## TO OUR READERS.

---

WE know of one who would not have on the parlour chimney-shelf a dial with a second's hand, because it made him see and feel how life lessens, as it were, drop by drop. What he would have said, or how he would have felt, if he had to write these Prefaces surpasses our power of surmise, for they at once tell of six months gone—and how quickly gone!

Grateful are we to record that truth, for miserable is he over whom time passes on heavily. But no such weight has been upon us: no day has been long enough or slow enough—each day's evening seemed to arrive before its morning had passed into noontide.

This was not because there were no sorrows around us; for we have had by our desk refugees from the once United States, telling of homes crushed, and of brother in arms against brother in fratricidal and suicidal war: we have had a blast from that war among our own homes, and our pages have told of one small passage in the wide and deep amount of privation and sorrow which it whelmed over our cotton districts. Death has not been less frequent than usual in his visits among those whose aid we had; nor have we found jealousies less jaundiced, nor envyings less detraactive.

But we have had compensations for all these ills. We were able to give occupation to the unemployed and to point out to others those who deserved assistance. When a chasm occurred among our friends others stepped forward to render the vacancy less observable; and as for the jealous and the envious, we had no leisure for being inconvenienced by them.

Thus have we passed on through 1862; and over its close we will inscribe the hope that from its days our readers, as well as ourselves, have passed on into 1863 wiser, happier, wealthier—wealthier not merely in this world's gear. May its harvest of wisdom, happiness, and wealth be even more abundant than that yielded by its predecessor; and we will include in that prayerful hope our brethren across the Atlantic. Many of our readers are there, and they may accept from us as truth that great is the delusion which suggests that "Britishers wish nothing but evil to America." If that fiendish desire actuated our countrymen, they would not so earnestly hope that the internecine war waging there may speedily cease.

Heartily do we join in that hope—nay, more, it is the most prominent in a cluster of good hopes, including one for the well-being and well-doing of each and all of our contributors, and another for the vigour and endurance of those so abundantly recording themselves as our "Constant Readers." May they all be evergreens, and then our concluding wish will be gratified, for we shall all have

A HAPPY NEW YEAR!

# INDEX.

- ABIES MICROSPERMA**, 34  
**Acacia**, *Drummondii* pruning, 90; *armata* in summer, 230  
**Acanthoneura strigosum**, 553  
**Acer**, *palmatum atro-purpureum*, 540; of the Romans, 593  
**Achimenes**, 727; at rest, 618; *Mauve Queen*, 678  
**Aconitum of the Romans**, 702  
**Acrotrema Walkeri**, 790  
**Adelaide Botanical Garden**, 349  
**"African (South) Economic Flora,"** 678  
**Agave glaucescens**, 495  
**Agricultural Society's (Royal) Show**, implements at, 254  
**Agrimonia eupatoria**, 398  
**Ailanthus silkworm**, 118, 246, 531, 688  
**Ajuga reptans purpurascens** as an edging, 476  
**Alexander, James**, 164  
**Almeida rubra**, 555  
**Alopecia metallica and macrorrhiza variegata**, 85  
**Aloe**, about to bloom, 221; family and their culture, 574  
**Alphabetical arrangement of poultry exhibitors**, 772  
**Amaranthus melancholicus ruber**, 369, 430; *tricolor*, new, 419  
**Amaryllis—belladonna culture**, 55; *Unique*, 143; *belladonna* soil, 166; culture, 479; blue, 480; *alica*, 705; *formosissima* culture, 769  
**Amaryllises in pots**, 618  
**American plant, leaves diseased**, 224  
**Ammoniacal liquor destructive of caterpillars**, 192  
**Ammoniacal gas in a hothouse**, 490  
**Amphitheatre of verdure**, 455  
**Anemone, apennina culture**, 34; *narcissiflora*, 395  
**Anemones after flowering**, 146  
**Angers, its tree and fruit trade**, 745; market-gardening produce of, 783  
**Angræcum fragrans** as a medicine, 16  
**Anguria Warezewiczii**, 52  
**Anisanthus splendens**, 488  
**Annals, for edging Geranium-beds**, 35; select list of, 644  
**Anomochloa marantoidea**, 378  
**Antholyza æthiops**, 488  
**Anthurium Scherzerianum**, 196, 337  
**Antirrhinum**, wintering seedling, 479  
**Ant-hills, to get rid of**, 146  
**Ants, in Melon-bed**, 241; in grass, 262; in Cucumber-frame, 343  
**Aphelexis culture**, 765  
**Aphides and their destruction**, 176  
**Apianian, events of 1861**, 17; notes, 18, 423; Miscellany, 708, 775  
**Apiary—"B. & W.'s" in 1862**, 129; of "Upwards & Onwards," 731  
**Apple-trees, heading down**, 55; trees cankering, 127; Irish Peach, 378; trees unfruitful, 594; trees, vitality in, 714; renovating, 741  
**Apples—sweating before storing**, 83; storing, 302; selection of, 705; keeping, 719; Ribston and Cox's Orange Pippins, 761  
**Apricot shedding its blossom**, 127  
**Apricots—under glass**, 228, 240; scale on, 705; in pots in orchard-house, 785  
**Aquarium—parlour**, 235; Warrington's, 262; water for, 685  
**Aquariums, in garden-que scenery**, 103, 123, 141  
**Aquilegia glandulosa**, 398  
**Arabis alpina**, propagating, 229  
**Araucaria, Cookii**, 237; not thriving, 704  
**Arbor Vite, cutting American**, 495; hedge, 617, 618, 671  
**Arbutus procera**, 84  
**Archerfield Early Muscat Grape**, 451, 457  
**Architectural features in gardening**, 494  
**Arctotis, new, for edgings**, 368; reptans, 407  
**Argemone grandiflora**, 398  
**Aristolochia Gibertii**, 677  
**Arnot's stove, brick**, 726  
**Arrowroot culture**, 94  
**Artichoke, is it hardy?** 668  
**Artichokes, are they hardy?** 716, 725; culture and hardiness of, 744; protecting, 762, 763  
**Arundo donax culture**, 108  
**Ascidia intestinalis, communis, arachnoidea, tubulosa, and prunum**, 452  
**Ascidiens, compound**, 438; social, 437  
**Asparagus—earliness of**, 118; beds, mismanaged, 127; culture, 127, 637; sowing, 166; beds, 281, 321; tops, 398; salt for beds, 402; moving, 479; beds, wireworms in, 499; forcing, 578, 724; beds, manuring, 618; bed, removing old, 770  
**Asphalt, flooring**, 540; walks, making, 783  
**Aspidiotus ostreiformis**, 562  
**Aspidium Picu**, 437  
**Athanas nitescens**, 399  
**Atriplex hortensis**, 332  
**Aubrieta purpurea**, propagating, 229  
**Aucuba japonica, male and female**, 3  
**Auricula, Show, National**, 10; exhibitors, North and South, 116  
**Auricularia, in 1862**, 83; George Lightbody and Southern Star, 294  
**Australia—South, at the Exhibition**, 293; Western, at the Exhibition, 319  
**Aviary, birds for**, 624  
**Aylesbury ducks, characteristics**, 226  
**Azalea—its characteristics and culture**; 415; varieties, 416; *indica*, cuttings, 108; *Duc d'Arenberg*, 196; *Mars*, 294; *Brilliant*, 495; leaves, insects on, 541  
**Azalacs—classified list of**, 42; list of, 154; in summer, 230; to barden-off, 382; propagating Indian, 685; manure for, 686; in ainery, 726; and liquid manure, 769  
**Axius atirynchus**, 375  
**BABIANA RUBRO-CYANEA**, 488  
**Balance the good and the evil**, 318  
**Balconies, management of plants in**, 389  
**Balsams, sowing**, 36  
**Bantam cock, points**, 584; hybrid with Pheasant, 584; class at the Crystal Palace, 750  
**Bantams losing head-feathers**, 76; Duckwinged, 150; Black cock's ear-lobes, 150, points in Game, 168; colour of ear-lobe, 266; Pied, 599, 665, 666; classes at the Crystal Palace, 600; (Game) classes, 619; food for, 624; Black, at Darlington, 770, 797; plea for, 772  
**Basket plants**, 302; pendulous, for greenhouse, 705  
**Baskets for fowls**, 286  
**Bath and West of England Poultry Show**, 72, 184  
**Beauty and utility combined**, 220  
**Bedding-out**, 55, 182, 202; at the Crystal Palace, 398; at Cliveden, 336; at South Kensington, 387; plants, propagating, 457; system defended, 777  
**Bedding plants—in pots**, 146; and the Derby Day, 189; supporting, 223; propagation of, 417; preparations for propagating, 438; wintering, 597  
**Beds, circular, of three kinds of plants**, 127  
**Beech hedge, making, &c.**, 670  
**Bee-keepers' perplexities**, 284  
**Bee-keeping—in Cueshire**, 110; Woodbury on, 129; in Cornwall, 167; in Staffordshire, 163; commencing, 325; hints to practical, 385, 405  
**Bee—flowers, late**, 804; cells in Jamaica not enlarged, 323; season, Middlesex, 346; Gloucestershire, 346; Larkspur, two-coloured, 495; parthenogenesis in, 564; season, in North Lancashire, 74; in Devon, 92; season, Berwickshire and Lancashire moors, 622; East Lothian, 623; Beeyear, 1862, 709; Dzierzon on parthenogenesis, 731; apparatus (Swiss) in the International Exhibition, 753  
**Bees—in winter**, 17; uniting, 20, 37, 364, 443; removing, 38; as chemists, 58, 112, 149; over-feeding, 58, 112, 149; and swallows, 93; early swarms, 93; travelling by railway, 139; death of a queen, 110; cross between English and Ligurian, 112; zinc about, 112; attaching combs to bars, 149; winter management, 149; feeding, 149, 346; queens, destroying, artificial swarming, artificial comb, and milk as food, 150; deserting their hives, 187, 226, 245, 442; do they vary? 207, 225, 242, 284, 463, 642; queen destroyed by workers, 207; swarming, in a storm, 225; season in North Lancashire, 243; tithed, 226; present season; death of a queen; hybrids; as chemists, 265, 305; Who ascertained first the sex of queen? 266; do they make honey? 284; settled facts about, 286; Ligurian queens, 304; in Jamaica, 305; Ligurians not irascible in America, 305; fumigation, deserting hives, 305; losing a queen, 345; misfortunes of season, 345; Ligurian, 385; queen from worker-egg, 404; fumigating, 405; introduction of a Ligurian queen, 423; artificial combs for, 423; practical observations on, 423; queen mutilated by workers, 424; transferring and uniting, 442; hiving in a frame-hive, 442; transferring, eggs not hatching, 463; abandoning hive, 482; foresight of, 483; in Staffordshire, 484; varying in their proceedings, 501; in smoky places, ejecting eggs, chloroform for stupefying, 502; and bee-hives at the International Exhibition, 583; queens becoming drone-layers; queens assailed by own workers, 544; queen's fertile age, 601; do workers become fertile? 604; using embossed wax, 604; queen's age of fertility, 623; longevity of working, 643; fertile workers, 643; hybrid Ligurians "B. & W.'s" apiary in 1862, 665; deserting their hives, 688; fertile workers, queen drone breeding, 774; bottle-feeder for, 776; in buildings, 798  
**Beet, Itca**, as a border plant, 592  
**Begonia prismatocarpa**, 52; *fuchsioidea* culture, 745  
**Begonias, propagating**, 55  
**Bejarina coarctata**, 277  
**Belladonna Lily culture**, 779, 795  
**Berberis japonica, intermedia, and Bealii**, 146; *aurahuacensis*, 255; *Wallichiana*, 698  
**Berberidopsis corallina**, 677  
**Bessera elegans**, 488  
**Beverley Poultry Show**, 203  
**Bird question**, 298  
**Birds, and the crops**, 124; utility of small, 151, 175, 219, 283; protection of in Switzerland, 196; why they should be protected, 200; destruction of small, a plea for, 256, 258; spare the, 315, 318; uses and destructiveness, 536; migration, 533; mischievous, 576; small, &c., 660; use of, 696; balance of, 681; cause pleaded, 792  
**Bird's Nursery**, 625  
**Birmingham Rose Show**, 63, 180, 272  
**Birmingham Poultry Show**, 619, 638, 706, 727, 729; pens at, 520; Exhibition week, 640; Judges at, 664, 688  
**Bishop's weed**, 146  
**Blackberry, Lawton, to train**, 412; wine, 504  
**Boiler, adapting a stove to**, 55; for vinery, 617; at back of parlour fire, heating by, 705; Clarke's, 767  
**Boilers leaking**, 35  
**Bois de rat**, 64  
**Bolbophyllum rhizophora**, 52; *cupreum*, 196; *pimentatum*, 378  
**Bone-crushing**, 15  
**Bones and potash**, 55; dissolving, 281  
**Borders, good form of**, 764  
**Borecole, report on varieties**, 293, 314  
**Boronia serrulata culture**, 64  
**Botaists, meeting of workmen**, 271, 318  
**Potrychium lanceifolium**, 553  
**Botryllus**, 437  
**Bottle-feeder for bees**, 37, 58  
**Bougainvillea glabra culture**, 218  
**Bouquets**, 493  
**Bowling-green, size of**, 541  
**Box-edging, management of**, 83; destroyed by salt, 183, 233  
**Box ledge, making, &c.**, 671  
**Brachmia Pootras**, 776; merits, 38; hens as layers, 464  
**Bridgesia spicata**, 712  
**Brisbane Botanic Garden**, 589  
**Broccoli, Carter's Champion**, 142; manured with sewage, 158; moving large, 638  
**Broccoli, report on**, 333, 374  
**Brodiaea grandiflora**, 489  
**Brugmansia leaves yellow**, 363  
**Bryanthus erectus**, 277  
**Bucket, Holmes' self-titting**, 786  
**Bulb-to flower throughout the year**, 498  
**Bulb (Cape) culture**, 778  
**Bulbs, Cape**, 303; for out-door planting, 488; management of spring-flowering, 508; in pots, 509; care in testing, 527; out-door, 561; in beds, 579; rare, 638; vegetating strongly, 747

- Bullfinch paralysed, 544  
 Bullfinches' eggs disappearing, 345; 385; Black, 776  
 Bupleurum fruticosum, 712  
 Burmah, notes from, 197  
 Butter, large yield from one cow, 38  
 Butterflies, killing for specimens, 286  
 Buxus obtordata, 4
- CABBAGE—SOWING AND PLANTING**, 351; caterpillars, 581; Jersey Sticks, 490  
 Cabbages, report on, 492  
 Caladiums in winter, 641  
 Calampelis scaber culture, 34  
 Calavansa Bean, 99, 123  
 Calceolaria—leaves spotted, 54; history, &c., 129; as a bedder, 120, 135; cuttings, 561, 625; planting, 684  
 Calceolarias—wintering, 480; shrubby, 609; cuttings, 617; for exhibition, 638  
 Californian orchards, 613  
 Callianassa, Underground, 375  
 Calistemon brachyandrum, 535  
 Calce Poultry Show, 610  
 Calcearis Macandreae, 375  
 Calceobrotus pallidus, 515  
 Calves—fattening, 88; rearing on milk and linseed meal, 188  
 Camellia—and its culture, 59, 169, 261, 445; watering, 59; seeds, sowing, 163; list of varieties, 170; propagation, 267; Contessa Lavinia Maggi, 294; seedlings culture, 322; flower-buds breaking, 562, 618; buds falling, 747  
 Camellias—in summer, 230; cross-breeding, 332; recently grafted, 598  
 Campanula Vidalii, 615  
 Canaries—diseases of, 19; selling, 38; mortality among, 38, 283; in a room, 55; model prize list, 73; dying, 584  
 Canary—and British Finches, 37; cock eating eggs, 150; hens sitting without laying, 185; sick, 688  
 Cantua luvifolia, 657  
 Cape Gooseberry culture, 281  
 Carex Fraseri, 36  
 Carnation—characteristics and culture, 47; varieties, 48; tree, culture, 756; list of, 757  
 Canebrakes—tree, culture, 71; striking, 382; sowing, 439  
 Carrot—grub, 281; crop failing, 557  
 Carrots on clay soil, 302  
 Carter & Co.'s Nursery, 156  
 Caterpillars—on fruit trees, 139; venomous, 246  
 Cat, destructive, 305  
 Cats v. birds, 219  
 Cauliflowers—under glass, 107; protecting, 560  
 Caution, 299  
 Ceanothus genus, species described, 21  
 Celery—turnip-rooted, 34; culture, 239, 280, 517, 725, 789; grubs on, 241; roots, 261; leaves brown, 479; fly, 587; culture in Lancashire, 592; white-leaved, 598; growing and failure, 655; fly, preventing its attacks, 700; failure this year, 744; how to grow good, 762; failures, &c., 788  
 Cells, formation of royal, 482  
 Cement walks, making, 784  
 Centaurea—candissima, 518, 691, 795; propagating, 229; cuttings, 519; argentea as an egg, 742  
 Cephalotaxus Fortunei, 51  
 Cephalotaxus foliolaris culture, 562  
 Cerasus—japonica flore pleno culture, 71; ilicifolia, 712  
 Cerastium—tomentosum, propagating, 16; frosted, 71; Eibersteini, 127, 367, 425; for flower gardens, 45, 84  
 Cerastium, tomentosum and Biebersteini, 129; treatment of, 402  
 Cereoglia Gardneri, 57  
 Charcoal—as manure, 370; making, 701  
 "Chemistry of Soils, Handy Book of," 142  
 Cherry—blossoms falling, 70; Trip-leton, 99; Nouvelle Royale, 145; trees, winter-pruning young, 748  
 Cherries—on walls, 240; falling, 281  
 Cheshire Poultry Show, 542  
 Chickens—large brood of, 158; noise in throats, 306  
 Chinese Primrose, Double-flowered, 196  
 Chinese Primroses, Delicata and Rubra grandiflora, 378  
 Chippenham Poultry Show, 730  
 Chiswick, Royal Horticultural Society's garden at, 372  
 Chiton cinereus, &c., 558  
 Chlidanthus fragrans, 489  
 Chloride of lime as an insect-killer, 177, 250  
 Christmas, poultry market, 770; time, 794  
 Chrysanthemum—culture for show, 82; notes on, 647, 650; at Mr. Salter's, 652  
 Chrysanthemums, 625, 779; twelve superior, 16; list of, 730; management of seedlings, 727  
 Cinchona, trees introduced into India, 606; plants, introduction of into India, 659  
 Cineraria maritima—cuttings, 14, 34, 540; seed sowing, 70; propagating, 498, 748  
 Cineraria flowers not opening, 685  
 Cinerarias—preservative from green fly, 98; compost for, 224; James Andrews, The Artist, and The Winner, 378  
 Circumstantial information, 451  
 Cissus discolor, growing specimen of, 11  
 Clarkia, White-margined, 678  
 Clavelina lepidiformis, 437  
 Clay soil, to improve, 581  
 Clayey loam, lightning, 769  
 Clematis—viticella venosa, cutting down, 34; lanuginosa, hardy, 770  
 Clerodendron—Thomsonae, 143, 173; culture, 514  
 Clethra arborea, 402  
 Clivanthus Dampieri potting, 499  
 Climbers—for conservatory, 127, 480; in verandah, pruning, 254; for a greenhouse, 421; for an arbour, 580  
 Clipped trees, effect of in decorative gardening, 433  
 Clomeocoma montana, 52  
 Clonmel House, 81  
 Clover, four-bladed, 164  
 Clusia Brongniartiana, 294  
 Coal tar for vermin, 791  
 Colea scandens seedlings, 223  
 Coburgia incarnata, 488  
 Cobwebs, 457  
 Cochon-China cock, cold in, 688  
 Cochon-China fowls—falcon-hocked, 246; culture hocks in, 286  
 Cochon-China pullets—not laying, 20; combs, 326  
 Cochon-Chinas—points in, 366; Cinnamon, 624  
 Cockscumb culture, 56  
 Cockscombs, sowing, 36  
 Cocoanut fibre refuse, 381, 426, 430; for seedlings, 15; as a manure for flowers, 16; mixing soil with, 55, 146; for drainage, 218; for peat, 231; for cuttings 241; as a general manure, 272; for Cyclamens, 281; and clay soil, 769  
 Cologerie Parishii, 293  
 Coix lachryma, 362

 Rhododendrons—grafting, 146; for conservatory, 146; bardy, in pots, 231; select bardy, 664; planting, 748; pruning, 796  
 Rhopalas, to propagate, 439  
 Ribbon-border, 71; distance between, plants for, 90  
 Ribbon-borders, 35, 55  
 Ridge-and-furrow planting, 16  
 Ritchiea polyetala, 677  
 Rogiera amœna, 656  
 Roofing, waterproof, 275  
 Roofs, measuring angles of, 781  
 Roman Candle plant, 717  
 Room plants, 280  
 Rookery, establishing a, 770  
 Root—pruning, 157; heat, in forcing, 142; blaster, 137; pruning young trees, 553  
 "Rosarium, The Amateurs," 85  
 "Rose Annual for 1861-62," 25  
 Rose Show, forthcoming, 9; Birmingham, 30, 156  
 Rose—stocks, wild, treatment, 15; Manetti, 23; cuttings, striking, 228, 421; mildew, blue vitriol for, 329; John Fopper, 262, 378; de Meaux, culture for market, 573; catalogues, 633; grafting by the fireside, 672; culture, suburban, 697, 719, 760; list of Roses for, 719; pruning, 727; beds at Kew, 795  
 Roses—forcing, 26; Manetti and stock, culture, 62; history of, 87; not blooming, 91; in pots, 168, 303, 701; lists of, 154; manuring, 166; at Royal Horticultural So-

ciety, 243; new, 249; mildewed, 262; at Birmingham and Crystal Palace, 271, 272; not thriving, 281; classed according to colour, 289; retarding, 302; at Paris, 350, 373; at Reed Hill, 354; hints on budding, 376; of 1862-3, 435; in autumn, 567; for the season, 558; the first two years, 587; tree, 598; yellow Banfshire, 598; pruning until two years old, 606; for standards, 617; Manetti, 618; cutting-back, 638; of 1862-3, 692; pruning, 705; a hedge of, 781; stock, and cuttings, 795  
 Ronen ducks, points in, 484  
 Roup, fowls attacked by, 621  
 Rony cock, 208  
 Rubus biflorus, 712  
 Rudbeckia pinnata, 397  
 SACCOLABDUM MINIATUM, 294  
 Saddle, Guernsey, 412  
 Salads, French, 533  
 Salt injurious to pigs, 697  
 Salvia gessneriflora, 634  
 Sandwich, origin of term, 413  
 Sap, why is its greatest force vertically? 634  
 Sarracenia purpurea a new remedy for small pox, 76  
 Sarmienta repens, 173, 378  
 Sawfly, ravages of Curraot, 358  
 Saxe-Gotha composita, 237  
 Scabiosa caucasica, 397  
 Scarceroles and early birds, 68  
 Sciadophytis verticillata, 50  
 Scilla Berthelotii, 52  
 Sereens, of evergreens, 638; of trees, 638  
 Scrophularia nodosa variegata, 71, 189, 395; aquatics variegata, 407  
 Sea-kale—culture, 54; forcing, 166, 578, 689, 724; use of flower-heads, 126; sprouts as a culinary vegetable, 158; sets, 260  
 Seashore, what to look for on, 234, 294, 334, 359, 375, 399, 416, 436, 452, 515, 535, 553; pebbles for walks, 362  
 Season—in Cornwall and Herts, 118; the present, of blossoms, 130; in Che-bire, 331; at Ashton-under-Lyne, 334  
 Scawed manuring in Guernsey, 449; uses of, 450, 532  
 Seeds, preserving from birds, 104  
 Self-coloured beds, 506  
 Septoclinium maculosum, 437  
 Serissa foetida variegata, 174  
 Sewage—use of, 127; well, 341  
 Shade on roller, 108  
 Sheco, Chinese, 93  
 Sheffield Poultry Show, 334, 383  
 Shelters, wall-fixers for, 44  
 Silene—compacta, 398; Schafta, 534  
 Silk fowls, 683  
 Siphocampylus Orbiennanus, 474  
 "Silvia Capensis," 678  
 Skimmia japonica unfruitful, 195  
 Slaters, 89  
 Slugs—and earwigs, 71; and their remedy, 275  
 Snake Millipedes, 223  
 Spangles on Oak leaves, 382  
 Spangels, breaking, 92  
 Spanish—towls' feathers diseased, 76; cock's comb, supporting, 226; fowl's eye, tumour on, 246; comb black, 246; pullet's comb, 235; hens dying suddenly, 346; hens as layers, 464  
 Sparkhoe Poultry Show, 459  
 Sparrow—its merits and demerits, 681; murder, 753  
 Sparrows are our friends, 298  
 Spencer, Mr. J., 45  
 Spermula—pilifera, 137, 241; saginoides, a plea for, 220  
 Sphaerogone latifolia, 174  
 Spinach—sowing, &c., 301; dying-off, 789  
 Spirantes autumnalis, 533; mode of fertilising, 163  
 Sprekella formosissima, 488  
 Spring crops, manuring, 561  
 Squilla Desmarestii, 399  
 Stachys lanata culture, 480  
 Stan-ford Floral Fête, 312  
 Standard, raising evergreen and deciduous, 132  
 Standish's Nurseries, 3, 50  
 Starch, chemistry of, 145  
 Starlings, 708  
 State Holford culture, 598

Stenogaster multiflora, 174  
 Stephania floribunda not blooming, 303, 747  
 Stock, Intermediate, forcing, 232  
 Stoke Newington Chrysanthemum Show, 650  
 Stokesia cyanæa, 685  
 Stove—for greenhouse, 35; for small greenhouse, 479  
 Strawfieldsaye, 556  
 Strawberry—spring culture, 107; plants, saving from grubs, 198; culture, 202; culture in pots, 343; produce in, 343; forcing, 362, 725; planting, 704; in pots, 705  
 Strawberries—insects on, 14; planted out after forcing, 192; protecting fruit, 222; after forcing, 239; in pots, 302; cross-breeds of, 672; cross-breeding, 721, 779; should the fruit be held upright? 763  
 Streptanthera elegans, 188  
 Streptocarpus Rhexii culture, 748  
 Stydium mucronifolium and saxifragoides, 296  
 Succulents, culture and lists of, 465  
 Sulphur—in hot-water troughs, 146; burning as a fumigation, 617, 618; fumigation, 726  
 Sunbenches, digging in, 165  
 Super-posting hives, 37  
 Supers, size of for hives, 20  
 Swainsonia, mauve-coloured, 294  
 Swallows, 708  
 Swarm, restlessness of artificial, 303  
 Swarming—artificial, 187, 774; excessive, 285  
 Swarms—artificial, 130, 263; not working, 265; uniting, 323; making artificial, 324  
 Sweet-brar hedge, 55  
 Sydserrif, R., 75; on bees, 325  
 Symplecos japonica, 179  
 TABERNEMONTANA LONGIFLORA, 67  
 Tacsonia manicata flowers falling, 770  
 Tagetes tenuifolia, 71  
 Tan, heating a pit by, 90  
 Tank, plants for, 421; heating a small greenhouse, 489; heating, 580  
 Tasmanian products, 358; timber, 379  
 Tate, Mr., again, 657  
 Taunton Poultry Show, 91, 146  
 Temperature of air, mean, 251  
 Temple Hill, 30, 46  
 Tenant removing trees, &c., 663  
 Tents at the Royal Horticultural Society, 155  
 Terraces, rustic, 160, 161; architectural, 198; styles at different periods, 356  
 Terrier, the Skye, 92  
 Thibaudia micrantha, 217  
 Thorne Poultry Show, 263  
 Thrips, destroying, 560  
 Throat disease in poultry and Pheasants, 322  
 Thunbergia luteo-virens, 174  
 Thunbergia coccinea culture, 727  
 Thyrsanthus rutilans for dianer tables, 633  
 Timber, causes of its decay, 333  
 Tithing or tolling bees, 226  
 Toads v. woodlice, 227  
 Tobacco fumigator, Stephens', 336  
 Tobacco-root, 61  
 Todea hymenodes, 281  
 Tomato culture, 239; management, 331  
 Tomtits destroy gall insects, 350  
 Transplanting, 540  
 "Travels in Fern and India," 639  
 Tredgar Poultry Show, 771  
 Trees, plantation of, 382  
 Trellis, plants for covering, 16; for house climbers, 795  
 Trichomanes bulbocodium, 331  
 Tritileja uniflora, 89  
 Tritomania varia sowing, 91; culture, 108, 657; plants, 519  
 Tritonia aurea culture, 334  
 Tropæolum Smithii, 721; pentaphyllum culture, 726  
 Tropæolums, propagating for bedding, 108; in window, 618  
 Tuberosa culture, 183  
 Tulipa sylvestris, 7  
 Tulip, its characteristics, 140; culture and arrangement, 190; list of, 191

Tulips after flowering, 146; for bedding, 648  
 Turf-edgings, 145; what to do with old, 241; for sloping bank, 480  
 Turkey culture in America, 109  
 Turkeys, raising, 323; weight of, 688  
 Turnip sowing, 239

**VALIKILI FOWLS**, 522  
 Vallota purpurea—in the open air, 34; soil, 166; forcing, 232; dividing, 617  
 Vancouver's Island—botanical expedition to, 451; fruit trees in, 737  
 Vanda, culture of the genus, 613  
 Variations effected by cultivation, 696  
 Variegation, progressive, 5; retaining, 46; in plants, 196; causing, 251  
 Vegetable, name of, required, 90  
 Veitch, arrival of Mr. J. Gould, 78  
 Veitch's Royal Exotic Nursery, Chelsea, 138, 321  
 Ventilation of hives, 37  
 Ventilators, new arrangement of, 10  
 Verbenas—cuttings, 224, 540; Lord Leigh, 343  
 Verbenas, 71; wintered in a bed, 15; new, 43; list of, 449; thrips, on, 480; new, 505; propagating, &c., 561  
 Verdier's Roses at Paris, 373  
 Veronicas, culture of, 726  
 Vertigo in fowls, 20  
 Viburnum suspensum, 712  
 Victoria, products of, 452  
 Vicia-seuxia villosa, 483  
 Villa Panfilii Doria, 199  
 Vinca minor, double, 7  
 Vine—injured by fire, 43; eaten by mice, 45; the Yeddo, 51; leaves curling, 55; leaves diseased, 70; from Elysian Fields, 272; leaves spotted, 83, 343; planting inside, 458; stems, air-roots on, 568; re-

potting, 580; borders, keeping warm, 616; shoot, cutting a long, 685; borders, dressing, 705; borders, slating, 741; roots, bringing to the surface, 719; stems, scrubbing, 727; border, 770  
 Vinery—borders, 127; cleaning, &c., 597; plants for a cold, 663; Rev. Mr. Busbby's, 673; early, not productive, 705; management, 768  
 Vines—in pots, watering and stopping, 4; forcing, 5, 429; in hot damp air, 15; watering during stoning, 35; classing in vineries, 64; crop permissible, 65; and Peaches in same house, 66; syringing, 67; injured by fire, 90; bearing and not bearing in the same vinery, 166; breaking at top only, 108; vigorous, 127; planting late in vinery, 146; grafting, 155; air-roots on stems, 156; in a corridor entrance, 260; and Vine-borders, 216; air-roots on, 220; in corridor, 220; luxuriant but unfruitful, 241; leaves spotted, 241; summer pruning, 254; leaves rough beneath, 262; in pots, 292, 402; arrangement in house, 293; in South Australia, 295; leaves brown, 302; sweet-scented, 302; very vigorous, 302; old unfruitful, 303; on trellises, 312; bearing at top only, 343; neglected, treatment, 363; planting, 480; in a greenhouse, 540; treatment of old, 598; over-cropped, 598; resting while maintaining stove heat, 612; removing young, 638; for forty-foot house, 617; grafting, 651; close pruning, 659; in pots, bottom heat for, 672; in a plant-stove, 673; in pots in pinery, 693; unproductive, 696; on back wall of vinery, 705; newly planted, 705; for vinery, 705; management and budding, 720; in pots, 727, 746; over-luxuriant, 789

Viola—pyrolæfolia, 595, 664; pennsylvanica and pyrolæfolia, 704  
 Violets, Russian and other, 35  
 Vraicing in Guernsey, 449  
**WAIZIYA TENELLA**, 553  
 Wakefield Poultry Show, 461, 563  
 Walks, management of, 747; their kinds and construction, 783  
 Wall trees, protecting, 581  
 Walls, constructing and heating, 256; pointing old stone, 580; plants for north and south, 712  
 Waltonian Case, described, 1; temperature, 90  
 Warrington and Wardian Case, 594  
 Wasps, queen, 268; destroying, 478  
 Water Cresses, cultivating, 70  
 Watering, notes about, 233; plants in a sunk frame, 672; in winter, 768  
 Watsonia fulgida culture, 334; Meriana, 488  
 Wax-moths, 265  
 Weather, the, 31, 52; vicissitudes, 69; near London, 658  
 "Weather Book, The," 789  
 Weeds destroying, 560  
 Weck, work for, 13, 33, 53, 69, 88, 106, 125, 144, 164, 181, 200, 222, 239, 260, 279, 301, 320, 360, 380, 401, 418, 438, 450, 478, 496, 517, 538, 560, 578, 596, 616, 637, 661, 683, 703, 723, 746, 767, 794; doings of last, 14, 33, 53, 69, 88, 167, 176, 145, 165, 182, 201, 222, 289, 260, 279, 301, 320, 342, 361, 380, 401, 419, 438, 456, 478, 497, 517, 539, 560, 578, 597, 616, 637, 662, 683, 704, 724, 746, 768  
 Weigela rosea, propagating, 202  
 Wellingtonia seeds, 519  
 Wellingtonias dying young, 362  
 West Riding Naturalists' Society, 496  
 Wild flowers, some of our rare, 331  
 Weymouth Pine, 726  
 Wheeler, Mr., testimonial to, 700

Wild fowl, confined, 36, 72  
 "Wild Flowers, Rambles in Search of," 722  
 Williams's Nursery, 99  
 Window-gardening, 389; in Ireland, 434; town, 471  
 Wine-making, 443  
 Wines of South Australia, 295  
 Winter, Cherry sowing, 71; greens, 156; Violet Grass, 697; covering, 759  
 Wintering plants in a frame, 331; greenhouse for, 673  
 Wire-fence strainer, 157  
 Wire fencing, 71  
 Wistaria sinensis flowerless, 534  
 Wood, formation of, 343; pigeons destroy Pilewort, 227  
 Woodbridge Poultry Show, 262  
 Woodlice, 795; in Cucumber-beds, &c., 240; on peach walls, 480  
 Woodstock Poultry Show, 521  
 Wood's Nursery, Maresfield, 567  
 Wool refuse, 59  
 Working man, what he can do, 791  
 Worms, expelling, 35; in pot soil, 55; destroying by Gishurst Compound, 68; lime water, 70; in lawn, 541  
 Wortley and Ainley Poultry Show, 564  
**XANTROXYLON ALATUM**, 712  
**YANPAH**, 84  
 Yates' Nursery, 218  
 Yew-hedge, renovating, 90; making, 671  
 York Poultry Show, 730  
 Yucca recutva, knobs on, 198  
**ZINC LABELS, INK FOR**, 26, 76; oxidising, 241  
 Zinc boxes for verandah plants, 519  
 Zoological garden, Hood's verses on, 241

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 56.4° and 36.0° respectively. The greatest heat, 79°, occurred on the 7th in 1859; and the lowest cold, 16°, on the 1st in 1838. During the period 138 days were fine, and on 107 rain fell.

THE WALTONIAN CASE.

HEN Paganini got his fiddle smashed in a storm, a friend sympathized with his case, and the Signor instantly made known that he did not care a fig for the case, if the fiddle in it had not

been broken. Here, on the other hand, after many storms and tempests, together with temptations to get bread and cheese, fame and fortune, out of the Case, the Case itself is now more safe and sound than it ever has been; and I am enabled, from a more thorough conviction of the fact, to repeat that "I never saw a better contrivance for amateurs to strike cuttings and raise seedlings with than this, and that there is not a better mode in existence, as far as I am aware of," and not likely to be, for just yet awhile.

But the fiddle! The fiddle in that Case is the grand secret, and we shall never get over that fiddle, depend upon it, as long as the inventor of it and the manufacturer of the invention choose to whistle the tune as they have hitherto done, or play it out for the use of all parties, and for the benefit of the manufacturer thereof, who had risked a large sum on it in the first instance.

Mr. Bennett, the clock manufacturer of London, sends me regularly drawings of all his best new "cases" for his clocks and watches; for which, of course, I am very much obliged to him, as I can now tell to a minute if any watch I see is, or is not, in the fashion. But I cannot make a watch from all the drawings, nor can I get a single individual who can make a watch for me from the drawings cheaper than Mr. Bennett himself, so I go to him because I cannot help myself to a cheaper article. And the Waltonian Case is exactly and entirely such another case in point. No man can hit the thing from all the underhand and overhand drawings of it that have yet appeared, and yet there are four people in the secret, and I am one of them, and the most conscientious advice I can give, is to warn my readers against the expense, pain, and danger of attempting to fiddle out this fancy by the best player in their town or parish. A friend of THE COTTAGE GARDENER spent £15 hard cash, amongst the best artists in New York, with the best drawings from London before them, and they were all just as wise as when they first attempted it. Lots of dowers in white-smith's ways in this country have just as signally failed as the New Yorkers, and if you knew what I do, you would not wonder at it. In all sincerity, therefore, my advice is as I have just given it.

There is no one now in Surbiton, or within my reach, who has any interest in the run of the Waltonian. But about three years since, when Mr. West, the manufacturer of it, was about leaving Surbiton, I made it a point with him, that if ever he made any alteration or improvement in it, that he should acquaint me of it before any one else, on account of my being the godfather of it, and was bound to see it kept from such people as I did not

altogether approve of. He said he would, but I have not had a scrape of his bow since, and, therefore, conclude the Case is just as it was when he left us. That enables me now to bring down the history of the progress of the invention to the end of March, 1862, and you may dismiss every other move and turn referring to this Case from your mind, and accept the present contribution as the very best on the subject, till you meet with a better one, to paraphrase a Roman motto at the end of one of my school books.

It is entered on the record that the boundary line between THE COTTAGE GARDENER'S straightforward course in this invention, and the course that was not so, in the conduct of a few, ran in a south-east direction to the Gulf of Pudibundus, Vol. XV., page 386, where the Case and the fiddle, the tune and the way to play it, are set forth in brief. From that day to this the invention had been steadily extending on all sides, and the knowledge of working it seems to have spread at the same rate, so that all that our own correspondent sees fit to communicate anent it, is simply that oil or gas, lamp or flexible tube from a gas-pipe, will do the heating equally well, if you know how to do it, and he argues that the know-how-to-do a thing can no more be taught in black and white, than how to make a boot or a stirrup, and that all that must be learnt by practice, and by pluck to stick to it till the boot is actually in the stirrup, and the man or woman is ripe for rough or smooth ground, or for Rotten Row in Hyde Park.

About ten years since Mr. Walton began the Case simply by putting hot water in a close tin case, and the tin case inside a wooden box with a glass cover—exactly like that for which Miss Maling has taken out a patent; but finding the plan too troublesome, and not of sufficient power to raise seedlings and cuttings, which he chiefly wanted, he set about contriving artificial means of getting more heat and less bother, and in his first communication in these pages, Vol. XV., page 430, he says "the boiler (tin case) is surrounded by a false cover of tin, which I found necessary to create a draught for the lamp. The false cover has a chimney which runs through the frame and out at the back, to carry off the smoke, if any, but there ought to be very little. The lights are divided into three, and are merely fixed in zinc frames, not wood, and let into the top, to lift on or off, or tilt. This is better and cheaper than glass in a wood-frame, as the water (why I cannot tell) does not drop inside, but rests on the outside [of the zinc frame] and may be tilted off. The lamp was made by Smithurst, of Bond Street, but it is quite plain [brass] and circular, holding more than half a pint of colza oil. It must be well trimmed, so as not to smoke, and then will burn eight hours—that is, without any more trimming, but now it is only trimmed twice in the four and twenty hours, and the expense in oil is a fraction over 2d. for the day and night."

Mr. Walton continues, "a tin lamp will do just as well. The smoke does not get at the plants, but would collect at the bottom of the Case and fall on the lamp. The lamp is 3 inches high and 4 inches across. . . .

If the lamp should go out, and the water become quite cold, draw off some, and add hot water, otherwise the lamp will not burn." The italics are mine to caution people how to take out patents for what has been done before them, as Mr. Walton, who is a first-rate lawyer himself, and is well acquainted with all our judges, and their ways, told me last week that any patent for keeping hot water in a closed case under plants in pots, as he had them, and for renewing the heat to make the lamp go, or to keep the water to a certain heat was not worth one night's purchase. I was sorry to hear that on account of Miss Maling's patent, for I was very much taken with her writings; but my duty will not allow me to plant a Manetti stock, or to sorrow for those who bud them, but to caution my readers when I can only see breakers ahead.

The only improvement in the working of the Waltonian since I last wrote about it is at this very point, and it is due to the practical head of Mr. Walton's gardener, who is one of the best plant-growers I know about Surbiton, and perhaps the most successful manager of the Waltonian Case in the three kingdoms. The meaning of the lamp refusing to burn, if all the water in the Case was quite cold, is well known to gardeners who have the old flue system in use. Cold air is difficult to dislodge out of a flue, or at all events some flues, and the little draught that is necessary for the lamp is not sufficient to dislodge the cold air round the tin case: therefore, the tin case had to be filled each time with as much hot water as heated the said cold air, and then it escaped and the lamp went as it should. Now, the improvement alluded to consists of this, the "chimney which runs through the frame and out at the back" as above is a tin tube, and is moveable; then, when the lamp limps at cold air before it, take the "chimney" off and hold the bottom of it over the lamp a little while, and the tube is soon so hot that no air can settle in it. Put it quickly on the end of the flue or coil; and, of course, the cold air around the tin case must go on to fill the hot "chimney," and so the draught is made perfect without the bother of filling-in the case with hot water as in the patented process.

Mr. Walton's gardener is now so thoroughly convinced of the handiness of this contrivance for raising seedlings and rooting cuttings, that he would not think of making up a dung-bed for the purpose; and, after providing stuff sufficient for one of the largest gardens in Surbiton, I found the Case half full of seed-pots from Barr and Sugden to prove them for their customers, all coming up nicely, and they seldom lose a cutting or a seedling out of a thousand. The same Case is in use from the beginning, the same lamp constantly under it, and all the difference I could see was owing to this extraordinarily sunless weather, through which they kept the inside of the Waltonian much drier than would be necessary if the sun had not hid his face from us here (about London) for the last six or seven weeks. I never saw more healthy young stock than these, and the greenhouse is quite a blaze with Azaleas, Coronillas, Cytisus, Cinerarias, Hyacinths, Tulips, Cyclamens, and other spring flowers. Their Golden Chains are certainly the best I ever saw, and the next best I recollect to have seen were in the garden of Sir Joseph Paxton. The Tropæolum elegans, a good test plant, good as a feather in the air to see how the wind goes, they kept over the winter in the cutting-pots, and only potted them off in February, without losing one of them, which is more than most can say. The cutting-pots of elegans stood over the winter on a front small shelf in the greenhouse, very near the glass, and all but quite dry the whole time; the young stock are now on an end-of-the-house shelf, high up, and facing the south-west, looking as

London-like as if they were in one of the splendid domes of the Exhibition building.

There must be two very different kinds of the German Ivy plant, for Mr. Walton's gardener flowered the one which the Misses Walton brought home from the Rhine, and it was in a head of small clear yellow flowers just like a head of Primula farinosa as he described it to me; while the one which bloomed in 1859 at the Pine Apple Place Nursery was a light lilac Ipomæa. Mr. Taylor wrote to me from Shrubland Park to say it was not an Ipomæa, and Dr. Lindley said the same thing more than once, and it is only fair that I should give both facts, though one of them be against myself, even leather is not better than the plain truth.

But I must return to the Waltonian. I do not take it that

X Door for lamp.

A Boiler. B Steam-chimney opening into middle of box through zinc tray. C C C Zinc tray. D D D Outer cover to boiler, through which the heat is conveyed from the lamp round the boiler, and the smoke out through E. F Lamp for heating boiler. E Tap to draw off the water, and if the mouth of the tap be turned upwards, and a long-tubed funnel used, the boiler might be filled by it.

a few inches more or less in the length, or breadth, or height of the Case would signify much in practice; but as this notice of it is to take in the cream of what has already appeared about it, I may as well give the exact dimensions, which are as follows:—The box for the tin case is 34 inches long, 17 inches wide, 13 inches deep in front, and 18 inches deep at the back—all inside measure. Such a box will hold three rows of No. 48-pots, and six pots in a row. When making a smaller or a larger box one ought to fix on how many of these two sizes of pots the box would hold conveniently without loss of space. An amateur should never use a pot larger than a 48-size for striking cuttings in, and that size is large enough for all his seeds. But more often a No. 60-pot is even better for seeds and cuttings than a bigger one. As long as the sun would keep up the heat inside the Case above 70° there would be no need of the lamp burning,

and if the water got cold in the meantime, if the moveable "chimney" is heated over the lamp, the air or draught is as safe as if the lamp had been burning the whole day.

A Gas jet under the funnel-head. B Coil of zinc tube, 1 inch in diameter. C Lid covered with sand. D Pots of cuttings or seeds. E Vapour-tube. F Smoke or smell-tube.

In very dry sunny weather the sand under the pots—say half an inch thick of sand—should be damped after breakfast, and let get dry before night, and in dull weather the sand to be constantly dry, and the temperature not higher than from 75° to 80°; but in the sun it may rise to 90°, or above it with air on. In a dull season it would be better to lift out the pots to water them instead of risking too much moisture inside from the drops or the spilling, which is not easily avoided. Like all things else in this world, one expense brings on another, and the Waltonian must have its own share. You must have a rough packing-case, with large loose squares of glass to cover it, or a polished one of exquisite make and finish, if you work drawing-room fashion.

This second case you must call by its proper name, else be out of fashion entirely—the cold case, which is here equivalent to the cold pit in the framing-ground. In this cold case, all seed-pots and cutting-pots are to be removed for a few days to get more air to harden them a little before they are parted for single pots, or for four or six or so in a pot. This, no one can overrate the advantage of—it is the marrow and the backbone of the whole concern. The cold box need not be deeper than just to hold the sizes of pots which are used in the hot case, and so as to have the heads of the cuttings not touching the glass covers; but it may be as deep as thought for all that if you put shelves in it to raise the seed-pots and some kinds of cuttings up near the glass. In that case when you potted the things off, the bottom of the deep box would be just the very place for them for two or three days till the little things pricked up their ears again, and were fit to be set on shelves in the greenhouse, or wherever one had the means of keeping them till the frost was over.

If I had been working a Waltonian in the drawing-room, or even up in the nursery, as "Flora" is just doing now, I should have my hot case and my cold case made as smart as the rest of the furniture, and I would keep them going there at full speed the whole year round. I knew all along that could be done; but then I have kept that to myself, thinking it was better first to learn to creep before attempting to walk; but seeing, or, rather, hearing the age of going on all-fours was over, and that several attempts at going right ahead across the whole breadth of the carpet without a hitch or a hop have been accomplished, I would have an attempt at it too.

Then the Waltonian Case shall be my stove for Ferns and foreigners of that ilk, and the cold case would be my conservatory, and the conservatory would be a little higher in the room than the stove case; and I would have another moveable tube to let pass some few degrees of extra heat from the roof of my stove into the bottom of the conservatory in very hard weather. And if anything was ever better done in this world, than all that would be, exactly as I put it, why I would try and see it, and find out the difference, although I cannot see at the moment how anything could exceed my own notion. Indeed, to tell the truth, a very rough-ready notion of the kind has been in use under my roof for some years past, and I have found it a source of never-failing interest, and of some good luck to the bargain; and I can see no more reason why a Waltonian should not be made an evergreen in the drawing-room than Tam O'Shanter should be "fou" on market-days from November to October.

But there is another Waltonian-garden contrivance for the

sheltering of fruit-tree blossoms, and for other moves in that direction, which I am perfectly sure will come into as universal acceptance as a new evergreen yellow *Mesa Rose* would be sure to do, if it were as certain as that I have no more room to say it to-day.

D. BEATON.

### MR. J. STANDISH'S, BAGSHOT AND ASCOT NURSERIES.

THERE is an empire on the far confines of the eastern hemisphere, of which, in our school days, little but the name was known. The passing navigator, traversing those distant seas, might view from afar its snowcapped mountains clad with a luxuriant vegetation full of strange forms; but woe to him if he ventured on its shores—he never returned to tell the tale, and the world went on no wiser than before—a good, easy-going world, that thought the perfection of travelling was comprised in the "Flying Comet" at ten miles an hour.

It was a country that had never been penetrated by the traveller, the soldier, or the priest; a country from whose inhospitable shores even ambassadors were driven away, or sacrificed to the genius of exclusiveness which repelled all intercourse with European nations. Our phlegmatic but thoroughly commercial neighbours the Dutch, had, it is true, by dint of much perseverance and many humiliations, obtained a footing—a few square feet of ground, with liberty to freight two ships a-year with the products of the country. But they were treated like prisoners, and never allowed to pass beyond their allotted bounds, so that their residence added little to our knowledge of the country.

This empire, it will already have been conjectured, is Japan.

A new order of things has now been inaugurated, not without severe struggles, and the ports have been at length opened to commerce. Seizing the opportunity, Mr. Fortune, whose indefatigable exertions in China are everywhere known, hastened to explore this virgin and fertile field; and penetrating in search of objects of horticultural interest where European foot had never trod before, he has gathered a rich harvest which he has committed to the able hands of Mr. Standish, of Bagshot.

To some gleanings from this we now seek to call attention.

There is a plant—familiar even to those least versed in plant learning, which is to be seen in the smoky squares in London, or breathing the clear air of the country; dingy it may be in the first case, and showing a fresh morning face in the other; which is to be found in every garden, and which succeeds well in all, alike resisting cold and heat, wet and dryness. This is the *Aucuba japonica*, or rather a variegated variety of that plant, for that which has been so long known under this name is merely one of many such varieties only now brought to light.

The true *Aucuba japonica* is not variegated, but has beautiful shining green leaves which, when young, are of the brightest colour; and when the female plants are impregnated, it will possess an additional charm in being covered with its large red berries. It may safely be predicted of this new introduction, that in a few years it will be planted in every shrubbery, where it will be quite as valuable as the common Laurel, and, like it, will form admirable hedges. For planting near London and other large towns it will prove invaluable, for the leaves will not look dirty so soon as those of the bleached-leaved sort.

Such a shrub as this is alone an ample recompense for Mr. Fortune's journey, being, as it undoubtedly is, one of the greatest acquisitions among hardy shrubs that has been made in our time.

The male *Aucuba*, which is also in Mr. Standish's possession is, as far as its general appearance is concerned, but little, if at all different from the female. Its great value lies in its producing long catkins of flowers, somewhat like those of *Garrya elliptica*, by means of which the female plants may be fertilised and enabled to produce their beautiful berries. It is very scarce even in Japan, where it is only propagated for this purpose; but in a few years, when it shall have become sufficiently disseminated, there is no reason why every female plant in the country should not be covered with fruit.

But besides these two important acquisitions, Mr. Standish has several remarkable varieties of the same plant; one of which, called the true *Aucuba japonica variegata*, has dark green foliage, with curiously branched yellow marks, painted, as it were, in the centre of each leaf. Another, the toothed-leaved *Aucuba*, has a large leaf, with a golden blotch painted in the

centre of each leaf, and occupying about one-half of the entire surface.

There is also a sort with a long, narrow leaf, with some variegation upon it; and a variety with large leaves, edged with white, which is stated by Mr. Fortune, who brought it home himself, to be a magnificent plant; but of course it is not as yet in a condition to allow of an opinion being formed as to what its ultimate appearance will be; that it has a white edge however, is certain.

The variegated Holly has been justly considered one of the best of our hardy variegated shrubs, but it is very difficult to grow in many soils; for such, therefore, a plant that would grow freely anywhere and still preserve the general aspect of the Holly would prove extremely useful. This want, it is expected, will be supplied by the new *Osmanthus*es from Japan, which have all the appearance of a Holly, and are said to grow as freely as the Privet.

There are, in the first place, the green-leaved species, *Osmanthus ilicifolius*, which a casual observer might easily mistake for a Holly, and its dwarf variety.

Then there is the *Osmanthus ilicifolius variegatus*, like a variegated Holly, but having leaves of a brighter green with white variegations. This kind attains the height of 20 feet or 30 feet, and is altogether very effective.

*Osmanthus ilicifolius variegatus nanus* is a dwarf variety, with foliage like that of the preceding, and closely resembling a miniature Holly. It is likely to prove a most useful substitute for the Holly, and to make capital edgings.

The gold-variegated *Osmanthus* is another beautiful dwarf plant, the foliage being very dark green with golden yellow variegations.

*Osmanthus diversifolius* is a plant more curious than beautiful, the leaves being of all shapes with whitish variegations. It is very dwarf.

A dwarf and very shrubby *Ligustrum* or Privet, with oval leaves as thick as those of a Holly, and of a shining green, is a really important addition to our stock of dwarf shrubs, and in the hands of the skilful gardener it is likely to prove of great value in flower-garden decoration.

There was likewise a variegated Privet, probably a variety of the preceding, having the foliage beautifully variegated with bright golden yellow, some of the leaves being entirely of that colour. The whole appearance of the plant is very handsome.

*Buxus obcordata*, and its variety *Buxus obcordata variegata*, are two handsome species of Box with very short obcordate leaves, those of the latter being variegated with yellow. Both are likely to be very useful for edgings, &c.

A species of *Illicium* with oblong greyish-green leaves had these variegated with rose colour when young; but those of greater age were painted with white. This will, probably, reach the height of 4 feet or 5 feet, and will form a pretty object in spring.

Of *Skimmias* there were three new sorts—a new species, unnamed, with larger and thicker leaves than the old kind. The fruit is also larger, depressed, globular, and of the same ornamental character as that of the one previously introduced.

There were, besides, a new kind remarkable for its free habit of growth and which quickly forms a large bush, and a variegated form of this with dark green and white leaves.

Of *Euonymus* there are several kinds. One with larger and thicker leaves than japonica, of a bright glossy green with golden variegations, is said to be a very free grower. Another has pale green leaves much covered with white at the edges, and viewed from a distance it appears quite white. Lastly, we have a climbing species with ovate leaves variegated with yellow, and being of rapid growth it will, should it prove perfectly hardy, supply a great desideratum in the shape of a variegated climber for out-door decoration.

Another handsome novelty is a *Cerasus*-looking evergreen, with long lanceolate leaves, calling to mind those of a Bird-Cherry; but green strongly edged with white, some of them being quite white. This will evidently become a tall tree, when it would form a beautiful object on a lawn. *Eurya latifolia variegata* is another valuable shrub coming from Yeddo, and which will, in all probability, prove quite hardy. The foliage is broad and Camellia-like, beautifully margined and blotched with white, stained here and there with reddish-orange, and has a patch of green as if painted in the centre of each leaf. The young leaves, however, are entirely rose-coloured.

Mr. Standish thinks the plant will grow as large as a Portugal Laurel; if so, it will have a splendid appearance when its young leaves are peeping forth from among the older white foliage.

There is also a pretty shrub, which may for the present be distinguished as the small-leaved variegated *Eurya*, with long, narrow, deep green leaves, more or less broadly edged with white, some of them being altogether white.

We also noticed an *Eurya*-like shrub with curiously shaped leaves, no two of which were exactly alike. Many of them had the appearance of an oblong-oval, with a piece bitten out of the side. The older ones were much variegated with white, and the young ones being pink, it will be readily conceived that the whole aspect of the plant was very interesting.

*Ilex Fortuni*, a new evergreen, is another invaluable addition to our collection of hardy shrubs; it is thickly set with small, glossy, dark green leaves, which shine like varnish, is of rapid growth, and stands clipping into any desired shape. It is, therefore, admirably adapted for hedges; those which are formed of it in Japan are, we are told, so close that one may walk on the top—and, of course, the sharp apices on the leaves render such a fence totally impenetrable to the boldest would-be intruder. Now that geometrical gardens are coming so much into fashion the want of a good hedge plant, more lively in appearance than the Yew and more rapid in growth than the Box, is much felt, and this want the new species is expected to supply.

A new *Pittosporum*-like plant, with glossy oval leaves, was likewise pointed out to us; its foliage was handsome and of great substance, but of its ultimate appearance and the character of the flowers, no opinion can as yet be formed. The same may be said of a new *Berberis* with dark green leaves, smaller than those of the Chinese kind; it is a free grower, and will probably reach the height of 6 feet or 8 feet.

In the above rapid sketch we have far from exhausted the rare and valuable plants which are contained in Mr. Standish's extensive grounds. There remain the magnificent Umbrella Pine, the *Reticosporas*, and other *Coniferae*, with many more of other families, to the notice of which we purpose devoting a second article.

(To be continued.)

## USES OF THE MISTLETOE.

I HAVE been where it is grown to a great extent, and bundles have been cut out of the Apple trees and thrown away because it was killing the trees. Now, I know that it sells generally very well about Christmas, for that season's decoration, but some may not know that the leaves are used to make tea of for people that are troubled with fits.—W. H.

[Gerarde says, that if the juice of the berries and leaves be applied outwardly, it mollifies old ulcers, and mixed with opiment "taketh away foul, ill-favoured nails," and that "a few of the berries bruised and strained into oil, and drunken, hath presently and forthwith rid a grievous and sore stitch." Dr. Hogg in his "Vegetable Kingdom," observes—"The fresh bark and leaves have a peculiar disagreeable odour, and a nauseous, sweetish, slightly bitter taste. The leaves and wood were at one time highly esteemed as a remedy in epilepsy, palsy, and other nervous diseases. Birdlime is prepared from the berries and bark boiled in water and then beaten in a mortar."]

## WATERING AND STOPPING VINES IN POTS.

I AM growing some Black Hamburgh Vines in pots; they are just in the berries, and looking well, as far as I can judge. Will you give me some information as to their treatment—whether they will require any water, what quantity, and what sort it should be? I have stopped each shoot close to the bunch, is that right?—A SUBSCRIBER FOR MANY YEARS.

[You ought to have left one if not two joints beyond each bunch; but as you have stopped each shoot down to the bunch, you had better encourage the laterals from that bud to grow a little to keep up brisk root-action. The plants will need watering, especially before the bunches are well swelled and getting ripe, when less will be required. No one can tell you what quantity to give or how often—that must depend entirely on circumstances. In cloudy damp weather once in seven or ten days might do. In bright weather in April and May the Vines might need watering once a-day, and sometimes oftener. Weak

manure water will be best, and the sorts are all good if used discreetly—perhaps the superphosphate of lime is the safest and best. Of course, if your pots are plunged, less water will be wanted than if standing on a stage or shelf.]

### FORCING VINES IN POTS.

I HAVE two dozen Vines in pots from eyes last year. I cut them back in the autumn, and started them in January in a temperature of 60°, raised to 70° at the end of January, and kept to that heat, with a rise of 5° to 10° with sun heat, and 65° at night. I started them earlier than I wished, because I have to grow Cucumbers in the same house. The Vines are 6 feet long, and I wish to fruit them next year. I find they do not grow much, and lately they are turning brown. Will you please inform me how to act with them? Have I given them too much heat?—T. H. J.

[You should have started the Vines more gradually, beginning with from 45° to 50°; but we do not think there is any harm done. It is too soon to stop growth. If 6 feet is long enough nip the point out of the shoots, and when it pushes let it grow several joints, and nip again; and so on. Do the same with the laterals at each joint. If there are none or few now, the stopping of the shoot will cause them to come. Give plenty of air and manure water in such heat, and by the end of July you may begin to thin out and cut back laterals; then in the beginning of August get your plants for a month against a south wall or fence, and after that rest them where you like behind a wall until you want to force. The wood, we presume, will be ripe enough. If getting brown now, we think you must have neglected watering, &c.

The tuber pressed quite flat we deem to be *Tropaeolum tuberosum*. If you want to bloom it, give it plenty of top room, and keep the roots in a pot.]

### CROCUS IMPERATI OR IMPERATONIUS.

WILL you inform me where I may procure roots of *Crocus Imperati*? The *Crocus* referred to is a bright purple inside, lighter outside, and shaded into yellow. I found it growing in old mossy walls and rocky banks, in full flower early in January, 1859, in the Valley of Ravillo, Anagni, and in one or two other places in the South of Italy; but few of the bulbs I brought home lived, and they have not increased, though two of them flowered in a cold frame this winter the last week in December. Both the beauty of the flowers and the season of flowering render them most desirable plants, and I am anxious to obtain enough to be of some use, but cannot find a nurseryman who sells them.—JANE.

[What you mean is *Crocus Imperati*, or *Imperatoni* (*Imperato's Crocus*), which, also, you may find under one of its other names *C. incurvus*, and *C. recurvus*. We do not know where it is to be obtained, but some of our readers may be able to tell you. There is a drawing of it in the "Botanical Register," 1993, with this note:—

"For the specimens of this charming plant I am indebted to the Hon. W. F. Strangways, who has furnished me with the following note upon it:—

"*Crocus Imperati*, so named by Professor Tenore, after an old Italian Botanist, *Imperato*, is, perhaps, the most beautiful of the genus. It varies greatly in the size of the flower, which is sometimes very large, and rises from a double spathe; the bulb, which is covered with irregularly interwoven fibres, is comparatively small.

"Although it belongs properly to the set of vernal *Crocuses*, it seems to connect them with the autumnal, beginning to flower in the middle of winter. It is fortunate that, flowering at such a season, it requires less sun to expand its blossoms than any other species.

"It increases readily by seed, which ripens in May. The diffuse character of its leaves, which are of a dark green, and appear long before the flower, is one of its distinguishing marks: seen before the buds appear, they might be taken rather for the leaves of some autumnal species that had done flowering, than for those of a spring *Crocus* coming on.

"The variety *albiflorus* is the most beautiful of the white *Crocuses*—it is rather more decidedly vernal than this, which is the common form of the species.

"There has been much controversy between Italian botanists on the identity, as a species, of this and *Crocus suaveolens* of Bertoloni, of which a short notice is given below.

"The habitats of these *Crocuses* are—*C. Imperati*, of this figure, in profusion all about Castellamare, La Cava, and Salerno, and other parts to the south of Naples, in every hedge bank to the height of 2000 feet or more above the sea. It is wonderful that so fine a plant has not attracted more notice in such a frequented country.

"*C. Imp. albiflorus* is rare, and found much higher up the mountains.

"*C. suaveolens*, *Bert. Fl. Ital.* is found in the pass called Le Gole d'Itri, near the town of that name; and also in the Valle d'Inferno, about two miles from Rome, behind St. Peter's.

"*C. suaveolens*, *Bert. Fl. Ital.* has the petals lanceolate, pointed; the spathe one-leaved; the stigma filiform, pale orange or yellow. It is sweet-scented; the leaves are short, appearing with or little before the flower. The petals are seldom finely veined as in *Imperati*; it blossoms regularly later in the spring, February and March."]

### PROGRESSIVE VARIEGATION.

I THOUGHT the enclosed leaf and a few words about it might interest you. It is a leaf of a cross between Flower of the Day and Tom Thumb. I have had it three years, keeping it with an expectation that it would turn to something; but it remains as fixed as any other variety. I crossed it last year, and it yielded just what I liked to have it—white or yellow variegation, or plain green, thereby producing a string of facts, to my mind conclusive, that variegation is perfected by degrees. But how the first degree of it originates, or what is the cause of it, at present remains the mystery.

Perhaps you will say, Circumstances alter cases, and the same results could not be produced in a different place. Well, having received much pleasure and profit from the labours of your pen, I thought if I could yield you a mite in return I should have very great pleasure in doing so.—WILLIAM SMITH, York.

[The examples of variegated leaves alluded to by Mr. Smith are really very interesting, and I am much indebted to him for sending them. There was a collection of the very same kinds of variegation, but of many more kinds, exhibited by Mr. Lennox at a May Show at Chiswick just before the Russian war. None of the plants were in bloom; but I think Mr. Lennox had a prize for them. Mr. Smith's argument on progressive variations through successive generations, or, as he says, "perfected by degrees," is well borne out by the samples he sent. But then the very contrary is just as common—that is to say, the most perfect variegation we know in *Geraniums* has been obtained at once without going through progressive stages.—D. BEATON.]

### EDINBURGH HORTICULTURAL SOCIETY'S HYACINTH AND SPRING FLOWER SHOW.

THE Edinburgh Horticultural Society have conducted their spring shows with much spirit, and they certainly have had their reward. Not only have the exhibitors increased in point of excellence year by year, but the public have come forward, in spite of the inclemency of the weather, in increasing numbers, until the magnificent Hall, apparently commodious enough in years bygone, is filled to overflowing, and not a few compelled to forego the pleasure of inspecting, in a manner satisfactory to themselves, the several meritorious subjects placed upon the tables. Owing to the peculiar arrangement in the placing of the tables, there was such a rush and a crush in the labyrinthian passages, which, to the lookers-on in the gallery, was suggestive of a wading through the Hampton Court maze; still, what with looking at any flowers they could see, and at one another, and anon listening to the stirring strains of music so masterly discoursed all seemed well gratified.

The Hyacinths were, unquestionably, finer than they have ever been exhibited in Edinburgh. Thrice has the champion of the southern growers (Mr. Cutbush) laudably crossed the Tweed and pitted himself against northern growers, and twice has only come off second best in the attempt. It certainly would have required an extraordinary effort to have eclipsed the superb collection of Cartairs & Sons, and James Dickson & Sons, on

this occasion. The plants, as individuals, were beautifully grown, having fine dark green foliage, stiff and sturdy grand pyramidal heads, and the pips horizontal and well defined. Their dress and finish, in fact, were almost all that could be desired, and reflect much credit upon the respective exhibitors who were placed first and second in the order they are named. The premier lot contained Von Schiller (the colours will be found in any nurseryman's catalogue), Mr. Macaulay (one of the most striking varieties in the hall), Count Carour (with a head of bloom  $8\frac{1}{2}$  inches deep, of perfect asymmetry), General Havelock, Cavaignac, Grandeur à Merveille, and double Lord Wellington. These were extra in whatever way the censors examined them. The others were Grand Lilas, Miss Nightingale, Alba Maxima, Clotilde, Seraphine, Charles Dickens, Maria, Prince Albert, Lina (a really chaste variety, but rather delicate in corpulence), Alba superbissima, and Mrs. Beecher Stowe. The second lot only differed from the above, in having Mont Blanc, Mimosa, P'Etincillante, and Queen Victoria.

Gardenera were also unusually well represented, Messrs. Walker and Henderson, as usual, carrying off the best prizes. The former gentleman had very handsome spikes of Cavaignac, Poniatowski, Madame Hodson, General Havelock, Grandeur à Merveille, and Von Schiller. The latter was singled out as the best Hyacinth in the room, either double or single, and Carstairs and Son carried off the premium for the best double Lord Wellington. Amateurs were also in strong force with pot Hyacinths; the Secretary, Mr. Young, carrying off premiums for the best six. However, an amateur from Trinity, whose name we regret we did not learn, had six most wonderful examples growing in glasses, eclipsing by odds anything that was exhibited or ever has been exhibited in this way. They were, we learned, his first attempt, and this only shows the glorious uncertainty of backing the winner for another year. Their names were Alba superbissima, Miss Nightingale, Baron Von Tuyll, Grand Lilas, Grandeur à Merveille, and Von Schiller.

Passing from Hyacinths to Camellias, Mr. Stark showed a very creditable twelve—Candidissima, Fra Arnold di Brescia (red with white stripes), Ocbrolenca, Hendersonii, Valteverado, Alba Plena, Archduchess Marie, De la Reine (fine smooth white, of good substance, and fine-formed petal, with faint carmine stripe), Saccò Nova, Picturata (good bold crimson), Guiardino Franchetti, and Emilia Campioni. The best blooms in the other lots differing from the above were Bernetii (large showy crimson), Duchess of Buccleuch, Frostii, and Jubilee.

Rhododendrons were largely exhibited, but not calling for any special remarks. The best were Prince Camille de Rohan, Bouquet de Flore, Grand Arab, Altaclerense superba, Albertus superbus, and the finely perfumed Edgworthi.

Azaleas were not exhibited in large numbers, but were very good. Mr. Henderson showed a fine pair very nicely bloomed—Criterion and Iveryana.

Heaths were extra fine, especially the premium pair Sindryana and Cavendishii, both full of bloom, and measuring 4 feet by 3 feet.

The best Cinerarias were Dr. Livingstone, Brilliant, Midshipman, and the old Sir Charles Napier.

Bouquets were briskly competed for, and upon the whole did not exhibit any marked degree of taste, with the exception of one that was disqualified, from Mr. T. H. Douglas, owing to non-conformity with some of the regulations. It was really a chaste, handsomely-got-up bouquet, each flower standing out individually in harmonious contrast with the other, and yet not too loose. Its chief features were Camellias half expanded, Azalea amœna, the pretty Melanthera Heath, and a few fronds of Asplenium trichomanes interspersed.

In hardy spring bulbs there were one or two interesting collections, comprising Scilla bifolia (blue and white), præcox, and the lovely sibirica, Muscari botryoides, Iris reticulata, Narcissus minor, Erythronium dens-canis, &c.

Vegetables were very well represented, more especially in the collections of Messrs. Thomson, Dalkeith and Woodburn. The former gentleman had fine samples of French Beans, Asparagus, Mushrooms, Spinach, Onions, Leeks, &c.

The several nursery firms had contributions, which added much to the general appearance of the Show; but there was a particular selection of choice things sent from Dalkeith which deserves to be particularised as showing what is doing and what can be done among the rarer samples of Flora in the "heart of Mid Lothian." Ranged on one of the centre tables were two or three specimen Acacias, two or three extra specimens of the horned Orange, one of the plants having twelve fruit upon it, and one

of the samples measuring  $12\frac{1}{2}$  inches in circumference. Also the Bird's-nest Fern, Pilea moschata, Coleus Verschaffelti, and Alocasia metallica, with nine leaves of nearly uniform size, one of them measuring 17 inches by 11 inches—a very grand example of this striking novelty. Among Orchids were Phaius grandiflorus, Zygopetalum erinitum, and cut spikes of Vanda suavis (Rollison's var.), Trichopilia suavis with five blooms, and one bloom of the interesting and lovely Uropedium Lindenii with its long appendages.

The Exhibition caused quite a sensation amongst the good folks of Edinburgh, and was the means of completely barring the traffic in this direction.

An extra award and the highest commendation of the Judges were unanimously voted to Mr. Methven for a species of Rhododendron from Bhotan named longifolia. This variety has a fine rounded petal in the way of Dalhousianum, French white, with a rich chocolate blotch at the base of each petal internally; tube  $2\frac{1}{2}$  inches long; foliage glaucous, silvery underneath, and fainter downy above. An extra award was also voted to Mr. Rose, of Floors Castle, for a nice example of retarded Lady Downe's Seedling Grape, which had been cut and preserved in the fruit-room for the last six weeks.

Mr. Thomson, Dalkeith, was successful with a nice bunch of Lady Downe's, also retarded, and the footstalk so green that it might have been considered an example of his early-forced varieties which he told me were all cut. He also was successful with a Pine and a dish of Strawberries.

Mr. Thomson, Woodburn, showed a mixed dish of Apples in good condition, containing, among others, Northern Greening and Yorkshire Greening.

## NEW BOOK.

### CRANSTON'S PATENT BUILDINGS FOR HORTICULTURE.

THIS neatly got-up eighteenpenny monograph, consisting of some forty pages of letterpress, and eight plates, some of them showing the outlines of several houses, is sent out by Mr. Cranston, the eminent architect, of No. 1, Temple Row West, Birmingham, and should be studied by every gentleman intending to build glass houses, and by all gardeners, and especially those who may have to manage such houses.

Besides the beauty of the designs, formed in the most simple manner of wood and glass, the lovers of the novel may well be satisfied, as the mode of construction, so far as we are aware, is entirely new. The chief characteristic novelties are two—First, the forming of the roof, be it high or low, lean-to or apan, the space enclosed wide or narrow, by means of horizontal longitudinal radial ribs, in other words, rafters placed lengthwise of the building, standing on edge, and some  $3\frac{1}{2}$  feet or more from each other, and connected by the more vertical rafters, or what gardeners would call sash-bars, the lower end fixed to the outer edge of the radial rib, and the higher end to the inner edge of the rib above it, as at A, so that the glass between each pair of radial ribs is formed into a plane of a different angle from the rest, instead of any one or two uniform slopes, and thus nearly all the advantages of a curvilinear roof are obtained, without the necessity of using bent or curved glass. (See accompanying lithograph.)

The second great characteristic novelty is, that these radial ribs are pierced with holes from 2 inches to 3 inches long, and

half as much in width, for their whole length, the holes being somewhat vertical in the depth of the rib, but becoming somewhat horizontal when it is fixed in its position—a matter of considerable importance. By these ribs, therefore, alike the supporting and ventilating medium of the building, a regular and uniform amount of air is admitted to all parts, and the quantity can be easily regulated by caps and slides inside; though, as all lines, pulleys, rods, cranks, &c., are dispensed with, we presume some other simple mode is adopted for opening and shutting the multitudinous holes.

With a little contempt for cheap orchard-houses, &c., very excusable in an architect, Mr. Cranston, without giving us any estimate to enable us to form comparisons, deserves credit not only for producing a substantial elegant building, instead of one of a meagre makeshift appearance, but also for the great economy of its construction, arising from its being put together with screws, and, therefore, easily reared and easily taken down, and from the entire absence of framed joiner's work—such as sashes, either sliding or fixed, with all morticing and tenoning, and other expensive workmanship, &c.

The glazing for common purposes, where great heat is not required, is effected without putty and without laps, each pane being glazed with squares of that length across, the top end going into a groove in the rib, and the sides into grooves in the rafter sash-bars, and the pane is prevented sliding downwards by a wooden nut fixed with a screw on the end of each of these rafters, which when turned longitudinally keeps each square in its place, and when turned the other way allows the squares to drop out. But for dust filling the grooves, and the screws rusting, there would, therefore, be little difficulty in moving a house, and the tenant question is met by putting nothing when desirable in the ground but stout posts, on which the base planks for the house are fastened by spikes or screws. Except for exotic tropical-houses, Mr. Cranston looks on stone or brick ends and sides for glass houses with abhorrence, and tells us in a burst of enthusiasm, that "A house almost entirely of glass, rising in a curvilinear shape out of a green lawn, with no horizontal patch of brickwork, no heavy timber, no flaps or shutters gaping outwards to form holes for rain and wind, is a building, the beauty of which must be seen to be understood, for mine at least is not the pencil adequately to portray it." Though not thoroughly agreeing in the implied censure, we can help sharing the enthusiasm of the author, merely on the principle that fitness for the object aimed at is ever in itself an element of the beautiful, though we are well aware that such light-looking structures would be considered by many much on a level with a huge hand-light that had little claims to artistic merit.

Leaving, however, these and other matters glanced at, we think the twofold purpose of radial ribs is the great feature of this new system. For giving, to a great extent, the advantages of curvilinear roofs with straight glass, we question if for small houses it would be found superior in that respect to the mode adopted by Mr. Niven (see page 215), though for large wide houses we rather think it would; but we possess no means of deciding. Without, therefore, troubling ourselves as to priority of invention, the great characteristic of this new system is ventilation by every radial rib used in the building. With every allowance for its merit and ingenuity, we think the onslaughts on present systems might as well have been spared. We have extracts from Dr. Lindley, "The Book of the Garden," and Mr. Walker, showing that though provision is made for great blasts of wind, and plenty of rain and snow, that yet under present systems there can be no thorough regularly diffused change of air on a scientific and natural principle. Anything of this nature just leads people to ask, Where is the house or the room so nicely ventilated for human habitation, with the walls pierced all round with parallel rows of holes; and how has it come to pass that by such barbaric modes the British gardeners have produced fruit and flowers finer and richer than when gathered in their own natural homes? It is one thing to have openings sufficient to counteract strong sunshine, and another thing the opening of them to their full extent in a storm. There are plenty of simpler modes, alike to keep out a gale of wind, and give air in wet weather without admitting the rain. Changing and freshening the atmosphere of a house is not quite the same thing as admitting air somewhat regularly from almost every part of its roof. We need not dwell on the fact that heated air will ascend, and that openings at the apex, and small ones too, alone will change the atmosphere, and set the whole of it in motion. Look at the simplicity

of the modes adopted by such men as Mr. Rivers and Mr. Niven. Is it likely they would use them if they did not answer? "Good wine needs no bush"—a good system will always get feet to stand upon.

With much to admire in this new system, I confess that I should be afraid that in many circumstances, if all the rib ventilators were open, the higher ones would be safe enough; but the streams of air passing through the lower ones, would carry destructive, cold, freezing air along with them.

Paradoxical though it seem, the larger the house, the greater the amount of atmosphere enclosed, the less care necessary to attend to the minutiae of ventilation. In span or circular houses like the one represented, the air-power may be sufficient. In a lean-to of moderate size, we fear there would not be near enough, and the danger would be apt to occur that happened with curvilinear houses when first built. Take one side of the pretty lithograph, and suppose an opaque wall runs up the middle; and then for a sheet of glass of some 14 feet exposed to a bright sun, there would be only from 6 inches to 7 inches of space for ventilation in all the holes combined. The plan with all holes open seems well fitted for large houses, as orchards, summer pavilions, and crystal palaces. It may be owing to ignorance or preconceived notions; but were I using such houses for early forcing, I would be inclined to go on in the old jog-trot way until learned better; and that would be leaving a few holes in the upmost rib open all night, opening more in the morning, getting to the second rib as the sun gained power, and so on to the bottom, if we reached there at all, which would only be in very fine days. Mind, I by no means presume that I should be doing the best; Mr. Cranston may easily show it would be all wrong, and thus throw fresh lustre on a system which has so much to recommend it.

