examined without interfering with any other part of the hive, or occasioning the loss of a single bee. The whole of the interior of the hive is open to inspection at any moment, and a choice can be made of the combs containing the most honey; or the apiarian is enabled to trace the devastation of the wax-moth and ascertain the presence of any other enemy without the assistance of any fumigation whatever. Ligurian queens can be introduced into this hive without difficulty, the glass observation-frame affording the necessary protection to the most timid operator." Major Munn's ingenious hive was invented, and, we understand, was patented by him both in England and France many years ago, but has never come into general use. Mr. Pettitt also exhibits a White's hive with a covered way between the two boxes. The communication with supers is formed by a sort of grating cut in the top of the stock-box; the interstices between the bars of which being only three-sixteenths of an inch wide, are expected to exclude both queen and drones from the super.

DOWNIE, ROBERT, Barnet, No. 2107 (in Taylor's conservatory), has a small wooden hive, 10 inches square by 9 inches deep, placed on a shelf, within a larger box, on what is usually called the American plan. The hive itself is fitted with frames, the interstices between which are closed by simple blocks of wood of the requisite width laid across the top of the hive and between the bars. When the bees have filled the small box, they continue their combs below the shelf, and may be inspected through a window in the back. Mr. Downie states that the under shelf with the combs attached to it may be taken out and returned without injury. This American plan is curious and interesting from the fact of the bees extending their combs below the hive itself, much in the same manner as they will sometimes do in the open air; but the queen cannot be kept from breeding in the combs thus built, and, as the plan affords few facilities for deprivation, we have been unable to discover the advantages which it offers. There is also a ventilator for bee-hives, which is simple and easily managed; and a unicombe-case, which is proposed as a substitute for a unicombe-hive, and to supersede the use of bell-glasses or supers of any kind. It is a flat case with glass sides, accommodating a single comb which can be removed and returned at pleasure, and is intended, we presume, to be worked as a super on the top of a hive.

DENMARK.—NIELSON, J., *Frederiksberg*, No. 66.—Dzierzon's bee-hive improved.—We have engraved this hive as the type of

a class of bee-dwellings introduced by Pastor Dzierzon, and very generally used throughout Germany. They are called "twin-stocks" or "double-stocks," the unit being a hive capable of accommodating two distinct stocks of bees side by side on the same level; and when this arrangement is doubled, trebled, or quadrupled, the hive is known as a "vierbeuter," "sechsheuter," or "achtbeuter" as the case may be. The one before us is an "achtbeuter," or a hive for eight stocks of bees. From our point of view we see the entrances to four of these, whilst the open door affords us a view through their glazed sides of the same number of interiors. Were we to take up our position on the opposite side we should command a view of the entrances to the remaining four compartments, and a similar door would afford us the opportunity of inspecting their interiors. Taken individually, each compartment may be considered to form a complete "lager" hive, which a partition placed at a distance of two-thirds its length from the entrance subdivides into "brood-room" and "honey-room," communication between which can be allowed or interrupted at pleasure. There are ten frames in every brood-room, and five in each honey-room, all being of the same size—viz., 9 inches wide by 10 inches deep, and of such width and at such distance apart as to be 1½ inch from centre to centre. The glazed side of each compartment is moveable, and by this means all operations of depriving, &c., are conducted. The whole exterior except the roof is well thatched with straw; and we can imagine that the combined animal heat of eight stocks of bees, which are only separated from each other by partitions of thin wood, is well calculated to set at defiance even the severity of a winter in the north of Europe.

(To be continued.)

THE ALANTHUS SILKWORM.

The more experience we have of the management of this insect, the more we are convinced that its culture is destined to become an important branch of native industry. We have just

received a communication from Lady Dorothy Nevill in which her ladyship says, "To show their hardness even in this bitter weather (thermometer 25° Fahr.), I have some worms spinning under some garden-lights just placed against the wall, where the frost has got in and killed all the leaves of the Alanthus they are feeding on. Some have died, but I have got a few nice cocoons only gathered a week ago, and there are others still spinning."

Nothing could be more confirmatory of the hardness of this worm, and it seems to be only a question of supply of food and organisation on a sufficiently extensive scale when this industry shall be established in the country.

OUR LETTER BOX.

COCHIN-CHINA COCK (*A Subscriber*).—Your Cochin cock with a rattling in his throat has a cold, and nothing more. In an airy house, with door and window, you never want a stove—all artificial heat of that kind is bad. Extra warmth should be produced by extra feeding. Your selection of food is varied, but not judicious. Take off the Indian corn, potato peelings, and sharps. Give ground oats mixed with water; for a change, whole corn and the sweepings of the table after every meal. Lettuce is better than cabbage. Give the cock some bread and ale twice per day till the rattling is gone. We advise you to breed only from the white Cochins that are not vulture-hocked. There is no hope of breeding perfect birds from defective parents.

FOWLS SUFFERING FROM DIARRHŒA (*C. S.*).—Your fowls purged and voiding slime, &c., suffer from disease of the digestive organs of most decided character, and we believe if you were to dissect one, you would find the gizzard ascid and totally unable to perform its functions, which are those of a mill; hence the passage of the stones, which should remain to crush the food. Shut up the diseased birds in a place where they can be easily caught and watched, give them daily a tablespoonful of castor oil, feed on stale bread only. Continue this treatment until the colour of the evacuation is brown mixed with white. When this takes place the bird is cured. If the dose prescribed seems too much, you may lessen it. When the bird has visibly improved discontinue the oil, and give the bread steeped in ale. Much green slime will probably come from the bird, and when the evacuations are firm, brown tipped with white, the bird is well. Fat would not account for this disease.

GAME COCKS BACKWARD IN MOULTING (*W. J.*).—Give your fowls stale bread, eggs if you have any to spare, cooked meat chopped fine, especially the knuckle of leg or shoulder of mutton, and a few peas or small Heligoland beans daily. Let them roost in a clean house and free from draught. You will see a great change in a fortnight.

WEIGHT OF TURKEYS, DORKINGS, AND AYLESBURY DUCKS (*Farmer's Wife*).—Thirty-eight pounds would be a good weight for three six-month-old Turkeys. You need not be discouraged if they weigh a little less. They should have, if they are to be comfortably shown, a pen at least 5 feet long, the same depth, and 4 feet high. There is no objection to its being rather longer. If you contemplate exhibiting, we advise you to put the birds together for some days before they go to the show, as it is not uncommon for the cock to spoil and sometimes to kill the hen by beating. The Dorking chickens are hatched late if they are for exhibition this autumn, but perhaps you have neighbour's fare. Cock and two pullets should weigh 18 lbs., a pen of Aylesbury Ducks 16 lbs. Make them heavier if you can. We have given you the ordinary weight of birds not prepared in any way for exhibition. Your Dorkings should have a coop or basket 42 inches high, 30 inches long in front, and 30 inches deep. If they are to be shown in the open air at this time of year, let the back and sides be covered with carpet or sacking.

WHITE DOWNY-FEATHERED FOWLS (*Othello*).—They are the Silk fowl, or Silkies, natives of China, Japan, and some parts of India. They are not rare, and having no particular merit no special prizes are offered for them. They are found occasionally in the class for "Any other variety." They require the same treatment and food as the Bantam, or, indeed, any other fowl.

DUCKS (*J. Bradley*).—There is no separate work about these birds. There is an abridgement in our "Poultry Book for the Many" of the articles concerning them which appeared originally in "The Poultry Book" with coloured prints, but which is now out of print.

RABBITS (*Gardania*).—If Rabbits are fed on green food, or even partially on green and partly on dry food, they do not require water; but if they are fed wholly on dry food—such as clover hay, meadow hay, oats, and bran, they should have water regularly twice a-day. The best daily food for Rabbits is clover hay, or oats, and bran morning and evening; and green food—such as sow thistles, endive, green clover, turnips, or mangold wurtzel in the middle of the day. As to the quantity, Rabbits will not eat more than they require. You will soon be able to ascertain how much to give them by noticing how much they leave after every feeding time.

BEES DESERTING THEIR HIVES (*An Old Waterloo Pensioner*).—The insects you enclosed appear to be immature specimens of an ordinary species of *Psocus*, which is frequently found in old combs, but which can exercise no injurious or other influence on the bees themselves.

SICK CANARY (*M. T. S. L.*).—The bird gasping and sneezing, &c., has a severe cold. It should be kept in a warm place free from draughts, a little chopped egg and bread given to it, and a piece of liquorice about the size of a pea put in the water. It must also have a glass of fresh water every morning if liquorice be given.

LONDON MARKETS.—NOVEMBER 24.

POULTRY.

Trade is very dull at Leadenhall, and we see no prospect of an improvement. The supply is greater than the demand.

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 47.2° and 35.2° respectively. The greatest heat, 60°, occurred on the 7th, in 1856; and the lowest cold, 14°, on the 5th and 6th, in 1814. During the period 114 days were fine, and on 131 rain fell.

SEA-KALE FORCING.

THE majority of our ordinary fruits and vegetables are in the best condition when grown without any application of artificial heat. Forced Strawberries rarely, if ever, have the flavour of those grown out of doors, neither have Peaches that come in very early, though later ones under glass, which receive almost total exposure at the time of ripening, are undoubtedly good; and Grapes rarely or ever

ripen properly in this country without such assistance. Fruits that will ripen during our summer are invariably better flavoured than the same kinds when forced into use at an earlier period. I do not mean that those which are starved into a sort of half-and-half maturity in the autumn are so good; for these evidently wanted a longer summer to perfect them.

A like remark holds good with vegetables that are subject to artificial heat. Kidney Beans in February rarely taste so well as out-of-door ones do in July, neither do Rhubarb and Potatoes, although the almost total exposure which is given to the latter before taking-up time makes them in a great measure out-door productions, and the season they come into use renders them acceptable; in fact, all forced things are more or less esteemed in consequence of the unnatural period at which they present themselves.

Taking, therefore, for granted the fact of most forced fruits and vegetable being inferior to the same kind when grown in a natural way, it may be safely pronounced that the one I now speak of is an exception to that rule; for when Sea-kale is grown in an ordinary way with full exposure to the atmosphere, it loses that crispness which is its most essential point of merit. Forcing, therefore, instead of diminishing the quality of this vegetable improves it, or, at least, a peculiar mode of cultivation is necessary to bring it to the condition fit for table, and this condition being so essential to the article, no apology is needed in bringing the matter before the readers of THE JOURNAL OF HORTICULTURE at the present time.

It is needless to point out the antiquity of this vegetable. It is likely its first qualities as an article suitable for human food may have been found out by some poor fishermen or others living by the seashore, who, attracted by the succulent and apparently edible character of the shoots rising through the sand, were induced to try how these tasted in a boiled condition. Having found them a greable in this state, it is easy to conjecture that culti-

vation followed on the heels of such a discovery; not fast, it is true, as there was no COTTAGE GARDENER in those days, and the spirit of inquiry was only sharpened so far as to secure the requirements of the individual rather than to compete for the fame which successful experiments invariably entitle the lucky discoverers to receive at the hands of a discerning public. It is, therefore, likely that some ages elapsed ere Sea-kale was thought of in any other light than as a useful weed, available at a certain time for human food, and receiving no further attention at the place it grew than field Mushrooms and some other things get at our hands at the present day. Be that as it may, certain it is that Sea-kale has been in cultivation for a long time with but little change in the mode of treating it, which, simple as it is, has, nevertheless, certain features in it which, if not duly attended to, the result is seldom satisfactory. I offer, therefore, a few observations on the subject.\*

SOIL.—It is easy to conceive that a plant inhabiting the seashore must of necessity like a fair share of salt spray: hence some growers have thought that adding large quantities of salt to a stiff clayey soil was all that Sea-kale wanted—nothing could be more absurd. Beef and pork require large quantities of salt to keep them; but no one ever thinks of using this useful seasoning to preserve summer fruits. And although salting a piece of clayey ground is not so bad, perhaps, as putting salt instead of sugar into Mrs. Storecloset's jam, marmalade, or jellies, the difference is less than many would think who have not noticed the effects of large quantities of salt on stiff clayey ground. It is, therefore, better in all cases where Sea-kale has to be planted on such ground to dig-in with it as much sand as can possibly be obtained, removing as much of the clay as possible, and after obtaining a depth of 2 feet of loose porous material with a perfect drainage, Sea-kale may then be planted with a fair chance of success. If plenty of sharp sand has been added that is free from all mineral matters of a noxious kind, salt may, after a little time, be given as a dressing, very little at a time; previous to that, however, I may say that some useful manure may be applied, for Sea-kale is not indifferent to good living—it likes other things as well as urine. Soils possessing the above requirements

\* The common people on the western shores of England have, from time immemorial, been in the practice of watching when the shoots begin to push up the sand or gravel, in March and April, when they cut off the young shoots and leaf-stalks, then blanched and tender, and boil them as greens. The precise period of its introduction to the garden is unknown, Parkinson and Bryant state, that the radical leaves are cut by the inhabitants where the plant grows wild, and boiled as Cabbage; and Jones, of Chelsea, assured Mr. Curtis that he saw bundles of it, in a cultivated state, exposed for sale in Chichester Market in 1753. Maher states (Hort. Trans., vol. i.), that the *Crambe maritima* was known and sent from this kingdom to the continent more than two hundred years ago, by Lobel and Turner; but Miller, in 1731, was the first who wrote upon it professionally. About the year 1767, it was cultivated by Dr. Lettson, at Grove Hill, and by him brought into general notice in the neighbourhood of London. In the "Gardener's Dictionary," published in 1774, by Gordon, at Fountain Bridge, near Edinburgh, directions are given for the cultivation of this vegetable, and for blanching it, by covering the beds 4 inches deep with sand or gravel. Professor Martyn has printed some valuable instructions for its cultivation, from the MS. of the Rev. M. Laurent; and Mr. Curtis, by a pamphlet on its culture, did more to recommend it, and diffuse the knowledge of it, than any of his predecessors.

in abundance, or, perhaps, superabundance, must have a little more depth given, and, if very dry, a larger proportion of salt may be added here than to the plantation resting on a clay bottom; for, notwithstanding the artificial mixture the roots may be in, such bottoms have a tendency to render composts laid on them somewhat like themselves. Sea-kale, however, is very accommodating, and rarely fails to grow anywhere, but in certain places it does so better than in others.

**SOWING AND PLANTING.**—It is a very good practice where a fresh bed in wanted to sow the seed on a bed of good garden soil, and when the plants are about the size of table Radishes to take them up carefully, and plant them where wanted. This operation ought to be done in moist weather. Sometimes the seed is also sown in rows 18 inches or more apart. When the plants are allowed to grow, to be taken up for forcing, some little thinning here is also wanted; but in very good soil, crowns with roots like fair-sized Carrots may be had in one year, and these do admirably for taking-up and forcing. In planting for forcing on the ground, on the old-fashioned system of covering them up with heating material—as leaves, dung, or tan—the plants may be about 3 feet apart each way, and if three plants were planted together at one place, something like flowering Stocks in a mixed border, there would be a better chance of a good head than if only one plant were put in. Plants from seed are best, but we have sometimes taken up an old plant, and having cut up its roots into small portions of 1 inch or 2 inches long, scattered them on a bed of good soil, and slightly covered them with fine mould, taking care that they did not suffer from drought until they began to sprout, and when sufficiently established to move they were transplanted to their final quarters. Seedlings, however, are better when they can be had.

**FORCING.**—Hardy as this plant is, and bad as the treatment it often gets, and yet recovers from, it is, nevertheless, not to be driven too hard at all times, and before Christmas it requires more coaxing than it does afterwards. The reason of this is obvious. The plant, like all others, requires rest, and as this does not take place until October it is not to be wondered at that it becomes impatient if urged into activity in less than a month afterwards. Very urgent forcing then is, therefore, resented; the plant either refuses to grow at all, or sends up a weak spindly head not much better than straw—a mere apology for what it ought to be. Slow and careful forcing must, therefore, be accorded to it for the first crop; the second may bear a little more urging, and after the middle or end of January it will endure pushing-on without complaint. Generally speaking the easiest way to obtain an early batch is to prepare some plants for taking-up, to lift them with as much root as possible, and to plant them in some corner of the Mushroom-house. If that is not available, a good deep box may be filled with roots planted in soil, and placed in some warm, but not too dry, dark place. The Sea-kale will begin to grow in good time, care being taken to exclude all air and light from the growing shoots by a covering of some kind. In some places where this vegetable is extensively grown there are, however, pits heated with dung or fire heat, in which are shelves of the proper depth to receive the roots at once. A moist heat must be given, otherwise the shoots instead of being crisp would be tough; a common hotbed frame or box with a darkened top answers very well, and covering ordinary glass lights with litter is also successfully resorted to; only at such times glass is much wanted elsewhere. But the modes in which this easy kind of forcing may be carried out are so varied and yet so easy as to present themselves to all who have only the most limited means.

Forcing in the ground is another matter, and though much discontinued in places where heating materials are scarce, it is still done extensively in most country places. The plants occupying sites about a yard apart, pots somewhat like chimney-pots, or boxes of a like shape are put over the heads, and a sort of lid over the orifice of each. The whole ground and these pots or boxes are then covered over with heating material, the ground underneath and the air inside the pot or box being, consequently, warmed, the plant is induced to grow, and is examined at times to see if all be going on right. Over-heating is the powerful evil to contend against here. It is better, therefore, to use leaves only if they can be had, as they seldom heat to injure anything; whereas, horsedung and tan often heat to excess. The gentle heat imparted by oak or beech leaves will bring on Sea-kale as fast as necessary, and the more slowly it is grown the stouter it is. Occasionally examining the heap to ascertain if any part of it lacks the necessary warmth is proper

now and then; for it sometimes happens that by a long succession of drying easterly winds penetrating the mass there is no heat. In such cases a barrowload or two of hot stable dung inserted in a place altogether, not mixed with the mass, but in a lump amongst it will create a heat which will be imparted to the surrounding leaves, and a good result will follow; but it is necessary to examine now and then to ascertain if any part be too hot, and if so, this evil must also be rectified by removing a part of the heating substance before it does much mischief, otherwise scalding, as it is technically called, will occur.

**CONCLUDING REMARKS.**—It is needless describing what a good head of Sea-kale is, that only good, healthy, well-grown plants can produce early in the season, afterwards it becomes stronger from plants that were no better in the autumn. Forcing always sacrifices quality in proportion to the extent to which it is carried. Some care is also due to the plants after the heads are cut off, which they do not always receive, and suddenly exposing such plants to the severity of a February frost is trying in the extreme. Gradually uncovering them until mild spring weather sets in must be adopted, after which the ground may be dug with the fork, and the plants allowed to grow on for the summer. Do not remove the flower-stems that will in all cases show themselves until they have been all fully out into flower, when all but such as may be wanted for seed may be cut away, and they will not form any more seed-stems then; but cutting off every effort to flower at the beginning only encourages other efforts in that direction. Should any plant die off, remove as much of the old soil where it has grown as possible, and bring in fresh before planting others, as like most other things they do not like to grow on the same spot again. I had almost omitted to say that in addition to the successional forcing in the open ground, the last batch may be covered-up with pots or boxes in the usual way, and instead of these being covered over with heating material they may be filled with sand or sand and ashes, through which the heads of the plant will force themselves, and produce a better article than can be obtained by forcing; it will, however, be late: nevertheless, on that account may not be the less useful. Darkness is the most essential thing to obtain good Sea-kale, whether in a forced or natural condition. J. ROBSON.

#### THE PLANT FROM NAZARETH—CENTAUREA CANDIDISSIMA AND GAZANIAS.

WHAT about the "plant from Nazareth," page 573, the *Paronychia arabica*—that "very pretty basket-plant out of doors in summer," and that "very pretty, interesting, and peculiar-looking plant?" And what about the fact, too, that nobody asks anybody else ought more about so "very pretty" a plant? a basket-plant, too, to hang outside the window in pairs, at the opposite corners, or from the doorsteps of the library, or from brackets, where you could see them, just at the height of the eye, glistening in the sun with their silvery, shining leaves, and their "peculiar-looking" tufts of emerald green, in close-jointed knots, along the full length of their gracefully slender pendulous stems. Surely all this is not going to pass off like that which goes in at one ear and out at the other.

But what else can we have, or what so "peculiar-looking," and so "very pretty," as the plant from Nazareth, and more especially so when grown as they grow plants in London?

The next thing will be how are we to procure a supply of it from seeds, for in no other way will it pay to grow it. Who has the best Syrian or Tyrian correspondent? The one or the other, or both in one, might manage to obtain it in quantity. But the fact is, we have had it already in abundance in the London seed trade; and in Surbiton, too, we had large supplies of it for ever so long, and no treatment would grow it half so well as that in the Waltonian Case.

Mr. Walton himself had the credit of surpassing every man and master in Surbiton in the management of the plant from Nazareth—the *Paronychia arabica*; but whether he picked up the seeds on his travels, or bought them in London like the rest, I do not know, but I know some bought seeds of it in London, for I saw the plants four or five years back.

In the long vacation, our best people in Surbiton travel all over the face of the earth. It was only last May that a lady here brought out two plants for me to name for her. The seeds were gathered the autumn before, on the very spot where Jericho is said to have stood. The plants were the common sweet Tarragon. The same party might have taken Nazareth

on their way to Jericho, if they went by the low country. But it is more likely the plant might be seen all over the country. At all events, we must have a supply of the seeds next spring if they are to be had, and see what can be done with it.

I was not aware that the plant was such a good basket-plant till I read of it in this Journal; but, when I was on my botanical horseback, this was just the sort of plant to pay for its keep, and if they had then spoken to me about a Dahlia without a bull's-eye, round as a target, I would sooner spur against a five-barred gate than listen to such folly.

*Paronychia arabica* is a very miffy plant for the first month after sprouting from seed, but, once established in single pots, it gives very little trouble. It often struck me as almost certain, that the way of lawyers in their studies, and in their practice of the law, is the next best way to ours to be first-class gardeners, and the best on the list for being the most successful amateurs. You might think the medical profession had a better start for gardening than that of the law: I thought so too at one time, but I am now sure of the contrary. It is not that deep study into the nature of plants as into the depths of our being, which can make a man a first-class amateur in gardening. It is only through the application of the simplest niceties—the minutiae as we call it, that an amateur can come up to a gardener in many things. The minutiae, or the essence of nicety, is constantly present in the mind of a lawyer, and by that quality of his mind he can split a hair into two equal parts, which is equal to dividing his attention to half a fraction in the summing-up of a process, or in the doings for a plant however minute. And all this time he is on the exact road for a plant to go on its course to whatever its nature is capable of being pushed to, while the man of means and medicine is still in the circle of the mysteries of the plant's being.

Then, to grow *Paronychia arabica* as Mr. Walton has done here in Surbiton, you must split the hairs between having it neither wet nor dry, too cold nor too hot, without too much or too little light for the first month of its coming from seed. Also, you must use very light soil, and the little seedlings must be put six together in a No. 60-pot at the first potting, and when that is quite full of roots divide the ball into six equal parts, and each part with its plant to have a No. 60-pot for itself, and the hair-splitting to go on all this time, and to the day that each No. 60-pot is fit to be changed for a larger, and from that day forth there is no more risk in doing it than there would be in growing *Lobelia speciosa* from seeds saved on your own premises, or at the Crystal Palace.

The next plant on my list I must put off, to tell of a very pretty little *Geranium*, which is mentioned at page 685, or last week, in the column for correspondents. Little Dot is the name, and it belongs to our worthy friend, "THE DOCTOR'S BOX." Well, "THE DOCTOR'S BOX" sent two cuttings of it in the summer of 1861, rather late, and they went the way of all *Geraniums*, in that frost which did my *Cyclamens* down to the roots; and so it was till towards the end of the last bedding, when "THE DOCTOR'S BOX," nothing daunted, sent up a full-blown plant of it, and I had it to prove, in full bloom, to the very end of the season, and the responsibility of the verdict rests on my shoulders.

Little Dot is the most dwarf I have seen of the *Lucia rosea* breed; it is also the best horse-shoe-leaf I have seen in that strain, and it is the most profuse bloomer I have yet seen of that much-admired section of the bedding classes. Young plants of it would make a match edging to a bed of old plants of *Christine*, and the flowers would be as much a contrast as the size of the plants, and the marking on the leaves of Little Dot. The shade of colour is very near that of *Lucia rosea*; but it might be a shade deeper or lighter in the height of summer.

The next lowest *Geranium* after Little Dot is my own seedling Harry Hicover, which, when planted in two rows for an edging, makes the most perfect ring of all round the garden; but unless the plants are two years old, one row of it is hardly sufficient for an edging.

I saw another *Geranium* at Mr. Salter's nursery the other day, which came out last spring for the first time, and I think it would take a place between Little Dot and Harry Hicover. I quite forgot to take down its name, but it is of the strain of *Lucia rosea*, and very lively and dwarf.

These very dwarf sorts are gaining in public estimation year by year. Mr. Gordon tells me that *Blush Minimum*, the least conspicuous of the lowest order of bedders, is more talked of at the Crystal Palace than any of the best large ones, and that is

why he uses it in all parts of the garden so freely as an outside row, or as a row next to *Lobelias*, or plants like them.

Now, Little Dot, Harry Hicover, and Mr. Salter's seedling of last spring, will be invaluable at the Crystal Palace, where people begin to look already for the best and greatest novelties.

I saw another move at Mr. Salter's which deserves extensive imitation with *Centaurea candidissima*, the most noble-looking of all our white plants for edgings, and for ribbon rows. A large batch of it was planted out last spring in pots, as is now done with *Unique Geranium*, and other bedders about London, to have them in bloom a month earlier for the London season. The plants must have been small in the spring, for they were in No. 60-pots; but the roots grew out at the bottom of the pots, and over the rims at the top, and made strong bushy plants, which stood all the frost of this November without a single leaf being hurt. This, then, appears to me to be the very best plan for amateurs to adopt with *Centaurea candidissima*—to have the plants in No. 48-pots in April, to plunge pots and plants 2 inches below the surface, to water the hole for the pot before putting it in, and to see the plant itself has been recently well watered, and if the time of planting is very dry, or very hot, or windy, to see the pots watered once more in about ten days, then to let them take their chance for the rest of the summer. Now what is more handy, when we are all on the trot by the frost, than to find, or to know that the very best plant of all the bedders may be left out without injury, as long as the glass keeps on the safe side of 20° of frost? Then up with them, pots and all, and if you are hard-up for pots, as most people are at that push, why the *candidissima* may be plunged in some light, half-dry compost in a cold frame without any pots, and be as safe as any of the cold-pit plants in common use.

There is no reason, therefore, why the cottager, who can have his Tom Thumbs in order, should not also have the most princely plant of the day by the selfsame process, if not by a far more simple one. I think my own plan is about as simple as any for keeping all odds and oddities over the winter without pots. I have twelve lights crammed as Mr. Fish crams his faggots into pots, but not over a score of pots beneath, and they with only one plant in a pot, some pot plant or another I can keep the frost off, and that is all.

The secret is in two parts. I take every morsel of a leaf off, the leaf-stalks, and the blades which accompany the joints; but I make no cuts to fester. Every shoot of *Geranium* is left the full length it was at the time of lifting, and such pruning as I may think necessary done some time before the lifting; then the whole are planted in a light moist compost as close together as they can stand; and as the work proceeds the whole surface is covered over with rather more than an inch deep of dust-dry compost, made so on purpose for this work, and for four months no water is given to three thousand plants. The lights are open every day that is not wet or frosty, and it is very seldom indeed that I see a damp shoot or any signs of damping. *Lobelias*, *Cyclamens*, *Gazania splendens*, *Cherry-pies*, *Aretotis*, *Farfugiums*, and all kinds of *Geraniums*, are thus treated the whole winter, and that puts me in mind of another turn I had this season, and which is not amiss in its way.

What would you say to doing *Gazania splendens* as Mr. Fish does the *Calceolarias*?—put in the cuttings in the middle of November, and keep them as cool and as moist as the *Calceolaria* cuttings through the whole winter. Well, from what has occurred with me, without trying for it, it strikes me that will be the best plan with *splendens*. But I put in my usual stock of cuttings of it at the end of August in the open ground, just like cuttings of *Scarlet Geraniums*, and nothing could do better; they all rooted, and while they were rooting the stems ripened and hardened, so that no damp can hurt them at all events, planted in that pit as closely as they can stand.

But I had three large old plants of it in pots the whole season with some of the shoots 18 inches and 20 inches long, and kept half-starved in pots on a high stand full in the sun, the shoots hanging down as from a vase. That plan was adopted as the last I could think of to cause the plant to seed, and if it seeded to cross if possible; but all would not do, the *Gazania splendens* will not seed here by any means known to me or that I can think of, neither will *Gazania rigens*.

In the beginning of October I shook the soil from their roots, cut off the long branches, and put the plants in by the heels in the open ground, and in the beginning of November I had them planted in my omnibus pit, and before I had all in I had to

change the *Gazania* plants to another light, and then I found every part of the stems which was in the ground, or touched it, had rooted as freely as if it were July, perhaps more so; and as the old roots were almost all cut away with the balls, and no sign of growth in the parts of the roots which escaped, while all the young wood or shoots were one mass of young roots, it would seem that November is as good as any, if not the best, time to put in the cuttings of splendens, and if so, probably also those of rigens and uniflora.

Another way would be still as handy for people who are pinched for room at the time of housing the harvest of the beds. It is this, and it is not too late now—to lift so many of the old plants out of the beds, or rows, to cut away all the spreading shoots, leaving only a cluster of very young shoots near the collar of the plant, and to plant the whole in a narrow box, or boxes, so that the young growth might hang out on either side of the box without coming in contact with the soil which might cause dampness. Several boxes of that kind of make have been so planted this and last season hereabouts, and at planting-out time last May, every old plant made so many plants by dividing, besides a whole complement of cuttings by the middle of last March, and the plants so obtained were not one day behind those which were had from autumn-struck cuttings, which had to be carefully kept and watched all through the winter. But who will put in a batch of cuttings now of *Gazania splendens* to see if they do as the *Calceolarias*? D. BEATON.

### FORTHCOMING ROSES.

THE opinion that I expressed after my run through the Paris Rose-nurseries in July seems to be but partially correct—viz., that this year would not witness so large a number of new Roses sent out as last. In the main it is so, and especially so far as the Paris folks are concerned; but still the number is sufficiently large—much, too much so, I have no doubt. Knowing the eagerness with which any information relative to the queen of flowers is sought after, I have appended to this a translation, as literal as I could, of the descriptions furnished by the several raisers. For the general list I am indebted to the kindness of Mons. Eugène Verdier, fils aîné, although, of course, he is not responsible for their correctness. Those only which I have seen are *Louise Margottin* (Bourbon), and *Madame William Paul*; and of both I am inclined to form a very favourable opinion. If one is to be guided at all by the former doings of the several raisers, we might guess that 2, 7, 8, 11, 13, 21, 23, 28, 26, and 42, are likely to be the cream of the others, but of this time can be the only judge. The raisers are extravagant enough in their praises, and in the names of the colours they employ. There is some difficulty in comprehending what a "Rose virginal" is; but what in the name of all that is matter of fact are we to understand by "euisse de nymphe satiné?" A nation that can fight for "an idea" may be able to comprehend it; but poor John Bull can only hide his blushing face, and say it beats him.

I believe that never since Roses were grown have so many been sent forth from the various growers as this season. From all quarters I hear the same story—overwhelmed with business, and unable to overtake the orders: and such contests as there will be for cups, and medals, and prizes, surely have never yet been seen. If the year 1863 be favourable it will be a Rose-year indeed. Many of the new Roses will, I think, take a good position; and vigour of growth is, I think, likely to be a marked feature in many of them. I hear, too, of more new English seedlings. Mr. Cranston has some of which he hopes well; and Mr. Ward will not be contented to be the winner in one battle, but hopes to bring forward others to follow in the wake of John Hopper. There will be work for all next year if we are spared to see it; and may prosperity attend the court of her Rose majesty!

### NEW ROSES OF 1862-63.

#### TEA-SCENTED.

1. *Comtesse de Brossard* (Oger), plant very robust; very full of flower, full canary yellow. Standard.

#### BOURBONS.

2. *Emotion* (Guillott père), plant robust; flower pretty full. Perfect form.

3. *Louise Margottin* (Margottin), plant very robust; flower large, full, and very well made; rose, soft, very satiny, verging into a white. Very fine.

4. *Mons. de Lunières* (Robert & Moreau), plant very robust; flower tolerably full.

5. *Rochambeau* (Robert & Moreau), plant very robust; flower tolerably full, blooming in clusters. Fine lively rose.

#### HYBRID PERPETUALS.

6. *Tricolore* (Robert & Moreau), rosy lilac. Very effective.

7. *Alfred de Rougemont* (Lscharme), plant robust; flower large, full, well-made, tinted crimson purple and shaded with bright red. Superb.

8. *Baron Adolphe de Rothschild* (Lscharme), tree robust; flower large, full, well made, lively fiery red, often tinged with white. Very effective.

9. *Belle des Massifs* (Ducher), plant robust; flower moderate, blooming in clusters, form of *Anemone*, lively rose. Flowering very abundantly.

9\* *Belle du Printemps* (Damaïsin), plant robust; flower tolerably full, globular, rose striped with red. Sport of *Duchesse de Cambacères*.

10. *Bellotte* (Souper & Notting), plant robust; flower tolerably full, form perfect, rose carmine, darker in the autumn.

11. *Caravane de Nîmes* (Damaïsin), plant very robust; flowers very large, well made, scarlet red. Blooming freely in autumn, and of highest merit.

12. *Deuil de Prince Albert* (Gruad), plant very robust; flower large, full, imbricated, very dark blackish-crimson, shaded in the centre with bright lively red. Very fine.

13. *Duc de Bassano* (Portemer), plant very robust; flower large, full, of a cup-shaped dark velvety crimson. Superb.

14. *Hortense Blanchette* (Damaïsin), tree robust; flower tolerably full, well made, white centre, blush. Flowering in clusters, and producing a good effect.

15. *Impératrice Maria Alexandrina* (Damaïsin), tree robust; flower tolerably full, very well made, white.

16. *Jean Goujon* (Margottin), plant robust; flower very large, well made, guard petals well-rounded, those of the centre smaller, fine clear red.

17. *La Esmeralda* (Fontaine père), plant robust; wood and foliage similar to *Jules Margottin*; flower large, full, lively cherry shaded with dazzling carmine.

18. *La Pivoine* (Robert & Moreau), plant robust; flower large, very full, globular, pæony-shaped, bright poppy-coloured; very flowering and effective.

19. *La Tour de Croucy* (Fontaine père), tree very robust; flower very large, full; very pretty, colour rose.

20. *Laurent Dascourt* (Liabaud), plant robust; flower very pretty, nearly full, interior velvety purple, reverse shining rose, flowering very abundantly. Excellent for grouping.

21. *Le Baron de Rothschild* (Guillott fils), plant very robust; flowers very large, dark red carmine, sometimes shaded with violet. Very fine.

22. *Le Juif Errant* (Granger), plant robust; flower large, full, purple, blackish-violet.

23. *Le Rhône* (Guillott fils), plant very robust; flower very large, full, well made, vermilion red; colouring very rich and brilliant. Plant excellent for grouping.

24. *L'Éclatante* (Guillott fils), plant very robust; flower medium sized, sometimes large, full, or nearly so, well made, black red, shading to purple violet. Very fine colour.

25. *Madame Bianson* (Fontaine père), plant very robust; flower very large, perfect shape, fine bright red carmine, shaded with poppy colour; free flowering. Superb. First-class plant.

26. *Mad. Crespin* (Damaïsin), plant robust; flower tolerably full, regular shape, rose shaded with dark violet.

27. *Mad. Emau* (Pernet & comp), plant robust; flower large, nearly full, globe-shaped, slatish-red purple.

28. *Mad. Freesman* (Guillott père), plant very robust; flower middling, very full, oval, yellowish-white.

29. *Mad. Hélyer* (Portemer fils), plant very robust; flower large, full, globe-shaped, red carmine with black tinge.

30. *Mad. Valenbourg* (Oger), plant robust; flower large, full, well made, bright purple, sometimes shaded with indigo.

31. *Madame William Paul* (Ch. Verdier fils), plant robust; flower medium, sometimes large, full, globular, well made, purple violet, shaded into crimson. Superb.

32. *Murillo* (Fontaine père), plant robust; flower middling, well made, full or nearly full, red velvety purple, shaded carmine and violet, flowering abundantly. Very pretty.

33. *Paul Desgrand* (Liabaud), plant vigorous; flower middling,

full, globular, clear red tinged with violet, flowering continually. Very good for grouping.

34. Peter Lawson (Thomas), plant vigorous; flower large, full, globular, well made, bright poppy shaded with velvety purple. Very beautiful.

35. Prince Henri des Pays Bas (Souper & Notting), plant vigorous, and flowering freely in autumn; flower middling full, well made, nearly globular, bright crimson; petals velvety purple, the reverse lilac. Very beautiful.

36. Princess Alice (Ducher), plant very vigorous, nearly thornless; flower very large, full, bright rose, on the reverse whitish, very sweet-scented, and very beautiful.

37. Sœur des Anges (Oger), plant vigorous; flower very large, very full, very pale carnation rose, passing to white. Sport of the Rose Duchesse d'Orleans; superb and first-class.

38. Souvenir de Charles Montault (Robert & Moreau), plant vigorous, free-flowering; flower large cup-shaped, fine appearance, bright fiery red. Seedling of Géant des Batailles; very fine.

39. Triomphe d'Angers (Robert & Moreau), plant vigorous; flower large, full, flat, very well made, dark velvety purple, shaded with bright red and Bishop's purple; free-flowering. Superb and first-class.

40. Vainqueur de Goliath (Parnet & comp), plant vigorous; flower very large, full, fine, bright fiery red. Stalk firm; foliage remarkable.

41. Valentine de Nerval (Robert & Moreau), plant vigorous; flower middling, full, open, regular, fine bright rose colour, whitened on the edges, free-flowering.

42. William Paul (Guillott père), tree vigorous; flower middling, or large, full, bright crimson red.—D., Deal.

### THYSACANTHUS RUTILANS FOR DINNER-TABLE DECORATION.

I HAVE been much interested in the various articles on this head which have recently appeared in your Journal; and I write to express my surprise that Mr. Robson has omitted in his list *Thysacanthus rutilans*.

It is, when well grown, perhaps one of the most suitable as well as most splendid plants for this purpose. Its long, tropical-looking, jointed stem carries the crown above the line of vision; while its delicate pendent racemes of brilliant scarlet flowers, show brilliantly by candlelight, without intercepting the view. I speak from particular experience at my own table.—A. D. A.

**THE GREAT EXHIBITION.**—A meeting was held on the 26th ult., at the Board-room of the Horticultural Society, for the purpose of presenting to Dr. Lindley an address from the Colonial Commissioners, expressing their thanks for the very valuable services rendered by him during the course of the Exhibition as Superintendent of the Colonial Section. The address runs as follows:—"Before the final closing of the International Exhibition of 1862, we, the undersigned Commissioners, beg to convey to you our warm acknowledgements for the admirable manner in which you have discharged the arduous duties confided to you by Her Majesty's Commissioners. No small share of the great success of our department, to which his Grace the Minister for the Colonies bore such gratifying testimony, a testimony echoed by the voice of public opinion, is due to your advice and co-operation. Personally, we have to thank you for many acts of kindness, and we shall not fail to convey to our respective Governments our appreciation of the valuable services you have rendered to the agricultural, commercial, and industrial interests of the British Colonies." This document, which was signed by thirty Commissioners, was presented to Dr. Lindley by Sir Daniel Cooper, Commissioner for New South Wales, whose short but eloquent remarks were cordially applauded by his brother Commissioners. Among those present were Sir William Holmes, British Guiana and Trinidad; Sir Henry Drummond Wolff, K.C.M.G., Ionian Islands; Mr. Knight, Victoria; Mr. Brown Chamberlain, Canada; Mr. Cowper, New South Wales; Mr. Chitty, Jamaica. Letters of excuse were sent from Sir Charles Darling, Mr. Denison, and others. An address of a similar character was then presented to Mr. Simmonds, a gentleman who has ably assisted Dr. Lindley in his duties. A resolution was then afterwards carried that the address should be communicated to the Duke of Newcastle.

This is not the first occasion on which the Colonial Commissioners have testified their respect and goodwill towards these two gentlemen. During the course of the summer a dinner was given to them at the Ship Hotel, Greenwich, and numerous attended.—*Times*.

### WATER IN GREENHOUSES.

IN greenhouses in the country, where soft water cannot be easily procured, it is highly important that the rain water from the roof should be saved, and in many cases underground cisterns of a costly kind are constructed, out of which the water has afterwards to be pumped. This arrangement is both troublesome and expensive, and can be easily avoided. By purchasing one or more old oil-butts, which can generally be had at the rate of one cent a-gallon, and which usually contain 150 to 175 gallons each, and placing them on end under the centre stage and by bringing an iron, lead, or tin pipe from the eave-gutter (as

shown in the wood-cut annexed), you can always draw the water from under the front stage or table by the tap at B. If more than one cask is required, they can be placed nearly in contact and connected with a short piece of leaden pipe bedded in white lead.

I would also recommend that the centre stage should be boarded-in entirely. It not only conceals a part of the house which is always unsightly, but it diminishes the volume of air to be heated almost one-half. By introducing a row of small lights in one of the risers of the steps at A A, sufficient light will be furnished for a good potting-room, access to which can be gained by a sash-door at one end. I had a greenhouse built on the above plan some five years ago, and have found it to answer perfectly.—(*American Gardener's Monthly*.)

[Without advocating the use of the enclosed portion as a potting-place, for we should prefer it for blanching Rhubarb, Sea-kale, &c., there is much to be commended in the above suggestion as to the receptacle for water. A slate tank might be substituted for the casks.—EDS.]

### VINES IN POTS AT BACK OF A PINERY.

I HAVE just made a stove 20 feet long by 15 feet. It is a lean-to with south aspect; wall 11 feet high; ventilation front and back near the top; door in the centre of one end. I have a six-foot bed in the middle for Pines, 2 feet 6 inches bench in front, and 2 feet bench at the back. Should I have a good chance of growing Grapes in pots on this back bench perpendicularly, or would it be better to have the pots in front, and run the Vines over the Pines? If the Vines would do well at the back, the front bench would be available for stove plants.—JUNUS.

[There is no doubt but that the Vines in pots will do very well on the back bench, if the wood is well ripened, and the Vines are brought on gradually. The plants, if convenient, might have their buds swelled in a frame or pit with a little fermenting matter, and then they would take no harm from being introduced to the heat of the stove at once. Other means, even in the stove, might be resorted to, for bringing them on gradu-

ally. Of course, we are supposing that the pit and the Pines in the centre are not so high as to prevent the light passing over to the back wall. If one hot-water pipe or more passed beneath the back bench, all the better.]

### WHY DOES THE SAP RISE WITH MOST FORCE VERTICALLY?

Has the reason been ascertained of the well-known fact that the sap of a tree pushes with most force in a vertical direction? When a trainer of fruit trees wishes to reduce the vigour of a too-luxuriant branch, he bends it towards the ground. A weak branch, on the other hand, he trains as far as may be in an upward direction, that more sap may flow into it. Other instances might be given: but how is it that the juices of the tree ascend most vigorously in that direction where there is the greatest resistance to their ascent from gravitation?

By-the-by, if the above law holds good, as I believe it does, was Mr. Fish right in saying in one of his communications last year, that the fruit which hangs downwards on a Strawberry, will be larger than those whose stalk is upright? Of course, the larger fruit bends downwards with its weight. But I imagine this largeness is in spite and not in consequence of the bending-down, and that if the stalk were held up the fruit would be larger still.—WYESIDE.

[Had we time and opportunity we might enter at great length into the subject of which your question treats; and if we wished to look learned and conceal our ignorance, we might introduce a great number of high-sounding phrases and scientific terms to show that, in our own estimation at least, we were perfectly conversant with the reasons why, as a general rule, one part of a plant reared itself upright into the light and air, and another part as uniformly buried itself in the earth and darkness; and why it is, as a general rule, not now alluding to exceptions, that the upright stem of a plant receives more of the general nourishment than the subsidiary branches; and why it is that the terminal bud of that upright stem is not only larger, but in general produces in the following season a stronger and longer leading shoot than comes from the subsidiary branches. We think it, however, to be more philosophical, and a great deal more honest, allowing that, as a general rule, the sap flows most strongly in a vertical direction, at once to confess our inability to explain the phenomenon. We just so far recognise it as a fact, and act upon that fact, though we are no more able to explain it than we are in the case of numbers of other facts connected with organised living existences, either in the vegetable or the animal world. In both cases we can investigate the machinery employed, and perceive its thorough adaptation to a destined purpose; but we have little hopes of being able to explain how that machinery works at one time in unison with, and at other times in opposition to, what we are pleased to call the usual laws of nature, until we are able to comprehend the whole of the secrets and phenomena of life. Of that very common thing, life, we know very little, though it be the mainspring in all the movements of organised existence; and until we know more it will be sound policy to reason from facts observed, rather than to puzzle ourselves unnecessarily as to the wholly or comparatively hidden causes of these facts. Having seen nothing in our own observation and experience to enable us to give a satisfactory answer to our correspondent's queries, and having met with nothing in the writings of others, but what to our dull comprehension seemed to render obscurity more obscure, we should all the more willingly and delightedly join our correspondent in wishing for more definite information on this interesting subject, and more especially if such information were the result of experiments and facts, and not of mere theoretical imaginings.

The two practical ideas to which our correspondent alludes are of general importance. When we grow trees for timber, the main stem is the chief consideration; and we allow or direct the chief flow of the sap thither, either by thick planting, in which case the lower branches drop off for want of light and air, or we resort to side-pruning to produce a similar result. When we wish a plant that otherwise might grow too upright for our purpose, we stop the strong shoots frequently, in order that the desired bush form may be gained. When we wish to have a large spreading tree as an ornament to a park, we allow the side shoots to grow along with the main stem, and the sap flows freely into the former, because naturally most of the large branches will start not at a right angle or horizontally, but at an

acute angle, very often of 45°, from the stem. When we cultivate a fruit tree, as fruit and not wood is the object, we must either wait until the stem naturally attains a degree of maturity, or we must resort to means to check the powers of growth, and direct them into processes of fruitfulness. In all such cases extra luxuriance and extra fruitfulness are thoroughly opposed to each other. Hence the whole system of disbudding strong, extra strong, shoots is more effectual for diverting the sap into weaker branches than even removing such shoots altogether. Hence the importance in fan-training against walls of giving a good start to the sides, and keeping back the centre until the sides are well forward, and when the space is filled preventing extra strength in the centre by disbudding, &c. Hence the importance of root-pruning for accelerating fruitfulness, and the mere bending of strong shoots for effecting that object. Bringing the shoot or branch from its upright position causes the sap to flow not only more regularly and slowly, but every leaf is more acted upon by sun and air, and from the increased elaboration of the sap and maturity of the wood fruitfulness is thus induced. But such a branch would in course of time be apt to lose its fertility from several causes—such as, for instance, if the bent branch were forced to make a right angle or an obtuse angle with the upper stem, whilst the generality of the other branches were joined to it by acute angles; if at the point of depression a strong shoot were allowed to grow upwards from the branch, and thus so far rob the rest of its due supply; or if a few branches were much bent near the base of the tree, and the rest allowed to grow upward naturally. The bending process to be successful without weakening must be rather a general process over all the strong branches of the tree. The strengthening effect of elevating the weaker shoots, if we are at all right in our conclusions, will depend not only on the vertical position of the points of these shoots, but also on their starting at an upright acute angle from the main stem. It is true that this will be greatly modified by the law of use and wont; for whatever the natural position of a branch, there will be a relative and correlative action between it and the stem. Hence, we shall be told, that in horizontal training, as in Pears, with branches on each side of the main stem, and placed at right angles or nearly so with it, there are not found the disadvantages of which you speak. But here we would say, that in addition to use and wont, the lower branches had the start over the upper ones; but that even when the space was filled, and the branches very equal in luxuriance, the allowing the stem of the tree to expand into a head above the wall would often starve all these low branches into barrenness. Again, in these cases of standard trees, or half-standard trees, trained in the star or circular manner, we shall be told that the depending branches will remain as healthy and fruitful as the more upright part of the tree; but here, again, we submit that this can only be done by preventing the upright part of the tree getting an extra supply of luxuriance; and that something will also be gained by having these depending branches starting from the bole at an acute rather than an obtuse angle on the upper side. The bend would only be a little sharper, but we have no doubt the flow of the sap would be more uniform. Thus in the representation given of a tree, at page 676, *fig. 1*, the second branch from the base if bent down so as to form the bottom of the tree, we should expect to keep in vigour longer than the base trunk shown, or one leaving the stem at even an angle more obtuse on the upper side.

Much, however, will depend after all on the law of use and wont, as where the sap has once flowed, and buds are formed, the buds and the sap will act and re-act on each other. In all such cases the more vertical parts of the tree must be kept under discipline. There are many cases where a knowledge of this vertical flow of the sap and the law of use and wont enable us to counteract it to suit our purposes, so far as to obtain an equal diffusion: thus, in such a plant as the Vine, spur-pruning will be more apt to equalise the sap than long-rod-pruning, and if the main stem is placed horizontally instead of vertically the object will be still more gained. In the case of a long young rod, the placing it horizontally is almost necessary to the getting every bud to break regularly; if placed vertically, the top buds would break first and strongest. When all have broken, each will, afterwards, pretty well look after itself.

The other practical fact alluded to as being somewhat in discordance with these—namely, Strawberries swelling faster and larger when hanging down than when they are tied-up, we may not be able to explain; though, after trying both modes repeatedly, we still believe that the dependent mode has the advantage.

Of course, if the main fruit stems were to be as much bent as to be injured, that is quite another thing; or if, grown in pots, they were allowed to be injured against the sides of the pots. When grown on a shelf, it may be necessary to guard against this by strings or otherwise, but still to allow them a bent position. Our practice is, that as soon as the flower-stems appear we give them every encouragement; if the leaves are luxuriant—at all extra—we take a lesson from our correspondent, and bend them down over the rim of the pot, so that any extra strength may go into the flower-stems. When the fruit in these begin to swell, and to become pendulous of their own accord, the proper juice passes freely through the main stem and the little stem of the individual fruit, which is not the case when you tie the stems upright; as, unless very great nicety indeed is used, there is not only this vertical flow, but there must be a directly opposite flow through the little stem that supports each fruit. We think, judging by analogy, we thus get good fruit in consequence of this unbroken flow, and not in spite of it, and that the swelling fruit acts as a strain in drawing more nourishment to itself, much on the same principle that the blacksmith's arm becomes strong in sinew and muscle from the use of the hammer. We could give numerous illustrative examples, such as, this season more especially, the best Pears on dwarf standards were those near the ground, and near the point of shoots, where their own weight seemed to bring more of what was needed; as Melons, which are always heaviest and best in proportion to size when the fruit has hung from the vine; as the fact that, in the case of Vines in deep borders, when the incipient bunches have threatened to run-off into screwed tendrils, they have been kept and ultimately made bunches, by clapping a weight on their end; and numerous experiments with bunches of Grapes when they had begun swelling, fastening some so that they should have none of their own weight, and allowing others to hang in their more natural position, and, in almost every case, the last turning-out the best every way. But we candidly allow that on all these matters, as well as the Strawberries, our conclusions may be wrong, even though we think that our observation and eyesight may be right.

We trust that, whatever our preconceptions, we will ever be ready to give them up when convinced of their incorrectness; and although as yet we are unconvinced, we are not the less obliged to our kind correspondent for endeavouring to give us more light on the subject, and only regret we cannot answer his queries more satisfactorily as a compliment in return. When last we visited Hatfield House, of which we have lots of reminiscences, we noticed some peculiarities in Strawberry-foreing, and chiefly, that a shelf, perhaps a yard from the back of a lean-to house, had all the fruit hanging, not to the front of the shelf, but to the back of it, the reflection of the heat and light from the back wall seeming to be more powerful in drawing them towards it than the more direct light from the glass in front. We hope our friend Mr. Burton, a most successful Strawberry-grower, will not think us too intrusive if we say that we and many others would be glad of an account of his experience, as to tying or supporting the fruit of Strawberries upright, or allowing it less or more to depend, and thus exert a greater or less strain on the flower-stems.—R. FISH.

P.S.—The above was written very hurriedly, and without giving the subject the thought it requires; but we may mention that we have omitted to state that weighting Cucumbers has often been resorted to, to cause them to swell large and come straight, and we believe the strain thus made on the fruit-stalk was the chief cause of the effect.]

### NEW GRAPES ON NEW-YEAR'S DAY.

YOUR correspondent, Mr. James Anderson, is in error when he says, in No. 86, that Mr. Thomson, of Dalkeith, is the first and only person that has new Grapes ripe on the 1st of January. I had new Grapes both of Black Hamburgs and Muscadines ripe last January, and have had ripe Grapes ever since. We had old and new Grapes all January and part of February this year. Our Barbarossas hung until February in fine, plump condition; and we should have been better satisfied if our new Grapes did not ripen until February, as I consider it is more difficult to get them to ripen in February and the first part of March than on the first day of the year.

I have a house 60 feet long by 16 feet wide now, in which the Grapes will be ripe by the 1st of January next. There are a fair

crop and some very fine foliage, numbers of the leaves measuring 18 inches and some over 19 inches across.

I have no doubt the berries will colour well, judging from their vigorous and healthy appearance. I have noticed to-day (November 21st), for the first time, that some of the berries are showing signs of colouring.—J. E. F., *Knowsley Hall*.

### A FEW WORDS ABOUT PITCHER-PLANTS AND THEIR PROPAGATION.

THESE ornamental and always-interesting plants should find a place in every collection, and with a little care they are not very difficult to manage.

The species in cultivation that I am acquainted with are *Nepenthes Rafflesiana*, from Borneo, Sumatra, and Malacca; *N. Hookeri*, from Sarawak; *N. sanguinea*, from Borneo; *N. phyllamphora*, from Malacca and Siogapore; *N. levis*, sometimes called *gracilis*, from Borneo and Java; *N. ampullacea* (which makes quite a nest of pitchers round the base of the stem), from Malacca and Sumatra, and its variety, called *pieta*; *N. villosa*, from Borneo; *Dominiana*, which is said to be a hybrid; and *N. distillatoria*, which is our oldest species, and, I believe, peculiar to Ceylon. Besides these, however, there remain many more splendid ones yet to be sent home, and any one having friends living near their localities, cannot too strongly urge upon them the collecting of *Nepenthes* seed at every opportunity, and sending it home as soon as procured; for such species as *Rajah*, the pitcher of which measures 12 inches in length, and 5 inches or 6 inches broad; *Edwardsiana*, with pitchers 18 inches long; *Boschiana*, with pitchers as long as the last; and *Lowi*, with its most peculiar-shaped pitchers, and, indeed, many others would be grand additions to our stoves, and I hope to see many of them in cultivation before long. They are found growing in swampy places at elevations of 1 foot to 8000 feet; the mountain of Kina Balou being the head-quarters, apparently, of some of the finest species. It is a class of plants to which botanists have attended little, nothing having been satisfactorily proved as to what other plants they are allied to. They are dioecious, and, consequently, even in large collections the entire stock may consist of one sex only, no difference being visible in them as far as my experience goes with the Ceylon species, so that few gardeners have had the opportunity of raising them from seed; but I may venture to say those who have done so were never engaged in anything so interesting as watching their progress, having myself had the pleasure of raising *levis* from a consignment of Java seeds, and *distillatoria* from Ceylon seeds, and some ripened at home of my own sowing. A word or two on the subject may not be out of place, and may induce others who have also been successful raisers, to give us a few hints respecting their experience.

It is often said that the seeds will not retain their vitality more than one month; but in that, from experience, I am an unbeliever, though I should always like the seeds as new as possible, whence the reason of urging friends to send them as soon as gathered.

In *N. distillatoria* the seed appears about half an inch long; but if opened the outside covering is like a loose tunic, the seed itself is in the centre, the coat being no doubt a provision to float it in the swamps till it finds a suitable resting-place.

Having obtained seeds, I take a shallow pan, filling it rather more than half full with potsherds, then fill-up with soil composed of chopped sphagnum, peat, and sand. I then sprinkle the seeds lightly upon the surface, but never use soil as a covering, but lay a piece of glass over them, or what is better, if it can be had, is a small frame that can be kept close, with a bottom heat of about 85°. In this, providing the seeds are good, they will commence to grow in about three or four weeks.

Here I may state the reason for doubting the notion of the seeds being short-lived. Some seeds of *N. distillatoria* from Ceylon vegetated in about twenty-seven days, in a moist bottom-heat of 88°; the remaining portion were placed in a temperature of about 60°, and were eight months before they began to make their appearance; indeed, I had given them up, and did not expect to see them grow at all.

The very first leaf after the cotyledon has a pitcher upon it, or rather the pitcher is the leaf, and the first dozen or so of leaves they make more resemble *Sarcocolla* than *Nepenthes*. As the plant gets stronger, the leaf, (or, as some call it, the petiole, and the pitcher the true leaf), gets broader, and the pitcher appears

sunk in the apex, soon after which, if all go on favourably with them, they take their normal form.

In striking them from cuttings, I have had various degrees of success, and have for the sake of experiment used the wood in all states; but I like one-year-old well, and that well ripened best of all. With this, and the never-failing cocoa-nut fibre refuse, I generally obtain nicely-rooted plants in about six weeks.

The soil I use for growing my plants in is similar to that used for the seed-pans, but much rougher, and I always study to give more surface than depth, as I like to see the masses of black woolly-looking roots near the surface, and upon it.

These plants flourish in a moist warm atmosphere: consequently the syringe should be used very frequently during the day, with the thermometer ranging from 70° to 85° in summer, and 65° to 70° in winter, when less syringing must be done; but the plants should never be allowed to be quite dormant. The time I usually choose for repotting is about the end of February.

I intended to say a few words upon *Cephalotus* and *Sarcenias*, under the head of Pitcher-plants, but must defer it until some future time.—JUVENIS.

### VARIATIONS EFFECTED BY CULTIVATION.

As you have been so obliging as to insert my query on the crossing of Strawberries, perhaps you will grant me the favour to insert two or three other questions, for the chance of some one having the kindness to answer them. I am writing a book on "Variation under Domestication," in which I treat chiefly on animals; but I wish to give some few facts on the changes of cultivated plants.

1st. The fruit of the wild Gooseberry is said to weigh about 5 dwts. (I am surprised that it is so heavy), and from various records I find that towards the close of the last century the fruit had doubled in weight; in 1817, a weight of 26 dwts. 17 grs. was obtained; in 1825, 31 dwts. 13 grs.; in 1841, "Wonderful" weighed 32 dwts. 16 grs.; in 1845, "London" reached the astonishing weight of 36 dwts. 16 grs., or 880 grains. I find in the "Gooseberry Register" for 1862, that this famous kind attained only the weight of 29 dwts. 8 grs., and was beaten by "Antagonist." Will any one have the kindness to inform me whether it is authentically known that the weight of 36 dwts. 16 grs., has, since the year 1845, been ever excelled?

2nd. Is any record kept of the diameter attained by the largest Pansiea? I have read of one above 2 inches in diameter, which is a surprising size compared with the flowers of the wild *Viola tricolor*, and the allied species or varieties.

3rd. How early does any variety of the Dahlia flower? Mr. Salisbury, writing in 1808, shortly after the first introduction of this plant into England, speaks of their flowering from September, or the end of September, to November. Whereas, Mr. J. Wells, in London's "Gardener's Magazine" for 1828, states that some of his dwarf kinds began flowering in June. I presume the end of June. Do any of the varieties now regularly flower as early as June? Have any varieties been observed to withstand frost better than other varieties?

If any one will give me information on these small points, I shall feel greatly obliged.—CHAS. DARWIN, *Down, Bromley, Kent.*

### VINERY UNPRODUCTIVE.

My vinery, a lean-to about 20 feet long, faces the south. The border, made fifteen years ago, 2 feet deep, bottomed with brickbats; a good mixed soil, replenished on the surface with horse-dung nearly every year. Now, this vinery has never done well. The Grapes generally become clung, and fail to get any colour, at least two-thirds of them: I am speaking of the Black Hamburgs. My man gives them plenty of air, and shuts them up every night. We do not force them by heat, but give them a little heat in March. We have had the opinion of efficient men, but their opinions vary. One says it is in the house, others say it is in the border. Will you give me your opinion in your Journal? This year the mildew spoiled those that would have ripened.—R. B. S.

[We should have been more able to decide between the different opinions given, had we known more of the state of your Vines; and if, in addition to brickbats at the bottom of the border, it is also sufficiently drained. We will, therefore, just

make two suppositions, and shall be glad if either meet your case. If the wood of the Vines is vigorous, long-jointed, foliage large, wood imperfectly hardened, and somewhat pithy in the centre when cut, then there is no doubt either that the border is not drained sufficiently, or the roots have descended even beyond your brickbats, or the soil altogether is too rich for the Vines. In such a case, the most effectual cure would be a good deep drain in front, and raising the Vines and planting them in fresh soil, consisting chiefly of fibry loam lightened with lime rubbish, and enriched with eighteen bushels of broken bones as the most lasting manure. This should be done now, and the roots as little exposed as possible, placed within 4 to 6 inches of the surface, and covered with fermenting matter to set them growing, and if the Vines break naturally, they will feel the operation but little the first season. The second remedy would be less troublesome. Secure drainage, and then remove the rich surface from the top of the border, doing it carefully so as not to hurt the roots; but getting down to the bulk of them, and then giving 3 inches or 4 inches of fresh soil, and then a layer of horse-droppings, and a little litter above will entice the fresh roots into it, and a little may be added every year.

If the wood is firm, short-jointed, and moderately strong, then something of the last remedy may also be applied, but greater care will be necessary in the management of the house; and, besides giving air plentifully during the day, air should be given early in the morning, and after the Grapes are set a little air should be left on at night, and fire used in dull weather in autumn to enable this to be done, and the heating medium, flue or pipes, brushed with lime and sulphur if never hotter than 160°. By these means and moderate cropping, you will secure colour and avoid the mildew.]

### THE ROYAL HORTICULTURAL SOCIETY.

No one can be more alive than we are to the mistakes and misdeeds of those in authority over this or any other public body, and we never have refrained, and never abate, from exposing them. The mistakes and misdeeds, however, must be specific—general and sweeping complaints never effect reform, and are unfair, because, like sneers, they cannot be refuted. On these grounds, and because we condemned the mistakes he notices as they occurred, we decline inserting the chief part of a letter which we have received, and at the same time assure the writer that he is labouring under a misapprehension, when he concludes that it is to Dr. Lindley that his causes of complaint are attributable. We believe we are correct in stating, that Dr. Lindley neither exercises, nor wishes to exercise, any paramount influence in the Society's Councils, and, therefore, any feeling the writer may have on that subject is groundless. But there is an alleged fact at the conclusion of our correspondent's letter which deserves explanation, and so we publish it without reserve.

"An eminent nurseryman near London very generously offered prizes of £3 value for Hyacinths, of which he is an ardent admirer as well as grower. The offer was accepted, and he announced it in his catalogue. To his surprise no notice whatever is taken of it in the 'Proceedings' of the Society, but he hears that the Council have changed the day of the Hyacinth Show from March to February, thereby making it a Show of forced, instead of unforced flowers, and entirely frustrating his intentions. He wrote, I am told, to the Secretary, complaining that it was not noticed in the 'Proceedings,' as other special prizes had been, and is informed they were only 'common prizes, and, therefore, there was no reason for discriminating between them and the other prizes.' Yet, when Sir C. W. Dilke offered his prizes they were announced; when the prize for dinner-table plants was offered that also was noticed; and when Master Somebody gives two gold fish to the pond, it is duly announced in large type. But no place could be found for announcing a nurseryman's prize. What wonder is it that he will never trouble the Society again with special prizes for Hyacinths?

"This is one example out of many. I have more at your service if you give place for this."—VIGILANS.

NEW CUCUMBER.—We have received from Mr. Edwards, of York, through Messrs. Hurst & Son, of Leadenhall Street, fruit of a new Cucumber called "Reynolds' Perpetual Bearer." Of

course, it is impossible for us to judge of its bearing properties without seeing the plant growing; but the fruit sent us was growing in pairs, and it is said that there are sometimes four together. The fruit itself is of the *Syon House* race, about 8 inches or 9 inches long, and with a few scattered white spines on its surface. It is tender and very nicely flavoured. Should the bearing properties be what they are represented to be, and we have no reason to doubt that they are, this will prove a very valuable Cucumber.

#### NOTES FROM MY POCKET-BOOK.

**RASPBERRIES.**—Why do so many gardeners plant Raspberries without cutting off the canes? To plant a Raspberry without cutting it down appears to me a very erroneous proceeding. Can it be expected that a Raspberry newly planted will the following season have strength to produce fine fruit and young canes sufficiently strong to insure a good crop the following year? It is seldom before the third year that the plants are in a good bearing state. If the roots alone are planted, strong canes may be expected the first summer and a full crop of fruit the second.

**SALT.**—Is it generally known that salt is injurious to pigs? Some years since, having a large quantity of Potatoes which it was feared might be lost by disease, I had them boiled, salted, and washed. Two pigs which were fed upon them died in a very mysterious manner. Every one who saw them said they were poisoned; but no one could suggest the mode. Some years afterwards I lost another pig, which exhibited the same symptoms during its illness. On inquiry I found the cook had put some brine in the swill-tub, and arrived at the conclusion that salt was a specific poison for pigs. I have been told by a friend that he has lost several from the same cause, and also a number of barn-door fowls. Though Pigeons are fond of salt and will eat it greedily, it has been long known that salt meat will kill Parrots.—J. R. PEARSON, *Chilwell*.

#### SUBURBAN ROSE CULTURE.

THERE is no gem in the whole diadem of Flora more suitable and advantageous to amateurs with limited space at their command than the Rose; for, besides its inherent beauties, a single Rose is an appropriate offering to the highest lady in the land, while the garden may be half stripped of ordinary subjects to make up a presentable bouquet. No doubt many of the readers of *THE JOURNAL OF HORTICULTURE* are enthusiastic admirers of this general favourite, many of whom would become cultivators were they not deterred by anticipated difficulties, and fear of certain failure.

There are no insuperable obstacles to Rose-growing, even in localities usually considered unfavourable, with a proper attention to preparing the soil, a selection of suitable varieties, and the observance of a few minutiae of cultural management. Perhaps the record of the successful practice of an amateur within three and a half miles of St. Paul's, may induce others to enjoy the delightful recreation, and experience the pleasure of presenting admiring friends from town with a few bunches of fragrant flowers to enliven and refresh the gloom and monotony of their city habitations. Besides, it is the least expensive of floral amusements; for, when the plants are once obtained, with a little care and protection to the more tender kinds, they will last from season to season, improving with their growth, without the trouble of propagating and keeping bedding plants, or the cost of fresh annual supply.

I have only one of those little plots usually attached to houses in the suburbs, some 40 feet by 20 feet in dimensions. The aspect is north, and it is divided from the adjoining strips by open palings, net walls; and this is no unimportant element in success. The ground is naturally light, over gravel, but I have corrected that defect by a liberal admixture of loam and brick earth, enriched by an admixture of old manure. The Rose must have a good strong soil, particularly when worked upon the briar. I have made up the beds very high, some 15 inches or 18 inches above the ordinary level, facing them with turf: this secures the maximum amount of air and sunshine, which, in the summer, is upon the garden the whole of the day—at times, perhaps, too much so. One long bed stretches down the centre, in which are grown the less hardy varieties; while a border sur-

rounds the remainder of the plot, in which are placed standards of various heights, and plants on the *Manetti*, an admirable and thrifty stock for unfavourable conditions of soil and atmosphere. Every autumn a good mulching of manure is applied to the beds to be forked-in in the spring, and during the summer a good dose of guano water is supplied to every plant once a-week. In this small space I have crammed about 150 plants on *Briar*, *Manetti*, and their own roots, and I find them all do equally well. There are about ninety sorts, new and old, that I am able to succeed with; but some are more satisfactory in their behaviour than others, giving abundance of blooms, of size and symmetry, and sending-up robust shoots of 6 feet in a single season. A list of these will form the matter of a future paper. Frequent syringing is an important feature in my practice, and the stems of standards are washed during the season with soap and water, and a scrubbing-brush to cleanse them from moss and prevent them from becoming bark-bound. On the whole I should recommend beginners to commence with plants on the *Manetti*, and not try many standards till experience with one or two gives promise of a satisfactory result. Every other year or so I take up the plants and replace them after having well stirred the soil, and added two or three spadefuls of fresh earth mixed with manure. Drainage must be provided for. The gravelly subsoil of this district (the neighbourhood of *Victoria Park*), renders it unnecessary with me; but when the soil is heavy and retentive some means must be adopted for getting rid of the superfluous moisture.—W. D. PRIOR, *Homerton*.

(To be continued.)

#### WINTER VIOLET GRASS.

CAN any of the readers of *THE JOURNAL OF HORTICULTURE* give the botanic name of the above plant, and state where it can be had? It is a delicate little plant, with violet-coloured flowers and tiny leaves, blooming in the winter, covering the surface of the pot like moss.—M. D.

[We do not know the above name. The description suggests *Ionopsidium acaule*, which, being a near relative of *Cochlearia* (*Scurvy-grass*), may have been called a "grass" likewise. It has been called "*Stemless Violet Cress*," and a portrait of it is in the "*Botanical Register*" of 1846, plate 51.]

#### PROPAGATING STRUCTURE IN A GREENHOUSE.

THE question put by "*KILWORTH*" in No. 86 is one of interest to many of your readers, I therefore make no apology for asking space for the following.

As the inquirer makes no mention of the size or form of his house I shall assume it to be a lean-to, and having the usual front shelf of say 2 feet 6 inches wide, have then a tank of zinc or galvanised iron 2½ inches deep, made 4 feet long and the width of the shelf. Box all in 6 inches deep in front, and 10 inches or a foot behind, and cover with one or two lights as may be preferred. Under the centre of this knock out a brick, and cover the aperture with perforated zinc, or put in a cast-iron ventilating-brick. Round this aperture construct a box large enough to hold a large paraffin lamp, and of a proper depth to bring the flame at the right distance from the bottom of the tank. Have a close-fitting door to it opening inwards, and a small square of glass in the centre of it to permit of the lamp being seen. Of course a tap and funnel inlet to the tank are improvements, and it should be strengthened by soldering in little pieces of zinc tube at every 6 inches previous to soldering on the top.

I have worked a case of this kind with gas, and it was all the most experienced propagator could desire for ordinary cuttings. I should have no fear in going to work with a paraffin lamp, as I know it would give more than heat enough, and attention morning and evening would keep it at work. Paraffin lamps are, however, ticklish things to deal with, and unless the party thoroughly understood their working he would be sure to come to grief. The precautions are, however, very simple if care be taken. First, be very particular as to the even cutting of the wick, and secondly, never permit the slightest incrustation on the cone or burner; in fact, to secure a good result, the wick should be screwed down, and the edges of the burner polished

each time the lamp is trimmed. Again: never extinguish your lamp by drawing down the wick; blow it out, and rub off the charred cotton. The reason for this is, that particles of charred matter are apt to get into the tube, and interfere with the regular mounting of the paraffin, thus causing unequal combustion.

I should have grave fears in permitting a paraffin lamp in any greenhouse of mine, as were it once neglected and began smoking it would play sad mischief. With the above-described plan, however, it might smoke its worst, and no evil could result, as the lamp is continually out of the house.—M. G. CUNNINGHAM

### ORNAMENTAL PLANTS.

*IXORA SALICIFOLIA* (Willow-leaved *Ixora*).—*Nat. Ord.*, Cinchonaceæ. *Linn.*, Tetrandria Monogynia. *Syn.*, Pavetta salici-

folia.—A splendid stove shrub, of erect habit, growing 2 feet to 3 feet high, probably higher. The leaves are opposite, rather closely placed along the stems, almost sessile, narrow-lanceolate or willow-like, a span long, shining green above. The flowers grow in large terminal corymbs, forming hemispherical heads, and are deep orange red or flame-coloured (in a variety with somewhat smaller blossoms, almost crimson); they are upwards of an inch in diameter, and consist of a long, slender, almost filiform tube, and a spreading limb of four lanceolate, ovate, acute lobes. From Java: Mount Seribu. Flowers in summer. Introduced by Mr. T. Lobb, collector for Messrs. Veitch, of Exeter and Chelsea.

*BERBERIS WALLICHIANA* (Wallich's Barberry).—*Nat. Ord.*, Berberaceæ. *Linn.*, Hexandria Monogynia. *Syn.*, *B. macrophylla* of gardens; *B. atrovirens*, *G. Don*.—A very ornamental, half-hardy, perhaps hardy evergreen shrub, growing 10 feet high, and furnished with dark green, dense, elliptic, sharp-pointed, serrated

*Ixora salicifolia.*

2. *Berberis Wallichiana.*

leaves, growing in clusters, the branches also bearing slender, three-parted spines. The flowers are clustered in the axils of the leaves on short stalks, and are large, and of a deep yellow colour, giving the plant a very ornamental aspect. From Java:

mountains, 9000 feet elevation. Introduced in 1845 by Mr. T. Lobb, collector for Messrs. Veitch, of Exeter and Chelsea. Flowers in summer. It has stood three winters at Exeter, without shelter.—(*Gardeners' Magazine of Botany.*)

### EARLY VERSUS LATE PLANTING POTATOES.

As the season for planting Potatoes will soon be coming on, I wish to state my experience in this season.

I commenced the planting of Kemps in the month of Decem-

ber last year, and continued planting them and Scotch Dons or Downa until the end of March, when I had all the piece planted (about two Irish acres), and which had never been under

cultivation before, being part of an unreclaimed mountain, and full of boulder stones. I had them planted in four-foot ridges, the manure being spread on the surface, the seed then dropped, and all covered from the furrows with about 6 inches of covering. The Potatoes came up well, and continued healthy all the season until fully grown, and the stalks had partly died away before the blight came, and when it did come, it took little or no effect; for at the lifting or digging-out of the Potatoes not one in fifty of them was diseased, and, in fact, the men used to say that there would be no want of Potatoes this year, as the disease had all gone; and the quality is so fine that it is with difficulty that they can be boiled.

So much for early planting. Now for April planting. I commenced planting about an acre and a half in drills on the 1st

of April, and had them all finished by the middle of the month, the ground being all trenched, ploughed, and well pulverised; the drills opened, and the manure spread in the drills; the seed dropped, and covered up with the plough; the after-cultivation being likewise well attended to, till the Potatoes came up beautiful and strong, and continued well and healthy until the disease came. They were in full growth at the time, and were soon cut down; and the consequence is, that one-half of them are diseased and rotten, and the quality not near so good as the early-planted ones.

You will see from this that unless the Potato is early planted, and brought too near maturity before the disease comes, that you cannot depend upon having a sound crop.—A. LINDSAY, *Glendalough*.—(*Irish Farmer's Gazette*.)

### CHAIN FLOWER-BORDER

AT EAST SUTTON, KENT.

FASHIONS alter in flower-gardening as well as in dress; so would our grandfathers say, if they could but see our masses of Geraniums, Verbenas, and the other flower-garden ornaments, and compare them with the double Wallflowers of old, from which cuttings were only to be had as great favours, and when a yellow Picotee was the gem of all gems. Now these things have fallen into a second or even third place in general estimation, and colour, quantity, and conspicuousness are all the rage. Even the arrangement and disposition of these has undergone, and is undergoing, considerable change.

The small patches of one particular colour dotted over a plot of turf has in many cases been altered more than once the last dozen years, and geometric gardens more or less intricate have at various times been predominant, and again superseded. More latterly highly elaborate designs, in which coloured materials rather than colour in flowers play a conspicuous part, have been introduced with good effect; these coloured substances being in connection with certain beds intended for planting.

Of the particular merits of this style so much has been said of late, that it is needless here re-opening that question. It is enough to say that the opponents to the permanent system of polychromic embroidery, as such ornamentation is called, may with a little pains have their favourite bedding done to their heart's content, and the polychromic work too, the latter being done

in the winter, the former in the summer; and the labour attending the change is far from being heavy or difficult, as has been shown in some former Numbers of THE JOURNAL OF HORTICULTURE, accompanied by drawings of work of that kind that has been done here at Liuton, and some other places in the neighbourhood.

When the case is understood with which the change can be effected from a fading autumn flower garden to a winter one of bright, clearly-defined colours, which will last until March, or longer, the plan will become still more fashionable; more especially as the winter decoration allows of even greater diversity than the summer planting. Mr. Skinner, the intelligent gardener to Sir E. Filmer, Bart., M.P., of East Sutton, has adopted the plan of introducing plants of a suitable kind into places allotted for them in the embroidery of his large bed, of which a design of the mode in which it was planted in summer appeared in THE JOURNAL OF HORTICULTURE a few weeks ago. This bed, which is somewhat between 40 feet and 50 feet in diameter, has now received its winter-dressing, and in the opinion of many looks as well as most beds do in the prime of the season—say August or September; but as the mode of doing this has been already explained, we will leave this and point out a few particulars on the chain pattern, as planted at East Sutton the past summer, and which met with the approbation of every one who saw it.

The design above is one often met with in mouldings of timber, stucco, or iron. I am not certain of the correct name it is known by, but I have long called it "the Florentine Chain," and whether this be right or wrong it is needless to inquire. I have more than once failed in planting it satisfactorily, although in winter decoration it comes in very well; but Mr. Skinner worked it in with plants admirably.

The position it is in is remarkably well adapted for it. Occupying the face of a slope, and seen from the top of another one, the point of sight was nearly at right angles with it, or what might be called a bird's-eye view was thus obtained. This favourable position would not, however, have made an indiscriminate planting look well; neither would any mode of planting, or every class of plants, have looked so well as those employed, which were as follows:—

- A A A. Circles 3 feet diameter, Geranium Tom Thumb.
- B B B. Chain band 1 foot wide, Cerastium tomentosum.
- C C C. Outer groundwork, Lobelia speciosa.

These were all the plants used, and what more colours are wanting in any design than red, white, and blue, which were here shown to great advantage. The white belt or band of Cerastium showed itself in its true colour before the Geranium came into flower; but the effect was equally good then, the silvery whiteness of the Cerastium contrasting so well with the glossy green leaves of Tom Thumb, and also with the blue flowers of Lobelia, while the latter stepped in between the end of one band and the side of another, to prevent that junction which creates confusion, and which it is right here to point out to all who may be planting a chain figure to avoid. The plants were all of a height until the beginning of September, when the Geranium shot a-head; but even then it was excusable, as the place where it was most looked at was nearly at right angles with the face of the ground. There were several more links than shown in the diagram which is merely given to explain the planting.

The chain pattern above given is of more than one season's standing, for I remember seeing it last winter. The Cerastium,

which had been planted at the usual bedding-out time in 1861, was allowed to stand; and though it does not always look well in winter, or even in autumn, in this case it did, and occupied the space above mentioned with scarcely a gap. Coloured material formed the groundwork c c c; while the central circles, A A A, were rendered pleasing by piles of stones that were thickly coated over with a beautifully pale green moss. These stones had been picked-up from the surface under trees, where they had lain undisturbed for many years. Of course, care was taken to keep the mossy side upwards again; and common and homely as such things may seem to be, it would have been difficult to have found anything to look better. The band of white *Cerastium* surrounded this miniature rockwork, and in its turn was bounded, I believe, by brickdust of a bright red colour. I have not been told what the present winter-dressing is to be, but I expect something simple, pleasing, and agreeable, and most likely very common.

I should like some one who has been successful with striped or ribbon-borders to report upon them in THE JOURNAL OF HORTICULTURE. Each season adds a little more to our stock of knowledge in this as well as in other matters, and it is not every planter that is successful with stripes. When there are really good and effective ones that have the necessary merit of coming into use early and continuing late, the fortunate, or it would be better to say, skilful managers of such borders deserve all the credit we can bestow on them. Two years' experience has confirmed me in the opinion, that our mode of planting a narrow border of three single rows with the tallest in the centre, is better than many other ways I have tried. But as I purpose giving a few notes on this head in another article, I will only invite others to do so also. The latter part of the past season was prolific in good flower-beds, the early part was not so. I hope, however, some of our travelling friends will give us their opinion on this and other matters, as useful hints may often be gleaned in unexpected quarters, and many out-of-the-way places present objects of interest we look for in vain in others that are more fashionable.—J. ROBSON.

#### ORCHARDING ON A LARGE SCALE.

I AM about to plant 2000 to 2500 Apple and Plum trees in the neighbourhood of Reading for the sole purpose of growing fruit to send to Covent Garden Market. The trees are to be grown strictly on the same principle as recommended for growing Cherries by Mr. Rivers, in Dr. Hogg's "Gardeners' Year Book for 1862," at page 56. Being an experienced budder and grafter, I intend working my own trees. I therefore beg to ask your advice on the subject. On what kind of stock should the Cox's Orange Pippin be grown on to induce early fruitfulness and constant bearing? Do you know of a better kind of Apple for the same purpose? One report on Apples at the recent great Show stated that the above Apple was the best flavoured of the whole lot in London. Will it stand pinching-in? Is it a good bearer? What kind of stock should the Mitchelson's Plum be grown on? Would it stand pinching-in, and still be a great bearer?

I intend growing a few May Duke and Morello Cherries on the Mahaleb stock on the same principle as the Apple and Plum.—W. W., *Liverpool*.

[To induce early fruitfulness you should graft your Apples on the Doucin or English Paradise stock. Cox's Orange Pippin succeeds very well grown in that way, and it is also one well adapted either for bush or pyramid training. There cannot be two opinions about the merit of the fruit, which is of the first order. Mitchelson's Plum requires, what is called among nurserymen "the commoner," or the common Plum stock. We hardly know how it would bear pinching-in, as we have never seen it subjected to that mode of culture; but it would do well as a dwarf bush, and does not occupy much space.]

**PRESENTATION.**—The presentation of the testimonial to Mr. A. C. Wheeler, of Gloucester, for his services as local Secretary to the Managing Committee of the late Agricultural Exhibition and Fête, took place on the 3rd ult. It is universally admitted that much of the success attending the arrangements of the great Meeting held at Gloucester on the 30th of July last, and of which a report appeared in this Journal, was undoubtedly due to the energy with which the Secretary carried out the instruc-

tions of the Committee under whom he acted. At the dinner at the Spa, Mr. Holland, President of the Society, thanked Mr. Wheeler for his exertions on behalf of the Society, and subsequently presented him with a beautiful gold snuff-box as a *souvenir* of the Meeting. But at the audit of the accounts it was felt that the public also owed a debt of gratitude to the Secretary, and a subscription for the purchase of a testimonial was determined on, the Society heading the list with a contribution of twenty guineas; between fifty and sixty persons, members of the Society or private friends of Mr. Wheeler, followed the example thus set. A sum of £60 was raised, and the Committee purchased a beautiful timepiece, a silver salver, and a claret jug as the testimonial. The following inscription was engraved on the salver:—

Presented to  
ALFRED CUMMINS WHEELER, F.R.S.,  
By the Gloucestershire Agricultural Society and Friends,  
As a token of their esteem, and as an acknowledgment of the valuable services rendered by him at the Meeting of the Society held at Gloucester in 1862.

The presentation was made at a dinner at the Ram Hotel, at which between thirty and forty gentlemen were present. Ed. Holland, Esq., M.P., had consented to preside, but was prevented by illness; and the chair was ably filled by Alderman Nicks.

#### PREVENTING THE ATTACKS OF THE CELERY FLY.

IN reference to your correspondent in page 655 I beg to offer a few remarks, as I have for some time known a sure preventive, and, no doubt, a great many use the same both as a preventive and as a cure.

Soot is the remedy. I begin to dust the plants with it directly I prick them out, and continue the dusting all through the season. When the foliage is damp is the time to apply the soot, and that mostly happens in the morning.

A large portion of your readers will, no doubt, say that they have tried it, and that it does not answer; but if such should be the case, I reply that the reason it did not prove efficacious with them is, that they either began dusting, as I call it, too late, or they only partially dusted. Every leaf must be covered with the soot; and the dusting continued, as I have said, the whole of the season. If this be done success will certainly attend their labours.

I do not believe that soot or any other application is remedial after the plants are attacked.

Respecting growing Celery I think a hint might not be thrown away. I sow in a pan filled with thoroughly rotted old Melon or Cucumber-bed dung mixed with a good dash of sand. I prick-out in similar rotted dung without sand, and plant in trenches in the same rich compost; but before I put the rotted dung into the trenches I put 5 inches or 6 inches of less-decayed dung at the bottom of each trench, and then the rotted to mould on the top.

In this way I have grown good sound crops for these last five years. Liquid manure I never use, as the plan I have described will grow Celery large enough for any purpose; and however large, or however long it may be, not once in my life could I induce the cook to send it to table whole.—W. W.

#### MANAGEMENT OF GREEN FROGS IN A PLANT-CASE.

I OBSERVED from your No. 80 that "H. B." is desirous of knowing the proper treatment of green frogs; and as Mr. Veitch does not seem either to feel quite sure upon the matter, and having myself both a kind feeling towards my rather green countrymen, as well as a desire to assist, I venture to add the following.

These animals live partly in and partly out of the water in and beside swamps and ditches. In Germany you find them in nearly every house, especially with farmers, who keep them principally for their great and valuable ability of prophesying the weather. They are kept in a tall tumbler filled more than half full with water, a small step-ladder being placed in it, and covered at the top with either tin or paper with small air-holes through it. In summer they receive, perhaps, six or a dozen flies in the week; in winter they receive nothing at all—perhaps a solitary fly which may have turned up somewhere—and they

seem to live partly upon water and the green substance which in time grows on the ladder. The water should be renewed occasionally.

I do not think that they could do without water at all. In fact, a friend of mine who kept them similarly in a fernery lost one after the other until I drew his attention to it. In Germany they are kept through the whole winter in the same way in front of the windows, which, although in the people's common sitting-room, are often thickly frozen.

If wet weather is likely to set in the frogs keep below the water; if the weather be changeable they sit half in and half out; and the higher they rise out of the water the more settled the weather will be.—W. HARRIS.

### THE NEWBURY ORCHARDS.

I DO not know whether in your travels you ever visited the orchards opposite the Carso of Gowrie. If not, you should do so next season. Newbury, in Fifeshire, on the south side of the Tay, is an extraordinary place for Pears. Dr. Lyall, a well-known botanist and horticulturist there, showed me a standard Crasanne tree in a neighbouring garden, for the fruit of which the owner refused £2 two or three years since. And many other tender sorts do well there as standards. The soil is dry on trap rock, and the surface rises gradually from the river's bank, with a direct northerly or north-easterly exposure; notwithstanding which the corn crops are as early as those on more southern slopes in the district. But the great secret in favour of the Pears seems to be, that immediately south of the town there is a considerable hill—in fact, what in England would be called a high mountain, which effectually shuts out the sun for the whole winter season, or till far on in March, so that the buds are not excited to be again destroyed by late frosts.—W. G.

### NEW BOOK.

*The Miniature Fruit Garden; or, The Culture of Pyramidal and Bush Fruit Trees, with Instructions for Root-pruning, &c.* By Thomas Rivers. Eleventh Edition. London: Longmans.

THERE is no better indication of the increasing taste for the cultivation of fruit trees than the repeated issue of new editions of these little books of Mr. Rivers'. When we compare the class of horticultural works that are now brought out with those that were most popular twenty years ago, we cannot but remark the greater proportion of pomological works in the present day. To have written a book on fruit trees twenty years ago was to blacken paper and add to "waste;" and the unlucky wight who was rash enough to indulge in such a work might consider himself lucky if his publisher did not bring a heavy charge against him for his rashness. Here is "The Miniature Fruit Garden" in its eleventh edition, and with no indications of senility about it. We have so often reviewed this useful little work that little more is required of us than merely to announce its reappearance, and to draw attention to some novel features in this edition. Among the engravings there is a very excellent one of a pyramidal Morello Cherry, illustrative of the following extract:—

"The Morello Cherry on the Mahaleb stock, cultivated as a pyramid, forms one of the most prolific of trees; but as birds carry off the fruit when only half ripe, each pyramid should have a bag of tiffany placed over it, and tied round the stem of the tree at bottom. Any garden, however small, may grow enough of this useful sort by planting a few pyramids, lifting and replanting, or root-pruning them biennially, and pinching in every shoot to three leaves (as soon as it has made five) all the summer. The Kentish Cherry, also a most useful culinary sort, may be cultivated as a pyramid with great success. A French variety grown near Paris, in large quantities, and known as the "Crise Aigre Hative," which may be Englished by calling it the Early Sour Cherry, is a most useful kind for the kitchen. In going from Paris a year or two ago to Versailles by the "Rive Droite" Railway, I was much struck by seeing in the market gardens between Suresnes and Puteaux, on the left, large plots of dwarf trees, about the size of large Gooseberry bushes, and some very low trees, all covered (as they appeared to me from the railway carriage) with bright red flowers. I found, on inquiry, that these were Cherry bushes—literally masses of fruit, of the above variety, the most prodigal bearer

known. The trees are generally propagated by suckers, but succeed very well on the Mahaleb stock, and form very nice pyramids.

"I need scarcely add, that the culture of all the Duke tribe of Cherries by closely-pinned-in pyramids, biennially removed, or biennially root-pruned, is most satisfactory. It is, perhaps, more easily performed than root-pruning, and the trees soon form perfect pictures. I have seen nothing in fruit-tree culture more interesting than handsome compact pyramids of such sorts of Cherries as the May Duke, Duchesse de Palluau, Empress Eugénie, and Archduke. One feels surprise to find that as yet but few lovers of gardening know of the existence of such trees.

"It will much facilitate the operation on their roots if the trees be planted on small mounds.

"In forming plantations of pyramidal and dwarf Cherries on the Mahaleb stock, it is necessary to arrange them with a little care. The two groups, those of the habit of the Morello tribe, and those of the compact habit of the May Duke, should be planted in separate rows. Bigarreau and Heart Cherries are too short-lived, when grafted on this stock, in most descriptions of soils, to be recommended."

### THE STUDENT PARSNIP.

IN the "Proceedings" of the Royal Horticultural Society for last month, page 739, I observe, "Parship 'The Student' ennobled from the wild Parsnip by Professor Buckman." What does this mean? or rather what was the ennobling process to which the wild Parsnip was subjected? Or was it the wild Parsnip at all which was experimented upon? I look upon many, if not all the wild Parsnips, which you see blooming in early summer by the sides of fields, on railway banks, &c., in the south of England, as being the offspring of cultivated plants, and quite likely under good cultivation to produce good large roots, although the parent plant grows away gross, and may have only had small and, it may be, woody roots. Sow seeds of this "Student" immediately when ripe among grass or in waste ground, and note the appearance next May, when they will be in flower, compared with the autumn produce of the same seed sown in spring and well cultivated.—INQUIRER.

### MAKING CHARCOAL.

[In answer to "IGNORANT," and two other inquirers, we reprint the following from a former volume.]

My practice is to commence by taking a sufficient quantity of split wood that will easily ignite on the application of fire, and with a sharp instrument cut it into lengths varying from about 3 inches to 9 inches. I then place it in a dry shed until I have prepared the whole of the wood which is to be burnt into charcoal at one time, and to preserve it from being wet; for I would have it particularly understood that the drier it is kept the sooner it will take fire when the whole is piled for burning, which will save much trouble, and probably partial failure in the operation.

The quantity of dry wood to be prepared will depend upon the size of the heap when complete and ready for being set fire to. A heap that measures about 4 feet in diameter at the base, and from 4½ feet to 5 feet high in the centre, will require a quantity sufficient to form in the centre of it a circular heap about 18 inches through at the base, and 12 inches high in the centre.

Charcoal is generally made, on a large scale, of the boughs of trees that have been cut down for sale, or of the underwood and prunings of trees that take place occasionally on the estates of landed proprietors. The wood should be as firm as can be obtained, and as free from sap as possible; but if it cannot be had of this kind take the best at command, and cut it also into lengths of about 6 inches, 9 inches, 12 inches, and 18 inches; and when it is cut be particular to make the lengths into three loose heaps—i.e., those lengths that measure the least in diameter into the first heap, those of the greatest diameter into the second, and those which range between the least and the greatest diameter into the third. Also, prepare a smooth, circular piece of wood from 4½ feet to 5 feet in length, and 6 inches through. Attention to these things at this stage of the process will greatly economise the amount of labour which will afterwards have to be bestowed upon the building of the pile.

The wood being thus prepared, next proceed to select a con-

venient plot of ground upon which to burn it, and which, I would remark in passing, might be the corner of an adjacent field, the Melon-ground, the compost-yard, or, for want of these, the centre of a spare quarter in the kitchen garden.

The ground being fixed upon, level and make it firm by beating it with a beater or the back of the spade, and then, in the morning of a fine day, when the weather looks settled, wheel the wood to it, keeping the heaps, as already, separate from each other when placed round the ground where the principal heap is to be formed, and also have brought from the field or common a cartload of sound turf, and placed at a proper distance from the material already on the ground.

Into the centre of the ground, which has been made even with a mallet, strike one of the thick pieces of wood, which, I would observe, must have been pointed at one of its ends when the rest of the wood was being prepared. Allow it, when fixed in the ground, to stand about 9 inches above the surface of the soil round it; begin to form the pile by placing a few of the shortest lengths of the dry wood equally round the bottom of it, and then against these others, with one end resting on the ground, so that the end which is the uppermost will incline towards the centre of the heap. They must be placed as closely to each other as possible in an imbricated style. In this manner proceed until the heap reaches to the top of the stake. Afterwards mix with the wood a quantity of shavings which have been got from the carpenter's shop, which will cause the wood to ignite sooner than it would do if they were not used. The form of the heap, when of the dimensions above stated, should be that of a cone, on the point of which must be mounted on end the long, smooth piece of wood which was made ready for the occasion as already stated. Be particular to make it firm by putting the end of three rods into the ground, so as to form the three points of a perfect triangle, and fastening the other ends of them to the top of the wood. Then take about one-fourth of the length which forms the first heap of wood, and tile-form layer them equally all over the central pile; also, take the whole of the second and third heaps, and use them one after the other in the same way, finishing with a layer of the three-fourths which remain from being used of the first heap.

The reason for arranging the wood in layers in this form is, that that which is of the greatest diameter, and which occupies near the central layer, is no more than ready for being drawn when the outward one is perfectly burnt into charcoal, and, consequently, the pile is ready for being taken down and the charcoal housed.

The piling of the wood being completed, cover it equally all over with the turf which is close at hand ready to be used; place the grass side downwards, and on the top of it a layer of sifted soil from 1½ inch to 2 inches in depth.

Having done this take out of the centre of the pile the smooth, perpendicular piece of wood, and deposit some light combustibles, in which a quantity of congrua matches have been mixed, on the top of the dry wood in the centre, by letting it drop down the hole out of which the wood was taken. Set fire to it by casting a few live embers upon it, and when it has caught fire feed it with a small quantity of wood, and then close up the hole with a little turf, so as not to allow the fire to escape. Afterwards take a rod sufficiently long to reach to the centre of the pile, and with it perforate the sides, letting it run to near the centre. By these punctures a ventilation will be created that may be regulated so as to keep the fire equally burning throughout the whole of the pile. As the fire continues to burn it will require to be fed occasionally with suitable material. This must be done by uncovering the open space in the centre which was left for the purpose, and carefully letting down the things with which to feed it, and then covering up the orifice as before.

The fire in its progress will consume certain parts of the turf and soil which serve as an external covering to the pile, and also to keep the fire smouldering, instead of issuing in flames, which is a point in the process worthy of being noticed by those persons who wish to have good charcoal with little loss of material. Therefore, on the first indication of the fire coming through to the surface, in whatever part of the pile it may be, immediately cover the place with turf and sifted soil, which must be always at command.

The length of time it takes to burn wood into charcoal varies according to the softness or hardness of it. Oak takes the longest, and is generally thought to make the best, and on that account it is to be preferred to any other kind.

Now, if the piles during its burning be properly attended to the

loss of material will be trifling. The ashes or refuse are, I consider, amongst the best articles that enter the kitchen garden for top-dressing the beds of Turnips, Carrots, Parsnips, Dwarf Beans, &c.; and for first early Potatoes, either mixed with any other kind of manure or alone, are equal, if not superior, to any thing I have used.—B. B., near Halifax.

## THE DISTRESSED WORKINGMEN BOTANISTS OF LANCASHIRE.

I SCARCELY know how to thank you and the many kind-hearted people who have put means into my hands to alleviate the distress of some of the poor naturalists here.

I have to acknowledge the receipt of 6d. from three school-boys at Kilkenny; £1 1s. from the Rev. J. Mague, of Killaloe, Ireland, for Mosses and Ferns; from Lady Dorothy Nevill and Mr. Nevill £6; and Lady D. Nevill intends to send me £1 monthly until April; £2 15s. from Mr. James Davies and the young men under him at the Marquis of Westminster's, Font-hill, Tisbury, Wilts; £1 16s. from "A Gardener" at Burton-on Trent; £1 5s. from Julia Masluteer; 3s. from the gardener at Clare House, Maidstone, Kent; 3s. from C. Rollison, gardener at Follifoot, near Wetherby, Yorkshire. "A Mother" from Ipswich has sent for three weeks together 2s. 6d. for Roger Schofield, and 1s. for J. Whitehead. Some one at Hull has sent 10s. to R. Schofield; and a gentleman from Hagley, near Stourbridge, has promised to send me 150 seedling *Calceolarias* of very good quality to sell for the benefit of these poor people. Mr. M., of Prescott, has sent 5s. to J. Whitehead, and "V. R." 10s. to me. I am also happy to say that the poor entomologists I named last week have received from Mr. Dean, A. House, and "W." 5s. each.

I have made arrangements to satisfy any of your readers who might have any doubts of an honest distribution. Mr. H. Hall, magistrates' clerk, of Ashton-under-Lyne, has kindly taken a collection of Ferns; and Miss M., Clonmel, has sent 5s. to R. Schofield. I have put some of the botanists who are doing nothing to collecting Ferns and other things that are wanted; and I have engaged one who is a book-keeper, but out of employ at present, to write me out a number of tickets, so that I can obtain a receipt from all I give anything to.

The botanists request me to thank all who have so kindly helped them in this hour of trial, which they never dreamt they should have to undergo.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

## FLORA OF THE ROMAN CLASSICS.

(Continued from page 594.)

### ACONITUM.

VIRGIL, among other instances of excellencies by which Italy was rendered superior to other countries, says there

"Neither do Aconites deceive the wretched gatherers."  
—GEORGE, II., 152.

—that is, there are there no eatable plants so like to their Aconite, that the gatherers have mistaken this for them, and consequently have been poisoned.

The plant known to the Romans as *Aconitum* is thus described by Pliny (*Nat. Hist.*, xxvii., c. 3):—

"It has leaves, not more than four, like those of the *Cyclamen* or *Cucumber*, slightly hairy, and springing direct from the root. This root, moderate in size, is like to the *Sea Cammarus*, on which account some call it *Cammaron*, others *thelyphonon* [because used for wife-poisoning]. The root is slightly curved inwards like a scorpion's tail, wherefore some have called it *Scorpion*. Others have chosen to name it *myocatonon*, because of its odour, even at a considerable distance, it kills mice. It is produced upon naked rocks, which are called *aconæ*, and thence some say it is called *Aconite*, there not being even dust for its nourishment [in Greek, *a*, without, and *konis*, dust].\* Such is the reason for its name given by some; yet others derive its title from its power to cause death as speedily as the wheat-stone [in Greek *akone*] brings an edge upon iron. Its rapid effect is immediately perceptible."

The shape of the leaves determines that the Roman *Aconite*

\* Ovid thus derives it, saying—"Which, because tenacious of life, being produced even from the hard rock, peasants call *Aconite*."—*Metamorph.*, vii., 418.

is not identical with our common Monkshood (*Aconitum napellus*), for the leaves of this are cut into many narrow segments; but we believe it to be the same plant as is now called by botanists *Ranunculus thora*. It was known to the older writers upon plants as *Thora Valdensium*, and the following are some extracts from Gerarde's description:—

"This plant took his name of the Greek word *Phthora*, signifying corruption, poison, or death, which are the certain effects of this pernicious plant: for this they vae very much in poisons, and when they meane to infect their arrow heales, the more speedily and deadly to dispatch the wilde beasts, which greatly annoy those moutaines of the Alpes: to which purpose also it is brought into the Mart-townes nere vnto those places to be sold vnto the hunters, the inice thereof beeing prepared by pressing forth, and so kept in hornes and hooves of beasts, for the most speedie poison of all the Aconites; for an arrow touched therewith, leaueh the wound vncurable (if it but onely fetch blood where it entereth in) except that round about the wound the flesh bee speedily cut away in great quantity, argueth also that Matthiolus hath vnproperly called it *Pseudoaconitum*, that is, false or bastard Aconite; for without question there is no worse or more speedie venome in the world, nor no Aconite or toxicall plant comparable hereunto. The stalke of this plant is small and rushie, very smooth, two or three handfulls high: whereupon do grow two, three, or foure leaues, seldome more, which be something hard, round, smooth, of a light greene colour tending to blewnesse, like the colour of the leaues of Woad, nicked in the edges. The root consisteth of nine or ten slender clogs, with some small fibers also, and they are fastened together with little strings vnto one head, like those of the white Asphodill."

The drawing given by Lyte in his translation of Dodoe's "Herbal" is the best we know. It shows the main root curved not unlike a scorpion. Indeed the root is more like a scorpion, for, as Jacquin describes it, the main root puts forth many sub-imbriicate fibres, the imbrication slightly resembling the scaliness of the scorpion.

It is a native of rocky places in the alpine districts of Italy. Parkinson says, "It groweth in shadowie places, on the snowie hills of Savoye, where there is scarce any crust of earth for the rootes to grow in, nere vnto Mura and in the top of Jura." All which facts agree in identifying it with the Aconite of the Roman classics.—G.

### PRESERVING FLOWERS IN SAND.

Those of our readers who attended the late Horticultural Fair in this city, did not fail to notice those two framed wreaths of natural flowers that hung upon the wall near the horticultural tools. They were the admiration of all, and many times did we hear visitors wondering by what process they were thus preserved in their natural form and colour. It is this:—

Get the finest and whitest of river or lake sand, wash it so clean that the water when flowing from it will be pure as if from the well. Heat it very hot, and while hot mix it thoroughly with stearic acid in the proportion of 1 lb. of the latter to 100 lbs. of sand. Let it cool. Take a small common sieve and nail boards under the bottom to prevent the sand from running through; place enough sand in the sieve to hold the flowers in position, not covering them; then with a sheet of paper twisted in the form of a cone or funnel, carefully let the sand pass through it, between, around, and over the flowers—cover about half an inch. Set by the stove or in some warm place where the sand will be kept at a temperature of about 70° Fahr. When they have remained sufficiently long, remove the boards carefully from the bottom and let the sand run out, leaving your flowers preserved in perfection.

The only difficulty is to know when the process is complete, different plants differing in the time required; those with thick leaves and petals needing more than light ones. Seven hours are sufficient for some, while others require twelve and even more. Experience alone can determine this. It is best always for a beginner to experiment with a single plant at a time at first. When he has succeeded with a certain variety and noted the time required he can proceed to others, and in a short time become versed in this art. It should be mentioned that the flowers for this purpose should be picked dry—say midday, after the dew is all evaporated.—(*American Gardener's Monthly*.)

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

As the weather permits, trench and manure every vacant piece of ground. *Asparagus*, if the beds are not already dressed let them be done immediately; half-decayed leaves or rotten dung laid on a few inches thick is all that is required. The alleys should by no means be dug out and thrown over the beds, as is sometimes practised to the certain injury of the roots. Any beds that are to be dug-up for forcing to be protected from frost; roots already planted in the forcing-bed will require a sufficient quantity of water to reach the bottom of the soil they are planted in. *Endive*, when the weather is mild give the plants in the frames abundance of air, to prevent them rotting. *Lettuce*, the Cabbage Lettuce planted in frames for winter use will require no water and but little air; cover them up every cold night. The young Cos Lettuce for spring use, on the contrary, should have abundance of air every fine day. Scils for all the various garden purposes should now be collected: turfy loam from a sheep pasture is undoubtedly the best for general purposes, but there are other places from which soil may be procured without cutting-up much of the pasture land. When the soil is procured it may be immediately chopped-up roughly with the spade, and laid in a ridge or in a square heap, to be turned over several times during the winter. The compost-ground to lie dry, but at the same time to be fully exposed to the weather.

#### FLOWER GARDEN.

Continue alterations in favourable weather, transplanting and pruning the trees and shrubs where necessary; stake them securely, and give a mulching to the tender sorts. Take up *Dahlia* roots, and remove them to an airy shed to dry before being stored. If young *Pinks* have been loosened by worms or frost, secure them. Plant all hardy bulbs. Protect *Chinese* and *Tea-scented Roses*, the roots by cinder ashes, and the tops by moveable baskets, so as to expose them to fine weather. Clean-out flower-seeds from the stalks, and tie them neatly into packets, correctly naming each sort. When lawns are disfigured by worm-casts, a stop may be put to these operations by watering the lawn with lime water in a clear state.

#### FRUIT GARDEN.

All heavy ground work—as draining, manuring, trenching, making new borders, &c.—should be proceeded with, always pruning and regulating the trees first, so that the ground is not trodden over afterwards. Transplant to fill-up vacancies, and continue pruning at all favourable opportunities. Keep the standard *Apple* and *Pear* trees open in the centre; take out the strong upright leaders often formed by the *Pear* trees. *Currants* and *Gooseberries* to be pruned, manured, and dug between, so as to crop the ground. Transplant *Peaches* and *Nectarines*, laying out the roots to their full length in fresh soil. Prune and nail *Pear* and *Cherry* trees on walls; do not crowd-in too much wood. Manure and fork over the *Strawberry*-beds if not done before, clearing away runners and decaying leaves.

#### GREENHOUSE AND CONSERVATORY.

Particular care is now required to keep the conservatory comparatively dry, water to be applied in the forenoon, and if any is spilled on the floor let it be mopped-up; if a drying morning cannot be chosen, apply gentle fires, with a sufficiency of air to allow the vapour to pass off. Everything in the way of decaying blossom, leaves, &c., should at once be removed. Water *Orange* and *Lemon* trees very cautiously; keep them cool. Admit air freely to *Heaths* and *New Holland* plants; water sparingly. Shift *Calceolarias* and *Cinerarias*, a few may be forwarded by a very slight increase of temperature. Shift and tie-out *Pelargoniums*; a few of the most forward may be accelerated by a little heat; give air and a little weak manure water freely to *Chrysanthemums*; water *Chinese Primroses* with caution; disbud those for late-flowering. Admit air freely to the greenhouse in favourable weather, but not in currents, and shut-up early; use water sparingly, and always tepid, giving little or none to succulents or plants in a state of rest.

#### FORCING-PIT.

Particular care should now be exercised in the application of water, atmospheric humidity, air, and heat; the latter should be generally applied a little extra by day, and very sparingly, indeed, by night, for some time to come. Gentle fumigations with tobacco should be occasionally given.

#### PITS AND FRAMES.

If the soil in the pots has become green on the surface, it

should be carefully removed with the point of a small stick. This must be done in mild weather. Scarcely any water will be required at this season; if the plants flag, a little should, however, be given in fine weather. Remove dead leaves, and give air freely on fine days. A cheap and effectual covering for pits and frames, are wood frames, the length and width of each light, thatched 2 inches thick with wheat straw. The frames to be made of well-seasoned deal, the sides, ends, and centre bar to be  $1\frac{1}{2}$  inch thick by  $2\frac{1}{2}$  inches wide, to be morticed and glued together, and small bars 1 inch square to be let in at about 1 foot apart, to support the straw. Any two handy workmen will thatch one in as short a time as it would take them to tie the ends of a garden mat. A more temporary framework may be formed of shingles, such as are used for making sheep-hurdles. Such coverings are neater, cleaner, cheaper, more easily put on and taken off, more efficient than mats, or any other covering that I am aware of, at present in use.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

WEATHER mostly frosty: therefore, besides wheeling, digging, trenching, and clearing the remainder of flower-beds, and glad to get them for fermenting-heaps, little has been done out of doors. These flower-beds remain, and a few leaves from the pleasure ground have come in so useful, as, a shooting party being expected, we must not let man or boy go after leaves in the park. Such matters, and the whole of this extra game-preserving, not only throw us in want of material, but, as previously intimated, give such a chance of extra numbers to the birds as threatens to be a nuisance. It is so far a satisfaction to find such a man as Mr. Robson, and other valued correspondents, seeing the matter in the same light as we do; and though, no doubt, as much charmed as we are with the sweet songsters, yet feeling, so far as their depredations are concerned, it is quite possible to have too much of a good thing. Most vegetables that require covering at night, as forward Cauliflower, and Lettuce, &c., require also uncovering during the day, as the frost has not yet been severe enough to permit of constant covering. Before ever young Cauliflower should be covered-up so, it must be pretty well curded, so that there shall be no growth during the covering.

### FRUIT GARDEN.

In the case of trees in the orchard-house, had, as stated formerly, all the surface soil removed for an inch or so, so as to get rid of the eggs of insects as far as possible, and then watered the surface with water from the rose of a watering-pot, not far from the boiling-point, to catch any that might have escaped. Moved also the surface soil from all the plants in pots, and some that were very dry gave a little water to, allowing it to soak into the soil by degrees. Then dug over the borders, or rather forked them over, so as to bury what eggs of insects we could not kill, and afterwards set the plants as thickly together as they could stand without being injured, and packed them all round and over with stubble. The trees that have several times been syringed with hot water, will be washed with soap and water the first opportunity, and a top-dressing will also be given; meanwhile, the pots being protected, they will be safe whatever frost may come. Examined the border in which the roots of the trees against the back wall grow, and finding that rather dry, watered and covered pathways and all with a few inches of stubble, to keep the frost out. As the wood is well ripened, a little frost to these trees, and to the tops of those in pots, will do them good rather than otherwise. All other fruit departments much the same as in previous weeks.

### ORNAMENTAL DEPARTMENT.

Used days, after the walks showed signs of softening, for packing Dahlias securely in dry earth; turned out Achimenes out of their flowering-pots, and placed the tubers in small pots in dry sand, where they could stand until wanted to start them in a vinery, as thus the pots in which they flowered would be at liberty for other things. Frames and pits have as yet wanted little but straw hurdles put on rather early in the afternoon, and taken off about breakfast time, giving plenty of air, chiefly at the back, for several hours, if at all bright sunshine, and closing and covering in good time in the afternoon. Lights for which we have no covers at present, have a little hay scattered over them, which we saved from the first mowing of a part of the lawn. Such soft material is far before straw for such covering. Ex-

amined bedding plants in such cold frames, to remove any plants or leaves that showed signs of damping, though there was little of that, thanks to striking cool, and keeping cool and airy. Potted Geraniums and Cinerarias; gave manure water to Chrysanthemums; watered all plants when necessary. Bulbs and shrubs in forcing-pit must have regular attention, and the former should never be placed in heat until the pots are full of roots and the flower-stems showing freely. We notice some interesting papers and remarks on the Lily of the Valley, but we consider the chief point in securing fine pots at an early season has been overlooked—and that is, selecting the roots, and nibbling the bud of each, and only choosing those that feel hard and firm between the thumb and finger. This attended to, it is scarcely possible to miss having fine, massive pots of bloom, if the commonest care is exercised. Took great care that Peach-house filled with plants rose only from  $35^{\circ}$  to  $40^{\circ}$ , with fire heat in frosty nights.—R. F.

## TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

"LEX."—A letter and a parcel for you from Ashton-under-Lyne are at our office.

WHITE PEONY (*Old Subscriber, Cheshire*).—Why trouble yourself with a common white Peony worth about 9d.? Many ailments may be the cause of its not flowering, and no one can know at a distance which. You had better throw it away, and begin with a proper plant of a better white Peony—say the common white. On your very sandy soil give it very rotten dung, as much as for a plant of Celery. Let the ground be deeply dug. Mulch from April to September, and water liberally in May and June with pond water, and you will soon beat every one in the parish. But do not waste time on a worthless subject.

ROSES IN POTS (*Idem*).—The best way for you to treat all Tea and Perpetual Roses on their own roots in pots, is to grow them exactly as pot Pelargoniums. The same soil, same quantity of it, same pots, same amount of water, and the very same kind of pruning, will suit pot Roses on their own roots and pot Pelargoniums. The only difference is, that the Roses need not the soil to be changed oftener than once in five years. *Scarlet Anemones* will never do good in that very light soil. We were in the same position once—went to great expense, but all to no purpose. Anemones never flourish except in a good loam, in an open unshaded situation. Excessive moisture at the root is fatal to them.

ARACARIA NOT THRIVING (*A. B.*).—We have no doubt but the severe winter of 1860-61, which you say killed a Decodar near your Aracaria, and likewise injured it, is also the cause of the slow growth that has since followed. We have known several instances of a like kind, even in places where the frost was not so severe as with you (Cheshire). Most likely it will recover its wonted health and vigour in a year or two, but it is not a fast-growing tree under the most favourable circumstances. Generally speaking, it is as hardy as most of our native trees; but the winter alluded to, following suddenly on a wet and mild autumn, caught most things unprepared for it: hence the result.

QUICKSET HEDGE (*A. B.*).—Last week you will have seen an article by Mr. Robson on hedges of various kinds, and his observations on a Quickset one will meet your case.

STRAWBERRY PLANTING—MOVING HOLLIES (*An Irish Subscriber*).—Under the favourable conditions you name, you may now replant your whole lot of Strawberry plants whenever the weather is open. The beginning of June, and again through the whole month of August, is the best time to remove large Hollies in general, and small ones in particular, and November is about the very worst time to move Hollies. You cannot keep young Scarlet Geraniums in a collar, or in the dark anywhere.

VIOLE PENNSYLVANICA—YELLOW VIOLETS (*H. R. Bromley*).—Its flowers are blue. The *V. pyrolaefolia* you purchased is similar to that of which we published a portrait, but not as a new flower. Our correspondent is very anxious to procure some of the yellow species of Violets, and would be obliged by information as to where they can be purchased.

VARIETIES (*H. H. Box*).—No heat at all is employed by Mr. Bird in striking Calceolaria cuttings. The little "white sweet-scented Clematis" mentioned by Mr. Earley, is Clematis flammula. They all should be planted in April. We have heard nothing fresh about Spargania pilifera. It is certainly not to be depended upon generally.

CHIEF BOOK ON BRITISH MOSSES (*A Novice*).—Miss Pines has published a small volume on the subject. It is entitled "Rambles in Search of Mosses." You will have seen what we said to other correspondents recently about *Lapageria rosea*.

**BOOKS (Inquirer).**—You can have the book at our office if you send postage stamps. The second edition of "In-door Gardening," price 1s. 6d., contains the same information as the first.

**DOUBLE LOBELIA (Idem).**—The name Rasoli has never been in print as that of a Lobelia or any other plant. Rasoli is the name of one of the best Horseshoe Geraniums. A double blue Lobelia—such as your seedling, has not been mentioned before. But you should not have allowed the plants to go on so long flowering. It will not come true from seeds, and the chances are that you will lose it altogether. We said last September, the only secret in keeping old plants of the blue Lobelias over the winter, is to cut down so many of them then. We have a hundred of them so managed, and there are twenty good cuttings on each of them now, and the plants are thus so tamed that none of them will go off.

**INTERPRETATION OF NAMES OF FERNS (A Subscriber).**—The "Cottage Gardener's Dictionary" gives the interpretation of their names.

**SELECTION OF APPLES (A Subscriber).**—*Dessert*.—Irish Peach, Gravenstein, Cox's Orange Pippin, Golden Reinette, Margd, Nonpareil, Sturmer Pippin, *Kitchen*.—Yorkshire Greening, Blenheim Pippin, Altristone, Reinette Blanche d'Espagne, Royal Russet, Hanwell Souring.

**AMARYLLIS AULICA (H. M. K.).**—Your beautiful Amaryllis is a true Hippastrum, and is very far removed from aulica. It is a cross-breed, aulica was its great-grandfather, Johnsoni was its grandfather, and psittacium its grandmother, and the immediate parents were some garden seedlings. The ground colour is from aulica, the white star inside is from Johnsoni, and the green shade inside and out is from psittacium. The number of flowers, four in the umbel, is inherited from Johnsoni; aulica and psittacium never produce but two flowers on the scape if they are true wild species.

**EARLY VINERY (P. L. C.).**—From the statements you have given of the Vines, and of the condition of the border outside, we are quite certain you will do no good by doctoring either the Vines or the border, and the Vines will languish more and more from every succeeding crop. The most economical way of guarding against a dead failure some day or other, is to begin again at the beginning, and get a new set of Vines established before the old ones are done with altogether, so as not to lose a year's crop. The best way would be, if you could manage it, to make a four-foot-wide border inside the vinery to begin with, and to widen it about a yard in the autumn each season till you get to the back wall; to plant the young Vines inside, and to train them up between the old ones till you had them fit to bear; then to unspruce the lower half of the old Vines, and fruit the young ones along the bottom half of the roof. And after that grab out the old Vines, turn out the old border to the bottom, put a foot deep of rubble at the bottom of it, in order to raise it up higher; then make a new border outside, also by degrees, beginning with 4 feet; but you should open spaces as large as the front wall will allow of, so as to join the inside and the outside borders, and as much on the same level as you can manage it. Plant the new Vines as shallow as possible, and put 2 inches deep of cocoa-nut refuse over the roots for mulching, and that will cause the roots to ramify all over the surface.

**CYANOPHYLLUM MAGNIFICUM CULTURE (M. C.).**—It is a native of Madagascar, and requires stove culture, and temperatures varying from 75° to 80°. Soil three-fourths turfy peat and one-fourth loam, mixed with bits of charcoal and potsherds broken small, to keep the compost open.

**ASPECT OF GREENHOUSE (E. P.).**—Your aspect, nearly S.W., will answer very well.

**FLOWER GARDEN PLANS (Rose).**—There is no volume devoted to this, in our "Flower-Gardening for the Many," there are several plans and how to plant them. You can have it from our office free by post for five penny postage stamps. To have THE JOURNAL OF HORTICULTURE free by post weekly for a whole year, you must pay 17s. 4d. in advance, or 8s. 8d. for six months.

**DRESSING VINE-BORDERS (Lunatics).**—You would see what has been lately stated in "Doings of the Last Week," as to the coverings of borders. If your Vines are vigorous, the roots may need no dressing at all, but a little fresh horse-droppings or half-dried cowdung will do no harm, and a covering of 9 inches or a foot of litter above it. Stable, straw, or leaves will be better for keeping cold out, than a large mound of fermenting material on the 1st of March, for sending heat in. If you had put on this covering in October, you would have needed no fermenting-heap to set the Vines going on the 1st of March. Now, a little hot dung placed next the soil in March, and the covering as proposed above it, will, at least, do no harm; but do not overdo it.

**PRUNING ROSES (Oryantelicha).**—It depends upon the state of the Roses whether the spring is the best time to prune them. If they are in ordinary good health spring is the best time, but there is hardly a private collection of them out of twenty without some kinds being more or less below the average health, and others ought to be stronger and more free in growth than they have been for the last year or two. All such ought to be pruned in November, and as much as is possible of the old wood cut out entirely, and all the young wood left entire and to be pruned back in March. No two roses, nor two kinds of Roses, can be pruned just alike. The best soil for Cauliflower is the best for Roses. The best soil for Apples and Pears is also the best for Roses, and the very best soil for the Grape Vine is also the best for Roses, both for pots and for borders. The following will suit you better than all the rest:—Baronne Prevost, Madame Yvot, Jules Margottin, Generals Washington and Jacqueminot, Senateur Yaisse, Mademoiselle Crapet, Comtesse Chabriat, Duchess of Sutherland, Géant des Batailles, and Louis Peyronny.

**HEATING FROM A BOILER AT THE BACK OF A PARLOR FIRE (A. J. W.).**—We see no difficulty in the matter, provided there is best enough in your boiler, and your tank is on a proper level. If the boiler is close to the tank would be all the better to be 2 feet or 3 feet above the top of the boiler. Whether close or open, it is no can-a-must it be below the boiler. A small boiler would not manage such an amount of water as 300 or 400 gallons; but if you want that quantity or more in summer, all you have to do is to make your tank deep enough, but in winter to confine the depth of water to 3 inches or 4 inches. That will be heated more quickly, and the heat will equally rise whatever be the sides or covering of your tank.

**CUMBER LEAVES BLOTCHED (A Constant Subscriber).**—We think the holes are partly due to the fumes of the turpentine, and the sun shining on the leaves before the fumes escape, or they have become dry by giving air early.

**GREENHOUSE FERNS.**—We inadvertently stated at page 673, in answer to "Ruscus," that Asplenium lucidum, belliferum, and lanceolatum will not succeed in a common greenhouse. The two first are moderately hardy New Zealand species, and will thrive well in a temperature of about 35° if no cold winds get to them; and the last is a Britisher.

**PENDULOUS PLANTS FOR BASKETS IN GREENHOUSE (H. K. P.).**—Almost all twining and creeping plants will answer if sufficiently supplied with moisture, such as the greenhouse Passifloras, and the stronger growing of the Kennedias, and Gompholobiums. Allowed to depend, all training would be saved. Amongst strong-growing semi-herbaceous evergreen shrubby plants, we would instance the Maurandias, Lobpospermums, Rhodochiton volubile, Cobaea scandens, Dolichos lignosus, Jasminum gracile. Among free-growing herbaceous and succulent in their stems—Tropaeolum Lobbianum elegans, Triomphe de l'lyris, and the beautiful tricolorum and pentaphyllum. Of small herbaceous evergreen trailers, we would instance—Lobelia gracilis and begoniifolia (blue), and Hibbertia grossularifolia (yellow), Saxifraga sarmentosa, and Tradescantia procumbens, leaves green, white, and purple. Of hardwood small plants, Kennedy prostrata would answer well. Where the assistance of a hotbed could be procured for cuttings and seeds in spring, the beautiful Torna nantica, and the various varieties of Thumbergia would look charming in summer if well syringed. Of succulents use Cereus flagelliformis and Mallesoni.—R. F.

**VARIOUS (Highlander).**—In your circumstances it would be best to plant the strong Vines against the back wall. The nearer they reach the rafter the better. If you had planted earlier you might have had fruit next season. To get it now the ball must not be broken much, but that will be against the plants afterwards. We would rather spread the roots nicely out and think little of a return the first year. Those in pots had better be kept in pots and top-dressed. The giving them fire heat or not is purely a matter of convenience and the desired time to get the fruit. The Vine will break quite as well if left to its natural time of breaking. If your Peach tree is too vigorous, root-prune or raise carefully and replant in poor soil. Your watering with such fresh rank manure water, would, of course, increase luxuriance at the expense of maturation. We should use no liquid that flows from a decomposing-heap, of which fresh heated grass forms a portion, unless it were greatly diluted for any plants in pots, and would prefer droppings from animals instead. We do not wonder at the appearance of the pots. If the liquid had been strong, we should have expected the plants to have been killed. The Peach tree may be treated after you like. It would have better been done in October. The dark green is no doubt owing to the nitrogen in the gas water. The tree was different from a plant in a pot. A little might do it good.

**GRAFTING (Country Curate).**—For 3s. 4d. you can have from our office, free by post, Johnson's "Science and Practice of Gardening," which contains drawings and directions for every kind of grafting and budding.

**PROPAGATING GYMNOGRAMMA PERUVIANA ARGYROPHYLLA (Delia).**—If there is no chance of getting suckers, keep the plant in a warm dry place, but with moisture at the roots, and then collect the fronds with the ripest sori and sow on rough peat, and cover with glass in a moist shaded place. It is a good plan to take the fronds with the ripest seed, and just shake them, and then pin them over the rough nodules of peat. It is better to keep the material moist from beneath, instead of watering on the surface.

**DESTROYING CRICKETS (Nottinghamensis).**—We have not been much troubled with crickets, as they soon leave a place where it is not warm and dry. We have tried with success thin bits of bread, with a little fat or butter rubbed on, and then dusted with arsenic; the bread then doubled and placed in the driest warmest place, and care taken that neither cats nor any other domestic animal could get near it.

**LAPAGERIA ROSEA CULTURE (Idem).**—Notes on the Lapageria were given last week. If the plant is not healthy, examine the drainage, and, perhaps, give a little fresh sandy peat or leath mould, and place it in a temperature of from 50° to 60°. It would be as well, however, not to encourage much growth until the end of January at soonest; then you may decide whether to grow in a pot or planted-out, in either of which modes it will do well.

**STRAWBERRIES IN POTS—VINE NEWLY-PLANTED (Oxonian).**—The Strawberries will do well without plunging in the frame if you keep the frost out. If that is not done by covering, better plunge the pots upright, and lay a few leaves or litter over the surface, below the leaves of the Strawberries. About the end of February, take-off the faded leaves of the plants, fresh top-dress, and move them into your house, increasing the heat in the first week to 50°, and gradually on to 55° and 60°. A little litter and a mat will do good to the roots of the fresh-planted Vine. Remove it altogether in the month of May, that the sun may warm the ground; and then, in your light soil, mulch in August with fresh horse-droppings. Send any contribution, however small, to Mr. Hague, 36, Mount Street, Ashton-under-Lyne.

**SCALE ON APRICOTS (Old Baring).**—Point out the stems and branches with a cream paint made of soft soap, flowers of sulphur, and water. It is impossible for us to say, whether guano would benefit old fruit trees, of which we have no information as to whether they are vigorous or decrepid, fruitful or unproductive.

**VINES (Gertrude).**—Supposing you plant on both sides, you will need about twenty-eight Vines. As you have already eight Vines, we would plant the others in equal numbers of white and black, as two White Tokay, two Royal Muscadias, two Buckland Sweetwater, two Trebbiano, one Dutch Sweetwater, one Raisin de Calabre, four Lady Downe's (black), four West's St. Peter's, one Black Prince, one Black Champion. From eight to ten bunches on a rafter will be fair—that is, from sixteen to twenty-four across the house. Peaches and Figs would be best in pots on the floor of the house; get the fruit set before the Vines make much growth, and take the trees out in the autumn to ripen the wood. See what was said lately on under crops with a roof covered.

**PLANTING VINES (Amateur).**—We should use some friable loam, with a tenth part of lime rubbish, and about as much of horse-droppings, and a bushel of broken bones. Plant the Vines out now, spreading out the roots regularly, covering them with 6 inches of the soil, water the roots before covering, place some litter on, that it to keep wet from the soil, and let the Vines come away in March.

**CYANOPHYLLUM MAGNIFICUM (Sigley).**—This is the proper spelling.

**SOIL FOR COTTON PLANTS (E. B. R.).**—Three-fourths light loam, mixed with one-fourth leaf mould or bottom of an old woodstack, and well drained, will suit them.

**FLUE-HEATED VINERY (B. Persevere).**—As great results have been obtained from a flue as from any other mode of heating; your determination to make the most of your circumstances is the way to get on. You may syringe the Vines until the buds show bloom; but the best plan is to have evaporating-pans set on the flue, it matters not what if they hold water. If your flue requires to be hot, put no sulphur on it within some yards of the furnace. To be safe, the flue should not be above 160° where you put the sulphur on. Half a pound of sulphur mixed with water to a pint, or with milk, will, if thin, go over a large space of flue. We prefer repeating the operation to doing it much at a time—say at an interval of ten days. Any time is the best to begin to force the Vines—say March, to have the fruit in the end of July; earlier, if you want them earlier. Coax the Vines to break by giving heat gradually, beginning at 45°, and rising from half to three-quarters of a degree a-day until you come to 60° and 65°. Mind the flue is not too hot for the sulphur.

**HOT-WATER PIPES (An Old Subscriber).**—You will require two four-inch pipes all round the 12 feet by 9 feet span-roofed house, except at the doorway. If you wanted a high temperature early, one pipe more might be necessary. If a bed were made on one side, a pipe might go through it. Plants will force rather better when plunged in a mild hotbed than when on a stage; but it does not make any very great difference, only the bed is more regular than the atmosphere. There have been no end of directions as to the modes of heating lately. It would matter little whether your boiler was placed at one end, opposite the doorway, or at the side of the doorway. We would have the two pipes nearly on the level, though one flow and one return.

**NAMES OF FRUITS (A. B.).**—1, Summer Strawberry; 3, Brookes; 4, Black Worcester; 5, Passe Colmar; 6, Dumelow's Seedling; 7, Winter Greening; 8, Forge; 9, Nonesech; 13, Dumelow's Seedling; 14, Margil; others not recognised. (W. H.).—1, Beurré de Rance; 2, Zephirin Grégoire; 3, Passe Colmar; 4, Conseiller de la Cour; 5, Beurré d'Arcberg; 6, like Glout Moreau.

**NAMES OF PLANTS (Arthur Cole).**—Yes. It is *Polystichum aculeatum*, var. *lonchitidoides*. (W. R. Hayward).—1, Galeopsis ladanum; 2 and 7, *Gentiana amarella*; 3, *Sonchus arvensis*; 5, *Hypericum hirsutum*; 4, *Rubia perigrina*; 6, *Atriplex portulacoides*; 8, *Chenopodium polyspermum*; 10, *Geranium columbinum*; 11, *Suaeda maritima*; 15, *Atriplex arenaria*; 16, 17, *Calamintha acinos*, not distinguishable in the specimen sent; 9, 12, 13, 14, too incomplete. We again say that, anxious as we are to aid our readers, yet we cannot undertake to name so many specimens for any one correspondent in one week. Here were seventeen bad specimens to examine! Three or four specimens are a fair number to send. (A. L.).—*Valloia purpurea*. (J. J. S.).—*Yucca* is a seedling of some form of *Lastrea dilatata*. (W. M.).—1, *Adiantum cucucatum*; 2, *A. bispidium*; 3, *A. asmitile*; 4, *A. capillus-Veneris*. (S. F. H.).—Two small fronds of *Lastrea spinulosa*; large frond of *L. dilatata obtusa*. The underneath frond a very elegant variety of *Polystichum angulare*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE

### POULTRY SHOWS.

DECEMBER 9th, 10th, 11th, and 12th. CRYSTAL PALACE. (Poultry, Pigeons, and Rabbits.) Entries close November 8th. Sec., W. Houghton.  
DECEMBER 16th and 17th. LOAN TREDEGAN'S, Newport, Monmouthshire. Sec., Mr. J. G. Palling, Newport.  
DECEMBER 20th. HECKHONDWYKE. Sec., Mr. J. Thornton. Entries close December 20th.  
DECEMBER 29th, 30th, and 31st. MANCHESTER.  
JANUARY 1st, 2nd, and 3rd. GLASGOW. (Pigeons and Canaries.) Secs., Mr. T. Buchanan. Entries close December 22nd.  
JANUARY 6th, 7th, and 8th. KENDAL. Secs., George C. Whitwell, and T. Wilson.  
JANUARY 13th and 14th. GLOUCESTER ORNITHOLOGICAL. Sec., Mr. G. Cummins, 89, Southgate Street.  
JANUARY 21st and 22nd. LIVERPOOL. Sec., J. T. Lawrence, 3, Cook Street. Entries close January 5th.

### BIRMINGHAM POULTRY SHOW.

THIS important Exhibition commenced yesterday, and will continue till Thursday next. We subjoin a list of the prizes, and shall give a full report next week. The number of entries of poultry was 1365, and that of Pigeons, 232.

**DORKING (Silver Grey).**—First, D. V. Allen, Inchtute, N.B. Second, T. Staller, Manchester. Third and Fourth, withheld. *Chickens*.—First, and Second, G. Cargay, Sandon Farm, Staffordshire. Third, Right Hon. Lord Hill, Shrewsbury. Fourth, T. Staller. *Hens*.—First, G. Cargay. Second, C. H. Wakefield, Malvern Wells. *Pullets*.—First, G. Cargay. Second, J. Drewry, Burton-on-Trent.

**DORKING (Coloured, except Silver Grey).**—First and Cup, W. Copple, Eccleston, Prescott. Second, T. Burgess, Burleydam, Whitechurch, Shropshire. Third, Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Fourth, Capt. W. Hornby, Knowlesy Cottage, Prescott. *Chickens*.—First, J. Drewry, Newton Mount, Burton-on-Trent. Second, C. H. Wakefield, Malvern Wells. Third, W. T. Everard, Bardon Hill House, near Ashby-de-la-Zouch. Fourth, Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst, Kent. *Hens*.—First, C. H. Wakefield. Second, Right Hon. Viscountess Holmesdale. *Pullets*.—Right Hon. Viscountess Holmesdale. Second, D. V. Allen, Inchtute, N.B.

**DORKING (White).**—First, Mrs. H. Fookes, Whitechurch, Blandford, Dorsetshire. Second, Mrs. Beardmore, Uplands, near Farnham Hampshire. *Chickens*.—First, H. Lingwood, Needham Market, Suffolk. Second, J. Robinson, Vale House, Garstang.

**SPANISH**—First, R. Teebay, Preston. Second, J. Martin, Claines. Third, J. K. Fowler, Aylesbury. Fourth, H. Lane, Bristol. *Chickens*.—First, H. Lauc. Second, R. Teebay. Third, J. R. Rodbard, Wrington, Bristol.

Fourth, H. Yardley, Birmingham. *Hens*.—First, J. Martio. Second, R. Teebay. *Pullets*.—First, S. H. Hyde, Ashton-under-Lyne. Second, J. R. Rodbard.

**COCHIN-CHINA (Cionamon and Buff).**—First and Mr. Wade's Cup, H. Bates, Edgbaston, Birmingham. Second and Amateur's Cup, H. Tomlinson, Balsall Heath Road, Birmingham. Third, G. Fell, Warrington. *Chickens*.—First and Amateur's Cup, J. W. Kelway, Merston, Isle of Wight. Second and Amateur's Cup, G. Fell. Third, E. Musgrove, Aughton, Ormskirk. *Hens*.—First, S. Statham, Forest Row, Sussex. Second, E. Smith, Middleton, Manchester. *Pullets*.—First, C. Felton, Erdington, Birmingham. Second, Rev. G. Gilbert, Claxton, Norwich.

**COCHIN-CHINA (Brown and Partridge-feathered).**—First, P. Cartwright, Oswestry. Second, H. Chavasse, King's Heath, Birmingham. Third, Mrs. Herbert, Powick. *Chickens*.—First and Cup, T. Stretch, Ormskirk. Second, R. White, Broomhall Park, Sheffield. Third, E. Musgrove, Aughton, near Ormskirk. *Hens*.—First, R. White. Second, E. Smith, Middleton (Grouse). *Pullets*.—First, P. Cartwright. Second, J. Heape, Sparkbrook.

**COCHIN-CHINA (White).**—First, C. Felton, Erdington, near Birmingham. Second, R. Chase, Birmingham. *Chickens*.—First and Second, Master K. W. Chase, Birmingham.

**BRAMA POOTRA.**—First and Second, R. Teebay, Fulwood, near Preston. *Chickens*.—First, J. K. Fowler, Aylesbury. Second, D. V. Allen, Inchtute, N.B.

**MALAT.**—First, N. Sykes, Mile End, London. Second, W. Manfield, jun., Dorchester. *Chickens*.—First and Second, N. Sykes.

**HAMBURGH (Golden-pencilled).**—First, Major Ward, Calne, Wiltshire. Second, J. Munn, Newchurch, near Manchester. Third, A. Nuttall, Newchurch, near Manchester. *Chickens*.—First, Mrs. W. Kershaw, Manchester. Second, H. Snowden, Great Horton, near Bradford, Yorkshire. Third, J. Howard, Redford.

**HAMBURGH (Silver-pencilled).**—First, D. Harding, Middlewich, Cheshire. Second, J. Martin, Claines, Worcester. Third, Rev. H. G. Baily, Swindon, Wiltshire. *Chickens*.—First, S. Shaw, Stanland, Halifax. Second, T. W. Walsh, Worcester. Third, J. Martin, Claines, Worcester.

**HAMBURGH (Pencilled).**—*Hens*.—First, J. Munn, Shawlough, Newchurch, near Manchester (Golden). Second, J. Martin, Claines, Worcester (Silver). *Pullets*.—First, J. Munn (Golden). Second, T. W. Walsh, Worcester (Silver).

**HAMBURGH (Golden-spangled).**—First, J. Dixon, North Park, Bradford, Yorkshire. Second, J. Robinson, Vale House, Garstang. Third, W. R. Lane, Bristol Road, Birmingham. *Chickens*.—First, S. H. Hyde, Taunton Hall, Ashton-under-Lyne. Second, J. G. Sugden, Eastwood House, near Kettlewell, Yorkshire. Third, W. R. Lane, Birmingham.

**HAMBURGH (Silver-spangled).**—First, J. Fielding, Newchurch, near Manchester. Second, J. Dixon, Bradford, Yorkshire. Third, W. Cannon, Bradford, Yorkshire. *Chickens*.—First, H. Beal, Wexham, Slough. Second, and Third, W. Cannon.

**HAMBURGH (Spangled).**—*Hens*.—H. W. B. Berwick, Helmsley, York (Golden). Second, W. Lawson, East Chevin, Otley (Golden). *Pullets*.—First, I. Davies, Bull Street, Harborne, near Birmingham (Golden). Second, A. Nuttall, Newchurch, near Manchester.

**POLAND (Black with white crests).**—First, T. P. Edwards, Lyndhurst, Hampshire. Second, G. Ray, Minstead, Lyndhurst, Hampshire. Third, H. Beldon, Bradford, Yorkshire. *Chickens*.—First and second, T. P. Edwards. Third, G. Ray.

**POLAND (Golden).**—First and Third, J. Dixon, Bradford, Yorkshire. Second, H. Beldon, Bradford, Yorkshire. *Chickens*.—First, J. Dixon. Second, C. Adkins, The Lightwoods, near Birmingham. Third, H. Beldon.

**POLANDS (Silver).**—First and Third, J. Dixon, Bradford, Yorkshire. Second, H. Beldon, Bradford, Yorkshire. *Chickens*.—First, G. C. Adkins, The Lightwoods, near Birmingham. Second, W. Newsome, Bingley, near Leeds. Third, J. Dixon.

**ANY OTHER DISTINCT VARIETY.**—First, J. Dixon, Bradford, Yorkshire (Black Hamburgh). Second, Right Hon. Countess of Aylesford, Odechurch, near Leamington (Cuckoo Dorking). Third, C. Baker, King's Road, Chelsea, London (Crève Cœur).

**GAME (Black-breasted Reds).**—First, J. Fletcher, Stoneclough, near Manchester. Second, R. Woods, Worksop, Nottinghamshire. Third, W. Robson, Worksop, Nottinghamshire. Fourth, J. Hindson, Liverpool. *Chickens*.—First, G. Cargay, Stone, Staffordshire. Second, Hon. W. W. Vernon, Eccleshall, Staffordshire. Third, W. Robson. Fourth, J. Fletcher.

**GAME (Brown and other Reds, except Black-breasted).**—First and Cup, J. Fletcher, Stoneclough. Second, R. Swift, Southwell. Third, T. Robinson, Poplar Grove, Ulverstone. Fourth, C. Curtis, Lutterworth. *Chickens*.—First, E. Archer, Malverno. Second, G. E. Meredith, Wellington, Shropshire. N. Grimshaw, Pendle Forest, Burnley. E. Ayrkroyd, Bradford. (An extraordinarily good class. Best class of Game in the Exhibition.)

**GAME (Black-breasted and other Reds).**—*Hens*.—First, R. Alkin, Hartshill, Atherstone. Second, W. Boyes, Beverley. *Pullets*.—First, R. Swift, Southwell. Second, Messrs. Parkinson & Lawrenson, Preston.

**GAME (Duckwings and other Greys and Blues).**—First, Col. Blackburne, Leamington. Second, H. Worrall, West Derby. Third, W. Dawson, Selly Oak, Birmingham. Fourth, G. Hellewell, Walkley, Sheffield. *Chickens*.—First, R. Woods, Worksop. Second, H. Snowden, Great Horton, Bradford. Third, Hon. W. W. Vernon, Eccleshall. Fourth, T. Carless, Hoveringham.

**GAME (Blacks and Brassy-winged, except Greys).**—First, J. Fletcher, Stoneclough, near Manchester. Second, W. Dawson, Selly Oak, near Birmingham. Third, G. Hellewell, Walkley, near Sheffield. *Chickens*.—First and Third, W. Dawson. Second, J. Fletcher.

**GAME (White and Piles).**—First, J. Fletcher, Stoneclough, Manchester. Second and Third, J. Cannon, Farnsfield, Southwell, Nottinghamshire. *Chickens*.—First, withheld. Second, B. W. Bretherton, Rainhill, near Prescot, Lancashire. Third, J. Camm.

**GAME (except Black-breasted and other Reds).**—*Hens*.—First, T. Goodwin, Everton, Liverpool (Duckwing). Second, J. Percival, Harborne, near Birmingham (Duckwing). *Pullets*.—First, J. Wood, Wigam. Second, T. Goodwin.

### CLASSES FOR SINGLE COCKS.

**DORKING (Silver Grey).**—First, T. Staller, Stand Hall, Manchester. Second, D. Steel, Windermete. Third, T. W. Hill, Woodlands, Heywood, near Manchester.

**DORKING (except Silver Grey).**—First, Right Hon. Viscountess Holmesdale, Linton Park. Second, Mrs. Arkwright, Derby. Third, E. H. Garrard, Brouday, Worcestershire.

SPANISH.—First, J. R. Rodbard, Wrington. Second, H. Lane, Bristol. Third, Burch & Boulter, Sheffield.

COCHIN-CHINA (Cinnamon and Buff).—J. W. Kelleway, Isle of Wight. Second, R. White, Sheffield. Third, H. Tomlinson, Birmingham.

COCHIN-CHINA (except Cinnamon and Buff).—First, E. Tudman, Whitechurch, Shropshire (Partridge or Grouse). Second, J. Shortness, Newcastle on Tyne (Partridge). Third, P. Cartwright, Oswestry (Partridge).

BRAMA POOTRA.—First, R. Teebay, Fulwood, near Preston. Second, Mrs. Seamons, Aylesbury.

HAMBURGH (Golden-pencilled).—Mrs. W. Kershaw, Heywood, near Manchester. Second, J. Munn, Manchester.

HAMBURGH (Silver-pencilled).—First, J. Dixon, Bradford. Second, Miss S. Cotes, Ricton.

HAMBURGH (Golden-spangled).—First, S. H. Hyde. Second, W. Kershaw, Manchester.

HAMBURGH (Silver-spangled).—First, J. Dixon, Bradford. Second, J. Fielding, Manchester.

POLAND.—First, G. C. Adkins, Birmingham. Second, J. Dixon, North Park, Bradford.

GAME (White and Pile, Duckwings, and other Varieties, except Reds).—First, T. Curless, Hovingham, near Nottingham. Second, Hon. W. W. Vernon, Ecclestone, R. Swift, Southwell. Fourth, J. Hindson, Everton.

GAME (Black-breasted Reds).—First, J. Stubbs, Stafford. Second, J. Fletcher, Stoneclough. Third, Hon. W. W. Vernon. Fourth, N. Grimshaw, B. Brintley.

GAME (Brown and other Reds, except Black-breasted).—First, E. Archer, Malvern. Second, T. Staller, Manchester. Third, G. Cargoy, Sandon Farm. Fourth, W. Robson, Workop.

BANTAMS (Gold-laced).—First and Third, T. H. D. Bayly, Biggleswade. Second, M. Leno, jun., Dunstable.

BANTAMS (Silver-laced).—First and Third, T. H. D. Bayly, Biggleswade. Second, M. Leno, jun., Dunstable.

BANTAMS (White, Clean-legged).—First and Second, T. H. D. Bayly, Biggleswade. Third, J. Rumsey, Shadwell and South Hackney.

BANTAMS (Black, Clean-legged).—First, J. Munn, Newchurch. Second, C. W. Brierley, Onkenrod Terrace, Rochdale. Third, G. Maples, jun., Wavertree.

BANTAMS (Any other Variety).—First, F. Musten, St. Alban's (Japanese White). Second, C. Felton, Erdington, Birmingham (Booted). Third, G. Duff, Southwell.

GAME BANTAMS (Black-breasted and other Reds).—First and Second, T. H. D. Bayly, Biggleswade. Third, E. Musgrove, Aughton, Ormskirk.

GAME BANTAMS (Any other variety).—First, J. Camm, Southwell. Second, R. Hawkley, jun., Southwell, Nottinghamshire. Third, Hon. E. N. Hill, Cranhill, Shrewsbury (Duckwing).

BANTAM COCKS (Game).—First, T. H. D. Bayly, Biggleswade. Second, R. Swift, Southwell, Nottinghamshire. Third, E. Musgrove, Aughton, near Ormskirk (Duckwing).

DUCKS (White Aylesbury).—First, Mrs. Seamons, Aylesbury. Second, J. K. Fowler, Aylesbury. Third, J. Smith, Breder Hills, Grantham.

DUCKS (Rouen).—First J. K. Fowler, Aylesbury. Second, T. Robinson, Ulverstone. Third, H. Worrall, West Derby, near Liverpool.

DUCKS (Black East Indian).—First, Miss Clifton. Second, J. Beasley, Northampton.

DUCKS (Any other variety).—First, J. Dixon, Bradford. Second, T. H. D. Bayly, Biggleswade.

ORNAMENTAL WATER FOWL.—First, T. H. Bayly, Biggleswade (Sebastopol Geese). Second, J. Morris, Wolverhampton.

GESE (White).—First, Mrs. Seamons, Aylesbury. Second, W. Mansfield, jun., Dorchester (Improved Dorset). Third, Right Hon. Lord Kinnaird, Inchture, N.B. *Goslings*.—First, W. Mansfield, jun. Second, Right Hon. Lord Kinnaird.

GESE (Grey and Mottled).—First, J. K. Fowler, Aylesbury. Second, D. V. Allen, Inchmartine, Inchture, N.B. Third, W. Lort, King's Norton, Birmingham. *Goslings*.—First, J. K. Fowler. Second, Mrs. Seamons, Aylesbury.

TURKEYS.—First, Mrs. A. Guy, Eaton, Grantham (Cambridgeshire.) Second, D. V. Allen, Inchmartine. Third, Mrs. C. Brawn, Withington. *Poulters*.—First, Rev. T. L. Fellowes, Acle, Norfolk (Cambridgeshire.) Second, J. Smith, Grantham (Cambridgeshire.) Third, Mrs. Wolfenstan, Tamworth (Cambridgeshire.)

PIGEONS.

POWERS.—First and Second, P. Eden, Salford, Manchester. Third, M. Rake, Brandon Hill, Bristol.

CARRIERS (Black Cock).—First, E. L. Corker, Croydon. Second, Messrs. W. Siddons & Sons, Birmingham.

CARRIER COCKS (Any colour except Black).—First, P. Eden. Second, Messrs. W. Siddons & Sons (Dun).

CARRIER HENS.—First and Second, E. L. Corker, Croydon. (Good class.)

CARRIER HEN (Any other colour).—First, M. Rake, Bristol. Second, P. Eden, Salford.

TUMBLERS (Almond).—First, M. Rake, Bristol. Second, P. Eden, Salford. Third, G. F. Nicholls, Cheltenham.

BALDS.—First, F. Esquilant, Oxford Street, London. Second, D. Thwaites, Cheshire. Third, T. Ridpath, Rusholme.

BEARDS.—First, W. H. C. Oates, Newark. Second, M. Rake, Bristol. Third, F. Else, Bayswater, London. (Good class.)

TUMBLERS (Of any other Variety).—First, Peter Eden, Manchester. Second, F. Else, London (Black Mottled). Third, F. Esquilant, London (Yellow).

JACOBIENS.—First, S. Shaw, Halifax. Second, H. Morris, Forest Hill, Kent. Third, F. Esquilant, Oxford Street, London. (Good class.)

FANTAILS.—First, G. C. Adkins, Birmingham. Second, D. Thwaites, Rock Ferry, Cheshire. Third, J. W. Edge, Birmingham. (A very excellent class.)

TRUMPETERS.—First, S. Shaw, Halifax. Second, W. H. C. Oates, Newark (White). Third, W. Cannan, Bradford. (An excellent class.)

OWLS.—First and Second, M. Rake, Bristol. Third, F. Else, Bayswater, London.

NOSES.—H. Morris, Forrest Hill. Second, C. Felton, Erdington. Third, F. Else, Bayswater, London. (Good class.)

RESULTS FROM OVERFEEDING POULTRY.

WE have had so many queries of late about diseases arising from overfeeding and mismanagement, that we think we may answer some querists, and anticipate others by putting together in one short paper the pith of many answers. Thus, "E. G." complains that some fowls that have been fattening for some weeks, and that were intended for Christmas, are losing weight, although they are very fat. "TYRO" says his fowls do not fatten, although they have lots of food always by them. "BOSTON" says after they have been a day or two in confinement they have no appetite—in fact, like the villagers with Jupiter, "Every one complained."

As it is hard and somewhat tedious to task folks to task one after the other on the same subject, we will get rid of all by telling them what they should do; they will then see their faults of omission and commission. Fowls are hatched to be made fools of. If they did but know how many are destined to supply the table at Christmas—instead of laying on fat and nursing themselves with the idea the extra food was unselfishly given in obedience to the advice of the "Poultry Chronicle," they would be disturbed with mortal anxiety, would pine, and keep obstinately thin, and thereby save their lives.

It must always be borne in mind that fattening means only what it implies. It is (in table phrase) adding fat to lean. It is useless to put up a skeleton, however healthy, and to fancy that good meat will be put on by feeding in confinement. As we wish to write familiarly, we will say the lean must be made while the bird is running at liberty. Another error against which we must warn our readers is the idea that any amount of feeding will make a hard fowl tender. Hardness is the result of age, and the distinction between "old" and "not very old" is, after a certain age, nonsense so far as eating is concerned. A fowl is an old one at ten months as certainly as at the end of ten years.

Premising, then, the birds put up to fatten shall be young—say sixteen, or eighteen, or even twenty weeks old, and fleshy, three weeks' confinement ought to make them very good. We do not advise cramming under ordinary circumstances. It is good where fowls are intended for market, but it is hardly necessary for home consumption. If a coop be made for twelve or eighteen fowls and four are put into it, they will not fatten, there will be too much room. The birds must have room to stand up, and to shift their position, but not to move about. They should be fed three times per day; their food should be ground oats, or oatmeal mixed with milk, of such consistence that when laid on a board in front of the coop it will not run off. The food should be fresh-mixed each time, and no more should be given than will be eaten clean at each meal. If the day's consumption is placed at once before the bird it eats to repletion to the destruction of appetite; the food turns sour, and then it takes a distaste and does badly. The fattening fowls must be fed every morning at daybreak; they must be covered up warm at night, and protected from cold by day. They should fatten in three weeks. If they have stale food, if they are fed irregularly, if they are kept in draughts and places where they are not protected from cold, if they are allowed to see other fowls running about, they will not fatten.

There is no process by which fowls can be kept healthy after they are fattened; it is, therefore, necessary to calculate the time and numbers. Thus, if a dozen will be wanted between Christmas and Now-year's day, they should be put up about the 3rd or 4th of December. This will allow three weeks for fattening; and of the twelve, these that have made most progress must be killed first. If the attempt be made to keep them after they are thoroughly fattened, failure will be the result. "E. G." is perfectly right; they will be fatter and they will be lighter. Persevered in, this process leads to death. All the functions of the body become impeded, and the birds die of compound jaundice. To one of these causes "BOSTON" may trace the fact they have no appetite.

## THE PIGEON SOCIETIES OF LONDON.

### I.—THE PHILOPERISTERON SOCIETY.

It has occurred to us that an account of the various Pigeon societies existing in London might afford interesting information to many of our country readers. As these societies have very distinct objects and aims, it would be undesirable to include the account of all in a single article: we shall, therefore, deal with them singly or in groups, and commence our series by one of the most celebrated—namely, the Philoperisteron Society. For the benefit of those of our readers to whom Greek is Greek, we may state that the term "Philoperisteron" signifies that the members are lovers of Doves or Pigeons.

The Society, which was founded in 1847, holds its meeting on the evenings of the second Tuesday during the months of October, November, December, and February at the Freemason's Tavern, and has an annual grand Show in the Great Hall during the month of January. The members are elected by ballot, and pay an entrance-fee of one guinea and an annual subscription of an equal amount. The annual Show, to which visitors are admitted only by tickets signed by the members, always receives due notice in our columns. It is attended by amateurs from all parts of England, and is in every way worthy of the distinguished patronage it receives. On no other occasion is so valuable a collection of birds ever got together, every variety being in general represented by specimens of far higher value than make their appearance at any of the competitive shows. The members, who number many of the *élite* of the fanciers throughout the kingdom, include amateurs of almost every breed. Thus, the President for the present year, Mr. Harrison Weir, is unrivalled in the excellence of his Fantails and Toys generally. The Short-faced Turnblers, including Almonds and Motiles, are worthily represented by the specimens exhibited by Messrs. Lung, Percivall, and Esquilant. In Carrier-fanciers the Society is particularly strong. We need do no more than mention the names of Messrs. Hayne and Date, of London; Messrs. Chalker and Square, of Plymouth; Everett, of Brighton; Oliver, of Bristol; and Eden, of Manchester. In Powder-fanciers the Society is eminent, but has recently sustained a great loss in the lamented death of the late President, Mr. Bult. At present the collections of Messrs. Eden, Smith, and Hayne include many birds of the highest excellence. Mr. Wicking, one of the oldest members, formerly had an unrivalled stock of Toys and Short-faced Baldheads; at present his stock included a valuable collection of German birds, such as Priests and Swallows. Barbs, which, from the difficulty of breeding first-rate specimens, may be regarded as amongst the most valuable of the Toys, are represented by Messrs. Eden, Stevens, and Tegetmeier.

Among the office-bearers of the Society are included the names of Messrs. Carrell and Archer, two old and well-known fanciers. The Honorary Secretary is Mr. Tegetmeier, who appears to be devoting his attention to experiments on the homing faculty of the Belgian Smerles. His birds, which have been obtained from several of the best flights in Liège, Antwerp, Verviers, &c., include many that have flown immense distances.

At the annual Show the members of the Society incur a great amount of trouble and considerable expense in fitting-up the large Hall of the Freemasons with ornamental pens. Their birds are forwarded from all parts of the kingdom, and they invite their friends to inspect what is unquestionably the finest collection of Pigeons to be seen in the kingdom. We should recommend all interested in this delightful fancy to obtain invitations to witness this annual gathering.

## THE SWALLOWS AND FLYCATCHERS.

OF Swallows we have four species common to England. The largest are the Black Swallows, or Swifts, sometimes provincially known as Screechers; they build in holes in walls or under the eaves of houses, churches, &c.

The common or chimney Swallow, sometimes called the Barn Swallow, may be known by its long forked tail. It builds its nest in the form of a cup of mud lined with hay or feathers, and placed in a chimney, under a bridge, or in a barn, from which reason it derives its name.

The Martin, known also as White Martin, House Martin, or Window Swallow, builds a dome-shaped nest of mud, and places it under the eaves or in the windows of houses and similar places, though sometimes on the face of overhanging cliffs or rocks.

The fourth species is the Sand Martin or Bank Swallow. These have the peculiarity of boring or excavating a hole in a sand-bank, where they form their nest; these holes are often a yard deep, bored in the face of some sand-pit or bank, from which circumstance they obtain their distinctive appellations.

All these Swallows are migratory birds, coming to this country in spring, breeding here, and departing again in autumn for a warmer climate, where they pass the winter.

Their food consists of insects, which they catch on the wing. In fine weather they may be noticed flying high in the clear sky, the fine weather attracting the insects to sport in the air; while in damp and rainy weather they mostly fly low, hunting along the walls, over the fields, or about the margins of streams for such chance prey as may there show itself.

As the Swallow tribe feed entirely on the wing, it is evident that they do not eat any grub or larvæ, but only the perfect insects; and as most of these spend their honeymoon or take their love trips in the air, it is then they fall a prey to the Swallows by day, even as the nocturnal insects are devoured by the Fern Owl and Bats at night.

Thus the Swallows do good service in diminishing the number of gnats, mosquitoes, flies, and small beetles, which in the larvæ state have revelled on many green things. From this it is evident that these birds are useful, and as they do not eat any vegetable substance, neither fruit nor corn, no ill can be laid to their account on that score; yet their usefulness and innocence are not sufficient to protect them from all people, as some very tidy persons destroy them on account of the dirt they make, while others will sometimes use them as a mark for their guns.

Of Flycatchers we have two species: the Pied, a somewhat local bird and rather scarce, and the Spotted Flycatcher, which is much more common, and frequently called Wall-bird or Post-bird, from its habit of resting on such places, from which it darts into the air to secure its passing prey.

These Flycatchers are also migratory, being summer visitors only. The common one builds its nest on stumps of trees or holes in walls, fences, &c., and is noted for the curious places it sometimes selects to raise its young in. They frequent gardens, orchards, and other such places, and help to thin their resorts of many flying things, blue-bottle flies being eagerly sought and devoured by them.

Although small birds are so much exclaimed against by some, often without discrimination, yet I trust that these Swallows and Flycatchers may be allowed to pass unmolested. The only accusation of a destructive propensity that I have ever heard of as being brought against the Swallows, was that they killed bees. I believe that it is unfounded; if, indeed, a young bird should catch a bee or wasp, I think the sting would be a caution to him in future, as, feeding on the wing, he could not, like the Tomtits, first peck it to pieces on the nearest bough and extract the sting before swallowing it.

The proverb says, "Experience is a dear master," and I have no doubt a young Swallow would find it so if he were induced to try a bee.—B. P. BRENT.

STARLINGS.—Mr. Brent is not quite correct about the Starlings (p. 661). They eat any amount of Cherries. I do not think they touch anything else.—H. R., Bromley.

## APIARIAN MISCELLANY.

To the other attractions which gradually but surely drew me to pay a visit to the International Exhibition, I must add the anticipation of a great treat in the large amount of objects connected with apian science, which, I fondly imagined, must be collected under the vast roof covering the productions of almost every country on the face of the globe. Accordingly, in company with a friend, a much-esteemed correspondent of this Journal, I went note-book in hand, intending to devote my first day almost exclusively to the apian department. But my anticipations of pleasure and profit were soon greatly doomed to disappointment; for, with one or two exceptions, there appeared to be so little worthy of inspection, that I relinquished the task of a more thorough investigation to my friend, and consequently made but few notes at the time. Having perused the various communications which have appeared within the last six weeks on this and collateral subjects with considerable interest, I am induced to give the result of my own observations and opinion respecting

the various matters of discussion arising therefrom. I propose therefore to avail myself of the notes of your other respected correspondents, and remark on the opinions advanced by them. It is a matter of regret that these papers appeared so late in the season. If some beneficent individual had given us the benefit of his experience almost as soon as the other guide-books appeared, many would have been saved considerable disappointment, and more would have had reason to thank him and THE JOURNAL OF HORTICULTURE for affording them a means of quickly getting through what there was to be seen.

We first come to the consideration of the case of R. Fenn of Woodstock, better known to us as your respected correspondent, "UPWARDS AND ONWARDS." On the whole this case gave me considerable pleasure. As we have since been favoured with some papers from the pen of this exhibitor, I purpose glancing through them and adverting to any subject which may seem to invite remark.

The hives are of a very useful class, of an admirable size for profitable working, and they appear well made. There is one little matter I should like to see altered; which is, instead of one central hole of communication I should prefer two or three placed nearer the side of the hive, so that one large-sized cup or glass which would just cover the three apertures or three smaller glasses might be used. Hives with central communications, no doubt, will give as good supers of honey as any other; but I have for some time past entertained the idea that the queen is by their use more inclined to ascend into the super than by the holes nearer the side. Since adopting the latter I have obtained some beautiful supers. Though by no means successful in every case in excluding the queen and brood from them, I still think the plan has other advantages; the chief of which are a less-obstructed communication, and the removal of the necessity for the crowding of the bees up over the chief breeding-combs in the hive for the purpose of passing into the super. But this, like many other plans, is with me only on its trial, and I should not like to speak too confidently of its undoubted superiority.

Mr. Fenn, or perhaps I should say "UPWARDS AND ONWARDS," will probably contend that the plan he advocates for the exclusion of the drones and queens will be found to obviate the objections which may be urged against central communications. Certainly by this plan may the drones be excluded, and possibly the queens; but with the exceedingly small means of communication which he affords, it would seem impossible for the bees to work rapidly, or to take the fullest advantage of a prolific honey harvest. So very limited a space afforded for the passage of the bees would not coincide with my views at all. It may be adapted for the very small supers which "UPWARDS AND ONWARDS" seems to have set his affections on, but would not do for such supers as I have been in the habit of using and obtaining, holding from 15 lbs. up to 53 lbs.; the latter quantity collected without a square inch of comb that had been used as a receptacle for brood. Small supers are very pretty, and may more frequently be obtained perfectly free from brood than large ones, but in my humble opinion are a sad hindrance to the full productive powers of the bees. I very seldom put on a super which will hold less than 15 lbs. or 25 lbs., and should the season be favourable to honey-gathering, the capacity of these is quickly increased by slipping between them and the stocks boxes of the same diameter, of greater or less depths, being mere ckes without tops or adaptors.

I do not know whether "UPWARDS AND ONWARDS" claims the invention of the system of exclusion of drones as his own. He may certainly have unaided hit upon the idea, but he cannot claim priority of invention. In 1849 and 1850 I corresponded on this very subject with W. J. Pettit of Dover, who then advertised for sale a hive on this principle. The letters received from him were destroyed only a few months ago, as I did not think them likely to be of further use. He exhibited a hive fitted with the drone-excluding communication, the plan of which I should much prefer to that shown in page 602 of the Journal—namely on the ground of its being composed of a greater number of slits, forming in the aggregate a much larger aperture. This would seem to be an improvement on the ordinary modes of affording access to the supers, and I have often reproached myself for not having given it a trial. Having tried most new ideas that have, from time to time been promulgated, it seems strange that this has not been included in the category. But another season will, I trust, see it somewhat extensively adopted in my apiary.

With regard to the disputed matter of cross-sticks, although

detesting them myself in ordinary straw or other hives, I am quite disposed to coincide with "UPWARDS AND ONWARDS" in advocating their use in hives of such large internal capacity as those he adopts. As it is intended that the combs shall be a permanent fixture until, from age or otherwise, these hives are broken-up, the objection to their use on the score of difficulty of removing combs comes to nothing. The obstruction which it is alleged is caused to the breeding of the queen, which may be true as respects very small hives, cannot be of any importance in such hives as our friend uses. That they may often be the cause of saving an unfortunate downfall of the combs would be sufficient argument in favour of their presence. I am, however, inclined to believe that the reason for the bees having fastened-down their combs to the board did not arise from their fear for the stability of their works; but that, owing to the large diameter of the straw hive, the boards had become pressed-down by the weight, thus approximating the lower edges of the combs to the bottom board, to which, of course, the bees would quickly secure them.

I do not like the feeder this exhibitor uses and recommends. No one who has become acquainted with the plan of feeding by bottle but must, I fancy, be convinced of its very great superiority to that shown in page 603, or to those advocated by almost any other authority.

Of the use of the milk-pan for a cover as a substitute for the straw hackle, I am rather inclined to think favourably, so long as the stock-hive remains unsupered; but the protection must be very imperfect when raised-up another story, and wholly inadequate to keeping off either burning sun or driving rain. I have used with advantage in such cases a ring made of old floor-cloth passed rather loosely round the lower live. Two of my straw hives have been thus protected for more than four years. But I much prefer well-ventilated wooden cases which, however, "UPWARDS AND ONWARDS" will contend do not come within the means or the requirements of the million. The cases most approved of are, so made that one only with a loose roof can be used for a single hive or box; or they may be piled-up to any necessary height, to meet the wants of one, two, three, or more supers, the same roof fitting any one case.

But what shall we say to the abomination, in the shape of a stone imitation of a human head, stuck-up on the top of the pan to prevent its being overturned? How any one with the smallest amount of taste can complacently put-up with such an incongruity I cannot conceive. Better have the roughest old stone, or the most dilapidated of bricks than this monstrosity. But there is no need of either. A very fine piece of copper wire passed over the pan and under the floor-board would effectually prevent the possibility of any accident from the effects of the most violent of gales. The small bell-glasses in this case were filled with beautifully white honeycombs. The various preparations of and from honey and wax were also nicely exhibited, and worthy of a high meed of praise.

I have dwelt thus long on the contents of this case, and the subjects for discussion, which have arisen from the remarks which have already appeared relative thereto, both from the pen of the exhibitor and others, because there was much well worthy of notice and of praise, and very strong proof shown that the well-known contributor to your pages is a thoroughly practical man, whose opinion and judgment on apian matters are worthy of very high consideration.—S. BEVAN FOX, *Exeter*.

(To be continued.)

#### DZIERZON ON THE BEE-YEAR 1862.

NOT one of the least benefits conferred by THE JOURNAL OF HORTICULTURE on its various apian readers is the admission to its pages of the well-weighed opinions and enlarged experiences of such distinguished and practical bee-keepers as Dzierzon, of Carlsmarkt, and Kleine, of Lüthorst. To Mr. Woodbury belongs the credit of having a translation inserted of several articles written for the "German Bee Journal" by these eminent apianists, and it is to be hoped that his good offices in this respect may from time to time be continued. The continental naturalists have always been foremost in exploring the hidden mysteries of bee-life, and it is pleasing to find that the German apianists of the present day do not lack that patient industry and persevering endeavours after truth which distinguished their predecessors.

Everything from the pen of Dzierzon especially, the celebrated

propounder of the wonderful doctrine of parthenogenesis in the honey-bee, must necessarily be fraught with interest; and, though, after a long battle against what is called the antiquated notions and confirmed prejudices of bee-keepers, he has lived to see these partially mollified if not altogether subdued, and to witness his long-cherished hypothesis in course of being elevated in the hands of the scientific physiologist to the rank of a regular theory; yet we find that additional study and a more varied and extensive experience have compelled him to sacrifice his theory to his convictions, and to leave the defence of this strange doctrine of parthenogenesis in other hands, such as Carl Theodor Ernest von Siebold, Professor of Zoology and Comparative Anatomy in the University of Munich, and others who may choose to take it up. In such circumstances, it would appear, he has retired, bewildered and confounded, seemingly, amidst the conflicting deductions of his own experiments, to take shelter under the antiquated and untenable theory of a bygone age—the exploded hypothesis adopted by Swammerdam of the vivifying action of an *aura seminalis*.

No apiarian, however, will think less of Dzierzon for doubting the correctness of his own theory in the face of facts, which, as they appeared to him, he could not conscientiously ignore. It is an evidence rather that he is not a man who can be led away by a preconceived opinion, whether right or wrong, but that his mind is open to the reception of the truth, come from what source it may.

No one who is intimately acquainted with the history and habits of the bee, and who fully understands the effects of those various influences which ever and anon are brought to bear on its welfare and prosperity, will fail to recognise in the writings of Dzierzon the opinions of a man who knows his subject well. And yet there is one remark he makes in the article entitled the "Bee-year 1862," which if left unexplained might lie open to question and doubt, as not harmonising with the findings of experience in such circumstances. It is this:—"Another remarkable observation which I make at this time is, that all stocks from which the old queen has been removed in the course of the summer, either with or without a swarm, are more populous, and work stronger than those which have not been disturbed;" and again, "Those, therefore, are mistaken who believe that stocks in order to remain strong must be left undisturbed."

Now, these remarks, though put in too general a way, and without regard apparently to circumstances, contain, nevertheless, a thorough knowledge of the bee community, and of what is most conducive to their increase and prosperity. Every experienced apiarian will have observed that in our climate, and with our pasturage, there is a limit beyond which we fail to increase the number of bees in any one hive, however much we may enlarge their accommodation.

In a good season, and with a prolific queen, I admit that a hive, if swarming could in such a case be prevented by an adequate enlargement of the domicile, would increase prodigiously in population and in stores; but there is a limit here also, nor can we always calculate on obtaining such results. In an ordinary season, and especially in a bad season, we find the aspect of affairs totally different, and the results also different. Indeed, I have almost invariably found, as a general rule, that my hives increase in strength up to a certain point, when, if by the intervention of bad weather swarming is prevented, then from that moment, increase the accommodation as I may, those thwarted hives become, if I may so express myself, demoralised, and their former activity and energy materially slackened and damped. The reason I assign for this is that swarming is strictly a natural act, and when bees are thwarted in their swarming propensities, a certain check is given to their ardour and industry which has a prejudicial effect upon the whole community. That swarming is a natural act I hold in opposition to a great many naturalists and apiarian writers of the present day, who, in my opinion, expend a great deal of unnecessary logic in endeavouring to account for what are termed the "causes" of such a "wonderful phenomenon." When, therefore, bees are prevented from swarming, when they are foiled in this their natural propensity, they are foiled in one of the principal objects of their existence, to the accomplishment of which the whole labours of the entire community in spring and early summer undoubtedly tend.

Properly managed and timely made, nearly the same beneficial results may be accomplished by artificial means. By both processes, the natural and artificial, a fresh vigour and a new impetus are imparted to the bees, which, because in accordance

with Nature's laws, will act most favourably on their welfare, instigating both bees and queens to increased activity and energy in their respective functions.

In my apiary during this most disastrous summer, my strongest hives ultimately became the weakest. Those which did not swarm, and which, consequently, had a crowded population and abundant brood, gave way first. The bees perished abroad in hundreds from pure inanition, and the broods were, consequently, neglected and cast-out.

It would not be right, however, to construct a general theory out of materials furnished in so exceptional a year; but, nevertheless, my experience quadrates with that of Dzierzon as to results.

In regard, however, to the removal of the old queen in every case from a hive which has not swarmed, if such be the meaning of Dzierzon's observations, I could never approve of it; and I most cordially join in Mr. Woodbury's caveat in this matter, to all bee-keepers, against such deposition of the queens regnant without some very cogent reasons. Indeed, I never do remove a queen alone from a hive in summer, unless I find, as sometimes happens, a radical defect in her productive powers. At the same time, believing as I do that a queen has the ability to regulate the business of oviposition according to the exigencies of the occasion, and the circumstances and conditions in which she may be placed, I am decidedly of opinion, that in order to impart full life and vigour into the apiary, and to insure the greatest amount of numbers—in short, to have prolific queens and vigorous colonies, natural swarming must be tolerated, or such other substitutes adopted as shall most nearly resemble the provisions which the wisdom of Nature points out for the multiplication of the species.—J. LOWE, *Edinburgh*.

OUR LETTER BOX.

EGGS WITH THIN SHELLS (*Ornithologist*).—All fowls must be supplied with the material for the shells of the eggs. Nature does not provide it, and your birds lack chalk or lime. Throw down a good large basketful of bricklayer's rubbish near to their roosting-place, or any other much-frequented part of their run. You will soon have hard shells.

SILVER PHEASANTS (*C. B.*).—Your Silver Pheasants will hardly be worth more in the spring than they are now. They are of no value till they are in colour, when they are nearly two years old. At that age they are worth about a guinea each. We cannot say what they are worth now; but think about twelve shillings each.

POULTRY WITH DISEASED LIVERS (*Mrs. Russell*).—As you say your fowls are very fat, we are disposed to think they have fat livers. They are much enlarged, and very pale. The change of colour is caused by the absorption of the bile into the liver, and this is caused by excessive fat. Indian corn and Potatoes will both induce this disorder. When over-fat, or confined too long for the purpose of fattening, poultry decreases in weight, while it gains in fat. The result is the fat liver so much esteemed by gourmands, and the principal ingredient in the celebrated "Pâté de foies gras aux truffes de Perigord." Diminish the quantity of food, give your fowls ground oats mixed with water three times per day, and give your Geese and Ducks plain oats; if they are in confinement, add gravel.

FOWLS WITH DISEASED DIGESTIVE ORGANS (*C. Spencer*).—Unless we know the food given and the treatment generally, we can offer no certain suggestion. Excessive feeding with insufficient exercise, violent transitions of temperature, and many other causes, may be the origin.

SPANISH PIGEONS (*An Amateur*).—Your Pigeons are evidently Runts. Any weight over 4 lbs. per pair is a very good weight for this variety, and will generally win at a show. Two odd-coloured birds in the Pantail or any other class would stand no chance of winning. Prizes are given for pairs, not for odd birds.

MILKING (*W. H. S.*).—A well-fed Cow may be milked until within a month of her calving. She should then have a drench of 12 ozs. of Epsom salts and 2 drachms of powdered ginger in a quart of warm water, and have less green food until she becomes dry. You unreasonably find fault with us for stating the yield of butter and milk from a superior Guernsey Cow. Why should an inferior Cow be kept, since the cost is the same? We have only stated facts; it is not the fault of the manager, but of the animal, if the latter has a full allowance of good food.

LONDON MARKETS.—DECEMBER 1.

POULTRY.

There is more than an ample supply at market, and the trade is nominal. We do not expect any improvement till the approach of Christmas.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 45.3° and 33.7° respectively. The greatest heat, 61°, occurred on the 13th, in 1842; and the lowest cold, 11° on the 13th, in 1846. During the period 152 days were fine, and on 93 rain fell.

NEPETA CÆSIA—EDGING PLANTS—PLANTS FOR SOUTH AND NORTH WALLS.

SOME plants are so and so, and others are so much like them, that people begin to say they are neither the one thing nor the other; but the first plant on my list to-day has proved itself, by a long course of service, to be the best plant in England for a poor man, and a prince could not procure a better for

certain effects, or for certain situations in his grounds. The name of it, as I booked it last September in the botanical arrangement in Kew Gardens, is *Nepeta cæsia*—that is, in good old English, Grey Catmint.

How many flower-gardeners should you suppose are in this, or in the next island, who would not join with those who would say that a Catmint was neither the one thing nor the other? But I say it is the one thing for a poor man, and the other thing for a prince. It is also the best thing for a company in the arrangements of their plants in a public garden. There is now no question at all amongst a very large number of men and masters, that this same Grey Catmint is the very best plant, and the most telling plant in use in Europe, for certain situations and for particular purposes. Every good gardener in the three kingdoms knows the plant as well as your humble servant, and yet I question if there is one of them out of a thousand who could tell the plant I mean at this very point. Do you know the plant? No. Well, that is more my fault than that of any of you; but when you come to recollect it, I often wished to be able to tell you the name, what it is you have known for many years, and you have, all of you gardeners, cried up the plant more than ever I did. Mr. John Caie, when he was gardener to the late Dowager Duchess of Bedford, at Kensington, was the first person who brought out this Grey Catmint, about five or six and twenty years since; and Mr. Eyles is the last gardener who made the best hit with it at the Crystal Palace, for it is the very plant which everybody has admired ever since Mr. Eyles planted it round the large clump or bed of tree Pæonies there.

Although I still claim to be a gardener, and always shall be proud to be so called, yet now I am only an amateur; and being but a poor one, I consider this Catmint would be the best plant in Europe for me to put round a bed of Rhododendrons, or a bed of Kalmias, or Ghent Azaleas; also to put round a bed of Nepal Berberis, or a mixed bed of the large evergreen Berberis, or one of Pæonies; or if I could not afford to have such beds, and had to do with a bed or two of fine-flowering common shrubs, as kinds of Spiræas, I am quite sure

there is no other plant which would do for the edgings to any, or to all of these, and similar beds so well, so appropriately, and so cheaply, and which could be kept on for a generation with so little trouble and cost.

I am equally certain of one other thing about it, and that is, that there is not one gardener out of ten thousand who knows *Nepeta cæsia*, and has seen it at the Crystal Palace, who will not agree with me in all that I have said about it, except it be the turn round those noble Berberises. Most gardeners are now aware of how much better these great Evergreen Berberises do under the shade of trees, and they plant out masses of them in the plantations, along the sides of walks and drives; and in such places with so much shade, *Nepeta cæsia* would be apt to get drawn-up and look weedy. But the poor man, whose ease is now on the eard, has no plantations, green drives, and shady walks, to be fringed with beds of Evergreen Berberises; he must be content to take the north side of his house, or of his garden walls, or fences, and there these Berberises will do just as well, and there the *Nepeta cæsia* will also do round them as well as if it were in the full sun, as it is where round the tree Pæonies at the Crystal Palace.

When we come to talk of a plant like this for a prince, no royal personage can have a better edging for a princely bed of noble things than the Grey Catmint which Mr. Caie first brought into notice round London. Even up in the wilds of Argyleshire, in the Highlands, where Mr. Caie now dwells, there is no better plant to set round a bed of pure-bred Rhododendrons than his own plant—this very *Nepeta cæsia*. I have seen whole flower-beds of it with him at Kensington, and by his neat way of keeping it in high trim it did very well, but none of us had ever seen the plant in its proper place until Mr. Eyles, and after him Mr. Gordon, took it in hand at the Crystal Palace, and made it an edging plant 18 inches wide, and nearly of that height. When left too long without being replanted it becomes higher than that, but is not so good-looking, and it ought to be lifted and reset every second or third year. It increases as fast as Box-edging, and every time it is lifted it could be so divided that one yard of it would plant three or four more yards of better plants. It also comes from cuttings as freely as a *Salvia*, and no frost seems to hurt it. It was never figured in this country, but it is believed by some botanists to be the *Salvia cæsia* of Willdenow's Enumeration of the plants in the Berlin garden. I examined the plant some years since, and my impression also is, that it must be a diandrous plant, and if so in reality, it cannot be a *Nepeta*; but, like Mr. Scott, I am now satisfied with the outward appearances of plants, and it is certainly down in our national collection at Kew as *Nepeta cæsia*. Our *Cineraria maritima* is *Senecio cineraria* of that collection.

There are some remarkable hardy wall plants which I noted at the same time on the walls round the botanic collection at Kew, which are seldom mentioned in the current talk about garden plants. One of the most conspicuous and out-of-the-way plants among them is a

running and very strong Bramble, called *Rubus biflorus*. This *Rubus* ought to be in every wilderness and Swiss garden, also in every large rock garden, and near ruins, and on rustic works. Every part of the surface of this Bramble, except the upper side of the blade of the leaf, is as white and shining as floss silk, with a milky-white down, which comes off by the touch like the "bloom" on a Plum or Grape. Indeed, it is the most conspicuous plant I know out of doors. If you had a pole or the stump of an old tree covered with Irish Ivy, and were to plant *Rubus biflorus* against it, and tie the wide-spread branches here and there to the fore shoots of the Ivy, I cannot conceive anything that could be made so telling, and at such long distances from the eye. Without knowing it, half the world might think the Bramble was whitewashed that morning, on purpose to make the strong contrast with the deep green of the Ivy. But it would face any kind of evergreens, and would be seen half a mile off, and no one could tell what it was, and you must all have it next spring if other things should go to the wall.

A directly opposite kind of plant is the next on my list, and I wondered why it was I never recommended such a plant, if only on account of the shine in the leaves for a gardener when shaving to use instead of a looking-glass. I once saw a bride adjusting her cap by the reflection in a bucket of water for want of a looking-glass; but if *Cerasus ilicifolia*, the plant in question, had been trained against a north wall before the bride she could have arranged her dress without stooping. The beauty of the real shine and glossiness of the leaves, the closeness of growth, and the turn it would give to the north-east corner of the house, or where the two walls meet near the summer-house, and the polished contrast a bush plant of it would give on the north side of a summer-house, or rock, or rootery would be irresistible. Go and see it to convince yourself.

The old fast-growing climber or trailer called *Bridgesia spicata* by Sir W. Hooker, after Mr. Thomas Bridges, who went out after plants to South America from the Botanic Garden at Bury St. Edmunds, is on that wall at Kew under the name of *Ercilla spicata*, the genus having probably been pre-occupied by a former botanist. That running plant is not used nearly so much as it should be for the driest and hottest south walls in the south and midland counties of England, or to reach the tops of the highest Eucalyptuses or Gum trees in Australia; but in the flowers there is no beauty.

Then there was the oldest and the rarest seen of our very graceful lawn-standard shrubs, a great favourite in my young days; grafted standard-rose height on the Laburnum it would droop down as a "fountain" rose, and sweep the grass with its hoary and silvery leaves and shoots; it is the Salt tree, or *Halimodendron argenteum*, and was trained against the wall like a Peach. If this reminiscence of my childhood had been fresh from China or Japan in the recent introductions, it would be cheap at 3s. 6d. a-piece as soon as rooted, but you could get a standard plant of it now for so many pence; and although they give it a wall at Kew, the lawn is warm enough for it in Ross-shire, and there is not a better lawn plant of the same habit and look between here and the bridge of Alness in the said county.

*Viburnum suspensum* was the next which took my fancy very much on account of its very thick deep green leaves. Here is a happy-looking standard plant if you please. Talk about pot and tub standards of Laurustinus, which is one section of *Viburnum*, and then look at *suspensum* in your mind's eye, how much more rich-looking it must be when both kinds are out of bloom, although tinus has the advantage over *suspensum* in the profusion of bloom. But for a noble mantle for the north side of a house or wall I know not a rival to *Viburnum suspensum*. Let us hear, however, how it has fared in Edinburgh and Glasgow, for it is of recent introduction, and we must be careful about how we recommend half-crowns, half-standards, and half-hardy plants, to be set out on the off side of the borders.

*Forrestia pubescens* was another peculiar wall plant, nearly as large as a Peach tree, with seemingly hardy wire-like branches, and soft leaves of the size and shape of those of the broad-leaved Myrtle; but the plant is a kind of bastard *Ceanothus*, and it certainly deserves purchasing when one is on the look-out for covering walls with suitable plants which are not very common.

*Ilex rotunda* is one of the very best of the very thick, dark, glossy-leaved Hollies; it is a Japan plant, and stands conspicuously against a south wall, where it does not require much room.

On the north side of the wall was *Coriaria sarmentosa*, a fine-foliaged and very curious plant, well worth inquiring after

as distinct, on its own merits, and to make a variety where one likes to show off in this style.

Then there was the old *Bupleurum fruticosum*, which one seldom sees now-a-days. It is 10 feet high, and as much along the wall. They do not train in the yearly shoots, but let them stare out all over the plant, these bloom at the extremities, and were then, last September, in full bloom after the manner of some *Euphorbia*; great, open, upright bunches of pale yellow flowers. I suppose these summer growths are closely pruned in before winter; for the young wood of this plant is very liable to be frost-bitten, but as the bloom comes on the year's growths this can easily be avoided, besides being the true way to obtain a mass of very curious bloom all over the plant.

There was a fine-leaved species of the prickly Toothache tree, which I had not seen before, *Xanthoxylon alatum*. It is on a south wall, and well deserves the indulgence on account of its fine pinnated leaves, for which alone these foliaged shrubs are so much admired by those who prefer collections of distinctly-marked species to the common run of everyday plants, which few gardens are without.

But there is one thing above all others which I should see to myself. If I had a garden under two acres in extent, either in the country or next to a large town, I would not have more than one pair of any kind of tree or shrub as long as I could find good things to fill up my grounds. The repetition of common shrubs which one sees at every turn of the road I would never allow beyond Hollies, Yew, and Laurels—the latter I would never use but for screens in small gardens. You could not walk 10 yards in my garden without seeing and learning more about the finer shrubs and low trees, evergreen and deciduous, than you now can do in a day's march, yet I should never seem to be crowded, nor have an inch to spare. D. BEATON.

#### COMMON PLANTS ADAPTED FOR ORNAMENTAL PURPOSES.

THE letter of Mr. Hague at page 592, recommends the foliage of Red Beet as worthy the attention of the flower-gardener, and adduces his experience in its use in an advantageous manner. Of this fact I have not the slightest doubt whatever; indeed, I have long thought that Red Beet, and some other vegetables and common things, possessed an interest and beauty not usually accorded them. In the present age of inquiry it is not unlikely that their claims to attention may be duly regarded; and names hitherto held in contempt may sound worthy of a place in more fashionable quarters than the kitchen, or perhaps the rubbish-heap. It is not so very many years since the bulk of our native Ferns were known only to the few deeply learned botanists who thought it worth their while to search for and investigate them merely as examples of scientific research, and the number of British species was thought not to exceed forty or so. Hooker's "British Flora," a work on native plants, held in high repute upwards of thirty years ago, enumerates only forty-one species; and that work was an especial favourite with young gardeners at that time, and regarded by them as an authority not to be controverted. Now the case is widely altered. The addition to the general flora during that time, though comprising some important specimens, bears no proportion to the additions made to the list of Ferns; and these additions have not been all made by learned but somewhat pedantic botanists, but by the florist and ardent flower-gardener, whose assiduity in searching-out new beauties for their especial departments has been the means of breaking-down the traditional prejudice that arrogated to itself that true beauty was only of exotic growth. During that period rocks that were previously regarded inaccessible have been scaled, and obliged to give up their long-established treasures. Mosses have been waded through for a like purpose, and waste and cultivated grounds have alike been investigated with a view to discover anything new in the Fern way; while a new and altered mode of cultivation in the artificial condition the specimens find themselves placed in, when transported to the stores of the affluent cultivator, has in many instances so altered their original form that new names have been awarded them—often, I fear, without any claim to the distinction.

The rage for new species, and the care and industry to secure them, have unquestionably led to many being discovered; and the list of native species of 1862 presents a strong contrast with that of 1825, while the public taste in like manner has under-

gone a proportionate change. At that time the name "Fern" served only to call up a feeling little short of contempt. Now, it is regarded as one of the highest forms of beauty, entering extensively into all the embellishments which place the present luxurious age so much in advance of the past. The young lady of 1825, who would turn with a sort of half disgust at the mention of the word "Fern," finds her prototype of 1862 proud to wear it in her hair. To attribute this change of popular feeling to any one particular class alone would be certainly wrong; and though much of the merit of placing the Fern in its present elevated position in the scale of real rather than ideal beauty belongs to the rich and enthusiastic class of plant-collectors and cultivators as well as the botanist, yet there is one class whose claim in calling-up the Fern from its former obscurity has never been sufficiently recognised by the gardening world, and that is the Poet. No Scotchman who has read the heart-stirring effusions of Burns or the Ettrick Shepherd, but must have noticed how much of their force was imparted by the natural energy thrown into them through contact with the native vegetation, "the ferny brake" especially; while the classic Byron finds an equally useful auxiliary in his alpine scenery depicted in "Childe Harold." That the imagery thrown into their works by the glowing pictures they gave of this particular branch of the vegetable kingdom should have been so long in directing the public taste has many parallels. They were men before their time; but it is now only fair to accord them some share of the credit of placing so beautiful a section of the vegetable world in its proper position, by the thrilling appeals they so often made to it so long before it was recognised. Let us see if other beauties do not also exist under names too common almost for utterance in fashionable company, and which, if they could only obtain the stamp of being fashionable, would make their way.

Beginning with plants whose claim to distinction for ornamental purposes no one has recognised, we may notice the common Globe Artichoke, not only for the singularly-formed head it presents, but for its foliage, which, when viewed at a distance, has quite a tropical aspect. The silvery whiteness of the under side of the leaf, now and then disclosing itself on a windy day, adds not a little to the soft grey tint of the upper side; and the size and form of the whole give it a noble appearance when viewed at a distance, for which it is particularly adapted. Let us suppose a group of these plants fronting some shrubbery at the distance of 200 yards or so, and it will be difficult to suggest anything more becoming. At such distances small forms of vegetation are lost to the eye; so that, unless the foliage presents something unusual in shape, size, or colour, the appearance differs but little from surrounding objects. But this plant possesses in a remarkable degree all these qualifications, and on that account is worthy of more extensive patronage.

Following in a different line, but scarcely less interesting in the graceful and fairy-like form it presents itself in, is the common Fennel, whose slender but singularly beautiful stem is branched and sub-branched into an infinite diversity of graceful shoots, each sufficiently firm to maintain its proper position, yet in no respect rigid and unnatural. As a compeer to it we have the Asparagus, whose slender summer shoots often enough assist in giving an easy gracefulness to a stand of cut flowers. I do not mean those bundles of packed flowers called hand-bouquets, but the nice agreeable stands which so often ornament a lady's boudoir, or, it may be, a dinner table. In days of yore a bouquet, either for the hand or bowl, was thought incomplete if it did not possess a sprig of one of these graceful-looking plants. The one that commended itself most to our notice was the old-fashioned but by no means unsightly Southernwood, which deserves better at our hands than it often receives. Some other plants in the same way as these may doubtless occur to some of our readers, but the above give a type.

Diverging into a smaller class of vegetation, I am not acquainted with anything that presents a more beautiful and long-sustained verdure than *Saxifraga hypnoides* or *S. tridactylites*—the latter a close mass of little tufts or heads of the most brilliant green, and each leaf that composes this thick-set head being in itself a gem of beauty. I have often wondered why this plant was not more extensively cultivated to cover vacant spaces amongst damp rocks or similar places. For at least nine months of the year it is a charming object; the only period it may be called in *déshabille* is the period of flowering

and after-growth. The family of *Saxifraga* also offers several examples of ornamental plants differing widely from the vivid green moss-looking one noted above. *Saxifraga marginata* is an interesting-looking plant, remarkable for the geometrical-looking form it presents; and differing but little from the last is *S. longifolia*, a neat compact-growing plant, at all times pretty whether in flower or not. This family is, however, far from exhausted by their members being called on, for there are others scarcely less pretty. But I will pass on to another group.

The family of Grasses has for a long time been deservedly esteemed for the graceful beauty of some of its members; bunches of them very often adorn the mantelpiece of the greatest patrons of good taste. The Quaking Grass, *Briza media*, is and has always been the favourite of childhood; and the same may be said of some of the Hair and Feather Grasses; and the Cotton Grass of our marshes has often been a source of inquiry. Indeed, a selection of Grasses might be made, the spikes of which might safely be introduced into the choicest mixture of flowers. Some of them might even be cultivated; while bunches of the others, gathered where grown naturally, might take their place in the front ranks of the aristocracy of the flower garden. Some of the Reeds, Sedges, &c., are also far from being uninteresting; in fact, inhabiting as they do the sides of ponds and ditches, their waving foliage presents a form in vegetation we are not well supplied with; while the variegated forms some of them are offered in, as Gardeners' Garters, the *Arundo donax* variegata, and others, are already amongst the fashionables, and need no comment here, but a *Dactylis glomerata* variegata is far from being so well known as it deserves.

In a miscellaneous class of plants with pinnated leaves, the Tansy is interesting and pretty. Scarcely less so is the foliage of the common Yarrow (*Achillea millefolium*), a close examination of which will discover beauties not previously thought to be possessed by weeds having a bad name. Differing from either of these, yet possessing a striking Fern-like form and habit of growth, is the common Carrot, the handsomely cut foliage of which entitles it to more respect than it often receives, as may easily be shown by any one taking a leaf and holding it against a sheet of white paper, not pressed against it. The shadow cast on the paper is not inferior to that of any of the Ferns over which the charm of poetry has thrown so much interest, but of which the Carrot has received no share. There are many other plants possessing foliage of an interesting kind in this way amongst the weeds of every plantation, but enough has been said to awaken an interest in them.

Taking another class of plants of divers forms, yet still interesting, we have the Sweet Marjoram, with its top-knots of buds, forming a feature in vegetation we have few examples of. Differing widely from that is Parsley; and in another direction we have several kinds of Thyme, one of a pale grey—a close compact creeper; while in the list of low-spreading plants are the various Sedums or Stonecrops, not the least important being the Houseleek. *Sedum stellatum* is also pretty and interesting. This list might be widely extended. Passing on to other things, and looking over the hedge, the Horsetail (*Equisetum*), presents a form differing from anything else we have had; while in the far corner of the kitchen garden the wide-spreading leaves of the Rhubarb exhibit a form also unapproachable by anything in the exotic line; and if we make an erratic excursion to some cottage garden we will find the common Pink occupy a much more important position in the ranks of Flora than we assign to it. There is also a plant of compact form, full of leaves, larger and more closely inserted to a common crown or collar, spreading evenly on all sides, forming a sort of hemispherical outline of from 1 foot to 1½ foot in diameter all the winter through, and these leaves each more agreeably blotched or spotted than the *Farfugium grande* or the yet more exotic *Begonia*. This plant, hitherto long neglected, forms a nice object all the winter, and may with confidence be recommended as an ornamental one. It is the variegated form of the *Pulmonaria officinalis*, and it is one of the hardiest plants I know. A fine specimen may be seen near the heathery in the botanical-arrangement part of Kew Gardens.

In the class of dark-leaved plants the Red Beet does not stand alone. An *Ajuga* of dwarf habit is far from an indifferent object. I have it as *A. orientalis*. It is of low growth, and a neat companion to *Arabis alpina* variegata, which is, by-the-by, one of the most useful edging plants we have; and being of compact habit, it takes up well and remains in autumn to supply beds that have been denuded of their summer ornaments.

It is not the proper place here to enter into the merits of things already acknowledged. There is, however, a plant of admitted beauty which has not yet become fashionable, although I draw attention to it two or three years ago. It is the old-fashioned Lavender Cotton (*Santolina canescens*), a plant more beautiful than any of the *Gnaphaliums* that I am acquainted with. That this plant should be rescued from oblivion is certainly advisable. The *Calla aethiopia* is also a plant of graceful and singular growth, deserving more attention than it receives; while the humble-growing *Neja gracilis* possesses a foliage at once singular and prepossessing.

In giving the above hasty list it is likely many highly ornamental plants may have been omitted. My object is to call attention to common things so as to admit the beauties they possess; and now, as foliage as well as flower is an acknowledged ingredient in the flower garden and ground features, some of the plants above named may come in for a share of attention. No one denies the beauty of the Pampas Grass; and trees of elongated foliage, as the *Ailanthus* and *Sumach*, have their admirers; the common forms of everyday life will eventually come in for theirs also; and it is easy by study and attention to the commonest rules of flower-garden law to discover how feasible it would be to have a striped or ribbon-border of ordinary vegetables that would look very well. Take, for instance, an edging of Parsley; then a row of a dwarf-topped good-coloured Red Beet; next, a row of Altrincham or Orange Carrot; afterwards a row of the Variegated Kale (pink, white, and purple), and back this with a line of Asparagus, and here we have a ribbon-border composed of things all useful as well as ornamental. These plants as well as others may be varied in many ways, but I leave the mode of doing so to other hands, contenting myself with having drawn attention to the matter, but may nevertheless report further on the same subject on another occasion.—J. ROXBOROUGH.

#### POINTS OF MERIT IN GRAPES.

To meet the wishes of many cultivators of Grapes, it perhaps would be better to divide the Hamburgs into two classes, Red and Black. My experience in Grape-growing compels me to say, that colour and flavour are inseparably united, and I hold the opinion that Black Hamburg Vines producing red-berried bunches are not healthy.

Has Mr. Thomson, or any of your other correspondents, noticed the fact, that red-berried bunches of Hamburgs will not hang so long as black ones?

Perhaps some of your correspondents can explain the reason why some Hamburgs produce red, and others black bunches. There are many people who would, doubtless, prefer large green Muscats to amber-coloured ones half the size; also, large red-berried Hamburgs to beautifully hammered black ones; but give me the amber in the one, and the black in the other.

I fancy not one of the craft would take it as a compliment to be asked by a party examining his Grapes, whether they were Black or Red Hamburgs.—T. J.

#### VITALITY OF APPLE AND PEAR TREES.

THERE are, perhaps, no fruit trees that survive a long voyage so well as the above. In 1861 I had a case of fruit trees packed for a present to a friend, living near Adelaide, South Australia. Owing to the presence of business I could not send it off so early as I wished to do (January is the latest month trees should be shipped for that colony), so that the case was not shipped till the beginning of February, and the vessel did not sail till nearly the end of that month.

I now give an extract from a letter received from my friend, dated Adelaide, January, 1862:—

"The trees arrived at the port the beginning of July, and as soon as I had intelligence of the arrival of the ship I posted off for my trees: to my great disappointment the package could not be found, and so I returned treeless and much mortified. Just at the end of the month a message came that my case of trees had been found at the bottom of the cargo. As nearly six months had elapsed since you wrote me they had been placed in the case, I sent for it with rather gloomy forebodings, thinking it impossible I should find one tree alive. When it reached me I unpacked the trees with a heavy heart; but to my surprise and delight I found all the Apple and Pear trees alive, and

quite plump and healthy. August is our early spring, and I had them all planted by the first week. Out of seventy-four trees fifty Apple and Pear trees have grown nicely. The Plums and Cherries all failed, dying down to the stocks. Some Vines have also done well."

Early in March of this year I sent a case of trees to the same friend, the ship did not sail from London till a month after the time advertised, and she laid in the port of Adelaide three weeks before she discharged all her cargo, so that he did not get the case till the 17th of August. He has recently written—

"I opened the case and found all the Apple and Pear trees in full life, and the Vines the same without an exception. The Cherries and Plums were dead."

These trees were packed in a close strong case, their roots in charred earth in a moist but not wet state, and their tops in dry moss firmly pressed down. This is the most simple and efficient method of packing; and, if deciduous trees are thus packed and shipped in December, or early in January, there is but little chance of failure. I give you this for the benefit of emigrants who may wish to take trees with them.—THOMAS RIVERS.

#### FRUIT-JUDGING.

A CORRESPONDENT of the *Gardener's Chronicle*, complaining of the decisions of the Judges at the late Show at South Kensington, "ventures to say that not one of them had tasted" the beautiful "Scarlet Admirable" Apple, to which the first prize was awarded. Whether this were so or not, I will venture to say that for any one set of judges to taste one-tenth part of the collection submitted to them in the time allotted for their judgment, it would have been quite an impossibility. With respect to the Ribston Pippins and Cox's Orange Pippins, I should presume that neither of these excellent varieties could be called ripe at that time, unless they had been gathered prematurely. For these well-known sorts I think some kind of extra test ought to be adopted, similar to carrying extra weight as applied to racehorses, or that they should be shown in a separate class; otherwise many beautiful and excellent Apples, but rather inferior to them in flavour, will cease to appear at our exhibitions, and the above two, although notoriously subject to canker, would constantly divide the stake between them, a consummation by no means to be desired. On the contrary, I conceive that the greatest variety of sorts ought to be encouraged in order to render such exhibitions interesting as well as valuable.—F. J. G.

#### PLANTS FOR DINNER TABLES.

INFORMATION being desired on this subject, and as the man of limited means is expected to follow close in the wake of those whose means are like those of Cressus, I am induced to give my meagre experience—not that I have any particular relish for decorating dinner tables, but because I feel bound to keep pace with the requirements of the times.

If such decoration be desired by employers, we, of course, must cheerfully comply: for to gratify an employer is a duty, and tends materially to render the pathway of life smooth and easy; but employers do not always make due allowance for disparity of garden power. Let us suppose that Lady Bountiful invites Mrs. Cockles to dinner, and that in the centre of the table is a forced specimen of *Dielytra spectabilis*, and at one end a plant of *Lastrea glabella*, whilst at the other is a *Lastrea acuminata*. A conversation ensues. Mrs. Cockles finds on inquiry that the first is hardy, and the last two greenhouse plants. There are a greenhouse and two vineries at home. Why should she not have her dinner plants like my lady? There's the rub. Mrs. Cockles' gardener has no forcing-house to afford *Dielytras* on New-year's day; his plants of *Lastreas* are not in condition, and his stock of plants being small, where is the substitute? "We never have anything like other people!" is the disagreeable unjust comment. Gardeners generally make the most of their charge, but it is impossible for a gardener with limited means to equal his compeer with extensive means, and no end of substitutes in case of subjects failing.

As I happen to be one having the control of limited garden power, and not exempt from duties of this kind, I give the results of my practice. I give only what I have tried, leaving out my own individual notions as to adaptability in respect to plants untried.

Suppose I have a large party to gratify—a long table, of course, and three candelabra or lamps, one light in the centre, and the others near each end. Thus :—

If the lights be lamps standing on the table two plants are ample, at X, but if the lights are candelabras four are an advantage, at O, as well as at X; the two larger in the middle, and smaller ones at the ends.

In no case ought plants to be placed under the lights, for the graceful forms of nature do not harmonise with the workmanship and design of a candelabrum, neither is it wise to distract the eye by gazing on two important objects at one time: neither is seen to advantage, and one impairs the beauties of the other.

Now I place two large plants at X, so high in stem that visitors can see their friends on the other side of the table when seated; for after the admiration of the plants ceases, conversation with friends on the other side of the table commences. Plants of that description are few, when of the proper size in suitable pots—not more than 12-inch. However, here are a few examples. Four plants on the table :—

1. Pteris scaberula	Cibadium Schiedei	Cyathea dealbata	Davallia Novae-Zealandiae
2. Blechnum gracile	Dracena australis	Blechnum covadense	Lastrea acuminata
3. Adiantum emarginatum	Nephrolepis davallioides	Pteris argyræa	Adiantum setulosum
4. Adiantum macrophyllum	Cyathea medullaria	Nephrolepis platyotis	Adiantum concinnum
5. Nephrodium molle corymbiferum	Adiantum cultratum	Adiantum trapeziforme	Scelopendrium vulgare multifidum
6. Platyloma flexuosa	Pteris umbrosa	Phlebodium areolatum	Platyloma rotundifolia
7. Cheilanthes lendigera	Croton pictum	Croton variegatum	Nothochlæna Eekloiana
8. Cyperus alternifolius variegatus	Dracena terminalis	Croton angustifolium	Maranta rosea-lineata
9. Cyrtopodium insigne	Epiphyllum truncatum	Rhipsalis	Impatiens Jerdoniae
10. Solanum capsicastrum	Citrus japonica	Ardisia crenulata	Skimmia japonica
11. Cineraria Crimison Perfection	Dielytra spectabilis	Weigela rosea	Azalea umbrata
12. Lastrea glabella	Cupressus funebris	Cupressus Cashmeriana	Polystichum angulare proliferum

The end plants are low proportionately to the centres, thereby permitting of a view directly across the table.

When two lights are employed, only one or three plants can advantageously be placed. In threes :—

1. Nothochlæna nivea	Cycas revoluta	Nothochlæna flavens
2. Cereus speciosissimus	Platys flabelliformis	Epiphyllum truncatum Russellianum
3. Asplenium bifidum	Asplenium Belangeri	Asplenium viviparum
4. Scelopendrium vulgare ramosum	Tillandsia splendens	Scelopendrium subcornutum
5. Asplenium cicutarium	A. premorsum	A. reclinatum
6. Aspidium trifoliatum	Croton discolor	Asplenium hemionitis
7. Nephrolepis pectinata	Aphelandra Lenpoldi	Platyloma falcata
8. Pleopeltis phymatodes	Pteris Kingiana	Drynaria diversifolia
9. Adiantum assimile	Begonia splendida	Adiantum capillus-Veneris Moritzianum
10. Nothochlæna trichomanoides	Gymnogramma chrysophylla	Polystichum mucronatum
11. Blechnum jamaicense	Gleichenia flabellata	Blechnum occidentale
12. Selaginella Lyalli	Lomaria magellanica	Selaginella Wildenovi
13. Selaginella atrovirens	Alsophilla radens	Selaginella africana
14. Selaginella umbrosa	Asplenium caudatum	Selaginella stolonifera
15. Lycopodium clavatum	Microlepis polyodioides	Lycopodium alpinum
16. Ananassa variegata	Dracena draco	Pandanus javanicus foliis variegatis
17. Poinsettia pulcherrima	Monochætum ensiferum	Poinsettia pulcherrima
18. Solanum pseudo-capsicum variegatum	Cordyline dracaenoides	Calliandra purpurea
19. Buonapartea juncea	Nepenthes lavis	Poinsettia glauca
20. Peach Royal George	Vine Sweetwater	Nectarifera Elrage

SINGLE PLANTS.

Greater part of the forenamed answer well as singles; but there being several left out that are suited for the purpose, I add :—

Prunus sinensis flore pleno	Polystichum aculeatum cristatum
Roses, forced	angulare proliferum Wollastoni
Primulas, not despicable	Scelopendrium vulgare latifolium
Convallaria majalis variegata, gold striped	vulgare latifolium multifidum
Acacias, standards, 1 foot to 1½ foot	vulgare cornutum
Peach, double-blossomed, standard	vulgare muricatum-fimbriatum
Dog's-tooth Violets	vulgare ramo-cristatum
Lachenalia tricolor	Asplenium cicutinum
Kirk's Plum, handsome	Halleri
Peaches, in nine inch pots	Osmunda regalis
Vines, Black, heavy appearance	clunanomea
White, not good	spectabilis
Coe's Golden Drop Plum, beautiful	Woodwardia radicans
Maranta zebra	Adiantum tornosum
Athyrium Filix-femina apiciforme	Leptogramma rupestris
erymbiferum	Cheilanthes hirta
enispum	micomera
depauperatum	Goniophlebium appendiculatum
multifidum	glaucum (Polypodium glaucum)
(The last five are deciduous: consequently require gentle forcing.)	loriceum
Adiantum pedatum	subpetiolatum
Struthiopteris germanica } if gently	Hypolepis m. lefolia
pennsylvanica } forced	Lastrea angescens
(these four centre plants second in none other. Old plants have stems from 9 inches to 15 inches in height, and are then most beautiful.)	(In old plants the fronds produced on stems, often a foot or more in height.)
Adiantum formosum	Nothochlæna distans
Asplenium formosum	lavis
laccatum	Ellisiana
Blechnum lanceola	vestita
Campylopus nitidum	Platyterium aleicorne
Davallia aculeata	stemmaria
bullata, deciduous	(Often lop-sided; therefore, not admissible when in that condition.)
dissecta	Polypodium effusum
tenuifolia	Pteris aspericulis
Maranta regalis	tricolor
Warszewiczii	Aralia reticulata
Sonerila margaritacea	Begonia Rex
Asplenium marinum	President Van den Hecke
Blechnum spicant cristatum	Reichenheimi
Lastrea Filix-mas cristata	(Most of the variegated varieties are too white looking.)
depauperata	Begonia miniata
Schofieldi	hydrocotylifolia
Polystichum lonchitis	minicata
aculeatum	Bilbergia acutis zebra
	viridifolia

All the plants mentioned are in season from September to March, except some of the hardy sorts: therefore these require forcing; and the hardy Ferns, if employed for decoration, must have greenhouse temperature to have them in good condition. Some of the greenhouse Ferns also require additional heat to have fine glossy fronds, for most Ferns make their growth in spring: consequently the fronds are frequently dingy in autumn and winter, which can only be removed by new growths; and unless they are in good condition the farther from dinner tables we keep them the better, for no plants at an exhibition are so severely criticised as those on dinner tables.

Some of the Tulips are pretty, yet no plants in flower equal those with fine green foliage; and, as Mr. Robson rightly observes, where a goodly collection of Ferns is grown, there is no end of subjects ready at all times for table decoration.

Small plants of Conifere are suitable, as—

Aracaria excelsa	Cupressus torulosa
Biota mildensis	Libocedrus chilensis
Chamaecyparis thurifera	Thuja aurea
Cupressus Bregeoni	filiformis
Lawsoni	nepalensis

When one light only is employed two plants only can advantageously be staged, which must be of similar habits, even in size, and so placed as to harmonise. For instance :—

Adiantum cuneatum	Ugly.	Blechnum jamaicense
Goniophlebium loriceum	Good.	Blechnum jamaicense
Adiantum cuneatum	Beautiful.	Blechnum jamaicense

Thus it will be seen that it is advisable to grow some plants in quantity so as to be able to have pairs; for, although most plants are beautiful when individually examined, unless our plants harmonise with each other they will not correspond with the mathematical arrangement of the dinner table—all articles at an equal distance, alike in shape, and ends to correspond with ends, and sides with sides. So with plants: they must not be lop-sided—one tall, the other dwarf; one graceful, the other grotesque; one elegant, the other drooping; but each must be as near like its opposite as possible.

Groups are sometimes staged when two lights are employed, the plants in fives :—

Primula .....	-	-	.....	Isolepis gracilis
			.....	Orange (1 ft. stem in fruit)
Isolepis gracilis .....	-	-	.....	Primula

In sevens :—

Calliæarpa purpurea ...	-	-	-	.....	Colena Verschaffelti
Adiantum cucurbitatum ...	-	-	-	.....	Adiantum cucurbitatum
Colerus Blumei .....	-	-	-	.....	Solanum capsicastrum
				.....	Croton angustifolium

VASES OF FLOWERS are also used; but unless tasty arrangement be followed, and plenty of forcing-houses at command, they are totally beyond the reach of most gardeners, for Lilies of the Valley, Roses, Azaleas, Heaths, Cinerarias, Geraniums, Violets, Deutzias, Dielytras, Kalmias, Thorns, and bulbs are required in quantity for such a purpose; and who can find room for all those, besides the usual quota of greenhouse and stove plants that flower in winter? Not many, certainly; but a few may be grown in the most circumscribed limits, and a change from plants to vases and dishes of flowers is good—there is the novelty of them.

In summer the garden teems with subjects for filling vases to any extent, and the lanes and hedges are decked with flowers, the fields with Grasses, and dells with Ferns and Mosses, enough to satisfy the most tasteful arranger.

Our hothouses abound with Caladiums, variegated and fine-foliated plants for summer decoration, with numerous flowering plants.

The beautiful *Ruscælia juncea* is seldom seen; and for dinner-table, vase, or house decoration it stands unrivalled; for its scarlet or coral-coloured blooms, produced along its graceful drooping branches, often a yard in length, are a rather out-of-the-way sight.