I fear that these trifling objections are mere matters of fancy, or that Mr. Cranston will make them so by suitable adaptations; and there is much in the mode worthy of all approval. Little or no rain can be driven in, the air is so far sifted through the holes in the course of admission, it will rise somewhat against the inside of the glass before falling among the plants; and, before entering the house at all, it will be somewhat heated by rolling against the plane of glass immediately below the ventilators, and then, a grand idea to many—the air, when desirable, may be admitted pretty equally all over the house. We trust that the genius, thought, and consideration employed in effecting a novel combination of the elegant and substantial, suitable alike for tenant and landlord, will meet with its due and legitimate encouragement.—R. F.

## WILD FLOWERS OF GREAT BRITAIN.

BEING a subscriber to your "Wild Flowers of Great Britain," I could wish to make a note or two upon the same. I much approve of it, and think the plants are beautifully represented as to correctness; and would now add my notes.

*Tulipa sylvestris*.—I think the plate would have been more interesting if you had shown the long stout fibre from its root, at the extremity of which the young bulb appears. It was from the knowledge of this that I found it near Gloucester, having never seen it in blossom.

*Finea minor*.—I have a double var., colour blue, quite as free-flowering as the single var. A great pet with me.

*Ononis arvensis*.—The beautiful white var. you do not mention. In my botanical rambles round Gloucester (since a boy), I have only found one specimen which still continues in the same place (seed from which I enclose you). Query, was not the same plant advertised in THE JOURNAL OF HORTICULTURE as a new edging plant for gardens?

I have also found near Gloucester variety alba of *Lathyrus nissolia*, a beautiful native plant; but only in one spot.—G. S. WINTLE, Gloucester.

## ORNAMENTING A BANK BENEATH A LAUREL-HEDGE.

I HAVE a bank of Laurels planted to hide a very ugly wall on one side of the garden. I have had occasion to lower the lawn, leaving the Laurels 18 inches above: consequently, there is a bank of earth which, not having any support, is constantly crumbling down. I am going to put in a row of small barrels

that have had oysters in them, painting them bark colour; and I want a Fuchsia and climber in alternate barrels. I shall have *Lobelia gracilis* to hang over the outer side. The inner sides of the barrels will, of course, lean against the bank, and I want some rich-coloured Fuchsias that will show against the Laurels. Will you advise me as to the best Fuchsias for the purpose? I think I shall have from twelve to sixteen barrels; therefore, say six or eight Fuchsias. I should have *Maurandias*, *Tropæolums*, &c., trained to match the Fuchsias in height, or they might be allowed to run over the Laurels. What made me think of the plan was, that all things planted in front of the Laurels were starved from the roots taking the nourishment.—KATE.

[An original and effective idea. No wonder at the rapid rise of our flower gardens when all the ladies in the land bear us onward on the tide. This is the very best place in the world to prove how effective the best white Fuchsias are when they can be rightly used in the right place, the very front of deep green evergreens, and rising from a lower level. Never was anything better contrived. But all the white Fuchsias ought to be as high at the top, above the bottom of the evergreens, and their roots are lower than the top of the slope—that is, they should be a yard high at the time of planting out. But that cannot be this season, as "KATE" is now only looking out for sorts, and red ones will not do there on account of the *Tropæolums* being a muddle colour of red and orange. There is no addition since we gave the last account of white and red Fuchsias, save *Minnie Banks*, the very thing for such a bank as this. No more than two kinds of white Fuchsias ought to be used in this design for fear that a contrast in the growth of sorts should spoil the harmony of the real contrast between orange, red, and the green background.]

### NEW PANCRATIUM.

Is Mr. Beaton not mistaken about this new *Pancratium* from Manilla? I believe it is understood that *Pancratiums* are natives of the old world only, and the *Hymenocallis* are all from the western hemisphere, but I am not so sure of *Choretis* of which he speaks.—CLERICUS.

[Not so far wrong, perhaps, as it might seem on the face of it. I recollect when Mr. Cumming introduced his Manilla plants, some three or four and twenty years back, that one or two or more of his kinds of bulbs were detected at first sight as natives of the hottest part on the face of the globe, according to Humboldt—that is to say, natives of the Spanish Main on either side of Cumana, opposite Trinidad, whence they must have been taken to Manilla by some ship captain. The fact of a bulb being now found wild in a country, is not always a surety that it is a native of that country. The leaf of Mr. Veitch's plant is much more like that of a *Hymenocallis* than of a *Pancratium*. The cup is that of a true *Pancratium*, with the pair of teeth between the stamens, if we take maritimum to be the type of the genus; but the union of the stamens to the whole length of the cup to the limbs, and their conniving posture put it out of court against *Pancratium*, and the reflexed form of the segments of the perianth falling low behind the edge of the cup is a new feature in that class of bulbs. The seeds of *Pancratium* have a hard, brittle, shelly black coat. Those of *Hymenocallis* are like *Crinum* seeds, soft and fleshy as a Bean. *Choretis*, natives of Mexico and Texas, is the link between the west world and *Pancratium* (*Hymenocallis*), and the Peruvian *Daffodils* (*Ismene*).—D. BEATON.]

### MESSRS. A. HENDERSON & CO.'S, PINE APPLE PLACE.

OUR readers will probably recollect that Messrs. Henderson hold every spring a show of unforced Hyacinths at their nursery at Pine Apple Place, and from the high reputation which these gentlemen enjoy in the floricultural world, it will readily be concluded that any display which they invite their friends to inspect, must be far above mediocrity; nor will the visitor be disappointed in the splendid exhibition which they have this season prepared.

Few who have not been accustomed to such sights could fail at being struck by the brilliant mass of colour and tasteful arrangement which are seen on entering the *Lapageria*-house, where the exhibition is held; passing in doing so through an alcove hung with baskets of Ferns and other drooping plants.

Along the centre of the middle platform runs a row of Orange trees loaded with fruit, and two fine specimens of *Daerydium cupressinum* forming a background to a multitude of *Hyacintha* varying in hue from the purest white to the brightest rose and deepest blue. But not in these colour alone does *Flora* array herself, for like her animate sisters she must follow the fashion, and is now decked out in magenta.

The side shelves are filled with *Hyacintha* arranged in ribbons beautifully relieved by a fine collection of *Tulips* and *Narcissus*, the pots being everywhere mossed over, so that nothing but the bloom and foliage appear.

Conspicuous among all the rest were the magnificent vases of *Hyacintha* which gained the prize at the Royal Horticultural Society's Exhibition on the 19th. One of them filled with *Grand Vainqueur*, was a mass of snow-white bloom; the others contained *Emicus*, *L'Ami du Cœur*, and *Grand Vainqueur*, both separately and in combination.

Having thus endeavoured to give an idea of the general aspect of the show, which comprises an immense collection of the best varieties, it may not be without its interest to those who are unable to visit it personally, to point out a few of the most remarkable. These were:—

*Double Red*.—Duke of Wellington, very fine, maintaining here, as elsewhere, its position as a first-rate sort; *Grootvorst*, delicate blush, densely set with bells; *Princess Royal*, large bells of a deep pink, with a dark eye; *Susannah Maria*, and *Waterloo* or *Bouquet Tendre*, pink, changing to deep red.

*Double White*.—*Francina*, pretty blush, small bells; *La Vestale*, lily white; *Prince of Waterloo*, magnificent bells and spike, pure white; and *Triumph Blandina*, blush, with pink eye, very fine.

*Double Blue*.—*Bloksberg*, fine marbled blue, splendid spike and bells; *Laurens Koster*, *Mignon de Dryfhout*, and *Paquin*, pale blue, very good; *Sir John Franklin*, splendid marbled blue bells; *Van Speyk*, which is always one of the finest; and *Othello*, with large almost black bells.

*Single Red*.—*Charlotte Marianne*, fine striped red; *Diebitz Sabalskansy*, very brilliant; *Duke of Wellington*, large bells, rose striped with carmine, a fine sort; *Fireball*, compact bright crimson; *Florence Nightingale*, striped pink, large and very showy; *Herstelde Vreede*, bright pink, closely set with bells, *L'Ami du Cœur*, a showy variety; *Lady Morgan*, deep blush; *Mrs. Beecher Stowe*, a magnificent sort with the bells very closely arranged; *Robert Steiger*, crimson, excellent spike and bells; *Sultan's Favourite*, a splendid kind; also *Keime des Jacinthes* and *Queen Victoria*, two new and handsome varieties.

*Single White*.—*Alba Maxima*, with immense pure white bells, not unlike *Mount Blanc* in character, new and very fine; *Blanchard*, fine spike; *Cloche Magnifique*, waxy white, splendid bells; *Grand Vainqueur*, *Madame Van der Hoop*, and *Mont Blanc*, three of the finest of their class; *Premier Noble*, white; *Seraphine*, blush; and *Tubiflora*, all three very showy varieties; and *Victoria Regina*, a superb waxy white.

*Single Magenta*.—*Haydn*, mauve, tinged with magenta, had magnificent spikes; *Honneur d'Overeen*, also quite new, a very fine purplish-mauve or magenta; *Unique* is also a good distinct sort, of the same colour.

*Single Blue*.—*Baron Von Tuyl*, *Bleu Mourant*, *Charles Dickens*, and *Oroindates*, were all first-rate; *Emicus*, *Nimrod*, and *L'Ami du Cœur*, compact and very good. *Grand Vidette*, with its large porcelain bells, very showy; *Richard Cœur de Léon*, splendid violet bells; and *Robinson*, of a peculiar nomenclature blue are likewise very showy. In addition to these we noticed an entirely new variety called *Priestley*, with magnificent azure bells, white on the outside, and a very large spike; also, *La Nuit*, a new and decidedly fine sort, which, perhaps, more properly belongs to the so-called black class, as it is of a deep shaded violet.

*Single Black*.—Among sorts not noticed elsewhere, were *Lampflinger*, royal purple with white eye; *La Plus Noire*, *Mimosa*, and *Uncle Tom*, all of them very good; also, *Tombeau de Napoléon*, with splendid spikes and deep indigo bells; and *Siam*, a new variety which we have not met with elsewhere, in colour royal purple approaching to black.

*Single Yellow*.—*König van Holland*, reddish-yellow; and *Overwinnaar*, lemon, are excellent; *Heroïne*, is a nice pale yellow; *Anna Carolina*, lemon; and *La California*, nankeen, are also very good.

The *Lapageria rosea* which covers a large portion of the roof

of the house, and is now developing its magnificent bell-shaped flowers, is believed to be one of the largest in the country.

In addition to this, there were hanging-baskets made of a kind of pottery, in what is termed the Indian pattern, and which being chaste in colour have an elegant appearance in conservatories and rooms. Some models of fountains taken from the designs of those in ancient cathedrals and churches, executed in a kind of soft-stone-ware, and filled with Hyacinths, were likewise exhibited. These, we were told, are intended for dinner-table decoration, and being comparatively inexpensive, it is expected that they will supply a desideratum to those who are unable to afford the more costly ornaments and the gorgeous foliage-plants which are only within the power of the rich. But without seeing them in their proper position it is impossible to say what their effect would be.

Although no part of our intention to give any detailed report of the remaining portions of the nursery, we could not refrain from visiting the other houses and making a few notes.

In the Camellia-house was a fine collection of all the leading sorts, such as Duchesse de Normandie, Donecknari, Mathottiana, with immense deep scarlet blooms; Candidissima, very fine; a fine plant of Storyii, 6 feet to 7 feet high, and covered with flowers; Chandleri elegans, Prince Albert, Sacciana, &c., in pots; and planted out were Eximia, Jubilee, Augustina Superba, Albertus, and De la Reine, with superb waxy-white flowers, all of them particularly fine both in the size and colour of the bloom.

In the fernery, suspended from the roof, were fine baskets of *Goniophlebium subariculatum*, and *Davallia bullata* which has very handsome foliage; also *Anaspeltis vacciniifolia*, an exceedingly fine Fern, with long downy tails which, when full grown, are stated to reach 10 feet in length; *Brainea insignis*, the young fronds coppery, the older of a lively green, spreading about 4 feet across, and gracefully curving outwards; a very large plant of *Drynaria morbillosa*, with stiff, slightly curving fronds, extending about 7 feet, and closely dotted on the under side with seed.

Among other Lycopods, of which there is a large stock, were *dentatum*, very large; *rubricaulis*, of a deep green, tipped with very bright green; *Selaginella Lyalli*, of an olive green; *S. densa*, forming a soft, mossy carpet of dark green, tipped with yellowish-green, and therefore appearing as if variegated; *S. caudata*, lively green, and very pretty, were also remarkable.

In a tank, with the bottom of the pot touching the water, there is a plant of *Saphnia alternifolia*, between 5 feet and 6 feet high, with long, strap-shaped leaves, forming an umbrella-shaped head. *Inatophyllum miniatum*, with its large, orange red Lily-like flowers, was likewise a conspicuous object.

In the stoves there were fine specimens of *Cyanophyllum magnificum*, one of which was 5 feet high, with leaves upwards of 2 feet in length; *Croton angustifolium*, a charming plant for the dinner table; *Ardisia crenulata*, covered with its scarlet berries, a very handsome plant for the same purpose; *Pandanus javanicus variegatus*, very fine; *Pavetta borbonica*, about 5 feet high, with its darkly mottled green leaves and bright red midribs; *Ananassa sativa aurea variegata*, another splendid plant for the dinner table; *Sonerila margaritacea*, with its pearl-spangled leaves; *Dracaena Rumphii*, with magnificent deep olive green leaves, having a fine white line round the edges; *D. ferrea*; a large quantity of *D. terminalis*, which is in great demand for table decoration; and numbers of the new *Cissus perphyrophyllus*, with its richly blotched emerald green leaves. *Begonias*, of course, are in abundance, many of the varieties being much sought after for table plants. We also noticed a collection of *Anceto-chilus*, which were quite a study in themselves; *Anceto-chilus striatus*, with a white stripe down the centre of each leaf, being very striking.

Trained along the roof of one of the stoves were *Allamanda Aubletii*, which is well worthy of the attention of any one in want of plants for this purpose, and that fine climber *Ipomoea Horsfallii*, with its twisting corkscrew-like stem. Occupying a similar position, and covering one side of the roof, was a very large edible Passion-Flower (*Passiflora edulis*), which bore last year, for the first time, between three and four hundred of its purplish fruit, as large as a hen's egg, and having a fine aroma of Peaches and Gooseberries combined. A fine specimen of *Bougainvillea spectabilis* trained against the back wall must not be forgotten. In two years it has covered a space of 12 feet by 8 feet—a luxuriance of growth which is no doubt attributable to the roots being in contact with the hot-water pipes with which the

soil is heated. If it flower, as it is expected to do, this season, it will be an object of rare attraction to the gardening, if not to the fashionable, world; at any rate, Messrs. Henderson appear to have gone the right way to work in order to insure this desirable result.

In the houses devoted to the growth of New Holland plants, of which this nursery contains some of the largest specimens in Europe, were a fine *Arancaria excelsa*; *Boronia pinnata*, 3 feet across and 4 feet high; *Eriostemon buxifolium*, 6 feet high and 4 feet through; *Eriostemon scabrum*, very large; *Eriostemon pulchellum*, beautifully in flower, one of the prettiest of this genus; *Acacia Drummondii*, 8 feet high and 5 feet across; and a very fine plant of the scented *Rhododendron Edgworthii*.

A whole house is filled with *Boronia serrulata*—a beautiful flowering plant which few persons know how to cultivate with success. The greenhouse was gay with flowering shrubs, and some fine Azaleas, literally a mass of bloom, gave it even a brilliant aspect. Hyacinths, Tulips, and Crocuses were there, too, in abundance; and there was also a fine new *Epacris*, called *Viscountess Hill*, with long spikes of rosy salmon flowers. As the Crocus seems to be a flower that seems every day growing in favour, we may mention that *La Neige* and *Queen Victoria* are fine whites; *La Majestueuse*, *Sir Walter Scott*, and *Van Speyk* excellent striped varieties; and *David Rizzio*, *Lord Wellington*, *Othello*, and *Sir John Franklin* beautiful purples.

Outside, the gardens were dotted over with fine old Box, *Laurustinus*, *Myrtles*, &c.; and the Tulip-beds were gaily edged with *David Rizzio* and large *Yellow Crocuses*.

#### GARDENING SHREDS AND PATCHES.

THERE are so many things which strike one, and of which one hears in the floricultural world that are hardly in themselves sufficient to form subject-matter for a paper, that I must crave permission from time to time to jot them down as they occur to me in the lump, as "Shreds and Patches," which may be useful to some of your readers. For instance, there is one of some considerable importance—

THE BEST WAY OF SENDING BLOOMS THROUGH THE POST.—As the season has already commenced when the raisers of seedlings are desirous of having one's opinion of what they raise, and as proof has already been afforded me of how little the instructions given in your columns have been attended to, permit me to bring before my correspondents in this matter a very simple and effective plan—one that owes its origin to my friend Mr. Miller, of Upway, near Dorchester, and which, if adopted, would save a great deal of disappointment. It is merely to procure a common tin canister or box about 4 inches or 5 inches in depth: indeed, the size may be regulated according to the description of the flower sent. In the centre of the lid a socket is to be soldered on about 1½ inch deep and about 1 inch broad. When you wish to send a bloom, get a Potato, and cut a piece that will fit tightly into this socket, and then place a piece of indiarubber band round it. Insert the stalk of the bloom into the Potato. Close your box, cover it with paper, and direct it, and it will travel quite safely. The advantages of this are obvious—the flower has no chance of rubbing; there is no mess round it; and sufficient moisture is contained in the Potato to keep it fresh during its journey. It was thus that Foxhunter *Verbena* was sent to Mr. Andrews, and in sufficiently good condition for him to make his drawing from it. How very opposite to this the state of a box I received only this week. It contained a pip of an *Auricula* and a bell of a *Hyacinth*. The box was carefully enclosed in a piece of oiled silk; but when I opened it a mess presented itself not very agreeable to the sight or smell. It looked as if they had been packed in seaweed, and one portion of the substance looked very like a squashed *Sea Anemone*. It was, of course, impossible to tell what either was; but one is tempted to ask, "Why send a *Hyacinth* for name? the bulb has flowered, and there is an end of it." Very different, of course, where the flower can be kept, as in the *Auricula*. Will those who intend sending flowers kindly bear this in mind?

Then there is another matter about which I have heard a little lately—

FORTHCOMING ROSE SHOW.—I was in a good quarter to hear of this, for I spent a day lately at Caunton Manor; and although the month of March, with a cold wet north-easter (and about whose character, I had rather take Mr. Punch's word than Mr.

Kingsley's), on a heavy clay soil, was not the very best time to see a place from whence so much has emanated to give an impulse to Rose-growing, yet the "genius loci" is the same, and the bitter cold without only draws us the more closely to the fireside, where, imagination being strong, we already saw box after box of radiant blooms, and sniffed in odours such as flow from "Araby the blest," and a pleasant chat it was. We all (that is, all interested in the Rose), know how the success of the National Rose Show was marred by the want of courtesy and ungentlemanly bearing of its founder! And, therefore, one could only expect similar treatment. Well, a truce to banter, and we are not going, Yankee like, to detail all we saw and heard; suffice it to say that none need wish him a better wish in his Rose-growing than that he may have as fair a bloom out of doors as he has within. Well, we chatted, and praised, and abused, as the fit came on us, and as we thought folks deserved. The subject was the Birmingham Rose Show; for as the day at Kensington has been fixed to suit the southern growers, the northern and midland ones are shut out. Our friend had intended to found a Midland Rose Show, and, indeed, had taken steps to that end, when an announcement was made that the Birmingham folks were bestirring themselves. The same feeling which led Mr. Hole to merge the National in the Royal Horticultural Society, led him at once to withdraw his own scheme and to throw himself heartily into the one which, though not originating from him, was calculated to work out the object he had in view. They seem to be going at it with real vigour, offer £80 and upwards in prizes, and encourage amateurs as well as growers for sale. Mr. Hole, however, still clings to the hope of a northern show; and if he succeed in originating one as he intends at Leeds, or in some such locality, then all England will be well represented, and the queen of flowers have ample justice done to her. There is a hitch about the time of the Birmingham one, which we hope may be got over. As arranged, it would only come a day before the Crystal Palace Rose Show. This would be a great mistake; but the Town Hall is required, and unless they can move those who want it, I fear it must be held so; and as it is intended mainly for the northerners and midlanders, this will not be of so much consequence.

There is one good piece of news in connection with

THE ROYAL HORTICULTURAL SOCIETY, which will gratify both exhibitors and those who desire to see—that the great shows are to be held under canvas at the lower part of the grounds, and not in the conservatory. Any one who recollects the heat there last year, and the miserable condition of the cut flowers after a few hours' exposure to it, will rejoice at the change.

I think "HORTULANUS" was a little too hard, and your reply correct; but that a watchful eye is needed there can be but little doubt. One subject of grumbling has been done away with—a little more agitation may do away with others. The remark which I saw in the report of one of the daily papers is quite true, that notwithstanding its apparent (and, indeed, real) prosperous condition, the Society must depend for its success on being up to the requirements of the times. I am glad, too, that Mr. Hole's conduct with regard to the Rose Show is, in future, to be acknowledged; it ought never to have been left for any one to complain that an act of such disinterested regard for the success of the Rose should have been passed over. There can be but one wish—that every society that endeavours to advance horticulture in its many branches should meet with public sympathy and support.

And now a word for that which, though last, is certainly not least,

THE NATIONAL AURICULA SHOW.—That which my blundering advocacy could not effect, the indefatigable perseverance of Mr. Douglas, of York, has accomplished; and we are promised a treat on the 30th April, of the first National Auricula Show ever held. The exceedingly judicious plan has been adopted of sending round to growers of the flower a paper to be filled up, with the place and time of exhibition marked according to the opinion of each person. The majority of votes has been given to London as the place, and the 30th April as the time (I fear the southern growers will find their bloom over, unless this very dull weather continue); and no more fitting home for it can be imagined than the Royal Botanic Society. It will fall on one of their spring show days—no expense will be incurred for room, &c., and the flowers will be seen by a large company. Great credit is due to Mr. Douglas for the zeal with which he has carried out an object so full of interest to all florists.—*D., Deal.*

## NEW ARRANGEMENT OF VENTILATORS.

I AM nothing of a gardener, but a bit of a mechanic, and amused myself last year in putting up a small greenhouse for my wife, who is fond of horticulture. I took up by accident your Number for January 21st, 1862, and felt interested in a letter signed B. Stevenson, and your remarks upon it, but I differ from you as to the long board at top for ventilation. The great objection to it is, that it is so liable to warp, and then it cannot shut close in winter. The plan I pursued I prefer, and if you think it worth recommending, here it is, it is cheap and simple. It may not be original, but it is so far as I am concerned, for I have not myself seen it elsewhere. The sash-bars are fixed, and lie on the plate, the house being a lean-to. The four top panes in the centre are set in tin frames (any tinsmith knows how to make these, they are very common), and these are put on to the sash-bars just as if they were glass, only that in addition to the putty they are fixed with springs. They are opened by a string running through staples to a pulley on the front sash, and this string is attached to a light iron rod in the form of a crank at the top, from which straight rods, equal in length to the chord of the angle which the top of the house forms with the back, are attached to a small staple of wire soldered on to the under side of the tin frame. It will be evident that the window cannot open wider than the length of the rod, but this is quite enough. There are tin frames of the same sort next the wall in each of the upright ends of the house, the only difference being that the hinges are at the side

instead of the end. These, with shutters in the front wall like an orchard-house, give sufficient ventilation. The drawings will make all clearer than any further explanation I can give.—G.

### CISSUS DISCOLOR.

No collection of beautiful-foliaged plants should be without a specimen similar to the figure of this truly beautiful plant. The leaves individually, when well grown, are fully 6 inches long and 2½ inches broad, of a lengthened, pointed, heart shape. The colours are rich beyond description, quite equal to the lovely leaves of the Anætochilus; but I need not dwell upon the beauty of the foliage of this plant. It is now so plentiful in collections that almost every one of our readers must have seen them.

My present object is to describe how to produce or grow a plant so as to be of the size and form of the specimen figured.\*

*Soil.*—This species being a rapid grower it requires a rich, light soil. I use the following compost—turfy loam, sandy fibrous peat, and half-decayed hotbed manure in equal parts. To keep it open I mix with the compost a few pieces of charcoal and a liberal addition of silver sand. This compost should be thoroughly mixed, but not sifted, and it should be placed in a warm shed to take out the cold. Many stove plants sustain a great check by being potted in cold, wet soil. It should be warm and moderately dry.

*Potting.*—Procure or raise a young plant, and when it has grown so large as to require a shift, repot in spring into a pot two sizes larger. Tie the shoot to a neat stick, give a moderate

\* We published this figure last year, but repeat it for the information of more than one querist.—Eds.

watering, and replace it in the stove in a temperature of 65° by night, and 75° by day. If you have the convenience of a bark-bed or any other method of giving bottom heat, place the pot containing the plant in it. In such a situation it will grow rapidly, and will soon require a longer stick. As soon as the pot is full of roots give the plant another shift, and still keep the shoot upright. In the August following repeat the repotting, and by that time the plant will be long and strong enough to commence the training it into form. Procure four or five strong sticks between 3 feet and 4 feet long, let them be painted green, and when dry thrust them at equal distances just so far within the pot as to stand upright. Then have a green circular ring of stout wire, place it near the top of the sticks, and tie each stick to it at equal distances all round. When that is done commence tying the stem of the plant to the nearest stick, very nearly close to the rim of the pot; tie it then to the next stick in a rather ascending line, and gradually go on round the sticks as far as the plant will reach, being careful not to injure a single leaf or the stem. The plant when brought into this form will probably send out other branches. Let these be tied in also between the circles of the main stem. By following on this training as the plant advances in growth the sticks will soon be quite hid, and the plant will form a beautiful pillar of richly-hued foliage, equal in shape to the figure.

By good management and frequent repottings such a specimen may be grown in two years, so quick a growing plant it is. Indeed, the quicker it is grown the finer will be the leaves, and the richer the colours.

*Watering.*—When the plant is growing rapidly it will require a liberal supply of water, which should always be in a tepid state—that is, heated to about 80° in summer. In winter it need not be supplied so warm, nor so freely. The plant should scarcely ever be syringed, for that has a tendency to tarnish the bright metallic lustre which is so richly developed on the surface. If the leaves become dusty, it must be, of course, washed off, but let the syringing be done just before air is given in the morning, in order that the moisture may dry up quickly.

*Shade.*—If this fine plant is fully exposed to a summer day's sun the rich hues on the leaves will be deteriorated: hence to keep it in perfect beauty let it be shaded from ten to three o'clock in the day. It is necessary, however, that every side of the plant should have an equal share of light, or the colours will not be so rich on the side that is short of light: therefore, if the plant is grown in a lean-to house it will be necessary to turn it round frequently. In a span-roofed house this is not needed.

*Propagation.*—This species is easily propagated by short side shoots inserted in sand and placed under a hand-glass on a heated surface, or plunged in bottom heat.

When the plant becomes old, naked at the bottom, or the leaves become old and faded, it should be thrown away; but a year previous to that let one or two young ones be started into growth, and trained to grow on to fill the place of the old faded one. Summer temperature 70° to 80°. Winter ditto, 60° to 65°. —T. APPEBY.

### GENERALLY USEFUL CULTIVATORS.

#### COW MANAGEMENT.

(Continued from page 397, Vol. II.)

WHERE two cows or more are kept we must suppose one to have already calved; but where one only is kept March or April will be time enough, as the cow would have the advantage of the summer's grass during her best milking period: therefore the present remarks will be applicable to such a case. And the cow having been dry seven or eight weeks—and we may reckon forty weeks from the time she was served—after this it will not be safe or wise for an inexperienced person to depend. Still, a person acquainted with those matters can tell to within twelve hours when a cow would calve; but the safest way is to put the cow at night in a roomy place and not tie her up, give her some hay, and a good bed of litter. I may just remark here that in this, as in many other matters, it would be well to have the opinion of some neighbour. I have met with plenty of people that have felt pleased to give their experience, often at no little inconvenience; and if the young beginner will pay attention to the remarks made he may pick out a good many grains of wheat from amongst the chaff that will fall in his way, but should they appear rather scanty he must begin to sift.

This leads a sensible man to think that you are in earnest, and are desirous of being taught.

Now, suppose a cow has gone several days beyond the fortieth week, and you are daily or hourly expecting to see signs of approaching calving, and are beginning to get nervous about it, you run across to Farmer Goodman's and ask his cowman to look in as he goes home in the evening, and just tell you whether he thinks your cow will calve before the morning; and when he has seen her and tells you she will not, "nor to-morrow night neither," then is the time and place to put in your "why?" If you think it a fact worth knowing and wish to be in possession of it, you have only to make a judicious use of the patent powers of persuasion, and you can glean a good many facts at a very trifling cost. But in the absence of any better judgment than your own it would be well to look at her two or three times during the day, and, if she has had one or two calves before, see her the last thing at night and again the first thing in the morning—that is, should all be going on well and no appearance of uneasiness exist. My own practice is with the first and second calves to see them once or twice during the night; but it is very rare that I see them more than one night. As a general rule, do not go near enough to disturb her until there are unmistakable symptoms of calving, and then do not interfere to render assistance unless you are fully acquainted with the assistance required; but if you think any help necessary, it would be better to run to Farmer Goodman's for it and take lesson No. 2.

But supposing there be no need of help or advice, and that so far all has gone on well, there is still danger, and attention is required. It is necessary the cow should lick the calf, as it is beneficial to the health of both; but sometimes young cows refuse to do so, but a little salt and oatmeal sprinkled over the calf will have the desired effect. Then get a bowl, and after rubbing the udder with the hand take a little of the milk from each quarter and give it to the calf, putting your finger in its mouth, then guiding it to the bowl: in this way the calf will gain strength and soon be able to stand. Then let it take from the cow as much as it will, but see that each of the teats is sucked equally; then milk the cow thoroughly and give her the milk to drink—I fancy it assists the cow to cleanse, for this generally takes place in an hour or so afterwards; afterwards give her half a bucket of warm water. Now this is farmers' treatment in nine cases out of ten; but your treatment must vary according to circumstances and the kind and character of the cow.

Cows kept by gentlemen are generally of the Alderney breed, or a cross between the Alderney and the Short-horn, good milkers, and better kept than farmers' cows. Now, in such cases it is advisable, as soon as the calf has sucked the cow, to give two quarts of gruel made with a quart of ale, a pound of treacle, and a little ground ginger; and, as soon as she has cleansed, a good warm bran mash. Cows often get eevie during calving time, and if she is a good milker and in good condition it often produces milk fever: the above treatment is to prevent this. If the calving has been some hours previous about half a pound of Epsom salts with the same quantity of treacle may be used. Two cases of milk fever have come under my notice this year, both of them Alderneys of the improved breed (which carries more flesh than the old breed). Both died within thirty hours after calving, and both were the property of gentlemen and young beginners. On inquiry I found neither of them had had either gruel or mash, and in each case the calf was taken from the cow immediately, and not permitted to suck till the usual time came for milking. Now this, to say the least of it, was bad management. I like to leave the cow loose and the calf with her, the mother is then more contented, and the calf will be frequently sucking, and thus keep down the milk. I know in Jersey it is a regular practice to take the calves away as soon as they are born, and are not allowed to suck the cow at all; but I have had the management of cows that have come direct from the island, and as a general rule there are some defects in the udder, which are increased by the better keep which they invariably get here, and they consequently give more milk than they do in their native island. They are, however, liable to disease, and require different treatment.

I make it a practice not to give a cow free access to the water for a week after calving. If the weather is fine and dry let her be turned out for an hour or two the third or fourth day, but by no means let her get wet, and after a week she may have cold water with the option of going in or out when the weather is

dry; but if the calf is kept in any portion of the house, there is little danger of her being out too much. It is too late to say anything about the putting dung on the grass land, and other work of the kind that should be done in the winter; but all land for mowing need be brushed and rolled, the stones and sticks all picked off, and nothing more turned in to nip the young grass, but reserve the whole of the growth for hay.—THE DOCTOR'S BOX.

### A PLANT WORTH MARKING SHOULD BE MARKED WELL.

THE importance of an effectual and simple mode of writing all kinds of plant-labels, must be acknowledged by every lover of gardening, and I trust my Solid Marking Ink Gardener's Pencil has contributed somewhat towards this desirable end. With all due deference, I beg to offer two or three suggestions for consideration.

First. Where wood tallies are used, the necessity of selecting wood most suitable for the purpose. Generally any bit of stick is taken which first comes to hand. Now, my experience leads me to believe that woods containing turpentine are the only ones really suitable for this purpose, and that known as yellow deal being pretty well charged with resinous matter, and at the same time being a good colour for showing up the marks, will be found to answer well. It also has the advantage of standing the weather without decaying. The white woods generally chosen on account of the facility with which they mark soon become discoloured and rot in the ground.

Second. Where paint is used to cover the part written on, when a common lead pencil is used, care should be taken to well cover such surface with good white lead paint. The wood tallies usually sold being merely partially covered with a little chalk or china clay.

Third. I would draw particular attention to the necessity of well covering the strokes. I believe the want of care in this particular to be one of the most common causes of the marks becoming illegible. I know it is so with my own Gardener's Pencil. Long exposure will change the colour of any wood, and if the marks are merely scribbled on, the colour of the wood (especially in the smoky atmosphere of a town) and the writing become nearly alike—the mark is not gone, but the tally has assumed a colour so closely resembling the writing, that it cannot be distinguished. I have tallies the marks on which were well covered in April, 1859, and they are perfectly legible now.

I know many gardeners will exclaim, "I have not time to take all this trouble." In reply I must refer them to the heading of this communication; and I am sure if they will only take the pains to well cover the strokes, so as to give my pencil a fair chance to cover and penetrate the pores of the tally, it will amply repay them for the trouble, and they will not be disappointed with its durability on any material.

Fourth. Where zinc tallies are used, I would say to all who can get it, Purchase some old zinc spouting or lining from water-tanks, of suitable thickness, and get it cut up into the shaped tallies required. This old zinc being oxidised on the surface, from exposure to the atmosphere, marks the best and blackest of any. When new zinc tallies are used, and time will not admit of allowing them to become oxidised from mere exposure, to free the surface from grease, with which newly-rolled zinc is always more or less impregnated, the best way is to throw them into an earthenware basin containing a mixture of about one part aquafortis, two parts spirits of salts, and fourteen parts of water, stir them well round for a minute or two with a piece of stick, so as to expose all the surfaces equally to the action of the dilute acid, pour off the liquid into another basin, well wash the tallies in water, and dry them in the air, and they are ready for use. Spirits of salts will do very well without the aquafortis.

In this way any number of tallies may be done at one operation, and the trouble is much less, and the tally made more efficient than by the old plan of rubbing each one with sand paper. The acid mixture may be kept in the basin, or put into a bottle for future use, and a little fresh acid may be added to it from time to time to keep up the original strength.

Fifth. I would suggest galvanised iron as a good material for tallies for open borders; but the iron must be galvanised or coated with the zinc after being cut into the shape and size required, so as to cover the edges as well as the surface, otherwise they rust at the edges, and the iron gradually oxidises throughout from the action of the atmosphere. The surface of

galvanised iron is quite bright and free from grease, and requires no preparation but damping with the wet finger to mark a beautiful black with my gardener's pencil.

The greatest objection to it is, the surface being rough and crystalline, small neat writing cannot be executed on it. I am now about to try some experiments with a view to render the surface smoother, and, perhaps, some of your scientific readers may be able to suggest some method of coating the iron with the zinc, so as to prevent the crystalline roughness it now presents. If this can be done I am satisfied that galvanised iron would be the most convenient, as well as the most durable material for garden tallies, and I see no reason why it should not also have the advantage of cheapness.—ARTHUR DUNN, 1, Dalston Terrace East, London.

## ENTOMOLOGICAL SOCIETY'S MEETING.

THE March Meeting of the Entomological Society was presided over by Mr. Smith, the newly-elected President, who announced that the Anniversary Address of the late President had been printed for circulation, as well as that delivered by Mr. Stainton at the last Meeting, which, it is much to be hoped, will have the effect, in conjunction with the steps since taken by the Council, of allaying the unpleasant feelings raised at the Anniversary Meeting. He also announced that the Council had taken into consideration the result of the experiments, which had for some time past been tried, of distributing the "Transactions" gratuitously to the members, and had come to the conclusion that it was no longer advisable to continue this plan; but that members resident within fifteen miles of London should be allowed the "Transactions" at one-half of the publication price, whilst those resident beyond that distance should be entitled to their copies gratuitously as heretofore; likewise that the forthcoming Part of the "Transactions" would form the commencement of a new series.

Mr. Newman exhibited a series of specimens belonging to the genus *Cabera*, a group of Moths, which had been reared by Mr. Hockett, with the view of proving that the transverse bars upon the wings are not sufficient to indicate distinct species. He considered, therefore, that the genus only comprised two species, each of which had varieties with two bars.

The President exhibited an extensive series of remarkable illustrations of insect architecture, consisting of the nests and combs of various kinds of insects, chiefly belonging to the order Hymenoptera, and including both British and exotic species. The elegance of many of these nests was greatly to be admired, and several of them showed modifications of instinct and habits heretofore unknown in the different families to which the insects belonged.

Mr. Plant exhibited some eggs of a species of Butterfly collected at Uruguay in South America. These eggs were of an elongated flattened form, and were attached to each other side by side; one at the base being fastened to a twig, and the others suspended laterally from it to the distance of an inch.

Dr. Wallace explained a very satisfactory method which he had invented of fixing small Lepidopterous insects in cabinets. The pins, instead of being fixed separately in the cork of the drawer, are placed in small slabs of flattened wax, each of a size sufficient to contain all the specimens of a species, which is then transfixed with a large pin, and thus the whole is easily moved at once.

W. W. Saunders, Esq., Treasurer to the Royal Horticultural Society, exhibited the stem of a *Passiflora*, which had been disfigured by the attacks of the Mealy Bug, which had formed warts on the stem, above which all the upper part of the plant died off. Also the larvæ, pupæ, and perfect insects of *Endomychus coccineus*, a pretty Beetle which feeds in the preparatory state upon a flocculent kind of byssus growing under the bark of Elm trees. Also some very curious species of Phasmidæ from the remote island of Aneiteum.

Mr. Stainton exhibited a new British Noctua, belonging to the genus *Toxocampa*—*T. cræcæ*, of which several specimens had been taken on the north coast of Devonshire by the Rev. E. Horton.

Mr. Kirby exhibited some of the proof sheets of Dr. Hagen's great work on entomological bibliography.

Dr. Knaggs exhibited a case of insects from Australia.

Dr. Power sent for exhibition a new British genus and species of Beetles—*Endophleus spinulosus*, captured in the New Forest

by C. Turner. This is a very interesting genus allied to *Bitoma*, and is a fine addition to our fauna.

Mr. Wailes communicated a note on the capture of *Bembidium nigricorne* near Newcastle.

Mr. F. Walker read a description of a new genus of North American Moths taken at Halifax.

Mr. Kirby read a notice of the different species of Butterflies hitherto captured in the county of Sussex.

Captain Cox stated that he had captured three specimens of *Pontia Delaplacei*; and he likewise made some remarks upon some letters which have lately appeared in the *Times* on the means of preventing the destruction of Elm trees by *Scolytus* destructor by disbarbing the trees, as practised in France by M. Eugène Robert; claiming the discovery for himself, he having, previous to M. Robert's experiments, gained the medal of the Royal Botanic Society for his successful experiments on the young Elms in the Regent's Park.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

As every important operation out of doors had been interrupted the greater part of the week by the incessant rains which have saturated the ground, reference had better be made to our last week's calendar, as the works there recommended have doubtless been delayed. *Beans*, *Broad*, earth-up growing crops, and continue sowing for succession. *Broccoli*, sow for a main crop. *Cabbage*, sow for a main autumn crop, fork-up the earth between those planted in the autumn as soon as the ground is in a fit state. *Cauliflowers*, stir the soil round those under hand-glasses, and earth them up. Sow for autumn crop if not already done. *Capsicums*, pot-off as soon as they are fit. *Celery*, that sown early in boxes will soon want pricking-out on 3 inches or 4 inches deep of very rotten and mellow dung on a hard bottom. If the plants are pricked out on this, about 3 inches apart, they will produce many fibres, and can be moved with a trowel with balls; it is an old but a very good plan. *Potatoes*, the main crop may now be got in. *Spinach*, sow small crops of the round in drills, but a little at a time, as it soon runs to seed. *Tomatoes*, these should now be potted-off. Sow seeds of herbs and other vegetables that may have been omitted during former weeks. Remove all litter and weeds. Earth-up early crops, sowing a little lime or soot about them to prevent the attacks of slugs. Protect recently-sown seeds from the attacks of birds.

### FLOWER GARDEN.

The stock of Neapolitan Violets for forcing to be propagated by cuttings or layers. Plant out the young stock of Pansies into the flower-beds or borders. The late heavy rains have been injurious to the roots of Tulips unless the beds were situated on a porous subsoil or were well drained. As soon as the beds are sufficiently dry the surface soil should be carefully and slightly stirred-up, and every cankered part of the foliage cut away with a sharp knife. When the seed of *Polyanthuses* was sown early and placed in heat to vegetate, the pans or boxes should be removed to a cooler situation to inure them gradually to the open air. To obtain fine trusses on the old plants, it is advisable to thin-out the pips according to the strength of the plant. Cuttings of Pansies to be now put in round the sides of small pots plunged in sand on a north border, and covered with a hand-glass. When the unfavourable state of the weather puts a stop to out-door operations, stakes for Dahlias could be got ready for use when required, and rods for tying-up plants in summer. Labels could also be prepared before the more busy season arrives. Climbers and plants against walls to be nailed when the weather is favourable.

### STOVE.

Pay due attention to the watering, shifting, and stopping of plants in general. Make cuttings as soon as they can be obtained of *Clerodendrons*, *Geissomerias*, *Eranthemums*, *Plumbagos*, *Justicias*, *Begonias*, &c., in order to keep up a stock of young plants. Supply growing *Oreliids* with plenty of atmospheric moisture and a liberal circulation of air in the forenoon, shutting up early in the afternoon. Be moderate in the application of fire heat, that a natural and pure atmosphere may be insured during the night. *Dendrobiums* making growth in pots to be liberally supplied with water, and those on blocks to be frequently syringed. Shake out and repot in succession those plants that have been previously recommended to be headed

back, and encourage a free growth; then a seasonal rest will secure a good bloom in due season, either by withholding water in moderation or by placing it for a time in a cooler atmosphere. *Plaius albus*, *P. grandifolius*, *Calanthe veratrifolia*, *Zygopetalum Mackayii*, *Neottia picta*, *N. elata*; and some varieties of *Stanhopea* that are now making their growth would be benefited by occasional applications of clear liquid manure. The shading to be in readiness in case of a sudden change.

#### GREENHOUSE AND CONSERVATORY.

Climbing plants beginning to grow should be frequently examined to regulate the shoots. *Kennedya*s, if crowded, to have their shoots thinned. *Ipomaeas* being subject to red spider, should be well syringed to prevent the increase of that pest. Put in cuttings of *Heaths* as soon as the young shoots are of sufficient length for that purpose. Cuttings of the free-blooming Hybrid *Rosea* struck last autumn and kept through the winter in store-pots, if potted now and treated with proper attention during the summer, will make pretty specimens for the autumn and spring, to be kept close after potting. All blossom-buds to be picked-off during the season if the plants should be wanted for winter or early-spring bloom. Cuttings of young wood struck now, will also by attention make flowering plants for autumn or early in the spring. The shrubs from the forcing-pit when done blooming in the conservatory, the best to be selected for blooming again next season, giving them some temporary shelter to mature their foliage gradually. Any that are cramped for room to be shifted into pots a size larger, and about the end of this month or the beginning of next to be plunged in an open situation to ripen their wood early. Plants from having been previously forced will bloom earlier than the new stock, of which a portion each year should be potted to replace such plants as become useless for further work.

#### FORCING-PIT.

This will now be found a useful structure for encouraging the growth of the young stock of various stove plants, such as *Poinsettias*, *Ixoras*, *Ardiasias*, *Euphorbias*, *Clerodendrons*, *Genenas*, *Gloxinias*, *Gardenias*, *Echites*, &c., the whole of which delight in a humid atmosphere with gentle bottom heat and syringings.

#### PITS AND FRAMES.

This being the season for the importation of *Tuberosa*s, they should be procured at once and potted in a mixture of sandy loam mixed with a very small portion of very rotten sheep or cow dung, to be then placed in a hotbed or forcing-pit; they require little or no water until they begin to grow. When advanced in growth to be removed to the conservatory to bloom. Look over the plants in the pits and frames, and attend carefully to the watering of any plants that are dry. Continue potting-off all cuttings. *Bouvardias* to be shaken out and re-potted in light sandy soil, and placed in a growing heat of about 65°.

W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

WET, wet, rain, sleet, and snow, ushering a warm muggy Monday morning with the barometer low, and showers still hovering have rendered the days, from the 20th to the 25th, almost useless for doing anything on the open ground, though, as soon as possible, Onions and Broccoli seed must be got in. Found that pea-sticks, branches laid along rows of Peas, kept the birds from them pretty well as nets would have done. Have kept forwarded Peas, Broad Beans, &c., still under protection, as the ground is too wet to plant them out, but exposed them fully during the day. The very change of planting will cause them to blossom earlier. Watered Potatoes in beds, and attended to seeds of many things lately sown. Sowed more Dwarf Kidney Beans, to come in under protection by-and-by, and planted more in pots for succession.

#### FRUIT GARDEN.

Much as the preceding weeks. Cleaned *Strawberries* coming into bloom from all appearance of fly. Smoked with Neal's Pastils, then with tobacco, avoiding excess and warm smoke to avoid injuring the plants, and sickened but did not destroy the fly. Had the pots down from the shelves, ran our fingers and thumbs through among the buds, and did for all that we saw; laid the pots on their broad sides, and syringed them well with sulphur water containing a little soap, and then with clear water heated, before setting them on the shelves, and none since have made

their appearance. With all that can be said and truly in favour of Gishurst Compound used in moderation, there is nothing after all like elbow grease where it can be used, and the remedy of kill them, and syringe afterwards in time. On examining with a microscope the mat on which the plants were thus turned and syringed, we could see moving dots that the naked eye could not discern. That lot of *Strawberries*, probably, will not want any more insect hunting until the fruit is gathered. There should be great care in smoking plants when the growth is tender and young—the smoke should neither be too strong nor at all hot, or the plants may be much injured as well as the insects. In large places this fumigating affair is an expensive one—as well keep smoking-rooms at once; and if taken in time, the fingers and the syringe, with a weak solution of Gishurst, sulphur water, or laurel water tea will often be more successful than repeated careful smokings.

Placed succession plants on a mild hotbed, not plunging them, just to give them a start. Watered carefully the plants in fruit, and have long found that in dull weather, especially at this season, to have the *Strawberries* with good flavour they should, if possible, be gathered in the sun, and when the plants are rather dry. Many a dish has been spoiled as to flavour by gathering an hour or so after a heavy watering.

Will finish attending to fruit trees outside as soon as possible. Some *Pears* against walls, that looked fine in autumn, are showing few flower-buds, though I expected it would have been otherwise. What with birds and frosts and other annoyances, the time is not far distant when we shall have miniature orchards of all our hardy trees; so grouped and roofed with rafters, as to permit of nets going over them at one time, and canvass at another, whilst top and roots will be equally under command and easy of access. Peach trees in glass-covered house are breaking strongly; and also a few *Apricots*, being quite as late as those out of doors, until we began to shut up the house lately.

#### FLOWER DEPARTMENT.

Weather permitting, regulated and lessened herbaceous plants out of doors. Planted out *Calceolarias* from the cutting-bed, giving them about 4 inches each, or at least 3 inches, and protecting them. Took off cuttings of a few sorts that are scarce, and gave them a little sweet bottom heat, as they will now strike in heat as fast in days as they required weeks in the cool autumn; though autumn, all things considered, is by far the best, as plants that never have had heat want but little hardening-off. Propagated *Lobelias*, *Salvias*, and *Cinerarias*, as they could be got and room could be obtained for them. Pulled up some *Cineraria maritima* that had been laid-in by the heels under protection to see how they were for cuttings. Found only a few scores fit for use, the others not being long enough yet, as we wish the short shoots that spring thickly from stem and roots near the collar to be about 2½ inches to 3 inches long before taking off, and not only do these strike surely and quickly now in a little heat, but for edgings are far superior to older plants, or to those raised from seed. We reared some four or five hundred plants last season from a sixpenny packet, but it was only at the end of the autumn that the leaves got their right silvery colour. These cuttings will have it at the first, and will give no trouble in showing their flower-stalks, as older plants are sure to do. Must wait until pots are emptied to pot a thicket of *Gazania splendens*, which in general kept open with us afternoon and evening pretty freely last year. Nothing can be more beautiful than such a bed edged, ringed, or crossed with *Nemophila insignis*, bnt, unfortunately, no coaxing or repeated sowing can make the latter lasting. *Lobelia speciosa* is just the thing for colour, but then the contrast between the flowers is that between a giant and a lilipt. As soon as the ground is a little drier will plant out *Scarlet Geraniums* into preparatory-beds, so as to give them more room, just placing a little sandy leaf mould, rough, round the roots so as to adhere to them when lifted. Propagated *Dahlias* and *Heliotropes* as they could be obtained, and kept an eye on the seeds sown the other week. Potted *Geraniums*, *Fuchsias*, and prepared for looking over greenhouse plants, &c.—R. F.

#### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All

communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**CORRESPONDENT'S ADOPTED NAMES.**—"Flora of the Orange Trees" writes to inform us that she is not "Flora of the Fansies," and that she thinks that "last week it rained Floras." It is true there were a good many who adopted the goddess for their patroness, but they were mere units in comparison with the hundreds who apply to our oracles as "Subscribers." We advise our correspondents to adopt their own initials, adding the name of their place of residence—thus, "P. L., Derby." Injurious mistakes might arise from one "Subscriber" accepting as an answer to his query, a reply intended for another "Subscriber."

**LEAVES OF CYCLAMENS (Inquirer).**—The leaf of *Cyclamen europæum*, "from the north of the Alps," is quite true, and the leaf "from the south of the Alps" plant may certainly be true, but it looks very far from it. But we have lost confidence altogether in the leaves of any one *Cyclamen* under cultivation, as marks of identity. The leaves and the flowers at the bottom of the box are very different indeed from the true verum, and from Mr. Gordon's description of it. Yours is coum with a dash of persicium, and there are scores just like it at the Wellington Road Nursery, from Mr. Atkinson's strain. We had a long talk with Mr. Gordon himself the other day about *Cyclamens* and *Crocuses*, in the office of this Journal, and he thinks the spur on the top of the bulbs is common to several sorts under certain conditions in a wild state, and that the spur would, or might disappear in cultivation—that is, seedlings from a spur-plant to give bulbs without spurs. Our own verum if it ripens the seed will soon prove the point.

**INSECTS (Rev. E. C.).**—Your minute insects belong to the order *Thysanura* or spring-tailed insects. They are the *L. fimitaria*, and are often found in such masses as you describe. As they differ greatly in size it is just possible for them to be young newly-hatched brood. They feed on decaying vegetable matter, and are not injurious.—W.

**VINES IN A HOT DAMP ATMOSPHERE (A Subscriber, Siston).**—We have seen Vines have their blossoms injured like yours by a hot steaming, such as causing a supply-cistern to boil furiously for want of water. Also, from too close and moist an atmosphere in dull weather as we have had lately; and now, after your second explanation of circumstances, we have no doubt the young fruit were parboiled by strong steam at night when the house was shut up. The evaporation or steam must be lessened, or air left on the top all night—say an inch all the way.

**BONE-CRASHING (Borax).**—We knew of no machine for doing this that is not large and expensive. If we wished to use the bones of an establishment for manure, we should adopt the American mode of putting the bones in alternate layers with caustic potash. This after a while renders them crumbly and in a fit state for manuring. An old cask with one head out would do thus to prepare the bones in.

**HEATING BY GAS (G. A. B., Basford).**—There is no difficulty whatever in heating a small greenhouse by gas. We employed it for years in one without injuring a plant. If you will buy our No. 424, you will there find a drawing and description of a very cheap and effective apparatus. It was constructed and used by Vincent Lichfield, Esq., surgeon, Twickenham, and we have no doubt he would courteously afford any further information. If you enclose four postage stamps with directions where it is to be sent, you can have the Number above named free by post.

**CRISUS DISCOLOR (G. G.).**—You will see notes upon its culture in another page of our Journal to-day.

**ROOT-PRUNING (W. Wood).**—The cuttings of the roots in November would rot influence the Pear trees against the wall for this season. Wait patiently for another year. If weak during the summer, you might assist them with liquid manure or new compost. If too strong you may have to prune more at the bottom. We would not think of watering either Cherries or Apricots out of doors, when in bloom, unless the ground was very dry, which it is not likely to be if exposed to the rains of winter. If the ground should get dryish, it will do them more good to receive a watering before they begin to skode.

**TWENTY-FOUR SHOW DALLIAS (A Seven Years' Subscriber).**—Beauty of Hilpertan, purple; Chairman, buff; Chernb, orange; Earl of Shaftesbury, shaded purple; George Eliet, deep purple; Golden Drop, yellow; Juno, rosy lilac; King, fawn, edged with purple; Lord Palmerston, scarlet; Marquis of Downton, rose, shaded with white; Mrs. W. Pigott, white; Perfection, orange; Midnight, dark maroon; Pioneer, bright crimson; Rosebud, rose; Triomphe de l'Éc, dark crimson; Umpire, white, edged; Lady Popham, white, tipped; Sir J. Douglas, yellow, edged with red; Jenny Austin, light, edged with lilac; Lady Franklin, rosy buff; Colonel Wyndham, deep rose; Disraeli, orange; Bravo, rosy crimson.

**WHITE EUPHONIA FOR BEDDING (A Subscriber).**—There is no such *Euphonia*. *Speciosa*, the best white among them, is very scarce and hardly fit for a bed. *Taraxacifolia* is the next and only next best; and that, too, is not at all a good subject for a bed, save a bed of mixtures; and there is no *Euphonia* of any sort that would do now to sow and be of the least help this season. But all the kinds of *Euphonias* might be sown out of doors about the middle of April to come into use that time next year.

**ITALIAN NAME OF CYCLAMEN (J. H. W.).**—The Italian name is *Pan porcino*, literally Pig's-bread, and synonymous with the old English name of the plant, Sowbread. Our correspondent intends having a sackful of the tubers from his friends in Sicily and Naples, where he has "seen them growing like the *Primroses* in our own hedges."

**PACKING CUT FLOWERS TO GO BY RAIL (Claud Royal).**—We shall give a full account of the process prominently next week. It is too serious to be pushed into a spare corner.

**TREATMENT OF WILD ROSE STOCKS (New Subscriber).**—The wild Rose stocks just planted from the woods should be pruned quite close—that is, to the bottom bud of all the side branches. They will hardly be fit to bud before the middle or end of August.

**GAZANIA SPLENDENS (Idem).**—This *Gazania* is best in a bed by itself without an edging, and it is not doing it justice to make an edging of it.

**VERBENAS WINTERED IN A BED (—).**—Begin to uncover by degrees a bed of *Verbenas* which has been covered with ashes to keep it through the winter, from the middle of April.

**CERASTIUM TOMENTOSUM TURNED GREEN (Idem).**—It will recover its colour if it is the true sort, which we never knew to turn green or anything like it.

**COCONUT FIBRE REFUSE FOR SEEDLINGS (Idem).**—It answers capitally, but mix one-half soil with it, and pass the whole through a coarse sieve. In that state all kinds of seedlings take to it better than any other soil we have ever tried. We have reared all sorts of seedlings in it by the tens of thousands.

**FLOWER GARDEN PLAN (C. E. Lucas).**—A most beautiful plan well planted—say a wheel with eight spokes, each spoke a bed; the beds planted in opposite pairs; a vase at the axle, and a nine-inch rim outside the outer walk to be planted with *Cerastium tomentosum* and *Lobelia speciosa* in alternate spaces—the width of the beds in *speciosa*, and the width of the space between the beds *tomentosum*. We would prefer two outside rows of *Cerastium* all round, and the *Lobelia* in a centre row the same. 8 and 4, Purple King *Verbena*, ought to have a band of white *Verbena* all round them, as Purple King in that style of arrangement is the most dull colour in the garden, and nothing brings it out so well as a white *Verbena*. The umbrella-stand would be out of place in that centre. Keep to the vase by all means; and nothing could be better round the bottom of it than *Perilla*, and a thin *Cerastium*-row outside of the *Perilla*.

**CYCLAMEN EUROPEUM (J. C.).**—We file every scrap of correspondence on *Cyclamens*. You are quite right. *Genova*, and not *Genoa*, is your word; and the Po, then, is still the southern boundary of *C. europæum*, as far as our information goes. You may not be aware of the fact, that the Italian botanist Tenore is the right authority for this the northern alpine summer-flowering *Cyclamen*, with the flowers shaped like those of *comu*, but less intensely red, and that he believed it to be the *europæum* of Linnaeus. Then what is your own knowledge of the plant called *europæum* which flowers in the spring? Have you ever seen yourself a true autumnal *europæum* blooming in the spring? It is known to bloom in Austria as early as July and August; but in the warmest locality on the Italian side of the Alps not till the 1st of September, and that only in the Trinli. Does your experience confirm this? Have you ever seen the *Cyclamen neapolitanum* growing wild to the west of Genoa? and have you ever seen the white variety of it in a wild state, or do you know if it is a garden seedling, and have you ever seen or heard of a wild white *Cyclamen* growing near Montpellier? Let us have all the facts and thoughts you spoke of without any arrangement—they will read all the fresher. It is all very well to arrange matters for such people as read, and let in at one ear and out at the other, and call themselves amateurs all the while. But true amateurs like the broken pitcher right fresh from the well just as well, if not better. You are quite right about a mistake in your seedlings. There could not be two opinions about the dash of persicum in the leaves you sent; but no amount of persicum pollen seems to have the slightest influence in altering the shape of the flowers of *comu*—that is, at the first cross. All such seedlings come exactly in the shape of *comu* flowers.

**EVERGREENS IN SOOT AND SMOKE (Terdans).**—The Royal Horticultural Society's new garden at South Kensington is just in the same fix—nothing seems to do well in it but *Rhododendrons*, *Bux*, and *Grass*, but all these are now doing most luxuriantly there. If you could get *Rhododendrons*, tree *Bux*, and *Aucubas*, some *Holly*, *Holly-leaved Barberry*, *Privet*, and *Yew* bushes, they stand the smoke better than most evergreens; and in your deep boggy earth, if you were to mulch them with some light rotten mixture from the framing-ground, it is all and the best you can do. All the old stunted evergreens you have ought to be cut back considerably about the middle of April, and be transplanted into the new border. The short grass from the lawn would be a better mulching than none.

**GRASS SEEDS FOR IMPROVING A LAWN (Idem).**—The creeping very small *Clover*-like plant called *Cow-grass*, *Trifolium medium*, is one of the very best seeds to sow on a bad lawn to improve the texture and give a fine bottom. The white *Clover*, *Trifolium repens*, is the next best; and the *Hard Fescue-grass*, *Festuca duriuscula*, is the best real Grass for such a lawn as yours. The patchy surface should be first well scratched with a strong iron rake, the sowing to be done with a liberal hand, then a thorough good rolling, and no time should now be lost in sowing. If you step the ground, and tell the seccoman the length and breadth thereof, he will be able to tell you the exact quantities. But the *Cow-grass*, or very small yellow *Trifolium*, will not assist you much the first season, although in the long run we have nothing at all like it for improving the bottom.

**USING A GREENHOUSE AS AN ORCHARD-HOUSE (R. M. C.).**—Although the floor of your greenhouse is tiled, you might grow in it fruit trees in pots. We should cover the portion on which the pots would be placed with cocoanut-fibre refuse for the sake of retaining moisture. If you used stages we should have the shelves of boards with a raised ledge all round, and the trays thus formed should be filled with the same refuse. For growing *Strawberries*, *Peaches*, *Nectarines*, and *Apricots*, you will require no shade, but abundant ventilation. To drive worms from your Carrot soil, sow salt, about 4 lbs. over every thirty square yards.

**GREEN GAGE SUCKER (An Amateur, Reading).**—There is little doubt that such a sucker is merely a Plum sucker from the stock on which the Green Gage was budded. There is no objection to your grafting or budding it from the parent tree; and insert a bud or scion on every branch.

**AMERICAN PLANTS (E. S.).**—Mr. Standish, Royal Nursery, Bagshot, could help you in the way you require.

**NEW CYCLAMEN (One of Flora's Devotees, Bath).**—Your seedling *Cyclamen* is worth ten guineas, perhaps ten times as much to some breeders. It is the first grand step we have seen towards the attainment of a long lost race of double ones. Pray be careful of it, and withhold nought from it that is good in goodness, and pleasant to the touch. Keep all foreign pollen from it by all means known in Bath, and never cease sowing seeds from it until you drive the stamens into ten more as effective "petals" as the ten white ones you now have with their cheerful deep lilac bottoms. Gardeners do not "decay" in Bath at all events.

**GEOMETRICAL GARDEN (*Devernia*).**—It would take our whole space for correspondence to answer properly one-half of what you want. In the first place, in the list you sent there is hardly a plant of the colour you give, and there is a complete middle of kinds. The only redeeming points in it are *Saponaria calabrica*, good; *Silene pendula*, good only in May from a September sowing; all Clarkias the same; Candytufts the same; *Portulacas*, dangerous to trust to; *Tom Thumb Nasturtiums*, just the thing. *Oenothera macrocarpa* will suit you well. All *Nemophilas*, all *Gillias*, and all *Collinsias* are very really good very early from autumn sowing or early spring sowing. Your place and the plan look beautiful—the flower garden is really well laid out, and a dial on a handsome pedestal would be good for the centre. But after all you may be a botanist, and if so, you have just hit upon the exact method of filling the beds; but we do not profess that line. A few kinds of *Geraniums*, and with all the kinds of hardy variegated, and plain white-leaved plants which we have recorded, and the few common *Calceolarias* and *Lobelias*, would make a better show than six times their value in seedlings such as you propose. Two plants shading, as shot-silk shades in the sun, make a shot-silk bed—say *Verbena venosa*, and any *Nosegay* variegated *Geranium*; but common variegated, as *Flower of the Day*, are not fit for shot-silking, and not one in fifty can do it properly even with the *Nosegay*.

**SOIL OF DESFONTAINIA SPINOSA (*P. P. P.*).**—You did not consult "all the books," for in *The Cottage Gardener's Dictionary* is this direction. "The soil should be one-third peat (two-thirds loam). It should be shaded from the mid-day sun, and have plenty of moisture."

**FAMM (*Inquire*).**—The best answer we can give you is from the part of "Chambers' Encyclopædia" just published. It is the native name of "an Orchid, *Angraecum fragrans*, native of India, &c., much prized in the east for the delightful fragrance of its leaves, which is owing to the presence of Coumarine, and resembles that of the Tonka Bean, and of Vernal Grass. In the Isle of Bourbon an infusion of Famm leaves is in great repute as a cure for pulmonary consumption and as a stomachic. In France it has been successfully employed under the name of *Isle of Bourbon Tea* as an expectorant, anti-spasmodic, and stomachic."

**VEGETABLES FOR THE AUTUMN IN THE SOUTH OF SCOTLAND (*P.*).**—As you say you only want vegetables from the 1st September up to Christmas, and complain of their being too early last year, it was some excuse of the cultivator attributing their forwardness to an unusually fine autumn—at least it was so in the south of England, and some little allowance must—at all times be made for such things. But if your gardener be not well versed in such matters the following details may be useful, assuming, as stated above, that vegetables for the autumn months only are wanted. Peas.—Sow Champion of England and Ne Plus Ultra from 10th May up to 20th June. If pea-stakes be not to be had sow *Pedman's Imperial* instead. Dwarf Kidney Beans.—Sow the *Victoria* or *Liver-coloured* on 20th May, and again 10th of June. Scarlet Runner Beans.—Sow 1st June. They will continue bearing until frost destroys them. Broad Beans.—Sow green or white Windsor 10th May and 1st June. Bovecole or Kale.—For autumn these may be dispensed with, as their uses are more for spring. Brussels Sprouts.—Sow as early in spring as you can, you cannot have them too early. Broccoli.—Sow white and pink Cape on 20th May and 1st June, and Walcheren on 1st May; the late sorts are not advisable. Beet.—Sow the best red Beet on 1st May. Cabbage.—Sow on 10th May, but generally an early plantation furnishes abundance of sprouts; if the latter exists this sowing may be dispensed with. Cauliflower.—Sow 1st May, 10th, 21st, and 1st and 10th of June. The last sowing, however, may be dispensed with if the situation be a cold late one. Celery.—Sow as early in spring as you can, and treat as described in other articles in THE JOURNAL OF HORTICULTURE. Cucumber.—Only the frame kinds will do in the locality you mention; and seed sown middle of June or later will be early enough. Endive.—Sow green and white Curled 10th June. Lettuce.—Sow Brown and White Cos on 15th and 25th May, and on 5th and 12th June, and one or two kinds of Cabbage Lettuce at the same time. Leek.—Sow early in spring, and cultivate as directed. Onion.—Sow as early in spring as ground will allow. Parsley.—Sow in April, and also in June. Potatoes.—Plant a few of the most useful kind in the neighbourhood. Parsnip.—Sow as early in spring as you can get the ground in order. Salsify and Scorzonera.—Sow middle of end of April. Sea-kale.—Assuming there is an established plantation you might have some by Christmas, but not well before that time. Spinach.—Sow middle of June and beginning of July. Turnips.—Sow 1st, 15th, and 30th June. The Early Stone is as good a variety as any. Herbs for general use, as Basil, Sweet Marjoram, Thyme, &c., may be sown early in the spring in a pan or box and planted out. Roots of Shallots, Garlic, and underground Onions may also be planted in very early spring if wanted. Mushrooms may also be had at the time you mention by preparing beds as directed in previous Numbers of THE JOURNAL OF HORTICULTURE.

**SOWING THE COMMON NASTURTIUM (*C. H.*).**—It always answers best, in all places, where Tropæolums do out of doors in summer, to have the seeds of annual ones sown in the very beds they are to occupy, only it is not the soonest way to have them in blossom.

**SINGLE BLUE and SINGLE LILAC VIOLETS (*Idem*).**—We can make out only that your Violets are very sweet, very large, and very handsome; the blue one has had at least twenty names. Oblige us by sending a root of No. 2 to Mr. Benton. That lilac ought to have a good name, and a good character, we think, and it is just in his way.

**COVERING A TRELLIS, &c. (*J. C. H., Ereter*).**—To have 60 feet or 90 feet of a four-feet-high of trellis work "look gay this summer," you must confine yourself entirely to annuals and half hardy trailers (not creepers) out of pots—say four good *Maurandias* a yard high at planting time, at four equal distances; four *Echincarpus*, the same but larger plants; four *Lophospermums* in four sorts, same size, and then fill in the panels between with the fancy and running race of *Tropæolums*. But what a sacrifice in such a place, instead of a whole fence of the very finest Tea Roses on their own roots. Your plant is probably *Iris variegata*, from Hungary and Dalmatia, but the specimen was bad. Do not apply "soapsuds and liquid manure" to any one of the Centers, and much more especially not to *Wellingtonias* and *Araucarias*. Conifers like rotten dung and plenty of it, if it is carefully mixed with the soil.

**TWELVE SUPERIOR LARGE CHRYSANTHEMUMS (*T. C., Huddersfield*).**—1, Jardin des Plantes; 2, Novelty; 3, Golden Hermione; 4, Lady Harding; 5, Little Harry; 6, Mrs. W. Holborn, the Annie Satter that was; 7, Rifleman; 8, Triomphe du Nord; 9, Wenderlin; 10, Alma; 11, Boudicca; 12, Prince Consort. As you did not ask for colours, consult our report of the shows last autumn.

**HUMUS, &c. (*Viridis*).**—Humus is decayed vegetable matter. Water is composed of hydrogen, oxygen, and caloric, or heat, the latter, we conclude Mr. Beaton means to be "half a thing." The decomposition of water takes place chiefly in the leaves. No seed has ever been detected in Mushrooms.

**ZINC LABELS (*L.*).**—No labels last out of doors so long as similar labels in-doors. How long they last depends upon seasons, extent of exposure, and care in preparing them.

**DOUBLE NARCISSUS (*P. Monypenny*).**—Many thanks: the specimen is very curious indeed, and the history of it more so. It is not of the same species or section as the *Polyanthus* group; but is a true species that has been in cultivation over three hundred years, and named *Narcissus biflorus*, *Bot. Mag.* 197.

**COCOA-NUT FIBRE REFUSE AS A MANURE (*T. Lincoln*).**—There is nothing we know which is a better dressing for all flower-beds, and all kinds of hedging plants, than this cocoa-nut fibre refuse. We have used it for the last seven years as such. The way we apply it now is to mulch with it, heavily as soon as every bed is planted, which, of itself, doubles the value of the appearance at once, and no plant requires to be watered under it, after the first watering, be the heat what it never has been with us. After the plants are housed in October, we fork this mulching into the beds and put on a fresh layer after the next planting. It is just as good for every plant that grows as it is for Ferns; but it will not keep off the Potato disease, although it is by far the best dressing for the Potato we ever tried.—D. B.

**CERASTIUM TOMENTOSUM (*Marguerite*).**—The plant you saw at Lord Stamford's, Enville Hall, is the very plant you inquire about—namely, the *Cerastium tomentosum*, and vast quantities of it they grow in that splendid flower garden. You might get a whole basketful of cuttings of it from his lordship, and every one of them would grow now if you were to put them in at once where you want it; and in future, when you want a thin nice-looking edging of it, it would need to be lifted out of the ground with a fork any time in April, be divided at the roots into little bits and replanted just as the cuttings were, or say about 3 inches apart along the line. On the other hand, if you required a bold, thick, massive edging of it, there would be no need to lift it oftener than once in four years. It is a charming flower of itself that way, and lasts so for six weeks. That is the way our clergyman has it; and all he finds necessary to do to it is to tell the gardener to run down his spade on each side of it any time in the spring, and then to fork out of the ground all the side roots and shoots, so as to make the edges of the row even on both sides, and we should think that would exactly suit you in some parts of the garden. Then, when a thick row of it had to be taken up for re-planting it, all the difference would be to plant larger pieces, or even lay it down in double rows 3 inches apart.

**RIDGE AND FURROW PLANTING (*Helena*).**—It is as the ridge of a house. A row of the highest plants in the very centre of a place, and the rows on each side lowering down successively like the front and back of a roof. Yours may do as well by having the highest row on one side next the low wall, without having pair rows.

**NAMES OF PLANTS (*Frome St. Quintin*).**—The smaller one is a form of *Polystichum angulare*, not mature. The larger is *P. aculeatum* v. *lobatum*. (*J. C., Hagley*).—1, *Nephrolepis tuberosa*; 2, *Polystichum angulare*, v. *plumiferum*. (*T. B.*)—1, Not recognised. What is the habit of the plant? What kind of flower? 2, *Adiantum reniforme*; 3, *Tecoma jasminoides*; 4, *Hibrolanum fasciculatus*, (*Jane*).—We happen to know it to be *Anemone pavonina*, but the specimens are incomplete.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY, &c., SHOWS.

MAY 14th and 15th. TAUNTON AND SOMERSET. *Sec.*, Charles Ballance, Esq., Taunton.

MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). *Steward*, S. Pitman, Esq., Manor House, Taunton. Entries close May 1.

MAY 25th and 29th. HULL AND EAST RIDING OF YORKSHIRE. *Sec.*, Mr. J.

Hooton. Entries close May 11th.

JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. *Secs.*, E. Holdsworth and J. Wade.

### KEEPING PHEASANTS IN A CONFINED SPACE.

It is a great point in their favour that Pheasants are not prone to disease, because there is no pleasure in confining birds if they suffer therefrom. The greatest part of the pleasure of keeping birds is to be able to show them to friends, and to be recognised by them. There are two objects in keeping such things: the first is the pleasure, the second is the profit. We have little difficulty in describing the first; we may have some in proving the second, at least, as far as London is concerned. Our publication tries hard to inculcate the great city with rural pursuits and luxuries—window-gardening, roof-conservatories, and now pheasantries and aviaries. The day will be too short. What with Ferns, Flowers, and Pheasants (three F's), the morning will not be long enough. It may be, however, the yard is not exactly suited for the erection of a pheasantry, or its other purposes and occupants render it unfit for a lady's morning visit. We must seek another place. Dry birds, or such as do not require open pans or other vessels to drink from, may be kept anywhere. The flooring, or rather the bottom of their cage or house, being covered with loose gravel, it is merely necessary to draw a broom, or rake very lightly over the surface now and then, to insure scrupulous cleanliness; and the use of a fountain will prevent a

drop of water from being spilled. Any little roof or the end of a balcony would answer the purpose for Pheasants or for other birds. A pleasing collection of song or feather birds may be kept almost anywhere; and they offer advantages, inasmuch as height is with them an available space that lessens the necessity of a large square at the base. Much may be learned on this subject by looking at the collections of small birds in the Crystal Palace. Provided with food, water, and moderate shelter, there is little fear of mortality, and less of that which may be rather called want of condition than illness, and which consists in squatting about with loose feathers, and looking twice as large as they are in reality.

Arrangements for nesting, such as were first made at the celebrated aviary at Knowsley, may be used anywhere. The stem of a tree put up in the cage, with the bark on, holes made in it fitting for nests, with perches projecting from each, often cause birds to breed when they would not but for these temptations. There is, then, no difficulty in dealing with the possibility of these things in any part of London. We need hardly say there is no profit in the small birds even if they reared their young. There would be in the Pheasants if they reared theirs, but that is impossible. The source of profit or the means of self support with them is in their eggs, and these are always saleable during the season at from 10*d.* to 1*s.* each. A hen Pheasant will lay from twenty to thirty eggs, and is not hindered by confinement. If they live long they will pay even their first cost, and it may be a profit; but they will always keep themselves. It is certain that breeding-birds are more interesting than others, and there is, therefore, one we would especially mention—a very handsome and remarkable bird, hardy, easily kept, very free layer, and by no means difficult to rear—we mean the Californian Quail. There is hardly a house in London where these may not be easily kept; and we are sure there is not one where they would not become favourites. In leaving London for a time, while we look at Pheasants in the country, we will only add two remarks—first, to insure cleanliness, do not let birds have water in open vessels; next, let the bottoms of the cages be covered with loose small gravel. It need not be always bright, level, and red on the surface. Dry hard dirt is no dirt; let, therefore, the bottom be kept dry, and there will be nothing to offend the most fastidious, even in close quarters.

A pheasantry in the country is a very different matter, and we know few things more attractive, or more amusing, than tame Pheasants in a pleasure garden. It is no longer necessary here to look for a spot or for room—in the way of place it is an *embarras de richesses*, and, therefore, we will choose such a one as we like. We dislike the easterly wind so much ourselves, that we never think anybody, or thing, can like it; we, therefore, will choose a southern or western aspect. There shall be a close shrubbery at the back. The house, a watchbox or very little larger, is in the centre; while the galvanised wire netting that forms the pen is stretched close up to the boughs, small branches work through, and the foliage gets thick till no wire is visible. The top is completely overhung, and the front being entirely covered with flowering creepers the Pheasants live in a little paradise.

These things are to be accomplished at so small a cost; and they are in reality, and to all persons, so humanising and so interesting, we have thought it worth while to show plainly they are within reach of most people. There are other birds of which we will treat hereafter.

**SILVER PHEASANTS.**—The first egg of our Silver Pheasants was laid Saturday, the 22nd ult.; the second by another hen on the following Tuesday. We have five hens, but have had but three eggs since March 27th.

#### DZIERZON'S REVIEW OF THE APIARIAN EVENTS OF THE YEAR 1861.

I HAVE much pleasure in laying before the readers of THE JOURNAL OF HORTICULTURE a review of the apiarian events of the past year, translated from a recent Number of the German "Bee Journal," and written by Herr Dzierzon, probably the most distinguished of modern apiarians.

Bearing in mind that the winters of Germany are far more severe and protracted than those of this country, "A DEVONSHIRE BEE-KEEPER" will probably not be displeased at finding

his views on the subject of premature breeding in cold climates so decisively confirmed by the highest living authority, whilst the statement that a queen bee cannot pass beyond the limits of the "brood-bed," except at the risk of her life, will, doubtless, surprise many. However extraordinary it may appear, my own observations tend to establish its probability, and the knowledge of the fact may save future experimentalists from a similar loss to that sustained by my friend, Mr. S. B. Fox, who in No. XV. of "Apiarian Notes," relates how a fine Ligurian queen mysteriously disappeared after some of his manipulations. At any rate no harm can result from a little extra care being taken in returning queens to those parts of their hives which happen to be the seat of breeding at the time they are examined.