Many plants that look poor by candlelight are handsome by daylight. As an example:—

<i>Cissna discolor</i>	<i>Humea elegans</i>	<i>Cissna discolor</i>
------------------------	----------------------	------------------------

Ornamental Grasses, though much neglected, are very useful; but as to their utility when dried, although they may please some, and look well in vases with Everlastings and in straw bonnets, they are fitter for the herbarium than to place alongside of Nature in her living freshness.—GEORGE ABBEY.

### ARE GLOBE ARTICHOKE HARDY?

THIS is a question raised by Mr. Beaton, at page 668 of your Journal, and my experience leads me to answer in the negative, providing that they are only from one to two years old, and, as with Sea-kale, they should never be allowed to remain in a garden after that age, if grown for profit. If older, I, for one, cannot say whether they are hardy or not. I will give my experience in France, twelve miles or so west of Versailles.

When I took charge of this place in the autumn of 1860, I found in the kitchen garden a quarter of an acre break of Artichokes, which, I was told, were planted in May of the same year, bearing very profusely fine heads—on an average two to four on each plant. They kept the kitchen supplied up to the end of November, when the frost set in, and in due course the leaves and stems were cut and cleared. I thought covering quite unnecessary, and accordingly they were left uncovered for the winter, which I know was intensely cold in England, although a Hatton-Garden registering thermometer never fell below 10° Fahr., making 23° of frost; but in the following spring five roots only threw up a few suckers, which were, with the whole, condemned to the rubbish-heap.

Now, if we had had the good fortune as Mr. Beaton had in the winter of 1840, of having the ground “deeply covered with snow,” not one in a hundred would have been killed, snow being as good a non-conductor of frost as litter or leaves. In fact, I would prefer snow to either as a covering, it clears itself, and is never unsightly; but as we cannot always depend on having snow on the ground when we have severe frost, prevention is better than cure, and I have always covered with litter and leaves since the lesson I learnt in the winter 1860-61.—HENRY KNIGHT, *Château de Pontchartrain*.

IN No. 87, of THE JOURNAL OF HORTICULTURE, Mr. Beaton in his remarks on the protection of the Globe Artichoke states that he is “not quite sure if the Artichoke does or does not require protection.” He also mentions one or two instances of

Artichokes not having been injured by frost, although they had not received any protection for several successive years. I will now give an instance which I think will prove that the Artichoke does most decidedly require protection from very severe frost.

Having left a bed of about thirty plants unprotected through the winter of 1860-61, the whole of them, with but one exception, were completely killed, the surviving plant only threw up one poor sickly sucker which did no good; thereby proving that although the Artichoke may withstand an ordinary winter without protection—and I know that it will do so, as the same plants I have just stated to have been killed in 1860-61, stood the two previous winters uninjured without any protection at all—it will not always withstand unacathed nor unkilld the test of a very severe winter. At least, not in this part, South Staffordshire.

To all those, therefore, who grow and have the management of Globe Artichokes, and wish to keep them unhurt through the winter, I say Protect them, as the time occupied by a man or boy in putting a little litter over the roots and round the stems in the autumn, is no longer than would be in digging-up the dead stools in the spring, and which I expect would often have to be done after a very severe winter, if the plants were left unprotected.—J. H. M., *Stourton Castle Gardens*.

### EMPLOYING WOOD IN CONSTRUCTING A FERNERY.

IN No. 84, page 612, appears this sentence—“Stumps and pieces of wood are the very worst materials for a fernery inside a house or out, and should be used only when the better materials are deficient;” the better materials being stones, clinkers, or brickbats. I doubt not that the writer had reasons for making the assertion, but I am at a loss to define the particular grounds on which it rests, unless it be that decaying wood breeds fungus. Certainly it does; but that it is in any way injurious to Ferns I have my own reasons for doubting. I have made several small ferneries, and in every case the material used has been principally old roots and rough blocks of wood; in the first place, because they were the materials most easily obtained, and best qualified to make a rustic appearance; and in the next place, I have always understood that woody fibre in a state of decay is a material on which Ferns like to root and feed; and, as far as I have observed, I have seen nothing to induce me to alter my opinion.

A few years ago I wanted to make a good-sized clump of the Male Fern (*Lastrea Filix-mas*) on a hillock, or small mound, with the small-leaved Ivy creeping round it to the ground level, and not having sufficient earth to raise it high enough a foot of brushwood was laid on the ground, and a foot of soil placed on that. Half a dozen Ferns and some pieces of Ivy were planted; the Ferns have now grown together, and form a solid mass 5 feet or 6 feet in diameter, with the Ivy trailing about it most luxuriantly. Close by this a fernery was made chiefly of roots and blocks of wood bedded-in with the soil. About this were planted *Lastrea Filix-mas*, *Athyrium Filix-femina*, *Lastrea dilatata* and *cristata*, *Scelopendrium vulgare*, *Osmunda regalis*, *Polystichum aculeatum*, *Struthiopteris germanica*, *Blechnum boreale*, and other Ferns, nearly all of which have grown to a very large size; in fact, so much so that plants have had to be taken out at various times by way of thinning. Some of the Lady Ferns make beautiful masses of fronds 5 feet across; the *Blechnums* make fertile fronds 15 inches in length, and barren fronds in proportion; *Oncoclea sensibilla* grows 3 feet high, and comes up in a fresh place every season. Altogether the Ferns do exceedingly well, and the wood is all grown over with moss, which is an improvement, as it looks green when the dead fronds of the Ferns are removed.

I certainly cannot see why wood is objectionable; and when Ferns do so well where it is used it would justify one in believing that the contrary is in reality the case—the more so when it is known that many sorts of Ferns are inhabitants of woods and forests, and must certainly be often surrounded with decaying wood. As a confirmation of my opinion in this respect I saw a fernery built some years ago in which not a scrap of wood was used; the whole was built up of burrs, or bricks burnt together in the kilns, flints, and pieces of stones and rocks of geological interest. Of course the main body of the fernery was made up of soil, and this of a good loamy kind, such as I should choose myself. The Ferns were planted in due time, and looked promising enough, but many of them died, and very few of them

grow satisfactorily. I do not profess to be able to give an accurate account of the cause of failure; the time of planting and the situation appeared to be favourable. Probably they might have done better had peat or leafmould been mixed with the soil; but this I did not do with the fernery referred to. Probably, as the burrs were cemented together, sufficient allowance was not made for drainage; but whatever the cause was, the Ferns did not grow nearly so well as those I have planted among stumps and pieces of wood.

With regard to an in-door fernery, I should object to the use of wood altogether, as it is far more apt to attract woodlice than stones and burrs, and is also more likely to breed fungus than out of doors; it is also apt to smell musty; and while cocconut fibre is so highly recommended, although I never used it myself, wood fibre will not be required, and perhaps would be injurious.—F. CHITTY, *Stamford Hill*.

### ROYAL HORTICULTURAL SOCIETY'S KENSINGTON GARDEN.

**FRENCH FOUNTAINS AND BRONZES.**—Only £800 have been subscribed for the purchase of these objects; and as nearly £2000 more would be required for the purchase of even the smaller and cheaper fountains, it now seems pretty clear that the idea of retaining either of them must be abandoned. So soon as this is put beyond doubt, the subscribers will be invited to say whether they wish their subscriptions returned, or if they may be applied to the purchase of some of the bronzes.

**DECORATIONS OF THE GARDEN.**—The dismantling of the Great Exhibition will carry with it a considerable number of the decorations in the garden, even after making allowance for those which may be purchased. The painful Milo will be taken down; most, if not all of the bronze-painted iron will disappear, and some of the bronze antiques will go. The Fine Arts Committee, in their recommendations to the Council, discourage the purchase of iron objects. Their oxidation is a strong objection to them, which has not yet been conquered, although very good palliatives have been suggested. So far as vases are concerned, marble or terra cotta is as cheap and more beautiful. Another recommendation of the Fine Arts Committee is in making purchases to give a preference to works of modern art over those of the antique. Every one is familiar with the latter. They meet us at every turn, and can be had at any time. With modern works it is not so. Even the best have not been so multiplied. There is more chance, therefore, of their offering something new and entertaining to the eye of the visitor, and there is no lack of beautiful modern subjects.

The dispersion of the art treasures in the Exhibition building, however, is not wholly without compensation. Some trickling streams are flooding their way from it into the garden—some of the articles there exhibited are now offered to the Society either on loan or as a gift. Mr. Westmacott, nephew of Professor Westmacott, has lent his lovely marble statue of the Peri at the Gates of Paradise, and it has been placed in the conservatory. Mr. Sharpe's model of "Non Angli sed Angeli" has been placed in a niche in the Council-room, where is also placed a marble statue of David with the head of Goliath, by Professor Westmacott. In another niche is placed a model of Ariel released from the cloven Pine, also by Professor Westmacott, which he has presented to the Society. Near it stands a terra cotta statue of Flora, which has been presented by Mr. Blanchard, who manufactured it in that material. Now that it is seen that statues can be successfully manufactured in terra cotta, as has been shown by this and other objects recently executed, it is recommended by the Fine Arts Committee that some of the models which have been or may be presented to the Society should be executed in that material. Mr. Durham has presented the model of his statue of Euclid. The bronze statue of Juno, presented by His Royal Highness the Prince Consort, which has been detained from its place in the Garden by being exhibited in the Exhibition building, has now been placed where the Diana à la Biche stood, alongside the Memorial, symmetrical with His Royal Highness's other gift, the Ceres, standing on the other side of the Memorial. Herr Geiss has lent for exhibition a beautifully executed group of a shepherd attacked by a lion and defended by his dog. The Marquis of Campana has sent for exhibition a number of articles executed in artificial marble. The Marquis is a political refugee from Rome to Naples, where he has utilised his taste and talents by establishing a manufactory

of objects in a kind of artificial marble or scagliola, which has been invented by himself, and which has much of the appearance of real marble.

Nothing strikes one more, in looking at the objects which were formerly in the Exhibition and are at present in the Garden, than the greater advantage to which they are now seen. They were lost in the Exhibition building. In the Garden they stand out clear and distinct, and each can be seen and estimated as a whole. It proves the justice of our lamented Prince's views, and shows, by their success, the necessity which existed for such a show-ground. The gentlemen who have exhibited their bronzes and vases in the Garden have found their own account in it, having been successful in their sales. A list of the prices of all the articles lent is kept at the Secretary's Office.

Mr. Durham's statue of H.R.H. the Prince Consort has been submitted to and approved of by the Queen, who has expressed herself satisfied with it in all respects. It now goes to be cast without delay.

It is satisfactory to know that Her Majesty continues to take the liveliest interest in the affairs of the Garden, of which periodical reports are regularly sent to her.

Considerable improvements have been and are in the course of being made on the horticultural part of the Garden. Bosquets of Rhododendrons and other evergreens now flank the corners of the terraces, and large single bushes and clumps are being introduced here and there with good effect. The beds are planted out with Tulips, Crocuses, and spring flowers, which in due time will make everything gay.—(*Proceedings of the Royal Horticultural Society.*)

### CONSTRUCTING SMALL PITS.

The subject of small pits is one of general interest with a large body of amateur gardeners who practise in a small way; and although the questions submitted by "A SUBSCRIBER," "H," and others have been so ably dealt with by Mr. Fish, a few further remarks may not be out of place. I have seen small brick pits, built both by amateurs who had never had any practice before in such matters, and also by those who had other appliances and wished to have a small pit in addition, in which they could propagate bedding plants in the winter and spring without the trouble of making and keeping-up the heat of dung-beds. The pits were, in almost every case, heated by means of flues; these being, in several instances, constructed of earthenware pipes.

A short time ago, a friend of mine asked my opinion with regard to the propriety of building some such appliance. He has a neat little garden, and last spring he bought a great many bedding plants; since which time, until October, his garden was a picture of gaiety and neatness in its way. On the approach of winter, he began to consider whether it was really necessary for him to let all those plants die in the beds, and so put him to a similar expense the following spring. There was a great number of Calceolarias and Geraniums, which he was desirous of saving, if it could be done by building a brick pit a little larger than a two-light frame; but he did not care to have it heated, as he would not be able to attend to the fire, nor did he wish to be at the expense of fuel. I told him that, provided he built such a pit, and potted-up the Calceolarias in October, he would find no difficulty in wintering them, but that the Geraniums were not so easily kept in a cold pit, and if he could not attend to the fire he would find it no easy matter to keep his plants without it; that suitable covering must be provided; that the walls must be thick enough to resist at least 20° of frost; that the plants must be uncovered and have air every day, or on every occasion when the weather would permit, and this all through a long winter, when one night's neglect might expose the whole to destruction. In fact, I have known instances in which the plants have been carefully tended till about March, and then one night's neglect has exposed them to a frost that killed them outright, and thus spoiled the work of the winter. I also told him, that if he could manage to take up the Geraniums and plant them thickly in boxes, and find room for them in the dwelling-house, he would find it a more certain method of keeping them, as they could be kept drier; that unless he could manage to attend to his pit, he would find it more an encumbrance than a gain, although it might be very useful in the summer time; and that, if he wished to avoid the annual expense of bedding plants, he might make his garden look quite

as gay and interesting by using hardy plants, of which there are sufficient, if we would only look for them, to answer all the purposes of massing and ribbon-planting.

A friend of mine built a small pit a few years ago of the following dimensions—12 feet long, 6 feet wide, and 4 feet high at the back. At one end he dug out a stokehole, and placed the fireplace a foot below the ground level; from this a flue of glazed pipes, about 7 inches or 8 inches aperture, passed along the centre of the floor to the opposite end, where it was conducted into an iron chimney placed outside. About 16 inches from the glass a stage was made, and this was filled with Scarlet Geraniums. So far all looked promising; but, during the winter, the plants gradually dwindled away till not one was left alive. To account for this was easy enough—coke was burnt; and although the pipes were sound and the joints perfect, being of Portland cement, still a poisonous fume rose from them every time there happened to be a fire, so that no plants could stand against it. I said that coke was burnt; but, from my own experience, I believe that any kind of fuel, with, perhaps, the exception of charcol, would have had the same effect. The following year, the glazed pipes were taken out and common earthen ones put in their places, and with a like result. After that a brick flue was put in, and the same thing happened again—the plants were destroyed, perhaps as much from overheating as from unhealthy fumes, or from the latter being accompanied by the former. The flue was next covered with clinkers and cinder ashes, and the result was, that the plants were almost steamed to death, the ashes being very damp when put on the flue. Having got over this difficulty, it was found that there was another great defect—it was impossible to get heat enough to keep out a sharp frost, so that part of the flue had to be uncovered, and then, once or twice, it was found that the plants suffered when the heat happened to rise above a certain point. It, therefore, became necessary to ascertain what kind of fuel was best suited to the concern. After a considerable time it was found that small coal, mixed with breeze or unsifted ashes, was best, for this would burn slowly without fear of giving that intense heat that coke will do. In this pit he can now manage to winter Scarlet Geraniums with tolerable success, having gained the knowledge of how to do so after many losses and much extra expense—enough, in fact, to have built in the first place a small greenhouse, in which he could have kept his plants in safety from the very first; and as to propagating, he cannot even now accomplish it. Either from the fact of the cuttings having to be placed so close to the flue, or because he does not know how to manage it, or from some other cause, his attempts to propagate plants in the winter and spring have proved abortive; and certainly I have never known it done successfully in a small pit heated with pipe flues. Besides, I have only found it partially successful in a pit having a brick flue, and arranged in the manner described—that is, the spaces on each side of the flue filled up to its level with stones and clinkers, and boards placed 3 inches above that, the boards being covered with 10 inches of earth, and pipes conveying the heat from the interior amongst the clinkers to the surface. This partial success appeared to me to be more in consequence of an unsuitable vapour or humidity, than from anything wrong in temperature.

Any one who has been used to strike cuttings in hotbeds, where every cutting may be depended upon, feels disappointed when half the cuttings in a pot fail; but the ammoniaical steam of a hotbed is not to be obtained in a pit heated by fire, and although the latter may do as a makeshift, no one would lose by using the former, notwithstanding there is a deal of laborious work attached to it. Although I have not been very successful in propagating in a flued pit, I have often forced Asparagus and Sea-kale in it; and forced into bloom Tulips, Hyacinths, Lilies of the Valley, and other spring favourites. This much I have done; but I would never recommend any one else to build a small pit to be heated by a flue, especially inexperienced hands, who will, at the best, find them very troublesome, and most likely have to bear numerous losses before they get into the proper way of managing them. Of half a dozen instances in which brick pits, averaging from 9 feet to 18 feet long, and 5 feet to 6 feet wide, have been built, not one of the owners, to my knowledge, but has regretted having furnished them with flues. A greater fire is of necessity used than is proportionate to the space to be heated; consequently, there is a great waste of fuel. The plants must be too close to the flue to do well; and, altogether, such small places are very unsatisfactory, and fail to meet the requirements of those who have them.

Cold pits, whether built of brick, turf, or wood, are most useful appliances, either in the flower, the fruit, or the kitchen garden. There are many plants which are nearly or quite hardy, that the protection of a cold pit will make exceedingly valuable. In the flower garden, Carnations, Auriculas, and other plants may be grown to perfection in a cold pit; and in the kitchen garden, salads and vegetables may be wintered or brought forward in the spring—facts well known to the experienced gardener, who takes advantage of them; but when an inexperienced gardener or amateur builds a pit, his only idea seems to be that it must perform the duties of stove and greenhouse; that he must winter his stock of bedding plants there, and endeavour to perform impossibilities, which, of course, turn to failures and disappointments. It is the same with others when building a greenhouse. Inexperienced amateurs I have known lay-in a stock of plants the most difficult to cultivate, and often lose them the first winter, because they cannot or do not know how to manage the firing. I would suggest that, in such cases, it would be better to save fire and heating apparatus by making orchard-houses instead of greenhouses, and cultivating fruits instead of flowering plants. The former are as easy to grow, look as well, and give greater satisfaction when the fruit is ripe and ready for the table.—F. C.

### CLEANING SMOKE FLUES.

THIS is by no means a desirable work, and is often accompanied with great inconvenience and suffering to both animal and vegetable life. The following mode entirely obviates all those disagreeables, and is the most efficient and expeditious way possible.

First, let the flue be provided with capping-stones at certain distances; have iron chains laid along the bottom of the flue in length to terminate at those special distances; then take an inch-thick board, and make it 2 inches less than the size of the flue; and fringe it round with strips of old leather, or, what is better, whalebone, to make it fully the size of the flue. Then attach a small broad wheel of wood on each side of this brush to keep it in a perpendicular position; fasten a ring in the centre upon each side of the brush, to which affix a chain in the flue to one side, and a strong rope to the other, draw it to and fro in the flue to each opening, and the operation is finished by taking out the soot with a short wooden scoop. Two or three of the garden labourers could by this means clean several hundred yards of flue in a very short time, and would dispense with the additional expense and trouble of getting bricklayers or sweeps.—P. M., *Combe Abbey Gardens*.

### SUBURBAN ROSE CULTURE.

(Continued from page 697.)

THE next point to be considered after the preparation of the soil is a judicious selection of varieties, according to the locality where they are intended to be grown. Want of proper attention to this has been, perhaps, the most fertile cause of discouragement to amateurs, resulting in their abandonment of the cultivation of the flower, and in unmerited blame to the nurserymen for sending out inferior plants. It must not be forgotten that although Rose catalogues contain florid descriptions of hundreds of named kinds, many of them are suited only for the most favourable soils and climates; many are only of use to those who grow a large number for exhibition purposes. Some are not worthy to remain in the lists at all, and only a limited few possess that hardihood of constitution and vigour of growth which fit them to contend with the adverse conditions of a townsman's rosery. Fortunately, however, among that number are the most beautiful types in the lists, whether as denizens of the garden or champions of the exhibition stand.

The following twelve, and my own experience is corroborated by competent authorities, are unsurpassed in all the good properties that distinguish the flower; and though it may be unnecessary to connoisseurs, yet for the information of the inexperienced, for whom these papers are chiefly intended, I shall venture to append a full description of them.

To begin with the CRIMSON SCARLETS. H.P. Général Jacqueminot, brilliant in colour, vigorous, though perhaps somewhat slender in growth; on its own roots in rich, free, Rose soil blooms almost as continuously as a China. The flowers are large and well formed, though perhaps scarcely full enough;

indeed, it has, when fully expanded, the defect of showing the eye. When three parts open, however, this is not perceived, and in that state it has few superiors.

**H.P. Sénateur Vaisse** (1860), similar in colour to the *Général*, but has much fuller and finer flowers. It is also stronger in growth, but scarcely blooms so frequently; both varieties open well.

**BRIGHT CARMINE.**—**H.P. Jules Margottin**, robust and vigorous, a most brilliant colour, a large and finely-formed flower, full to the centre; has a deep profile, and in its line has no superior.

**H.P. Victor Verdier** (1860), is somewhat similar to the last-named in its qualities, but the flower is not so perfect. It is, however, rather more continuous in bloom, "*Jules*" waiting to rest between his magnificent displays.

**DEEP ROSE, ROSE, AND PINK.**—**H.P. Madame de Cambacères**, *Anna Alexieff*, *Madame Domage*, *Madame Knorr*, *Comtesse Cecile Chabillant*; all these are full and finely shaped, rich in colour, robust in habit, and profuse in bloom. The last-named is the lightest in tint, and is, perhaps, unequalled for the exquisite regularity of its petals.

**TINTED WHITES.**—**B. Souvenir de la Malmaison**, the finest, taken all in all, of the light-coloured Roses, is a lovely flower; centre a delicate flesh, shading off to white. Though somewhat flat in profile, the flower is large and full, and I have seen the outline as perfect a circle as if struck by a drawing compass. The buds are particularly beautiful, the growth is vigorous, and it blooms freely in the autumn.

*Tea*, *Gloire de Dijon* in form and habit is much like the above, more vigorous, perhaps, in growth, and very hardy. The colour is a rich yellowish-buff, with shaded orange or salmon centre; one of the finest Roses known, whether for the country or for town.

**B. Queen**, a peculiar pinky fawn-coloured Rose, a profuse bloomer through the season, slender in growth, of a middle size, and well shaped.

**N. Aimée Vibert.** I give this one in to the dozen for a **PURE WHITE**. The flowers are small and pretty, and the growth renders it suitable for training upon a wall having a S.S.W. or S.E. aspect, on a dry rich soil.

The above are the varieties which rank the highest. I shall next proceed to review the secondary order—secondary, however, only as to towns; far from the haunts of smoke they are entitled to a place among the best.

**H.P. Alexandrine Bachmeteff**, red; *Alphonse Karr*, rose; *Anna de Diesbach*, satin rose, opens with certainty; *Baronne Prevost*, rose; *Belle de Bourg-la-Reine*, rose; *Caroline de Salsal*, flesh; *Duchess of Sutherland*, pink; *Duchess of Norfolk*, crimson; *Eugène Appert*, dark velvety crimson, and scarlet; *François Arago*, crimson maroon; *Général Pélissier*, pale rose; *Léon des Combats*, dark crimson; *Lord Palmerston*, carmine; *Lord Raglan*, dark crimson scarlet; *Louise Odier*, rose; *Madame Charles Crapelet*, carmine; *Madame Laffay*, crimson; *Madame Vidot*, pale pink, most symmetrical; *Mdlle. Louise Carique*, carmine, fine pillar Rose; *Marie Portemer*, purple crimson, moderate habit, but free autumn bloomer; *Mrs. Standish*, rose; *Pius IX.*, purplish-crimson; *Prince Léon*, vivid crimson, moderate grower, but most beautiful form; *Souvenir de la Reine de l'Angleterre*, rose; *Souvenir de Leveson Gower*, deep red; *William Jesse*, light crimson.

The best Bourbons for town culture are as follows:—*Apolline*, very vigorous; *Aurore du Guide*, crimson; *George Cayier*, rose; *George Peabody*, purple crimson, dwarf, but very free bloomer; *Prince Albert*, scarlet crimson; *Pierre de St. Cyr*, pale rose; *Sir Joseph Paxton*, rose, suitable for a wall. Experiment, I think, would much extend the lists in this class.

*China*, *Mrs. Bosanquet*, pale flesh. *Noisettes*, *Jean d'Arc*, white; *Jaune Desprez*, sulphur, centre pink, very tender; *Lamarque*, lemon; *La Biche*, blush white; *Ophirie*, salmon copper; *Narcisse*, sometimes entered as a *Tea*, pale yellow, good.

The *Tea* to be depended upon are few; perhaps only *Devoniensis*, tinted white, shot rose; and *Safranot*, apricot in bud, but, when expanded, fawn; too loose. The following may be added as probable successa:—*Homère*, pale rose colour; *Bougère*, rose colour; *Madame Willermoz*, white, centre salmon.

An opinion on very new varieties must always be hazarded with some reserve, and adopted with some degree of risk. I shall, therefore, only name the following, which promise to answer well:—1861, *H.P.*, *Duc de Cazes*, deep crimson purple; *General Washington*, brilliant red; *Jean Bart*, crimson purple; *Princesse Mathilde*, crimson maroon; *B.*, *Catherine Guillot*,

brilliant rose, better than *Louise Odier*; *Modèle de Perfection*, paler rose; 1862, *H.P.*, *Madame Butin*, cherry; *Charles Lefevre*, red, purple centre; *Maurice Bernhardt*, vermilion; *François Lacharme*, carmine; *Marechal Vaillant*, red, shaded; *Souvenir de Comte de Carour*, deep crimson. *Beauty of Waltham* and *John Iopper*, the new English Roses, are well spoken of, but I do not know them from my own cultivation.

Without doubt other names might be added to this list, but surely here are enough for any reasonable collection: nevertheless, I would recommend every amateur to experiment a little for himself, both in a few novelties and other kinds of good repute. A little uncertainty adds interest to every pursuit, and greatly enhances the pleasure of ultimate success.—**W. D. PRIOR**, *Homerton*.

(To be continued.)

## KEEPING APPLES AND PEARS.

SOME time ago I made a few remarks in a popular work on keeping Apples and Pears. I mentioned my having them until late in spring in a Sea-kale-pot on grass, behind a north fence, exposed to the wintery weather; likewise, that I sent some of both kinds to the Pomological Society, and that the Judges pronounced them to be of excellent flavour. I tried the same plan with equal success during the severe weather of 1860. But in this case the fruit was better protected by the snow which fell through the net tied over the top of the pot to keep out the mice and birds. The fruit was, however, severely frozen. I should remark, that I did not touch the stored fruit while in that state, otherwise it would have been injured, as grass is in rime frost by the tread of the foot just before sunshine.

It may be seen that what I have said agrees with the fact of sound Apples being found late in spring amongst grass, or under a bush, long after the same kinds may have decayed, however snugly stored, in a fruit-room.

Connected with this subject, I may mention that on the 20th of November I had some fine specimens of Pears—*Gansel's Bergamot*, *Brown or Golden Bauré*, *Louise Bonne of Jersey*, and a few other kinds of rather early autumn Pears. They were gathered at the usual time, put into a Sea-kale-pot, placed upon ice, and covered-up with leaves. I found them cold and damp, but after being a few days in a warminery their flavour was equal to that of the crop gathered at the same time. The ice referred to was from the remainder of a stack above ground made in 1860, and covered with about 3 feet of leaves. The house or shed stands to the south, thatched with straw, the door was open, especially during summer, to keep the place cool and dry.

This, however, is foreign to my subject, and only a few have such means of preserving fruit. But all may lengthen their supply of their best, though bad-keeping, kinds of Pears, by merely letting some of the crop hang longer on the trees. This may be known to those who are acquainted with the bad-keeping qualities of *Williams' Bon Chrétien Pear*. At present, November 24th, I have sound *Marie Louise*, *Winter Nelis*, and some late kinds, such as *Béurre Gris d'Hiver*, and *Jean de Witte Pears*, which were on the trees after the leaves were off and exposed to three nights frost, one of which was about 6° below the freezing-point. I need hardly observe, that the least ripe should be left for this purpose, and that I am speaking of Pears grown on walls.—**J. WIGHTON**.

## BRINGING VINE ROOTS TO THE SURFACE OF THE BORDER.

BY MR. D. THOMSON, ARCHERFIELD GARDENS.

IN the successful cultivation of the Grape it, I believe, generally considered an important point to have the roots near the surface of the border, more particularly where the subsoil is unfavourable, and where in the original construction of the border the matter of drainage has not been attended to with the utmost care. It certainly matters less, if—on an open gravelly subsoil, or where by artificial means superabundant moisture is rendered impossible—the feeders of the Vine are 6 inches or 16 inches from the surface of the soil. But in cases where such conditions as to dryness do not exist, it is of great moment that a mass of active roots should be got to the surface of the border, and encouraged to multiply themselves there. No doubt the

most thorough, and ultimately satisfactory, way of dealing with such cases of deep roots and wet subsoils, would be to lift the Vines, and entirely reconstruct the borders on the most improved principles as to drainage and composition. But in this way there might be a risk of the loss of a year's crop, more particularly as Vines which have their roots in deep damp material are less likely to have thoroughly well ripened wood, and are in all cases deficient in those tufted rootlets that make such operations comparatively safe and easy—a risk which in gardens where there is only one viney the proprietor may not choose to incur.

In cases where the roots are thus deep, the next best way that I am aware of, and that I have proved successful, is in the first place, to dig a trench in front and round the ends of the border considerably below the level of the principal roots and original border. This trench, which should be 2 feet wide, should be filled up with what is generally termed a "rumbling" drain of brickbats or small stones, and an outlet by a drain should be secured to carry off the water that may find its way to this open body of stones. In the next place, remove the whole of the inert soil from the surface of the border down to the roots of the Vines. Then cover the roots with a six-inch covering of equal proportions of lime débris, thoroughly rotted manure, and turfy loam in a rough state, all well mixed together. Just as the Vines are to be started, a bed of leaves of sufficient depth to generate heat sufficient to warm at least the 6 inches of open material should be placed immediately over the roots.

The stone drain in front cuts off all surrounding moisture, and in itself that would be an improvement to a wet Vine-border with deep roots. It will be discovered that the open rich material with its temperature raised above the lower strata of the border is sufficient inducement to bring up a lot of roots of a very different order to what is generally found in the bottom of such borders. If the leaves are allowed to remain on the border all the growing season, the roots will be up through the top-dressing and into the leaves themselves. When the leaves are removed, leave that portion of them next the border and into which the roots will penetrate, and simply cover them over with a thin layer of light dry soil, as already recommended. Next season let the same process of adding 6 inches of dressing and the fermenting material be repeated, and in the course of a season or two it will be found that the surface of the border has the lion's share of active well-ripened roots, and of course the state of the Vines will be much improved. Last season I placed a bed of leaves on a Vine-border in November, and allowed them to remain twelve months, and the lower half of these partially decayed leaves was found literally interwoven with a mass of the most beautiful healthy roots, and this too in the case of a border very recently and carefully made and drained, and the roots of which had a dry healthy medium for 3 feet deep to the bottom of the drainage. I could point to many other instances of bringing Vine roots to the surface of borders by similar means, and would strongly recommend those who have wet borders and deep roots to try the means I have been pointing out, as the next best thing to renewing the whole concern.—(*Scottish Gardener.*)

## THE MANAGEMENT AND BUDDING OF GRAPE VINES.

BY MR. FLEMING, STEWARD TO THE DUKE OF SUTHERLAND, TRENTHAM.

THE Mill Hill Grape was brought into notice a few years since, having been grown at a gentleman's seat near Derby, from whence, through the liberality of the proprietor, it soon found its way into several gardens in the neighbourhood, and from the size and beauty of the berries, it became in a short time generally sought after. Mr. Barron, of Elvaston Gardens, favoured us with a few eyes of it, from which were raised sufficient plants to furnish a house in 1846. The Vines, which were planted on a well-made border, 18 inches deep, resting on a concrete bottom, having a rapid fall and plenty of rough material to drain off the superabundant moisture, grew rapidly and ripened their wood well from the beginning; and five splendid crops have since been cut from them. The excellence of this Grape is now beyond all doubt; not, however, as an early forcing one, as it does not ripen so early by a fortnight as the old Black Hamburgh; but on account of its fine size and colour, and from its hanging so long after it is ripe. A Black Grape, possessing the qualities of size, colour, and long keeping, being so much

required for winter use along with the Muscat of Alexandria, and Charlesworth Tokay (than which there are no better White Grapes), I feel pleasure in stating what I know of the Mill Hill. With some the wood does not ripen well, but this must be occasioned by deep moist borders; as our Vines, which are pruned upon the close spur system, have ripened every inch of wood which they have been allowed to make since the second year. The bunches of this Grape are not large, but they are well shouldered and handsome. The berries, which are round and indented, are as large as the Black Damascus. The leaves are of a more regular form than the common Hamburgh, being nearly circular, less deeply serrated, and the upper surface smoother and of a shining dark green.

The "Pope" Grape is another kind of Black Hamburgh, which is well worthy of culture from its being the earliest and sweetest of the numerous varieties of this really useful and most generally grown Vine. It is the only kind of Hamburgh grown by Mr. Robertson at Swinerton, near Stone in Staffordshire; and we have seldom seen finer crops than he obtains. The bunches are large and handsome, and black as jet; and the berries, although not so large as what is called "Wilmot's Victoria," are better flavoured. The "Pope" Grape is the best forcing one we have tried, being a free grower, an abundant bearer, and becoming well-flavoured even when ripened in February or March. It is the best of its class to plant in small houses for producing early crops.

Next in importance to having Grapes early is having them to keep late; and, after trying several experiments, we have found the Charlesworth Tokay to keep longer without shrinking than any we have grown. Its flavour is very similar to the Muscat of Alexandria, and from its being of a more robust habit and setting freely, it is a more desirable Vine. The Muscat of Alexandria, grafted upon the White Tokay, keeps its fruit longer in a plump state than when on its own roots, which we believe, is owing to the latter being a strong rooting Vine, which grows very late in the season. We have the White Tokay here as a stock for the Muscat, with leaves still upon it (January 8th); while the leaves of the Muscat grafted upon it have ripened perfectly and fallen more than a fortnight. The fruit upon the grafted Vines are of a beautiful amber colour, and quite fresh; while those on Muscats of the same age on their own roots are shrivelling.

Grafting, budding, or inarching Vines of the late-keeping kinds is much to be commended; for although the size of the berries is smaller, the flavour is improved; and judging from our experience of the last few years, the fruit keeps three weeks or a month later.

The best time for budding Vines is when the sap is flowing freely into the buds in spring, and when the leaves are commencing to unfold. If done earlier they will bleed, and thus weaken the stock; whereas Vines do not bleed if wounded after the leaf begins to unfold, unless a shoot or branch be cut off. A strong stem of a Vine may be budded all over with one or several kinds; and if the operation is performed skilfully, and at the critical moment when the Vine is just coming into leaf an inferior variety may by this means be made to bear the best kinds of Grape in one year after budding, thus offering the readiest means of making the best of what has often to be considered a bad

stock, and the cause of much disappointment, as in the case of Vines purchased under a wrong name. The sketch will show clearly the way in which I have budded many Vines, all of which have done well. As soon as the bud is nicely fitted into its place, it is tied tightly and neatly with bass, clayed over as in grafting, and a little moss tied upon the clay to keep it moist. Care must be taken to keep the bud exposed, so that it may be able to grow without interruption from the surrounding material; and the moss should be moistened several times a day. As the buds begin to grow, the shoots of the Vine or stock must be gradually diminished in number until they are all removed, or they may be stopped-in constantly through the season, to give all the vigour of the stock to the buds. About midsummer the matting round the buds should be gradually slackened, and in a week or two afterwards the union between the bud and stock is perfect; afterwards it may be wholly removed. We have had a crop from

the main Vine the same year that the buds were inserted, and thus no time was lost.

Inarching is a most successful method for changing the kind of Grape without doing away with a healthy Vine, which may, perhaps, be more suitable for the soil in which it is growing than the kind it is desirable to have in its place. When this plan is to be adopted, a healthy young Vine of the kind desired should be procured in a pot, and placed in the same house with the old or existing Vine before either begins to grow, in order that they may advance together, and be as nearly as possible in the same state when the operation is performed; the best time for which is when the young shoots have grown about 4 feet in length. The Vine in the pot should then be brought so near to the shoot to which it is to be attached, and placed in such a position that they can be readily united. The young bark and a thin slice of the wood, 4 inches in length, should then be carefully removed from each, about 3 feet from their points; the two parts thus cut should then be fitted exactly together and tied neatly, taking care not to injure the soft young wood. Moss the part over, and the business is done for the present. In about three weeks the ligature will require loosening; but care must be taken not to disturb the shoots, as very little will separate them. Every encouragement should be given to the inarched Vine, by removing gross shoots from the stock during the summer; and, at the end of the season, the Vine in the pot may be carefully cut below the junction. If all goes on well, fruit may be expected the following year.

In cold damp places, where the more choice Grapes do not succeed well, I would recommend planting the strongest Vines, such as the Nice or White Tokay, and budding or inarching the Muscat or other choice kinds upon them. The success which has attended the experiments we have tried here is most satisfactory.—(*Gardener's Magazine of Botany.*)

ORNAMENTAL PLANTS.

*TROPÆOLUM SMITHII* (Smith's Indian Cress). *Nat. ord.*, Tropæolacæ. *Linn.*, Octandria Monogynia. *Syn.*, *T. peregrinum*, *Linnaeus*.—A very pretty climbing annual, with the habit of *T. aduncum*, to which it forms an admirable contrast. It has twining succulent stems, bearing smooth, dark green, five-lobed peltate leaves. The flowers grow singly from the axils of

the leaves, attached by long, slender, twisted petioles; the calyx is dull red; the cuneate fringed petals, orange veined with red. From Columbia: mountains of 9000 feet elevation; introduced

in 1847 by Mr. W. Lobb, collector for Messrs. Veitch & Son, of Exeter and Chelsea. Flowers in summer.

*METROSIDEROS TOMENTOSUS* (Downy-leaved *Metrosideros*). *Nat. ord.*, Myrtacæ. *Linn.*, Icosandria Monogynia.—A showy, large-growing, evergreen greenhouse shrub, with copious, compact, but spreading ramifications. The leaves are opposite, leathery, elliptical obtuse, ovato-lanceolate, or lanceolate-acute, dark green and smooth above, whitish and downy beneath. The

flowers, the conspicuous part of which consists of the bright red filaments of the stamens, grow in corymbs at the end of the branches. From New Zealand: the rocky seacoast and shores of the Bay of Islands; introduced by Mr. Allan Cunningham, before 1839. Flowers in summer.—(*Gard. Mag of Botany.*)

CROSS-BREEDING STRAWBERRIES.

In page 672, Mr. Charles Darwin asks whether any one has crossed Scarlet, Pines, and Chilis with the Wood or Alpine. It may, perhaps, interest him to know that the other day I saw at the nursery of Mr. Standish, at Bagshot, several boxes of seedlings, many of them, from their foliage, evidently hybrids. They were the product of a new Alpine variety—Reine d'Orleans of some, Blanche d'Orleans of others—which blooms and bears fruit until October. Mr. Standish, who is well known as a successful hybridiser, has been desirous of obtaining its free-bearing and late-fruited properties, combined with size; he has, therefore, hybridised it with La Constante, British Queen, and Myatt's Eliza, and the plants which I saw evidenced that the operator had been successful. The further question of their bearing, &c., time must decide; but I thought that this information even might be acceptable.—D., Deal.

MANURES: LIQUID AND SOLID.

WHATEVER difference of opinion there may be as to the quality of soil that produces the best flavoured fruit, there is only one opinion about vegetables of most kinds doing best on a rich good soil; and in order to maintain this state of luxuriance, manurial substances of various kinds are added from time to time, to make up for the loss occasioned by the removal of an exhausting crop after it has arrived at maturity. Fortunately, however, the managers of a kitchen garden generally have sufficient knowledge of the value of manures to save all that comes in their way, and all vegetable substances that can be dug into

the ground with the prospect of decaying there during the next three or four months, are buried under the surface at each digging, together with manure of some other kind. Annual weeds and herbage of all kinds are thus disposed of, and the ground which had previously been cropped with some of the Cabbageworts is put under a course of preparation for some tuberous or bulbous crop differing essentially from the preceding one. Now, as this rotation of crops is in most instances pretty well understood and followed-out by most cultivators, it is needless saying much on that matter here, but a few words on the manures which vegetables and other things receive may not be out of place at a time when provision can be made, as at the present moment, for the wants of next year. Beginning, therefore, with the most common of all manures, and unquestionably one of the best, if not the very best, it will be well to ascertain if the way in which we use it is the best for all the purposes it is intended for.

From time immemorial farmyard manure has always been the most important of all manures, and, in accordance with its quality, it has been estimated as the best and most nutritious, supplying most plants with the food they want to carry them onward to maturity. Its popularity has in no degree abated since artificial and highly concentrated manures have been more common; and though each fresh addition to the list of artificial compounds offered to us in the shape of fertilisers threatens to drive farmyard manure "out of the field," instead of "into it," the dungcart still keeps on its useful plodding course; and until greater results have been accomplished without it than with it, we need not fear for the result. With all the well-directed skill of the chemist, and the puffing announcement of the quack vendor of something wonderful in its way, good cowyard dung is still the standard by which other things are tested, and there is no doubt but it will long continue to be so.

Now, valuable as the contents of the dungcart doubtless are, the cowyard affords other fertilising materials as well. Solid manure is scarcely more useful than liquid, and the latter has so many claims to attention, that a few words on its utility have of late appeared so necessary, that I have been induced to make it the subject of an article for THE JOURNAL OF HORTICULTURE; certainly not with the view of confining the observations to the drainings of the cowyard, but to treat of the subject of liquid manure in the manner that includes all kinds given in the liquid form. Commencing first with those from the farmyard, let us see in what way their action on tillage ground is effected, and in the first place it is right to consider the character of that ground, its requirements, and other features.

It requires very little argument to prove that the addition of a proper quantity of solid manure to a given plot of ground improves that ground, and renders it likely, if not certain, to produce a better crop of whatever it be planted with than it would have done without it. Whether that manure were given some three or four months before sowing or planting time, or just on the eve of performing these operations, the dung will produce its effect. This statement needs no confirmation, and the very few exceptional cases are so few as to be not worth mentioning here. But, supposing that instead of this dung being added to the vacant ground, a quantity equivalent to it of liquid manure which, for the sake of illustration, we suppose to be the drainings of the dungyard, were given instead. Some would say the result would be the same; others might contend that, as plants always draw their food in a liquid form, the return would be better; but from this class I beg respectfully to differ, and this on grounds which require but little explanation.

If we look to the way in which Nature performs her work of replenishing the earth, we see a liquid evenly and regularly diffused over all her works; but it is a liquid differing widely from the one poured out of the watercart. The one is clean, pure, and undefiled by contact with any substance, and when given to mother earth percolates freely through, unless some component in the soil impedes it, but in every case it leaves no stain behind. If it passes through, it leaves additional fertility by the air and moisture it carries with it; but no sourness which the other does. Hence, we see the impropriety of giving liquid manure to naked ground, for however useful such a fertiliser may be to the growing crop, it certainly has the reverse tendency when given to the naked ground; and this sourness is much increased when the liquid is thick and strong, as the inexperienced might call it. Clear and diluted, the liquid manure may, perhaps, do good, but its uses are more apparent, and certainly more important when it is given to some growing crop at a

period when such crop requires an additional stimulant to urge it on—say a row of Celery in September, a bed of Onions in June, a piece of Cabbage in April, or Peas at all times when in flower or making pods. At these periods the stomachs of the vegetables just mentioned are prepared to digest, and even devour with becoming relish the food that at another time would surfeit them. Many other crops in like manner may be also benefited by the food here spoken of being always given them when, to use a common expression, they are hungry.

Useful as liquid manure is in another case, that of potted plants, it must here be given with caution, for it is quite possible to surfeit if not completely poison the grossest feeder with strong potations too often given. Even Chrysanthemums, which are, perhaps, the strongest feeders we have, may have too much of this stimulant, and the result is loss or disfigurement of many of the leaves. A reasonable quantity, clear and well diluted, is best, as the plant is enabled to absorb all the grosser parts, and the soil is not soured to the injury of the roots. Much more might be said on this head, but sufficient has been advanced to prove that the application of liquid manure requires more prudence than that of solid, otherwise the chances are that it will do harm, or, what is nearly as bad, it will do no good. Giving it to plants while in the period of their most rapid growth will generally be beneficial; at the same time the ground it is poured upon must, if possible, be stirred as soon after as it will bear it, otherwise the caked surface which usually follows all watering, excepting that of Nature's doing, will be hurtful; for air is one of the elements to fertility as well as manure. Though an Oak or other forest tree will force its roots through very hard ground in quest of the food necessary to its enlargement, and will continue for many years—nay, centuries, to do so, plants artificially reared and expected to arrive at a condition not found in a wild state must be treated in accordance with the artificial condition they have arrived at. Ground well tilled and manure prudently applied are likely, if not certain, to insure success; but let the inexperienced beware of using liquid manure until he be assured that the object he uses it to can partake of it with advantage, for unless this be the case it is likely to sadden and sour the ground, and surfeit rather than benefit the plants it is applied to.—J. ROBSON.

## NEW BOOK.

*Rambles in Search of Wild Flowers, and How to Distinguish Them.* By Margaret Pluec. London: Journal of Horticulture and Cottage Gardener Office.

"Those who love botany would find themselves neither solitary nor desolate though they had no other companion than a 'Mountain Daisy.' The humblest weed or moss will ever afford them something to examine or to illustrate, and still more to admire." Such is the testimony of one of our masters in the science; and so fully do we agree to that testimony, that if we would and could bestow mental propensities upon a child, foremost among them should be a love of botany.

Let us give an illustration. Two cousins, one September morning, set forth from the neighbourhood of Honiton, one provided with a gun and pointer, the other with walking-stick and plant-collector's case. The sportsman in the evening complained of the "slowness" of the place, he had seen but one covey and that so wild that he had not had a chance. He was tired, bored, ate his dinner, told his sister "not to make that noise with the piano," and slept until tea-time. Wakening he saw his cousin busy with his magnifier examining the contents of his case, and inquired, "What he found to poke about?" Now, his cousin, had been more than usually successful in his botanising, giving full illustration to the lines quoted by Miss Pluec:—

"But he alone that, stooping low,  
Will stay with curious hand to cull,  
Can all the many virtues know  
That dignify the beautiful."

We cannot afford space, nor would it afford much amusement to our readers, to enumerate all that that case then contained, but we will copy one leaf from the note-book, on which eventually were recorded the ingatherings of that day:—

"September 18th.—Foremost amongst this day's prizes must be noticed that rare English plant *Lobelia urens*. It is really an English plant, for it has not been found either in Wales, Scotland, or Ireland. I found it on Shute Common. This, like all the *Lobelias*, is very acrid and poisonous—the blue *Lobelia* of

our garden-borders is no exception. They all, especially in their roots and seeds, contain a vegetable alkaloid called *Lobelinia*, on which their acridity seems dependant. If Dr. Lobel had any participation in the murder of Sir Thomas Overbury, which has been suspected, this genus of poisonous plants has been made appropriately commemorative of him. The best account of Lobel I have met with is in Pulteney's "Sketches of Botany," where credit is given him, I believe justly, for having first grouped plants according to a natural system. Some of the merit, perhaps is due to Penna, a brother botanist, who aided him in preparing the work in which this arrangement is adopted.

"I am glad to see reason to think that our Lobel was not implicated in Overbury's murder. Those who raised the question were not aware, probably, that his name was Matthias Lobel, and that the apothecary suspected of being an accomplice in that crime was 'Paul de Lobell.'—(*Calendar of State Papers. Domestic Series. 1611-1618. Edited by Mrs. Green, pp. 312-349.*) Our Lobel died at Highgate in 1616, aged seventy-eight, and was superintendent of a physic garden at Hackney, cultivated at the expense of his patron Lord Zouch. When staying with M——, I must see whether there are any records of him there in the church or elsewhere."

But what has all this to do with Miss Plues' book? Much, for it was just such a book as her's, and much such a mother as she was blessed with, that led the writer of that note-book to the study of botany. The tone of Miss Plues' volume may be appreciated from its

#### "DEDICATION.

"In memory of the pleasant conversations on wild flowers, which ever followed upon our returning blossom-laden from childish rambles through field and wood, and which sowed in our minds a love for the study of Nature, this book is dedicated with tender reverence and gratitude

#### TO MY MOTHER.

Thus do we think of her, and keep unbroken  
The bond that Nature gives;  
Thinking that our remembrance, though unspoken,  
May reach her where she lives."

It is just such a book as should be placed in the hands of the young, yet it is just such a book as the young of larger growth will read with pleasure. It is a mingling of the entertaining and the useful—an epitome of plant-knowledge stripped of all dryness, and gaily and gently revealed. No better gift-book could be found, and whoever receives such gift, whether young or old, shall say in the words of its last page, "Great is the pleasure and profit we have derived from these rambles in search of wild flowers, and all around us testify to the increased health of body and mind which has followed this pursuit."

We must not omit to mention that eighteen good coloured plates, from drawings by the authoress, illustrate the volume, and as each plate contains from nine to fourteen specimens, there are about two hundred portraits of plants.

### THE DISTRESSED LANCASHIRE WORKINGMEN BOTANISTS.

SUCH has been the generous sympathy shown to the poor "distressed botanists" here, by the readers of THE JOURNAL OF HORTICULTURE, that I am enabled to put most of these poor votaries of science in circumstances such that they will be able to weather the storm with some degree of comfort with the subscriptions I have and with what is promised; and to see the expressions of gratitude which they display would more than repay the kind-hearted donors who have responded to their call. To see them has brought many a tear to my eyes, for they remind me of time past when I was a poor struggling lad without parents or guardians, endeavouring to be honest yet surrounded with temptations, and I can assure you it is doubtful if I should have worked so hard for these poor unfortunates if I had not been as they are—in want of a friend to help me over the bridge of the river of difficulties. If there is one thing more than another that I should never like to be effaced from memory, it is gratitude; and many good Samaritans who read your Journal have engraven in the hearts of some of England's best workmen "gratitude," which cannot easily be worn out.

I have been enabled to give out to my brother botanists in distress a large quantity of good clothing and some bed clothes, amongst which were one blanket, and some good men's and women's clothing. I have given out ninety-three pairs of new

stockings, fifteen pairs of flannels, or flannel to make so many, and thirty-seven pairs of clogs (shoes with wooden bottoms), and have made some donations in money. I have received in money since I last wrote, from William Moulton, Esq., Knowsley, £5, to be given out in twenty weekly instalments at 5s.; Mrs. Horsfall, Derby, £1; A Friend, £1; W. Bosanquet, 10s.; a Working Gardener, 2s. 6d., to be continued monthly; P. P. Whitecombe, Esq., £2 2s.; the Rev. J. B. Roberts and Parishioners, Shilbottle, near Alnwick, £5 7s.; and a kind-hearted lady, who styles herself "A Mother," from Ipswich, has sent four weeks together 2s. 6d. to R. Schofield, and 1s. to J. Whitehead. And the following orders have come in for Messes and Ferns—namely, from Lady Honora Cust 150, Miss Mager (second lot), 150; and some kind inquiries have been made by others, whom I am sorry to say, that I cannot answer for a day or two.

The following clothing, &c., have come to hand—viz., from Miss Ager, Weston, flannel, one blanket, one pillow, three petticoats, one pair of slippers, one pair of boots (women's), a pocket, a bedgown, and a book for R. Schofield; from the Messrs. Harrison, of Fellfoot Ridge, Yorkshire, three pairs of drawers, five ditto trowsers, seven ditto socks, seven ditto of men's boots, one pair of gaiters, five coats, eight waistcoats, and nine neckties.

I have made a weekly allowance to an old persevering botanist who lives about three miles from here, and he has, I believe, one of the best collections of British plants in Lancashire (dried). We have got up a collection of dried specimens of Sedges (*Carexes*), Grasses, and Ferns for a lady, and the lady has expressed herself pleased with the collection. I know where there are some good collections of Grasses and Ferns, nicely preserved, which would be ornaments to anybody's cabinet.

I fear we are trespassing too much on the columns of THE JOURNAL OF HORTICULTURE, but these are exceptional times.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

SHOULD frost prevail, advantage must be taken of it to wheel manures and composts on to the various quarters requiring them, and if they cannot be trenched-in at once, let them be laid in heaps at convenient distances and covered with soil. Ridged ground to be occasionally forked over and knocked about, to expose fresh surfaces to the ameliorating action of the atmosphere. *Asparagus*, if the soil in the frame in which the roots are planted should become dry, it will be necessary to water with water of the temperature of the bed; but this is not often necessary if the bed heats moderately, and the roots were properly watered when planted. There should be at least 4 inches or 5 inches of a loose open texture—such as leaf mould or old tan, above the crowns of the roots. Admit air freely every day to the productive beds. *Beans (Broad)*, where they have been planted in rows, and have made their appearance, draw the earth in ridges on each side of them, so as to afford them some little protection from cold cutting winds. Peas in rows should be similarly treated. *Cauliflowers*, watch narrowly for slugs amongst the young plants, and keep them free from dead leaves. If any are planted in pots for the purpose of protecting them during severe weather, they must be carefully attended to with water, or they will prematurely button in the spring. Surface-stirring amongst the young growing crops of these and Cabbages, Lettuces, &c., must be as diligently followed up now as in the summer, when vegetation is more rapid; indeed, there is no season when these operations can be neglected with propriety. Frequent pulverisation of the soil acts as a great check to the penetration of frost in winter, and to the evaporation of moisture in summer. To realise such good effects, the ground must not be trodden on after the operation is completed. *Herbs*, any that may be wanted in a green state to be taken up with balls of earth about their roots, and immediately potted and placed in a forcing-house. Attend to keeping-up a regular succession of Sea-kale, *Asparagus*, and Rhubarb, by introducing moderate quantities at short intervals into heat.

#### FLOWER GARDEN.

Now that the leaves are off the trees, let lawns and shrubberies have a thorough cleaning. Examine pillar and trellis Roses, and, if the weather is favourable, see if the soil wants renewing or the kinds changing. Preparatory to severe weather, it will be very desirable to go carefully over the stock of Carnations and Picotees in pots, and if any of their lower leaves are withered

or mildewed, they should be removed with a small pair of sharp, pointed scissors; and if any dirt or other extraneous substance be lodged in the axils of the other leaves, it must also be carefully cleaned away. The surface soil to be stirred, and a constant circulation of air to be kept up among the plants in dull weather, except during severe frosts. Pinks on beds will require but little attention if well established. Where rabbits or hares are likely to attack them, give a top-dressing of soot: this is a great preventive. Auriculas and Polyanthus in frames require but very little water, and the slight attention of removing decayed leaves. Store away Dahlia roots, and attach the name or number with metallic wire if the proper tally is desired to be retained to each root.

#### FRUIT GARDEN.

Prune Filbert trees, and standard Pear and Apple trees, and where the latter have made an over-luxuriant growth, dig a trench 2 feet from the stem all round, and cut some of the strongest roots, and especially any "tap roots" that may be found: this will induce a more fruitful condition. Although we have given 2 feet as the general average, it is to be understood that the distance from the stem must be more or less according to the age and size of the tree; the larger the tree, the further it will be necessary to keep from the stem in making the trench.

#### STOVE.

Many things will now be sinking into repose here, and from such water must be entirely withheld. Of these may be named the Erythrina, the Clerodendrons, the Achimenes, the Gloxinias, with many bulbs. It should be borne in mind that the Gloxinias and Clerodendrons are very liable to suffer from a low temperature, and that when at rest they are not safe at a temperature below 50°.

#### GREENHOUSE AND CONSERVATORY.

In foggy dull weather like the present, the conservatory will require very careful management. The best plan is to keep as low and dry a temperature as can possibly be permitted—that is, from 40° to 45° at night, allowing it to rise a little in the daytime. In mixed greenhouses, see that the young stock of Heliotropes, Cyclamens, and other flowers grown especially for winter, have light situations and regular attention as regards watering. Pay attention to the plants intended for successive blooming—such as Rhododendrons, Azaleas, Persian Lilacs, Sweet Briars, Moss, and other Roses, Ledums, Kalinias, Daphnes, Anne Boleyn Pinks, Dutch bulbs, &c.

#### PITS AND FRAMES.

The present is a very trying season for the inmates of these structures, and every advantage must be taken of mild dry days to give air freely. Scarcely any watering will be necessary here for some time to come, and the plants will be all the better for being kept rather dry at the root; but strong healthy plants will probably be found to require water occasionally. A dry awning, if possible, to be selected for the purpose, and air to be given freely during the day. All decayed leaves to be removed.

W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

ASPARAGUS being chiefly in rows, covered it with a few inches of half-rotten leaves in a frosty morning; this will not only enrich the ground, but by keeping out frost, enable us to get at what roots we want any time for forcing. We believe that, on the whole, the best plan for forcing Asparagus is to have pits made on purpose, heated either by dung linings, or by hot-water pipes, and forcing them every other year, covering the pits with glass after the shoots appear, that these may be green their whole length. Strange, however, people accustomed to white Asparagus, actually find fault with the green, even though they allow it is crisper and sweeter. For a long time we have depended chiefly on the dung-bed for early Asparagus, and though it destroys a great many plants, it gives the chance of rotation of cropping in the kitchen garden. Our first bed, made chiefly of the remains from flower-beds, as Verbenas, Calceolarias, Ageratums, &c., has answered very well, and given us a good supply, just producing the mild heat that was necessary. In these mild days the glasses are slid down a good part of the day, to prevent too much coming on at once, and the glass has been well washed to let in all the light possible. Changes of weather must be guarded against, as a dry cold air will cause the shoots to eat

stringy and hard. Extremes of heat and cold guarded against, forced Asparagus, independent of the rarity, we think even sweeter than what comes in the open air; though we prefer Asparagus green, yet the crop may be obtained in a dark place, in a temperature of from 50° to 55°, and the shoots when cut may be set in damp moss, and kept in the light a few days before being used. A correspondent wishes for the minutiae about a common frame for forcing the Asparagus, and says that we are not minute enough in describing operations, and that they fail oftener from that cause than anything else, as he has already burnt the roots of one lot, and in another bed few shoots are coming, because he is told the large roots he put in have hardly any buds. Now, we plead guilty to the charge. We are apt to suppose a certain amount of knowledge in our readers, because so many have been readers so long, and, on the other hand we do not like to clog them with the same tale over and over again. Now, then, as to these minutiae, and first as to the hotbed. Any thing that will secure a bottom heat of from 70° to 80° will do. The most economical as to time and labour would be a bed from 24 inches to 30 inches in height, formed of equal parts of tree leaves rather damp, and the other part of clearings from the flower-beds, and dryish litter from the stable. The latter will prevent the former getting too compact, and thus allow of a slow, gradual decomposition. The leaves might be thrown into a heap to heat first. In previous volumes we have given full directions how to sweeten stableyard manure, &c., but we are so short of all fermenting matter that we sweeten or decompose it previously very little, and for such purposes as Asparagus-beds, little or none at all. We thus not only save labour, but save material, by making the bed at once. As soon as the heat rises, a few inches of rotten leaves are thrown into the box, and above that 2 inches or 3 inches of soil. Then we go to the Asparagus-bed or row, with fork, spade, and mattock, and take out a good opening at one end, so as to undermine the many-branched Asparagus roots, not losing any that are sound. If the bed is old, many of these roots will be deficient in fresh buds, and we, therefore, break-up the large lumps and remove those pieces destitute of buds. All the roots well furnished with fresh buds we place carefully in a barrow, and take to the hotbed. Placing a board across the bed to stand on, we commence at the back, placing the part with the buds close to the back, and bringing the long pipe-like roots to the front, and, thus finishing one row, scatter a little sandy soil among the roots. We then commence with the second row, placing the buds as near the first row as we can, though in doing so, we place them and part of the roots over the roots of the first row, and so on until we get 9 inches or so from the front of the bed. We then scatter a little sandy soil among the crowns and roots, and give a pailful of warmed water to a light, using a rose, but holding the pail high, that the water may wash a little fine soil among the rootlets. We then cover with an inch or so over the buds. With such slight covering there is little danger of over-heating, as, if the soil below the roots gets a little extra warm, giving plenty of cool air would soon lower it, even without making holes through the bed. Little or no more covering of soil will be wanted, unless white-stemmed shoots are desired, and then as many inches of old tan or dry leaf mould may be used as the stems are required to be blanched.

For Sea-kale nothing suits better than a similar bed, not quite so deep in material, the roots taken carefully out of the ground with all their length; the larger the crowns the better, the roots doing well when strong of one year's growth, but better when two years old. These roots should be packed firmly in light, sandy, rich soil, leaving the crowns about an inch out, and about 1½ inch apart. As frames may be scarce, nothing answers better than four boards, about a foot deep, forming the sides and ends of a bottomless box, and an old door, or a thick thatched straw hurdle laid over the top. A space 6 feet by 4 feet well packed will yield a great amount of cutting, and a few good barrowloads of fermenting material would be sufficient. We have seen a couple of packing-boxes of equal size so used, close to the line in a greenhouse, the plants packed in earth in the one, and the other set bottom upwards over it, and a broad piece of list run round the place where the boxes meet. Good-sized pots may be used in the same way, but in such cases the earth will want more watering than when the plants are placed over a fermenting bed, and want of moisture always makes the Kale hard and stringy. When a little bottom heat can be given in a dark place, as in a Mushroom-house, and the plants are allowed to come on gently, the mere length of root is of less importance. We have found 3 inches or 4 inches do very well.

From 50° to 55°, and never above 60°, are the best top temperatures, and from 70° to 75° on to 80°, the best bottom temperatures for the forcing of this vegetable. The heads to be thoroughly good should not only be white, but not more than 6 inches in length. We are thus particular in minutiae from two simple facts. First, a grumble from an amateur that his Sea-kale was watery and had no substance in it. The stalks were drawn from excess of heat and moisture, were thin, and from 15 inches to 18 inches in length. They afforded scarcely any resistance to the thumb and finger, we can fancy what they would be when boiled. The second fact was, meeting with an amateur with a large basket of large roots of Sea-kale, seemingly three, four, or more years old, and these were to be planted in a trench-bed, covered with pots, and a lot of manure obtained to force them in the ground directly. Now, so treated, we could almost make certain that the smaller part of these roots, cut off and kept in dry soil in a cool place until spring and then planted out, saying nothing of seedlings, would rival if not beat these old plants in the following year; and after being thus treated, the roots might have been placed in a dark box above a small fermenting-bed, and thus produced better Kale and with less than a tithe of the manure and labour necessary to force it out of doors. Late in the spring it is obtained most economically by covering it up out of doors, the simplest modes being generally the best. We have had it very nice in beds 2½ ft. wide, with rather deep alleys between, the alleys filled with litter, and the beds covered 8 inches with coal ashes or bog earth. As soon as a leadlet got through it was time to cut it. Those who force out of doors on the ground now, cannot use anything for giving heat so good as tree leaves, with a little long litter on the top to prevent the leaves blowing about. These leaves will, unless very wet, produce a mild sweet heat. Stable dung, &c., can scarcely be used round the crowns without giving a rank taste to the heads. If we should use a little in a mild hotbed in which the plants are taken-up and put, this rankness is prevented by the covering of half-rotted leaves and soil. These in such circumstances are as useful as clay or loam for absorbing the ammoniacal gases, and this fact enables us to use the bulk of manure for hotbeds much fresher and ranker than otherwise it would be advisable to do. Cleaned away all the leaves from plants in the ground, and covered the crowns with ashes to keep snails and extreme frost from them. Must sow a good piece this spring as our stock is getting short.

Gave plenty of air to Radishes, Lettuces, and Cauliflowers, either by taking the lights off, or elevating them back and front, this mild, muggy weather. Sowed a few Dwarf Kidney Beans, though of late have given up growing them in the dead of winter, though few vegetables are more tempting at that time, they eat so crisp and nice. The Newington Wonder is the best for small pods to be kept whole. Sowed a row of Tom Thumb Peas; but, in general, prefer sowing the earliest Peas in March under cover, and transplanting when 3 inches in height. The weather has been too greasy and muggy to do much in the way of digging or trenching. Our Celery showed a little of the maggot in summer and autumn, but the leaves being picked off, it has left no bad traces behind it. We have lots of complaints as to Celery being tough and coarse, or brown at the centre, and either bolted or rotten in the middle—the results of over-rich feeding, letting manure water get into the hearts of the plant without being washed out with clear water, and from the practice of bit-and-bit earthing-up of Celery, as generally followed out.

We had next to forgotten the field of investigation opened-up by Mr. Beaton, as to the hardness of the Globe Artichoke. So far as our own experience is concerned, we do not advocate placing some long litter around the stems without cause. We think three times we have known those under our care suffer severely from frost. We should think that in the spring of 1861, we had a score of applications for plants, and as to the price they could be got at; the places whence the applications were made being left destitute of them, or nearly so. We are, however, so far of Mr. Beaton's opinion, as to believe that other causes besides frost contribute to such losses—such as allowing them to remain too many years in the same place; and, again, from growing in a damp shady place. From the first cause we have seen once-pleasid plantations degenerate and die away. In the second case the plants died from damp and the extra cold, the consequence of damp. We have no doubt, that in light, dry soils, they will be found as hardy as Asparagus. We recollect of a case of a plantation in a midland county somewhat in point. The plants had received a rough winter-dressing, and the ground was being

forked-over before a little litter should be added. The soil was deep, stiff rather than sandy, but had no stagnant water, owing to an open, marly bottom. The first rows had been forked-over, and several inches of soil raised against the plants; another row was forked, but no extra soil put about the plants, and the frost coming rather sharp before the job was finished; some rows had the surface soil unbroken and hard on the surface from the autumn rains. In spring, the first rows were all right; the second lot with the soil stirred on the surface, was a little injured; but the third lot with the unbroken, unprotected soil was very much injured, more than half of the stools in the middle of March being a mass of rottenness. In strong clayey, loamy soils, retentive of moisture, we have often noticed losses in winter, but that might be owing to excess of moisture, as well as to excess of cold. A little mound of earth, open at the surface, and a little litter over it, round the stools, would help to counteract the excess of either, and hence, under such circumstances, we would say, use a little protection. In exposed, light, dry soils, we should think that little protection would be necessary, though even there a ridge of rough dung could do no harm in the general run of years. The evil is, that when such a frost as 1860-61 comes, we may not think of the half of the things needing our aid, until the mischief is done. We are very glad the matter has been thus prominently brought before us, and would be pleased with a detail of facts bearing on this point; stating also the character of the soil as to staple, and its conditions as to dryness; the frost of the above years furnishing us with a good test on the subject. Such facts will be of more extensive usefulness than as bearing alone on the Globe Artichoke, not but that it is a matter of importance in many families, though our own opinion is, that Artichokes however dressed, are something like good flint soup, depending more on the other auxiliaries to make the soup palatable, than upon the flints.

#### FRUIT GARDEN.

In addition to the routine of looking after Grapes, washing Peach trees in pots, &c., filled a two-light box with Keens' Seedling Strawberries. This bed had been formed with rubbish and tree leaves from the pleasure-ground, much the same as the beds for Asparagus about three weeks ago. There was a good heat in the bed, though the materials had been placed there without any preparation at once—far too much, in fact, to think of plunging or half-plunging the pots. If plunged at all at this season, the heat must be mild indeed. If very hot the roots will be burned; if pretty hot an impetus will be given to leaf-production. It is better that the pots should stand on tiles or boards, and little or nothing about the pots; in the beginning of December we were not so particular, but the bed was trodden firm on the surface, and then 2 inches or 3 inches of ashes thrown over it, and on these ashes the pots stood without any plunging. Whatever heat rises between the pots can also be easily regulated by air-giving. The plants seemed in good order—the ball like a firm cheese with roots. A few plants that were rather dry were watered. All the half-withered leaves—in fact the great proportion of the leaves, were removed, leaving in general two or three of the smaller next the bud. We do not see any use in retaining the withered and half-withered and spotted leaves. They have served their purpose in ministering to the strength and the maturity of the bud. Before we want to start the plant into fresh growth these leaves act as a protection. When growth is excited they first act as drags and robbers until they are finally removed, taking the strength and nourishment that should go to the central column of the plant. We think, therefore, it is best to remove these at once. There is then a better opportunity, too, for scraping off a little of the surface soil with a pointed stick, and adding a little fresh rich soil firmly pressed down.

Another two-light box has been set on a similar bed of leaves and the remains from the flower-beds. This, about 20 inches deep, has a good heat. Four large barrowloads of fresh horse-droppings were thrown over the top and levelled, and then two or three rows of Vines in pots were set on tiles from the back of the bed, and the shoots tied down to the front. There will also be room for a ridge of droppings in the front. The ammoniacal gases thus given off would kill most things, but it will do no harm to the stems of the Vines, though it will cause the buds to swell, and give a quietus to any insect, if there should be such a thing. Of course the pots have no plunging in such a bed. We have done little in this way of late, though our earliest experiences did much to show that, but for its appearance, a great heap of fermenting manure is a fine thing in a vinery. We

did not care how rank the dung was at first if it came, as it generally did, fresh from the stable, or how dense the vapour and ammonia from it, provided it was all sweet before a bud expanded. Under such treatment no insect of any kind could hope to live.

The chief work elsewhere has been getting the lawn swept and cleaned.—R. F.

### TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PEARS INFESTED WITH SCALE (*W. Brown*).—Your trees appear to be infested with what gardeners call the scaly coccus, an insect anything but easy to eradicate, though not so bad as the American blight on the Apple. However, we have known the following remedies efficacious, though, at the same time, they are troublesome:—Mix cowdung, soot, and soft soap together, and add as much tobacco liquor, pretty strong, as will reduce the mixture so as to lay on with a paint brush, and try it, and if it dries too dark a colour add a little lime, so as to bring the mixture as near the colour of the tree as possible; then coat every part of it over, twigs and stem, and let it remain until it shells off in summer of its own accord. A slight coating of oil will effect the same object, but it is more expensive, as vegetable oils ought only to be used. We shall be glad to hear how the above plan answers.

PEARS FOR LATE USE (*Idem*).—The following will materially assist your already good selection:—Bœufé Gris, d'Hiver, Bœufé d'Arenberg, Calabasse Grosse, Chaumontel, Napoléon, Vicar of Winkfield, Passe Colmar, Winter Nelis, Ne Plus Meuris, Shobden Court, Crasanne, and Prevost. The last we know only by report, but it is said to be a good late kind.

CYANOBYLLUM MAGNUM (*Idem*).—This handsome stove plant requires keeping in the shady part of a stove, otherwise the leaves speedily become blotched and disfigured. It is said, however, to bear cutting-down well; and the top, by being cut into lengths, forms excellent cuttings. Like most plants, however, it seems to like a rest in early autumn; and by being cut-down in December, and shortly afterwards placed in heat, it speedily throws up fresh shoots and leaves. It is seldom, however, that more than two shoots arise, but this is plenty.

BOOKS (*G. Grove*).—Lindley's "Theory of Horticulture," 21s.; Thompson's "Gardeners' Assistant," 31s. 6d.; Geometry, in Chambers' "Educational Course," 2s. 6d. If you send a post-office order with your direction, you can have the whole from this office.

GAS STOVE (*C. L., Liverpool*).—We do not know the stove you name; but any gas stove having a tube large enough and quite tight, so as to carry off the fumes arising from the burning gas without any escaping into the house, is quite safe for the cultivation of Ferns or any other plants. A vessel of water suspended over the funnel is not sufficient for keeping the air moist enough for growing Ferns. The path ought to be wetted daily. The fronds you enclosed seem dying naturally, and will be succeeded by others. Moisture in the soil and in the air are essential for greenhouse Ferns.

APPLES FROM GUERNSEY (*G. W.*).—The Apple you have sent under the name of Barcelona Pearmain is not the Barcelona Pearmain of the Horticultural Society, although in many parts of the country it is grown under that name. It appears to us rather to be Adam's Pearmain, or very much like it. Your *Guernsey Pippin* is a fine little fruit, tender-fleshed, and with a very nice flavour, brisk, and sweet. This is well worth cultivating.

FOLLOWING A KITCHEN GARDEN (*L. G. H.*).—As it is full of slugs and other vermin, you cannot do better than to throw it up roughly into ridges, allowing these to remain through the winter, and your fowls to have a free range over it. Before doing so, if the soil is at all heavy, we would pare and burn the top spit of the whole surface. That destroys not only vermin but their larvae, more effectually than any other treatment.

BRICK ARNOTT'S STOVE (*W. Walden*).—You will find a description of this and of other modes of heating, with drawings, in our "Greenhouses for the Many," which you can have free by post from our office for seven postage stamps. There is a drawing and description of the Arnett's brick stove in Mr. Rivers' "Orchard-house," price 3s. 6d.

PRUNING ESCALLONIA MACRANTHA (*An Amateur*).—In the county Tyrone, the *Escallonia macrantha* must be a complete evergreen, and it should be pruned there twice in the year—first in April, and all the young wood to be cut-in very short, something between close-spruing a Grape Vine and close-pruning a Moss Rose. From each spur then left, two or three or four young shoots will issue all over the face of the plant, which is on a south wall, and is getting "out of bounds;" all these shoots bloom at the points, and in August, when the first bloomers are past their best, the plant should be pruned, or, rather, thinned, as one would do a Rose in July; then the increased room, and the whole strength of the roots, will go to keep the plant in bloom to the very end of the season. But, as the plant is getting out of bounds now, it may be necessary at the first pruning next April to thin-out some of the main shoots entirely, as the whole plant should be in the way of a Peach tree against a wall.

TROPEOLUM PENTAPHYLLUM (*Idem*).—There is not a more graceful climber than this; but in your climate it does not get a winter's rest, and that is the cause of its not being so good as it has been. You ought there to take up so many of the largest roots at the time of lifting the Potatoes, keep them like Potatoes till the spring, plant them like Potatoes, and let the small fry of roots take their chance in the ground—they will come in their turn for lifting.

CULTURE OF VERONICAS (*Idem*).—Your plants of New Zealand Veronicas are not yet big enough for your climate to bloom freely. What they really want with you is the treatment which the London and Dublin market-gardeners give to their Red and White Currants, to the very eye and letter of the practice. First get them into good-sized bushes, not in pots; then, in November every year, prune them as close as Red and White Currants; lift them with balls, place them behind a north wall, and put lots of hay, or fern, or straw among them, halfway up the shoots, keep something at hand to put over them during frost, and at the beginning of April plant them out in good ground, and they will all bloom as freely as Beans and Peas every year. A cold pit would be best in most parts of England; but the secret is the kind of pruning, and the lifting.

WEYMOUTH PINE (*A. S.*).—Quite right. It was your own tree, the Weymouth Pine, which we intended, and not the Hemlock Spruce; and it is the Weymouth Pine which does so well all along the valley of the Thames. The Hemlock Spruce, however, does remarkably well in some of the very poorest and driest soils along both sides of the Thames, although it does not rise so high as the Weymouth. Much obliged for the correction.

ROYAL HORTICULTURAL SOCIETY'S CHISWICK GARDEN (*Pampinus*).—You must obtain an order for admission from a Fellow of the Society. The garden is open every day in the week but Sunday.

BOOK (*Canood*).—Hogg's "Vegetable Kingdom" will best suit you. You can have it free by post from our office for 5s. 8d. You will need no botanical dictionary to understand it. *Passiflora Colvilli* will do for your conservatory.

WHITE SCALE ON PINE APPLES (*An Eight Years' Subscriber*).—The safest thing we have tried is soap water, at about 120°, holding about 1 oz. of soap dissolved in 3 gallons of water. For small plants we have used clean water, at 120°, with about a quarter or pill of turpentine in 4 gallons, thoroughly mixed. This does not do well for large plants, as the water should not remain long on the axils of the leaves. We have known cases in which syringing the pipes when hot with strong drainings from the dughill, and double the above quantity of turpentine, has done for the insects, as they could not stand the ammoniacal and turpentine fumes. The best plan for all plants in pots is to give them a good steaming from rather fresh horse-dung. We hardly know a plant that would stand this, except the Pine Apple. If the scale has got to the roots, the best plan is to remove the soil and expose the whole plant to such steaming.

PIT FOR PROPAGATING AND FORCING (*Kilworth*).—1. The back wall would be better to be 9 feet, or you might make the front wall a foot lower. 2. We are afraid that sinking 5 feet under ground will involve more trouble from damp than you will gain in heat, and it is no joke removing such a mass of soil; and if you went that depth you would have to go some 5 feet more for a stakehole for your fine. A foot or 18 inches is a different affair, and sinking beyond 2 feet is seldom any advantage. We would ourselves, if we had the choice, prefer hollow walls, and the floor to be on the level of the surface soil, or a few inches above it. 3. It will be a great advantage to have the ends and front of glass, 3 feet from the ground. The ventilator may be in the front wall and the back wall; 16 oz. glass will do, or rather about 15 oz., for there is no 16 oz., though called so. 4. We presume your pit 5 feet deep and 5 feet wide will be sunk, or there will be no great space between it and the glass for plants of any size; if bottom heat is to be given by fire, we do not see why 3 feet would not have done equally well as 5 in depth. Provided the pit does not stand too high in the house, your arrangements will answer. There is no necessity for your plants being close to the glass, if there is nothing else growing above them. 5. Your proposed fire will do, but you must have openings for top heat; but of this you will see ever so much in late Numbers. Why should you have the furnace so far from the house? 6. You may do all you want in your proposed house, with the exception of early Vines. To do them well and yet keep this as a hothouse, the Vines should either be in pots or, if planted in an outside border, you should have the means of taking the Vines out of the house when at rest. You would also see various modes for doing that lately.

GREENHOUSE (*Sugatin*).—We have no doubt the plans will answer if well managed. Our suggestions are these:—1. The stage at back should be a foot or 18 inches higher, otherwise your lower shelves will be shaded by the front platform. 2. That platform seems a bed, beneath which are two pipes. You will require slides to let the heat out of that chamber. 3. In such a nice house do not think of a board partition, have it of glass. 4. That hothouse end you should be able to heat independently of the other by means of a box valve or tap. 5. You have shown no spouting for the house. 6. Your mode of planting may do for the late house, but you should have means of taking the Vines out of the hothouse part. See late Numbers. 7. We do not see the advantage of the triangular termination of your front wall. 8. To make the most of the house for plants you must not plant too many Vines. In the hot part two would be enough—one Black Hamburgh, and one Muscat of Alexandria; but if you preferred an early White, substitute Dutch Sweetwater or Royal Muscadine. In the second, one Bowdoin Muscat, one West's St. Peter's, one White Tokay, and one Lady Downe's. If you venture on five one Trentham Black.

AZALEAS IN VINERY—SULPHUR FUMIGATION (*A Constant Reader*).—You cannot do better than as you propose. When the Vines are in full leaf a cold pit after June would do, shutting up close in the afternoon. You will gain your object best by allowing no flowers next season. The best time to shift Azaleas when established is after flowering and pruning, and the shoots are coming away kindly, shading and syringing until the roots are taking hold of the fresh soil. You cannot use the sulphur more safely than by putting it in the pans along with the water. That water will rarely be above 160°, seldom so much, so that you will be safer than putting the sulphur on the fire.

YOUNG MUSHROOMS DECAYING (*An Old Subscriber*).—Seventy degrees was a good heat for the bed, or even 10° more for the first fortnight; but 70° was 10° to 15° too high for the atmosphere of the bed. We can hardly tell the cause of the decay, probably excessive heat and excessive moisture.

**DEODAR (B. B.).**—Deodar is merely a contraction of the botanical specific name *Deodara*, and is used in the singular number. Deodars, of course, is its plural.

**SCRUBBING VINE STEMS (A Reader).**—By casting your eyes back to "Dooms of the Last Week," you would see that your proposed plan of scrubbing the Vines is all right. Take the loose bark off your Vines, scrub the stems well with soft soap-water. Do the same with all the woodwork of the house and walls. Then paint the stems of the Vines with clay and sulphur, and whitewash and clean the house.

**POACING DIELYTRA SPECTABILIS (Idem).**—You may take up *Dielytra spectabilis* any time after the leaves fall, except in frost. Use pots just large enough to squeeze the roots in. If you can give the roots a mild bottom heat, whilst the atmosphere is kept cool for a month, they will do all the better, but they will do very well without, raising the temperature gradually from 50° to 60°.

**FIG TREES AND VINES IN POTS (Dalkey).**—Your Fig trees if you see young fruit at the axils, had better remain in the same 7½-inch pots if you wish to have fruit from them next season. When you wish to start them, you might set the pots into large pans half-filled with earth, or into larger pots so half-filled. If the pots should be very small for the plants, you may shift into 12-inch or 14-inch at once, and set the pots in a bottom heat of about 70°, and keep the branches not higher than 40° to 45°, until the roots are filling to the sides of the pot, and then gradually raise atmospheric heat to from 50° to 60°. Thus doing you may get the first crop and also a second. If without such care you shift now, you will get only an autumn crop, the first crop being very apt to fall. Of course, we can only speak in general terms, in ignorance of the appearance of your plants. We have seen nice little bushes in 7½-inch pots, and very small plants indeed in the same sized pots. We do not think it is at all likely you will get any fruit from your 6½-inch pots of Vines. Unless there were some reasons to the contrary, our advice would be to cut them down near the soil, or to the lowestmost bud. Set the plants in the bottom heat in your greenhouse in March, water as they require it. As soon as shoots have pushed 2 inches or 3 inches long, have some warmed soil ready, take the plants out of the pots, shake away a good portion of the old soil, repeat into nine-inch pots, plunge again and shade a little for a few days, and about the end of May give a shift to 14-inch pots, and treat just in proportion as you wish to plant out or to fruit in pots. If you need minutiae in either respect, jog our memory again, referring to chapter and verse.

**HYACINTHS (Ignorance).**—The piece of wire to be simply used as a stake inserted near the bulb and the spike tied to it. It is more slightly than wood.

**ROSES (Idem).**—The standards are not to be cut back till March. The Teas should be well washed, potted, and then cut back, but not close, if you wish them to flower in the house in April.

**GREEN FROGS (S. Tebb).**—We believe you can obtain them from Messrs. Veitch, Exotic Nursery, Chelsea. They might be kept in a fish globe with some chinkers to imitate rockwork, rising just above the water for the frogs to rest upon when inclined to leave the water.

**SEEDLING CHRYSANTHEMUMS (Elizabeth).**—In the report of the Floral Committee on the Chrysanthemum seedlings of this season, it is stated that the members of the Committee were unanimous in their belief that many more of Mr. Salter's new seedlings would merit higher awards as soon as the seedling plants recovered from the ill effects of this untoward season for them. Your seedlings with imperfect blooms must have been under the same influences, and it is only reasonable to expect they will be much better another year, or even if that should not turn out to be the case, there can be no harm in taking good care of them for another chance. The seedling plants want no particular treatment from that of the old kinds. All old plants of Chrysanthemums are more safe out of pots and in the open air, in all parts of the three kingdoms, than being kept in pots and in a cold frame or pit. When turned out of pots, the side of a wall is the best place to keep the hails, plunged all their depth, and in severe frost some loose straw or fern to be thrown over them and taken off in fine weather. The suckers are then in the best natural state for making cuttings in April, or the balls to be merely shaken and divided at the end of the month.

**ACHIMENES (Idem).**—They cannot be grown in a greenhouse till they are showing for bloom, and then they would grow in the open air. They require hotbed culture till they are about to bloom.

**POTTING YOUNG PELARGONIUMS (Nursery Foreman).**—You struck a lot of most beautiful Pelargoniums last August, and have had them since in No. 72 pots—that is, in very small No. 60's. You say they are "quite pot bound;" but they were more than pot bound two months ago, and they have been slowly murdered every day and night since last Michaelmas. Such cuttings ought to be fine, large, bushy, and very stocky plants in No. 32 pots on Lord Mayor's Day, and be in their flowering pots by the 1st of January. But, as it is, anybody could excel you now by cuttings just put in. Starving young plants, whether they be for pots, beds, or forests, is the ruin of plants, and the cause of so many complaints about them afterwards. Pot the starvings at once into No. 48 pots and keep them a little warmer for the next three weeks, and pot them again very early in February, unless you mean to sell them off in the 48 pots. But who will buy plants that have been so badly used?

**THE PURPLE SATIN COLEUS (Idem).**—How could you think, much more attempt, to keep old specimen plants of any Coleus over the winter, when ten times better plants could be had next year, and plants, too, four times the size of those of this season by merely making a few cuttings last August, which should now and to the middle of January be cramped in No. 60 pots, just like your poor Pelargoniums? Therefore, be it known to all men and masters, that Coleus Verschaffeltii is the, or one of the, best drawing-room plants in the world; that ladies are most particularly fond of it there all through the summer months, and there is only one right way of doing it for that work, and that way is to make it an annual like a Balsam, but from cuttings in place of seeds. Of course, first-class gardeners will have it for dining and drawing-room decoration in Nos. 48 and 32 pots all through the winter; but such men never have large specimen plants of it to face a winter with.

**NAMES OF FRUIT (T. G. F.).**—Your Pear is *Passé Colmar*, and it is not likely to be better in a stiff cold soil.

**NAMES OF PLANTS (J. C.).**—It is the good old *Thunbergia coccinea*, which we have not seen in bloom since the winter of 1834. It is one of the

hardest greenhouse climbers, and one of the most difficult to bloom freely. Keep it in the pot, and it will now flower freely enough every winter; but if you were to plant it out it would soon cover an ordinary greenhouse, and not bloom for another ten years. It comes from cuttings as easily as *Verbenas*. (*W. B., Barton-on-Trent*).—*Pteris tremula*; *Achyranthus grandiflorus*. (*Alethea*).—A frond of *Polystichum angulare*, too young to show if it be of any peculiar variety. (*H. B.*).—1, *Acacia decurrens*; 2, *Brachycoma lanceolatum*, var.; 3, *Asplenium trichomanes*; 4, *A. magellanicum*; 5, *Woodwardia (Doodya) caudata*. (*A. B.*).—*Calampelis scaber*, also called *Keeremecarpus scabra*. (*A Subscriber, J. P.*).—1, *Begonia rupestris*; 2, *Pilea serpyllifolia*; 3, *Nothochloa flavens*; 4, *Jussiaea speciosa*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### BIRMINGHAM POULTRY SHOW.

The merits of this great Show, and the perfect arrangements of Bingley Hall, are so well known, that they need no mention. Almost every one who takes interest in the pursuit is acquainted with the locality and its peculiar merits. All know the value put upon a first prize gained there. It is the war of the giants, and a success stamps a character on the yard. It is the meeting of all others, and a high commendation is more than an equivalent for the first prize at some small local shows. By great exertion we were able to give our readers the awards last week: it will, therefore, now only remain for us to comment on the principal classes and the prizetakers, observing that we hardly ever recollect such dissemination of the prizes. We like to chronicle the success of the old names of our old friends and exhibitors; we also like to see our new names encouraged by prize-taking. Success makes people careless in all pursuits, and nothing is so beneficial as a check now and then. We have also to note the re-appearance of many old exhibitors. Those who exhibit for the first time, and being very sanguine, are somewhat disappointed that they get no higher than, perhaps, a high commendation, may be comforted by the fact, that great success is never attained the first, and seldom the second year. It is a progressive thing, there is no royal road to it. There will, however, always be enough to give zest, and to teach a lesson.

The first class was for adult *Silver Grey Dorkings*. We confess we have doubts as to the policy of classes for this breed. For adults there were only six entries. There were four prizes to award, and the Judges were compelled to withhold two of them. This will at once prove there were but two out of six pens that answered the requisitions of this breed. They belonged to Mrs. F. Blair and Mr. Stoller. We congratulate the lady on her success. It may be, perhaps, that as these birds get older they become grey, especially on the breast. This would explain that whereas only two pens of old birds could be found perfect, that among the thirty-three pens of chickens there were twelve found worthy of notice in the prize sheet, and many others that lacked merit had no positive fault to disqualify them. Those classes have been in existence long enough to come to a correct judgment, and we shall be curious to know next year how many of the thirty-three pens of chickens shown here retain a plumage that will enable them to compete among old birds. By this should be measured the amount of support to be given to these classes. They have accomplished one thing—they have gone far on the road to overtake their coloured brethren in size. They formed a beautiful class. Mr. Cargey took first and second, Lord Hill third, and Mr. Stoller fourth. These all deserve especial mention, as did many of the highly commended. The classes for hens and pullets do not fill as they should. They are made to suit those who have difficulty in sending a whole pen, and to meet the requirements of purchasers. Formerly in buying a pen, there was a dread that it contained brothers and sisters, but now they can be bought from different classes, and different owners. We are at a loss to know why the hens and pullets are not as well represented as the cocks.

The only classes that showed a falling-off were the *Spanish*. We do not wish it to be understood there were not good birds, but the general entries were not such as we have seen in former years. Mr. Teebay's adults, and Mr. Lane's chickens, Mr. Martin's second-prize adults, and Mr. Fowler's, were very good. Here, again, the hens and pullets were weak in numbers.

The *Cochin-Chinas* in every class were most excellent. We believe we may say they were as good as were ever shown. Mr. Kellaway's were perfect. The same may be said of Messrs. Bates, Fell, and Musgrave. The White, Grouse, and Partridge were equally meritorious. Messrs. Stretch, White, and Musgrave, showed beautiful pens. In all these classes extra cups were given, and added much to the competition and interest. There

was one feature that deserves notice—the absence of birds with faulty-coloured breasts. Messrs. Chase and Felton deserved their prizes.

*Brahma Pootras* were excellent, and are now thoroughly understood. Mr. Teebay, and Messrs. Fowler and Allen, took all the prizes.

We can speak in terms of unqualified praise of the *Malays*. The classes for this breed were very numerous; but we are always surprised that in large towns they are not more kept. They are made for confinement, and there is no back yard that will not suit them. Their merits are not appreciated. Mr. Sykes took three out of four prizes, and Mr. Manfield the fourth.

The *Golden-pencilled Hamburgs* were a great class, and all that has been asked by Judges was shown by exhibitors. Formerly the pencilling was often complained of. In the Spangles the breasts were dark, in all faulty combs were common, but now every class has its perfect specimens. They were well represented in numbers, bringing 152 pens. Messrs. Martin, Munn, Dixon, and Luce, were large prizetakers.

Nowhere was improvement more apparent than in the *Polish* classes. They were in all respects the best we have had for many years. We saw it with much pleasure. The Black brought nineteen entries; the Golden fourteen; the Silver eleven. For some years we have lamented the decline of these classes, both in numbers and merit, but now we can speak in unqualified praise. Messrs. Ray and Edwards, in Blacks; Messrs. Adkins and Dixon, in Golden and Silver, showed birds that were perfect.

The *Distinct Variety* class was very rich, and this also showed an improvement. Several breeds here brought in numbers that indicate a necessity, if they maintain their growing entries, of asking a class for themselves. The Black Hamburgs showed seven pens, Crève Cœurs five, Cuckoo Dorkings four. A class does not necessarily require three prizes, and we think next year Crève Cœurs might stand alone. If they maintain their ground in public estimation, they will give good entries in 1863. We think they might have two prizes, and the Black Hamburgs the same. Good Silkies were shown.

The next classes were for *Single Cocks*. Among Silver Greys Mr. Staller was first. Some exhibitors declare they cannot now understand what is a Silver Grey. Messrs. Staller and Cargey both know not only what they should be, but also how to select them. Next were thirty-five Grey Dorkings, nearly all perfect birds. Lady Holmesdale won first prize easily, spite of competition of no ordinary nature. Mrs. Arkwright and Mr. Garrard were deservedly rewarded with second and third. Nearly the whole of this class was sold. The Spanish cocks were better than their brethren in the classes, and the competition was very hard and close. Messrs. Rodbard and Lane deserved their honours, but it was not an easy victory. The names of those who won in the Cochín-China classes will be the guarantee for the excellence of the birds, and the nature of the contest. Mr. Teebay won with a beautiful Brahma Pootra cock, but the class was numerically weak. With the exception of the Golden-pencilled, Hamburgs brought few entries in these classes. The Polish were excellent, and Messrs. Adkins and Dixon showed birds of rare merit.

We must now retrace our steps to review the *Game* classes, which form an exhibition in themselves. If our readers will refer to the list of winners published last week, they will see the truth of our assertion. Eighty-eight pens were named in the awards. Among many new names, some of the old ones will be seen—Messrs. Archer, Fletcher, Swift, and others. The Brown-breasted Reds were the best of these classes. The White and Piles the weakest. The Duckwings were very good. The Blacks and Brassy-winged do not increase or improve. Among all the single cocks, Mr. Edward Archer stood as the owner of the best bird. We thought very highly of those belonging to Mr. Stubbs, Mr. Staller, and the Hon. W. W. Vernon.

All judges proclaimed it the best show of *Bantams* yet seen. The success of Mr. H. D. Bayly in these classes is no novelty, but it is an exploit to take nine prizes. Nothing can exceed the merit of the birds shown by this gentleman in Gold and Silver-laced, White and Game. Fifty-six pens of Bantams received especial notice at the Judges' hands. Messrs. Musgrove, Leno, and Rumsey struggled well, but were obliged to be content with second honours. In the class for Any other variety of Bantams, some Japanese oddities deserve especial mention. They are very singular and pleasing birds, having large combs, ample tails, and no visible legs.

The *Aylesbury Ducks* were very good, but they seem almost to have reached their maximum of weight. The first weighed 26½ lbs., second 25½ lbs., and third 24½ lbs. *Rouens* rise; first 21½ lbs., second 20½ lbs., and third 19½ lbs. One pen in this last class weighed 25½ lbs.; but, unfortunately, the only bad bill shown was in it, and disqualification was the consequence. The Black Ducks were very beautiful, and are fast losing the proportions that a mistake in breeding was giving them. They cannot be too small. Mandarin, Top-knotted, Wild, Muscovy, Brown and White Call, were perfectly represented in the Various class; as were Cape, Sebastopol, and Barnacle among the Geese.

This brings us to the most notorious and meritorious (rare conjunction), pen in the Show. Three *White Geese*, perfect in shape, colour, and condition, weighed 76½ lbs.: they belonged to Mrs. Seamons. Mr. Manfield's weighed 65 lbs., and Lord Kinnaid's 64 lbs. In the next class Mr. Manfield was first, 55½ lbs.; Lord Kinnaid second, 50½ lbs. It deserves especial notice that Geese should travel from Perth to such a competition as the present, and be successful in each class. Mr. Allen did the same in the next class. The *Grey Geese* weighed 72½ lbs., 67½ lbs., and 58 lbs. The young birds 61½ lbs., 57½ lbs., and 55 lbs.

We have seldom seen *Turkeys* better shown, and Scotch birds were second among the adults. The prize birds weighed 62½ lbs., 60½ lbs., and 51 lbs. Young ones 50½ lbs., 45½ lbs., and 45 lbs.

We shall have to do with some details next week; our remarks are so lengthy we must postpone them till that time.

One thing is, however, urgent. It is to tender our best thanks to Messrs. Luckcock, Shackel, Matthews, Wright, Adkins, Lowe, Mapplebeck, and many others for another successful and pleasant meeting. These gentlemen are indefatigable, and their continued success must be the reward of their long and unselfish services on behalf of their townsmen, and all interested in the pursuit.

JUDGES.—Rev. R. Pulleine, G. J. Andrews, Esq., Messrs. Bailly, Chaloner, and Fould.

We published the prize list last week, and we now add a list of the commendations.

DORKING (Silver Grey).—*Chickens*.—Highly Commended, Right Hon. Lady Bagot, Blithfield Hall, Rugeley; Right Hon. Lord Hill, Hawkstone, Shrewsbury; G. Cargey, Sandon Farm, Stone, Staffordshire. Commended, Right Hon. Lady Bagot; Mrs. Arkwright, Spendon House, Derby. *Hens*.—Highly Commended, G. Cargey. Commended, D. V. Allen, Inchmartine, Inchture, N.B. *Pullets*.—Highly Commended, Countess of Chesterfield, Brethly Hall, Burton-on-Trent; J. Robinson, Vale House, Garstang. Commended, Mrs. Seamons, Hartwell, Aylesbury.

DORKING (Coloured, except Silver Grey).—Highly Commended, T. W. Hill, Heywood, Manchester. Commended, Mrs. A. Guy, Eaton, Grantham; A. Potts, Hoole Hall, Chester; J. D. Hewson, M. D. Stafford; C. H. Wakefield, Malvern Wells. *Chickens*.—Highly Commended, Mrs. Arkwright, Derby; Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst, Kent; A. Potts; Rev. J. F. Newton, Kirby-in-Cleveland, near Stokesley, Yorkshire; D. V. Allen; C. H. Wakefield. Commended, Rev. J. G. A. Baker, Biggleswade; Capt. W. Hornby, Knowsley Cottage, Prescot; A. Potts; J. Robinson; E. Garrard, Broadway, Worcestershire. *Hens*.—Highly Commended, Capt. W. Hornby; D. V. Allen; H. W. B. Berwick, Helmsley, York. *Pullets*.—Highly Commended, Right Hon. the Earl of Chesterfield, Brethly Hall, Burton-on-Trent; Miss L. D. C. Fenwick, Newton St. Loe, Somersetshire; J. Smith, Henley-in-Arden. Commended, E. Smith, Middleton, near Manchester.

DORKING (White).—Highly Commended, Mrs. Beardmore, Uplands, near Fareham, Hampshire. *Chickens*.—Highly Commended, Mrs. Beardmore. Commended, Mrs. Beardmore.

SPANISH.—*Chickens*.—Highly Commended, J. K. Fowler, Aylesbury; J. Smith, Hillingdon, Middlesex. *Hens*.—Commended, J. K. Fowler, Aylesbury. *Pullets*.—Highly Commended, J. K. Fowler. Commended, H. Yardley, Birmingham.

COCHIN-CHINA (Cinnamon and Buff).—Highly Commended, H. Bates, Edgbaston, Birmingham. Commended, E. Musgrove, Aughton, near Ormskirk; W. Cople, Eccleston, Prescot; S. Statham, Forest Row, Sussex. *Chickens*.—Highly Commended, J. G. Sugden, Kighley, Yorkshire; E. Musgrove; H. Bates. Commended, J. Heape, Ladypool Lane, Sparkbrook, Birmingham; T. Stretch, Ormskirk. *Hens*.—Highly Commended, T. Stretch. Commended, H. Bates. *Pullets*.—Highly Commended, Rev. G. Gilbert, Claxton, Norwich; S. Statham; H. Tomlinson, Balsall Heath Road, Birmingham. Commended, T. Stretch.

COCHIN-CHINA (Brown and Partridge-feathered).—*Chickens*.—Highly Commended, P. Cartwright, Oswestry. Commended, P. Cartwright; E. Tudman, Whitechurch, Shropshire. *Hens*.—Highly Commended, H. Chavasse, King's Heath, near Birmingham; T. Stretch, Ormskirk. Commended, Master R. W. Chase, Moseley Road, Birmingham.

COCHIN-CHINA (White).—Miss E. Biggar, Nethermilne, Moffat, Dumfriesshire; G. C. Whitwell, Kendal; R. Chase, Birmingham. Commended, C. Felton, Erdington, near Birmingham. *Chickens*.—Highly Commended, G. Lamb, Compton, near Wolverhampton. Commended, D. V. Allen, Inchmartine, Inchture, N.B.; C. Felton.

BRAHMA POOTRA.—*Chickens*.—Highly Commended, Mrs. Hargreaves, Reading; Mrs. Seamons, Hartwell, Aylesbury; D. V. Allen; T. W. Hill, Heywood near Manchester. Commended, C. Dain, Southampton.

MALAY.—Highly Commended, J. Rumsey, Shadwell, London. *Chickens*.—Highly Commended, J. Rumsey. Commended, Miss C. E. Ballance, Taunton.

**HAMBURGH** (Golden-pencilled).—*Chickens*.—Highly Commended, Rev. T. L. Fellows, Beighton Rectory, Acle, Norfolk; Messrs. Carter & Vallant, Poulton-le-Fyde; A. Wilkinson, Birmingham. Commended, Mrs. Wolfertan, Tanworth.

**HAMBURGH** (Silver-pencilled).—*Chickens*.—Highly Commended, E. Smith, Middleton, near Manchester. Commended, W. Mitchell, Keighly. *Pullets*.—Highly Commended, Messrs. Carter & Vallant.

**HAMBURGH** (Golden-spangled).—Highly Commended, S. H. Hyde, Taunton Hall, Ash-on-under-Lyne; I. Davies, Harborne, near Birmingham. Commended, W. R. Lane, Bristol Road, Birmingham. *Chickens*.—Highly Commended, J. Dixon, Bradford, York-shire; W. Kershaw, Heywood, Manchester. Commended, G. Lingard, jun., Birmingham; N. Marlow, Denton, near Manchester.

**HAMBURGH** (Silver-spangled).—Highly Commended, W. Cannan, Bradford, Yorkshire. *Chickens*.—Highly Commended, Mrs. Pettat, Asbe Rectory, Basingstoke; J. Fielding, New Church, near Manchester. Commended, Right Hon. Viscountess Holmesdale, Linton Park; S. Saaw, Stainland, Halifax. *Hens*.—Highly Commended, S. H. Hyde. *Pullets*.—Highly Commended, H. W. B. Berwick, Helmsley, York; Right Hon. Viscountess Holmesdale; S. Shaw.

**POLAND** (Black with White Crests).—Highly Commended, J. Dixon, Bradford. Commended, T. P. Edwards, Landhurst, Hamshire. *Chickens*.—Highly Commended, J. Ludlow, Solihull, near Birmingham; T. Battye, Holmbridge, near Huddersfield.

**POLISH** (Golden).—Highly Commended, Mrs. Pettat; H. Child, Sherborne Road, Birmingham.

**POLAND** (Silver).—Highly Commended, G. C. Adkins, the Lightwoods, near Birmingham. Commended, G. C. Adkins.

**ANY OTHER DISTINCT VARIETY**.—Highly Commended, Hon. E. N. Hill, Cronk Hill, Shrewsbury (Buff Polish—"Shamois leather"); W. Chamberlain, Desford (Sulphurs); S. Shaw (Black Hamburg); Miss Clifton, Whittington, Worcester (Negro, or Seinde); D. V. Allen (Crevo Cour and La Fêche); W. Marlow, jun., Dorchester (Rumples). Commended, Miss C. H. Ballance, Taunton (Chinese Silky); D. V. Allen (Houdans).

**GAME** (Black-breasted Reds).—Highly Commended, W. Boyes, Beverley, Yorkshire. Commended, E. Archer, Malvern. *Chickens*.—Highly Commended, G. Cargey, Staffordshire; E. Archer, Malvern. Commended, J. Firth, Halifax; J. Hay, Sudbury, Derby.

**GAME** (Brown and other Reds, except Black-breasted).—Highly Commended, J. H. Braikenridge, Chew Magna, Bristol; R. Swift, Southwell, Nottinghamshire; G. Cargey, Stone Staffordshire; W. Boyes, Beverley; E. Archer, Malvern. (An extraordinarily good class. Best class of Game in the Exhibition.) *Hens*.—Highly Commended, J. Wood, Wigan; T. Carless, Hovingham, near Nottingham. Commended, E. Aykroyd, Bradford, Yorkshire; E. Archer, Malvern. *Pullets*.—Highly Commended, J. Wood; Wigan; E. Archer, Malvern; G. Cargey, Staffordshire. Commended, W. R. Lane, Bristol Road, Birmingham; J. L. Lloyd, Soho, Birmingham.

**GAME** (Duckwings and other Greys and Blues).—Highly Commended, W. Kershaw, Heywood, near Manchester. *Chickens*.—Highly Commended, J. Stubbs, Stafford. Commended, J. Wood, Wigan.

**SINGLE COCKS.**

**DORKING** (Silver Grey).—Highly Commended, D. V. Allen, Inchmartine, Inchture, N.B.

**DORKING** (except Silver Grey).—Highly Commended, Mrs. Rothery, Haslemere, Liphook; J. D. Hewson, M.D., Stafford; Rev. J. G. A. Baker, Biggleswade; T. W. Hill, Woodlands, Heywood, near Manchester; J. Smith, Henley-in-Arden; W. Endall, Henley-in-Arden; T. W. Hill; J. Hill, Burton-on-Trent; Master E. A. Tudman, Whitechurch, Shropshire. Commended, Rev. E. Cadogan, Walton Parsonage, near Warwick; E. H. Garrard, Broadway, Worcestershire.

**SPANISH**.—Highly Commended, Miss E. de Conroy Drevar, Keso Hill, Black Rock, County Dublin; Miss E. Biggar, Dumfriesshire; R. Tebbay, Fulwood, near Preston; J. W. Smith, Oundle, Northamptonshire; T. P. Wood, jun., Cheshire; C. H. Wakefield, Malvern Wells; J. Choyce, Atherstone.