Do extremes meet? and is the ignorant cottager who, whilst boasting the number of times his bees have swarmed, consigns three-fourths of his apiary to the murderous brimstone-pit, wiser in his generation than the scientific bee-keeper who with cunningly devised and expensive apparatus exults in the fact that he never purposely kills a bee? Such are the questions which arise in one's mind whilst perusing the axiom laid down by so great an authority, that from "divided hives" is got, on the whole, more than "double profit." If this be indeed the case, we may bid farewell alike to the palatial edifices of Nutt, and the ingenious storifiers of Taylor. Stewarton "bar-and-slides," and the more modern "frames," will be equally at a discount, except in the hands of experimentalists, and we may look forward to dome-shaped straw hives and their congenial hackles resuming undisputed sway. Natural swarming may, perhaps, be assisted by artificial means, and "driving" take the place of suffocation; but if the above axiom be correct, it would appear that beyond this there is little scope for the profitable application of science to bee-keeping.

The concluding observations on the impregnation of autumn-bred queens are, however, of unquestionable value, and are in perfect accordance with the experience of—A DEVONSHIRE BEE-KEEPER.

#### PRACTICAL CONCLUSIONS DEDUCED FROM THE EVENTS OF THE YEAR 1861.

Annual reports have but little interest for the reader if they contain only a statement of the bare results—whether there have been many or few swarms, much or little honey, &c. These reports would be much more instructive if the results which they describe were traced back to their causes, so that from them rules for future practice might be laid down. The year 1861 was on account of its unusual temperature particularly instructive, and affords many hints for our future guidance which ought not to be neglected.

The spring, as has been already reported, was here—and it appears also in most parts of Germany and beyond its boundaries—extremely destructive. And what was the reason of this destruction? Was it the great and continuous cold, or, to speak more correctly, the want of warmth alone? By no means. We have had winters when severe cold lasted a great deal longer, and yet the bees got much better through them into the spring than last year. The mischief lay in the repeated and great vicissitudes of temperature. Premature breeding was induced without any important results, owing to the severe cold which set in compelling the bees to contract their cluster and expose the brood to the cold.

Hence follows this practical rule:—"Keep the hives during winter and spring as long as possible in an equable temperature and in perfect quiet, thereby keeping them from breeding." This end is most perfectly obtained by placing them in some such locality as a cellar. The stocks which I had put in were brought out as populous and almost as heavy as when they were deposited—not one of them had sustained the least injury by the severe cold of January. But to my grief I was misled by the mild weather that set in to put them out too early. Had I, as soon as they had cleansed themselves, put them in again, I had done well. But the bee-friend rejoices at the humming and lively flights of his bees, believing when he sees them take wing that the spring is arrived, not considering that weeks or months of cold may follow, as was indeed the case. The bee-keeper, therefore, if his aim be profit rather than pleasure, should in the spring look on the dark side—always be prepared for a cold and destructive season, and keep his bees in perfect winter quiet as long as possible. This for the hives he had put in can be obtained by opening the *locale* at the coldest hour of the day—that is, early in the morning, and by lowering the temperature

by means of ice or snow when the weather becomes unseasonably warm. Should then a cold time ensue, as is often the case, that "the lame post comes after,"\* the bees would be safe, whilst those which have been prematurely set in motion, and in which breeding has commenced, are frequently destroyed. The loss of the queen is often the result of repeated interruptions in breeding, as was experienced here and in other places during the last spring. Herr Kaden, whose experience tallies with my own, thinks the queens have frequently been stung to death by the bees; and this may be possible, because the bees getting, after a long period of cold and quiet, into full life again find the brood-combs† empty, and the queen, therefore, as it were beyond them where she is always in danger of life. The frequent interruption of breeding, and the want of opportunity to relieve themselves of their eggs which have begun to increase in their ovaries, seem also the probable cause of the death of many weak queens. And lastly, many an old queen, having laid what eggs she was able, now reaches the natural end of her existence which would have happened at a later period, perhaps not until swarming time, if the early warmth had not occasioned premature breeding.

But, it may be asked, If no more cold should ensue, if the temperature should continue warm and the spring come unusually early, would not then the bees which have been treated as aforesaid, remain behind those which had begun betimes to breed? This is, however, not to be feared, as the experience of last year proves. It has been reported that when at last more favourable weather came, the bees recovered with extraordinary rapidity, and still distinguished themselves in working. The full pasture cannot appear suddenly as if by magic, but must be preceded by a warm period of several weeks, during which time the bees are able to gather strength so that they may avail themselves of the first load.

In the report which has been before referred to, I instanced what one stock did, as it increased to six good hives. Those which remained undivided had, of course, a larger stock of honey in the autumn, but the clear profit of each stood in no proportion. From the divided hives was got, on the whole, more than double profit, although the harvest time was very short owing to the season being so far advanced before warm weather set in: hence follows the rule that if the year bids fair to be a good one, and the bees have already gathered something in store, you must increase the number of stocks if you will not have a falling-off in the profits. In excellent years, as the last was in the latter part, the profit from undivided hives, even if the bees never want room, will not amount to so much as from those which have swarmed either naturally or artificially.

The fair weather, which is so exceedingly favourable to bees, lasted in the past summer until the middle of September, when it suffered an interruption, as from that time it rained daily for sixteen days. This was the time when I had taken a journey to Gratz, from thence further to Trieste, Venice, Verona, &c. It was raining when I left on the 12th of September, and the weather was dull when I came back on the 28th. During this time, as I learnt on my return, the bees had been able to work only about twice. On the honey-harvest the weather had no longer any influence, as the pasture was, of course, closed long ago; but to me it was unpleasant, because I had a number of young Italian queens which, at the time of my departure, were unimpregnated and which, of course, still remained so when I returned. As there was yet a tolerable number of drones, impregnation was still possible but became, at this advanced season, every day more improbable. On the 29th of September it cleared up, and the following days were also pleasant. Some of the young queens were seen flying off in the morning, but, for the most part, did not remain long in the air. If their excursions had been successful was very doubtful, and I was afraid of being left in this uncertainty, when the 9th of October—an unusually fine day for the season (20° Reaumur in the shade‡)—relieved me from it. At noon of this day I saw a queen, four weeks old, return with the sign of fecundation; and, when I examined the other hives, two hours later, I saw eight other queens in possession of this sign. On the preceding days the bees had played exceedingly—the number of drones had increased, whilst the number of workers decreased every day, and yet copulation had not taken place: hence it follows that a good warmth of the air, about 20° Reaumur, is necessary if the excursion of a young queen is to

be successful. The day may be light and pleasant, but if the air be cool copulation will not take place. From the before-mentioned circumstances, one may also learn how to ascertain whether late-bred queens are impregnated. Daily observations would be tiresome, and take up much time. All that is necessary is to open the hives and examine the queens about three o'clock on those warm days, during which only copulation can take place. If you cannot determine the point with any certainty, then you must feed the bees every day. Should the queen be impregnated her abdomen will soon begin to enlarge, and she will, even in October, lay at least some eggs. If on the contrary she turn out to be unimpregnated, she should not be kept till winter.—DIERZON.

## APIARIAN NOTES.—No. XVII.

MY APIARY IN 1861.

(Concluded from page 487, Vol. II.)

No. 13.—Early in the spring this stock (a common straw hive), was in good condition. On the 23rd of May, and also on the 28th, it was deprived of a considerable proportion of its bees for the purpose of strengthening, or rather peopling hives, from which all the bees had been driven to make artificial swarms. Nevertheless, on the 19th of June I obtained a splendid swarm from it by driving, transposing the old stock with No. 12. An artificial queen which had just commenced laying eggs was taken from No. 10 (the nucleus before described), and confined in a small queen-box inserted among the combs for twenty-four hours. When liberated she was received by the bees, and is still at the head of the colony. The hive is not again alluded to in my journal—no honey was taken from it; but in October, when all the stocks were either inspected or weighed, it was very heavy and full of bees.

No. 14 commenced its career on the 28th of May, as an artificial swarm expelled from No. 12 (described at page 487), hived in a Langstroth frame-box. The following day two combs had already been commenced, each of which contained a quantity of eggs. A brood-comb from No. 11 was given to strengthen the hive. On the 11th of July Mr. Woodbury was able to supply me with a pure Ligurian queen, for which I had been long anxiously waiting. The common queen was first captured, in truth a fine one, and vastly superior in size and appearance to the one to be substituted for her. This last was confined in a small wooden box, with some of her own bees, separated only by perforated zinc for nearly thirty hours, over the central hole in the cover of the stock. On the communication being opened, every Ligurian bee was quickly destroyed; and no doubt the queen shared the same fate, as on inspection a day or two after no queen was to be found, but many royal cells were in progress. On informing Mr. Woodbury of the failure, he very kindly offered me another fertile queen, also small and rather dark, one of a batch of young artificial queens which, about that time of the summer, all partook of the same character. On this occasion she was confined with a few subjects in a small zinc box, secured among the combs, and liberated about eighteen hours after. As in the former case, the worker Ligurians were immediately hustled out of the hive, and I greatly feared for the fate of the queen; but the next day I was gratified by finding her quite at home in her new domicile. By the 23rd, or four days after, she had laid a considerable number of eggs. As related in the case of No. 8, her offspring proved to be true; and the artificial queen raised from her brood was very superior in appearance to herself. From the failure reported above, together with several others which occurred about this time and prior to it, Mr. Woodbury wisely resolved to send out no more queens, unless in connection with stocks, at the head of which they should be fairly established.

No. 15.—This is an observatory-hive—a unicomb, in the shape of a Gothic window, made more for appearance sake than with any idea of superiority for working and observatory purposes. Its interior dimensions are 3 feet 3 inches in height, by about 17 inches in width to the spring of the arched portion; the space between the glass sides varies from 1½ inch at bottom, to 2 inches at the upper part. It was stocked on the 19th of June by a swarm driven from No. 13, as described at the beginning of this paper. The bees were first hived in a long, shallow box, furnished with bars, which fitted into the unicomb. Honey at this time was most abundant, so that this box was filled with combs, a great proportion of it sealed honey, in ten days.

\* German proverb.

† Literally "brood-bed" or "brood-camp."

‡ 20° Reaumur are equal to 77° Fahrenheit.

On the 2nd of July, combs and bees were easily transferred to the unicomb. Considering the length of the bars, and that no guide-combs were used, the combs were worked beautifully straight; and this I think may be attributed in a great measure to the use of the principle of the Woodbury-bar. On July the 5th this hive was exhibited at our horticultural show, the bees being confined creating a considerable degree of interest. The great object of attraction was, of course, the queen, which was easily seen all the time. The bees bore the confinement and prolonged exposure pretty quietly. For several years in succession have I exhibited observatory-hives with the bees confined in this way, occasionally with much injury to them. Once, in the case of a large globe-hive, the combs collapsed as if placed over a fire; and although the hive was removed the instant it was discovered that the temperature had risen to excess, the combs, with brood, bees, and honey were totally lost. To return to No. 15. At the end of autumn the combs and bees were transferred to the stock-box, where they still remain in good working order, ready to be reshifted at any time.

No. 16 is a flat-topped straw hive, from which a fine swarm was driven on the 23rd of May. Mr. Woodbury having presented me with some sealed royal cells, that same evening I fixed them as well as possible among the combs. Some bees were obtained by putting the hive on the stand of No. 13, removed to another part of the garden. In due time a queen was hatched out, and though most probably fertilised by a common drone, she is a magnificent breeder, and her offspring are the purest possible looking Ligurians. This spring, long before the other hives in the same garden showed much activity, these bees carried considerable quantities of pollen.

No. 17.—A Langstroth frame-hive, stocked with a natural swarm from No. 1, found by accident at nine o'clock in the evening of June the 20th, clustered round the stem of a standard rose tree. The swarm was not a large one, and the bees made poor progress in their over-sized habitation; but on July 1st a very fine cast issued from No. 1 which, in the evening, was safely united to the first. A good stock was the result.

No. 18 was a swarm from the adjuster No. 7, on the 2nd of July, hived in a large Stewarton-box. Owing to the unsettled weather which soon after set in, these bees did not succeed in their endeavours to establish a colony; but starvation and the wasps ended their inglorious career. The hive, being kept at a distance of nearly three miles from my house, could not receive the attention requisite to have saved it from destruction.

No. 19.—A second swarm from No. 7, which was found after the lapse of a week to have made no comb whatever; consequently, the bees were united to another colony.

This concludes the category of my hives in 1861. It will have been apparent to those who have perused these articles, that I was more desirous of transferring my stocks into Langstroth-boxes, or of peopling the same with artificial swarms, than of reaping a good honey harvest. Had the entire resources of my apiary been devoted to the object of obtaining honey, I believe the amount would have been very far beyond anything ever before experienced by me. I never remember honey to have been anything like so abundant as during the months of April, May, and June of last year; but in addition to the swarms obtained and stocks established, I was rewarded with about 175 lbs. of honeycomb, most of it of superior quality. This day I have melted and refined about 6 lbs. of prime wax, from the refuse of combs from last year's manipulations. This, as the price of wax is at present, is rather a valuable addition to the proceeds of an apiary.

One peculiarity in my experience with regard to supers last summer I must notice. I never remember any season where the queens ascended so much, or laid such a quantity of eggs in the supers, the chief proportion of which was drone. I turned up one of the largest of these—a box afterwards weighing 50 lbs., and excised many pounds' weight of drone brood. The space was filled up with new combs and sealed honey. The hive contained at that time many thousands of adult drones, and there must have been almost as great a number in embryo. For a thriving stock, it was the most overpowered with drones of any in all my experience.

I believe the cause of so much breeding in the supers, may be attributed to the early abundance of honey having deprived the queens of much of the proper breeding portion of the hives. In some of the frame-hives where combs of brood and honey were removed for the strengthening of other stocks, on empty combs being substituted they were immediately filled with brood,

and no breeding in the supers took place. Also in two flat-topped straw hives, where shallow ckes were added early in the summer, with the object of enlarging the breeding part of the hives, the supers of 23 lbs. and 32 lbs. respectively, were totally free from any trace of brood. By the adoption of the moveable frame-hives, I intend in future to remove the breeding-combs which may become too much the depositories of honey, to the sides or to other boxes, substituting empty combs. No one who has not tried this plan can imagine how it excites the bees to work, either how much combs they may be compelled to build, or how populous the hive will become, from the rapidity with which the queen avails herself of the new and empty space at her command.—S. BEVAN FOX, *Exeter*.

## THE CANARY AND THE BRITISH FINCHES.

(Continued from page 506, Vol. II.)

### AGE—DISEASES—PARASITES.

The Age to which Canaries live differs much, as birds that are used for breeding do not often live above six or eight years, while those that are kept single for singing only, if judiciously fed, have been known to survive for twenty years.

As I have been a fancier and breeder for many years, it will be expected that I should say something of the Diseases to which Canaries and other Finches are liable; but, in this respect, I fear I shall disappoint that expectation. It is not that my stock have enjoyed total immunity from the ailments incident to the feathered tribe, for, like most fanciers, I have had at times diseases among my pets, the cause and cure of which I have not always been successful in accounting for or relieving, yet, on the whole, my stock has generally been healthy, which I attribute to careful tending and judicious feeding, and I am of the opinion that more may be done as a preventive of disease than as a cure. My advice, therefore, is care, cleanliness, and wholesome food as nearly as possible adapted to the nature of the bird, and to rather underfeed than overdo it, or fatten a bird that is caged-up, and is, consequently, deprived of its natural exercise. Repletion or overfatness I regard as the origin of many diseases, while the indulgence in many pungent or exciting seeds, as rape and hemp, is liable to disarrange the delicate organisation of the prisoner. It is true that some birds may overcome the effects or get inured to the food and live to a long age; but how many die in the process! In the same way many men, though habitual drunkards, live to a good old age; yet, seeing how many die from that cause, no one, I should think, would argue that hard drinking was conducive to health; and yet we find bird-fanciers advocating the pungent rape and exciting hemp seed for the feeding of birds, because a few have lived long on those seeds, while numbers annually die of inflammation of the bowels, surfeit, or apoplexy, most certainly induced by the use of such food.

*Inflammation of the Bowels* may proceed from a cold, and is very common among young birds at the first moult, when they are only partially covered with feathers, and nature is under an extra tax to provide fresh ones; but I attribute it much more frequently to the use of rapeseed, and since I discarded the use of that seed I have scarcely been troubled with the disease. In this complaint the bird becomes thin and emaciated, the abdomen is swollen, and the intestines appear red, the bird sits with its head behind its wing, the feathers ruffled-up as if cold, and soon dies a mere skeleton. As I have before said, it has rarely appeared among my birds since I discontinued the use of rape seed, the pungency of which I consider too hot for the delicate digestive organs of young birds. My advice is at once to discontinue the feeding on rape, give bread and milk, and put a drop of sweet nitre in their water. If far gone I fear there is little hope of the bird's recovery: therefore, again I urge that prevention is better than cure.

*Husk, Asthma, and Consumption* are diseases of the respiratory organs, and generally proceed from colds caught by hanging in a draught, sudden changes of temperature, or a damp aviary. I have found great advantage by putting some tar in the water from which they drink, which has quite cured some cases if taken early, and before the lungs became seriously affected. Bread and milk, and plenty of chickweed and groundsel, are also beneficial. One gentleman strongly recommends the use of rice-water as a cure for asthma in Canaries.

*Decline* is a gradual loss of health and wasting-away of the bird—the constitution being undermined by some cause. The

feeding on hemsced, or other stimulating and fattening food, causes the bird to become unduly fat ; having arrived at ripeness, as the poulterer would say, they rapidly decline and lose flesh and die. Some tonic would, perhaps, be useful with less stimulating food, but I cannot advise what ; as a preventive I would say, Do not fatten them ready for the cook.

There are other causes that may destroy the health of the birds and induce decline, among which I class the continual worry and sucking they undergo from the mites or red bugs that often infest the cages, and until they are extirpated but little improvement can be expected in the health of the little patient.

*Obstruction of the Oil-gland* is another of the ailments of cage birds. Above the tail is a double gland from which oil is secreted, and with which the bird dresses its feathers. This sometimes becomes obstructed, and the oil thickens in the gland, the whole becoming inflamed, and the bird seems to suffer much pain, is dull, inactive, ruffles its feathers, and pants. To relieve it, take the bird in hand and lift up the rump feathers ; having found the swollen gland, gently press out the thickened matter with some smooth blunt instrument, and anoint the part with fresh butter or oil. Some advise the use of powdered sugar applied to the place to draw it gently. The bird is generally much relieved at once, but it may require to be pressed out a second time ; the bath and exercise are good for the patient.

*Dislocation of a Joint* may be reduced by gently stretching the limb and pushing the joint in place, and, if done before inflammation has set in, the cure is complete.

*Fractures of wings or legs* are best left to natura. If the bird is put in a cage by itself, liberally fed, and kept quiet, the broken bone soon joins. If the shank of the leg, or more properly speaking the foot is broken, it will be advisable to put it in place and bind it up, using small pieces of quill from Pigeons or fowls as splints, as from the absence of flesh on that part to form a natural ligature by swelling round the broken ends they do not so readily unite.

*Sore Feet* arise from dirt, or from fine hairs of wool, silk, or cotton getting round them and cutting to the bone (such materials are very objectionable for nest-building on that account, and should never be used). As a cure remove the offending substance, wash the feet, and anoint with butter, lard, oil, or some healing salve ; see that the perches do not cross, so that when the bird sits on an upper one, the dung does not lodge on the lower ; keep the cage clean, and allow the bird the occasional use of the bath in fine weather, which is very healthful to all birds.

*Tumours* may be opened and the matter pressed out, putting a little salve on the place.

*Apoplexy.*—When birds are in high condition, they sometimes are affected by a sudden fit of apoplexy. Any excitement or fright may bring it on ; a tendency of blood to the head, or rupture of a bloodvessel on the brain may cause sudden death.

*Partial Paralysis or Fits.*—When death does not immediately ensue, relief may be given by bleeding in cutting off the tip of the beak, or cutting the toe-nails till sufficient blood is drawn. A purgative should be administered, as sop of unboiled milk and bread with moist sugar, and treacle in their water ; all stimulating food should be avoided, and the bird kept cool and quiet. The pulling out of the tail will be found beneficial towards recovery, as the reproduction of the feathers draws a supply of blood to the opposite extremity of the bird's body. Rotten-feathered, or unnatural moulting, is often produced by the birds being too fat, or fed on too stimulating food and kept too warm : a cooling and lowering diet, a little flowers of sulphur in their food, and the frequent use of the bath with plenty of green food may be found useful.

*Egg-bound.*—In cold or backward springs, hen Canaries sometimes experience a difficulty in laying ; this is more particularly the case with maiden hens. A drop of castor oil put down the throat, and introduced into the vent by means of a feather, have been found to assist the sufferer. As a preventive, moist sugar should be given in the soft food, and plenty of green meat when the birds are expected to lay ; a lump of old mortar with a little salt in it, or a piece of cuttle-fish bone, are good for the birds to peck, and assist in the formation of the egg-shells.

It is, however, hardly necessary to state that breeding from birds too nearly related produces weakly offspring, which are more delicate and less able constitutionally to resist or overcome the attack of the various diseases to which caged birds are liable.

Of PARASITES, I am only aware of two that attack Canaries. A louse sometimes annoys them ; but this I should regard as an indication of dirt and neglect, and may easily be got rid of

by dusting powdered sulphur or brimstone among their feathers, and more attention to cleanliness.

The red mites or cage bugs are a species of *Acarus*, similar to what infest pigeon-houses and hen-roosts. They live in the cracks and joining of the cages, and at night sally forth to suck and annoy the birds ; they multiply in great numbers about the cage and in the nests, tormenting the poor birds, causing the death of the young, and frequently of the old birds likewise.

Some fanciers have recommended the use of the Persian insect-destroying powder ; but I have not tried it, finding that by thoroughly cleaning the cages, saturating the cracks with linseed oil, and then filling them with flowers of sulphur, and dusting sulphur among their feathers, also by cleaning the nest and sprinkling powdered sulphur in, that I can get rid of these pests. Wherever any floury or mouldy appearance is noticeable about the joins or crevices of the cage, these torments to the birds may be suspected, and no time should be lost in giving them notice to quit.—B. P. BRENT.

### OUR LETTER BOX.

**COCHIN-CHINA PULLETS NOT LAYING EARLY** (*D. Binny*).—We can only suggest and name some of the causes that would prevent your pullets from laying. We say "prevent," because in the ordinary course of things, laying birds must do so at the proper time. Some, like Pheasants, lay only in their season, the difference between young and old being but a few days. In fowls, a pullet lays at a certain age, a hen at a certain season : therefore, unless something prevented, your pullets must have laid. Correct registers have proved to us Cochins hatched in May ; generally lay in November, always in December. Many of ours have laid at seventeen weeks. It is the first and the inevitable law of Nature, and after these first eggs are laid, then the pullet settles into the hen, and the regular course of laying, sitting, and moulting goes on. Are you sure the pullets were hatched in March, and that they have never laid, because according to our theory they should have laid in August and September, and would have laid again in February or the present month. There is no such thing as a Cochin pullet being twelve months old before she begins to lay. Over-feeding and fat may prevent ; close confinement and poverty from bad feeding may prevent, but a fowl that breed must lay or die before twelve months. One might be an exception, but as yours were all alike you must find the cause.

**GAME COCK DROOPING** (*Idem*).—When a Game cock gets into the state you describe, the best, almost the only remedy, is to give him raw yolks of new-laid eggs. They will often drink them out of the half-shell, three or four at a meal. We cannot account for the Geese ; we have two, one old and one young, they have laid an unusual number. Have you rats ? Do the birds eat their eggs ? We believe eggs are laid.

**SPANISH FOWLS** (*B. S. H.*).—The very limited space is against them, and renders less food necessary. Do not give them peas. We cannot afford space to state their general management. You can have it in our "Poultry Book for the Many," free by post for seven penny postage stamps.

**VERTIGO IN FOWLS** (*G. II.*).—Fowls troubled with giddiness, partial blindness, want of power in the legs, and finally death, intimate that they are apoplectic, and that this arises, probably, from their being overfed. "Bread and barley" in excess are far too fattening for breeding fowls. A little bread mixed with boiled potatoes, barley meal and boiled potatoes, and a very little whole barley would be better given at different times. Give such fowls as are suffering as you describe a dessert-spoonful of castor oil, and no other food than a little bread mixed with boiled potatoes.

**GOATS** (*M. D.*).—We wish you would oblige us with full details, stating how you feed and manage them ; how long is gestation ; time for weaning kids ; and even the details which to you may seem the most trivial. No work gives such information. We believe Mr. Kidd still resides at Hammersmith.

**UNITING BEES.**—In reply to the inquiry made by my friend Mr. S. Bevan Fox, in the last Number of THE JOURNAL OF HORTICULTURE, I may state that my experience leads me to indorse his conclusion, that confining a queen during the operation of uniting bees is of very doubtful advantage. His concluding request has been anticipated in an article by me on the same subject, which appeared a few weeks ago.—A DEVONSHIRE BEE-KEEPER.

**SIZE OF SUPERS, &c.** (*S. A., Braintree*).—Your boxes are not too large for supers on strong stocks in a good season, but would be more generally useful if two or three of them were reduced to 7½ inches in depth. The use of adapters obviates any inconvenience from difference in size. Read the reply to "J. F." in another column.

**PRESERVING GINGER.**—We shall be obliged by an answer to the following from some experienced reader :—"I have succeeded in growing a good crop of green ginger roots ; but now, having 'caught my hare,' I am quite at a loss how to cook it, and should feel greatly obliged if some one of your correspondents could give me plain directions how to proceed in preserving it. The roots are at present in the dry earth in a state of rest, as they have remained since the commencement of winter, it is now full time to start them again ; but other business has prevented at present. From a book on "Tropical Fruits," I learn thus much—that the time to preserve it is when the roots are just started into growth, and the young shoots are 2 inches or 3 inches high. Of all else I am ignorant, and shall be most thankful for information.—A SUBSCRIBER."

### LONDON MARKETS.—MARCH 31.

#### POULTRY.

We have some difficulty in making quotations, the qualities of the birds being so variable.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 55.6° and 35.6° respectively. The greatest heat, 73°, occurred on the 14th in 1852; and the lowest cold, 20°, on the 10th in 1860. During the period 124 days were fine, and on 121 rain fell.

THE GENUS CEANOTHUS.\*

THE different species and varieties of Ceanothus are all very ornamental free-growing shrubs, of moderate size, and mostly evergreen. Some are tolerably hardy, others quite so, and nearly all are suited for planting in small gardens, especially the Californian kinds, if trained against a

wall, in which situation many of them will produce a profusion of brilliant blue flowers during the whole summer and autumnal months, retaining their foliage all

the winter. They require but little care or pruning, and only a slight protection in very severe weather, and are never infested with insects like the Rose and other climbing plants in such situations.

SECTION.—BLUE-FLOWERED KINDS.

No. 1.—CEANOTHUS PAPILLOSUS. *Torrey.*  
(The Pimpled-leaved Ceanothus.)

This is a beautiful evergreen shrub growing from 6 feet to 10 feet high, with long slender shoots covered all over with coarse hairs, resinous tubercles, and narrow oblong or tongue-shaped leaves, rounded at the points, deep green above, and furnished with numerous lateral veins, on the under side covered with a downy substance. Flowers bright blue, and produced abundantly in rather small round terminal thyrsoïd or globular heads, on long slender footstalks.

This kind is found plentiful on the outskirts of woods in Upper California, flowering more or less from May to September.

No. 2.—CEANOTHUS DENTATUS. *Nuttall.*

SYNONYMES.—*C. floribundus. Hooker. C. dentatus angustifolius. Hort.*

(The Toothed-leaved Ceanothus.)

A handsome slender evergreen shrub growing about 4 feet high, thickly furnished with long slender shoots, and small more or less wedge-shaped leaves toothed at the ends, and full of glandular hairs, deep green above, and more or less downy below. Flowers deep blue, in small terminal globular heads, on short footstalks, and in great abundance.

This kind is found on the margins of woods in Upper California, flowering during the summer and autumn; but very much altered in stature and general appearance by soil and situation.

\* The name "Ceanothus" was originally given by Theophrastus, and is derived from "Keo," to prick or cleave, on account of the first species to which the name was applied being spiny or prickly shrubs; but all of which are now transferred by modern botanists to other genera, so that the plants to which the name is applied have nothing to do with the species first so named except in belonging to the same natural order.

No. 3.—CEANOTHUS VEITCHIANUS. *Hooker.*  
(Veitch's Ceanothus.)

A fine species closely allied to *C. dentatus*, papillosus, and some others of the blue-flowered Californian kinds; but easily distinguished from them all by its perfectly glabrous branchlets, glossy or almost varnished leaves, calyx, and footstalks, and its bright mazarine blue flowers, which are produced in close heads.

A fine evergreen shrub, found abundantly in Upper California, flowering during the summer and autumn months.

No. 4.—CEANOTHUS RIGIDUS. *Nuttall.*  
(The Stiff-branched Ceanothus.)

A dense-spreading evergreen shrub, with a much-divided head and rigid branchlets, growing from 2 feet to 3 feet high, and thickly covered with small wedge-shaped leaves; of a deep glossy green above, very pale and notched below, and spiny-toothed at the ends. Flowers in small close clusters or umbels, thickly placed along the branches on the ends of very short spurs, and of a deep purple or violet colour.

It is found in open places in the woods near Monterey in Upper California, and on the Sacramento Mountains forming scrubby thickets, flowering in May and June.

No. 5.—CEANOTHUS PROSTRATUS. *Bentham.*  
(The Prostrate Ceanothus.)

A prostrate and very branching evergreen shrub, with rigid smooth shoots trailing along the ground, and thickly clothed with foliage which is from six to nine lines long, wedge-shaped, trident (three-toothed) at the ends, thick, leathery, obscurely nerved, glabrous, and opposite. Flowers somewhat umbellate, or in short, thyrsoïd heads, and of a deep blue.

It is found on the Sacramento Mountains in Upper California, a prostrate creeping shrub covering large patches of ground.

No. 6.—CEANOTHUS THYRSIFLORUS. *Eschscholtz.*

SYNONYME.—*C. divaricatus. Lindley.*  
(The Thyrse-flowered Ceanothus.)

A large evergreen bush, or small tree, full of slender twigs, and growing from 10 feet to 20 feet high. Leaves oval, rather small, glossy, dark green, smooth on both sides, and crenated on the edges. Flowers in close globular or thyrsoïd heads, on long footstalks, or axillary along the last year's wood, and of a deep blue colour.

It is found plentiful in many parts of Upper California, particularly about Monterey and San Francisco, growing in woods sometimes 20 feet high, and flowering all the summer and autumn.

No. 7.—CEANOTHUS LOBBII. *Hooker.*

SYNONYME.—*C. Hartwegii. Hort.*  
(Lobb's Ceanothus.)

A large evergreen bush thickly furnished with bright green shoots, more or less angular and rather rigid. Leaves rounded, rather large, toothed on the margins,

bright glossy green on the upper surface, and thickly placed all round the shoots. Flowers bright blue, in close round or thyrsoid heads, on long footstalks, and mostly terminal.

It is found mostly intermixed with *Ceanothus rigidus* in open woods near Monterey and other parts of Upper California.

No. 8.—*CEANOTHUS AZUREUS*. *Desfontaine*.

SYNONYMES.—*C. bicolor*. *Willdenow*. *C. cœrulens*. *Loddiges*. (The Blue *Ceanothus*.)

A handsome shrub, growing 5 feet or 6 feet high, with long slender branchlets. Leaves ovate-oblong, smooth above, downy beneath, and acutely serrated on the margins. Flowers in large elongated thyrsoid heads, on long footstalks, and axillary on the young shoots; of a brilliant celestial blue, and produced from May to October.

It is found in the colder parts of Mexico, where its bark is used as a febrifuge.

There is the following variety—viz.,

*Ceanothus azureus albus*. *Masters*.

SYNONYMES.—*C. azureus intermedius*. *Loudon*. *C. azureus flora albo*. *Hort*.

A seedling variety with whitish flowers, raised by Mr. Masters, of the Canterbury Nursery.

No. 9.—*CEANOTHUS PALLIDUS*. *Lindley*.

SYNONYMES.—*C. ovatus cyanus*. *Baumann*. *C. tardiflorus*. *Horneman*. *C. Baumannianus*. *Spach*. *C. Delilianus*. *French Gardens*. *C. Dillinius*. *Rinz*.

(The Pallid-flowered *Ceanothus*.)

A fine evergreen shrub, somewhat resembling *Ceanothus azureus*, but with the leaves much smaller and more ovate. Flowers in close globular thyrsoid heads on long branching footstalks, axillary, placed along the shoots, of a very pale blue, and in great abundance.

It is supposed to be a native of the southern states of North America, and flowers freely during the autumnal months.

No. 10.—*CEANOTHUS VERRUCOSUS*. *Nuttall*.

(The Warted *Ceanothus*.)

A large evergreen shrub growing from 8 feet to 10 feet high, with long, stiff, rod-like, downy branches, covered in winter with numerous large oblong, or roundish brown buds. Leaves opposite, roundish-oblong, either slightly notched or entire at the ends, the larger ones being nearly 1 inch long, flat, deep green and shining above, but with grey hairy pits distributed over all the under surface, and with a pair of stipules at the base of each leaf, which gradually lose their thin extremities and change into soft fleshy conical prickles. Flowers very pale blue, and produced in great abundance in dense corymbs at the ends of very short stiff lateral branchlets.

It is found forming thickets on the Santa Cruz mountains, in California, flowering in June.

SECTION.—WHITE-FLOWERED KINDS.

No. 11.—*CEANOTHUS AMERICANUS*. *Linnaeus*.

(The New Jersey Tea Tree.)

A half-shrubby deciduous bush growing from 2 feet to 4 feet high, with ovate-acuminate leaves, serrated on the margins; pubescent beneath, and from 2 inches to 3 inches long. Flowers small, in dense thyrsoid heads on long footstalks, axillary on the branches and of a whitish colour.

It is found plentifully in the dry woods of North America, from Canada to Florida, flowering abundantly in June and July.

The Canadians use the plant for dyeing wool and nankin of a cinnamon colour, and the dried leaves were formerly used as a substitute for Chinese Tea by the inhabitants, and the plant is still known by the names of "New Jersey Tea" and "Red Root" in the States.

It is a very variable kind and has the following varieties, some of which are considered as distinct species by closet botanists.

*C. americanus intermedius*. *Torrey*.

SYNONYMES.—*C. americanus pallidus*. *Gordon*. *C. intermedius*. *Pursh*.

This variety has ovate-oblong deciduous leaves, pubescent beneath, and white flowers, in loose round heads, on long footstalks, and is readily distinguished from the species by its very much smaller foliage, which is not more than quarter the size of those of the species.

It is found plentifully in dry woods in the state of Tennessee, flowering in June and July.

*C. americanus perennis*. *Pursh*.

SYNONYMES.—*C. ovatus*. *Desfontaine*. *C. ovalis*. *Loudon*. *C. herbaceus*. *Torrey*.

A half-shrubby plant growing 2 feet high, but frequently with the shoots killed down to the ground in winter, and then little more than herbaceous. Leaves ovate or oval, smooth on both sides, serrated on the edges, and as large as those of the species. Flowers white, in close heads, and on rather short footstalks.

It is found plentifully in Carolina and the southern States, flowering in July.

*C. americanus sanguineus*. *Loudon*.

SYNONYMES.—*C. americanus Pitcheri*. *Torrey*. *C. sanguineus*. *Pursh*. *C. oreganus*. *Torrey*. *C. americanus oreganus*. *Loudon*.

A very variable variety, growing from 2 feet to 4 feet high, with the shoots of some plants deep blood red, while others are hardly stained. Leaves oblong, serrated on the margins, and more or less pubescent beneath. Flowers white, in close round heads, on rather short footstalks.

A variable shrub found along the banks of the Missouri River, near the Rocky Mountains, and in the Oregon country, blooming in May and June.

No. 12.—*CEANOTHUS COLLINUS*. *Douglas*.

SYNONYMES.—*C. Douglasii*. *Don*. *C. oreganus*. *Of some*. (The Hill *Ceanothus*.)

A decumbent evergreen shrub, never growing more than 1 foot high in its native state, with smooth roundish shoots. Leaves ovate, or egg-shaped, somewhat clammy and glandularly serrated on the edges, with the upper surface shining, and the under one covered with flattened or adpressed hairs and three-ribbed. Flowers white, and produced in numerous panicles in June and July.

It is found on the hill sides along the Columbia River, and on the north-west coast of North America.

No. 13.—*CEANOTHUS VELUTINUS*. *Douglas*.

SYNONYME.—*C. levigatus*. *Hooker*.

(The Velvety-leaved *Ceanothus*.)

A large sub-evergreen shrub growing from 6 feet to 8 feet high, with the branches somewhat pendulous. Leaves orbicular or elliptically ovate, obtuse at the points and somewhat heart-shaped at the base, glabrous and shining as if varnished on the upper surface, velvety or canescent and strongly three-ribbed below. Flowers in panicles, on long footstalks and axillary.

It is found on the north-west coast of North America on sub-alpine hills.

No. 14.—*CEANOTHUS MICROPHYLLUS*. *Michaux*.

SYNONYMES.—*C. hypericoides*. *L'Heritier*. *C. scryphillifolius*. *Nuttall*.

(The Small-leaved *Ceanothus*.)

A small, somewhat decumbent shrub, with straight shoots, seldom growing more than 2 feet high; with very small, oblong, obtuse-pointed, entire, smooth leaves, seldom more than three or four lines long. Flowers white, in loose terminal heads.

It is found in sandy woods from Carolina to Florida, flowering in May and June.

No. 15.—*CEANOTHUS INTEGERRIMUS*. *Hooker*.

SYNONYME.—*C. californicus*. *Hort*.

(The Entire-leaved *Ceanothus*.)

A large erect bush, growing 10 feet high, with long, slender, smooth shoots. Leaves ovate, bright green, quite entire on the margins and smooth. Flowers white, in large, loose, plume-like heads, on rather long footstalks, and in great abundance.

It is found in woods and along the banks of streams, particularly in the Sacramento Valley in upper California, flowering in June and July.

No. 16.—*CEANOTHUS INCANUS*. *Lobb*.

(The Hoary-leaved *Ceanothus*.)

A very distinct kind, with small, evergreen, Holly-like leaves, in opposite pairs, from six to eight lines long, and from four to five lines broad, more or less oval in outline, glossy green above, feather-nerved, downy, and snow-white below, with a few short, stout, spiny serratures round the margins, the larger ones pointing upwards. Flowers supposed to be white.

A kind found in northern California by Mr. Wm. Lobb, and introduced by Messrs. Low of the Clapton Nursery. It proves quite hardy.

NO. 17.—*Ceanothus cuneatus*. Nuttall.(The Wedge-leaved *Ceanothus*.)

An evergreen shrub, growing from 6 feet to 8 feet high, with somewhat thorny greyish shoots very closely interwoven. Leaves half an inch long, wedge-shaped or somewhat oval, and not unfrequently with two serratures near their extremities, and furnished with numerous elevated, simple, and oblique veins on the under side. Flowers white, in small axillary umbels.

It is found on the Sacramento Mountains in California, and on the dry gravelly islands and bars of the rivers in the Oregon country, flowering in May.—GEORGE GORDON.

## MANETTI ROSE STOCKS—PACKING OUT FLOWERS FOR TRAVELLING.

A BROOM-HANDLE article is just as useful at times as a change of subject, if only to sweep out the office, and turn over a new leaf. Well, when you go to bed of a Monday night this Journal goes to press, and by four in the morning it is on the road, and you ought to have it as early as you can get the *Times* and the morning penny papers from London of a Tuesday. If I had been as far from London as you are, I should have it at the same time; but in this part of the S.W. delivery we have nothing yet faster than a go-cart, and the day is well nigh over before I can see what they say about the "work of the week," so your crops may be so much the more early than mine, if you have a mind to have it so, and not forget this the first few strokes of my broomstick article. Brooming it, without raising a dust, however, would be out of the question, and I have and must use the broom though it raises a cloud.

First, however, I will rest on the broom-handle and talk a while, first thanking the Rev. W. F. Radclyffe, of Rushton, for his most excellent article on the Manetti; and, above all, for not having "kicked over a bee-hive" in writing it. That was a practical illustration of what I have always been so earnestly inculcating on young gardeners. Write with all the force of the old "grey goose quill," if you can, but never raise a dust in doing it, and you will gain your point in the long run, as I have done on the point of having all Roses on their own roots as the best way, and Manetti is but one way of doing it—not the easiest way for those who can grow them from cuttings, but a safe way for those who cannot; that is, if the Manetti is, or has been done as it should, if not it is ten times worse than losing your Rose cuttings, for nothing on earth, or under it, will save one single Rose on a Manetti stock, if the stock has not been done right in the first instance. Mr. W. F. Radclyffe very justly remarks of it that "it is remarkable what a mess propagators and cultivators have made of it between them." Most remarkable I should say to my cost, for I lost three sets of sixty kinds of the best Roses, three times running in the Experimental Garden through that very mess—a mess that three very popular nurserymen fell into in budding the Roses I bought of them on Manetti stocks, from which no eye was ever taken. All the mess that cultivators had their share in was the mess of losing their plants consequent on the mess of the propagators. I got into that mess deeply, and my conscience tells me to warn my readers, lest they, too, get into the same mess; and unless they are first-rate hands at Rose-culture, I have now the authority of one such, to tell them that they *shall* get into the same mess as I did. That one is candid enough to admit that he never met with one who approved of it but nurserymen and himself. My experience is different. Two of the first Rose-nurserymen in England told me Manetti was bosh, and nothing more, and that people would find it out sooner or later. I can testify myself that the best Rose-growers in the kingdom failed with Manetti in pots most completely, and most decidedly. I registered the battle of the Roses since they were grown in pots; and no Rose, or a collection of Roses on that stock have yet taken a first prize, nor yet a second, that is the test. Talk will not do, and Mr. Rivers had to give up Rose-showing altogether for no other reason more certain than that Roses on Manetti could never get over Roses on their own roots. But Manetti is one very good way of getting a collection of Roses on their own roots, and THE COTTAGE GARDENER looked upon it from the first in that light.

Now, with such authority as Mr. Radclyffe before me, I shall earnestly advise in future to work on Manetti, if you can make the cuttings of Manetti for stocks yourself; but if you cannot, you will as surely get into the "mess" as I did, from nursery

stocks, for not one of the stocks in ten thousand, at some nurseries, is ever made as it should.

The best Rose-grower in Surbiton is Mr. Walton, of the Waltonian Casc, and no matter what I say, he will not have a Rose on its own roots. So there is the other side of the question for you. He buys every new Rose as it comes out, if he is sure it is good, and he says he should soon have no room for Roses at all, if he had them on their own roots, for then they would grow twice the size, and never die!

There is one thing I should like to know to guide me in the matter for a portion of readers. How is the budding of Manetti done in the nursery so low as it is necessary? Do the men go on all fours? and has the blood ever been known to flow so much to the head the while as to endanger madness, or any cracking about the brain? And how would you set a lady to do it? They are the best budders when they try.

Every word that has been said in praise of Manetti applies with equal force to all kinds of Roses on their own roots; and it is now made as clear as the evidence of our senses that the Manetti stock is of no other use than as a safe and certain means of getting Roses on their own roots, even if you have the best soil, the very best experience and brains, together with the best climate in England; also that the muck-pie must not crust long together if you are getting a collection of Roses on their own roots by the help of Manetti stocks.

There is no other conclusion that I can come to, as a practical gardener, after reading Mr. Radclyffe's article. No Rose will grow on the Manetti for any length of time, if the whole stock and the union is not buried in the ground according to the evidence of its greatest advocates. No nurserymen in a hundred ever think of preparing Manetti stocks so as to relieve them of making suckers from above the collar. The consequence is that all such Roses become actual pests in the gardens of ordinary growers; and to suppose or support the idea of a benefit accruing to a Rose, or to any kind of plant under the sun, from having two sets of roots under it, as Roses on the Manetti will soon have, is an entire fallacy in scientific culture. I should not desire a more weak point in the argument of a physiologist against me than that; I should soon be able to shut his book for him, yet it is a prevailing idea notwithstanding. A runner from a Strawberry plant is fed by it till a new plant is rooted at the end; the new plant roots, and is then fed by its own roots exactly as is the case with a Rose rooting over the stock. The question then is, How much or what the value of the quantity of the nourishment the young Strawberry plant derives from the old one through the runner? Some say one thing, some another, the truth being that no one knows. But if you have two such runners and two new plants of equal size and strength at the ends, you will be able to judge pretty near the mark if you cut one of the runners and leave the other as it is. I know what would be the result to the turn of a shade, but shall not prejudge the question; try it and see. That is the lowest degree on the scale for calculating the force or the value of the nutriment derived by a plant on its own roots from the parent plant with which it is still attached.

The next degree upwards is also a familiar one to gardeners. A stout common Laurel in a dry shrubby puts out a weak shoot from near the bottom not bigger than a parasol-handle, and not able to support itself, and it rests on the loose ground at last and roots there, just as did the Strawberry. In six or seven years the young Laurel is as big as the old one; but how big is the parasol-handle-like shoot, which still exists as a connecting link between the two, as the Manetti is between its own roots and the roots on the Rose above it? Why, the little Laurel shoot is not one whit bigger than it was seven years back, although there is a strong Laurel at each end of it; and how is that? Or do you or I mean to say that if the old Laurel had been cut down in the first instance all the strength from the roots of it would have gone through the body of the little shoot into the new Laurel at the other end of it? There is just where I should like to have a smart physiologist in close argument, and if I could not shut his book or his mouth it would not be for want of more degrees on that scale to measure his skill against my practice; therefore, to question the benefit a Rose would derive from its own roots and the roots of a "Rhinceros" Rose-stock at the same time, would not be going beyond the bounds of fair argument.

But it is not fair argument, but a very unfair inference, to pit the practice of the best growers on the best soils, and in the best situation and climates, and muck to boot, against the

attempts of such people as know next to nothing of Roses, soils, stocks, and management, and whose back yards and front gardens are barren as the desert, or if just as good as goodness itself, but no good done to it for goodness knows how long. The latter class come to me for advice, and I give it conscientiously when I say, Avoid Manetti stocks, and never use them farther than as a convenient mode of putting your Roses on their own legs.

All this is merely to show up the folly of taking things for granted out of the column for private correspondence. You might just as well go about and tell it in Bath or Barnstaple that the British Parliament was just what it is, because you had seen something in the private letter of an old Scotch woman who took snuff and who had a son in New Zealand. Mr. Rivers and your humble servant decreed, by common consent, that Signor Manetti should be allowed a holiday for a good while; and when we met the other day at the March Show of the Royal Horticultural Society, after pawing as we always do for "Auld Lang Syne," we both of us regretted the indiscretion of that "NURSERYMAN" who made all this piece of work; and all that we could do in the matter was to wish with Burns that some power would give us both the gift to defend us from our friends, for if either of us ever had an enemy he or we well knew how to forgive him.

**PACKING CUT FLOWERS.**—The next corner which needs the broom is filled with cut flowers. Some one sent a box full of cut flowers, and no one ever saw such a mess of packing flowers before. The fact is, or rather was, the flowers crushed each other, and some of them turned some others heads and tails. They were all in a mess like Manetti and the propagators. When I was on that staff we used to have flowers on the rail every week the whole winter long, made nosegays, button-holes, and all manner of bundles, some on wire, some on "Spanish Grass," and some on their own stalks, when they have had them in lengths sufficient to enable us to bundle them; and without being in proper bundles no one thought, then, of sending them at all, much less to London.

Perhaps you may not remember the last wedding which was at Buckingham Palace, but I do, and I have reason for doing it. I had a medal, and a good medal it was too, for eight wedding nosegays which I sent to that wedding, fresh and fast as a lover's knot. I forget how long they were on the rail, but they were in the packing from four o'clock of the previous afternoon to after breakfast the next day in London, or say about eighteen hours, and if they had been going all the while, and as much more time to the bargain, I cannot see how they could take hurt.

I recollect at another time, when Her Majesty was far down in the country for nearly a week, at the baptism of an infant lady, who is now well nigh the age of thinking of something that way herself, and there one of the ladies of the grand party came down to breakfast every morning, and to dinner in the evenings, with a fresh nosegay each time, and no one in the establishment knew how that lady came by her nosegays, nor am I going to let the cat out of the bag, but so it was, as certain as I tell of it.

At another time I recollect starting from a Chiswick Show, with Mr. Fleming, of Trentham, to Stafford House, in London, to see how he packed all the flowers he sent to an evening party there of two thousand people. But all these things are now old-fashioned, and the packing of cut flowers may be very superior now to what it was then, yet such as it was; it would help a fellow now from making an April fool of himself by putting them heads and tails, and by allowing them to do that on the way to the office. Mr. Robson would be a likely man to know how ladies like their cut flowers to be sent in these latter days, if he had a mind to tell us, for had it not been for that box of spoilt flowers in our office, the very last thing I should think of would be to push old notions under new nostrils that way.

I had twenty-two boxes of different sizes for that purpose, and that number would last out a whole month, taking all chances of "returns;" but of all the chances in this world, that of getting a flower-box returned, if you sent a present in it, is the last chance on which I should be inclined to venture a stake. Of course, no one would be so rude, in times like these, as to keep back a flower packing-box, so you may send them to all your friends, if only to try if the experiment of packing will answer. The first way is a good way for short distances, as from Liverpool to London, the second is a better, and would do

between London and Vienna, or thereabouts. The first is a square basket, quite flat at the bottom, and from 10 inches to 16 inches deep, the length and breadth to be according to the quantities to be packed. The second is of three-quarters-of-an-inch deal box, same depth and width, well painted inside and out, and with iron binding at the four corners, and the lid hinged on, and a lock and two keys for boxes or baskets. All cut flowers to be in handfuls, or bundles, not big ones, but put up as close as for a hand nosegay, to put the stems in a ball of well-squeezed moss after wetting it, to tie a dried blade of Rhubarb leaf round the moss; but a fold of oiled paper would be best, and the same with care might last as long as needful. Round each ball envelope a piece of newspaper just as tea is put up by grocers, then you will see only the top side of each bundle of flowers, as when a truss of Narcissus bursts the spathe. Your paper represents the spathe of most flowers at that period, the peak of the spathe or envelope rises above the flowers behind, but not in front next to you. You put three or four or five of these balls in a row close to one end of the basket, with the paper-hood or spathe rising behind to save the flowers from the end of the basket. Then, with a packing-needle, you draw a stout thread through the side of the basket, then across the top of the ball and out on the other side of the basket; pull it tight as a drum, and make a knot on it outside to keep it on the pull. The balls are now "clipped," as in a vice, and nothing can move them from their position till that string is cut. Do so with each row till the box is full, or half-full, or three-quarters full, or with only one row all round the sides and the ends. You will need some broken newspaper to tighten in between the balls occasionally, and that will be all the packing-stuff you need. But recollect to send so many bundles of leaves with each basket; Lily leaves, or those of Irises, or of Grasses, and plants like Pampas Grass are the best to put into the glasses with cut flowers; for nothing can be more hungry-like than to see lots of naked flowers in a drawing-room without some such leaves. Then lock the basket, and you may throw it over the monument without hurting a petal, and throw it back without the smallest injury. Nothing can hurt the flowers now but the damp from their own perspiration; and their hoods, or spathe, or involucrems, if they be of any paper on which smart politics are printed, will keep the damp from spreading; but the basket itself being a self-ventilating contrivance, will keep down or let off the perspiration for a day or two.

The flower-box is more for carrying ready-made nosegays; and every nosegay that was in Covent Garden this spring might be sent to Galway, in the west of Ireland, and be as fresh as if only to Eaton Place on your way down to Fulham, and perhaps a deal more safely; but bunches of cut flowers would travel just as well; for what else is a nosegay after all? Well, the box is on the same principle as the boxes in which they take Dahlias and other cut flowers to the show, but the application of the principle is quite different. There is a half-inch deal made like a lid to fit just inside the flower-box; and, if you let it slip down into the box, it would fit in the four corners and on both sides, and you must turn the box upside down before you could get the flower-stand out again, for that is the name of it. Now, fasten four legs to the flower-stand, one at each corner, and let them be 6 inches long; and on the upper side, in the very centre, nail a bridge across the flower-stand. Now, take it by the bridge and put into the box again, and see if the lid of the box just presses on the top of the bridge, and if it does, can you not see almost through the lid that the flower-stand is fixed firm as London, first on its own lawful legs in the corners, and, secondly, by the pressure of the lid on the bridge—which, in fact, is the handle, only one does not like to squeeze a hand as he would a wooden bridge? Then there are four, or six, or eight, or more holes made in the flower-stand, each hole 2 inches or so across, and each hole will hold a bunch of flowers, with the stalks, in that diameter; and to fill the board or stand you put it on its side and put the bunch of flowers through the hole from above; you then gather the flower-stalks and pack a little damp moss round them, then with a little wooden wedge and a bit of cotton wadding wedge the flower-stalks in the hole, so that no jerk can shake them, and that bunch is finished; all the rest the same way. The Iris and grass-like leaves being laid flat in the bottom of the box in a fold of paper, put some dry moss over them, and put in the flower-stand, and you will find that the damp balls below the board will nestle in the dry moss, and the dry moss will suck any damp that way, and all above is as

dry as a bone, quite open between the different bunches of flowers. Now lock the box, and all within it is as safe as the Bank of England.

D. BEATON.

### THE ROYAL HORTICULTURAL SOCIETY.

THE April Number of the "Proceedings" of this now prosperous Society is just delivered to its Fellows, and contains one or two announcements which require from us some comment.

The waterworks being now completed, the Society are desirous of stocking the basins with fish, and for this purpose they ask for donations of gold fish and the common carp. Of the latter, "none but large specimens are desired."

We are very pleased to see that Sir Wentworth Dilke renews his prizes for dinner-table decorations the same as last year; and that Lady Dorothy Nevill, in the same liberal spirit, offers two prizes "of six guineas and four guineas, for the best arrangement of flowers for drawing-room decoration, to be competed for at the Great Show on the 21st of May."

For that Show we regret to see the announcement, that "immense tents are in preparation." We should have thought that the results of the shows under canvass at Chiswick would have been an unfaceable warning not to risk at Kensington a repetition of those signal defeats by wind and rain. We most emphatically warn the Council not to risk such disasters. That period of May is especially liable to heavy continuous rains, and, moreover, there is no need for risking such a frustration of the hopes, and such a destruction of the pleasure, both of exhibitors and visitors.

The great and telling advantage of the shows at the Crystal Palace is, that the purchaser of a ticket knows that be the weather whatever the most ill-tempered of the winds and seasons may devise, the Exhibition will be as enjoyable as if there were only zephyrs and sunbeams outside. So might it be at Kensington Gore, for there is ample space under the arcades. The Council admit the desirability of such weatherproof buildings for the purpose by announcing, as they have, that the Azalea Show on the 9th inst., "will be held partly in the council-room, and partly in the adjoining colonnade."

We have heard it objected, that the arcades are not quite light enough. We differ from that opinion, but, at all events, they are quite as well lighted as the council-room; but if not, the roof of a part of the arcade might be covered with glass, towards the payment for which the money proposed to be expended on "immense tents" might be diverted. For the summer shows the arcades would have the additional merit of being cool. Tents in blazing weather oppress the visitors and injure the flowers.

### MR. W. PAUL'S "ROSE ANNUAL FOR 1861-2."

A MAN who works for the public should receive the acknowledgments of the public. I, for one, thank him for his "Rose Annual." It is valuable, and, as far as I have proven the new Roses of 1861 out of doors, in a more limited way, and under more trying circumstances, his description of most of those that I have proven is exact and truthful.

The work commences with four beautiful plates, of which one Rose, Beauty of Waltham, belongs to 1862. They are:—1, Beauty of Waltham, a well-shaped, thick-petalled Rose, of good outline and with good foliage. 2, Marquise de Foucault, a lovely delicate-coloured Tea Rose, apparently the masterpiece of the four. 3, Souvenir de Comte Cavour (Margottin), a rich deep shaded crimson, lovely and effective. It is sure to please. A first-rate judge told me that it was the best new Rose that he saw in France last summer. It looks in the plate like a superior Jacqueminot in the colours of Victor Trouillard, and better shaped. 4, Catherine Guillot, perfect in shape, in the way of Louise Odier. It seems to defy criticism. I have three nice plants of it not yet bloomed. I see no fault in the two first and last, and only one in the third Rose—viz., the calices of the smaller expanded specimen are "reflexed." The large specimen does not show this. It is inferior to the other three in outline, and yet ninety-nine out of one hundred persons would prefer it.

With regard to the Marquise de Foucault, Mr. W. Paul observes—"Probably the plant is best suited for a pot Rose, or for placing against a wall or pillar in a conservatory, but it is also worthy of general cultivation."

In pages 121 and 122 there are descriptions of twenty-five

favourites of 1861. Eleven of them I do not possess. Two kinds, Catherine Guillot and Jean Bart (a nice shrubby plant with good foliage), are but just arrived. Of the remaining twelve, I will endorse Abd-el-Kader, Amiral Gravina, M. Melaine, Princesse Mathilde (four rich dark Roses, apparently with good constitutions and habits), General Washington, La Boule d'Or (for glass), Parmentier (small but very hardy and perfect), Madame Furtado, and Triomphe d'Aniclus.

The others require a word of comment. Reine des Violettes, a seedling from Pius IX., is a good grower and free bloomer, but it is inferior to its parent, being too small, unfixed, and clouded in colour, and quickly deciduous; Prairie de Terre Noir is all that Mr. W. Paul says of it, but out of doors it did not bloom so freely last cold summer as could be wished. It is hardy, of a fine purple crimson colour, but its peduncles are too long to show the foliage in a four-inch show-cup. It would be good as a corymb Rose shown on a long stem, so as to display the foliage. Duc de Cazes was very fine at the National; and if its habit is good, and its constitution equal to our climate, I think it will be worthy of a place. A Briar budded with it broke early this spring, and has stood severe weather. Two Furtados budded on Briars made wood after budding and are alive. Abd-el-Kader and M. Melaine are good dark Roses, and will stand some time. The first is much better than has been allowed. I have a high opinion of the dark Roses, Princesse Mathilde and Amiral Gravina. The plants of them (twelve), look well. The Princesse was beautiful at the National; and buds of the Amiral (not fully open), on the plants sent just before winter set in, were fine in form and colour. I fancy the Princesse will be A1 of the dark Roses of 1861. Your readers, however, will be pleased with and cannot hurt themselves with M. Melaine and Abd-el-Kader. They are rich dark colours, of good growth, and hardy constitutions, which very dark Roses are generally deficient in.

I pass over many interesting particulars and come to some instructive matter. Pages 131 and 132 give an account of the number of times summer and autumnal Roses were produced last July at the Crystal Palace and Kensington, at the grand Rose Shows; and I am glad to see that those Roses (with rare exceptions), which I have recommended so often in one periodical or another, are the Roses that appeared the greatest number of times. As a general rule (not "rule absolute"), you may assume, that the Roses which appear oftener in the pans at the National, are the best for the public to purchase. Gloire de Dijon appeared eighteen times; Général Jacqueminot sixteen times; Victor Verdier fifteen times. Of this last Rose I have many plants which have wintered well in a severe place. Their wood is of a firm character. The blooms are a thick-petalled and smoother-edged Jules Margottin. I had a beautiful shelly specimen of it at Langport, among my twenty-four winners. Nevertheless, though superior to Jules Margottin in these two points, Jules Margottin is still one of the most accomplished Roses in the world. I should think you might predicate more good and less evil of Gloire de Dijon, Baronne Prevost, Géant des Batailles, and Jules Margottin than of any other four. I have, I think, 225 plants of the four, and I never find them fail in any season, any soil, or position, or on any stock. Angletterre, Cambacères, M. Regnier, Mr. Griffiths, and La Ville de St. Denis are also very accomplished Roses. The three last are A1. As to bud and sepal, Jules Margottin has no equal. The sepal is beautifully "etched."

Page 134 brings me to the description of eighty of the forthcoming brood, with this noteworthy and proper prefix, "the descriptions are not ours, but the raiser's."

The descriptions would make your mouth water. I like to see the new term "Vermilion." Amongst these eighty there is only one pure white H.P., and that one is not full-sized. This I regret; but I am glad to see that there are some full-sized purple and crimson purple Roses of vigorous growth. These are wanted. Right or wrong, I have ordered twenty plants of the full-sized ones, leaving it to the nurseryman to substitute one Rose for another in the same line of colour; as, though he cannot on such short acquaintance be quite sure of them, yet he is more able to judge of them than the purchaser is by the raiser's descriptions. Be it remembered, that a Rose that is very suitable to France may be very unsuitable to England.

These are the Roses which I have ordered (subject to correction)—viz., 1 Adolphe Noblet, 3 Alexandre Dumas, 3 Comtesse de Seguier, 2 Souvenir de Comte Cavour (Margottin), 1 Duc de Rohan, 1 Gloire de Chatillon (a seedling from M. Massou),

1 L'Eblouissante, 1 Madame Boutin, 1 Madam C. Wood, 1 Maurice Bernardin, 1 Notre Dame de Fourvières, 1 Pourpré d'Orleans, 1 Robert Fortune, 1 Beauty of Waltham, 1 Triomphe de Caen, perhaps I ought to add Madame Julie Daran, as a northern amateur says he has been strongly advised to buy it. These are all H.P., and marked large, full, and vigorous, and the colours are tempting. Shall I get one good Rose worthy of being called "variety?" Will it be growable, hardy, free-blooming, and fit for exhibition? One only such plant will be worth the money that I am to pay for twenty plants!

For the colours and descriptions I must refer your readers to the "Annual," in which they will perceive at least one good feature—viz., that seventy-eight out of eighty are marked as vigorous, very vigorous, or more vigorous than its parent (Jaquemot). Two are not described as to growth.

Let me advise your readers, who wish to buy new Roses, to trust greatly to a respectable nurseryman to send what is best, describing what it is they want, and he will do better for them than they will do for themselves; but if they are determined to buy at all hazards by the raiser's description, and find disappointment, they must not turn round upon the English nurseryman, already "wounded himself," and call him hard names.

I have not forgotten what a horse-desler said to me years ago. A gentleman came into the yard while I was there, and had "a chop." After the deal, and the departure of the gentleman and new purchase, he said to me, "I dare say the 'gent' thinks he has 'done me;' but you see, sir, he learnt nothing from my man; but I happen to know the faults of his horse and mine too!" He added, with a pleasing smile, "I hope the horse will 'please' the 'gent.'"

May Mr. W. Paul be spared many years to reap the fruits of his new nurseries, and to benefit, by his exhibited Roses and accurate "Rose Annual," the purchasers and cultivators of the "Queen of Flowers."

Professor Blackie shall address him on our behalf—

"O thou first-rate Hertford man,  
Still be first in labour's van,  
'Tis the mission of the Highest given visible to thee,  
With the pickaxe and the spade,  
To ply thine earth-subduing trade;  
And thou shalt be a prince at home, and a king beyond the sea!"

—W. F. RADCLIFFE, *Rushdon*.

## CULTURE OF CYPRIPEDIUM INSIGNE AND CALCEOLUS.

I have a *Cypripedium insigne* which has just flowered and the bloom dropped, but the stem is still left. Ought this to be cut off? It has also two leaves springing from the base of the plant about 2 inches high, which I suppose will grow this year to flower next year. Should I therefore grow it on vigorously, or let it go to rest?

I have also a *Cypripedium calceolus*, which I am trying to grow this year. It has four reddish stems springing up about an inch high, with the leaves just visible. Ought it to have much water just now? and had it better be kept in a greenhouse or in the open air?

One more question. Is there more than one variety of the *Orchis maculata*? I have one with globose leaves spotted with violet; and another, which I suppose is *maculata*, with lanceolate leaves double the length of the other plant, and of a violet hue all over, except the edges and the base of the leaves where the light does not get much, and there it is spotted like the other.—ARTHUR COLE.

[*Cypripedium insigne* is a terrestrial evergreen herbaceous perennial Orchid from Nepal: it therefore requires stove heat all the year, but less in winter than when growing fast in summer. The old flower-stem is of no use, and should be cut off as soon as the flower fades. The two leaves springing at the base are forming a side offset, which in time will increase the size of your plant, or, when it has made roots, may be taken off to make you another plant. Grow the plant on vigorously this summer, and in winter give it a partial rest by a lower atmosphere and less water.

*Cypripedium calceolus* is, as no doubt you know, a British plant, though now it is becoming rare. The best place for it is a cold pit or frame. It is found in thickets, growing in loam and leaf mould; such a soil it ought to be potted in. Till it acquires strength and size you had better keep it in a pot, and

then you may, if you choose, plant it out in a shrubby border in similar soil. Properly managed it may be grown successfully; but hundreds of plants ruthlessly dragged out of their native wilds have perished for want of due care in attending to the conditions of growing them in a similar soil and situation to that in which they grow wild. We hope you will be more successful with your plant. As yours is now growing, it will be as well to keep it in your greenhouse, watering moderately till the leaves are more grown, and after that more freely. It is a deciduous herbaceous perennial, and therefore loses its leaves in the autumn. When the leaves begin to turn yellow give less water, and place the plant in a shady place in the open air till the autumn; then put into a cold frame or pit, sheltered from frost through the winter. Towards spring repot it into a larger pot, still keeping it sheltered, and when the hard frosts are gone plant it out of doors in the position above described.

Your *Orchis maculata* is the true species. What the coloured-leaved variety is cannot be told by your description; probably it is *Orchis mascula*. When the leaves are fully grown send us one, and also a flower: we may then be able to inform you what species it is.]

## INK FOR ZINC LABELS.

I HAVE just been at a druggist's here (Kilmarnock) with the recipe for ink for zinc labels given by you, but he informs me he has made up the same recipe several times, and the parties never renew it finding it not indestructible; but he wrote on a piece of zinc with a solution of the bichlorate of platinum, which he says is a perfectly indestructible ink for zinc labels; in fact, while the zinc decays the writing does not, but will stand out in relief. The price is the only objection. I got one drachm of it in a small phial for 1s., but it will write a great many labels. Use a quill in writing with the ink the same as in your recipe.—M. S.

[Bichlorate of platinum is an excellent fluid for writing on zinc, and very permanent. The same character, however, attaches to the ink for which we gave the recipe, if the zinc is freshly scoured bright before the ink is put on, and is allowed to dry thoroughly before being exposed to the weather.—EDS. J. OF H.]

## FORCING ROSES.

WILL you inform me the best mode of forcing Roses early? We have some in pots that have been placed in a bottom heat of leaves, and top heat of 60° by hot water; but they have not yet shown flower, although placed in that situation in October.—G. H.

[You have been too kind to your Roses, or in other words you have overforced them. You do not state the degree of your bottom heat; and a heat at first of 60° is too great for a shrub hardy enough to bear open-air culture in April and May. The bottom heat should not have been more than 60°, and the top heat 40° by night and 55° by day. In your case you had better lift the pots out of the bottom heat and give plenty of air in order to strengthen the shoots, and then if they are Hybrid Perpetuals they are sure to flower shortly; but if they are Provence including Moss Roses, or of the Gallica class, it is doubtful if they will flower this year at all.

You ask for general instructions in regard to the time of potting, cutting down, soil, and after-treatment. In addition to these heads of culture, to produce Roses in January, February, March, and April, you should know what kinds to pot for that purpose. There are a great number of varieties suitable for forcing, and out of that number we will select for you the following twenty-four sorts:—*Moss*: Common. *Provence*: Cabbage. *Hybrid Chinese*: Elizabeth Plantier and Paul Ricaut. *Hybrid Perpetual*: Edward Jesse, Général Jacqueminot, Géant des Batailles, Jules Margottin, Louis Buonaparte, Madame Laffay, Prince Albert, Reine des Fleurs, and William Jesse. *Bourbon*: Acidalic, Armosa, and Queen. *Chinese*: Cramoisie Superieure, Mrs. Bosanquet. *Tea-scented*: Comte de Paris, Devoniensis, Niphotos, Gloire de Dijon, and Triomphe de Luxembourg.

*Time of Potting*.—If good plants are taken up early in autumn, carefully, with all their roots entire, potted immediately and placed out of doors for a month and then pruned, they will flower pretty well the season following; but, unless in a case of

necessity, it is far better to grow them in pots twelve months previous to forcing them; they then become established in the pots, and are in a better state to bear a forced growth and earlier bloom. Roses that have been forced have attained a habit of blooming early, and are, therefore, to be preferred for that purpose. Every autumn following they should be repotted, disturbing the roots as little as possible, but yet picking out with a stick as much of the old soil as can be conveniently removed, and use fresh to fill up the pots. The best soil is two parts strong turfy loam, and two parts hotbed-dung; if a part of burnt rubbish can be had, mix it with the compost. For Chinese and Tea-scented varieties add a part of decayed leaf mould; and in potting take care that the pots are well drained, and cover the drainage with a thin layer of broken charcoal, and let the compost be used in a moderately dry state.

**Pruning.**—The time for this operation is early in November. Strong growers should have the weak shoots cut away close, and the strong shoots shortened-in a little only. If they are cut-in close the flowers will be few and far between; others that are weak growers should be cut-in rather severely, say to two, three, or, at the utmost, four buds. This latter rule applies chiefly to Hybrid Perpetuals, Chinese, and Tea-scented varieties. To obtain Roses at Christmas, the best plan is to choose all Hybrid Perpetuals for that purpose, and prevent them flowering at their due season by nipping-off their early buds, only mind to keep them growing and they will form a second crop of buds as late as November; then put them into a warm greenhouse and they will open their blooms admirably at the end of the year, coming in before such as are regularly cut down and brought into the forcing-house. After Roses for forcing have been potted and pruned, they should be placed in a cold pit till required to be removed into the forcing-house; here they will be protected from the heavy autumnal rains, which are very injurious to the young delicate roots of Roses, especially such as are intended to be forced into early flowering; in such a pit, too, the wood has a better chance of being well ripened: hence older plants should have that benefit, care being taken to give them plenty of air during the later summer months, and only just water enough to keep the soil moist. The last week in December or the first week in the new year is quite soon enough to commence forcing for the general crop. To keep up a succession take in a few every month afterwards up to April. Keep your plants as near the glass as you can, only leave room for the young shoots. At first let the heat be moderate—that is, 45° to 50° by day, and 40° by night. As growth goes on increase the heat to 10° higher by day, but not much higher during the night. It is very weakening to the Rose-shoots to keep up a high stimulating atmosphere during the time they are in darkness.

In giving air be careful that no draughts rush across the young and tender leaves, or they will suffer much from the cold. In warm weather, air, of course, may be given freely. If the air-openings are opposite the pipes or flues, so that the air in entering becomes softened and partially heated, it will be a very great advantage.

**Watering.**—As the leaves expand water may be given more liberally. Every third time give them some liquid manure. Gnano water is strongly recommended, but it must be given in a weak state: about 1 oz. to the gallon is quite strong enough. The syringe may be used freely till the buds begin to expand; but in dull cloudy weather refrain from syringing.

After they have bloomed place them in a cold pit or some other shelter, and as soon as the frosts are over plunge them in an open place in the garden to make summer growth; but if intended to be forced the next season allow no flowers to bloom on them. Roses in pots during the summer are too often placed in some back out-of-the-way place, and utterly neglected during the summer months. No wonder they do not flower the year following; whereas, with moderate care all the year round, the Rose will thrive and bear forcing annually for many years.]

## ROYAL HORTICULTURAL SOCIETY.

APRIL 1ST.

**FLORAL COMMITTEE.**—The subjects for examination by the Committee at this Meeting were not numerous. The most important was a new form of *Musa*, similar in growth to a *Canna*, and finely marked with a broad band and blotches of white, from which it had been named *Musa vittata* on the continent. It was considered a first-class plant of that stamp, and a First-

class Certificate was awarded for it to Messrs. Veitch. It will make a splendid exhibition plant. The same firm and Mr. Bull, of King's Road, sent two small Ferns, *Asplenium flabellatum* and *rachirhiuæ* to each of which a First-class Certificate was awarded.

The same merit was accorded to a new form of a double French White *Primula sinensis*, from the Messrs. Smith, of Dulwich. This was unanimously agreed upon to be a first-rate plant, with immense large flowers, in which the stigma, style, and germen are perfect, and it is, therefore, in a condition to continue itself by seeds, or be the parent of a new race of improved stamp. On this point Mr. Beaton congratulated the florist members of the Committee on their good sense and judgment in agreeing with the rest in giving a first-rate prize to a pin-eyed *Primula*, which he maintained was always the best of the two wild forms of these flowers on account of the facility it offered of crossing them.

There were two very superior varieties of *Lycaste Skinneri*, from Messrs. Veitch, making hard upon twenty kinds of that sportive Orchid known to one or other of the Committee, some of whom asserted that cut flowers of this beautiful Orchid kept longer in water than any other Orchid, and that with the exception of *Odontoglossum grande*, that this was the most easily-managed plant of them all in a cool house.

There was another improvement, and a marked one, on *Cypripedium barbatum*, from Mr. Williams, of the Paradise Nursery, for which a Certificate was granted; and a most promising Perpetual Moss Rose, called *Hortense Vernot*, a basketful of small plants of which was sent by Mr. W. Paul, and the Committee requested that it might be sent again in the autumn, considering it a very promising Rose, which could not be properly judged from forced specimens. Mr. Todman the successful raiser of many good seedlings, sent five kinds of new *Azaleas*, of which one called *Lord Canning* is a perfect "self" flower—that is, without a spot, or shade, or eye, and is of the most beautiful colour, the highest colour in the race. This, also, was desired to be seen when the plant was older.

There was two *Rhododendrons* sent up from the open ground, from Mr. Veitch, sen., of Exeter, one of them white and intensely spotted in the throat, which as a conservatory flower would be very handsome, but out of doors at this season all but lost; the other a deep self red.

There was a small specimen in bloom of the Paris fashionable *Wigandia caracasana*, an immense large-leaved plant for turning out in the summer, and to be kept as the *Indiarubber Plant* in winter. The flowers are not much, only they come circinate, or, in a twist, like those of *Forget-me-not*, and are of a violet blue tint. All circinate flowers like this might be cut as soon as the first of them opened, and if the twisted buds were thrown into water, they would unscrew and open successively in the drawing-room, some for days and some for weeks according to the kinds and time of year. Also, two samples of a Willow-leaved *Berberis aquifolium*, a sport not common among the seedlings, and which for a rock-garden or a Chinese one would be highly desirable.

Then, there was a *Hippeaster* of a long descent from *crocatum*, still maintaining a glow of that rare colour in bulbs—an orange yellow, but from injudicious crossing the flower itself was flimsy as could be, and not worth retaining in a select collection which one never sees near London; and a collection of *Cinerarias* from the Messrs. Smith, of Dulwich, of the same strain as they exhibited at the March Meeting of the crowds. And, finally, the gardeners at the Chiswick Gardens sent up two baskets of little pots of *Anætochilusæ* to show that they too fall in with the times, and instead of botany take more care of how to please the ladies by the sterling honesty of high cultivation as for prizes. On these a highly interesting discussion took place, the tendency of which was to show that the prevailing custom of keeping these *Anætochili* under glass in stew-pan treatment, was a highly unscientific mode of cultivation and altogether unnecessary in their case.

## SOWING LOBELIA SPECIOSA AND GRACILIS, AND MANAGING THE SEEDLINGS.

I SHOULD be very much obliged if you would inform me the best time of year for sowing the blue *Lobelia*; also, if the light blue kind can be raised from seed as well as the dark, and how they should be treated to bring them forward for bedding purposes.—C. B. W.

[Now is a good time to sow both the *Lobelia speciosa* and

the lighter blue grscilis, but there is not a moment to spare, the seedlings ought to have been up by this time. Have them in a hotbed till the seedlings are up a few days; then put them where they can get more air, and when they are big enough for you to handle them transplant them into little pots, three or four plants in each pot; after that keep them close for another week, and then they are fit to stand in any kind of cold pit, with the same treatment as young Verbenas; and at the time of planting them out, divide the balls into four pieces with a good plant in each, and plant them 6 inches apart.]

## A PLEA FOR PYRAMIDAL PELARGONIUMS.

BY THE LATE MR. GEORGE M'EVEN, OF THE HORTICULTURAL SOCIETY'S GARDEN AT OHISWICK.

PRESUMING that we shall have gained an important point, if we can satisfy our readers that the form of training which we recommend is worthy of imitation, we deem it expedient, before entering upon the practicality of the subject, to show that variety of form is desirable; not that we wish, or expect, to see the present dwarf form abandoned. No; but only that another form—viz., the pyramidal should be introduced. We are prepared to show that it is not less natural, practicable, nor is it less appropriate, than the dwarf, squat form; and that it will much increase the beauty and interest of a collection of these plants as a whole, and would add largely to the number of admirers and growers of the Pelargonium, if this form of growth were to be generally introduced.

Because of the delight which variety of form produces, pyramidal training is desirable. Who is not fond of variety? Let us go and look upon yon forest—scan the fields—glance at the wild flowers and plants by the highways and byways—take a grand survey of the vegetable creation; or, if you choose, let us confine our range, and take the same species or varieties, and have them each shorn of their now varied forms, and then say if they have not lost more than half their beauty and interest by the change. Now, all we plead for is, that we should not pay exclusive attention to one, the dwarf, form; but that we should grow the tall form also.

Another inducement we would urge in favour of the pyramidal training, is novelty. To tell gardeners that anything new gives increase of interest, and oftentimes pleasurable excitement, is to repeat what they must have constantly observed. Indeed, much of the success of gardening may be traced to, if it does not altogether depend upon, thus giving an agreeable excitement.