**COCHIN-CHINA** (Cinnamon and Buff).—Highly Commended, H. Tomlinson, Balsall Heath Road, Birmingham. Commended, Capt. Heaton, Lower Broughton, Manchester.

**COCHIN-CHINA** (except Cinnamon and Buff).—Highly Commended, P. Cartwright, Oswestry (Partridge).

**BRAMA POOTRA**.—Commended, C. Dain, Southampton; Messrs. Philpott & Weeks, Bromyard, near Worcester.

**HAMBURGH** (Golden-pencilled).—Highly Commended, J. Munn, Shawclough, Newchurch, near Manchester; Mrs. W. Kershaw, Heywood, near Manchester. Commended, Mrs. W. C. Worrall, Knotty Ash, near Liverpool; C. H. Wakefield, Malvern Wells; J. Choyce, Atherstone.

**HAMBURGH** (Silver-pencilled).—Highly Commended, Messrs. Burch and Boulter, Sheffield.

**POLAND**.—Highly Commended, G. C. Adkins, Birmingham.

**GAME** (White and Piles, Duckwings, and other Varieties, except Reds).—Highly Commended, G. Hellowell, Walkley, near Sheffield; H. Worrall, West Derby, Liverpool.

**GAME** (Black-breasted Reds).—Highly Commended, H. Shield, Northampton; R. Swift, Southwell, Nottinghamshire; J. Keable, Thatcham, Newbury, Berkshire.

**GAME** (Brown and other Reds, except Black-breasted).—Highly Commended, J. Fletcher, Stoneclough, near Manchester; W. Dawson, Selly Oak, Birmingham. Commended, T. Robinson, Ulverstone; G. E. Meredith.

**BANTAMS** (Gold-laced).—Highly Commended, R. M. Stark, Hull; M. Leno, jun., Dunstable.

**BANTAMS** (Silver-laced).—Highly Commended, R. Swift, Southwell, Nottinghamshire; Mrs. Pettat, Basingstoke; M. Leno, jun., Dunstable.

**BANTAMS** (White, Clean-legged).—Commended, N. Sykes, Glohe Road, Mile End, London.

**BANTAMS** (Any other variety).—Highly Commended, F. Musten, Marshal's Wick, St. Alban's (Japanese Ruffles and Cream).

**GAME BANTAMS** (Black-breasted and other Reds).—Very Highly Commended, W. Wood, Walkley, Highly Commended, W. R. Lane, Birmingham; T. Burgess, Burfleydam, Whitechurch, Shropshire; W. Newsome, Bingley, Leeds; J. Grocott, Cheshire. Commended, C. W. Brierley, Rochdale; H. Bates, Edzbaston, Birmingham; J. W. Kelloway, Merston, Isle of Wight; J. Camm, Farnfield, Southwell, Nottinghamshire.

**GAME BANTAMS** (Any other variety).—Highly Commended, Mrs. Sheild, Northampton (Duckwing); Messrs. Parkinson & Lawrenson, Preston

(Duckwing); R. Hawksley, jun., Southwell, Nottinghamshire. Commended, R. Moon, jun., Wavertree, Liverpool (Duckwing); J. Munn, Newchurch, near Manchester (Duckwing); C. Brierley.

**GAME BANTAM COCKS**.—Highly Commended, W. Pares, Ocbrook, Derby; R. Hawksley, jun., Southwell, Nottinghamshire; J. Camm, Southwell, Nottinghamshire; W. T. Everard; A. H. D. Bayly, Biggleswade. Commended, W. C. Worrall, Knotty Ash, Liverpool; J. W. Haslam, Shropshire, (Black-breasted).

**DUCKS** (White Aylesbury).—Highly Commended, Rt. Hon. Lord Kinnaird, Rosie Priory, Inchture, N.B.; J. K. Fowler, Aylesbury.

**DUCKS** (Rouen).—Highly Commended, Rev. H. G. Bally, Wiltshire; D. V. Allen; W. H. Deason, Woburn Sands, Bedfordshire; W. Mitchell, Keighly; J. Holme, Knowsley, Prescott; T. Hollis.

**DUCKS** (Black East Indian).—Highly Commended, R. M. Stark, Hull; F. W. Earle, Jessop, Lancashire. Commended, Miss C. H. Ballance, Taunton; J. R. Prescott, Hull; J. Martin, Chaires, Worcester; A. Smith, Atherstone.

**DUCKS** (Any other variety).—Commended, Mrs. Whitehead, Kingsland Road, London, N.E. (Grey Call); J. Dixon, Bradford, Yorkshire, (Grey Call); T. W. Hill, Heywood, near Manchester. Commended, Hon. Mrs. Colville, Lullington Top-knotted Aylesbury.

**GREYS** (Grey and Mottled).—Highly Commended, Hon. Mrs. Colville, Lullington, Burton-on-Trent (Tonlouse).

**TURKEYS**.—Highly Commended, Right Hon. Lord Hill, Hawkstone, near Shrewsbury (Black American).—*Poultis*.—Highly Commended, D. V. Allen; S. H. Truelove, Hoppesford, Coventry (Black); J. F. Tempest, Wootton Hall, Henley-in-Arden (White). Commended, J. F. Tempest.

**PIGEONS.**

**CARRIERS** (Black Cock).—Highly Commended, P. Eden, Salford, Manchester. Commended, E. L. Corke, Croydon. *Hens*.—Highly Commended, P. Eden; Messrs. W. Siddons & Sons, Birmingham.

**ALMOND TUMBLERS**.—Highly Commended, G. C. Adkins, Birmingham.

**JACOBS**.—Highly Commended, J. T. Lawrence, Liverpool. Commended, J. Baily, jun., Mount Street, London, W.

**PASTALS**.—Highly Commended, D. Thwaites, Cheshire. Commended, F. Else, Bayswater, London; J. W. Edge, Aston New Town, Birmingham; G. C. Adkins, Birmingham.

**TUMBLERS**.—Highly Commended, F. Key, Beverley. Commended, C. Felton, Erdington, near Birmingham; W. H. C. Oates, Besthorpe, Newark, Nottinghamshire.

**OWLS**.—Commended, H. Morris, Forest Hill, Kent; F. Else, Bayswater, London.

**NUSS**.—Highly Commended, S. Shaw, Stainland, Halifax.

**TURBITS**.—Highly Commended, G. F. Nicholls, Cheltenham. Commended, Miss L. C. D. Fenwick, Newton St. Lo, Somersetshire; S. Shaw, Stainland, Halifax; F. Else, Bayswater, London.

**NUSS**.—Highly Commended, G. C. Adkins, Birmingham. Commended, C. Baker, King's Road, Chelsea, London.

**DRAGONS**.—Highly Commended, F. Else, Bayswater, London. Commended, J. Lowe, Birmingham (White); H. Yardley, Birmingham.

**ANY OTHER NEW OR DISTINCT VARIETY**.—Highly Commended, Her Grace the Duchess of Sutherland, Trentham Hall, Staffordshire (Spots); H. Yardley, Birmingham. Commended, G. F. Nicholls, Cheltenham.

**THE DORKINGS AT THE BIRMINGHAM SHOW.**

The Birmingham Poultry Show is very justly considered the first in the kingdom, and the description of bird which there obtains prizes or commendations in the respective classes may be fairly looked upon as the standard of perfection. The colour, shape, size, and characteristics of such birds may be considered as establishing and fixing the rules which should guide poultry-fanciers in the breeding and choice of their exhibition specimens.

Now, I have just returned from Bingley Hall, where I went, according to my wont, as a devoted Dorking-fancier, as well to improve my judgment by the sight of the perfect specimens of that class of birds there exhibited, as to buy stock for next season's breeding. I have returned perfectly bewildered! and I hasten to impart the causes of my astonishment to you, in order to draw the attention of your Dorking-fancying readers to what has puzzled me, and to seek for some explanation, if any is possible, of the strange things I saw.

I am only going to speak of the Dorking class. I do not understand other birds; but Dorkings I have bred successfully for some years, and with their points I am pretty well acquainted.

From the results of all former Shows the following rules have become established:—

- 1st. That a Dorking, whether cock or hen, must have five toes distinct, fully developed, and healthy.
- 2ndly. That excellence of condition and of colour, and of general symmetry should be preferred to mere size. (There is a special notice to this effect in the schedule of the Birmingham Show.)
- 3rdly. That the colour for a Dorking cock should be on breast and tail as nearly black as possible; saddle and hackle should be either white or straw colour, with certain well-defined markings on the wings.
- 4thly. That the hens exhibited in one pen should be uniform in colour, marking, and size.

Such I believe to be the general rules which Birmingham Judges have up to the present time impressed upon Dorking-breeders the necessity of adhering to.

Either the Judges have most erroneously given their judgments at the present Show, or else they intend us for the future to be guided by new rules, or, more probably, by no rules at all. As soon as I entered the Hall I hurried to see the first-prize birds in Class 5, old birds. To my astonishment, in the pen distinguished as the best pen of Dorkings in the Show (pen 81), I saw a cock, certainly of great size, but with quite as much white on his breast as black, and with as many white feathers, if not more, in his tail, as black ones. His fifth toe far from well put on, and like that of each of his two hens, sadly disfigured and swollen.

I next turned to the second-prize pen in the same class. Here I found a hen positively with nothing more than the merest apology for the fourth or lower toe! On one foot she had but a small, dependent nail to represent the lower toe, and on the other foot a tiny stump or excrescence, without a nail on it, to represent the corresponding toe.

Are five toes necessary in a first-class Dorking hen? Is any mere undeveloped or malformed toe to be accepted for the future instead of the "well-developed and distinct" formation?

I passed on to Class 6, young birds. Here I came to a highly commended pen (128), in which one pullet had a pale white-crowned breast, and the other had a full-coloured salmon breast. The general colour of the two birds was also quite distinct, the one with the light breast being altogether of a lighter colour. In addition to this difference in their colour, which, according to all rule and precedent, should be fatal to the pen, the pullet with the light breast had not got five distinct toes. The hind toes had grown together, forming one thick toe, which had a short slit in it at the end, and two nails!

Is one pretty long toe with a short slit in it, about one-fourth the length of the whole toe, to be considered a sufficient representative of the characteristic of the first-class Dorking?

Amongst the single cocks, again, I saw one cockerel highly commended (pen 934), which had the fourth toe represented by a mere diminutive excrescence, as in the case of the hen in the second-prize pen of old birds. The toe had either never assumed a defined form, or else it had been partially removed; in other respects the bird was a good one.

Another bird, also highly commended, was in such wretched condition that, even at the early hour at which I saw him—viz., 10.15 A.M. on Monday, he looked dreadfully ill. His comb, face, and wattles were pale and flaccid, and he had evidently scarcely done moulting, as his tail-feathers were few, and he was otherwise ragged. Is "condition" represented by a bird in such a state? There was another bird commended, whose most remarkable feature was a general bottle green hue toned down with soot. I saw another bird of this curious colour in Class 6. Is a white or golden saddle, with clean, well-marked hackle, necessary to a good Dorking cock or not?

I repeat that what I saw, and what I have described, puzzled me very much. Nor was I alone in my astonishment, for several gentlemen, who were at the same time eagerly examining the pens, expressed much the same feeling. I do not presume to say that this or that pen should have prize or commendation in preference to others; I only pretend to assert that certain broad, well-established, generally-accepted rules and principles in the characteristics of good Dorkings have been broken and disregarded; and if they are to be so broken, disregarded, or even relaxed, I think it should be well understood that such is, for the future, to be the case.

For my part, I shall be very sorry if more latitude is given in the choice of a first-rate bird. If delicacy and purity of colour—if well-formed, distinct, and healthy toes—if the brilliancy of plumage—if "good condition" are no longer to carry the day against mere size and weight, we shall soon have a coarse, ugly, and ungainly brute in the place of our present noble-looking and high-bred favourite. Huge size, if colour and "breeding" are no object, can easily be obtained by a dash of the Partridge Cochins or Brahma Pootra; and I shall be quite surprised if the decisions of our Judges at this Show do not tend greatly to deteriorate the quality of the birds at the next.—E. C.

CRYSTAL PALACE POULTRY SHOW.—This Show commences on Tuesday the 9th instant, and continues the three following days. We are pleased to hear that the entries are most

satisfactory. The number of pens of poultry are in excess of last year. The Pigeons show a slight decrease; but the Rabbits will be in greater number than upon any former occasion. The following are the number of pens:—Cochin-China, 83; Brahma Pootra, 19; Dorking, 178; Spanish, 79; Game, 184; Hamburg, 95; Polish, 31; Malay, 11; other distinct breeds, 26; Bantams, 92; Geese 13; Ducks, 69; Ornamental Water Fowl, 6; Turkeys, 10; Gold, Silver, and other Pheasants, 19; Pigeons, 277; Rabbits, 118. Total, 1310.

### CHIPPENHAM POULTRY SHOW.

The Chippenham is one of those few Agricultural Societies which consider poultry to be worthy of their notice. They, therefore, offer a sufficient amount in prizes to produce a very spirited, though principally local competition, which would, doubtless, be less local if the Show was more generally advertised, and in papers more likely to fall into the hands of distant exhibitors. That poultry adds materially to the attractions of an agricultural show admits of but little doubt; and that it is not, as some imagine, a clog round the neck of the Society to which it is attached, the Chippenham Society does, we think, most definitely prove, as few local societies stand better in point of funds than this; and we cannot help regretting, when we see agricultural societies so blind to their own interests as to exclude poultry from their list altogether, the result of which is they lose support they would otherwise obtain, both as regards exhibitors, visitors, and subscribers. The exhibitors of poultry are much more numerous than of stock, the crowds round the poultry pens at the shows plainly showing where the great point of attraction lies, especially amongst the fairer sex, and there are many who would subscribe to a poultry show, who would not care to do so to a society rigidly excluding their favourites.

*Dorkings* headed the prize list, though if we except the prize pens, we can scarcely say they were worthy of that honourable position, as they were neither numerous nor particularly good. Messrs. Blinkworth and Heath were the successful exhibitors of *Spanish*, the cock bird in Mr. Blinkworth's pen being very good; but we fancied his comb a little inclined to droop behind. The Black-breasted Red Game formed the class of the Show, producing a most spirited competition; Mr. Waller eventually carrying off the first prize with a very beautiful pen of chickens, and we think the cock bird only required a little care and attention to make a first-rater. Many other pens in this class might also be well spoken of, especially Messrs. Hanks' and Bridges'. Mr. Elling showed two good Brown Red hens with a very coarse cock. In the other varieties of Game there was nothing of note. The Golden-pencilled *Hamburgs* mustered well, though curious to say, there was not a single pen either of Silver-pencilled or Spangled, though there were special classes for them. *Cochins* were represented by two pens only, and those were inferior. In *Polands*, Silvers alone entered an appearance. The first prize for Game *Bantams* was withheld, there being one pen only of inferior Brown Reds. Black and White Bantams were well represented, but no Sebrights were entered. In the class for breeds not mentioned in the prize list, Mr. Fox stood A1, with a beautiful pen of Malays, there being also some good Brahmas and Silkies.

Miss Milward, as usual, headed the list for *Turkeys*, with a remarkably fine pen. *Geese* were not particularly good. We have seen much better *Aylesbury Ducks*, but Rouens made amends, mustering ten pens, with scarcely an inferior one amongst them. Messrs. Hanks' and Fry's pens being particularly good. Mr. Phillips' East Indians in the "variety" class, well deserved the position they held. They were, however, hard-pressed by Miss Milward's and Mr. Fox's pens.

In the sweepstakes for *Game Cocks* two very inferior Black Reds only appeared.

The Judge was Mr. Geo. Saunders Sainsbury, Devizes.

### THE YORK POULTRY SHOW.

The sixth annual Exhibition of the Yorkshire Society for Fat Stock, Poultry, and Roots, was held in the new buildings at the Cattle Market, York, on Wednesday, Thursday, and Friday last. Much more space was allotted than in previous years for the accommodation of both the animals and visitors; indeed, it is said the Society's showyard is now one of the most perfect in

England; and, whether with regard to the arrangements, or the number and superior quality of the animals, this is, undoubtedly, the best Show of fat stock that has ever been seen in York.

We subjoin a list of the awards in the Poultry classes.

**DUNKINS** (Any colour).—First, J. White Warblay. Second, Rev. G. Holdsworth, Aldborough. Third, H. W. B. Berwick, Helmsley.

**SPANISH**.—First, J. Shorthose, Newcastle-on-Tyne. Second, E. Brown, Sheffield. Third, H. A. Hudson, Ousecliffe.

**COCHIN-CHINA** (Cinnamon or Buff).—First, H. W. B. Berwick. Second, Rev. G. Gilbert, Norwich. Third, R. D. Ewes, Knareborough. (Any other Variety).—First, J. Shorthose. Second, G. Hatchinson, York. Third, J. Bell, Thirsk.

**GAME** (Black-breasted and other Reds).—First, H. Adams, Beverley. Second, F. H. Dodds, Ovendon, Halifax. Third, A. D. Sunderland, Oakworth. (Any other Variety).—First, H. Adams. Second, A. Cattley, York. Third, J. Firth, Halifax.

**HAMBOURH** (Golden-pencilled).—First, S. Smith, Northorham. Second, J. Sunderland, jun., Hipperholme, Halifax. (Silver-pencilled).—First, J. Sunderland, jun. Second, J. Firth. (Golden-spangled).—First, G. D. Mann, Hemstet. Second, H. W. B. Berwick. (Silver-spangled).—First, J. Mitchell, Hipperholme, Halifax. Second, W. B. Richard-son, York.

**ANY FARMYARD CROSS OR OTHER VARIETY NOT PREVIOUSLY CLASSED**.—First, Lady Hawke, Pontefract (Brahmas). Second, R. M. Stark, Hall (Polish). Third, T. Jolly, Warblay.

**GUINEA FOWL**.—First, J. R. Jessop, Hall. Second, G. Trotter, Poppleton.

**BANTAMS** (Game).—First, R. M. Stark. Second, E. Brown. (Black or White).—First, A. Cattley. Second, R. M. Stark. (Any other Variety).—First, R. M. Stark. Second, A. Cattley.

**TURKEYS**.—First, Lady Hawke. Second, J. S. Tenge, York. Third, R. M. Stark.

**GESE**.—First, H. Ambler, Halifax. Second, J. R. Jessop. Third, T. Dickson, York.

**DUCKS** (Aylesbury).—First, T. E. Thell, Wetherby. Second, B. Storey. Third, R. M. Stark. (Rouen, or any other variety).—First, W. Cannon, Bradford. Second, J. R. Jessop (East Indian). Third, B. Chadwick, Manston, Leeds.

The Judges of Poultry were J. F. Smith, Esq., Skelton Grange; and Mr. Charlton, of Bradford.

## THE PIGEON SOCIETIES OF LONDON.

### II.—THE NATIONAL COLUMBARIAN CLUB.

THIS Society, which was established in 1857, meets at Anderson's Hotel, Fleet Street, on the evenings of the fourth Tuesdays of the months of October, November, December, January, and February, the annual Show being held on the ordinary day of meeting in February.

The National Columbarian Club was started by some young but enthusiastic fanciers, and was originally formed by several members of the older Philopeteron Society. At the present time the officers of the Society are—President, Mr. Fry, of Brighton; Vice-Presidents, Messrs. Jones and Freeman; and Secretary, Mr. Betty. The annual subscription and entrance fee are 10s. 6d. each.

Although so recently founded, this Club must be considered as firmly established—a fact which is, in great part, owing to the active and zealous exertions of Mr. Betty, the Hon. Sec. The number of its members is increasing, and the quality of the birds shown at its monthly meetings is very good.

Most classes of birds find supporters amongst the members: thus the Secretary is distinguished for his very valuable stud of Carriers. Mr. Jones is notorious for his Barb. The Short-faced fanciers are well represented by Messrs. Percivall, Jeans, Smith, and Freeman. Mr. Baechus is very strong in Powders. In Toys, Mr. Morris is a host in himself. Amongst the members is included Mr. Potter, one of the breeders to whom the Carrier-fanciers of the present day are deeply indebted for short birds of very superior quality. We regret to record the fact that a large number of Mr. Potter's birds were stolen during the last season, and no trace of them has ever been discovered. The members of this Society are diligent in their attendance, and there is usually a very good show of choice specimens on every meeting night. At our last visit to this agreeable *réunion* of fanciers, we saw several new pattern show-pens well adapted to display large birds—such as Carriers in pairs. These pens were cylindrical in shape, being about the size of one of the sale-baskets used at Stevens' auctions. The wires forming the sides were perpendicular, and inserted into a mahogany ring or moulding at the top. As show-pens for pairs of birds they were the most effective we have seen.

## “UPWARDS AND ONWARDS” DEFENDS HIS APIARY.

I NEVER intended to claim priority of invention of the narrowed drone-refusing passages from a hive into a super. I

merely adopted the peculiar entrance *apropos* to my hives having central holes in their tops. I was led to do so to redeem their character from that severe condemnatory castigation which “A RENFREWSHIRE BEE-KEEPER” administered, who erst explained his plan in preference, and which, if I remember rightly, read much the same as that now propounded by Mr. Fox. Both the “RENFREWSHIRE BEE-KEEPER” and Mr. Fox, for their respective counties and practices, are right in what they say, but very large supers will not do here. I tried them for years and could seldom get them completed. Furthermore, for the million, the three side entrances would, I think, complicate a hive too much. Mrs. Barratt would be sure to cast over it her wet blanket, and say, “Your gentleman's bee-keeping won't do for poor people.” If I lived in Mr. Fox's beautiful county of Devon, trust me but I should have adopted the plan when first broached by “A. R. B. K.” long ago. I know his prolific honey neighbourhood, and I made more friends down there in one week than I have been able to make here during a residence of sixteen years.

My large hives are equal to the propulsion of any amount of cold-shoulder-extraneous coverings, and in summer they become shaded by the trees by twelve o'clock, so when supering I never find any difficulty; and if I did, I would cause larger, thin, topless hives to be made to slip over the stock-hive, in preference to the “oilcloth.”

I beg to assure Mr. Fox that my bee-boards would bear 1 cwt., at least, without bending. The bees certainly did work their combs down to the board, and that at once, and they would do so again if I dispensed with the crossed sticks. I do not lay any very great stress about central holes incommoding the breeders in these large hives through press of workers. The honey-gatherers, agreeably to my observations, instinctively take their ways outside, and along the top, and not through the central brood-combs; and as far as the means of communication is concerned, I have allowed for measurement more than half the main entrance to the hive, which is quite proportionate enough for the up-honey-gatherers—say one hundred each minute. Much more room could be given by skeletonising the flaps with a few more slits, though upon repeated examinations and watchings I feel convinced the space I have given would do for almost any super.

I wonder if Mr. Fox ever tried my bee-feeder? It answers with me very well. In fact, I have the very original which I exhibited along with its quarter-of-a-peck-measure substitute, doing duty this very moment. I deferred feeding two of my hives till I had my second-best honey from the Exhibition, to make it into artificial food. I administered the feeders yesterday evening, the 1st inst., containing 7 lbs. of food each; and this afternoon, the 2nd, there is scarcely an ounce of food left in both. Could bottles beat this? Pray let it be understood, that I say nothing against bottle-feeders, never having tried them; but as Mr. Fox openly pits them, and every other feeder, against mine, I will merely observe, that it strikes me in the application of the bottle, the bees must take the contents whether they feel inclined to do so or no, or become saturated with it.

I am sorry that I have offended so much against Mr. Fox's good taste. Amongst visitors here, I have not met with a single instance of disapprobation, but considerable hilarity has been displayed at the caricatured conceptions. Again, at the Exhibition, I was told by a regular attendant upon an adjacent machine, that “almost every one who visited your case was very much amused with your head.” Now, is not that something to congratulate oneself upon in this serious workaday world? For the sake of these good-humoured people I hope Mr. Fox will reconsider his verdict. I fancy they form a preferable finish to the flat bottom of the pan being bound. I have tried cord in lieu of “copper wire,” after that fashion, which, with the fragmentary bricks and rough stones, I must beg to be allowed to object to. I am now having some stone protectors against all comers sculptured, one in the shape of a lion couchant, and the other, old England's device—the rose, the shamrock, and the thistle.—UPWARDS AND ONWARDS.

## DZIERZON ON PARTHENOGENESIS IN THE HONEY BEE.

No one can fail to recognise in the articles from the pen of Mr. J. Lowe, which have recently graced the pages of THE JOURNAL OF HORTICULTURE, the same qualities which he ascribes

to the writings of his distinguished contemporary Dzierzon—viz., that they enunciate the opinions of a man who is well acquainted with apiarian science. He has, however, made so great a mistake in his last communication, with regard to the estimation in which Dzierzon now holds his well-tryed and firmly-established doctrine of parthenogenesis in the honey bee, that I deem it important to lose no time in correcting it.

I speak advisedly in saying the estimation in which Dzierzon now holds his doctrine of parthenogenesis, since it is by no means one of the least singular of the circumstances which attended the promulgation of this remarkable discovery, that the original promulgator of what was then merely a colourable hypothesis, based on his own unassisted observations and experiments, should, at one time, appear to have succumbed to what Mr. Lowe terms the antiquated notions and confirmed prejudices of bee-keepers, so far as to doubt the perfect tenability of his own theory. This curious instance of a great originator of a new idea faltering in the advocacy of his own discovery, until it was raised by the investigations of others to the rank of an established scientific fact, seems to have occurred about eight or nine years ago, and this it is which has probably caused Mr. Lowe to entertain the mistaken notion which pervades the first part of his last article.

Von Siebold, writing in 1854, says:—"I must not omit to mention that Dzierzon himself, after calling a number of opponents into the field by the promulgation of his new theory, and after all possible imaginable objections had been raised from the most various sides against its correctness, began to doubt the perfect tenability of his theory. Notwithstanding that very recently Dzierzon expresses himself with peculiar reserve and caution upon certain points of his theory, other experienced apiarians still held firmly to it, as, after it had once become perfectly familiar to them, by its assistance every occurrence in a bee-hive, however unexpected or apparently strange, was instantly understood by them. Above all, we must mention Herr von Berlepsch, who has set himself the task of testing Dzierzon's theory in every direction, with his abundance of beehives." Here follows an account of several interesting experiments made by Berlepsch, which Siebold considers "must again convert Dzierzon himself, since he appears to have become a doubter of his own theory."

Whether the experiments of Von Berlepsch were attended by the anticipated result, or whether, as appears most probable, it was due to the conclusive investigation of Von Siebold himself, I am unable to state. All that is certain is, that Dzierzon was reconverted to a belief in his own discovery, which he, in common with all his apiarian contemporaries in Germany, now holds to be perfectly indisputable, as will be perceived by the following extracts from the last edition of his work, entitled "Rational Bee-keeping," and written no longer ago than 1861:—

"We find queens in many stocks, young as well as old weak ones, which are only able to lay drone eggs. Under certain circumstances workers also lay eggs, from which, however, only drones arise. With a truly impregnated queen, however, we find the wonderful power of adapting to the cells the eggs which she lays in them—of laying female eggs in the small workers' and male eggs in the large drone-cells—thus fixing arbitrarily the gender of the egg. To solve this riddle recourse was had to the most diverse hypotheses, whereby, however, the matter only became more complicated. Why male and female eggs were laid according to the cells some tried to explain by supposing drones to be the offspring of certain workers, whilst the queen was supposed, in contradiction to all experience, to lay only worker eggs. Every attentive observer may, however, often see the queen lay eggs in drone-cells. The long and acrimonious dispute, which, notwithstanding this was carried on with regard to this point, was brought by the Italian bees to a sudden end; for when an Italian queen was introduced into a common stock, not only Italian workers but Italian drones appeared also, proving incontestably that they owed their existence to the queen. The appearance of mothers (whether queens or workers) laying only drone eggs was attempted to be explained by the hypothesis of an imperfect impregnation, owing (according to Busch) to its having taken place within the hive, or (according to Huber) to its having been retarded. These hypotheses are, however, perfectly incapable of proof, and are found on closer examination to be altogether untenable. Impregnation never takes place within the hive. Although a multitude of drones may exist, a young queen will not be fertilised if the weather or

the season does not admit of her flight. Both parties are indisposed to copulate within the hive. If, also, the sexual ardour of drones could be excited in-doors, the queens would have no rest whatever during their existence. So long, however, as a young queen flies out for copulation, which certainly in the warm summer will, at the most, last four weeks, but which in the cool spring or autumn, when life and development in the stock is more at rest, will take place after five or even six weeks, she is able to become perfectly fertile. No reason can be assigned why a retarded impregnation should be less perfect, or why it should only enable the queen to propagate the male gender. The truth is this, that with queens which only produce drones no impregnation has taken place, or it has remained without effect, or has become inoperative, since fertilisation is unnecessary for drone eggs, as they bring the germ of life from the mother's ovary, and become drone eggs from this circumstance—that they are laid unfertilised; but if the egg be fertilised, if from the spermatheca of an impregnated queen, filled with semen, a spermatozoon is slipped into the passing egg, by this the germ of life for a different bee-individual, a worker or queen, is awakened. In this proposition lies the key for solving all questions which have hitherto seemed inexplicable. This proposition forced itself upon the Silesian Bee-friend\* when he had an opportunity of observing several young queens, which, from either having defective wings, or being hatched in the cold season, had evidently been unable to undertake the wedding-flight, and which afterwards were proved by dissection to have remained unimpregnated, but were yet laying eggs, from which proceeded drones only. Now, as these eggs, germinating first in the ovary, would most certainly have become worker eggs if impregnation had taken place, no other conclusion could be arrived at than that all eggs are originally equal or generically indifferent, and that they become male or female eggs according as they are laid unfecundated or fecundated. By this is easily explained why unimpregnated queens or workers, which are incapable of impregnation, can lay only drone eggs, whilst impregnated queens lay both worker and drone eggs, and this at will, since it is easy for the queen to prevent fecundation, or permit it to take place by the motion of a muscle.

"This proposition, which the author ventured only to submit as a hypothesis in the first volumes of the 'Bee Journal,' and which in his earlier writings he more fully explained and proved, met with the most violent contradiction because it was opposed to a law hitherto universally considered valid—that no life is possible without fecundation. As, however, this theory explains the phenomena of the bee-hive as perfectly as the Copernican hypothesis the phenomena of the heavens, it found more and more adherents; even physiologists began to take an interest in it, and now it is received as a doctrine, after having passed the fiery ordeal of science under the microscope and dissecting-needle of the great physiologist, Professor Theodor Von Siebold, formerly of Breslau, now of Munich.† At this time there is no longer any dispute as to the correctness of his theory."

These, then, were the opinions expressed by Dzierzon on this subject so recently as 1861. Having myself been a constant reader of all articles from his pen which have appeared in the German "Bee Journal" during the present year 1862, I can vouch for the fact that since that time he has never in any one instance swerved from his faith in the truth of the doctrine of parthenogenesis in the honey bee, or even once referred to what Mr. Lowe so justly designates "the antiquated and untenable theory of a bygone age."—A DEVONSHIRE BEE-KEEPER.

\* Dzierzon speaks of himself under the above name.—A DEVONSHIRE BEE-KEEPER.

## OUR LETTER BOX.

**Cows (Inquirer).—**There is no difference between the breeds of Alderney and Guernsey if pure. Of Devons, the usual colour of the best is entire red; but there are many brown, chestnut, and even yellowish. The last are said to be particularly liable to diarrhoea.

**MILK-BOWLS (A. B.).—**We are of opinion that bowls or pans of glass are in every respect to be preferred. Made of green glass one-eighth of an inch thick, they are very strong, are most easily kept clean, are neat in appearance, and yield as much, if not more cream, as vessels made of any other material. Sixteen inches wide at the top, with a thickened edge; 12 inches wide at the bottom, and 6 inches deep, is a good size, holding about eight quarts, but not more than six quarts should be put in. They only require to be rinsed with lukewarm water, and then with cold water. Scalding or boiling water is totally unnecessary.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 44.7° and 33.5° respectively. The greatest heat, 58°, occurred on the 16th, in 1849; and the lowest cold, 7° on the 16th, in 1855, and 19th, in 1859. During the period 133 days were fine, and on 112 rain fell.

COMPARATIVE MERITS OF POTATOES.

LAST summer twelvemonths, as we were walking in the garden, I said to the rector as I cast my eyes over many sorts of Potatoes—a motley group which were growing there, “I really think I shall give up scouring the country, and confine myself to Mitchell's Early Albion Kidney, Early Shutford Seedling, the Lapstone Kidney and the Fortyfolds—those

four sorts that suit us so well. It costs a good round sum one time with another for the sake of introducing and proving for the people here the best kinds which are likely to suit them; and after all they do not care one farthing about the giver.” “Well,” the rector said, “you will do it.”

On the following autumn I paid a visit to Suffolk, to the old folks at home, and of course the ruling passion soon led me in search of Potatoes of the best local sorts; and fourteen varieties were carefully packed in a hamper, soon to find their way to Woodstock, to be spread out in trays (see No. 48, page 436), and looked fondly upon as coming from the old home, and in consideration of the trouble that the dear friends and villagers had taken to procure them for me.

On passing through London I happened to go to a coffee-room, and the subject of Potatoes was on the tapis. Some tubers from Lambton Castle were being handed about and extolled as an excellent sort. Of course I turned beggar at once and got a share. Though their name was forgotten I hope, if Mr. Stevenson should cast his eye over this, he will kindly let us know their name, if he recognise the sort from my description. Well, not many weeks after my return a letter arrived to me from Mr. Daintree, of Fen Drayton, to say that he had forwarded me a peck of his Earliest Seedlings, requesting me to try them against any approved sort which I might have, and in due time to oblige him with the result. Now here was I, after having half vowed to restrict myself to four sorts, booked to a certainty for twenty during the following summer, which “is a thing,” as Lord Dundreary would put it, “that no fellow can understand.” I did not get that peck of Potatoes which Mr. Daintree was to have sent, so after an unreasonable time I wrote to him to say so; and he replied that the Potatoes had been to Woodstock, but were returned to him with a superscription written on the label that no such person was known here. Now that was a thing I at once understood. So, having shortly to go to London, I sent Mr. Daintree my direction there, where he sent me another peck of Potatoes, and they arrived there where I was known almost to the hour when I expected them. I had yet another peck sent to try with some late sorts at a late planting, and the results were as follows:—

COMPETITION 1.

March 14.—Planted Mitchell's Early Albion Kidney, Walnut-leaved Kidney, Shutford Seedling, Early Prolific, Early Shaw, and Daintree's Earliest Seedling Potatoes.

June 9th.—Examined a root of each sort, and singled out the largest tuber, which weighed respectively—Mitchell's Albion, 2½ ozs.; Walnut-leaved Kidney, 2 ozs.; Shutford ¾ oz.; Early Prolific, 1½ oz.; Early Shaw, ½ oz.; Daintree's Seedling, 1 oz. Mitchell's ate the firmest, and was sufficiently forward for use; and the Shutford came palatably next. I wish it to be observed that I received the Daintree's only a few days previous to planting them, and they were a fortnight later in making their appearance aboveground than the rest, in consequence of the others having undergone my usual winter preparation, and were endowed with strong green shoots, thick, and as long almost as one's little finger, and as firmly attached to the sets as the limpet is to the rock, which I always calculate make a difference of a fortnight or three weeks in the maturation of the tubers. I presented a few of the Daintree's to my gardening and bee-keeping friend, Mr. Morris, who planted these at the same time with his other sorts which had not undergone any previous preparation, and the Daintree's were up the earliest by ten days, and kept the lead towards maturity, with the exception of a kind he calls the “Racehorse,” that beat the Daintree's for the potato by a neck; but with a few months' running the Racehorse would be nowhere for a first course on the dinner table; and if the Daintree's were, and if they are in the future to be beaten with me by the Mitchell's and the Shutfords, still it is immeasurably their superior in keeping and cropping qualities, and at any rate will come in for use just upon their heels.

June 16th.—Two roots of each sort weighed respectively—Mitchell's Albion, 1 lb. 1 oz.; Walnut-leaf, 1 lb.; Shutford, 1 lb.; Early Prolific, 1 lb. 6 ozs.; Early Shaw, 1 lb. 2 ozs.; Daintree's Seedling, 1 lb. 4 oz.

July 29th.—Took up the Potatoes, all of them quite ripe, and perfectly clear from disease. To 4 yards of drill or ridge (36 inches between each apex), each sort weighed—Mitchell's, 20½ lbs.; Walnut-leaf, 18 lbs.; Shutfords, 20 lbs.; Prolifics, 22 lbs.; Shaws, 23 lbs.; and the Daintree's, 28½ lbs.

COMPETITION 2.

April 15.—Planted Cambridge Kidney, Blooming Astor Kidney, Salmon Kidney, Fluke Kidney, Lapstone Kidney, “Lambton” Kidney, Negro Kidney, Freebearer, Early King, Fortyfold, and Daintree's Seedling Potatoes.

June 9th.—The tops were all well aboveground, excepting the Daintree's Seedling, which came up a fortnight later for causes above stated.

July 29th.—Tried a root of Daintree's Seedling, quite mealy, white, and excellent flavour; ditto Lapstone Kidney, quite mealy and excellent. These, which I consider to be a first-class white Potato, appeared even to have a

tinge of yellow when side by side with the Daintree's in the dish.

July 30th.—Tried a root of Negros; waxy, white, and no flavour. Ditto Early Kings; close, yellow, and poor flavour.

August 1st.—Tried a root of Fortyfolds; mealy, white, and excellent. Ditto Cambridge Kidney; mealy, yellowish, and of very good flavour.

August 2nd.—Tried a root of Freebearers; mealy, white, and fair flavour. Ditto Fluke; mealy, of a yellowish cast of countenance, and fair flavour.

August 3rd.—Tried a root of Blooming Ashtop, consisting of three long Potatoes; mealy, white, and excellent. Ditto Salmon Kidney; close, yellowish-salmon colour, poor-flavoured. "Lambton" (pear-shaped) Kidney; mealy, slightly yellow, but of excellent flavour.

August 16th.—Daintree's, Fortyfolds, Lapstones, "Lambton," and Early Kings, have their tops turning quite yellow; whilst the Freebearers, Flukes, Negro, and Cambridge Kidneys, maintain their tops as green as grass. The Salmon Kidneys and Blooming Ashtops are quite withered and gone.

August 17th.—Took up Daintree's Seedling. The tubers for 4 yards of drill or ridge, 42 inches between each apex, weighed 31 lbs.; ditto Fortyfolds, weight 27 lbs.; ditto Lapstones, weight 29 lbs.; ditto Salmon Kidney, weight 24 lbs.; ditto Early Kings, weight 25½ lbs.; ditto Blooming Ashtops, weight 18 lbs.; "Lambtons," two roots, which is my extent of crop, weighed 2 lbs. 4 ozs., which may be compared for bulk to the Salmon Kidney.

September 29th.—Took up Freebearers: 4 yards of tubers weighed 33½ lbs.; ditto Negros, 34 lbs.; ditto Cambridge Kidney, weight 30 lbs.; ditto Flukes, weight 24 lbs. The tops of these were scarcely yet turning yellow, and the haulm, with the exception of the Flukes, was monstrous. That of the Cambridge and the Negros, moreover, began to show symptoms of spot. The tubers, however, were all free from disease.

#### COMPETITION 3.

May 19th.—Planted Daintree's Seedling, Haigh's Kidney, Lapstone Kidney, York Regent, Pink Regent, Freebearer, and a late sort from Suffolk partaking something of the appearance of an Ox-noble. I could not ascertain its name, so I will call it the Unknown. It is said to be never known to have had the disease.

August 27th.—The tops of Daintree's and the Lapstones are become quite yellow, and those of the Haigh's, being spare and brittle, were blown completely away by the wind; whilst the Regents, the Freebearers, and the Unknown, are perfectly green—the latter are monstrous. I never saw such tops in my life. Some of the stems near their junction with the ridge would measure almost an inch in diameter. Dug-up and cooked a dish of Pink Regents, close, yellow, and unflavoured; ditto York Regents, moderately mealy, whitish, and with the flavour that can be sworn to, let it come from what part of the nation it may. The Unknown was waxy, unripe, and tasteless. The Daintree's, Lapstones, and Freebearers of this late planting are equally good with their relations mentioned above. On the 27th I dug-up the Daintree's, which weighed per 4 yards of drill, 20 lbs.; ditto Lapstones, weight 22½ lbs.; ditto Haigh's, 6 lbs.

October 7th.—Took up York Regents, weighed 24½ lbs. per 4 yards of drill; ditto Pink Regents, 23 lbs.; and the Unknown reached to 30 lbs. I attribute the falling-off of the weight of crop in the Daintree's and Lapstones mostly to the late planting, but something to the wind having lacerated their foliage when it was in full vigour of growth. The leaves of the Regents, &c., in a great measure defied it on account of their breadth and coarseness of foliage. I believe the Unknowns would have flourished till the frost; nevertheless, the time of planting was too late. They would all have given better crops had they been planted earlier; though even the Lapstone, as can be seen, now gains a step on the Daintree's, which I account for from its greater measure of haulm, which, again, helps to verify my previous recommendations—that all coarse-topping Potatoes are more suitable for cottagers on poor land and for field cultivation than the meagre-topping finer sorts. Starvation of root is made-up for comparatively by the multiplication of the mouths of the foliage feasting on the carbon of the atmosphere. The smaller the top the better should be the soil, and *vice versa*. I could never get a coarse-topping Potato to give me a crop at all in this garden. It was "all tops and no bottoms,"

as they say, till I took to the ridge-and-french system, and I find most of the coarser-foliated Potatoes that I have introduced maintain themselves amongst the allotment-holders here, light soil inclining to stone brash, whilst the finer sorts soon get lost to them.

#### COMPETITION 4.

June 30th.—Planted a row of Shutford Seedling, having shoots to the sets 4 inches long, on the site of a row from which I had taken my first Mitchell's Albion.

August 16th.—Dug a dish: their skins scraped off as freely, and they were as firm and quite as full-flavoured as their predecessors of the spring time. They served us for a change as new Potatoes into the middle of October, though their foliage by that time became much spotted, and some of the tubers began to be diseased. I shall adopt this plan again if I can instinct-out a good Potato season betimes next year. I can remember an instance when some of those late young Potatoes were tubbed in nice moist earth, and sold as quite youngsters at a fabulous price in the next February to good people of an island town not one hundred miles from Portsmouth! Much better to have finished them off in October and have done with them.

#### SYNOPSIS.

*Mitchell's Early Albion Kidney*.—Will do either to force or to come in as a first early in the open ground; firm and slightly yellowish when cooked. An excellent Potato.

*Shutford Seedling*.—A small glazed-topper, very much like the Mitchell's, but it is a round Potato, very early and a tolerable keeper; precocious in meanness, and of a yellowish cast when boiled. Its only fault is in producing a good many little ones.

*Walnut-leaved Kidney*.—Later, and of coarser growth than the Mitchell's Albion. It is a multiplied identity of that variety.

*Early Prolific and Early Shaws* are good-flavoured, white, mealy Potatoes; but their tops are too coarse and sprawling to please me as early sorts.

*Daintree's Earliest Seedling*.—I should not like to positively affirm that it will be the earliest Potato grown; but, if not, it will be difficult to find a round-keeping household Potato to beat it. It proved with me a first-rate second early, an excellent cropper, precocious for meanness, perfectly white, and an excellent-flavoured variety.

*Lapstone Kidney*.—The best of all household Kidney Potatoes within my knowledge. It is a second early, and will do its work as quickly as Daintree's, and will keep to the end of another year. It has fine delicate foliage, and requires room. It is precocious as to meanness, white, and of first-rate flavour. Everybody should grow it.

*White-blossom Ashtop Kidney*.—Is long as its name; rather early, white, and of first-rate flavour. A meagre cropper, though a fine Potato, and few in a hill.

*Haigh's Kidney* (Mottled purple and white).—Is very satisfying. A rich Potato, so to speak, and requires a very rich soil to grow it in, and thus it will produce fine, showy, exhibition tubers. I grew it chiefly for that purpose; but I shall give it up, for it is very subject to the disease, and its foliage will not stand the strong winds we are so often favoured with.

*Fortyfold* (Blue and white-mottled).—An excellent round Potato up to the new year; second early, white, and mealy; capital for mashing, and of first-rate flavour. It has been for many years a favourite with me, but it must now give place to Daintree's.

*Cambridge Kidney*.—Large, pear-shaped, and a bountiful cropper; yellowish, though mealy, and very well flavoured. It produces enormous foliage. The leaf is glazed and very handsome; but I fear it is disposed to disease, otherwise it is a poor man's Potato.

*Salmon Kidney* is a kind I should say that would resist the disease; and that is all, I think, I ought to say about it.

*Early King* would also suit the cottager, but it is not suitable for a parlour table. It is close, yellow, and pretty well flavoured.

*Freebearer* (Mottled blue and white).—A large, coarse-eyed Potato, and an enormous cropper, but without good flavour, and white. Suitable for the gardens of district unions, or any poor or rich man either who is fond of a large roasted Potato. Foliage immense.

*Negro* (Dark blue).—This is another to astonish the natives; great parallelograms of gluten, farina, and water; coarse, with many eyes, though when boiled white as a napkin, and of middling

flavour. It is monstrous for crop and top; but no longer than prizes continue to be given for large coarse things would I entertain the idea of it.

*Fluke*.—Of course everybody knows the Fluke, though I am rash enough to own that it is no favourite of mine: I never could think it a good-flavoured Potato. It is of a yellowish hue when boiled; and let a Potato be however good-flavoured, it loses caste with me unless it is white as the driven spray.

*"Lambton" Kidney*.—A first-rate second early, pear-shaped, a moderate topper and good cropper. An excellent-flavoured Potato, mealy, but with the shade of yellow when boiled.

*York Regent*.—It is a popular London Potato, and known far-a-field; whitish when boiled, though in the spring it is apt to show the black nose. It is too astringent in flavour for a connoisseur, though a good rich Potato for a poor man's family, and capital to "bring on" his pig; and there is no better judge than a porcine epicure of what a Potato should be in a general way.

*Pink Regent*.—This is a favourite amongst labourers, but a pig would much prefer the former, and so would I; and the Unknown, which I feel also bound to say a word for, is a coarse, very late, whitish Potato, of no flavour to speak of, though if, as it is said to be, impervious to disease, it is a great point gained, and its coarse deep eyes would be winked at by the labourer's family.

As a synopsis within a synopsis, I would say to cultivators of limited space, Grow the Mitchell's Early Albion Kidney, the Lapstone Kidney, and Daintree's Seedling, and you cannot do wrong.—UPWARDS AND ONWARDS.

## PROPAGATING CYCLAMENS AND FARFUGIUM GRANDE FROM CUTTINGS.

FOR my theme to-day I have one of the most interesting cases that have yet been broached in these pages.

A man has a Cyclamen with leaves "as large and blotched as those of *Farfugium grande*," and I happen to have some *Farfugiums* new whose leaves are not so big as those of some of my *Cyclamens*: therefore, we shall say this Cyclamen has very large leaves, and they are marked, or banded, or blotched out of the common run; and for the last year no one, not even the owner, could find out or suggest how to seed it; and if they did, it is a hundred to one if any of the seedlings would have the leaves similarly marked.

Now, failing in the means of increasing this extraordinary variety of the *Cyclamen persicum*, the owner of it is willing to give a leaf or two of it to our correspondent "T.," if he, the said correspondent, can find the means of rooting them; and "T." applies to us to know "if it be possible to produce *Cyclamens* from leaves?" and I am not quite certain that there is a man in the kingdom who can say if it be really possible or not. There is nothing published in English, as far as I know, to tell either way. There may be many who have failed in rooting leaves of *Cyclamens*, but we have no account of them and how they went to work. A thousand might have failed in rooting a particular leaf, and yet the leaf be capable of rooting nevertheless. I never tried to strike a *Cyclamen* leaf, and I do not know of any person who did try them in earnest; but I take it for granted, that as the Messrs. Henderson, of the Wellington Road Nursery, have not propagated their new strains of *persicum* by the leaf, that they are aware of the impracticability of that mode of increasing them.

But I have just said I had a most interesting case. So I have; yet I must ask that no one be disappointed if what I say, as it were, in a private letter should not come to pass.

Well, between "T." and Donald Beaton my opinion decidedly is, that *Cyclamens* of sorts may be so grown that they can be propagated by cuttings. It was one part of my scheme for the last three years to test this thoroughly, but the frost and the failure of this time last year put an end to the experiment for a time. But I will tell you how it was.

Four years back there were very few of us who knew that any other *Cyclamen* than Sweet's *vernum* had spur-stems on the crown. I did not know it, and I took the spur to be a specific distinction. Since then some of the great *Cyclamen*-growers put me right, and said there were spurs on all kinds of *Cyclamens* occasionally, and even that they could be increased from spur-cuttings, but that such cuttings never formed tubers—a result as interesting as anything I know of in gardening. Meantime I

had *Cyclamens* from Italy with spurs over the crown, some with one, some with two or three, and I had one with six spurs. Then, it struck me as curious that one *Cyclamen* should have spur-growths, and another of the same kind, and by all appearance an older plant, should have none; and my experiment was designed to prove how such came to pass in the pastures and passes of the south of Italy.

As far as my experiment went, I am sure that it is possible to cause all kinds of *Cyclamens* to produce spurs to flower on; and if so, I have found out the reason why it is that *Cyclamens* in the wilds and woods of nature do occasionally produce crown-spurs, like those Sweet first describes on the *vernum* he figured from. But I have not such a proof in my hand as I could wish, otherwise I would take the responsibility of detailing the whole process to all my readers as much as to one correspondent, but here they are.

Italy has been said to be the land of rivers and fountains; and we all know from the accounts of travellers how rapid and how strong the fountains and rivers roll down their waters from alpine regions in the times of heavy storms, and on the melting of the snow along the high ridges. By such means, and by other natural causes, quantities of soil, sand, and débris, are brought down and overlay the lower grounds near the margins of the streams, and cover the surface-vegetation deeply in some places, in others less so, and still less deeply towards the extreme limits. Then, when a *Cyclamen* field becomes covered with the less amount of sand and silt, and the bulbs are not covered so deeply as to ruin them, they make efforts to extend their leaves up into the light and air as usual, and that effort causes the substance of the bulb itself to be expended in the form and manner of these spur-growths.

That is the only way in which I could account for the formation of many of the bulbs which I have handled for the last three years. I have seen some, and many of the best gems in the British flora, under similar conditions—from the Sundew on the margin of the lake in the bottom of the valley, to the Cloudberry flanking the verge of the limits of vegetation on the mountain side, and I had no reason to doubt the idea; and, therefore, I made the attempt in that experiment to follow Nature as closely as my garden would allow of, and the cocoa-nut fibre refuse helped me more than I had reason to calculate on.

I planted bulbs of the *persicum* breed, and of all the sections of *Cyclamens*, from 2 inches to 3 inches deep over the top of the crown; and in two years' growth, or rather in one growth and one-half of a season's growth, owing to the frost, I had evidences enough to warrant me in believing that all kinds of *Cyclamens* would form spurs on the crown of the bulbs, if they were thus buried in planting or in potting. Several of my *persicum* tubers have made two or three spurs, but very short ones, in the period just stated.

I had the experiment not been cut short by that frost of last year, I intended to put one more inch of the cocoa-nut fibre refuse over these bulbs, and I think that would have been a more safe practice than to have put too much, or say 4 inches deep, on at the first planting.

When I used to say that I could make all kinds of *Cyclamens* look like *macrophyllum*, this was the means by which the leaves were to be had so large. One could not prove this in pots, because the pots, to allow of that deep planting, would be too big for good practice; but in a pit or border the practice is quite safe, and not only so, but deep planting has given me finer leaves and larger flowers than I ever saw in pot culture.

There are two ways by which I think I could increase the *Farfugium-grande*-like *Cyclamen* in question. The first is to plant it out of the pot in the front of a cold pit where the sun could not strike it direct, for none of them like that; to use good strong yellow loam, and to reduce the strength of the loam with the cocoa-nut refuse until it is as loose as sandy peat; to plant the bulb in this stuff; to have the bulb fully 2 inches deep over the crown, and to press the soil very much under the bulb and all round it. At the end of twelve months I would put on another inch of half loam and half cocoa-nut fibre refuse; and I am satisfied, from the age of the bulb and from the account of the size of its blotched leaves, that it would bear to have a second application next season—that is to say, in two years it could bear to have the crown of the tuber fully 4 inches below the surface, and that it would make half a dozen spurs in its attempts to throw-up the leaves to the light; also, if the luxuriance of the tuber is the cause why the plant refuses

Indeed, this way of taking that pride out of it would be the means of making it a fruitful plant.

Then, suppose you cut off five of the six spurs to within one-quarter of an inch from the bottom, and left the one for fear of the spurs going blind, the five spurs would make five plants certain, for one of the best authorities has said so not long since in these pages. Under such a gardener as our friend Mr. Holland, who has a three-year green *Cyclamen europæum*, I should have no fear but the rooted spurs would grow on and bloom as well on their own roots as from the strength of the mother tuber. It would, indeed, be a strange thing if we should be able at last to have a generation of stemmed *Cyclamens* without tubers; and as they, or some of the kinds, can be kept green from year to year, like one of my vernums—my original, and like one of Mr. Holland's *europæum*s, there can be no doubt about some of the stemmed plants keeping green, advancing slowly, and flowering as they go.

At all events our correspondent "T." has two chances for getting hold of the *Farfugium*-like *Cyclamens* which he seems so much to have set his heart upon. The second chance is even more curious than that just suggested, yet I am as confident of it as I can be. Since I planted-out my original plant of vernum, which blooms from a knotty burr of spurs, it has made two more effect-like spurs from the lower sides of the tuber, not from the under side; and now if I were to break off the spurred crown these bottom spurs would, or must, grow on the faster, and I could propagate the tops of them as in the former case, sure enough. Here, then, would be the beginning of the second chance for a *Farfugium*-foliaged *Cyclamen*. We will suppose it to be established one, two, or more years in the front of that cold pit, like my vernum, only that it is covered 3 inches or 4 inches over the crown, which my vernum is not; then at the beginning of the next growing season the one-half of the crown, or part from which the leaves come, would be blinded by scraping-off the parts from which the leaves spring. That check to upward growth would induce the tuber to form means of side growth, just like my vernum, and, if I recollect rightly, like Mr. Holland's bulb of *europæum*. Or, if the stopping of one-half of the crown did not effect the desired end in two or three months, one-third more would be blinded in the same way; and if the tuber still persisted in spending force only in crown-growth, it would be reduced to the last extremity by blinding all the eyes on the crown but one. As two distinct kinds have made side growths under cultivation, and as I have seen many bulbs of neapolitaness with side shoots on from their native wilds, and having more than one bulb of it in which all the growth came from the sides of the tuber, and the crowns completely blind, I cannot conceive of any structural difference in the tuber of a persicum variety of *Cyclamen* to render this *Farfugium*-like variety proof against a second chance for its propagation.

By the middle of next spring I shall be able to resume the experiment of planting so many *Cyclamens* at such and such depths, so by that time my frosted stock of last year will be up to the mark again, and the same plants will do for the trial of enduring so much cold, and for this way of propagating the kinds. Meantime, some of our *Cyclamen* correspondents might set about the same inquiry at once; I mean those of them who now grow their *Cyclamens* out of pots planted in beds in cold pits. All that would be necessary for them to do would be to put two more inches in depth over so many of the plants at one corner or one side of the bed, and watch the difference, and I would guarantee that the extra depth would not hurt any of their established plants, but rather the contrary.

Another branch of the subject might be set about early in February, long before I can do much in it for want of means, the use and power of a propagating-bed or place. Any one who has more than one top spur on the crown of a *Cyclamen*, could then try one spur of each kind as a cutting, and, after rooting it, endeavour to keep it green all the year round, for there is no other means of keeping in existence plants so obtained according to our present experience; but who knows but in a fresh start amongst so many, and all bent on the same ends, some one or other, or some chance not looked for, may, or may not, reveal another opening for the preservation of spur-propagated plants?

D. BEATON.

#### CAUTION IN USING GISHURST COMPOUND.

On Saturday, while giving my trees their annual wash with Gishurst compound, 8 ozs. to the gallon of water, I found many

of the Cherry buds showing green; this proves the trees to be earlier than usual. Will you allow me, therefore, to suggest to those of your readers, whose orchard-houses are like mine in forward situations, and who act on Mr. Rivers' directions and use Gishurst as a winter wash, that December will be a better time for its application than later. Strong applications of Gishurst, though most beneficial to trees at rest, have, when not followed by water-washing, been found in several places to injure buds when applied after swelling had begun.—GEORGE WILSON.

#### THE FUTURE OF THE GLADIOLUS.

FEW flowers have, in one's recollection, more rapidly taken up a leading position than this easily-cultivated and most showy bulb; and it is because it is so popular, so easily grown, and so showy, that I desire to say something in its favour, and to lift up both my hands against some false ideas which I conceive to have been promulgated concerning it, and injustice from which it has suffered. I think no one can now deny but that it is to be justly ranked amongst florists' flowers. The immense variety that it exhibits in its colours and markings, the points of shape which the eye of a connoisseur sees needful to its perfect beauty, and which those who only grow it for "effect" can also distinguish, claim for it that position; and hence the idea of treating it merely as a border flower and of exhibiting it in bundles must, I think, be pronounced as most arrant heresy; and yet not only was this recognised by judges during the past season, but advocates for a continuance of the system have, unfortunately, made their appearance since. The two exhibitions at which it was brought forward during the past season were the Crystal Palace and South Kensington, and in neither case was there, I think, a true standard or correct arrangement set forth. It was a mistake at the Crystal Palace, for instance, to offer prizes for the best collection. It was this, perhaps, that led M. Loise to make that formidable array of pint bottles, which so offended the eye of any one with an atom of taste, surmounted, too, as they were with starveling blooms of *Gladioli*; but doubtless he thought, as M. Barral seems to have done, that we cannot grow any flowers in England except under glass, and that his must necessarily take first place. He must have been a little astonished at what he beheld, and perhaps laid it to the charge of that "perfidious Albion" which is ever lying in wait to bring dishonour on "la belle France." It was this, too, that induced Mr. Youell to exhibit the bundles or sheaves of *Gladioli* that he did—very showy, very attractive, no doubt, but in no way meeting the requirements of a refined taste. If any one had taken twenty blooms of a sort, instead of three or four, doubtless he would have occupied the post of honour which Mr. Youell took. Mr. Standish, with a more correct taste and clearer appreciation of what is needed, exhibited single blooms, and hence was placed in the second rank. Another grand mistake was, I think, that of excluding amateurs altogether; not that it was done so positively, but the natural effect of offering prizes in this way, and of not dividing the classes of amateurs and growers for sale, was that the former felt utterly helpless, and in not one instance entered the lists against those whose bulbs, perhaps, outnumbered theirs in a hundred to one. There is another autumn flower, the admired of all but a few—the noble *Dahlia*. Now suppose the same principles were adopted with this—suppose that it were to be exhibited in bundles—suppose that prizes were offered for a collection—would amateurs ever venture to exhibit? And we must recollect that, after all, it is to amateurs that the grower looks for encouragement—it is the large amateur element which has made floriculture what it is in England—it is the lack of it which causes it in France to drag behind, to expend itself mainly in raising novelties for exportation, or plants for the "marché aux fleurs."

There is one excuse which has been made that has some little weight in it—viz., that the flower has so lately become a favourite one, that there was not a likelihood of amateurs coming forward; and their absence in the autumn of 1861, when a prize was offered for them at South Kensington, may justify this. Such is not likely to be the case again, and, therefore, in the future of the *Gladiolus* we hope to see this remedied.

Passing on to the Royal Horticultural Society, there we find one of the errors existing—the non-recognition of the amateur class. But more definiteness was given to what was expected by having the numbers required; and some variety was introduced by offering prizes for dark-coloured flowers of the French-

leyensis type, as well as for the spotted, striped, and lighter ones. Will it be allowable for us to hope that the other mistake will not be perpetuated?

If one may judge from the number of advertisements, and the number of inquiries concerning the *Gladiolus*, it will be very extensively grown during the ensuing season; and if only fair play be given to it in the exhibitions, we shall see it, I believe, occupying a prominent place at our autumn shows. A word or two, then, as to its cultivation.

I see Mr. Beaton recommends the bulbs being left in the ground all the winter. There seem to me two objections to this, which I have found more or less to affect all bulbs. First, that the cold wet soil is very apt to cause them to rot, and secondly, that worms and grubs of all sorts are likely to prove injurious to them; they work their way through the bulbs, and this also causes them to decay; hence I must still maintain that the old plan is the best of taking them up carefully, and keeping them in a place neither too hot nor too cold. So again with regard to soil. It is quite clear that they will flourish in any good rich loamy soil, and that they have no objection to a tolerably good coating of manure. And then with regard to sorts. There ought to be, I think, a mixture of the best varieties of French and English origin; and I have, therefore, given several lists, from which the needful information may, I think, be gained. As in honour bound, we will give the precedence to the stranger; and in list No. 1 will be found the newer varieties of the last three seasons. Those marked with an asterisk have only been let out this autumn, and have, consequently, not been seen on this side of the channel.

LIST No. 1.

- Belle Gabrielle, rosy lilac, shaded with bright rose.
- Cuvier, deep amaranth flamed with crimson. Very large and fine in shape.
- \*De Candolle, clear cherry flamed with rose, and striped with brilliant carmine.
- Dr. Lindley, rose shaded, deeper centre, tipped with carmine.
- \*Endulia, lower petals white, striped with violet, upper with white line.
- Eldorado, pure yellow with white stripes.
- \*Flore, ground white, shaded with lilac rose, with very large lively red spot.
- \*Impératrice Eugénie, white flamed with rose, interior violet, exterior lilac. Said to be the most remarkable of all known varieties.
- James Watt, brilliant vermilion scarlet, pure white spots, slightly striped with delicate rose.
- Leonardo da Vinci, orange, striped with violet rose.
- \*John Waterer, clear cherry, with lively red stripe; large white spot, marked with rose.
- Madame Adèle Souchet, white flamed with rosy carmine.
- Madame Percire, pure white with violet spots.
- Reine Victoria, pure white spotted with violet. Very large and fine.
- \*Stephenson, very beautiful spike; carmine cerise, with white lines.

The varieties in this list range in price from 5 to 8 francs in the French lists, and from 5s. to 10s. 6d. in the English lists.

LIST No. 2.

- Achille, bright currant red striped with pure white. A very attractive variety.
- Ceres, pure white striped with rose violet.
- Comte de Morny, bright cherry, spotted with white and striped with violet.
- Duc de Malakoff, orange red flamed with a brighter colour; white centre.
- Linné, orange cherry spotted with yellow.
- Eugénie Domage, bright red, beautifully shaded and striped.
- Madame Lesèble, pure white spotted with violet rose.
- Ophir, yellow spotted with purple.
- Raphael, vermilion, white shaded and spotted with violet.
- Rembrandt, deep crimson scarlet.
- Solfaterre, yellow. Very large and fine.
- Turenne, bright red spotted with yellow; white centre.
- Victor Verdier, brilliant scarlet. Extra fine.

The average price of the above is in the French lists about 2 francs, and in the English about 2s. 6d.

LIST No. 3.

- Aglæ, salmon rose.
- Brenchleyensis, vermilion. Showy.

- Calendulaceus, nankeen.
- Docteur André, bright orange.
- Don Juan, deep orange red.
- Galathée, pale yellowish-flesh spotted with white.
- Fanny Rouget, bright rose, flesh centre.
- Hebe, delicate flesh striped with carmine.
- Isoline, blush striped with red.
- John Bull, white.
- Mars, scarlet erimson.
- Mathilde de Landeroisin, white striped red.
- Napoléon III., erimson scarlet striped with white.
- Oracle, rose cherry.
- Sulphureus, sulphur yellow.
- Vulcan, deep red.

The above are cheap, varying in price from 4s. to 10s. 6d. Some of them are very fine, and such kinds as *Napoléon III.* and *Brenchleyensis* very showy.

LIST No. 4.

- Adam Bede, peach, lower petals deep scarlet.
- Bacchus, beautiful carmine, with delicate white lines; rich centre.
- Basil, beautifully pencilled carmine, with deep crimson blotches.
- Earl of Carlisle, bright rose, deep lake feathers.
- General Cabrera, bright scarlet.
- Isaac Anderson, deep red, white throat, and purple feathers.
- Isa Craig, pale lemon, purple stripes.
- John Leech, salmon, purple feathers, bronze lower petal.
- J. W. Lane, bright vermilion, centre yellow, deep carmine eye.
- Lord Downshire, bright yellow, blotch of reddish-brown on under petals.
- Mdlle. Victor Balfé, clear white, distinctly marked with violet blotches.
- Mrs. Dombrain, pale rose striped with lake, and lake feathers.
- Mrs. Edward Nott, fine yellow.
- Mrs. Hole, pale buff shot with pink; purple stripes.
- Paul Bedford, scarlet crimson, purple throat.
- Robin Hood, scarlet, violet throat.
- Rosenberg, deep scarlet blood colour.
- Sir Walter Scott, creamy buff, with puce feathers.
- The Ensign, fine red, light erimson feathers.
- Tom Moore, erimson, with erimson violet feathers.

This list contains a selection from Mr. Standish's *transmission* progeny; such as I have myself, through his liberality, had an opportunity of testing in my own little garden, where they flourish very well. Their price ranges from 2s. 6d. to 5s., and although I have selected these, there are a number of others equally meritorious.

Those who desire to compete will find, I believe, their wants met in lists 1, 2, and 4; while those who simply desire effect will find the most desirable for that purpose in lists 2 and 3. But I have no great opinion myself of the *Gladiolus* simply as a decorative plant; its true place is as a cut flower, whether for the exhibition table or in the drawing-room. It has the admirable property of opening its bloom-buds regularly in water, so that all that is required is to shorten the stalk as the lower blossoms decay. I hope that many will attempt their cultivation this year who have never done so before, and that I may not be far out in predicting a glorious future to the *Gladiolus*.—W. Dool.

FRUIT TREES IN VANCOUVER'S ISLAND.

THE following extract from a letter dated September 29th, 1862, received a short time since from a correspondent wishing for a consignment of fruit trees sent to him "round the Horn," may be of interest to some of your readers who think of making that fertile spot their home.—T. R.

"The fruit trees imported into this colony are without names and not always good sorts. They are raised across the sound at Olympia and other places in the Washington State, and also at Portland, in Oregon. A few are sent from San Francisco.

"The climate of this island, judging by trees already planted, seems specially adapted for the production of all hardy fruits. Little trees, planted only two or three years, are loaded with fruit, the trees at the same time growing most vigorously, and perfectly free from disease or blight of any kind. Plums hang on the trees literally in masses. I think every blossom produces its fruit, which seem to be all perfectly formed, with scarcely an ill-shaped one among them. Young Pear trees on Pear stock that in England one would scarce expect to see produce a fruit for the space of five or ten years, here bear the second year

after planting. No Quince stocks wanted here. The soil is principally a black decomposed vegetable deposit, or what in England we should call peat, resting on a compost subsoil of drift-sand, gravel, and clay, liable to burn in summer.

"A very small proportion of the surface of this island will ever be available for agricultural operations, it being too mountainous, too poor, and too rocky. Some of the valleys when cleared of the heavy crop of Pines, of which you may have bushels of seed, will form good farms. There is a little prairie land, but not above, perhaps, 15,000 acres in the whole island."

## ROYAL HORTICULTURAL SOCIETY.

DECEMBER 9TH.

**FLORAL COMMITTEE.**—Rev. J. Dix in the chair. The most attractive of the objects exhibited at this Meeting were the new *Chrysanthemums* brought home by Mr. Fortune, and which are in the hands of Mr. Standish, of Ascot and Bagshot Nurseries. The most striking were a very large yellow of rich golden colour, called *Grandiflorum*, and which, Mr. Fortune says, "grows as large as your hat;" and a beautifully striped one, white and pink, also large and showy, called *Striatum*. The former of these was awarded a Second-class, and the latter a First-class Certificate. A pretty little quilled variety with fringed florets and pure white, called *Laciniatum*, was awarded a First-class Certificate. It is very beautiful and singular, but not so telling in its effect as the other two. There was another sort called *Speciosum*, which is rather a singular-looking oddity. The florets are twisted-up tight, like lengths of brown twine, and are crowded close together. This, however, was not quite in full bloom, and no award was made to it. Among the other plants exhibited and to which no awards were made, were *Plumbago rosea coccinea* from Messrs. Veitch; a fringed Chinese *Primrose* from Mr. Treen, of Rugby; a fringed white *Cineraria* from Mr. Earley, gardener to F. Pryor, Esq., Digswell, Welwyn; and a beautiful variety of *Cypripedium* insigne from Messrs. Maule & Son, of Bristol, a plant of which Messrs. Maule liberally presented to the garden at Chiswick.

**FRUIT COMMITTEE.**—Mr. Osborn in the chair. At this Meeting prizes were offered—Class A, for the best three dishes of dessert Apples; B, for the best three dishes of dessert Pears; and C, for the best three bunches of White Grapes.

In Class A there were seven competitors. The first prize was taken by Mr. Simpson, of Stoke Farm, Slough, with very excellent specimens of *Rosemary Russet*, *Cockle Pippin*, and *King of the Pippins*; and the second prize was also awarded to that gentleman for equally fine *Cornish Gilliflower*, *Keddleston Pippin*, and *Cox's Orange Pippin*. We cannot speak too highly in favour of the *Rosemary Russets* and *Cockles* in these exhibitions. The former, not at all a common Apple, is a very fine one, and these were some of the best specimens we ever saw. *Cox's Orange Pippins* were also excellent, and *Keddleston Pippin*, a small variety like a *Golden Pippin*, deserves to be better known. Mr. D. Cunningham, of the Palace Gardens, Fulham, had very nice specimens of *Blenheim*, *Ribston*, and *Cockle Pippins*, but they could not approach Mr. Simpson's in flavour. Mr. Earley, gardener to F. Pryor, Esq., of Digswell, near Welwyn, exhibited beautiful specimens of *Court of Wick*, *Golden Pippin*, and *Cockle*; very beautiful and even dishes they were, and would have graced any dessert. Mr. Hall, gardener to Capt. Tyrrell, Fordhook, near Ealing, had good examples of *Golden Winter Pearmain*, *Blenheim Pippin*, and *Court-Pendu-Plat*. The same may be said of the exhibitions of Mr. Smith, of Nassau House, Enfield, and Mr. Curd, of Sulhamstead.

In Class B, Mr. McLaren, of Cardington Gardens, Amptill, was first with very fine examples of each—*Glou Morceau*, *Winter Nelis*, and *Burré Diel*; and Mr. Simpson was second with *Glou Morceau*, *Joséphine de Malines*, and *Easter Burré*. Mr. Cunningham exhibited good specimens of *Burré de Rance*, *Ne Plus Meuris*, and *Chaumontel*. Mr. Earley had nice specimens of *Passe Colmar*, *Winter Nelis*, and *Glou Morceau*; and Mr. Hall had *Burré Bosc*, wrongly named, *Bishop's Thumb*, and *Winter Nelis*; but they all came short in flavour of those that took the prizes.

In Class C, Mr. Hill, gardener to Ralph Sneyd, Esq., of Keele Hall, exhibited three splendid bunches of *Trebbiano Grapes*, and, as a matter of course, had the first prize awarded them. These were the production of a Vine grafted on a Black *Hsm-burgh*, and the result is larger bunches than are got from the

plant when it is on its own roots, and such berries! The three bunches weighed 10½ lbs.

Bunches of two seedling Grapes were sent by J. B. Faviell, Esq., of Stockeld Park, near Wetherby, Yorkshire. They are both White Grapes, and produce large bunches. No 1 appears to produce the larger bunch, which is shouldered and ovate in shape. The berries are thickly set, and are on rather long foot-stalks, quite round, and of a greenish tinge, with the skin so thin and transparent as to show the texture of the flesh through it. The flesh is very firm and crackling, crisp as an apple, and with a sweet and refreshing Sweetwater flavour. Unfortunately it was not sufficiently ripened. No. 2 is also a large-bunched Grape, producing a large oval berry of the size and shape of the *Muscat of Alexandria*, but without any *Muscat* flavour. The flesh is firm and crackling, with a sweet, rich, and sprightly flavour. This was awarded a First-class Certificate, and is a very excellent Grape.

Messrs. Jackson & Son, of Kingston-on-Thames, sent a fruit in a pot of *Fairrie's Queen Pine*, a small, dwarf-growing plant with a fruit which weighed 1½ lb. Unfortunately it was so late in the season the flavour of the fruit was gone, and the Committee reserved any decision on the subject; for the same reason a nice handsome fruit of *Oates' Seedling Pine*, sent by Mr. Oates, gardener to Lord Doneraile, at Doneraile Castle, Ireland, was also passed without an opinion being given upon it; but as this variety has been before the Committee in its best state, and has already received a First-class Certificate and Sir C. W. Dilke's prize of £5, there can be no doubt of its merit.

Mr. Rivers, of Sawbridgeworth, sent specimens of *Tangerine Oranges* grown in the *Orange-houses* in his nursery. They were perfectly ripe and in flavour superior to those that are imported from Lisbon. The fruit was accompanied by some branches of the plants bearing fruit less fully matured, which show that the trees are quite prolific. Lieut.-General Rawdon sent a fine large *Pine Apple*, grown by Mr. John Davies, gardener to Sir Charles Coote, Bart., but it was far gone in ripeness.

A nice collection of Apples was exhibited illustrative of the varieties grown on the coast of Sussex; they were sent by Thomas Boorn, Esq., Chidham, near Emsworth.

A collection of Apples and Pears was received from the Local Committee of the Valley of the Tweed, accompanied by the report of a meeting held at Kelso. The report being read, the thanks of the Meeting were voted to the Tweed Committee.

A very pretty exhibition of vegetables was sent by Mr. W. Earley; it consisted of enormous *Parsnips*, excellent *Sea-kale* (forced), *White Broccoli*, admirable *Salsafy*, capital *winter Lettuce* and *Endive*, *Variiegated Kale*, *Jerusalem Artichokes*, and a number of other things; and the Committee unanimously awarded Mr. Earley a *Label of Commendation* for his interesting exhibition.

## HEATING A SMALL CONSERVATORY.

WOULD a boiler heated by gas be the best means of warming a conservatory about 12 feet by 10 feet, and very lofty for its size? It is exposed to the air on three sides, and has a glass domed roof; it is, therefore, very cold in winter. Owing to doors, &c., on the fourth side, the hot-water pipe could only be carried round the floor on three sides, and on the fourth it would have to go under the floor, which would diminish the amount of heat emitted. At page 38 of "Greenhouses for the Many," it is stated that the efficiency of the boiler does not depend so much on its size, as on the amount of surface exposed to the fire. Economy of space being a great object in so small a conservatory, I wish very much to know on good authority what sized stove and boiler, and what sized pipe would be required to keep the temperature in my conservatory at about 45° through the night in winter. I should also be very glad of information respecting the probable price, and also the name and address of the best maker of such stoves. One has been named to me, a patent of Pettit, of Oxford Street. It is 2 feet high and 10 inches in diameter, and contains a tubular boiler holding a gallon, with a small feeding-cistern of a pint. The boiler is heated by gas jets, forty in number, in two rings; the hot water to circulate in a two-inch cast-iron pipe—price about £15. This sounds well, but I should like to have the opinion of an experienced person before deciding. The conservatory faces the west.—MRS. GARLAND, 15, Queen's Gate, London, W.

[We have no doubt that such a boiler as that given at page 38 of "Greenhouses for the Many," that you refer to would suit

your purpose; and you would need two three-inch pipes all round, or at least on three sides, to keep the heat up if the house is so lofty and domed. Instead of having the boiler with a convex bottom, we would have it concave, or, rather, with an open tube through it, for the gas heat to play upon. We think, however, that for such a house a small gas stove to hold the burners, and three-inch pipes round the house for the heat of the gas burners to go through, would be sufficient. But for some necessity for using gas, the cheapest and simplest of all would be a metal stove with a square top for holding water, and a cast metal pipe for taking the smoke out where most convenient. The shorter the horizontal pipe the better, and if the most part is upright, or sloping in an upward direction, there will be little trouble in its lighting or drawing well. The chief thing for such a stove is, that it should be wide enough—say 18 inches, so that the firebrick little fireplace in it shall never allow the fuel to touch the sides or make it red hot. This would be the most economical; the gas stove the next, where a small flue could not be placed under the floor with a furnace outside.]

### NEW BOOKS.

*The Gardeners' Annual for 1863.* Edited by the Rev. S. Reynolds Hole. With Coloured Illustration by John Leech. London: Longman & Co.

NOR so long since there was a festival in the far far East. There were assembled the brilliant, the beautiful, and the gay; there were damsels ripened by a warmer sun than ours; there were music and the gentle song, such as *Taza bu taza ta bonou*; there were fireworks, and sprinklings with Rose water, and all were assembled in a Rose garden. The book before us puts us in mind of that festival, and, like it, we fear that it will never be repeated. Annuals are not the class of books in request; they meet nobody's requirements. There was a great effort made to establish them once, but "The Keepsake" was not kept; "The Souvenir" soon ceased to be remembered; and "The Forget-me-not" soon passed from memory.

In the volume before us there is much that deserves success. A bright frontispiece by Leech, of five "daughters of England" looking archly over their souchong as they sip it among Tea Roses, and the Cupid turning his back upon us in that picture is no more than they ought to expect of whom it may be said "Time has thinned their flowing locks, and the few now left are grey." Then, all the contributors to the volume are "good men and true." There are such craftsmen as Reynolds Hole, Rivers, Dombrain, Paul, Turner, Dix, Standish, and Dean. There is not much of novelty in their contributions, but they write pleasantly and truthfully of what they thoroughly understand—Roses, Hollhocks, Pansies, Japan Plants, Pelargoniums, Greenhouses for Working Men, and such like. We shall gladly welcome their "Annual" for many lustrums of years, and shall rejoice if this differs in its fate from that of most of its kindred, which, true to their name, have died at the end of the year.

*Science and Practice of Gardening.* By G. W. Johnson, F.R.H.S., &c. Journal of Horticulture Office, 162, Fleet Street, London.

FOR the last two years I have had many inquiries after such a book as the above from amateurs and young gardeners; and within these three months I have had a number of private interrogatories as to the character of the above book, and if it was likely to meet the requirements of those who wished to know the principles on which common gardening operations were based. I regret not being able to read it attentively earlier; but now having done so, though there is not so much on practical details as the title would suggest, leaving these to be largely inferred, though never left in doubt if the science is studied and comprehended, giving thus to the reader a generalising power more useful than minute directions, I can honestly say that the book will meet a want long felt, and enable young gardeners to know as much as those getting grey in the profession.

In judging of the success of a work, it is right we should keep the object of the author clearly before us. This is, as stated in the preface to the work, "to place before all who delight in gardening, not only directions how to perform its various operations, but to explain how these operations are needful. In doing this the author has followed a cultivated plant through its whole existence, from its birth to its death; explained all the

modes and phenomena of propagation, growth, disease, and decay; at the same time illustrating as he proceeds all that can be done for the protection and prolongation of the life of plants. Such knowledge is absolutely necessary for all who cultivate plants intelligently, whether in the open ground or in glass structures; and to place such knowledge within the power of the greatest possible number of readers, this volume is published at the lowest remunerative price."

The above plan, which has both peculiar advantages and disadvantages, has been successfully carried out by the author bringing all previous and modern experience and investigation, as well as his own, to bear upon the subject of inquiry. That our young friends especially may form some idea of what they are to find in this three-shilling volume of nearly four hundred pages, we prefer giving a running outline of its more particular contents instead of a mere notice or review.

**SOWING.**—After some introductory remarks on the importance of chemistry to horticulture, the author introduces us to the sowing of seeds, and here discusses the varieties of seeds—the processes of germination in exogenous plants—the great diversity of seeds as to their powers of retaining vitality, being low in the Coffee plant and high in the Celery; and that this, too, is greatly dependent on the presence of starch and the absence of nitrogenous matter, being high in Rice and low in French Beans; but that seeds abounding in oil, though they soon lose their vitality when exposed to the air, will often keep it for long periods when shut out from its influence, as in the case of Mustard and Charlock seeds growing when dug up from great depths. Interesting lists of seeds are given from Loudon and Mr. Baxter, of Oxford, as to the age in which seeds have germinated; but the practical rule deduced is not to trust to old seeds. Tables are also given as to the time many seeds require to germinate, though this will greatly depend upon the treatment. Instances are adduced to show that seeds may be all right, though they do not grow when we do not place them in the right position for doing so, as De Candolle found Tobacco plants came every year for ten years in succession from one single sowing, and we can fancy such seeds coming up for twenty years longer, just as those too much buried were brought in contact with the air; and then we are treated in detail to the three chief agencies in germination and growth.

The first of these is **HEAT**. Though many seeds, as Grounsel, will germinate at a low temperature, few or none will do so below the freezing-point. A few seeds will bear a high temperature, even that of boiling water, for short periods with impunity; but, in general, a continued high temperature is much more dangerous to vitality than the greatest amount of cold and a long continuance of frost and cold, provided germination has not commenced. The influence of different soils in securing the necessary heat; dry, dark-coloured soils being heated more quickly, and parting with it more slowly than wet light-coloured soils: thence the necessity of draining and pulverisation, as such soils will be less frosted in severe weather, illustrated by interesting tables of the temperature of the air and the temperature of various soils at various depths, the surface soil being warmest in summer, and the temperature increasing as we descend in depth in winter. The second agent in germination is

**MOISTURE.**—And here, for general purposes, pure rain water is the best. All acid steeps should be continued only for a short time. Before sowing, seeds cannot be kept too dry. When sown, extra moisture is to be avoided: hence the importance of shallow sowing, and especially in stiff soils, and well-aerated pulverised soil to sow in. I will add here, that all seeds that there is any doubt about as to their thorough ripeness or too weak vitality on account of age should be allowed to absorb moisture very slowly. I have sown some in dryish soil, and others in similar soil but watered; and whilst the first have grown, the second from the same bag have all rotted. The third agent is

**AIR**, or, as most books tell us, the oxygen of the atmosphere. I prefer myself the common term—air, as with few exceptions, such as experiments recorded by the author, seeds will grow better on having access to our common atmosphere than either in oxygen alone or any other combination of gases. Here, in addition to numerous interesting experiments, will be found additional reasons for shallow sowing, that the seeds may be within the reach of the air. I, myself, firmly believe that one-half of the complaints from amateurs of bad seeds would never be heard of could they be induced to sow more shallow.

These three agencies our author considers, if properly directed, sufficient to produce all the wondrous phenomena of germination

and growth; as he does not consider light to be at all injurious, if the seed is kept suitably supplied with moisture. I know that this is now a general opinion among those qualified to be our teachers, upheld, too, by many experiments here detailed; and yet I cannot help believing, that if comparative shade and darkness are not essentials, they are at least great auxiliaries. The covering of seeds not only secures them the requisite amount of moisture more easily than any other mode, but the keeping off the full force of the sun's rays I consider such an advantage, that I would advocate keeping seeds before sowing in a shaded as well as a dry place. It may be only an impression, but observation seems to confirm it, that many seeds are deprived of their vitality by being exposed to the full force of the sun's rays for long periods before they are sown or germinated. Passing descriptions of phenomena in germination, times and rules for sowing, regulated more by the state of the soil than the day of the month, we come to the

Root, and are here treated to its duration, its character, its direction to get nourishment: hence the importance in cultivating such roots as the Carrot not only of deep trenching, digging, and pulverising, but of securing the richest soil deepest; the number of roots in proportion to the poverty of soil—a matter of importance, I think, when flavour rather than bulk is an object; the importance of roots being kept near the surface, when fine fruit is the object; no analogy between the extent of root and branches, for whilst the former at times may be measured by yards, the latter may be measured by inches, and yet the importance of reciprocal action between roots and branches in all cases, and especially of heating the soil for roots in the case of forcing (page 47); beneficial influence of rotation of cropping; importance of pulverisation for securing the necessary amount of moisture and air (see interesting tables, page 57); light sandy soils often need compressing, and the very different effects of stagnant water and running water on roots, owing to the access to oxygen in the latter. Then we have the whole processes of hoeing, digging, and trenching; and in relation to the first we are with great truth informed, page 61, "Very few people ever consider in detail the expenditure of labour required from the gardener when digging. It is a labour above most others calling into exercise the muscles of the human frame, and how great is the amount of this exercise may be estimated by the following facts:—In digging a square perch of ground, in spits of the usual dimensions (7 inches by 8 inches), the spade has to be thrust in 700 times; and as each spadeful of earth, if the spade penetrates 9 inches, as it ought to do, will weigh on the average fully 17 lbs., 11,900 lbs. of earth have to be lifted, and the customary pay for doing this is 2½d.;" and thence it follows, that the weight of the spade considered, and the weight of the soil in digging an acre, at least 1278 tons weight will be moved. Digging, therefore, is very hard work, especially when engaged in now and then; and I commend the above extract to those who can see no necessity for a labourer straightening his back, whilst they sit comfortably at a parlour table. Then, in addition to preferring four-pronged light forks to spades for digging, we have most interesting tables of the resistance to labour in various soils, in proportion to their character and their dry or wet condition; the great superiority of hoeing over weeding, not only for eradicating weeds when young, but enabling the soil to be furnished with moisture and air; the benefits of ridging; the fact that when perpendicular roots are stopped fresh ones are pushed out more horizontally, and that "the lateral branches from perpendicular roots are always the more vigorous the nearer they are to the trunk, whilst, on the other hand, the lateral branches of horizontal roots are the less vigorous the nearer they are to the trunk" (page 67); and also that roots extend farthest in the poorest soils, roots of trees having been traced down perpendicularly 14 feet without finding their termination; followed by very instructive tables, showing the effects of drainage in raising the temperature of soils, and others showing how that temperature is influenced by colour and density when exposed to the sun, though cooling more quickly in the shade; analysis of soils; ditto of water from drained land; superiority of rain water to land water, owing to the presence of more nitric acid and ammonia, and water for irrigation being chiefly valuable in proportion to its nourishing qualities; analysis of manures; absorbent properties of manures, of charcoal, &c.; mixtures of dung and artificial manures. On burning weeds our author states, page 143, "It is a common practice to burn Couch Grass, Dock, Gorse, and other vegetables, which are very retentive of life, or slow in decay. A more

uneconomical, unscientific mode of reducing them to a state beneficial to the land of which they were the refuse cannot be devised. In all cases, if the weeds, leaves, &c., were conveyed to a hole or pit, and with every single horse-load, and with barrowloads in proportion, a bushel of salt and half a bushel of lime were incorporated, it would in a few months form a mass of decayed compost of the most fertilising quality; the lime retaining many of the gases evolved during the putrefaction of the vegetable matter, and the salt combining with the lime to destroy noxious animals, which might form a nidus in the mass. By this plan nearly all the carbonaceous matters of the refuse vegetables are retained. By burning, all of them are dissipated. The forming of a compost, such as that recommended, is justified and approved by the experience of many." I may just add, that the more heat evolved, the greater the chance of destroying all seeds of weeds; and if steam or gases are apt to escape, a little earth thrown over the upper layer will arrest them.

STEM, AND BRANCHES, AND LEAVES.—Here we are treated to an analysis of woods; the composition and functions of the bark and the other parts of the stem; the functions of leaves; the necessity for keeping bark and leaves clean; the influence of light on leaves as respects decomposition and assimilation of carbonic acid, and perspiration through their pores; the lowering of temperature thus produced by perspiration, even in the hottest days. Transpiration is influenced by dryness and heat, showing the importance of a moist atmosphere in hothouses, especially in the growing period; as, if a plant in a house at 75° exhales fifty-seven grains of moisture, if raised to 80° it would exhale 120 grains in the same time, if no means were taken to increase the humidity of the enclosed air. But, on the other hand, the danger of scalding in high temperatures is also to be avoided; the danger of an atmosphere over-supplied with carbonic acid, sulphurous acid, and ammonia, as in dung-beds; and among many other matters the danger to plants from being placed in an atmosphere deprived of its usual portion of carbonic acid. Our author states, page 183—"Though an excess of carbonic acid gas is detrimental, yet its partial absence from the atmosphere is equally fatal to a plant's leaves, for without it they wither and fall. It is not a matter of indifference, therefore, whether a greenhouse or hothouse be whitened with a solution of lime, which absorbs that gas from the air, a fortnight or only a day or two before the plants are introduced or forcing commenced, for it is the infliction of several trivial injuries to a plant that prevents its successful cultivation. No one who is entitled to practise in the higher departments of his art ever makes such great blunders as at once to destroy the plants under his care. That fresh-limed walls do injure plants is beyond dispute; for the plants in a row of small pots next the back wall in a propagating-house, which had been thus whitened only the day before, have been more than once observed to be the only plants that acquired a sickly hue and shed nearly all their leaves. Fleshy-leaved plants would not be so liable to injury if obliged to be brought into a house fresh-limed, for these require much less carbonic acid daily than thin-leaved plants. Fine plants of *Cactus speciosissimus*, in the injured row just noticed, were not apparently affected. Thin-leaved plants consume daily from five to ten times their own bulk of carbonic acid gas; whilst fleshy-leaved plants, such as *Cacti*, *Aloes*, *Agaves*, and *Mesembryanthemums* do not consume more than their own or double their own bulk of that gas."

I consider the above extract well worthy of notice and of warning. I am not prepared to say from investigation how long quicklime would take to become mild under such circumstances, nor how much it would affect the plants in its vicinity; but I consider that the reflection of heat and light from such a white wall would be quite sufficient to produce the effect on the shelf near the top that is here stated. Would such effects have followed if the part above the wall had been somewhat darkened with lamp black or soot? I have frequently been obliged to do so in the case of such shelves. In fact, the bright white, or the more subdued colour of the wall, should be regulated according as we wish that to reflect light and heat, or so far absorb these as to be safe for plants placed close to them. That it would be advisable to allow houses to sweeten a little after lime-washing there can be no doubt, but I just think that any other bright white colour in the present instance would have been nearly as hurtful as the lime.

SAP.—Under this head we are treated to its nature and composition at different times, the force of its flow, the unsatisfactoriness of the theories respecting it; the theory of grafting,

budding, inarching, ringing, &c., with numerous illustrative woodcuts; influence of temperature on the flow of the sap; but the importance of knowing not the mere average temperature, but the highest during the day and the lowest during the night, and the same as respects the temperature in summer and winter at those places from whence exotic plants come, in order to secure their successful cultivation; high temperatures at night in hothouses generally unnatural; reasons for stopping shoots to secure equally-balanced wood; of pruning, to admit light, equalise growth, secure fruit-spurs, &c.; the whole theory and practice of rooting cuttings, with numerous illustrations, whether as respects cuttings by slips, buds, or leaves, and the due importance rightly given, in all cases where nicety is required, not only to secure abundant drainage, but to place the cuttings close to the hard drainage, or, better still, to the sides of the pot used for propagating, not only "because there the atmospheric air gains a salutary access," but also because in my opinion there is there not only less danger of damping, but the resistance given by the hard sides of the pot to the swelling albumen causes roots sooner to be protruded in self defence.

**THE FLOWER.**—Here we are presented with the various parts of a flower, the organs of fructification, the inhaling of more oxygen, and the exhaling of more carbonic acid by flowers than by leaves, with illustrative table; changes of colour in flowers; predominant colours; fertilisation how naturally and artificially effected; cross-breeding known to Moses; phenomena and principles of hybridising and cross-breeding, with illustrative experiments by various authors, and chiefly by Mr. Beaton, leading us anxiously to desire that that great experimentalist and botanist would give us a little book on the subject, to which we might refer as an authority and a pocket-companion, facts being always so superior to theories; convertibility of leaf-buds into flower-buds, and *vice versa*; theory and modes for obtaining and retaining double flowers; odours of flowers, day-scented and night-scented flowers; and sweet scent of flowers not sufficiently attended to by cultivators—a charge to which I fear most of us must plead guilty. Under

**FRUIT AND SEED** we are told all about the kinds and forms of seed-vessels and seeds; that each fruit has an elaborating power, according to its condition; "during the green and growing state, they are usually converting growing matter into an acid, but during the ripening they are as commonly converting an acid into sugar;"—illustrative tables are here given of the constituents of fruit at different periods; the contest that must ever exist between extra luxuriance and extra fruitfulness; influence of light and heat on ripening fruit; theory and practice of shelter and protection in securing heat, illustrated by the beautiful phenomena of dew and hoar frost (see page 321 and onwards, which thoroughly explains the whole principle of protection); the influence of colour in absorbing, and retaining, and radiating heat; artificial means of giving heat to glass houses; tables showing the heating powers of different kinds of fuels, showing as the useful lesson that what may be the cheapest is often the most expensive in reality; the different modes of heating, as stoves, flues, steam, and hot water, and the preference rightly given to the latter, where much is to be done especially, and a preference seems rather to be given to tanks instead of pipes; but with illustrative tables showing the size of boiler, and the quantity of piping needed under various circumstances, according to size of house, and temperature required; angles for the roofs of glass houses, so as to admit most light when most wanted; followed with directions for gathering and storing keeping-fruit, the chief requisites for keeping being a uniform low temperature from 34° to 40° and freedom from exposure to the atmosphere—setting the fruit on sand, and covering with the same thoroughly dried, being much recommended for keeping out air and moisture, and keeping carbonic acid round the fruit, which is one of the greatest opponents of decay, charcoal dust being better still, if the fruit were kept clean, such fruit to be taken out and placed in an airy, warm place a few days before being used; Pine deal shelves to be avoided, as likely to communicate a turpentine flavour.

**DISEASES OF PLANTS.**—Strange that so little attention has been paid to this subject. Comparative ignorance on the whole matter; analogy between the composition of animals and plants; canker in its various forms being chiefly alluded to, with shorter notices of spot on Pelargoniums, and shanking of Grapes, the latter being owing chiefly to a want of reciprocal action between roots and branches, and also, I may add, to deep planting and heavy cropping.

**DEATH AND DECOMPOSITION.**—Exhausting effects of heavy cropping, unsuitable soils, improper supplies of moisture, deleterious food, un congenial temperatures, and deficient light, tend to shorten the life of a plant, and the reverse to prolong existence, though not to perpetuate it; and the processes of decomposition and putrefaction are explained; but much has been adduced on this subject in rules for making and preparing dung-beds for forcing, &c.

I have thus glanced at some of the more salient contents of this closely-packed, interesting volume, leaving many, very many, matters wholly unnoticed; but enough, I hope, to whet the curiosity of our readers to judge for themselves. I feel sure it will prove a source of great gratification to the intelligent amateur; and though, so far as I know myself—and that is no easy matter—I am pretty well a stranger to what I am told are the gnawings of envy, I rather think I felt some twinges of that failing when thinking of the improvement and advantages young gardeners might gain from such a volume in these long evenings. If they use these privileges aright they ought far to exceed the Beaton, and Spencers, and Flemings, and Thomsons of our day, as they can occupy the vantage ground which ere long the forwardest of them must leave; but even that they will not do without study and working.

I would in conclusion express a wish that in a new edition, though costing a little more, the large sections should be thrown into lesser chapters, or the paragraphs so numbered as to afford another means of ready reference, in addition to the excellent index; and that the section of diseases and their remedies, so far as known, should be extended; and a new section or chapter given to the insects and other vermin most troublesome to the gardener, and the best-known modes of preventing or settling their depredations. Such a subject would, with illustrations, be well worthy the attention of the author, either as an addition to the present, or as forming the nucleus of another volume to which we could refer in our difficulties.—R. FISII.

### RENOVATING STANDARD APPLE TREES.

WHAT will your readers say to standard Orchard Apple trees—say thirty-years' growth, being most wonderfully renovated by burying the stems 3 feet in depth in nothing but solid clay?

Three trees, as above, quite stunted, hidebound, and fruitless, have been changed into fine healthy trees, producing a profusion of fine clean fruit of a large size, and making abundance of healthy young wood 2 feet long, by having the clay from constructing a pond thrown up against them to the amount of many tons three winters ago; the effect is marvellous.

I have always considered burying trees deep to be certain death; such has not proved to be the case in the present instance. The experiment may be worth trying by parties who have orchards and trees in a similar condition. I should say, Place three or four cartloads of clay on the roots, and around the stems quite close up, and try a few at first. My experiment is actual fact.—HENRY MAX, *the Hope Nurseries, Bedale.*

### SLATING VINE-BORDERS.

I VENTURE to lay before you the plan I have adopted with my Vine-borders. In the beginning of September I felt anxious to secure my Vine-borders from the drenching rains we get in the autumn and winter months. I have found macintosh and asphalt very expensive, and not so durable as I would wish. The next thing I thought of was slate. I procured some of 3 feet 2 inches long and 1 foot 8 inches broad. The next thing was to get spars. I laid them on the border 19 inches apart (rows of bricks will answer the purpose equally as well as spars). The next thing I commenced was laying on the slates, giving them a lap of 2 inches. I feel perfectly satisfied with what I have done, and intend letting them remain on all next summer. When the border wants watering I can draw out a few slates, as I have not used either laths or pegs. The slates are from 2 inches to 3 inches from the soil, and I think the roots will be almost as comfortable as though they had been planted inside the house. I have slated two borders each 50 square yards. Perhaps you will give me your opinion of what I have done.—W. C.

[We agree with your plan, except for summer; then, if we left the slates on, we should place them on the soil, and not leave air beneath them.]

## CULTURE OF ERIOSTEMONS.

THE *Eriostemons* are greenhouse evergreen shrubs, generally of compact habit, and much sought after by exhibitors of plants. They, as well as most other of the races with which gardeners have to deal, possess their peculiarities, which must be attended to in order to insure success in their cultivation. Some of them, particularly *E. buxifolium*, *scabrum*, and *intermedium*, are better grown as pyramids, than as dense dwarf bushes. To have them of this shape, it is necessary to begin with young healthy plants having a leading shoot. It is immaterial whether the plants be grafted or not; but the nurserymen generally graft them, as they thus obtain more readily a supply of plants.

*Eriostemon intermedium*.

If the plants are obtained in the spring, set to work with them immediately. Those that want repotting should have a liberal shift at once into the following compost, which will also serve to grow them in afterwards:—Three parts good turfy peat earth to one part of silver sand, using a liberal quantity of charcoal, both for drainage, and also mixed with the soil. The pots should be well drained with potsherds; and a little of the roughest peat, or some moss, should be placed over the drainage to keep it free and open. This is a great point in the growth of potted plants. After they are potted they should be watered freely, and then placed into an intermediate-house, if large good plants are wanted in the shortest space of time. If not, and slower growth is preferred, which is, perhaps, preferable, the ordinary greenhouse will do very well for them, if the part of the house where they are placed is kept rather close, until they are established in their new pots, when they will soon begin to grow vigorously. It is then necessary to keep the middle stem, or leading shoot, protected by means of a small stake, which, for that purpose, should be a little longer than the shoot. If one side of the plant is inclined to grow more than the other, keep that side cut back a little until the other side has made equal growth, and that part of the plant which is thus behind should be turned towards the lightest part of the house, in order to encourage it as much as possible. If they go on favourably, they may be syringed every fine morning, and a little air given. Bear in mind, however, that they must be shielded from cutting winds, which check them, and turn their foliage of a brownish colour. When they are growing freely, they sometimes show a disposition to callous up the stem; if any sign of this should appear, discontinue the syringing, and give more air until the wood gets a little hardened, which will be a kind of rest for them. After a time they may be examined, and repotted if they are pretty well rooted. This will give them as much pot room as they will require in one season.

After the second shift, they would do best in a frame that could be kept close until they had got rooted into the fresh soil, and raised by degrees, to admit plenty of air round the bottom of the plants; for it is necessary that the second growth should be slower and more stocky; and, to this end, watering over head should, to a great extent, be discontinued, that the wood may become firm and well ripened, so as to withstand the winter. The plants will at this latter season continue rooting without any growth of wood, and will be pretty well pot-bound by the following spring, when they should be treated in the same way as before; and this treatment must be continued year after year, until they are good specimen plants, which will be in the third or fourth season.

The stronger-growing kinds may be managed in the same way, except that they require more pot room, and should from time to time be stopped-back to produce bushy growth.

The following are the best half dozen of the introduced species:—

*E. scabrum*.—A dwarf evergreen shrub, with linear acute leaves, covered with minuta asperities, and numerous axillary whitish flowers, deeply tinged with pink. New Holland. Introduced since 1840.

*E. buxifolium*.—A dwarf evergreen shrub, with small, smooth, broadly elliptic leaves, and white flowers, tinged with pale rose. New Holland. Introduced 1822.

*E. intermedium*.—A moderate-sized evergreen shrub, with large, oblong, obovate leaves, rather glaucous, and having glandular dots, and large white flowers, somewhat tinged with pink. New Holland. Introduced since 1840.

*E. myoporoides*.—A moderate-sized evergreen shrub, with smooth lanceolate leaves, having glandular dots, and large flowers, white tinged with pink. New Holland. Introduced 1824.

*E. cuspidatum*.—A strong-growing evergreen shrub, with large, oblong, lance-shaped glaucous leaves ending in a hooked point, and pale pinkish or rose-coloured flowers. New Holland. Introduced 1823.

*E. salicifolium*.—A strong-growing evergreen shrub, having large linear-lanceolate smooth leaves and pinkish flowers. New Holland. Introduced 1824.

They all bloom during the spring and early summer months, from April to July or August; and the flowers are, in all other species, more or less deeply tinged with pink or rose colour, when developed in a low temperature, and exposed to free air and light. They also generally open with more of the pinky tinge than they retain as they approach the period of their decay.—(G. FREEMAN, *Botanic Garden, Chelsea, in Gardeners' Magazine of Botany*.)

## CENTAUREA ARGENTEA AS AN EDGING.

I AM a'raid the truly beautiful *Centaurea argentea* or candidissima cannot be very generally known, otherwise it would meet with the extensive circulation it merits.

I cannot remember seeing it this season either at Kew, the gardens at South Kensington, or the Crystal Palace, though there was not any scarcity of the much inferior *Cineraria maritima*. I put out nearly 600 of it last spring, as edging for beds on turf, and in ribbon-borders I find it exceedingly effective when placed in front of the Crystal Palace Geranium. Rain or shine, it always looks well. It grows freely, keeps a uniform height, requires no attention in the way of stopping or pegging, "that pest to gardeners," and is in my humble opinion one of the best and most easily cultivated plants of modern introduction for the embellishment of our gardens. I trust some of your correspondents will endorse the character I have given it.—G. J. O.

## HARDY CONIFERÆ.

THERE is nothing more pleasing to a benevolent mind than to observe, amid all the bustle and competition of this age of excitement, the daily increasing taste for the beautiful *Coniferæ* diffusing itself over the length and breadth of the land. In no other manner, to my apprehension, is the disinterestedness and the noble-mindedness of man so finely developed as in planting for posterity. How barren and dreary is a country without trees! What scene so beautiful as the landscape adorned with the tall, stately, and conical forms of some trees, the gracefully drooping

branches of others, and the ever-changing and beautiful features that each revolving season gives to all. When we now admire the landscape scenery of the country, adorned as it is principally by the natives of the soil—fine fellows, too, the brave old Oak, Elm, Beech, and many others—we cannot help picturing to our minds how great the change will be, and how enriched the embellishment produced over the whole face of the country when the fine and noble race of Coniferae, having arrived at the perfect state of maturity, shall contribute an oriental grandeur to the scene. Posterity cannot be too grateful to the many gentlemen—philantropists in the true sense of the word—who have planted, or are preparing to plant, the hardy denizens of other climes, to give splendour and beauty to the pleasure grounds and parks, to the hills and valleys of their own estates.

Juniperus excelsa.

The accounts given by travellers of the rich luxuriance of the large and handsome trees of foreign and distant climes are interesting and instructive. They are also useful, as it has been generally in consequence of such accounts that collectors have been appointed to different parts of the world to send home seeds or plants of all that would be useful or ornamental in this country. It is pleasant to picture to one's self the marked change that the whole face of the country shall undergo, when the noble and majestic *Arucaria imbricata*, the graceful *Deodar Cedar*, the beautiful *Abies Douglasii* and *Pinus insignis*, *P. monticola*, and many other majestic Coniferae of varied and vivid greens, shall be luxuriating with us in all the natural beauty of their native drees.