Another and yet more important inducement, we would urge, is their utility, or adaptation to almost any situation. Yes; you can place them with effect, whether in or out of bloom, on the centre or side stages, where the sun, light, and air may play freely upon them; or you can lodge them on circular

hoops of iron or brackets, in a hall or staircase, as represented in the woodcut. How much, too, would they enliven the tameness of the Pelargonium-house as it is; or, where they are still more at home, yet greater favourites, in those large conservatories, where you can walk past, and around them, and feel as if in a garden. Again: decorative objects are perchance wanted for special occasions. None will be found so suitable as the pyramids for centre-pins in the group of flower-stands or baskets; whilst as pillars in the entrance-hall, or by the corridor, or as beautiful plants for the table, they are equally appropriate.

Again: they will "fit in" to any style of gardening, whether geometrical or gardenesque; in rows by the straight walk, singly on the smooth lawn and in the dressed border at intervals, or as a centre plant in the mass of colour; by turns relieving, surprising, and always greatly pleasing. And who can doubt that, in the time coming, when a yet higher standard and a purer taste is exemplified in the arrangements of our exhibitions, our pyramidal-formed plants will be there, and so managed as to bear a thorough inspection, when no stakes nor glaring artificial props need be theirs—while the admitted dull uniformity of the collections in the Geranium-tents will have passed away, to be no longer tolerated.

If we have done justice to our subject, we have succeeded in showing that our pyramidal Pelargoniums are, or may be, objects of great beauty and interest, as well as great novelty and utility, and will largely compensate for the labour bestowed on them; we now proceed, therefore, to treat on the not least important part, the practicability, of the subject.

methinks I hear some one argue that the strength of the plant will be sure to go to its top, leaving the bottom and body of the plant naked. Another says that it will be so long before a Geranium is grown to the height and girth you require (say 6 feet by 3 feet, not more). And another will not think of it, because they occupy so much room. To the first objection it is replied, that the tendencies spoken of can be successfully counteracted, on the same principle that we train our wall trees wheresoever we will. To the second, we submit that one season is not long; and, when once the plant is trained, it lasts for years. And to the third objection we reply, that the stage room required is not more than that occupied at present, the extra height requisite being now unoccupied. It may, however, be well to remark here, that it is necessary to have in "the mind's eye" the model at which to aim in producing. We suggest that the height of the plant should be twice its diameter—that is, if the breadth of the plant at the base (which shall be just at the rim of the pot) is 3 feet, the height may be 6 feet, or thereabout. We must also remark, that in ordinary circumstances this height should not be exceeded; for this reason, amongst others which could be adduced: in this class of plants the flowers are so placed as to display themselves better when looked upon, than when looked up to; and, for a similar reason, there should be no swell on the body of the plant. With such plants as the Rose, Fuchsia, Scarlet Geranium, Heliotrope, &c., there need be no limit to the height, if due proportions are maintained. In a future paper we may give a few suggestions on the fitness and adaptability of these subjects for pyramidal training.

[We append to the above very suggestive remarks some notes on the same subject, showing the effect of pyramidal plants as ornaments to the hall and staircase; with the accompanying practically illustrative sketches, which are furnished by Mr. H. Noel Humphreys:—"When last in Paris," writes Mr. Humphreys, "I was much struck with a beautiful effect produced by plants placed outside the rich iron balustrade of a principal staircase, at the hotel of the Count Auguste de B—. In that instance, the pots containing the plants were lodged in circular loops of iron, connected by a strong bar fixed firmly to the exterior of the staircase, at and between each loop. By this inexpensive means the odour, the freshness, and the floral beauty of the plants accompanied the visitor to the very door of the principal saloon, without encumbering the staircase, or encroaching in any way on the space devoted to free ingress and egress, which is seldom, in modern buildings, sufficiently spacious to bear curtailment. Geraniums grown in the pyramidal form would be peculiarly suited to place in such a situation, as their height would bring them above the balustrade, and leave their best flowering portion to the unimpeded view of the visitor, while a plant grown in a lower form would not possess this advantage. But instead of the iron loops, which can only be regarded as a cheap temporary

contrivance, I would suggest a more decorative, and at the same time more permanent mode of placing flowering plants outside the balustrade of a staircase, and, at the same time, one which might be made subservient to other purposes. I propose making the principal moulding beneath the exterior of the balustrade jut out at certain distances, and by describing three-fourths of a projecting circle, form a series of brackets, upon which ornamental vases containing plants might be placed.

Thus, on other occasions, when a profusion of light might be more desirable than flowers, bronze candelabra, each surmounted by a single light, with a ground glass globe, might be substituted for the vases containing flowers, or they might alternate with them, which would produce a very rich and pleasing effect. In the accompanying sketch I have shown the Geraniums placed upon the circular brackets as described, and, in the hall beneath, I have arranged a row of vases exactly beneath the Geraniums,

Staircase and Hall, with Geraniums in Vases and on Brackets.

PEDESTAL.

which I suppose to contain finely-formed Hydrangeas, grown with a single stem like the Geraniums, but with bushy round

tops, in the Orange-tree form, to contrast with the pyramidal figure of the plants above. Between each Hydrangea I would

VASE.

BRACKET.

place a climbing plant, neatly trained to a tall rod; they might be *Maurandya Barclayana*, *Thunbergias*, or *Loasa lateritia*; but they should be all the same, and very trimly trained, as this symmetrical repetition is necessary wherever irregular forms have to be grouped with architecture."

In a future paper the management of pyramidal *Pelargoniums* will be explained; and accompanied by illustrations of their application to garden terraces, with some practical suggestions by Mr. Humphreys.]

### THE BIRMINGHAM ROSE SHOW.

THE first Meeting of the Committee of Management was held on Thursday last (3rd inst.), at the Committee-room of the Town Hall. The Mayor of Birmingham (H. Manton, Esq.), in the chair. Among the gentlemen present were Sir John Ratcliff, the Revs. S. Reynolds Hole, P. M. Smythe, W. K. R. Bedford, E. H. Kittoe, John Green, and Messrs. T. B. Wright, John Jaffray, John Lowe, John Shackel, J. B. Gansby, G. P. Tye, Job Cole, Samuel Evans, B. A. Hallam, and E. W. Badger. It was decided to hold the Show on Tuesday and Wednesday, July 1st and 2nd, which, coming midway between the Royal Horticultural and the Crystal Palace Shows, seems a very sensible arrangement, as it will enable the most important growers in all districts to exhibit at Birmingham, without in any way interfering with the metropolitan shows. A liberal prize list was framed, in which two divisions occur, to which we desire to give prominence. They are both in the open class C.—viz., No. 12. The best six varieties, cupped Roses, single trusses, with stem and foliage as cut from the tree, shown together as a bouquet, in a vase; and No. 13, the best six varieties, expanded Roses, single trusses, with stem and foliage as cut from the tree, shown in the same way as No. 12. The Committee will provide vases for these two divisions. Unless we are much mistaken, these will produce a very interesting and a most useful display of Roses, *au naturelle*. It will be observed that an attempt at classification has been made, separating cupped from expanded Roses, which we regard as a step in the right direction. It cannot be denied that hitherto, while by far the larger number of our best Roses are expanded ones, the palm of precedence has always been awarded to those pans in which "cupped" flowers have predominated. If the experiment at Birmingham successfully tests this question, a new era in Rose growing and exhibiting will most undoubtedly be inaugurated. A Sub-Committee to assist the Hon. Secs. was appointed, consisting of the most practical members of the General Committee. We wish this vigorous young Society all success, and think we may venture to assert, that the Committee, who are evidently regarding their work as a labour of love, will succeed in establishing an Exhibition of great and growing importance. The Committee comprises such a large body of practical and influential men, amateur and professional floriculturists, that the most sanguine expectations regarding the Show may be safely entertained. Of one thing exhibitors may rest quite assured—there will be on the part of the Committee every desire to conduct all the proceedings in such a spirit as will best answer the ends they have in view, the advancement of the interests of horticulture, and the supply of an additional source of refined and innocent enjoyment to the inhabitants of the midland counties.

We understand the prize list will be ready for issue in the course of a week or nine days.

### GARDEN INFESTED BY GRUBS—NEAL'S APHIS PASTILS—COTTON-SEED REFUSE.

LAST season, and again still worse this season, our vegetable garden, more particularly in the oldest part, is infested with a great number of blackish-looking grubs, three-quarters to an inch long, called in the district "botts," which eat off most of our Cauliflower, Cabbage, Lettuce, and other young plants. We have killed many by looking them out at the roots of the plants, but they still increase in number. We have tried to drive away or kill them by planting in soot, sprinkling lime, watering with manure water and ammonia water from our gas-works, but all to no permanent cure. Our neighbours are also similarly annoyed; as many as 150 were taken from the roots of a perennial plant in a garden near to us.

Whilst writing I may say, that seeing advertised in THE JOURNAL OF HORTICULTURE "Neal's Aphis Pastils," I was induced to purchase a two-shilling packet, and having used two at one time in a house 36 feet by 14 feet in which half a pound of tobacco paper answered, I find that after using the whole lot of six in three weeks the insects are still alive, especially on some Strawberry plants. We used them as directed. Have you had any complaint of them, or do you know whether they answer the purpose intended?

As at present cocoa-nut refuse, flax-refuse, &c., are much praised as fertilisers, may I ask if any of your correspondents (more especially from Lancashire) have tried the broken cotton

seed or refuse made in the first processes of cleaning cotton for spinning? Being of an oily, warm nature, I feel certain it would answer in the growth of many plants.—HARRY.

[Your kitchen garden wants but a thorough good and deep trenching. It is all vexation to attempt to rid old kitchen-garden soil of grubs and maggots, either by means of such trenching or by paring and burning. But all the trenching for this kind of reformation, if not for all others, is to be done when the ground is driest, and at the hottest point of the season—say in August. That is the right time to trench kitchen-garden ground if one could afford to do it, and if you can you must, or else these grubs will turn you out of possession altogether in the long run. When one is trenching a piece of ground is the right time to see to the drainage of the place. Nothing is more easy than turning the trenches in the direction of the fall of the ground; and at the bottom of so many trenches go a foot deeper and put in a drain, and say nothing about it till you come to where the next drain should be, and put that in also as quietly as you like, and you can then talk loudly of the vast improvement, and how you killed, &c., and that the draining was no expense at all—that you merely wanted to know the geology of the subsoil, and while it was open that you thought it was just as well to keep it so.]

### A FEW DAYS IN IRELAND.—No. 19.

(Continued from page 519, Vol. II.)

#### TEMPLE HILL.

THIS beautiful residence of Robert Gray, Esq., is, like Mr. Cowley's, also situated at Blackrock, near Dublin. The mansion is a handsome square building, built with dressed stone, and surrounded mostly by terraces, and about an acre of pleasure ground. There is also, we were told afterwards, on one side of it a handsome conservatory about 50 feet in length, and half as much in width. From the elevated position, the views obtained of the Hill of Howth, the Bay of Dublin, and the harbour of Kingston are not only interesting in themselves, but ever changing in the variety of the objects presented. We regret that from some inadvertence we saw nothing of this conservatory, and had only a glimpse of the pretty lawn. In passing from the gateway down a hollow to reach the glass houses on a bank just not so high as that on which the mansion stands on the opposite side, there was one object on the lawn at a considerable distance from the house which at once attracted our attention, and which must form a prominent feature from every window on that side of the mansion, and that was a good-sized mound of white flints standing alone in its glory. Now, though to our eye and sense of propriety such a huge heap in such an open spot was perfectly incongruous, yet not being near enough to examine what were its particular purposes, or what effects it had on the sense of fitness when seen from the mansion, we are not in a position to think, and far less to say, that our taste is superior to that which planned and constructed this heap of flints on an open lawn. The proprietors of Temple Hill have far more right to please their own taste and sense of what they deem suitable on their own ground, than we or any one else has to hint that it would have pleased better if some little thing or other had been different. Besides, so little is generally gained by taking exception to the doings of others in such a mere matter of taste and fitness, that but for the large liberal-heartedness of the proprietor, we would not humbly insinuate the wish that the flints might be removed to a more fitting position, such as the large rookery forming in the hollow on the way to the garden—that is, if there are not stronger reasons than any we know of for keeping it where it is. This might be of much more importance in fixing ideas of fitness and taste than at first meets the eye. There is, in many places at present a perfect craze about rookwork and rookeries, altogether irrespective of position. Only get a few loads of ugly stones thrown together, or as many crooked and twisted roots of trees—it matters little where, as in front of a splendid Gothic residence or a Grecian mansion, and you are expected to say, "Oh! how pretty!"

In front of such a mansion as the last mentioned, some twenty yards or so from it in a low, level position, is a huge mound of stumps of trees, roots, flints, and stones, with plants and Ferns, &c., stuck among them, so huge as for size to throw Mr. O'Brien's Fern rookwork into the shade, interfering with the beautiful rich scenery beyond, and costing many pounds in

money, and no end of labour to make and to keep, and the object attained—a huge deformity! We could speak, too, of rough root-heaps in front of the drawing-room windows of a beautiful Gothic mansion, wreathed with Ivy and other climbers. We do not deny but such masses may look tolerable in summer when the romantic roots, as the owner calls them, are concealed or nearly so; but would such a man of generally exquisite taste think for a moment of adorning his drawing-room with such proofs of retrogressive barbarism? Is it much better to have such ugly heaps on a fine lawn just outside the window? Must the truly beautiful within be enhanced by contrast with such so-called beautiful roughness without?

The large rootery in the hollow seemed to be in the process of forming; when planted with Ferns, alpines, &c., we have no doubt it will be constantly increasing in interest and importance. Shortly after passing it we met our new friend near the houses, Mr. Tobin, the very intelligent and successful gardener; and after premising that everything about the garden bore signs of being carefully attended to, having so far used the flint stones as a text for a practical discourse, we will confine ourselves to notice what was grown under glass and other protection.

The chief houses seemed to be placed something like a square in two principal ranges. The front range is 80 feet long, and in three divisions. The first compartment is 30 feet long, 14 feet wide, 14 feet in height at back, and 7 feet in front. The roof is a lean-to, with curved glass in front. This is devoted to Peaches. The front trellis is curved so as to occupy the greatest amount of space without shading any but the very bottom of the back wall. The front trellis is filled with a beautiful tree of the Noblesse Peach; the back is furnished with two trees, riders, of the Royal George Peach. The wood in this house was in fine condition. The middle division is a stove but span-roofed, 20 feet wide, 26 feet long, 14 feet high to ridge, and about 7 feet at the sides. There is a low pit in the centre 10 feet wide, so as to admit of tall plants being grown. A nice pathway all round 3 feet wide, and a broad shelf or stage 2 feet wide all round the sides. Many of the hardier plants of this house were ripening their wood in the greenhouse, &c., so that the house was set nice and thinly with Ferns, Mosses, Achimenes, and Begonias. Of the latter were nice plants of the following, which were rather strange to us, and looked very pretty—Count Alfred de Limminghe, Ebenezer Pike, Engène Guleno, Jas de Sibra Carvalho, Rex Fernandez, Victor Lemoine, &c. Among stove plants we noticed neat specimens of *Stephanotis floribunda*, *Echites crassinoda*, *Rondeletia speciosa*, *Allamanda Schottii*, *Rhopala corcoradensis*, *Pandanus utilis*, &c., ranging from 4 feet to 6 feet in height, and generally as much in diameter.

The third division is a Peach-house of the same size as the first. The back wall is filled with one tree of the early Grosse Mignonne, and one of the Double Montagne. The rounded front or roof-trellis is occupied, or will be, with a Royal George Peach, brought from the open wall in December, 1860, and which produced in 1861 eight dozen of very fine fruit. The wood seemed in capital order in September, but Mr. Tobin had made up his mind not to overcrop next season, nor yet to test it to the full until thoroughly established.

In what may be termed the back range is a span-roofed greenhouse 50 feet long, 18 feet wide, with a flat stage; from stage to ridge-board 10 feet; from shelf, height at sides, 6 feet. This house was chiefly supplied with Fuchsias well grown, some Ferns, a few Begonias, and the hardier stove plants. The great proportion of the usual plants and good specimens were rusticated under the slight shade of a wall, to be ere long introduced into the house. Among these we noticed fine plants of *Azaleas*—as *Gledstanessii*, 5 feet by 4 feet; *Triumphans superba*, 6 feet by 4 feet in diameter of head; *Tricolor*, 5½ feet by 3 feet; *Exquisita alba*, 5 feet by 4 feet; *Marie Louise*, nearly 6 feet by 4 feet; *Ardens*, 5 feet by 4 feet; *Duke of Devonshire*, 4 feet by 2 feet; *Lateritia punctata*, 5 feet by 3 feet; *Semiduplex maculata*, 5 feet by 3 feet; *Concinna*, 5 feet by 3 feet; *Perfecta elegans*, 3 feet by 2½ feet; and several standards from 3 feet to 5 feet in height, forming nice heads; with many plants of smaller size, all healthy and bristling with flower-buds on well-ripened wood.

Among nice compact plants of *Heaths* there were two *Erica Cavendishii*, 3 feet by 2½ feet in diameter; *tricolor elegans*, 4 feet by 3 feet; *tricolor Wilsonii*, 4 feet by 3 feet; *ferruginea*, 2 feet by 2 feet; *Irbyana*, 3 feet by 2 feet; *tricolor*, 3 feet by 2 feet; *depressa*, 2 feet by 2 feet; *aristata major*, 2 feet by 1½ feet.

Among varieties were nice plants of *Leschenaultia biloba major*, 1½ foot by 1 foot in diameter; *Diosma bucco*, 2 feet by 3 feet; *Eriostemon buxifolium*, 4 feet by 3 feet; *E. pulchellum*, 4 feet by 2½ feet; *E. neriifolium*, 3 feet by 2 feet; *Pimelea Niepergiana*, 2½ feet by 2 feet; *Hardenbergia monophylla*, 5 feet by 3½ feet; *Epacris grandiflora*, 5 feet by 3 feet; *Hovea purpurea*, 6 feet by 3 feet; *Gastrobium Brownii*, 4 feet by 1½ foot; *Acacia grandis*, 6 feet by 3 feet; *Araucaria excelsa*, a pretty plant, 7 feet by 4 feet; *Pimelea decussata*, 3 feet by 2 feet; *Clethra arborea*, 7 feet by 4 feet; and good handsome *Camellias*, from 4 feet to 7 feet in height.

Among the newer *Rhododendrons* standing here, and also in the orchard-house, we noticed good plants of *R. Bletinn*, 4 feet by 3 feet; *Elfrida*, 4 feet by 4 feet; *Griswoodiensis*, 4 feet by 4 feet; *Calophyllum*, 2 feet by 1½ foot, with six fine large-awelled flower-buds; *Boothii*, 4 feet, with several flower-buds; and a nice plant of *Dallousianum*, with six strong well-swelled flower-buds.

There were also some pretty *Rose* plants in pots looking strong and healthy—such as *Blairii*, *Paul Ferras*, *La Reine*, *Coupe d'Hébé*, &c., ranging from 2 feet to 5 feet in height and from 2 feet to 3 feet in diameter, with which Mr. Tobin had secured the honours at the horticultural competition for five years successively.

We mention these plants that will ever be increasing in interest year after year, not only as testifying to the unremitting attention and skill of Mr. Tobin, but also as showing the liberality with which his worthy employer fosters a taste for the higher departments of gardening. From what we have mentioned of other places, and hope still to do, it will be seen that Mr. Grey has many associates. Whatever may have been in the times of the past, it is evident there is no backwardness in this respect in Ireland now. We question if anywhere in a similar amount of time, except immediately around the metropolis, we could have seen equal signs of progress in England. With many honourable exceptions there is something of a retrogressive character obtaining among us, as to the highest department of ornamental gardening. In many places great blazes of colour in summer are the all-in-all as respects ornament; and to secure that the gardener with very limited means must contrive to rear and plant from twenty to a hundred thousand plants, and then when the frost has swept them off, contrive not only for space again, but how with old materials he can make fresh arrangements and combinations the following year. A few shillings or a pound or two for bedding plants being all that he can obtain in the way of direct novelty. In this land of free masters, and free servants, even in such cases there is no right to complain, as, so long as we continue to serve, the wishes of an employer should ever regulate the particular direction of our labours. Still it is nothing but fair to state that the bedding system has not only vastly increased the labours and the anxieties of the gardener, but when ever so successful it does not yield him such pleasurable interest in his work, as the getting and growing specimens of good new things. Perhaps this latter fact might be one reason why in all the places we visited, the gardeners uniformly spoke so highly of their employers. But few ladies and gentlemen have any idea of the more than zest and encouragement it is to an intelligent gardener to obtain possession of desirable novelties as soon as they are in the market.

R. FISHER.

(To be continued.)

## THE WEATHER.

THE weather is very inclement here at present, and has been since the 13th. At that date the wind changed from W. to N.E., and has continued to blow from the east for the last twelve days. On the 13th the earth at 1 foot deep had reached 40°; but since then the temperature has fallen to 35° on the 22nd, and that temperature has been registered the last five days, which is 7° below the corresponding period of 1861, 5° lower than that of 1860, and 6° below the average.

At 4 feet from the ground the temperature has ranged between 45° and 24°, and the mean temperature 36°·5. Thermometer in sun's rays was not affected excepting on the 22nd, when it registered 68°. On the other days its reading was the same as that at 4 feet.

Snow fell on the evening of the 23rd, covering the ground 9 inches deep; and rain followed on Monday, amounting (with melted snow) to 1.55 inch during the twenty-four hours. The

day (March 26th), .78 inch of rain has fallen, making a total fall for the last four days of 2.51 inches.

Just as a weather problem for your weatherwise readers, I give the state of meteorological observations here at 9 P.M. of the 26th.

Barometer 29.596 inch. Thermometer at 4 feet 38°, on grass 36°, earth 1 foot deep 35°. Hygrometer, dry bulb, 38°; wet bulb, 38°. Amount of cloud, 10. Wind, east, calm. Rain, and densely overcast.

What is the benefit derived from meteorology if we cannot foretell future events?

Thanks, my grandfather (and he had it from his grandfather), used to be able to tell what would follow the changes of the sun being at the equinoxes. Acting upon his weatherology, I respectfully but reluctantly prognosticate, "This year we shall have a cold and wet spring, a prevalence of easterly winds, and but little range of temperature."—GEORGE ABBEY, *Bradford*.

## KEW GARDENS.

### EXTRACTS FROM SIR W. J. HOOKER'S REPORT.

THE number of visitors to the Royal Gardens during the year 1861 was 480,070, being 54,656 in excess of the year 1860. They were distributed in the following proportions:—Number on Sundays, 189,462; number on week days, 290,608. This is exclusive of the increasing number of persons engaged in scientific or commercial pursuits, who have visited the Museum, Herbarium, and Library, for the purpose of obtaining special information.

### BOTANIC GARDEN.

The means adopted for introducing Cinchona (trees yielding quinine) into the East Indies and our tropical Colonies, rank first in point of interest and importance of the works of the past year. In my report for 1860 I mentioned the erection, at the desire of the Secretary of State for India in Council, of a forcing-house, especially for the cultivation of the Cinchona, with the view of establishing plantations of them in India. The operations of the several parties organised to proceed into the Andes and procure young plants and seeds have been described in detailed reports laid before the Secretary of State for India, by Clements R. Markham, Esq. Upon the Royal Gardens devolved the duties of receiving and transmitting the seeds and plants to India, of raising a large crop of seedlings, of nursing the young stock, lest those sent on should perish or the seeds lose their vitality, and of recommending competent gardeners to take charge of the living plants from their native forests to the hill country of India, and to have the care of the new plantations there. Farther, with the sanction of the Indian and Colonial Governments, it was arranged that our West Indian Colonies and Ceylon should be supplied with a portion of the seeds. The results hitherto obtained are the following:—

In the Nilgherrie Hills, I am informed by Sir W. Denison (Governor of Madras), that there are at this time flourishing 3477 plants of the Red Bark, *Cinchona succirubra* (one of the best kinds), many of which are from 3 feet to 3 feet 9 inches in height; and 2370 of other kinds, equally healthy.\* Many of these are ready to be planted out in sites already selected by Mr. Markham.

In the Royal Gardens we have 2170 healthy young plants, which will be ready for transmission to India at the proper season.

In Ceylon, under the management of Mr. Thwaites, Director of the Royal Gardens at Peradenia, the experiment has been equally successful, in proportion to the quantity of seeds received. A plantation of different kinds is flourishing at Nevra-Ellis.

In Jamaica the *C. succirubra* is succeeding admirably. A quantity of healthy seedlings have been transported to a locality 4000 feet above the sea, and are now ready for planting out.

Mr. Wilson, the Superintendent of the Botanic Gardens there, has made a requisition to Government for 50 acres of land to form a plantation therewith, and for an assistant to take charge of the plantations.

Seeds were sent to Trinidad at the same time as to Ceylon and Jamaica, but unfortunately not one has germinated.

THE WINTER GARDEN, OR NEW LARGE CONSERVATORY.—Great progress has been made in the construction of this edifice,

for which the designs were supplied by Mr. Decimus Burton in 1859, and the tender of Messrs. Cubitt & Co., for the construction of the grand centre and two octagons, was accepted in 1860. This building, which is intended to supply our main desideratum—a means of cultivating the trees and shrubs of temperate climates, especially of our colonial possessions, and which will afford to the public an attractive and instructive resort during the winter months, will consist of—

	Length.	Breadth.	Height.
1. A grand centre .....	212.6	137.6	60 feet.
2. Two octagons .....	50	50	25 feet.
3. Two wings .....	112.6	62.6	37 feet 9 in.

These several portions communicate with each other by a long central vista.

The superficies will be 48,392 feet, or about 1 $\frac{1}{4}$  acre.\* Total length, including the vestibules, 583 feet.

Of these portions, the two octagons were completed during last autumn, and immediately filled from the overflowing contents of the conservatories in the Botanic Gardens. Workmen are now engaged on the grand centre, which is to be finished in the course of the ensuing autumn. The arrangements are completed for planting the trees, &c., in the ground of the main area, and the heating apparatus for the centre and octagons is fixed.

The erection of the magnificent spar of Douglas's Pine was also effected. This superb pole is unrivalled in Europe for height, symmetry, and excellence of material; it was presented to the Royal Gardens by Edward Stamp, Esq., and was erected not less on account of its ornamental character, than because, towering as it does to nearly twice the height of the fine trees around it, it is admirably calculated to exhibit to the public the relative size and bulk of the timber trees of one of our own colonies, British Columbia, where the forests, from which it was obtained, mainly consist of this kind of tree (*Abies Douglasii*), and where it often attains a height of 300 feet. For the erection of this spar, the services of a party of mast-makers from the Dockyard at Woolwich were liberally accorded by his Grace the Duke of Somerset; and the operation was successfully accomplished in May last, under the superintendence of Mr. Isaacs, the Inspector of that department. The following are its dimensions:—total length, 159 feet; diameter at heel, 1 foot 7 inches; cubic contents, 160 feet; weight, 4 tons 8 cwt. 2 qrs.; age, about 250 years. Total length of the original tree, about 220 feet.†

### SCIENTIFIC DEPARTMENT.—MUSEUMS.

These receive constant additions of objects of interest and value, and are annually more resorted to by persons in search of information regarding woods, drugs, dye-stuffs, textile materials, &c. During the last year the inquiries relating to timber have largely increased, and some valuable specimens have been received, especially from the Oak forests of the South of Europe and from West Africa; both procured by officers despatched by the Admiralty for the purpose. A large and very beautiful collection of specimens has been bequeathed to the Museum by the late Rev. Professor Henslow, of Cambridge.

HERBARIUM AND LIBRARY.—Large additions have been made to these, and especially to the Herbarium. Amongst these I would especially mention admirable collections from Western Tropical Africa, by Mr. Mann, particularly from the hitherto wholly unexplored high mountain regions of Fernando Po, Cameroons, &c.; from Eastern Tropical Africa, by Dr. Kirk, the energetic and accomplished companion of Dr. Livingstone; and by Dr. Seeman, whose mission to the Fiji Islands was mentioned in my report of 1859; also from the Secretary of State for India, who has made over to the Royal Gardens the enormous collection of plants that had been accumulating at the India House during the last thirty years; together with the whole of the MSS. and drawings of the late eminent botanist, Dr. Griffith.

I have also to announce the mission of a collector to Japan, under the joint auspices of our own Board and the Admiralty.

The most important step, however, taken in this department, has been the commencement of a uniform series of inexpensive Colonial Floras, which are urgently required by colonists, manufacturers, and travellers, as well as by scientific botanists, horticulturists, and amateurs, but which, owing to the labour and expense of compiling them, and the necessity of doing this in

\* A more recent letter from Governor Denison, dated 9th January, 1862, informs me that they have now upwards of 8000 plants in most vigorous growth.—W. J. H.

† Our Palm-house contains 24,000 feet superficies; the conservatory at Chatsworth, 15,276 feet; and that at Syon, 7785 feet.

† This will be exceeded by the Pine spar coming to the International Exhibition from Vancouver's Island, and which is to be erected in the Royal Horticultural Society's Garden at Kensington Gore. This gigantic spar is 230 feet long.

such an establishment as the Herbarium at Kew alone affords, can never be undertaken by private individuals unaided by Government.—W. J. HOOKER, *Director*.

### LATE GRAPES.

THERE are some men who may be called "Vine Tamers." They seem to do with that apparently pliant plant just as they will—cramping it into pots, twisting it into all sorts of odd shapes, pruning it this way and that way, and finally decreeing that it shall produce fruit just at the time they desiderate. Of these men Mr. Hill, gardener to Ralph Sneyd, Esq., of Keele Hall, is one. We have received from that gentleman a bunch of Lady Downe's Seedling on this 2nd of April as fine as it is possible for it to be produced. It has been ripe ever since last August, and by Mr. Hill's skill has been preserved all the time without a shrivel or a blemish upon it. We sometimes hear it said, "There is nothing new in gardening." "Old Miller knew quite as much as we do." Such observations may refer to Cabbage gardening, but horticulture is a science, and must progress. What would "old Miller" have said to new Grapes on New Year's-day, like Mr. Thomson's, or to these old Grapes on the 2nd of April of Mr. Hill's?

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

As the opportunities of proceeding with work here have been but occasional owing to the frequent occurrence of rain, every opportunity should be embraced for completing the important operations which belong to this period. *Basil*, a warm sheltered spot may now be chosen to sow in the open ground; but to insure success it is a better plan to sow in pans on a slight hotbed, and afterwards to plant it out. *Beans*, earth-up the early crops, but before doing so lay a little soot close to the stems; timely earthing will also prevent the wind damaging them. *Cabbage*, pull up any of the plants that are running to seed in the autumn plantations, and fill up from the reserve-bed; at the same time stir the soil between the plants and earth them up. *Carrots*, thin-out those in frames, and sow the main crop if not already done. *Celery*, the main sowing for the winter crop should now be made. Continue to prick out from the early sowings. *Gherkins*, an early sowing of them, and also of *Nasturtium*, may now be made, they will require a gentle heat and to be gradually hardened-off before transplanting. *Kidney Beans*, a sowing may now be made in early localities. The early sowing of this useful vegetable is sometimes cut off above the ground by late spring frosts, but the portion beneath the surface of the soil occasionally throws up shoots, from which a crop will be produced nearly as soon as if the leaders had remained uninjured. *Lettuce*, give air to the plants in frames night and day in mild weather. Loosen the soil about those planted in the open ground. *Sea-kale*, remove the covering immediately it is done with; if there is any yet to be covered, let it be done before it grows much. Box-edgings should be clipped immediately.

#### FLOWER GARDEN.

If not already done patches of some of the most showy hardy annuals should now be sown in vacant places, which usually exist in the herbaceous-beds and in the edges of clumps and borders in the shrubbery. A sufficient quantity of cuttings and seedlings of half-hardy climbers should now be potted for planting out in May, Cobæas, Maurandyas, Lophospermums, Tropæolums, and other such plants would be found useful for covering bare places on walls, fences, and trellises, which otherwise would give an unsightly and unfinished appearance to the place. Pot-off Carnations and Picotees as soon as the weather will permit. Have the turf swept, well rolled, and made thoroughly firm without loss of time, and remember if the first mowing is deferred till the grass gets long it will require much time and labour to get the turf into proper order. I called a few days ago on my friend Mr. Marcham, Nurseryman, Earl's Court, Kensington; he was then busily engaged arranging his flower garden with Daisies and Heartsease of various distinct colours, Cerastium tomentosum, Forget-me-not, London Pride, and other such spring-flowering plants; and as an experiment he had marked out several devices, such as V.R., the Prince of Wales's Feather, and others separately on the beds, each device to be distinctly defined by the arrangement of the colours in each bed. Persevere in stirring the surface of the beds of Pinks, Pansies, &c., after rains,

Propagate Pansies for succession, and fill up vacancies that occur in the beds. The Chrysanthemums will now be well rooted; pot them off singly into small pots, to be occasionally stopped as they progress in growth, to have dwarf sturdy plants.

#### FRUIT GARDEN.

Disbud Peach and Apricot trees: this should not be done severely at once, it is better to go over trees three or four times for this purpose, removing a certain proportion each time.

#### GREENHOUSE AND CONSERVATORY.

Continue to shift the greenhouse plants which require it. Pelargoniums and Calceolarias for early blooming to be kept comparatively close and frequently syringed. Take care before potting that the old balls of Heath and other hard-wooded plants are sufficiently moist, as it will be impossible afterwards to moisten them properly without saturating and souring the fresh soil. A succession of Achimenes to flower late in the autumn to be placed in heat. Climbers, both in pots and borders, to have due attention, retaining no more shoots than will be required for the allotted space. The leading shoots of Epacris, Heaths, Chorozemas, Correas, together with as many others as produce the best effect in a bushy condition, to be frequently pinched back or stopped to produce good specimens.

#### FORCING-PIT.

As the season for forcing flowers is now drawing to a close, this structure will be useful to give additional encouragement to Clerodendrons and other such free-growing plants which require plenty of room. Some of the plants may also be removed from the dung-frames to this pit to make room for Balsams, Cockscombs, Globe Amaranths, and other plants for the summer and autumn decoration of the greenhouse and conservatory.

#### PITS AND FRAMES.

Scarlet Geraniums, Petunias, Verbenas, Calceolarias, and other plants for bedding-out may be removed to cold pits or frames, that a hardy habit may be induced preparatory to being planted out. If plunged in old tan, ashes, or other light material, much of the labour of watering will be saved, and the plants will be in a better state when the planting-out season arrives. Calceolarias, Verbenas and other young stock intended either for decorating the flower-beds, or for succession in pots, to be pinched back to make them bushy. If no plan has been formed for the arrangement of gay masses of flowers, it should be done forthwith in order that sufficient stock may be got together without delay. Not a moment's time should be lost in propagating extra things for the purpose. Choice Carnations and Picotees may soon be turned out into the beds or borders; three in a group, in rich soil, produce a fine effect. The Mimulus family may soon be planted in fresh patches in a moist soil and situation, not forgetting the Musk, which should be removed in large patches.

W. KEANE.

### DOINGS OF THE LAST WEEK.

THESE doings out of doors have been but few, as the rains and Scotch mists still continue, and with but little signs of intermission. On Tuesday, the 1st of April, the glass rose, and having been rather dry on Monday, we hoped to be able to sow Onions; but the showers came down in torrents in the afternoon, and on Wednesday continued without intermission. In our heavy soil there has not been a chance of Onion-sowing; for I have long proved that the middle of March is quite early enough for us, and for early Onions it is better to depend upon autumn sowing, and transplant these early in spring, merely fastening the roots, and leaving the bottom of the stem just on rather than in the ground. No thinning of autumn-sown Onions will be equal for bulbing to transplanted ones. If not clearing up soon we will sow a bed thick, and transplant them likewise. We got out a portion of what is intended for the first Peas and Beans from under a slight protection; but we could not finish even that. Pea-sticks have been prepared under shed-covering, and stakes and tallies of all kinds made, and every dirty pot washed as soon as emptied. Planted out more Dwarf Kidney Beans, and removed the early Potatoes in pots to the orchard-house, now of a nice size and the skins firm. Pricked-off Capsicums, Tomatoes, and many other seedlings, Celery, &c., finding difficulty to hold them all.

#### FRUIT GARDEN.

Chiefly confined to work of routine. Changed Strawberry-pots, and brought in fresh gently started a little under glass;

there could scarcely be worse weather for *Éac*-flavoured fruit, and a few hours' sun would do much service to orchard-houses now in full bloom. Find there is a black beetle on the Peach trees this season that never troubled us before—a lazy, inert rascal that seems to multiply by myriads, and pastils, tobacco, and other things seem next to powerless against it.\* We have been forced to squeeze and wash. I never saw one of the gentry before this season, and now even some of the young trees are clustered with them near the buds. What a fine thing for the spontaneous-production theorist! Of course, the old ones must have come across us, and deposited their eggs last season. Our Muscats do not break so kindly this season as usual—partly owing, we think, to extra heavy crops for many years, the extreme hardness of the wood last season though not strong, and the not protecting the borders from wet so much as we used to do. We fear the crop will not be so regular as usual, and that there will not be so many bunches to cut off for tarts, which when used shortly after setting would puzzle an epicure to distinguish from young Gooseberries. It is just likely we may leave too many after all; but it is more pleasant to cut off half a dozen bunches for every one left than to have to wish that there had been more of them. A little sun would be a great help to everything under glass, and out of doors too.

#### FLOWER DEPARTMENT.

Rolled the lawn when possible, the grass growing amazingly. Planted out Pinks and Carnations; divided herbaceous plants, and forked over the beds when possible. Propagated Neapolitan and other Violets under a hand-light, though dividing the plants into little bits does very well; the great thing in the Neapolitan is to encourage the crown, but never allow a runner to grow all the summer without being nipped off. Pricked-off Primulas, Polyanthus, and Hearts-ease. Made cuttings of Dahlias, chiefly those intended for bedding, and will divide the roots ere long. Pricked-off Lobelias. Made cuttings of *Cineraria maritima* as detailed last week, and though we got some four hundred—the young shoots not coming fast enough to our mind—we took the old roots, packed them thickly in soil in moveable boxes, and set them in a Peach-house at work, so as to hasten them on a little. We consider no old plant or part of an old plant is safe for edgings because so liable to spindle into flower-stems. These young plants raised from little slips scarcely ever show a flower-stem the first year afterwards. Singularly enough many plants stood out last winter twelve months ago here uninjured. A row of some five hundred seedlings last year left to see what the winter would do are almost entirely gone. The wet seemed to have done for them what the frosts of the preceding winter failed to accomplish. Potted *Primula sinensis* for late-flowering, Geraniums, &c. Cut down Begonias, Poinsettias, Eranthemums, &c. Put a few cuttings in. Potted-off *Fuchsias* just struck and older plants growing, and stopped the oldest in large pots, to make them bushy. Removed fading *Cinerarias*, and introduced fresh, and potted more. Looked after Orchids beginning to grow. Regulated climbers. Picked-off decaying blooms of Camellias; none are yet fit for more heat, and that is as well, as I have not a corner to give them the chance. Potted Roses just struck, and put in more cuttings, cutting to a joint, and leaving part of the shoot there, moving the leaves, if any, from the joint and bud above. Potted *Gloxinias* and fine-leaved Begonias, the latter disliking too much room, but glorying in open rich soil. The weather has put a stop to our *Calceolaria*-planting, though the plants want moving badly. Some of the earth-pits got so wet that we dug a deep hole in a corner to collect and thus get rid of the extra water. We must go ahead in this work as soon as the soil becomes moderately mellow.

#### BOILERS.

To add to our trouble in such weather, a boiler gave way that heats three pits filled to overflowing with many things—as Cucumbers, &c., too tender to depend upon atmospheric heat. I mention this chiefly because, as I am not in a particular hurry about a boiler, I should like some evidence from friends and correspondents, as to the relative endurance of cast metal and wrought-iron. I chronicled how a boiler that heated a conservatory gave way in the severe weather, at Christmas, a twelve-month ago. That was wrought-iron from an eminent country firm. The present is a large-saddle-back, from a then-celebrated metropolitan firm. The first lasted some eighteen years, the second about fifteen or sixteen years. In the first case the iron

over the fire was worn to the thickness of a mere film. In this last case the fault was not over the fireplace, but on the outside next to the smoke-flue on the side. The water poured out at the soot-plate. The boiler is about 3 feet in length. On putting a candle on the end of a stick we could see the water issuing in several streams. It took us the most of that day to get down to it by removing the brickwork. We could put our fingers through the iron for a space of several inches, and on clearing the boiler of scales, two other places were found where a child's hand could go through. Now, we make it a rule to clear out these flues very frequently with a wooden hoe and stiff brush. Yet, nevertheless, the smoke and the soot had thus perished the iron. There are two small metal boilers on the place, that I should suppose have not been emptied for a score of years, and nobody seems to know anything about their age. Now, these two series of facts would seem to be in favour of metal boilers, though as I have seen them crack within a few hours of the fire being lighted, the subject is one well deserving elucidation by facts. No doubt some will say it was time they were burned out, but that is not to the purpose. I have known boilers taken out before they had done half as much service; but then the owner of a garden does not like these mischances too often, and most generally such things happen in the very worst time.

"How coolly 'R. F.' takes it in being in no such hurry for a boiler." Well, by removing about half the pile of brickwork which people will insist on having round and above boilers, we managed to make it waterproof again in a very simple way, and with little or nothing in the shape of tinkering—the how we might leave at least for a time for our young friends to decide. So that now I feel pretty secure, but should not like to trust long, lest the other side should give way in the same manner.—R. F.

#### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

CUTTING-DOWN *CLEMATIS VITICELLA VENOSA* (*Amateur*).—This *Clematis* on a south wall, and all the new *Clematises* from Japan and the Continent, ought most certainly to be cut down to the ground annually for the first three years.

ANEMONE APENNINA (*Idem*).—This, and *Anemone ranunculoides* with us, require to be lifted and divided every year, else they will not bloom freely; but where they bloom they need not be lifted often than once in four or five years. We do not dry them, but separate the roots, and plant the biggest of them the same day. We have them both now just going out of bloom, and pretty spring flowers they are too; with such plants as *Hepaticas*, *Anemone amplexicaulis*, *Triteleja uniflora*, and *Ajox minor* all in bloom together.

CALAMPÉLIS SCABER (*Idem*).—This, the good old *Eceremocarpus*, has been so often cut down by the frost, that close cutting is now unnecessary for it—that is to say, the roots must have come to that state by this time, that they can send up stems of sufficient capacity to receive all the sap as it comes and look for more; whereas, without such cutting, the spindly growth of the first few years is not able to pass up one fourth part of the quantity of sap in the roots. The consequence is they, the bottom part of the shoots, get as hide-bound as *Manetti*, and the space allotted for the climber is not filled up in one-half the time it might be.

VALLOTA PURPUREA (*Idem*).—It would stand out with you in Tyrone as well as *Agapanthus*; but then the question is, would it also bear to lose the leaves with impunity like *Agapanthus*? Just try, and let us hear. The great English experimenter of the geothermal system of growing all such plants with bottom heat in the open air, told us the other day that of all the hundreds of plants he tried that way *Vallota purpurea* did the best, and seemed to approve of the plan the most.

VARIEGATED ONONIS (*Somebody*).—Your seeds, for which we are thankful, may be those of the *Ononis variegata*, which is not a true variegation, but a natural striation, and comes from seeds as the hairiness of *Cineraria maritima*, which is not a variegated plant, neither is *Cerastium tomentosum*.

COCOA-NUT FIBRE REFUSE (*An Irish Amateur*).—If sifted, so as to take away the fibres, the brown powder is the correct refuse.

TURKISH-ROOTED CELERY (*Old Deer*).—It is also called *Celeriac* (*Apium graveolens rapaceum*), and full particulars of its culture are given in *The Cottage Gardener's Dictionary*. Celery is much preferable. *Carter's Champion* is a very good smooth-skinned *Cucumber*.

\* Larvæ of *Aphis persicæ*.—Eds.

**PHENOCOMA (H. H.).**—It has been starved for want of water, and then been glutted. Let it alone as it shows flower-buds. Give it, when dry, a little manure water of a cool kind, and when done flowering prune back, and set in a close, warmer place, and whenever there are signs of growth repeat in the same size pot, getting rid of a good deal of the old soil.

**LIQUID MANURE (C. R. B.).**—This, which you require for greenhouse plants, may be made of sheep's-dung, a peck to thirty gallons of water. Cowdung may be used, a peck to twenty gallons, but the water should be boiling, as this dung is liable to contain the larvæ of injurious insects. Five ounces of guano to ten gallons of water is also a good liquid manure. Superphosphate of lime, one pound to twelve gallons of water, will benefit your Pelargoniums. All the preparation required by any of these liquid manures, is to let them remain undisturbed until quite clear, and then to pour off the clear portion for use.

**LIME WATER (A Subscriber, St. Nicholas).**—One peck of lime to forty gallons of water makes the lime water required for killing worms on lawns.

**INDICES (G. D.).**—That for Vol. XIV. can be had free by post for three penny postage stamps. That for Vol. XV. is out of print.

**HIPPEASTRUMS AND DISA GRANDIFLORA (S. S. S.).**—Your means and your practice would only increase your trouble were you to attempt these flowers. You say that you cannot have Mignonette or force a *Deutzia gracilis*: therefore, your money and your patience too, would be lost were you to embark in the higher flights in gardening. Buy our "In-door Gardening for the Many," and master the directions there given. Next week we shall give a chapter on Hippeastrums, if only to assist the Royal Horticultural Society, who now make them a standing number in their schedule of prizes.

**NOTCHING FRUIT TREES (G. K., Subscriber).**—You are just in time to notch. Now is as good a time as any in all the year.

**ANNUALS FOR BORDERING GERANIUM-BEDS (R. I. D.).**—The most lasting annuals to plant round an oval of Scarlet Geraniums are *Saponaria calabrica*, *Sanvitalia procumbens*, the dwarf French Marigold, and the tall botanical Marigold called *Tagetes tenuifolia*. These four will last out the whole season till the frost comes, from seeds sown just now. The first is a bright pink; the rest are yellow.

**LAURELS DYING (Idem).**—These, failing after two years in front of that wall, die entirely by inches for want of food. Nobody ever planted Laurels in such a scorching place without first trenching and improving the ground, and yours has not been even trenched, nor yet dug one-half the depth to keep Mignonette alive. Just try and prove the fact. But the fact is, not one out of one hundred ever does justice to ground for Laurels, and some few do too much to it as we now know to our cost. We have loads of it to cut out every year to keep it at all within bounds.

**GLASS STRUCTURES (Tokay).**—We would have a hipped roof for conservatory or greenhouse, which would give the advantage of the north wall, and then take a span-house north and south from it, like the leg of the letter T. If you wished a wide house make a double span. We prefer such a house for your purpose to one facing the south. We do not equally approve of a span running east and west, as there is only one side for direct sun. We find as respects glass that fifteen-ounce, called sixteen-ounce—in fact, ranging from 13½ to 16½, will yield and bend when a hailstone or other missile will break twenty-one-ounce. However, on the whole we think twenty-one-ounce the cheapest in the end. See notice of a new style of houses at p. 6. Yours from the position should be elegant.

**WORMS (A Subscriber).**—You will see a recipe for lime water in answer to another correspondent. It is quite as effectual as any other application, and not dangerous. The chemical mixture you allude to probably is corrosive sublimate, but it is a deadly poison. London's "Hortus Britannicus" will suit you better than his "Encyclopædia of Plants."

**COCOA-NUT FIBRE REFUSE (Swansea).**—The sample has not the slightest resemblance to the refuse useful for garden purposes. We have said that the true is like brown rappee snuff, but yours are bristles.

**RIBBON-BORDERS (F. A. Martineau).**—All your plants will do except *Petunia* between the two Geraniums, *Petunias* being bad in any part of a ribbon by the bother they give to keep them in their places. We had seventy-five yards of the *nyctaginiflora* to keep in form in the fourth row of a nine-row border for some years, and that *Petunia* occasioned more trouble than the eight other rows put together. Nevertheless, when one can manage them, some *Petunias* make grand rows.

**STOVE FERNS (J. L., Yorkshire).**—By plunging the pots in a hotbed of tan they will grow faster, but unless the tan is kept fresh you will be apt to be troubled with worms in the pots, which will more than neutralise the advantage. All things considered, the stand will be best. The north aspect will be best for most Ferns; but where the light is too strong, the glass may be shaded or muffled.

**WATERING VINES WHEN STONING (Idem).**—The Vines may be watered if dry, which we can only conceive of them from being planted inside the house. The manure water we fear would be rather strong if not diluted. We suppose the chill was taken off it. We suspect the honeydew is the result of too much watering in dull weather. The leaves cannot evaporate the moisture—you had better sponge it off.

**STOVE FOR A GREENHOUSE (Tyro, Blackpool).**—No stove without a chimney can be used among plants without injuring them. As you cannot have a chimney, we recommend you to have a small gas-stove constructed like Mr. Lichfield's, as mentioned at page 15 of our last Number.

**PINE APPLE SOIL (R. E.).**—The cocoa-nut fibre refuse is not for Pine Apples at all, unless you had very sickly ones, which the refuse would soon put on their legs again—fit for the very best strong, well-pulverised, but knotty loam. Brick earth, like yours, is altogether unfitted for growing Pines in; but Mr. Beaton tells us that if one-third the quantity of the refuse were to be added to any sort of clay, and kept in a ridge for full two years, and to be turned four times a year in very dry weather, he thinks it would make an excellent soil for Melons, Pine Apples, Palms, and Musas. No garden plant will flourish in your soil. We would pare and burn it. The burnt soil mixed with the top spit would much improve the staple.

**EARLY GRAPE (Viator).**—We have never yet seen or heard of Grapes so early, or at all like those of Mr. Thomson's, of Falkcith. The earliest besides we ever saw were produced in the second week of February, and were little scraggy bunches, and the fruit, though coloured, unripe. Mr. Thomson's are bunches worthy of August, and in flavour not to be surpassed.

**TURF PITS (Edith).**—Turf pits are made by laying the turves say a foot wide longitudinally on each other. Mr. Fish's Calceolaria-pits are from 4½ feet to 5 feet wide, 6 inches in front above the level, and 15 inches at back, and from 6 inches to 9 inches below the level. The earth taken out forms the chief part of the walls, with a layer of turf here and there to keep it firmer; a layer of turf covers all outside for neatness. He prefers turf altogether when it can be had, and the bed to be as high as the surrounding surface; those so raised have been little affected by the late continuous rains. Those sunk, required a hole 2 feet or 3 feet deep to be sunk at the lowest corner to receive the excess of water; but such a season rarely happens in March. When much larger than the above a few posts—say 5 feet apart, are driven in the line of the turf, and a rail placed along the top. We have turf walls thus formed from 2 feet to 4 feet in height, and a sloping grass bank has kept the turf dry for years. Mr. Fish also uses four-foot Celery-beds for similar purposes; the Celery comes in after the plants are removed. If you get some fresh tan and throw it in a heap until it ferments, about 2 feet of that will be deep enough for the purposes you want.

**CENTRE BED (H. B.).**—As you have "most of Beaton's Nosegays at command," put a thick row of his *Carmine Nosegay* round the Golden Hollies and inside the Variegated Mint, and you will never regret it. If you have not got that Nosegay put in Christina instead.

**VARIOUS (Tyro).**—The "Osage Orange" is not an Orange, but belongs to the Natural Order Moraceæ. Its botanical name is *Maclura aurantiaca*. The Citrus fruit you enclosed is some kind of Lime. The plant you enclosed a spray of is *Kuscus hypoglossum*, it has the same properties as the common Butcher's Broom, *R. aculeatus*. Your *Eucharis amazonica* having one spike with three flower-buds, and another spike with four, is a good specimen. After they have flowered part the bulbs and grow them singly in small pots.

**INSECTS (G. C. C.).**—The Caterpillar which has gnawed out the interior of young Ash branches, is that of the Wood Leopard Moth (*Zenzera Esculi*). (*Aron*).—The Beetle which has been so injurious to Vines this spring is the *Othiorhynchus sulcatus*, or Striped-back Weevil. It should be hunted for with a lantern after nightfall, when it will be found on the leaves and twigs. (*R. F.*)—You Peach blooms and twigs are infested with the young black larvæ of the Aphides attached to that tree, *A. persicæ*, upon which there is an excellent memoir by Morrens.—W. W.

**BACK NUMBERS (C. B.).**—You can have from our office, from No. 2 to No. 12, both inclusive, of Vol. XXIII.; but No. 1 of that Vol. is out of print. We can let you have Vol. XXIII. complete, and in its cloth cover.

**WALTONIAN CASES (M. H.).**—The boiler must have been allowed to become dry while the lamp continued to burn. Zinc, we should think, must be employed to mend it; but you had better consult the maker.

**GOOSEBERRY CATERPILLAR (A Subscriber, Te'worth Hall).**—We know of no other preventive than tan, as we recommended; unless taking off the surface soil 3 inches deep and burning it might be effectual. If the Caterpillars come there is no mode of destroying them but by hand-picking, or dredging with white hellebore powder.

**RUSSIAN AND OTHER VIOLETS (B. Westy).**—To grow these plants to perfection, a rather deep loamy soil is necessary, stiff rather than light, the situation quite open. It may, however, be sheltered from the north and other cold winds. Trench and prepare the ground some time before planting, but if it be in good condition dug is not wanted, as that causes the plants to run too much to leaf. Take off rooted layers or offsets as early in the season as they are to be had, and plant them out on the ground so prepared. Rows about 15 inches apart, and the plants about a foot from each other in the row will do very well, and if the weather be moist at the time of planting they will in general start at once and grow; but in long periods of dry weather red spider is apt to attack them. Dusting the plants with sulphur underneath the leaves as well as above will, to a certain extent, check it, giving them at the same time a good watering with weak liquid manure; but one of the great secrets in obtaining good well-formed plants loaded with bloom, is to pick off all runners as they appear. Attention to these matters, and with a soil suitable to their growth, success is certain; and if you want to force *Violets*, the same course must be adopted, only endeavour to get them matured as early in the preceding season as possible, and do not hasten them on too fast, as the plant will only produce leaves if hurried on at improper speed.

**LOBELIA SPECIOSA—PERILLA AND AGERATUM (J. T., Tadcaster).**—The seedlings now up on a gentle hotbed ought to make good bedding plants and flower this summer. No public journalists ought to say where such and such plants or seeds are to be bought; that would be recommending one dealer at the expense of others, and would be most unfair. Any nurseryman who advertises in our columns can obtain any plant or packet of seeds that is on sale in Europe for any one who orders and pays for them.

**CUTTING DOWN ORANGE TREES (E. C.).**—If your Orange trees were in an unhealthy condition, your gardener did not act unwisely in cutting them down, although by your sketch he may have cut them lower than we should have been inclined to do, as we would only have cut them in severely, much in the same way as an old standard Apple or Pear tree is cut down to graft afresh, the limbs being cut off a short distance from the main bole. If, in addition to this, the roots were thoroughly examined, and dead and useless ones cut away, and the tree reotted in fresh soil with plenty of drainage, and the plants set in a warm close house, it is likely they will break and make fine heads by autumn. It is also good practice to tie moss loosely around the stems and branches, and to keep it always moist by syringing, taking care to remove it by degrees when the small shoots appear. But the moist atmosphere of an ordinaryinery in the course of forcing will usually suffice for this, taking care, however, that the roots do not get saturated with superfluous water at a time when there is no foliage to absorb it. In repotting it is not unlikely but smaller pots will do when the roots are pruned.

**NARCISSUS (M. B.).**—The upper half of a leaf ought to be sent with the flowers of all sorts of bulbs if they have them. No class of bulbs is more difficult to determine from single flowers than Narcissus. Yours is the good old "Butter and Eggs," *Narcissus aurantiaca flore pleno* of old books, and the *Quetta aurantiaca* of modern classification, one of the richest of all yellow Narcissus. Pray can you spare a root or two of it when the leaves die down? Pray also make us a memorandum on the posture of the seed-pods after the flowers are past—now they are horizontal from the scape. Some do and some do not turn up the seed-pods quite erect as the seeds advance to maturity; but we are not certain which of the postures the "Butter and Eggs" take to at last.

**CAREX FRASERI** (*A. R., Fromley*).—This, the finest of all that rigid race, is a native of sedge places in North America, and requires much about the same kind of soil and treatment in every respect as *Disa grandiflora*—that is to say, as an evergreen bog plant, requiring to be kept out of the sun in very hot weather, and not to be exposed to the vicissitudes of a variable climate like ours in winter. The snow keeps it warm at home.

**SOWING COCKSCOMBS AND BALSAMS** (*A Subscriber, Bath*).—No time must be lost in sowing Cockscombs to obtain good large heads for August; and when the plants are fit to handle, prick them off into a pan or box for a time, as it saves the watering of so many small pots; but they ought never to be allowed to stand so as to get a check, but pot off as soon as you see they require it, and continue to repot afterwards until they are placed in the pots you intend them to permanently remain in. A close frame or hotbed is the best place for them, with frequent syringings and a rich soil. Balsams require more air and arrive sooner at maturity: therefore, about the 1st May will be soon enough to sow for what you want. A good bottom heat and plenty of top air, amounting in fine weather to total exposure, is what they do best in, as by that means good bushy short-jointed plants are obtained. We presume you have a good variety, as much depends on that. Balsams from the first must have separate pots, but ought never to get pot-bound.

**NAMES OF PLANTS** (*Warwickshire*).—1. *Siphocampylus bicolor*; 2. *Origanum siveolum*.—(*R. E., Monmouth*).—A large frond of *Polystichum angulare lobatum*. We found no other. (*B. W.*).—Sphagnum is a kind of pale-coloured Moss found abundantly in wet boggy places. The *Cystopteris* is nothing but *C. fragilis*. The other frond appears to be a narrow and somewhat revolute variety of *Blechnum spicant*, but we do not recognise it as a named variety.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY, &c., SHOWS.

MAY 14th and 16th. TAUNTON and SOMERSET. *Sec.*, Charles Ballance, Esq., Taunton.

MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). *Steward*, S. Pitman, Esq., Manor House, Taunton. Entries close May 1. MAY 25th and 29th. HULL AND EAST RIDING OF YORKSHIRE. *Sec.*, Mr. J. Hooton. Entries close May 14th.

JUNE 3rd. ESSEX AGRICULTURAL ASSOCIATION. *Sec.*, R. Emson, Slough House, Halstead. Entries close May 10th.

JUNE 4th and 5th. BEVERLEY AND EAST RIDING. *Sec.*, Mr. Harry Adams. JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. *Secs.*, E. Holdsworth and J. Wade.

### WILD FOWL.

AMONG other erroneous notions that have prevented many from indulging a taste for keeping aquatic birds, is one that a "piece of water" is necessary. Now, this implies nothing less than a lake or very large pond; and, in the mind's eye, it is studded with islands, and peopled with flocks of fowl. Like many other notions this is a wrong one. On such a piece of water, if there be hundreds of birds, many of them large, of the Goose tribe, and by far the greater number of the common Wild Ducks, some will always be visible; but the amateur of beauty of plumage, or one who seeks to have really tame and familiar birds will be disappointed; they will be hiding away—rendered shy by the space granted to them, and by the facility for concealment. He who has lakes at his disposal must, if he will enjoy tame wild fowl, resort to the limits imposed by necessity on those for whom we write these papers. As in those that treated on Pheasants, our aim is to show (and we write from experience) how easily and inexpensively these tastes may be encouraged. It is not impossible to keep wild fowl in London, but it would be difficult except where there are gardens. Our remarks, then, are addressed to those who have these luxuries, and this will include most of those who live in country towns and their suburbs. In these and similar papers we may publish from time to time, it must be borne in mind when we give limits or measurement, it is not because such are in any way necessary, but to show how little is essentially required to indulge the pursuit, and to enable the birds to be properly kept.

Many descriptions of wild fowl are in keeping with a flower garden: they are things of beauty, colour, and contrast. Most persons are acquainted with the marvellously-beautiful plumage of the Mandarin and Carolina Ducks: they are also very hardy, more so than many of the commoner sorts; but they are expensive, and we will, therefore, pass them by. We will speak of others that have beauty, and are yet easy of attainment at a moderate cost. The Dun bird, or red-headed Pochard, with his red head and neck, grey breast, and bright red eye; the Tufted Duck with his rich purple black head, neck, and back, his white side and breast, his falling crest and golden eye; the merry whistling Widgeon with his varied plumage; the spotted-breasted Teal with his green face, chestnut head, bright streaming saddle-feathers and lustrous wing; the Garganey with its white-striped face, beautiful breast, blue wing, and white and blue streaming feathers; the elegant Pintail with its long taper neck, blue and black striped bill, and brown and white striped neck, its long

tail giving it the name of the Lea Pheasant; the Gadwall with its maroon-patched wing and curiously waved breast; and the Shoveller with its rich variety of colour. All these are to be purchased for small sums, often only a few shillings per pair.

They have been bred wild, and so long as they can indulge the instincts of such a state they do so; but it is astonishing how soon they become tame after they have discovered they cannot get out of their new place. As they will not be convinced till after thorough inspection, care must be taken to make all secure, and this will bring us to describe such a place as is necessary wherein to keep four or five pairs of these beautiful birds, a piece of water 8 feet long by 4 feet wide, and 18 inches deep; a rough pollard stem put in the middle of it adds to the appearance, and is pleasing to the birds. The water should be surrounded by from 3 feet to 4 feet of grass, and this should be planted with small shrubs, and such as have branches close to the ground. It is well the water should not be level with the grass; but there should be three or four places as far apart as can be, where the bank should be cut through to afford landing-places for the Ducks: these should be paved with large pebbles. This enclosure should be made secure by means of wire netting stretched around it. It should be from 3 feet to 4 feet high, and must be close to the ground all round: this is absolutely necessary.

(To be continued.)

### POINTS IN GOLDEN-SPANGLED HAMBURGH COCK.

POOR "YORKSHIREMAN!" When will he learn the points required in the above breed? or how much longer must he keep and breed them before his judgment equals those who reside in other counties?

It is quite new "to me" to hear that Yorkshiremen love, or prefer a black breast to a spangled one. I thought all fanciers concurred the latter was essential.

In a correspondence which took place about twelve months ago, what I believe to be the true characteristics of the breed were then stated—viz., "a well-serrated comb not too broad, firmly fixed and straight on the head, and good spike behind; ear-lobes white; hackle deep gold, striped down the centre with black; saddle to match; breast well mooned with green black moons; back and upper part of wing a good maroon, with two distinct bars across, separating the flight-feathers; tail green-black, and ample; legs blue."

Should my judgment be at fault I shall be glad to be put right; as the nearest approach to the above are what I send out as good specimens, and think I am not far from the mark, as I was breeder of birds which took prizes at the late shows—Birmingham, York, Crystal Palace, Manchester, and Liverpool. But a black-breasted hollow-combed bird I never keep to breed from; as to the ear-lobe being lightly flushed with pink it should not mar the bird's success, being superior in other points. Ear-lobe alone should not rule entirely, and black breasts will only be loved by some jolly old Yorkshiremen. Mr. Dixon, Mr. Berwick, and several others, never show black-breasted birds, and the way the question was answered in your Journal of March 4th I thought cast a slur upon all Yorkshire breeders, exhibitors, and judges. And as I only get the Journal monthly, it came in on April 1st—a day that all fools meddle, this is my apology for interfering.—YORKSHIREMAN, Ripon.

**HEN WITH MALE PLUMAGE.**—There is belonging to a person close to my house a Silver Hamburgh, three years old. In the second year she laid two sets of eggs, which were hatched under another hen. In her third year she moulted, and she has now the plumage of the cock, the hackles on the head, and neck, and rump, and the long tail-feathers. She does not lay now, and is sickly.—A SUBSCRIBER.

[It is not at all unusual for old hens to acquire the plumage of the male bird. They lose their productive power at the same time.—EDS.]

### STINGING BY LIGURIAN BEES.

I CAN fully endorse the statement of your correspondent Mr. Barrell, as to the comparative innocuousness of the sting of the Ligurian bee. A few days since, whilst engaged in changing

the floor-board of my Ligurian stock, I accidentally jarred the hive: this apparently irritated the bees very much, for they instantly poured out and covered me. Two of them left their stings in my hand and wrist. The pain and swelling, however, yielded to the speedy application of a little tincture of arnica, and in a few minutes had entirely subsided.

Upon several previous occasions I have experienced a similar slight inconvenience from the sting of the Ligurian bee, although upon many occasions I have suffered most acutely when I have been stung by the common black bee. A pinch of tobacco soaked in water, and applied instantly, seems to be the best remedy, and generally subdues the swelling and irritation.—RECTOR.

**BOTTLE-FEEDERS—FLAT-TOPPED HIVES—  
VENTILATION AND FUMIGATION.**

THE London feeding-bottle will do very well if you have the hives in a bee-house, but it is very awkward if outside, as you cannot put a milk-pan or anything on; I would therefore suggest that they should be made of a low flat shape, the neck going into the hole of a straw hive or standing on top of a box-hive, and this would not expose the top to the cold and wet weather.

Can any of your correspondents inform me what advantage flat-topped hives have over the conical ones? as I fancy the conical are best for winter and keep the bees warmer, for I find in my flat-topped that the bees hang down a good way, and those at the bottom nearest the mouth drop from the cold and die.

If bees require ventilating, how is it that by nature they stop up every little hole but the one they go in and out at, and are not ventilated when in a state of nature?

Can any of your correspondents inform me who first found out fumigation for bees, and if any other nation besides ourselves used brimstone for destroying them?

Are bees natives of England? and, if not, where were they introduced from?—A. W.

[We have been favoured by Mr. J. E. Briscoe, of Albrighton, near Wolverhampton, with a sketch and description of a feeding-bottle, which he has invented and practically tested, and which we think will answer your purpose.

The annexed woodcut represents a section of the bottle, which is 6 inches in diameter, and 5 inches high, and contains above five half-pints of liquid food. The neck is short, 1½ inch in diameter, and is meant to be inserted in an aperture in the top of any kind of hive. Mr. Briscoe has experienced an inconvenience from these bottles not standing steadily whilst being filled, but this might easily be remedied by altering the shape as indicated by the dotted line. The bottle-mouth when in use is tied over with a small bit of tiffany, which is better than cap-net where perforated zinc cannot be interposed, as bees soon gnaw the net through if left unprotected.

The only advantage of flat-topped hives is the facility they afford for supering.

The subject of ventilation is being itself "ventilated" by some of our most able correspondents, and the circumstance you mention has not been lost sight of by them.

Fumigation by means of puff-balls was recommended by the Rev. John Thorley in 1743, but we do not know if he was the originator of the process.

If bees are not actually indigenous to Great Britain, they became naturalised at so early a period that no record remains of their first introduction.]

**UNITING BEES—CHANGING SUGAR INTO  
HONEY.**

I OFFER you my mite of practical experience upon this subject, if it has not already got too stale. Having fed up all stocks that required it by the end of October last, I expected that all was safe for the winter, but to my disappointment one cold morning in November, one of my stocks was thrown from its stand (but by what agency I know not, neither do I wish; but I suspect foul play, as it was close to one whose doings may appear in your pages at some future day), and every comb broken out. Of course, it was hopeless to attempt refitting and

keeping it together at this late season, so I swept off all the bees into the hive, and made the queen a prisoner, as I wanted to keep the adopted one of the other hive that the bees must be put to all safe. I must confess that I had some doubts about uniting the bees so late in the season, as destroying them was out of the question. I made ready for the evening, and united them in my usual way, and I believe without a single combat, an occurrence not unusual with me. As the season advances I shall see the results and compare notes with some of the crotchets upon this subject. I made twelve unions with the same results as above last season. As the subject has been so ably explained, I forbear at present making any remarks upon it, only I hope those who have not done so will try, and be their own judges, as I am sure it will well repay the trouble.

What next? Chemistry again! some will say; and well they may, if they have ever given it a practical test. In the stock referred to there was pure honey gathered upon the moors, and syrup also as pure as could be made, given a month previous to its downfall. I was able to see the difference distinctly, so as to keep the two separate; but the great test was still to come, the syrup had not undergone any change in its passage from the bottle to the cell, nor had its month's stay in the hive given it any perceptible change, and I have some of it in the comb at the present time unaltered. But I am now speaking of the labours of the black bee.

There may be some magic power possessed by the yellow Italians, which none but their owner is acquainted with. If this be so the seasons will make little difference to him, if he can convert sugar into honey.

One thing more, and I have done. If the honey undergoes a change in the stomach of the bee, how is it that we have all the different flavours; of course depending on what flowers it has been gathered from? I have a few hives in one locality, the honey of which (like counting chickens before they are hatched) is sold before it is gathered, on account of its fine flavour. I think it is gathered from the white clover and the bramble, of the latter there is a great quantity.—A NORTH LANCASHIRE BEE-KEEPER.

**RESULT OF "A. W.'s" EXPERIMENT IN  
SUPER-POSING.**

THE other day being fine I looked at the two hives I joined last autumn, and found the bees had gone into the lower hive, and I therefore took the top one away; but from this last cold weather I find very many dead, and am afraid there are very few left, but will look the first fine day. We have lately had nothing but cold, wet, and snow.—A. W.

[Never were opinions more completely verified by subsequent events than have been those which were promulgated by us in reply to the original inquiry of "A. W." in page 38 of our last volume, and to which so many objections have been made. Not only has the massacre at which we then hinted actually taken place, as has been already related by our correspondent in page 429 of the same volume, but we now learn that the bees have, as we predicted, "ultimately descended into the lower hive."]

**BEE'S DYING OF DYSENTERY—"VAGABOND  
SWARMS," AND VENTILATION.**

THIS morning (24th March) I found the young virgin queen spoken of in page 488 of the last volume, turned out of the hive, her death having, doubtless, been occasioned by the same fell disease which had already proved fatal to so many of her working sisters. As this event puts a stop to all chance of my observing by her means a new phase of parthenogenesis, exemplified in a queen bee bred so early in the spring as of necessity to remain unfeucundated, I shall lose no time in uniting the remaining bees to the colony to which their parent was introduced in the manner already related. On the whole, perhaps, I have little reason to complain, having lost but two stocks by dysentery out of a total of twenty-six—no great per-centage when it is considered that nearly all were artificial swarms formed late in the season.

I regret to state, that in a letter recently received from Mr. E. Wyndham Jones, of Nantwich, Cheshire, who is the distant correspondent mentioned in the latter part of the article above referred to, he says—"The bees in my box have ceased to exist,

having gone during the sharp frost which followed the January mild weather." Speaking of internal moisture, he also says, "I imagine it brings on dysentery. What magnifies the difficulty is, that two hives fail and two escape—viz., one straw and one wood gone, one straw and one wood saved, a swarm and an old stock in each case, all being subject to the same temperature, the room in which they are placed being dry and well ventilated."

My own experience is of exactly the same contradictory character, but the novel and unwelcome appearance of dysentery among my stocks this winter has pretty well determined me in future to follow the advice of our Renfrewshire friend, and fly to ventilation during winter, as, at any rate, the least of the two evils.

In a former letter Mr. Jones informs me "that above the south porch of Acton church, about a mile from Nantwich (a place that was once made a prison by Cromwell's 'ironsides,' when a desperate battle was fought), there is a strong colony of bees which were there twenty-five years ago, and the parish clerk says he has seen them there ever since, having taken an interest in their welfare. I was curious enough when there last summer to get some workmen to erect a ladder close to the entrance, and after a careful inspection, I do not see there is the slightest chance of any escape of air, &c., otherwise than through a small aperture in the wall, which serves as an entrance for the little rascals. In Combermere, Chiondeley, and several other parks in this neighbourhood, there are some colonies of bees which throw off swarms annually, and I am assured that persons who have fortunately met with what Richardson calls 'vagabond swarms,' have the best of luck, boasting of the superiority of their favourites."

In a more recent letter my esteemed correspondent says, "I was at Acton church some days since, and noticed the bees were then alive. I intend taking a regular tour through the different noblemen's parks this summer, for the purpose of making inquiries on the subject of bees and their movements in the trees, the result of which I shall in due time communicate to you."

With regard to ventilation during winter in the case of swarms which have taken possession of hollow trees, &c., it is very probable that in most instances the cavity is too large to be completely filled with combs, and that if this be so the vacant space underneath serves the same purpose as the cke used in Ayrshire, and successfully adopted by "A RENFREWSHIRE BEE-KEEPER." In conclusion I may state that if Mr. Wyndham Jones will fulfil the promise he has given of reporting the result of his observations, he will confer a favour on many others as well as on—  
A DEVONSHIRE BEE-KEEPER.

### PRESERVING GINGER.

PARE it nicely with a sharp knife and throw into cold water. Then set it on the fire (in cold water), and boil till tender, throw it into cold water again until quite cold, then drain the ginger and put into a china bowl. Clarify the sugar in the proportions of 8 lbs. to 7 lbs. of ginger. Let the sugar become cold, then pour over the ginger enough to cover it. Let it stand two days, then strain the syrup from the ginger and boil it with the remainder of the sugar, let them boil together twenty minutes. When cold again pour over the ginger, and let it stand three or four days. If the ginger is nicely swollen and the syrup rich, nothing more is necessary; but if not, boil it again at the interval of three or four days. Wide-mouthed bottles are best for keeping it in. Divide the syrup to each; cork and seal, or dip in bottle-cement.—REBECCA.

### LARGE YIELD OF BUTTER BY ONE COW.

AS you have given the management of a cow, I now send you the weekly butter produced by our cow if you think it worth your notice. She is a small one, particularly handsome, bred between the Ayrshire and Alderney, but not showing the slightest appearance of the latter. The custom in this county is to put butter up in half-pounds: therefore, in 14 lbs. there would be twenty-eight draughts. This, if considered, would add considerably to the quantity, as my servant places a penny-piece on the scale in addition to the half-pound weight; also cream used for the table, which, during fruit time, is no little.

During winter the butter is as yellow as a buttercup. The cow has nothing but grass and hay, no roots of any kind. Her time of calving was yesterday. My man has not succeeded in drying her, although kept up and nothing but hay given her. She gives

at all times a very small quantity of milk, but so rich that the third skimming is like leather. The cow I had before the present one gave pails of milk, and the most butter she produced in the week was 5½ lbs.

The cow calved 2nd March, 1861.

March 15, first day of churning, the calf with her seven days .....	18 lbs.
March 22, 14 lbs.; 29, 13½ lbs. April 5, 14 lbs.; 12, 14 lbs.;	
19, 14 lbs.; 26, 15 lbs. ....	84½
May 3, 14 lbs.; 10, 13½ lbs.; 17, 14 lbs.; 24, 13½ lbs.; 31, 13½ lbs.	
June 7, 13 lbs.; 14, 12 lbs.; 21, 11½ lbs.; 28, 10½ lbs. ....	116

Total produce in year .....

In addition to the above account there are sundry pats of butter not accounted for.—H. S. S.

### OUR LETTER BOX.

AFRICAN DUCKS (*R. C.*).—We have little doubt from your description the Ducks are Muscovics. The plumage tallies with them. If, however, they are drakes, they will easily be known by the dipping motion of the head, the swaying to and fro of the tail, and the hoarse hissing noise they make.

SPANGLED POLANDS (*C. F. S.*).—It would occupy too much space to go into detail of all the points of Spangled Poland. You will find them in the poultry books. The feathers of the top-knots should be laced, not spangled. A whole colour is 'a defect. The tail-feathers of the Silver cock should be spangled with black at the ends. The Golden should be streaked and made up of rich golden and lustrous black shades.

BRAHMA FOOTRES (*Hypnum*).—We consider Brahma Footres quite as good layers as Cochins. We cannot say whether they may average 150 eggs the second year—that is, an egg every day for five months of thirty days each. They do not eat as much as Cochins, and they have more meat on the breast The best cross (if any cross be a good one) would be between a Brahma cock and a Dorking hen. In sitting and rearing Cochins and Brahmans are pretty much alike.

GAME COCK HAVING DIARRHEA (*Fowl Faucier*).—The Game cock must be thoroughly purged, as the craving for drink is entirely caused by a disordered inside. He may be allowed to drink a little four times every day, but each time the water must be removed as soon as he has drunk. It is an excellent thing to put chamomile flowers in the water. He must have a table-spoonful of castor oil every day, and be fed on stale bread steeped in ale. This must be continued till the evacuations are firm, and brown or dull green tipped with white. The hen requires the same treatment. Discontinue the Indian corn, and feed simply, as with oats or barley ground. Something disagrees with them.

BREEDING POWTER PIGEONS.—*A. H.* inquires the probable result of mating a blue Powter cock with a red or yellow hen. The young would not come mixed in colour, but would take after the parents respectively. The arrangement, however, is not a good one, as the reds so bred would probably be somewhat slaty in colour. A preferable arrangement would be a blue cock with a mealy hen, as that colour readily yields to the blue; or a red and yellow may be mated together, or either with a mealy. Powters generally bring up their young very well for about three weeks or a month; when, if they neglect them, the young should be fed once or twice a-day with whole beans until they feed themselves freely, or the eggs or young may be shifted under other birds. But the most successful Powter-breeder in the kingdom does not keep feeders, but the young Powters are fed by hand for about a week or so after the old ones leave them.

REMOVING BEES TO GREAT DISTANCES (*Bee-keeper, Ulverston*).—Bees, when accompanied by their owners, will travel safely by rail at almost any time (very hot weather is perhaps the most dangerous) if ample ventilation be secured. When trusted to the tender mercies of railway guards and porters the risks are, of course, infinitely increased, and in this case we should think the spring the best time—say April, or even May, according to the season. The bees should be perfectly recovered from the effects of winter, and sufficiently numerous to repair an accident to their combs, if any such should happen, whilst these latter must be well secured and not very heavy. If a long voyage be contemplated, such as that to Australia or New Zealand, the latter end of October or beginning of November is, probably, the best time for commencing it.

FATTING CALVES (*A Subscriber*).—We have no particulars as to the proportions of the ingredients, but you will find a fuller statement, we believe, in "Dickson's Practical Agriculture," vol. ii. One of the most experienced men says that the best substitute for new milk is made by mixing two bushels of linseed with one bushel of wheat, grinding them, boiling them in water to a gruel of moderate thickness, and then giving the calf a mixture of half gruel and half skimmed milk.

PARROT EATING ITS FEATHERS (*Fanny Fern*).—Let the bird have a bath daily—that is, fill a soup-plate with water, and let the bird get into it and wash.

SELLING CANARIES—MORTALITY AMONG THEM (*A Subscriber*).—The price you mention is a very fair price to the trade for ordinary class of birds, but from the description which you give of your birds they should command from 4s. 6d. a-pair, or 3s. 6d. each cock bird. For fine good birds in London, the dealers ask for Jonques, 10s. to 20s. a-pair, Mealy and Pied, 6s. 6d., and upwards. Write to some respectable bird-dealer (see "Post-office Directory"). They usually contract for a quantity at a certain price, taking one with the other. If only a few are to be disposed of, would it not be more advisable to sell them in the country at a less profit than to risk sending them to town? We should fancy Newrick would be as good a place as London for the disposal of a few pairs. Your birds which died were starved, owing to the stronger birds not allowing them to feed. The cock birds should be separated, or while together there should be several feeding-boxes in the cage. The usual method of sending birds a long distance is to cover the cage with coarse canvass, taking care that they are fed just before leaving.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 58.1° and 36.2° respectively. The greatest heat, 77°, occurred on the 19th in 1851; and the lowest cold, 20°, on the 16th in 1847, and 19th, 1852. During the period 147 days were fine, and on 98 rain fell.

NOTES ON CYCLAMENS, ESPECIALLY ON C. VERNUM AND C. EUROPEUM.

SEVERAL parties having addressed inquiries to me on the subject of Cyclamens (more especially as regards *C. vernum* and *C. europæum*) since the reply in THE JOURNAL OF HORTICULTURE to "HALESLEIGH," February 4th, and later notices therein of that tribe; and presuming your object is to clear up any doubtful points relating to

this sadly-confused genus, I cannot do better, perhaps, than reply through the columns of your Journal, more especially as my experience varies in some particulars from that of Mr. Beaton.

I speak from long and close observation, Cyclamens having been pet plants of mine for a very long period, more especially during the last sixteen or eighteen years; and I have not spared time, trouble, nor a little expense in collecting all the kinds I could find likely to prove anything distinct, both in this country and on the Continent, so that a large number of so-called species have passed through my hands, and for many years past I have bloomed several hundreds of Cyclamens annually.

First, as regards *C. vernum*. I take Mr. Gordon's description of that species (*Gardeners' Chronicle*, 1843, page 660) as quoted by Mr. Beaton, to be very good, with one or two slight exceptions noticed below, mostly to be accounted for by different modes of culture. I copy his description at length, as many of your readers may not have an opportunity of referring to it. He says, "*C. vernum* (the round-leaved winter-flowering Sowbread). This species has leaves double the size of those of *coum*, and nearly four times those of *C. europæum*; they are quite round and entire, with the lobes at the base overlapping the stalk, and marked on the upper surface with an irregular band of white, which is not the case with the leaves of *C. coum*. The flowers are like those of the two preceding kinds (that is, *C. coum* and *C. europæum*) in form and colour, but a little larger, and produced from November to January. The roots are rather larger than those of the two preceding kinds, and the plant is frequently confounded with *coum* in collections. The name *hyemale* (winter) would be far more appropriate for this very distinct species, for it has done flowering before spring commences; this may account in a great measure for its always being confounded with *C. coum*, the spring-flowering kind, but it may be distinguished at first sight by its larger leaves having a very conspicuous white band on their upper surface. I have raised this species from seed, and the plants have always retained this character, and that of flowering during the winter if

protected from the wet. It has the leaves of *C. persicum*, and the flowers of *C. coum*."

The leaves of *vernum* with me are not much, if any, larger than *C. coum*, and certainly but little above the average size of *europæum*. The latter species varies so exceedingly in size and markings in its natural habitats (noticed further on), that it is by no means a safe rule to be guided by.

The flower in colour Mr. Gordon gives as being like *C. coum*, which he calls "reddish-purple"; Mr. Sweet, in "British Flower Garden," Vol. I., page 10, says "It is rosy red, darker near the mouth, where there is a white circle, inside striped with red." My experience confirms both of these, the shades varying from one to the other. Neither of them says a word about lilac; but when pressed and dried for the herbarium they do become a direct lilac, with the dark markings very much increased in intensity. This probably may have misled Mr. Beaton.

In size of flower, Mr. Gordon says "a little larger than *C. coum*." Mr. Sweet, "nearly the same size as *coum*," and his figure represents it as such. I believe them correct in this. As regards the time of blooming, Mr. Gordon says, "November to January." Sweet says, "beginning of March;" but Mr. Beaton says, "October to the beginning of November." With me it comes sparingly in November and December, but fully from the middle of January to the end of February. These variations in a great measure depend on the mode of culture there can be little doubt—a fact I think pretty well established at once by an accident which happened to one of my pans of *C. vernum* the last summer. For many years previously they had bloomed with the rest of my stock in January and February; but a pan of it was unintentionally subjected to earlier rest, and for a time greater drought than usual. These commenced blooming in October—their fellows not so treated, as usual in January and February. I am confident Mr. Beaton lays too much stress on what he terms "the family crest of *vernum*," which, in fact, by no means exclusively belongs to that species, neither is it so fully developed in some specimens of that as in others. It equally belongs to the whole of that section of the tribe, consisting of *C. coum*, *vernum*, *ibericum*, and *Atkinsii*. There can be little doubt but Mr. Beaton's conjecture that the "crest" in the one from which Sweet drew his description was the result of extreme age of the tuber.

I have very lately, in company with a friend equally interested in the culture of Cyclamens as myself, gone over a large number, including all of the above sorts, and find the "crest" present in all in some stage of growth; though, in young roots especially, it is frequently found simply in the shape of a cluster of buds or nodules, yet these are easily removed altogether with the point of a knife. From this the leaves and flowers arise, and this, as the tuber attains age or other local circumstances, elongates, and eventually becomes a very prominent stem. When from age or other circumstance the top becomes blind, or is removed, it will send out one or more new stems from the sides or base. We found one fine old *C. coum*

tuber with no less than eight of considerable length shooting from the sides of the old one, which was decayed at top. A venerable old tuber of *C. ibiricum album* (which has this year treated me with no less than 145 blooms) has a cluster of stems  $1\frac{1}{2}$  inch in diameter; and one of the original bulbs of *C. Atkinsii* has a cluster of equal dimensions, and both of good length. It evidently does not altogether depend on age for the development of the leaf and flower-stem, as we found a small tuber of *C. coum* not much larger than a horsebean, with a stem half an inch in length.

I cannot see any reason for supposing *C. vernum* to be a hybrid. Mr. Gordon speaks of it as "a very distinct species." I have cultivated it nearly, if not quite, thirty years, and have found it much more constant from seed, both in leaf and flower, than most of this genus, when grown by itself. The Hon. W. F. Strangways, when speaking of it in his paper on *Cyclamens* (see "Botanical Register," and *Gardeners' Chronicle*, 1842, page 383) says, "*C. vernum* seems intermediate between *C. coum* and neapolitanum; but I judge only from the figure, not knowing its history." But whether he means to convey

an opinion that it is a hybrid, or only that it is a connecting link between the species, does not appear clear; at any rate, not having seen the plant, his testimony is not of much weight.

With respect to *C. europæum*, not the one still too frequently sold for it, which is only neapolitanum, the autumn bloomer, but the true summer-flowering sweet-scented one, I believe all botanists are now agreed; but it varies so extensively in leaf, root, and flower in its different natural habitats, as at first to puzzle many; and it is at times difficult to be convinced until brought home and grown together, that they can be all of one species. In the more northern localities the leaves are thicker, more decidedly toothed, and with comparatively slight marbling on their upper surface; whilst in those south of the Alps and in Northern Italy, the leaves are much smaller, rounder, finer in texture, with marbling of white on their upper surface, sometimes almost equal to *C. persicum*, and in other localities they are intermediate between the two. I send you leaves to illustrate what I mean (though most of mine being grown in the open garden have now nearly died down, and leaves, therefore, very inferior) No. 1, the northern variety; No. 2, the southern and No. 3,

intermediate. These are from tubers collected myself from their natural habitats, and not changed by cultivation. The flowers also vary considerably from a short petal with a somewhat square-shaped eye, not much larger than *C. coum*, to a delicate long petal approaching *C. persicum*, and colours vary from deep red purple to a delicate rose pink; white are rarely met with, but I possess three roots collected in my rambles in their native habitats.

The roots vary exceedingly both in size, shape, and colour. On rocky stony ground they are often mis-shaped, knotty, and covered with gouty excrescences, altogether very irregular; but in other places well shaped, round, flat tubers, but always more or less inclined to throw up a stem (and that at times from different parts of the tuber), from which the leaves and flowers arise; in some cases they are of considerable length and numerous. I have occasionally dug *C. europæum* out of the mountain *détris*, consisting of shattered stones, mixed with a little vegetable soil amongst it, as clean as a washed Turnip, sometimes brown, and at others of a creamy yellow, with stems from 6 inches to 9 inches long, and swollen into gouty knots. These, broken up, will grow and produce leaves and flowers for years; but not, as far as my experience goes, proper tubers. On my showing some of these to the late Mr. Loddiges, he at once recognised them as being what in former times they had been in the habit of purchasing from the Dutch florists as *C. anemonoides*, but added that for many years they had not been able to procure them. So much for *C. anemonoides*! Is it not probable that this was the sort alluded to by your corre-

spondent "H. N. E.," page 497, as *Anemone radice*? and I have very little doubt but the "evergreen *Cyclamen*" shown by Mr. Holland at Kensington, and so well described by him in your *Journal* of March 25, page 514, is one of the North Italian varieties of *C. europæum*. I have them answering the description well. It is one of the varieties called by some "littorale," a very bad name by-the-by, as it is not a littoral species, at any rate exclusively, for it is found with other varieties in the country bordering on the Lake of Como, but is equally abundant in other parts very far removed from any shore as I have frequently found. It is not inclined to die down so completely as the more northern varieties, and I have frequently had them bloom for many months together; but I have found them bloom more abundantly and stronger by giving them a moderate rest. When strongly and well grown it is a very good variety. Those of them I have under shelter are now just throwing up their flower-buds; but the others out in the open garden only now losing their leaves partially and at rest. I potted one to-day having two stems, one erect, the other stolon under the surface, issuing from opposite sides of the tuber, measuring  $3\frac{1}{4}$  inches and  $2\frac{1}{2}$  inches in length respectively. By my notes I see I found these with others in North Italy as thick as Violets on our banks in spring, as early as July 22nd and August 10th in different years, which does not quite agree with Mr. Beaton's account.

As regards the culture of *C. europæum*, about which many inquiries are made, I may say I lost plants of it repeatedly until I studied them in their different habitats. They are found in

various situations—rough rocky ground, amongst mountain *débris*, moss-grown banks, under the shade of woods, but generally the finest in some snug nook where, by a rock or friendly bush they are protected from rough winds and mid-day sun, at the same time enjoying free air and full light, with complete drainage at all times. If these conditions be secured, with a little friable loam, decayed leaf mould, or peat and sharp sand, there need be no fear of success; but they must have none of that extreme drying process too many *Cyclamens* are subjected to.

As to double *Cyclamen persicum*, I have a note of a fine one having been shown at the Norwich and Norfolk Horticultural Show in April, 1830. Semi-double are not unfrequent with me. I have one now with thirteen petals, and had one of *C. Atkinsii* here this season also semi-double; but not considering them any improvement, have hitherto paid no attention to them.

Permit me to call the attention of the admirers of *Cyclamens* to the vast advantage of growing them in masses. Without seeing them in this way, no one can form an adequate idea of their beauty, more especially the section comprising *C. cornu-vernium*, *ibericum*, and *Atkinsii*. I have grown very few singly in pots for some years; but either in pans, or planted out in pits or frames. I have one of the latter measuring 8 feet by 5½ feet, with the above varieties mixed, this season one mass of bloom during the whole of January and February; and in order to form some estimate of the number of flowers, I measured off, in company with a friend, a fair sample of 18 inches square, and found it contained the remains of upwards of 450 flowers in that space.—J. A. P.

#### ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.—APRIL 9TH.

THIS was chiefly intended for Azaleas, and they were the chief plants there; but, in addition to them, there was an excellent spring show of greenhouse, stove, and conservatory decoration plants, some good novelties, and some very good old notions which, when put all together, made a very pleasing exhibition. The arrangements were fully up to the occasion this time.

The Azaleas had the whole side of one of the wings of the arcades next to the council-room, and they extended 36 yards in three rows on the slope against the back wall of the arcade, with the light from the front only, which is a disadvantage. The best was made of the council-room by the absence of the centre stage down the middle of it; the sides and both ends were quite full of choice things, of which the *Cinerarias* were the gayest. The Tulips, the Roses, the Hyacinths, the immense number of cut *Rhododendron* hybrids between arboreum and cinnamomum, sent up from Devonshire by J. Luscombe, Esq., of Combe Royal, Kingsbridge, together with *Auriculas*, new *Primroses*, new seedlings, both of crossed *Rhododendrons* and of Azaleas, *Begonias*, with collections of rare or new plants, collections of forced flowers, and collections of April flowers not forced—just such another assemblage of various classes as many of the great families enjoy now down in the provinces during the holidays in their own conservatories.

But how different the effect from the difference of the arrangements! Effect must, necessarily, be so far sacrificed at the very best arrangement that can be made for the best of shows. Next May we shall have effect marred from a different cause—from too much green and no flowers in the forests of fine-foliaged plants by the hundreds. Now, it is from all flower and too little space for green, or brown, or variegated-leaved plants. Thus, people, or say, in plain English, critics, who must take their ideas from assemblages of flowering plants at London shows, because they can see no others, are sure guides to direct in the way of selections—they cannot help it, and it is not their fault, but the inevitable consequence of a bad school for teaching which is, or is not, the best style of plants for this or that purpose, for the grand conservatory or the more ambitious flower garden. Your London critic can at best but put his thumb in his mouth, and if he would keep it there, instead of often making a fool of himself, he would be thought the wiser man. You cannot judge from a show how Mr. Henderson, or Mr. Spencer, or all the rest of them can give such magic effect with the very selfsame kinds of plants in their conservatories at home. I knew I never could, and I have seen as many shows as most of my own age: therefore, the wisest thing would be never to expect magic effect from a show, nor hold up your own notions of effect from all you could collect of it that way.

The greatest want we had at this April gathering was want of foliage below and behind vast masses of varied flowers. Greenhouse collections generally supply green sufficient for their effect on the eye: they did so on the present occasion in a very remarkable manner. The whole end-breadth of the wing, in which the Azaleas stood in need of back-foliaged plants, was covered with all sorts of greenhouse plants in all styles of training, from tight lacing to the natural curvature of the shoots of the *Sindryana Heath*, the best-trained plant there, though it never had any training at all. The effect along that end, as contrasted with that of the finest kinds of Azaleas that ever were staged together on one occasion, was most remarkable when the place was all but empty. When the eager crowd fill in, all ideas of effect are squeezed out of the question, if not out of the critic himself if he has to undergo the ordeal.

I said 36 yards of Azaleas in three rows—the miscellany of greenhouse kinds across that wing, 27 yards of prime stuff. Then in front, as if you said front stage of a greenhouse, 12 yards of low plants, among which were half a dozen splendid *Hippeasters*, at last, from Mr. Williams, of the Paradise Nursery. Also a fine variety of Wood *Anemone* in a collection of hardy spring flowers from Mr. Young, of Highgate; a lot of fancy *Begonias* from Mr. Cutbush, on the top of Highgate; forcing Pinks and others from Mr. Turner, of Slough; and a profusion of most beautiful and mostly hardy variegated plants from Mr. Salter, of the Versailles Nursery. Among them were *Veronica chamaedrys variegata*; *Symphytum asperimmm variegatum*, fit for an empress, a grand specimen; Lilies; *Arum italicum*; *Cheiranthus*, most unwallflower-looking in its variegation, and yet the true thing, and many things like it; and one thing like *Luzula sylvestris*, and just as like a *Cyperus vestitus* as that.

In the council-room were 12 yards of *Cinerarias*, fine specimen plants, three deep; 4 yards of one collection of rarities and fine-foliaged plants from Mr. Bull, five rows deep; 6 yards of Hyacinths, three or four deep; 10 yards of Tulips, with a dozen of Roses in pots in the centre from Mr. W. Paul; 6 yards of *Auriculas* in three rows. Then the whole end farthest from the entrance was filled with collections from the Messrs. Veitch, Fraser, Cutbush, and Williams; while the Messrs. Henderson, of Pine Apple Place Nursery, Messrs. Veitch, Williams, Parker, and Smith (of Dulwich), occupied the stands at the end next the door with quaint things, fine crosses and most extraordinary-looking somethings as nothing ever looked before.

I allude to three most-out-of-the-question plants, from the Pine Apple Nursery, and if you were in London, or within twenty miles of it, nothing would pay so well as a visit on purpose to see them. They belong to the acid order of Arads, as our Arums do. Their name is *Arisæna ringens*, and they look very much like *Arisema Pythonium*, of Dr. Martens' Brazilian "Materia Medica," and no one ever saw a plant look like them in flower, or look more like an Arum without the flowers. The curious part is the hood, which is of rhinoceros substance, and comes forward in a bend, and falls over the front of the flowers, so that you can see very little of the inside at all.

By these stood *Rhododendron Falconeri* with twenty-three blooms in one truss. This is your florists' flower, or what will some day turn the wavy and wavering of this race into Tulip-shape and form, they are so prim and so mathematical already. Then a fine, large, white Sikkim hybrid *Rhododendron*, called *Denisoni*, from Mr. Bousie, of Stoke, and another more in the way of Princess Royal, more wavy and more pink in the white, like all the hybrids from *ciliatum*. It was named *Magnalia*.

Here stood a splendid *Grevillea Hillii*, from Messrs. Veitch, which might put one in mind of the old *Agnostis sinuata*, with longer and much narrower leaves. *Alalia leptophylla* from the same firm will also make a very genteel-looking plant for a collection. Also, two plants of *Passoqueria undulata* in full bloom, and a basketful of their lovely little *Stenogaster concinna*, which seems to be never out of flower, and which all the boys and girls who were at the last July Show in the great conservatory never seemed tired of talking about.

Robert Warner, Esq., had another of those new lovely forms of *Lycaste Skinneri*, at this point; and some fine Ferns and foliage plants from Mr. Williams, of the Paradise Nursery; also, a fine plant of the Countess of Haddington *Rhododendron* from Mr. Parker, a fine white blush, as if with the blood of *ciliatum*; and Azalea *Barclayana superba* from Mr. Ivery; and a *Duc d'Artemberg*, pretty Azalea seedling, from the Messrs. Smith, of Dulwich. Some called it a sporting gentleman, as one of the flowers came plain; some *occulatum*, on account of the most beau-

tiful eye, which is different from all the eyes of all the Azaleas. It is a charming little thing—the Duc d'Areberg Azalea. Their first-class Primula with pin eye was there too, and called Delicata, and a more dwarf one called the Fairy, and some others. That was a rich corner, and one of the best in it was a new colour and style of Auricula from Mr. Jas. Holland, of Isleworth, and called Mrs. Eyles.

On the opposite side of the entrance began a collection of Cinerarias; then a collection of fine-leaved plants from the Messrs. Smith aforesaid, of which *Cyperus aternifolius variegatus* was the prettiest; then three or four collections of Cinerarias in succession; then a large collection from Mr. Bull of real good things in thorough good style; then another collection of Cinerarias; then fifty Hyacinths from Mr. Cutbush; and then at the farthest end of the room and the farthest corner, the first collection of forced flowers, from the Messrs. Fraser, in which the Snowball Gueldres Rose was even better than it was in March. Then the centre was filled up with a collection of spring forcees, from the Messrs. Veitch, good Pinks and good Lilies of the Valley, showing as good management in the forcing as the best Rhododendrons and Azaleas; then Mr. Cutbush with forced flowers, in which the old Solomon's Seal, *Polygonatum vulgare*, was as good-looking as you ever saw it out in the borders, and no bother to have it so. The same as for *Dielytra* will do it. Then a large collection of mixed stove plants from Mr. Williams.

There were two forcing Geraniums at this end which some of my friends down the country will be glad to hear of. The Reine Hortense, from Messrs. Fraser, is of the French streaked, very showy, and capital to force: the other is called Albion, and a great improvement on *Alba Multiflora*, from Mr. Cutbush. I am asked more about forcing Geraniums than any other of the race, and by people whom you would be astonished to hear if I were to tell they have better gardeners of their own, only they have too much to attend to for seeing what is done about London.

There was a fine specimen of *Hymenocallis fulva* in two collections—that of Mr. Sulter, and in one of Messrs. Smith's groups; and in the latter was a plant, a climber of the *Desmodium* looks and habit, called *Rhynchosia albobitens*, with spikes of botanical flowers, of no other merit. Three plants of the best telling Heaths there were of *Sindryana*, from Mr. Tegg. A collection of tall *Cacti*, including two plants of *crenatus*, were very early and well done. One of the best specimen Rhododendrons was a plant of *Gibsonii* from the Messrs. Veitch. *Acacia Drummondii*, *grandis*, and *longifolia*, in three different collections from Messrs. Veitch, Lee, and Fraser, and a *Hedera tulpifera* from the former, were particularly fine. *Erica elegans*, *Beronia*, *Eriostemons*, *Epacris*, *Leschenaultia*, *Polygala*, *Pultenaea bicolor*, *Chorozema Lavraenciana*, *Rhododendrons*, *Azaleas*, and *Camellias* were the chief plants in exhibition.

The new Azaleas were exquisitely grown. Mr. Turner was particularly fortunate, in kinds, in setting and in style of growth. His Duc and Duchesse de Nassau were grand; Brilliant and Gem ditto; Bride and Gledstanesii, Variegata and Eulalie, with Grand Monarch were amongst the best kinds there.

But selecting sorts and colours out of all the mass I put them thus: Brilliant the richest there, deep orange scarlet; then Gem in the same tint; then Roi Leopold ditto; Grand Monarch ditto, and Rubens. The best and the only purplish there was *Constantia Rosea*, a fine showy kind; the hose-in-hose *Arcana* is the next tint to *Constantia Rosea*. The best light Rose is Duc de Nassau, a noble flower; *Coronata*, the old *Coronata*, was yet the highest coloured, and Mr. Dodman's new seedling self is in that tint. Of the variegated kinds the best were *Criterion*, *Baron Vriere*, *Eulalie*, *Vittata Rosea*; and of pure Whites the Bride was the best there; then *Leana*, *Magnifica*, *Virgin Queen*, and *Iveryana* all but white. There are too many whites with flakes and spots not very constant. Of peculiar tints, *Rosy Circle* is a good example; and of this unique breed there was a fine one from Mr. Todman after *Petunioflora*. And, in a collection of small plants of very varied aspect from the Messrs. Veitch, there were several kinds of peculiar tints, such as *Etoile du Gand*; *Hortense Verraene*, light straw cast; *Ramentacea*, a white botanical plant; *Prince of Wales* and *Princess Alice*; and *Rubens*, aforesaid, a very good kind.

The prize list will show the winners; and if I were to repeat all the names it would only be like counting the fingers over again. Besides, we all expect next May will eclipse everything that ever was seen or heard of in Azaleas, in size and numbers, and in the perfection of growth. Tickets will be sold without end.

Fellows' privileges will be put to a severe test. Music will be ten times more noisy than ever, and no one yet knows the exact size for crinolines, only that there does not appear the smallest chance of any of them being an inch smaller at all events, and some of the gardeners talk of having Merinaes and Monitors to save themselves, if not their plants, from a general sweep when the crowd rush after the bands. The French have not only invaded this country, but they have actually taken possession of ours at South Kensington, and were then throwing up immense earthworks and putting in foundations thick enough to stand anything, and the Emperor is coming to see it is all right.

D. BEATON.

THERE can be no question of the success of the Azalea Show, or of the wonderful skill by which in such a sunless, cheerless spring as this has hitherto been, a mass of bloom of such surpassing beauty was brought together. All honour be to those florists by whom it was achieved, conspicuous amongst whom we must mention Mr. Turner, of Slough. The size of his blooms of Azaleas was really something wonderful. How gloriously the exquisite shape of Gem, and the glowing orange scarlet of Brilliant were brought out! This latter flower being without question the best, largest, brightest, and most perfect in shape of that class. I must, however, pass these lightly by, though legitimately coming under the designation of florists' flowers.

Roses were exhibited in considerable quantities by Messrs. Paul & Son, of Cheshunt, and Mr. Wm. Paul, of Waltham; but I hold it to be utterly impossible to decide anything as to the merits of Roses from blooms taken at this early period. There is this to be said, that if a Rose comes out well now, it is likely to prove a "stunner" by-and-by; and we may, I think, confidently pronounce Beauty of Waltham to be one of the best English Roses ever raised, and, indeed, a first-rate one, worthy of being placed alongside of the hitherto only Rose of decided English origin, "*Devoniensis*." It seemed to be a cross between Jules Margottin and Général Jacqueminot, partaking of the excellent qualities of both parents. In the same box exhibited by Mr. Wm. Paul, the fortunate raiser of the above, were some of the new French Roses, but of these it is impossible to say much, as plants are so thoroughly worked and cut about that the blooms must be inferior. Amongst them were Adolphe Noblet, Paul Leval, Charles Lelebre, Eugenie Bouciere, Vulcan, Madam Charles Wood, Souvenir de Mons. Rousseau, and Monte Christo. Of these, the only one I heard anything good of in France was Madam Charles Wood. It promised here to be a large flower, but inclined to be loose; but as I have said, it is unfair to judge of them now. Amongst the older sorts in Messrs. Paul and Son's boxes, were fine blooms of Gloire de Dijon, Madlle. Bonnaire, Louis Guillion, Celine Forestier, *Devoniensis*, President, Narcisse, and Baron Gonella.

Of Auriculas one must speak with becoming modesty. The season is backward, and even growers had but little to choose from. Mr. Turner contributed good plants of Taylor's Glory, Fletcher's Mary Anne, Ensign, Netherwood's Othello, Spadry's Mary Grey, Dickson's Duke of Wellington, Page's Champion, Smith's Mrs. Smith, and Ann Smith; while I never expect to show finer plants of Maclean's Unique, Hudson's Apollo, or Page's Champion, which were in my own six. Unique had eleven fine pips, and Champion, nine.

A novel-coloured seedling was exhibited by Mr. Holland, called Mrs. Eyles, which promises to be an acquisition for a stage, it was of that delicate lavender colour one sees in alpinas; but instead of having a yellow paste it had a fairly white one, and the flower was well-shaped and large; while not meeting the requirements of a florist it was still worthy of what it received—a Label of Commendation.

In new Cinerarias there were some promising flowers. Lord Elgin, from Mr. James, gardener to Mr. Watson, of Isleworth, was a dark rich coloured self of fine form and substance; while Mr. Turner had "James Andrews," a dark-coloured purple self, and "The Artist," a rich-looking rosy carmine, with very little white, and novel; this received an extra prize.

Messrs. F. & A. Smith, of Dulwich, had a handsome new Azalea, Duc d'Areberg, in the way of that exquisite flower, *Etoile du Gand*; but besides the regular rose-coloured star, it had dark shading in the centre of the petal, which increased its beauty. I have already mentioned Mr. Turner's flower, Brilliant. It seems to be a continental variety, unknown to growers here; and as I saw some very fastidious acquaintances of mine putting it down in their note-books, it may be relied upon as worth some-

thing; it is a grand-looking orange scarlet flower, deeper and better than Perryannum.

Mr. Bragg, of Slough, had two boxes of Pansies, but, although good, it was too early to say aught about them. They were very meritorious, considering it was the 9th of April.—D., Deal.

The following are the awards of the Judges:—

- Twelve GREENHOUSE AZALEAS, distinct kinds (Nurserymen).  
 First, C. Turner, Royal Nurseries, Slough. Second, J. Ivory & Son, Dorking and Reigate Nurseries. Third, J. & J. Fraser, the Nurseries, Lea Bridge Road.
- Nine GREENHOUSE AZALEAS, distinct kinds (Amateurs).  
 First, T. Todman, gardener to R. Hudson, Esq., Clapham Common. Second, J. Blog, gardener to S. Gassiot, Esq., Clapham Common. Third, M. Higgs, gardener to Mrs. Barchard, Putney Heath. Fourth, J. Tegg, gardener to Baron Hambro, Roehampton.
- Six GREENHOUSE AZALEAS, distinct kinds (Amateurs).  
 First, T. Todman. Second, J. Tegg.
- Six GREENHOUSE AZALEAS, new distinct kinds (Open).  
 First, C. Turner, Royal Nurseries, Slough. Second, J. Ivory & Son, Dorking and Reigate Nurseries, Surrey.
- Three GREENHOUSE AZALEAS, new distinct kinds (Amateurs).  
 First, T. Todman.
- Single specimen of GREENHOUSE AZALEA (Open).  
 First, C. Turner, Nurseries, Slough. Second, J. Ivory & Son, Dorking and Reigate Nurseries, Surrey. Third, T. Todman.
- Six RHODODENDRONS in bloom, distinct kinds (Open).  
 First, J. Veitch & Son, Royal Exotic Nursery, Chelsea and Exeter.
- Three RHODODENDRONS in bloom, distinct kinds (Open).  
 First, W. Young, gardener to R. Barclay, Esq., West Hill, Highgate.
- Single Specimen of RHODODENDRON (Open).  
 First, J. Veitch & Son. Second, W. Young.
- Nine CINERARIAS, distinct kinds (Nurserymen).  
 First, J. Dobson & Sons, Woodlands Nursery, Isleworth. Second, C. Turner, Royal Nurseries, Slough.
- Six CINERARIAS, distinct kinds (Amateurs).  
 First, P. Lamb, gardener to Miss Thaehtwaite, Norwood Green, Southall. Second, J. Wiggins, gardener to Walter Beek, Esq., Worton Cottage, Isleworth. Third, J. Gray, gardener to W. F. Watson, Esq., Isleworth.
- Twelve SPRING FLOWERS, forced, distinct kinds (Open).  
 First, J. & J. Fraser, The Nurseries, Lea Bridge Road. Second, Veitch and Son, Royal Exotic Nursery. Third, W. Cutbush & Son, Highgate Nurseries.
- Twelve GREENHOUSE PLANTS in Flower, not forced, distinct (Open).  
 First, J. Veitch & Son. Second, J. & J. Fraser. Third, J. & C. Lee, Vineyard Nursery, Hammersmith.
- Twelve HARDY HERBACEOUS PLANTS in Flower (Open).  
 First, B. S. Williams, Paradise Nursery, Holloway. Second, W. Young, gardener to R. Barclay, Esq.
- Nine AURICULAS, distinct kinds (Nurserymen).  
 First, C. Turner, Royal Nurseries, Slough. Second, J. Dobson & Son, Woodlands Nursery, Isleworth.
- Six AURICULAS, distinct kinds (Amateurs).  
 First, Rev. H. Dombain, Deal. Second, J. James, gardener to W. F. Watson, Esq., Isleworth. Third, J. Holland, gardener to R. W. Peak, Esq., Spring Grove, Isleworth.
- MISCELLANEOUS PLANTS AND FLOWERS.  
 First, W. Bull, King's Road, Chelsea (Group of New and Rare and other Plants).  
 Equal Second, W. W. Cutbush & Son, Highgate Nurseries (Collection of 50 Hyacinths). W. Paul, Cheshunt Nurseries, Waltham Cross (Cut Roses). Paul & Son, the Old Nurseries, Cheshunt, Herts (Cut Roses and Roses in Pots). W. Young, gardener to R. Barclay, Highgate (Tall Cacti). J. Luscombe, Combe Royal, Kingsbridge, South Devon (Cut blooms of Rhododendrons, hybrids from arboreum and cinnamonum, grown in the open air). J. Veitch & Son (Collection of Azaleas). B. S. Williams, Paradise Nursery, Holloway (Collection of Amaryllis).  
 Third, J. Salter, Versailles Nursery, Hammersmith (Collection of hardy variegated plants).  
 Fourth, W. Paul, Cheshunt Nurseries, Waltham Cross (Cut Rose Beauty of Waltham).  
 Equal Fourth, J. Tegg, gardener to Baron Hambro, Roehampton (Erica Sundryana). W. Bragg, Star Nursery, Slough (Pansies). B. S. Williams (Collection of plants and Alsophila species).  
 Extra, C. Turner, Slough (Seedling Cineraria Artiste).

## NEW VERBENAS.

I WAS very much pleased with Mr. Robson's very able remarks on the Verbena in THE JOURNAL OF HORTICULTURE of March 11th, where he has so ably reviewed the Verbena from its commencement nearly down to the present time. I have for many years grown them extensively for flower-garden decoration and pot culture, and have had all the new kinds of any promise each year as they have been sent out, and have spared no pains in crossing them. I think I have at last succeeded in raising some that I think will nearly come up to Mr. Robson's idea of what a good Verbena should be. They are at present in the hands of Messrs. E. G. Henderson & Son, who will, I believe, send

them out at a cheap rate so as to enable purchasers to have them in quantity the first year. The following is a faithful description of them:—

SIR PHILIP will be found one of the best Verbenas ever raised. It is an exceedingly brilliant carmine scarlet, with free, compact style of growth and profuse blooming habit; will prove to be one of the most telling objects in the flower garden, and for a row in a ribbon-border it stands pre-eminent. This is without doubt one of the finest Verbenas in cultivation.

LITTLE HARRY.—This is one of the most distinct varieties I have ever seen—a dwarf, compact, free-flowering habit, not growing more than 6 inches to 9 inches high. In colour a rich velvety crimson, with a brilliant white eye. Of free, erect growth. This will make a charming bed.

CICELY.—A clear, rich peach or almond-coloured pink, with a beautiful erise or rose eye. Neat and compact style of growth. Flower-trusses large and well formed. Is of a free-blooming habit. A very great improvement on all the known varieties of that colour. It is a seedling from Bonnie Dundee crossed with Souvenir de l'Exposition. It is also a charming variety for pot culture. I have had some plants of it beautifully in bloom for the last three months. It is not quite so compact in habit as the two first-named varieties.

LADY GREY EGERTON.—Beautiful magenta crimson, displaying a large, well-expanded truss; the most beautiful coloured Verbena I have ever seen with Purple-King style of growth and habit. Stands the weather well. A very profuse bloomer. I am sure when this has passed through Mr. Robson's hands he will give a very favourable account of it to the readers of THE JOURNAL OF HORTICULTURE, and put it down in his book as A1 with the varieties above named.

JENNY LIND.—A beautiful mauve with lilac tint, very large truss. A splendid variety, great improvement on Azucena.

CORONET.—Rich dark mulberry with extra large truss and pip, dwarf compact habit. A great improvement on Ocean Pearl. Well adapted for pot culture. The finest Verbena of its colour.

QUEEN.—Beautiful, rich, indigo purple, with large white eye; fine truss and pip. An improved Annie Gray, from which it is a seedling. A very fine variety, well adapted for bedding purposes.

GEM.—Rich violet-tinted crimson, medium-sized truss, dwarf compact habit, a very profuse bloomer, and excellent bedder.

ISOLINE.—Rich puce colour; fine, dwarf, neat growth, with profuse bloom, and good flower-truss. This variety will also make a very beautiful bed.

KEEPSAKE.—Magenta-shaded mauve, with a well-formed truss.

EYEBRIGHT.—An exceedingly rich violet-tinted mulberry, medium-sized truss, an improvement on Lord Elgin. It is the darkest Verbena out, rather a strong grower, fine for large masses, extra.

MASTER CORBET.—A great improvement on Lord Clyde and Miss Trotter.

MODEL.—Bright carmine tinted lake, with canary-coloured eye, and large flower-truss. A decided improvement on Morning Star.

CADUCEUS.—Rich violet tinted purple, with fine white eye, large truss, and close compact flower-lobes. An improvement on Standard Bearer and Leviathan.

Tropæolum Oulton Park Beauty is also a very great advance on Elegans or any other variety at present in cultivation.—T. WILLS, *The Gardens, Oulton Park, Cheshire.*

## VINE INJURED BY FIRE.

I HAVE a small vinery heated with a fire and filled with a fine strong healthy Vine. A few days ago when the buds were just bursting they were dried up and killed by the heat from some woodwork, which unfortunately took fire and smouldered all night. The stems were not scorched, but they seemed dry, and where I cut them no sap came; in forty-eight hours the sap returned with such force that having no buds to expend itself on, it is bleeding, not only where I cut the stems but even through the uninjured bark.

The Vine being so full of sap—1st, How long will it take to form new buds and to come into leaf? 2nd, Is there any chance of fruit from spring-formed buds formed in the place of those destroyed autumn-formed buds? 3rd, What would be the best treatment for the poor Vine—moist heat or cool dry air? The stems are not injured.—VIRGO.

[We are sorry that you have had the accident, and think you

must have had a strong fire in such weather to set the wood a smouldering. We are sorry in the second place that you cut or did anything to the Vines. As the buds were just breaking, and if you kept only a gentle heat most likely fresh buds would have started from the base of the injured buds; and if the Vine was well stored with fruitful sap, these second starts would most likely have shown fruit. In support of this opinion we once cut off every bit of young wood from a Vine, and yet had plenty of fruit. We can give no direct answer on this subject, as we do not know the exact state of the Vine; and, besides, the cutting and wounding you have subjected it to is depriving the Vine of the flows of sap, which would have helped to throw out fresh, or rather the latent buds. We think the sap must be trickling down the bark instead of bursting through it. It is late to try to stop it. However, you might let the vinery get as cool as possible, and then in the evening dry the cuts; place a red hot iron over them for a few seconds, and then daub-up with thick red lead. You will be sure to have good wood for next year, and though you may now have some fruit, we should have been more sanguine if you had done nothing in the way of cutting or wounding the Vine.]

### COMBINING GLASS WITH TIFFANY IN CONSTRUCTING AN ORCHARD-HOUSE.

I HAVE a lean-to tiffany-house, 18 feet long by  $7\frac{1}{2}$  feet broad, placed against a wall facing the west. Supposing I remove the tiffany and cover the top with large glass—say 20 inches by 15 inches, and the side beads to the depth of 2 feet, and the remaining 3 feet with wood in the shape of an eighteen-inch drop ventilator, and the other 18 inches, with fixed planking, should I have a chance of ripening Peaches and Nectarines in pots in it? To enable you to assist me with your counsel I must mention that the sun never reaches the foot of the wall until half-past one; but then on a fine day the heat is very great, and I keep it until it sets. Our climate is mild, but damp; yet from my situation, half-way up a steep hill, and the lightness of the soil, I have no reason to complain of the moisture save that in very wet seasons the atmosphere becomes charged with an excess of it, owing to the circumstance of the surrounding moors for miles being inundated. In days of old by some I'm told (pardon the rhyme) the good monks of Muchelney Abbey had a vineyard within a stone's throw of my abode, although the sea in its desire to minister to another of their wants, during Lent especially, swept over these moors. Surely, then, I may hope to have some success with my western aspect, although it is adulterated with a slight dash of north. The tiffany-house was originally placed against a north wall as a protection to various plants, Ferns, &c, during the summer months. Finding, however, that the shade was too great, I had it removed to its present site. There unfortunately it will be exposed to the Atlantic gales which blow over my garden at a rate sufficient to carry away everything but a man's creditors. However, I mean to let it stand one to see how tiffany will resist a strong wind. It has already withstood several slashing ones from the north-west without showing a single rip. Should I find it equal to the demand made upon it I feel inclined to leave the sides as they are of tiffany, and content myself with covering the top with glass to secure more light and dryness. I may add that the tiffany is nailed on wooden frames made of inch laths, and slide into their places like shop shutters. A quarter of an hour is sufficient to strip the house of every morsel of tiffany, and I therefore find these side frames very convenient in summer time, as I am thus enabled to let the balmy air ramble as it lists. Supposing the tiffany to give way, what would become of the glass roof? I do not ask whether it would go, because I am more likely to know than yourself; out would it resist the gust? I fear not.—A READER, *Somerset*.

[If you had the angular piece above each doorway made to open and a couple of squares in the centre of the roof close to the ridge, a foot ventilator might do in front. We think the tiffany might stand a long time for sides if properly supported; but enough of air would not go through it on a sunny day, and, therefore, you would need more top air. In lean-to houses the want of air at top is ruinous with a ventilator at front. We think two in the centre at the ridge would do if the angular piece at each end can be opened. But for having the tiffany we should prefer the ends to be of glass and wood, as you propose. The plants will succeed well enough.]

### THE WALTONIAN FIXER FOR WALL SHELTERS.

TALK about fixing, here is a fix and a finish at one stroke which will fix anything against a wall that is good and useful for screening the blossoms of fruit trees from frost, and the fruit itself from birds and insects. This fix is made to "clip" a nine-inch wall without a coping; but it may be made so as to clip any coping, and a wall of any thickness. Let the width, between the two claws of the fixer, be exactly the same as the wall or other substance is in thickness, and it will clip anything, from the ridge of a hothouse to the thickest wall in the country, and the moment you fix it you may hang a ton weight to the eye of it by means of a hook, and it will bear it on the perpendicular as long as the strength of the wall, or wall-plate will bear so much perpendicular pressure.

These fixers are put on the wall or taken off as easily as one's slippers. Mr. Walton had them in use for the last four years, and I had been watching them the whole time. He has them and glass lights, the same as for Cucumbers, on the hook-and-eye system of fastening.

There are two hooks to each light, one on either side, screwed to each stile or corner, and each light has two fixers clipping the wall so as to receive the hooks. The length of the eye at the end of the fixer is about 3 inches, and the bend of the hooks makes about another inch, which allows each light to hang down perpendicularly against the wall, and 4 inches from it or from the trees; but it may be suited to a less or a greater distance. Then, on the two lower corners of the light he has a bolt-plate, 3 inches long, screwed on; but two small staples, 3 inches apart, will explain the bolt-plate easier. Through these two staples he runs down an iron bolt into the border, about a foot or so. This iron bolt is not more than half an inch in diameter, and has a turned end like the end of a walking-stick, and that turn rests on the upper staple when the bolt is fixed down.

The night that hurricane blew down the north wing of the Crystal Palace Mr. Walton's hanging light, in another part of his garden, did not budge the eighth of an inch. He has a whole run of these lights, close together as the roof of a Peach-house, over his Peach and Apricot trees, Cherries and Plums at times, without the slightest accident from wind or weather.

The bottom of the lights stands 2 feet above the border, and yet they save the blossoms as effectually as if they were down to the ground, and in frosty weather and cold nights he has a coping of wood; a board 6 inches or 7 inches wide to cover the four-inch space at the top, or all along the top, the board is fastened to the fixer by a bit of leather after the manner of a hinge, so that the coping in fine days may be turned up and back to rest on the top of the wall all day, then the trees are as free as if in the open air, and by pulling a string at night they are as close along the top as if they were on the back wall of a Peach-house.

This contrivance answers perfectly, and there is no end to its application. Get a quantity of these fixers made at the blacksmith's, and a boy could fix them all round the walls of the largest garden in the kingdom, at 4 feet or 5 feet apart, in a few hours. If it were merely for holding a temporary coping while the blossom lasted they would be worth the expense, for they

will last a whole lifetime if they are painted with iron paint. But nets, or canvass, or frigi, or tiffany, might be applied that way as easily as glass lights. The shelter might even be done like window blinds or bad-curtains—a small iron rod with a hook at each end to fall into the eyes of the fixers, and rings and curtains of any material to draw sideways in the morning and pull tight at night. But the housemaid would put you up to that way of it better than a gardener, and you can see yourself how easy it would be to arrange the glass, the canvass, or the what-would-be-necessary to keep out the wasps and tomtits when the fruit is becoming ripe.—D. BEATON.

### CERASTIUM BIEBERSTEINII FOR FLOWER GARDENS.

Who does not remember with what surprise the news was received a short time, comparatively, since that the hardy perennial *Cerastium tomentosum* was a suitable plant for our highly decorative and still improving flower gardens? And what should we do without it now? Where shall we find a substitute for it? And where shall we find another plant to surpass it for the same purpose? Is it possible?—That is a question time will answer better than I can do now; but this I know, that there is one of the species in this same genus which should be somewhere in England, that would totally eclipse *tomentosum*, valuable as it is at present.

There is in some botanical works a species described or noticed, said to have been introduced into English gardens about forty-two years since, called *C. Biebersteinii*. Now, where is this lovely, white, woolly, perfectly hardy perennial to be found? It is larger in the foliage, more woolly, whiter, more dense in habit, and in every way superior to the before-mentioned *C. tomentosum* for an edging, or for groundwork in panelling; and see it at what season of the year you will, compared one with the other, *Biebersteinii* is the superior kind. In fact, if the two were growing side by side, I venture to say, as a practical man, that there would not be one in a thousand but would say, "Give me the latter. *Tomentosum* must go back to the herbaceous borders, rockeries, &c., for us."

If this species is so valuable as I assert, the question next forces itself upon us, Where is it to be found? Who is there acquainted with it? Has it been lost? Can it be reintroduced? Will it pay the nurserymen to seek it out as a commercial speculation? I answer each of the questions in the affirmative. Then which of our firms, famous for their energetic movements in the case of anything new in the bedding-out class of plants, will be the first to obtain and exhibit at the meetings of the Floral Committee of the Royal Horticultural Society plants of this particular species? Let them exhibit if they will a plant of each, or plants of each, side by side, and if they do not receive a good recommendatory note of introduction to the gardening public I shall be deceived in my judgment. But, I feel persuaded that it will be ordered by thousands if it is offered at a reasonable price; and let it, if possible, be introduced into our elaborate flower gardens during the present season, that our visitors may look with increasing delight at the persevering energy of the English gardener who will, can, and does, turn every useful plant to advantage. In conclusion, let us hope that among the wonderful improvements of new plants that are to be produced this year, *Cerastium Biebersteinii* may be one.—NICKERBOOR.

### PACKING CUT FLOWERS FOR TRAVELLING.

HAVING seen in your periodical of April 1st a suggestion made by you for the purpose of elucidating a system of packing cut flowers for safe transmission to a distance, I beg to send you a description of the system employed here (Combe Abbey) by the intelligent gardener, Mr. Miller.

First, a box is made of half-inch deal, the length, breadth, and depth of which may be according to the size of the bunches of flowers. Then take two cords along the box longitudinally, 1 inch apart and 2 inches from the bottom. After which take other two lines of cord transversely, and at right angles to the first two lines put in, 1 inch apart and 6 inches above the other two lines, just according to the length of stalk of the bunch. Nothing more is done but tying two ligatures round each of the rows of cording. This done, prepare your bunch by tying some damp moss round the footstalks of your bouquet, insert it

down through the cross lines of cord, and run the small ties previously made close to the bunch, which makes it quite secure from moving in any direction.

By this means you have a simple, economical, and effective mode of transmitting flowers to any distance, and preserving them as fresh as when cut.—P.

### A CAUTION.

"To whom?" ejaculates the reader, and I reply, To all who have vinerics; more especially to you (and there are very many such), who have a little pet viney of your own, not enclosed, within a garden, in entirety by walls—one of the many advantages of which being to protect the contents more or less from the many enemies to successful cultivation. Did I not write this, "A Caution," but head it more properly, "Vines Eaten by Mice," the chances are, you whom it most concerns would pass it over in anticipation of the usually more pleasing matter contained in the pages of the Journal you are at present perusing, with a censure upon any who could negligently permit such a thing.

Having decoyed you to perusal of this, I will proceed at once to explain how those pilfering little michers, the smallest of all beasts, mice, have twice within my experience destroyed the whole growth, once of Vines some six years old, by eating, or, perhaps to speak more within the meaning of my deductions, gnawing it in two at the base. Last January the second unfortunate occurrence of this sort was shown to me, when Vines with fine wood of two summers' growth were served in precisely the same way as the former ones. This was entirely unknown to the sufferers, until the Vines, being forced, drooped all at once, which necessarily led to inspection. The moss placed in the vacancies in the wall to admit the Vines from the exterior border to the interior of the house being removed, it was seen, by the Vines falling in at the base, what was the mortifying cause. The mice had cut them clean in two. This is the place they select upon which to satiate their nibbling propensity.

Ere I conclude I will recommend as a possible preventive, that traps be kept regularly supplied with baits in gardens, whether the accustomed depredations of those little pests are visible or not, as they will accept of anything in the form of what they have an habitual liking to, and that the more readily above than below ground.

Why they eat a Vine in the way mentioned above cannot be satisfactorily affirmed. I am led to infer that the mischief only occurs in dry weather when no heavy dews fall, and that it is done for the attainment of the moisture in the sap when no water is near and the accustomed rain or dew-drops upon blades of grass or points of straw in the thatch are not attainable. As a prevention it would be advisable to place some small garden-pans or saucers containing water within or around.—W. EARLEY, *Digswell*.

### REMEDY FOR MILDEW ON FERNS.

To recommend an article which answers its purpose better than others of its class, however much it may serve the interests of the producer, is to confer a very far greater benefit on the consumer. Under these circumstances I shall be glad to recommend to other Fern-growers, "Bell's Preparation for Killing the Mildew." This being one of the most unmanageable pests of our ferneries, and the remedy being, hitherto, so bad as the disease; for as all the beauty of Ferns depends upon the foliage, to have this looking as if the leaves had been sprinkled over with a whitening-brush, at once renders them objects of disgust, instead of being attractive; and it is something to be able to subdue the enemy and at the same time to give the plants the benefit of a thorough detergent, which leaves them freshened-up and as clean as if newly unfolded.

I have found it thoroughly successful, and if used with soft or rain-water all that can be desired.—W. K. BRIDGMAN.

[We never before heard of this remedy. Why does not the proprietor advertise it?—EDS. J. OF H.]

MR. JOHN SPENCER.—It will be gratifying to many of our readers to hear that Mr. Spencer, who has for twenty-five years acted in the capacity of gardener to the Marquis of Lansdowne, at Bowood, with so much credit to himself and benefit to the

profession, has so secured the respect and confidence of his employer, that he has been appointed steward over the whole of the Wiltshire estates. This is a noble testimony to the integrity and ability of one who has for so many years occupied a place in the first ranks of horticulture, and who has, by an honourable and consistent career, enjoyed the esteem of all who have had the advantage of his acquaintance. In addition to this appointment, Mr. Spencer will still retain the superintendence of the garden.

#### MILLER'S HORSESHOE-LEAF PINK GERANIUM—RETAINING VARIEGATION.

I do not think this plant is so near extinction as Mr. Beaton assumes it to be; at any rate twenty years ago there existed large bushes of it in my father's garden, which looked shabby enough when put away for the winter under the greenhouse stage, but in summer were a perfect sheet of bloom.

I perceive that some of your correspondents claim credit for an ability to produce variegation at will. Perhaps they can assist me to maintain it. All my stock of Brewer's Variegated Geranium has returned to the original colour, and my *Farfugium grande* is fast accomplishing the same process. I have several very fine four-year-old plants of the latter that are fast losing all their spots, and I am quite at a loss to account for the circumstance. They have been kept and grown in a cool greenhouse, and occasionally watered with weak guano water. Could this have had anything to do with it?—ALFRED COPLAND.

[Our plants of *Farfugium grande* and all others that are kept so cool as yours are just in the same condition. Stove heat will do all you require. Mr. Beaton assures us he never said anything about a scarcity of Miller's Pink Horseshoe Geranium.]

#### ORCHIDS PRODUCING SEED-PODS.

A CORRESPONDENT in a contemporary asks for information bearing upon this question which, so far as we are aware, up to this time has received no reply. His case is represented thus:—

"CATTLEYAS.—R. C. K. says that last August he impregnated a flower of *Cattleya crispa* with pollen from *C. amethystina*, and has now on the plant a fine fruit the size of a bantam's egg, not yet ripe. He asks 1, whether this is unusual; 2, if any of our readers have succeeded in obtaining seedlings; and 3, for any practical advice as to germinating the seed and treating the seedlings."

So far as my experience goes, there is nothing unusual in obtaining seed-pods and seed in abundance from more than one species; but I have never yet been fortunate enough to get the seed to germinate. However, I never had so successful a hit as during last season, and that, too, was obtained without the slightest manipulation. We have no less than five seed-pods of *Cattleya Mossia*, one of *Lelia cinnabarina*, one of *Odontoglossum grande*, two of *Epidendrum aurantiacum*, one of *Chysis aurea*, and one of *Dendrobium heterocarpum*, all full of seed in the very best order, and the majority of them just now undergoing a series of trials with the view of testing the best materials and the proper temperature to induce and promote vegetation. It will be at once apparent to those who are familiar with their geographical distribution, that we have examples from Brazil, Rio de Janeiro, Guatemala, Peru, Chili, and the East Indies in the way of reproduction.

All these seed-pods are from last season's flowers; nearly all of them required from eight to nine months to remain on the plant, and should never be taken therefrom until beginning to burst their three-lobed seed-vessel. If placed in common garden saucers in the hottest part of the East India house, where no water can get access, the seed will rapidly disunite, and each seed-pod, by a shake of the hand, will disperse its contents like very fine sawdust, and might easily sow moderately thick a square yard of ground. On the other hand, if the manipulator attempts to sow before adopting some such treatment, he will find the attraction or cohesion of the seeds so great that they will not disunite individually, and are therefore not in a condition to warrant sanguine expectations.

We never had more than three seed-pods *in toto* until last season. These were sown in pots, prepared after the manner of established plants, but no symptoms of their race ever appeared.

I had not a clear conscience upon this experiment, as although there was an apparent similitude to their indigenous habits, by the seed being scattered, as one would naturally expect, by the breeze upon mother earth; yet such precious matter, not to speak of the peculiarity of the habits of the whole genus, merited a wider range of practical tests. This season we have filled shallow pans with potsherds within an inch of the brim, some of the edges protruding upwards to the surface; then mixed simple and charred wood, and sphagnum in greater and lesser proportions—sowing the seed now thickly, again thinly, covering with a slight sprinkling of sand, and not covering at all; placing bell-glasses in some cases over them, and in others leaving them to their fate. Some are plunged in strong close heat, others placed in a medium temperature, and under many other circumstances too tedious to mention until we know of successful results.

I have attempted cross-breeding between some of the *Cattleyas* and *Lælias*, but with no fortunate results. I have also, like the correspondent mentioned above, tried the pollen of one variety upon another variety of the same species; but, unlike him, have hitherto been unsuccessful. I am aware that *Calanthe* has produced seedlings, one of them named *Domini*, I believe, in honour of the raiser. Do any of your readers know if any other species has produced like results?—JAMES ANDERSON, *Meadow Bank, Uddingstone.*

#### A FEW DAYS IN IRELAND.—No. 20.

TEMPLE HILL.

(Continued from page 31.)

The greenhouse is connected with a lean-to vinery 70 feet long, 16 feet wide, 16 feet high at back, and 3 feet high in front. This is divided into two houses. The front sashes all open out with a lever, and every alternate top sash slides for air. The houses were filled with young Vines. The first division consisted chiefly of Muscats and Frontignans, with one Lady Downe's Black; the second with Black Hamburgs, Black Prince, West's St. Peter's, and Prolific Sweetwater, of which Mr. Tobin spoke highly. The wood formed was strong, short-jointed, and getting as firm as a piece of oak. We found there was a little difference of opinion about cutting back, and taking only a few bunches in 1862, and taking a more general crop. The Vines were strong enough to yield a good crop, but we hope that Mr. Tobin will be able either to cut back freely, or take only a few bunches, as otherwise if a good crop is taken it will likely be the first and the last good crop the Vines will yield. We have proved it over and over, that a crop from young Vines is just like taking a heavy crop from young Vines in pots. It is rare that such plants ever do any good afterwards.

Besides some nice crops of Melons, we were shown two specimens in a fruit-room. The one was a sort of Canteloup, a fine well-swelled specimen, with an aroma to tickle an epicure, and 20 lbs. in weight! The plant had no particular attention except severe thinning, and a pretty good supply of manure water. The other was a beautiful, smooth, green-rinded, and green-fleshed Melon, about 1½ lb. or a little more, called the Patteridge Melon, a fine variety of the Egyptian, which we grew true for many years and never found one better for the table; but we lost its purity because in a small space this friend and the other friend would send seeds with flaming recommendations as to their respective merits.

Keeping to these forcing departments. There is a nice Pine-stove, though in a rather shady place, but the plants looked remarkably healthy and strong. This house is span-roofed, 50 feet long, 13 feet wide, a bed on each side 5 feet wide, and a passage down the middle 3 feet wide. The house is divided into two equal compartments, and the heating-boiler at one end, at which end are the fruiting plants, the other being devoted to successions. The house is so shaded by a Peach-wall to the south of it, that it scarcely gets an hour of sunshine from November to February, and yet the plants were strong and short, without the least sign of being drawn-up or spindled. This we believe to be entirely owing to the mode of giving air. In each division there are three ventilators on each side wall, 18 inches long by 8 inches wide, hung on pivots in such a way that the fresh air admitted is thrown in over the heads of the plants, and is warmed before reaching them. We hope to tell how Mr. Roynance, at Killakee, by a very simple arrangement effects this

with front air. Much the same principle is carried out here though by a plan a little different. Besides the above, there are three drains, or ventilators, on each side of each division that come from the outside, through the beds on which the Pines are grown—that is, twelve altogether, and the open internal end of these comes against or near to the hot pipes which run on each side of the passage. These drains, or ventilators, are left open night and day, unless in the very worst weather, and to such practice Mr. Tobin ascribes the compact bushy character of the plants. There can be no question that but for the expense of fuel, most forcing-houses would be better of more fresh air than they obtain, especially if heated before coming in contact with the plants. Our friend, Mr. Thomson, of Dalkeith, by similar modes can colour Grapes splendidly in winter, though scarcely ever seeing sunshine.

We must now content ourselves with noticing what may be termed two orchard-houses. The first is a wood and glass span-roofed house, 84 feet long, 24 feet wide, 13½ feet from level of floor to ridge, height at sides from 8 feet to 9 feet, 7 feet of that being glass and moveable. The interior is divided into three beds, those on each side being 5 feet wide, and 2½ feet above the pathway. The centre bed is 8 feet wide, 1½ foot above the pathway, and a walk 3 feet wide goes all round it. A row of nice stubby Peach trees with the wood looking beautiful was planted along the centre, and a row is placed in pots on each side to fill the openings. The side borders are supplied with two rows of trees in pots. A good proportion of these were out of doors to get all the sun and air possible before being housed for the winter. We noticed, however, some fine specimens of Duchesse d'Angoulême Pear in a small pot in the house, fully 1 lb. weight and nearly ripe, and some pretty specimens of Eugenia Ugni, covered with its small aromatic fruit.

There are main-bearers for the roof 8 feet apart, and supported by iron pillars. These bearers were tied by iron rods crossing from side to side of the house. Vines were planted in the side-borders to go up the roof, and also against the pillars, so as to form transversely and longitudinally something like a series of arches, which will have a fine effect in summer when the Vines are established. About forty Vines are thus used, and will yet permit a great amount of light to the plants in the beds. Pipes for heating go round the pathways, but are never used except in frosty weather. Under such circumstances the Prolific Sweet-water ripens three weeks before the Royal Muscadine. There were fine bunches of Raisin de Calabre, which were getting ripe, and which will hang a long time without shrivelling.

The other orchard-house is an out-door Pear-house, with which we were so much gratified that to its dimensions and details we would direct the attention of general readers, and especially amateurs who wish to make the most of their little gardens. This simple structure is also 84 feet long, 18 feet wide, 10 feet high at ridge, being span-roofed, and 7 feet high at the sides. The roof is formed of stout spars for rafters fastened to the ridge-board at top, and at a neat wall-plate at the sides. The sides, and therefore the roof, are supported by inch-and-a-half iron bars beaded at bottom into large stones, and fastened to the wall-plate at the top. The house is so light-like, and seems to stand without support; as the rods are concealed by a Privet-hedge at each side, which is kept closely clipped in summer, and allowed to grow a little in winter and spring. The roof is furnished with canvass in spring, pulled up and down as desirable by means of rod and pulley. This simple structure has three rows of Pear trees standing 6 feet apart each way. The centre row under the ridge had trees from 8 feet to 9 feet in height. In the two side rows the trees ranged about 5 feet in height. There was not much fruit—not owing to frost, but to the season of 1860 being so dull and wet as to prevent the ripening of the buds. Notwithstanding the wet of 1861, there had been more sun, and almost every tree was a picture, bristling with fine rounded bloom-buds from the top to the ground. The centre row needs root-pruning in three years, as they are planted on what was a hard walk with about 18 inches of soil to grow in. The two side rows growing in the free soil with no hard substance beneath them are generally root-pruned every other year. What with devastation by birds and ruin by frost in our getting-more-uncertain climate, need any comparison be instituted between such a system, and growing fruit on tall standards, or in a dwarf state in lines or borders, as respects ease of protecting, certainty of a crop, economy of space, pleasure of attending to the trees, and examining the fruit? We do not know what many amateurs may now be inclined to do—we

know what we should like to do. We rather think we felt a spice of envy about Mr. Tobin possessing such a nice Pear-orchard so completely under control, and perhaps all the more, as it had to be kept bottled-up; for Mr. Tobin is not more distinguished for kind courtesies than for retiring modesty. R. FISK.

## FLORISTS' FLOWERS, THEIR DISTINGUISHING CHARACTERISTICS, CULTIVATION, AND VARIETIES.—NO. 4.

### THE CARNATION AND THE PICOTEE.

We have grouped these two flowers together, as they are generally grown so in collections, and because there are some dear good people who frequently want to know "which is which." We can, therefore, say to all such, "Look on this picture and on that," and there will be but little difficulty in your minds afterwards. You will, observe, my good old friend, if you put on your best specs, that the markings in the Carnation are in bars from the base to the edge of the petal, while in the Picotee they are confined to a lacing on the edge." "Oh! but," some florist will exclaim, "surely no person is so idiotic as not to know the difference!" Ah, we little know each other's ignorances; only let us be tender when we know we ourselves are so very far out in a great many things. A worthy gentleman, who, I doubt not from his bearing and peculiar method of dealing with the unfortunate letter H, was a worthy citizen of London town, accosted me the other day at the Flower Show at Kensington, as we were standing together opposite a number of Cinerarias, "Pray, sir, are those a kind of Polyanthus?" Now, would it have done to have laughed in that good man's face and told him "No?" I could only say, "Not exactly, they are called Cinerarias;" for I feel that while I could stand a pretty good competitive examination on the subject of florists' flowers, I had rather not take up the subjects of banking, the stocks, or the funds, about which my friend, whoever he was, I have no doubt was quite *au fait*. There is one thing about which a florist cannot be so charitable—when those who have no taste for his special hobby affect a sort of contempt for his puerility, or pronounce his fine house full of Pelargoniums or stage of Auriculas as like as two peas, and ask, "What difference now is there between them?" So have I seen a country boor lounging through a room full of Etruscan vases of the most exquisite models, "Lawks! them pitchers be all the zame, beant they?"

Well, I am getting far away from my subject, although I dare say a good many folks would make the same observation about a first-rate collection of these fragrant and attractive flowers; but let any one grow them, and they will then discover those delicate differences of markings and colours which a florist's eye so immediately detects. Is it not the same in other matters to the eye of an educated person even? If you open one of Mr. Lovell Reeve's magnificent monographs of shells there is an immense similarity in the species that form the genus; but become a conchologist, and then all these delicate markings, those little tubercles, those varieties in shape, all become invested with peculiar interest, and you wonder you could have been so daft.

The CHARACTERISTICS of a Carnation are best seen by the figure, which is, however, not more than half the size to which modern floricultural skill has brought this flower. The pod (as the calyx is technically called), should be long, as then the flower is not liable to burst it, as is the case when it is short. The flower should be quite circular, and rising up gradually towards the centre so as to form half a ball. The outer or guard petals should be large and few in number; and the other petals should be regularly disposed on them, and diminish in size towards the centre. In saying this, we beg it be borne distinctly in mind that such a flower as is represented in the drawing is what is called a dressed flower (of this more anon). The texture of the petals should be thick and waxlike, and the markings distinct and clear; the ground a pure white, any flushing or running of the colour being a decided disqualification.

In the case of the Picotee the same rules hold good in reference to shape and substance; while the colour should be confined to the edge, and not run down the petals in bars.

The grass, as the foliage of the plant is called, should be a fine bluish-green: and now-a-days I think that no new flowers of

delicate habit ought to be tolerated at all. There are some we cannot yet throw away which unfortunately are delicate, Brooks' Flora's Garland and Easom's Admiral Curzon for example; but if a new flower in either of these classes be admitted it ought to be superior to them in point of habit, for in other respects I question if they can be beaten.

The CULTIVATION of these classes can only be properly managed by growing them in pots. The old-fashioned plan of beds has been deservedly going out of vogue for some years past. I say deservedly, for one is so much more free from the depredations of insects, and the work of layering is not of that terrible break-back character. The pots should be about 10 inches

across, and a pair may be placed in each, one stake answering for the two flower-stems. The compost (but I am going over ground I have trodden before), should be one-third loam, one-third leaf mould, and one-third rotted frame-manure, well mixed together and carefully looked over, as one wireworm—a nasty, yellow-looking monster—will completely destroy the best pair you have. When they are potted it is a good plan to place a piece of potato or carrot in each pot, and examine it every three or four days. This acts as a trap to the vermin, the only way to get rid of them being that of the finger and thumb. I have tried all kinds of mixtures, and they rather seem to thrive in them than otherwise. The pots should be placed on a walk or other

CARNATION.

PICOTEE.

convenient position, and kept clean. When the plants begin to spindle, as it is technically called—that is, the flower-stems begin to increase in length, they should be loosely tied to the stake, which we suppose to have been already placed between the plants; and if any green fly appear on the shoots they should be brushed off, or the shoots washed with diluted tobacco-water. Keep the surface soil, too, well stirred; and as the blooming time approaches it will not be a bad plan to top-dress with some well-rotted manure—remembering, however, that the higher-coloured varieties are somewhat impatient of too much manure, and are apt to run when they are overdone with it. When the flower-buds appear they should be pinched off, leaving only three on each stem, and these tolerably wide apart. As the bud swells a piece of bast mat should be tied round it, and the segments of the pod split down on each side, so as to prevent bursting. It will now be time to place them on a blooming-stage, with an awning over them to protect them from the rain and sun. I have bloomed mine very well in a tiffany-house open at the sides, so as to admit a free current of air and prevent the plants from being drawn. If you desire a really good bloom eards must be placed under each pod; and as the petals open they should be gently assisted so as to lie flat on the card. But many varieties will open without this trouble. When blooming is over, unless you wish to save seed, cut down the flower-stems, take out the stakes, and have all ready for layering. I have already given in Vol. I. of THE JOURNAL OF HORTICULTURE, pages 6 and 456, 457, lists of what seem to me the most approved varieties; but to make this short paper complete I add a list, which comprises some good and sterling sorts.

THE MANAGEMENT AND TRAINING OF PYRAMIDAL PELARGONIUMS.

BY THE LATE MR. GEORGE M'EWEN, OF THE HORTICULTURAL SOCIETY'S GARDEN AT CHISWICK. WITH SOME INTRODUCTORY REMARKS AND ILLUSTRATIONS BY MR. H. N. HUMPHREYS.

IN those parts of the Continent, where the nature of the climate admits of the cultivation of the Orange tree with much more facility than in England, those noble plants, in their massive square tubs, form the grandest and most appropriate decoration to terraco walks that can be conceived. The effect thus produced can only be witnessed in this country for a short month or two in our royal gardens at Hampton Court, and in a few celebrated private gardens where expense or inconvenience is no object. The immense accommodation required in the form of orangeries, necessary to furnish terraces with Orange trees in this country, renders their general culture for such a purpose impossible; but other plants, if cultivated expressly for

the purposes of terraco decoration, might advantageously supply their place. At more than one establishment with which I am acquainted, I have seen Fuchsias trained to a height of 6 feet and 8 feet in height, especially for placing out on a terrace during the summer, and if they were trained to the same form as the Pelargoniums, and made to alternate with them, the effect would be very good. I succeeded myself in training some of these plants to a height of about 5 feet, and then suffered them to form a bushy head, similar to standard Roses or Pomegranates. This forms a pleasing variety, and would contrast well with pyramidal Pelargoniums, for artists find that effects produced by striking contrasts are sometimes more valuable than those obtained by uniformity.

Garden Terrace, showing the arrangement of Pyramidal Pelargoniums.

The above sketch exhibits a terrace on which pyramidal Pelargoniums are placed in a manner to produce a very agreeable effect, the acuminating lines of the Pelargoniums contrasting well with the predominant horizontal lines of the terrace, but the full advantage of the arrangement can only be shown by the aid of colour. Sufficient indication is given, however, to enable any person to judge of the general effect which might be produced by Pelargoniums trained in this manner and in a similar position. The species that has been tried for this purpose is not one of the most robust; and I imagine that for out-door purposes the common horseshoe Pelargonium would form a larger, and perhaps more effective object, particularly if it were to alternate with the new pink variety, or that with variegated foliage. [With these remarks of Mr. Humphreys on the artistic effects of pyramidal Pelargoniums, we proceed to Mr. M'Ewen's practical instructions on the subject.]

The end of January, or beginning of February, is a good time to begin to form pyramidal Pelargoniums. Both old and young plants are available; but, as an expeditions mode has many advantages, we recommend to select from the old plants the most healthy and high-coloured, and, as the unhandsome can be best spared, choose from those with whose symmetry you are not pleased. Preserve the best centre shoot as the leader; and from it cut away all its rivals, or side shoots; this act will increase lateral shoots, which it must be an object to encourage. Tie-up the main shoot to a good strong stake, which may be left longer than is requisite at the time, as a vigorous growth may be anticipated.

The chief attention must now be directed to divert the growth

from the top to the under lateral shoots. Stopping the main shoot would tend to it, but this would, for a time, thwart a not less important point—the getting up of the plant. However, by a constant pinching of the upper shoots or rival leaders, by taking off occasionally there a large leaf, and by preserving every leaf, and bending downward, and regulating the shoots at the base and body of the plant, and also by turning and exposing fully to the light the vacant parts, an approach to the form you aim at will be daily augmenting. You must lay aside, for the present, the standing rule, “that when you stop one shoot, you must stop all.” Stop and bend to the place wanting, wherever the strong shoots appear, always excepting the centre.

But it will be found that the leader will be occasionally running to flower; in this case stop it, and draw in the next wood shoot. We may here mention that, previous to bending the side shoots much, it is indispensable to have, near the heel of each lateral, what we shall call a guard-tie, that when the shoot is bent—and it can be done by degrees to a great distance—the stress of the bend may come upon the tie, and thus prevent the laterals breaking off. We may assume that, about the middle of March, there is a great growth upon the plant, and that the pot is full of roots; and as the making of wood is of primary importance (for it will take another season to make this a show plant), it must have a large shift, the drainage perfect, and the soil rich. The size of the pot must be regulated by the vigour and size of the plant; but a shift from an 11-inch, or rather an 8-inch pot, to a No. 6 or 13-inch pot, is quite compatible with success; this size, too, will support well, and give good proportion to a plant from 5 feet to 6 feet in height. The soil compose

nearly thus:—Turfy loam drawn asunder by the hand, and well decomposed dung, equal parts; one-fourth peat; and silver sand sufficient to colour the whole. Little water will be required until the plant takes with the new soil, and of course this is hastened by giving it a shady, close, and moist atmosphere for a day or two. We said that one stake is sufficient, and we say so still; but, in a little while, a few temporary stakes for the tender shoots may be of service, before provision is made for their permanent support. By the middle of May, the plants should have made an apparent fulness of shoots, and will present an outline of the pyramid. But this fulness is only apparent, for when each of these shoots is extended 9 inches or more, large vacant spaces will present themselves; therefore, a general stopping of the whole plant must shortly take place. If other things are equal, the best time to do this is when the shoots at the base extend nearly to the rim of the pot after being thus finally stopped. The reason for this will appear, when the final tying-in of the plant in June takes place, of which we now speak. Surround the under side of the rim of the pot with a strong wire, with or without eyes. To this fasten, at intervals of 6 inches or 7 inches, smaller wires to run vertically, and fastened near the top of the stake. To these upright wires may be fastened, if necessary, a few pieces of wire or twine running horizontally; upon this the flowering shoots are tied, and the work is done. We close by submitting a few general directions, which will, no doubt, be useful to a large class of those amateur readers who may be beginning to "grow Geraniums." We will suppose the growing season to begin in February.

*February and March.*—Temperature at night from 40° to 45°; by day, 10° more. In dull, cold weather, light a little fire; increase the moisture as the season advances, and keep the atmosphere of the house pure by airing daily. Guard against cutting winds. Fumigate, for two or three nights successively, at the first appearance of green fly. In the evenings, towards April, a little guano or liquid manure may be cast about the house. Water the plants only with soft water. Avoid steaming at all periods.

*April and May.*—Night temperature, from 45° to 50°. By day, 10° to 20° more. Saturate the atmosphere with moisture. Shut up with sun heat, but give air daily, and at night also when the air is calm and warm. This will prevent the plants drawing. And this also do: keep the plants standing free of each other, and turn them often; see that the sun does not strike on the pot.

*June and July.*—Night temperature, from 50° to 55°. By day, 60° to 80°. We have entered the maturing and flowering period. Give increased air and less moisture. When the trusses of flowers appear, then apply weak, clear liquid manure at every alternate watering. The display of flowers will be only moderate compared with what should be next year. To prolong the blooming season, shading and coolness are indispensable; and not less so is gauze or lace over the openings of the house, to prevent insects, as bees, touching a flower. Pick off the bloom so soon as it fades. Seed-bearing exhausts plants, and so does prolonged flowering; avoid both, for the first year particularly.

*August and September.*—Night temperature, from 55° to 60°. By day, 20° more. Remove the plants to pits or a sheltered situation. Withhold water, and give the plants the full glare of day. If they are out of doors, lay the pots on their sides. When the wood is brown and firm, and growth stopped, cut the plant well in, giving due attention to keeping the pyramidal shape; and if the shoots at the base are cut to about 7 inches, or flush with the pot, it will be right. This is the resting period. But we would greatly recommend to steal a march at this period, and try to have the plants fully matured, and cut back in August. By the end of September the young shoots will be appearing. Lift the pot, syringe, and give them the benefit of night dews, without watering the ball. Shift the plants, and induce them to grow freely.

*October and November.*—Temperature decrease with the season—from 55° to 40° at night. If the plants are not shifted, do it early, by shaking away the old soil, slightly pruning the roots, and using say an 11-inch pot. The soil must be lighter than before, less rich, perfect drainage, also some bits of charcoal mixed with the soil. A caterpillar infests the plants at this period—keep watching and hand-picking it. Take every advantage of sunny days and dewy nights; but frost must be vigilantly guarded against from the middle of October. A luxuriant growth is not, at this period, desirable, but a healthy, short-jointed, and vigorous break or push, which must be kept in check until the end of January. Do not excite the plants now in any way.

*December and January.*—Night temperature from about 35° to 40°. Day from 5° to 10° more. Avoid using much water. In severe weather the house or pits should be covered at night by mats or shutters. This will economise the fuel, and save the energies of the plants. About the beginning of the year the plants may be finally shifted, the house whitewashed, and the temperature slightly increased, advancing afterwards with the season. By fair management you may expect a fine display in time for the June shows.—(*Gardener's Magazine of Botany.*)

## MR. J. STANDISH'S, BAGSHOT AND ASCOT NURSERIES.

(Continued from page 4.)

IN resuming our account of the new Japanese plants sent home by Mr. Fortune, it is but justice to give the place of honour to the noble *Sciadopitys verticillata*, the Umbrella Pine, or Parasol Fir as it is variously called, the latter being the more correct rendering of the scientific name. It has been erroneously described by Eiebold as forming a tree of from 12 feet to 15 feet high, with yellowish-green leaves; but in reality it grows to the height of from 100 feet to 140 feet, and has deep green leaves. These are linear, about 4 inches in length, blunt-pointed, and rather broad. They are arranged in whorls or clusters of thirty or forty at the ends of the branches, and radiate regularly like the ribs of a parasol; from each of these parasols others spring, so that the tree is covered with thousands of these peculiar parasol-like clusters of leaves.

In its growth the tree assumes a pyramidal form with wide-spreading branches at the base and tapering regularly upwards; even in the young specimen which we saw this characteristic was well marked. Altogether the *Sciadopitys* is described by those who have seen it in its native country as a tree of a peculiarly striking and ornamental character; and should it, as it is expected, prove hardy, it must be regarded as an acquisition, second only to the giant *Wellingtonia* itself.

It is now pretty generally known that the *Thuja dolabrata* is perfectly hardy in this country, it having stood uninjured the severe winter of 1860, when even in some places the common Holly was killed to the ground—a property which, coupled with its handsome appearance, must render it a favourite for ornamental planting; but here we have a variety called *Thuja dolabrata variegata*, in which the blackish-green *Arbor-Vitæ*-like foliage is much variegated with white, the variegation like that of most of the Japanese Conifers, coming in large patches. Like the species, it will withstand any amount of cold that it may be subjected to in this climate; and from the height which it is expected to attain here, it will in all probability form an object of great beauty and effect for landscape scenery, as well as for single specimens on lawns.