Nearly all the Coniferae are valuable for timber, or for ornament, and generally for both. The *Thujas*, *Cypresses*, and *Junipers* are particularly interesting in their habits of growth, and are suitable either for exposed situations or on very rocky poor soils about the home grounds. When we hear of some of the Coniferae being introduced from tropical climates, we are disposed to doubt that they will ever become useful in this country; but we must consider that, although there are many parts, even within the tropics, exposed to a bright sky and intense heat, there are other parts exposed to frost and snow. In such climates the range of vegetation naturally adapted for each locality progresses as the range of temperature extends from the sultry valleys to the snow-capped mountains. With the uncertainty that always exists about the proper management of plants introduced from countries but slightly explored, it is satisfactory to know that many Coniferae have been tested by the most severe winter on record in this country (1837-38), and have proved hardy.

As it is probable that many persons who have been nursing their Coniferae through a severe winter will be disposed to plant them out at the first approach of fine weather, I am induced to caution them against so doing, and to give them a few hints that may be useful when the time arrives for carrying

them into practice. At present, the best thing to be done is to select the situations in which they are to be planted, and to turn up the soil into mounds 18 inches or 2 feet high, the better to ameliorate and pulverise it by exposure to frost and other atmospheric influences. The situation to be selected should be rather exposed, where a good growth could be made sufficiently early to become matured before the nipping frosts of autumn appear. No practice that we can adopt will change the nature of a plant, but we may be able to influence its susceptibility so far, by good management, as to enable it to withstand the many atmospheric changes to which it may be exposed. The soil being well pulverised and raised into finely sloping mounds, about the middle of May, when all danger of frost is over, is the best time for turning the plants out of their pots into the open ground, where they are to remain to adorn the park scenery or pleasure-ground views. The object in planting them upon mounds is to produce a thorough drainage for the roots and a more agreeable appearance in the landscape. The soil being mulched or covered with the mowings from the pleasure grounds, or with leaves or any other litter easily procured in summer, will prevent evaporation, and the moisture in the soil will be retained for the healthy vegetation of the roots.

During the summer, when the days are long, the sunlight powerful, and the temperature high, vegetation is excited to produce luxuriant growth. As the days become shorter, the sunlight less powerful, and the temperature lower, a change is produced in the system of the plant, and it gradually subsides into a comparatively dormant state—the leaves being dependent upon the influence of heat and light for their excitability, for the proper elaboration of the sap, and for their healthy perspiration; and when these influences are on the decline the plant is approaching the state of rest natural to vegetables in all parts of the world. It then attains to a state of rest in which it is able to withstand the severity of winter. Although roots are never entirely inactive, nevertheless their action will in a great measure depend upon the active vitality of the leaves. It is principally by the action of the leaves that the roots are excited to imbibe nourishment from the soil; but when the power of the leaves to perspire aqueous matter, and to absorb the nutritious gases supplied by the atmosphere, ceases, the roots gradually, and in less quantities, imbibe food from the soil to supply the waste produced in the system during the summer and autumn growth of the plant, and to collect a store of organisable matter to supply the demand of the leaves and branches the following spring. When the roots are surrounded with a superabundance of water in badly drained soils, they imbibe it in immoderate quantities, the vessels of the plant become gorged, the tissues lax, and the whole system disorganised; then they are most susceptible of injury from frosts. It is for such reasons advisable to plant Coniferae in open or exposed situations, where their growth would be gradually arrested by the coldness and other atmospheric influences of such situations. The truth of the principle is proved by the fact, that in severe winters the more exposed plants have been grown, the less they have suffered; and, on the contrary, the more they have been sheltered, without being protected artificially, the more severely they have been injured.

The following is a list of hardy and handsome Coniferae, selected either for diversity of foliage or habit of growth:—

MEXICAN.	<i>Pinus insignis</i>	<i>Abies Bruniana</i>
<i>Pinus Ayacahuite</i>	<i>Lambertiana</i>	<i>Murinda</i>
<i>apulcensis</i>	<i>monticola</i>	<i>Smithiana</i>
<i>Devoniana</i>	<i>Caulteri</i>	<i>Webbiana</i>
<i>Hartwegii</i>	<i>Sabiniana</i>	<i>Thuja orientalis</i>
<i>Llaveana</i>	<i>Sir-clairiana</i>	<i>Cryptomeria japonica</i>
<i>Mantezumæ</i>	<i>Abies Menziesii</i>	<i>Juniperus chinensis</i>
<i>macrophylla</i>	<i>Douglasii</i>	
<i>patula</i>	<i>Picea amabilis</i>	EUROPEAN.
<i>Russelliana</i>	<i>nobilis</i>	<i>Pinus halepensis</i>
<i>Teocote</i>		<i>bruta</i>
<i>Picea religiosa</i>		<i>Picea cephalonica</i>
<i>Juniperus flaccida</i>	INDIAN.	<i>Pinusapo</i>
<i>tetragona</i>	<i>Pinus excelsa</i>	<i>Juniperus excelsa</i>
N. W. AMERICA.	<i>Gerardian</i>	<i>occidentalis</i>
<i>Pinus macrocarpa</i>	<i>Cedrus deodara</i>	

—(W. P. KEANE, in *Gardeners' Magazine of Botany*.)

### RASPBERRY PLANTING.

ALLOW me to say a word or two on this subject. I never recollect seeing my mode of planting the Raspberry described in print or in practice, except by the man I learned it from, and

that was thirty years ago: therefore, it may be new to some of my brother readers.

In the first place, I prepare the land as any other gardener would that wishes the plants to do well, any day after Christmas when time and opportunity offer, and take care to have the ground in good condition by the time the suckers are about a foot or 15 inches high. I have planted them when 18 inches high, but would rather have them lower, as the sun does not affect them so much.

I select the strongest suckers that are well rooted. I am particular to have a good fibrous root with a good collar, though the cane is small, rather than a strong cane with what I call a carrot root. I then dig out the holes, and put three plants in each hole, in a triangle, about 9 inches apart, spreading the roots out nicely; fill-in the soil, give a good watering, and then the work is done, all but paying attention to watering till the plants have got good hold of the ground. I never shade; but where time will allow, and the weather is very hot, shading will benefit.

As far as my experience goes, this beats all the ways of planting Raspberries I have ever tried or read of. I have tried Mr. Pearson's way.—WORCESTER.

### FAILURE OF CELERY THIS YEAR.

"P. L. C." inquires, as any one would reasonably inquire, why Celery should be bitter, stringy, and rotting at the heart after giving it such excellent treatment as he describes. I do not profess to be able to assign a reason unless it be that Celery is, like many people, the better treated the more perverse; but if by giving my experience of the last few years I can throw any light on the subject, I am willing to do so. In truth, I believe the worst Celery I ever grew is the present crop, which is taken up daily, and which yields a very small per-centage of eatable matter, although very few plants have gone-off entirely, and the flavour is pretty much as it should be. It has been tolerably free from the fly; the worst pest appears to be a small worm that eats into the leafstalk, beginning at the bottom and working upwards. The crop is below the average size. In July and August it made little progress, being almost at a standstill, but in September it began to grow vigorously. It was planted in double rows, and had at least 6 inches of good rotten manure—rather more than I have usually given former crops. Another advantage it had was, that the ground had been unoccupied six months previous to planting in the trenches, so that with all these advantages and better treatment the crop is the worst I ever had. It was sown in March, pricked-out in April, and planted-out in the trenches in June, and well watered when necessary. The sorts are Coles' Red, Crystal White, and Incomparable Dwarf White, the same as I usually grow.

The best crop of Celery I ever grew was about ten years ago, on a rather heavy soil sloping to the north. The ground was never to my knowledge trenched or dug more than one spit deep, and very little manure was given when the crop was planted-out. It was treated in other respects just the same as the crop above mentioned, saving that, whilst I generally prick it out on a bed of manure, manure having been scarce then, I had to prick it out on the common earth. When the crop was taken up for use it was of good flavour, very clean, solid, and of immense size. The excellence of the crop might be derived from the nature of the soil and a favourable season; but I imagine that Celery does not like altogether the peculiar mode adopted in its culture. The ground is generally thrown out to the depth of a foot or 15 inches; the dung is put in the trenches, and either dug-in or some of the soil that was taken out is put in again. Generally speaking, neither the manure nor the soil is in a fit state for the plants to root into immediately; for, the soil being from beneath, the surface requires aerating, and the manure wants to be further decomposed; and what is unfavourable to immediate root action is unfavourable to the growth of the crop the rest of the season, but is favourable to the development of grubs and worms.

Five years ago I had a very bad crop of Celery on a piece of ground that had been trenched 3 feet deep the previous winter, after a crop of early Peas. The Celery was planted and it scarcely grew at all till the end of September, and the same thing happened two years ago, while that planted in untrenched ground did much better. I had very fine crops three and four years ago on untrenched ground, when the Celery was planted

in very shallow trenches and received very little manure. I thus appears to me, that though Celery is a gross-feeding plant, it is possible to feed it too grossly, or, at least, that the soil may be too highly enriched with manure, and too loose and friable, and that a firm tenacious soil would suit it much better.

Another important matter is in the time of sowing and pricking-out. It is all very well to sow in February in heat to get an early crop, but for the main supply I believe it is bad policy either to sow in heat or to sow too early. What has to stand the season should not be stimulated in the early months by artificial heat. If for the main and late crops the seed is sown on the open ground late in March or early in April, it will be quite soon enough if the plants can be kept in a growing state, and it will be far more crisp and solid than that sown in February, and placed under glass, hardened-off, &c.—processes which, but for the sake of getting it very early, are not only unnecessary but inimical to the crop, which towards autumn becomes weak and sickly, and falls a ready prey to the fly and the wireworm.—F. CHITTY, *Stamford Hill*.

### CULTURE AND HARDINESS OF THE GLOBE ARTICHOKE.

This plant is said to be indigenous to the countries which bound the Mediterranean, and is, consequently, a native of a more genial climate than our own.

The soil best suited for the Globe Artichoke is a stiffish loam, impregnated with a portion of saline or alkaline matter, as nothing is more inimical to the successful cultivation of the Artichoke than a dry soil; in dry sandy soils where the roots of the plants are burnt up in summer the produce is rarely worth the gathering—diminutive in size, and of bad quality. We have attempted its cultivation in such a soil, and the result was a dead failure.

As a manure, seaweed must have the precedence; for Artichokes, Asparagus, and Sea-kale, there is nothing equal to seaweed. I have been so situated as to be able to obtain it in almost any quantity, and am ready to testify to its superiority as a manure for the plants just named over all others; it contains the ingredients which it would seem are essential to their full development, the only difference being that the sandy soil suited to the two latter is altogether unsuited to the Artichoke. The finest Globe Artichokes I ever remember seeing were growing in a deep loamy soil, and the only manure they ever had was an annual top-dressing of seaweed spread over the surface of the soil between the rows of plants to the depth of 5 inches or 6 inches; it was put on early in winter, and allowed to remain till spring, when a part of it was taken away, and the remainder dug-in between the rows of plants. This, of course, is all very well where seaweed can be had, but this is not always procurable, and the next best substitute, so far as I am aware, is well-rotted stable-manure. It is better, however, to dig the dung in, and not to leave it exposed on the surface as in the case of the seaweed.

In preparing the ground for the Globe Artichoke it should be trenched to the depth of 2 feet, and pretty well enriched with manure, and the plants placed 5 feet apart both ways; they will also be benefited by having the ground between the rows of plants sprinkled with a little salt at least once a-year in the same proportion as is usually given to Asparagus.

Propagation is a very simple affair, as it is readily accomplished by suckers from the roots; this may be done in March or April, or any time after the plants have pushed to a height of 5 inches or 6 inches. These will probably produce a few heads the same year, but not abundantly, but will do so the following summer.

It is proper to make young plantations at short intervals—every second or third year; for, although the old plants will continue to produce for an indefinite period of time, the edible part degenerates both in size and quality when they become too old. In our soil, which, for the most part, is of a stiff heavy nature inclining to clay, and resting on a subsoil of the same material, the Globe Artichoke does well, producing magnificent heads; but though the plants grow well, even grossly, in summer, they are very apt to rot at the crown in winter, owing to our naturally damp soil conjoined with the annual rainfall, which is above the average of most other countries in England, if we except, perhaps, the lake districts of Cumberland. We are, therefore, less apprehensive of frost than wet; indeed, we are inclined to think that the plant is much more hardy than most

of us are willing to believe. We seldom have recourse to covering the plants in ordinary winters. We take away the soil all round the crown of the plant to the depth of 3 inches, and fill up either with sand or riddled coal ashes. This keeps the collar of the plant dry, and prevents rotting; and in general we find it ample protection in winters of ordinary severity.

It is recorded that the Globe Artichokes in England were almost annihilated by the severe winter of 1739. How that winter would stand in comparison with 1860 I have no means of knowing; but I am not aware that they suffered extensively in the latter. But in winters of extraordinary severity, as we have recently experienced, protection, of course, is indispensable, and that, too, to a considerable extent. When I use protective matter at all for Artichokes it is usually dry tree leaves, with a sprinkling of soil put over them to prevent them from being blown away by the wind. But as Mr. Beaton has been the first to agitate the question, "Is the Globe Artichoke hardy?" the opinion of others would be both interesting and instructive to many of your readers.—J. DUNN, *Harrock Hall Gardens, near Wigan.*

**THE TREE AND FRUIT TRADE OF ANGERS.**

THE trade in fruits and trees at Angers is so extensive, that the district may justly claim to be entitled the nursery of France; and in proof of this assertion we adduce the following statements of the quantities of trees and of Apples and Pears sent away by railway by the nurserymen and fruiterers of Angers. These statements have been prepared by M. Baptiste Desportes, from the books of the railway company, and may, therefore be relied upon.

The trees and plants sent by railway from Angers in the year 1860-61 weighed in round numbers 1476 tons; and it is estimated that about a third more, or 492 tons, is conveyed away by boat, carriers, and carts, making the total weight sent away 1968 tons in a single year. This enormous quantity of fruit trees is sent to all parts of France, to Belgium, Holland, Germany, Switzerland, Spain, Portugal, the coast of the Mediterranean, America, &c.

Although the trees sent by railway give such a large tonnage, that of the fruit, Apples, and Pears, is yet greater, as will be seen by the following table, which shows the quantity conveyed from July, 1861, to February 1862:—

Month.	PEARS.		APPLES.	Total.
	Fast Trains.	Slow Trains.	Slow Trains.	
	tons.cwt.lbs.	tons.cwt.lbs.	tons.cwt.lbs.	tons.cwt.lbs.
1861.—July .....	14 19 21	70 6 48	.....	25 5 69
August .....	64 0 49	244 5 101	.....	308 6 33
September .....	38 1 59	158 5 79	.....	196 7 26
October .....	19 7 82	113 3 73	323 17 88	456 9 19
November ..	3 11 90	15 5 11	503 1 27	523 18 16
December ..	2 12 95	.....	284 9 53	287 2 36
1862.—January ..	0 2 107	.....	220 7 87	220 10 82
February .....	.....	.....	128 13 3	128 13 3
Grand Total .....	142 16 55	541 6 88	1462 9 34	2146 12 65

On glancing over the table, it will be seen that the fruit traffic commences in July, and that during August and September it consists in Pears only. The quantity conveyed is greatest in August, when it averages nearly 10 tons a-day. Williams' Bon Chrétien, which is extensively grown in the orchards of Anjou, and which is in great demand at Paris, is almost the only variety which is sent by the fast trains. This circumstance is easily accounted for by the fact of its being of better quality, handsomer, and more sought after than other kinds ripening at the same time [more probably owing to its not keeping when ripe], and, consequently, it brings a higher price, which admits of a greater expenditure in carriage.

It must not, however, be supposed that all the fruit sent otherwise than by the fast trains is of inferior quality, for at least one-fifth of such is estimated to be first-rate. The remainder consists of inferior fruit for selling in the streets, which is carried in the goods-waggons without being packed, a little straw being thrown over the bottom to prevent bruising.

Again, referring to the table, it will be seen that the traffic continues brisk in September and October. The choice kinds principally consisting of Louise Bonne of Jersey, Duchesse d'Angoulême, Beurré Diel, Beurré d'Arenberg, and Easter Beurré; the others, with few exceptions, are inferior kinds for selling in the streets.

The total quantity of Pears sent throughout the season amounts to 684 tons, and is of an estimated value of £8342, and taking into account the other railways in the department, this estimate may be doubled.

The common kinds of Pears are all sold at Paris; those of superior quality only in part there, the remainder going to Havre for shipment to England and Russia.

The traffic in Apples is even greater than that in Pears; it begins in October, amounts to 323 tons in that month, and in November it reaches 505 tons, as much as 30 tons and 40 tons being sometimes sent off in a single day. The quantity of Apples carried by the Angers railway up to the end of April was 1727 tons, and it is computed that the other lines in the Department bring up the total weight sent by rail to 2950 tons, whilst about 1970 tons more are loaded on to boats, making altogether 4920 tons, of the estimated value of £19,230. The total value of the Apples and Pears sent from Angers to Paris, and abroad, approximates, therefore, closely to £36,000.—(*Proceedings of the Comice Horticole de Maine et Loire.*)

**THE DISTRESSED LANCASHIRE WORKINGMEN BOTANISTS.**

I PURPOSED giving the many kindhearted people, who have so generously answered my call for help to distressed brethren, a sort of epitome of the character of the men relieved, but must forego it this week. I have been under deep obligations to our worthy Mayor of "the Borough" (for we have two Mayors here), who has kindly sought out some information that I wanted about some persons I have relieved; and others here high in station have rendered me all the assistance I required, for it could not be supposed that I could know all who might come before me, and therefore I sought for reliable information.

As a whole I have found the private characters of these poor naturalists very good. Of course there are black sheep in almost every flock, but I feel convinced your readers who have helped these poor lovers of "humble-looking weeds" will have no cause to regret their aid.

I have received since I last wrote the following:—Mrs. Elliot, 2s. 6d.; A Gardener, 5s.; Mrs. Wigan, £1 1s.; Mr. J. Stollard, 10s. 6d.; G. S. W., Esq., and family, £2, with a lot of very valuable bed and other clothing; Miss Hammer, £1 1s.; Miss Shore, Kensington, £2 (some of the above are for Mosses, Ferns, &c.), Mrs. Henley, and servants of Leigh House, Chard, Somerset, a box of very good and substantial clothing. The servants at the above house have subscribed and bought a blanket and one pair of stockings for my poor scientific friends, and I wish especially to thank them.

The botanists purpose to thank you and your numerous readers, who have so kindly helped them in this hour of trial, in the course of a few weeks.

There is a little sickness in two families; and the doctor, a worthy alderman, who attends them, has ordered me to get some wine for some of the invalids, and he will give it them in such manner that it will be used properly.—JOHN HAGUE, 36, *Mount Street, Ashton-under-Lyne.*

**CONSTRUCTING SMALL PITS.**

IN the letter of your correspondent "F. C." in last week's Journal upon the above subject, it is stated, amongst the many other mishaps which befel his friend's flue-heated pit, that "it was impossible to get heat enough to keep out a sharp frost." I think there must have been some mistake in the construction of the flue, as with my small roughly-made furnace (as described in No. 87), the following heat was attained. On the 1st inst. my frame thermometer stood at 51°, and as I have only Mushroom-beds under the lights at present, I lit the fire and allowed it to burn for some five or six hours; forgetting, however, to open the lights. On the 2nd, at 8 A.M., on inspecting the frames I found the thermometer at 95°; the outside temperature being 36°, and having been down as low as 30° during the night. The flue also retained sufficient heat in spite of day ventilation to keep the mercury up to 75° till the 4th inst., when it sank quickly. My forgetfulness has, I expect, in your correspondent's words, "steamed to death" my Mushrooms; and the degree of heat attained is therefore the only fact worth notice. Unless, however, the flue be covered to some depth with rubble, broken

bricks, &c., as advised by you in answer to "H," it is useless to expect the heat to get through properly. With regard to the vapour from the flues killing the plants, I have experienced the same mishap when requiring top heat and removing the earth from the flue for that purpose, and I attribute it to a very minute escape of coke gas. To obviate this, I intend to adopt your suggestion to "H," as regards a pipe leading from the broken bricks, &c., into the frames; but, instead of a pipe, I shall construct a small square tower of brick, which I shall cover with a thin sheet of iron. This I expect will allow the upper air to be warmed without the slightest escape of coke gas, as I have never found it rise through the earth in the frames.—  
LEX.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

PROCEED with former directions as regards maturing and trenching. Gravel walks should come in for a share of attention in rolling, &c. Sifted coal ashes is an excellent material for the back walks, as it bears the winter traffic well, and is always pleasant to walk upon. A coating of such material may now be given if they are in a bad condition. *Asparagus*, if the heat of the beds should decline, a slight lioing may be added, but care must be taken that it does not heat violently. *Beans*, those advancing should have the surface soil stirred and the earth drawn over them. Keep the *Broccoli* free from dead leaves, as after frost they materially injure the plants by causing them to rot. *Celery*, take advantage of every favourable opportunity till frost occurs, of earthing-up the late crops, both for the purpose of blanching and protection. *Lettuce*, those in frames for present use to be kept dry and free from dead leaves. *Parsnips*, where they have not yet been taken up they should be left in no longer, as they are not in the slightest degree benefited by remaining in the ground, and should severe frost set in there will be a difficulty in getting them up. *Peas*, those which had been sown on a warm border, as advised, will now be peeping out of the ground, and should have the surface soil stirred about them, and a covering of decomposed leaf mould or any other light soil laid immediately over the rows; and also in the event of cutting winds prevailing, some branches of spruce fir or birch stuck in on the windward-side will be useful. *Turnips*, on the first appearance of severe frost it is advisable to get some under cover. They may be laid in sand after the tops are cut off.

### FLOWER GARDEN.

Where the tenderer kinds of *Roses* are found to require protection, this should be applied at once, or it may be soon too late to save the plants. Protection may be given by strewing a good thickness of fern or any other dry material amongst the stems of the plants. Those varieties which are budded upon the standards may be easily protected by tying on a few furze branches round the head, securing the whole with a strong stake to save it from being injured by the wintry winds. Those standards which, by the weakness of the shoots and the paucity of their blooms this season, are showing evident symptoms of decay, should have all the surface soil taken off down to the roots, and all the suckers removed, after which a thick coat of well-rotted dung should be laid about them and covered with a portion of the soil. This applies with equal force to those standards that are planted out on turf; in which cases, taking it for granted that the turf is not nearer to the stem than 18 inches, the soil should be removed as in the former case, and a good dressing of strong compost applied. If this be covered with flints or white pebbles the unsightly appearance of the soil upon the turf will be done away with. Valuable plants also, as variegated *Hollies*, &c., if not growing as freely as they should do, would be benefited by a liberal allowance of rotten manure or well-decayed leaf mould being applied as a top-dressing, covering it with a little fine soil, and working it into the ground around the ball, towards the extremities of the roots.

### FRUIT GARDEN.

Planting, hitherto deferred, should be immediately attended to. The roots of all newly-planted trees should be secured from the effects of severe weather by mulching. Fruit trees are injured by the accumulation of moss and lichen on their branches; where the hand cannot reach it, a dashing of lime will effect its destruction. Any of the more choice varieties of *Pears* which do not ripen properly should be removed to a warm dry room for a few days, which will be found to greatly improve them.

### STOVE.

Some of the early-ripened tall *Cacti* may now be introduced, either in the stove or the forcing-pit, and receive a liberal watering to commence with. If, however, the blossom-buds are not well matured it is of little use forcing them. Do not encourage any fresh growth among stove plants at this period; rather aim at that kind of routine management which will serve to consolidate the growth already made, and to develop the blossoms of the late-flowering things in a proper way. Great caution will be necessary to provide against drip.

### GREENHOUSE AND CONSERVATORY.

The ill effects of humidity and stagnant air in plant-houses should be guarded against, most particularly at this season. *Pelargoniums* to be kept rather cool and dry, giving whatever water may be necessary on the mornings of fine days, so that the superfluous moisture may have evaporated before the evening; avoiding the use of fire heat, except when necessary to prevent the temperature falling below 40°, or to dispel damp, when this cannot safely be done, by giving air. Herbaceous *Calceolarias* require similar treatment, except that they are very subject to the attacks of thrips unless afforded a moist atmosphere. They must, therefore, be narrowly watched for this enemy, and smoked lightly two or three evenings successively if this pest makes its appearance, keeping the atmosphere moist, but giving air on every favourable opportunity.

### FORCING-PIT.

Dutch bulbs should be largely used for forcing at this season. A good batch of *Roses* to be introduced, choosing the most promising plants of *Teas*, *Bourbons*, and *Hybrid Perpetuals*; *Rhododendrons*, *Azaleas*, *Persian Lilacs*, *Sweet Briars*, *Honey-suckles*, *Kalmias*, *Daphnes*, *Rhodoras*, &c. A sweet bottom heat of from 75° to 80° max., and a temperature from 60° to 65°. It may be necessary to state, that it is in vain to introduce anything unless properly set for bloom.

### PITS AND FRAMES.

Now while the weather is open give careful attention to the bedding plants, taking advantage of the favourable state of the weather to expose them freely to the air. W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

FIND that even with company our *Asparagus* comes quicker in this mild weather than we want, and wish we had taken up less, as even rich delicacies cease to be so whenever they are extra plentiful. Swept-over last earthen-up *Mushroom-bed*; as it was rather damp and wet on the surface, put a little straw on the surface, which will help to dry it before the *Mushrooms* appear, as, if the surface is too moist the *Mushrooms* are apt to damp-off, as mentioned by a correspondent. This bed is on a shelf, and the next succession will be below it; and as the dung for it there in preparation has thrown up some heat, that heat and the straw together will cause the extra moisture to disappear. The bed before this one has borne well, and the individual *Mushrooms* just too large and thick to be easily cooked; the strong stems were so crisp and sweet that, if cut up, we are sure none would have detected them from the best little bits of button *Mushrooms*. It has often grieved us to see delicate white buttons, not half an inch across, pared deep as if they were rough *Potatoes* and *Turnips*, and half of the delicious things thrown away, and this even more so with large *Mushrooms*. On the other hand, we have seen careful cooks save every morsel, even of the stems, and bring them in for use. In addition to looking after slugs, and what is much worse—rabbits, that have got into a fenced garden from leaving the gates of the pleasure ground open, the chief work here has been removing all the last of the pea-stakes, clearing the borders of leaves, and picking what few weeds appeared on the walks, brushing them well and rolling them firm, which will keep them better for walking on, whether wet or frost visits us.

### FRUIT GARDEN.

In addition to what was lately detailed, put in more *Strawberries* on a bed of leaves, not plunging them, but setting them on the surface, examining each plant before doing so. The object of this is just to give the plants a slow incitement to growth, and thus bring them on gradually before they are taken into the forcing-houses, and thus gain time, as it were, before fire heat is used in these houses. We had also struck some *Vines*

late last season, which were in smallish pots, and for a purpose respecting which we were disappointed in not being able to carry it out. The pots, like a correspondent's last week, were too small for fruiting Vines; but, as the young things had many of them nice buds, we gave them another shift, beating the soil quite hard about the ball, which was a little disengaged, so as to let the roots out, and then these pots were plunged into a bed of leaves with a fairish heat in them, and some old sashes placed over them, and air given unless in times of severe frost. The object in this case is quite different from what was stated last week with Vines placed on tiles and slates on a hotter bed. In this last case the pots were crammed with roots, and extra heat at the sides would have been prejudicial. In the present case our object is to increase root action, that the pots may be pretty well filled with fresh roots before the buds break. If these small plants should, nevertheless, show fruit, as many did last year, there will be material in the pots to support them; and if a few do not do so, nothing will be lost—for, if disposed, we can grow them afterwards on the single rod, or bush, or branched-stem system. Gathered about the last Figs for the season, leaving only a dish or two, though the leaves have all been removed. These Figs, though small owing to the dryness of the soil, were, nevertheless, owing to that dryness, very good and sweet in flavour. A few late Melons we have not used much; for, though the colour and the scent were pretty good, the flavour was so great a deal better than a Cucumber. Looked over late Grapes, which are now as much prized as early ones; and removed all speckled fruit from the fruit-store-room. Unfortunately, we find that we had gathered our Filberts early enough, as we like to see them plump and full. Found, however, it was merely a choice of evils; as, not to speak of squirrels which gamekeepers do look after, found the larger birds were carrying them off wholesale. Did a little pruning in fine days.

#### PLEASURE GROUNDS.

Removed the last of the summer-flowering plants, cutting-down Phloxes, Solidagos, to the ground. Cutting-down also stools of Fuchsias, using the shoots when well frosted for stakes; finding that even if the shoots of planted-out Fuchsias are saved, either by protection or the mildness of the winter, that they do not bloom so well next season as fresh shoots from the stool. Dug a little in slightly frosty mornings, but in general it was too sloppy for that. Most of the leaves of the deciduous trees having now fallen, had the lawn well swept, using a small broom with a long handle, similar to what we described for the daisy-knife, which enables a man sweeping right and left to clear about as much as two or three mowers' swathes, leaving rows to be swept-up with the usual short brooms. Then rolled the lawn, and after brushing the walks rolled them likewise, and for two reasons, besides making them comfortable in the meantime. The first is, that the firmer they are on the surface the less will rains penetrate, and the less will the walks be influenced by alternations of frost and thaw; and, secondly, as the surface of the walks is seldom disturbed by hoeing, digging, or otherwise, there is apt to be a little green mossy matter here and there on the gravel, and when thus smoothed-over on the surface, and a sudden sharp frost comes in a morning, a few scrubby brooms used with a little elbow-grease will remove the most of the green matter and not disturb the gravel at all. Such operations are necessary wherever neatness in pleasure grounds is an object; much, however, as we may admire the changes in the colour of leaves as they fade, there are few things in a garden more suggestive of melancholy feelings than wet decaying leaves on a walk or lawn. The smoother the surface of either the less will they be disposed to remain even when blown there.

#### PITS AND FRAMES.

This, for young plants in them, is the worst season of all the year, as the dull weather is apt to make the plants damp. The great preventives are—first, air back and front in all mild weather, shutting-up at night when the weather is a little doubtful, and especially if the moon rises after midnight, but giving no covering unless frost is expected. To make a compromise when it is feared there may be a little frost before morning; it may often be better to cover the glass, and leave a little air on—say half an inch at the top which, if frosty, may be taken away in the morning. It will take several degrees of frost to penetrate through a small opening for air, if the glass is covered. When the latter is uncovered, and air on likewise, a very few degrees will injure small tender plants. The second preventive is, using

the nimble fingers and the supple backs of boys to pick off all mouldy and decayed leaves as they appear; and of these there will be few in proportion to the coolness, air, and light given to the plants.

Old Geraniums (Scarlets) stuck like faggots into pots in a cold pit, have as yet had no water; but as the soil now appears dry, and on examination find new spongiolo-roots protruding, would give a little water, if we could depend on a few sunny days. If the present mild, dripping, muggy weather continues, will refrain from giving water, as the plants, having no leaves, will suffer less from dryness than from excess of moisture.

In conservatory, re-arranged plants, removing Chrysanthemums past their best. Cinerarias, that had a little thrips, set in a frame, and placed a bushel of laurel leaves in front of them, which settled them. Potted-off some of the scarcer Geraniums; top-dressed Orchids, and stove plants; cut-off the most of the leaves of fine-leaved Begonias, and set them thick under Fig trees to dry, and be cool until spring. Violets, bulbs, and forcing shrubs will require all the care several times alluded to, though of late we have done little in that way in comparison to what we used to do. Plants, in general, much as before, timing watering to the state of the plants and the weather.—R. F.

#### TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

ADVERTISEMENTS.—A correspondent, "J. R. W.," complains, and justly complains, that "Dunn's Gardener's Pencils," and the "Bijon Drainer," are advertised as "to be had of all seedsmen, &c.;" and that, having inquired of four or five seedsmen in Liverpool, they told him that they did not keep either, and that "it is the usual mode of advertising." It is quite true that it would be worth while for seedsmen to keep those articles; but it would be more to the interest of these advertisers to appoint an agent in each principal town, so that the public need not be balked and troubled in the way complained of.

BULBS VEGETATING STRONGLY (*Subscriber since 1856*).—All those spring-flowering bulbs which we put in the autumn for forcing, and which we plunge or cover till the pots are filled with roots, need not flower one day the sooner for being so treated, unless we wish it, and push them on accordingly. You have done yours very well indeed, and they are now in the very best condition for the time; and as you do not wish them to come in early, take off all the loose leaves you put over them and let them stand under the two inches deep of ashes only, and they will remain all most as they now are for the next two months—or most of them will. No you are quite safe yet; but if hard frost set in put the tree leaves over them again, and again take them off in fine weather as long as you mean to keep back the bulbs.

ZYGOPETALON MACKAYI (*W. C. P. Glasgow*).—Your plant is the true *Zygopetalon Mackayi*, the most easy to grow and to bloom of all the Orchids, and always blooms, or ought to bloom, at the end of the autumn, and grows on slowly all the winter.

PHALANOPES (*Idem*).—No one knows how big *Phalanopes* grow. The first plant that was sold of it, for one hundred guineas, had only one leaf and one-half of a young leaf coming and one spike of bloom. We had that plant in our hands soon after it was bought. We have seen them with one leaf and with one and twenty leaves; but Mr. Fortune bought a plant of it with probably hundreds of leaves, and it took two natives to carry it on a pole between them, as he says in one of his books of eastern travels.

CAMELLIA BUDS FALLING (*Timothy*).—We think it very likely that, if your plants are well drained, the balls of the large plants have got dry in the centre, as the smaller plants do not shed their blossom-buds.

ROMAN CANDLE (*J. Smith*).—You say your plant is so called, and that it is "like a dip candle with a tuft of leaves on the top." We are not sure of the plant. Is it a succulent? We think we have heard the *Cacalia utricularata* so named, and that has a little resemblance to your description. Very likely we might know something of it if we saw a piece of it.

STEPHANOTIS FLORIBONDA NOT BLOOMING (*Bellvue Park*).—Supposing the walled-in pit is well drained, pick away with a pointed stick and fingers a good portion of the old soil and replace it with fibry loam and old cow-dung, and a quart of small broken bones. Give little water in winter, but plenty in the summer, and encourage the stems to grow down under the glass.

PELARGONIUMS AND FUCHSIAS (*Beginner, J. C.*).—The six *Pelargoniums* are all good and so are the six *Fuchsias*, and any others from the same families might not please you so well as these; therefore we shall not alter your own lists.

**DOUBLE WHITE PRIMULA AND CAPE BOLBS** (*Young Beginner*).—Keep the bulbs as cool as Calceolarias for another week, when we purpose to give a detailed account of the yearly management for them and for the Primulas.

**INTELLECTUAL OBSERVER** (*F. B.*).—With postage 1s. 4d. Or you can procure it through any bookseller. It is a periodical.

**GRAPE JOGGING** (*G. J. O.*).—The subject is now ventilated, but we think will not be settled unless an authority like the Fruit Committee of the Royal Horticultural Society will promulgate a code of merit.

**COCA-NUT FIBRE DUST** (*K. H.*).—Your gardener having dressed all the flower and kitchen garden heavily with the refuse of the cocoa-nut fibre, his "madness" is a bold attempt to keep a good comfortable place, and to shine in it to the satisfaction of his employers by improving in all the departments, and before this time next year you will be the first to propose another heavy dressing to some of the parts, if not to the whole. Mr. Beaton informs us that in his neighbourhood many are all but mad on the cocoa-nut fibre dust, but none of them use the short refuse fibre; that they all put on heavy dressings of it; that the Rev. E. Phillips is now making Vine-borders with it, flower beds, also roseries, and a complete renovation of his whole grounds and plantings, in order to introduce this great improvement, which he, the said Rev. E. Phillips, characterises as "the nervous system for soils."

**CYCLAMEN SEEDLINGS** (*T.*).—As you "always lose your Cyclamen seedlings while in their first rest," turn over a new leaf and never let them rest at all till they have bloomed, as we recorded not long since as being the practice of the Messrs. Henderson and Carter & Co. The only book "profusely illustrated in colours of hardy and half hardy plants, with reliable cultural notes," is Sweet's "British Flower Garden." There is something wrong in your account of the Cyclamen seedlings putting up two leaves at the first start. Are all your seedlings as you say? If so, pray send us one or two in a pill-box. We sent about your *Farfugium* Cyclamen to Mr. Beaton, and you have his notes on it in another page.

**NELSON APPLES** (*C. B. A., Staffordshire*).—This, usually called Nelson's Codlin, is a very excellent Apple for kitchen use and even for dessert. It is in season from September to January.

**LIME WATER** (*D. Scotchman*).—A peck of freshly-slacked lime put into 40 gallons of cold water. The water may be used after they have been mixed for an hour and it has become clear.

**WEED, SEED, AND ANT KILLER** (*J. B.*).—The apparatus described at p. 242 of Vol. XIII is an American invention, but we have no further information concerning it. If any of our readers have tried it, we shall be obliged by information as to its success or failure.

**FERNS FOR A GLASS CASE** (*H. W. Down*).—Supposing you have three rows of Ferns, plant in the middle row the following, or a selection from them:—*Adiantum pedatum*, *A. brasiliense*, *Onychium lucidum*, *Adiantum formosum*, *Davallia canariensis*, and *Doodia aspera*. On one side of that row *Doodia media*, *Platyloma rotundifolia*, *Adiantum capillus-Veneris*, *Lycopodium stoloniferum*, and *Pteris bicolor*. On the other side *Adiantum hirsutum*, *Pteris cretica*, *Asplenium planicaule*, *Lycopodium variable*, *Allosorus crispus*, and *Cystopteris fragilis*. Give air freely every day; drain thoroughly, yet keep the air and soil moderately moist. Temperature not lower than 40° at night nor higher than 65° by day. Do not expose to sunshine. We keep the sides of our Fern case open partly all day.

**HEATING A SMALL PROPAGATING-HOUSE** (*A. B.*).—We think your safest plan would be a waterproofed box in the greenhouse supplied with hot water every night, or when wanted. Your next best would be a small brick Arnott's stove in the chamber of the propagating place, arranged as described several weeks ago. The next best, and best of all so far as the cold "pit" is concerned, would be to have a small furnace and a small brick flue all round the chamber of the propagating part joining the greenhouse chimney; but the flue so made that a damper should be inserted or taken out at pleasure, so that the heated air should pass along the cold pit and out at a chimney at the further end when desirable. The heat for the furnace and the flue kept round the chamber for a time would give heat to last long enough until you could shut it off from the pit. The heat in the pit will enable you to give more air. After getting into the pit, earthenware pipes, 9 inches in diameter, will do; but Portland cement would do better.

**BEGONIA FUCHSIoidES AND STREPTOCARPUS RHEZII CULTURE** (*S. H. L. C.*).—*Begonia fuchsioides*.—Cuttings put-in in February, potted when struck, grown freely and potted as soon as the pots are full of roots, all summer, until August, and all the sun given in September, and water lessened in the end of September and October, will give nice flowering plants for winter in a temperature of from 55° to 60°, and rarely 65° at night. The soil should be sandy peat, loam, and a little sweet cawdung or leaf mould. Your two-year-old plants in 32-pots we should think have been too stunted, or grown too much in the shade. You may get them to bloom yet; but if not, either take cuttings next spring, or repeat your plants, first into 16's, and then into 12's. Give plenty of light from August, and lessen water from September, so that the plants do not flag, and we are sure you will have plenty of bloom next winter and spring. *Streptocarpus Rhezii*.—Seeds sown in February in a hotbed, seedlings pricked-off when they can be handled and then potted, first in 60's and then in 40's, will bloom well the first autumn and winter, and almost constantly if more pot room is given them. Afterwards the plants may be divided, or repotted, like any other herbaceous plant; light, rich, sandy loam suits it—as two parts of loam, one of fine old dried leaf mould, and nearly one of silver sand. The plants get shabby if they are long kept below 45° and flourish better in a temperature from 50° to 55°. A regular stove heat is rather too much for them. The other plants we cannot make out. You can have the *Cottage Gardener's Dictionary* free by post for 5s. 8d.

**PLANTING RHODODENDRONS** (*A. B., Westmoreland*).—You are running a very great risk in planting a large piece of newly-trenched common soil with "the best kinds of scarlet Rhododendrons," which you say you want cheap; but ten to one, if you have any notion of the prices. They are from 7s. 6d. to 10s. 6d. a-piece, and you will not get them one farthing cheaper. Brilliant is one of the best of them, then Prince Imperial, Charlotte Bronte, Sunset, The Colonel, Sultan, Lucifer, Robert Burns, Marmion, Lago, Hildebrand, Blandytanum (one of the best and cheapest of them), and Erectum. If you buy these by the score you might probably get them at from £3 10s. to £5 per dozen, and the best Hollyhocks are in "D. Deal's" list of first-class sorts a month back. Public journalists would act most unfairly if they were to recommend one tradesman in preference to another. Any "house" in our advertising columns can supply any plant or seed that is on sale; as, if the firm should not have it, the firm knows best where to procure it.

**PLANTING FLOWER-PATTERNS** (*Kate*).—Your three ways of planting would be almost equally effective, but they thus stand in our estimation:—No. 3 good; No. 1 better; and No. 2 best.

**PROPAGATING CINERARIA MARITIMA** (*W. W.*).—The spring is the best time to increase *Cineraria maritima* in a hotbed, the cuttings to be made of the smallest side shoots, about 3 or 4 inches long, and to be put in one row only round the sides of a No. 48-pot, in one-half sand and one-half any light soil, with a thin covering of sand all over the top of the pot—that is, to keep in the moisture; and keep the place round the cuttings as free from damp and dirt as possible. Your flower is from a *Valloia purpurea*, much blanched for want of more light and air.

**RED CURRANTS FAILING** (*R. J. B.*).—It is difficult to account for your Red Currants failing as you describe at the time of ripening. We have often enough had them what is called blighted—i.e., a considerable portion of the berries in each bunch either do not set perfectly, or fall-off immediately afterwards, the remainder swelling-off the full size. Give manure, and by pruning a little harder, as we think your failure at the time of ripening arises from the soil or plants becoming exhausted and unable to perfect the fruit. Generally speaking, the Red Currant likes a deep, rich, garden soil, not too retentive of water, and at the same time not too dry. Mulching will doubtless do good; but we would advise manure during the winter, and a more than ordinary thinning of the shoots. Observe in digging not to cut the roots. A very slight digging with the fork ought to be given, as we are far from certain that your present failure does not arise from the mutilation of the roots, and this would account for it at once.

**COMFORTABLE COTTAGES** (*A Subscriber*).—We congratulate you on your purchase and purpose. You can have C. V. Bernard's book entitled "Healthy Moral Homes," if you enclose 3s. 4d. in postage stamps to our office. It gives plans and estimates for the construction of good cottages for from £50 to £150, with such full details that you cannot fail to please yourself.

**FLOWERS MENTIONED BY SHAKESPEARE** (*W. W.*).—There is a volume upon this theme, but we forget the names both of the book and of the author. The "Gardener's Magazine of Botany" died ten years since. We presume from the site selected that there will be a garden attached to the Paris Crystal Palace.

**PRUNING AND TRAINING PLUM TREES** (*A Beginner*).—If your maiden trees are against a wall, we would say, Do not cut them in much if they are only recently planted, but just tip them; and in spring, when the buds break, pick-off all the top ones, one or two a-day, so as only to reserve the lower ones, and by-and-by the shoot will die, and may be cut-off a little above the highest young shoot left on. If, however, your trees have stood a year where they now are, they may be cut-in to about a foot, or less if weakly. A careful spurting is better than laying-in such large quantities of young wood each year, and is attended with less trouble, looks better, and bears quite as well. If your wall is above 8 feet high you may train them fan-shaped; if lower, then horizontally. The Green Gage is not so vigorous a grower as some of the others, and ought to have the best position. You will see more particulars about treating such trees in our back Numbers, and very likely further instructions will appear in future ones.

**WINTER-PRUNING YOUNG PEACH, PLUM, AND CHERRY TREES** (*A Lover of Fruits*).—Your young trees, consisting of five shoots each, may be cut-in thus:—The bottom two laid horizontally and left longest; the next two, trained diagonally at an elevation of about 30°, may be 3 inches shorter than the bottom shoots, and the central shoot of all may be cut-in to about 8 inches or about half the length of the middle shoots. This may be done at once if the trees be healthy, and the buds all likely to grow; but if the trees have been infested with mildew, or otherwise diseased, it would be better not to cut them until the next year. But be careful in noting the swelling and bursting of the wood-buds, and pinch the end ones all out by one at a time, beginning at the tip and working backwards—say one bud a-day. By doing this the end of the shoot dies, and may be cut-off when all appearance of life has left it. This practice requires attention, and the operation must not be all done at once. Be careful to destroy every appearance of insect in the early growth of next year, and it is likely you will have nice trees by the end of it, attending to other instructions that will be given from time to time on such matters.

**NAMES OF FRUITS** (*P. Lang*).—1, Gilgizi; 2, Catillac; 3, Marie Louise; 4, Beurtic Rance; 5, Easter Beurrd; 6, Glou Morecan; 8, Too decayed. The large Apples are Blenheim Orange, and the small Apples Yellow Ingestrie. The numbers were rubbed off.

**NAMES OF PLANTS** (*F. B. A.*).—1, 2, 3, unnameable scraps of Conifers—1 and 2, apparently *Thuja*; 3, a *Juniper*; 4, *Berberis Darwinii*. (*H. D.*)—*Lastrea tenericulis*, not *paludosa*. (*G. P. S.*)—No one can name such imperfect scraps. No. 1 looks like a *Cystopteris*, but there is no evidence; 2 is *Asplenium lanceolatum*; 3 is some deformed growth of *Polystichum angulare*. (*Bishop*).—1, not recognized; 2, one of the *Mitre Aloes*, and apparently *A. distans*. (*E. G.*)—Apparently *Atriplex haelimus*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### THE CRYSTAL PALACE POULTRY EXHIBITION.

THE Exhibition of Poultry, held in December at the Crystal Palace, has always proved itself to be one of the best collections of poultry brought before the public during the season; and, consequently, the attention of those amateurs desirous of improving their breeding stock, or of others requiring general information relative to poultry-culture, has been especially directed to this annual meeting. As a whole, the Show just concluded holds quite as honourable a position in public estimation as the best of those preceding it.

As the entries were heavy—viz., 915 pens of Poultry, 227 pens of Pigeons, and about 120 pens of Rabbits, it was obvious the

office of arbitrator would not in any case prove a sinecure, more particularly as regarded the well-filled classes of poultry. To meet this contingency Messrs. Andrews, Baily, and Hewitt were the selected officials; but, most unfortunately, at the last moment the first-named gentleman found it impossible to be present; and, therefore, the whole onus of judging so large a collection rested with Messrs. Baily and Hewitt alone. In no wise depressed by mishap, but encouraged by a day of brilliant sunshine, these gentlemen took the matter at once spiritedly in hand, finishing their labours long before daylight disappeared. When our readers reflect, that at the Birmingham Show somewhat above three hundred pens of Game fowls are judged by other parties specially appointed for these classes, it must be obvious, when, as in this instance, the Game fowls are added to the category of arbitrations, the labour must be greatly enhanced, more particularly as Game fowls require a greater amount of time to arbitrate upon; as, to do justice, the "handling" of all the best of the specimens exhibited is indispensable.

The *Game* classes at the Crystal Palace Show proved themselves on examination to be unusually praiseworthy.

In the *Buff Cochins*, which headed the catalogue, the entry was a good one, and excited a great deal of attention, the birds being mostly of high character. A remark may be made as to Mr. Bates's first-prize pen, which is also to a great extent applicable to others. It was surprising to see how much they had retrograded in appearance since the week previous when competing at Birmingham.

In the *Buff Chickens*, Mr. Kelleway's pen was remarkably good; but we have oftentimes seen birds throughout this class shown in better trim at the winter Crystal Palace Shows.

As a whole we were quite disappointed in the adult *Partridge-coloured Cochins*; in fact, the Judges must have been of like opinion, as a prize was withheld altogether. The *Chickens* of this variety were much superior.

The *White Cochins* were better than customary. We noticed particularly some chickens that will most probably figure highly in the prize lists of next season.

The *Brahma* classes were as perfect throughout as we have yet seen.

The great feature of the Show was the *Dorkings*; and here Lady Holmesdale took not only precedence, but left scarcely a prize unappropriated otherwise than to her extensive yards. All her ladyship's birds were shown in extraordinary condition; but it occurred to us that, if less fattened, they would have been more useful as store fowls.

The *White Dorkings* mustered better than on any previous occasion.

The class for *Dorking Cocks* was quite as good as have ever been shown at this Meeting.

In the *Spanish*, it struck us that the birds were not so well recovered from their moult as we anticipated; but the quality of the principal portion of them was of the highest character.

In the *Game* fowls were to be seen *Piles* far beyond accustomed merit, the *Brown Reds* having a superiority over the *Black-breasted*, and the *White* ones being decidedly an improvement on those of former years.

From some cause or other, the *Hamburgs* were not so good as we had hoped for; indeed, this was one of the weakest points in the Show. Perhaps it may have arisen from a large number of our best breeders having reserved their best birds for the Darlington Show, which happened simultaneously, a laudable desire to win at their own doors being a prevailing sentiment. Taken in this view, as the north is the stronghold of these breeds, the result seems not to be wondered at.

The *Poland* classes were perfect, every breed being equally creditable; and we rejoice to find these valuable varieties becoming more generally prized, as few kinds of poultry lay better, nor can any be more pleasurable adjuncts to a villa residence.

The *Geese* and *Turkeys* were prodigies of breeding and management; but the *Ducks* were certainly not so favourable in the scale as we have repeatedly met with.

The *Sebright* and the *Game Bantams* were the best varieties of these "little pets;" but some most extraordinary *Japanese*, *Black Silkies*, and *Friesland Bantams* are worthy of favourable mention also.

The *Ornamental Water Fowls* and the extensive class of various breeds of *Pheasants* were not without many admirers, and added very materially to the attractiveness of the Meeting.

We must not let this opportunity slip of speaking in the highest terms of the general management of the Show on this

occasion. Through the indefatigable energy of the Secretary, Mr. Houghton, everything was done well and in order; the catalogues were ready at the opening of the Show, and every card connected with the prize list was properly affixed. As this attention was so highly appreciated, we hope for its continuance in future years.

**COCHIN-CHINA (Cinnamon and Buff).**—First and Second, H. Bates, Birmingham. Third, E. Musgrave, Aughton, near Ormskirk. Commended, Mrs. H. Fookes, Blandford. *Chickens*.—First, J. Kelleway, Isle of Wight. Second, G. Johnson, Surrey. Third, Rev. G. Gilbert, Norwich.

**COCHIN-CHINA (Brown and Partridge-feathered).**—First, T. Cartwright, Oswestry. Second, B. J. Ford, Exeter. Third, withfield. *Chickens*.—First, T. Stretch, Ormskirk. Second, R. Adams, Birmingham. Third, E. Tudman, Whitechurch, Salop.

**COCHIN-CHINA (White).**—First, Master G. Chase, Birmingham. Second, W. Dawson, Hopton. *Chickens*.—First, Master G. Chase. Second, G. Lamb, Wolverhampton. Highly Commended, G. Lamb, Couisced, Master G. Chase.

**COCHIN-CHINA COCKS (Coloured and White).**—First, E. Tudman, Whitechurch, Salop. Second, H. Ransom, Ipswich. Highly Commended, J. W. Kelleway, Isle of Wight. Commended, Mrs. H. Fookes.

**BRABMA POOTRA.**—First, C. Priest, Muntham Court, Worthing. Second, R. Teabay, Fulwood. Commended, R. Teabay. *Chickens*.—First, C. Priest, Second, R. Teabay. Highly Commended, J. K. Fowler, Aylesbury; J. Pares, Cherisey. Commended, G. Lotham, Slough; J. Wright, Suffolk. *Cocks*.—First, J. Wright, Suffolk. Second, J. Hinton, Bath. Highly Commended, J. K. Fowler, Aylesbury. Commended, R. Teabay, Fulwood.

**DORKING (Coloured).**—First and Second, Viscountess Holmesdale, Linton Park, Staplehurst. Third, H. Lewly, Sussex. Fourth, A. Potts, Chester. Highly Commended, Hon. W. W. Vernon, Staffordshire; H. Beal, Slough; J. Frost, Parham; S. Griggs, Essex; K. Warner, Brooifield. Commended, H. Lingwood, Suffolk; C. Smith, Salisbury.

**DORKING HENS.**—First, Viscountess Holmesdale, Staplehurst. Second, Mrs. Craigie, Chigwell, Essex. Highly Commended, T. S. Brown, Chard, Somerset. Commended, Lady M. Macdonald, Liphook; Sir J. Paxton, M.P.; Rev. M. Amphlett, Church Leuch Rectory, near Evesham; W. Brown, Northampton; E. H. Garrard, Worcestershire. *Chickens*.—First and Second, Viscountess Holmesdale, Linton Park. Third, C. H. Wakefield, Malvern Wells. Fourth, Hon. W. W. Vernon, Staffordshire. Highly Commended, J. Frost, Parham; G. Griggs, Essex; H. Lingwood, Suffolk; Mrs. St. John, Oakley. Commended, Lady M. Macdonald; Rev. M. Amphlett; G. Griggs; H. Lingwood.

**DORKING PULLETS.**—First, C. Priest, Muntham Court, Worthing. Second, Viscountess Holmesdale, Linton Park. Highly Commended, Sir J. Paxton, M.P., Sdenham; E. H. Garrard, Worcestershire; Miss Milne, Kelso, N.B.; C. H. Wakefield, Malvern Wells. Commended, J. Simmons; T. Tatham, Northampton.

**DORKING (White).**—First, Mrs. Beardmore, Fareham, Hants. Second, J. Robinson, Vale House, near Garstang. Highly Commended, Mrs. Beardmore; H. Lingwood, Suffolk. *Chickens*.—First, Miss E. Hodson, Bridge-water. Second, Lady M. Legge, Dorking, Surrey. Highly Commended, H. Lingwood; J. Robinson, Garstang.

**DORKING COCKS (Coloured and White).**—First, Viscountess Holmesdale, Linton Park. Second, T. L. Brown, Chard, Somerset. Third, T. Tatham, Northampton. Highly Commended, Viscountess Holmesdale; Major W. S. Altham, Somerset; T. L. Brown; W. Copple, Prescott; C. Priest, Worthing; T. Tatham. Commended, Lady M. Macdonald, Liphook; T. Tatham.

**SPANISH.**—First, J. Martin, Claines, Worcester. Second, J. K. Fowler, Aylesbury. Third, R. Wright, Highgate. Fourth, T. L. Brown, Somerset. Commended, R. Teabay, Preston. *Chickens*.—First and Third, J. R. Rodbard, Wrington, Bristol. Second, R. Teabay. Fourth, J. K. Fowler, Aylesbury. Highly Commended, J. Barry, Wadsworth Road; H. Dawson, Camberwell; H. Lane, Bristol; R. B. Postans, Essex; J. Smith. Commended, J. Barry.

**SPANISH HENS AND PULLETS.**—First, J. Martin, Claines, Worcester. Second, Mrs. Craigie, Chigwell, Essex. Highly Commended, C. Cayford, Northampton; J. K. Fowler, Aylesbury; J. W. Smith, Oundle. Commended, W. Parrott, Aylesbury.

**SPANISH COCK.**—First, J. R. Rodbard, Wrington, Bristol. Second, H. Lane, Bristol. Third, A. Heath, Wilts. Highly Commended, W. Parrott, Aylesbury; J. W. Smith, Oundle. Commended, J. K. Fowler, Aylesbury; A. Heath; R. B. Postans, Essex; T. P. Wood, jun., Chesterfield; R. Wright, Highgate.

**GAME (White and Piles).**—First, J. Fletcher, Stoneclough. Second, A. Gny, Grantham. Third, H. Baker, Worcester. Highly Commended, S. Matthew, Stowmarket. Commended, R. R. Clayton, Slough. *Chickens*.—First, J. Wilders, jun., Grantham. Second, Rev. G. S. Cruwys, Devon. Third, A. Ewen, Melton Mowbray. Highly Commended, H. Baker, Worcester. Commended, J. Fletcher, Stoneclough; Messrs. Phillips & Wiuwood, Worcester.

**GAME (Black-breasted Reds).**—First, J. Hindson, Liverpool. Second, Rev. F. Watson, Woodbridge, Suffolk. Third, E. Archer, Malvern. Highly Commended, H. Lee, Isle of Wight; A. H. Philpott. Commended, J. Firth, Halifax. *Chickens*.—First, Hon. W. W. Vernon, Staffordshire. Second, S. Matthew, Stowmarket. Third, E. Burton, Cornwall. Highly Commended, Rev. G. S. Cruwys, Devon; W. T. Everard, Ashby-de-la-Zouch; T. Moss, Ponton-le-Fyde. Commended, H. Heffer, Suffolk; W. Rogers, Woodbridge, Suffolk.

**GAME (BROWN-BREASTED AND OTHER REDS EXCEPT BLACK-BREASTED).**—First, Rev. F. Watson, Woodbridge, Suffolk. Second, E. Archer, Malvern. Third, V. Sandford, Plymouth. Highly Commended, E. Burton, Cornwall; V. Sandford. Commended, J. Firth, Halifax. *Chickens*.—First, E. Archer. Second, T. Moss, Ponton-le-Fyde. Third, B. Vaughan, Salop. Highly Commended, A. Heath, Calne, Wilts. Commended, R. Swift, Southwell, Notts.

**GAME (Duckwings and other Greys and Blues).**—First, G. W. Langdale, Beverley. Second, S. Matthew, Stowmarket. Third, J. Bradwell, Southwell, Notts. *Chickens*.—First, Hon. W. W. Vernon, Staffordshire. Second, R. Goodwyn, Suffolk. Third, W. Burgess, Dorset. Highly Commended, Hon. W. W. Vernon; E. Burton, Cornwall. Commended, W. Dawson, Selly Oak; H. Griffiths, Worcester; V. Sandford, Plymouth.

**GAME (Black and any other variety).**—First, J. Fletcher, Manchester

Second, J. Winn, Coventry. Highly Commended, T. Burman, Hookley Heath. *Chickens*.—First, J. Fletcher. Second, W. Dawson, Selly Oak.

**GAME COCKS.**—First, Hon. W. W. Vernon, Staffordshire. Second, J. S. Butler, Poulton-le-Fylde. Third, S. Matthew, Stowmarket. Highly Commended, J. Fletcher, Manchester; G. Wilders, Graftonham. Commended, E. Archer, Malvern; J. Firth, Halfax.

**HAMBURGH (Gold-pencilled).**—First, W. Cannan, Bradford. Second, N. Barter, Plymouth. Third, W. H. Field. *Chickens*.—First and Third, A. Nuttall, Manchester. Second, A. Houghton, Melton Mowbray. Commended, R. R. Clayton, Slough.

**HAMBURGH (Silver-pencilled).**—First, Rev. T. H. Fellowes, Norfolk. Second, J. Martin, Claines, Worcester. Third, T. H. Turner, Sheffield. *Chickens*.—First, withheld. Second, C. Moore, Poulton-le-Fylde. Third, J. Martin.

**HAMBURGH COCKS (Gold or Silver-pencilled).**—First, G. Botham, Wexham Court, Slough. Second, T. Boniface, Sussex. Highly Commended, Mrs. Pattison, Maldon, Essex. Commended, T. Bowick, Kenilworth.

**HAMBURGH (Gold-spangled).**—First, I. Davies, Birmingham. Second, H. Carter, Holmfirth, Yorkshire. Third, S. H. Hyde, Ashton-under-Lyne. Commended, W. Cannan, Bradford. *Chickens*.—First, S. H. Hyde. Second, Rev. T. L. Fellowes, Norfolk. Third, G. Brook, Huddersfield. Commended, I. Davis.

**HAMBURGH (Silver-spangled).**—First, W. Cannan, Bradford. Second, J. Dixon, Bradford. Third, H. Carter, Holmfirth, Yorkshire. *Chickens*.—First, T. L. Brown, Chard, Somerset. Second, E. Collinge, Middleton, near Manchester. Third, J. Dixon, Bradford. Commended, Viscountess Holmesdale, Linton Park.

**HAMBURGH COCKS (Gold or Silver-spangled).**—First, Mrs. Pattison, Maldon, Essex. Second, Mrs. Beardmore, Fareham, Hants.

**POLISH (Black with White Crests).**—First and Third, T. P. Edwards, Lyndhurst, Hants. Second, H. Carter, Holmfirth, Yorkshire. Highly Commended, J. Dixon, Bradford; T. P. Edwards. Commended, G. Ray, Lyndhurst, Hants.

**POLISH (Gold).**—First, J. Dixon, Bradford. Second and Third, Mrs. Pettat, Overton Hampshire

**POLISH (Silver).**—First, Mrs. Blay, Worcester. Second, J. Heath, Nantwich, Cheshire. Third, G. C. Adkins, Birmingham. Highly Commended, G. C. Adkins; J. Dixon, Bradford. Commended, P. Hardy, Bradford.

**POLISH COCKS.**—First and Second, G. C. Adkins, Birmingham. Commended, G. C. Adkins.

**MALAY.**—First, N. Sykes, jun., Mile End. Second, J. Rumsey, High Street, Shadwell. Commended, Miss C. H. Ballance, Taunton. *Chickens*.—First, N. Sykes, jun. Second, W. Hill, Bethnal Green. Highly Commended, J. Rumsey.

**ANY OTHER DISTINCT BREED.**—First, S. Waters, Woodbridge Road, Ipswich. Second, P. P. Cother, Salisbury. Third, E. Collinge, Manchester. Fourth, Mrs. Blay, Worcester. Highly Commended, E. Pigcon, Lymington; E. Hutton, Pudsey, near Leeds; Mrs. Prescott, Southampton; W. Manfield, jun., Dorchester. Commended, C. Baker, Chelsea; C. Boquet, Paris.

**BANTAMS (Gold-laced).**—First, M. Leno, jun., Dunstable. Second, E. Jones, Clifton, Bristol. Commended, Rev. G. S. Cruwys, Devon.

**BANTAMS (Silver-laced).**—First, Rev. G. S. Cruwys, Devon. Second, E. Jones, Clifton, Bristol. Highly Commended, M. Leno, Dunstable. Commended, T. H. D. Bayly, Biggleswade, Beds.

**BANTAMS (White, Clean Legs).**—First, T. H. D. Bayly, Biggleswade, Beds. Second, Mrs. F. Tearle, Kittering. Highly Commended, J. Rumsey, Shadwell. Commended, Rev. G. S. Cruwys, Devon; H. Loe, Isle of Wight.

**BANTAMS (Black, Clean Legs).**—First, E. Hutton, Pudsey, near Leeds. Second, R. Brotherhood, jun., Almondsbury. Highly Commended, Miss J. Hodson, Bridgewater. Commended, S. Ridley, Clayton, Sussex.

**BANTAMS (Game).**—First, J. W. Kelleway, Isle of Wight. Second, T. H. D. Bayly, Biggleswade, Beds. Third, M. Turner, Preston. Highly Commended, W. S. Forrest, Greenhithe, Kent; J. W. Kelleway; R. B. Postans, Essex; V. Sandford, Plymouth. Commended, H. Bates, Birmingham; M. Leno, jun., Dunstable.

**BANTAMS.**—First, Mrs. H. Fookes, Whitechurch, Blandford. Second, Rev. P. W. Storey, Daventry. Highly Commended, G. Daft, Southwell, Notts. Commended, Capt. F. Marten, St. Albans; W. Brown, Northampton.

**BANTAM COCKS.**—First, J. W. Kelleway, Isle of Wight. Second, W. S. Forrest, Greenhithe, Kent. Highly Commended, Capt. F. Marten, St. Albans; T. H. D. Bayly, Biggleswade; T. Moss, Poulton-le-Fylde. Commended, R. B. Postans, Essex.

**GESE (White).**—First, W. Manfield, jun., Dorchester. Second, G. Daft, Southwell, Notts. Highly Commended, Mrs. E. Herbert, Worcester; W. Manfield, jun.

**GESE (Grey and Mottled).**—First and Second, J. K. Fowler, Aylesbury. Highly Commended, W. Peters, Devonshire.

**DUCKS (Aylesbury).**—First and Third, J. K. Fowler, Aylesbury. Second, J. Harris, Brighton. Highly Commended, Mrs. G. H. Cook, Cheshire; J. K. Fowler; Mrs. Pattison, Essex; E. Shaw, Oswestry.

**DUCKS (Rouen).**—First and Second, J. K. Fowler, Aylesbury. Third, C. Priest, Worthing. Highly Commended, Capt. Barthropp, Wickham Market; Rev. T. L. Fellowes, Norfolk; J. H. Braikenridge, Bristol; W. H. Dennison; Mrs. H. Fookes.

**DUCKS (Black).**—First, T. Tynce, Halstead, Essex. Second, J. W. Kelleway, Isle of Wight. Third, J. K. Fowler, Aylesbury. Highly Commended, Mrs. E. Herbert, Worcester; E. Phillips, A. Smart, Blackheath Park; W. Syson, D-bach; Mrs. Wolferstan, Tamworth.

**DUCKS (Any other variety).**—First, A. S. Yates, Aylesford, Hants. Second, T. H. D. Bayly, Biggleswade. Third, Mrs. Wolferstan, Tamworth. Highly Commended, C. Baker, Chelsea.

**ORNAMENTAL WATER FOWL.**—First, Second, and Third, C. Baker, Chelsea. **TURKEYS.**—First, J. Smith, Grantham. Second, Mrs. A. Guy, Grantham. Third, Mrs. H. Fookes, Blandford. **POULTS.**—First, J. Smith. Second, Rev. T. L. Fellowes, Norfolk. Third, W. Manfield, jun., Dorchester.

**PRESANTS (Gold and Silver).**—First, A. S. Yates, Aylesford, Hants. Second, Mrs. Welsh, Twickenham. Commended, Mrs. Pattison, Essex; J. Houghton, Melton Mowbray.

**PRESANTS (Any other variety).**—First, C. Baker, Chelsea. Second, C. Boquet, Paris. Commended, A. S. Yates, Aylesford, Hants; Mrs. C. Baker; M. Leno, jun., Dunstable.

#### PIGEONS.

**POWENS ON CROPPERS (Any colour).**—*Cock*.—First, T. H. Evans, Lambeth Walk. Second and Third, H. Fulton, Deptford. Very Highly Com-

mended, E. L. Corker, Croydon. Highly Commended, E. L. Corker; Mrs. Evans, Lambeth Walk. Commended, R. Fulton, Deptford. (An excellent class.) *Hens*.—First, E. L. Corker. Second, F. Elze, Bayswater. Third, T. H. Evans. Highly Commended, E. L. Corker; T. H. Evans; C. J. Samuels, Manchester. Commended, T. H. Evans. (A good class.)

**CARRIERS.—Cocks (Black and Dun).**—First, E. L. Corker, Croydon. Second, F. Waller, Turnham Green. Third, P. Goss, Plymouth. Very Highly Commended, P. Goss. Highly Commended, P. Goss; J. F. Mortimer, Plymouth. Commended, Major F. C. Hassard, Hilsa, near Portsmouth; T. Colley, Sheffield. (A very meritorious class.) *Cocks (Any other colour).*—First, E. J. J. Holmes, Lewisham. Second, J. C. Ord, Piccadilly. *Hens (Black and Dun).*—First and Second, E. L. Corker. Third, P. Goss. Very Highly Commended, J. F. Mortimer. Commended, J. F. Mortimer. *Hens (Any other colour).*—First and Second, W. H. Elmonds, Westminster.

**DRAGONS.—Blue.**—Prize, G. F. Treataway, Paddington. *Any other colour.*—Prize, F. Esquilant, Oxford Street. Commended, Master E. Altham, Somerset.

**ALMOND TOMBERS.**—First, E. L. Corker, Croydon. Second withheld. Third, G. J. Harris, Wanwick.

**SHORT-FACED MOTTLES.**—First, E. L. Corker, Croydon. Second, F. Elze, Bayswater. Commended, J. Ford, London.

**SHORT-FACED BALDHEADS.**—First and Second, F. Esquilant, Oxford Street. **SHORT-FACED BEARNS.**—First, F. Esquilant, Oxford Street. Second, J. H. Eden, Hammersmith. Highly Commended, G. R. Ellenden, Greenwich. Commended, F. Elze, Bayswater.

**SHORT-FACED TOMBLERS (Self-colour).**—First, W. H. C. Oates, Newark, Notts. Second, F. Esquilant, Oxford Street.

**KITES, AGATES, DUNS, AND GRIZZLES.**—Prize, E. T. Archer, Norwood. Commended, F. Elze, Bayswater.

**JACOBIENS.**—First, F. Esquilant, Oxford Street. Second, H. Morris, Forest Hill, Kent.

**OWLS.—Blue or Silver.**—Prize, H. Morris, Forest Hill, Kent. Highly Commended, G. Fleming, Peckham. *Yellow or any other colour.*—Prize, F. Elze, Bayswater.

**NUNS.**—First, F. Elze, Bayswater. Second withheld. **TURBITS.**—First, G. Fleming, Peckham. Second, G. F. Nicholls, Cheltenham. Third, Major W. S. Altham, Somerset.

**PANTALS.—Black.**—Prize, J. W. Edge, Aston New Town, Birmingham. *White.*—Prize, J. W. Edge. *Blue.*—Prize, J. W. Edge.

**MAGPIES.**—First, E. M. Pierce, Taunton. Second, W. H. Beadon, Taunton. Third, F. Elze, Bayswater.

**TRUMPETERS.—Black Mottled.**—Prize, F. Elze, Bayswater. *White or any other Colour.*—Prize, R. Swift, Southwell, Notts. Highly Commended, Messrs. Guest & Coleman, Birmingham.

**SPANISH AND LEOPARD RUMTS.**—First, T. D. Green, Saffron Walden. Second, F. Key, Beverley. Highly Commended, J. E. Mason, Lincoln. (A good class.)

**FOR ANY NEW OR DESERVING VARIETY NOT BEFORE MENTIONED.**—First, A. L. Silvester, Birmingham. Second, A. Heath, Caine. Third, H. Morris, Forest Hill, Kent. Fourth, J. Simmons, Fareham. Very Highly Commended, Mrs. C. Baker, Chelsea (Californian Quails). Commended, C. Baker (Wonga Wonga).

#### RABBITS.

**LONGEST EARS.**—First, Second, and Highly Commended, Messrs. Guest and Coleman, Birmingham. Commended, J. J. Olley, Plumstead.

**BLACK AND WHITE.**—First, R. Cook, Denmark Hill, Camberwell, Second, C. Sellen, Surrey. Highly Commended, C. Sellen. Commended, C. Ashdowne, Brighton; R. Cook; J. Hale, Millbank; H. Hinds, Norwich; A. Stedman, Surrey.

**YELLOW AND WHITE.**—First, J. Hincks, jun., Birmingham. Second, J. Harris, jun., Kent. Highly Commended, J. Hincks, jun. Commended, C. Ashdowne, Brighton; A. H. Bunnett, Deptford.

**TORTOISESHELL.**—First, J. Sutton, Pembroke. Second, R. Cook, Camberwell. Commended, W. Griffin, Plumstead; Messrs. Guest & Coleman, Birmingham; J. Hale, Millbank; H. Hinds, jun., Norwich; T. T. Wose, Essex.

**BLUE AND WHITE.**—First, H. Hinds, jun., Norwich. Second, C. Sellen, Surrey. Highly Commended, Messrs. Guest & Coleman, Birmingham. Commended, J. B. Mason, Lincoln; C. Sellen.

**GREY AND WHITE.**—First, R. Cook, Camberwell. Second, A. Stedman, Oxford, Surrey. Highly Commended, G. Lewis, St. John's Wood. Commended, R. Cook; Miss H. Hawksley, Edgeware Road; C. King, St. John's Wood; E. Mapplebeck, Molesey.

**SELF COLOUR.**—First, G. Jones, Birmingham. Second, C. Sellen, Surrey. Commended, J. Daby, Brighton; W. Griffin, Plumstead; J. Hincks, jun., Birmingham; J. J. Olley, Plumstead.

**FOR WEIGHT.**—First, J. Harris, Brighton. Second, J. Daby, Brighton. Highly Commended, W. Hudson, Chesterfield.

**FOREIGN RABBITS.**—First, C. Sellen, Surrey. Second, Master I. de la Saux Simmonds, Winchester.

**JUDGES.**—*Poultry*, Messrs. Baily and Hewitt. *Pigeons*, Messrs. Bellamy and Cottle. *Rabbits*, Messrs. Fox, Housden, and Webster.

#### BANTAM CLASS AT THE CRYSTAL PALACE.

WITH regard to my remarks a few weeks ago about the division of the Game Bantam class at the Crystal Palace Show, I would point out, as further confirming what I then stated, that all three of the prizes were this week carried off in Class 54, by the Red birds, although there were some good Grey and Pile birds shown against them. The fact is, that, as with the larger Game fowls, the Reds must always, as a general rule, win when shown against any other colour, on account of their possessing a hardness of feather and smart tightness which the other colours do not possess in the same degree. That exhibitors of Game Bantams may fairly ask to have the class divided is evident, for no less than thirty-seven pens were shown at the

Palace this week in Class 54 alone, though classes 50 to 53 inclusive could only muster thirty pens between them. Again, Class 54 paid for entrance money £11 2s, and received £5 2s. for prizes; whilst the other classes I have mentioned paid altogether only £9 for entries, though they received for prizes £16.—P.

LEEDS POULTRY SHOW.

THE annual Show of fat cattle, sheep, pigs, poultry, &c., in connection with the Leeds Smithfield Association, took place in the Leeds Smithfield Cattle Market, on Tuesday, Wednesday, and Thursday last. The Exhibition was held under cover, the place being decorated with flowers, evergreens, banners, statuary, &c., and illuminated in a brilliant manner, producing a very pleasing effect. Notwithstanding unfavourable weather, on the first day there was a large attendance of visitors, and the Show throughout was a decided success.

The Poultry and Pigeons numbered 384 pens.

*Dorkings* formed the first class. Mr. Berwick's were good birds. In Mr. Dixon's highly commended pen the hens were slightly deficient in matching, yet we thought the birds should have obtained a higher position. *Black Spanish* were not particularly good. The first prize was awarded to chickens which we thought should have given place to Mr. Brown's adults. In *Cochins* Mr. Stead's first-prize Partridge were excellent. Good *Buffs* obtained second and third. *Black and Brown Red Game* competed together, the entries numbering thirty-two. Mr. T. J. Charlton's were very fine *Brown Red* chickens; the other prizes also being awarded to *Brown Reds*, while *Black Reds* received high commendation. *Duckwings* carried off the prizes in the class for "Game any other variety." *Gold-pencilled Hamburgs* formed a good class with close competition, the prize birds deserving their position. *Silver-pencilled Hamburgs* were also fairly represented. Mr. Dixon's was an excellent pen. *Gold-spangled Hamburgs* were numerous and good, Mr. N. Marlow's being especially so. *Silver-spangled Hamburgs* were an average lot, but we thought the third prize a mistake—in fact, the birds were deficient in every respect. In *Polands*, Miss E. Beldon's were capital *Silvers*. Good *Black Hamburgs* took first in "Any other variety," and *Brahmas* second. The prize *Black Bantams* were excellent. *White Bantams*, with the exception of the first-prize pen, were inferior. *Game Bantams* were good. Mr. Dixon showed a good pen of *Gold-laced* in "Any other variety of Bantams."

*Turkeys* and *Geese* were average classes.

*Ducks* were good. Mr. Kell's *Aylesburys* deserve especial notice.

There was a good show of *Pigeons*. Mr. Sylvester sent good *Dun Carriers*. In *Pouters*, Mr. Robson's *Whites* were once more successful. In *Almond Tumblers* we fancied Mr. Sylvester's second-prize pen should have been first. Mr. Cannan's *Blue Owls* were very good. *Jacobins* were an average lot, the first-prize pen being rather coarse in head and beak. In *Trumpeters* both prizes went to excellent *Blacks*. The first-prize pen being unusually good.

The following is the prize list:—

- DORKINGS**.—First and Second, H. W. B. Berwick, Helmsley. Third, G. Whitwell, vendall. Highly Commended, J. Dixon, Bradford. Commended, F. Key, Beverley.
- SPANISH**.—First, T. Greenwood, Dewsbury. Second, E. Brown, Sheffield. Third, D. Illingworth, Surley, Otley. Highly Commended, E. Smith, Middleton. M. Incester. Commended, Lady Hawke, Womersley Park.
- COCHIN-CINA**.—First, T. B. Stead, Leeds. Second and Third, H. and G. Newton, Leeds. Highly Commended, J. Bell, Thirsk. Commended, E. Smith.
- GAME** (Black Breasted and other Reds).—Cap and First, T. J. Charlton, Bradford. Second, J. Hodgson, Bowling. Third, T. H. Dodds, Ovensden. Highly Commended, W. Byles, Beverley; C. W. Brierly, Rochdale; J. Firth, Halifax; A. J. Dodds, Ovensden.
- GAME** (White and Piles).—First and Second, H. C. Mason, Drighlington. Third, H. Adams, Beverley.
- GAME** (Any other variety).—First, H. Adams, Beverley. Second, J. Hodgson, Bowling. Third, R. H. Jones, Badsworth Hill. Highly Commended, A. J. Dodds.
- HAMBURON** (Gold-pencilled).—First, H. Pickles, jun., Earby. Second, W. H. Dyson, Horton. Third, J. Firth, Halifax. Highly Commended, W. H. Dyson. Commended, R. Hemingway, Shelf.
- HAMBURON** (Silver-pencilled).—First, J. Dixon, Bradford. Second, J. Sunderland, Coley Hall. Third, W. Cannan, Bradford. Highly Commended, S. Fielding, Middleton. Commended, H. Pickles, jun.
- HAMBURON** (Gold-spangled).—First, N. Marler, Denton. Second, J. Ashcroft, Ashton. Third, G. D. Mann, Hunslet. Highly Commended, J. Dixon; T. Birdsall, Woodhouse Carr.
- HAMBURON** (Silver-spangled).—First, E. Smith. Second, J. Dixon. Third, M. Worsley, Meltham. Highly Commended, W. Cannan. Commended, J. Crookes, Meltham.

- POLAND** (Any variety).—First, Miss E. Beldon, Bradford. Second and Third, J. Dixon. Highly Commended, D. Illingworth.
- ANY OTHER VARIETY**.—First, S. Butterfield, Kettleby (Black Hamburg). Second, Lady Hawke. Third, J. Dixon. Prize, T. W. Hill, Heywood (Crisp Coar).
- FARMYARD CROSS**.—First, J. Bilton, Cottingham. Second, T. Jolly, Warby.
- BANTAMS** (Black).—First, E. Hutton, Pudsey. Second, R. M. Stark.
- BANTAMS** (White).—First, E. Holdsworth, Leeds. Second, A. and B. Farrar, Bramley.
- BANTAMS** (Game).—First and Second, J. Crookland, jun., Wakefield. Highly Commended, S. Brain, Potternewtown; T. Carr, Beotham.
- BANTAMS** (Any other).—First, J. Dixon, Bradford (Gold-laced). Second, R. M. Stark, Hull (Silver-laced).
- GUINEA FOWLS**.—First, Lady Hawke, Womersley Park. Second, J. Dixon. Third, Miss E. Beldon, Bradford.
- TURKEYS**.—First, Lady Hawke. Second, R. M. Stark. Third, J. Dixon.
- GESE**.—First, H. Bentley, Oulton. Second, H. Ambler, Halifax. Third, J. R. Jessop, Hull.
- DUCKS** (Aylesbury).—First, T. E. Kell, Wetherby. Second, T. W. Hill, Heywood. Third, J. Dixon, Bradford.
- DUCKS** (Rouen).—First and Second, J. Dixon. Third, W. R. Renton, Rife.
- DUCKS** (Any other).—First, T. W. Hill. Second, R. M. Stark. Third, J. Dixon.

- EXTRA POULTRY**.—First and Second, J. Dixon.
- PIGEONS**.—*Carriers*.—First, A. L. Sylvester, Birmingham. Second, S. Robson, Brotherton. *Pouters*.—First, S. Robson. Second, W. Cannan, Bradford. *Almond Tumblers*.—First, W. B. Van Haansbergen, Newcastle. Second, A. L. Sylvester. *Tumblers* (Any other).—First, J. W. Edge, Birmingham. Second, F. A. and W. J. Stead, Leeds. Highly Commended, W. Cannan; T. Birdsall, Woodhouse Carr. *Owls*.—First, F. Else, Buyswater. Second, W. Cannan. Highly Commended, J. W. Edge. Commended, W. B. Van Haansbergen. *Fantails*.—First, J. W. Edge. Second, F. Key, Beverley. Highly Commended, J. R. Jessop, Hull. *Barbs*.—First, T. Ellington, Woodmasey. Second, A. L. Sylvester. Commended, W. Cannan. *Turbits*.—First, J. W. Edge. Second, J. R. Jessop, Hull. *Jacobins*.—First, W. Carlton, Howden. Second, W. Cannan. *Trumpeters*.—First, T. J. Charlton, Bradford. Second, G. Sharp, Brotherton. Highly Commended, F. Key. *Nuns*.—First, J. W. Edge. Second, T. Birdsall. Highly Commended, F. Else. *Any other Variety*.—First, W. Cannan. Second, H. Yardley, Birminghams. Highly Commended, A. L. Sylvester.

JUDGES.—Mr. Thompson, Dewsbury; Mr. Smith, Halifax; and Mr. Jackson, York.

DARLINGTON EXHIBITION OF DOMESTIC POULTRY.

THE annual meetings of this Society have been for a number of years past considered the best of any held in the northern counties. Much of its present success is, without doubt, to be attributed to the unceasing care and universal courtesy of the Hon. Sec., Mr. Hodaon. Always at his post, and ever willing to advise with those who may experience any temporary difficulty in understanding the general arrangements of the Exhibition—everything goes on under his guidance with perfect order and regularity, the result being that Darlington stands second to none in the kingdom as to the efficiency of its management. Most luckily, on this occasion the railway company had just completed a very large and commodious building, to be used in future years as an engine-house for the locomotives.

The building was liberally placed this year at the service of the Darlington Exhibition. It is very rarely that so perfectly constructed an erection for the purpose can be seen anywhere, the ventilation being perfect; whilst being lighted, not only along the whole roof, but also along each side, the pens stood equally well for the most minute inspection. The pens used were those so well known as Turner's of Sheffield. The whole of the classes were well represented, the fact being universally the theme of congratulation among the poultry amateurs assembled, that it was verging on an impossibility to point out a really indifferent pen.

As customary, *Black Spanish* stood at the head of the collection. The competition was very severe; still Mr. Teebay, of Preston, held his own against all comers both in adults and also in chickens, Mr. Shorthose and Mr. Brown being no mean rivals.

The coloured *Dorkings* were of undeniable excellence, and formed one of the strongest features in the Exhibition; and, independently of the customary class, the extra prizes for pairs of hens and single cock birds brought together a far more extensive and praiseworthy collection than we can call to memory at any local show. Great improvement was also a feature of the *White Dorkings*.

The *Cochins* were represented by picked pens from all the principal yards of our Cochin-breeders; the four pens of *Buffs*, respectively belonging to Messrs. Bates, Shorthose, Tomlinson, and Stretch, being so good as to elicit the strongest expressions of admiration from all visitors. The *Partridge-coloured* ones were scarcely inferior; nor could we view without unfeigned

regret the fact that Mr. Stretch's old Partridge-coloured cock, for so many years past quite unexceptionable in feather, has now most unfortunately moulted "a mottle" on the breast, notwithstanding the hackle and saddle feathers still retain that extraordinary perfection of marking that has placed him hitherto far beyond his fellows. So will it ever be as age and infirmities creep on throughout all animated nature.

In *Game fowls* Mr. Harry Adams, of Beverley, monopolised the lion's share with birds that were shown in faultless condition. The fact is also pleasing to refer to, that the specimens shown by many other exhibitors were closely pressing in the rear. As the time of year would naturally lead to suppose, the Brown Reds stood quite in advance of the Black-breasted ones.

The greater proportion of the *Hamburgs* were very perfect, and showed that great attention must have been paid to the breeding of them.

The *Polands* are evidently quite looking-up, first-rate specimens of every variety abounding.

In the class for "Any distinct variety" were some capital *Brahmas*, and as good *Black Hamburgs* as could be desired.

The class for *Golden and Silver-laced Sebright Bantams* was not only well filled, but with birds of the most excellent character. To report that Mr. Harvey Dutton Bayly, of Biggleswade, took first honours cannot be deemed any reflection on the remainder, for even had that gentleman's yard remained unrepresented, the portion still exhibited would have proved far better than ordinary. The prize pen of *White Bantams*, the property of Mr. John Crossland, jun., were as good as we ever saw, and exhibited in the most praiseworthy condition; Mr. Dixon showing some capital birds in this class also. In the *Black Bantams* Mr. Crossland again stood ahead of all rivals with a capital pen; Mr. Cannan, of Bradford, taking second to him. We hold it a duty, as public journalists, though a most unpleasant one, to refer in terms of the highest reprehension in respect to the pen of *Black Bantams* shown at Darlington, and which at the recent Birmingham Meeting took first prize among a heavy class. At the Darlington Meeting they were "disqualified" by the Judge, Mr. Hewitt, and a card, "Disqualified, the Cock's Legs being Coloured," was affixed to the pen, exciting considerable attention. In proof beyond the possibility of cavil that it was so, the arbitrator carefully washed the right leg perfectly white, leaving the other as unnaturally blackened as when received at Darlington. Of course many jocular remarks ensued, and a most extensive exhibitor of poultry was heard to satirically remark, "Served him right; it's all very well till cotched at it," and other jibes of similar character prevailed. It is not open to question that to have recourse to such illegitimate means to secure undeserved success is a flagrant injustice to the honest exhibitor of poultry; and we quite agree that thus openly to expose them on the spot in every case, altogether irrespective of social position, where a keen sense of honour has failed to restrict them from so doing, will most probably, after a few such facts are elicited, act strongly on those whose minds contemplate similar deceptions. The *Game Bantam* class was a marvel; *Black Reds*, *Brown Reds*, *Duckwings*, *Birchen Greys*, *Blacks*, *Piles*, *Furnaces*, and several other breeds being in the class.

In *Geese* Mrs. Seamons "ruled the roost;" and in *Turkeys* of the present year Mr. Dixon, of Bradford, exhibited the most beautiful cockerel, in respect of size and plumage, imaginable.

The *Ducks* were superior, and a small collection of *Pigeons* contained specimens of the highest character.

**SPANISH.**—First, R. Teabary, Fulwood, Preston. Second, J. Shorthose, Newcastle-on-Tyne. Highly Commended, E. Brown, Sheffield. *Chickens.*—First, R. Teabary, Fulwood. Second, E. Brown. Third, S. Burn, Whitby. Commended, R. S. Branfoot, Sunderland; S. Corner, Sunderland.

**DORINGS (Coloured).**—First, Rev. J. F. Newton, Second, H. W. B. Berwick, Helmsley. Highly Commended, T. Braithwaite, Darlington; Rev. J. F. Newton; T. H. Barker, Hovingham.

**DORINGS (White).**—First, A. Hawe, Hull. Second, W. Grey. Commended, G. Pease, Darlington.

**DORING CHICKENS (Any variety).**—First, T. E. Kell, Wetherby. Second, Rev. J. F. Newton, Kirby. Third, H. W. B. Berwick, Helmsley. Highly Commended, Rev. J. F. Newton. Commended, J. White, Warlaby, Northallerton; G. Pease, Darlington; Rev. J. F. Newton; H. W. B. Berwick; T. H. Barker, Hovingham.

**COCHIN-CHINA (Cinnamon and Buff).**—First, H. Bates, Edghastoa, Birmingham. Second, J. Shorthose, Newcastle-on-Tyne. Highly Commended, H. Tomlinson, Birmingham. Commended, T. Stretch, Ormskirk.

**COCHIN-CHINA (Any other variety).**—First, J. Shorthose. Second, R. White, Sheffield. Highly Commended, T. Stretch, Ormskirk.

**COCHIN-CHINA CHICKENS (Any variety).**—First, T. Stretch, Ormskirk. Second, Rev. G. Gilbert, Claxton, Norwich. Third, H. Bates, Edghastoa. Highly Commended, H. Tomlinson, Birmingham; R. White, Sheffield. Commended, J. Shorthose, Newcastle-on-Tyne.

**GAME (Black-breasted and other Reds).**—First and Second, H. Adams,

Beverley. Highly Commended, A. Perkins, Darlington; W. Boyce, Beverley; D. Parsons, Lincashire.

**GAME (Duckwings, Greys, and Blues).**—First, H. Adams. Second, G. Hellewell, Sheffield. Commended, T. Cleminson, Darlington.

**GAME (Any other variety).**—First, H. Adams, Beverley. Second, G. S. Thompson, York.

**GAME CHICKENS (Black-breasted and other Reds).**—First, H. Adams. Second, H. M. Julian, Beverley. Highly Commended, C. J. Dodds, Halifax; G. Longbottom, Halifax.

**GAME CHICKENS (Duckwings, Greys, and Blues).**—First, J. Grocott, Haughton. Second, G. Hellewell, Walkley. Highly Commended, H. Adams, Beverley; A. Cattley, York; T. Cleminson, Darlington.

**GAME CHICKENS (Any other variety).**—First, H. Adams, Beverley. Second, J. Crossland, jun.

**HAMBURGH (Gold and Silver-pencilled).**—First, W. Cannan, Bradford. Second, J. Dixon, Bradford.

**HAMBURGH (Gold and Silver-spangled).**—First, H. W. B. Berwick, Helmsley. Second, J. Dixon, Bradford. Highly Commended, G. C. Whitwell, Kendal; W. Cannan, Bradford; Commended, H. W. B. Berwick.

**HAMBURGH CHICKENS (Golden-pencilled).**—First, S. Smith, Halifax. Second, J. Munn, Shawelough. Highly Commended, J. Munn. Commended, J. Dixon, Bradford; W. Cannan, Bradford.

**HAMBURGH CHICKENS (Silver-pencilled).**—First, R. and T. Longbottom, Bingley. Second, Froget & Harop, Sheffield.

**HAMBURGH CHICKENS (Golden-spangled).**—First, W. Cannan. Second, J. Dixon, Bradford.

**HAMBURGH CHICKENS (Silver-spangled).**—First, J. Dixon, Bradford. Second, W. Cannan, Bradford. Commended, T. Renshaw, Darlington.

**POLANDS (Black, with White Crests).**—First, H. Beldon, Bradford. Second, J. Dixon, Bradford.

**POLANDS (Any variety).**—First, H. Beldon, Bradford. Second, J. Dixon, Bradford. Highly Commended, J. Dixon. Commended, W. Newsome, Bingley.

**POLAND CHICKENS.**—First, W. Newsome, Bingley. Second, H. Beldon, Bradford. Third, J. Dixon, Bradford. Highly Commended, J. Dixon.

**ANY OTHER DISTINCT BREED.**—First, R. Teabary, Fulwood. Second, H. Adams, Beverley. Third, J. Dixon, Bradford. Commended, Mrs. M. Seamons, Aylesbury.

**BANTAMS (Gold and Silver-laced).**—First, T. H. D. Bayly, Biggleswade, Beds. Second, E. Yardly, Sheffield. Commended, Miss Elliot, Yarm.

**BANTAMS (White).**—First, J. Crossland, jun. Second, J. Dixon, Bradford. Highly Commended, T. H. D. Bayly, Biggleswade.

**BANTAMS (Black).**—First, J. Crossland, jun., Wakefield. Second, W. Cannan, Bradford. Highly Commended, A. Cattley, York.

**BANTAMS (Game).**—First, G. T. Allen, Sunderland. Second, W. Lawrenson, Preston. Third, J. Cragg, Kendal. Highly Commended, J. Crossland, jun.; W. R. Lane, Birmingham; T. H. D. Bayly, Biggleswade; G. Hellewell, Walkley. Commended, Hon. W. T. W. Fitzwilliam, Rotherham; W. R. Lane, Birmingham; H. Adams, Beverley; W. Newsome, Bingley; J. Munn, Shawelough; C. W. Briery, Rochdale; T. Wilson, Kendal; J. Stainsby, Sunderland; J. G. Pearson, Whitechurch.

**DUCKS (Aylesbury).**—First, G. Pease, Darlington. Second, J. Grocott, Tarporley. Highly Commended, Mrs. M. Seamons, Hartwell. Commended, N. Cawthorn, jun., Middlesborough.

**DUCKS (Rouen).**—First, J. Dixon, Bradford. Second, T. H. Barker.

**DUCKS (Any other variety).**—First, J. Dixon, Bradford. Second, J. R. Jessup, Hull. Highly Commended, T. H. D. Bayly, Ickwell House. Commended, Mrs. Braithwaite, Stokesley; W. Wooler, Darlington.

**DUCKLINGS (Any variety).**—First, J. Smith, Grantham. Second, D. Parsons, Cierdon. Third, J. Dixon, Bradford. Highly Commended, Mrs. Seamons. Commended, W. Grey, Northgate; Mrs. Milner; W. Wooler.

**GEESE.**—First, Mrs. Seamons. Second, G. Pease, Darlington. Highly Commended, J. Dixon, Bradford. Commended, Miss Sherwood, Yarm. *Geosings.*—First, Mrs. M. Seamons, Aylesbury. Second, Mrs. Sturdy, Greenhow. Highly Commended, Mrs. Milner, Thirsk.

**TURKEYS.**—First, Mrs. A. Gny, Grantham. Second, G. Pease, Darlington. Commended, J. Dixon, Bradford. *Poult.*—First, J. Dixon, Bradford. Second, J. Smith, Breder Hills. Highly Commended, Rev. T. L. Fellowes, Norfolk; T. Ward, Waidby.

**GENEA FOWL.**—Prize, G. Pease, Darlington.

**DORING PELLETS (Any variety).**—First, G. Mowbray, Bradford. Second, H. W. B. Berwick, Helmsley. Highly Commended, J. Bell, Thornton-le-Moor; J. White, Warlaby; Miss G. E. Palleine; H. W. B. Berwick.

**GAME PELLETS (Any variety).**—First, H. Adams, Beverley. Second, A. Perkins, Bellevue. Highly Commended, C. J. Dodds, Halifax; G. Pease. Commended, G. Mowbray.

**SINGLE DORING COCKS (Any variety).**—First, A. Perkins, Bellevue. Second, Rev. J. F. Newton, Kirby. Highly Commended, J. White, Warlaby; Miss G. E. Palleine, Crake Hall. Commended, T. Braithwaite, Darlington; Rev. J. F. Newton; H. W. B. Berwick, Helmsley.

**SWEEPSTAKES (Game Cocks).**—First, J. Firth, Halifax. Second, H. Adams, Beverley. Third, A. Perkins, Bellevue.

**SWEEPSTAKES (Game Cockerels).**—First, W. J. Cope, Barnsley. Second, G. W. Binns, Darlington. Third, H. M. Julian, Beverley.

**SWEEPSTAKES (Game Bantam Cocks).**—First, R. Wood, Stockton-on-Tees. Second, W. Lawrenson, Preston. Third, Lady Hawke, Womersley Park.

## PIGEONS.

**CARRIER COCK (Any colour).**—First and Second, J. W. Wooler. *Hen.*—First, J. W. Wooler, Sadberge Hall. Second, W. Cannan, Bradford.

**POWER COCK (Any colour).**—First, E. Brown, Sheffield. Second, W. Taylor, Sheffield. *Hen.*—First, W. Taylor. Second, W. Cannan, Bradford.

**ALMOND TUMBLERS.**—First, A. L. Sylvester, Birmingham.

**TUMBLERS (Any other variety).**—First, W. Cannan, Bradford. Second, A. L. Sylvester, Birmingham.

**FANTAILS.**—First, T. C. Taylor, Middlesborough. Second, W. Taylor, Sheffield.

**TRUMPETERS.**—First, J. J. Wilson. Second, W. Cannan, Bradford. Commended, R. Fawdon, Gateshead.

**BARNS.**—First, A. L. Sylvester, Birmingham. Second, T. Ellrington, Woodmansey.

**JACOBS.**—First, T. Ellrington. Second, F. Else, Bayswater, London.

**TURBITS.**—First, R. Fawdon, Gateshead. Second, T. C. Taylor, Middlesborough.

**OWLS.**—First, W. Cannon. Second, F. Else.  
**ANY OTHER NEW OR DISTINCT VARIETY.**—First, J. W. Wooler, Sadberge Hall, Spabians. Second, T. Rule, Gilesgate, Durham. Third, W. B. Van Hansbergen, Enfield Lodge. Fourth, H. Yardley.

**JUDGES.**—Poultry, Mr. Edward Hewitt, of Sparkbrook, Birmingham. Pigeons, Mr. T. W. Botcherby, of Darlington.

### FATTENING POULTRY.

I READ in No. 88, New Series, a reply to questions respecting the difficulty in fattening fowls, which, I have no doubt, all who have had the management of poultry have met with more or less. I have seen the attempts of others years ago, and the same results have taken place that your correspondents complain of; still they were not all failures, but the exceptions were effects that we did not then try to discover the cause of. Even in the early part of the present season I met with the same difficulties; but knowing there must be a cause for every effect I tried to discover it, but there was nothing to discover. The evil and its remedy have been stated in the poultry portion of the Journal times out of number; even in the above Number sufficient is said to insure a good supply of first-rate fowls for any table whatever. The fourth paragraph in the editorial article I consider sufficient to put any thinking person on the right track. But there are people that, because they cannot carry out the exact instructions laid down, get fainthearted, and, after one or two very bad attempts, give them up as impracticable; and yet those are the people that are always asking advice and always behind their neighbours.

Now, in searching for the cause of my failure I had to look over several volumes of the Journal, or COTTAGE GARDENER and Journal, and it was hardly to be supposed that I could find all I wanted in one or two papers, or in the exact words to suit my local circumstances; but there I found the ideas which I had to enlarge or contract, or twist and turn, to bring them to fit my present means, and I succeeded so far that the fowls gave satisfaction when placed on the dining-table. I do not aim at anything beyond a well-mented and fatted fowl, and that I obtain with very little trouble, otherwise it would not be done where there are so many other things to be attended to.

My fattening-pen, which at other times I make use of to put brooding-hens into, I found nearly ready-made. It is a small place between two walls, about 4 feet by 3 feet, with a slate covering; and I put round larch sticks for a bottom, about 15 inches from the ground; and the front and door are made of two inch strips of half-inch deal an inch apart. I made a box about a foot long, such as I use for cuttings, and that is fastened to the front, otherwise the fowls would stand on the edge of it and tip it over. I have another box a little smaller, in which I put their food. I place this food-box into the other and larger one, and the first thing after milking I give them their breakfast. By the time I have finished feeding the others and giving them water they have eaten as much as they want. I then take away what is left and throw it to the others. I feed them three times during the day; the first and last feed consisting of corn—oats one time and barley the next, and now and then a few crushed beans. The mid-day meal consists of any scraps I can get from the kitchen, mixed with barleymeal: this they always eat up clean. I give them fresh water daily, and always keep a box of the sweepings of the gravel walks in the pen, and it is surprising the quantity a fowl will eat. I endeavour to put in a fresh fowl every four days when there are two used weekly, as the fresh one put in stimulates the others to feed. I keep four or six in the pen according to circumstances. I generally allow them three weeks, but I have them in five weeks well fattened.

I have just used-up the old hens I commenced with last spring, and this is the way they were managed. After being killed, picked, and drawn, they are hung-up in the larder for several days, then boiled; the next day the skin is taken off and they are cut up into joints. With a portion of the breast of mutton stewed in the usual way according to taste, no dish of stew could be better, and there is no difficulty about making it.—THE DOCTOR'S BOX.

### WILD DUCKS.

CAN any of your various correspondents inform me how to rear a few Wild Ducks along with tame ones, subjected to the same treatment as the latter? I have more than one lost a promising part of a brood which was composed of both kinds,

the tame ones all living, and the wild ones perishing. I have been told that placing them in the full sun as young Pheasants are done, is beneficial; but then the old hen's opinion has to be asked on this point, and if she spit out her displeasure, what then? I believe this is a question more for gamekeepers and others that way than the patrons of fancy poultry; but I am not particular from whom the answer comes, so that it is to the purpose.—J. R.

### THE PORTSEA CANARY SHOW.

THIS Show took place at Commissioners' Hall, Landport, Portsea, on Tuesday, November 26th. There were a great number of birds, and from the most celebrated breeders in England. In the Norwich classes, Mr. Walter, of Winchester, took the lead, having some very fine specimens. In the Belgian classes were observed a cage of ten, called a collection, for which the highest prize was given, and most deservedly won by Mr. T. Moore, of Fareham, he having, as the Judge remarked, ten of the best altogether that had ever come under his observation. The colours were almost brilliant, and some even of the deepest orange, and together with the points so much sought for by the fanciers, and there was the greatest satisfaction given in awarding the prizes. The first prize in the sweepstakes was awarded to a very good bird belonging to Mr. Triggs, of Landport. In the Mealy classes the first prize fell to Mr. T. Moore; his bird was a perfect specimen of Belgian birds. The Show gave general satisfaction.

In the British birds the Blackbirds were excellent; Mr. J. Nicholson's attracted some attention. A novel sight also appeared in a White Blackbird. Too much cannot be said in praise of the Secretary, Mr. Baker, who was assisted by Mr. Triggs in getting up the Show. The room was very tastefully decorated with flowers, and at the end were a few pairs of first-rate Carriers and Powder Pigeons, lent by Major Haasard, of Hilsca, which added much interest to the Show.—G. GALE.

### SPARROW MURDER.

THE following appeared in the *Times* of Friday last:—

“CRAWLEY SPARROW CLUB.”

“The annual dinner took place at the George Inn on Wednesday last. The first prize was awarded to Mr. J. Redford, Worth, having destroyed within the year 1467. Mr. Heavaman took the second, with 1448 destroyed. Mr. Stone third, with 982 affixed. Total destroyed, 11,944. Old birds, 8663; young ditto, 722; eggs 2559. Yours obediently—A REAL FRIEND TO THE FARMER.”

### PIGS INJURED BY SALT.

SALT is very injurious to pigs, but I never knew it kill them, but it gives them diarrhoea dreadfully, which soon would kill them if the salt were continued to be given. I have seen pigs in a dreadful condition from potatoes salted down as Mr. Pearson's were, and the same fate would have happened to my employer's pigs this year if I had not prevented the man that feeds them doing the same thing. The injurious action of salt is, I am sorry to say, not generally known, as I have seen a great many pigs suffering from it, and their owners did not know what was the cause.

**CURE FOR DIARRHOEA IN PIGS.**—Get a lot of scraps, the same that some people boil for young Ducks, from a leather-parer; boil them up into a jelly, and if the pigs will not eat it drench them with it.—WORCESTER.

[We shall publish next week a letter denying that salt is injurious.—EDS.]

### SWISS BEE-APPARATUS IN THE INTERNATIONAL EXHIBITION.

I DO not remember having seen in THE JOURNAL OF HORTICULTURE any notice of the “apparatus for assisting the bees in constructing their combs,” as the exhibitor styles it, at the Great Exhibition. It is to be found in the Swiss department, on the side of the northern gallery next the nave, and within a few yards of the western dome. It appears to me quite novel; and, as it may be so to others also, I append a description. I should likewise be glad to know if any of your readers have ever put similar contrivances into practice, and with what result. I

only regret that I did not draw the attention of "A DEVONSHIRE BEE-KEEPER" to it when he was in town, as it bears considerably on his own inventions, and he would probably be able to say something on its use.

One of the articles is a small metallic roller very similar in size and construction to the boxwood roller butter-prints in common use in many dairies. This is indented upon its edge, so that when passed along a wooden bar (similar in size to the Woodbury-bar), which has been previously coated with wax on one side, it leaves slight raised projections, which form the commencement of the walls of the first cells. I should think this would be a very useful plan for causing the bees to work

the bars regularly, as I have once this year found Woodbury-bars commenced on the wrong side, notwithstanding the small space between them and the crown-board, and guide-combs being affixed below.

The other matters are plates apparently of type metal, and very similar in form to printers' stereotype plates, indented in a hexagonal cellular manner, like the bottoms of the cells in a comb without the walls, and made so as to exactly fit the surfaces of each other. A layer of wax being introduced between them, and a pressure applied, it becomes, so to speak, embossed with cell bottoms. The specimens exhibited are as regular and show as great an economy of

material as if executed by the bees themselves. There are two pairs of these plates indented, of sizes respectively for common and drone cells. As the foundation of every cell in the hive could be laid in this way, and the drone-cells arranged exactly as the apiarian desires, one would think this contrivance must immensely facilitate the labours of the bees. There is something in the way of description, but I am not sufficient of a linguist to decipher it. The question of practical utility would appear somewhat doubtful. The necessary fragility of so large and thin a plate of wax would almost suggest a negative.—G. F. B., Colney Hatch.