Another *Thujaopsis* with charming yellow variegation was also pointed out to us, as well as a fine kind called *Thujaopsis Standishi*, with beautifully plaited dark green leaves.

*Retinospora obtusa* is another grand Conifer, which is described by Japanese writers as the glory of the forests. In its native country it grows with a straight stem 70 feet or 80 feet high, and 5 feet or more in diameter, and the wood being white, very close-grained, and susceptible to a high polish, always commands a high price as well for timber as for ornamental purposes in the arts. In habit the plant combines the sturdiness of the Cedar of Lebanon, with a foliage smaller in size than that of any Cypress, in colour of a sad green, the young leaves, however, being of the brightest green. Being found very far north, there can be no doubt of its hardiness; and should the wood acquire the same degree of solidity here that it does in Japan, the tree will be valuable to us not for its ornamental character alone, but also for planting for timber. *Retinospora obtusa variegata*, is a variegated variety of the above with the foliage much blotched with white.

*Retinospora pisifera*, a species with glaucous finely divided leaves, forms a slender ornamental tree of lower growth. Of this there is a variety with white variegations; and another, *aurea*, in which the whole of the young shoots are of a golden hue, like those of *Thuja aurea*. This had a very elegant moss-like appearance. *Retinospora selaginoides* is another species, somewhat like a *Selaginella*, with small branches covered with dark green leafy scales.

*Nageia ovata*, from Yeddo, where it forms a fine evergreen bush, with broad, thick, ovate leaves, without any apparent midrib, of a glossy dark green; and its variety, *Nageia ovata varic-*

gata, which is beautifully striped or blotched with white, are also great acquisitions.

We also noticed a variegated Juniper somewhat resembling *chinensis* in its general character, with glaucous green leaves and white variegations; the true *Juniperus japonica* with glaucous foliage closely imbricated and extremely minute; and two variegated species of *Podocarpus*—one of which, called *corrugatus*, had ovate shining leaves, finely variegated with white, the other having yellow variegations.

A fine variety of *Cephalotaxus Fortunei*, distinguished as *robusta*, is worthy of particular mention on account of its handsome dark green leaves, which differ from those of the species in being broader, thicker, more flat, and much more regularly placed in two rows along the branches. It may also be remarked that it stands the smoke of London very well, and being of free growth it would form a very desirable evergreen tree for suburban gardens.

In cold frames was a large collection of plants, many of which had only come home a few days ago. Among them were fourteen or fifteen sorts of Maple, with curiously cut or variegated leaves—those of one calling to mind the fronds of *Pteris tricolor* both in colour and shape; several double-flowering Cherries, reported to have flowers as large as a Noisette Rose; a new *Deutzia* with red flowers, said to be splendid; a variegated Jasmine; a *Forsythia*, stated to be climbing; a *Lonicera* with green leaves dotted all over with yellow; three or four Clematises; a variegated Cinnamon; and a silver variegated variety of the well-known *Kerria*, or *Coreborus japonicus*; a variegated Bamboo, a pretty dwarf grass-like tuft; a variegated Ivy; and several varieties of *Chrysanthemums*, said to be of altogether an extraordinary character, and likely to give rise to quite a new race from those at present in cultivation; several Oaks with curiously cut leaves; and lastly, *Quercus chinensis*, an evergreen Oak found near Peking and in Chinese Tartary, and, therefore, perfectly hardy. The leaves are long, like those of the Sweet Chestnut, only smaller, and the acorns are large, with handsome cups. The tree, we were informed, attains the height of 30 feet or 40 feet, and is of a very ornamental character.

Passing into a propagating-house we found a beautifully variegated Lily of the Valley, *Convallaria majalis variegata*, its ovate dark green leaves having broad distinct stripes of the purest white running from base to apex. Of course, the specimen shown to us was very young; but should the same purity of colour and distinctness of marking be retained in the more advanced stages of its growth the plant will be invaluable for flower-garden decoration. There was also a variety in which the leaves were merely tipped with green; and another had the leaves striped with yellow. Among a host of other things in this house Mr. Standish pointed out a Saxifrage much esteemed by the Japanese for baskets, the leaves green and rose-coloured on the young shoots, shading down to white on the older ones—quite as free as *sarmentosa*, and, like it, admirable for baskets and covering rockwork; a new *Vitex* just coming up; several sorts of Lilies, one of which of the lanceolatum breed is reported to have finely-spotted flowers 8 inches across; *Lychuis Senno*, described as having beautiful crimson flowers, and its white variety, both of which have only just arrived; the pretty variegated *Gardenia*, the leaves edged with white; a herbaceous *Spiraea*, said to have magnificent red flowers; an Egg Plant from Peking, producing, it is said, fruit as much as 16 inches round; and a fine and very distinct hardy Fern with fronds 2 feet long, and which, when full grown, will probably reach at least twice that length. The fronds being of the brightest green, when young, and much cut, the plant is peculiarly ornamental.

The fernery contained a large collection of new Ferns, to notice more than the names of which would take up more space than we can afford. Among the most remarkable were *Cyathea Cunninghamii* and *Todea pellucida*, and the following new kinds, which are so hardy as to resist five or six degrees of frost and are perhaps capable of bearing even a greater degree of cold:—*Lomaria Fraeeri fluvialis*, and *elongata*, from New Zealand; *Lastræa atrata*, *Cyrtomium caryotioides*, *Cyathea Smithii*, *Polystichum vestitum venustum*, *Woodwardia japonica* and *orientalis* and *Linsæa trichomanoides*. These might be cultivated in rustic boxes or small stone caves with glass fronts, and placed under trees or at the north part of a house, so that the sun could not shine upon them; they will grow with very little light, and merely require to be kept cool and moist, and to have the glass covered with mats or canvass in severe frosty weather. That this mode of culture is eminently successful was proved

by a large glazed case standing beneath a tree and having a fine plant of *Todea pellucida* in the centre, surrounded with *Hymenophyllums*, *Davallias*, *Lomarias*, &c., all in beautiful condition, the only drawback in its appearance being two or three of the more tender Ferns, which Mr. Standish had put there by way of experiment, and which had been unable to withstand the winter. All the protection the case received was that afforded by the tree and slight coverings in frosty weather.

There are many persons who are ardent admirers of Ferns, but who cannot afford to erect a house for the growth of these interesting plants, or who, owing to the small size of their gardens, cannot spare the room which would be taken up by such a structure. To these, then, the knowledge that they may yet grow some of their favourites in the way we have indicated may not be without its advantages. Once a demand existed for glass cases for this purpose manufacturers would soon produce them of all sizes and shapes so as to suit different tastes, and the greater or less means for the gratification of these. It may be well to add that *Hymenophyllum demissum*, *erispatum*, *seruginosum*, *flexuosum*, *polyanthos*, *dilatatum*, *pulcherrimum*, and *scabrum*, with *Trichomanes reniforme*, *T. elongatum*, and *Todea hymenophylloides* will flourish with the same mode of treatment.

Before quitting Bagshot we had just time to glance through some span-roofed pits used as vineries, in which a brisk heat was kept up by linings of dung and leaves. The paths running up the centre of each pit are sunk 3 feet below the surface of the borders and filled up with dung and leaves, and the heat thus generated passes directly beneath the borders in consequence of a space of 9 inches being left between the bottom of these and the floor of the house. Of the excellent result of this ample supply of bottom heat, the enormous size of the bunches was the best evidence. The Vine, it must be remembered, is a native of Asia, where its favourite climate lies between the 36th and 48th parallel of north latitude. Here, though the atmospheric temperature may at times be low in winter, the soil is never so cold as in Britain, and as the season of growth approaches there is a powerful sun which quickly warms the soil and starts the roots into action. And in the culture of the Vine, if this root action is not properly secured in the first instance by a proper degree of heat in the soil, the foliage will derive its supply of nourishment not through the roots but at the expense of the stored-up organisable matter of the stem.

English horticulturists have paid more attention to the subject of bottom heat than those of, perhaps, any other nation; but when even our farmers carrying on their cultural operations on a ruder and more extensive scale are keenly alive to the advantages of draining, not merely in carrying off the surplus waters, but also in raising the temperature, and consequently the productiveness of the soil, it is not too much to predict that the subject of bottom heat will acquire a yet higher degree of importance in the more limited area of the garden.

To resume, however, after this digression. We here saw the Yeddo Vine, which is stated by Mr. Fortune to be a medium-sized red Grape of great excellence, and quite equal to a Grizzly Frontignan in flavour. Possibly it may prove hardy enough for out-door culture against walls. In other houses were Ingram's Hardy Prolific Muscat and Muscat Troveren in pots, furnished with numerous large bunches, and, it may be added, a large batch of seedling varieties, Mr. Standish being assiduous in crossing.

In the Rhododendron grounds, containing about 15,000 American plants, it was, of course, too early in the season to see anything but the foliage; but in this Mr. Standish has effected by skilful hybridising very considerable improvement. One variety, which he has named Mrs. Gair, was beautiful even when in leaf, its foliage being like that of a Magnolia. All the stock on this ground is ultimately to be removed to the nurseries which are in course of formation at Ascot, to which we next proceeded. Here, Mr. Standish has secured upwards of eighty acres of ground opposite the Grand Stand, and surrounding the Royal Kennels. About a fourth of this extent is a nice loam suitable for fruit trees, the remainder being a deep fat peat admirably adapted for growing large specimens of American plants. Digging, trenching, draining, and roadmaking were being actively carried on; in the latter department alone one long avenue, which is intended to sweep round the grounds, will require about two miles of road to be made. On each side of this arc to be ranged all the different hardy Conifers. Already in places the ground was being stocked, and the centre house of a range of glass had been erected and the heating apparatus

completed. One boiler with a heating surface of about 25,000 square inches is to warm the whole of the houses; it is constructed of two-inch pipes connected with syphon bends forming a box surrounding the fire on all sides, and the whole is arched over like an oven. The fuel it is to consume is peat.

It would be premature now to enter into details of the plans which Mr. Standish is working out, but on a future occasion we shall take an opportunity to "report progress."

### PORTRAITS OF NEW AND RARE PLANTS, FLOWERS, AND FRUITS.

**DENDROBIUM LOWII** (Mr. Low's Dendrobium).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Borneo, at an elevation of 3000 feet. Flowers bright yellow, with red lines on the lip and crimson fringes. Blooms in November.—(*Botanical Magazine*, t. 5303.)

**ANGURIA WARCEWICZII** (Warczewicz's Anguria).—*Nat. ord.*, Cucurbitaceæ. *Linn.*, Dicaia Diandria.—Native of Panama. Stove climber. Flowers brilliant scarlet, blooming in December.—(*Ibid.*, t. 5304.)

**PHYSURUS MACULATUS** (Spotted Physurus).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Ecuador, South America. It bloomed in November, at Mr. Osborne's, Fulham Nursery. Sir W. Hooker thinks the white spots on the leaves "may not be constant."—(*Ibid.*, t. 5305.)

**CEROPEGIA GARDNERI** (Mr. Gardner's Ceropegia).—*Nat. ord.*, Asclepiadaceæ. *Linn.*, Pentandria Digynia.—Found by Mr. Gardner, at Rambaddo, Ceylon, at an elevation of from 4000 feet to 5000 feet. Flowers white, thickly spotted with dull purple.—(*Ibid.*, t. 5306.)

**BEGONIA PRISMATOCARPA** (*Prism-fruited Begonia*).—*Nat. ord.*, Begoniaceæ. *Linn.*, Monœcia Polyandria.—Native of Fernando Po, at 3000 feet elevation. Flowered at Kew in December. Flowers yellow, but insignificant.—(*Ibid.*, t. 5307.)

**SCILLA BERTHELOTII** (Berthelot's Squill).—*Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—Native of Cameroon River, tropical Africa, and Canary Islands. Flowers pinkish-white, inconspicuous.—(*Ibid.*, t. 5308.)

**BOLBOPHYLLUM RHIZOPHORE** (Mangrove Bolbophyllum).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—"A very lovely little plant." Found growing on Mangrove trees by the Nun River, tropical Africa. Flowered at Kew both in April and November. Flowers reddish-purple, yellow, and brown.—(*Ibid.*, t. 5309.)

**CLOMENOCOMA MONTANA** (Mountain Clomenocoma).—*Nat. ord.*, Compositæ. *Linn.*, Syngenesia superflua.—It has also been called *Dysodia grandiflora*. Native of Guatemala. Crimson orange, "colour of the flower very rich, and it may prove to be a valuable summer bedding plant."—(*Ibid.*, t. 5310.)

**PETUNIA ELIZA MATHIEU** (*P. inimitabilis flore pleno*).—Very double; petals purple and white. "Unquestionably the sensation flower of the season, 1861." Flowers very large, some 4 inches in diameter.—(*Florist and Pomologist*, i., 49.)

**TRANSPARENT GAGE PLUM** (*Syn.*, *Reine Claude Diaphane*).—Yellowish-green, dotted and speckled with bright dark crimson. "A dessert Plum, larger than the old Green Gage, and of the greatest beauty, and most exquisite flavour. Ripe in the beginning and middle of September."—(*Ibid.*, p. 56.)

### THE WEATHER.

WITH the difference of being farther to the south, the weather in Gloucestershire has been nearly similar to that reported by Mr. Ashby, from Lancashire. We have had almost the whole of March and part of April (up to the 10th) very wet; but March and April are rarely both all wet. I have not noticed these two months wet for at least 55 years. The verdure on the grass fields is most superb at present, and the grass on the meadows and pastures, where they are drained and well manured, is very forward. Yesterday the "Black-thorn winter" commenced, with the full blossom of the Sloe or Black Thorn, and who ever saw this take place without frost and cold winds?"

"Emblem of Life, see changeful April sail  
In varying vest along the shadowy skies;  
Now bidding summer's softest zephyrs rise,  
Anon recalling winter's stormy gale,  
And pouring from the clouds her snow and hail."  
—(H. K. White.)

In answer, the last ten days, to those who have been predicting

so early a spring, I have always said "our Black Thorn is only getting into blossom. Wait until this blossom is entirely gone."

The sudden check to vegetation this week will, probably, save the great promise of bud and blossom ready to burst on the fruit trees of all descriptions.

I will read a short paper to some of the young people who fancy when there are a few warm days in March or April, that real spring or summer is approaching.

In the year 1802 we had snow on the 16th of May, and severe frost that day.

In 1805 we had snow about the 10th of May.

In 1809 we had snow in Gloucestershire 6 inches deep on the 21st of April.

In 1816 we had hail and snow in May.

In 1830, after a very warm week, we had snow on the 1st of April, and the thermometer fell in fourteen hours 40°, from 65° Fahr. to 25° in the morning (recorded in *THE COTTAGE GARDENER*.)

In 1837 we had twenty-six days of frost in April, and twenty frosty days in May, real spring only commenced about the 21st of May.

In 1838 another late spring with a fortnight's frost in May. In 1845 we had nineteen severe frosts in March, and ten days skating at the middle of the month.

In 1853 and 1854, about the 7th and 8th of May, snow fell each day in heavy storms.

In 1855 we had a very late spring. The Black Thorn was in blossom until the 10th of May. Frost more or less severe during the first ten days. The White Thorn was not in blossom in the earliest districts before the 28th of May.

On the whole I agree with Mr. Abbey, that we shall have a cold and wet spring, a prevalence of easterly winds, and but little range of temperature.

No one who has studied and noticed the climate of England expects a continuance of genial weather before the middle of May.

In giving a prognostic of the summer, my opinion is that it will be what they term a medium one, that we are likely to have a preponderance of dry weather in May and June, and that July is likely to be a drier month than it was in 1861; but August is likely to have a greater quantity of showery and unsettled weather than in 1861.

The twenty-five fine harvest days in last August saved the Wheat crop throughout England.

Notwithstanding the rich appearance of the early grass above alluded to up to this day (the 10th of April), we are very likely to have a light crop, as I never yet saw premature grass in April turn out well in June and July, the land being chilled by wet previously.—H. W. NEWMAN, *Hillside, Cheltenham*.

### FLAX, WOOL, AND CORK REFUSE FOR GARDEN PURPOSES.

FLAX REFUSE has long been used as a manure, mixed with farmyard manure, in the neighbourhood of York; perhaps, ever since its manufacture commenced. However, the first use of it as a garden material that came to my ears was at Fairfield, near York, about eight years since, and being inquisitive like most other gardeners, I took the trouble of visiting the gardens there, hoping to glean something new about hotbed-making.

Well, having asked to see the new-fashioned plan, I was shown a bed 15 feet long, 9 feet wide, and 6 feet high, in reality composed of flax refuse and stable-dung in equal proportions, which I was informed produced a milder heat but of longer continuance than stable-dung alone. This bed was said to have been made on the 5th of February, and Cucumbers planted a week after that in the bed were, when I visited the place on the 6th of April, producing fruit, some of them 1 foot 10 inches in length, and the plants were pictures of health. The temperature inside the frame was 75° with a dull day and overcast sky, and a thermometer plunged in the soil indicated 87° at 6 inches deep.

Near the same bed was another, newly made, for Melons; and the heat of it, and in the frame above it, was mild and very little higher than that of the Cucumber-frame which had been made six weeks prior.

Flax refuse, therefore, is a material useful for hotbeds; and, applied as manure for Strawberries, the results are equally satisfactory; but the plants are not stimulated into growth so rapidly, nor produce such abundant foliage, as they do when stable-manure is applied. However, the plants continue to

produce annual crops of fine fruit (after a thorough dressing of flax refuse at planting and an annual mulching an inch in depth in March, which also prevents the fruit from being spoiled with heavy rains), for several years. For kitchen-garden crops it is a good fertiliser, but slow in its action, and (as far as my experience goes), not to be preferred to ordinary manure.

**WOOL REFUSE** is a material well adapted for raising a mild, strong, and violent bottom heat, according to the quantity used. Formed into a bed 1 foot 6 inches deep, a mild heat of 75° to 80° is the result; a bed 3 feet high will make the mercury rise to 120°, and sometimes to 180°; whilst a bed 6 feet high will soon set the whole a-blazing, and if we are unfortunate enough to have a frame on the bed that soon is reduced to ashes. Nevertheless, as a heat-producer and used in moderation, and with care, wool refuse, or Billy-muck, is inferior to none other fermenting material; it retains its heat longer than stable manure or tanner's bark.

Used as a manure, after it has laid a year or so to rot its application as a top-dressing to grass is very beneficial, and for garden crops it is a good manure—superior to ordinary dung.

To make a compost of it, it should be laid in a heap to decompose for three years at the least, when it makes a good ingredient for the potting-bench, for enriching the compost for any description of softwooded plants.

**CORK SHAVINGS** are said to heat spontaneously so violently as to ignite. Be that as it may, I find the few Orchids we have are much benefited by its use as an ingredient in the potting or basketing compost; in fact I think cork shavings are equal if not preferable to charcoal. However, as my experience is but very limited I speak reservedly; but should any person have tried it I hope they will give us their results. I certainly had intended to have tried cork shavings, especially as I had the promise of a cartload for the fetching. But to my consternation I found promising and performing were two very different things—it proved a promise only made to be broken.

In conclusion, I have to add in favour of flax refuse that, when used as a mulching on orchard-house trees in pots, the trouble of watering is lessened, and the trees are benefited by its application.—*GEORGE ABBEY, Gardener, Horton Hall, Bradford.*

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

**DURING** the last month we have had such a continuance of rain that little progress has been made in the sowing of seeds, or even the digging and trenching of ground. Surely the late drenching rains, and the astounding articles which are daily appearing through the press of this country will convince the owner and occupier of every plot of ground of the necessity and importance of thorough drainage. Ground that is thoroughly drained takes but a few hours to drain off the superfluous moisture, and under such circumstances it is soon in working condition; whereas ground that is imperfectly drained will be days, and in some instances weeks before it is in a fit state for the reception of seeds. The cultivator who has his ground thoroughly drained will have his crops appearing above ground before those whose ground is undrained will be able to deposit the seed; and, should the season throughout prove unfavourable, the latter will not produce as much as will pay for the labour. If a few fine days should occur prepare for getting in the main crops, if not already done, as soon as the ground is dry and workable. *Broccoli*, if a sowing has not yet been made of the various winter and spring varieties, it should be made at the first favourable opportunity. *Brussels Sprouts*, a good sowing to be made for winter use. *Cabbage*, a sowing of the Sprotborough to be made for winter and spring use. *Cardoons*, the seed may now be sown in trenches where the plants are to remain, the trenches to be about 4 feet apart, and a few seeds dropped in at intervals of 18 inches or 20 inches. *Carrots*, they succeed best in a deep rich soil; if it is of a light nature it is the more suitable for the long tapering roots. They should follow a crop for which the ground was previously well manured; for if manure is applied in the spring the roots will be forked and wormy whenever they come in contact with it. *Cauliflowers*, prick out the young seedlings on a warm border, earth-up those which have stood the winter beneath hand-glasses. *Mushrooms*, in making beds to produce through the summer, a portion of loam should be mixed with the dung: this will give greater solidity to the bed, which will in consequence produce more

fleshy Mushrooms. *Marigolds*, to be sown if required for kitchen purposes. *Nasturtium*, a sowing may be made at the foot of a fence or any other suitable place, either for the purpose of forming a screen or the production of seed for pickling, or for both. *Parsnips*, the seed, if not already committed to the earth, to be sown in drills from 15 inches to 18 inches apart in drills and about an inch deep. Drilling crops, where it can be done, is far more convenient than sowing broadcast, as the intermediate spaces can be easily cleaned and stirred-up, which is of great benefit to the plants.

### FLOWER GARDEN.

As the unfavourable state of the weather most probably interfered with the performance of previous instructions, we would advise a reference to them when the weather will become favourable for executing all arrears. The following plants, if not already there, may be introduced with advantage to the flower garden:—The *Phloxes* of various colours and sizes, as seen last season in the beds at Chiswick, may be recommended as worthy of special notice. Most of the varieties of *Pentstemon gentianoides* are handsome; *Snappedragons* are numerous, and many of them are very showy; *Delphiniums* when pegged-down in beds or allowed to grow erect in borders make showy masses of blue; *Alströmérias* are easily managed and showy, also the *Gladioli* of various colours. The hardy *Diclytra spectabilis* when planted out is one of the gayest things grown, blooming freely through the season. Commence in earnest with mowing and cut down close, it will mow better for it all the season afterwards.

### STOVE.

Pay attention to watering, shifting, stopping, &c., the plants in general. The greatest care will be necessary to prevent the soft-wooded plants from drawing; during this unseasonable weather they should have all the light possible. Some of those potted early may now require a second shift. Take every opportunity of keeping down insects by fumigation and the active use of the syringe; but caution must be taken that the syringe is not plied with such force as to tear or injure the leaves.

### GREENHOUSE AND CONSERVATORY.

Proceed with the staking and tying-out of plants requiring such assistance; but if former instructions had been carried out relative to growing plants with short-jointed wood, a good deal in the way of stakes may be dispensed with, although some will be necessary to give the plant its desired shape, but on no account use more than will effect that purpose. Turn each plant frequently round that it may not become one-sided. Orange trees require particular attention when they are making their young wood. Stop luxuriant shoots at the fourth or fifth joint, no one part of the head should be allowed to grow stronger than the rest. Young trees may require some of their strong branches to be tied-down for a time, which will strengthen the others. Climbers should soon be planted, if additions are to be made to them this season, and see that the young growth of the old ones does not get entangled for want of training.

### FORCING-PIT.

Preparations must now be commenced for the autumn, by propagating such plants as *Euphorbias*, *Justicias*, *Poinsettias*, &c.; nor must the forcing *Pinks* and *Picotees*, *Roses* for potting, *Sweet Briar*, &c., if not attended to already, be forgotten. Cuttings of *Fairy Roses* to get the plants strong, must be put in at once. Pay strict attention to *Violets* so as to get a good stock of them.

### PITS AND FRAMES.

Persevere with the potting-off all plants for bedding-out. Those which have been established and hardened may be removed to temporary pits and protected with mats.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

**THERE** is as yet little or no change in the weather for the better. We had it dry on the 4th, but little sun. Forked the surface of the rain-caked ground intended for *Onions*, &c. Did it still more slightly on Saturday morning. Trod and raked it by mid-day, and just managed to draw shallow drills, and sow *Onions*, and cover with light, dryish soil before the rains came down again. Sowed also *Parsnips*, which ought to have been earlier, a few *Carrots*, and a row or two of *Beet*, deferring the main crop for some weeks. Also, a few *Turnip*

Radishes, and a slight sowing of Broccoli and winter Greens. Cut over Cabbage plants in the quarter that were throwing-up their flower-stalks, a too common thing in this neighbourhood this season. By cutting these over pretty low, the cut-off heads would be useful, if there were not such a supply of all sorts of Greens from the mildness of the weather. This mildness, and two or three sharp frosts have made this havoc among the Cabbages, much to the loss of the cottagers; but cutting-down will often, when done so early in the season, cause the stools to produce at a later period three or four tidy Cabbages instead of one. Gave some Broccoli some manure water, though there has been wet enough; but such rich watering does good even in wet weather, if the plants are not waterlogged. Cut up the roots of *Sea-kale* plants that had been forced into lengths of 3 inches ready for planting, and got ground ready for thinning last year's sowing. Where ground is plentiful would thin as soon as up fairly, or sow thin enough at first, as this plant does best when sown to remain there. The roots cut up into pieces we do not consider to be so good as seedlings, except it be the crown ends. We have sometimes slit up the latter when large into several pieces, to secure buds at once, but seldom with advantage, as vermin that will not penetrate the rind of cut pieces will devour the inside to a shell, if split down its middle. Those who intend making a fresh plantation should, therefore, get last year's smallest seedlings instead of these cut pieces, as dealers will be apt to send the latter mixed up with the former, and charge the same price. A little salt thrown along between the rows of growing-beds will now do them good, and Asparagus-beds would like a sprinkling, which would not only assist the shoots, but keep down weeds. Covered a score or so more heads of *Sea-kale* with largish pots, putting them firmly an inch in the ground, covering the holes at top with a slate or tile, and half a spadeful of earth to keep out all light. In sunny weather when the sun heats on the pot the crop will be fit to gather in a few days; in dull wet weather it will be longer in coming. Sowed Basil, Marjoram, &c., in heat, and Thyme, Borage, Burnet, Sage, &c., in pots and boxes. These things, though hardy enough, are apt to be lost when small, and, therefore, the extra care in sowing and planting out the seedlings is not labour lost.

#### FRUIT GARDEN.

Much the same as last week. Moved Strawberries set from shelves close to the glass to some farther from it, and supplied the top ones with plants that had stood under glass on the top of a slight hotbed for two or three weeks. Some people succeed pretty well by bringing plants from the open air at once into a temperature of 60° to 70° or more. We trace no such practice from the lessons that Nature gives: all her operations speak of gradual bit-by-bit working. In forcing-houses, if Strawberries are placed in them when the houses are shut-up, the plants have all the advantage of the gradual rise in temperature, and the flower-trusses come boldly. For succession crops in the same house we prefer the plants being gradually excited before shelving them. No weather could be worse hardly for obtaining rich-flavoured fruit, &c.

#### FLOWER DEPARTMENT.

Out of doors this has been well nigh at a standstill. Cold pits holding thickets of *Calceolarias* are much as they were, as the ground in the temporary pits is so claggy for moving them. Wet or no wet out they must go soon, or I fear what the struggle for existence will accomplish. Seeing we shall want more room than our earth pits afford, cleared a small quarter of last year's Cabbages, and dug out trenches 4 feet wide, which will first be filled with *Calceolarias* and other things, and would be a capital place, if bottomed with a little hot dung, for sowing half-tender annuals. These for the time being answer all the purposes of the best turf pits, and will come in for Celery afterwards.

A, Ground level of garden.

B, Pits dug out.

C, Slope for walking on, sending rain past, generally covered with a little litter to keep the shoes clean.

D, Tops of sides, for placing hurdles, or calico, or wattled hurdles, such as common old fence hurdles, with a few spruce or laurel boughs drawn through them.

E, Showing such covers laid across. Calico, frigi domo, fixed to poles would be handiest. A person walking at c, and another at d, put it off and on pretty well as fast as they can walk.

Whatever protection is used, means should be taken to throw the heavy rains past by having one side lower than the other, which in making is as easily done as not. See section of two such makeshift pits. Divided Dahlias and planted them out about 3 inches apart under glass, from whence *Calceolarias* had been removed, and may thin them again before going out. This, especially in bedding kinds, saves much labour in potting. Planted out in temporary beds many of the green and horseshoe-leaved *Geraniums* where I could cover with old sashes, as they lift well without potting. Turned out lots of variegated ones that had been potted into shallow wooden boxes, and placed them in a verandah where they can be protected. Filled the pots with more variegated ones. Sowed Zinnias, Stocks and Asters in pots and boxes, and set them on the floor of a Peach-house until they got up nicely. Pricked-off lots of seedlings, *Petunias*, *Lobelias*, &c. Potted *Pelargoniums*; trained earliest kinds and strongest plants. Potted young *Fuchsias*, *Vincas*, fine-leaved *Begonias*, &c. Old plants of these should have most of the soil shaken from them, and be placed in smaller pots. The soil, loam, and peat, with almost a third of old cowdung or hotbed manure, old, well sweetened, and dried before using, and a little silver sand. Plants old and young should be under rather than over potted; no place suits them better than ainery at work, the heat and the shade just suit them. The sun, if strong, is apt to make the leaves spotted and brown. They seem to thrive in a temperature from 50° to 65° and 70°. If kept in rather small pots they will need watering often after the pots are full of roots, and weak manure water will be acceptable; if in largish pots they will need watering much more seldom. Much was expected from these plants for out-door decoration. A great gardener wrote to me last season—"I have got a new idea for this season that will, I think, make you old jog-trot fogies stare." Well, I believe this was some 500 to 1000 of these plants turned out in the flower garden; but I heard nothing afterwards of the "idea." We have seen them pretty fair in some places. Mr. McDonald, of Woodstock, Ireland, had a bed of them and the Chinese Coltsfoot, &c., about the best we noticed. With us and elsewhere neither too much wet nor too much sun seemed to suit. In any shady place under glass they will be more at home than out of doors even in summer.—R. F.

#### TRADE CATALOGUES RECEIVED.

*Charles Turner's General Spring Catalogue for 1862*, is a descriptive list of all that is new in Florists' Flowers and Bedding Plants. Those who are interested in such matters, will find it well worth a perusal.

*A Catalogue of Forest, Fruit, and Ornamental Trees, &c., by Benjamin Whitham, Clough Nursery, Moltram*, is a good general nursery list.

#### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**CALCEOLARIA LEAVES SPOTTED (*Sigma*).**—You have had a little red spider on the *Calceolarias*, and a good deal of thrips, both caused by the plants being kept too hot and too dry. Put a quart of lime and a quart of soot into twenty gallons of water. When mixed, and settled, and clear, syringe the plants well, turning the plants over and over. When dry dust with a mixture of dry soot and flowers of sulphur. After a few days shake that off and syringe again. If all the leaves are as bad as the one sent, the plants would not be worth the trouble.

**EVERGREEN CLIMBERS (*A Subscriber*).**—We have often said there are no evergreen climbers for the climate of England. Properly so called, the Ivy is not a climber, but is the nearest to it. A plant like a *Clematis*, or a running Rose, and to be green the year round like the Ivy, is what we repeatedly have said is not to be had for our climate. Then, of course, it is like all other varieties highly to be desired.

**CAMELLIAS (J. E.).**—We cannot distinguish the buds, the roots were quite dried up, but, otherwise, seemed to have nothing the matter with them. Try the Camellias in the lightest place you can command, and be sure the ball is watered throughout. We think it must be some peculiar variety, as the gardener succeeds so well with all the others.

**ADAPTING A STOVE TO A BOILER (H. M. F.).**—Putting a sheet of iron round your circular stove and placing a boiler on the top would answer, but we are doubtful if anything but sheet-iron would stand round your stove. You should take your flue-pipe from near the top of the boiler, instead of so near the bottom of it as you suggest. We would not like to work it so place. The cheapest plan we know of would be to have a brick Arnot's stove, and an Arnot's stove-boiler on the top of it, which Mr. Highes, of the iron foundry, Bishop Stortford, sells for about 35s. However, your plan will answer well enough, if you attend as above to the flue-pipe, though unless you can command the services of a very handy man, your boiler may not be so cheap after all. Vulcanised India-rubber tubing would not answer for hot water.

**BOOKS (G. D. H.).**—You can have *The Cottage Gardeners' Dictionary*, free by post for 5s. 8d., from our office; and "Johnson's Modern Dairy and Cowkeeper," for 3s. 8d. (A. B. C.).—Buy the new edition of our "Green-houses for the Many," which will be published in a few days. It contains much about orchard-houses.

**ALANTHUS TREE (Mrs. P.).**—Any nurseryman can obtain it for you, for it is in the catalogues of the London nurserymen.

**POTATOES AND CELERY (A Nottinghamshire Inquirer).**—Do not put any manure to the ground for the Potatoes, unless it be two bushels of soot and 14 lbs. of Epsom salts mixed together and spread over the ground before digging. Give no liquid manure to your Potatoes, but as much as you like to the Celery. It will make it crisp, not soft.

**PROPAGATING EVERGREENS (Limerick).**—Now is as good as any time of the year to layer all sorts of evergreens and all kinds of deciduous shrubs. The Portugal Laurels and the Bays—that is to say, *Laurus nobilis*, will need tonguing or twisting, the Aucuba and the common Laurel will do without, and both will come from cuttings out in the open field, if put in in July, as well as Scarlet Geraniums. No one thinks of layering *Berberis aquifolium* now-a-days, but every one raises it from seeds like the Larch, or Scotch Fir, into the birds take to the berries of this *Berberis* when the seeds are fit for sowing, and get the best share of the seeds on account of their better knowledge of when it is fit to sow. Watch the birds or you will soon learn to your cost the best time to sow the seeds of *Berberis aquifolium*.

**EUPHRAZIA AMAZONICA (G. Liverpool).**—This *Euphrasia* is the very pink of drawing-room plants, but as such the treatment must be as different as possible from what it would need in a hothouse. There is where the great error lies with half our plants. Some gardeners find out the true way, and the best way for him, of growing a plant, and amateurs take it for granted that all that is needful is to do as he did, and, of course, they must fail under the circumstances; and if your drawing-room *amazonica* is grown as if it were in an Orchid-house, you will fail as surely as any of them. Your bulb wants a pot, about the end of next May, just one size bigger than the one it is in, and no more for the next twelve months. Mind that it is to be a drawing-room ornament. In June, July, and August, put it in a saucer of water once a week for ten hours at a time, that is to make up for a bigger pot, and water as usual notwithstanding—that is, when it seems to want water. Little pots always do best in the drawing-room.

**PLANTING FLOWER GARDEN (A Young Beginner).**—We can only reply to you as we have for more than twenty years uniformly replied to all such applications—namely, that we never plant for any one, we only point out errors in the proposed plantings submitted to our judgment.

**POTASH AND BONES (A Seaman).**—We do not know the best proportions. If we were about to practise the operation we should merely cover the bones with powdered potash and pack them in the cask. You had better write to Mr. G. West, Beurnmouth, Hants, describe the Waltonian Case you require, and ask the price. The Cases are sent from London. It is far superior to the In-door Plant Case for your purpose.

**VINES UNHEALTHY (J. N.).**—From your description we should almost conclude the Hamburgs had been diseased when you planted, if all others do so well in the same circumstances. We can form no idea what would remedy them as all the rest are so healthy. We would certainly change the plants if they showed any such symptoms last year.

**FLUES EMITTING SMOKE (C. D. Danvers).**—We are very glad that you have succeeded so well. Flues are apt to draw badly in damp weather, when there is not a little rise all the way. The mortar for unplastered flues should be the best, as fine as lime putty, and made with little water and plenty of elbow grease. In these there is little chance of smoking, as the joinings get even as hard or harder than the bricks. We once had an old wall pointed by a first-rate bricklayer, and did not the labourer who made the mortar grumble! The work did make his arms sore, the best sand and no water except what could not be done without, and though the bricks have been going piecemeal since, the joint's stand as firm as pieces of rocks. If necessary you may fresh point, or even plaster the outside. An old gardener told me how he served a smoky flue. He had some old flimsy cloth, as frigi dome, old bags in fact, these were cut and spread over the flue when wet, and washed with thick lime wash. What is the expense of cocoa-mat covers? Long lengths of canvass, frigi dome, &c., can be affixed to poles.

**HEPATICS (Thom.).**—Divide the plants as soon as the flowers have faded. Buy our No. 57, and you will there find full notes on the culture of Hepatic. The sample you enclosed is pure decayed wood and leaves. After being exposed for a few weeks to the air it would be an excellent manure for flower-borders, or, indeed, for any soil or crop requiring manure. It will not do as a substitute for peat, or heath soil, for American or other plants.

**HEADING DOWN APPLE TREES (A. Q.).**—If there are buds on that part of the stem immediately below where you intend to cut them down to, then you will be quite safe in reducing them to that height; but if, as is frequently the case, the buds have been effectually destroyed in trimming up the stem you will be disappointed. All will depend on whether or not there are any buds left to break after you have headed-down the stem.

**ORANGE AND LEMON TREES FROM PIPS (X. F. Z.).**—They will certainly both blossom and bear fruit without being grafted. If grown in a proper temperature and soil they ought to blossom when four years old.

**VINE LEAVES CURLING (B. S. H.).**—We fear the wood of the Vines was not perfectly matured, or a stoppage at the roots. Fasten a little stone to a

piece of matting, and then the other end of the matting to the end of the bunch, and see what that will do. If you have been growing the Roses some time, and the shoot showed no bloom, you did right in stopping it, as you will most likely have later flowers from the side shoots; but it should not have been stopped until it was seen there would be no flower-truss. Roses in such dull weather as we have had can scarcely be expected to come to their full colour.

**PROPAGATING BEGONIAS (Elizabeth Causton).**—Cut up your blotched leaves into strips and insert them as cuttings, having a piece of midrib at the bottom. You cannot have a better place for the Begonias than your viney. Grow them in heath soil and loam, and very old dried hotbed dung or compost in equal proportions, and rather underpot them. See "Doings of Last Week" in to-day's Journal.

**PEACH AND NECTARINE-BUDS FALLING (A. F. W.).**—Yours is a very plain case. Your Peaches and Nectarines, according to your statement never ripened their wood, the others would be harder and more ripened. We should not have been surprised if your blossom was defective. Under the circumstances we should not have thinned the blossoms so much until we saw what they would do, and in their imperfect state watering should have been given in great moderation once a week or fortnight, when planted out, in case of every two or three days. The less heat such trees had the better, as the weather has not been cold enough to hurt Peaches, and if fire heat were given, then plenty of air should also have been given, so as not to hasten the plants at all. You must make the most of them now for next year. If you have not much experience, you had better have kept the plants in pots. Pears will not endure much fire heat. We think Ivy of various sorts would be best for your cottage covering.

**GLADIOLI FOR POTS—EVERGREENS UNDER TREES (L.).**—All the Gladioli will do in pots with good management, but ten times better for you and them without pots. Those which will do best in pots out of your stock are *Brenchleyensis*, *Conranti fulgens*, *Madame Henric*, *Floribundus*, *Dan Juan*, *Blandus*, and *Sagittalis*. Flowering shrubs will do no good under trees in a shady border, and very few evergreens either. The large trees have got full possession of the ground by their roots. Try Tree Box, *Berberis aquifolium*, *Yew*, and *Aucuba*.

**CUTTINGS (L. T. P.).**—Far too general a question; for all the year round some such cuttings are best done, but the great bulk of evergreen cuttings are better made in the autumn, and the deciduous ones at the same time as Gooseberries and Currant cuttings—that is, in October and on to Christmas.

**PRICE OF WALTONIAN CASE (C. Horwood).**—Write to Mr. G. West, Beurnmouth, Hants, describing what you require. He will send you prices and where he can deliver the Case.

**VARIEGATED MINT (D. N. Northwood).**—It is a variety of *Mentha gracilis*, sometimes called *Mentha pratensis*. It is found in the New Forest, Hants, and somewhat resembles *M. piperita*, but is not so agreeably aromatic.

**MIXING SOIL WITH COCOA-NUT FIBRE REFUSE (Edith).**—Any sort of loam may be used with cocoa-stuff, just as you would use peat and sand. We believe it takes the place of peat and sand in all composts.

**SWEET-BRIAR HEDGE (Idem).**—It is not at all difficult to make. It is like planting a row of Geraniums, straight or curved. Do it in October or November, or in the beginning of March, and much about the roots. Cocoa-nut fibre refuse would do for this purpose. You may plunge the potted Tulips in the borders.

**BEDDING PLANTS IN POTS (F. W.).**—Decidedly we prefer planting all bedding plants out of pots, but unfortunately in some few places most of the Geraniums and Cherry Pies go too much to leaf and give very little flower, and much more is the misfortune, that very few make suitable beds to bloom these plants. Anybody can make any bed or beds in any county, or part of our kingdom, to suit any plant in the catalogue; and the next best thing is to plunge the pots and to attend to the watering.

**RIBBON-BORDERS (A Reasoner).**—Verbenas do not do well as ribbon-lines the trouble to keep them in lines is more than most can afford to give them. You have an excellent assortment without them. Put first *Lobelia speciosa* then Variegated Mint, then *Perilla*, then Tom Thumb Geranium, then *Calceolaria aurea*. You want something for a back to the bright yellow *Calceolarias*, and the *Mignonette* must go somewhere else. If you could get a row of the *Zelinda Dahlia* at the back, it would be just the plant for the purpose.

**DISA GRANDIFLORA (Malpas).**—No one has ever yet gathered a pod of a *Disa* of any kind. The seeds which we mentioned were sown on Table Mountain by Nature's own hand.

**CULTURE OF AMARYLLIS BELLADONNA (Idem).**—It puts up the flower-stalk, or scape, in October, and then begins to grow, when Hippeasters, the *Amaryllis* of the shows, are going to rest for the winter. All the *Amaryllises* grow from October to the end of May or near it, and all the Hippeasters go to rest during the winter save one kind. June, July, or August therefore would be the best time to bury *Belladonnas*. This sad all the true *Amaryllises* like a lighter soil than Hippeasters—say pure loam, friable as for pot *Pelargoniums*, and no dung, or nothing beyond as much sand as would make a friable loam, if you want to preserve the bulbs for an heir. After the *Belladonna* flowers, you will recollect it must have the same treatment as a Cape Heath. In a cold frame all the winter, and the glass entirely off every fine day and night in the spring.

**COCOA-NUT FIBRE REFUSE (L.).**—We can only repeat to you as to another correspondent last week, that your specimen is totally unlike the correct kind. We have repeatedly said that the useful refuse is a powder like brown snuff, and you send us a bunch of bristles, and ask "is it the proper thing?"

**WORMS IN SOIL IN POTS (T. E. C.).**—Water with lime water. A piece of slate put over the hole in the pot excludes worms, yet allows surplus water to escape from the drainage.

**ALANTHUS SILKFORM (Rev. J. B.).**—Lady Dorothy Nevill's book on the subject will give you all the information you require. It is published at our office, and can be sent by post for thirteen postage stamps.

**RABBITS (Westmorlander).**—There is no law preventing you destroying in any way, on your own ground, the rabbits which invade your garden crops. To keep the rabbits away there is nothing so effective or so cheap as three-foot-high galvanised iron netting. It is very much more reasonable in erecting than that required to exclude mountain sheep, which you seem to have endured painfully. To scare the rabbits away a terrier in a kennel near the crop of Carrots would be effectual, probably.

**VARIOUS (C. F.).**—No evergreen will cover your fence so effectually as Irish Ivy. Do not apply any manure to your Strawberry-bed until you can see the blossom-buds. It is impossible to give an answer about the stable-manure, so much depends upon circumstances. The area question could be answered from any arithmetic-book. A circle 100 feet in circumference contains 79,557½ square feet.

**COCKSCOMB CULTURE (Correspondent).**—When the seedlings are half an inch high prick them into pans about 2 inches apart, grow them on fast, and do not give much water, which will cause the combs to appear early. Those having good-shaped combs lift with good balls to their roots after watering the day previously, and plant in light rich soil in 3-inch or 4-inch pots, and plunge in gentle heat.

**SELLING FLOWER-STICKS (A. H.).**—We know of no other mode a poor person could adopt for selling these than offering them wholesale to the seedsman and nurserymen near London, and calling at houses where flowers are cultivated.

**FLOWER GARDEN (S. E. L.).**—You have arranged all the beds but four very well, and these two pairs you could not have done worse. The figure is one of the centre figures in Lady Granville's flower garden at Dropmore, and is of beds of various shapes and sizes placed all round a circular bed in the centre. The centre bed is mixed Verbenas, and none better. The rest of the beds are in opposite pairs, the colours standing thus:—1, scarlet; 2, blue; 3, yellow; 4, purple; 5, white; 6, white; 7, scarlet, and so on to white again. Then you see 5, white variegated "Alma or Bijou," and 6, Variegated Alyssum side by side: but put 7 between 5 and 6, then the arrangement will tell its own tale more than it does your way of putting it.

**GREEN FLY (Seven-years Subscriber).**—"The best preparation for destroying the green fly" is unquestionably the best tobacco—there is no question at all about that. But the best way to apply tobacco is a very serious question, and if the best way could be discovered it would be the cheapest way in the long run. The best preparation at present for killing the fly on standard Roses is to make tobacco liquor and dip the shoots in it one by one. And the rule for knowing if any sort of liquor is dangerous is first to try it on some useless plant—say Mint or Nettles—there is no other reliable rule. The cheapest and best mode of destroying green fly on Geraniums, Verbenas, and all plants in pots is by tobacco-smoke, and the best tobacco is certainly the cheapest and the most safe for strangers to that work.

**EDGING (Idem).**—The best and the only sure edging to the bed where the cats hold their parliament is, that of glass advertised in our columns by Messrs. Kilner. A little Stonecrop, as you suggest, might be tried; but where your Box-edging could not bear the traffic, the Stonecrop will have but little chance.

**LATE AND EARLY GRAPES.**—"In your notice (see page 33, JOURNAL OF HORTICULTURE, April 8th), of Mr. Hill's late Grapes, you either forgot or were unaware of the fact, that the Vine on which the Lady Downe's Grapes were hanging was actually showing bunches three weeks back, and some of the Vines in the house were very much forwarder. When I saw them it was, indeed, a sight to set a gardener's mouth watering, and to set his wits to work to find out how Mr. Hill had carried such splendid Grapes though in a house which has been used as a storeroom for bedding stuff all through the winter. That the Lady Downe's is the best late Grape out there cannot, I think, be a doubt now."—R. C.

**NAME OF APPLE (A Constant Reader).**—The Apple you sent is Normanton Wonder, the correct name being Dumelow's Seedling. If you have received it from Mr. Pearson, of Chilwell, under the former name you have, no doubt, got it true.

**NAMES OF PLANTS (H. B.).**—1, A worthless *Oncidium*; 2, *Piptanthus nepalensis*; 3, *Acacia verniciflora*. (H. A. E.).—*Anemone pavonina*. We do not know your *Orchid* by the description, but it is not unlikely to be some form of *Ophrys fuciflora*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY, &c., SHOWS.

APRIL 21st, 22nd, and 23rd. EAST HANTS (Southsea). Sec., Mr. F. Baker. Entries close April 16th.

MAY 14th and 15th. TAUNTON AND SOMERSET. Sec., Charles Ballance, Esq., Taunton.

MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). Steward, S. Pitman, Esq., Manor House, Taunton. Entries close May 1.

MAY 23th and 29th. HULL AND EAST RIDING OF YORKSHIRE. Sec., Mr. J. Hooton. Entries close May 14th.

JUNE 3rd. ESSEX AGRICULTURAL ASSOCIATION. Sec., R. Emson, Slough House, Halstead. Entries close May 10th.

JUNE 4th and 5th. BEVERLY AND EAST RIDING. Sec., Mr. Harry Adams.

JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. Secs., E. Holdsworth and J. Wade.

### HATCHING EARLY CHICKENS.

OUR correspondents, as in this instance, often give us the one for a paper, by reminding us of the season of the year and the natural processes which it introduces. There is with many people a great liking for May chickens. We are of the number. They are strong, and deserve the appellation our forefathers gave to the month itself, *Lustie Maie*. All things are young, fresh, and growing; it is, also, the natural time for hatching. Those pullets that have passed into hens, and subsided into regularity after their youthful vagary of laying in the winter, bring out their chickens at the end of May in obedience to the same laws that govern Pheasants and Partridges. Where we interrupt Nature we have to find substitutes or apologies for those things that we forestall. If we hatch when night is twice as long as the day, we must press artificial light into our service. During cold weather and biting winds we must provide shelter. As the

hen is kept in close confinement, we must provide another guard; but whenever we can we shall do well to follow nature, or rather to let her have her own way. All birds of the gallinaceous tribes in a wild state make their nests on the ground, *literally on the ground—on the earth*, and to this may be attributed the fact of their hatching so well. Any wooden flooring for a sitting-house is bad, and being raised up in the air is far worse. It is unnatural. Nests such as that described by our correspondent are full of vermin, quite as destructive as rats; these latter would eat the eggs, and the vermin we speak of—fleas and lice, prevent the hen from hatching them. They make her sit hollow and uneasily, we need hardly add ineffectually. There are coolness, ventilation, and freshness in a nest made on the ground: this is so necessary that in making a nest in any out-house or covered place we always put a sod or turf at the bottom. Our hens come off but once in twenty-four hours. They are then provided with dust, food, growing grass, and water. They are off about twenty minutes, and return cool, fresh, and dusted to their duties. For seven or eight days before hatching-time the eggs are regularly wetted every day when the hen is off. The hand is dipped into cold water, and shaken or wrung over the eggs till they are wet. The success of hatching depends much on this; when chickens are dead in the shell it is for lack of moisture. The inner membrane of the egg becomes so dry and hard the chicken cannot pierce it, and extricate itself.

We have here stated the method that has been uniformly successful with us. We should attribute the failure of our correspondent to bad sitting caused by vermin, and this latter caused by wooden flooring, and, above all, nests made of hay, the worst possible material. The remedy may be gleaned from the preceding remarks. Let the nests be on the ground; let the bottom of each be a sod of grass; let these be only covered with a little straw—no hay, and let the hens have dust at hand when they come off.

**LUSUS NATURE.**—I beg to enclose particulars of a remarkable freak of nature hatched 24th of last month. Out of nine Spanish eggs set five chickens came out; one of them had two heads, four wings, four legs; the body was in one, but appeared wider than usual on the back. This animal, for it was as much like an animal as a bird, lived but six hours, and I should think its functions were not complete in every respect, as it did not appear able or willing to bend the head to pick up food, or to suck it in when offered.—F. CROOK.

### VENTILATION OF BEE-HIVES.

I have been much interested in reading at page 386, Vol. II., the extract of a letter from Staffordshire inserted by your intelligent correspondent and apiarian, "A DEVONSHIRE BEE-KEEPER." The idea of free ventilation was maintained very strongly nearly a century ago by a very strenuous promoter of the system, who was at that period not only a learned advocate at Paris, but during his leisure hours a very expert manager of bees.

He gave the following reasons of the practice he adopted for leaving hives open all round at the bottom:—"I find in summer it facilitates the labour of the bees, and their tumultuous entrance when the weather threatens a storm: that at all seasons it contributes to their health, by maintaining in the interior of the hive a pure air, free from the humid vapours usually proceeding from the bees when the opening at the entrance is single and small. It obviates also, when the season is cold, an inconvenience which is perceptible in all hives that have only a small entrance— which is, that the heat being often too great within, the bees being forced to go out to cool themselves are seized with the cold, as we ourselves are in winter sometimes when we quit a small room where there is a hot fire, and then they die outside, being unable to regain their hive; whereas, by the other method, the bee, without quitting the bulk of their companions, whose union supports them in a degree of warmth sufficient for their preservation of life, they perceive within the hive the quality of the external air, and judge without danger if it be suitable for them to venture out, or more prudently to remain at home."

The French bee-hives, at the period when these remarks were written, were commonly made of osier, like our present wicker baskets. A very good representation of them, and a garden of bees, may be seen in a vignette in Rapin's History of England by Tindal, on title-page, vol. i. and ii. The author continues—

"This ventilation prevents too great a consumption of the provisions of a hive, by the coolness that the openings allow to enter; for it is known by experience, that the more considerable the interior warmth of the hive is, the greater is the consumption of the stores within. Lastly, it allows, during all weathers, while the bees occupy the lower part of the hive, one to judge of the weakness or strength of the community without moving it, which is always prejudicial to it, but by only looking beneath, it is seen what one may be required to do at any moment.

"With respect to cold, I do not think its effects so injurious to bees as some imagine. It forces them not to separate themselves from each other, and thus enables them to pass without danger the most rigorous winters.

"One might, on this subject, put the question, Whether it be quite so certain the safety of a hive depends on the preservation during the whole year of all the bees that it contains?" For my own part, I am inclined to the negative; and that if the great increase of bees during the spring and summer be advantageous to a hive, as one can have no doubt of, so as to cause it to throw strong swarms, in order that the provisions for the following winter may be abundant, it is no less necessary that there should remain a diminished population during autumn and winter, in order that the said harvest may last the longer.

"In fact, of the two mortalities of bees which happen annually, that of the autumn, joined to the expulsion of the drones, produces the effect of which I speak—that is to say, of diminishing the number of mouths to feed during winter. As to that of the spring, I think it designed to carry off a good part of the bees of the preceding year, in order to give place to the young which are to succeed them. Now, by the method of leaving the hives open all round at the base in winter as well as summer, I am well persuaded that bees only perish that should; whereas, by that of shutting them up too close, a far greater number of them die than is necessary for the preservation of the hive."

"However it may be, I leave to every person the liberty of his opinion and his practice; not only without blaming, but praising, on the contrary, the efforts of those who seek the best; for I do not think everything has yet been discovered on this subject."—E. K.

### INSULATION OF BEE-HIVES.

In order to prevent the access of insects, such as ants, millipedes, and snails, &c., which not only annoy the bees, but often devour or spoil much of their stores as fast as they gather them in, it is an exceedingly good plan to place the legs of a bee-house, or the feet of a bee-stand in pans of water, taking care continually to keep them filled, and all weeds removed from near them, lest the ants, whose cunning as well as ingenuity are proverbial, should make so many ladders of them, and thus defeat the end proposed.

The Tomtit, or Great Ox-Eye, Sparrows, and Swallows—the Great Tomtit during winter, and particularly in the spring—make great devastation among the bees of an apiary. The Large Tomtit, or Great Ox-eye, is a most mischievous bird; the smaller species, some of which are exceedingly beautiful, are quite innocent of all bee slaughter; but the great criminal above mentioned (of which I have destroyed about a dozen this winter), is easily entrapped by a small cage baited with a tempting piece of fat, of which he is most dainty. These birds generally come in pairs: two cages should always, therefore, be in constant readiness to receive them, and to supply them with their dainty repast.

Ants may be readily put to the rout by a little fresh lime, or if a pointed broomstick be driven through their nest, about 2 feet into the ground, and carefully pulled out again, hundreds will fall daily into the well thus made, and may be easily destroyed by a little lime or hot water poured into the pit. Millipedes are readily caught by laying a board or slate on the ground, and afterwards crushed. Snails are readily caught by flower-pots inverted.

Sparrows should never be suffered to build their nests near an apiary. I have frequently seen these marauders catch the bees and the drones in the air flying, and carry them off to their young. They are far too cunning to touch poisoned corn. A gun, with a little dust shot, is the best remedy; and the same may be had recourse to for Swallows, even by those who are not great adepts in shooting; for these birds, though they fly ever

so swiftly, may be easily brought to the ground by seizing the moment when they are on the turn, which they always make in their flight, however swift it may be.—E. K.

### PARTHENOGENESIS.

LIGURIANISING AN APIARY—THE MYSTERY OF DRONE DEVELOPMENT.

M. HERMANN says (page 13), "It will be well to be cautious to leave one hive undivided and untouched that they continue to breed many drones, for the divided hive will not produce any more drones in the same year: therefore, one hive must be kept strong and untouched, so that you do not run short in drone-breeding."

Now, when a hive has swarmed naturally does it not continue to produce drones? And why not when artificial swarms are formed? Or must the possessor of a single stock of Ligurian bees leave its increase to nature? As I am desirous of Ligurianising my whole apiary as speedily as possible, any information will greatly oblige—F. H.

[After repeated perusals of M. Hermann's little book, I am still in doubt as to whether he was aware of the fact that drone eggs were entirely free from male influence, and that, therefore, a pure-bred Italian queen which has been impregnated by a black drone will breed as pure Italian drones as one that has received true impregnation from a male of her own species. That this is really the case follows, as a matter of course, if parthenogenesis in the honey bee is a proved fact; and that it is so cannot, I think, be for one moment doubted. Those who have read the apian articles in the last two volumes of THE JOURNAL OF HORTICULTURE will be aware that to Dzierzon, the eminent German apian, we are indebted for the discovery that drone eggs are unfecundated by the male semen, and that the truth of this discovery was proved by the microscopical investigations of Professor Siebold. These investigations having been verified and confirmed in America by Professor Leidy, and in this country by myself, have resulted in establishing beyond question the fact of parthenogenesis in the honey bee.

Having due regard, then, to this important fact, I believe that the most feasible, and, in the end, also the most speedy mode of Ligurianising an entire apiary from a single pure Ligurian stock is that recommended by me in page 507 of the last volume—viz., to content yourself the first year with furnishing all your stocks with young Ligurian queens from the colony in your possession, leaving their impregnation to chance. Next year any of these queens, about whose true impregnation there is any doubt, may be weeded out and replaced by young sovereigns bred, as before, from the original Italian queen. These will stand a fair chance of a true impregnation from the multitude of drones of their own species, which will then have been bred by the mother queen and her offspring, whether hybridised or not.

Something may be done the first year to increase the chance of a true impregnation by multiplying the number of Ligurian drones and diminishing those of the black species in the manner recommended by M. Hermann—i. e., by placing drone-combs in the breeding part of the Ligurian-hive (feeding liberally if honey be not very plentiful at the time), and transferring them to the black stocks as soon as filled with brood, removing, at the same time, all the original drone-combs from the latter.

When a hive swarms naturally the production of drones does not immediately cease, because there is usually a great number of embryo drones in the hive; but, as it is well known that the old queen always leads off the first swarm, it follows, as a matter of course, that, beyond the hatching-out of whatever brood may remain in the hive, no farther increase, either of drones or workers, can take place until her successor commences egg-laying. Notwithstanding the occasional irregular production of drone eggs by young queens, which has been noticed by Fabricier and Dr. Bevan, and still more recently by myself, it may be laid down as a general rule that the laying of drone eggs is at an end for the year whenever a natural swarm issues from a hive, and that the remaining drones will be ruthlessly expelled as soon as the young queen becomes impregnated.

The old queen having led off a swarm will breed no more drones for the year, unless the new colony becomes sufficiently prosperous to throw off a swarm, in which case there will be another laying of drone eggs prior to the issue of the swarm, and the same course will be repeated as in the old stock.

When artificial swarming is practised, the suspension or entire

cessation of drone-breeding depends upon the mode in which the operation is performed. If the old queen be placed at the head of the swarm, all will follow in the same manner as if it had issued naturally. If on the other hand the old queen is left in the parent stock, the swarm being furnished with brood-comb from which to raise a queen, the suspension of drone-breeding will be but temporary, and, in fact, need not take place at all if the number of bees abstracted be not sufficiently large to check the prosperity of the colony.

That distinguished apiarian, Dzierzon, writing so recently as the 14th February last, says, "that drone breeding is the first step towards increasing the species that is to swarm, and that it begins and is continued when there is a feeling of prosperity and growing strength in the colony." Any interruption to this feeling of prosperity and growing strength puts a complete stop to the production of drones\* which is not resumed until prosperity is restored. If this axiom be borne in mind it will afford a clue to the mystery of drone development—a mystery which, it may be remembered, the experiments and researches of the illustrious Huber failed completely to elucidate.—A DEVONSHIRE BEE-KEEPER.]

### BEEES AS CHEMISTS.

"Bees are able to make honey of sweetened water. By way of trial, I fed a stock with hard sugar,† which, after I had put it into a feeding-pan in pieces, and sprinkled abundantly with water, I placed before the bees. When I afterwards cut the combs out of the hive, which I wished to empty on account of its queen, I found that this sweetened water had been changed by the bees into honey, and was well sealed. It had all the taste of real honey. —*Die Korb-Bienenzucht*, by Friedrich Otto Rothe.

It will be perceived by the above quotation from a work written in 1854, that German bee-keepers have long been aware of a fact which was indeed established by M. Reaumur nearly a century ago, but which has been denied by some of our best English apiarian writers, and is even now controverted in the pages of THE JOURNAL OF HORTICULTURE. The results of my experiments and observations entirely coincide with that of Herr Rothe, although they have been so frequently repeated, and under such a variety of circumstances, as to induce absolute conviction in my own mind. I have this day (29th of March) extracted from the late artificial swarm mentioned in page 428 of the last volume, a small piece of sealed comb, itself fabricated from, and containing only what was originally simple syrup. This piece of comb I shall be happy to submit to the Editors or any tribunal they may point out, with the view of having it tested, and the result made public, after it has been ascertained if any, and what change, has been made in the flavour and chemical character of its contents.

The artificial swarm from which this piece of comb was taken was formed on the 9th of last August, after the honey season here was entirely over (as proved by the fact that several ill-provided swarms in this neighbourhood died of starvation at the time), and, being supplied only with simple syrup, fabricated combs and stored them with sufficient food to last the winter.

This evidence is the most conclusive I can offer, and if accepted may fairly be presumed to decide the point. Should any bee-keeper, nevertheless, be of opinion that he can, either by confining a newly-bived swarm in a room, or by any other means, induce bees to store their food without changing its character, I now repeat my offer to present such person with a good Ligurian stock, upon his producing a piece of sealed comb in which simple syrup—i.e., lump sugar and water only—has been stored by bees, and in which the syrup remains unaltered.—A DEVONSHIRE BEE-KEEPER.

P. S.—Since the above was written, I have perused the communication of "A NORTH LANCASHIRE BEE-KEEPER" in last week's Journal. He appears, from what is therein stated, to be the very man to claim the stock of Ligurians which I offered. As preparatory steps, I would suggest that he should first prepare a certain portion of simple syrup from lump sugar (such as I suppose his bees were fed on), and, with the assistance of one or two friends, carefully compare its flavour with that of syrup taken from the sealed combs of his defunct stock. If neither himself nor his friends can detect any difference in taste, then place a small quantity of each in shallow vessels, and expose them to a current of dry air until one or the other

becomes crystallised. The effectual manner in which his bees have destroyed the crystallising property of the syrup which he submitted to them will, in this way, soon become evident. Every bee-keeper is aware of the different flavour and varying quality of honey, and knows also that it depends upon the season and the pasture from which it is obtained. It is, of course, a very fair argument to adduce against the mere assertion that bees effect a change in the food with which they are supplied, and as such has been repeatedly made use of; but as soon as this assertion is supported by sufficient evidence, "both must take equal rank as established facts, which, however apparently antagonistic, are doubtless in strict accordance with each other.

[Another practical bee-keeper gave last week a totally different evidence. The question will not be set at rest until a swarm has been confined in some room—say an empty greenhouse, and supplied for some time with syrup of sugar and water only. It is an interesting inquiry, and we shall be equally pleased whatever the truth proves to be—we only wish to ascertain that.—EDS. J. OF H.]

### OVERFEEDING BEES—CHEAP FEEDING BOTTLE.

WATERPROOFING WOOD OR STRAW HIVES.

It appears to me that many persons err on the side of over-feeding, supposing, as is generally done, that a hive ought to weigh 20 lbs. nett at the close of the season. My experience goes to prove that half that weight is amply sufficient. I have always found that those hives that contained only that quantity have invariably done better the succeeding season than those that had been made up to 20 lbs. by feeding, and I find this corroborated by several bee-keepers of my acquaintance.

Some difference of opinion exists as to the kind of bottle to be used when feeding is necessary. I have used an empty glass pickle-jar (such as pickles are usually retailed in) and have always found it answer well; I tie it over with the canvass ladies use for woolwork, which is the most durable of any kind of netting. A piece of perforated zinc is placed over the hole in the crown-board, the bottle inverted upon the zinc and covered with a wooden box, which effectually keeps wet from entering.

I should fancy from your correspondent "A. W.'s" remarks last week that he sometimes finds wet enter his hives. I have for three or four years used the varnish from the recipe I give, which makes either wood or straw perfectly waterproof—viz., half an ounce each of gums—thus: benzoin, and guaiacum, and 2 ozs. shellac dissolved in 8 ozs. of naphtha, and strained after standing a day. It is applied in the same manner as paint, dries perfectly in ten minutes, and, therefore, can be used at any time in the year without injury or annoyance to the bees, and leaves no smell behind. New wood may require two or three coats, and if previously slightly stained will present the appearance of French polish, of which, in fact, it is a species. It has lasted three years with me, quite unprotected, and is yet unimpaired. The quantity given would do a dozen hives or boxes and ought not to cost eighteen pence.—G. F. B., *Colney Hatch*.

### OUR LETTER BOX.

GOLDEN-SPANGLED HAMBURGERS.—"CORRESPONDENT" likes "POOR YORKSHIREMAN," only, he thinks, perhaps, the poor man is like Gil Blas' beggar, quite able to take that which he asks. We fancy the alms were given more for fear of the blinddebt than for the love of the Virgin; and he who descants on "well serrated, firmly fixed comb; white ear-lobes; deep gold hackle, striped down the centre; maroon wing, and distinct bars;" has not much to learn "in re Golden-spangled Hamburgers." We should not like to cast a slur on Yorkshire, her judges, and her breeders. The black breast certainly was a Yorkshire here-y, and it is only of late it has been repudiated. When once upon a time, the best of the Yorkshire judges acted at a show of Hamburgs only, the prize was given to a bird with a purely black breast. It was held at Huddersfield. We think rose ear-lobes will always be fatal to success.

CANARIES IN A ROOM (*Malvern*).—The young birds may be allowed to leave the nest when they like, the old ones will continue to feed them on the boughs or floor. You will find a description of the points in the varieties of Canaries in earlier volumes of this Journal. The series will soon be published in a separate form.—B. P. B.

PREVENTION OF ROTTEN FEATHER IN PIGEONS (*J. S. A.*).—The disease known as "rotten feather" is one of the most troublesome to the fancier. It is more frequent in high-bred birds than in the stronger and more common varieties. It appears to depend on imperfect formation of the feathers. Beyond placing the bird in those circumstances which tend to promote its vigour, we know of no prevention, nor have we ever met with any one who has. Rotten-feathered birds will breed freely, and throw sound-feathered young ones.

KIDS (*N. N.*).—Advertise them as being for sale, describing them and stating price.

\* If the check be severe, it may result in the destruction of all the drone-brood and of every adult drone in the colony.

† By this is meant sugar-candy which is extensively used in Germany for feeding bees.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 58.6° and 36.6° respectively. The greatest heat, 81°, occurred on the 28th in 1840, and 4th, 1833; and the lowest cold, 18°, on the 24th in 1854. During the period 187 days were fine, and on 108 rain fell.

THE CAMELLIA AND ITS CULTURE.—No. 5.

MOISTURE. — Dr. Lindley, in "The Theory and Practice of Horticulture," most emphatically observes that plants should never have more moisture than their system can consume. This is certainly an axiom accepted and practised by all who deserve the name of cultivators; and an infringement of its due observance is fatal in its consequences in proportion to the respective capabilities of the multitudinous race of Flora of withstanding, or succumbing, under a given amount of fatigue. Plants with small wiry roots, such as the Cape Heaths, cannot endure fatigue with impunity; while the Camellia, and many other subjects of like nature, are not materially injured by a moderate amount of excess either way. Such excesses, however, on the part of the cultivator had better not become systematical. The parties in charge must not be "habit and repute" in the abuse of their subjects, else the latter will soon have to undergo hospital treatment—by no means a happy condition for the plants themselves, and an eyecore to every onlooker, not to speak of the mental disquietude experienced by the unfortunate cultivator. It is, therefore, absolutely necessary that one should have in their mind's eye the axiom, "Plants should never have more moisture than they can consume;" and it might be added, they should always have a supply according to their needs.

There is one period in the annual history of the Camellia which deserves to be recorded as the most critical. More failures occur at that particular period than any other throughout the season, judging, at all events, from my own not unattentive observations. Scores of people complain of buds dropping from November to January—in other words, from the time that the buds are properly formed—that is, almost full-sized, until the time they are expected to expand. With impunity, aye, and even with the best results, especially to shy-blooming varieties, you may allow the plants to get what is technically termed bone dry at the root, on a long summer day, when the young wood is pretty well consolidated, and flower-buds expected to be in the course of formation; when such treatment, during the short days of winter, would bring them down like a shower of hail (if the plants were large enough) about your ears.

A moderate state of moistness at the root, and a moderate state of humidity in the atmosphere during the period in question, is what should be aimed at. In fact, to speak in medical language, they should be "kept quiet." How often does one see, especially among the uninitiated, who fire away without ever looking at the thermometer, an almost parched atmosphere occasioned by strong artificial heat, necessitated in turn, in some degree, by probably 20° or more of frost out of doors. Let the plants be ever so well watered at the root, if the atmosphere remain a couple of days (we speak safely) in such-like predicament, the buds, without inquiring into the physiological cause, will drop off in dozens. The work of a season is mis-spent, and the only satisfaction obtained, if the unsuccessful party is inclined to ferret out the cause, is the seeing his or her case replied to in the answers to correspondents. It is almost unnecessary to be more emphatic on this point, but we again reiterate that a strong, dry temperature at that dull season is about the best means possible for getting rid of the flower-buds.

Again: one other fertile source of mischief in connection with moisture, especially to plants that have been liberally repotted the same season, and also to plants that have been planted out into conservatory, or other borders, even though they have been growing there for a series of seasons, is an excess of moisture which the plants by their roots cannot absorb and digest. Hence follow the decomposition and death of the rootlets which the growing season has engendered; and next, as a matter of course, follows the sluggishness of the continuity of the sap, which at this more than any other season gives the system of the plants such a shock of paralysis, so to speak, that they quickly relieve themselves of their buds, and all the while without much apparent debility of the plant itself, as exemplified by its foliage. We happen to know a case in point where a border was thoroughly renovated early in the spring, and the plants luxuriating in the fresh compost to the satisfaction and delight of all concerned who saw them. Buds were formed in thousands, and doing well up to that critical period. The chief of the establishment who expected great things of them, was chagrined beyond measure to see the buds dropping. On giving some of the large plants a shake the buds came down like a shower of Lammis Pears from a heavy-cropped tree in the month of September. On investigating the cause it was found to be an excess of moisture at the roots, and what aggravated the case much more, an incautious and injudicious appliance of manure water at a time when it was not needed. No extra stimulant should be given to these plants until the pot is crammed full of roots. Weak applications once a-month at that time will assist the vigour of the plant, and, consequently, add strength and stability to the blooms when expanded.

Camellias are by no means gross feeders at the root, and although it is necessary to furnish a proper ingredient for the roots to revel in, as has been suggested and disposed of in former chapters, their success as flowering

plants is probably more attributable to strong heat in the growing season, and an atmosphere charged with humidity in proportion to the state of the temperature. It is wisdom in my opinion to shut up the house or houses they are growing in early in the afternoon, and deluge the atmosphere with humidity by means of freely plying the syringe, giving the plants a thorough good bath; while I am sceptical as to the practice of resorting to syringing overhead in the morning, which I have, indeed, abandoned. In the former case experience teaches that if the temperature be high, probably 80° for an hour, falling, we shall say, to a minimum of 55° during night, and the plants in proper health, their systems will greedily absorb the greater portion of extreme humidity which the houses contain. Their bending and flaccid shootlets caused by the extraordinary call upon their vital energies during a hot day's sunshine, will betake themselves to an erect position, and their whole system will be re-invigorated; whereas, if their thirst is not properly quenched, there is not, and cannot be, the same amount of success. On the other hand, it is malpractice to ply the syringe overhead in the morning when the plants by their leaves are evaporating instead of absorbing moisture, and one only defeats the end they have in view by following up such-like method. The careful observer who may not have the slightest smack of vegetable physiology, knows well that where drops, or blotches as they turn out to be afterwards, of moisture remain on the leaves during the day, and perchance the direct rays of the meridian sun come in contact therewith, it is certain destruction not only to the epidermis on the upper surface, but to the entire part of the leaf or leaves so exposed. In fact they are so susceptible of injury while making their young wood even under the best treatment that they require at that period more especially, quite as close shading as a house of Orchids.

The successful cultivator has, however, occasionally to resort to what might be called negative means to bring about uniform fortuitous results. The constitutions of the different varieties of the same species often require slight modifications of the usual routine. The truth is that practical gardeners ought to know, and very often do know quite as much about the system of the plant as the doctor about the system of his patient. That is why I argue that gardening is quite as much entitled to be called a science as doctoring. Those high-up in dealing with the matter in a scientific point of view, botanical and physiological, set it down as such *simpliciter*; but looking upon us low down and our humble capacity, are slow to elevate our practice and the method we have in going about it above an art.

It does not require a very lengthened experience to see that a Black Hamburgh Vine and Canon Hall Muscat will not set fruit equally well under similar circumstances. The former will scarcely refuse to set in a house kept considerably above the ordinary degree of moistness; while the latter, speaking in general terms, will scarcely fructify to the cultivator's mind in a very dry house where we would suppose the pollen would of its own accord scatter like dust in a hot summer day. Again, take another example at a different stage of maturity—one of the most delicious Grapes in cultivation, possessing a vigorous habit, a strong tendency to fruit freely, a handsome bunch, and large individual berry, immediately it begins to change colour, if there is anything like moisture in the house, looking at the interpretation of the term in the gardener's mind, almost every berry will crack, and bunches become unsightly and unfit to be placed upon any nobleman's or gentleman's table; while most other Grapes, in like circumstances, are unaffected in this respect and may be all that can be desired as examples of cultivation. I need scarcely say I refer to Chasselas Musqué. One might multiply instances of this description like anomalies *ad infinitum*. I was only endeavouring to fortify Flora's position in referring to compæx examples of Pomona. All these wayward subjects such as Mathotiana, Mrs. Abby Wilder, Regea, Centifolia alba, Rubini, and some others, must receive somewhat diverse treatment from the general stock in order to induce formation of flower-buds. As soon as the cultivator finds the wood pretty well elongated, and the leaves assuming somewhat their natural size, it is judicious to withhold moisture both in the atmosphere and at the root, or they will form little else but wood-buds. A very good proof of the wisdom of this practice is to be observed in flower-buds forming in scanty numbers; they only appear on the weakest shoots of plants treated after the usual method, which is a tolerably patent proof that such-like varieties elect to grow wood-buds in preference to flower-buds, and, therefore, show good-enough cause why they ought to be subjected to a

low diet. Indeed it is not a bad plan to allow the whole plantation of them at this period to remain on the dry order for two or three weeks. Any one may do so without the slightest compunction, taking care once the buds are properly formed to see that the balls are uniformly moistened.

Liquid manure water, guano water, and nitrate of soda diluted have each their supporters, and I am in no wise inclined to be churlish with other people for adopting them; but I may state that unless to large-plants that have been growing in from 12-inch pots to 30-inch tubs, and have remained in such for two or three years, we have never applied such stimulants with very good effect. If the physical condition of the soil be such as we have endeavoured to press upon the reader, the drainage perfect, the resting, growing, and checking of the plants all attended to at the proper time, there is little, very little to fear in the shape of abundance and quality of bloom, which is the great desideratum. Remember that I do not wage a war of extermination against stimulants. By no means. If plants remain in small pots quite full of roots, then stimulants must be applied to keep up the system. I only contend for a moderate supply of pot-room so long as the plants are small or medium-sized and in portable-sized pots in preference to a small modicum of soil support, and an absolute necessity for liquid appliances.

The Camellia is a plant, which if allowed to become filthy—that is, if its leaves are not syringed and occasionally sponged like a child's head in the same predicament, is liable to vermin. The brown scale is its worst enemy, and may occasionally be found in well-managed collections. Such collections, of course, are always adding to their stock, and although these incomers are subjected to a rigorous process of ocular investigation there may be larvæ of that insect on some of the plants. It is very easily kept down by periodical washings of Gishurst Compound, or even soft soap. A couple of ounces to the gallon make a capital safe ingredient of either of them, and plants so affected washed three times in so many weeks will be perfectly clean. Some of your readers know the Scotch maxim, "a steek in time saves nine," which is probably not so offensive to the generality of your readers as the very expressive one quoted by the Chancellor of the Exchequer in his Budget speech as to require interpretation. A few minutes' attention to keeping down vermin infesting plants at the proper time may save days of labour and anxiety months afterwards.—JAS. ANDERSON, *Meadow Bank, Uddingstone.*

#### A YARN OUT OF A WEE PICKLE TOW.

I HAD a private letter the other day from a first-rate grower of plants, a good practical botanist, and a great reader. What he chiefly wanted to know was, how to set about writing his notions for publications, knowing that his secret was as sure as the name of his lady love in my keeping. There may be a thousand like him at this moment, wishing to be useful to others, and at the same time improving themselves, and probably laying the surest foundation for future fame and fortune: therefore, it struck me that by merely begging your pardon for another broom-handle article so soon, at such a busy season, I could just tell the thousand what I had written to him, and show him and them, at the same time, how to begin, and how to find a ready-made subject to write about, at any season of the year, by merely writing a review of the last Number of this Journal; and as it comes in weekly, a man need never be at a loss for a subject to write about, or make a broom-handle article, while so much is before him to choose from. I wrote as follows:—

His first plan should be to write under a different name; to keep a copy of your manuscript, and to compare it with the printed article; to avoid mannerism as he would the evil spirit—that is, not to write two articles just alike in words and sentences, for fear of getting into one style, or one manner of writing only; to write exactly as if he were writing to private friends of very different dispositions, which, as he meant to please them all, would compel him to a change of style, and keep him from all ideas of nervousness, which is entirely ruinous to young writers. That exercise would soon show him if he wanted or where he wanted touching up, and no one could be the wiser.

Then, to begin a review of the last Number of this Journal, as an example to young beginners I must do as usual—keep to fair argument and straightforward criticism, and neither spare myself nor blame others if I can at all help it.

The first article is on CYCLAMENS, by "J. A. P.," a gentleman who has shown more practical knowledge of the Italian species

than all the botanical authors who wrote about them for the last sixty years, save Tenore alone. His is the best and most reliable account of *vernum* and *europæum* in all our books, and no doubt but he is as well at home on the *Cyclamens* of Naples and central Italy, and on the Calabrian species, the true Ivy-leaved kind. One of the most singular coincidences I ever met with, is the exact form of tale and language by "J. A. P.," and the descriptions that were given to me of his Swiss and Italian rambles by Mr. Atkins himself, the great cross-breeder of the family. But no gardener or botanist, as far as I know, was aware till this season that the *Cyclamens* assumed such different forms in the wild state; and no author, except Sweet, had ever noticed the spur, and he knew it only on *vernum*. My *vernum* was in ill health for five years before I had it: the first time it flowered with me was in March, and the flowers then and the following year were much deeper in colour than they have been since they took to flowering at the end of October. The reason why my *vernum* flowers so early is, that it is planted out in a pit, where it has been kept warmer and more confined in order to bring it round from a long course of illness. I was not aware that I was wrong on the family crest—that spur, till early this season, when I received a true *europæum* with the crest on, from the gentleman who dug it up twelve miles beyond Genoa. Ignorance is never a fault, only a misfortune, and my misfortune in this heraldry is now its own reward; and we are, certainly, all of us much indebted to "J. A. P." for his very lucid and practical account of the family. He also confirms the view which this Journal has held from the beginning, on the system of drying these half-bulb sort of roots. It is the hard drying which keeps them down so much, as, if they were not so dried, no one would ever see the end of one of them. Any kind of *Cyclamen* would see out two generations at least, if people would cease from roasting them alive, as the practice is in many places.

The reason why I take *vernum* to be a cross-seedling is, that no one has ever yet assigned it a native locality. I look upon *sibiricum* in the same light as *vernum*, another cross without a home. Mr. Atkins has changed our old notions of species in this family so completely, that unless we are sure and certain to the contrary, any new or old addition that may be made to this section of *Cyclamens* may safely be referred to intermixtures from foreign pollen. True *vernums* and true *sibiricums* might very probably be now picked out of seedlings of *Atkinsii* in the Wellington Road Nursery, where this race varies as much as *Calceolarias*. The fact that a plant will come true from seeds is not the least confirmation of its being a distinct species, for the merest accidental garden variety often does the like, even among annual plants. What we were all so much in ignorance about was the extreme range of the variation the leaves of *Cyclamens* assumed in different localities. None but those of neapolitanum were hitherto known in cultivation to vary much; but now we know, thanks to "J. A. P.," that *europæum* varies even more than we know of in neapolitanum; and no doubt the *vernum*, on travelling as far north as Naples, assumes forms of leaf very different from what is or may be seen in the middle and extreme point of Calabria; and it may also prefer a lower elevation at the northern limits, and possibly to come near enough to the coast as to warrant the name *littorale* to one of the forms of it there; or a fresh-water botanist might be excused for calling some form of *europæum* by that name, if he found it near the Lake of Como—*littorale* meaning a shore plant. The *Cyclamen* figured by Dr. Sibthorp in his "Flora Græca," looks very much like Mr. Holland's evergreen *Cyclamen*, as far as I recollect, and now there can be no doubt about that being one of the forms of *europæum*. It has the exact fragrance of the best known variety of *europæum*.

The next article in the last Number is my own on the *Azalea* Show, and I ought to be pulled over the coals for writing it so carelessly. Here, then, is a lesson for young writers. Look here, "critics who must take their ideas from assemblages of flowering plants at London shows, because they can see no others, are sure guides to direct in the way of selections." They cannot possibly be any such thing, but "they cannot help it;" therefore what I ought to have said was that they "are not sure guides." Then there is Dr. Martius, the great demonstrator of Brazilian botany, down as Dr. Martens.

And what is the use of hammering at all if you are hitting the wrong nail even in seven times, as I did there with two most beautiful variegated plants which I meant to praise skyhigh, and yet never even told they were as much as variegated?

"There was a fine specimen of *Hymenocallis fulva* in two collections, that of Mr. Salter, and in one of Messrs. Smith's groups." *Hymenocallis fulva*—why, that is the common shrubby border yellowish flower called Day Lily. Of course it is; but in my notes there was a high-sounding name to one of the plants which put me out so as to forget myself, and what I was going to say. Both were most beautiful specimens of the finest hardy-variegated plant there, after *Symphytum asperimur variegatum*. If this *Hymenocallis* (not *calis* as one had it) keeps as slick and slim as both were that day all through the summer, no one can hammer the plant too much on the nail.

The third article is on florists' flowers, a review of itself; and the only thing I could touch up in it with a clear conscience is Mr. William Paul's new H.P. Rose, the Beauty of Waltham, a splendid grower. I saw the plant last autumn at the Floral Committee, and I should say it beats both its parents, the Margottin Rose and the Général Jacqueminot. I was also pleased to read that the author and the writer came so near as a toucher on the merits of the new Auricula Mrs. Fyles, so you see I can do a little of floristry in a quiet way. Then as to the new *Verbena* from Outton Park, they are sure to be right; for Mr. Wills was a contributor to the Experimental Garden. The burning of the Vines in the next article was a sad misfortune, for which we must all sympathise. In such another case, or one like it by frost, the plants should not be cut until new shoots are made, and then to be cut back to a promising shoot.

I pass the next two articles and come to "*Cerastium Biebersteinii*," and I think it is at Kew, and that I had a hunt after it there last spring, and, if so, there was then only one plant of it; but we must not rest till we get to the bottom of it, and many thanks to "NICKERBOR" for the contribution.

"Packing Cut Flowers" is the next article, and I can vouch for it being one of the very best plans, for it is identical with that I saw at Stafford House by Mr. Fleming, of Trentham; and if I had not had a regular go-in the boxes and my packers in routine on that plan, I should certainly have taken to the crossed strings just as "P." put them down in that box.

The Vines eaten by mice in the next article was another sad loss, and the "Caution" is good. There is another way of getting rid of them, and of rats, cats, and dogs. Take a piece of liver, cut it in the form of dice into small bits; prick one side of the dice, and inoculate the slit with a drop of strychnine; and for a rat take the inoculated bit on the point of a skewer, dip it in the frying pan after something good, and cast off the bit in the run of the rats with the point of a knife, so that the rat may not smell a foe, and the thing takes like a fly-hook after a rainy day; and either of the animals will take to his heels immediately for his home as fast and as far as they will carry him, but down he goes ere he reaches the place, unless it is high at hand.

It is always gratifying to hear of such confidence and such a rise in a fellow-labourer as is recorded of Mr. Spencer in the next chapter; and in the next it is not at all surprising to see Mr. Beaton saddled with the crupper the wrong way. He deserves it all; for if he never spoke of Miller's Pink Horseshoe Geranium, he did his crimson; and what is the difference? For if the plant was in "extinction" itself, who ought to bear the blame more mildly than he?

Orchid-pods come next; but, O Teacher! you never told us how you did it—how you crossed, or how you sowed or reaped the goodly harvest I often registered in your name and mine; but I have been at it and know all about it, yet even now I hesitate to take the cheese off another man's crust, and shall only say my plan is the second best. Get the seed-pod of an Orchid emptied on a piece of smooth paper, the seeds being as small as the dust in the sunbeam. Take a very clean No. 32-pot, and put a No. 60-pot upside down over the hole at the bottom, and put a piece 2 inches square of ragged turf of fibry peat over the hole of No. 60. Then take four pieces of rough cracked charcoal 3 inches or 4 inches long, and half that in width and thickness, place them on their ends against the sides of the big pot at equal distances, put your finger on the bottom hole outside, and fill the pot with water, holding the pot in the left hand. Now sow the seeds on the water, and breathe against it till the whole surface is equally dusted. Then begin to let off the water from under your finger by the bottom hole very, very gradually. As the water subsides in the pot the seeds will stick to the sides of the pots, the peat, and the charcoal, just like so much of a tide-mark. When the water is all off place the pot in a saucer of water with an inch deep of water in it, and hold it to that

point till your seedlings are safely on the wing, put two twigs across the mouth of the pot, and put a square of glass over the twigs, so as to have a space for air all round the thickness of the twigs. Put the pot where it will not get more dry at the sides than it is now, and where the heat is at Calcutta point, and if ninety-nine out of every hundred of the seeds will not vegetate and that very soon, why, the pollen has not given them the germ of life. I brought a thousand Orchids into this world just that way; but, truth to say, they all of them found the means of getting out of the world by a route I never could fathom. So, as I have just said, my plan is only second best after all.

And then we have "A few Days in Ireland, No. 20," and it is always twenty to one if ever you can catch that man turning a corner. He will be an Irishman as sure as Paddy O'Reardan before it is all done, or else he wants to get all the goodness out of them for this side of the channel and make them believe all the time his aim is just the other way. But I should like to have seen some of the sights! Captain Whitty, however, from the inspection of prisons in Dublin, called on me last week, and told me all the Irish news in a lump, and the best part of the whole story was the continued success of his good lady with the Waltonian Case; and if Mr. Fish knows a gardener in all Ireland who would venture a risk of propagation against that lady and the Waltonian, I should like the name to book for the Derby.

Then another first-rate article on "Florists' Flowers" succeeds. I always thought there was a wheel within a wheel in managing Carnations, and there they are sure enough, no less than five of them besides the guard wheel, and now I can see what I could not for a length of time—the real and substantial difference between a Carnation and a Pink of the present fashion. I recollect mistaking the one for the other seven years back, at a show in the Regent's Park. So one can live and learn to the last.

Then those beautiful architectural terraces and balustrades and pyramidal Scarlet Geraniums. How exquisitely beautifully they have been delineated! That is the place and style for Nose-gays, and the right school for young artists. But how they make one's teeth to water from the reading of Mr. Fortune's run to Yeddo and back again before the arrival of the ambassadors from the Emperor of Japan, in the accounts from Mr. Standish's nurseries at Bagshot. But have you seen *Prunus trilobus* from a former trip, by Mr. Fortune? if not, it is the prettiest thing you ever saw. Just like a true cross between two pink Pompons—say Madame Rousselon on the one part, and the best pink you know on the other part, and the flowers of that *Prunus* are better still, and come with the leaves early enough without forcing. And did you book that beautiful new "summer bedding plant," from the "Botanical Magazine," I mean that very rich crimson orange composite called *Clomencocoma montana*? We must have it out and see to it. Nothing in that way should ever slip between the fingers for want of trying.

Then the "Weather," just such as it is, and then to end in wool, flax, and cork, is nothing more than another form of hot-beds, with blankets, sheets, and cork bottoms; but the things tell as well in the newer style, and some of you ought to try them certainly, and some may wish I was there too, but how could I, seeing I had a thousand young ideas on my hands, and had to demonstrate how easy a thing it is to spin a yarn out of "A wee pickle tow?"

D. BEATON.

### DISA GRANDIFLORA.

In the answers to correspondents in the last Journal there is a mistake as to the seeding of this plant, which I would take this opportunity of correcting. It has seeded under Mr. Eyles' care; and he told me the other day at South Kensington that he had a number of seedling plants, besides about sixty which he had made out of the plant presented by Mr. Leach to the Royal Horticultural Society; in fact, there is no plant that I know that is likely to become more generally grown after a few years than it is, provided people attend to the very plain rules laid down by Mr. Leach for its culture. But what is one to say when people are so wrongheaded as they will be at times? I was some time since showing to a very eminent plantman the beautiful drawing of it made by Mr. Andrews for the *Floral Magazine*, when he said, "Ah! By-the-by I don't believe all that is said about that plant being easy to grow." "Don't you?" was my reply; "have you got it?" "Yes—two little weakly plants." The plants were brought, and poor enough they looked. "What was your treatment?" "Oh, I have kept

them tolerably dry during the winter in the stove." All I could say was, "I wonder you have them at all." Had he kept them in a cool house from which the frost was excluded, and standing in water, he would have had nice healthy plants by this time.

A short time ago I was again the guest of my friend Mr. Leach, and saw all his plants in their fullest vigour. They had been kept moist, and were throwing up offsets in all directions; while the main stems were stout and saucy-looking, as if they intended to bear a large head of bloom. One pot he had kept in an intermediate-house all the winter, but it was not in as good condition as the others, and not a bit more forward, clearly showing that the cool house is the proper place for them. I have kept the small plant which Mr. Leach so kindly gave me in a pot standing in a saucer of water, and it is growing away fast.

There is one peculiarity about it which I do not remember to have seen noticed. Just at the base of the main stem there is now a small shoot or offset, which remains very much the same size for some considerable time; but when the main stem begins to decay this offset begins to increase, and when the head of the family has done its work this one is ready to take its place. The bump of philoprogenitiveness is very strongly developed in *Disa*, for no sooner is an offset potted off and started for growth, than it begins to increase also. And as ere long Mr. Eyles' plants will be distributed amongst the Fellows I presume, and Mr. Veitch must be getting into a stock of it from those he obtained from Mr. Leach, it will ere long be generally grown; and notwithstanding the sneer with which the idea was received by a classical contemporary—that it would some day be seen growing out of doors, on the margin of pools, &c., I have sanguine hopes of seeing it ere many years realised.—D. Deal.

### MANETTI STOCK AND MANETTI ROSES.

I HAVE no desire that my name should ever appear in print, or that my rosetry or Roses should ever be mentioned, except for public instruction. I sign my name at full length for one only reason—viz., that the public may have the opportunity of seeing the truth of what I say. I have no predilections or prejudices whatever—they are beneath an educated mind. No man can be called prejudiced that bends to his circumstances, whether those circumstances relate to fortune, locality, or soil. I can truly say that I never had, in any article that I have written, any other object than the public good. I have no secrets; and I believe that "the liberal deviseth liberal things, and that by liberal things he shall stand." I was amused and gratified by a letter that I received some years ago from a gardener, living with a lady of title in the Isle of Wight, who paid me the great compliment of saying, "I wish all people were like you, who tell us what will do us good. People are got so selfish, that if they know anything (say about Cinerarias) that will do us good, they will only tell us enough to do mischief." Let me endeavour to wipe off this foul blot from the escutcheon of florists, and say a few things relating to Manetti and Manetti Roses, which may do good. I must always suppose that this is admitted—that unless people mean to cultivate Roses in "earnest," they had better, for "satisfaction," have nothing to do with them, especially if Nature is not likely to supply that which Art refuses.

1. *The Introduction of the Manetti Stock.*—This stock was sent many years ago to Mr. Rivers in a parcel directed to Messrs. Longmans & Co. It was a solitary stalk. "How great a matter does a little fire kindle!" Mr. Rivers has made a fortune out of it. Mr. Cranston says he cannot propagate it fast enough to supply his customers, who prefer it; and I suppose that Mr. Francis has done himself some good by it. I do not propose here to praise this stock, or prefer it above others. My predilections for it are well known, and arise from my soil. To the question often proposed to me, "Which is the best stock for me?" I can return no answer, till I know the circumstances of the querist. Till these are known, the question to me is like the mouths of the Ganges, "lost in marshes!" I propose, in the following observations, simply to give a few hints as to the management of Manetti Roses. I know how the stock should be raised, how propagation by grafting should be done, how it should be planted for budding; but, as I learnt these from the "trade," I should not think it right, without asking permission, to inform the readers of this article. I bud but very few Manetti stocks myself. One thing is certain, that the stock cannot be budded well without going down "all fours." I buy

Manetti Roses and bud Briars because I do not like going down "all fours."

2. *Soil*.—Manetti Roses will grow and bloom well in any soil—sand, chalk, or clay. They grow more rank in stiff soil than in any other. This is the objection to them; but, they have this advantage—viz., that they will do well in soil where it would not be expedient to grow Briar Roses.

3. *Planting*.—This is always the basis of successful arboriculture. If the land is stiff, cold, and wet, when you receive the plants, you will gain by planting them in clumps as tied up, and putting them out at the spring. If the soil is healthy, they may be planted at once. Those that are huddled high—say 8 inches, should not be planted to the full depth, but 4 inches, and earthed-up the other 6 inches—that is, 2 inches over the collar, like Potatoes. The stock may be exposed in winter, but it should never be exposed in summer. The greater part of mine when first received were budded too high; but, being thus planted, have always done well. I tie all my plants to a stick; the small ones are tied to a spar. They should not be cut when planted. Budders are now beginning to bud lower—close upon the roots. These may be planted on the "flat."

4. *Replanting*.—When Manetti Roses run to blind wood, they should be either root-pruned or removed. Auguste Mîc is given to this: hence I cut but little wood, even useless wood, out of it. Where ground is strong and first-class, annual removal and root-pruning "may" be advantageous. As I have no such ground, I cannot give a certain opinion. It is a rule with me, when a plant does well to leave it alone. Manetti Roses may be removed with care, without injury, when in foliage and bud. Two out of the treble Angleterres, cut for Kensington in September, were cut from two-year-old stout plants, removed from the upper to the lower part of my garden with their balls of earth on, and kept watered as to foliage for a day or two. This removal took place in the beginning of August. The blooms were fine, some of them being over 4 inches in diameter. I removed some plants of Manetti Roses (31), from Blandford here on the 24th of May, last year. They had their foliage on. The plants had suffered from the winter, but they became fine plants by the latter part of the year, and one (Cambacères), threw up for Blandford Exhibition as fine a bloom and truss as I ever saw. I gave 7d. each for the plants. They were all shielded after planting from the sun. They soon "took," all did well, and all look well now.

5. *Manuring*.—The ground should be well trenched and manured before planted; and, as the trees bear, so should they be manured. Feeding cattle and feeding trees are both matters of "judgment." Half-inch bones; new maiden earth; black highly-decayed manure, made from horses and pigs; nitro-phosphate; guano; liquid manure; wood-ashes; occasionally a little salt; soot; and strong-beer grounds are what I use. This latter I put on for gala days, when the bloom is nearly full for expansion. It must be greatly diluted by about nine times the quantity of water. My twenty-four trebles at Kensington in September had had a potation of this. I use also, besides the above, stale twenty-years-old "humanioribus," which looks like Hardham's thirty-seven snuff.

6. *Watering*.—We have lately needed but little advice on this subject. For the last two years it has rained like the Atlantic Ocean coming through a sieve. Manetti Roses do not want so much watering as Briar Roses; but, when they are watered, sufficient should be put on to touch all the points of the roots. This, with many hundreds of Roses in a torrid summer, is a serious affair. I plant the Roses in trenches with all their roots one way, so as to know where to place the water with more economy. Manetti roots, however, run on all sides.

7. *Suckers*.—These should be cut off close to the stock whenever they appear. I am never, except in the case of weak pot plants, ever troubled with them, owing to careful planting in the first place. Briar Roses, summer and autumnal, as well as Briar stocks, are very troublesome; in strong ground, no doubt, less of these will appear. I would advise Manetti Rose-planters, when they plant the Rose in light soil, to tread the ground very firm on the radicles of the roots and close up to the stock: the exclusion of air would stop suckers, which, it is possible, in very light land might prevail till the tree has completed an adequate volume of wood.

8. *Plants Cut Hard by Winter*.—When this occurs, or when you cut down a bush to the stumps, you must be careful, when you cut into the quick, to seal with Robinson's liquid glue, rubbing on also a little dirt. I also use a cerate made of oil, soap,

and Burgundy pitch, or cobbler's wax. As the ground is usually, after a wet winter, very cold, in order to quicken the roots I move the ground with Parkes' fork deeply in the baulks on which the plants stand, and also between the rows where I walk. That has been done to-day (April 8th), to supply health to the ground which this wet March has denied to me. I never know ground more unhealthy. The plants are very healthy.

9. *Mildews*.—There are three kinds of mildew—white, orange, and black—which affect Roses. If you should overlook any of them till the foliage is hopelessly spoilt, take up the plant and shake it out, and put it back again. This will stop for awhile the flow of sap, which, having no lungs to go to, will be confined to the wood, and spoil it for next year. Highly-mildewed trees, unless their wood is ripe previously, have a salmon mark in the pith of the wood, and cut soft as a Turnip at the enaung spring. It cannot be denied that Manetti Roses, as a class, are more subject to white mildew than Briar Roses, and that the higher you cultivate the more you will be subject to it. This arises from the succulence and quick growth of Manetti plants, and also of very highly cultivated Briar Roses. I tried last year with complete success, after sulphur failures, 2 ozs. of pounded vitriol dissolved in a stable-bucket of water, and poured from a watering-pot with a fine spout over the foliage. The trees are perfectly healthy now. The plants were some on Briars and some on Manetti. When foliage is very young and tender in the spring a weaker solution would be advisable. I have only tried it on hard-leaved plants. Sulphur is not a sure remedy.

I cannot conclude without dispelling a few errors as regards my soil and situation. My home garden is exposed to the furious assaults of the south-west wind, which has just knocked down 39 feet of my garden wall in defiance of two buttresses. The land in this garden is dry brown land wanting in aluminum. My other garden faces the north-east, and is dry black soil mingled with and resting upon gravel. This also wants aluminum. It is the better soil of the two, and the British Queen revels in it. Still Mr. Worthington, when here, observed, this soil is too deficient in clay for Roses. In winter the situation is very severe. No doubt some of the Manetti Roses have Rose roots; but I have examined two trees—a ten-year-old fine Duchess of Norfolk, and a four-year-old Inermis, and they have no other roots than the Manetti.

I hope and believe that my Roses will tell their own tale on the 11th of June at Kensington. High cultivation, universal attention, and a knowledge of the peculiar habits of each Rose plant, are the keys of success. I believe that I could grow them on the tops of the hills equally well.—W. F. RADCLIFFE.

## INTERIOR ARRANGEMENT OF A GREENHOUSE.

I HAVE a greenhouse erecting, span-roofed, against a south wall, 19 feet by 10 feet, 7 feet to the spring of the roof, and 10 feet 7 inches from the ground to the ridge. Will you advise how to plan it inside for plants and fruit trees, so as to make most use of the room and the blank wall against which the house stands?—H. A. W., *Enfield*.

[For making the most of such a span-house we would have a tree or two against the end of the house, a walk in the middle, and a border on each side for plants. In the case of a lean-to, facing the south, we would cover the north wall with fruit trees, have a walk a couple of feet from it, and a border in front either for plants in pots or turned out, and to be root-pruned when required. You could do little with the end or back of the house in either of these cases if you had a stand, and if you had you would have more trouble with fruit trees and Roses. Your house would, however, be properly a fruit-house instead of a greenhouse.]

THE BIRMINGHAM AND MIDLAND ROSE SHOW.—The Committee met on the 3rd inst., in the Committee-room of the Town Hall. The first business was to fix the time for holding the meeting. Tuesday and Wednesday, the 1st and 2nd July, were the days determined upon after some discussion, being as near as possible midway between the show of the Royal Horticultural Society, and the one at the Crystal Palace. The prize list was next considered, the premiums it was finally determined to offer amounting to £84 10s. The schedule, together with the regulations for the display both of Roses and of horticultural imple-

ments and garden ornaments, will be issued in a short time. The project is exciting great interest, and will, there is every reason to anticipate, prove a decided success.

### BORONIA SERRULATA CULTURE.

I SHALL feel obliged by your acquainting your readers and myself with the secret of the management of *Boronia serrulata*. My gardener cannot keep it alive, and I have heard the same complaint from others. It is intrinsically a very pretty flower, but to me it has peculiar charms, because it is common all round a city where I spent many years of my life—Sydney.

It is called by Australians "the Native Rose," and about Christmas time, when it is abundant in the Bush, great quantities are gathered for ornamental purposes. Its strong and peculiar odour perfumes the whole house.—AUSTRALIAN.

[You do not say one word too much in favour of this peculiarly-scented plant. It often fails because we cannot give it the keen sunlight it obtains in its native home in the Bush. It will not, therefore, stand the same amount of cold with us in winter as it will do near Sydney, because with all our care in our dripping, cloudy climate we cannot get it both to grow and to ripen its growth as well as it does in its native country, and all plants cultivated in pots require more attention than when growing in the open soil, with all circumstances favourable. Passing everything about propagating, we will just instance a few of the matters necessary for successful culture, merely premising that you have a small, bushy plant to begin with that ere long will require more pot-room.

The first thing, then, with those not having much practice, is to secure a pot just a single size larger, perfectly clean, and which if new has been soaked in water, and dried again before using. Nearly a quarter of such a pot should be filled with drainage, the larger below, and fine-washed grit on the surface. The compost should be chiefly the best fibry peat, and in proportion to the size of the plant and shift. It should consist chiefly of pieces from the size of a Pea to that of small Mazagan Beans. About half the quantity of peat may consist of equal portions of broken charcoal, broken pots, sifted so as to exclude all dust, and the best silver sand. Such a compost even when pressed tight will allow the water to pass freely, so that drainage is continued from top to bottom, the least stagnant water being ruinous. In the spring of the year, when it is desirable the plants should grow freely, a little dressing of old, sweet cowdung rubbed fine will be acceptable. In finishing potting with such roughish material it is advisable to cover the surface half an inch or so with the finer soil, so as to prevent the air entering too freely and drying up the fibres. In all cases it is advisable not to over-pot. In weak or decaying plants turning the roots carefully out of the old soil, putting them in compost more sandy than the above, and keeping the plants warm and rather close, are the best means for restoring them.

Established plants should be repotted if they need it, after the bloom is gone, the faded bloom cut back, and the plant pruned back considerably (keeping in mind that the bloom this season is produced on the points of the young wood formed and ripened the previous year). The potting should not take place until fresh growth is taking place—say when the young shoots are an inch or two in length. After nipping the flowers off and pruning, the plant should stand in an airy place for eight days, then be removed to a closer and warmer one, be kept there after potting, and only be moved to an opener place, but seldom out of doors, when it is desirable to harden the young shoots—say in the end of July and August.

*Position and Temperature.*—Unless then when commencing to grow, and for a short time after potting, the plants must have little or no shading. All the sun, when able to bear it, that the shoots can obtain the better will they stand the dulness and colds of winter. When the shoots are getting long enough, the plant should stand close to the glass in a greenhouse, or in a cold pit, with air front and back, if necessary, but so as to get the full force of the sun; and the roots under such circumstances had better be protected by setting the pot inside of a larger one. Such plants will in five days stand a sun heat with air on of from 70° to 80°, and rejoice in it.

By the middle of September the plant should be transferred to its winter quarters, where it will get all the sunlight possible and plenty of air, so long as out of doors it ranges about 40°, and is not too foggy. In December, November, and the first

part of January, the plant should only rarely be under 45°, because unless in extraordinary seasons the wood will not be so firm as in Australia. From the middle of January to March the plants may have an increase of 5° and 10° of rise from sunshine. When in bloom ordinary attention will be sufficient. When done flowering proceed as already detailed to get fresh growth and ripen that growth.

*Watering* must be done carefully, or all the above will be labour thrown away. Properly speaking, the plant should never be very dry nor very wet. The compost and the drainage must guard against the latter, and the pot must be frequently lifted and rapped with the knuckles to make sure the plant is not dry. A waterer who slips his work and keeps the surface moist for an inch or so and allows the ball to get dry in the centre will soon have the plant sickly or dead. On the other hand, with such careful attention as hinted at above there will be a reward for all the labour. The plant looks best when bushy and grown so as to form nearly three parts of a circle. When fully established and regularly pruned it will stand the knife pretty well. The young shoots if numerous will frequently need thinning. In old plants it is best to nip off the old flowers and not cut back much, and then the young growth being short is easier ripened for blooming the following season. Even in young plants a growth of 3 inches or 4 inches is more easily ripened than a shoot of double the length. The water must be pure and soft—exposed rain water if possible. Manure water should never be given unless a little of a weak and cool nature, such as old cowdung, just when knotting for bloom, and again when making new wood.—R. FISH.]

### IDENTIFICATION OF PLANTS.

You will greatly oblige *A City Merchant*, if in the notice "To Correspondents," in your valuable work you say what the *Bois de rat* plant is, from the Island of Bourbon; also, what is the *Yampa*, which is said to be a root in common use and largely consumed as an article of food by the Snake Indians along the Rocky Mountains; also, what is the *Kooyah*, or Tobacco Root, another edible root much used by the Indians in the same country; and what is the *Mansanita*, or chocolate-coloured shrub of Fremont's exploring expedition in the Oregon country, which he says is an evergreen about the size of an Apple tree, with bark as smooth as glass, and bearing clusters of berries in the autumn which are edible.

[The *Bois de rat* is so called from the fruit of the shrub being grateful to rats and mice. It is the *Myonima obovata* of botanists, and the generic name from *mys*, a rat, and *onemi*, to delight, refers to the fact we have stated. *Kooyah*, or Tobacco Root, as stated by Dr. Hogg in his "Vegetable Kingdom," is the root of *Lewisia rediviva*, native of the west of the Rocky Mountains, and gathered in great quantities by the Indians, who value it highly for its nutritive qualities. It is boiled and eaten as arrowroot, and is well calculated to be a provision for long journeys, 2 ozs. or 3 ozs. being enough for a man even when undergoing great fatigue. It is called Tobacco Root, because it smells like Tobacco when cooked.

Of the *Yampa* and *Mansanita* we have no account, and shall be obliged by any of our readers sending us relative information.—EDS. J. OF H.]

### CLASSING VINES IN VINERIES—AMOUNT OF CROP PERMISSIBLE.

I HAVE three vinerias at this place under my care, the Vines planted by my predecessor in the spring of 1860, and have made very good wood. The first season I cut them down to the wall-plate, this season I left them one-third of the rafters on account of their strength. They are showing fruit nicely in the first house. How many bunches would you leave on for first crop? and would you let a bunch remain on the leading shoots, as they are showing very well on them? They are planted inside of the house and allowed to root out under arches. I am afraid as they are planted they will not answer. In the first house are planted, 2 Golden Hamburgs, 1 Pope's Hamburg, 1 Bowood Muscat, 1 Charlesworth Tokay, 1 Muscat Hamburg, and 1 Black Hamburg. Second house—6 Muscat of Alexandria, 1 Canon Hall. Third house—1 Lady Downe's, 2 West's St. Peter's, 2 Black Barbarossas, 1 Grizzly Frontignan, 1 Bowood Muscat. I am

afraid the present arrangement will not answer, and how would you alter them?—R. J., *Ireland*.

[We do not see much the matter with the plauting. In the first house the Muscat might be in the warmest place, and would yield Muscats before the second came in. We allude to the Bowood. The Muscat Hamburg would come in with the other. The second house could not be better; and the third house will hang a long time after the Grapes are ripe. We would limit the bunches to about four to a Vine, if the bunches are fine; and if enough equally good can be obtained, we would not leave a bunch on the leading shoot. However, if very strong, a bunch will not hurt it much. You might take the double of the above, as we have often done, but never without regretting it afterwards.]

### CONSTRUCTION OF A GAS-HEATED MELON PIT.

A *Subscriber* inquires whether a Melon-pit would be successful if constructed as follows:—1, A strong ashlar wall, 12 inches thick, all round, such as frost could not penetrate; 2, The inside of pit to be level with the ground; 3, To be 21 feet long, seven lights, at 3 feet each; 4, Lights to be each 7 feet long; 5, 5 feet high at the back, 2 feet 6 inches at front; 6, A stove in one corner, partitioned-off from the soil in the pit by brick-work; 7, A tile pipe to lead from stove across the pit, through the soil, and return to the open air to get rid of vitiated air from stove; 8, Inside this tile pipe (the joints of which not to be hermetically sealed) the pipe from stove to run, thus conducting the heat all round; 9, Stove-heat to be from gas, giving thus an even steady heat; 10, A stone path behind the pit to stand on to work the lights.

[Everything will depend on the setting of the stove, and the pipe that takes the heat. If your return earthenware pipe, enclosing the close pipe from stove is lower considerably than the stove we have no faith in your proposed system answering. We question whether you would not require a quick ascent instead of a long descent. All that we have known of gas-heating leads us to the conclusion that for diffusing heat much the same principles must be attended to as in constructing a flue. To get enough of heat at all early, a good supply of gas will be necessary. All things considered, but for getting gas cheap or for nothing, we think a small brick Arnott's stove with or without a small Rivers' boiler on the top of it, and three inch pipes, two below the bed and two above, would be more satisfactory and less liable to easulities—in fact, we would sooner have an Arnott's stove alone, low enough to heat bed from a chamber beneath, and the top by openings from chamber. For cheapness nothing beats a stove now, and there would be less intricacy than in your plan. However, if you try it let us know the result, as many are enamoured with the idea of heating a house by merely turning a gas-tap.]

### A BUNDLE OF WANTS IN THE BEDDING GERANIUM WAY.

MUCH has been said of late about variegated Geraniums and their origin and other features, all in its way very good, and skilful cultivators have extended our lists of names to an extent which renders a wedding-out of indifferent kinds now and then necessary. But my purpose here is not to undertake the nugracious task of condemning varieties that have done good service in years gone by, but to point out new wants in this way, and direct the attention of the ardent cultivator towards supplying that want, and I do not doubt but he will ultimately be able to do so. I will, therefore, state my requirements in a form that will be easily understood, and as I expect they are such as will meet the views of all flower gardeners, the attainment of the object asked for will be a general boon. Commencing, therefore, with

**WANT THE FIRST.**—I want a silver-edged Geranium of good habit and quick growth, with white flowers; so that when it becomes necessary to plant variegated Geraniums in lines as string-work to a panelled garden, or in a white line to a ribbon or striped bed, the colour of the flowers should coincide as much as possible with that of the plant. Unfortunately, all the attempts at variegation have been with a view to obtain flowers of the best form or brightest scarlet, and in this respect some

very excellent varieties are in general cultivation; but I am not acquainted with any silver-edged one having white flowers. Perhaps some sport from *Virgineum*, *Lizzie*, *Hendersonii*, or *Boulo de Neige*, the kinds nearest approaching to white that I have, may supply the desideratum. The habit of the plant I will describe below.

**WANT THE SECOND.**—I want, as one of your correspondents cleverly expresses it, a Mangles' Variegated Geranium with a gold-laced jacket on. In other words, I want the white edging of this most useful Geranium turned into a bright yellow; the flowers for the time might remain as they are; the prostrate but quick-growing habit of the plant to remain as it is. In fact, I simply want the silvery margin of its leaves turned into gold—a want, by-the-by, not more unreasonable than that of the world in general, who seemingly all give the preference to the more valuable metal.

**WANT THE THIRD.**—As the last-named variety is better adapted to cover a considerable space of ground than form an edging, I want a gold-edged kind, of a compact habit and quick growth, to form lines or rows; and if I take *Tom Thumb* as the type of habit I would like to see in gold lace, the requirements of my case will be understood. It would certainly be as well if a stronger grower than *Tom Thumb* were also dressed up in gold lining—say *Punch*, *Mrs. Maylor*, *Emperor*, or others of that breed; but I would be content with one that presents as uniform a habit as *Tom Thumb*, and, what is equally important, retains its foliage to the very last—a feature which *Purple Nosegay* and others are very defective in.

**WANT THE FOURTH.**—I want a golden-edged variety of the Oak-leaved class of quicker growth than the white-edged kind we have under the name of *Lady Plymouth*. In fact, I may say here I would like a more vigorous growth thrown into all the variegated varieties we have; but in this particular case I do not stipulate what colour the flower is to be. It would be best white; but once obtain the variegated form of right colour and constitution, and the flowering part will follow.

**WANT THE FIFTH** is an improvement on *Purple Nosegay*, giving me a plant of better growth that does not lose its leaves so quickly, and does not get so leggy. It is too much to ask for a better flower at the same breath; but one with the footstalk shorter would be better, and if the colour could be brightened up so as to approach the same tint as *Verbena Purple King*, there would be a good chance of having a blue Geranium in a short time. However, I hope to hear of much improvement this way, and would like to give the so-called improvers of our *Scarlet* section a hint that I am perfectly satisfied with their attainments in that direction, and would like them to try their hand on this and some other branches.

**WANT THE SIXTH** is something more in the Ivy-leaved way. In fact, I do not despair of seeing most of the colours of the *Verbena* transferred to this plant, and in dry situations and hot summers it will be a formidable rival to that popular bedding plant. It is hardly likely that the mass of bloom on the best of our *Verbena*-beds can ever be excelled in Ivy-leaved Geraniums; but the latter looks better as a plant not in flower. We all know *Verbenas* are not the earliest nor yet the latest of bedding-plants, and when not in flower can never equal the Geranium in the same condition; but the Ivy-leaved Geranium is best adapted for vases, very dry banks, or places where *Verbenas* would only drag out a sickly existence: therefore, I hope to see it more generally adopted where improved forms are forthcoming.

**WANT THE SEVENTH** is some considerable improvement in the *Unique* section. No greenhouse plant can possibly look better than *Rollisson's Unique Geranium* when trained in a pyramidal form and full in flower, but as a bedding plant it lacks bloom the latter part of the season. I fear this cannot well be improved; but if it could be made as abundant and continuous a bloomer as the best *Scarlets* we have, we would have a very important boon. In this section such kinds as *Moore's Victory*, *Prince of Orange*, *Shrubland Pet*, the white, pink, and scarlet *Unique*, as well as *Rollisson's*, and others, are all very good while in flower, but in the latter part of the season leaves instead of flowers predominate: and though I fear the character of the plant is against continuous blooming, it may, perhaps, nevertheless be improved in that respect by degrees.

**QUALIFICATIONS OF A BEDDING GERANIUM OF THE VARIEGATED CLASS.**—In an article on the Geranium in *THE JOURNAL OF HORTICULTURE* of last year I mentioned some of the points I thought essential in a bedding Geranium, and subsequent observation has confirmed me in the views I then took of the

matter. In the Variegated class two colours only are wanted, as a clear white and green, or yellow and green. The inner zone, which in such kinds as Countess of Warwick and others gives a certainly pretty effect to a potted plant close under the eye, are certainly a defect in the bedding plant, by neutralising the effect the combination of the two other colours creates when viewed a few yards off, which flower-beds usually are.

Another requirement I would insist on is that the leaves should be cuppy or concave, with as broad a margin of pure white or gold as can be had pointing upwards; so that the plant when looked at horizontally should present the greatest possible amount of light-colouring. In this respect *G. Bijou* is much superior to *Alma*, the foliage of the latter being convex, thereby bringing the centre or green more into view. But the best *Geranium* of the Variegated class that I have is *Shottesham Pet*, which grows as freely as most plain-leaved *Scarlets*, and its leaves are of the wrinkled cuppy form, which shows all their whiteness to the best advantage. In the autumn of 1859 *Brilliant* partook of this character to an extent which led many to expect a greater breadth of white margin might become permanent in it, but it relapsed the next season into its original condition. A most excellent bloomer, but not sufficiently variegated to meet the requirements of the present day.

**QUALIFICATIONS OF A BEDDING GERANIUM OF THE PLAIN-LEAVED CLASS.**—This also was treated of in the article alluded to, so that I need only repeat here that, as flowers, not foliage, form the interesting feature, the latter need not present anything beyond a plain green surface, the brighter the better. Zones of black and red, or black and brown, though pretty enough in an individual leaf when examined closely, only look dirty when viewed a few yards away. I therefore prefer the plain-leaved kinds to the horseshoe-marked kinds: neither do I think the white or transparent appearance of the stem of the plant or flower-stem as of any use in a flower-bed, though interesting in the plant-house. An abundant bloomer is of course requisite; and if I were to add to the wants already specified, I would ask for a *Tom Thumb* to bloom as freely as *Brilliant* now does; but I am for the present content with *Tom Thumb*, and like it better than any of the other *Scarlets* I have. But if it were in any way interesting to the reader, I may say that next to *Tom Thumb* *Punch* is a favourite here, though a much stronger grower than *Tom*. In the rose-coloured class *Trent-ham Rose* is the best; in dark reds *Paul L'Abbé* and *Rubens* divide the palm; while in the pink class *Christina* and *Pink Perfection* are good; in pale colours *Lizzie* and *Boule de Neige* are the best. But I do not by any means assert that such may be the case everywhere, neither do I disclaim all connection with the horseshoe-marked class, which embraces several good kinds, as *Scarlet Globe*, *Compactum*, *British Flag*, *Mrs. Ricketts* and others; but for the reasons given above I give the preference to the plain-leaved kinds. I need hardly add that compact habit, with free growth neither too stunted nor too leggy, are necessary qualifications; and such kinds as carry a respectable appearance to the latest possible period in the year, combined with other good points, are the sorts of most use in the flower garden.

In my bundle of wants, No. 1 is most likely to be first supplied—in fact, I shall not be surprised at being told that it already exists, but I am not acquainted with it. The palest-coloured flowering one I have that way is *Silver Queen*, and it is a shy grower, and of a dead creamy-coloured leaf-margin. A clever correspondent has promised to furnish No. 2, which I suspect he contemplated doing by subjecting *Mangles*' to some drugging process, and making the discoloration persistent. No. 3 means a better grower than *Golden Chain*, *Cloth of Gold*, *Golden Vaise*, or *Golden Fleece*. If this be forthcoming I will do without No. 4; but I hope to see No. 5 attended to. No. 6 will take more time to accomplish, as likewise will the next No. But I will be glad to hear what progress has been made in any of these changes in other quarters, and may possibly trouble the reformers of bedding plants with some wants in other classes of plants.—J. ROBSON.

#### VINES AND PEACH TREES IN THE SAME HOUSE.

THE respected clergyman of this parish has built a lean-to house on the south wall of his garden, 10 feet by 8 feet, having a glass front, also having the east end glass. It is 5 feet high in

front, and well ventilated. He asked my advice about what to put in it. I advised him to plant two Vines to train up the roof, having the roots outside; and to plant a Peach or Nectarine on the back wall, with a border inside.

The builder took another gardener to look at the house, and he told him (the gardener) what I had advised to plant in the house. The said gardener replied, that the clergyman should never have the pleasure of eating a Peach or Nectarine of the trees if planted where I proposed. Now, I find that the builder has told this to the clergyman, and, of course, he does not know whose advice to follow; and I take the liberty of referring to you to ask your uninterested judgment on the affair.—CORESUNN.

[If your friend the clergyman wishes to have Peaches and Grapes in his small house, there is nothing to prevent him; though, as a general rule, houses devoted to one fruit tree answer best. Had he glass at both ends, it would have been better. Now, for success, these things are necessary:—First, that the Vines should each be about 2 feet from each end, and each trained to a single stem, and to be pruned on the spur system—in other words, the Vines must not cover the roof, to prevent the sun reaching the back wall. Secondly, if artificial heat is applied, it should be so gentle at first, that the Peaches shall have flowered and set their fruit, before the Vines are doing much more than breaking. Thirdly, the Vines should be partly pruned back as early as possible in the autumn, in order to let all the light possible to the Peach tree. Fourthly, at that time the Peach roots should not be too wet, so that the ripening process should be hastened. Fifthly, in winter enough moisture should be given to swell the buds gradually. If too dry they will be apt to drop. And lastly, no plants of much height should be grown on the floor of the house; and no stage of any kind should be allowed, or that will just spoil the Peach tree. These little matters attended to, there is no reason why first-rate Peaches should not appear on the table at the parsonage.]

#### ORNAMENTAL STOVE PLANTS.

*IXORA LAXIFLORA* (*Lax-flowered Ixora*).

*Nat. Ord.*, Cinchonaceæ. *Linm.*, Tetrandria Monogynia. An ornamental stove shrub, growing 3 feet to 4 feet high. The leaves are opposite, oblong, lance-shaped, acuminate, attenuated at the base into a very short petiole, with ovate-acuminate

adpressed stipules; the largest leaves a foot or more in length. The flowers grow in large, terminal, trichotomous panicles, white, delicately tinged with pink, very fragrant; the calyx is deep red; the corolla consists of a very slender tube,  $1\frac{1}{2}$  inch

long, with a spreading limb cut to the base into four spreading obovate segments. From Sierra Leone; introduced by Mr. Whitfield in 1848. Messrs. Lucombe, Pince, & Co., of Exeter. —(*Botanical Magazine*, t. 4482.)

TABERNEMONTANA LONGIFLORA (*Long-flowered Tabernamontana*).

*Nat. Ord.*, Apocynaceæ. *Lin.*, Pentandria Monogynia. A fine stove shrub, of erect branching habit. The leaves are large, opposite, elliptical. The flowers grow on axillary peduncles, or two placed together at the ends of the branches, bearing about

three flowers in a cyme; the corolla is white or pale cream-colour, large, and having a delicious aromatic fragrance like that of cloves; its tube is 4 inches long, twisted and swollen below the middle, terminating in a limb of five waved, or reflexed tongue-shaped lobes. From Sierra Leone; introduced by Mr. Whitfield, in 1848. Messrs. Lucombe, Pince, & Co., of Exeter. —(*Ibid.*, t. 4484.)—(*Gardener's Magazine of Botany*.)

### MESEMBRYANTHEMUMS AS BEDDERS.

"I wish all the Mesembryanthemums were swimming down the Trent, the bothering, miffy, finical little beggars! Why can't her ladyship be content with Scarlet Geraniums and yellow Calceolarias like other folk?" "Have patience, my good fellow." "If you preach patience to me I'll shy one at your head!" "Rather a rough reception, you will say. Yes, to a stranger it might appear more raspy than friendly; but to us, who knew the evanescent nature of our friend's wrath, it did not appear so. We quietly sat down in the potting-shed where he was at work, potting-off some young Mesembryanthemums, and waited. We did not wait long before he broke out into a laugh, and said, "Her ladyship has seen some of these things (still fingering them contemptuously, and we're to have a bed or two in the flower garden; they're rather ticklish customers to deal with, and I've a hundred and fifty jobs wanting me." It was in the throng of the spring propagation.

One bright summer day we called again, and had scarce got within hail, when our friend sings out, "You're just the fellow I want to see, come on;" and, as if he possessed the seven-league boots he strides off, leaving us to trot after him, wondering what now the wind brings down to us. "By Jove! you never saw such a hed." At last he stopped in the centre of the flower garden, and, before we had time to get breath, he takes us by the shoulders and places us before two beds, one mass of star-like flowers of a lilac rose, or rosy lilac colour. "Arn't

they glorious!" "They are," we reply. "Pray, what are they?" "Mesembryanthemum ——" (we forget what). "Well, but the last time we were here, you were storming at some Mesembryanthemums," we slyly said. Shaking his head, he smiling says, "Come, none o' that, and thou lov'st me, Hal!"

In pondering over what we must sow or get for two neutral beds in our floral arrangement, we remembered these Mesembryanthemums; and, as our knowledge of them is limited, we write now to ask some of the curious plant-collecting readers of *THE JOURNAL OF HORTICULTURE*, "NICKERBOR," for instance, if they can tell us something about them. Now then, "NICKERBOR," you oddly-named man, tell us all you know. Where are they to be obtained? when to sow and how? when to plant and how?—N. H. P.

[These Mesembryanthemums have been used for the last twenty years in all large gardens in the country, and at the Crystal Palace. McIntosh brought them out first at Claremont about 1835 or 1836.]

### SYRINGING VINES.

My Muscats in a thirty-two-foot house are nearly all set; those at each end of the house, where the pipes by turning the corner give more heat, quite set. My gardener contends that it is right to recommence syringing overhead, in order to prevent red spider. I, on the other hand, relying upon the authority of Mr. Sanders on the Vine, discourage the practice, more especially during the present cold and sunless weather. Which is right, Sanders or my gardener? Of course he confines the syringe to the Grapes that are already set.—T. F.

[These are matters as between employer and employed that we do not like to give an opinion upon without knowing all the particulars, nor yet agreeably then, as more depends on thoroughly carrying out a system than in the mere superiority of one system over another. The gardener would be quite right in syringing the Vines when fully set to clear off all refuse of flowers, &c. If deficient in evaporating means, or afraid to use sulphur with them, he might continue syringing for some time with propriety if quite certain the water was pure and left no sediment. For ourselves, after one syringing we rarely repeat it, because the water at command is not pure, and enough of evaporation is obtained from troughs and plants growing in the house. A little air all night at the top or early in the morning will, under such circumstances, be as much opposed to the spider as constant syringing. When these aids cannot be obtained there can be little harm in syringing if the water is pure until the fruit is stoned. Of course in dull weather less will be wanted.]

### INK FOR ZINC LABELS.

No better, more lasting, nor more easily applied ink can be than that so often recommended by *THE JOURNAL OF HORTICULTURE*. Mine was made up in 1857, and I have what will last me years yet, it seems to gain strength with age; in fact, I suppose it does by parting with the lighter parts of the mixture in the form of invisible vapour.

I have noticed many inquiries and opinions lately on this subject, the last one being "M. S.," page 26, April 8, 1862, who says, that on application to a druggist to make up the ink-compound that he, the druggist, has made up the recipe many times, but the parties never renew it, finding it not indestructible. The druggist recommended bi-chlorate of platinum as a substitute, being more indestructible. The expense will be a fatal stumbling-block towards its general adoption; 1s. for a drachm is rather dear.

"Use a quill pen in writing with this ink, bi-chlorate of platinum, the same as in your recipe." I have quoted the substance of "M. S.'s" communication, as I have to differ in many points from it. My practice is in few words thus, Cut the pieces of zinc to any shape you like. I prefer thin strips 3 inches to 4 inches long, and 1 inch wide. On a wet day get all your materials in some of the houses that are heated by either hot-water pipes or flue. Make yourself a seat near the pipe or flue, arranging your pen and ink beside you, put a piece of board across your knees, and with an old knife scrape one side of the zinc label the width and length of your name, then with a steel pen (a quill draws too much ink and often makes either foul strokes or a blot), write it legibly, put the label on the pipe or

fluc, and go on to the next. As quick as they warm and dry they are ready for removal, and anything more black and indelible need not be desired. I marked labels for a miniature fruit garden of Pears, Plums, Cherries, &c., some hundred or two, and I discovered the fixing process by accident. The steel pen ought to be wiped after use. The old knife is quicker than sand or emery-paper.—N. H. P.

### DESTROYING WORMS BY GISHURST COMPOUND.

A WANT has been long felt, and that I believe very generally, of a simple and efficient cure for worms in lawns and gravel walks. This, it has accidentally occurred to me, may be supplied by Gishurst Compound. I therefore beg to give you my experience on the subject.

A short time since, while using a weak solution of the Compound on a large plant that had been removed out of doors for the purpose, some of the wash, of course, fell to the ground, when it was discovered that a great number of worms had been drawn up to the surface of the ground for the last time. It struck me at once that this was the thing wanted—viz., a cheap and easily-applied remedy for an unsightly nuisance. What can be more annoying to a gardener, or to the owner, to see (only perhaps the morning after mowing) his refreshing green lawn thickly studded over with little black heaps of dirt, to be disposed of only by dint of much labour in sweeping, rolling, &c.

No doubt by giving publicity to this, if it be a new idea (and I believe it is), further experiments will be made, and further information given.—JAMES PONSFORD, *Loughborough Park Nurseries, Brierton.*

### SCARECROWS, AND CRAFTY BIRDS.

I NEVER have had such trouble as this season with the small birds. They have devoured my early-sown seeds, and I am afraid they will finish my principal sowing; they are such a hungry lot here by the south coast, for they seem to be continually feeding. We want Mr. Frost to pay us a long and severe visit next winter to devour some of these old wide-awake customers, they seem to know every dodge.

I heard of a gardener a few days ago, who stuck up a scarecrow to frighten the birds away. This was in the image of a man, and a Robin forced a passage under the hat of the scarecrow and built its nest there. Was that not enough to make that gardener give up all thoughts of sticking up a scarecrow?

I performed the same in this garden, and am in the habit of moving it at different times of the day, and almost as soon as I turn my back they are on its poll, turning up in their way; not only that, but they will even strip the old hat of its fur to build their nest; so I advise your readers to knock the crown out if they want to keep the small birds from building in it—also strip it of its fur. But that was not the only means I tried to prevent their attacks. I laid four lines of netting, one on top of the other; they were not very close knitted, it is true, but these vermin would find their way to get in, and took good care to get out. The chaffinch and linnet are the worst. I also used that scarecrow recommended by McIntosh, and which I have found very useful in other localities, but here it is a total failure. It is a long rod, 6 feet or 8 feet long; from the point drops a line of small cord, and at the other end of the cord is fixed a Potato stuck full of feathers of different colours. Now, these south-coast birds might live to an old age, when they enjoy such a lovely breeze as we get and scarcely any winter; this last we have scarcely caught sight of any snow, and the thermometer not falling below 22°, they get more crafty every year, so that they will not partake of a little adulterated food as a change. Out of so many thousands of your readers, perhaps one might be kind enough to give a plan that would prove successful.—J. VICKARY, *Aldwick Pavilion.*

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

As soon as the seed-leaves of the Cabbage tribe appear, sprinkle root or wood ashes over them, for the purpose of preventing the attacks of insects. It should be frequently repeated until the plants are an inch or two high. Continue the destruction of all

noxious insects and vermin. *Capsicums*, repot the plants of the larger varieties intended for turning-out next month. Harden them off when they have taken fresh root-hold. The small sort, commonly called Chilies, should also be potted as they require it in rich soil, and be kept in some warm place. *Carrots*, the frames may be removed from the early sowing if required for other purposes. Thin and water them as may appear necessary. *Celery*, some of the earliest sowing that has been pricked into boxes may now be planted in a frame; no artificial heat is required, but the light should remain on in cold wet weather. Prick-out the successional sowings. *Lettuce*, forward the spring-sown plants where there is a scarcity of autumn-sown ones. Water them in dry weather, and loosen the soil around them. Sow seed of the Paris Cus and other good sorts. *Onions*, thin the autumn sowing. The plants drawn out may be replanted into beds after they are thinned to regular distances. Loosen the soil carefully between them. *Peas*, earth-up and stick the advancing crops. Before earthing, strew some soot beside the rows to prevent the attacks of grubs. *Radishes*, make a sowing of the Turnip-rooted kinds. Water those in frames when dry, to preserve their juicy and mild qualities. *Rhubarb*, sow seed to produce roots for forcing.

#### FLOWER GARDEN.

When the whole stock for bedding-out is potted-off, attention must be paid to the hardening of them gradually for their final destination in the open air. This should be done by degrees, avoiding too sudden changes, and stepping straggling growth in order to have bushy plants. All pruning is probably finished, but if not it should be completed immediately. Plant *Gladioli* and *Ferarias*. Plant evergreen shrubs if you are obliged, and take care when so doing to preserve every fibre, the holes to be much larger than the balls and roots will fit into. Attend to watering, and fix stakes to prevent the injurious effect of the plants being wind-waved. Commence in earnest with mowing and cut down close, it will mow better for it all the season. Finish edging walks, and clip Box-edgings.

#### FRUIT GARDEN.

Where wall trees are protected by netting or other such materials used as curtains they should be drawn from the trees in the day, unless there is a bleak-cutting wind, when they may remain. Remove suckers from fruit trees as soon as they appear. Hoe between Raspberry, Currant, and Gooseberry bushes. Plant out early-forced Strawberries.

#### STOVE.

The plants here are now in vigorous growth, they must be assisted with a lively bottom heat, a brisk-growing temperature with plenty of moisture and air, and weak liquid manure to such plants as require it. *Clerodendrons* should now be in vigorous growth, at least the first lot, and, therefore, must be assisted; and the younger stock of these plants must also be encouraged. *Allamandas* of all sorts, *Rondeletias*, *Gloriosas*, young *Ixoras*, *Dipladenias*, *Franciscas*, and many more free-growing plants must be encouraged by potting when necessary, and due attention to cleanliness. *Stephanotis* now showing bloom to be properly attended to, and give plenty of manure water to the young specimens. *Ixoras*, now expanding their bloom-buds, to be set close to the glass, and where they can have plenty of air to colour the blooms properly. Young *Cactuses* for early bloom next year to be induced to make an early growth. Start a fresh stock of *Gesneras*, *Gloxinias*, and *Achimenes*.

#### GREENHOUSE AND CONSERVATORY.

As the *Camellias* in the conservatory are nearly out of bloom, they and the Orange trees and climbing plants will be benefited by a little extra heat to start them into growth. Advantage must be taken to close the house pretty early in the afternoon, at the same time sprinkling the borders and the plants lightly with tepid water to produce a moist-growing temperature. If not previously done, the borders should also receive a good soaking of weak tepid liquid manure. Although it is not advisable to use shades unless under peculiar circumstances, nevertheless it sometimes happens at this season that sun-bursts, after the late sunless weather, are too powerful for the plants to bear, and, therefore, will require the intervention of a shade to protect them from their scorching influence. In the greenhouse many plants are advancing into bloom, and care must be taken that they, especially the large specimens, are duly supplied with water, and that they receive no check. All the principal plants have been potted long before this time, and are now making

root, therefore, guard against east winds, and shade when the weather is very bright. Give such plants as young *Boronias*, *Pimeleas*, *Polygalas*, *Dillwynias*, *Leschenaultias*, *Eriostemons*, &c., a tolerably close corner of the house; keep them clean, and repot them when necessary. Attend closely to stopping the young growth as it requires it. Remove flowers of young *Leschenaultias*, and, indeed, of all other young plants where growth and not bloom is the first object to be attained. Syringe the plants occasionally, and a little weak manure water will be found beneficial to the strong-growing kinds. Guard the *Heaths* against strong currents of dry air, more especially the newly-potted ones. The young specimens should now be removed to a pit or frame where the lights can be put on or off at pleasure; the pots to be placed on cinder ashes.

#### FORCING-PIT.

This being nearly done with for the season may now be appropriated to the young *Azaleas*, which should now be forced into vigorous growth as soon as possible. Those choice kinds which have been forced and have done blooming may be potted and brought in here at once. Stop the shoots as the plants progress in growth, so as to make them strong and bushy, and maintain a brisk-growing temperature, with plenty of air and moisture. Guard against thrips by syringing the plants and sprinkling the pots with clear soot water, and fumigate slightly every week for several weeks consecutively if insects make their appearance. The thrips may also be kept in check by the timely use of tobacco water. Syringe the plants daily at the time of shutting up the pit, and introduce the specimen plants of *Azaleas* into the pit as fast as they go out of bloom.

#### PITS AND FRAMES.

Graft and inarch *Camelias*; keep them in a close gentle heat. Divide and pot *Lobelias*. Pot-off rooted cuttings of *Dahlias*. The old roots of common sorts which are not required for propagation may now be placed in the forcing-pit, and when they break may be divided and planted out as soon as all danger from frost is over.

W. KEANE.

### DOINGS OF THE LAST WEEK.

MUCH the same as to routine as the previous week. Transplanted *Sea-kale*, prepared ground for *Asparagus*, and planted a quarter of *Cauliflower* plants. Thinned out finally those under hand-lights, and top-dressed with rotten dung and a little lime to frighten the slugs. Sowed *Broad garden Beans*; also in boxes under protection *Scarlet Runners* and *Dwarf Kidney Beans* for transplanting. Nipped the points of *Peas* in pots full of bloom. Potted *Cucumbers* and *Melons*, watered the first in a bearing state.

Among fruit—thinned out *Figs* a little, fresh regulated *Vines*, and stopped where showing. Changed *Strawberry-pots* when done with, bringing pots into heat by degrees, and took great care in giving air in such cold, fitful weather.

Pricked-off seedlings of all sorts that could be got at, finding that is the great and only secure remedy against shanking, even though we lift and prick-in little patches, instead of individual plants; still, when the seedlings do not stand too thick in the pots a little stirring of the surface with a bodkin-like stick, and a fresh dusting of fine soil and charcoal dust, will generally keep them all right. When time prevents any of these modes being tried, avoid watering overhead with a rose, as you would fever or plague. In very particular cases give moisture from beneath, by setting the pots in a tub, within an inch of their rims, or even less. In other cases flood the pot by pouring on a potherd at the sides, but without wetting the tops much. Planted out in earth and turf beds *Calceolarias* and *Gersaniums*.

#### MILDEW.

The dull weather has been rather productive of mildew in many places, and sulphur is in general the best preventive, and the fumes of sulphur best of all. The great thing is to get the fumes without being so hot as to approach ignition. In houses heated by hot water, or flues, the safest plan would be to put the sulphur in evaporating-troughs and basins. We think 170° is as high as sulphur ought ever to be exposed to, and we would prefer 160° to go among tender plants. Mr. Lane, the great *Rose-grower*, who seems to get myriads of them on their own roots, for the trouble of saying, "I want you," for in great batches in autumn and spring it is rare to find a cutting wise, has used a very simple mode for destroying the mildew which appeared in one of his large houses.

Some time ago I stated that Mr. Lane is one of the few men that thoroughly understand the Polmaise system of heating. In a large house so heated by a small brick stove, there is a funnel-opening for throwing the hot air into the house. In fact, a wooden box without bottom or top, unless when it is desirable to cover it—say 2 feet in length by 16 inches in width, and some 2 feet in depth, communicating directly with the chamber over the stove. Now, sulphur if it could have been thrown on the top of the stove might have got too hot, and carried destruction to the plants as well as the mildew; but this is all avoided by a very simple process, and we like it all the better, and think it well worthy of being recorded because it is so simple. A slate is suspended in the opening of this shaft, with plenty of room for air passing all round it, and the slate is daubed, and the daubing renewed with sulphur. If an experienced person put his nose over it, he would know that the odour he inhaled would do for the mildew, and not hurt the *Roses*. Mr. Wright the well-known forman showed us plants where the mildew had been, and which was thoroughly shrivelled up and gone. Now, those who force with flues or resort to iron stoves or brick stoves, may here cut a leaf out of Mr. Lane's book, and use it for themselves, without any danger of igniting, or over-heating the sulphur, and thus pretty well set red spider and mildew at defiance; and I need not add, that if much benefited by such a simple and safe mode, they will easily find a legitimate way for expressing their gratitude.

#### WEATHER VICISSITUDES.

I had intended saying something about the care required in the sudden change of the weather, from fog and rains to frost and sunshine. The frost, we fear, will carry destruction with it. Our *Apricots*, though protected with *Nottingham netting*, are much blackened. *Peaches*, as yet, are safe. *Gooseberries* are a little touched, though they had a little litter and old hay sprinkled over them. *Cherries*, &c., were protected with a rather close net, and seem, as yet, to have escaped. A few degrees in an orchard-house, all being dry, have done no harm. We hear of rather dismal accounts where no protection was resorted to out of doors, and of scalding and burning in houses and pits, even though plenty of air was given. Many of these accidents were due not only to the sudden change from dull to bright cold weather as we had on the 12th and 13th, and continued on to the 16th, but to want of allowance being made for the change. I cannot, however, enter on the subject, but must be content with the following hints:—

First. In such a case there should be as little fire heat as possible to meet with the sun heat. It would be better to make a fire, if necessary, in the middle of the day, than put on the fire wanted for weeks past in the morning, when there was every prospect of the sun shining. It would be better also to shut up houses earlier with sun heat, and get the fires merely to come in as the sun heat was going.

Secondly. The coldness of the heating medium would necessitate the giving comparatively little air which was biting and cold behind the sun, and that air in lean-to houses should be chiefly given at the apex. We have heard of cases, where houses with rather tender plants in them were well opened top and bottom on the 12th and 13th, and a good heat kept on at the same time, and then surprise was expressed that the leaves were blotched and curled at the edges. The poor things must have had a treat, with the air from a furnace roasting one side, and a frosty air playing on the other. In such days we would say, Put out the fires, let the sun be the only or almost the only heater, and give air almost entirely in tender cases at top, so that it shall be heated and moistened before reaching the plants. It is surprising how, even in such days, people will at once pull back the lights from frames and pits, and give front air so freely to forcing-houses, and then shut them up at night in a stifling heat. In all such weather air should be given gradually, and taken away gradually, and it is amazing how little frosty air need be admitted if that little is given early, and heat by artificial means is reduced or taken away. And

Thirdly. In such sudden changes, with cold air, bright sun, and artificial heat combined, it is next to impossible to keep tender plants and newly-potted plants from flagging, when such bright weather follows damp, cloudy, and foggy weather, because the plants are unable to meet the sudden change. It is no use watering if the soil is wet enough, but a syringing overhead, and a close atmosphere, with attention to air-giving, and artificial heat as referred to above, will generally keep all right. If that will not do, it is better to give a slight shading in preference to

inundating the plants, or giving them much frosty air. For shading much glass in a hurry, nothing is better than water just coloured with whiting. This thrown on the glass with a syringe or engine, will give a slightly clouded appearance to the glass, which will be removed in a slight breeze, or a shower of rain. Of course, those who have regular shades will use them in preference, and remove them as soon as the sun loses power or is shaded. These are some of the little essentials to success. The giving great quantities of frosty air to tender plants is much on a footing with the practice of taking tender plants into a cold shed, allowing them to stand as objects of attraction there for a considerable time before and after potting them afresh in cold wet soil. Such plants are sure to suffer though they may not show it at once, just as a man may die from a blow on the head, received months and years ago, though showing little bad effects at the time.—R. F.

### TRADE CATALOGUES RECEIVED.

*A Retail Catalogue of New, Beautiful, and Rare Plants, offered by William Bull, King's Road, Chelsea, S.W.*—This is an excellent catalogue and contains a great many novelties. All or most of the plants are fully described, some of them so minutely as to convey a pretty correct idea of what they really are.

*A Descriptive Catalogue of Bedding Plants, by John Scott, Merriott Nurseries, Crewkerne.*—This, too, is a most respectable catalogue, very copious, and appears to contain everything worth growing in the way of bedding plants. The information communicated is good.

### TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**HEATING BY GAS** (*A Lady Gardener*).—For a small greenhouse 20 feet long, heating by gas is quite effectual. We heated one for several years merely by an ornamental stove placed at one end, with a tube to carry off the gases evolved running along in front to the other end of the house. The heat may be increased readily by having two or even three rings of burners instead of one ring. In that case the upper rings should each be of a smaller diameter than that below it. It is better to have more than is ordinarily required, because the heat can always be kept down by only turning on the gas partially.

**HEATING BY GAS** (*Curiosity*).—See what we have said in answer to the above correspondent. If you apply to Messrs. Smith & Co.'s book-stall at the Railway Station, Liverpool, you can have our Journal on the afternoon of the day of its publication.

**VINE LEAVES DISEASED** (*Edgarley*).—The leaves were so withered that we could find no trace of spider living, though signs of where they had been. There seemed also something like signs of mildew. If you use lime be sure you do not make the sulphur too hot. Did we know how you heat the house we might advise differently. It is not safe to have the sulphur above 160° or so. The *Acucba* is very careless as to soil. Give it a little heath soil and loam, if very particular; but it thrives alike in shade and exposed, and will even stand a good coating of smoke and soot with comparatively little injury. Of course in such a sooty place it is glad of having its stems and leaves washed.

**CHERRY BLOSSOMS FALLING** (*H. Mathews*).—We suspect your Cherry tree wood was not ripe enough, or had got too dry in winter or autumn, or, perhaps, had not been sufficiently established in the pot. Any of these causes will produce such a result. When blossom-buds are very thick on a small tree, if time could be spared, the weakest and those which may not show an embryo fruit, should be thinned out. We have a fine Elton tree, producing a fair crop every year, but still a good many drop, and a great many after setting never swell, but gradually shrivel up. The tree seems in self-defence thus to get rid of the redundancy. Cacti cannot be named from such scraps as you sent.

**PLUNGING MATERIAL IN A PIT** (*A Constant Reader, Stoke Ferry*).—We presume that you mean your propagating-pit to be above hot-water pipes or flue; and if you have plenty of heat nothing is better than rough stones, smaller ones above, a layer of smaller ones still, and then fine sand for plunging. If a worm should get in soak the whole with lime water. The same would clear the mould and gravel. That would be the cleanest. The cocoa-nut refuse or tan would also answer, but sand would be the cleanest. The cocoa-nut fibre refuse you enclosed is the right kind.

**DIVIDED FLUE NOT DRAWING WELL** (*L. C. W., Warwickshire*).—We do not quite make out the size of the flue owing to the obscurity of the figures. Divided flues require a little coaxing by means of dampers to regulate the draught, and then there is generally little difficulty. We do not see your object in thus dividing your flue. Why not return a single flue instead? Your flue rises from the bars to the dividing, 15 inches; but we do not know how far that distance is. A fire will always draw better when the rise from the bars is sudden. Then from that point for the most of the length there is a rise of 2 inches, and from thence round the end to the base of the flue a rise of 12 inches. We think so many different levels may check the smoke, the strength of draught may differ in the two divisions, and may make the smoke waver whether to go on or to return. Is your chimney high enough? Try a chimney-pot without making other alterations. In such circumstances with a good rise from the bars to the base of the flue, and a gradual rise all the way, such a flue, single or double, ought to burn anything.

**WORMS IN LAWNS** (*R. B. W.*).—Watering with lime water as often as the worm-casts appear is the usual remedy; but see what Mr. Ponsford says to-day about the use of Gishurst Compound for the purpose.

**CULTIVATING WATER CRESSSES** (*E. E.*).—The following is extracted from the *Cottage Gardeners' Dictionary*:—"Planting in Water."—The trenches in which they are grown are so prepared, that, as nearly as possible, a regular depth of 3 inches or 4 inches can be kept up. These trenches are 3 yards broad, and 87 yards long, and whenever one is to be planted the bottom is made quite firm and slightly sloping, so that the water which flows in at one end may run out at the other. If the bottom of the trench is not sufficiently moist, a small body of water is allowed to enter to soften it. The Cresses are then divided into small sets or cuttings, with roots attached to them; and these are placed at the distance of 3 inches or 4 inches from each other. At the end of five or six days a slight dressing of well-decomposed cowdung is spread over all the plants, and this is pressed down by means of a heavy board, to which a long handle is obliquely fixed. The water is then raised to the depth of 2 inches or 3 inches, and never higher. Each trench is thus replanted annually, and furnishes twelve crops during the season. In the summer the Cresses are gathered every fifteen or twenty days, but less frequently during winter; care is taken that at each gathering at least a third part of the bed is left untouched, so that neither the roots may be exhausted nor the succeeding gathering delayed. After every cutting, a little decayed cowdung, in the proportion of two large barrowfuls to each trench, is spread over the naked plants, and this is beaten down by means of the rammer above mentioned. After the Water Cresses have been thus treated for a twelvemonth, the manure forms a tolerably thick layer at the bottom of the trench, and tends to raise its level. To restore it to its original level, all the refuse should be thrown out upon the borders which separate the trenches from each other. These borders may be planted with Artichokes, Cabbages, or Cauliflowers. The drainage from a dung-heap might be allowed to flow into the stream if it did not foul it much; and if the water were so enriched we question whether any annual addition of cowdung would be needed.

**SOWING CINERARIA AND PRIMULA SINENSIS** (*A Subscriber, Clapham*).—If only a new beginner do not think of striking Moss Roses from cuttings, better buy a few that are established in pots. Sow *Primula sinensis* now, and again in June for succession. You may also sow *Cinerarias* now, and again in July. These will most likely give you a great variety. If you wish to have a few first-rate sorts get some half-dozen of the best from some tradesman florist, and when done flowering cut the flower-stems off, and turn the plants into a shady border. Water them as they require it, and by August and September you will find each plant possessed of a number of healthy suckers or young plants, which divide and pot. *Cinerarias* may also be raised by cuttings, but they do not make such nice plants as suckers. The *Cineraria maritima*, cuttings of which were advertised to, is used for flower-gardening purposes.

**NOTCHING FRUIT TREES** (*An Old Subscriber*).—"Notching" is cutting a notch above a bud through the sapwood as well as through the bark, to induce that bud to become a branch rapidly by preventing the upward flow of the sap and diverting it to the bud.

**HEATING A SMALL GREENHOUSE** (*Tyro*).—A small iron or a brick Arnett's stove would heat such a house nicely, but being connected with the drawing-room it might be unsightly or troublesome. These would be cheapest. The next best and cheapest would be a flue; and if you can get deep enough for a small stovehole we would have the flue under the floor. Then for the arrangement inside. The house being 16 feet long and 10 feet wide, the centre at back being the drawing-room door, and the centre in front and opposite to it the door into the garden. Such a house would look best with a pathway right across it, say 3 feet wide. This would leave 6½ feet on each side; and if the ends were opaque a sloping stage on each side would hold the greatest number of plants. But if the ends and fronts were chiefly glass, then we would have a shelf of 9 inches all round ends and front, a border at back for climbers, &c., for back wall, a walk all round of 2 feet besides the central, and a small flat or pyramidal stage on each side. By this plan every plant may be easily examined, and neatness will be secured. If we did not floor all the house with tiles we would do the pathway, and under that we would have a flue all round—the pathway, in fact, forming the top of the flue. This also would make the pathway dry and comfortable in winter.

**CYCLAMEN CULTURE** (*A. G. L.*).—Yours is a nice red variety of *Cyclamen persicum*, not in a very strong condition, owing to having been too much dried last summer, or being a very young root. All the family do best turned out in their balls into the open border while they are at rest during the summer, and to be repotted in the autumn when they show signs of growth; then to be kept as cool as possible during the winter with *Ixias*, and such like bulbs in a cold frame, but not to let the frost to them, nor give them too much water, or confinement from free air in all fair weather. They all require the very best drainage and a generous soil, such as would do for nice pot *Geraniums*, and if there is any dung in it be sure it is very rotten, as for *Anriaculas*, and quite dry and crumbly when it is mixed with the loam and sand. Very good sorts and good flowering plants of *Cyclameus* are sold in Covent Garden at about 1s. 6d. the piece on the average; but the best and cheapest way would be to bargain with a nurseryman for a dozen of sorts as so much, and to raise seedlings from the whole lot, then there would be no end to the variations and the markings of the flowers. A selection of the very best flowers might be made from time to time for a family stock, and the rest be given away, if only to extend the knowledge of such beautiful flowers which require so little trouble, and pay for it in such abundance of gay flowers.

**SOWING WINTER CHERRY** (*J. S. A., Wanstead*).—This, *Physalis Alkekengi*, may be sown in the open air at the end of April, or sown in a slight hotbed, and the seedlings planted out. If it is *P. peruviana*, it should be sown in a hotbed, potted-off, and grown in a greenhouse, or planted out in June; but it would be best kept in the greenhouse for the first season, and most likely it would produce plenty of fruit the following year, which may be eaten, or used as tart. There are so many things that go under the name of Winter Cherry, Cape Gooseberry, &c., that we really cannot say how to treat exactly, unless we knew which was the one in question. However, a little heat at first can do no harm, and keeping in the house the first season, will be sure to make all right.

**GERANIUM LEAVES DISEASED** (*J. Z.*).—The "frizzling," as you term it, is caused by insects, either red spider or thrips, for the specimen sent was defaced by the post-office stamper. The air of the house has been kept too dry and not sufficiently ventilated. Flowers of sulphur, syringing, and more ventilation are the remedies.

**GRUBS IN CARBAGE-BEDS**.—*R. Hodgkin* says, he saved his plants, entirely destroyed the grubs, and has not seen one since, by putting 4 lbs. of common salt upon every 9 yards in length and 3 yards in breadth.

**OVAL BEDS** (*A. G. T.*).—We never say what should be planted in beds. We only give notice of everything worth planting, and tell if the plantings of others are in the fashion. In a large oval like yours, with a mass of scarlet in the centre, most people would put a row of *Perilla* round the scarlet, then *Flower of the Day* round *Perilla*, and *Lobelia* in front; and some would put yellow *Calceolarias* instead of *Perilla*; and some one thing, and some another. A *Camellia* greenhouse with *Passion-Flowers* is just the place for *Mandevilla*, and just not the place for *Stephanotis*.

**COCOA-NUT FIBRE REFUSE** (*G. W. H.*).—The sample enclosed was the right kind.

**CERASTIUM TOMENTOSUMS FROSTED** (*Idem*).—Your *Cerastium* are done for; they came out of a hot forcing-place, and Oaks and Elms from hot forcing would have just gone the same way. Probably the bottoms are not dead, and if not the plants will do just as if they had no hurt, only they will be a month or six weeks later, that is all; and you may as well plant them out at once, and put a little mulching of some very light stuff down each side of them, and see they do not want for water.

**CYCLAMEN AND ITS SEEDLINGS** (*E. W.*).—No wonder at all at their admiration of your most admirable *Cyclamen*, which is the very best of them all. No name short of a Sultan could give people any idea of the grandeur and richness of "fifty blooms" on such a plant. According to the leaf, you have done it as a Sultan ought to be done; yet, nevertheless, the name is merely *Red Persicum*, or *Cyclamen persicum rubrum* of nursery catalogues, but there are ten rubrums, not one of which is so good as the real one, and you have it. You have a treasure in it that few know anything about, it is the best mother breeder in the family, and it never yet produced a bad seedling. We have seen magnificentums from it, and of all colours, too, without crossing; but then it stood while in flower among such beauties as must tell on its seedlings for two or three generations. Save every seed from it, and sow them the day they are ripe, which will be about the first or second week in July. Plunge the seed-pots in the open ground, and put a bigger pot upside down over the seed-pots to keep off everything; they will then want no water till the seedlings are up one month, and by that time they will need to be taken to a cold pit; and if you could plunge them there for the winter they would want no water till the end of January. The seedlings might remain two years and two months in the same pots; then to be divided out into separate pots, and then for the grand secret of seeing flowers such as few had ever the chance of seeing before.