[These artificial combs have recently been tried in England, and are found to answer perfectly. We believe Messrs. Neighbour & Sons intend to manufacture them.]

### "DZIERZON RECONVERTED!"

In the article which I inserted in a recent Number of THE JOURNAL OF HORTICULTURE, "Dzierzon on the Bee-year 1862," I made a passing reference to that distinguished apiarian as the original promulgator of the theory of parthenogenesis in the honey bee; and also to the fact that he had afterwards been so perplexed, apparently by unforeseen difficulties and new unsolvable mysteries, as to make him doubt the correctness of his own theory, and to have recourse for an explanation to the antiquated hypothesis of the action of an *aura seminalis*.

In addition to the quotation made by Mr. Woodbury from Von Siebold's writings as to Dzierzon becoming a doubter of his own theory, I quote the following as Dzierzon's own words on the subject:—"Continued observations," he writes, "of the hybrid hives also must be no less adapted to raise the veil, more and more to penetrate into the obscurity, and finally bring the mysterious truth to light. If the drone egg does not require fertilisation, Italian mothers must always produce Italian drones, and German mothers German drones, even when they have been fertilised by drones of the other race. The Silesian Bee-friend (meaning himself) possesses hybrid hives of both kinds, and did not permit any want of observations so far as the limited time enabled him to make them, but he met with new unsolvable riddles. The Italian hybrid mothers have throughout completely confirmed the supposition, and produced the most beautiful Italian drones, one almost more beautiful than the genuine stocks—the maternal stock itself. Of two German hybrid hives one also produced only the ordinary black drones, the other the same; but unexpectedly amongst these a few appeared which glittered like gold, and were yellower than any single bee even in the genuine Italian hives. It certainly was possible that even

here a beautiful Italian amongst the workers, of which a portion had the colour of the indigenous bees, and another portion that of the Italians, might have laid some eggs, from which the few yellow drones might have been produced. Nevertheless, the Silesian Bee-friend is not particularly inclined to explain the phenomenon in this way, so as not to expose himself to the suspicion that only a predilection for his hypothesis led him to have recourse to this explanation, as, in point of fact, the deposition of eggs by worker bees when a queen is present is an exceptional occurrence of the rarest kind."

Then follows the explanation of the problematical action of an *aura seminalis*.

It will be seen, then, from Dzierzon's own words, and from Von Siebold's writings, as quoted by Mr. Woodbury in the last Number of this Journal, the grounds of my so-called "mistaken notions."

I find, however, from the extracts furnished from more recent writings in 1861, of which I was ignorant, that Dzierzon is reconverted, as Professor Siebold, his great friend and defender, predicted and hoped he would be long ago.

It certainly did strike me as strange, though perfectly allowable under the circumstances narrated by me, that Dzierzon, after fighting-down all opposition against his theory, should himself stand out afterwards, isolated as it were from his friends, as a sceptic; but it never occurred to me for a moment that, after having so taken up his position, no doubt from mature consideration, he should again be found to have changed sides. Such unusual transitions of opinion, whether to be found in the politician or the naturalist, must entail upon the parties concerned, to say the least of it, not a little inconvenience; and they must bear the brunt of having their opinions occasionally not only less valued, but their ultimate and more mature views, it may be, necessarily liable to misconception and misrepresentation.

I, and other apiarians who have not had access to the pages of the German "Bee Journal," must, however, feel obliged to Mr. Woodbury for making known the fact, which seems undoubted, that Dzierzon is "himself again."

Dzierzon, therefore, being now reconverted, and all Germany at one as to the truth of parthenogenesis, apiarians may be expected henceforward to have a period of hitherto-inexperienced and unfeared repose; for this theory, according to its author's latest views, "explains the phenomena of the bee-hive as perfectly as the Copernican hypothesis the phenomena of the heavens," and by it "all the mysteries which we have hitherto vainly endeavoured to unriddle are completely solved." The allusion to the Copernican or planetary system of the heavens reminds me of the story told of the great astronomer Galileo, of whom it is recorded that when the Inquisition at Rome made him abjure on the open Gospels his belief in the fundamental truths of that system of which he was so distinguished a supporter, he, rising from his knees after this mock solemnity, whispered to a friend standing by in reference to the motion of the earth these emphatic words, "It moves for all that!" So Dzierzon, it would appear, after a temporary but unconstrained and voluntary recantation, or recording of his doubts of parthenogenesis, can yet say, not in subdued whisperings to friends merely, but boldly and publicly to the community at large, "It is true for all that."

—J. LOWE.

[Here the subject must cease from discussion in our pages, for to debate it fully requires details not suited for the columns of a Journal which, a friend significantly remarks in a letter, and for which we thank him, "hitherto has laid on his drawing-room table."—EDS.]

### OUR LETTER BOX.

DRAKE'S FOOT (*A Constant Subscriber*).—We regret that you will again be disappointed, for we have no such inquiry on hand, and do not remember it. Write again the particulars.

CONSUMPTION IN PIGEONS (*J. T. T.*).—The Carrier with diseased lungs filled with purulent matter died obviously from consumption. As your diet is unexceptionable and the birds fly, the disease must have been due probably to hereditary predisposition. Many of the high-bred birds have a tendency to tubercles which may be developed in their young; no medicine would avail in such a case. The Hyacinth was treated properly by opening the tumour. Is your loft kept sufficiently clean, or have your birds to pick up their food from the dung on the floor? Without cleanliness no birds can be healthy. Have they clean water to drink, and is there any ventilation at night?

CANARY MANAGEMENT (*W. J., Yarmouth*).—We know of no good separate work on the subject; but it is very fully given in a work we have now in the press, entitled "The Singing-Bird Manual," which will be published early in next year.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 43.0° and 30.6° respectively. The greatest heat, 58°, occurred on the 28th, in 1855; and the lowest cold, 1° below zero, on the 28th, in 1860. During the period 149 days were fine, and on 96 rain fell.

THE HOLLY.

THE festive season which this Number of THE JOURNAL OF HORTICULTURE ushers in brings with it an emblem of times long since passed away; but the relic left us promises to survive many centuries yet to come, for it has a deeper hold of our national affections than the vapour-like fashions of many things which change many times during a lifetime. But the tree of which I speak, though not often placed in the front rank of the parterre or shrubby favourites, has

nevertheless retained a creditable position everywhere, and at this particular season stands prominently forward as the most conspicuous ornament either our artificial shrubberies or our natural woods afford. Had Dame Nature placed this singularly beautiful tree amongst those, to procure which our ships are freighted to the antipodes, it is not unlikely but it would have stood higher in the estimation of those who profess to guide public opinion in matters of good taste; but scattering itself more or less profusely over the length and breadth of the land, its commonness has occasioned it an amount of neglect anything but creditable to us.

Fortunately, however, for us, in this case as well as in many others, there are amongst us many whose education has not been so completely artificial as to exclude the love of national beauties of home growth. The ecstasies with which oriental writers extol the productions of warmer climates might be met with a similar echo, if the talent were forthcoming, from those who behold what our own sea-girt island possesses; and that we shall speedily see full justice done to the merits of our native trees and shrubs is the more likely, since the beauty of our indigenous Ferns is now acknowledged, and there are forms amongst them not exceeded by those from any other country.

This being admitted, I have the hope that the merits of other things will be allowed also; and to send to the antipodes for what is at our back door will, I hope, be no longer a reproach to us; nor yet that somewhat cruel and paradoxical proverb, reflecting so wantonly on the idea of the fair sex saying something about things must be dear-bought and far-fetched, and ending with other naughty words. It is, however, impolitic our laying this charge against our fair patrons when we are open to so many taunts of the same and worse kinds ourselves. Under the favour, therefore, of a truce, let us see what can be done to do honour to such of our neglected ornaments at home as have hitherto been kept in the background, and amongst these the beautiful plants whose limbs and other members are alike the ornament of places of worship and recreation, the cottage and the palace, the butcher's shop and the ball-room; while the tree itself, nestling for protection under the monarch of

the forest, stands out perhaps the more conspicuously by the rich colours it presents to us amidst the withered mass of decay by which it is surrounded. On the other hand, we see it occasionally crowning the brow of some eminence, but more often clustered in groups by the sides of some rocky glen. Occasionally it is also in exposed places, subject to the attacks of cattle; and in such spots it presents a feature in its growth which has elicited the following exquisite lines from the gifted but unfortunate poet Southey:—

"O reader! hast thou ever stood to see  
The Holly tree?  
The eye that contemplates it well perceives  
Its glossy leaves,  
Ordered by an Intelligence so wise  
As might confound the atheist's sophistries.

"Below a circling fence its leaves are seen  
Wrinkled and keen.  
No grazing cattle through their prickly round  
Can reach to wound;  
But as they grow where nothing is to fear,  
Smooth and unarmed the pointless leaves appear."

As it is superfluous to add anything to the above, it is also difficult to conjecture at what precise period the Holly came into use to decorate our dwelling-houses and churches during Christmas. Some have affirmed it to be the remains of a custom of the Druids, who used the Holly to deck their abodes at this inclement season, in order that the sylvan spirits they worshipped might remain with them until the return of milder weather called them forth to their mystic woods and forests.

Whether this be so or not is needless here to reason upon. Evidences are neither few nor unimportant of a pagan custom having worked itself into one of Christianity, and nothing could more forcibly present itself to those original children of the forest as calculated to captivate the good will of the mystic deities of their religion than the most showy specimens of the vegetation they possessed; and might we ask, What country produces anything more remarkable than the Mistletoe, or more beautiful than the Holly?

The researches of botanists and of enterprising plant-collectors, sent to explore near and distant regions, have not yet, to my mind, produced anything more truly beautiful than the Holly. Its dense green foliage, that no weather seems to affect, is of the brightest hue; while in contrast with these are the masses of fruit of the most brilliant coral. Compare these qualities with any shrub we now possess, and our Laurels, Alaternuses, Rhododendrons, Boxes, Spiræas, Ligustrums, and the whole host of foreign productions fall to the rear. Neither is the gay apparel the Holly now appears in one of short duration. The berries hang on for many months but little impaired, while at no period of its growth does it ever appear unsightly; neither do its young shoots ever present that delicate succulent look that some young growths of evergreens do. True to its character, it is the monarch of shrubs, none equalling it for height and bulk of stem; and if some of the gayest of the Rhododendrons claim attention for the beauty of their flowers, they cannot boast of so long-continued and well-sustained

verdure. Even in the mutilated form in which its fragments appear in our dwelling-houses and elsewhere at this season, its leathery leaves carry it through a longer period than any other shrub. Sufficient, however, having been said on its merits as a home ornament, let us see in what way its advantages are used outside.

There are few people connected with rural affairs but can point to some place where the Holly is found luxuriating in the wild profusion of the home it has selected for itself, seeding and reproducing itself, and in many instances attaining the dimensions of a moderate-sized timber tree, unassisted, or, I ought to say, uninjured by axe or spade. In some native woods when the general fall of the timber takes place the Holly is not unusually spared, when such fine specimens are produced. It is seldom, however, that any quantity of fine trees are to be met with in woods of this description within a circuit of twenty miles or more of London. The great temptation there is for trampers and others cutting it to supply the great London demand for this article at Christmas, is fatal to the well-being of trees within the reach of such marauders. Even the pet tree in the dressed grounds is not always safe from depredation; and some parties, to save their trees from injury, take the precaution to pick off the berries in November.

The Holly, however, like everything else, has its favourite place of abode, and it is not found in all spots alike vigorous; and, contrary to the condition of most forest trees, I have never seen it so fairly at home in the south of England as I have seen it in the north. At Gilside, in the county of Durham, I have seen some very fine trees of it, the stems of which had assumed the dimensions of several cubic feet of timber—and these not solitary examples, but plentiful. The soil was a light-coloured hazel loam resting on a sandstone shatter, the soil itself being very stony. It was not a damp soil, and yet it could not be called a dry light one; the hilly condition of most of the sites precluded stagnant water affecting the trees. I believe, however, the understratum possessed iron, and for a certainty it did coal, but that at too great a depth to affect the surface.

Most of the places where I have met with the Holly in a wild state have been in such positions, the other woods being generally Oak, and, not often, Beech. In some of the natural woods in Kent Holly is met with but sparingly. Generally these places are too dry for it, or the barbarous practice of cutting it every now and then for the sake of the boughs with berries on has checked it very much; and it is provoking to see a fine promising young tree, tall and uniformly grown, cut for some waggoner's whip-handle. This and similar misfortunes have tended to keep the growth of the Holly down in many places; while in former times its bark was sought after for birdlime, and country carpenters, aspiring to some fancy piece of cabinet work, sought after a piece of Holly to make veneers, or rather stringing, of a pale or nearly white colour. I believe some other woods are used for this work now. It has, however, been often used for the teeth of corn-mill machinery, where wooden teeth alternately with iron ones are used, its hardness rendering it very suitable for that purpose. Many other duties it is often called on to fulfil; but whether it is adapted to wood-engraving in conjunction with Box I am not aware; for the latter purpose I should think it scarcely equal to the White Thorn, but no doubt all have been tried.

It is, however, more as an ornamental tree that I now write about it; and as a single tree on the lawn, or one amongst others in the shrubbery, a Holly is rarely out of place. It is, perhaps, more difficult to transplant than many other trees, and I confess not having been always successful with it; but I am told by one, who has moved several with great success, that May is the best time, and next to that early in September. Much, however, depends on the condition of the plants to be moved; to attack a plant that has been installed at its present place of abode twenty years or more cannot possibly succeed without some little loss one way or the other, and of course the more so if done at the wrong period. It is, therefore, in most cases advisable to inquire if the plants have been moved some short period before they are purchased, as a little lack of vigour may be not only excusable but highly recommendable, as being more likely to prosper in their new situation than more robust specimens.

On the varieties of Holly it is not my intention to enter, as this article is dedicated to the common one; there are, however, many varieties of great beauty, and some of them of singular

growth, but the ordinary one is the most useful of all, and when wanted for a hedge it is unquestionably the best. This subject will be treated of in a future article, so that it need not be entered into here; and while our readers are admiring the twigs of this tree, which, with their rich coral-looking berries, ornament the market-stalls and windows of all that can obtain it at this season, let them make a resolve each in their respective station to do all they can to increase the number of trees of this emblem of festivity, which, in addition to the interest attached to it as such, is unquestionably one of the most ornamental if not the very finest trees we possess.

J. ROBSON.

## THE TREE CARNATION.

THE question of a lover of Carnations as to the mishap that has befallen his new, and, to say the truth, somewhat expensive lot of tree Carnations, suggests, in replying to it, a few observations on this interesting class of winter-blooming plants. A collection of them exhibited by Messrs. E. G. Henderson & Co., at the Royal Horticultural Society, showed that to designate them by this term was not a myth; and that, whether for the brilliancy of their colour or the delicacy of their perfume, they form an exceedingly valuable addition to the autumn and winter-flowering plants which we already possess.

We are indebted for them, as for a vast number of our improvements in floriculture, to our continental friends. I do, indeed, remember many years ago "when I was young," that a very earnest florist in Dublin used to have his tree Carnations; but then they were only the ordinary florists' varieties treated as perennials, much in the same way as we make tree Mignonnettes out of the annual herbaceous plants, whereas the tree Carnations now grown are evidently quite distinct from them; and although the French growers have sent over varieties which, from their dwarf habit, are little better than the older florists' varieties, yet Messrs. Henderson & Co. have been wise enough to reject them, and to retain only those which, from their height and general character, are deserving of the name. At first, as in the case of Fancy Pansies, the flowers introduced were but little better than Ragged Jacks, with no outline or form of any pretensions. But perseverance and skill have, to a great extent, remedied this, and many of the newly-introduced sorts are quite equal to what florists' Carnations, as a general rule, were some twenty years ago; and this has been obtained without detracting in any way from their brilliancy of colour—one of the newer sorts, Perfection, being really a very excellently-shaped flower with good petals.

The cultivation required to have the tree Carnation in perfection must be, of course, different from that ordinarily pursued with the florists' varieties. They ought not to be allowed to flower the first year; but when the plants are received from the nursery they should be at once, if well rooted, placed in the blooming-pots. These should be about 6 inches or 8 inches in diameter. The tops should be pinched-off in order to encourage them to throw-out shoots; but, at the same time, no shoots should be allowed to come out low down the stem, the growth being encouraged on the head of the plant, while no flower-stems should be allowed to rise. They may be placed during the spring and summer months in a cool and airy situation, and when they have obtained their growth may be placed out of doors, but sheltered from very heavy rains, which are always injurious to plants in pots: they will then form their flower-stems and bloom-buds. Water should be carefully applied, the plants never being allowed to flag; and then, when there is appearance of frost—say in October, they should be brought into the house.

The soil in which they delight is a rich and friable one, but not too much manured, as this is apt to cause the colour to run. Loam about one-half, leaf mould and old manure one-fourth each, with the addition of some sand, form a very excellent mixture, in which they will be sure to thrive.

It will be seen, I think, from these few remarks, how it is that your correspondent has failed. He received the plants with flower-buds on them. Now, if they were young plants, he would have done well to have left them where they were, nipped-off the buds, and waited patiently until the spring before he reported them; if they were older plants, it was sheer madness to have treated them in this way. No one could ever take a plant of that nature, and, just before its flowers were opening, when all the vigour of the plant was directed towards that end

reput it—set it to work making roots, without doing injury. The probability is that he will lose most of his plants. The soil gets soddened, because, at this season they will not make much root, and for the same reason the buds will drop off. I think his best plan—and without seeing one can hardly prescribe for a patient—is to put them back into smaller pots, pinch-off the buds, keep them rather dry, and then in the spring give them a fresh start.

It is to Messrs. E. G. Henderson & Son that the credit is due of forcing this flower on the attention of the public, and they are each year adding to their lists of new varieties. From their catalogue I have selected the following varieties, combining great diversity of colouring with delicate and curious markings.

Abbé Beulard, salmon rose, flamed and flaked slate colour.	L'hermine, pure white.
Alphonse Karr, eluret ground, striped and suffused with purple.	Madame Adèle Calmels, flesh, tinged violet.
Aramis, yellow ground, striped with cherry.	Mirabeau, dazzling red.
Ariadne, delicate rose, with purple and crimson flake.	Oscar, clear yellow, marbled rose, striped with cherry.
Beauty, pure white, with rosy pink narrow stripe and edge.	Perfection, white ground, with bizarre flakes of purple and crimson.
Christian, violet purple.	Queen of Whites, beautiful self white, fine form.
Flambeau, pale yellow; towards the base flamed scarlet, striped with crimson.	Raquelaire, yellow, striped with shaded crimson.
Garibaldi, rich fawn yellow, with heavy red edge.	Seigneur de la Malmaison, flesh; good form.
Joséphine Debray, orange salmon, slightly suffused with slate colour.	Targioni, deep violet purple.
Louis Napoleon, large, white, flamed with bright rose.	Ulysse, salmon ground, flamed and striped with shaded purple.
	Vandyke, rosy white, flaked cherry.
	Virgile, bright yellow ground, flamed and tipped with cherry.

—D., Deal.

### NEW BOOK.

*Flower and Fruit Decoration.* By T. C. March. With Many Coloured Illustrations, &c. London: Harrison, 59, Pall Mall.

THIS is, indeed, a very charming book—a book which the force of circumstances, as the elder Napoleon would say, rendered inevitable, and the third original book which has appeared on a branch of our calling since I put my foot on the first step of the ladder. The first great original was Dr. Herbert's "Amaryllidaceæ," in 1836; a few years later, "The Theory of Horticulture," by Dr. Lindley, the best book he ever wrote; and this book now by Mr. March, the winner of the blue ribbon in 1861 and 1862 at South Kensington, in the running for dining-room and drawing-room decoration with flowers, fruit, and "greens."

As an instance in illustration of the adage that some have achieved greatness while others had greatness thrust upon them, I may mention that gentlemen in arm-chairs in London have thrust upon the writer, against the grain, the agreeable duty of standing godfather to these three original and very different books. No matter how many gardeners there were who could have done the "Amaryllidaceæ" and the "Theory" as well as any other, I only know of four, or, perhaps, five gardeners who could do this decoration-book more ample justice than I can, and here is my voucher. I had a regular college training for this very branch, and my college professor was the first who was appointed to be one of the judges where our author won his spurs. He, too, must have been in good hands for training before he could make such an appearance. There is no man and there never was one who could learn all that by induction. Depend upon it the ladies have been at the bottom of it all, for it is a most difficult thing for a man to understand. I found it so, and, except in getting hold of the English tongue and in parsing the *Æneid*, I never met with so difficult a subject as the dining-room and drawing-room decoration from the flower garden; but as luck and long experience would have it, I succeeded so far that for the last seven or eight years before I left the college I was permitted to do it just as I thought best, and on the last best occasion I had the pleasure of conducting Dr. William Russell of *The Times*, and five other gentlemen representatives of the London press, round and round the labyrinth, just before the select company who were invited to meet the Prince Consort came down to dinner. But all that has reference to you only, and I mention it on purpose for you as a guarantee that I mean what I say, and that I know what I mean when I say that this is, indeed, a most charming book, an original book, a lady's book to the last page of it, and a book which lets the cat out of the bag entirely at last, at the end of eighteen long years.

It is not much over twenty years since the subject of this book has had a fair trial in England. It was the fancy of a

few ladies at first, and between them and their head gardeners all the compounding was done. Gardeners, as is well known, do not keep secrets, but there did not seem to be any demand for such secrets as this. You must recollect how often I stated the wonder that no one ever thought of exhibiting collections of fruit after the manner of setting the dessert, and that I had not seen any such collection which, if tested by the rules of that "institution," would not be without a pig with one ear somewhere round the table; but as to decorating the dinner table with flowers and "greens" only, the public never seemed to me to care one single straw about it, and the cat was in the bag the whole of this time. But as Mr. March had the temerity to let it out as soon as he himself got to the top of the ladder, I shall be Yorkshire too in the cause of my calling, and let out a lot of the kittens before I have done with him and his most beautifully illustrated book of drawing-room decoration.

The book is short and sweet, and to the point—108 pages; nine principal chapters, divided into sections according to the different branches which grow out of the principal leader of each chapter. Then there is a "list of ten large coloured engravings of flower and fruit arrangements published separately from this book, and recommended as working drawings in respect to the shape and colours most desirable for these decorations." Also, "thirty coloured diagrams intended to assist the judgment in the choice of colours," together with "thirteen coloured diagrams of ribbon-garden borders" for London gardens, which the author tells us, the cats use for their music-halls. Then there is a "list of bedding plants for the above ribbon-borders and rustic stands." The last pages contain a "reference to some of the principal nurseries round London." In addition to all this, almost every other page is illustrated with engravings explaining the right and the wrong way of doing-up the decorations, and several of the highest order of these decorations in a finished state are given, and these are beautifully painted, true to nature, and to this style of high-art decoration. The style of the author is plain table talk, just as any neighbour would tell another across the table how all this finery could be done at home, how to manage it after it was done, and, if they were Londoners and in London at the time, how and where to look about for the next lot of things to try their taste and skill upon; and if either their skill or their taste should happen to differ from those of the rest of the company round the table, there is no dogmatism; "all in this free country can indulge their liking;" for "the sense of colour differs with different people as the sense of taste and smell." (Page 15.)

The first chapter begins with "Glass as a Material for Displaying Flowers;" and another reading of it might be to say that plain, clear, crystal glass is as essential to the decoration with flowers as it is to the growth, and health, and beauty of those exotic plants which bear so many of their numbers, as it were, for this only purpose. Another branch of the first chapter is that "flowers should be grouped according to some design," and "it will not suffice to crowd in a quantity of different flowers with no relationship to each other except their bright colours." The italics are mine, in order to give me the opportunity to say how much I coincided with the Judges of 1861, who awarded the first prize to our author against a formidable and most profuse use of the exact opposite of every syllable so underlined. But under the fifth chapter I shall tell you another tale about these.

Chapter II. is on colour and contrast, and "it requires much tact and good taste to manage many colours" in a composition. There is not the value of a shade between the author and the old COTTAGE GARDENER on this the most important part of the chapter.

In the beginning of Chapter III. you also begin to see the pricked ears of a tortoise shell rising out of a green bag, with tassels of drooping flowers in a rosette of leaves hanging from each of the four corners. You begin to feel as you never felt the whole season; but you read on and on, and before you have done with Chapter III. you will know six times as much more of the secrets of the art of these decorations than I knew when I was eight and thirty years and seven months old, or when I entered that college where I took my degrees.

There is a slight difference here between the author and your humble servant in our mode of fixing the foundation for the furnishing; and unless the "plastic clay" in the centre of the *épergne* is necessary for the support of the glass rod there is not the slightest necessity for clay at all, even if the diameter of the base be a yard across, and the glass be as shallow as those

of the beautiful glass epergnes represented in this book. I never used glass rods, or glass attached to the stem of an epergne; but I made a thousand "tops" and "bottoms" quite as fast as those glasses, and some much wider than these, without ever using one particle of clay, but the stems had ring-sockets to screw on and off.

Sand is the grand material; and there is a better way of doing it, and a much easier process than is here described. The way I was taught to do it was to put so much common white sand—a peck or half a bushel at a time—into a horse pail, or a wooden tub, to pour in so much water as would float the sand and rise over it; to shake this mash two or three times, that all the particles of the sand should get wet; and then to strain off the water gently by turning the bucket or pail on one side, and let it remain so for some hours. That was done as soon in the day as a boy could be spared from his other morning work; or if the sand was mashed and drained two days or a whole week before it was wanted, it was none the worse. Then pack a soup-plate full of it, and in a cone as firm as you can beat it down; then thrust your walking-stick into this cone—say 5 inches deep, put your hat on the top of the stick, and try the nerves of your new groom of the chambers by requesting him to be so good as to carry it upstairs, and along the front corridor to the first turning to the left, and into your study or private sitting-room: you know the rest. Nevertheless, if you have timid young people about you, I can see very clearly that the clay bottom is a most excellent thing; but, as you must all read the book, it will not be amiss if you have two strings to the bow, and that is all that I mean by these precepts.

After the foundation comes the fixing, and here you have a branch of the subject which will not be much improved on to the end of this century to begin with. In this "free country" they may arrange the colours differently, but they will not be able to fix them better: and there are two diagrams here, the one for the bottom, the next the top—the bottom and the stem of an epergne all in one, and both are fixed in the right way on one side and in the wrong way on the opposite side; and if you believe me, if I had seen these two diagrams when I was eight and thirty and seven months old, each of them would have saved me the minding of the substance of a lecture once a-week for nine months of the next two years, and very like the saving of an hour now and then in the examination-room—the hottest room in the house, of course, when I could ill afford the time.

But the best part of this branch of the third chapter is this:—"Spargula pilifera will also replace moss very effectively"—that is to say, to cover the sand and clay before the fixing, and the "also" pertains to Ivy as "a good substitute" for moss, and better still, as I can vouch for. German Ivy is much better than moss in many instances, for it will root in an epergne in a few days, live on the damp sand and clay, or sand, a whole season, stand gas, climb up the glass stem, run round and round the edges of the top glass, and will fall down in pendants even from a height of 20 feet. They do all sorts of "winter greens" with it in Russia.

The next branch of this chapter is full of the most sterling instructions about the arrangements of all kinds and classes of flowers on a natural-system-like arrangement, with diagrams to show off the effects. This would be the best part of the book for the florist to study, Mr. Turner, of Slough, excepted; he has the eye for effect already, and yet I am not sure if he is not the very type of those who need it most. I have learned a good many turns from it myself, after seeing as much of it in practice as most men of my age.

The epergne at page 41 is very beautifully set; but I was never allowed to put a single flower in that style in all my practice; or if I did, I had to go to the front to be told never to depart from nature in giving a position to a flower. Nature has bunches of Grapes, bunches of flowers of Laburnum, and bunches of Glycine, or Wistaria (not branches) in the pendent form, but never a Lilac or a Delphinium, unless it were from the weight of the flowers. You will think it strange, perhaps, when I say a lady is set to the best advantage, in my eye, when mounted on a spirited palfrey, and a bunch of Grapes, or a score of them, is nothing "in my eye," unless it hangs free as on a Vine, or as on the epergne on page 42; and yet I was never allowed to put a single flower in the same dish with Grapes, or any kind of fruit; but more of that under the fifth chapter.

On page 41 occurs the first and the only wrong spelling of the name of a plant in the whole book. I refer to the good old

Zebra plant, the *Marsilea zebrina*, which has an extra *u* all through. The Maiden-hair Fern of the author, which Mr. Dunsford allows to cool before he parts with it from his hot-houses, is not that of books on botany. The Maiden-hair Fern is a native of the wildest parts of the Highlands of Scotland, of Scandinavia, and of similar places in many lands; but it will live in a greenhouse. *Adiantum cuneatum* is the one Mr. March means, and is the best of them all for that purpose; but with this exception, and one or two Covent Garden names, and the use of capitals in distinctive specific names, as *Cissus Discolor* for *discolor*, *Lycopodium Cæsius* for *cæsius*, there is not a single error in all the names, which is wonderful, seeing the first edition was got out in a hurry for Christmas presents, and it strikes me the whole edition will be out before Twelfth-night; and if so, I would vouch for it the second edition will be exhausted in wedding presents before Lent is in.

I would not wish to seem to press this book on the bulk of our great gardeners, for they have all their own different ways, or the ways of the families whom they serve; the ladies are sure to take it up, and to lead the fashion until the whole country is full of it.

The last part of this chapter is a résumé of what has been said and what to avoid; for there is nothing left to chance, and there is no dictation.

The fourth chapter opens with an array of most beautiful glass baskets with glass handles, of different shapes and sizes, with other engravings showing how they should be fixed, filled, and set off in the most artistic designs; also designs for "Fern cases and Mosses," and ends with the way Mr. March would preserve cut flowers and foliage for future use; and to this I would add a few words in addition to his very capital system.

The late Mr. Petersen, gardener to the King of Denmark, who made the decorations for the christening of the Princess Alexandra, told me in 1846 that charcoal water was the best thing to keep cut flowers and leaves in, and I have found it so ever since. About a quart measure of charcoal pounded into dust, thrown in a bucket of water for a couple of hours, and then strained-off clear, is all the work. About 3 inches deep of this clear charcoal water should be put into some wooden vessel—say the half of a nine-gallon cask, or some such thing—then half fill the tumbler-glasses with the same kind of water, put in the flower-stalks and leaves in separate kinds, and place the glasses in the wooden vessel, and have a couple of panes of glass to cover it, but not very tightly; and of all the means I ever saw that was the best for preserving cut flowers for future use or present ornament. But I think one of my men improved on it by double-sifting the powdered charcoal, so as to leave him a quantity of the size of Marrowfat Peas, and in that size to float the whole surface of the water in the wooden vessel with the charcoal, and the purifying influence of the whole, in the game larder, is sometimes wonderful; such things should not be long in the dark, or in a close or warm room. Our author is also alive to this purifying influence of charcoal.

Chapter V. If I had been the fortunate author of this book, this would have been my first chapter. Why it is not so I think I can guess; but as I may have to speak of the whole chapter some other day, I shall merely state the chapter is on the subject of "Where to Place Flower and Fruit Decorations," and that the author tells us on the next page, "it is not my intention to enter into the details of the dessert."

The sixth chapter is on the "purchase of flowers in London." A town guide, in fact, if people would but get up in time, like Mr. March, and keep the middle of the street to Covent Garden, to avoid the girls shaking the door-mate, and the pot boys who tease them into dust and fury not safe to encounter before the day is well aired. And then to be able to understand the market dialect about Jasmynes, Creeping Jennies, "scents" by the dozen, and "thumbs" by "the score," with Brady's "Clavis Calendaria," and a consequent supply of Holly, Leaks, Shamrocks, and Palms, on all the days of tutelary saints and other occasions distinguished by floral emblems, you must read this chapter from first to last, and the next with it, which contains most useful lists of all the flowers and foliage you can buy in Covent Garden from November to October, with their colours and shades for every month of the year, with references how to use some particular kinds, and not a single error in the names of that vast variety of plants, except that unlucky *u* in the corner of *Maranta*.

Chapter VIII. is prodigious in floral display—no less than "fifty different groups of flower or fruit recommended from

experience," and a sectional chapter for each distinct colour, all of which are wonderfully good selections.

The ninth chapter is on London gardens and conservatories, lead flats, and stone terraces, from which the Mignonette and Stocks, the Cherry Pies and the scented old-fashioned Geraniums, are twice as sweet as we have them in the country, or rather they seem to us, fresh from the country, to be so, because the London air is so much less refreshing than with us. But I shall have a chapter on these London gardens myself, if only to keep the author before us in making them more becoming than as "music-halls for the cats."

Then, there are thirteen beautifully-coloured engravings of plans of London gardens, and forty designs of coloured rustic baskets and vases to place upon the centre of the grass plots, and all this on our own plan and principle of ribbon-planting, our own plants to do it, and our own selections of plants for the very purpose; and, of course, I need not tell our readers that all this is just as we have had it, and that there is not a single error in all this designing. The wonder is, how a Londoner could pick and choose all the titbits, and let the "Good Gracious" lie on our hands.

Then, there are thirty exquisitely coloured engravings, "showing what colours will agree when three flower-groups are placed on one table, a single colour being used for each decoration." These are placed in threes across the page, as the three epergues are placed on the centre of the dinner table, or one epergne and the two flanks. Here the printers have made a desperate blunder in transposing two of the engravings on the first page, and two more on the third page. The top and bottom rows or threes are so mismanaged on both pages; and if you never understood the meaning of a pig with one ear, the explanation is here, safe enough; but, of course, it will only be in the first edition.

After these there are three pages and a half of very select lists of plants and colours for ribbon-borders, all as we have been selecting them for the last dozen years. But, of course, the author selected them himself from the public gardens, as we did; but he never saw our old friend, the blue variety of *Campanula carpatica*, when they had it at Kew, nor the white *carpatica* either. The author is a perfect Londoner in exactness in all these lists, and, therefore, one feels pleasure in drawing his attention to the minutest error. There is just one such on page 106, where he says *Amaranthus tricolor* was lately introduced by Mr. Veitch. *Amaranthus tricolor* was introduced long before Mr. Veitch was born. What he means is *A. melancholicus ruber*, quite a different plant from the tricolor race. He is very fond of our Black-eyed Susans, the annual *Thunbergias*, for the *Caladium* shape of their leaves in high decorations, and for their free-and-easy manners and long endurance in the music-halls aforesaid—a thing I never was aware of. Mrs. Captain Whitty, and Mr. Malleson, at Claremont, were the best managers of *Thunbergias* out of doors I have ever seen.

If I had been introduced to the author, I would have sent him a specimen of "the plant from Nazareth," which is equal for effect to any plant on his lists for the top part of an epergne, and should come in with his Hop-borders and pendants, and a row of tufts of *Briza major* in the middle distance.

But read the book, and we shall have plenty time to speak of auxiliaries to it.

D. BEATON.

### WINTER COVERING.

AMONGST the many introductions of late years, multiplying the accommodations of various kinds in almost all the departments of industry or luxury, there are none which seem to bear on the subject now treated of, or at all events we have nothing in a general way better at the end of 1862 than we had ten years ago; garden mats and the like being garden mats, &c., still. And though structures of timber and glass, or iron and glass, have undergone, or have been said to have undergone, many changes of fashion, and new and cheaper modes of erecting them have been said to be found out, the means of covering such of them to protect their contents from severe frost has not advanced in like manner. Bast and Indian matting, wooden shutters, and now and then an old carpet or piece of cocoa-fibre matting, may be seen doing this duty the same as they or like articles performed the same office thirty years ago; but nothing new has been put forth for the purpose. I cannot say but I am sorry at this, as there are many things of much less importance for which patents have been taken out; and they have been paraded forth with all the pomp of new and useful

inventions, while coverings for half-hardy plants have never been thought of: and it is, therefore, to stir-up the inventive powers of our manufacturing friends that I again call on them to furnish us with something suitable for the purpose—something that is stout, durable, waterproof, and reasonable in price. The article called tiffany is much too slight, and even a material that preceded it—a sort of felt under the odd name of frigidomo, was also too slight, and, I think, speedily fell into pieces. A cocoa-fibre matting is a more durable article; and from what I have seen of it endures the alternation of wet and drought better than most things, but it lets the rain through. Wooden shutters are, perhaps, the best thing, but they are not easily managed by one individual; and sometimes things require covering for which they are quite unsuited, as single trees, and the like. For a cold frame I do not know of anything more suitable; and I may mention, that for several winters I have kept great quantities of *Calceolarias* in cold pits with no other covering than wooden shutters when they required them—no glass. But everything is not so hardy as *Calceolarias*, so that a useful and portable covering is wanted, alike adapted to cover a cucumber-frame or a half-hardy tree; and at the same time it ought to be cheap and handy to deal with, and something that will drive thatched hurdles from the field, as well as quantities of loose litter thrown on like tedded hay every evening.

It is more my purpose in this article to ask for a useful article at the hands of some one well versed in manufacturing lore. Perhaps something in the oilcloth way, that would be pliable as well as strong—say a good canvas dressed in some way to turn the water, and finished with some other colour than black or green—say some light one, not white, which would not become so heated in a hot summer's day. I think much of the dressing matter hitherto used in giving a face to waterproof cloth injured its texture, and a speedy decay was the result. If something different could be employed that would strengthen rather than destroy the substance it was placed upon, it would be better, at the same time retaining pliability, and a prospect of not being affected by the weather, or as little as possible. To accomplish all these qualifications, we must give up what manufacturers have for some years regarded as their first aim—appearance. But when they are able to furnish us with a good heavy wrapper of this description, we will by no means find fault with its colour, and assuredly the quantity of coverings wanted each year being on the increase, it is to be hoped our expectations of something good will ere long be fulfilled. I do not want a substitute for glass in the shape of a transparent calico, or anything of that kind, but something that will supersede Russian mats, thatched hurdles, or wooden shutters, or the many other makeshifts we are obliged to use to keep out frost.—J. R.

### THE BARBADOES POTATO.

CAN any one give any information as to whether this species of Potato is still in existence?

About sixteen years since it used to be with us the best sort grown, both for size and quality, and, being the best cropper, it was nothing unusual to see the tubers a foot long, and to turn out a gallon to a plant. We used always to purchase about three hundred bushels annually for domestic purposes; a farmer in our neighbourhood growing them especially for us.

I have made inquiries at Covent Garden Market and of different individuals likely to give information, but no one knows anything of it.

Myatt's Seedling is about the best Potato with us, both as to cropping and quality; but the Barbadoes would make four of them. The Fluke is also excellent, but not an abundant cropper. If any one could give any information as to where this remarkable variety could be procured he would confer a great favour on—A CONSTANT READER.

### FLOWER SHOWS FOR THE POOR IN TOWNS.

THE season is now approaching when those who intend next summer to have flower shows for their poor people must set about making-up their schedules and perfecting their rules. I have no doubt that these most beneficial shows will be much more numerous next year, in consequence of the success of those already held, and the prominence which you have given the subject in your columns. As I had the pleasure of assisting

Mr. Parkes, the energetic originator and promoter of the flower shows which have been held in the parish of Bloomsbury, perhaps you will allow me shortly to give some of the results of my experience on the subject. On more than one occasion I discharged the very difficult and equally thankless task of judge, and on that subject I shall have a few words to say to any who may in future occupy that position at any of these shows. From the fact of my being judge I was, perhaps, better enabled to observe what kinds of plants are most generally cultivated by the class of persons for whom these shows are intended, and when they are first started I think it is most important that this should be known and kept in view.

Before the schedule of the prizes offered at the last Bloomsbury Flower Show was issued, there was some discussion as to what different plants should be allowed to compete. Judging from what I had seen in the previous year, and considering that we were still experimentalising, I advised that the competition should be confined to Geraniums, Fuchsias, and Annuals, the last-named being inserted as a trial; for I was anxious, if possible, to promote the cultivation of a class of plants which are so easily grown and so amply repay for the trouble expended on them.

Now, the result is worth the attention and consideration of those who intend to follow our example and will avail themselves of our experience. All the classes for Geraniums were well filled, and I think all the prizes in those classes were given away. The majority of the classes for Fuchsias were well filled; but in scarcely one class for Annuals were there as many plants shown as prizes offered. This entirely confirmed the experience I had derived from the show in the previous year—namely, that the poor will not at first, nor until they become more interested in these shows, purchase or grow any plants for the sake of exhibiting them, but will simply send any they may happen to have in their possession, and nine times out of ten those plants are Geraniums.

The question, then, and it is a difficult one, is how to induce the poor inhabitants of the narrow streets and alleys to believe that they can, with scarcely any expense or trouble, grow other plants besides Geraniums and Fuchsias, which will interest them more and repay them better for the pains they take with them.

At present I have been unable to think of any better plan than collecting together some evening as many poor people as possible, explaining to them the way to grow some of the most common hardy annuals, and sowing the seeds of one or two sorts in pots actually before their eyes. I have not done this as yet myself, but should be ready to do so if no better plan suggest itself to any of your readers who may be equally interested in the subject.

There is one great difficulty connected with the exhibitors, some way of overcoming which must be found. We made a rule that every exhibitor should have his plant or plants in his possession, and register them for exhibition, a certain number of weeks before the day of the show; but no steps were taken to insure exhibition of the identical plants registered. The result was that some of the exhibitors purchased plants shortly before the day and substituted them for the registered plants. This is a serious difficulty, and one that will, I am afraid, cause much trouble. Can any one suggest a way of overcoming it more effectual and less troublesome than marking every pot?

And now a few words of warning to the unfortunate man who may accept the office of judge—an office which I am by no means desirous of filling again! I cannot do better than recount my own experience. Immediately on entering the room where the plants have been arranged for my inspection, I am almost assailed by some lady who takes a most active part in the district-visiting of the parish. Before I know what I am about, she drags me to some plant which belongs to an exhibitor who is a *protégé* of hers, and begins expatiating on its various merits, and gives me directly to understand that it excels all the other plants; and, indirectly, that if I do not give it a prize she will have nothing more to say to me in future. This same process is, perhaps, repeated by the same or some other lady until I am nearly crazy, and when I have set them at defiance by failing to award prizes to the miserable specimens exhibited by their *protégés*, they undo much of the good which may be done by these competitions, by giving prizes of their own to their disappointed pets. In the evening, perhaps, the rector comes down to distribute the prizes, and is immediately seized upon by these zealous ladies, who strive to prove the unfairness of the awards. The only way he has of silencing them is, to announce that he intends in no way to interfere with the decisions of the Judge.

When flower shows have been once held in a parish they should, I think, be continued every year; or the interest of the poor will flag. For some reason unknown to me there was no flower show in Bloomsbury this year; and I am afraid "the good cause" has in consequence received a serious check, as many, relying on the promise that there should be a show, had provided themselves with plants and were disappointed.

There is only one more point to which I wish to draw attention, and that I also consider of importance: it is the inadvisability of having classes for mixed plants. At our last Bloomsbury Show one class for domestic servants was introduced, and (without my approval), they were allowed to exhibit any sort of plant. The consequence was, that I found it well nigh impossible to decide between the best plants of the different sorts which were exhibited, and some of them were very fine. I am, therefore, decidedly against classes for mixed plants, unless the prizes are offered for groups—as, for instance, for the best Fuchsia and Geranium together. It is my impression, however, that such a class would not be filled, and at the first show should not be thought of. I hope the importance of this subject will be deemed a sufficient excuse for my troubling you at such length.—WALTER H. BOSANQUET, 5, Torrington Place, London, W.C.

## SUBURBAN ROSE CULTURE.

(Concluded from page 719.)

HAVING decided upon the varieties to be cultivated, amateurs must recollect that good plants require no more space nor attention than bad, and that, therefore, no pains should be spared to obtain robust and well-grown subjects for experiment, without which all previous trouble and preparation will be in vain. To secure this, dearly-bought experience during my earlier attempts at Rose culture has convinced me of the absolute necessity of procuring plants direct from the first-rate nurseries only, where every improvement of culture is introduced, and from which the reputation of their proprietors forbids the dispatch of inferior trees. Besides, by so doing, the plants will suffer but one check by removal—an important consideration, and will sooner reach their ultimate position in the rosery. They will also be cheaper in price, as well as reliable in quality, to those who are content with old favourites of the highest merit. Of course, novelty must be paid for. This brings me to the "whereabouts."

All the eminent Rose firms, I believe, advertise their lists in this Journal; but for the information of the inexperienced, I shall name some of the most renowned as cultivators and exhibitors. For my own part, I obtain most kinds I require for carrying out my experiments from the Messrs. Fraser, Lea Bridge Road, and Messrs. W. Wood & Son, Woodlands Nursery, Maresfield, Sussex; not simply because their plants are fine, but because they endure removal well to the London suburbs, which is not always the case, however well trees may thrive at nurseries. I name this here because it has an important bearing on the object for which these papers have been written—viz., to encourage and popularise the taste for growing Roses in the neighbourhood of towns, particularly near the metropolis. Other celebrated Rose-nurseries are those of Messrs. W. Paul, Waltham Cross; Paul & Son, Cheshunt; Rivers & Son, Sawbridge-worth; J. Cranston, Hereford; Lane & Son, Berkhamstead; Cant, Colchester; Francis, Hertford; Smith, Worcester; Mitchell, Piltown. These various growers may not only be depended upon for supplying excellent plants, but for good advice also to those who seek it.

Directions for pruning, destroying insects, preparing manures, and a general routine of operations for cultivating the Rose, equally applicable to town or country, will be found in the pages of THE JOURNAL OF HORTICULTURE. To repeat them would be an unnecessary consumption of valuable space. There are a few hints, however, which it may be desirable to give.

Do not be afraid of plying the syringe and garden engine; but do not wet the foliage when the sun is on it. Liquid manure should be commenced with weak, and increased in strength gradually. When it is applied be careful it does not settle round the collar of the plant, as, by doing so, it rots the bark, and injures the diffusion of the sap. It is a good plan to have a slight hollow, in a circle, about a foot or so from the plant, in which the water may lodge and soak through within reach of the spongioses, which will better collect the nourishment thus bestowed. When mulching is applied, a handful or

two of charcoal dust first placed round the root will very much conduce to preventing mildew, and the tendency to damp-off, which affects young plants, particularly those upon their own roots. In Manettis the work must be at least an inch below the surface of the soil; but Briars and plants on their own roots must not be planted deeper than the collar.

Plant all *Roses* as soon as possible after they are received. If they are obtained very early, or very late, after having dug a hole the requisite size, pour in water, and mix the soil to the consistency of mortar, so that the roots may expand to their natural extent; then fill-in firmly with dry earth, and, if a standard, affix it securely to a stake.

Sufficient chloride of lime mixed with tepid water (to the colour of skim milk), will make an effectual wash for destroying blight and grub on *Roses*, if applied twice or thrice early in the season.

Let your beds and borders be well dressed every autumn with a coat of fresh loam and well-rotted manure, to be forked-in during the ensuing spring. Pigeon and charcoal dust, or wood ashes, form excellent manures for *Roses*. When *Roses* are planted out of pots in the spring, protect them for a time with some kind of covering, leaving it off by degrees.

Keep a watchful look-out for suckers, particularly those from the *Manetti*, and remove them as soon as they appear.

I do not know that I can add much more. Many little points of culture will suggest themselves to observant amateurs during their practice; and if these little papers should encourage any to undertake the delightful recreation of *Rose-growing*, or assist them in the enjoyment of the pleasures attending its pursuit, I shall feel amply repaid for the trouble of penning them.—W. D. PRIOR, *Homerton*.

### ORANGE-TREE CULTURE.

MR. RIVERS has been lately growing the *Tangerine* and other of the more hardy species of the *Orange* tribe on a large scale, for the purpose of fruiting in orchard-houses for the dessert. I have this last year tried several plants of the *Tangerine Orange* in the soil near the back wall of a cool vinery, sheltering them with mats during severe weather, and I have reason to think they will turn out productive. They were removed from the pots last spring into a compost of peat, loam, and rotten manure. They flowered in the early summer, and set pretty abundantly, though some of the fruit fell off when about the size of peas. The larger fruit are now beginning to turn yellow. I have been rather troubled with the black fungus and scale, but have succeeded in getting rid of these pests by means of water and a penknife, with an occasional slight application of Gishurst, and they are now remarkably clean and healthy. I have two or three times given them a little liquid manure, and in mild weather I frequently use the syringe with pure water. I should like very much to obtain some hints from the Editors or correspondents on the culture of these hardy *Oranges* for useful purposes, and to be informed whether the fruit at all approaches in flavour that of a southern climate. I should tell you that I have a brick *Arnott's* stove in the centre of my vinery, and light it about the beginning of March, for a few hours each day, to start the *Vines*. The *Vines* are close-spurred, and not allowed to shade the *Oranges* too much.—JAS. C. BARNHAM, *Grove Cottage, Norwich*.

[We think you have treated your *Orange* trees very successfully. It would not be advisable to ripen these or any *Oranges* now, in our dark days. Those that are green we should just keep healthy. In summer and autumn, we have no doubt you will find these *Oranges* delicious in flavour. We should be glad of the experience of those who have had more practice with these kinds than ourselves. We know they ripen well, and are delicious at *Sawbridgeworth*.]

### TESTING POTATOES.

LADY GEORGINA OAKLEY has read with great interest the paper on "Comparative Merits of Potatoes" in the Number for December 16th signed "UPWARDS AND ONWARDS." Her husband, Rev. W. Oakley, and brother, Earl Ducie, have a large body of allotment tenants in this neighbourhood. Many of these tenants have suffered very much from the disease in that vegetable. She has determined to devote about four acres of land next spring—partly an old pasture newly broken-up and

partly old worked ground—to experimenting on the sorts best suited for general cultivation in this locality. It is on the rail between Bristol and Cheltenham, and many of the poor people might make good profit by supplying these markets with early and other *Potatoes*. The soil is a limestone rock, mountain limestone being the prevailing formation in the neighbourhood.

Lady Georgina has tried many sorts on a smaller scale, and under worse conditions of soil and general culture. She now wishes, in the season of 1863, to give a fair trial to any sorts which may be sent her by growers of seed *Potatoes*, if sent in small assorted quantities by *luggage* train, gratuitously, and prepaid, to the "Wickwar Station, Midland Railway." Her gardener shall plant each variety so sent, by itself, in ground of both sorts—fresh broken-up and old cultivated in equal proportion; and, when the roots are taken up, will forward to each sender an account of how they succeeded, absolutely in each locality, and relatively to other sorts.

Lady Georgina Oakley feels she must apologise to the Editors for this lengthy letter; but she is sure that they will, under the circumstances, do what they can to forward a plan which has for its object the supplying a poor and industrious class—the allotment tenants, with the most profitable tubers in future seasons for cultivation in the south-western district, where a damp climate so injuriously affects many of the best sorts of *Potatoes*.—*Lisburne House, Wickwar, Watton-under-Edge*.

[No greater boon could be bestowed upon allotment tenants than demonstrating which vegetables are the most desirable for them to cultivate, keeping in view not only which are the most abundant producers when they do succeed, but which are the least liable to failure. Foremost amongst such vegetables is the *Potato*; and we hope such of our readers as have a variety characterised by prolificacy and healthfulness will aid Lady Georgina in the way she requests. If, in addition, the variety is an early ripener, it will be all the more valuable to allotment tenants.—Eds.]

### THE RIBSTON PIPPIN AND COX'S ORANGE PIPPIN.

YOUR correspondent, "F. J. G.," says, "These sorts are notoriously subject to canker," and I am sorry to say it is true; but let us try if something cannot be found to militate against this sad feature in two of our finest-flavoured Apples.

As regards the *Ribston Pippin*, I had it, I may say, as a standard under my doctoring, both here and in *Shropshire*, for twenty years at least; and all that I could do or think of would not eradicate the disease, and at last I gave up the attempt in despair upon the standard here, and grubbed it up.

I then sowed some pips of the *Blenheim Pippin*, as it is a fine, clear-skinned, and free-natured tree, and grafted two branches of a young two-year-old stock with scions of a *Ribston Pippin*. In the following season I rung-flayed the bark clear away from the wood to the extent of 2 inches close above the junction of one graft, then bent it down, and covered the excoriated part and half of the young shoot with earth, and kept it moist all the season. Cicatrization and roots followed, and in the following (last) spring I severed the shoot away, and it is now growing as an independent dwarf *Ribston Pippin* tree on its own roots, having its bark perfectly clean. I intend to train it as a dwarf pyramid. It will bear the year after next, and, if I am spared and remain here, I shall report progress.

I am training the other part of the grafted stock as a dwarf for the wall. It, also, has its bark clean, is perfectly healthy, and it will bear, I think, next year. I trust these experiments may, in a measure, prove satisfactory; and if I may judge by a feature which I think I can perceive in the *Cox's Orange Pippin*, I buoy myself up that they will.

I rushed after the *Cox's Orange Pippin* the moment it was advertised, and a nice-looking standard tree arrived. It had been double-worked, grafted on to an *Apple* stock, which had been grafted low down. The first season induced a slightly cankered stem, and the next seriously so, which, of course, affected the grafted head; and to that degree, that last year and this the *Apples* mostly fell off, and what remained on became preciously ripe, though they were of excellent colour and flavour, and fair size, but they soon became "woolly." The head of the tree now looks prematurely aged, and some of its shoots are affected with canker.

I wrote to Mr. Rivers as soon as I saw what was going on

when he immediately presented us with a dwarf pyramid tree of the same variety, which remains perfectly healthy, stem and branch. Its fruit ripens three weeks later than the standard, and keeps well.

Now, the question that follows is—Are these Ribston and Cox's Orange Pippin trees to be cultivated more successfully as pyramids than as standards? Perhaps some of your numerous practical readers can help us here. Mr. Rivers' opinion would be valuable, for we must not let the Ribston become lost to us and to posterity if we can possibly help it, nor Cox's Orange either.

I quite agree with "F. J. G." in his remarks upon the great International Fruit Exhibition. My premature Cox's Orange Pippins were ripe at that time, and I should have much liked to have entered them, had not the fear of there being no competition in a separate class for them decided me not to do so. And now allow me to put a question as regards tasting.

Instead of steel knives, would it not be much better for the judges to be provided with electro-plated or silver instruments? The flavour of any fruit becomes injured in contact with steel; and for a thoroughly ripe Pear or Melon, how much more convenient it would be for a judge to test them through the agency of a dessert-spoon. Why, their slippery flesh on its way to one's mouth has the propensity of quicksilver to escape from the end of a knife, more particularly when one is in a hurry. I did not envy Mr. — his Melon-tasting feat with a shut knife, whilst one hundred pairs of eyes were being concentrated upon him. In one instance he made four attempts to convey a luscious morsel to the desired receptacle (equivalent to tasting four Melons with a spoon); but he went through the trying ordeal bravely, like a true and hearty-looking Briton which he is.—UPWARDS AND ONWARDS.

### HOW TO GROW GOOD CELERY.

I AM not about to tell you to grow it to an enormous size, for it is no improvement to have it weighing more than 5 or 6 lbs., and even half of these weights is plenty if it has to stand the winter.

In the first place it is necessary to get good seed and of a good kind; and in the next it is indispensable that the seedlings be not raised too quickly. I have found that if the seed is forced in too much heat the plants are liable to two faults—namely, running to seed, and to be hollow.

In commencing to raise Celery, it will be found a good plan to get some well-rotted turf and well-decayed cow or horse dung in equal quantities. Mix them well together. If the dung is wet, dry it till it can be handled without sticking to the fingers. Place 2 inches deep of the mixture in a shallow box or seed-pan, and about half or quarter of an inch of fine soil on the top of this. Make it level, then sow the seeds, carefully covering them with fine light soil or sand, but taking care that they are not buried too deeply; a covering of an eighth of an inch is plenty. Place the box or pan in some place near the glass so that the young plants will not be drawn, and never let the heat get above 65°. Give a dose of clear liquid manure once or twice a-week when the plants are up.

When they are grown so large as to have two leaves besides the seed-leaves, prick them out into beds or boxes, and let the soil into which you prick them be the richest you can get. Put them in some sheltered situation if not possessed of frames. They generally grow well enough if pricked-out in April where old bags or pea-rows can be thrown over them on severe cold days or nights. I raise my main crop this way, and have not had half a dozen bad sticks in five hundred.

I have found it a good plan to make Celery-trenches, leaving a little soil in the middle, to insert the plants before manuring, putting the manure in afterwards with a basket. It is a little more labour than the old or common plan of putting in the manure first, but I think it pays better before the end of the season.

The Celery, being naturally a marsh plant, requires in its cultivation a cool bottom with plenty of moisture. This is one reason why I prefer planting before I put in manure, as the manure laid on the top, or rather up each side of the plants, helps to keep in the moisture. It can also be kept in by placing layers of short grass, or litter, or old sawdust, mixed with equal parts of good rotted manure and common soil. This I like better than manure alone for growing them in for the table.

Never allow the plants to want water in dry weather, and give once or twice a-week a dose of liquid manure, which may be

made of guano or cow, sheep, rabbit, or horse dung; also, of potash or common house slops.

The great point in Celery culture is to keep the plants steadily growing without too much heat. There are many plans for blanching Celery, but the best and easiest is to put a handful of clean sawdust into the centre of the plants when soiled-up for the last time. The soiling is best performed in three or four operations, and not all at once, but just as the plants keep increasing in size.

I should recommend Bossom's Pink as the best. I get it very good from Mr. Watkinson, seedsman, &c., of Manchester. I try every new sort that comes out, but keep Bossom's for the main crop. I have, without any egotism, produced some of the best table Celery in this neighbourhood.

I think your correspondent "P. L. C." makes a grand mistake in having too much heat at the beginning or sowing time, for I have known an old gardener fail with the same seed as myself by too much heat at the beginning. It is quite unnatural to expect things to do as well in an artificial state as they would do in a natural one; and I think that your correspondent "P. L. C." must reflect that the heat of the soil in any part of England, or in most other countries, will, probably, never get up to 75° in early spring. I have numerous testimonials as to the goodness of my Celery. I take a little pride in the matter, and if there be anything I have left vague to your readers, I shall be happy to give the best explanation I can.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

### PROTECTING ARTICHOKEs.

In this part of the country, where ground is valuable, kitchen gardens are mostly of very limited extent. We are, therefore, obliged to grow only such vegetables as are in most request, and these are generally such as yield the largest return on a given space. The Globe Artichoke is not considered one of these, and is, consequently, not largely grown. I have of late years grown but a single row of a dozen plants. These, until the year 1859, had occupied the same spot for many years. In the spring of that year I transplanted them—that is, I took offsets from the old plants, and planted them in trees a foot apart; each clump of three being 4 feet apart. I then destroyed the old roots. The new plants grew vigorously, and produced a small crop the same year. In the winter they were not protected: the leaves were cut off by frost, but they came up and bore enormously in the year 1860. In the autumn of that year the old stalks were cut down, and the plants threw up an abundance of offsets; and as I had left off protecting them with dung and litter, they were left unprotected to pass the winter as they might. I had every confidence that they would pass the winter of 1860-61 as they had done former winters; but the fact was they were nearly all killed, as nothing of them came up but a few weak shoots, that bore no fruit. This, perhaps, is not to be wondered at, when it is known that Baye, Laurustinuses, Euonymus, and other presumed hardy shrubs, were killed to the ground, and some killed outright, within a short distance.

But, Mr. Beaton calls into question the assumed hardness of the Artichoke, and starts from the observations of Mr. Keane, who recommends protecting Globe Artichokes, and Mr. Fish, who reports on having done so. Now, we know that both Mr. Fish and Mr. Keane are thoroughly practical men, as well as men of sound judgment, and not likely to recommend or to do anything solely from the dictate of custom. I rather think that when the chances are even that once in ten years we might have such a severe winter as would materially injure the roots, that it is worth while to be prepared for that emergency; besides the fact of giving the plants manure at a time when it will afford them protection, and further by reducing, possibly, the abstraction of heat from the ground, they are prepared to start earlier, even though it may be but a trifle, in the spring. Had I protected my plants every winter successively, the doing so for ten years when they did not require it would have been repaid in the one winter, when it so happened that they did, and might have been saved.

With regard to the hardness of the plant, I agree with Mr. Beaton that time has not yet clearly decided the question either one way or the other, for it is not because a plant will stand the average of our winters that it is to be adjudged hardy or otherwise. On this point the Artichoke must take its stand among various shrubs, &c., that were wholly or partly killed in the winter of 1860-61 under like circumstances. But I

do not think that a fair test, since the preceding season was unusually wet and cold, and plants were in no condition to stand the extra severe weather that followed; and I believe now, as then, that still harder frosts might follow a dry summer and autumn without having such a destructive effect. Again, supposing plants were buried under a foot or more of manure, scarcely any amount of frost would injure them.

Take, for example, the plants found in the arctic regions, among which are represented the Campanula and other families, as spoken of by arctic voyagers. These could not possibly survive the intense continued arctic frosts, unless covered by so excellent a nonconducting material as snow; but then protected by such a thick covering, they do survive, and break out again as fresh as ever in the short summer that visits those inhospitable regions, and with it the reindeer, that finds its summer diet.

Take another instance. There are several plants found in a wild state inhabiting our woods and forests which, when brought under cultivation, will not stand an ordinary winter, but require the protection of a frame or pit. How is this? Every gardener knows the nonconducting power of dry leaves, and how a few inches laid on the surface of the ground will prevent the frost entering it. The leaves are shed by the Oak and Beech in the autumn, and are blown hither and thither by the autumn winds until they cluster round the Fern or Arum, and thus protect it from the nipping frost or chilling blast. Yet without this protection the plant could not claim to be classed as hardy. Before we can decide what plants are hardy or not, it is necessary to ascertain what really constitutes hardiness.—F. CHITTY, *Stamford Hill*.

### DOES THE GLOBE ARTICHOKE REQUIRE PROTECTION?

As far as my opinion goes I am bound to give an explicit No, notwithstanding the reverse of such from two correspondents in last week's JOURNAL OF HORTICULTURE, and go thus far with Mr. Beaton. In the winter of 1860 and 1861, which we all remember, I lived gardener in a situation just at the foot of the Campsie Hills, about as cold a spot as is to be met with in the three countries. I had ten rows of the above in a bleak exposed situation, growing in a strong loam with a subsoil of the most tenacious clay. These stood all the winter without the least protection—all the loss was some half dozen plants; the rest broke from the neck quite vigorously, and produced heads the following season. At this place they stood unprotected all last winter, growing in the centre of a four-acre kitchen garden in strong black loam, with clay as subsoil to a considerable depth. Up to the time I write they are as green as Leeks, and my intentions are to allow them to take their chance as usual, under the impression that they are constitutionally hardy—at least, sufficiently so to enable them to withstand all the cold we are subject to in this locality.—JOHN EDLINGTON, *Crom Castle, Ireland*.

[It is quite certain, from the above reliable testimony which we have published, that in some localities the Artichoke will endure usually the winters of our climate. On the other hand, we have testimony that in other localities it perishes in winter if unprotected. We incline to the opinion that it is not altogether intense cold that kills the Artichoke, but the alternations of mild and severe weather—the mild weather arousing vegetation sufficiently to render the plants more tender. Be this as it may, we think it right, as the trouble is but trifling, to recommend our amateur readers to be on the safe side, and even if Liberals, to be thus far Protectionists.—Eds.]

### SHOULD THE FRUIT OF STRAWBERRIES BE SUPPORTED UPRIGHT?

I HAVE just noticed Mr. Fish's concluding remarks in his reply to "WYESIDE" (see page 695), respecting some peculiarities in Strawberry-forcing at Hatfield. I am not aware there is anything very novel in our system of management, as we have hitherto pursued the ordinary course of treatment. But what appears to have attracted Mr. Fish's attention was all the fruit hanging on the back of the shelf and none on the front.

The shelf alluded to by Mr. Fish is, as he has described, about 3 feet from the back of a lean-to house, and about 18 inches

from the glass. The flower-stems have always a tendency more or less to draw to the back. This I have always attributed to the heat and light reflected from the back wall; but this is by no means a general rule, as some will incline to the front, but these I invariably turn round; hence it was that Mr. Fish probably came to the conclusion that they all grow in that position.

My object in thus having all the fruit to hang on the back is that it gets more air and not quite so much sun; as, when hanging in front of the shelf, I have often found the fruit injured by being exposed to the full rays of the sun, which will prevent it keeping any length of time should it be required. This is a very important object to me, and I have no doubt to many others, as it often happens that I have to keep it a considerable time after it is ripe. But, on the other hand, should the fruit be required for table as soon as it is ripe, I should in that case give it the full benefit of sun and air.

So far as my own experience goes, I am not an advocate for tying or supporting the fruit of Strawberries upright, as I have never found fruit from plants so treated equal in size those that were pendent. However, should the flower-stems be of great length I would place a string, or some similar contrivance, the entire length of the shelf, so as to afford a little support, at the same time allowing the fruit slightly to depend, and thus break the great strain on the flower-stems.

As this is a subject which may probably interest some of your correspondents, I, with many others, would be glad of their experience.—J. B., *Hatfield*.

### MELON CULTURE.

DURING my various sojournings I had the good fortune to live with a nobleman's gardener, who has distinguished himself as being one of the most successful cultivators of nearly all kinds of fruits that are generally cultivated in British gardens, among which was the Melon; and the means he adopted to do so were as follows.

The soil used was merely the scrapings of the public road, mixed with small portions of turf that had been cut off the edges, the whole put together into one heap until required for use.

The pits were heated both by fermenting material and hot-water pipes, which could be turned off or on at pleasure.

The soil was just put-in in ridges along the centre of the bed, and firmly trodden to prevent overluxuriant growth.

When these ridges had become sufficiently warmed through, the plants were put in, and had a slight sprinkling with tepid water, and were kept close, and shaded for a few days till they showed evidence of laying hold of the fresh soil, when they had a little air and less shading.

When the plants had made shoots about 4 inches in length they were then stopped, and when each shoot had made about three leaves more they were again pinched, and were then allowed to grow till they reached the sides of the pits, and by this time they were showing flower. Sprinkling was then discontinued, and plenty of air admitted on every favourable opportunity. Rambled shoots were thinned-out, and others stopped and regulated as necessary.

They were thus treated till a sufficient quantity of fruit was set, when they were afforded an atmosphere more favourable to their growing and swelling, and occasional waterings with weak guano water at a temperature a degree or two warmer than that in which they were growing. They had a slight shading during the middle of the day if necessary, and were syringed, and shut up early in the afternoon to secure as much sun heat as possible, avoiding at all times pouring water near the neck of the plants, and giving at every opportunity plenty of air, but avoiding cold currents, or anything like having a certain amount of air on at a certain hour during the day. Existing circumstances ought always to be the guide of the attendant on forcing-houses. By the above treatment the plants produced large green foliage, and fruit that obtained a prize at the Caledonian Horticultural Society's Show.

Having given you what I have experienced to be a successful way of growing the Melon, I will now give an instance of a failure; and hope that you or your numerous correspondents, after reading the treatment which the plants received, will be able to offer me a reason. When I say failure I mean that the return was not an equivalent for the labour bestowed.

The pits were originally intended for succession Pines. They were 5 feet deep from the top of the wall-plate to the hot-water pipes for supplying bottom heat. These pipes were one flow and one return for bottom heat, and the same for top.

The pits were filled with dung and leaves to within a foot of the top. When the fermentation had subsided a little the soil was put in. It consisted of a strong adhesive loam mixed with decayed leaf mould to lighten it a little; I think there was a little more of the latter than justifiable. The plants grew away very luxuriantly at first, and required continual pinching and thinning to keep them within bounds.

When they began to show flower they had abundance of air and a dry temperature during the middle of the day. When leaves and flowers were dry I went round and impregnated every fresh-opened flower, but all to no purpose. In a few days they became yellow, and dropped off, and continued to do so for several weeks. At last a good many set, and began to have a very promising appearance. They then had a watering with tepid water, avoiding pouring water near the necks of the plants.

The water had to be taken out of hot-water pipes that have

been in use for thirty years, the smell of which when running into the pots was very disagreeable.

They had a slight sprinkling every bright afternoon, and were shut up early to lessen the expense of coal.

Things went on in this favourable manner for some time until a kind of dirty almy stuff commenced to collect round the neck of the plants, when both plants and fruit apparently came to a standstill, or at least made very little progress; and it was evident the plants were deriving no benefit from the roots; for, on scraping away a portion of the stuff the necks of the plants were found to be quite dead.

Some of the most forward of the fruit became serviceable for the table, but were not first-class fruits, and others never came to maturity. The only sort grown was the Benares.—R.

[Watering with fetid water, and sprinkling the leaves with the same was treatment calculated to produce such results; in addition to which the soil was too rich. This would cause over-luxuriant foliage; and such foliage is, more than healthy foliage, liable to suffer from the carburetted hydrogen and other gases emitted from foul water.—EDS.]

### EXCELLENT FORMATION OF BORDERS.

THE enclosed is a section of a span-roof vinery, in which the trees are grown as described in a previous communication (p. 632). The house is 75 feet by 20 feet. The trees are, as before stated, grown in tubs placed down the centre walk. The Vines are planted in the front of the raised beds 3 feet 8 inches apart, and trained to the uprights shown in the section, so the roof is densely clothed with foliage; and, in addition to this, we have smaller fruit trees in pots on the raised beds, one between every two Vines, so it will be seen there is but little chance for the trees in the centre of the house obtaining a glimpse of the sun at all.

As our able adviser "R. F." hinted, in answer to my last article, moving the trees to get a peep at daylight or sunshine, this, of course, would be quite useless in such a case as mine. My reason for sending the section is to give "R. F." a more clear view, also that the readers of the Journal may better understand it. I confess that I am not well versed in such matters as describing my case to so many well-informed horticultural readers; however, I am anxious to do my best for myself, and if any use to others, "Well and good," say you.

The Vines ripened in August last about five hundred bunches of what I consider good Grapes, and I think you would second me in this if you had only seen them. I have, at the present time, upwards of two hundred bunches hanging on the Vines in fine condition, most of them Black Hamburgs and Black St. Peter's. I have one Vine of Raisin de Calabre, named at your office a month later than this last winter, and it proves to be an excellent late Grape. I may add that, up to the present time, I have not cut-out 1 lb. of decayed berries. This I attributed to the border being well drained, and plenty of air during fine weather, a little in damp with fire heat. We have paid extra attention to the draining of the border, on account of its lying in a hole. The drainage consists of stones from the seashore—say about 10 inches deep; on that 3 inches of concrete, made of hot lime and sea gravel; over the concrete

place 4 inches or 5 inches of stones from the fields. I prefer brick and lime rubbish over the concrete in the place of stones, as I consider it drier; but had not the latter, therefore used stones.

I also send for your inspection a section of a Peach-passage proposed by me a few weeks back, which "R. F." kindly gave a hint upon as to width. I can manage 8 feet 9 inches, but not more, as the allotted place will not allow it; this space will give plenty of room to the trees from the tubs. I cannot have the front less than 6 feet, as the trees will require all that; they are not over-bushy, and I will allow a good space between each tree or bush, so that the trees on the back wall will not be overshadowed by those in front. The front wall will be 2 feet 6 inches; rubble stones to the surface; 6 inches brick wall above ground; boards hinged on in six-foot lengths, 18 inches deep, to act as ventilators; the remainder of the front to be a fixture. The roof will also be permanent, all glazed with large glass. The top ventilator would, as "R. F." states, be better glass, but I think it more liable to break, also expensive; and these ventilators would mostly be open during the heat of the day, so that the top of the trees would have the benefit of the sun.

Having not shown in section any middle supports to the roof, would it be advisable to have an upright 3 inches square—say one at every 12 feet, resting on a stone at bottom, and a piece of scantling secured to the rafters resting on the uprights? —A. R. M., Ireland.

[There is one fine feature of your span-roofed house, and that is the raising the narrow borders inside from 3 feet to 4 feet in height above the level of the floor, so that the inside border shall at least be as high as the highest part of the sloping border outside. With the thorough bottoming and drainage given to that border outside and inside, we are not at all surprised that the Vines should do so well and also keep so well. With Vines in such a house 44 inches apart, of course there would not be

sun enough to ripen the wood of Peaches, &c., beneath; but still if that house were allowed to come on pretty well naturally, as we presume is the case, then we do not see why the Peach trees there should not be forwarded a little and set before the Vines can shade, and thus, when moved to the orchard-house, give a crop a little earlier than those which stand there all the season. The width of this orchard-house or Peach-passage, 8 feet 9 inches, will be much better than what was first proposed. No doubt the ventilation will do, though our first opinion remains unchanged.

As respects the large span-roof, we do not think that supports in the centre are at all necessary, and the pillars would interfere with the open expanse of the open floor. The upright supports for training the Vines on each side ought to be sufficient, and if there are any doubts, a tie-rod across from one to the other at every second or third support would be quite sufficient, and not break-up the outline of the house. Without infringing on the patent shown in Mr. Pearson's orchard-house, you may get a good hint from it. Even a horizontal cross-bar would not be unsightly, especially with the shoot of a Vine along it.]

### EVERLASTING FLOWERS.

THERE is an appeal to the imagination from all flowers which retain their beauty after their life has departed. The young select them as emblems of affection that knows no change, and the old point to them as illustrations of life beyond the grave. They are appropriate, whether woven into the chaplet to be placed on the bride's brow, or hung upon the funereal urn. Such flowers are cherished in every country of Europe, but in none more than in Switzerland. One of these Everlasting Flowers is there especially coveted; it is a *Gnaphalium*, which grows on the most inaccessible cliffs of the Tyrolean mountains, where the chamois dare hardly venture, and which the hunter, tempted by its beauty and by his love—for it is dearly valued by the Swiss meidens—climbs those cliffs to gather, and is sometimes found dead at their base with the flower in his hand. Botanists call it *Gnaphalium alpinum*, but the Swiss know it as the *Edelweisse*, or "noble purity." It was long since introduced into this country, for in the reign of Queen Elizabeth, old Gerarde says, "The flower being gathered when it is young, may be kept in such manner as it was gathered; I mean in such freshness and well-liking, by the space of a whole yeere; wherefore our English women have called it Live-long, or Live-for-ever, which name doth aptly answer its effects."

#### APHELEXIS.

Of the greenhouse Everlastings, the *Aphelaxes* are one of the most beautiful groups. Besides the *spectabilis grandiflora*, of which a figure is here given, though the whole family is worthy of cultivation, yet *humilis* and its varieties of *macrantha purpurea*, and *rosea*, along with the creamy-coloured *sesamoides*, are certainly the most worthy of extra attention.

Coming all from the Cape of Good Hope or New Holland, the plants when established like plenty of sunshine, provided the sun does not beat too fiercely upon the pot in which the plant is grown; and water should be carefully proportioned to the state of the plant and to the presence or absence of sunshine, a considerable quantity being wanted in summer, and but a very small amount of moisture in dull weather in winter.

**Propagation.**—We have struck these plants at two periods with equal success—in the beginning of April and the beginning of June; and though the last were as sure, they took a little longer time to root. For April, slip off some shoots from 2½ inches to 3 inches long, that do not show flower-buds, dressing them at the base for half an inch or so, and insert round the sides of four-inch pots three-parts filled with drainage, a layer of sandy peat above it, and half an inch of sand above that. If a piece of charcoal fills up half the diameter of the pot in the centre all the better. This four-inch pot is now set into a six-

inch one, so that both rims are level with each other, and the space between them filled up with broken crocks, and sand on the top. The bell-glass is to be put on between the rims of the two pots. In this case the plants may be placed, plunged in a mild hotbed, where the temperature may be about 5° higher than the plant had in the place whence the cuttings were taken. Water when necessary, a little air especially at night, and shade from bright sunshine, are the chief essentials for success. We have struck them exposed on a shelf, but they generally need longer time.

When propagating in June (not later, or the young plants would not be established before winter), the cuttings should not only be firm at their base, but pretty well ripened all over. The same process as to preparing pots may be gone over; only, if there are several pots, they may go under a hand-light in a shady part of a cold pit, and bell-glasses be dispensed with. In this case, the wood being riper, there must be no extra excitement given to the cuttings; the heat of the summer will be quite enough. If not allowed to get too dry, nor yet be soaked with water, and air given at night to prevent damping, and no shading given, provided the direct rays of the sun do not reach them, the cuttings will be rooted in from six weeks to two months.

When rooted, pot off singly into small 60's, using sandy fibry peat, and some small bits of charcoal and broken pots from which the dust has been excluded. Set the plants in a cold frame or pit not far from the glass; keep close, and shaded in bright sun, until growth is going on freely; then nip the points of all shoots to insure a dwarf bushy habit; and

expose to more sun and air by degrees, until in fine weather they are fully exposed in September and the first part of October, getting them by the middle of that month to a dry airy shelf in the greenhouse, and close to the glass for the winter, taking care not to over-water, nor yet to allow frosty air to play directly upon them. About the end of March they will want a larger pot, to be kept rather close for a fortnight afterwards; if growing freely, the shoots to be stopped again, and another potting given about the middle of June. After this they will do best in a cold pit until growing freely, when the plants may stand in a sheltered place out of doors, or, better still, in a cold pit, with glass on, but plenty of air back and front, wintering again in good time. Next summer pursue a similar course, giving two shifts, the last in June into 12-inch or 15-inch pots; and if duly attended to in stopping, not after the end of July, and well looked after in winter, fine specimens for blooming in the third year will be secured.

To avoid much of this nicety, choose from the stock of a nur-

*Aphelaxis spectabilis grandiflora.*

seryman good, compact, bushy plants, in four-inch or six-inch pots—not larger, unless they have been grown for specimens; shift in April and June, stop as necessary, peg-down or tie-down to the rim the base shoots, and you may have a tidy specimen the following year, and a very fine one in the second year. Plants to bloom in 1863, should not be potted after June and July, in 1862, and should receive no stopping after July, as it will take all the autumn to ripen the shoots for flower-buds. Established plants will often keep in health for several years without repotting, with merely a good top-dressing every season, and a little weak manure water when making fresh growth. When the plants are already in large pots, and it is deemed advisable to repot them, it is well not to increase the size of the pots much, but, rather, carefully to remove a portion of the old soil, and replace in a similar-sized pot; and the best time to do this is after the plants have been pruned back after blooming, and the new growth is making way. A little shade must be given, and a rather close atmosphere kept until the roots are working freely in the fresh soil.

There only remain a few particulars as to *Soil*. This should chiefly be rich fibry heath mould. The sand, which is necessary for a young plant, to be lessened in its quantity for old established ones; and the compost may well be rougher, consisting of three parts heath soil, and one part of broken crocks, charcoal, and silver sand. For the last potting, the soil may chiefly range in roughness from the size of peas and beans to a number of pieces like walnuts, pressing all, however, firmly together in the last potting. In earlier pottings it may be a little looser.

*Time of Potting*.—As already indicated, this should always be in time for the roots to get to the sides of the pot before winter.

*Time and Mode of Pruning*.—After flowering never cut back into old wood, but yet cut far enough down on last year's wood to give room for the new shoots. In order that these shoots, at least enough of them, be matured for blooming, never stop after the beginning of July or even a fortnight earlier. Long shoots then stopped, or short stubby shoots then existing, if matured in autumn will be likely to produce flowers next spring and summer. Many little stubby shoots that do not bloom in established plants will be sure to do so the following year, when more light and encouragement are given to them from cutting away or shortening back the flowering shoots after blooming.

*Watering*.—Extra care must be given to drainage; a water-logged plant will never thrive. The roughness and openness of the soil are on purpose to help drainage; but, with all this, great care must be taken not to over-water in winter. When the flower-buds show, a little weak manure water may be given; perhaps the best is that from cowdung a year old, and then in bright days a little syringing overhead will do good in the morning and early forenoon. After the flower-stalks are cut back, the plants should be kept rather dry and cool for a fortnight or so, and then they should be kept a little closer, and slightly syringed and dewed, to cause the young shoots to break.

*Temperature and Position*.—The general average temperature in winter should be about 45°, with a rise of 10° to 15° in sunshine. In winter the plants should either be near the glass, or, at least, no other plant should intercept the light. Though kept airy, no frosty air should beat directly upon them. This will be easily secured by keeping them near the front, and admitting air in cold weather at the back of the house. A cold pit, or a sheltered somewhat shady place out of doors, will do in summer. We prefer the first; but in autumn, when the plant would rejoice in all the sunshine, the pots should be protected from its full influence. Even in the greenhouse, large plants on a front shelf would be all the better in spring and early summer if the pots were screened a little from the sun, by being set in a larger pot, or a piece of white calico hung in front of the pot.

#### PHENOCOMA PROLIFERA.

Or *Elichrysum*, or *Helichrysum proliferum*, is, perhaps, the next most interesting of this class. It propagates rather more easily than the *Aphelexis* by using pots in a similar manner, but moisture must be avoided. We have struck it successfully with and without a bell-glass, the pot standing on a shelf, and merely shaded from the brightest sunshine. The silvery-dotted stumpy foliage is almost as interesting as the bright brownish-white flowers. In purchasing, a small bushy plant should be selected. The great thing to guard against in the plant is legginess and upwardism; unless well stopped and tied-down at the bottom, it will get bare and stemmy below. The chief feature in the culture, as distinguished from the *Aphelexis*, is using a little

fibry loam in the compost, from a sixth to a young plant, until, in the various pottings, it may reach to fully a third in a large plant. The other constituents much the same as for *Aphelexis*. We confess being hardly up to the changes that have been made in this and other allied genera, but think we may mention the following *Elichrysiums* as also well worthy of cultivation for their lasting flowers:—*Speciosissimum*, *spectabile*, *argenteum*, *retortum*, and *sessmoides*, &c.

#### GNAPHALIUMS.

These, also, have been much changed. They are very easily cultivated, requiring a cool greenhouse in winter, and light sandy loam to grow in. The most of these would bloom freely out of doors in summer. Of these some of the best are *grandiflorum*, *congestum*, *tephrodes*, *ericoides*, *teretifolium*, *stæchas*, and the new edging plant *Gnaphalium lanatum*.

The *Aphelexes* and the *Elichrysiums* will keep their flowers in good order for years if gathered before they are too far gone, and hence are useful for winter and room decoration. The *Gnaphaliums* are generally weaker in the flower-stalk, and need more support, such as a stick or a piece of wire, to keep the flowers up.

Many who might wish to have some of these Everlasting Flowers, but who may have no greenhouse, may secure their object by sowing *Elichrysum bracteatum* in a mild hotbed in the beginning of April, pricking the plants out, and finally planting them out in rich light soil in May. The *Gnaphalium luteo-album* may be sown in the open ground in April; and so may all the varieties of *Xeranthemum*, though in cold places they will do better if sown under glass and planted out in the end of April. These, with their large flowers, should be gathered before they open, or they will open and shed their seeds all about the room. For low-growing herbaceous plants, with their pretty everlasting flowers, such as you may see dyed of all colours in Covent Garden, I know of nothing more beautiful than the low-growing yellow-flowered *Gnaphalium arenarium*, which flourishes in sandy loam in any flower-border; and the white-flowered and white-leaved *Gnaphalium margaritaceum*, which is even less particular as to soil, and is the same plant, we believe, which Mr. Beaton describes as being so much used for broad edgings at Hampton Court under the name of *Antennaria margaritacea*.

Any of our readers, therefore, who feel disposed may grow their own Everlasting Flowers for winter; and when mixed with a few nice Grasses they will produce a nice effect, even where the choicer greenhouse ones cannot be obtained.—R. FISH.

#### GERANIUMS FOR EDGINGS.

In your Number for December 2nd, Mr. Beaton, when speaking of a new Geranium, "Little Dot," says—"After Little Dot is my own seedling Harry Hieover, which, when planted in two rows for an edging, makes the most perfect ring of all round the garden; but unless the plants are two years old, one row of it is hardly sufficient for an edging." Now, doubtless on Mr. Beaton's authority, many of your readers like myself would be glad to include such a ring in their next year's arrangement. But I suppose, in the first place, two-year-old plants would be out of the question; and, in the second place, will strong cuttings of this year's striking be sent out at a price that we, who "love the good and the beautiful," though with limited means for such purposes, should feel warranted in booking a moderate number of each to bring on for two-year-old plants to carry out our wish the following year?—EDWARD OLLIS.

[If all the world were to look before they leaped, and were to cut according to their cloth, like our present correspondent, we should seldom hear an outcry or a grumble about the use and value of new plants recently introduced, or of old kinds which are from time to time brought to mind; nor yet about particular seedlings which are suitable for certain gardens, and for stated purposes only. And if the importers, the reminders, and the raisers of seedlings, were, on their part, a little more careful than some of them have been heretofore, and would state, as far as they knew, the purpose for which this and that plant was more particularly suited, that also would go a long way to keep the pot from boiling over; at all events I am sure these have been the views by which the writers in this Journal have been guided in their selections of plants, and in their recommendations from the first day.

But good intentions can never over-rule natural causes. We can no more alter the constitution of a seedling, even one of our own creation, so to speak, than we can turn the tides of the ocean. In a small number of genera some of us believe that through the pollen we can govern and guide the stature of the seedling, and some have asserted, and do believe, that they can influence the constitution also; but from my own acquaintance with the bypaths of a wide field of practice, and of practical observation, I would much hesitate before I would subscribe to that doctrine.

Harry Hieover is not the smallest of my seedlings, nor yet the third weakest in constitution of the kinds like it now in common use. If the oldest of our edging Geraniums were to appear now for the first time, and if it fell to my lot to describe it for general recommendation, if I may so put it, I should feel myself bound in honesty to say at once that you would need to plant three lines or rows of it for an effective edging to a moderate bed. But I have planted edgings of it, and with others smaller than Harry Hieover, with one row only; yet to be on the safe side of the ferry with a new plant, and especially with a pet seedling of my own, it looks better and tells best in the long run, that I should not put the best foot foremost about them at the first going-off.

The smallest edging Geranium now in use is the oldest of them all, and is still the prettiest and the greatest favourite with the ladies—all but the name, which is Dandy; and if you did but know what ladies have told me about their appreciation of the title you would never give that name to one of your own seedlings. But as luck would have it, Dandy and the Golden Chain, inseparable associates, were not seedlings at all, but sports of nature, but not in the sense of the sport the ladies make of dandies. Golden Chain is an extraordinary departure from the "Cape Scarlet," the inquinans of botany, and is considerably older than Dandy, but not so old as Dandy as an edging plant. Dandy is four times more extraordinary in its origin than Golden Chain. It came as a sporting shoot from the bottom of the old scarlet variegated Geranium—the one of the shot silk bed. The flower came in the true stellate form and in genuine crimson in the Mile End Nursery with the late Mr. Thompson, and a friend of mine saw it there before a cutting was made from it. I like Dandy and the Golden Chain, as all the world knows—not from having been once a greater dandy myself—for the looks of them, and I look upon Harry Hieover with equal favour and partiality.—D. BEATON.]

### THE DISTRESSED LANCASHIRE WORKINGMEN BOTANISTS.

I PROMISED to give your kind-hearted readers an epitome of the character of the men I have been so fortunate in being able to put in a good position to weather the storm. I have not only been able to do much good by the means placed at my disposal by your readers, but by the kindness shown me by some of the good people here, of all parties, I have been able to get one an allowance of 12s. per week; for he, though with ten children, has had no relief from parish or otherwise. I made inquiries of the relieving officer for Dukinfield district, and he gave a most excellent character to Schofield and Whitehead. The landlord of J. Kirk Smith said to me that he owed him nearly twelve months' rent, but he would never ask him for it if it were twelve years to come, for he believed him to be a very decent man, and he had lived under him for a long time. The landlord is Mr. R. Gould, an amateur Rose-grower possessing one of the best collections in this neighbourhood. Richard Bird, of Tame Valley (here), I found had maintained himself for twelve months on 14s. per week, and paid house-rent 3s. 6d. per week. He has a wife and five children, and owes nothing for rent or for anything else, but had not been able to buy anything in the way of clothing for about ten months. Some kind-hearted person has sent twice to the above persons "The Evening Mail!" for two of which they beg to return thanks.

To detail all the cases would take too much of your space; but they are very creditable to the men, who will all personally thank your readers in a body.

I have helped a number of cottage gardeners out of the funds put in my hands, and the clothing. I would suggest to your kind-hearted readers in sending orders for Mosses, not to order more than 150; and the botanists say that they would rather

supply dried specimens than green ones of other things, for most plants, being dead or dormant now, are difficult to find.

I have received the following:—From Lady H. B. and Friend, 15s.; Mr. Rabone, and under-gardeners, and nurserymen, 10s. 6d.; J. R. Lucas, Louth, £2 2s.; J. E. M., Taunton, 5s.; Mr. Gauthorpeall, &c.; a Friend of Mr. Hague's from near Silkstone, Yorkshire, 6 tons of coal; Mr. Wintle, 10½ yards coburg, 130 yards regatta shirting, 29½ yards check, 6½ blankets; Mrs. Henley, 2s. 6d., and 1 straw hat, 1 lustre dress, 3 pairs drawers, 1 pair men's shoes, 1 pair women's, and 1 pair boys' ditto, 3 night-caps, 3 regatta shirts, 5 pair stockings, 1 paper bedcover, 3 pair trousers, 4 pinafores, 4 collars, 5 petticoats, 1 blanket, 4 chemises, 3 girls' frocks, and 1 sheet.

I give the money that comes for Mosses to those persons who are most qualified to complete the orders, as they have to do all the work. Out of the money that comes for Ferns I pay the men who go out to collect them a day's wages, and they waive any further claim upon the funds sent for that purpose; the remainder goes to the general fund.

Next week I will give a list of the amount of money and clothing distributed.—JOHN HAGUE, 36, Church Street, Ashton-under-Lyne.

### CLARKE'S BOILER.

I OBSERVED a remark in a late Number of your Journal to the effect that many were going back to the old saddle-back boilers. I have watched subsequent Numbers to see if any one took notice of this remark, as my opinion is that the writer of it has never seen a similar boiler to the one I use. Permit me to give you my views of its merits compared with a saddle-back.

When I bought the house and garden I now occupy I found a small span-roofed greenhouse, 25 feet by 9 feet, heated by a saddle-back boiler. Early this year I erected a new range of glass lean-to houses 50 feet by 14 feet, divided into three houses, and employed Mr. Clarke, Liverpool, to fix his new patent boiler with suitable piping, &c. I now give you my experience of the two boilers, which, for brevity, I shall contrast. And first, as to fuel, I find that Clarke's boiler heats my new range and old small house with at least as little fuel as was required to heat my old house alone; and second, I find Clark's requires only one-fifth the attention; the facility of feeding it from the top and its capacity for holding so much fuel explains this. It is a capital boiler for amateurs who keep no gardener, from requiring to be fed once in twelve or twenty-four hours, as the weather, &c., demands.—WM. LEGG, Trammore, Cheshire.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

THE wet weather we have lately experienced will, in some situations, have greatly retarded much that would otherwise have been done. It is, therefore, necessary to forward all that can be done within-doors, which will be available when the weather becomes fine. There are numerous operations which can be performed within-doors, which, if not immediately necessary, will at another time reduce labour when most wanted. The making of labels, brooms, flower-sticks, shreds, &c., is usually done in bad weather, as also the cleaving of wood, the making of wicker baskets, trellises for specimen climbing plants in pots, and straw mats. *Broccoli*, they will be advanced by the recent mild weather; look over the most forward for protection against the return of frosty weather. Continue to remove all dead and decaying leaves. *Carrots*, if young ones are wanted very early seed should be sown on a slight hotbed. *Mint*, pot it for forcing. *Peas*, sprinkle wood ashes or lime over them as they appear above ground; the weather that causes their appearance excites insects to activity. Set traps regularly for mice. *Radishes*, sow, and also small *Salad* in frames. *Sea-kale*, continue to cover a small portion at a time. When the first portion is cut, and the pots or tubs are taken off, cover the roots with a little litter to prevent their being injured by frost. The examination of old or the formation of new drains, if required, should on no account be forgotten; the importance of this matter is not sufficiently estimated.

#### FLOWER GARDEN.

Every advantage of the present favourable weather should be taken for transplanting shrubs, trees, &c. See that all the principal and choice plants in this department have sufficient

scope to develop their true and natural characters. There are few situations in a garden more interesting than a well-regulated and well-arranged shrubbery, where every plant, from the largest to the smallest, has room sufficient to form perfect specimens. Collections of shrubby plants appear to be much less attended to than their true merits entitle them to. Dahlias, though most likely stored away, will require occasional attention; those placed under a greenhouse-stage, or similar situation, will be safest, yet from the wet autumn and the sudden frosts just previous to their removal we fear that many will suffer. Roll walks due lawns after frost.

#### FRUIT GARDEN.

It is always desirable to get as much of the pruning and nailing done before the approach of spring as possible: therefore lose no favourable opportunity for forwarding these operations; for, besides the advantage of having so much work done before the busy season, the garden will present a much neater appearance after the wall trees are nailed, the borders made trim, the small fruit-bushes pruned, and the ground among them forked over. See that standard trees, which have been recently transplanted or root-pruned, are firmly secured against injury from high winds, and also get any root-pruning or transplanting remaining to be done this season executed as soon as possible.

#### GREENHOUSE AND CONSERVATORY.

A free admission of air at all times, if the weather is favourable, will be advantageous. At the same time care should be taken to prevent as much as possible strong currents of cold winds from passing through the house, for they invariably prove extremely injurious to vegetation. A few of the earliest and strongest herbaceous Calceolarias, Cinerarias, and Geraniums adapted for forcing, may now have their final shift. After potting, the shoots of the Geraniums to be carefully pegged-down as near to the rim of the pot as they can be without breaking; they will require to be sparingly watered for a time, and placed as near the glass as possible. A liberal supply of water will be requisite to Camellias swelling their flower-buds. When they are planted-out in the open border of a conservatory they should be carefully examined, for fear of any deficiency of moisture at their roots. Should any signs of over-dryness be apparent, get the soil forked-up as deep as the situation of the roots will allow, and give them a good soaking of soft or rain water. Two or three of such applications at short intervals will do no harm provided the flower-buds are fast swelling, that more than ordinary dryness is perceptible, and that the drainage of the border is such as it ought to be. The same kind of treatment may be advantageously adopted with many plants under similar circumstances.

#### FORCING-PIT.

This structure will have to be kept in full activity to supply the various calls for plants in bloom, which, during winter, are more or less frequent in most establishments. Care should be taken before plants are moved to sitting-rooms to gradually harden them for a day or two either by placing them in the greenhouse or any other intermediate-house. Azaleas, Rhododendrons, and other such shrubs for forcing, still out of doors, should have some protection during severe weather, or should be removed to any sheltered place till wanted. Narcissus, Hyacinths, &c., should be protected by a frame; and as they now begin to grow, remove the plunging material down to the surface of the pots to prevent their rooting upwards. W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

In addition to the routine in the kitchen garden of examining blanched Endive, stirring the soil among Lettuces and young Cauliflowers, and folding leaves over Broccoli coming in for use, put a number of sets of early Potatoes into small pots, in leaf mould, and placed them in the Mushroom-house until they need more light and we find a place for growing some in larger pots, or planting-out in slight hotbeds, when we can get the material for them. When grown in pots we generally place two or three of these sets, after having well filled the smaller pots with roots, into a 12-inch pot, and the curbing previously in the small pots causes them to tuber more quickly; but when fresh tubers are required in the shortest possible time from planting, we know of no plan so good as growing the set in a pot of 5 inches or

6 inches in diameter, and, after the stem is 6 inches high, plunging the pot in old leaves just where there is a little heat, and giving but little water afterwards. Throw a layer of barley-awns over a row of Peas, to keep the mice from getting at them, and slugs have quite as great an aversion to crawl over them.

#### FRUIT DEPARTMENT.

The work here was much the same as last week, with the exception of cleaning ainery, from which we finished cutting. The leaves had previously been removed some fortnight ago. The whole house, glass, woodwork, and Vines, were well syringed with hot water, about 150°, after the Vines were pruned. The Vines were then cleaned so far as removing all loose bark, &c. The glass and woodwork were then washed with warm soap water; the Vines were well scrubbed with the same, and when dry were painted with clay and sulphur, with a little Gishurst mixed with it. They were then fastened horizontally along the house, instead of vertically, so that they may be encouraged to break more regularly, and also be more out of the way whilst the stage is filled with plants. Finished the woodwork by well scrubbing the stage and limewashing the back and front wall inside, after these two had been scrubbed with hot water. The floor of the house, being earth, had about 1½ inch of the surface carefully taken off, then the surface left watered with hot water from the rose of a watering-pot, the soil inside being very dry to keep the Grapes from damping; and as some Vines are planted at the back of the house, the surface will be gently forked or broken, and well watered where driest with manure water heated to at least 90°. A little manure will then be put on, and a surfacing of fresh soil put over all. The bottom of the house or the floor will then be filled with the hardiest and roughest bedding plants, as the fag-goted Scarlet Geraniums, and the stage will be filled with Pelargoniums, &c., where they will remain for two months before the Vines come to be started. We have been thus careful, as we had some bunches of Muscats disfigured with the thrips, and we want to reach any eggs that they might have left behind them. The general bulk of Vines here are planted outside, and brought in through holes in the front wall—not that we approve of that plan, but simply because it could not be helped without getting all the internal arrangements altered. We all know that Vines will do well under such a mode of planting; but that is no reason why we should not advise every person to plant inside if they can. If we were making fresh houses, we should never think of planting outside. Letting the roots go freely out is quite another matter. The great thing, when planting in front and inside is resolved upon, is to be sure to have the inside border the highest. We were lately informed of Vines getting into a bad state, even though they were planted inside; but we elicited the fact which accounted for the whole, that the arches in the wall through which the roots alone could get out, were, as respects their highest point, 27 inches below the surface of the border outside.

#### ORNAMENTAL DEPARTMENT.

The chief work besides attending to plants, cleaning pots, and getting-up leaves in the park to be used for so many purposes, has been looking over the plants and cuttings in cold frames and pits. Many of the tenderest of them we like to get into a house, where a little fire heat can be used for two or three months at this time. Though the weather has been so cloudy, wet, and muggy, yet we have been little troubled with damping. We believe almost every cold pit, not appropriated to such plants as Calceolarias, would be the better of some simple mode of heating, not merely for dispersing damp, increasing the movement and circulation of the air, but saving much time and material in covering in cold weather. The chief points of management during winter are these:—Do not water a plant until it actually needs it. Do not spill a drop of water in the pit; better lift the plant out that is to be watered, and replace it when drained. In a fine, airy, mild day, and especially when sunny, pull-off the sashes. In mild weather, but dull, foggy, and liable to sudden showers, give air largely back and front by raising the sashes up, but keeping them over the plants to prevent any damp falling on them. When nights are at all likely to be frosty, cover the glass and shut up closely. When the frost is pretty sharp, do not uncover until the sun begins to tell upon the covering, or the external air is above the freezing-point, or the sun shines so powerfully as to raise the temperature within above 40°, and then give air chiefly at the back by raising the lights, not sliding them, and shut-up when the sun leaves in the afternoon. When severe continued frosts come, as this

time two years ago, as soon as the temperature inside sinks from 40° to 35° cover-up securely, turn the litter carefully and frequently, but do not uncover in any hurry. In such circumstances, with the thermometer inside ranging from 38° to 34°, we have had plants covered-up for six and seven weeks, and, there being no growth, when uncovered they looked nearly as well as if they had been covered only one night. If a mild day should intervene during such a continued cold, or if a bright sun should mellow the air, we would give a little air at the back of the lights, to let out any accumulated vapour without removing the covering. There is, therefore, but little difficulty in these continued frosts; the bother is, when frost and thaw, mild weather and severe, follow each other so rapidly that you cannot depend on twelve hours at a time, let alone twenty-four hours. Now, in all such cases, a little dry fire heat would be a great advantage, and save many a covering. The simplest contrivances are a brick Arnott's stove and a small flue. The first, for convenience in such cases, should have the feeding-door either in the front or back wall, the latter generally being the easiest to get at, though in small places it would do as well at the end. When the flue is used, the great essentials to success are sinking the fire-box sufficiently below the flue, and letting the flue rise gradually from the fire-place. The good draught thus secured is one of the chief advantages in such a simple furnace as that figured at page 640, and alluded to by "Lex" at page 673 and page 745, leaving not a doubt on our mind but that such a flue will do everything that is said of it. This good draught secured, it is easy to regulate its force by the ashpit-door or a damper. Of course it is very easy to have too much of a good thing. So many pills a-day may be a good medical prescription; but it would in most cases, where the pills were not mere lard and flour, be a very different thing if a whole box were demolished at once.

We refer to that the more prominently, after reading the very lugubrious and melancholy statement of "F. C.," at pages 717 and 718. He must have been truly unfortunate in his observation and experience. Having had a great deal to do with flues, both in large and smaller houses and pits, our experience would point to a totally opposite conclusion. In small places we are told "a greater fire is of necessity used than is proportionate to the space to be heated: consequently there is a great waste of fuel; the plants must be too close to the flue to do well, and altogether such small places are very unsatisfactory, &c." We demur altogether to the "necessity." We see no necessity for sticking our fingers into the parlour fire on a cold night, and we see as little necessity for having as large a fire in a small place as would be needed in a large one. The misfortunes detailed were more the result of simple mistakes than of any necessity. Even the fuel by implication recommended—charcoal, we should have deemed the worst under the circumstances. That such a place can be managed without thought or care we never could imagine. With that thought, there can be no doubt that pits will do all that it has been said they will do. We never have recommended earthenware pipes except where only a mild heat was required, and even then we would have a yard or two next the furnace of brick to prevent cracking. The pipes should never be less than 9 inches in diameter; and when hard-burned and the common soft-burned are in competition, we would choose the latter, if equally thick. We are not sure if even Portland cement pipes will stand a very high temperature, as might be needed for tropical-houses; but we know they answer remarkably well for greenhouses and conservatories, as witness those at Linton Park under Mr. Robson's management. A small flue would be little more expense, and would be safer; though for mild, gentle heat at times, we are sure the pipes will answer well enough, more especially if the draught is regulated more by the ashpit-door than by any damper in the chimney. We know of one case, where in a brick fire the damper was thrust in altogether, and, of course, the smoke was forced through the pipes; but we did not see any necessity for such treatment.

We agree with what "F. C." says as to the usefulness of a cold pit kept as such, and in the superiority of a greenhouse to a pit cold or heated—so much so, that we always recommend such a place to an amateur for plants, be the house large or small, to be sufficiently capacious to allow him to walk in it and examine his favourites in all weathers. But though thus agreeing with him in the great superiority of such greenhouses, we have a strong conviction that the man who cannot heat a small pit without forcing, scalding, and burning his plants, would be very likely to find a necessity for doing the same thing if he had a flue in his greenhouse.—R. F.

## TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**FORCING POTATOES IN POTS (*Indefessus*).**—The quantity you plant must depend on the quantity required. The Cucumber-house is too hot at all times for the Potato. Vinerias when starting do well until they come to be above 65°. About 55° is a good temperature for Potatoes. No plan is better than pots for a regular supply. We should start some more in small pots—say 60's, in a coolinery. When well filled with roots, and one stem left to each pot, take No. 12-pots, fill them half full with sandy loam and leaf mould, and place three plants out of the small pots in these large pots, filling-up with similar material, leaving room for a little top-dressing. The more pot-bound the plants are in the small pots before transplanting, the sooner will the tubers form. When well grown, remove the pots to the orchard-house, and protect from spring frosts. The same is a good plan for planting in beds, but you do not say if you have them. The vinery will be first-rate until too hot and shady.

**PERMANENTLY LIGHTENING CLAYRY LOAM (*H. B.*).**—We can say from experience that the best mode of permanently rendering the staple of such a soil open and readily workable is by paring and burning the entire surface to the depth of 9 inches; spreading the ashes and an inch in depth of cocoa-nut fibre dust over the whole, and digging it in. It would probably offend the party you name to make the proposition you specify, and, moreover, there is not the slightest need for such aid.

**CRINUM CAPENSE AND AMARYLLIS FORMOSISSIMA CULTURE (*Crinum*).**—Crinum capense is too big for a window in a dwelling-house. It will make leaves a yard long, and some longer at times. It flowers from the end of May to the end of September in the open ground, and is as hardy almost as a Red Onion. It seeds by the quart measure, and the seeds are as large as horsebeans. It will cross with all other Crinums, and render the offspring nearly hardy at the first start. But to do so much it would need to be planted on the edge of a marsh. It will live and bloom, however, in any part of the garden. The Amaryllis formosissima does best planted-out in the richest vine, or other border, till the leaves are killed by frost; to be kept till April the same as Potatoes; then to be potted, and it will bloom in May, and after blooming to be turned-out as before. But it would force and be in bloom any week from January to May, and it is the only hardy bulb known that will bear the heat of a Pine-stove year after year. In the good old times the Jacobea Lily—this very bulb, and the Coral tree, used to bloom twice a-year, and take rest as often. They would be put into the Pine-stove on the 1st of January, bloom and finish growth in time to go to rest for two months some time in May, up again in August, bloom, and be at rest early in November.

**CLAY SOIL AND COCOA-NUT REFUSE (*No Name*).**—The first thing to be done with a "dreadfully stiff and clammy" clay soil in a garden or farm is to drain it thoroughly. The next best thing is to pare it, and burn as much of the surface in March and April as one can do—say so much every year till all the garden is gone over; and any time in summer, when a piece of ground is free from a crop, the top spit, or 3 inches or 4 inches, should be burnt. Then say that 3 inches or 4 inches of the burnt surface will much improve the next 6 inches or 8 inches of the clay, and thus 10 inches or a foot deep is good fair till, but still very stubborn to work and had to do in wet weather. At this point the refuse from the cocoa-nut is by far the best thing that has yet been tried to improve clay soil, also the cheapest, because the most permanent. From careful calculations which we have made, however, 3 inches deep of this stuff on a clay surface will improve the next 6 inches below as much as 4 inches deep of burnt clay would do; but as burning is, or may be, a cheaper process in many places, we would begin with it, and put in the "nervous system" afterwards. We were told last week that the dwellers next to the cocoa-nut fibre mills at Kingston-on-Thames are now using it heavily on all descriptions of land, and that for the clay lands they find it extremely effective in its operation, and the demand for it now is increasing steadily month by month. We have ourselves used it for six years, 2 inches deep, between Strawberry-rows, where the surface of the refuse formed a thin crust after the first rain, which prevented it from being shifted by wind, and we consider it the best and the cleanest thing for that purpose. If it were thoroughly dried in the sun, we should think it the best material to preserve Apples and Pears in where there is no regular fruit-room.

**AZALEAS AND LIQUID MANURE (*Amateur*).**—We reconcile the two "passages" you refer to by saying we wrote the one about the liquid manure as poison in Azaleas, Rhododendrons, and Heath, intending it for amateurs like yourself; and some one of our staff more bold wrote the other passage on "sweet old cowdung" and so forth, for the use and benefit of first-class gardeners who understand perfectly when old liquid manure is "weak and sweet" it is not poison to any plant; and when liquid manure is "weak and cool" it is as good as rain water from the eaves of the house, and quite as harmless. Then, as you have used liquid manure for Azaleas "with marked beneficial results," you are, fortunately, up to the requirements of a first-class gardener in that respect.

**SEEDLING GERANIUM (*W. Legg*).**—Your seedling Geranium is a true old kind from the Cape. The quarter-stem of Le Heritier and other old authors, but not the "Oak-leaf Geranium of the present day. It has a pale pinky flower, and the leaves are among the very best for tasty nose-gays and for floral designs.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

## CHRISTMAS MARKET.

AN event looked forward to for many months. The excitement of it divided between the Lord Lieutenant of the county who has viewed his Shorthorns, Scots, and Southdowns during the two years fattening has lasted; and the weaver who has reared and fed a Rabbit that turns 17 lbs.; or the good Suffolk dame who has taxed her abilities, and pledged her reputation to produce two capons weighing 2½ lbs. There is more of heartiness about this market than about any other. The creeping customer who generally crawls to a shop or stall, and adds to the wrinkles that already exist in his face, by endeavouring to contract his features so as to concentrate all his power in his eyes, that he may detect any fault in the article he is about to purchase—who never asks the price of anything till he has examined all and made his selection—who never releases his hold till he has bought or given it up, and who follows his purchase all over the premises if it be taken away to be trussed or packed—this man at Christmas asks the price cheerily, gives it cheerfully, and only stipulates for the best. Crowds who never dream of poultry at any other season of the year now flock into Leadenhall, and form a class of customers peculiar to the season. If the visit be deferred till Christmas-eve, Paterfamilias generally comes *en famille*. On these occasions retail shops are despised. Customers like to buy first hand, and father and mother show their skill in selection. It is part of the Christmas treat.

No little practice is necessary to enable a salesman to judge his trade on these occasions. Many turn thousands daily during this market, and a difference of 20 or 25 per cent. often occurs within twenty-four hours. The Turkey that on Monday may be worth 15s., will make 21s. on Thursday. The Goose that was bought well at the time at 9s., may, on the other hand, be worth only 7s. Hundreds of pounds depend on the weather. If the morning be dry, cold, and starlight, the goods feel the effect—they may be kept without injury; the market may be described as firm with a tendency to rise. If the morning be heavy, dull, and drizzling—if the gas lamps, instead of shining like stars, gleam dimly through their wetted glasses, and every man opens his great coat, nudies his comforter, and says it is "muggy," then it is safe to be—"things is down." We are like the old optimist in the smuggling galley. If the night were dark and she lay at anchor, at least she was safe; and if it were light they could see pirates as far as they could be seen. If the weather be unpropitious, senders will be dissatisfied; if poultry be cheap, buyers will be pleased.

Nevertheless, seeing the uncertainty of these things, we, for credit sake, avoid giving any quotation. Like our old friend "Francis Moore, Physician," who declares, "rain about this time, four days sooner, or four days later," we affirm that Turkeys, being of good quality, were like roasting beef—the heavier they were the more they were worth, and that Geese were the same.

We trust that all bought young, tender, and juicy poultry, that they bought at a muggy time, and that nothing connected with the Gallinææ could impede or prevent that which we wish to all

A MERRY CHRISTMAS.

## BLACK BANTAMS AT DARLINGTON.

In your notice of the Darlington Poultry Show, in last week's issue, you remark that the pen of Black Bantams, which at the recent Birmingham Meeting took first prize, were, at the Darlington Meeting, "disqualified by the Judge, Mr. Hewitt, and a card 'Disqualified, the Cock's Legs being Coloured,' was affixed to the pen," and add that "the arbitrator carefully washed the right leg perfectly white, leaving the other as unnaturally blackened as when received at Darlington."

There cannot be a doubt as to Mr. Hewitt having adopted the only course open to him; but the question arises, How far is the owner of the bird to blame? That gentleman is unknown to me. If a close observer, even granting that the fraud had been perpetrated by another person, it seems curious, to say the least, that he should have been unaware of a fact so plain as to be a matter of general remark at Birmingham. An explanation is due, and it will doubtless be forthcoming.

CUCUMBER-FIT (*The Abbey Gardener*).—Your pit would be all the better if a foot or two wider. Your proposed plan of ventilating is good; training to trellis ditto; mode of getting atmospheric moisture from holes placed in top of tank doubtful. How does it get through the soil? What means do you propose for preventing the soil getting too moist and too hot? See answers on such subjects for the last month or two. We would keep the soil from resting on the iron tank; we would also have the top of the tank close, and then we could have moist heat or dry heat from it just as we wanted. A moist atmosphere could also be conveniently obtained by evaporating-pans on the pipes for top heat.

TACSONIA MANICATA FLOWERS FAILING (*A Constant Reader*).—Your plant is extra luxuriant, and the temperature is not high enough for the flowers to open. If you had a night temperature of from 45° to 50°, and a rise of from 10° to 15° from sun during the day, the flowers would open. You may prune back the plant when you like. Every well-ripened bud you leave will produce a shoot that will be likely to bear flowers next season. We would not delay after Christmas, as the shoots will then be induced to bloom more early. Most likely the roots want curbing.

VINE-BORER, &c. (*A Constant Subscriber*).—If you have provided good soil for the vines, the pitching the surface with stones above will not be injurious. Dark-coloured stones would be best. To destroy red spider you may try the lime and sulphur now safely. But we should also well wash with soap and water afterwards, and then paint with sulphur and clay or Gishurst compound, not using it too strong.

ROOM-HEATING WITH HOT WATER (*R. B.*).—As far as we can judge, you will need fully 400 feet of four-inch pipe to heat the unceiled room containing 72,600 cubic feet, if you do not wish the pipes to be very warm. If kept as high as 200°, less would do, but it is healthier to have more piping and less heat in them.

ESTABLISHING A ROOKERY.—"On the north-east of my house is a small plantation of well-grown Elm, Fir, Beech trees, &c., and on each side of the drive are well-grown trees; a brook runs through one part of the garden, and on both sides of it is a belt of lofty trees. Can any one inform me how to induce Rooks to build in any of the trees?—GATLEY."

[The Rook is very perverse in selecting a nursery for its young, nor did we ever know any one who succeeded in overcoming their perversity. We shall be obliged by any relative information.]

PROTECTING CROCUS-BULBS FROM MICE (*Donsland*).—Dust over the surface of the soil where the bulbs are planted thickly with dry soot, and renew the dusting as often as it is washed away or soddened by rain.

CABBAGES, &c., AT CHISWICK GARDEN (*S. E.*).—We published all that the Royal Horticultural Society published on the subject, and we had no means of acquiring further information. No book contains a complete list of kitchen-garden varieties and their synonyms. The numbers of THE COTTAGE GARDENER containing outlines of Peas and their synonyms may still be had.

ROYAL HORTICULTURAL SOCIETY.—"What a wonderful paper is the *Gardener's Chronicle* for finding mares' nests! Let me, however, distinctly state that the nurseryman alluded to at p. 696 neither wrote the letter nor had anything whatever to say to it; but the matter was a common topic of conversation amongst a large body of dissentients. When I put the reply in inverted commas, I did not for a moment mean that those were the very words, but the *purpose* of what was written; and I might have added that I had known that the donor distinctly stated that he did not care about his name being inserted, if only the prizes were announced.—VIOLENS."

PLANTS AGAINST AN ELIZABETHAN HOUSE (*S. Northampton*).—For the south side no plant is so good as Glycine or Wistaria sinensis; then the Chimonanthus fraccans trained as a Peach tree, the best front-of-the-house plant in this world; then the Japan Honey-suckle, for the east and for the west front, and Jasminum nudiflorum on the three sides, so as to have it in bloom from October to March. Spiræa Lindleyana is one of the most noble wall plants we have, and would do on the east front, and Magnolia grandiflora is grand indeed on the west wall; but there ought to be a double-flowering Pomegranate on the best part of the south side of such a house. Of course, there will be some Roses on all the fronts—such as Lamarque, Triomphe de Rennes, Gloire de Dijon, and Celine Forestier, from the Noisettes and Teas, and Sir Joseph Paxton the most telling Hybrid Perpetual for that way, though not the best-shaped Rose; Senateur Vaisse, Eugène Appert, Anguste Mû, Comtesse de Charbrillant, and such fast and vigorous growers, but unless they are on their own roots the fly and the honeydew will "catch" them in hot weather.

POND MUD FOR CONIFERS (*Idem*).—Your plan is most capital, all but the "leaves." No leaves or sticks should ever be mixed up in compost for Conifers until they are entirely decayed, and the mud should have a winter's frost and airing before using; and if it had twelve months' exposure to the elements it would be all the better, and then it would be just the thing for these Roses, and the rest of your wall plants. The very composition you intend for the Conifers would be better for the house-wall borders than any other.

REMOVING AN OLD ASPARAGUS-BED (*Wyeside*).—It would be better to take up your old plants at once, and force them on a dung-bed, as recommended by Mr. Fish in a late article, and plant young ones on your new bed. You would then have the luxury of forced Asparagus at a season when it is far from plentiful, and you would have the pleasure of seeing your new bed go on vigorously. Old plants may be removed, but it is better, on the whole, to have young ones, preparing the ground well beforehand, as recommended in former Numbers of THE JOURNAL OF HORTICULTURE. Your question on the "Ascent of Sap," was answered at length, page 691.

CLEMATIS LANUGINOSA HARDY (*Idem*).—We have every reason to believe this perfectly hardy, when planted in favourable situations. We have seen it in Kent growing and flowering against the south side of a house, and in such a position it withstood the winter of 1860-61, with only a laurel bough or two in front of it. In damper or later places where it has not such a good chance of ripening and hardening its shoots, it is not unlikely to suffer.

NAMES OF FRUITS (*J. A.*).—1, Red Doyenné; 2, Beurcé Die!

It strikes me, however, that the identical birds were exhibited at the Crystal Palace Chicken Show in August, receiving high commendation at the hands of the Judges, Mr. Hewitt himself, I believe, being one of them, the present owner then claiming the pen. If this be correct, it appears they "passed muster" at that time. It would seem that Messrs. Day & Martin's patent had not passed also, by virtue of the claim; and at Birmingham the cock's legs could scarcely have been "touched-up," otherwise they would have presented a different appearance. Then who is to blame? The present owner is more like the scapegoat than the real offender, the claim at the Crystal Palace being, perhaps, much induced by the position the birds then obtained.

A similar case was detected a short time ago, and it is believed there is at least another pen of Black Bantams equally faulty being exhibited: therefore, it is high time such impositions were put a stop to, and the subject ventilated.—JUSTITIA.

[The most satisfactory course to be pursued by the owner of the pen at Darlington would be for him, through our columns, to declare that he neither caused the Bantam cock's legs to be blackened, nor knew that they were blackened.—EDS.]

### LORD TREDEGAR'S POULTRY EXHIBITION.

THIS Exhibition, as its name would suggest, has been for many years past anxiously supported by his Lordship; annually gaining ground in the good opinions of the residents near Newport, and increasing wonderfully as to the importance and perfection of the poultry exhibited. It is held in connection with a cattle and horse show, forming one important item in the varied sights that every year seem to draw a still greater attendance from those parties who feel an interest in such matters. The trains that hourly arrived at Newport from all parts of South Wales were filled to overflowing; and the weather, we are glad to say, on the whole was satisfactory. There cannot be a doubt entertained that the Show of last week has been, so far as the poultry and Pigeons were concerned, an infinite improvement on every preceding one; and when we consider, too, how very commonly such meetings appear to clash their general interests during December, we cannot do otherwise than honestly congratulate the Newport Committee on their present success. The whole of the arrangements were both orderly and well matured.

In Spanish Mr. Martin, of Claines, Worcester, stood first with a pen that are now getting not only well known, but which have also been adding very materially of late to the reputation of his yard. The second-prize pen were also very good. In the class for Spanish chickens Mr. Oliver had it all his own way, having no rival. The coloured Dorkings were, both old and young, of first-rate character, the whole of the birds shown being far better than ordinary. Some White Dorkings shown at Newport were also excellent. In Game, the exhibitors of the district around Newport were much interested by the exhibition of two pens sent by Mr. Harry Adams, from Beverley, Yorkshire. It was evident at a glance they were sent to win, and convince the Game-breeders of South Wales what the northern counties of England can accomplish in that direction. One pen were Brown Reds, the other Red Piles, and certainly such condition was not ever approached by competitors. They were one of the gems of the Show. Many capital local pens were most favourably noticed in the prize list, belonging to the neighbourhood. In adult Cochins, all colours together, it is very long since we saw so closely balanced a competition as the prize pens—one being a very true-feathered Partridge-coloured pen, the other a lovely pen of Silver Cinnamons. The ultimate triumph was to the Partridge birds, but never were perfections more evenly developed. In the chicken Cochins, a pen of really good White ones took precedence over a pen of the best Partridge chickens we have seen for a long time, save that the cockerel betrayed an inclination to be "throats-breasted;" though we believe the slight ruddy tinge on the throat, new so truly objectionable, may moult out rightly at the next change of plumage. Very excellent Brahmas, both light and deep grey, were exhibited. The Hamburgs and Polands of every variety were superior to our most sanguine hopes. The Black Polands and Silver-spangled ones were quite meritorious enough for even the largest shows. A pen of very good Silver-laced Sibrigh Bantams were shown, and some equally creditable Game Bantams.

In the class for "Any other variety" were some perfect Malays, Indian Game Fowls, Silkies, both white, black, and

brown in their extraordinary plumage, for to apply the term "feather" would be inappropriate altogether; and some remarkably good Black Hamburgs.

The Aylesbury Ducks were perfect, and weighed well. The Rouen Ducks, too, maintained a high position.

The prize pen of Geese were the largest-framed birds we ever saw, but shown in really breeding order. The weight was precisely that of the second-prize pen; but, on handling the latter, they bespoke much of the over-feeding so common among Geese at Christmas tide.

The Turkeys shown were of high excellence; but, as a bystander observed, "they were large in size and advanced in years."

In the Pigeons, the Carriers were remarkably good. Some extraordinary White Runts were also shown, some Satinettes, a pair of very good Short-faced Red Mottled Tumblers, and some exquisite Fantails.

In the extra stock, a pen of red-legged Partridges drew especial public attention. They were in perfect plumage, and seemed as tame as the poultry around them.

The Cottagers' prizes were well deserved, and caused rather a spirited competition, adding materially to the public interest. Special prizes were given to these parties, both for fowls and Ducks likewise.

SPANISH.—First (given by Lord Tredegar), J. Martin, Claines, Worcester. Second, J. Parsons, Maesteg, near Bridgend. Highly Commended, A. Heath, Wilts. Commended, J. Llewellyn, Caerphilly. Chickens.—First, and Second, C. H. Oliver, Newport.

DORKING (Coloured).—First (given by Lord Tredegar), F. T. Parker, Rockfield, Monmouth. Second, C. H. Wakefield, Malvern Wells. Highly Commended, C. B. Fox, Newport. Commended, R. Crawshaw, Merthyr; J. Logan, Newport. Chickens.—First, J. Jones, Llanarth, Abergavenny. Second, C. H. Wakefield. Highly Commended, C. B. Fox, Newport; F. T. Parker, Rockfield, Monmouth. Commended, R. Crawshaw.

GAME (Any variety, except White or Piles).—First (given by Lord Tredegar), H. Adams, Beverley, Yorkshire. Second, W. Nicholas, Glamorganshire. Highly Commended, J. Martin, Claines, Worcester; S. Dupe, Evercreech, Somerset. Chickens.—First, J. Martin. Second, W. Nicholas. Highly Commended, R. Crawshaw, Merthyr Tydvil.

GAME (White or Piles).—First, H. Adams, Beverley, York-shire. Second, W. Nicholas, Cardiff. Highly Commended, W. H. Gayton, Newport. Commended, J. Horton, Shirenewton, Monmouthshire. Chickens.—First, J. Horton.

COCHIN-CHINA.—First, J. Carr, Hafod, Swansea. Second, R. H. Nicholas, Malpas, Newport. Chickens.—First, R. H. Nicholas. Second, J. Carr.

BRAMA POOTRA.—First and Second, J. Hinton, Hinton, Bath. HAMBURGH (Golden-necked).—First, C. H. Wakefield, Malvern Wells. Second, A. Nuttall, Newchurch, Manchester. Highly Commended, W. Cannon, Bradford, Yorkshire. Commended, E. Payne, Cardiff.

HAMBURGH (Silver-pencilled).—First (given by Lord Tredegar) and Second, J. Martin, Claines, Worcester.

HAMBURGH (Golden-spangled).—First, W. Cannon, Bradford. Second, W. Cuff, Cardiff.

HAMBURGH (Silver-spangled).—First, T. Davies, Newport. Second, W. Cannon, Bradford.

POLAND (Black, with White Crest).—First, H. Beldon, Bradford. Second, T. P. Edwards, Lyndhurst, Hants.

POLAND (Golden or Silver).—First and Second, Mrs. Blay, Worcester. Highly Commended, H. Beldon, Bradford.

BANTAMS (Game).—First, E. Payne, Cardiff. Second, T. Davies, Newport. Highly Commended, J. Carr, Swansea.

BANTAMS (Golden and Silver-laced).—First, Miss G. Everett, Gibraltar Cottage, Monmouth.

BANTAMS (Any other variety).—First, E. Hutton, Pudsey, Leeds. Second, Mrs. Leigh, Pontypool Park.

ANY OTHER DISTINCT BREED.—First, E. Hutton, Pudsey, Leeds. Second, Master C. A. Ballance, Taunton. Third, P. Cother, Solihull, Wilts. Fourth, R. H. Nicholas, Malpas, Newport. Highly Commended, H. J. Evans, Cardiff; R. H. Nicholas.

GUINEA FOWLS.—Prize, Sir G. F. R. Walker, Castleown, Cardiff. Commended, F. T. Parker, Rockfield, Monmouth.

DUCKS (Aylesbury).—First (given by Lord Tredegar) and Second, J. Logan, Newport. Highly Commended, Mrs. A. Hounfay, Woodlands, Newport; R. H. Nicholas, Malpas, Newport.

DUCKS (Rouen).—First (given by Lord Tredegar) and Second, J. H. Braikenridge, Chew Magna, Bristol. Highly Commended, W. Cuff, St. Fagans, Cardiff.

GEESSE.—First, A. Cuthbertson, Llångibby, Newport. Second, R. Rees, Abergavenny. Commended, R. Crawshaw, Merthyr Tydvil; R. Rees.

TURKEYS.—First (given by Lord Tredegar), Miss J. Milward, Newton St. Loe, Bath. Second, Hon. F. C. Morgan, Glamorganshire.

#### SWEEPSTAKES FOR COCKS.

SPANISH.—Prize, R. Crawshaw, Merthyr Tydvil.

DORKING.—Prize, J. Jones, Abergavenny. Highly Commended, F. T. Parker, Rockfield, Monmouth. Commended, F. T. Parker.

GAME.—Prize, C. W. Brierley, Rochdale, Lancashire. Highly Commended, J. Martin, Claines, Worcester. Commended, J. Phillips, Newport; E. Jones, Newport.

COCHIN-CHINA.—Prize, J. Paddon, Swansea.

GAME BANTAM.—Prize, C. W. Brierley, Rochdale, Lancashire.

ANY OTHER VARIETY.—J. Carr, Hafod, Swansea (Silver-pencilled Hamburgs).

#### COTTAGERS' PRIZES.

ANY DISTINCT BREED.—First and Second, W. Jenkins, Malpas, Newport (Dorkings). Third, T. French, Newport (Black Game). Fourth, J. Ford, Malpas, Newport (Hamburgs). Commended, Mrs. M. Pillinger, Malpas, Newport (Silver-pencilled Hamburgs).

Ducks (Any distinct breed).—First, J. Bunday, Malpas, Newport (Aylesbury). Second and Fourth, W. Parsons, Marshfield, Newport (Aylesbury). Third, E. Morris, Malpas, Newport (Aylesbury).

Pigeons.—*Carriers*.—First, J. W. Edge, Birmingham. Second, A. L. Silvester, Birmingham. Commended, S. Dupe, Bath; C. D. Phillips, Newport. *Pouters*.—First, A. Heath, Calne, Wilts. Second, G. Paddon, Swansea. *Tumblers*.—First, A. L. Silvester. Second, J. W. Edge. Commended, F. Barfoot, Newport. *Fantails*.—First, J. W. Edge. Second, Miss J. Milward, Newton St. Loe, Bath. Highly Commended, H. B. Pring, Newport. *Any other variety*.—First, H. B. Pring. Second, A. L. Silvester. Third, Miss J. Milward. Highly Commended, C. D. Phillips. Commended, J. W. Edge.

Edward Hewitt, Esq., Eden Cottage, Sparkbrook, officiated as Judge, and expressed himself well pleased, both with the quality of the poultry exhibited and the whole of the general arrangements.

## ALPHABETICAL ARRANGEMENT OF POULTRY EXHIBITORS.

ALLOW me to call your attention, and that of poultry exhibitors, to the fact that the entries in the Crystal Palace catalogue have all been arranged alphabetically in each class, with the exception of those of the aristocracy and clergy, which take precedence in each class where they occur. I was not aware that this was the case until I looked into the catalogue of the present Show, and I find that it has been the practice at the Palace shows for the entries to be so arranged. Now, without desiring to make the least reflection upon the honesty of our Judges, I must say that I think this arrangement most objectionable; and were I one of the Judges I would do all in my power to obtain an alteration of this plan, for the prosperity of the poultry interest requires that amateurs should possess perfect confidence in the arrangements at every exhibition for placing every exhibitor whether rich or poor, aristocratic or plebeian, clerical or lay, in a position of equality, so that the merit of the birds shown by each may alone determine the awards; and this cannot surely be accomplished where the above-mentioned systematic classification of names is understood by all parties concerned to be the plan adopted in the catalogue.—SPRIGHTLY.

## REQUISITE CHARACTERISTICS OF BLACK-BREASTED GAME.

KNOWING that your valuable paper is always open to those requiring instructions, I venture to ask you to enlighten me on the following points arising out of the late Birmingham Poultry Show—viz:—

Ought a Black-breasted Red Game cock to have a black breast, or may it be laced and blotched with brown?

Ought a Black-breasted Red Game hen to have a black tail or a partridge tail?

Ought a Black-breasted Red Game hen to have a red earlobe or a white earlobe?

Ought a Black-breasted Red Game cock or hen to have white toes and white nails; or what should be the colour of the toes and nails?

I am led to ask these questions because I feel that in Class 48 (Black-breasted Red Game) the first prize was awarded to No. 666, which contained a cock having his breast throughout laced with brown, and two blotches of brown, one on each side of his breast, and the hens having partridge tails and white earlobes.

That the second prize was awarded to No. 664, the cock's breast having almost every feather laced with brown besides two blotches of brown, one on each side of the breast near the wing, and the hens having partridge tails and red earlobes.

That the third prize was awarded to No. 654, the cock's breast being perfectly black, and the hens having partridge tails and red earlobes.

That the fourth prize was awarded to No. 653; that No. 661 was highly commended, and No. 651 commended, in all of which the cocks had perfectly black breasts and the hens partridge tails and white earlobes.

I also find that in Class 49 the first prize was awarded to No. 716, the cockerel having a black breast, and the pullets black tails and white earlobes.

The second prize was to No. 669, in which the cockerel had a black breast, and the pullets black tails and red earlobes.

The third prize was to No. 713, the cockerel's breast being marked with brown with a bar of brown across the sickle-feathers,

and the feathers from the bottom of the thigh having evidently been removed, and the pullets having partridge tails and red earlobes, and the middle toe on each foot white.

The fourth prize was to No. 710, the cockerel's breast being again marked with brown, and the pullets having partridge tails and one of them a white nail.

No. 679 was highly commended, and the cockerel's breast was black, and the pullets' tails black and earlobes red.

No. 689 was also highly commended, and the cockerel's breast was black, one pullet having a black tail and red earlobes, and the other having a partridge tail, white earlobes and white nails.

Similar discrepancies in the markings will be found in the commended birds in this class.

I also find that in Class 74 the first prize was awarded to a Black-breasted Red Game cock with willow legs, which had a white nail. And I observed that in the Black-breasted Red Game classes the heads of the majority of the prize birds were very thick and coarse, and that but very few had the thin and long head which I always understood was a prime characteristic of first-class Game birds.

If brown lacing and blotches of brown on the cock's breast, partridge tails, white earlobes in the hens, and a white toe or nail and a thick coarse head are to be regarded as the proper characteristics of the Black-breasted Red Game, the sooner the Game-fanciers throughout the country are aware of the fact the better, as many good birds are yearly consigned to the spit for these defects only, and which at Bingley Hall have proved to be meritorious.

At the time I made by notes in the show-yard, I had not seen your papers of the 18th and 25th November (THE JOURNAL OF HORTICULTURE reaching me only monthly), and although I have now read Mr. Hewitt's statement therein contained—viz., "I certainly never yet have, and most decidedly I never shall, accept the office of arbitrator at the meeting of any society in which my awards are to be previously made the subject of private dictation," I still fancy there must be some mistake; and that these words are not intended to convey that the Judges do not form their unbiased opinion, but receive instructions from others. Will you kindly enlighten the poultry world on this matter also? When such things are reported of the first Bird in the kingdom, who will take the trouble to send their birds to any show whatever?—E. A. S.

[For reasons easily understood by any reflective person, I decline to make any observation, *pro* or *con*, on the awards alluded to by "E. A. S." at the late Birmingham Poultry Show; but he personally refers directly to a remark in my letter published in THE JOURNAL OF HORTICULTURE just prior to the late Birmingham Show, in which I stated, "I certainly never yet have, and most decidedly I never shall, accept the office of arbitrator at the meeting of any society, in which my awards are to be previously made the subject of private dictation."

I never for a moment intended to imply that private directions were previously given, as to the parties who were to be the recipients of the Birmingham Society's poultry prizes. Such an idea appeared so foreign to common sense that I never thought so great a perversion could have arisen. My only objections to officiate as dictated were grave and sufficient enough—viz., that as the appointment of the Birmingham poultry Judges professedly rested with a single gentleman, I would not encumber to have my duties dotted out for me by any private correspondence carried on with a third party in the rear.—EDWARD HEWITT, *Eden Cottage, Sparkbrook, Birmingham.*]

## A PLEA FOR BANTAMS.

I AM one of the many who rejoice in the existence of such a periodical as THE JOURNAL OF HORTICULTURE. Each week there is a rush among my boys in order to get the first look, and an exclamation from my eldest girl—"Anything about Bantams this week, Papa?" followed by "Oh! I am so glad," or "Nothing! Oh, Pa, I am so sorry." Now permit me, as an admirer and breeder of Bantams, off and on for five and twenty years, to say a word in their favour, for I do think that these pets of our forefathers are not now sufficiently appreciated.

First, there are many people whose premises resemble mine, having no fences between pleasure ground, kitchen garden, and stable-yard, except formed of easily penetrated laurel and other shrubs. Under such circumstances, it is clearly impossible to

keep large fowls; but then people so situated may have, like myself, a yearning after poultry and new-laid eggs, and can they not gratify such tastes? Certainly they can by keeping a few Bantams, and the better bred the birds are the less harm they will do with their feet, for they will be all the smaller; of course taking one precaution—viz., to give them, in some sunny corner, a heap of coal ashes for their dust bath.

"Do you dislike the Bantams being in the garden?" said I to my occasional gardener. "Lor' no, sir; bless the little things, I ha' been watching them while I was digging, and the heaps of live things they picks up!"

It is so. I saw, for instance, this last summer, a brood of half-grown blacks picking at something on a mignonette-bed. I went to see, and they were clearing it of green caterpillars. Then, too, who now-a-days has not, alas! a delicate wife or child? and how such relish a Bantam's egg! Spanish! oh, the huge horrors! Cochinchinas the high-coloured! Commend me to a Bantam's egg, or two if you please—no eggs like them. The eggs the old woman brings for the kitchen are well enough for kitchen purposes; but they will have a taste sometimes: therefore defend me from them for breakfast, especially as the farm boys, the old lady's suppliers, put in a nest egg now and then.

But, again, there is the pleasure of the thing. A garden never looks complete without some birds about it—Plovers, a Hawk, Call Ducks, Pigeons, or, best of all, Bantams—so pretty, so tame, so useful.

But then I plead for real Bantams—little, strutting, impudent, wing-drooping things. I plead for a real Bantam cock and real motherly-looking Bantam hens, not merely large fowls dwarfed. See that Game cock walking across the yard. Take a child's shilling telescope, look in at the wrong end, and there you have a Game Bantam cock. Or again, see those Game Bantam hens. Take up said telescope, look in at the right end, and there you have Game hens. Perhaps I am writing with a strong bias for the older class of Bantams, from long association with them—as far back as my school days. Let every one situated as I am, with a garden open on all sides and having only a tiny yard, but who loves live things, keep Bantams. How many fathers who buy pets for their children still properly prefer pets that are of some use. Now my little Bantam friends are both ornamental and useful, and how right it is to bring up children to love and to take care of live things. Then, too, a "pet" must be a little thing. Who ever petted a giantess? No man ever married one for love; no, the sharp dog married such to make a show of her, and to earn money by the poor big thing. Yes, rely upon it, little pretty things are the things most loved. As to what sort of Bantams to keep, there is plenty of room for taste. I own I prefer the Black; they are good winter-layers, their eggs are most excellent, and they are hardy as well as full of spirit. As to laying, I have had them lay at twenty weeks and three days old. Moreover, they never stray, and so give no offence to captious neighbours. White Bantams, another genuine kind, have their admirers; so have Sebrights, though clearly not a genuine race.

Finally, good readers of THE JOURNAL OF HORTICULTURE, if at all situated as I am, keep Bantams—pleasure, some profit, and perhaps a prize await you. By the way, what has become of that other genuine kind, the once-common "Nankin?"—WILTSHIRE RECTOR.

### WILD DUCKS BRED WITH TAME DUCKS.

In reply to your correspondent "J. R." in reference to "the rearing of young wild Ducks along with tame ones, subjected to the same treatment as the latter," permit me to give him my experience.

I believe in all cases where a hatch of ducklings is composed of both wild and tame ones, the difficulty "J. R." speaks of will be almost inseparable—viz., that the young wild Ducks will die-off, leaving their more hardy brethren in undisturbed possession of their foster-mother's care. The difference of habit at the onset in the newly-hatched ducklings almost entails such a result to a certainty. I never failed to rear wild Ducks, however, when I made the attempt, without the admixture of the eggs of tame Ducks in the same nest. Some thirty years ago, previously to going to reside at my present residence, I enjoyed the advantages of a small pond, with abundance of grass around it. It was then "the hobby" of my late sister and self to keep wild Ducks—Pintails, Widgeons, and so forth. As the latter birds, though

thoroughly domesticated and in perfect plumage, lived healthily, but only in a single case produced any eggs whatever, I will confine my observations exclusively to the wild Ducks. A tenant of ours could generally get three or four sittings of wild Ducks' eggs from the pits on the farm most years; and, at my own request, they were forwarded to me. I found a Bantam hen a capital mother to bring them out, and for after-attention also; but, unfortunately, the Drakes thus hatched, when adult, were troublesome among poultry. A small Irish Duck generally was substituted.

As a rule every egg produced a duckling; and, to render them more tractable, they were always closely confined the first two or three days. Whilst quite young we fed simply on bread, very small strips of raw meat, and plenty of white canary seed floating in the saucer of a large flower-pot. They also, as they grew on, ran about *ad libitum* on the grass, and evidently ate many slugs, &c. We also gave "duckweed" on the water. Thus treated there was very rarely a death, save by accident, the canary seed being especially to their liking, and to it I mainly attribute this success. Until a month old we "cooped" the old Duck, but left the youngsters free. They grew up invariably quite tame, and bred freely the next and following years. There was one universal drawback, however. Although not admitted when grown up to the society of tame Ducks, they always, in two or three generations, betrayed prominent marks of deterioration; in fact, they became domesticated. The beautiful carriage of the wild Mallard and his mate, as seen at the onset, changed gradually to the easy, well-to-do, comfortable deportment of a small Rouen; for they, at each reproduction, became much larger, and the legs took the fineness and elasticity so easily recognisable in the first parents. As every year this retrogression became still more extensively developed, simply from the power of domestication—for it is beyond doubt no common Ducks had access to them—we oftentimes reverted to a new stock from the eggs of wild birds frequenting the farm, always hatching and rearing them successfully; but, in about four or five reproductions, getting precisely in the same fix as before described.

If your correspondent wants to rear some wild Ducks to keep as ornamental birds, or to use for the table, the difficulty, if attempted without rearing tame Ducks with them, will be very trifling. I will just mention that I have known many wild Ducks poisoned by eating the ripe fallen seeds of the laburnum tree, commonly in this county called the "golden chain," of which, although to them so deadly, they appear to be especially fond.—EDWARD HEWITT, *Eden Cottage, Sparkbrook, Birmingham.*

NOTHING is easier. Consider wild Ducks bred with tame Ducks exactly in the same light that you would if you were breeding some Dorking fowls with Bantams of the same sitting. What would become of the poor little fellows if the Dorking chicks were allowed their full swing at the food? Why, the Bantams would most assuredly come to grief like "J. R.'s" wild Ducks. The great overbearing tame species have, most likely, been allowed to gobble-up all the food, whilst the poor little wild fellows were obliged to peep about like lightning, as their only chance of getting a few fragments.

Only watch the latter in their youth up, and see that they get their share, and all will then go well. A few worms extra daily for the issue of the Mallard, introduced to them on a spade, would be highly relished and beneficial, they soon learn to pester on to it; and the spade may then be lifted up out of the way, as a special dining-table, with the ducklings upon it.

As to the hen, if she is placed in a coop with its back, top, and sides boarded, the sunniest place in the world would afford her shade.

I had the pleasure of being amongst some of the first to write upon poultry and Pheasant breeding in THE COTTAGE GARDENER, and I illustrated a coop in No. 191, page 134, which would prove exactly applicable to "J. R." I will also further mention, that if your correspondent wishes his wild Ducks to breed on the premises, he must pinion them, or they will pair and be off to a certainty at their natural breeding season. Formerly we used to do a great deal in that intermixing fancy way, and the Ducks used to go and squat in the henhouse to roost. The poor things were so tame and pretty, that we could not muster up heart to kill them, and we also thought it cruel to pinion them: therefore, at the breeding season, away they used to go, and the tame ones, too, very often—viz., down the

river Corve, where stray fishermen, by some unaccountable peculiarity of vision, used to mistake them for trout!—UPWARDS AND ONWARDS.

### ARTIFICIAL DUCK-HATCHING IN CHINA.

THE hatching-house, at Chusan, is built alongside of the Chinaman's cottage, and is a kind of long shed with mud walls and thickly thatched with straw. Along the ends and down one side of the building are a number of round straw baskets, well plastered with mud to prevent them from taking fire. In the bottom of each basket there is a tile placed, or rather the tile forms the bottom of the basket; upon this the fire acts, a small fireplace being below each basket. The top is open, having of course a straw cover, which fits closely, and which covers the eggs when the process is going on, the whole having the appearance of a vase placed on a pedestal. In the centre of the shed there are a number of large shelves placed one above another, upon which the eggs are laid at a certain stage of the process. When the eggs are brought, they are put into the baskets described above; the fire is lighted below, and the heat kept up to range from 95° to 102°; but the Chinamen regulate the heat by their own feelings, and not by the thermometer, and therefore it will of course vary considerably. In four or five days after the eggs have been subject to this temperature, they are taken carefully out, one by one, to a door in which a number of holes have been bored exactly the size of the eggs; they are then held in the holes, and the Chinamen look through to the light, and they are able to tell whether they are good or not. If good, they are taken back and replaced in their former quarters; if bad, they are of course excluded. In nine or ten days after this—that is, about fourteen or fifteen days from the commencement, the eggs are taken out of the basket, and spread out on the shelves already noticed. Here no fire heat is applied, but they are covered over with cotton and a kind of blanket, remaining in these circumstances about fourteen days more, when the young Ducks burst their shells, and the Chinaman's shed teems with life. These shelves are large, and capable of holding many thousands of eggs. The Chinese who rear the young Ducks, know exactly the day when they will be ready for removal, and in two days after the shell is burst, the little creatures are sold and conveyed to their new quarters.—(*Athenæum*.)

BATH AND WEST OF ENGLAND SOCIETY'S MEETING.—This will be held next year in the city of Exeter, on the 8th, 9th, 10th, 11th, and 12th of June. J. Pitman, Esq., and Dr. Brent are appointed Stewards of the poultry department, and Honorary Secretaries.

### SALT NOT INJURIOUS TO PIGS.

AN article in your Journal, December 2nd, signed "J. R. Pearson, *Chilwell*," stating that salt is injurious to pigs, has, I must confess, surprised me, as I do not think his statement is in accordance with the experience of those who know anything about the pig.

It has been my lot to take many voyages at sea, on which occasions we have frequently had pigs on board; and I appeal to all those who have been similarly situated to bear me out in what I am about to state—that the pig is almost, if not quite, the only animal that does well—nay, I may even say, thrives at sea; and I am sure their food has been salt enough in all conscience, and must have necessarily been so, as I am in a position to know that there was no special pig food on board. I remember some years ago returning from Hongkong in charge of invalids, principally Artillery, and before leaving the port we took on board several pigs. Those pigs were fed on pea soup boiled in the same water with the salt pork, and biscuit mixed with pot-liquor, the water in which the very salt beef taken to sea was boiled in. The sailors also made pets of them, and gave them portions of their own food, which was entirely salt provisions; yet the pigs, so far from dying, rapidly got fat, and when killed made most excellent pork, as I can vouch for.

That Mr. Pearson may have lost some pigs from giving them food into which salt had been introduced is very probable; but we all know the carelessness of servants, and the abominations they will throw into the swill-tub. I am, therefore, inclined to think that their death, if occasioned by the swill at all, must have been caused by some decomposed matter in the swill, not having

reference to the salt at all—that is to say, not in its condition as salt. Again: Mr. Richardson, in his book on the pig, which is considered a good work, says at page 68, and I will quote his own words:—"Do not omit adding salt in moderate quantities to the mess given. You will find your account in attending to this." That salt may be injurious to some animals (I believe it is not a good thing for dogs), I do not deny, but I do believe, so far from being injurious to the pig, that the animal thrives better with it than without it.—AUGUSTUS R. R. PRESTON, *Surgeon, Outlands, near Plymouth.*

### ARTIFICIAL SWARMING.

#### FERTILE WORKERS, OR A DRONE-BREEDING QUEEN.

SINCE my last communication on the artificial swarming of bees, I have had several private inquiries about the success of the one of which I gave an account, and of the process I adopted. With your permission I will now give an answer to those and others who take an interest in bee-keeping. It will be remembered that, on our last inspection of the combs and bees of the artificial swarm, we saw that eggs had been laid in the cells, which we naturally supposed would turn out working bees, being laid in worker's cells. When we looked again, on the 9th of August, they were found to be all drone eggs. Here, then, was a case proving the theory of parthenogenesis—viz., that a queen can lay drone eggs without the aid of male bees, and not working bees. Seeing this, we took another bar-frame of comb and young brood from the original Ligurian to enable the bees to make another queen, being aware that the bees would not allow a queen to remain which could not produce working bees. We removed all the stocks of bees to the hills on the 16th of August, and consequently could not examine them until the 28th, when we found only drone eggs. We gave her other two combs of young brood, and examined her again on the 8th of September, and found her much the same, and on the 27th found no brood in any of the cells. Still the bees seemed as if they did not want a queen, and we resolved to allow her to remain till the 13th of October, when we again found new-laid eggs. On the 29th of October, we examined her carefully again, and found a number of drone-cells sealed-up, and new-laid eggs in workers' cells. We were then strongly impressed with the opinion that her majesty had this time been successful in her hymeneal fights. But, alas! no. On the 22nd of November, we found only young drones running about, but no young working bees, and still some new-laid eggs; but these I think perished with the cold.

Such, then, is the state in which the first artificial swarm we attempted remains at the present time. Of course she must remain now till spring, and as soon as we can get young brood from the old Ligurian, I will give her some. Had this been the only one which we tried, it might have prevented us from trying it again; but the second one we attempted has been entirely successful. When we examined her on the 29th of October, she had a number of young bees out, others sealed-up, and also new-laid eggs; we had also a sight of her majesty. On the 28th of November, we found all the young bees had been hatched, with the exception of a few which had evidently perished from the severe frost of last month.

I think I may safely say that the oldest bee-keeper will admit that this has been the most unfavourable season for bees, and that there may have been many natural swarms this season which have been no better than the artificial one, although not detected, from not having the power of inspecting them so minutely in the straw hive as we have in the bar-frame hive. It is well known that during this season there were many days and even weeks in which young queens could not get out on their love excursions, thus proving the truth of Huber's observation that after a time impregnation becomes impossible. I believe, too, that breeding so late in the season as these have done is seldom seen, and that drones in the month of November are quite as rare. It will be interesting to notice the result, which I will do at a future time. I have had no reason to alter my opinion as to the hardy nature and prolific qualities of the Ligurian bees, as the old one, notwithstanding that it has been twice emptied of comb and brood, has made 40 lbs. of honey and comb. I am compelled, however, to alter my opinion as to their docility. They are perfect savages—ALEX. SHEARER, *Yester Gardens.*

[The above interesting narrative affords strong ground for

suspecting the non-existence of a queen in the first swarm, and for attributing the drone eggs to fertile workers. So few instances of this last-mentioned phenomenon have been observed by British apiarists, that we hope Mr. Shearer will do his utmost to verify the fact. Bees will sometimes remain satisfied with a drone-breeding queen, or even with fertile workers only. It is stated that these latter will frequently destroy royal cells if they are introduced, and that they display as much enmity to queens, as if they were themselves endowed with the full faculties and powers of royalty.

The best mode of restoring such a demoralised colony to a healthy state would have been to change places with it and another stock. In a few days, when both parties had become accustomed to their new position, all the bees from the drone-breeding stock should have been swept off the combs upon a cloth spread midway between the two, and allowed to return to a new hive furnished with brood-combs put ready to receive them. The drone-breeding queen, or the fertile workers which appear to adopt the stay-at-home habits of queens, would then have returned to the old spot where they would be at once put to death by the strangers, whilst the others, returning to the new hive, would have reared a queen in the ordinary manner.

I can only account for the ferocity attributed to these Ligurians by supposing that the enforced idleness of the late untoward season has had the effect of rendering bees spiteful and suspicious, and that the Italians, being the strongest colonies, show these symptoms of a bad honey harvest the most. No one can try their bees' tempers more than myself; and I can conscientiously aver that in my hands the Ligurian bee is by no means an irascible insect.—A DEVONSHIRE BEE-KEEPER.]

### APIARIAN MISCELLANY.

(Continued from page 703.)

IN reply to the letter of "UPWARDS AND ONWARDS," at page 731, I may remark, that it was not my intention to assert that he claimed any priority of invention respecting drone-excluding communications. I am very glad the plan has been tried by so practical a bee-keeper, and hope to adapt it to some of my own hives next summer. Where wooden crown-boards are used I cannot see much complication in making three side apertures instead of one central passage. A zinc slide, a large cork, or a flat piece of wood effects all that is required for closing them over. I may add, that side apertures were adopted by me long before the communications of "A RENFREWSHIRE BEE-KEEPER" appeared in the columns of this Journal.

"UPWARDS AND ONWARDS" claims the character of writing for the million. If so, he may ease himself the trouble. Not one in a million of the lower class of bee-keepers will permanently adopt any of his plans. I have for many years laboured to infuse ideas of very simple improvements in the management of their hives among cottagers. I have purposely avoided any recommendations which could be called complicated, and have frequently practically shown them, by hives of my own working among their own bees, and by simple alterations for themselves of their own hives, what could be done in the way of improvement: but all, or nearly all, to no purpose. With, however, the upper and middle classes, if I may so term them, of bee-keepers, the results are far more encouraging, and I claim in future to write for them alone, and would advise "UPWARDS AND ONWARDS" to do the same. I wish to ask if there is anything in the adoption of side passages, plain boxes with loose bars, Stewarton-hives, and other plans which might be alluded to, which can be called complicated to any bee-keeping mind of ordinary intelligence. Does "UPWARDS AND ONWARDS" think seriously for one moment, that one cottager out of a thousand will adopt his plan of drone-excluding passages? Which to them would appear the more complicated—the three holes bored with a large augur, or the nicety required in fitting up the affair described by him in his former paper? To any bee-keeper really desirous of adopting improvements, there is nothing that can be called complicated in his plan; and he does well in recommending it to the notice, not of the million, but of those who are likely to be benefited by his valuable communications.

"UPWARDS AND ONWARDS" speaks in high praise of the character of our district as a prolific honey-neighbourhood, and of the friends he has made here. Of the first point I would say that we consider this as a honey district a most uncertain one, and by no means equal to many other parts of the kingdom. Of

the second point I would say, that should he ever find his way again to this locality, I trust he will give me the opportunity of being added to his list of Devonshire friends.

With respect to the bee-feeder recommended by our friend my confession must be made, I have never tried it. It has the great objection in all such apparatus of compelling the bees to leave the stock to obtain the food. That large quantities of food may be supplied, and that such feeders answer the purpose intended I have no wish to dispute—in fact, the statement of quantity transferred and general effectiveness will admit of none. But for all this I prefer the bottle. I have never tried to give more than 5 lbs. of food in twenty-four hours by means of a bottle-feeder, but I know that this quantity will be taken down by a good stock in that period of time.

"UPWARDS AND ONWARDS" makes the common mistake of all objectors to the bottle as a feeding medium, when his objection is on the ground of dripping of the contents, and that the bees must take it whether they will it or not, or be saturated with it. There is no drip whatever. If from weakness, cold, or other cause, the bees of a hive refuse the food, it will remain for weeks or months undiminished in the bottle. Nearly every kind of feeder have I tried, but there is none I think that can at all approach in general excellence to the very simple plan of an inverted bottle. For gradual spring-feeding in diminutive quantities, a small bottle with contracted mouth is best. For autumn-feeding, bottles may be used capable of containing many pounds, having a mouth of 2 inches diameter. In neither case if properly managed will there be the slightest drip of the liquid, and there will be generally found less excitement among the inmates than by any other system I have tried.

But what shall I say with regard to the stone caricature of a head, used as a weight for the milk-pan cover? Surely its adopter and recommender strengthens my position when he admits the universal amusement which the sight of it causes. There is a species of child's toy which causes amusement by shifting various heads on to different shoulders. The more incongruous the result of the adaptation the greater the mirth and laugh to be excited. I really think in this case the head must be said to be on the wrong shoulders. It might well have fitted those of some stone-walled-innured monk of former times, but will not appear in its fit and proper position as the crowning-point of a hive of industrious bees. Still, if "UPWARDS AND ONWARDS" likes to have his laugh and see other people enjoy theirs, there is no earthly reason why he should not indulge in this little foible, and, doubtless, he hopes that others besides himself will find "sermons in stones."

To resume the consideration of the hives at the Exhibition. In due course of order we come to MARRIOTT'S STAND. I was rather pleased with the appearance of the rotary observatory ninecomb-hives; but for actual facilities afforded for stocking them with bees, and for inspection, they do not equal the flat single-combed hives.

Of this character, one exhibited in Messrs. Neighbour's stall afforded the most perfect example of what an observatory-hive should be, and reflected great credit both on the inventor and exhibitor. Having had one constructed on the same principle of shifting bars with combs and bees from an ordinary box, I can speak confidently of its efficiency and the facility afforded for scientific observation of the interior economy of a bee-hive.

There were also shown at this stand a number of well-made Taylor's bar-hives, and the Woodbury pattern of the bar-and-frame hives, all of which are most admirably adapted for advanced apiarists.

Of the COTTAGE-HIVE brought out by Messrs. Neighbour, though very well and neatly made, I cannot speak in such high praise, though, doubtless, it is an improvement on the common straw hive. The hives of "UPWARDS AND ONWARDS" are far more practically useful in my humble opinion. These of Messrs. Neighbour might easily be improved with a few slight alterations.

MR. TEGEMEIER'S boxes are very moderate in price, but a fatal objection to their use by me would be the distances he has adopted between the centres of the combs. Nor would I be bothered by the use of the, to me, very objectionable slides between the bars in lieu of a loose cover.

MR. LOVEY showed some boxes which were altogether unsuitable for bees' domiciles on account of size, besides being fitted with objectionable slides.

Of BOOTHMAN'S HIVE the less said the better. It seemed an absurdly complicated affair, fitted-up with a nasty lot of wires and bits of zinc, looking for all the world like a ~~row~~ of gridirons.

The wax-refining apparatus appeared to be ingenious, and doubtless well adapted for the purpose.

W. J. PETTIT exhibited one of Major Munn's hives. I would praise it if I could. The office of censor is by no means a pleasant one, particularly where censure and not praise is to be given. Of the ingenuity of the contrivance there can be no doubt, and it might not suit the capabilities of some manipulators; but a bar-and-frame hive, with a thin bag of black muslin or net to slip over the hat, is much more to my mind. Mr. Pettitt also, as I have previously stated, exhibited some boxes furnished with drone-excluding communications, which seemed likely to answer the purpose intended.—S. BEVAN FOX, *Exeter*.

(To be continued.)

ERRATUM.—In my last read "bands" instead of "boards," page 709 second column, sixteenth line.

### BOTTLE-FEEDER FOR BEES.

I OBSERVE from a letter in your Journal of the 9th inst. that your esteemed correspondent "UPWARDS AND ONWARDS" entertains the idea, although it has been more than once contradicted in your columns, that when a bottle-feeder is used the bees are compelled to imbibe the syrup in self-defence, or would otherwise be inundated with the contents of the feeder. This is entirely an erroneous impression, as even when a very wide aperture is used (in my bottles  $1\frac{1}{2}$  inch internal diameter), if muslin or tiffany is tightly stretched over the mouth of the bottle not a single drop will fall, with the exception of a small quantity which runs out when the feeder is first inverted, and if placed over an empty hive it would remain full for an indefinite period. Once or twice I have had the feeder, holding about 5 lbs. of syrup, emptied in little more than twelve hours, but generally find a strong stock in warm weather will empty one in about twenty-four hours; this is, I imagine, quite quick enough to satisfy most bee-keepers. At the same time I doubt not that a still larger quantity would be removed in the same time if supplied underneath in a large feeder with floats, because a vast number of bees are then able to work at the same time on the large surface exposed for their accommodation, and in warm weather this system of feeding answers very well. In cold weather, however, the bees are disinclined to descend, and, if they do, many perish from the cold.

Last winter furnished me with an instance which illustrates strongly the advantages of the bottle system. In December, my attention was called to a common straw hive which had been very populous in summer, but subsequently suffered so severely from the inroads of wasps that it then contained scarcely more than half a pint of bees, and these were at that season in a complete state of pauperism, and there was little expectation of carrying them through the winter. I recommended the use of an ordinary half-pint sauce-bottle. The bottle was filled with sugar and water, and the neck pushed down through a hole in the top of the hive, thus bringing the supply of food into the very centre of the cluster of bees. This hive progressed so wonderfully that it sent out a large swarm in the very beginning of June. No other plan of feeding would, I believe, have succeeded. The hive was large, and the population so very scanty that the life of every individual bee was of great importance, and I do not think they could have been induced to ascend into a feeder on the top of the hive if an ascent of only a few inches had been required, and feeding at the bottom was under such circumstances quite out of the question.—J. E. B.

EXCLUSION OF DAMP FROM BRICKWORK.—The following methods for obviating this evil have been described at the Royal Institute of Architects. Three-quarters of a pound of mottled soap are to be dissolved in one gallon of boiling water, and the hot solution spread steadily, with a flat brush, over the outer surface of the brickwork, taking care that it does not lather. This is to be allowed to dry for twenty-four hours, when a solution formed of a quarter of a pound of alum dissolved in two gallons of water is to be applied in a similar manner over the coating of soap. The operation should be performed in dry settled weather. The soap and alum naturally decompose each other, and form an insoluble varnish which the rain is unable to penetrate; and this cause of dampness is said to be effectually

removed. The other method consists of sulphurised oil as a varnish or paint, and is said to improve the colour of brick and stone, as well as preserve them. It is prepared by subjecting eight parts of linseed oil and one part of sulphur to a temperature of 278° in an iron vessel. It is said to keep out both air and moisture, and prevent deposits of soot and dirt, when applied with a brush to the surface of a building of stone, or even of woodwork.

### OUR LETTER BOX.

KEEPING POULTRY PROFITABLY (*Hoylake*).—Poultry may be kept profitably when it is well attended to, and not over-fed. Do not attempt too many breeds at first. It seems to us, you will be trying enough if you start with two breeds—one for eggs, and one for table. When is your season? If in the summer or early autumn, keep Spanish. Those accustomed to Spanish eggs will never eat any other. They are, besides, intrinsically worth more, they weigh more, and contain more food. If it be in the winter, you must keep either Cochins or Brahmas. You must always recollect laying depends on the age, and not the breed of the birds. Brahmas, or Cochins, or Spanish, will do in any confined place, but Dorkings must have a run. If you intend to sell poultry for the table, keep Dorkings; if you do not, keep any of the other breeds. A Dorking hen is a paragon in most poultry qualities, a full average layer, an excellent siter, a good mother, and unrivalled for the table; but she must have elbow room, and cannot bear confinement. 13 yards by 8 yards is not space enough for forty fowls. You want really good, but not prize birds to start with. They must be young, and we doubt not you will succeed in making your poultry profitable. Do not, however, crowd too many into a small space. Better succeed with a smaller number than fail with a large one. Give them as much run as you can, and none is better than an old garden. Do not go to any expense with houses, the cheapest are the best, and all that is necessary is to have them wind and water tight, with gravelled floors. Do not make a particular enclosure for hens and chickens. They will have to be acattered about for the sake of health and run.

POINTS IN GOLDEN-PENCILLED HAMBURG COCK (*A Novice in Hamburgs*).—A Golden-pencilled Hamburg cockerel must have a perfectly-shaped comb, well pointed, and the pipe turning up behind; perfectly white earlobe, shaped like a fourpenny-piece; copper plumage; and ample tail, the sickle-feathers being black in the centre, and shaded from the edge on both sides with rich copper bronze.

HEN'S SPURS (*J. W. S.*).—We should not consider the spurs of a hen at all important in a Dorking. They are common to them and to Game, but they are unusual in Spanish. When all the points have been enumerated, any addition in the shape of a new one is a disadvantage, especially when it cannot be called an improvement. It is not, however, a disqualification.

BAHMA POOTRAS (*J. W.*).—There are two breeds of Brahma Pootras—dark and light. The first are pencilled all over, and have silver-striped hackles. The cocks have straw hackle and saddle, black breast spotted with white, black thighs, and tail. The light should be white all over save the tail and flight, which should be black, and the hackle which should be striped. The pullet you mention will breed good chickens if put to a light cock. This latter should be marked like the hens.

SILVER GREY DORKING HEN (*Idem*).—We believe you will be as likely to breed some good birds from the hen you mention, as from any others. You will never succeed in breeding all Silver Greys from any birds, however carefully chosen. You will have to breed a good number, and to choose from them.

BENT SICKLE-FEATHERS (*J. W. S.*).—If you had named the breed of the cock you would have enabled us to answer more easily. Straighten the bent feathers, and, if necessary, bind them till they have recovered strength. If the bird is likely to be exhibited again, do not on any account pull them out. It is a great disadvantage for a cock to lose his sickles. No special diet is necessary.

PLUMAGE OF A DUCKING GAME COCK (*G. R. Lyndhurst*).—The Ducking cock should have very light straw-coloured hackle; black tail, breast, and thigh; copper-coloured saddle, and duck wing, with the mallard colour. The bird you mention would seem to be a Silver Duckwing. The Greys vary in many ways in colour, some being much lighter than others.

DUCKS DYING (*S. L. Q.*).—From the symptoms you mention, your Ducks appear to have picked up something of a poisonous nature. Had you any corn dressed for sowing that might have been dropped in their way? You will find oats and oatmeal good substitutes for Indian meal and potatoes. If you notice any more of your Ducks drooping, keep them penned-up for a few days, give them plenty of clean straw and gravel, and let them be fed on oats whole, and not allowed too much water. It is possible that the birds you mention as having pined and died had been fasting some time when turned into your yard, and then gorged themselves with food and were unable to digest it. A stoppage would cause the drooping of the wings and the cramp as described.

ROSEN DRAKE SICKLY (*A Constant Subscriber, Manchester*).—If your Rosen drake had been taken up from a run where he had liberty and plenty of water, the confinement in the enclosure you mention would account for his pining away and for the cheek in his mouth. It is always unadvisable to move a bird when deep in moult, as many of the young feathers are killed even by the most delicate handling. The thick white matter in the corner of the eye is a sign of very low condition. If the skin around appears puffed or inflated wash it with vinegar and water, and gently press it with the thumb that any matter may be dislodged. The bird should be shut up in a dry, warm place and well fed.

PIGEONS AT THE PORTSEA SHOW.—In your last Number of THE JOURNAL OF HORTICULTURE, I see a correspondent gives me credit for lending to the Portsea Catary Show some Powder Pigeons. This is a mistake, as they were sent by Mr. Body, High Street, Portsmouth, and are first-class birds, being from the renowned stud of the late lamented Mr. Bult.—J. C. HASSARD, *Major, R. E., Hilsa*.

BLACK BULLFINCHES (*T. Cave*).—We have seen many black Bullfinches. The colour is the result of feeding on food that is too stimulating.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 44.1° and 31.5° respectively. The greatest heat, 57°, occurred on the 3rd, in 1860; and the lowest cold, 4° on the 2nd, in 1854. During the period 149 days were fine, and on 96 rain fell.

A PLEA FOR MODERN FLOWER-GARDENING.

UCH has been said of late having a tendency to disparage the modern system of parterre flower gardening, and it is well worth while inquiring whether the expressions of those who would have us revert to the individual beauties of the mixed flower-border represent the general opinion of the country; and whether, after all the ex-

cellent logic that has been spent to point out the defects of the one and to extol the merits and adaptability of the other, the real facts of the matter have been elicited.

It is a mistaken theory to suppose that a mixed flower-border, however well arranged, excites the admiration of the general community in the same way as one having the dress and finish of this elegant though much-abused bedding system; and it is also a mistake to suppose and promulgate that these mixed flower-borders are all but totally neglected or misguided since the advent of ornamental and artistic flower-gardening.

True, attention has been more fixed upon plants suitable for this modern decoration; and every gardener and lover of flowers is on the alert to obtain—either from cross-breeding, hybridising, or selecting from herbaceous borders—plants that are either remarkable for foliage, elegance of habit, or redundancy of bloom; and every year is adding to the stock of novelties either in variety or species, so that before many years elapse there may be as many favourite flowers for this sort of work as there were select individual border ones before bedding-out was known. Does anybody imagine for one moment that the thousands of visitors who throng and promenade the gardens of the Crystal Palace, Regent's Park, South Kensington, or Kew, week after week and year after year, and who have been neither slow nor sparing in their laudations of the gorgeous array of flowers, their happy combinations, and their general contour, would look on with the same amount of pleasure if the one half of the space were devoted to individual objects, from the Christmas Rose onwards and upwards, which the botanist and the gardener at all times admire either less or more, but which are lost or dwarfed as pictures of beauty in the artificial landscape immediately the eye or microscope is taken away from them? This, I contend, is the beauty of modern flower-gardening, because it introduces whatever is compatible to its interests, no

matter whether it be annual, biennial, or perennial, and sets it off, like any other well-arranged material, to the best advantage. The florist is a severe stickler for form and quality of bloom. The mixed-border pleader advocates a return to the objects of his solicitude and love, and promises a hearty welcome; and each, quietly speaking, is a little empirical in his own way, but the much-abused innovator makes a selection from each, and deserves a little more consolation and moral support from both.

Some ridicule it because it is artificial. So is the fine smooth-shaven lawn; so are the broad, straight, gravel walks; so are the fountains; so are the statues; so are the very beds that in days of yore were filled with the much-vaunted herbaceous material, which the partisans of parterre flower-gardening are accused of banishing from their gardens, but which in fact are only removed to less artificial borders, where they are more at home. And what garden of eminence in the country, beginning even with some of the less pretending villa residences up to those which it is the pride and the boast of gardeners to revert to, but possesses either more or less of those adjuncts to the mansion, which is artificial enough to be sure?

By all means let the herbaceous subjects have proper justice accorded them; but do not introduce the more cumbersome, which are neither remarkable for flower, foliage, or habit—nor those puny sorts which require microscopic examination to exhibit their merits—nor, in fact, any of them which unavoidably become a blank in midsummer—into these artificial parterres. They are nothing but an eyesore there. The proper places for these are in borders outside of the smooth-shaven lawn, and as a break in the beginning of the true English landscape. There they may be introduced into wavy or straight lines in these irregular or other-formed borders, or in detached figures—in fact in many ways; and a very interesting field of observation will they present to the amateur and botanical student, not to speak of their gradual relief between sylvan shade and the extreme ornamental landscape.

Then, again, it is contended that this system is but a fleeting show at the best—that in the vicissitudes of this climate it is a great deal of labour and little return. Can any of the opponents of the system indicate a plan so effective as to disarm the criticism of all and sundry? Can they point to the experience of the past where an equal amount of gratification was afforded with less adequate efforts? or can they read the admirers and promoters of this innovation such a lesson as to induce the former to see only beauty in its similitude to Nature, and thus ignore everything from a hand-bouquet up to a ribbon flower-border? This once accomplished, then the gardener must soon follow suit. There are, no doubt, heavy engagements upon his time at the propagating and bedding-out seasons, but this is often accomplished at very little extra expense; and his employers, as a rule, are so gratified at the generally improved appearance of their parterres—many of them residing in their country

residences only during the gayest season—that the little extra expenditure incurred is passed over without comment; so that there is exceedingly little room for evincing a morbid desire to curtail, if not to annihilate, the system altogether.

It has been called monotonous because it presents a uniform dumpy surface. Its success has been questioned because an unfavourable season occasionally occurs to mar or retard its growth and beauty; but the originators of this opinion forget that what affects and retards the ultimate beauty of the one must also considerably deteriorate the ornamental appearance of the other. More than that, I maintain that this system affords much the best groundwork for advantageously displaying all sorts of spring-flowering bulbs, as well as portable specimen Conifers and other ornamental plants, which can be lifted and disposed of in shrubberies and reserve gardens when the planting-out season arrives; and if the accommodation of the gardener be proportionate to the space he is expected to fill, there cannot be a doubt that his dress garden will be an object of interest throughout the whole year—such an interest in fact (for the earnestness of our opponents compels us to be candid with them), as will completely eclipse the best-arranged botanical mixtures.

But I have something to say in conclusion concerning the dumpy monotonous surface which this arrangement and material presents. It is certainly by no means satisfactory to my own ideas: but the system is only in its infancy, and is steadily progressing every year. The great public gardens in England should lead the van in this respect: and if there is one place more than another, with all the influence of English aristocracy and English wealth at its back, where we should expect to see the best examples of modern gardening and modern design introduced, it is South Kensington. But there the design has all but been condemned. Even the graphic pen of our friend Mr. Beaton has failed to excite there a reactionary movement in its favour.—JAMES ANDERSON.

### CAPE BULB CULTURE.

THE two ends or extremes of the management of the larger kinds of Cape bulbs, but not of the largest bulbs from the Cape, having been inquired about at our office by a young hand down at Leamington, it struck me as an excellent opportunity to refresh the minds of the Journal's readers on that subject, and to request once more that they will divest themselves of the old notions which have hitherto deprived this country of the enjoyments of some of the finest of flowers—the flowers of half-hardy bulbs; and nine-tenths of all the bulbs on the face of the earth are either altogether hardy or half-hardy. The few kinds of stove bulbs inhabit the coast line in a narrow belt within the tropics round the globe, and a very narrow belt it is compared with the range on which the rest of "the Lilies of the field" are displayed. So far within the tropics, and no farther, will you find a stove bulb; and so many feet above the level of the sea, and you will not discover a bulb to which the heat of a stove is not certain death in the long run. You may keep stove bulbs alive for many years in a lower temperature, and yet be able to bring them up to the mark again by changing the climate to their liking; but there are scarcely any of those half-hardy kinds which, if once deranged by the unwonted stimulus of extra heat, will recover from the over-excitement. *Sprekelia formosissima*, the *Jacobaea* Lily, is the only half-hardy bulb known in practice which will endure the heat of the stove and forcing-bed from year to year with impunity. This bulb, therefore, may be added to those in the extreme limits of different treatment under cultivation.

*Cyrtanthus* and *Nerine* are the two kinds inquired about from Leamington, and they are at the extremes. The evergreen *Cyrtanthi* require a little more warmth while they are at rest, with their leaves on, than any other Cape bulb whatever. They and *Vallota purpurea* grow on the verge of marshy lands; and from their roots being constantly supplied with moisture, the drought has not the power over them to cause them to shed their leaves like most other bulbs of that country or colony; but *Vallota* being from a higher locality, and requiring less heat in winter to keep it growing, however slowly, it does not differ materially from the great family of Cape bulbs, except in being an evergreen. But the *Cyrtanthus obliquus*, the only evergreen one we ever see now from the Cape, rests entirely from growth for five months from the end of September, and requires 10°

more heat during these five months than any other bulb from the same country—that is, it should be in a climate of 50° the whole winter; and no other bulb from the Cape of Good Hope should ever be in a winter temperature above 40°, at least not for long at a time.

The whole secret of growing all Cape bulbs to perfection, is never to let one of them experience more warmth in winter than 40°, except the one in question, *Cyrtanthus obliquus*; and if that is not up to 50° from October to March, it will never bloom in this country, although it may live.

Many years since I had to look out for a couple of flowering-bulbs of this *Cyrtanthus* for experiment, and there were not in all the nurseries, or in all the private collections of this country, as many as two bulbs of this *Cyrtanthus* which the owners would guarantee to flower next year, or say had flowered the year preceding. And knowing that if the bulbs did not flower for the last three years, the chances were they could not be brought to do so for the next ten years, if ever it could be effected, I had to send out to the Cape for some bulbs, received them in good condition, bloomed them as freely as *Gladiolus*, crossed them, and subverted two botanical genera in doing so, sent a seed-pod to Dr. Lindley, who pronounced the seeds half ripe only; but every one of them made a plant in the Chiswick Garden, though eventually every one of them was lost.

Now, if this *Cyrtanthus obliquus* down at Leamington has not bloomed for the last three years, it is of no use but as a botanical specimen. All the gardeners in the country in a committee could not cause it to flower under five years certainly, perhaps not under fifteen or twenty-five. So you see the necessity of placing *Cyrtanthus obliquus* at one of the extreme limits of the proper cultivation of Cape bulbs. Yet, to a certainty, it would bloom every year as regularly as *Vallota purpurea*—that is, it would bloom at any time from May to Christmas, as freely as *Gladiolus brenchleyensis* if it had the proper cultivation, which is extremely simple—that is, to be allowed to make the yearly growth from April to September in a cold-frame temperature, and that, of course, could be done in a greenhouse by placing the pot near to where the top or bottom air was given, and by keeping the bulbs in an intermediate temperature between a stove and a greenhouse from September to March, and giving very little water through the winter. In order to keep the fat fleshy roots from shrivelling the pot ought to be put inside another, and be placed in a saucer of damp sand, merely keeping the sand damp the whole winter, and giving one good watering to the bulb once in six weeks. The Portugal Laurel never moves a bud from the end of September to the beginning of March, and yet if its roots were left to dry-up and shrivel, it would lose all its leaves, if not die right out; and so it is with the "evergreen *Cyrtanthi*," as they say of one kind of bulb only, for I do not think the variety *carneus* is new in.

After this explanation it would do us very well in the column for correspondents, "Keep your *Cyrtanthus* on the front shelf of your late vinery from October to March, and give it cold-pit culture for the rest of the year."

Now for the other extreme of Cape bulb cultivation. The Leamington correspondent had received a supply of the last-named bulbs and of some *Nerine*, of which he did not get the name; but from his description of it there is little doubt about its being *Nerine curvifolia*, a very pretty kind, and quite as easily cultivated as a Dutch *Crocus*, and very much in the same way all the year round, only that this *Nerine*, and all the other *Nerines* we know of in cultivation, should not receive so much frost as would kill or pinch the points of the leaves. The only one of the *Nerines* which has the least difficulty about it is the *Guernsey Lily*, *Nerine venusta*, of which there are four varieties, and the one which comes to us yearly through the seed-shops and nurseries is the variety *sarniensis*; and I am not aware that any one has ever taken in hand to cultivate the *Guernsey Lily* in England as all *Nerines* ought to be done in our climate. All the *Nerines*, like all the true *Amaryllises*, rest during the summer months with us, and grow on all the winter like the *Belladonna Lily*, the type of the Linnæan *Amaryllises*; and all *Nerines* but one, *Nerine undulata*, require exactly the same treatment from October to April as one-year-old plants of bedding *Calceolarias*. *Nerine undulata* is hardy enough to do in front of a greenhouse without any protection; and if there were a demand for it here, we could so farm it as to be able to sell it at one-half the price per bushel which is charged for the earliest kinds of Potatoes. Then, if that be so, and so it is undoubtedly, the *Nerines* stand at the

opposite extreme to *Cyrtanthus* from the same country; they also ran out in a line, as it were, getting hardier and more hardy from *Nerine coracea*, the brightest of them all, through *pulchella*, *curvifolia*, or present plant, *flexuosa*, *sarriensis* or *venusta*, to *undulata*, which is quite hardy. There were two or three more kinds of them known years back, but they are now, in all probability, lost.

There was a consignment of "roots" of *undulata* sent to me for the Experimental Garden from a kind correspondent in Guernsey through Mr. Salter, of the Versailles Nursery, to whom I gave some of them, and who has it on sale. The reverend gentleman below Bristol, who first discovered the value of the cocoa-nut dust for bulbs, wrote me at the beginning of last November that he had then "a lovely bulb in flower which he believes is scarce. It was given him by Dr. Burchell, of Fulham, the old African traveller, and was discovered by him, and is the *Amaryllis undulata* of Willdenow, but now goes by some other name." I thought it might probably be the same as the Leamington *Nerine curvifolia*, as I take it to be, and I much wished a bulb of it if that were the kind. Next week I had a spike of bloom sent me to see the difference, if any, and it was the true *Nerine undulata*; and this will be the first notice of the fact which his reverence will see; and by so saying, the Leamington possessor of *Nerine* with the "very curled leaves" will also see how much I should value a "root" of *Nerine curvifolia*, but not now; for just at this time the plant has nearly finished the length of its leaves, and will not be fit to move until the end of May, unless it be in a pot, or be different from what I take it to be; for there is no bulb like it in the waxy margin of the leaf except *Hæmanthus undulatus* from the same country.

All the *Nerines* flower in September and October, and at no other time. Most of them come like the *Belladonna Lily*, and at the same time with a host of flower-stems and flowers only; and when the flowers are over then come the leaves, or with some of the kinds the leaves come simultaneously with the flowers. When they are bloomed in pots the best way would be to turn them out of the pots as soon as the flowers were past, and to plant them out with their balls in a light at the end of a cold pit, to grow on during the winter and spring, and to have the glass tilted at front and back the whole time, as long as the frost was not more than 5°, 6°, or 7°, which would not hurt them; but when the thermometer fell below 25° to shut them up until there was a change of weather, to keep them well watered from the end of February to the middle of May, and to keep down the glass close over them all the summer months when they are at rest, for our hottest summers are not too hot for them while they are at rest, nor for the *Belladonna* either, which requires the same treatment all the year round as the *Nerines* if they are grown, or rather bloomed, in pots.

Another correspondent who has been growing the *Belladonna Lilies* in pots and who cannot get them to bloom, has been on the wrong scent altogether. He put them into 60° of heat after the blooming time was gone, and, of course, he put them off flowering by so doing. The *Belladonna* must be in good hands to flower in pots one year with another; but in a warm border in front of a stove or greenhouse they flower every year and increase fast by offset bulbs. If any one took the trouble to make a bed on purpose for *Belladonna* and *Nerines* at the end of a cold pit, he might pot them at the beginning of September, bloom them in pots, and then return them to the same bed after flowering for the rest of the year. They would give no more trouble than *Gladiolus*; and a whole host of *Irid* bulbs could be grown in the same cold pit, and in front of these *Amaryllids*, if the first foot in depth of the front part of the bed was of peat and one-third loam. But the oldest plan of all is still the best for amateurs for their *Nerines* and for the *Belladonnas*—that is to say, make a bed for them on purpose in front of some hot-house or greenhouse. The bed should be fully 2 feet deep and 1 foot above the level of the ground round it. Any good garden soil will suit them. What one would use for a Peach-border would be about the best, but no dung and no peat should be in it, as, though dung and peat are good for one or two years, they are not safe for permanent beds for bulbs which do not require peat—as *Irids* and many *Lilies*. June and early in July is the best time to plant them; and the roots or bulbs should stand 6 inches apart each way, be fully 6 inches deep in the ground, and have mulching in winter, for which coal ashes are as good as anything, and have straw put over it in very severe frost.

D. BEATON.

## CROSS-BREEDING STRAWBERRIES.

As you request information from any one who may have it to impart relative to the cross-breeding of Strawberries, I beg to say that I have crossed British Queen and the Alpine, and British Queen and the Russian Alpine.

The produce of the cross first named was a lot of very diminutive plants, remarkably free-flowering, and having large flowers but quite sterile.

The plants of the cross named secondly were large and free-flowering, shy-blooming, and also sterile.

Enclosed I send you three small runners of another cross between a wild Hantbois (which I gathered on Bramham Common under a Thorn bush, where, apparently, it had been growing for many years, having a woody stem about 10 inches long), and a fine seedling that I obtained between British Queen and Black Prince, having the flavour and nearly the size of the first, with the prolific properties of the last. I have only reared one plant. It was sown in March last, and it has made a large plant with four large crowns. It has not flowered yet, and is very shy in forming runners, having only produced about six through the summer, and those have grown mostly since I took it up in September.

If you thought it might in any way interest Mr. Darwin, it is at your option to send him one or all. I gathered some of *Fragaria vesca* to plant on the rockery, and they are greatly improved in size and perpetual. Has any one noticed this before?—WILLIAM SMITH, York.

[Mr. Darwin, to whom we forwarded all the runners, is very much obliged, and has planted them. We had a large bed of *Fragaria vesca* (Wood Strawberry) some years since, and the fruit was double, both in size and quantity, that obtained from plants growing wild.—EDS.]

## CHRYSANTHEMUMS.

"I DON'T like Chrysanthemums," said a London friend to me some time ago; "there's a sort of mock gaiety about them. They mean to look handsome and attractive; but there's fog and gloom all round, and they are out of place. There are like ornaments on an old person—and so—and so I don't like them." I wonder whether this feeling is general, or how it is that the flower seems this season to have been very much in the background. As for myself, I felt personally aggrieved—hardly done by, having never seen a really good Chrysanthemum show. I had made up my mind this year to do so. Alas! it was no use making plans, for neither the Crystal Palace folk nor the Royal Horticultural Society found room for one; and although Stoke Newington still continued loyal to the flower, yet I did not seem to be drawn towards that, and so contented myself with a peep at Kensington. It could hardly be called a show; and therefore the conclusion which was drawn in the Society's "Proceedings"—that because so few persons went to the Gardens on that day, the wisdom of not having a Chrysanthemum show was patent, was what I should call a very fine *non sequitur*. It was not a show—had none of the adjuncts of a show; the sum offered was not sufficient to bring together many exhibitors, and was, moreover, so completely an after-thought, offered so late in the season, that there was no possibility of people preparing for it: hence I hope that it will not be taken as a precedent.

I look upon the Crystal Palace Company not having one as more ominous still. They are so ready to cater for the public in every way, provided it is likely to bring grist to the mill, that I fear they regard it as an unprofitable thing. I hope this may not be so, for I do not agree with my London friend; and even now, as on Christmas-eve, I look at my little lot, and can see a brilliant bloom of *Jardin des Plantes* and *Carissima*, I do not think their gaiety forced, but am glad to welcome anything in the shape of a flower. Nor had I this season my usual treat at my excellent friend, Mr. Salter's, of Hammersmith. Had I known it, I should have preferred a visit there to that to Kensington; but there were friends I wished to see and business to be done, and so the visit to Hammersmith was not paid. Mr. Salter has done what he could with his usual kindness to make up the loss. I saw some of his seedlings at the Floral Committee. He kindly sent me blooms of some others, and has also furnished me with a list of those novelties which he intends sending out in the ensuing spring.

Of the flowers of this year which, through his kindness, I

have had blooming in my possession, the following seem to me to be very desirable:—

*Carissima*, a very beautiful large flower; blush white, and beautifully incurved.

*Duchess of Wellington*, rosy carmine with blush tips; large incurved flower.

*Edith Dombrain*, makes an uncommonly pretty plant; colour a pinkish-blush.

*Sparkler*.—When I saw this flower in the autumn of 1861 it struck me as being likely to be a more general favourite than *General Slade*. Although it only obtained a second-class certificate while the *General* was first I still hold to that opinion, and think that, although both are good, as a general rule *Sparkler* will be preferred.

*Lord of the Isles*, too, is a very fine flower, high in the centre; and although not novel in colour, beautifully incurved, and a most desirable flower.

*Lord Ranelagh* is a light reddish-orange, beautifully incurved, and of fine habit.

Of the *Pompones Citronella* is a very pretty clear yellow; and *Lucinda*, rose and lilac, and very full.

It seems strange that the new varieties should run much more amongst the large flowers than the *Pompones*, but so it has been of late years. In 1860 Mr. Salter had twenty-four new large flowers and only ten *Pompones*. In 1861 he had twenty-one large flowers and five *Pompones*; while, as will be seen from the following list, he has this year eighty large ones and only six *Pompones*. The fresh blood that is likely to be infused into the flower by the late introductions from Japan will not make any alteration on this point, for they are larger than anything we have at present, one of them being described by Mr. Fortune as being as large as his hat.

I now subjoin a list of Mr. Salter's novelties, and am the rather glad at having this early opportunity of doing so, as, owing to the very late season, Mr. Salter was unable to supply his list in time for the "Year-book." I have seen some of the flowers, and think Her Majesty will take the place she ought to do in all loyal hearts, as the habit is so excellent; while *Lord Palmerston* is as great a novelty as his namesake. *Princess Alexandra* and *Princess Louis of Hesse* are very good flowers; and amongst the *Pompones* *Julia Engelbach*, *Mary Lind*, and *Fairest of the Fair*, will, I think, be general favourites.

*Her Majesty* (Smith), ivory blush, beautifully incurved; compact dwarf habit. Every flower a perfect model.

*Abbé Passaglia* (Smith), large, brassy orange, beautifully incurved.

*Antonelli* (Smith), reddish-orange, incurved. A splendid flower.

*Aspasia* (Smith), rosy purple, incurved blush. A very pretty pot plant.

*Beverley* (Smith), large creamy white, finely incurved.

*Cleopatra* (Salter), blush, with rosy shade, finely incurved.

*Cardinal Wiseman* (Smith), bright red crimson; dwarf, and fine pot plant.

*Duchess of Buckingham* (Salter), fine incurved white. Excellent conservatory plant.

*Daphne* (Smith), sulphur. Fine and distinct.

*Golden Fleece* (Smith), clear golden yellow, incurved; fine dwarf habit.

*Holman Hunt* (Smith), clear rose. Large and very fine.

*Handel* (Smith), large, dark rose anemone. Very distinct and noble flower.

*Jane* (Salter), large, silvery pink, finely incurved. Very distinct and beautiful.

*Lord Palmerston* (Smith), dark rose amaranth, incurved, and tipped with silvery white. A very fine and distinct variety.

*Mrs. Brunlees* (Smith), delicate rose, with light centre, incurved, and fine large flower.

*Mr. Jay*, reddish-orange, with gold centre, incurved, and fine.

*Oliver Cromwell* (Smith), dark ruby red, beautifully incurved.

*Othello* (Salter), dark rose carmine, finely incurved.

*Orpheus* (Clark), large rose lilac, tipped blush. Fine large flower, after the form of *Themis*.

*Princess Alexandra* (Smith), delicate lilac blush, with lemon centre, finely incurved. A lovely flower of exquisite form.

*Princess Louis of Hesse* (Smith), bright rosy pink, incurved, blush. Dwarf, and excellent habit.

*Queen Margaret* (Smith), large rosy anemone, with light centre. Fine and distinct.

*Samuel Broome* (Smith), orange salmon, incurved. Very full and noble flower.

*St. Andrew* (Davis), orange nankeen, incurved, and fine show flower.

*Talbot* (Smith), rose purple, tipped blush; very close, stiff petals, beautifully incurved.

*Victor Hugo* (Smith), dark brown crimson with chestnut centre, finely incurved.

#### POMPONES.

*Fairest of the Fair* (Salter), delicate lilac blush with silvery tips. Very double, and fine habit.

*Helen Lindsey* (Salter), cream white, a complete ball. Fine, early, and free-flowering variety.

*Julia Engelbach* (Smith), golden orange with brown points. Very double, and excellent habit.

*Lilac Cedo Nulli*, a sport of *Cedo Nulli*, with lilac flowers.

*Mary Lind*, blush with purple shade. Very distinct.

*Pyramidalia* (Smith), red and orange hybrid. Very free, every branch forming a pyramid of flowers.

#### LARGE FLOWERS.

*Cresna* (Smith), dark golden amber, incurved; very close and full rosette form. Very dwarf and fine pot plant.

*Pomona* (Smith), dark rosy fawn with bright orange centre, incurved.

*Princess Mary* (Smith), large blush white, finely incurved. Beautiful show flower.

*Fair Rosamond* (Smith), rosy yellow with lemon centre, incurved.

The above four flowers will be also in my first section; but *Daphne* and *Pyramidalis* will be put in the second section.—*D., Deal.*

### PROPAGATING CONIFEROUS PLANTS BY CUTTINGS.

I WILL add a mite relative to successful practice upon the above subject.

Now is a very good time to put in cuttings of all the kinds desired to be increased by that mode. The cuttings will do either in a cold pit or hot pit according to convenience, the difference being only a matter of time. The warmer they are the sooner they will strike.

Supposing some one wants to increase any of the beautiful *Cupressuses*, *Thujae*, *Junipers*, *Thujopsis*, &c., take some long strong pieces of the ends of the side branches—the larger the piece the sooner you make a handsome tree—say from 6 inches to 12 inches long, yet some of them will strike from bits of 2 inches.

We have had a great deal of instruction about preparing these cuttings from time to time, embodying certain rules, which, of course, the writers considered unlawful not to observe; but in these "trotting days," as Mr. Beaton calls them, if the laws that were made for a past generation do not meet our wants, we must go ahead and take the responsibility of making laws for ourselves. It is so with Conifer cuttings. Having the pieces, take one up and cut a shaving off its bark about 1½ inch long from the base upwards; cut that shaving clean off at one cut, so as to expose the wood from top to bottom of the cut, and so on till you have finished. Never mind about the bottom end of the cutting, whether it be square, round, or oval, eye or no eye, joint or no joint; all that is non-essential. There is not a plant that will strike from a cutting that requires to be cut in any given form; but if it will break with a bend without bending double, it will strike from that break as soon as from the most precisely cut end—in many instances much sooner—because there is more alburnum exposed, from which the roots proceed.

Perhaps I shall be put down as an unmistakeable descendant of the "uncouth Goth." Be it so: my aim is success, and I base my practice on scientific principles—so I will next take a large seed-pan, crock it, and secure the drainage; fill it with fine sandy soil, finishing-off with half an inch of silver sand, and dibble-in the cuttings as thick as their tops will allow them to stand, water them, and give the usual significant rap on the potting-bench. Then I want a large saucer, and three little stones an inch or two thick placed in a triangular form in the bottom; on these set the cutting-pan, and keep water in the saucer up to the bottom of the pan continually, and give no water at top. Put them into the pits above mentioned, and keep close till growth has commenced, when they should have a little more light and air, gradually exposing them till you get

them out altogether, and when they have been out a week or two, shake them carefully out and plant in a nursery-bed.—  
WILLIAM SMITH, *Fork.*

MEASURING THE ANGLES OF ROOFS.

THE following is in answer to "PATELIN'S" inquiries on this subject:—

There is a want of a thorough understanding, as to the mode of calculating the angle between the perpendicular wall of a lean-to house, or the supposed perpendicular line in the centre of a span-roofed house, and the sloping glass roof, because some authors count from one side of the quadrant and others from the opposite side. It is much to be wished that the Editors of this work would give a certain sound on the subject, as frequently when the angle of a house-roof is given, we have nothing to judge from except the context as to whether that roof has a slope very steep or very flat. We presume the youngest of our readers are aware that a quadrant is the fourth part of a circle, formed by dividing the circle into four equal parts, by two transverse diameters. The fourth part of the circumference thus forms the arc of the quadrant, and the two diameters, meeting in an angle in the centre of the circle, form the two straight sides of the quadrant. The arc of the quadrant is then divided into 90°, being the fourth part of 360°. So far all is clear. See *fig. 1.*

Fig. 1.

There may be many other ways in taking the angles of roofs; but I used to amuse myself doing so with a quadrant formed of wood, or stiff paste-board, with a string and bob, fastened at the angle E. Thus: place either of the sides C or D parallel with the slope of your roof, and the string with the bob will mark the angle on the arc. In deciding on the slope of a roof to be made, you can just elevate or lower

the back part of a long rod intended to represent the slope of a roof, until the requisite degree is marked on the arc by the string. For instance: in a house 9 feet wide, and the back wall 9 feet higher than the front wall, as in *fig. 2,* either side of the quadrant, placed parallel with the sloping roof A, will show an angle of 45°. This will always be the case when the height of the back wall above the front wall is

Fig. 2.

Fig. 3.

Fig. 4.

the same in feet and inches as the width of the house. But now comes the bother and worry about these angles. According to the side of the quadrant we thus use, the difference becomes greater as we go from the point of agreement at 45°. Thus you are recommended to have a roof at an angle of 34°, as the best, and as your front wall and glass together are 6 feet in height, you wish to know what height the back wall should be. Now, the mode by which I always calculate, is to use the side C of the quadrant, or that which is nearest the numerals, 1°, 2°, 3°, 4°, and so on, on the arc; and to have a roof, B, in *fig. 3,* at an angle of 34°, the back wall will require to be about 13 feet higher than the front one, or 19 feet altogether, supposing the width of the house to be 9 feet, and just so much higher or lower as the house is wider or narrower than the 9 feet specified. You will at once see that such a house would be chiefly useful for late

and early work, commanding most of the perpendicular rays of light in the dark months. You will also perceive that 0° being the perpendicular, 24°, 14°, &c., would give you roofs all the more steep, until you came to upright sashes at 0°. On the other hand, however, many people calculate their angles by using the D side of the quadrant, which is next to 90° on the arc, and this, as specified above, alters the whole matter. On this mode your desired angle of 34° for roof would be shown at B, *fig. 4.* To secure this angle according to that mode, you would require to raise the back wall only 6 feet higher than the front, 12 feet in all, provided the width was 9 feet. We incline to think that this must be the angle of roof you require, as with upright glass in front, such a slope would prove a very generally useful house. On such a mode of calculation, the roof and angle in *fig. 4,* of 34°, will be exactly the same as an angle of 56°, according to the first mode referred to. In one word, according to this last mode, the lower the figure of the angle, as 10°, 15°, 20°, &c., the flatter will be the roof. According to the first mode, the lower the number of the angle, as 10°, 15°, &c., the steeper will be the glass roof. Thus the angle of the glass sash of a garden-frame, will, according to the last mode, be about 10°, according to the first mode it will be 80°. Such differences ought to lead to one general usage to prevent misconceptions. I approve of the first mode—that is, of using the side of the quadrant C next the units on the arc. Others have just as good a right to use the side next 90°, until some authority shall settle the matter. By the first mode I have computed all angles of roofs mentioned by me. What is said of the garden-frame, and *figs. 3 and 4,* will explain the difference. There may be some better method of deciding on an angle than a quadrant and a rod, &c., but I know of none.—R. FISH.

A HEDGE OF ROSES.

YES, "A Hedge of Roses." The very words at any season give an idea of the beautiful; and they do not sound ungenial even now at Christmas, the season redundant with its many happy reflections. So there is given an illustration of a "hedge of Roses," and does not the very phrase bring from the past some of our sunniest memories?

But these pages are for the "real," not for the merely "ideal," so let us pass on to "a hedge," a veritable one—composed of the cream of the Rose-catalogues, a combination of colours and varieties; the van being led by the warlike Géant des Batailles, followed by Generals Jacqueminot, Washington, and Simpson; accompanied by the fine-formed, unwieldy Colonel de Rougemont, with the Mesdames Alexieff, Boll, Furtado, Melanie, and others; having as companions such partners as Jules Margottin, with Monsieurs Ricaut, Lafitte, and a name that sounds strange—John Hopper, with many others, and last, though not least, Mr. Wm. Paul's Beauty of Waltham.

Though I here enumerate a few essential ones, the outline of the hedge, as I devise it, admits of every facility for the furtherance of individual likings and fancies, giving each an opportunity to select for himself. So, now bring your rod and line, and let us proceed to peg-out the necessary space within which to plant our hedge. Yet, first let me tell you that, as usual, we again submit to individual fancies or desires as to the form, whether it be straight, abruptly curved, or rotund; though it will be better where applicable to give the preference to a line more or less north by south, as thereby both sides will the better be benefited by the direct influence of the sun.

Having selected the spot, well trench and manure the ground some 5 feet or 6 feet wide the whole length required, and, if possible, 2 feet or 3 feet further than just where the hedge is to be. Here let me state, that where the nature of the soil is really adverse to the growth of Roses, I would not advise the attempt to be made unless the proper space for the whole growth of the individual plants be made artificially, as however well you may prepare a certain space in one of those harsh ungenial soils, though it may suit them, and they may do well for a few years, yet it would not be wise to plant them for the purpose specified above, for in time the roots would roam beyond the limits of the artificial soil prepared for them, and the result would be very unsatisfactory.

Having prepared the soil, turf if necessary the space to within a foot each way of where your centre is to be (the centre of the hedge). By so doing you have a border some 2 feet wide. Now, procure some rough, knotty, rustic-looking stakes, or poles, about 7 feet long, and drive them firmly in two rows. Each stake

in those two rows to occupy the centre of the interval between the opposite pair thus:—

Each of the said stakes to be some 5½ feet apart from each other in each row, the distance between the two rows of stakes in the line being 1½ foot apart. This done, procure the necessary number of Rose plants, giving preference to the following sorts:—Glorie de Dijon, Blairii No. 2, Chénédolé, and, perhaps, the Queen of the Prairies; although I am not very partial to the last, it may do in some soils. But, suppose you take to the three sorts enumerated above, then proceed to plant them alternately all ways; and if odd ones are necessary, give the preference to the former one. Having planted them as directed, cut each of them in to one eye—the bottom one, if it is likely-looking; if not, and it appears weak, take the next, rubbing the discarded one out, as I have mostly found that eyes or buds, like shoots, consist of weak and strong ones, the weaker ones never doing like the others. Now, secure the plant firmly to the stake, but so tie it as to admit of its settling down with the soil, otherwise you may hang each of them.

When they break, to use a gardening phrase, and are started to grow, encourage them by giving them repeated waterings with manure water, &c., supporting them by tying them to the posts. The next spring again cut them down to the one eye, and again encourage a good strong growth, treating them in all ways as they were treated the previous season.

The next spring so prune them back to five or six eyes as to secure for the next summer's growth fine, good, strong shoots. I say prune to five or six eyes, as I would wish you so to prune the single stem of each individual plant (as they may vary materially one from the other), as to secure the five shoots, for get the five this season you must by some means or other, so that if either does not look likely give six a chance to break. Then, when you have secured five healthy young shoots to each plant, encourage again each of those shoots to make a thorough good growth. Your requirement now is rather to attain good, strong, short-jointed, well-ripened wood than great length, as the after-growth of the hedge will prove. As they grow tie them loosely and carefully. Pray do not bundle them together as Roses often are, tied for tying sake; mulch the ground, and give most copious waterings if dry weather should set in.

When the shoots get about 5 feet long pinch the tops off. When they are again safely started in growth secure the bottom shoot that has started in consequence of being pinched back, and rub out all others upon each point save this one. By so doing, as doubtless you will see, you will materially strengthen the growth of all; as vegetation, even when most luxuriant, benefits by a little relaxation, for this enables it to muster its resources and start again with strength and freshness.

You, doubtless, perceive that I am quite an adherent of Mr. Beaton's mode of treatment when a thorough good growth is needed. By all means cut the shoots down; cut away the whole growth of last summer, and in the roots below you have a firm basis upon which to set to work, and form a shoot or shoots—say three or four of them, 14 feet long if you wish. I have done it, so write from experience; and let me tell those who have not done so, and who may have now oldish plants of Roses, that if an eye can be found at the base of any of them, cut them down to it.

Having pinched the points of the shoots off and given the unobserved hard-working roots breathing time, we leave the shoots to make good hard wood for next spring, as we shall want it all. Leave them until a mild week in the very early spring succeeding, when the border should be thoroughly well treated as regards manuring and forking; and now the want is a wherewith to extend and support them when formed into "the hedge,"—in a word, a Rose crinoline is wanted. A crinoline for a hedge! how absurd!

Very well. Now take the pattern of your main support from the letter U; upon the now upper crosses of it place strong tines, or, as some would say, "legs." This, as you will see when inverted, will form when placed in the ground a permanent oblique stay, thus—

The bent part of this above ground

should be flattened. Through this when properly flattened, &c., holes will be made, in number 11—that is, five on each side and one in the centre of the upper bend. The number of these bent supports which may be requisite will depend upon the length and the strength individual ones possess when made. I would have them about 3 yards apart. Through these pass the customary small fencing wire so—

The Rose plants, grown as I have stated above, are to be trained to this fence, but first let me give a size for the same. It may be some 48 inches high—that is, above ground. The number of wires being, as I have stated above, five on each side and the centre one, might be equalised thus—six wires 8 inches apart bring the required figure by multiplication to 48 as above. Now get the five shoots ready upon the first plant; select the weakest; train it straight up to the centre; when there turn and tie it some few inches along the top or centre wire; then select the next two weakest shoots and train them up in a workmanlike manner, and in opposite directions along the fourth wire from the ground. Tie nicely, and leave at a tolerably good length until you have trained the next Rose, when you must arrange so as to cut them back where two eyes meet. If one shoot to do this must be longer, of course let it be the strongest from the strongest plant. By cutting them back so you have the means of getting a shoot to go up to the fifth wire, and down to the third at the very end; try to fill out the ends and the bottom, as the base and the top of the shoots are sure to do so. Now, select the two last and two best shoots to go along the second wire from the ground, the best in the worst place; and if you follow my directions, treating the other side in the same way, you should not have an inch of vacant space upon either the second from the ground, the fourth, or the sixth wire—each will be a continuation of good well-seasoned wood, save just where the first shoot runs up, and this seldom fails to fill out.

Well, now, perhaps, you have caught my idea and I need not go further, though if a thing is done it should be done well, and so we will proceed with the "finis."

Try your utmost to get every eye to break, to start, to grow. Encourage each to grow well, and as they grow tie those you can, alternately up and down, to the vacant wires, Nos. 1, 3, 8, and 5 left on purpose. Some few shoots may not readily bend into their places now; if so, stick a stake in the ground, and tie each such shoot to it. Overlook the appearance this one season, even if you have stakes protruding, giving you an idea of a bristled hedgehog.

If when growing some of the shoots should be weaker than others, when the strongest are 4 inches long, or long enough to tie to the proper wire, stop them, and so encourage the weak ones; next look carefully after them, and find out when the wood is just right for budding upon. Then, when you find the sap begins to lessen within them, and they are ready, bud, upon every conceivable point of them where applicable, any Roses you like, but do it neatly and cleanly. You need not cut half the slit budders in general do. You need not also have more than half the heel to the buds you have been used to. If you notice three parts of all Rose-buds, those that have too much bark to them generally take hold of their fresh support close to and around the eye, when the outer part of the bark dies, and consequently there is a much larger wound for the foster-parent or stock to heal: so pray, upon this occasion in particular, bud in a clean, neat, and workmanlike manner. Try also so to insert the buds that when the shoot is tied to the next wire it may be at the side of it; for these, when they grow, will in their turn have to be tied down and in with the others, and that neatly and tidily. Another thing let me tell you—when tying the buds

in, whether you use matting or worsted, pray tie them loosely. Do not catch hold of the shoot with one hand, and with the other twist your material around as if your only intention were to stop the flow of the sap. Take an example from your own finger when wounded. There is a certain tightness at which a bandage wound round feels comfortable: either tighten or loosen if it is not. So with a plant. Excessive tightness of the ligature interferes with the equalisation of the sap. Perhaps it does not stop its upward flow, but it stops its downward tendency in the liber, sometimes wholly. I have seen instances where the untied bud grew the best. When your buds have taken and grown even Teas can be placed upon this trellis with impunity, as you can mat it in severe weather.

If the contemplation of this our "Hedge of Roses," does not give a zest to your happy Christmas thoughts, I hope many and more worthy things may.—W. EARLEY, *Digswell*.

### POTATOES AND THEIR QUALITIES.

YOUR correspondent, "UPWARDS AND ONWARDS," has written a very servicesable paper on this excellent root; but he mentions one of the best Potatoes in this country in rather a flippant way, insinuating that it is now an old Potato; but this is not the case, as it has not been known in Gloucestershire for more than twelve or fourteen years, and only more generally during the last seven or eight.

I do not agree with your correspondent that the very white powdery Potato is best, as many of this description are very indifferently flavoured.

In praising the Fluke (from Lancashire it has been stated originally), I can only state that it is a sort which commands a higher price than any one of the late-keeping Potatoes named by your correspondent, and we are extremely fond of them at our dinner table. I consider the Fluke one of the richest-flavoured Potatoes grown. This Potato is not so prolific as many others, but where the soil agrees with it, it is an excellent bearer; but I have heard that newly-broken-up pasture ground is not favourable to its growth and numbers.

The great thing to persuade all Potato-growers is to vary the varieties every year, and plant them not too frequently on the same soil. The custom of small occupiers of growing Potatoes and Wheat in succession for sometimes twenty consecutive years has favoured the increase of disease all over the country, and it would be well if this were guarded against for the future. In addition to this injurious custom, Potatoes have been planted for many years too late in the season.

The public are obliged to your correspondent, "UPWARDS AND ONWARDS," for naming several new sorts; and I trust in seasons to come Potato-growers will purchase their seed Potatoes from a distance much greater than heretofore, and then we shall have every chance of a cessation of the disease which has been so long a scourge, and which has certainly been in a much more modified form this year than in any season since 1845.—H. W. NEWMAN, *Hillside, Cheltenham*.

### GRAPES THROUGHOUT THE YEAR.

WE have forcing and cool vineries, which give us an abundant crop of Grapes from May till December, and I am most anxious to produce fruit all the year round. Will you inform me what are the best proportions for pits or houses, and the method to adopt for top and bottom heating to obtain a crop of Grapes to supply the table from January to April? Also, what sorts of Vines you recommend to answer this purpose, and how to retard the Vines till the required time for bringing them into action?—A. BURGE.

[Consult Mr. Sanders' book on "The Vine." He has no particular house for the purpose. See answer to correspondent about the angles of hot-house roofs. Could we have our wish, a steep roof at an angle of from 33° to 38° would be our choice. Then supposing we settled on a house 9 feet wide, we would have the front wall 2 feet high, the back from 15 feet to 16 feet, a raised border inside 6 feet wide, and 18 inches deep; two four-inch pipes below it for bottom heat, either in chamber or rubble, with means for draining the bottom of the border, and at least four five-inch pipes for top heat, and plant the Vines inside, and keep the roots there. The wood of these Vines ought to be ripened and pruned early in summer, and rested by

the roots being kept dry, and plenty of air and shade, and then started in August and September. If pots are used, they should, after being well ripened as to their wood, be pruned, and laid down against a north wall, and kept dry and cool before starting them. We shall be obliged by some correspondent answering more in detail.]

### WALKS.

WHATEVER difference of opinion there may be as to certain appendages of a garden, there can be no question but that a really good walk or roadway is a favourite with every one. A firm dry walk, or a good hard road, is so essential to the general character of a place, and very often is the first thing a visitor notices, that where these necessary requirements are indifferent in quality, it is not easy for the other attractions of the place to mend the reputation that suffers by the second-class pathways. Certain localities, it is true, lack the materials necessary to make a first-class walk or roadway; but there are many makeshifts, which, when well and skilfully worked-up, make a very good road or walk; and sometimes very unpromising materials, when so worked-up, do more credit to the manager than when a fine walk is made at great expense of articles that could hardly fail to be successful however used. Believing, therefore, that some light may be thrown on the subject by a few notes on principles generally applicable, as well as some having reference to particular localities, I will endeavour to make my remarks meet the cases of the majority if not of all classes. Commencing with what unquestionably was the first of all paths for human beings—the "public footpath," let us see how this is best made in the localities where such exist.

PUBLIC FOOTPATH.—It is likely this still-necessary mode of communication between one place and another has existed since the earliest times of the world being peopled. Following the beaten track of the wild beast may have originated the first public roadway; and, gradually, the removal of certain obstructions in the way led by degrees to other improvements, until the wants of the times, and the better peopling of districts, led to the construction of thoroughfares exhibiting an industry which has won the admiration of succeeding ages. The paved causeways which are supposed to have been introduced into England by the Romans, and of which there are several remains in a good state of preservation, attest the skill and industry of that singular people; but we are told that paved causeways, of still greater magnitude than any the Romans ever created, existed in South America centuries before that country was visited by Europeans. However this may be, a good paved causeway is certainly the most durable public road we now have; and though there have, even in our time, been many attempts to substitute something else for a hard stone pavement by the advocates of Mr. McAdam, and the various schemes of wood and iron paving, it seems almost certain that good hard stone will maintain its supremacy after all. But the streets of large towns are not the only places a pavement is adapted for. In many parts of Lancashire and Cheshire, turnpikes and parish roads are alike paved with large stones; and it has long been a question there whether such paved roads are not, on the whole, better than those made of small stones. This question, however, need not be argued here. Suffice it to say that, for a public pathway through very dirty ground, a hard stone pavement is unquestionably the best of all pathways; but where such a walk passes through a dry grass field, the chances are that the turf is preferred to the walk, and an objectionable trackway parallel to the walk is made. This is not unusual even when a smoother material is used for a walk than ordinary paving stones, for the coolness of turf is much relished in summer. Some discretion must, therefore, be exercised in having paved walks only where there is much traffic; and even then, if there be wheeled carriages or horses to traverse them, it is likely that something else than limestone or granite would not form a more agreeable path.

ASPHALTED WALK.—The adoption of this article in the formation of railway platforms, public thoroughfares in the neighbourhood of towns, and in many private places, has created quite a revolution in walk-making. Even the mode in which this article is used has undergone so much change of late years, that it is only in consequence of the most important material not being very plentiful, otherwise it is difficult to say how far the use of tarred walks, as they are often called, would be carried. It is certain that when well done nothing makes so easy and

agreeable a walk that we know of, neither is it wholly useless for resisting the action of carriage wheels; but in this case it must only be as an accompaniment to a stoue causeway or pavement, where it can be poured on hot, and by its filling-in the crevices and partly covering the stones the noise of vehicles is much reduced. Sometimes the stonework is entirely covered over with the soft plastic substance, which the feet of horses indent at every footstep, as I have seen in some large manufacturing towns; but pieces are liable to break off, and it is expensive to often renew it. Where the traffic of foot passengers only has to be sustained, a coating of gas tar and small gravel over stones makes an excellent pathway, rolling and smoothing at the same time. Generally, however, the formation of a walk on a foundation of another kind is adopted, the conditions for that being far from difficult to obtain in almost any position; one of the most necessary qualifications for that purpose is a little descent one way to carry off the water, for, although railway platforms are sometimes level, in general most other places done with this material have a sufficient declivity to insure the water being all carried off. If water be allowed to stand in shallow pools on the face of the walk, it quickly rots and perishes the material, and a break-up is the result. The outlet side also must be clear—no kerb to stop the water and form a stream on the asphalted part of the walk; but if there be a kerb, let it be slightly below the face of the walk, so as to allow the water to run off freely. In fact, it is the due preparation of the foundation, rather than the care and skill in putting on the material, that constitutes the quality of the walk.

In laying down asphalt, an ordinsry hard-beaten footpath of the proper level or inclination, and a fine hot day to do the work in, are all that are wanted. Those accustomed to the work have a boiler and fireplaces moveable on wheels, which they take from place to place, and some well-sifted gravel about the size of peas and beans, and free from sand and anything larger than a small marble. The tar, being heated in the boiler, is run-out into iron pails and carried to the walk, and is roughly spread, or, rather, thrown on by one man with a ladle, while another spreads it with a long-handled brush made on purpose, and a third with a barrow throws on gravel with a shovel at the same time. When a few ysds are done, the roller is drawn over it several times. The quantity of tar laid on must fall short of half an inch thick, but as much gravel is given as will adhere to it, so that the mixture may be a good inch thick and often more. After repeated rollings a part of the loose gravel is swept off, and it is again rolled; but sufficient gravel is at all times left on to insure the feet of the pedestrian always treading on the gravel rather than on the tar. The latter, however, by being well heated over the fire before putting on, loses much of that soft stickiness it had before; and the gravel, being left on rather higher than the tar, works down by wear, so that the walk is better some weeks or months after it is made than it is at first. It gets smoother by wear; and the cold weather of autumn and winter removes, in a great measure, the liability it might have to get soft. It must not, however, be supposed that such a walk is of everlasting wear; on the contrary, it wants renewing like other things, and a slight coating of tar and gravel, as before, is given every two or three years where there is a great deal of traffic, the quantity of material given being much less than was the case when the foundation sucked-in so much at the first doing.

Asphalted walks are not recommendable in the front of mansions or dwelling-houses, where they approach close to the windows, the smell being disagreeable in hot weather; and I have been told of a case of which I have the fullest reliance, that the strong smell of the coal tar used in this mode of making paths penetrated into a house, and even the food tasted of it, milk particularly so. It must, therefore, be used with caution in such places; and if it be advisable to do it under such circumstances, it would be better done, if possible, when the family are from home. That the smell goes off in a great measure every one knows; but a very hot day will revive it to a certain extent, and we all know it is not agreeable. A perfectly level place is not adapted for asphalt, as it is almost impossible to prevent the existence of some slight hollows or basins in which water will stand; and it quickly decays the tarred substance, besides looking badly, as there is always a stain left when water has no other way of escaping than by evaporation. For general purposes we would, therefore, advise extensive level plots—as terraces, promenades, &c., to be done with something else than asphalt.

**CONCRETE WALKS.**—Many directions have been given in papers more especially devoted to mechanical pursuits for the making of walks or floors of this kind; but, in general, the modes recommended are too expensive for ordinary purposes, and it is only lime of a particular description that will stand out-door work, and this not very well at all times. Various substances are mixed with it, as gravel, shells, coals, broken clinkers, refuse of mines or furnaces, or other substances of that kind not possessing any antagonistic quality opposed to the lime. There are many ways of mixing and using these ingredients. One of the best modes I have seen adopted was by pounding the lime, not slaking it, and mixing it in a dry state with the stone or other substance forming the compound, and only wetting it at the moment it is used. Another way, and a favourite one with some architects when using concrete for the foundation of a building, is to mix the material and carry it to the height of 15 feet or 20 feet, and let it fall with considerable force on the place it is intended to occupy. This, however, is not applicable to walk-making in an ordinary way. When concrete has to be used as a walk, it may be merely laid on the proper thickness, which ought not to be less than 3 inches; and the surface being nicely smoothed, with a sufficient descent in certain directions for water to run off, a tolerably good walk is formed. Its expense, however, will, I fear, prevent its general adoption.

**CEMENT WALK.**—Like the last, this is also an expensive walk, but there is reason to believe when the mode of making cements becomes better known it will be more extensively used. In fact, I believe we are only beginning to find out the many uses to which cements may be put; and I expect other kinds than those we now have will be brought forward, that will make a revolution in many of the arts in which stoue and brick are now used. Even the last few years have added very much to the purposes for which Roman or Portland cement may be employed.

In-doors Portland cement makes an excellent floor or path to a greenhouse. One we have here has been down five or six years, and looks quite as well as at first. It is, however, too expensive for general out-door purposes; but where the cost is not objected to, it will be found to make an excellent path. Portland cement is better than Roman, and allows a large portion of sharp clean sand being added to it, as well as broken sandstone, the latter, however, not to appear at the top, as is the case with concrete; but there is much difference in the quality of the cement, and some little knack also in the way of using it, so that all are not successful who try their hand at it. Even those in the building line often make mistakes with it, and I confess having, therefore, some reluctance in advising its use, excepting to those who know how to mix and work it. In general, a mixture of three parts of coarse sharp sand that is free from salt or mineral impurities, with two parts of broken Portland stone, and one part of cement, laid down immediately it is wetted, and smoothed over with a little cement with less sand in it, and no stone, will be found to answer; but as some mistake may occur, I cannot undertake to say that in all cases it will be found to answer. Even cements are not always alike, and I have seen some excellent work and some very indifferent by the same workmen, the quality of the material deceiving them. There are other misfortunes to encounter in cement work than the action of the weather; but this is one of the most likely to fear in walk-making. The plastic substance ought not to be less than 1½ inch thick.

**PEBBLE-PAVED WALK.**—Some very pretty walks are made of pebbles carefully assorted to size and colour; but where the walk is of great length I would only advise a plain stripe, or some exceedingly simple pattern. Promenades, courtyards, and other places of greater breadth and not so long may be treated with a more elaborate pattern; but a long, straight, or even a curved walk, of from 6 feet to 10 feet wide, looks best when not cut up into diminutive fractions. Assuming only two colours in pebbles to be available—say a pale buff and a black or dark, and the edging of the walk to be turf; for a ten-foot walk of considerable length, I would say let there be 1 foot of the pale-coloured pebbles at each side, then 1½ foot of dark, and the centre 5 feet all pale. Some, perhaps, might prefer more variety; but I am no advocate for cutting anything up into scraps and fragments. Pebbles about the size of a hen's egg, or a trifle larger, will do best, and with a little practice they can be set in their places very quickly. It is best to have the bottom firm, excepting about an inch or so of fine material, in which the pebbles are

set, and this had better be dry sand and dry pounded lime. A sifted mixture of the same may be scattered over the top, but only very little of this. As the lime may, perhaps, show above the dark stones and neutralise the colour, it is best to put only a very little of this, and then put on sand only. Some fancy-work of this kind is painted or coloured to a certain design, but the deception is so apparent that I by no means advise it. Channels of pebbles by the sides of walks of other kinds, where the descent is long and great, and when they are well set, look not amiss. Side openings now and then, where convenient, to carry off the flood water, will in many cases obviate the necessity of having them.

**PAVED WALKS OF OTHER KINDS.**—There are various kinds of fancy tiles as well as bricks, both plain and ornamental, that are occasionally used for special purposes; but as these generally form an accompaniment to something else of an architectural description, and are not properly garden walks in the strict sense of the word, they need not be alluded to any further here. We will, therefore, at once proceed to the formation of walks with the substances of which most walks are made of.

J. ROBSON.

(To be continued.)

### APRICOT TREES IN POTS IN ORCHARD HOUSES.

I HAVE been an orchard-house cultivator (amateur) for more than three years, having about a dozen Apricot trees, but during this time have not had the pleasure of pulling three ripe Apricots; whilst the trees outside against a wall have borne fair crops.

If any one succeed, it must be mismanagement on my part; yet it is, perhaps, some consolation to know that my friends and neighbours are equally unsuccessful.

It would appear Apricots are much more difficult to fruit than Peaches and Nectarines, for, with the same apparent treatment, these succeed whilst the others fail. If the Apricot requires any special management, with the roots cramped-up in a pot, I should be glad to know what it is. I may say that my trees bloom profusely, but either do not set at all, or the few that do set drop when very small. I also give them the advantage of more abundant ventilation than the Peaches and Nectarines; and as the whole of the front sashes (glass) of a lean-to house, and 4 feet deep, lift up, there can be no lack of this. Is there too much?—A CONSTANT SUBSCRIBER.

[It must be admitted there is greater uncertainty as to the crop of Apricots in an orchard-house than in the case of Peaches and Nectarines. My Apricots almost entirely failed one season, and nearly so another, whilst generally they have been loaded with fruit. There is no doubt we ought to be sure of a crop every year; at any rate, there should be no more uncertainty than in any other cultivation. I believe Apricots ought to be sprinkled over their shoots and blossoms now and then, before and during their blooming season, and I have an idea that the want of this causes the bloom to be too weak. The reason I have arrived at this conclusion is, from observing that Apricots set the best on the walls during changeable weather, when it rains about every other day. Last year I had two trees watered with a rose from overhead every morning, and thought it answered a good purpose; but did not intend saying anything about it till after next season, so as to have further proof. As far as my experience has gone, there are several things which appear necessary to success. First, a strong rich soil; the pots filled with roots; the trees well stopped the previous season, so as to be full of short thick spurs; well watered before coming into bloom—as if dry at the bottom of the pots when in flower, and afterwards watered, they appear to be unable to set—and above all plenty of ventilation. Orchard-house Apricots are so delicious! such bags of honey! that I have made up my mind to know all about their cultivation; and if I live shall pay more attention to them, and shall be glad to give or receive a hint on the subject.—J. R. PEARSON, *Chilwell*.]

**MUSHROOMS IN RUSSIA.**—These, kept often in huge glass jars, sometimes in immense barrels, while rather revolting to look at, are most worthy of a moment's attention. How we had rejoiced, while staying at certain houses here, whenever Mushrooms were introduced at dinner; they were food fit for an emperor, and were served out without stint. In England the

mere mention of Mushrooms brings up the idea of a wealthy gourmand making researches in theoretical gastronomy to please an over-indulged palate; but in Russia while equally good, they are in such prodigious quantities as to form a great part of the food of the whole people. An accurate return of the total quantity of these plants annually consumed in Russia would be a startling and important document; but is not likely to be procured, for the greater part is eaten by the same peasants who gather them, and who, besides feasting on them all through the season, pickle, salt, and dry them on strings against the winter period; when fried with a little hemp-oil, and eaten with rye-bread, they supply well the place of animal food; but if, with a little more art they be fried in sunflower oil, then there are some "Mushroom outlets" which look and taste very much like the same preparation of chicken. The acquisition of this most notable stock of nutritive human food depends not on Russia being richer in species of agarics than Great Britain, for it is the contrary—but in the extraordinary skill of Russian peasants in knowing how, when, and where to look for them, how to distinguish the edible from the non-edible, and how to cook them when procured. This skill is a something handed down traditionally from parent to child; and if it could be written in words, would prove a valuable addition to what scientific botanists yet know in the matter; for many Mushrooms never ventured on in this country are daily used by all classes in Russia, and others which are really so bad that they cannot be eaten, and some actually poisonous, are yet occasionally employed to profit in furnishing an aromatic alcohol.—(*Professor Smyth's Three Cities in Russia*.)

### HURST HOUSE SEEDLING PINE, SYN. FAIRRIE'S QUEEN PINE.

THIS Pine, I perceive, is advertised in your columns under the above names, pray which is the proper one? Now, happening to live in the neighbourhood just at the time negotiations were going on respecting the transfer of it from Hurst House to Mosely Hill, I am of opinion, until we are further enlightened upon the subject, that "Hurst House Seedling" is its true name.

It was raised there, and I believe I am right when I assert that all Mr. Fairrie did in the matter was to advance the requisite sum of money wherewith to purchase the stock on the conditions that Mr. H. Williams, his gardener, was to advance him the same after leaving him in possession of a good stock; and if the Messrs. Jackson's plants are true, those from the Paradise Nursery are equally as much so, as part of the original stock went there. Perhaps the gardener at Hurst House will inform us whether it is a seedling from any of the Queens at all.

"Honour to whom honour is due." Let the man who was the successful raiser of the Pine at least have a voice in naming it; and as far as my humble opinion goes, I consider Mr. Fairrie has no more right to call it "his Queen" than the man who never heard of a Pine.—FAIR PLAY.

### PEACH-TREE BUDS FALLING.

SOME of the buds on my Peach trees are falling-off. The fruit was ripe in July, and ever since the trees have had as much air as possible, the roof being a fixed one, and the soil kept in a proper state as regards moisture. Being about to commence forcing, I find that some of the buds are falling-off, and others are black in the centre, I am quite at a loss to know the cause. Your opinion would very much oblige.—ANXIOUS.

[Dryness at the roots will produce the symptoms you speak of. Have you given them an extra dose of strong water in washing the trees? We have known trees suffer much from drought in August and September when the soil was moist at the surface.]

### THE SWEET-SCENTED COLTSFOOT.

*Tussilago fragrans*, Linnaeus. *Nardosmia fragrans*, De Candolle  
Nat. ord., Compositae.

THE term *Tussilago* has been derived from the Latin *tussis*, a cough, and *ago*, I drive away; while that of *Nardosmia* is from *nardos*, the spikenard, and *osme*, smell, its delightful scent being likened unto that of the spikenard of the ancients.

No hardy plant for winter decoration is more desirable for small or suburban gardens than the Sweet-scented Coltsfoot, for

it is of the easiest cultivation and very suitable for confined situations, where it thrives without any care or trouble when once established. In planting it only requires to be placed on a raised mound composed of any good garden soil, with a few rough clinkers or stones placed over the surface in imitation of rockwork, and should have a northern exposure not over-shaded or crowded with shrubs. It is a hardy perennial with creeping or, rather, running underground roots, and is what might be called a weed when it gets fully established, and one, if in the open border, which would be difficult to eradicate. The leaves are produced in spring, after the plant has done flowering, and are large, orbicular, on long footstalks, and finely serrated round the edges; and the plant itself resembles the common Coltsfoot of our fields, which many a worthy farmer regrets his too intimate acquaintance with. Nevertheless, the fragrant Coltsfoot will be highly valued for the odour of its blossoms, produced as they are at a dreary period of the year, and when a few spikes of the flowers, gathered and placed in water in the sitting-room, will perfume the whole place, and last for more than a week in perfection. The scent is very similar to that of the Heliotrope, and the flower-spikes are produced in succession from December to February, especially if protected by a mat or other slight covering to keep the severe frost, snow, and damp from them; and though very severe frost may occasionally seem to conquer their tenacity for life, yet no sooner does the severest frost relax its icy grasp than the flowers appear again in spring-like freshness to exult and spread their fragrant sweets, and that at a season when Flora's gifts are scarce, and when we seem most capable of such enjoyments.

The flower-stems grow about 8 inches in height, with from ten to twelve tassel-shaped flowers of a bluish colour on each stem, and which open in succession.

This interesting plant is a native of Italy, where a practice is prevalent among the country people of carrying burning touch-wood, which is made of the dry roots of this plant, the smoke being intended to protect them from the annoyance of gnats. The leaves also form the principal ingredient in the manufacture of herb tobacco; coughs have been frequently much relieved by persons smoking the dried leaves; and an infusion of the dried flowers sweetened with honey has been found particularly efficacious in complaints of the same nature.—GEORGE GORDON.

### HOLMES'S SELF-TILTING WELL-BUCKET.

MANY people prefer to have wells from which they obtain water for drinking and domestic purposes entirely open. Pumps are often objected to on account of the unpleasant taste which wood or metal communicates to the water.

To obviate these objections different kinds of apparatus have been used, from the "old oaken bucket" attached to a pole and sweep, to that represented by the above cut. The latter we regard as decidedly the best of anything we have seen applied to this purpose.

In connection with the cut, the inventor gives the following description: "There is a double pulley on the end of the shaft, the outside being ratcheted and the inside plain. In lowering the bucket, reverse the motion, and keep the break on to prevent the too rapid descent of the bucket."

The machinery described does not appear in the cut; but we can state, from having seen the operation of it, that it works with ease and exactness. Mr. Holmes exhibited his apparatus at the shows of the Norfolk and Plymouth Agricultural Societies last autumn, and the committee by whom it was examined, spoke of it in commendatory terms.—(*Prairie Farmer.*)

### ORNAMENTAL PLANTS.

GAULTHERIA BRACTEATA (Bracted Gaultheria).—*Nat. ord.*, Ericaceæ. *Linn.*, Decandria Monogynia. *Syn.*, *G. erecta*; *G. odorata*, *cordifolia*, and *rigida*; and *Andromeda bracteata*.—A handsome, low-growing, evergreen, greenhouse shrub, growing

a foot high, or upwards, having rigid, hairy branches, and alternate ovate or cordate-ovate acute leaves, serrated and usually shining above. The flowers grow in simple axillary or terminal secund racemes, and are tubular-ovate, contracted at the mouth,

rose-coloured, the pedicels having comparatively large, ovate, acute, rosy bracts at their base. From the Andes of Columbia. Introduced in 1848. Flowers in summer.

*MONARDA AMPLEXICAULIS* (Amplexicaul Monarda).—*Nat. ord.*, Lamiaceæ. *Linn.*, Diandria Monogynia.—A very distinct and handsome hardy herbaceous perennial, growing about 2 feet high, with erect, slender, obtusely, four-angled stems, having re-

are large, solitary, somewhat depressed; the corollas very handsome, large, and freely produced, white, having a rosy tinge, and, on the lower lip, elegantly marked with four rows of purple spots. Native country not known. "For a number of years grown in the Botanic Garden of Leige, and was raised from seeds obtained from M. Fée, director of the Strasburgh Garden. In M. Fée's catalogue it is called *M. amplexicaulis*, which name is stated to have been given to it by M. Fischer, of St. Petersburg. We have not, however, found it noticed by that author, and M. Fischer does not know any *Monarda* bearing such a name; but we retain it to avoid confusion." Flowers freely from May to July.—(*Gardeners' Magazine of Botany.*)

*Monarda amplexicaulis.*

marksably long internodes, and clothed with soft, spreading hairs. The leaves are 2 inches to 3 inches long, sub-amplexicaul, acutely lanceolate, subcordate at the base, serrated and fringed with white hairs; the upper leaves have the nerves and veins of a beautiful purple red (shown black in our figure). The floral leaves are sessile, ovate-lanceolate, acuminate, ciliated, pale green, tinged with red on the paler centre. The verticillasters

### THE MISTLETOE.

At a time when this singularly beautiful plant is brought so prominently before us, a few observations in connection with it may not be out of place, especially as there is still much misconception regarding it, and it is far from being so common in some districts as it might be if means were taken to cultivate and encourage it; but somehow, in the districts more famed for its growth, it is reluctantly sacrificed every year to a custom which it is next to sedition or sacrilege to find fault with. The upshot, however, is that large specimens are rare in places best suited to its growth, while the accidents it is liable to from natural causes will even prevent fine specimens growing in places beyond the reach of those who cater, rather unceremoniously sometimes, for our Christmas holiday. Still, Mistletoe will ever remain a favourite with all classes, and however much it may be sought after to adorn the dwellings of all classes at this festive season, its eradication is hardly likely to occur. Perhaps it is in greater danger in those fruit-growing districts where the habit of destroying an orchard when it has turned old and indifferent has superseded the very common way of endeavouring to restore it by re-grafting. Old Apple trees are the favourite homes of the Mistletoe, although it will thrive on many other kinds, as will be shown below.

It is needless to repeat the oft-expressed opinion that the Mistletoe had its present importance given it at a much earlier period than the Christian era, and some assert that the specimen found on the Oak was the more especial objects of veneration. Be this as it may, Mistletoe on the Oak is exceedingly rare, the examples we have of it being few. A friend of mine assures me that he has seen it on the Oak at Eastnor Castle, the seat of Earl Somers, a tree near the carriage drive containing it. It would certainly be worth while some one ascertaining if this plant be of the same species as those occupying stations on trees of other kinds, and if not it might be perhaps artificially propagated. Old Oaks are plentiful enough everywhere, and Mistletoe is often near them; yet we never see the union of the two, or so rarely that the number of such lucky ones is far from great. Of the other trees it is found on more plentifully are the Apple, Crab, Thorn, Maple, Mountain Ash, and Lime. I believe it is also found on the Poplar sometimes. Generally old sickly trees are its home, and it is needless to say that it does not improve their condition. Perhaps the most healthy tree it attacks is the Lime, on the top of which it not unfrequently fixes itself out of the reach of the plunderer, but where it is liable to much breakage by high winds. I have seen good specimens on the Maple, while an old scraggy Thorn is much embellished with it, and it is far from diminishing its beauty.

There is certainly great misconception about the Mistletoe disliking certain districts, and we are told it is not much seen in some of the south-western counties; and some assert it will not grow in the north of England at all. Of the latter I have the most ocular proof to the contrary, as the largest specimen I ever saw in my life was in an old walled-in garden at Belsay Castle, Northumberland. The situation was a sheltered and favoured one for the neighbourhood. It was growing on an old Apple tree, and had been planted in its place there by the worthy baronet, the owner of the place, now the oldest member of the Horticultural Society. An excellent specimen of *Aruncaria imbricata* stood near it some twenty years ago, second to none I have seen in the south of England save the one at

Dropmore; and I believe the same garden, or rather nursery, contained an excellent *Cedrus deodara*. This, however, is diverging from the subject; suffice it to say that the Mistletoe presented as healthy and vigorous an appearance as I have ever seen it do around London, that there is no doubt but it may be cultivated in districts it has never yet been introduced into by care, time, and patience; and, as the Editors have shown that the simple process of cutting the bark and inserting the seed will produce a plant, it is certainly worth the trying. For my own part I prefer fastening on the seed without cutting the bark, when it can be so. I may, however, remark that I have never seen it near the coast, and suppose that the strong sea air is inimical to it; but the places where it will grow are plentiful enough, and it is not unlikely but it may be induced to grow on other trees than those heretofore tried, that here is a fine field for the experimentalist, and none will be more glad to hear of unexpected results arising from such enterprise than—  
A SUBSCRIBER FROM THE BEGINNING, H. N.

### THE MARKET-GARDEN PRODUCTS OF ANGERS.

An account having been given in a previous article of the trade of Angers in trees, Apples, and Pears, some details as to what is done there in Cauliflowers, Strawberries, Cherries, early Peas, Kidney Beans, and Dandelions, may not prove uninteresting.

**CAULIFLOWERS.**—The traffic in Cauliflowers begins in March, and during that month and April 772 tons 16 cwt. are dispatched, chiefly to Paris, but some also go to Nantea and Poitiers. Assuming that the Cauliflowers weigh 29½ lbs. per dozen, which is about the average, it follows that 58,165 dozens are carried, and taking their value at from 15d. to 20d. the dozen, we have an amount of upwards of £4100. The cost of the carriage alone comes to £3000; and making allowance for the expense of packing and the profits of the parties through whose hands they pass, it is evident the Cauliflowers cannot reach the consumer at less than 4d. or 5d. a-piece.

**STRAWBERRIES.**—For a long time after the railway was made it was considered doubtful whether this fruit would travel safely to Paris; but with careful packing it reaches that city—not, it is true, so fresh as when just gathered from the fields, but sufficiently so to fetch a good price. The Strawberries are packed in long, narrow, and very shallow baskets, each containing from 5½ to 7½ lbs., and sell at from 7d. to 1s. 5d. the basket. The quantity sent last year was 64 tons 7 cwt., representing a sum to the grower of £1088, and costing about £260 for carriage.

The varieties principally cultivated for market are the Old Pine, Princess Royal, Myatt's, Elton, and Sir Harry, the last of which is beginning to be extensively grown.

**CHERRIES.**—The weight of Cherries sent by railway was rather greater than that of Strawberries, being 78 tons 12 cwt., worth about £958, and costing £320 for carriage. They chiefly come from the districts lying to the north and east of Angers, a very small portion being produced in the neighbourhood of the town itself.

**EARLY PEAS.**—Of these 118 tons were carried; and the value may be estimated at £960, while the cost of carriage was £480. They partly come from near Angers, and the rest from Sainte-Gemmes which has the merit of producing the earliest.

**KIDNEY BEANS.**—Early Kidney Beans have been forwarded to Paris, but hitherto the quantity has been small—not quite 25 tons, worth £350 to the grower, and costing £100 for carriage.

**ARTICHOKES.**—Another plant cultivated to a considerable extent at Saint-Laud is the Artichoke; and yet it is not sent to Paris. To see the quantities of heads which arrive at our markets every morning in May and June, one would think they must be intended for that great market which lays the whole of France under contribution; but such is not the case. There are two obstacles. The first is that the Artichoke is of great weight as compared to its value, and, consequently it does not pay to send it by the fast trains, whilst, as the luggage trains take six days to go to Paris, it could not arrive there fresh if sent in this way. The second cause is that the variety cultivated, the "Gros Camus," is not held in much estimation at Paris, where the Laon Artichoke is preferred on account of its larger leaves, and its more fleshy as well as perhaps more tender receptacle.

**DANDELIONS.**—Another plant which, though requiring no culture, is sent to Paris in considerable quantities, is the Dandelion. In the end of winter and beginning of spring, all the unemployed women, and they are numerous in the neighbourhood of the quarries, go off in the morning, often before sunrise, and especially in frosty weather, and spread over the meadows on the banks of the Loire. There they collect the plant which is the object of their search, and return, sometimes late at night, bent under a burden which they have gone six or eight miles to seek for, and the value of which is from 1s. 9d. to 2s. 6d. according as they find places where the plant is less or more abundant. But, before they touch their hard-earned gains, nearly as much more time must be consumed in cleaning the Dandelions, and rendering them fit for the eye of the purchaser. Here, however, the work changes hands; it is no longer the same women who take this part of the labour; but the children and other members of the family, who are unable to make these long and fatiguing journeys, now step in. Thus the gathering a plant scattered over the fields, gives employment for nearly three months to all the women and children in the above populous districts who are not otherwise engaged, and greatly alleviates the hardships which their families would often have to endure.

As regards the amount of traffic to which the Dandelion gives rise, the authorities of two railways have furnished exact statements of the quantities carried. On the Bohalle line, from the 8th of January to the 26th of April, 72 tons 17 cwt. were forwarded to Paris; on that of Saint Mathurin, 101 tons 1 cwt.; the Menitré railway is estimated to have taken 100 tons, and that of Trelazé 25 tons; so without taking other lines into account, these four alone carried about 300 tons of Dandelions to Paris, the carriage of which by passenger train came to £1200 in three months.

The Dandelions consist of two kinds, the green and the blanched; the former comprise about four-fifths of those carried, or about 240 tons, and their value may be taken at £1920; the blanched, which constitute the remaining 60 tons, may be set down at £1080, and the total value of both classes at £3000. If the question is asked, What is done with such a quantity of Dandelions, a plant almost unknown for culinary purposes before the construction of railways? we would answer that the green plants form an excellent substitute for Spinach, and the blanched make delicious salads. Thus this wild plant, growing in the winter, without any culture whatever, in meadows and waste ground, affords a large revenue to the needy population of several large villages, and that too at a period of the year when out-door work cannot be carried on.—(*M. Baptiste Desportes in Proceedings of Comice Horticole de Maine et Loire.*)

### CELERY FAILURES AND OTHER DISASTERS.

I PERCEIVE I am not alone in having indifferent Celery this year, and I may certainly say with Mr. Chitty, I never grew a worse lot in my life. I grow but one sort—Laing's Mammoth, as I always found it first-rate before this year. I sow at two different times—about the middle of February, and the same time in March. I never depend on the first sowing for a general crop, as it is liable to bolt if not used early; but it will generally be fit for use until the end of October, and often through November. This year my early Celery was a complete bolt. I did certainly take a few of the best hearts in, but I expected to be called over the coals for it. So far, however, things have gone on smoothly; but I would rather have a good grumbling bout than a silent rebuke any time; and I am sure if I were master instead of man, I should want an explanation on the subject.

I have until this year been very successful in the cultivation of this favourite vegetable; and if there be one thing more than another in which I pride myself in the kitchen garden, it is Celery. The very first exhibition I competed at, I beat all the cracks in our neighbourhood with Laing's Mammoth. That was the second year it was let out, and I have stuck to it ever since; but I have done with it now. I must try another kind, for I believe it is run-out, or I have been cheated by the seedsman. I am inclined to the former opinion, as I had more bolted sticks last year than I bargained for; but this season has surprised me completely.

My second sowing did quite as badly as the first. It came up all right. I took advantage of a showery day (by the way we

had little else last spring), in the early part of May, and pricked it out on a sheltered border. The snails tithed them pretty freely, but they did get a start at last. When a job is done with me it has to stand for done—I cannot go round into every nook and corner daily, and see how things are looking. I am always doing the job that wants doing most, with fifty more staring me in the face. Talk about a six-o'clock man, I believe if I could see, I should work till six o'clock next morning sometimes, to satisfy myself.

I now and then cast my eye towards the plants as I hurried by, and I thought they made but little progress, but did not guess the cause until I examined them. They were swarming with green fly. I dusted them over with quicklime, which settled both the fly and slugs, and left them to take their chance a little longer. They were middling plants by the middle of July, when they were lifted with balls, and planted in single trenches. If transplanting had ever proved fatal to Celery, I should certainly have given this up, for it looked as if it had caught the jaundice, and turned as yellow as a frog. It recovered, however, eventually, but it was too late—it had not time to do its work.

I do not believe in dribbling earthing, I like it to grow before it is earthed; there is then something to keep the soil out of the heart, and there is a chance of feeding it with liquid manure, which is very beneficial when it is growing freely.

I always earth mine up at three times, pressing the earth firmly round the plants with the hand each time, and being particularly careful in keeping the soil out of the hearts the last earthing, or it will be sure to rot.

Another thing attending its culture requiring care, is the transplanting. Each plant should be taken up with a good ball, and planted with a trowel; giving a copious watering and shading are beneficial for a short time. I find that my late Celery, small as it is, is bolting.

It has certainly been the worst summer I ever knew for kitchen-garden crops. Brussels Sprouts instead of growing have gone to flower; Broccoli has flowered prematurely before it has acquired any size; Dwarf Kidney Beans were a complete failure; Onions ditto; Carrots very indifferent; Lettuce ditto; Peas never filled; Cauliflowers blown up by the roots; Potatoes blown to shivers. Such an accumulation of disasters is enough to make a gardener wish he were a chimney-sweep.—**Huddersfield.**

[Under such circumstances it would be useless to wish our correspondent a merry Christmas; but we do wish him a happier new year. We do not think he need abandon Laing's Mammoth, nor look suspiciously at the seedsmen, for all varieties of the Celery have been complained of this year in some locality or other, and, in most instances, on inquiry we have found that the failure, as in "Huddersfield's" case, arose from severe checks to the growth of the plants in their seedling state. We once heard Lord Brougham say, "I dispose of so much work because I think only of the one subject before me." Our correspondent, in a similar spirit, concentrates his energy; but Lord Brougham used to find time also "to go round and see how things were looking."—**EDS.**]

### CELERY CULTURE.

In looking over the November Part of your Journal I see that "P. L. C." complains of his Celery being bitter, stringy, and rotting very fast. He tells us of the quantity of manure he used, and from the pains he took with it he had every reason to expect a good crop, but it was a failure; and as a guide for him I will state a few facts.

For fifteen years I grew Celery largely, sometimes it was pretty good and sometimes bad. In 1860 it was very bad, rusty, cankered, and bitter—indeed, it had always been so more or less. In 1861 I used no farmyard manure to two rows, one of Red and one of White, and was so satisfied that these two rows were better than the rest, that this year, 1862, I planted my whole crop in the same way.

My plan was as follows. At the bottom of the trench I threw in about two quarts of fine Peruvian guano with the lumps well broken. The trenches held 105 plants each. I covered the guano with from 4 inches to 6 inches of soil, and then planted. The plants grew slowly at first, but in about a month they commenced growing vigorously. I then began applying liquid manure, about every ten days, from a large tank supplied from byre, stable, and large laundry; we find the crop all that we could wish—perfectly clean, crisp, and sweet.—**T. W.**

### VINES OVER-LUXURIANT—SPINACH DYING-OFF.

We have a viney here, the Vines in which are making exceedingly strong wood and rather thick leaves. The Vines have been increasing in strength for some years, with a corresponding degree of deficiency in showing fruit; the bunches inclining to become tendrils, with a part of the berries turning red and not coming to perfection, although the others are as black as jet and well flavoured, but, of course, not in such compact bunches as could be wished. I was thinking of lifting these Vines into an entirely new border, but have not been able this autumn on account of the fruit being on, and I fear it will be the same another year. They are Black Hamburghe, and, perhaps, from sixteen to twenty years old.

Having sowed a considerable breadth of Spinach in the beginning of August, it came up and grew well till about ready to use. All at once it turned yellow without any apparent cause and died-off, scarcely a live root left. I understand it is in the habit of doing so most seasons in this garden. I should like to know if there is a preventive known.—**A FEW-YEARS SUBSCRIBER.**

[Your Vines at twenty years old will require great care in lifting. Autumn would be the best time; but any time now in open weather would do, provided you could cover the new border so as to throw into it a heat of about 75° to 80°, and start the Vines as late as you can. We should be inclined to try first what securing a deep drain in front would do, and removing a good portion of the surface soil until you reach the roots, putting a couple of inches of fresh soil on, and throwing a gentle heat into the surface. This latter mode will depend for effect on whether you can go down from 6 inches to 12 inches without finding roots worth speaking about. Taking the soil from the surface is sometimes as effectual as lifting and replanting.

We have lost Spinach this season for the first time. We attribute it to the dull drenching weather. Plants on ridges have not suffered.]

### NEW BOOK.

*The Weather Book: a Manual of Practical Meteorology.* By Rear-Admiral Fitz Roy. London: Longman & Co.

AFTER perusing this valuable work we have come to the conclusion that it is calculated to prove a great boon to mankind in general, and to seamen, farmers, and gardeners in particular. When we recollect the direful effects of storms sometimes on land, but more especially at sea, and when we reflect on the great saving of life and property which might have resulted from a few hours' previous warning of those disastrous storms, we cannot but hail with satisfaction the appearance of this volume, in which the Admiral has explained much that will tend to impart that knowledge so fraught with safety.

"This small work," the author says, "is intended for many rather than for few, with an earnest hope of its utility in daily life. The means actually requisite to enable any person of fair ability and average education to become practically 'weather-wise,' are much more readily attainable than has been often supposed. With a barometer, two or three thermometers, some instructions, and an attentive observation, not of instruments only but of the sky and atmosphere, meteorology may be utilised."

In Chapter II. the author mentions the instruments necessary for ordinary purposes. For such purposes they need not be so extremely delicate, and, consequently, expensive, as those very fine instruments employed in highly scientific investigations. Those most essential are pointed out to be the barometer, two thermometers, one of which kept moistened will serve for a hygrometer. This indicates lower than the dry bulb thermometer in the same situation, the difference being in proportion to the dryness of the air and consequent evaporation, being sometimes as much as 12° or 15° in this country, 20° or even more elsewhere; and about 7° of difference is considered healthy for inhabited rooms. A rain-gauge is stated to be interesting and useful, though not a necessary adjunct everywhere. The direction of the wind should be noted; but wind-vanes, or weathercocks, are seldom placed well or correctly. When set by a magnetic compass the variation of this from due north is seldom correctly allowed for. A line towards the pole star gives the true north and south. The direction of the horizontal movements of the lower clouds should be ascertained, and those of the upper

clouds should always be noticed likewise, for when different from the lower the wind will shift to the direction from which those upper clouds are coming.

Instructions are then given respecting the indications of the barometer, and the change of weather which usually takes place, and which may be expected on its rising and falling, in connection with the direction of the wind, the temperature of the air, and its moisture or dampness.

In treating of the wind the author gives the following observation:—"Another remarkable peculiarity is that the wind usually *appears* to veer, shift, or go round with the sun (right-handed, or from left to right), and that when it does not do so, or backs, *more* wind or bad weather may be expected, instead of improvement, after a short interval."

"A sudden fall of the barometer with a westerly wind is occasionally followed by a violent storm from N.W., or N., to N.E."

"Instances of fine weather with a low glass occur, however, rarely, but they are always preludes to a *duration* of wind or rain, *if not both.*"

"There may be heavy rains or violent winds beyond the horizon and the view of an observer, by which his instruments may be affected considerably, though no particular change of weather occur in his immediate locality." This is sometimes the case; and although such instances are the exceptions and not the rule, they are occasionally adduced as proof of the indications of the barometer being not trustworthy.

"If a fall [in the barometer] takes place with a rising thermometer and increased dampness, wind and rain may be expected from the south-eastward, southward, and south-westward."

"In winter a considerable fall with rather low thermometer (from 30° to 40°), foretells snow. Exceptions to these rules occur when northerly winds with wet (rain, hail, or snow), are impending, before which a barometer often *rises* on account of the direction of the coming wind alone, and deceives persons who from that sign only (the rising), expect fair weather *immediately.*"

The author does not wish to discourage attention to what is usually called "weather wisdom." On the contrary, every prudent person will combine observations of the elements with such observations as he may obtain from instruments; and will find that the more accurately the two sources of foreknowledge are composed and combined, the more satisfactory their results will prove.

We have heard it said that sailors and shepherds are good judges of coming weather; and there are many old sayings and proverbs relating to the subject, doubtless founded on facts and observations, that are worthy of being taken into account, in combination with the indications of instruments. At p. 21 of the work before us we find some of the more marked signs of weather "useful alike to seaman, farmer, and gardener." If we might speak prospectively in behalf of the latter class, we should say that their acknowledgements are due to the Admiral, for we have no hesitation in giving our opinion that his work will be of advantage both to gardeners and their employers.

Our hints will only admit of giving a very few of those which are termed the more marked signs:—

Whether clear or cloudy, a rosy sky at sunset presages fine weather; a sickly-looking greenish hue, wind and rain; a dark (or Indian) red, rain; a red sky in the morning, bad weather or much wind (perhaps rain); a grey sky in the morning, fine weather. So long as we can remember we have heard a rhyme which seems to correspond with part of the above:—

"The evening red and the morning grey,  
Foretell the fitness of the coming day."

But to return to our author: "A bright yellow sky at sunset presages wind; a pale yellow, wet: therefore, by the prevalence and kind of red, yellow, or other tints, the coming weather may be foretold very nearly; indeed, if aided by instruments, almost exactly. When birds of long flight—Rooks, Swallows, or others—hang about home, and fly up and down, or low, rain or wind may be expected."

In subsequent chapters there is much interesting information respecting climate in different parts of the world, in the tropical and temperate zones of both hemispheres, and in the polar regions; and as phenomena and peculiarities are noticed, explanations with reference to their causes are given. From the great mass of information that has been collected, it appears that much has been recently turned to most useful account. In the year 1838, a system of meteorological observations on an

extensive scale was strenuously advocated by Sir William Reid the author of the first "Law of Storms," and chiefly in consequence of his exertions, officers of the Royal Engineers at detached stations, and Consuls in foreign parts, were requested to collect and transmit such information to this country. By wind and current charts published of late years, navigators have been enabled to shorten their passages materially, in many cases as much as one-fourth, in some one-third of the distance or time previously employed.

In treating of the gulf stream, the author says, "It has been much discussed, especially in Scotland, whether the gulf stream has really so much effect upon our climate as has been usually thought. It has been chiefly questioned, because experiments have been made with thermometers close in shore, within twenty or thirty fathoms, where the water has been affected more or less by rivers or the land near it, and has not been found nearly so warm as the winds or water of the Atlantic; but this seems to be rather a fallacious ground of argument. There is no doubt that along the coast of Norway, as well as the coasts of Scotland and the Hebrides, the warming effect is such that all ice is kept out of the harbours there. The climate is mild all the year round, even at the North Cape; while on the western or opposite side of the Atlantic, ice comes down in-shore to a very much lower latitude, even below Newfoundland." We think he adduces perfectly convincing proof of the correctness of his opinion, and we may add, long may that stream continue to flow as it does. We do complain of our climate; but better bear the ills we have than wish for such a change. Were its course to become diverted, the eastern coast of the new world might be benefited, but Devonshire would soon lose its greenhouse climate, and Cacti and south of Europe plants would quickly disappear from the Scilly Islands, where they flourish in winter in the open air.

There is so much interesting and varied matter in this useful work, that our limits will only permit us to slightly glance at a few of the subjects. At chapter XIII. we come to the utilisation of Meteorology; but to this we must advert in a second notice.

(To be continued.)

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CYPRIPEDIUM STONEI (Mr. Stone's Cypripedium).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Diandria.—A superb Lady's Slipper, imported from Sarawak, Borneo, by Messrs. Low & Son, Clapton Nursery. Blooms in October. The petals yellowish blotched with purple; the lip, or alipper, purplish, with net-like red veins.—(*Botanical Magazine*, t. 5349.)

HELIPTERUM SANDFORDII (Major Sandford's Helipterum).—*Nat. ord.*, Compositæ. *Linn.*, Syngenesia æqualis.—Native of Western Australia. Raised by Mr. Thompson, of Ipswich, from seed sent by Major Sandford, of Swan River. Flowers yellow. "Likely to be a good bedding-out plant for our summer flower-borders."—(*Ibid.*, t. 5350.)

PHALANOPSIS LOWII (Mr. Low's Phalanopsis).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Diandria.—A beautiful native of Moulmein, and introduced thence by Messrs. Low & Son, Clapton Nursery. Petals and sepals white tinged with purple; lip purple tipped with white.—(*Ibid.*, t. 5351.)

DRACENA PHRYNTOIDES (Phrynium-like Dracena).—*Nat. ord.*, Asparagaceæ. *Linn.*, Hexandria Monogynia.—Native of Fernando Po. It is a night-flowering plant, its white flowers opening during the night and closing again by ten o'clock. Blooms in August. Leaves like those of the Arum and white-spotted.—(*Ibid.*, t. 5352.)

ACROTREMA WALKERI (General Walker's Acrotrema).—*Nat. ord.*, Dilleniaceæ. *Linn.*, Polyandria Trigynia.—Native of the mountains at altitudes of from 2000 feet to 4000 feet, in central Ceylon. "Its deeply-plaited leaves and humble growth remind one of our Primrose; but the young foliage is pale and deeply tinged with rose, while the flowers more resemble a Buttercup." Flowers yellow, open in June.—(*Ibid.*, t. 5353.)

PANSIES.—*Princess Alice*, pale straw and purple blotch, raised by Mr. Dean, as were the two following:—*Mrs. Moore*, purple, yellow, and rose-coloured; and *Leotard*, yellow, crimson, and purple. All, but especially the last-named, very attractive. *Double-purple* has before been noticed in our pages. It is very rich and striking, and is now to be had of Messrs. Carter & Co.—(*Florist and Pomologist*, 177.)

**VIOLETTE HATYVE PEACH.**—"No Peach is more melting and delicious. The tree is hardy and long-lived in almost all soils." (*Ibid.*, 1st.)

**POMPONE DAHLIAS.**—"Little *Whitemina*, bluish, tipped with rosy pink; *Little Darling*, a bright amaranth rose, of exquisite shape; *Little Philip*, reflexed in shape, and creamy buff, edged with rosy pink." The flowers are gems; but until they can be obtained on stems less than 5 feet or 6 feet high they will be comparatively little valued.—(*Floral Magazine*, pl. 125.)

**VARIEGATED JAPANESE HONEYSUCKLE (*Lonicera reticulata*).**—"We have had occasion more than once to notice this golden-netted, very striking plant, discovered in Japan by Mr. Fortune, in gardens near Yedo. He says, "In Japan it produces a pretty effect when trained over trelliswork, or allowed to ramble on the ground like our common English *Vinca*, or *Periwinkle*. It will, probably, prove quite hardy in this country, and will, I think, be useful in cool greenhouses and conservatories."—(*Ibid.*, pl. 126.)

**LARGER GLITTERING NERINE (*Nerine corusca major*).**—Native of the Cape of Good Hope. Flowers crimson. Introduced by C. Leach, Esq., King's Road, Clapham.—(*Ibid.*, pl. 127.)

**MAUVE-COLOURED NOLANA.**—Raised by Messrs. Carter & Co., Holborn.—(*Ibid.*, pl. 128.)

### WHAT A WORKING MAN CAN DO.

SAMUEL GIBSON, a distinguished member of the Manchester Botanists' Society, born at Sowerby Bridge, Yorkshire, his father being a whitesmith; died May 21st, 1849, at Mytholmroyd, near Hebden Bridge, Halifax; only went for a short time to a Sunday-school; was apprenticed to his father; was a very ingenious mechanic, and an expert and elegant turner; worked as a spindle and fly-maker at Hebden Bridge; began to employ his leisure in the study of Botany (1818); opened a whitesmith's shop on his own account (1820); and followed the business for the remainder of his life. His contributions to the "Phytologist," and other publications, bear ample testimony to his industry, and to his devotion to science. At his death he left a valuable herbarium, containing a collection of the flowering plants, Ferns, and their allies, of Great Britain, complete to within twenty specimens; extensive collections of Mosses, Lichens, *Jungermannia*, and marine Algæ; about 1000 specimens of British and other seeds and seed-vessels, ingeniously and neatly mounted between thin plates of glass; about 140 specimens of British woods and plants, prepared and mounted for the microscope. In 1826 he commenced the study of Entomology, and collected a very valuable series of British insects, arranged in thirty-four boxes. In Conchology he made valuable and extensive collections of British, marine, fresh-water, and land shells, as well as a considerable assortment of foreign specimens. In Geology he collected and arranged a cabinet of the fossil shells of mountain limestone, shale and coal measures, which was considered unique. Situate in a country village remote from books and men of science, and destined to earn his bread by a laborious employment, this intelligent and excellent man, by his energies and industry, overcame all the difficulties that beset him, and accomplished very much in the way of collecting new objects in almost every department of local natural history. His example gave an impulse to the study of nature in the surrounding districts. He suffered a long illness prior to his death, and his means became circumscribed; but he found a resource in his collections, a good part of which he sold in order to obtain the means of subsistence. The rest he left to his widow and children.—(*Mayhall's Annals of Leeds*.)

**COAL TAR DESTRUCTIVE TO VERMIN.**—Since the discovery of the antiseptic properties of coal tar, numerous experiments have been made with this substance in order to ascertain whether it possesses any deleterious qualities in relation to the insect world, or to those lower quadrupeds which are considered as pests by the farmer and housekeeper. Some of these trials have led to very satisfactory results. The "Journal de la Société d'Horticulture" informs us that an agriculturist, M. Thenard, having lately caused certain frames to be coated with coal tar, was surprised to find the Cabbages growing near the places where the frames were standing quite free from the unwelcome visits of the *Italia*, or beetle, so destructive to cruciferous plants. The observation was not lost upon him; he

immediately caused 1500 kilogrammes of sawdust to be mixed-up with 2 kilogrammes of coal tar, and then to be strewed over several acres sown with Rape seed. The consequence was that no beetles ever infested the plants from the moment of their appearance to the time when they were got in. He has been repeating this process for the last five years, and always with the same success, while his neighbours' fields suffer more than ever from the invasion of the obnoxious insect. Instead of sawdust, sand or even earth may be advantageously used; but care must be taken not to use coal tar in an excessive quantity; for since its virtue resides in the strong empyreumatic odour it emits, a very small dose will be sufficient; whereas a large quantity would kill the plants themselves. We have had personal experience of the efficacy of strong resinous smells in removing insects; for, several years ago, we succeeded in ridding a garden of vast colonies of ants, which had literally taken possession of it, by pouring spirit of turpentine upon the ant-hills. In twenty-four hours not an ant was to be seen.—(*Galignani*.)

### THE DISTRESSED LANCASHIRE WORKINGMEN BOTANISTS.

SINCE I made an appeal in your paper on behalf of the above-named distressed persons, I have received as donations towards aiding them, £31 15s.; for collections of Mosses, £16 7s.; for collections of Ferns (green), £6 5s. 6d.; for other things, £8 4s. 3d.; in donations of clothing to the value of £40; and the two naturalists I named have received a good help from Mr. Dean, of Appleton House, Warrington, for collections of butterflies and moths, for which they are very thankful. They are very worthy men, and one (John Kinder), has studied and been a collector of insects for over thirty years, and has a most excellent character.

I have given out 113 pairs of stockings and socks, 9 blankets, 27 pairs of shirts for men and boys, 24 shifts for women, 10 dresses for women, 9 suits of clothing for men, some of which I have been helped out with by two of our schools here—that is, the committees of the schools, who have kindly furnished me with things that I was short of to complete suits; and I have given out 25 pairs of flannels, and numerous other things, all of which Mr. Dean has booked for me, and I have helped fifty-four families, comprising botanists, cottage gardeners, naturalists, and deserving widows of such men, and I feel confident that your numerous readers who have thus contributed have done a good work.

I have in my hands a few pounds that are to be given out in weekly instalments, and have more promised, which will enable me to do a great deal of good.

The kind-hearted "Mother" from Ipswich has sent to Roger Schofield and John Whitehead, since I last noted it, one week 2s., and 2s. 6d. the last two weeks, and now 2s. 6d. each to them.

I shall still be happy to get collections from the botanists for any person, and hope all who have sent for collections and have not received them, will let me know as soon as possible, for some may have been neglected by accident.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE December Meeting of the Entomological Society was well attended (the President, F. Smith, Esq., being in the chair), in consequence of the Meeting having been made a special one, with the view of taking into consideration certain proposed alterations in the bye-laws, chiefly with reference to the annual election of the Curator by the Society at large instead of by the Council, which proposals were adopted after a sharp contest.

A considerable number of new works, presented to the Society since the last Meeting, were placed on the table, including a valuable series of publications on different orders of insects by the Smithsonian Institute of Washington, as well as the "Proceedings of the Entomological Society of Philadelphia," established in 1861—a gratifying proof that, amidst the political excitement of the United States, Science still maintains her peaceful career. It was suggested that a special vote of thanks should be passed on these grounds; but some of the members thought it better not to introduce the slightest allusion to such exciting topics as the war now raging in America.

Percy C. Wormald, Esq., was elected a member of the Society.

Mr. S. Stevens exhibited several boxes of Butterflies and Beetles collected at Salwatty, near New Guinea, by Mr. Wallace, containing a great number of rare and beautiful species.

Mr. Moore exhibited some pieces of a white saccharine matter collected on the leaves of Eucalypti, in North Western Australia Felix, being the exudation from the larvæ of *Paylla Eucalypti*, a small Neuropterous insect. This material is collected and eaten in considerable quantities by the natives, and is called Lerp. It is described in the first volume of the "Transactions of the Royal Society of Van Dieman's Land."

Mr. Hewitson sent portions of the stem of a Laurel tree, which had been bored to the length of 4 feet or 5 feet from the ground by some larva, most probably that of a *Zeuzera*. This was the more remarkable, as the Laurel is ordinarily very free from the attacks of insects.

Mr. G. R. Waterhouse exhibited and read some remarks upon *Quedius umbrinus*, *Oxytelus picus*, *Haploenemus nigricornis*, and *Latridius rugosus*, four minute British species of Beetles hitherto confounded with other species.

Mr. McLachlan exhibited a small species of Two-winged Fly belonging to the family *Muscidae*, which had been reared as a parasite by Mr. Parfett, of Exeter, in the case of *Limnephilus marmoratus*, one of the species of Caddice Flies, for which, being undescribed, the name *Hydrotachina Limnephili* had been proposed. This was the first instance in which a Dipterous insect had been observed to be parasitic upon one of the *Trichoptera*, the larvæ of which are aquatic.

Major F. Parry read descriptions of a number of new exotic species of Stag Beetles (*Lucanidae*), and made some severe but well-deserved comments on a catalogue of the species of that family recently published by Mr. Thomson, in the "Annales" of the French Entomological Society.

Professor Westwood also commented on the systematic arrangement adopted by Mr. Thomson, as well as upon the strange latinity of his descriptions.

## FLOWER-GARDENING WITHOUT FLOWERS.

ALLOW me to introduce to your readers an idea I have long entertained, and which, to some small extent, I put in practice during summer, of substituting plants with contrasting foliage, instead of contrasting flowers, and producing what was very effective as a flower-border without a flower in it. There are a great many plants suitable for this purpose, and if we give our attention to the subject, many things will come to hand. Should *Centaurea argentea* prove useful, it will be a great acquisition. Then we have *Cerastium tomentosum*, and better still, the variegated *Alyssum*. The *Geranium* tribe furnishes white, green, and yellow; and for contrasting colours we have *Perilla*, *Cattell's Beet*, and *Mountain Spinach*. Our experiment was made on a border 11 feet wide, with a south aspect, planted in a formal style—that is, in what we call a diamond pattern. To relieve the stiffness, a few plants of *Arundo donax variegata*, and of *Humea elegans* were placed in the centres of a few of the beds; the effect was good, and we mean to try it again, perhaps using *Lobelia* for blue, and *Saponaria* for pink—more so, as both are such neat growers. *Arundo donax* does not seem to be appreciated as an ornamental plant. I can only say it is deserving of attention; it may not be quite hardy, but we winter it in an orchard-house, where no fire heat can be applied. A few degrees of frost did not seem to hurt it. *Farfugium grande* was good here in beds, and others I have no need to mention. Some of our moderns will perhaps say, Why not have scroll or embroidery work? It is the substitution of the dead for the living, of inanimate for animate nature. Works of this kind may be admissible in certain cases, but however fantastic the design, or neat the execution, the effect on our whole system is cold and chilling. When we look on living beings, animal or vegetable, the effect is pleasing, genial, and warming; but this glow of feeling is never produced by looking on any combination of pounded brick, broken stone, and shining spar.—A. DAWSON, *Road Ashton*.—(*Scottish Gardener*.)

## HORTICULTURE AND HUMANITY.

If there is one thing more than another that should be kept entirely separate from politics, it should be Horticulture. In the present struggle which assumes such a personal shape to every one of us, it is almost as difficult as for an editor of a

magazine like this to ignore his personality as he ought to do. Still we think it should be done, and horticulture be considered as common ground—as one of the humanities of life, due alike to loyalist and rebel, Christian and pagan—to man in its widest sense.

Of its humanising influence we have an instance now before us which we cannot withhold from our readers. In one of the Pennsylvania regiments, a subscriber and former contributor to the pages of the "Gardener's Monthly" fell wounded at the battle of Antietam. Within a few feet of him, wounded in the same charge—perhaps wounded by each other's bayonets—lay a soldier of a Georgia regiment. As is the custom in our service, the wounded of the enemy and our own are all treated alike together in the same hospital, and these two were carried together with the rest. Our correspondent, in the last of two letters we have received from him, writes: "The rebel prisoners of whom I before spoke are all recovering, and they are for the most part friendly with our men. I may say all but one, who belongs to a South Carolina regiment, and keeps almost entirely to himself. In talking with the one who fell on the field near me, I discovered that he too was interested in horticulture, and there seemed at once a bond of sympathy between us. He showed me a pod of seed which he had gathered as a memento from the vegetation that formed his bed one night during the terrible campaign before Richmond, which I found to be the *Passiflora incarnata*, or wild Passion Vine. That particular flower was very suggestive to us both; for each felt that the vessel of agony might be passed from our lips, for we have had our share at least of it. His father also has a great love for horticulture, and is interested particularly in the cultivation of the Grape. On his plantation near Macon he has a very fine vineyard, on which it was his pride to collect all the varieties of note he could get. He made me promise that as soon as possible after the war shall be over, if we both live through it, I should go down and spend a month with him, assuring me, both for himself and his father, that I should be welcomed as if we had never met on the field of mortal combat together.

I promised to try to get him a few cuttings of the newer kinds of Grapes to take with him when he is exchanged, and if you can help me in this I shall be obliged. I suppose these would not be considered contraband, and that the officers will let them pass.

Some of our comrades, listeners to our conversation, jokingly said "we should be in Richmond before the next vessel with exchanged prisoners, and his cuttings would die before they reached the next rebel wharf." "Well," says he, in the same spirit, "I shall have to go nearer home to be exchanged, that's all." It has often been asked how can North and South ever be united again after fighting together as we have been; but my intercourse with rebel soldiers assures me there will be no difficulty on that score, if those who hold the reins of power will only let us. Horticulture alone will be no mean restorative to this desirable consummation. I could not help noticing the different effects our little garden talk had on the squad of our comrades about us, beyond what any other topic of conversation had, that had ever been mooted since I had been in the hospital. The young man tells me that Mr. Fields, the well-known nurseryman at Macon, was still with his business there quite recently.

How touching to the humane sensibilities is this simple narration. If we ever had any doubts as to the wisdom of the American Pomological Society's recent action at Boston, in retaining for the present all its southern names on its list of officers, until they could be heard from, we should have none after reading this. May we not wish, as horticulturists, without expressing any sympathy for the cause that parts us, that the long agony of our parting will soon be over?—(*The American Gardeners' Monthly*).

## THE BIRDS' CAUSE PLEADED.

CANNOT some understanding be arrived at between the antagonists and friends of birds? Surely the subject is not in its most intricate forms invested with difficulties so insurmountable as some would have us think. Few subjects in these our days, when once received into the columns of a leading journal, go to rest without an issue—a verdict either *pro* or *con*. Yet, as a hitherto-looker-on, excepting in the last Number or two of this Journal, few subjects seem to me so little understood, so badly ventilated, as this.

Here is the question at issue. Should birds of all species, birds of prey excepted as a matter of course, be strictly preserved, or even passively, in a highly cultivated country? Or, should birds, great and small, be indiscriminately destroyed, either with or without extenuating circumstances?

It is "passing strange," yet true, that the advocates for the preservation of birds, with few exceptions, in *THE JOURNAL OF HORTICULTURE*, have advocated the cause of their favourites very weakly. Take the following paragraph as in substance given by a past correspondent:—"P.S.—I do not allow any birds whatever to be destroyed here." On the other hand the advocates for their destruction have been endeavouring to prove the great mischief they do, though they let, here and there, a little praise peep forth, as they proceed, as if to show a certain amount of impartiality, which, nevertheless, is not sufficient to hide the real texture of the undergarment from view. I do not blame them, for I can bear witness myself to the annoyance small birds are to the gardener at certain seasons. Fancy, after taking all the pains possible with your fruit trees for a whole twelve-months, and just when you expect your returns for the same, a small army of birds assail your garden, and take away your best fruit, like foragers in a legitimate warfare. Such a loss will, at times, raise the ire of the most even-balanced temperament.

I could not take a more general example than the rook to begin with. Wherever corn is sown, or ripening—if Beans are planted, or Potatoes set—more especially if the weather is dry—there you will find an army of rooks bent upon the most active mischief. Under those circumstances they are really exceedingly troublesome, and, indeed, if unchecked, hurtful; but the rook's activity does not end here. Pray watch him in his stately walk through your field of young corn, see him busy around those yellow-tipped patches: there he serves us—he is destroying grubs. See his beak, how dirty it has become in a war with one of man's greatest enemies; watch him, as he grubs up and around those dwarf and deformed insect-eaten Turnips, as he scours your pastures, and your fore and after fallows, and say can you even find wherewith to recompense him? In the former instance, the distinctive division, you can easily stop him, you have a practical preventive; but are you—is not man—powerless and impotent to combat with myriads of grubs?

The sparrow I consider to be as useful a bird as any, in some instances, most certainly as a town bird. The good he does there alone amply repays any injury he may be guilty of in the country; but even there I believe his shortcomings are few. Among them we find him to be exceedingly destructive to the grain crops, commencing on them when very young and green, and destroying a great quantity more than he actually consumes. Sparrows are, in some winters, very destructive to the buds upon trees, not omitting fruit trees. They studiously make a certain amount of semi-cunningness answer the purpose of incessant hunting for food in the fields in winter, as they will sit upon surrounding trees and watch for hours for an opportunity to pounce down and glut themselves upon the contents of swine-troughs and corn-stacks, protruding their whole body into the latter in search for grain. I once found one which had hung himself in a recurved straw in a wheaten stack. In their favour it must be said that they consume during the year a vast amount of seeds from weeds in indifferent-cultivated land. They, also, assuredly destroy a vast quantity of insects in the summer months, more especially caterpillars, which I believe are their favourite food for their young. But here, as I would with equal pleasure write a few lines in confirmation of views in general opposite to mine, I must make the admission, that I think it may be advisable, even if we could, not to leave them totally undestroyed; as when we come to consider the general safety of their nests from the reach of boys, the breeding capacity, and the general shrewdness of this bird, with the destruction of the hawk, named from its known fondness of the sparrow as a prey, we cannot help coming to this conclusion—leave the sparrow to take care of himself. I do not say, Destroy every one you can; I simply wish to give as my opinion, that if left undestroyed, he would in numbers in a few years almost equal the locusts of old.

The blackbird, who can deny his usefulness the whole year round, excepting in a dry season, when the fruits abound? He never attempts to peck or destroy our fruits in moist weather. He is driven to feed upon any fruit within his reach when he really can get no other food; even when he eats it, it does not agree with him, he suffers in health in consequence. And now you who read my assertions with incredulous look, will you walk through your little forests of Brussels Sprouts, and ask

yourself the question, What do those blackbirds do here? and you cannot fail to say, or I misjudge you, Why they must be catching the caterpillars as they hasten down into the ground, driven there for protection by the past frosts, and to propagate their own, preparatory for another summer, to give fresh illustration to our national bard's phrase—

"The worst of creatures fastest propagate."

Years ago I received a severe check, when destroying one of those beautiful birds. It proved also to be a good illustration of the useful and injurious capabilities of this bird. Having charge of the fruit department in a large garden, I shot a blackbird as he stood beside the Box-edging upon a border, pecking one of my best dessert Gooseberries, as I supposed. Hastening to the spot, judge of my remorse, when, instead of one of my Gooseberries, his beautiful yellow beak lay buried in one of the wounds he had punctured in a huge snail, and I felt sorry. When picking him up again I felt pleased—beneath his extended wing even now, lay one of the very fruits which I had suspected him of purloining. I say I then felt pleased, though the case was really little altered. He was driven, undoubtedly, from want of more suitable food, to where he knew the berries grew, and was possibly going with it to his helpmate, whom, perhaps, he had then to support, when, finding a snail, he left the one to partake of the other: and herein lies the pith of the whole bird controversy, however simple and commonplace. Was it just to judge him in his injuries only?

So with the tomtit, poor fellow. I believe he is oftentimes unjustly blamed. Let those who consider him so universally destructive but initiate themselves more into his manner of living. Let them follow him from branch to branch, as he labours untiringly and incessantly, and you will see him peep into, beside, and beneath each bud, and extract from it your enemies; and if he does, when he knows an insect is within, peck the bud to pieces to get at it, even if he at times consume your flower-buds, have you no thought for the great good he otherwise does? No individual bunch of Apple or Pear blossom expands, upon which the tomtit has not previously been at work insect-hunting. But he will also as certainly, if the humour takes him, destroy your bees. No exquisite will knock at your door with greater assurance than does he at the mouth of the hive; but this simple fault of his is so easily provided against, that it gives rise to no inconvenience. It also gives additional proof, more especially if done in frosty weather, that he is fond of insect food, which he cannot then very readily attain.

Adverting to the troublesome Gooseberry caterpillar, we are here surrounded by wood, and birds are very numerous; so also, in general, are the above caterpillars in spring. I knew sparrows were very fond of caterpillars, which they give their young whenever they can find any. To make the birds acquainted with the whereabouts of the insects, knowing how fond birds are of fresh-moved ground, I procured a fork and freshened-up the soil around two or three of the worst bushes. Having finished, I strewed a little mustard seed round also, as an additional inducement, and so left it for a while. Returning in twenty minutes or so, instead of seeing upon the fresh-moved ground a host of sparrows, some half a dozen or so chaffinches only were there. Nothing daunted, I went to each bush, and shook therefrom some of the insects, which also fell upon the new-moved ground. The birds returned, they ate the seeds, found the caterpillars upon the ground, then upon the bushes, and, pleasing proof, from that day until the next spring, very little trouble was I put to by caterpillars. And so I do each spring; but remember, from that date until the fruit season commences, I studiously avoid the use of a gun in that quarter. Some birds there are, as the blackcap, the bullfinch, and the hawfinch, which I cannot say much for as regards the good they do; but we cannot make a computation in justice to them of their actions through the year. I would raise an enduring monument to the following—the hedge sparrow, of all birds are there any more useful? the wren, titmouse, robin, and wagtail. They should be preserved. We should all take an active part in their preservation. I do not know a single instance of injury done by them, save a little roughness by the robin sometimes; yet it is to be regretted, that the habits of the assiduously industrious hedge sparrow and wren (I have one of the latter busy insect-hunting in the stove each winter; I tell him when shutting-up time comes by rattling the syringe, though in severe weather he will at times fly behind the pipes) endanger materially their number, their

nests being so readily taken by boys and others. I used to make a practice of giving each lad a penny if he would show me near to home a hedge sparrow's nest, with a promise to leave it unmolested, until one day, after giving a young villager my contribution, having cause to go through the village, I caught the young urchin, with both arms extended, showing one of his nesting compeers, in one hand the nest, and in the other the penny which I had given him.—W. EARLEY, *Digswell*.

## EXTRACTS FROM A TOO-MUCH NEGLECTED BOOK.

CHRISTMAS TIME.—December 21.—Mild, but snowing a little; we may yet have sleighing for Christmas.

It is a very busy time within doors just now; various important labours connected with Christmas cheer are going on. Cake-jars are filling-up with crullers, flat, brown, and crisp; with dough-nuts, dark, full, and round; with raisened olecakes, with spicy, New-year cookies, all cakes belonging to the season. Waffles, soft and hard, make their appearance on the tea-tables; mince-pies, with their heavy freight of rich materials, are getting under way; and cranberries are preparing for tarts. Ducks and turkeys are fattening in the poultry-yards; inquiries are heard after any grouse or woodcocks that have been shot on the hills; after any salmon-trout, or bass, that may have been caught in the lake. Calves' head soup and calves' foot jellies are under consideration; and fresh oysters are arriving in the village from the coast by scores of kegs; in short, the activity in the rural housekeeper's department is now at its height.

But at this busy season, during these Christmas preparations, the female Vatal is supported and cheered by a sort of holiday feeling which pervades the whole house; there is a dawn of the kindness and good-will belonging to Christmas perceptible in kitchen and pantry; the eggs are beaten more briskly, the sugar and butter are stirred more readily, the mince-meat is chopped more heartily than on any other occasion during the year. A pleasant reflection this, and one upon which it is sometimes necessary to fall back for consolation when the pies are a little burnt in the baking, and the turkey proves rather tough after boiling.

But the larder, though an important item, is very far from being the only object of attention in these Christmas tasks. Greens are put up in some houses. Santa Claus must also be looked after. His pouch and pack must be well filled for the little people. Hoary heads, wise and grey, are just now considering the merits of this or that nursery-book; weighing sugar plums and candies; examining puppets and toys. Dolls are being dressed by the score, not only your wax and pasteboard beauties, such as may be seen in every toy-shop window, but also other members of the doll family which are wholly of domestic manufacture, such as those huge babies of cotton and linen, almost as large as the live baby in the cradle, with pretty painted faces, and soft supple limbs. These "rag-babies," as they are sometimes called in the nursery—Moppets, as we are instructed to name them by great dictionaries—are always pets with little mammas; no other dolls are loved so dearly and so constantly as these.—(*Miss Cooper's Journal of a Naturalist in the United States.*)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE operations here must now depend upon the state of the weather. If frosty, all manures ought to be carried or wheeled on where they are wanted. *Asparagus*, if the beds are not soiled-up for the winter, no time ought now to be lost in getting them done. *Cauliflowers*, during the present very mild weather the glasses may be left off night and day, to prevent them from drawing. Divest the plants of dead leaves, and look frequently for slugs. If the autumn-sowing failed, it will be advisable to sow in a box, which may be placed in a forcing-house, and when the plants are of sufficient size prick them out in a frame on a slight hotbed. *Celery*, if it continues to grow vigorously, it will be necessary to earth it up, so that whenever frost may set in it will not be injured so much as it otherwise would. Some gardeners dig out trenches now, so that they may receive the benefit of the frost in the spring; *Cauliflowers* are planted in

them, and dwarf Peas or Lettuces between, which will be off by the time the trenches are wanted for the *Celery*. *Herbs*, they may be taken up and planted in boxes or pots, and introduced into heat as wanted for use. *Lettuce*, any young plants in frames should have the glasses left off night and day during mild weather. *Mushrooms*, save horse-droppings for spring-beds, the droppings are most valuable now, as the horses get more dry food than during the summer. *Potatoes*, if young ones are wanted very early, some Early Frame, or any of its varieties, may be planted in a slight hotbed. If it is not convenient to plant them immediately, they may be laid in a forcing-house till they begin to shoot. Dung should now be prepared for forcing the various culinary vegetables which are required early; a considerable quantity of leaves may be used with it.

### FLOWER GARDEN.

Except in particular cases little more can be done in this department than paying attention to order and neatness. During these long evenings it is advisable to take a retrospective view of the operations of the past year, for the purpose of avoiding for the future any mistakes that may have been made. Let us hope that the rising generation of amateurs and gardeners will avail themselves of the facilities for improvement which THE JOURNAL OF HORTICULTURE and the other gardening periodicals of the present day afford; and although we may not see a Pine sufficiently heavy to satisfy the appetite of some, the extinct Polmaise system revived, or the pot-culture of fruit trees generally adopted, we may still hope, by the combination of theory with practice, to realise great results in the various departments of gardening. This makes us rejoice to see Mr. Darwin seek the assistance of Mr. Beaton and other practicals.

### FRUIT GARDEN.

Prune Gooseberries, Currants, and Raspberries in open weather. When the frost sets in lay a coat of manure about 3 inches thick around each bush. Where the Gooseberry and Currant bushes are old and covered with moss, a good dredging of quicklime put on when the bark is moist will entirely destroy it, rendering the stems clean and the bark healthy. Make a point of regularly examining all the choicer kinds of fruit that may be approaching ripeness or are found not to be keeping well, so that everything may be used at the proper time, for the finest Pears are worthless if allowed to get over-ripe before being used, and the same is the case with many varieties of Apples.

### STOVE.

Here all is still and quiet. Keep a moderate heat, from 55° to 60°, and give plenty of air. The *Ixoras* to be elevated near the glass to set their bloom, and to be kept comparatively dry. *Stephanotis*, *Allamandas*, &c., may be potted, and trained preparatory to starting in a week or two, and the staking of all specimen plants to be proceeded with as fast as possible.

### GREENHOUSE AND CONSERVATORY.

The weather has been so mild that many hardwooded plants are growing too freely. As this young growth will be found very tender, abundance of air must be given to the plants, and great precaution must be taken to prevent the ingress of frost, which in the present state of the young wood would do serious injury.

### FORCING-PIT.

Continue to introduce such plants as are generally used for forcing, especially the sweet-scented things—Lily of the Valley, Roses, Sweet Briars, Lilacs, and bulbous plants.

### PITS AND FRAMES.

Plants of a succulent character will require much attention during damp weather. *Geraniums*, *Calceolarias*, *Petunias*, and *Verbenas* are liable to become mouldy. Remove all mouldy leaves as soon as they are discovered, or they will be sure to contaminate others, and thus spread all over the pit or frame.

W. KEANE.

## TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**ARRANGEMENT OF GREENHOUSE (Patelin).**—Wood planks would do for letting out heat just as well as slides, or a thin iron brick with a ring to draw it out by, as there is no necessity for having them very tight. You may have a tank of any size under the stages for rain water; but you will require an over-dow-pipe to prevent the house being flooded, and you should have a wooden cover for the tank, if all the rain water from the house passes through it, or it might cool the house very much in spring. Ashes and tan are both good, the latter is much liked by many plants, but is apt to breed worms. Ashes when once heated will retain heat well, but as the pipes beneath will generally give plenty of heat, we would prefer cocoa nut fibre or clean sand to either for plunging in. With respect to the angles of roofs, see what Mr. Fish says in another page.

**PEARS LONG-KEEPING.**—“Are not some sorts of Pears keeping this year longer than usual? I have still some fruit of Reurc Superfin sound and good; also of Baroque de Mello, Marie Louise, and Duchesse d'Angoulême.—E. B., Dent.”

[We shall be glad of information on this.]

**ASPHALT WALKS (A Lady Subscriber).**—In our No. 48, New Series, you will find full directions for making them. Bricklayers' limy rubbish, coal ashes, and gas tar form the compound. Either gravel or spar, broken small, will do for the surfacing. See also page 734 in this Number.

**BELLADONNA AMARYLLIS (A. S. P.).**—It was wrong to grow it in heat after it had flowered, and you will not see a bloom on it for the next two years. See what Mr. Beaton says about it in another page to-day. Many of the Caladiums are apt to rot if the roots are not ripe when they go to rest, but bicolor is not of the number. The roots which perished of it could not be half ripe—that was the sole cause.

**CHRYSANTHEMUM (Idem).**—Nothing is more common than Chrysanthemum plants producing some flowers not true to the usual colour.

**LARCH SUCCEEDING SCOTCH FIR (A Constant Reader).**—It is neither a safe nor a good practice to plant Larch or any of the Conifer tribes after Scotch Fir; but the Larch is most likely of them all to pay. It will never do, however, to sow it anywhere but in nursery-beds. You must use two or three-year-old plants. If the land is at all good, Elm, Ash, and Poplar would be the best to succeed Scotch Fir; and for all country work the Black Italian Poplar is a better wood than that of the Scotch Fir, and comes to hand in one-half the time that the Scotch Fir would.

**HEATING A SMALL FERNERY (J. Hill).**—We should have liked a section, so as to show the height of the fireplace and the fernery to be heated. You cannot take the pipes down from the boiler at the back of the parlour fire. If that boiler has an open top, the pipes and cistern must be below that level. If the top is close, you may raise the flow and return pipes above that level, but the flow must go from the top. It matters not so much about the size of the boiler, as the exposure of it to direct heat; and hence we do not think you will get heat enough from it to suit tropical Ferns, for then in your fernery, 12 feet by 13 feet by 11 feet, you would need about 80 feet of four-inch pipes. For the hardier exotics, and the tenderer British Ferns, you would get heat enough from a small close boiler, for about 40 feet of piping would suit your purpose.

**CENTAUREA CANDIDISSIMA (H. B.).**—It has no other name, and we are not aware if seeds of it can be had; but it comes easily from cuttings, and when it is planted out it makes abundance of them.

**COLEUS VENSCHAEFFELTI (Idem).**—We believe this will do out of doors if the plants are full-sized at the time of planting. We had some out last summer, and have seen others, and that is all that we or any one can yet say about it.

**WOODLICE (Idem).**—We are not aware that phosphorus or any other paste will kill these troublesome insects. It is not very likely that new bread would harm them. Scalding them, and trapping with moss in pots or boxes, are the only sure modes of dealing with them according to all experience.

**LIVING HOT-WATER PIPES (M. X.).**—The water will flow well enough on the level, but quite as well if the pipes rise 2 inches or 3 inches to the open cistern. Of course, the return-pipe must be lower than the upper, at least, as it approaches the boiler, so as to enter at its bottom. It will also be as well if the return-pipe starts lower than where the down enters the cistern.

**CUMBER-BIT (A Young Gardener).**—We do not exactly understand the construction of your bed and chamber, nor are we sure that your flag-covering is strong enough to prevent cracking; hence, in general, we prefer tiles. If there is heat enough you can avoid the bad smell, if the fire is sound, by leaving on a little air at the top, and prevent making a smell by not cracking your flue with putting water on it. You would not require to go back far to find that practice disapproved of. Instead of its pouring on the flue, secure a moist atmosphere by setting pans and basins along the flue. Your could not have a better place than that proposed for raising your Cucumber. Eighteen inches from the glass would do, and you could easily secure 10° more heat by covering the box with a hand-light or large squares of glass.

**DENDROBIUM NOBILE—PHAIUS TANKEVILLEI (Orchidophilus).**—Water your Dendrobie showing flower without delay, giving a little for several days until the earth gets moist enough, which is better than soaking or dipping so as to moisten at once. Do not think of shifting the plant now. You may use a little weak manure water. Your Phaius may yet show bloom, but it is doubtful, if the shoots are now a foot in length. If not, we would say that the plant had been kept too shaded in summer, and too moist in autumn to ripen the buds. Although, therefore, we would not quite banish hope, we would treat the plant so as to make sure for next year—that is, encourage growth in the sun all summer, and curtail water early in autumn.

**VARIEGATED HOLLIES (D. M. P.).**—No variegated Holly, or any other variegated plant, comes true from seeds.

**STOCKS FOR AND CUTTINGS OF ROSES (E. L.).**—The Dog Rose stocks from the hedge-grows should be cut and trimmed before they are planted, and the sooner they are now planted the better. If you could plant them in rows, or two rows, along the sides of one of the walks in the kitchen garden—say between two rows of Strawberries, and melch them and the Strawberries together, you would find them much more convenient for budding; for then you could bud them all without once stepping off the walk. And if you were, at the same time, to stick-in cuttings of the best Roses round the stocks, some of them would root, and the standard stems would make centre stakes to your pillar Roses on their own roots, and in two more years you might arch over the walk from end to end with the very best Perpetual Roses, and not lose one of your standards the while. The most singular thing about Rose-cuttings happened this season near to us. A gentleman set a man to work to work a piece of clay ground for Rose cuttings; he told the man to work-in 4 inches deep of the cocoa-nut refuse dust, but the man misunderstood the order, dug the ground first, then put the stuff all over the top of it. The gentleman put in the cuttings, not knowing the difference, and now the cuttings are all rooted in the middle, and only well callused at the bottom. The same gentleman has had the refuse dust between his Strawberry rows for the last three years, and says “nothing will beat it.”

**GALVANISED IRON WIRE CABLE (S. P. A.).**—Messrs. Newall, Wire Cable Makers, Strand, London, supply all kinds, and would send you a list of prices if you asked them.

**WORK ON ROSES (H. P. E.).**—“The Amateur's Rosarium” by the Rev. R. Thomson, is the “latest” work and may suit you. You would puzzle us if you were to insist upon being told which is “the best.” One work may be fuller upon one mode of culture, and a second work may be more full upon other modes.

**ENTOMOLOGIST'S WEEKLY INTELLIGENCER (C. G., Tonbridge).**—We do not know anything about this periodical.

**ROSE-BEDS AT KEW (Mrs. F.).**—The oblong Rose-beds at Kew are 6 feet wide and 18 feet long, and there are no dwarf Roses in them, or tall Roses either, only botanical abstracts of Roses, which few ladies care to see in their own gardens. But, doubtless they will turn over a new Rose-leaf at Kew when they get through their heavy works about the new conservatories, and it is very likely, before many years are over, that both at Kew and at Hampton Court we shall see all the Roses on their own roots doing as the climbing Roses and the China Roses have already done on their roots on the west side of the grand conservatory. The climbing Roses at Kew will be splendid in two or three more years, and very likely they will festoon them on chains as they did the festooning of *Cissis discolor* in the Victoria Lily-house, which all of us admired so much.

**SEEDS FOR A KITCHEN GARDEN (A Five-years Subscriber).**—It is not easy to give a correct estimate of what seeds you may want for your garden, 76 yards by 69 yards (rather more than an acre); but, assuming you to grow Potatoes elsewhere, the following will be about the quantities that might be wanted in a great many cases; but, of course, the requirements of families differ so much that it would hardly meet the wants of all!—Broad Beans, 4 quarts; of French Beans and Scarlet Runners, each 1 quart; Peas of various kinds, 12 quarts; Mustard and Summer Spinach, 1 quart each; Cress and Winter Spinach, 1 pint each; Radish, 1 quart; Brussels Sprouts, Cauliflowers, and Savoy, each 1 oz.; Onions, 10 ozs.; 12 ozs.; Carrots and Turnips, each 8 ozs.; Lettuces of sorts, 4 ozs.; Endive, Parsley, and Parsnips, 2 ozs. each; Broccoli of four or five kinds, half an ounce each; Kale of two kinds, half an ounce each; Cabbage of three or four kinds, including the Red, half an ounce each; Leeks, 1 oz.; Celery, 2 or 3 packets; and a packet each of Basil, Sweet Marjoram, Scorzoneria, Salafy, Rampion, and any other thing that way that may be wanted. Roots of Garlic and Shallots may perhaps be wanted in a new garden, and Cucumber and Melon seeds are not unusually included in a seed-bill. We may also observe that in small seeds, as Onion, Turnip, Carrots, &c., it is best to sow thickly. The expense of seed is not a serious affair, and they are easily thinned out; but Broad and Scarlet Runner Beans need not be planted thicker than wanted, unless the seed be of doubtful quality, in which case some judgment is necessary.

**GLADIOLI (A Constant Subscriber).**—If they are bedding varieties let them remain in the soil, covering the surface over each clump 6 inches or 8 inches deep with coal ashes.

**GERMAN IVY (M. G. T.).**—This climber is not an *Ipomæa*, as had been thought by many, but the old name German Ivy is the best popular name for it. The same treatment as given to Tom Thumb Geraniums will do for it, but a very few degrees of frost kill it. The heat of the Orchid-house is not too much for it. We have had it to screen Orchids where old strong plants of it in a rich border made many shoots from 40 feet to 50 feet long in one season, and we never saw an insect on it. Out of doors it makes good imitation for common Ivy on rustic work; and if allowed root-room in a window-sill box it would soon make an Ivy casement all round. But in winter it is of no use if the frost cannot be kept from it. Where a shoot of it touches the ground it roots faster than a Strawberry runner.

**TRELLIS FOR HOUSE CLIMBERS (N. D.).**—We have no more liking for the green diamond wooden trellis than your employers. There are cast-iron studs with a wedge end to drive into the joints, and an eye-card to pass wire through, which is the best contrivance we know, provided the wire is galvanised, and is stretched in horizontal lines, with a stud at every 4 feet or less. Sometimes people place such wire up and down the face of the wall, but that is the wrong way, as every twining shoot twists round and up the wire faster than one man could undo them; and if they are allowed one month's possession in the height of summer, they swell their growth so fast that it is difficult to manage them, or get them off all their own way for two or three years, and lots of the iron studs had it all their own way before the plants could be put in order again. But perhaps on your rough stone wall, “roughly dashed,” so that you cannot hit on the joints, wooden uprights would be better; and if these were 1 inch thick, and 2 inches wide, and not more than 5 feet or 6 feet apart, you could easily fix galvanised wire against them, with staples also galvanised. But galvanised iron net would not do, as twiners would get fixed in the net worse than in the upright wire, and old leaves and dirt would soon accumulate between the wire and the wall, making it very difficult to keep the place tidy.

**PRUNING RHODODENDRONS (P. B.).**—It is very seldom indeed that Rhododendrons, require pruning, but if they are too much crowded and get naked at the bottom, they require cutting back just after flowering, or immediately before flowering-time, and they will break from the hard old wood almost better than any other plant if the roots are good. Rhododendrons, Kalmias, Ledums, Azaleas, and all such Americans ought to be thinned as soon as they interfere with each other, and then none of them would require pruning in a lifetime.

**NAMES OF FRUITS (Dr. Davies).**—There must be some mistake about the Apple now sent for Hanwell Soaring; that which came formerly was a roundish-ovate Apple, awfully acid. This is a round one and quite delicate and mild in flavour. This is doubtless your seedling from the Kilmston, which it is not unlike in appearance. No. 2, marked Red Calville, is Emperor Alexander; No. 4, Joséphine de Malines, is Winter Nellis; No. 3, Lovedon's Pippin, is Court-Pendin-Plat; 10, unknown; 12, unknown; 13, is very much like Bull's Golden Reinette; 13, Pear, is the true Joséphine de Malines; 14 is not Beurré d'Amanlis, more like B. Diel; 17, unknown. Your seedling from Mère de Ménage is a good deal like Sturmer Pippin in appearance, and may prove equal to it in quality; but at present it is unripe. The light and the highly-coloured large Apples are the same kind, and are not unlike Mère de Ménage. All the others are correct. *Apples (Blason).*—1, Drap d'Or; 2, Forge; 3, Manks Codlin; 4, not known. *Pears.*—5, Winter Nellis; 6, not known. (R. K.)—23, Golden Knob; 24, Nonpareil; 25, Golden Reinette; 27, Braddick's Nonpareil; 28, Yorkshire Greening.

**NAMES OF PLANTS (J. M.).**—We believe it is a selected variety of *Phacocoma prolifera* Barnesii, with brighter-coloured flowers. At any rate it is the form Mr. Barnes used to show in such fine condition when an exhibitor of stove and greenhouse collections. (G. Bowers).—Specimens too damaged to be identified. It is useless to send unprotected specimens to be smashed by the post-office stampers.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

JANUARY 1st, 2nd, and 3rd. GLASGOW. (Pigeons and Canaries.) *Secs.* Mr. T. Buchanan. Entries close December 22nd.  
 JANUARY 6th, 7th, and 8th. KENDAL. *Secs.* Mr. George C. Whitwell, and Mr. T. Wilson. Entries close December 23rd.  
 JANUARY 7th and 8th. CORK AND SOUTH OF IRELAND. *Sec.* J. C. Beale, Esq., Cork. Entries close December 20th.  
 JANUARY 8th and 9th. PERTH. *Sec.* Mr. D. Brown. Entries close December 31st.  
 JANUARY 13th and 14th. GLOUCESTER ORNITHOLOGICAL. *Sec.* Mr. G. Cummings, 89, Southgate Street.  
 JANUARY 21st and 22nd. LIVERPOOL. *Sec.* Mr. J. T. Lawrence, 3, Cook Street. Entries close January 5th.  
 FEBRUARY 10th and 11th. DEVIZES. *Secs.* Mr. J. Long and Mr. J. S. Mullings. Entries close January 23th.

### THE PAST YEAR.

THE approach of Christmas is not without its effect on most people. We have met with those who declare they are not naturally lazy—they say work is a pleasure, pastime, and recreation. We don't believe them. It is none to us. There is a great fuss made about the words "if" and "but." They deserve it, *but* they are not the kings of the company, and *if* any other can make a good resistance, why should it not? The past of a man may be full of lessons, but the future is full of hope. The future scorns "if" and "but"—it tacks its faith on "then." Those who have a weekly or daily task are strangely lazy when the end of the year is at hand. Turn the year, and *then*. The truth is, we like to put all we can to the account of the future, in order that we may extract what we may in the way of pleasure from the present. The days are short, the mornings are dark, and things are stationary. The shortest day is past; but we are told there will be no real difference for a fortnight. Then, say we, it should be a holiday. "What!" says a friend who had just dropped in, "a holiday! How long?" "Till the days lengthen," say we. "My stupid friend," he says, "have you considered? The commercial year is made up of fifty-two weeks, and the exports and imports amount to—" "Stop, sir," say we, and we think of Robert Macaire, who, having breakfasted with Bertrand at a restaurant, and having, as he said, *unfortunately taken no purse that morning*, was compelled to offer either some shares in a company he was about to form, or Bertrand's hat. Now albeit the latter was a "Goss," and by no means a new one, the waiter took the hat; and we preferred our correspondence to our friend's "rifacimento" of McCulloch and Adam Smith. We therefore wished him good morning, and began to open letters.

"T. W. S. M. B. F." writes he has been trying for years to get a prize, and has succeeded at last at the Crystal Palace, and there is no report. "W. W." thinks it would save trouble if the previous exploits of a pen were written over it. He, like all complainants, disavows any idea of finding fault, but cannot make out why he should win at Birmingham and be only com-

mended at the Palace. He forgets the effect of a bilious attack he had a short time since. He was ill only three days, and hardly knew himself; but then it is nonsense to say fowls are ever bilious. Now we will go to our arrears.

Three weeks since Birmingham, and no details save the report. It is not enough to know there was fair weather, but we want to know how the glass stands. We will go to stern figures. Spite of distress in the north and croakings in the south, Bingley Hall was visited by the largest number that has ever attended the Poultry Show—60,961 people were admitted. The receipts at the doors were £1257 5s. 6d. Such success is well deserved.

While speaking of the Crystal Palace we cannot talk of increased numbers; but we can talk of an attendance produced entirely by the attraction of the poultry, and we can give some of the reasons that limit the attendance. First, the abominable railway accommodation. We know numbers who would attend but for that; and the aristocracy who attended numerously on the Tuesday were all there early in the morning, and all gone by twelve o'clock—they would not bear the squeeze. The railway accommodation that suffices for the four or five hundred daily visitors before the Poultry Show, is left to do duty for the time of the quadrupled numbers. No allowance is made for the time of year and the fact that nearly all want to go at the same time; and a family that has paid for first-class tickets is enabled, after a hard struggle, to get two in a third-class compartment made for ten and carrying sixteen, two in a second-class, and two in a first. People tire of this and forget to call it pleasure. Another drawback is the transformation of the centre of the Palace into a huge carpenter's shop and unpacking-room. Enough of that, and we will proceed to our chickens, remarking on those points that may possess interest after the Show.

The Cochins were not as good as at Birmingham, but the Spanish were better. It seemed as though the two breeds could not supply two shows with pens of equal merit. The coloured Dorkings were chiefly remarkable for the great success of Lady Holmesdale. This Show is held in the heart of the Dorking country; but Messrs. Vernon, Wakefield, Priest, and others hold their own and take their places in the prize lists. We were glad to see the Rose-combs well represented. The Single Cock class in Dorkings was declared by the Judges to be the best they ever saw. The Spanish were superior to those at Birmingham. Mr. Martin was very successful. The Game were excellent, and the awards were remarkable for the number of new names they brought before the public, not, however, to the exclusion of Messrs. Archer, Hindson, Vernon, and other well-known prizetakers. The Golden-pencilled were weak, and the Silvers formed a bad class; they may be good layers, but as specimens of the breed they are bad. The Golden were better than the Silver-spangles. In all the Hamburgs there were many faulty combs. Poland maintained their upward tendency in quality and numbers. Mrs. Pettat, with Messrs. Adkins and Dixon, sent perfect birds. Malays were faultless, but not so numerous as usual. The Game Bantams formed a very large class. The White Geese weighed 61 and 53 lbs., the Grey, 70 and 58 lbs. The Aylesbury Ducks, 22½, 21½, and 20 lbs. Rouens, 18, 17, and 16½ lbs. The Black Ducks were beautiful. Turkeys weighed 63 and 61½ lbs.; young birds, 56 and 55½ lbs. There was a beautiful show of Pheasants.

### DURATION OF THE CRYSTAL PALACE POULTRY SHOW.

#### CARRIAGE OF POULTRY.

I THINK I am not the only one of your readers who is of opinion that the Crystal Palace Show is just one day too long. Surely three clear days of exhibition ought to suffice.

My own birds at the recent Show were absent from home close upon ten days! and as I live only 150 miles from London, the journey is not long. They are at the place of exhibition a whole week, which I think is too long.

While I am writing, will you permit me to touch upon another point, which, if taken up by a number of first-class exhibitors would tend greatly to increase the number of entries at poultry shows, and thereby assist to solve the problem of the day of "How are we to make poultry shows answer?" I allude to the present heavy expense for carriage. For one pen of Cochins and two of Pigeons packed in light baskets, and the distance only 150 miles from town *via* Great Western Rail, I had half a

sovereign to pay for bare railway carriage there and back, besides incidental expenses. Now, I think that if a club or society were formed which would open a negotiation with all the railway companies to try to induce them to carry show poultry, and at greatly reduced prices, great advantage would be gained by all the societies by a considerable increase of entries; and it may be reasonably expected that, on the penny-post principle, railway companies would be rather gainers than losers by agreeing to a very liberal scale of reduction. The simplest mode of doing it would be to induce all companies to carry exhibition poultry, &c., free on the return, if unsold. This is already done in many cases, and prevents unfair and dishonest advantage being taken of a reduced rate both ways by sending poultry as if for exhibition, which may not *bono fide* be so.—W. H. BEADON, *Cheddon, near Taunton.*

### THE BLACK BANTAMS WITH COLOURED LEGS AT THE DARLINGTON SHOW.

HAVING noticed in the last Number of your valuable Journal a letter from "JUSTITIA," in which he insinuates that the pens of Black Bantams which I exhibited at the last Crystal Palace Summer Show, and which were claimed, were not shown in their natural state, but with coloured legs, I feel it my duty, in justice to myself and the arbitrators of that Exhibition, to state publicly, which I now do without the least hesitation, that not the least particle of colouring matter, or any kind of stain whatever, was laid on, or came in contact with the legs of the birds referred to by either myself or any other person previous to their being dispatched to that Show. As to the position the highly-commended pen held being an inducement to their present owner to purchase them, they were in the catalogue at £3, while my first-prize pen was only in at £2; and the gentleman referred to being present and claiming them himself, and he a well-known judge of poultry, attending most if not all of our principal exhibitions, you will agree with me that he could not have been expected to purchase birds of any description, without first consulting his own judgment in the matter.

If a maturer development of the birds have produced the change in the colour of the legs, surely there is no reason to blame me in the matter, for they were naturally a good dark colour, and fit to "pass muster" at any exhibition before the most exact and scrutinising judge, at the time that I sent them to that Show.

Your correspondent "WILTSHIRE RECTOR," says, in his "Plea for Bantams," that he has had Black Bantams laying at the age of twenty weeks and three days. Allow me to state in support of his assertion, that two out of the four pullets sent to the Crystal Palace Show were laying when a few days short of seventeen weeks, and at the end of nineteen weeks I had a sitting of eggs from them under a hen. When hatched the chickens were weaklings and did not live many days.

In conclusion, I cannot refrain from saying, that if parties writing to your Journal were compelled to give their proper names instead of being allowed to shield themselves behind fictitious appellations, it would be much more easy for your readers to discern the true lover of justice from those who write only from personal animosity.—E. HUTTON, *Pudsey.*

[We have the real name and address of "JUSTITIA." If he intended any reflection on Mr. Hutton, he was not justified in so doing; but we do not think he did. The owner of the Bantams when exhibited at Darlington has not denied that he knew their legs were coloured, and until he does so there is but one conclusion, and no one else ought to be suspected.—EDS.]

### PENGUIN DUCKS.

If any of your readers have kept Penguin Ducks, and will have the kindness to observe one little point, and communicate the result, I should be greatly obliged. On examining the skeleton, I find that certain bones of the leg are longer than in the other breeds. I formerly kept these birds alive, and as far as I dare trust my memory, they could run considerably faster than other Ducks. Is this the case? It would, perhaps, be a good way to test their running powers to call the two kinds, when hungry, from a distance to their food, and see which arrived first.—CHARLES DARWIN, *Down, Bromley, Kent.*

### HYBRID BETWEEN THE COMMON PHEASANT AND THE SILVER PHEASANT.

CAN you inform me what sort of birds a cross with a common cock Pheasant and a Silver Pheasant hen would produce? Would they produce what are called Spangled Pheasants?—J. D.

[We believe we are correct in saying there has never been a cross between the common and Silver Pheasants. Such a bird is desirable, and would be highly prized; but we do not think it possible.]

### SALT DOES NOT INJURE PIGS.

I DO not pretend to have much knowledge about "grunters," but it appears from some statements which have appeared in your widely circulated Journal, that salt is a most dangerous thing to give them in their food. I am living in a pig locality where salt is generally mixed with their food, and I have not heard of a single case of injury to the animal arising from it. The prevalent opinion is, that the animal relishes its food far more with a little salt in it than without it. I was extremely doubtful about giving it to them until my neighbours persuaded me, and I must confess that the pair I am owner of are no worse for the saline ingredient.—J. E., *Co. Fermanagh.*

### BEEES AND BEE-HIVES

IN THE INTERNATIONAL EXHIBITION.

(Concluded from page 688.)

FRANCE.—In this department we found some very well-made common straw hives, and some straw storifiers, which do not appear one step in advance of those used by the Count de la Bourdonnaye in the last century, and described by Wildman as nearly identical with his own. M. HAMET exhibits a so-called observatory-hive, which is, however very inferior to those of English make.

We cannot find any reference to French hives in the official catalogues, but on quitting the court we accidentally discovered an octagon storifier by M. Vignon; a frame-hive by M. Debeauvoys; and a square storifier by M. Gaillard. We saw nothing to remark in the two former, but may refer to the latter at some future opportunity.

AUSTRIA.—KOLB, J. F., *Maria Enzersdorf, Lower Austria*, No. 599, circular hives made of straw and of rushes, and of both combined; also, square straw lager-hives of various descriptions. There are two machines, one for making round hives, and the other for making the sides, doors, &c., of square hives. The principle of each being the same, we engrave the latter, as being most readily understood. It will be perceived

that the straw is subjected to pressure by means of a lever, and confined by means of iron pins passing through holes in the uprights. The binding or stitching is applied before these pins are removed, and the result is a straw fabric of great firmness and solidity. The extreme cold of German winters is provided against by these straw hives being 2 inches thick.

MELICHER, DR. L., *Vienna*, No. 601.—A moveable-comb hive of wood covered with traced straw, affording, we should think, a

most complete nursery for the wax-moth and other vermin. A clumsy hive of two-inch wood. A tall bar-hive three stories high, and a "Schew-glass moveable comb-hive," of no particular novelty or merit.

NACHTMANN, J., *Hermagor, Carinthia*, No. 603, exhibits Carinthian hives, which are made of straw, and do not differ much from the hive delineated below, except that the brood-room only is fitted with frames, the honey-room having simple bars. Herr Nachtmann also shows some strips of hard wood an inch wide, engraved on both sides thus:—

This is placed between two bars, one side of each of which has previously been coated with wax, and this side being placed in contact with the engraved bar the whole is subjected to pressure in any kind of press, and the result is the foundation of worker-combs ready laid for the bees in wax on the surface of each bar.

OETTL, J. N., *Puschwitz, Bohemia*.—We engrave Herr Oettl's hive as the type of a kind extensively used in Germany. It will be perceived that it is a frame-hive with two sets of frames ranged one above the other, the lower forming the "brood-room," and the upper the "honey-room." Deprivation is

effected, and operations are performed, by opening the hive either at the back or front, as represented. There is also a wax-filtering pot in tin, wherein the wax rises through a perforated tin horizontal divider inserted and fastened at about 4 inches or 5 inches from the top.

WURTEMBERG.—WEITZEL, E. (Society for bees' breeding), *Sonnenberg*, No. 2729.—A neatly-executed model of a bee-shed with twenty-six wooden hives, eight on each side, the same number in front, and two over the doorway. Each hive is fitted with nine frames, and space is left above the frames for a honey-room. The boxes being placed in pairs, have side communication as if intended for collateral working.

RUSSIA.—KLIKOVSKY, PROFESSOR, *Kazan*, No. 303.—Models of a unicomb-hive of rather a pyramidal shape, and of a storifying-hive, both of them on a very small scale.

ROCHEFORT, COUNTESS OLGA, *Ossa Circ, Perm Gov.* No. 154.—Oleaginous honey produced from the lime-tree blossom, growing on a ferruginous soil on the estates of the Countess Olga de Rochefort at the foot of the Uralian Mountains, and used medicinally throughout Russia and Persia for diseases of the chest and respiratory organs, &c. Obtained by cold pressure. This honey is very remarkable as being produced entirely without the aid of bees, and has, of course, a very strong flavour of the blossom from which it is derived. It is moreover stated to be most valuable as a medicine, and superior to cod liver oil in cases of consumption. The Jury have marked their appreciation of its merits by their award of a medal.

SWITZERLAND.—MENZEL, PROP., & GRABERG, *Zurich*, No. 120.—New contrivances to guide bees in constructing their combs. Of these "new contrivances" the artificial combs are doubtless valuable, but have been many years in use in Germany, and are so fully described by our correspondent "G. F. B.," that we need not further allude to them here.

## BEES IN BUILDINGS.

WOULD any of your apianian correspondents who may have tried keeping our little favourites in buildings or working through windows, &c., oblige me with the result of the experiment, giving height from ground, aspect, thickness of wall, &c.? as I am thinking of trying a stock or two in a building with a N.W. aspect next season, but should like the opinion of some of your correspondents; and if this should meet the eye of a "RENFREWSHIRE BEE-KEEPER," I should be exceedingly obliged if he would favour me with the history of a hive referred to in *THE JOURNAL OF HORTICULTURE*, No. 51, page 507, March 18th, 1862, and No. 25, page 202, which was an observatory-hive. Would he be so kind as to say whether this stock prospered and swarmed or not, with such particulars as may seem to suggest themselves to him?

What can be the cause of vagrant swarms generally preferring a high situation, such as a roof, or in the tower of a church, &c.? so contrary to the usual practice of apianians. Are we wiser than they? or is it in accordance with their instinct? It strikes me the charm of these situations is in their equable temperature and freedom from disturbance. Perhaps Mr. Wyndham Jones might throw a little light on the subject if he would be so kind as to favour us with the promised result of his inquiries and observations at Tatton Park. Any replies to my queries would oblige—A NORTH-STAFFORDSHIRE BEE-KEEPER.

[We should be obliged by replies to the above inquiries, not only from the correspondents especially alluded to, but from any others who may have had experience in this mode of keeping bees.—EDS. J. OF H.]

NEW USE FOR GUTTA PERCHA.—One of the most ingenious applications recently made of gutta percha is that of forming artificial hoofs for horses' feet. Many skilful devices have been resorted to to attain this result, but the adoption of gutta percha will, doubtless, supersede all others as soon as its efficiency becomes recognised. What is required is a substance possessing the consistence of horn, to retain the nails of the shoe, that will readily soften by heat, so as to mould itself into the required form; that it be indissoluble in water, seeing that the horse's hoof is generally in contact with moisture; and that it be capable of uniting perfectly with the hoof. The gutta percha is first cut into nut-size fragments, and softened in hot water; the pieces are then mixed with half their weight of powdered sal-ammoniac, and melted together in a tinned saucepan over a gentle fire, keeping the mass well stirred. The mixture should assume a chocolate colour.—(*Cincinnati Gazette*.)

## OUR LETTER BOX.

RABBIT JUDGES AT THE CRYSTAL PALACE (*A Constant Reader*).—We do not know their addresses. Ask Mr. Houghton, Secretary of Poultry Show, Crystal Palace, Sydenham, enclosing with the inquiry your address on a stamped envelope.

JUDGES AT BIRMINGHAM (*Patelin*).—We have received your note on this subject, but think it best not to insert it, because we have reason to believe that next year all will proceed in accordance with common sense, and further discussion might only hinder so desired and desirable a result.

WILD DUCKS WITH TAME.—Please to correct a mistake in my reply to "J. R." respecting the rearing of wild Ducks. It occurs in your publication of the 23rd instant, at page 773, the second column, and thirtieth line. It should have stood thus—the young ones "at each reproduction became much larger, and the legs *lost* the fineness and elasticity so easily recognisable in the first parents." I would not trouble you, but in the above sentence the word *took* being printed in mistake for *lost* alters the meaning of the paragraph altogether.—EDWARD HEWITT.

CUP-COMBED DORKINGS (*P.*).—It is a common error considering that a cup-comb is a grave defect in a Dorking. It is no such thing. There is no specific comb for a Dorking; and the only rule relative to its comb of the slightest importance is that which requires similarity of comb in a pen. A double back, or the presence of a few sprigs, does not constitute a cup-comb. This last is circular, or cup-form at the back.

AMERICAN WILD TURKEY (*C. A.*).—You can have the American wild Turkey from Mr. Eaily, Mount Street, Grosvenor Square.