**CYCLAMEN** (*C. T. H.*).—Your seedling *Cyclamen* from rubrum is the handsomest that has yet been raised as far as we know. It is as densely spotted on a light ground as *Sinningia guttata*; rubrum is a sport, and never comes true. No one can tell a *Pinus* from the seeds.

**SPELLING AND PRONUNCIATION** (*Plants*).—The *Cottage Gardener's Dictionary* gives the correct spelling, and shows which syllable the emphasis should be laid upon. There is no book published showing how names are pronounced.

**DAHLIAS** (*R. Hodgkin*).—Buy our "Florists' Flowers for the Many." For five penny postage stamps you can have the book from our office free by post. It gives fuller directions for cultivating the Dahlia and other florists' flowers than we can find space for in answers to correspondents.

**VERBENAS** (*An Amateur, Tavistock*).—Robinson's *Defiance* for scarlet; *Purple King* for all blues, purples, and darks; and Mrs. Holford for white, are the three principal *Verbenas* which have been used for the last seven years for what you want. We cannot recommend one set of plants in preference to other plants, or one nurseryman, or house of business before another.

**TAGETES TENUIFOLIA** (*Subscriber from No. 1*).—This *Tagetes* will not do instead of *Calceolarias* in a ribbon-row in front of *Scarlet Geraniums*, it grows too tall for that row; but just behind the *Scarlets* it would make the cheapest yellow row in the kingdom, and probably one of the very best—say if *Punch* were in front of it, and the seedlings were to be transplanted 6 inches apart in the row, and the row to be a foot or 15 inches beyond *Punch*. This is a most permanent and bright yellow for a row a long way back from a walk, where other plants would hide so much of the stems and leaves as would render the line conspicuous for tidyness.

**AGATHEA CÆLESTIS** (*Idem*).—This is usually called *Cineraria amelloides*. We have often placed the merit of *amelloides* before our readers, but must leave it for their own decision.

**SCROPIELARIA NODOSA VARIEGATA** (*Idem*).—We have not yet seen it tried as an edging against *Mangles* or any other plant, but we have the very highest opinion of the parties who have seen it, and who have used it, and also who recommend it and offer it for sale; but we ourselves would prefer using this plant as we would four-year-old plants of *Flower of the Day*—that is, in the third or fourth row of a ribbon or such arrangement. But Mr. Beaton seemed to think last autumn the proper place should be at the back, as between evergreens and the *Scarlet Geraniums*, such as were suggested for Sir Joseph Paxton's sash-pattern planting.

**VERBENAS** (*Idem*).—You will see all the best *Verbenas* in our lists; but choose for yourself, and ask us then what we think of your proposed selections and combinations.

**TRITOMA UVARIA CULTURE** (*E. S.*).—It is about the same way as for bedding Dahlias. Look for whole dissertations on the plant in back Numbers. *Veratrum*, which of them? What would do for some would be undoing it for others.

**CERASUS JAPONICA FL. PL.** (*G. S. A.*).—Your pretty little *Cerasus* is quite right, but is not quite strong enough yet to flower. Leave it just as it is, it never wants much pruning. Once in six or seven years will be quite often enough to prune it, and all the pruning it wants then is merely to thin out the branches where they are too close or getting bare at the bottom. We know another *Cerasus* just like it which has not had any pruning since 1848, and it is one sheet of blossom every spring; also, a splendid *Ribes sanguineum* which has not been pruned since Her Majesty came to the throne. Why are you so anxious about pruning such nice little bushes which do so much better without it? Your seeds are of the Black-eyed Susan, the yellow *Thunbergia* with the dark eye or "purple heart."

**PLANTS FOR SMALL STOVE** (*Yorkshire*).—The things grown in such a house must be regulated by the height, of which we know little. The finer Ferns, as *Adiantums*, *Gymnogrammas*, &c., and *Gloxinias*, *Achimenes*, and fine-leaved *Begonias*, would just be at home, and in fact any stove plant for which you may have room. We think you should have some means for securing atmospheric moisture. The iron will often be too hot for pouring water upon it. Instead of the flats we would have preferred rough pebbles, and smaller pebbles on the surface. If the flats reversed get too hot you might use neat pieces of wood with a ledge on two sides, which would keep the base of the pot coolish, and enable the heat to pass from underneath the board.

**TEEE CARNATIONS** (*M. H.*).—The nurseryman who informed you that no reliance can be placed on tree Carnations coming true from seed either as to habit or colour was quite correct. We remember as many as twenty-five years ago seeing a tree *Picotet* which had been so trained by an amateur in Dublin, and we imagine the plan is that very much adopted now. It would be well to obtain the seed advertised as such, because there may just be the probability that it has been saved from varieties which are inclined to make leggy growth. In the earlier stages of their growth the material would be the same as that adopted for the ordinary *Carnation*, but they should not be allowed to flower the first year. The side shoots, too, should all be pinched off—and, in fact, the treatment very much resembles that adopted for the tree *Mignonette* we should imagine.

**FLOWER GARDEN** (*Novice*).—You have planted the beds very well. Unless the ribbon is shaded from the other side as well as by the house, the kinds you have in it will take no hurt from the house; and *Defiance* is still at the top of the scarlet *Verbenas* as all the world knows by this time.

**NAMING PLANTS FROM SEEDS** (*A Subscriber, G. B.*).—This is very difficult to effect, and requires more time than we can spare for one query. Yours are the seeds of *Acacia melanoxylon*.

**KEEPING CUCUMBERS FRESH FOR A FEW DAYS** (*A Two-years Subscriber*).—Cut the fruit with an inch or two more of stalk than usual, and slightly burn the cut end with a hot iron, and place it in a cool cellar on a plain flat board, without any packing material till the day of the show. We do not recommend standing Cucumbers in a dish of water as is sometimes done, as we think that they lose more than they gain in that way; whereas, sealing-up the wound, and the atmosphere not favouring evaporation, they will keep longer that way than any other.

**QUICK AND HOLLY HEDGE** (*G. B.*).—A *Quickset* hedge with *Holly* plants a yard apart looks very well, and is a more impregnable fence than *Quickset* and *Privet*, but the latter is of quicker growth, the *Privet* taking the lead, and throughout appearing the more prominent plant. The *Ossage Orange* (*Maclura aurantiaca*) has been used as a hedge, and its glossy green leaves look well in summer, but the tips of its shoots never yet ripened, and in winter it is not so compact and ornamental as *Quickset* in planting *Holly*, *May* is said to be the best time.

**KEEPING POTATOES** (*Idem*).—A dry, cool place is the best for keeping *Potatoes* to as late a period in the season as possible; but it must be quite dark, and they must not lie too thick, as that generates heat, and they sprout, and, consequently, lose weight. If the place be not dark, put them thinly into the bottom of a box or bin, and place the lid over them. A covering of straw, ashes, sand, or similar substance, encourages growth, which it is advisable to prevent, and the season having arrived for their doing so, a cooler atmosphere than the natural one is the only thing that will arrest their growth. Keeping them dry at the same time.

**WIRE FENCE** (*Idem*).—There is great variety of wire fencing. The best we have seen is a kind of galvanised wire cable, consisting of seven small wires twisted into a sort of rope. The best standards are also galvanised tubes, through which the wire rope passes. The straining standards are much larger, and being notched and shod at the bottom are not easily removed. A brace secures them on the side the strain is on; but there are many other kinds of strained wire fencing, ordinary wrought iron standards with six wires of the kinds in the trade called No. 4 and No. 5, make a very good fence, the standards being not more than 5 feet apart, and the height of the top wire about 3 feet 9 inches. The standards are best if secured to stone blocks; but rough timber ones will do, only these seldom last more than four years. A stout wooden post with a good brace is best to strain to, but lengths of about 200 yards may be strained in one piece. A wooden post in every fifth place strengthens it much; but it need not necessarily be so, and without these the fence is less visible, and if painted a dark green is nearly invisible at 200 yards distance.

**SLUGS AND EARWIGS** (*J. M., Londonderry*).—The slugs first make a wound in your *Nectarines*, and then the earwigs may take advantage of the wound; but we think they have nothing to do with the injury. Syringing with lime water would kill the slugs if they harbour in holes in the wall; and sowing salt over the soil will settle them there. We have suffered from snails eating our *Nectarines*, and hand-picking is the best remedy then.

**INSECTS** (*Ipstones*).—There was nothing in the box except a little dry soil and a few white fragments which might be skins of insects, but not detectable. The insects, probably, are *Acaris*, and if so are not injurious to plants. They live on decayed vegetable matter.

**NAME OF FERN** (*M. B., Staffordshire*).—It may be an *Asplenium*, perhaps *lancoletum*, perhaps *Adiantum nigrum*. No one can tell which from so immature a scrap.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### WILD FOWL.

(Continued from page 36.)

It is necessary the fence should be close to the ground, because however tame birds may be when they are bought, the tameness is only to place. Their nature is not changed, and they will for many days examine every part of their new abode. No weak spot will escape them. Wire is not the only fence that will answer the purpose, a wattle fence will do as well. We had such a one that lasted well for seven years. Whatever the means may be that are used for confinement frequent inspection is necessary, not only to prevent the inmates from getting out, but to prevent enemies from getting in. Thus, if the fence be wire, it is necessary to look for places where scratching has been begun to get under the wire. If a wattle fence, there will be signs of gnawing. Attention to these trifles will prevent many losses and disappointments. Most people are familiar with that exclamation, "I wish I had seen this before!" We wish to prevent it.

As soon as the birds have satisfied themselves they cannot get out, they become tame, they are "tamed to their cage," and reconciled to confinement. They should always be fed at stated times, and it is a profit to feed with that which will swim. Food should be thrown on the shallows, the places made for landing, and the bottom of these even in the water should be of hard gravel pebbles well rammed in, nothing is then lost. But if the water is clear, and dun birds and tufted Ducks are among the birds kept, it is most amusing to throw in some grains of good barley that will sink, the divers will be seen to follow their vocation, and to go after every corn as it sinks. In this, as in keeping poultry, we advocate a bare sufficiency of food. Nothing makes birds so tame as to look for the usual feeding time, and it is a pleasing pursuit to collect the crumbs from the breakfast table, and to feed wild fowl with them. They soon learn to look for it. Everything like a hopper or feeder is bad. As soon as the birds are satisfied they go away and hide. Half the charm of these pursuits is to be able to show the pets in which we take an interest to a friend, and this can only be depended upon when they are lightly fed, and learn to associate the coming of their owner with food. We can give little hope of breeding. They do so sometimes, but only after a long lapse of years, in most cases fourteen or fifteen. We know many instances of their breeding after this time. We also know exceptions. We know a case where some Sheldrakes were turned into a small pond in a rick-yard, and within a month they burrowed into a hay-rick and bred there. Where space permits, the smaller kinds of Geese may be kept. These are much tamer than Ducks. The Barnacle has beautifully pencilled plumage, slate-coloured and black. The Brent is most elegant in shape, with taper neck, very small head, black plumage, and white ring or necklace. The white-fronted; the Bean; the Egyptian, with pink legs and bills, and plumage of varied colours; the Canada, all these are easily kept and cheaply, their chief food is grass. Where space is at all limited, the small Barnacles and Brents are most desirable.

We have endeavoured to show how all these beautiful birds are to be kept, and we have, we think, shown at how little cost. They are inexpensive to buy, they are not subject to disease, and they consume little food. They are among the charms of a country residence, and they form part of the out-door, and, consequently, healthy pursuits of a country life. We have tried to dispel the idea that an indulgence of these tastes is only to be permitted to those who have long purses; and as we write from experience, we know those who may be induced to try to carry out our suggestions will find they may be depended upon in every particular.

### RATS VERSUS POULTRY.

THE complaints that this spring have reached me respecting the depredations of the rats on the early broods of both chickens and ducklings, very far exceed anything I can call to mind in previous years. One party who had succeeded in raising, to nearly a month old, ten Egyptian goslings (and who plumed himself not a little on so doing), lost all ten of them in a single night; the very first, too, that they were allowed to pass out-doors.

Every breeder of either useful or merely ornamental poultry will admit that the annoyance to the mind, from such unlooked-for disappointment, quite overbalances the loss, as only regarded pecuniarily. The breeding season passes on with a feeling that no outlay will make up this deficiency of early stock, and, indeed, sometimes provokes only to the abandonment of the pursuit altogether. The pest seems this year almost universal, as, within my own knowledge, both Spanish, Dorkings, and Cochins have fallen victims to these marauders.

The sagacity of these vermin is certainly far greater than most persons would credit, nor could a more striking proof be given than that of the ornamental gulls above referred to. They had reached the size of Moor-hens, and were strong and heartwell, having the protection of a large Rouen Duck as foster-mother. On inspecting the place very early the next morning (attention having been called by the movements of the old Duck), it was evident that a portion of the youngsters had been killed and eaten likewise on the spot, but that four or five were simply scalped and brained by the rats, and afterwards dragged away to some neighbouring sewers. On one of these birds strychnine was placed, and on the others white arsenic; but for a fortnight or more they remained untouched, consequently were removed to prevent mishap or unpleasantness. The owner, thus hopeless, unfortunately disposed of his old birds.

Strange to say, as evidence of the dexterity of rats in obtaining access to places thought secure, the owner of the Dorking chickens actually saw a rat walk along a clothes-line that a washerwoman had put up temporarily—the line being only a quarter of an inch in diameter, and 18 feet long, but which his servant had tied to a hook in the lintel of the chicken-house. After walking "Blondin-like" the whole distance from a stable, along these 18 feet of cord, the rat forced its way through a small aperture at the top of the door, 6 feet 6 inches from the ground. She was now killed, and was proved to have had young ones suckling at some not very distant place, and doubtless was one of the party that destroyed the young Dorkings.

The old adage says, that "ill-luck always grows in clusters," and so it seems, for on employing a neighbouring ratcatcher, a ferret was lost; and, although seen several times since, it had not, when I last heard, been recaptured. The owner despondingly remarking, "I'm afraid I am out of the rain, but only to get into the river."

With a hope to turn this to some beneficial issue, I will briefly narrate a plan, that, if carefully pursued in its entirety, seems to be the most perfect way of giving rats and mice their quietus I know of. Get some Scotch oatmeal, or barley-flour will do, and place it at first sparingly in a small heap at some spot well-frequented by the rats. On examining it in the morning it will be soon seen if any portion has been eaten; if not, let it remain night after night until you find they have consumed the greater proportion. Now place more, but not too lavishly; you will find, in a few nights onwards, the rats greatly increase in numbers; but never give more food than appears to be well eaten up. In the next place provide yourself with some newly-made plaster of Paris; if not good and recently manufactured it is valueless for this purpose altogether. Mix, in a perfectly dry state, without any water whatever, in equal proportions this ingredient with the same kind of meal previously used; but not in a greater aggregate quantity than the previous nightly supply. Carefully managed, after such lengthy enticements, rats or mice will consume ravenously their "last meal;" for, in a very short time after eating it, the plaster causes intense inflammation of the bowels to set in, with fearful thirst; whilst water instantly produces death, though they will invariably take it if within reach. The great advantage over "poison" of this plan is this—after the death of a mouse or rat, even should cats or other domestic animals eat the defunct no injury will arise to them, as the plaster has become powerless altogether, and they may therefore consume it with impunity. In conclusion, the bait should be nightly laid for at least a fortnight, to inspire thorough confidence and secure a full attendance.—CHANTICLEER.

BATH AND WEST OF ENGLAND SHOW.—We learn that the various departments promise the greatest success yet attained by the Society; the entries of implements exceeding by many hundreds those in previous years, and those of stock promise to be even greater. The poultry department does not close until the 1st of May. Certificates can be still obtained from S. Pitman, Manor House, Taunton.

THE CANARY AND THE BRITISH FINCHES.

(Concluded from page 20.)

CLASSIFICATION, EXHIBITING, &c.

In now drawing this series to a close, I may as well give a few hints on the classification of the different breeds and varieties of Canary birds. Shows and exhibitions of Canaries and singing birds are becoming so general throughout the country, that it is desirable to see a better arrangement of the various breeds than exists at many of them, by which many excellent breeds or varieties are discouraged or entirely omitted. In different localities one or two breeds only are cultivated, and it often happens that the other sorts are omitted, discouraged, or have not even an extra class in which they could be shown, even if their admirers were sanguine enough to exhibit them under the cold shade of neglect. This, in my opinion, is narrow-minded and false economy, as the more varied the show, the more interesting it becomes, and the larger will be its general support. Desirous that every variety should have a fair chance and a position at all good shows, I offer a sketch of a model list of classes for the guidance of secretaries and committees in framing their prize lists.

MODEL PRIZE LIST FOR CANARIES.

Class.	CRESTED OR TURN-CROWNED.
1st. Wild Canaries	Class.
2nd. Grey Canaries'	22nd. Clear Jonque or Yellow.
3rd. Grass or Parrot Green	23rd. Clear Mealy or Buff
4th. Quakers, Cinnamon, or Dove	24th. Crested Cinnamon or Dove
NORWICH BIRDS.	25th. Crested Green
5th. Jonque, Orange, or Yellow	26th. Crested Pieds, Piebalds, or Variegated.
6th. Mealy or Buff	Extra Class.
7th. Pied Norwich	27th. Any other variety or colour not previously named
ERECT BELGIAN OR DUTCH.	MULES OR HYBRIDS.
8th. Jonque, Orange, or Yellow	Grey Linnet Mules.
9th. Mealy or Buff	28th. Pied or Variegated Linnet Mules
10th. Pied, Marked, or Variegated	29th. Whole-coloured Linnet Mules
BOWEN BELGIAN OR HOOPER FANCY.	Goldfinch Mules.
11th. Jonque, Orange, or Yellow	30th. Jonque Pied Goldfinch Mules
12th. Mealy or Buff	31st. Mealy Pied Goldfinch Mules
13th. Pied, Marked, or Variegated	32nd. Other coloured Goldfinch Mules
SCOTCH FANCY.	Extra Classes.
14th. Jonque, Orange, or Yellow	33rd. Any other kind of Mules or Hybrids having the Canary for one parent
15th. Mealy or Buff	34th. Mules or Hybrids not having the Canary of either parent
16th. Piebald, Pied, or Variegated	
LONDON FANCY.	
17th. Jonque, London Fancy	
18th. Mealy ditto	
19th. Old birds ditto	
LIZARDS.	
20th. Golden-spangled Lizards	
21st. Silver-spangled Lizards	

This arrangement embraces all the varieties of Canaries which I am aware of as cultivated by the English fanciers, and to prevent jealousy and disappointment, each breed at least should have a separate class at every show. There are, doubtless, many other breeds or varieties that may be introduced to swell the already long list of English varieties; but Class 27, the extra for any other variety or colour not previously named, would receive them when they make their fitful appearance among our longer-established breeds.

Exhibitors should send their birds in good health and feather, putting them in neat clean cages, and pay particular attention to the schedule of prizes that they enter them in the correct class; for a mistake of this kind must prevent their obtaining a prize. However meritorious their birds might be, the Judge, in justice to other exhibitors, could do no more than commend the wrongly-entered bird. Judges are, however, liable to make mistakes in their task of awarding prizes, yet I think exhibitors are more frequently prejudiced to their particular fancy, and are apt to overlook defects in their own birds. If, therefore, these chapters may be found successful in drawing the opinions of exhibitors and judges to the same conclusions, my descriptions of the various breeds, their various properties and points of excellence which I have endeavoured clearly to explain, will not I trust be in vain.—B. P. BRENT.

THE WOODBURY FRAME-HIVE, COMPOUND BAR-FRAME,

IMPROVED COMB-BAR, SUPERS, &c.

In compliance with the wishes of numerous correspondents, I have much pleasure in submitting to the readers of THE JOURNAL OF HORTICULTURE a description of my frame-hives, supers, and outer cases, as at present in use in my apiary.

FRAME-HIVES are made of inch wood, 14½ inches square, and 9 inches deep inside, dovetailed and put together with paint, the ends of the dovetails being pinned through with stout iron wire driven from the top and bottom, and meeting in the centre. A window, 7½ inches long by 4 inches deep, affords a slight view of the interior from the back (not the front as engraved), but is much obstructed by the frames. The crown-board, which is raised in the engraving, is keyed to prevent

warping, and is secured by four long brass screws passing through the ends of the keys. A two-inch central hole for feeding is the only aperture, and this is closed when not in use by a circular block of one-and-a-quarter-inch wood 5 inches in diameter. A three-eighth rabet is cut out of the top inner edge at the back and front, and below this are notches seven-eighths wide by three-eighths deep, in which rest the ends of the frames. This arrangement affords the bees a free passage above the frames as well as below and at their sides. The annexed sketch of the interior angle of one of my hives is drawn the full size, and will

serve as a guide for the arrangement of the frames, which are ten in number, and are placed at equal distances apart.

COMPOUND BAR-FRAME.—This is a contrivance of my own, which I have found very advantageous in enabling me to use frames in stock-hives and bars in supers without forfeiting the advantages arising from the unlimited interchangeability of every comb in every hive and super in the apiary. Its construction will be readily understood by an inspection of the annexed sketch, in which the comb-bar is shown slightly raised from its frame. The bar itself is 13¼ inches long by seven-eighths of an inch wide and three-eighths of an inch thick; these dimensions must be rigidly adhered to, as every comb-bar should fit every hive and super in the apiary.\* The slips of wood forming the frame are seven-eighths of an inch wide and five-sixteenths of an inch thick, with the exception of the projections at the top which are the same thickness as the bars, and are five-eighths of an inch long. When the comb-bar is in its place the whole forms a frame 13 inches long by 7¼ inches high (inside measure), with a five-eighth projection at each end, which rests in its appropriate notch in either the back or front of the hive. The accompanying engraving represents the frame filled with comb, in which state the bar becomes so

firmly cemented to the frame as to admit of its being handled with the greatest facility.

\* It is a good plan to commence by making a pattern bar of mahogany, which should be taken care of and used as a guide whenever comb-bars are required.

**IMPROVED COMB-BAR.**—This little contrivance has proved very effectual in securing straight combs when guide-combs are not attainable. The annexed sketch is a section of the new bar. It will be perceived that the lower angles are rounded off; whilst a central rib is added of about an eighth of an inch in breadth and depth. This central rib extends to within half an inch of each end, where it is removed in order to admit of the bar fitting into the usual notch. All that is necessary to insure the regular formation of combs is to coat the underneath surface of the central rib with melted wax. My practice is to use plain bars whenever guide-combs are attainable, as these can be attached with much greater facility to a plain than to a ribbed bar; but whenever I put in a bar without comb I always use one of the improved ones. By this method crooked and irregular combs are altogether unknown in my apiary.

**FLOOR-BOARDS.**—My floor-boards are made of one-and-a-quarter-inch wood, keyed to prevent warping, are 18 inches square, and show a projection of about an inch beyond the exterior of the hive, from which they are chamfered down on all sides nearly three-eighths of an inch. An entrance 3 inches or 4 inches wide is cut in front out of the substance of the board commencing at the edge, and continuing on the same level until inside the hive, where it slopes upwards. The entrance formed in this manner is five-sixteenths of an inch in height where the hive crosses it.

**ALIGHTING-BOARDS** are moveable, being attached to the floor-boards by means of a couple of pins of stout wire; they are made from a piece of a silk-roller, 2 inches in diameter by 8 inches long, rounded off at the ends, which when quartered makes four alighting-boards. The surface should be roughened by a toothed plane.

**SUPERS** are 13 inches square inside and of various depths.

6 inches deep is a convenient size and when filled will contain nearly 30 lbs. of honey. The engraving represents a very neat glass super of this size, which is manufactured by Messrs. Neighbour. It shows

also the adapter with its longitudinal communications near the sides of the hive, and which replaces the crown-board when a super is put on. As the honeycombs in supers are better when made of a greater thickness than those intended for breeding, I place only eight comb-bars in a thirteen-inch super.

**HIVE-ROOFS AND OUTER CASES** are made of half-inch wood 11 inches wide. The former is separate, and is cross-braddled

together at the angles with a two-and-a-quarter-inch turned acorn in the centre; its frame fits loosely over the cover and

rests on angle-pieces at the corners. A half-inch opening is left under the eaves all round for ventilation. The hive-cover is dovetailed together and glued, with a brad driven through each of the tenons; it rests on the exterior projection of the floor-board, and is retained in its place by a plinth 2 inches wide, which fits loosely outside the latter. It must not be forgotten that all wooden roofs and outside cases require to be kept well painted, whilst no paint should ever be applied to the hive itself.

When a super is put on a second outer case becomes necessary, and this fits loosely on the first, when the hive appears as it is represented in the annexed engraving.

In conclusion I may add that the Woodbury frame-hive with all its appurtenances is manufactured from my designs by Messrs. Neighbour and Sons, 149, Regent Street, and 127, Holborn, London, to whom also I am indebted for the use of many of the engravings, by which I have been enabled to illustrate my meaning.—  
A DEVONSHIRE BEE-KEEPER.

#### THE BEE SEASON IN NORTH LANCASHIRE.

IN your last I see that a correspondent predicts a cold wet spring, and that denotes a late one, or, at least, when combined they are the materials that such is made of. In comparing notes I find that so far we are at least a month earlier in this district than in 1861. The first pollen gathered in that year was on the 16th of March; but this year the first was on February 6th, making a difference of nearly six weeks. Upon the whole it was a warm month; on the 22nd and 23rd the thermometer rising in the shade, a north aspect, to 50° and 52° respectively, a height never reached in March of last year. On the 22nd and 23rd of that month we had 3" and 5" of frost accompanied with a heavy snow storm.

April with the exception of to-day (the 11th), has been favourable, the wind north and only 42°, yesterday 56°. On the 8th the young bees were out in great numbers. Last year I did not see any until the first week in May, but, perhaps, they had not shaken off the dull cares of 1860.

It is an old saying, "Early drones, early swarms." If so, I shall expect them early, as I had one drone turned out to-day dead but fully matured. Last year no drones made their appearance from the same hive until the swarm had issued, June 11th. A second issued on the 23rd, and a third on the 25th, by this time rather too much; and to add to this it came home from the moors in the beginning of September queenless. I selected one of my strongest stocks with a young queen to be mated to this. After this "ventilation" became a necessity in all. I had three ventilated at the top until the latter end of February, and they are the most forward stocks at the present time; but it must not be taken for granted that I recommend it in all cases, it entirely depends upon the strength of the stock. If weak, my plan is to keep them as snug as possible after the cold sets in. I have practised the above since 1858 with the best results, and with confidence I recommend it to those who have had some experience in the management of the bee.—  
A NORTH LANCASHIRE BEE-KEEPER.

#### THE QUEEN IN DANGER.

I STATED in page 19, that my experience induced me to think it likely that Dzierzon was correct in declaring that a queen bee cannot pass beyond the limits of the "brood-bed" except at the risk of her life. This opinion was very strongly confirmed no longer ago than yesterday (16th April), when, on opening one of my hives for examination, I immediately found the queen a

close prisoner amidst a cluster of workers, of the size of a bantam's egg, on the floor-board and quite away from the brood-combs. With some difficulty I effected her majesty's release much against the will of the workers, several of which attempted to end the skirmish by piercing their sovereign with their stings. Having freed her from these disloyal traitors, I introduced her between two of the bars, to which I knew brood-combs were affixed, and proceeded with my examination. On arriving at the comb on which I had placed the queen I found her again a close prisoner, and had again the same difficulty in releasing her. Being willing to see if she would be better received in the centre of a brood-comb, I laid one on its side and placed her just in the middle of the brood-cells. No sooner had she touched the comb than she was seized and attacked in the same manner as before, and once again I had the same difficulty in releasing her. There could, therefore, be no doubt that a similar spirit pervaded the entire colony, since three different sets of bees had acted precisely in the same manner in three different parts of the hive. Not knowing what better to do, I separated two brood-combs which had not before been meddled with, placed the queen in the middle of one of them, and, putting them again in their places, closed the hive as rapidly as possible without waiting the result.

This circumstance caused me no little anxiety, owing to the queen being a beautiful Ligurian, and also the last survivor of those originally imported from Switzerland; but this anxiety was completely allayed on examining the hive this morning, when I found her majesty once more parading the brood-combs in all the pride of undisputed sovereignty, and receiving the voluntary homage of her erstwhile rebellious subjects. — A DEVONSHIRE BEE-KEEPER.

### ROBERT SYDSERFF.

THERE is a rather rare little volume having this title page: — "Sydserrf's Treatise on Bees; being the result of upwards of thirty years' experience. Executed on a more general, extensive, familiar, and useful plan than any other work of the kind yet published. By R. Sydserrf, Leigh-on-Mendip. Salisbury, printed by B. C. Collins, 1792."

The perusal of the volume at once enabled us to conclude that its author was a thoroughly practical bee-keeper; and no sooner was he thus established in our good opinion than, as is our wont, we wished to know all that could be known about one really so worthy.

The only clue justifying a hope that from some old survivors of Sydserrf we might glean fragments of his biography was furnished by the fact, that in 1792, as the above-quoted title-page states, he resided at "Leigh-on-Mendip." Now, this little hamlet lies about eight miles westward from Frome in Somersetshire; and the hope at once arose that we might enlist for our research that mortal, characterised by energy and common sense, who is so favourably known to our readers as "THE DOCTOR'S BOY." We were not deceived by that hope, nor in our estimate of our coveted agent. This is testified by the following letter we have received from him:

"I took the first opportunity, after receiving your note, of visiting Leigh-on-Mendip, which is about eight miles from Frome. I at once inquired for its "oldest inhabitants," and was soon in company with one of them, but he was too deaf to be of any service to me; but his daughter directed me to another old man that was not deaf, and a native of the place.

"I soon found him out, and at the first appearance I thought I was all right, as he was an active, lively, old man. But in him was a greater disappointment; for although he could hear and understand, and seemed very desirous to give information, his memory was "no worth a prun;" and when I tried to refresh it by taking him back to his earlier days, he had forgotten which was his oldest child, or where he married his wife from—i.e., from what house. I then asked the grand-daughter if there were any farmers or other respectable people about the age of her grandfather, natives of the place, still residing there; and she recommended me to one, Dr. Moon, a retired army surgeon; to whom, after a short delay (he being at tea), I was introduced. After attempting to make an apology for thus intruding I handed him your note, believing that to be the quickest and best way to make him acquainted with my business. But he declined reading it, and wished me to do so; at the same time desiring me to draw a large arm-chair, the ditto of the one he sat in, near to his and be seated.

"I then began the note; and as soon as I mentioned 'Robert Sydserrf,' I found I had deposited the pinch of salt on the right spot at last.

"This gentleman deserves a chapter for the benefit of posterity by a pen that can do him justice in the transactions of your Journal, as he belongs to a class that is fast disappearing from amongst us, and much to be regretted. He had been much abroad, had seen both sides of the globe and both sides of mankind, and he retains a vivid recollection of, and likes to dilate on the beauties of both. But I must return to Robert Sydserrf.

"Dr. Moon knew Mr. Sydserrf well; and I will briefly give the information I received from him without the garnish of anecdote or raciness with which it was delivered.

"ROBERT SYDSERFF was a native of Scotland, by trade a tailor, and by calling a local preacher of the Methodist Connection. He married in the neighbourhood and had two sons, both regular preachers, and one daughter, now all dead. During his residence at Leigh-on-Mendip, he had some property left him in Scotland, but had not the means to go there to receive it, and it was to raise the means to do so that he published his treatise on bees. Dr. Moon was well acquainted with him, as he used to make the clothes for the family at their own house. He showed me a bust of Sydserrf by himself, and he assured me it was an exact likeness, but I forgot to ask whether it was a cast or a model. Sydserrf had what the Doctor called a cherry lip, about which he told a humorous tale.

"Sydserrf left Leigh-on-Mendip, and went to reside at Mells, about four miles from Frome, and there he died and was buried; but with regard to dates Dr. Moon could tell me nothing.

"Since then I have been to Mells, and called on some distant relatives of Sydserrf's, where I saw a grand-daughter of his. Still they could only just remember him. So I then called on the parish clerk with a view of getting the register of Sydserrf's burial; and he, being an old man, could remember him well, but he could remember no dates.

"He referred me to the curate for the register, and fortunately the curate called on the rector to ascertain the fees to be charged; and the curate having your note showed it to the rector, the Rev. J. S. H. Horner, and, fortunately, he had been a subscriber to THE JOURNAL OF HORTICULTURE from its beginning: therefore, to render all the assistance he could to promote the interest of the Journal was to him a labour of love, and he cheerfully made the copy enclosed gratis. Nor was this all, for he obligingly showed me over the gardens, which owe their chief attractions, which are not a few, to his own personal attention, as he informed me he kept no regular gardener but had a handy labouring man—which leads me to the remark I have often made, that it is really surprising what some gentlemen, and ladies too, can accomplish with the assistance of a handy man. Finally, the rector desired me to say he would be most happy to give any further information on the above if it was in his power, or at any time upon any other subject connected with his neighbourhood."

The extract from the Mells Parish Register is as follows:—

"Burials in the Parish of Mells, in the County of Somerset, for the year 1815.

Name.	Abode.	When Buried.	Age.	Officiating Minister.
Robert Sydserrf.	Mells.	June 30.	71.	J. Higgins, Curate.

When you once get hold of the end of a thread, whether of a silkworm's cocoon or of a biography, you are always enabled to unwind more than was at first apparent, so the above dates enable us pretty clearly to establish Sydserrf's birth-date and birth-place.

As he was 71 when he died in 1815, he must have been born about the year 1744; and, confirmatory of this, we find the following passage in his "Treatise:"—"The first part of my life—viz., from December 1, 1743, to December 4, 1769, I resided, unless at intervals, at Stalbridge in Dorsetshire."

We may conclude, therefore, that Stalbridge was his birth-place, and December 1, 1743, the date of his birth. So far, then, Dr. Moon is wrong in calling him a Scotchman; but we have no doubt he was of Scotch extraction, for Sydserrf is a Scottish family name.

Dr. Moon's narrative that the "Treatise" was written to raise a fund to enable him to obtain property which had devolved to him in Scotland is quite compatible with Sydserrf's own statement, that the completion of the work was hastened by his narrow escape from death. He says in the preface, "When I had wrote about thirty pages, I laid it by inclosed in a book,

without thinking any more about it; but some time after, a person, opening the book, saw it, and, unknown to me, took it away. He showed it first to one, then to another, till it was no longer a secret. Being under many obligations to different persons, I was under a necessity of lending it from one to another. Most of those who had then seen it, earnestly intreated me to get it printed; this was a measure I could think nothing of. I was then desired to write it over again (as much of it as was lost), and finish it, which I promised to do, but postponed from time to time, until I was importuned by the Rev. Mr. Watkins, of Leigh-on-Mendip, for that purpose. On assuring him that I would get a book and do it, he then gave me one, telling me at the same time that now I had no excuse for delaying it. Though I fully intended to do it, it was still put off from time to time, until the latter end of the year 1783. I was then seized with a putrid fever, and soon became insensible. Being given over by the physician, and nothing but death appearing probable, it lay much on my mind in the interval of my senses, and I was determined (if I should be spared) no longer to put off the business till to-morrow.

"Having thus informed the reader by what steps this treatise has arrived to its present state, I have only to add, that there is not, in the whole book, one page, nor even a line, which I do not know, or have not reason to believe, to be true."

Tailoring and preaching, though Sydeserff's chief occupations, were not unassisted as a matter of revenue by his apiarian knowledge, for we find this postscript to his preface:—

"Any gentlemen whose bees have omitted swarming until the latter end of June, and are desirous of increasing their stock, may have swarms taken out of any old hive, by Mr. Sydeserff, the author, which shall do as well, or better, than those which come forth of their own free choice. In like manner bees are taken out of hollow trees, walls, or any other places on the following terms, if not farther than four miles from his house:—

For taking a swarm from an old hive .....	£0	5	0
Out of a hollow tree or other place of danger .....	0	2	6
Taking the honey and comb without hurting the bees ...	0	1	6
For a common swarm from a bush or tree .....	0	1	0

This leads us to make a few extracts as evidence of his knowledge of bee-keeping being in advance of his age.

"The queen or mother bee is of a comely and stately shape, brown of colour, as other bees, about the shoulders, but her hinder part darker; under her belly she is of a brighter red; her legs proportionable, and of the colour of her belly, but her two hinder legs more yellow. She is longer than a working bee by one-third part, and much larger. I never knew one of them to sting either man or beast, although I have often tried to provoke them to it that I might know the efficacy of their poison. Her office is to reign over and direct the other bees in all they do, to head the swarm, and to raise a new brood. She brings forth ten, fifteen, or twenty thousand young ones in a year, so that she may literally be said to be the mother of her people."

"Close under the honey, at the upper part of the combs at the bottom of the void cells, is the place where she first begins to lay her eggs, which are about the bigness of those that the butterfly leaves upon the cabbage; but they are of a different colour, those of the butterfly being yellow, but those of the bee are white. She first puts in her head to examine the cell, and, if void, she lays her egg, and so goes on, from one cell to another, until an egg be laid in every upper cell."

"If there is a sufficient number of bees let them not be taken barely because of their old age, for there is not a bee in the whole hive which is a year old, although the hive may have stood more than ten; and such hives seldom fail swarming twice or three times every year. I had a hive of bees which I kept near seven years, and then spared them to Mr. Isaac Budgett, in 1783, and this hive was one of the best in his garden in the summer, 1790, and I do not recollect that ever they missed swarming once a-year, and in general twice, and often three times. Bees which are designed to be taken should stand until all the young are come forth, and if any remain they should be separated from the sealed comb, otherwise the honey will be but of little value."

**SARRACENIA PURPUREA, A NEW REMEDY FOR SMALL-POX.**—The *Medical Times and Gazette* reports an interesting discussion at the Epidemiological Society, upon a paper sent from Nova Scotia, by Mr. Miles, surgeon in the Artillery. Captain Hardy, of the Royal Artillery, an accomplished and intelligent officer, who has been for years among the Indians, says that "the old

squaw's remedy had long been known to them as an infallible cure for small-pox," and that "the Indians believe it to be successful in every case." From the information gathered from the Indians, the following observations have been carefully sifted:—1. In the case of an individual suspected to be under the influence of small-pox, but with no distinct eruption upon him, a large wine-glassful of an infusion of the root of the plant *Sarracenia purpurea*, or Pitcher-plant (several specimens of which, including the root, were exhibited on the table) is to be taken. The effect of this dose is to bring out the eruption. After a second or third dose, given at intervals of from four to six hours, the pustules subside, apparently losing their vitality. The patient feels better at the end of each dose, and, in the graphic expression of the "Micmac," "knows there is a great change within him at once." 2. In a subject already covered with the eruption of small-pox in the early stage, a dose or two will dissipate the pustules and subdue the febrile symptoms. The urine, from being scanty and high-coloured, becomes pale and abundant, whilst from the first dose the feelings of the patient assure him that "the medicine is killing the disease." Under the influence of the remedy, in three or four days the prominent symptoms of the constitutional disturbance subside, although, as a precautionary measure, the sick person is kept in camp until the ninth day. No marks of the eruption (as regards pitting, &c.) have been left in cases examined, if treated by the remedy. 3. With regard to the medicine acting (as is believed by the Indians) in the way of a preventive in those exposed to infection, it is curious to note, that in the camps where the remedy has been used the people keep a weak infusion of the plant prepared, and take a dose occasionally during the day, so as to "keep the antidote in the blood." A discussion followed the reading of this paper, in which Mr. Marson, Dr. Copland, Dr. Waller Lewis, Dr. Babington, Dr. Morehead, Dr. Milroy, Mr. Radcliffe, Mr. Lord, and Dr. M'William, took part. All of the speakers concurred in the desirability of requesting Mr. Miles to procure a further supply of the root of the *Sarracenia purpurea*, with the view of having its anti-varioid properties tested in this country.

OUR LETTER BOX.

**DORRING WITH DISEASED LEG (C. P.).**—The bone of the thigh was carious and greatly enlarged, and the periosteum or membrane covering the bone was highly inflamed. No treatment could have cured it, or averted a lingering death. The disease was, probably, caused by a severe blow.

**SPANISH FOWLS' FEATHERS DISEASED (E. Brown).**—The feathers enclosed are not in a healthy state. The white points are immaterial. All Spanish chickens are hatched with white flights, and many of the best birds throw white spots and stripes in their plumage. When there is any defect in the quill, it is the result of a fevered state of the skin, which prevents due nourishment being conveyed through the soft pipe which afterwards becomes the quill. The cure is to purge freely with castor oil, to feed on light ground food, and to give the birds a grass run. A change of weather will cause the earth to teem with food and medicine for tows. It is a common thing for feathers to turn the wrong way; it generally happens to the flight-feathers, and is hereditary in some strains. If the birds are in good health we always pull out these feathers as soon as they are found. It is always wrong to pull out growing feathers; it causes a hard substance to form, and frequently prevents after-feathering. When the fowls are in full health the feathers will come right.

**DESTROYING VITALITY OF EGGS (H. B.).**—Pierce one end of the shell with a needle.

**BANTAMS LOSING HEAD-FEATHERS (A Subscriber).**—Continued wet and cold winds have contributed to injure the health of fowls. When feathers fall it is evidence of a bad state of body; if they are picked off by their companions it is the same. Give them castor-oil, a table-spoonful, every other day, and rub the bare spots with compound sulphur ointment; the oil need be continued only so long as the disease exists. The comfortable appearance of the birds will tell when they are cured.

"A STEWARTON APIARIAN" would much oblige "A DEVONSHIRE BEE-KEEPER" by stating the result of the experiment with the Woodbury comb, which he mentioned in page 286 of the last Volume of THE JOURNAL OF HORTICULTURE.

LONDON MARKETS.—APRIL 21.

POULTRY.

There are not wanting proofs in the market that the winter has been a mild one. For the last day or two small chickens have been more plentiful, and there is reason to believe we shall not have a recurrence of the scarcity that has marked the last two or three years during the months of May or June.

Large Fowls .....	Each—s. d.	4	6	to	5	0	Ducklings .....	Each—s. d.	4	0	to	4	6

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 61.6° and 39.2° respectively. The greatest heat, 81°, occurred on the 4th, in 1833; and the lowest cold, 20°, on the 2nd in 1855. During the period 149 days were fine, and on 96 rain fell.

SUPPLY OF KITCHEN VEGETABLES.

THE TIME WHEN EACH MAY BE IN USE, AND THE CASUALTIES WHICH MAY PREVENT IT.

I have allowed this subject to be a theme for our pages with some reluctance, not because it is unimportant, not because we have had few relative inquiries, but because we apprehend that a statement of what culinary vegetables may be had usually, will be liable to induce employers to be dissatisfied, when really soil, season, locality, disease, or depredators may be in fault, and not the employed. With this warning we will publish one of the letters we have received, and the reply of one of our most experienced contributors, to whom we submitted it.

"I am one of the numerous class of masters who have plenty of gardeners, but get little or no return in the vegetable department for the money laid out. Day after day nothing but one vegetable (the Potato) adorns the board. You would be doing no small service to gardeners' masters, if you would kindly publish a weekly list of what ought to be brought to table, where no expense or trouble is spared; we should then know whether we justly complain, or are merely crotchety.—ONE OF YOUR EARLIEST SUBSCRIBERS."

I confess having some hesitation on commencing a series of articles describing what vegetables may be reasonably expected at different times of the year by those who possess a kitchen garden of about an acre or so, occupying a fair average site in localities which for distinction will only be called north and south. The former being the less favoured by natural means, the other having these advantages yet lacking some advantages which the other possesses. But independent of these distinctions there are so many considerations to be taken into account, and so many contingencies to act on, crops depending on their principal success on natural agencies over which the most skilful cultivator has no control, that it is only fair to state some of the many uncertainties a kitchen gardener has to contend with, in order that when everything proper for the season is not forthcoming, some allowance may be made for deficiencies which may be from causes which if not impossible to avoid, are certainly difficult to foresee. At the same time, the uncertainties here mentioned ought not by any means to be put forth as excuses on any occasion but where they can be legitimately used, and these cases in the ordinary course of things will not be very often.

With these preliminary observations, I will at once enter into the subject of casualties as likely to befall the various crops the kitchen gardener has to deal with, and must beg all those whose tables are not only supplied with the vegetable that may be said to be due at the time that will be mentioned, to carefully consider whether any of the reasons here given, can, or can not, be justly put forth as an excuse for the absence of the article in question; and as the culture of the various kitchen garden productions has been given in another place, the uncertainty which each is liable to, is more

particularly recorded here, where the weather, soil, or other feature bearing on their well-being, is of an adverse kind. A due allowance for this will enable both employer and employed to form a more correct opinion of what shortcomings may be reasonably and fairly accounted for, and what ought to be present, and the conditions here entered into are such as may be met by most small gardens, where one man or more is kept; but for distinction it is only fair to say that there are two men employed, as very often other things as well as those connected with the kitchen garden, are to be thought of at the same time.

*Artichoke.*—The Globe Artichoke suffered very severely in the winter of 1860-61, so much so, that very few plants were left alive in many gardens where they had stood unscathed for many years. A little protection round the collar will, in most instances, preserve them; but a very severe winter by destroying all the larger leaves, necessarily retards the plant in furnishing the large heads expected; but when planted on a dry soil, and some rough dung laid round each plant early in December, it will usually survive the winter with little injury, and bear heads in the south of England by the end of June, and continue doing so during July and August. Of course, a few plants will only produce a proportionate number; but as it is not in general one of the popular vegetables, only a few plants will be wanted.

*Artichoke (Jerusalem).*—Unlike the last, I do not know of anything likely to injure this, and where there is space to grow it, its appearance on table may be reckoned on at any time from September to May; but like the last-named vegetable it is not one of the popular class, but as a change, deserves attention. Good ordinary garden soil not too dry suits it best. In fine autumns like that of last year it flowers; but this does not seem to have any influence on the root.

*Asparagus.*—Few vegetables present greater apparent cause for dissatisfaction than this, for it is but comparatively few gardens that yield such fine heads as those sent to Covent Garden. The vale of the Thames is certainly unrivalled for this article, and the inexperienced amateur can hardly hope to equal the produce of this district on a soil of an opposite character to the one it is grown in to so much perfection. I have seen the stiff loamy soil of a district that produced some of the best Wheat in the kingdom, trenched 2 feet deep, and a deep layer of brickbats and other rubble laid in the bottom, as well as drains of the most approved fashion, and dung lavished without stint, and salt, sand, and the other ingredients thought necessary to form a compound resembling the one it flourishes in to so much perfection, but the result fell far short of the expectation. Medium-sized Asparagus may, however, be grown in most places, and it is possible it may be in reality better at table than the large London kind; but in soils adverse to it the plant does not thrive so well, and in very wet or severe frosty winters there are often great losses amongst the plants, that due allowance must be made by those whose table may not be so abundantly served as they would

wish; but, in a general way, heads fit for table may be had from the end of April through May, but it is not good policy to cut it too late in the season, as that weakens the plants for another year. Young plants especially ought not to be overdone that way.

**Beans (Broad).**—These hardy legumes accommodate themselves to all soils, and after the middle of June a dish of Beans may usually be had all the summer, where there is sufficient ground to admit of the repeated sowings required to keep up a supply; but usually a few early ones, and a second crop suffice for small gardens, for other things coming in at the same time Beans are often set aside. The Mazagan is the best to stand the winter, but the Long-pod or Windsor is more admired for the main crop. The cultivation, however, having so often appeared need not be repeated here.

**Beans (Dwarf Kidney).**—These universal favourites may be had all the year round where there are heated glass structures to furnish them; but in small gardens this cannot well be the case. Plant, therefore, the first crop about the 20th of April, and succeeding ones up to the end of May. Generally speaking, the Dwarf Kidney Bean is admired as coming in before the Scarlet Runner, and when the latter commences it is thought sufficient. If, therefore, Dwarf Kidney Beans can be had in July, the other will fill up the rest of the season.

**Beans (Scarlet Runner).**—Certainly this is the most prolific of all the legumes used at table, and the fact of cottagers growing it extensively is a sure token of its being worth its place. Plant the first week in May, and again about the 20th, and if you like plant another row at the end; but usually the first planting, if successful, will carry on the supply to the end of the season. In average seasons, from the 12th to the 24th of July, is as soon as the first will be gathered in the south of England, in the north later, but as this vegetable furnishes so great an amount of food of a kind relished by all classes, where ground is scarce, and the situation a dry one, it would be better to omit the late sowings of Peas entirely, and have more of this, as it is the more certain cropper. Remarks on its culture, however, having appeared in other papers, it is needless repeating it here, only it is fair to say that in cold, wet situations it does not answer so well, and may be reasonably excused if not forthcoming. The cultivator and his employer must, therefore, both exercise their discretionary power in this case, and in the cool, damp situation sow more Peas, which are better bearers in such a place.

**Beet (Red).**—A little care at sowing time to prevent the slugs injuring, or rather destroying the young plants, will secure a crop of this; but another and much more difficult matter arises. All Beet seeds do not produce roots of the requisite good colour: hence the propriety of only dealing with the best seedsmen, as many complaints of Beet of indifferent quality arise from causes over which the gardener has no control whatever. If he saves his own seeds, which many do who have once possessed themselves of a good variety, he may insure the article being good, and many seedsmen also send out only good varieties; but there is nothing more likely to sport and degenerate, if not duly kept up to the mark, and the appearance of the salad bowl is sadly marred by a coarse, stringy substance of a half Mangold Wurtzel breed.

**Borecole, or Kale.**—A useful class of vegetables, especially in spring, as it is principally the young shoots that are admired. The Curled Green or Scotch Kale is one of the hardiest, but the class partaking more of the character of Chou de Milan is a greater favourite at table, the Cottager's Kale and Asparagus Kale are also useful and good, and it may fairly be set down that a dish of Greens of one or other of these kinds will be forthcoming every day in February, March, and April; but for autumn and mid-winter use, the services of the following are more decidedly useful.

**Brussels Sprouts.**—Of all the vegetables the garden can boast of, perhaps none can be so certainly depended on to fill up a gap at the most inclement season as this. Brussels Sprouts are usually to be had in good condition for table from October till April, and the hardest weather has but little effect on them: therefore, to the owner of a small garden it is prudent to plant a considerable breadth of this, quite as much as of all the other kinds of winter Greens and Savoys put together. For cultivation see former articles.

**Broccoli.**—This popular vegetable often deceives the most experienced, as the mildness or severity of the season has so much influence on it that it is difficult to foresee with anything like a certainty when it may be likely to come into use. The best way is to plant three or four sorts, as the Purple and

White Cape for autumn, Walcheren and Snow's Winter with Knight's Protecting for winter, and the Portsmouth and any other large kind for spring; the Wilcove being about as late as any. In very severe weather throwing a little litter over the most forward heads will protect them much, and in ordinary winters the kinds above will furnish a supply all the autumn and winter up to within a short time of when the first Cauliflowers are expected. Where there is space for planting a good breadth, with a late border for the latest Broccoli, and an early one for the first Cauliflower, there should not be more than a week, or at most ten days intervening between the one and the other.

**Cabbage.**—Second in importance, perhaps only to the Potato, a good bed of Cabbages affords a something to cut from nearly all the year round; for after cutting the Cabbage, the second and third crops of shoots furnish an exhaustless supply of greens until severe weather in February arrests their growth; and the ground being wanted for something else, the old stalks of the preceding year may be then removed, as it is expected another bed of young ones is coming on. But common and accommodating as this plant is, it is by no means exempt from the uncertainty which all vegetation is subject to. An unusually hard winter kills many of the plants; and a very mild one, by allowing their growth to go on almost uninterrupted, they arrive at too large a size in March, and not unfrequently run to seed instead of forming useful compact hearts or heads. This evil is the case in more places than one in the present spring, while the other misfortune befell a still larger number the year before. Cabbages and Cabbage sprouts may be reckoned on for the most part of the year.

**Cauliflower.**—When well managed and a few early plants are preserved through winter in hand-glasses, and allowed to stand on the same spot, they will generally come into use by the middle of May; and from thence up to November Cauliflowers ought generally to be forthcoming, excepting in very hot seasons and dry situations, when a gap must be excused in the supply. Some other misfortunes now and then occur in their cultivation, but usually the Cauliflower is a constant and acceptable accompaniment to the good things of the dinner-table.

**Carrot.**—A few sown very early in a hotbed will be found very useful, after which a bed on a south border will come in well, the main crop being sown the third week in April. Some soils are, however, not adapted to the Carrot, in which case it is better to buy the winter stock than struggle against difficulties to grow them; but by all means sow some for early and general summer use, and as an article for table April and May may be regarded the scarcest months.

**Celery.**—Good ground and a liberal allowance of manure will generally secure good Celery, and if the seed be from a good solid kind there is no difficulty in obtaining a good article; but the fastidious admirer of Celery must not be unreasonable in requiring too large a quantity, for to have it good it requires a large space, and the due supply of other things does not always allow of this. Nevertheless, a large breadth of Celery may be, or ought always to be planted, and its presence at table may be reckoned upon from September to the end of March. A little for soup may be also had in the intervening time, but an article for salad cannot well be had in good condition before September. Dry weather and a dry place check its growth, so that in the north of England it is often earlier than in the south, where its growth is mostly confined to the autumn.

**Cucumber.**—Up to the middle or end of July these must be looked for under glass; but in August and September favoured situations produce them plentifully enough out of doors. With the assistance of a frame and hot dung they may be had without any great amount of care or skill by the middle of April, and from thence up to October may be regarded as plentiful. After then, being less cared for, the frames we presume may be wanted for something else. It is right, however, here to mention that the Cucumber is subject to a singular disease—a gummy substance exudes from the fruit on the places where the spines ought to be, and often destroys the whole crop. It, however, is not of frequent occurrence; but where it does appear its virulence is only equalled by that of the Potato disease, and, like it, it is equally difficult to cure or prevent. J. ROBSON.

(To be continued.)

ARRIVAL OF MR. J. GOULD VEITCH.—We are happy to announce the safe return of Mr. J. Gould Veitch from Japan. He arrived in London on the evening of Saturday, the 19th inst., in excellent health. It is now just two years since this young

gentleman set out on his maiden journey to a land which to Europeans was a land unknown. He went, not to follow a trodden path, or to visit scenes that had been depicted by former travellers; but with the stout heart and firm resolve that were necessary for such an undertaking, he set out prepared to meet the dangers and difficulties incident to such an expedition. How he has carried out the object of his mission is now pretty well known. To him we are indebted for many of the rarest Conifers of Japan, besides many other plants which had never before been introduced, and we understand he has brought home with him seeds of numerous plants hitherto unknown.

### THE GENUS HIPPEASTRUM.

WHEN Linnaeus named the original species *equestris*—a bright orange flower with a green star at the bottom—he meant it to signify the Equestrian Star, or Knight's Star, a badge of an ancient order of knighthood, and *Hippeaster* means the same thing. Singularly enough, *equestris*, the species on which the genus was founded, was the first plant of the order of Amaryllids which the first collector of the reformed, and Royal, Horticultural Society had met with in Brazil last August; and no less singular, if we date back to the time of Linnaeus, that *equestris* is now met with, in a wild state, within sight of a railway station.

He found it on the woody hills above Belem, forty miles from Rio (see our "Proceedings," 1862, page 53). He found more of them also there, but he missed some good ones up the gorges of Corcovado, and on the south side of the bay. The whole family are natives of Brazil, except *vittatum*, which is from the opposite side in Peru, and *regium*, or *regina*, a native of nobody knows where, but somewhere on the low coast of Mexico. A very fine variety of *solandriiflorum*, with red stripes on the outside, was sent from Lima to the Glasgow Botanic Garden; but whether that was a garden plant or a native has not been stated. As there is now no difficulty in procuring all the best kinds for garden use from some one or other of the Brazilian ports, and as the Royal Horticultural Society have them in their schedules for prizes, and also because there are very few of them now in England, and still fewer who know much of the high estimation they acquired in the latter part of the last century, and the first quarter of this, I mean this contribution to be half historical and half biographical of what was known of them, and what they had been brought to by the skill and industry of a race of growers now nearly gone to their last account.

No plants in the world were in higher repute, in my younger days, than these very plants; no race of plants is more easily improved by cross-breeding, and crossing is yet very far from producing results such as were effected in this family forty years back. The nearest to it will be the crossing of the large-flowering Sikkim Rhododendron. Even then I do not see how you could excel some of the crosses I have seen from *Hippeastrum solandriiflorum*, the flowers being full 10 inches long, and from 5 inches to 7 inches across. What you see of them now are merely the dregs of a former world, not worth talking about, and to make a fresh start with what you can muster, without fresh importations, would be as wise as to graft at the wrong end of the stock as they do Manetti.

With the above limitation the genus is confined within the tropics in Brazil; but on account of the various elevations at which the different species are found, some of them are hardy greenhouse plants, some prefer an intermediate treatment between stove and greenhouse plants, some are hardy stove, and some very tender stove plants—meaning hardy and tender in respect to treatment, not as to the degree of heat. One is an evergreen the year round, and one or more are inclined that way, if encouraged; the rest cast their leaves and remain dry during the winter, and a section of them, if well managed, will rest in winter and at midsummer, flowering both in the spring and in the autumn. There are only ten or a dozen wild species known to be good crossers; but some of these have several local wild varieties, and some of the wild varieties are better garden plants than the species; but let me take the species in alphabetical order, and tell the tale of each, and where a figure and full description of it may be found and verified.

1. *HIPPEASTRUM AULICUM* (*Bot. Reg.*, vol. vi., 444), with two varieties—*glaucophyllum* (*Bot. Mag.*, vol. lvi., 2983), and *platypetalum* (*Bot. Reg.*, vol. xii., 1038). These have only two flowers on a scape, the flowers chiefly a crimson and a green throat. The glaucous-leaved sort is the best to cross, and the three are hardy stove plants.

2. *H. BULBULOSUM*, under which eleven varieties or kinds come in, because they produce blind offsets, and only vary in the shades of colour, or leaf, or stature. They have different degrees of orange and red to crocatum (*Bot. Reg.*, vol. i., 38), which is coppery orange. They are all of easy growth. The following are the best breeders of them—*ignescens*, with a small fiery orange flower; *rutulum* (*Bot. Reg.*, vol. i., 28), a brilliant scarlet; *fulgidum* (*Bot. Reg.*, vol. iii., 226), pale orange scarlet; and *pulverulentum* (*Bot. Mag.*, vol. xlix., 2273). All these kinds grow in the vicinity of, or not very far from Rio, and some of them may now be in Chiswick garden, from Mr. Weir, the Society's collector. They made an exquisite strain by crossing with *solandriiflorum*, and quite another strain of high orange scarlet tinged with purple, and very tender, by crossing with *fulgidum*, and *rutulum* with *reticulatum*; but the two races have been extinct for the last thirty years.

3. *H. CALYPTRATUM* (*Bot. Reg.*, vol. ii., 164).—A tender stove plant with two flowers on a scape; colour greenish, and the green netted over with red. With the least encouragement it is an evergreen, but crosses from it and by it are very beautiful and require rest in winter.

4. *H. EQUESTRE* (*Bot. Mag.*, vol. ix., 305).—A hardy stove kind with bright orange flowers, with a green star at the bottom. This was the original kind, and was from Trinidad, Surinam, and West India islands. It is not so good as *stylosum*, with the same colour, to breed from; but *stylosum* is difficult to get.

5. *H. PSITTACINUM* (*Bot. Reg.*, vol. iii., 199).—A hardy greenhouse plant. A most valuable breeder with two flowers only on a scape. The colour a dark green richly netted and margined with bright red.

6. *H. REGIUM* (*Bot. Mag.*, vol. xiii., 453).—Bright scarlet flowers with a green star. A much better plant than *equestris* for crossing, the flower is of better substance and colour, and of much better form, while the bulb is equally hardy in the stove. Named *Regina* from having first flowered in England on the Queen's birthday, in 1728. Said to be a native of the shores of the Mexican Gulf.

7. *H. RETICULATUM* (*Bot. Mag.*, vol. xviii., 657).—A delicate, tender stove plant of exquisite brightness and beauty. Colour purplish-red, as in some of the new *Nosegay* *Gersniums*, and that regularly netted or reticulated with a darker colour, and a clean clear white star at the bottom. The locality of this splendid bulb has never been recorded, but as the collector of the Society found the only known variety of it, *striatifolium*, near Belem, we may presume the species is not far from Rio, and, perhaps, nearer the coast. *Striatifolium* with a white band down the middle of the leaf, has a larger and a paler flower than the green-leaved *reticulatum*, and it is now at Chiswick garden, from the collector.

8. *H. SOLANDRIIFLORUM* (*Bot. Mag.*, lii., 2573, and another variety of it, *Bot. Reg.*, xi., 876).—Two forms of this magnificent plant with the flowers from 8 inches to 10 inches long, which are of the same form and nearly the same colour as those of *Solandra grandiflora*—that is to say, creamy white with a tinge of pale green in it, and faintly striped with red on the outside, and a deeper red at the end of the tube. This is a tender stove plant, but has been the parent of a hardier race of the most magnificent crosses ever raised, and with the pollen of *vittatum* and *psittacinum*, the seedlings require only the treatment of the greenhouse. The *rutulum* and *fulgidum* varieties of *bulbulosum* made another race with it, which were as hardy in the stove as those of *aulicum*.

9. *H. STYLOSUM* (*Bot. Mag.*, xlix., 2273).—A tender stove plant from near Maranham, with a more coppery orange than *equestris*, and giving a deeper tinge of orange to the cross seedlings than that species.

10. *H. VITTATUM* (*Bot. Mag.*, vol. iv., 129, and *Bot. Reg.*, 988).—Two varieties of the most valuable of all the *Hippeasters*, being the hardiest of the race. It lived out of doors at Mitcham, in Surrey, for many years, and even ripened its seeds in the open air, and had nothing but a coat of ashes over the border in winter. It is the male parent of *Johnsoni*, now the hardiest and the oldest cross we have of them, *regium* having been the mother. But a free florid race between it and *psittacinum* was still more hardy, yet they have all disappeared. *Vittatum* is soon weakened in stove heat. A strong bulb of it would have as many as nine flowers on a scape. It is a white flower with double stripes of red in it, and a green eye in one variety.

These were all the wild kinds that we have crossed, and there were only two more that I know of which were worth crossing

the longiflorum variety of ambiguum from Lima in the Glasgow Botanic Gardens, which was very like vittatum, with a larger and longer flower, and another red one found on the Organ Mountains, by Mr. Gardener, which is a hardier form of alicium, with better-shaped flowers. This last I had through Mr. Wailes, of Newcastle, as soon as it came over, and I had a fine race of hardy, stout, well-formed flowers from it at Shrubland Park, but less brilliant than those from alicium. Dr. Herbert also bred from it, but I never heard the result. It seemed as hardy as psittacinum, and it ought to be still at Woburn Abbey.

D. BEATON.

(To be continued.)

## ROYAL HORTICULTURAL SOCIETY.

APRIL 22ND.

FRUIT COMMITTEE.—Mr. Robert Osborn in the chair. At this Meeting the following prizes were offered:—

Class A. For the best and second best dishes of dessert Apples, distinct sorts.....	20s.	10s.
„ B. ditto ditto ditto kitchen Apples.....	20s.	10s.
„ C. The best and second best dish of Strawberries, not less than 50 fruits.....	20s.	10s.
„ D. Best three heads of Broccoli.....	10s.	

In Class A, Messrs. Ivery & Son, of Dorking, were the only competitors. They exhibited Mickleham Pearmain, a fine dessert Apple so late in the season, but considerably shrivelled; Hertfordshire Pearmain, also much shrivelled; and Court of Wick, very good, but small. To this collection a second prize was awarded.

In Class B, Messrs. Ivery & Son exhibited French Crab, Norfolk Bessin, and Bess Pool; and Mr. Hall, gardener to Captain Tyrrell, Fordhook, Ealing, exhibited French Crab, Dumelow's Seedling, and Bess Pool. Those of Mr. Hall were much superior to Messrs. Ivery's, and the first prize was accordingly awarded to them; the second prize being awarded to Messrs. Ivery.

Mr. Charles Turner, of Slough, sent three heads of Broccoli of the Frogmore Protecting variety, which appears to be a form of Knight's Protecting. The prize was awarded to them because of their being the only exhibition for the prize. The heads were "leafy and frothy," and not good specimens of what a good Broccoli ought to be.

Mr. William Thomson, gardener to the Duke of Buccleuch, Dalkeith Park, sent a bunch of Lady Downe's Grape in very fine condition for so late in the season. The berries were as plump and fresh as if it had been autumn, and still the bunch had hung on the Vine till the young shoots had begun to break. So highly did the Committee appreciate this example of horticultural skill, they awarded a Certificate of Merit to the exhibition.

Mr. Cox, gardener to H. Coore, Esq., Scruton Hall, Bedale, sent a very nice bunch of Barbarossa Grape of large size, produced in a greenhouse where plants were grown. The berries were rather small and shrivelled, but their flavour was excellent.

Mr. David Thomson, of Archerfield, near Dram, N.B., sent berries of the Archerfield Early Muscat Grape, the Bowwood Muscat, Tynningham Muscat, and Muscat of Alexandria. The Archerfield Early Muscat was quite soft and ripening, while the others were quite hard and green; and it exhibited all the character of being fully six weeks earlier than the others.

Mr. Pring, gardener to the Hon. Mrs. Vernon Harcourt, sent a seedling Apple which was very richly and highly flavoured, but which proved so like Russet Nonpareil, which was also exhibited at the Meeting, that the Committee could not distinguish the difference between them.

FLORAL COMMITTEE.—J. J. Landy, Esq., in the chair. The first plant brought forward was Lithospermum fruticosum, from the Messrs. Lee, of Hammersmith, for which a Second-class Certificate was awarded, the plant being considered a useful rock plant to be treated and used as a rock Cistus. The aspect of the plant at a short distance was that of a free blue Anagallis, but is more woody than that; it blooms from May to October out of doors, and cuttings of it taken in September, should be kept over the winter with Verbenas and other bedding plants to be turned out at the end of the spring.

From Mr. Anderson, the great cross-breeder near Edinburgh, were cut flowers of a fine seedling Clematis, a cross between cœrulea and lanuginosa, distinct in colour between the two parents, for which an award was made.

Also a pale blue Gentiana received from Dr. Jameson, from

Peru; it is one of a class of numerous alpine plants of the same genus, natives of high localities on the Peruvian Andes, and was considered a nice botanical herbaceous plant.

Also some nice cross-seedling Rhododendrons between ciliatum and Edgworthii, a numerous race now springing up from different quarters, of which the best in habit we have yet seen is Countess of Haddington, a cross between ciliatum and Dalbousiæ, which was exhibited by Mr. Parker at the Azalea Exhibition recently held in the garden of the Society.

From Mr. Bull, of Chelsea, was a free-looking green-leaved Dracæna, called Ghiesbreghtii, for which a Second-class Certificate was given; and a slender Fern-like-leaved Lomatia, named elegantissima, which had the same award. Also Alsophila elegans, a strong-growing Fern, which was requested to be sent again when more advanced.

There were several other Ferns, and many seedling Azaleas, Rhododendrons, and Epacrises, among which were several Bhootan seedling Rhododendrons of the kinds sent out a few years since from the Clapton Nursery, from Mr. Tillery, of Welbeck.

Also Centaurea argentea from Mr. Salter, who sent besides a strange tinted sport of Scrophularia nodosa.

Mr. Standish, among other plants, sent a most beautiful new Solomon's Seal recently brought from Japan by Mr. Fortune. It is one of the most beautifully-variegated plants yet seen from Japan, the leaves being dark green and beautifully broad-banded with two or three silvery white ribbons on each leaf. It should be called Vittatum, and find a place in every good collection; a First-class Certificate was unanimously awarded to it. The whole beauty is in the leaves, the flowers being just the same as those of the Lily of the Valley.

Another most useful plant was from Mr. Everest, near Reading, and named by the Committee Genista Everestiana. Without being in flower you would take this plant to be the same as the old Cytisus or Genista rhodophena, and it must be a seedling from that race, with dense spikes of deep golden yellow—a most profuse bloomer, which will some day displace all the varieties of Cytisus racemosus, or yellow spring Cytisus now in use. This also had a unanimous award given to it as being likely to be "everybody's plant."

There was a "remarkably sweet" Dendrobium from Japan from Mr. Standish, a little alpine-like plant with small white flowers.

A large wide-spreading flower on a Hippeastrum from Mr. Williams, called after himself. It is distantly affected by vittatum, and is a better kind than is generally seen about London; but would not have been a great acquisition five and thirty years back.

Here Mr. Eyles reported favourably of the "Amaryllises" which the collector of the Society sent home from the neighbourhood of Rio; the Brazils being the native country of almost all the Hippeasters, and no Amaryllis has yet been met with in the new world.

From the garden of the Society were the same well-grown Anæctochilus which we mentioned from a former meeting, together with some interesting variegated plants from the collector of the Society, which are soon to be set up for Fellows of the Society to ballot for, that there may be no more room for complaints about the plants introduced by the Society being given away to those Fellows who might soonest hear of them and had the boldest face to ask for them. We consider this balloting for plants to be one of the best rules of the new Council.

## OXALIS SPECIOSA PRODUCING BULBS ONLY.

In the autumn of 1860, I planted several bulbs of Oxalis speciosa in No. 32-pots, three bulbs in each. Not one, however, made its appearance above ground.

Supposing the bulbs had rotted, I recently turned out the mould, when to my great surprise I found a cluster of bulbs at the bottom of each pot, or about treble the number planted. I have repotted them 1½ inch deep, but shall be thankful for any information as to the habit and culture of these bulbs.—Z. A.

[We expect that the bulbs had been kept too dry and too long out of the ground, as naturally the bulbs should have been in leaf and flower when you planted them. The bulbs also were, most likely, rather deep, and, in self defence, wasted their strength in throwing off small offsets. You are right in planting these rather shallow, in sandy loam and peat, and encouraging them to grow. It is doubtful, however, whether they will bloom

this autumn or not; but by watering as long as the leaves are green, and wintering in rather a dry state afterwards, you will be sure to get flowering bulbs next season. It is just possible they may greet you with their pretty flowers this season.]

## A FEW DAYS IN IRELAND.—No. 21.

(Continued from page 47.)

### CLONMEL HOUSE.

RESIDENCE OF J. M. NELIGAN, ESQ., M.D., MONKSTOWN, BLACKROCK.

THERE can be no question of the pleasure obtained and the improvement gained from visiting large princely places employing their scores of under-gardeners and laborers; or if more limited in extent, sparing no expense that everything alike rare and common should appear in the best possible condition. No greater misconception however can exist, than the somewhat-too-general idea that such only are the places worth seeing, or capable of exercising a beneficial influence on their possessors, and through them on the general community. In the first place, it is seldom that the smallest garden can be visited even by the greatest gardeners, without presenting to them some objects of interest which in their great establishments may either be wholly overlooked, or not so well attended to. From the very nature of things, it often happens that in small places many productions individually show more signs of careful unremitting attention than they do in larger places, just because in the latter attention is not only much more divided, and the gardener must often depend upon mere directions imperfectly carried out, or even counteracted; whilst in the former the principal operations will be performed by the gardener himself, or under his direct and immediate supervision. These circumstances will not so much apply in those very large places where several regular continuous foremen are kept and encouraged to stay; but they will more or less apply in such largish places where under-gardeners, to suit themselves, seldom remain more than one or two years in a place. At any rate the fact remains, that smallish places are not the least worthy of notice.

Again. But for the increase of these small gardens, the publishers of such serials as this could not expect a remunerative circulation, and thus gardening as an ameliorating influence would exercise but little power on the general community. Rejoicing, then, as we do in the neat profitable garden of the cottager, because other things being equal, and, humanly speaking, the man possessing a well-kept garden is likely to be a better man than his neighbour without one; and delighting in the princely establishments of the Trenthams in England, the Dalkeiths in Scotland, and the Cartons and Woodstocks in Ireland; we have equal pleasure in contemplating the great increase of gardens, in every possible position between the two extremes referred to, that is now taking place, not only in the country, but in the streets and suburbs of our towns, ranging in size from the so-many-days-a-week of the jobbing gardener, up to those that require a gardener constantly, and on to one or several assistants.

Our touching upon this subject naturally leads us to notice another great misconception as to the social position which such gardeners are presumed to occupy—in other words, the remuneration that is deemed sufficient for them. We are far from assuming that gardeners, even in the best places, are overpaid—quite the reverse, though we see reasons in daily operation why there will be no general improvement in this respect for the better. But we see no reason why there should be something like a recognition of a sliding scale, to the effect that the man who superintends a score pair of hands may be worthy of £100 a-year; whilst a clever man who has only to superintend his own pair of hands, is well paid with from £20 to £30. Of course, every employer has the undoubted right to decide what he is able and willing to give to his servant, and if wise will proportion his expectations accordingly. He should be well aware, that except in extreme cases of necessity, a man will not continue to serve unless on suitable terms. The expecting so much by the employer, and the receiving so little by the worker, are too generally the simple causes of the heart-burnings, the dissatisfaction, the constant changing that take place, and the wrecks of all that is economical in the garden premises as a consequence. What else can we expect, when almost every week we find advertisements for gardeners who must know this, and must do

that, be conversant with hothouses, forcing-houses, greenhouses, and, to make the most of them in fact, possess a good deal of the genius of a Fleming, and the talent of a Thomson, and then be paid munificently with from 12s. to 18s. per week? Not but that there are plenty of gardens, and plenty of men for whom such wages would be ample payment. The error is in supposing that a small place with any pretensions, requiring the best talent to make the most of it, can have that talent at such wages. The late Mr. London long ago advocated, that to make the most of a small garden, the best talent must be had, and suitable remuneration should be given. In large places more general intelligence may be necessary, and the faculty of directing and regulating men, and of properly organising and managing with efficiency labour-power—a matter altogether different and far more important than the mere seeing that men are actively employed, and which faculty also should be paid for as it deserves. But this faculty though less developed, will be necessary to make the most of comparatively small places, and the practical ability must not be behind. It is true there will be no comparison in the extent of responsibility; but, on the other hand, instead of chiefly observing and regulating, the gardener in the small place will have to observe, think, decide, and carry out with his own hands chiefly at one and the same time. When all these matters are taken into consideration, we trust it will be seen, that gentlemen who are ambitious to make their little gardens distinguished—that is, to make the very most of them in the way of pleasure and profit, must not only endeavour to get good gardeners, but keep them by paying them liberally.

Some such ideas swept through our mind in looking in upon Dr. Neligan's suburban or rather street garden, suggested chiefly by the size of the garden. Otherwise the remarks have no relative application, as Dr. Neligan unfortunately was from home, visiting the "land of the mountain and flood," so that we missed the pleasure that numbers told us we should have in meeting with a thorough enthusiast; and we know nothing of how he and his gardener Mr. Byrne, stand to each other, further than like most gardeners in Ireland, he seemed as if he could not speak too highly of his employer, which we always take to be a favourable sign, and in his shirt-sleeves, and active industry, seemed as enthusiastic and eager about his little paradise as his neighbour Mr. O'Brien could well be in superintending the rare and splendid plants of Mr. Bewley. We could not help wishing then and now that such gardens and gardeners were multiplied, not a hundredfold, but thousand by thousandfold in old Ireland, and Britain too, just because thoroughly believing that every one of these thousands of homes would or might be the recipient of new and pure sources of pleasure.

The whole extent of the ground of Clonmel House is 240 feet by 150 feet, the most of it being behind the house. On one side is a small elevated greenhouse in which, in addition to some nice Epacrisae and other plants, were some huge plants of Fuchsias, past their best, which not long before had carried off the honours at the Show of the Royal Horticultural Society of Ireland. Mr. Byrne does not approve of the roots of Fuchsias being dried too much when in a state of rest in autumn and winter. When he wishes to start them, he cuts or prunes them in pretty freely, and then places them in the stove, in a heat of from 50° to 60°. When the plants break their buds nicely he takes the plants out of the pots, shakes the old soil from them, thus reduces the balls, and prunes the roots if very long or weak, and repots in smaller-sized pots, keeps them in the stove in such temperature until the roots are coming out at the bottom of the pots, when they are transferred to the larger pots in which they are to bloom, kept in the higher temperature a little longer, and then placed in the greenhouse. The compost used is three parts good mellow loam, and one part dried horse-droppings, with a little silver sand. The plants had been very massive and full of flowers.

The other houses consisted of a vinery 50 feet by 12 feet; a plant-stove 24 feet by 14 feet; and an orchard-house 30 feet by 14 feet, with a pit in front of the stove 24 feet by 6 feet, assisted by the flue that heats the stove. These are low houses of wood and glass, on Mr. Rivers' system—for instance, the orchard-house is 8 feet to the ridge, and 4 feet high at the sides, with ventilating-boards there and no ventilation at the top, the side openings being found to be quite sufficient. In this house were some beautiful Pear trees, and others were standing in different parts of the ground in pots receiving the necessary treatment. A few Pine-Apple plants were grown in the stove, which seemed to us rather out of place where so many things were attempted.

Part of the stove was devoted to Melons up the roof, the kinds said to be some grand Indian sorts, of which we failed to be impressed with their value, so far as appearance went; but, perhaps, the flavour when ripe might neutralise our opinion. We should certainly be agreeably disappointed if any amount of sugar or of wine would render them delicious. We notice this because we have observed that the worthy proprietor and others have been, of late, sending to different places foreign Melons—we mean raised from foreign seeds—for the opinion of connoisseurs. It is a good thing that there are some who will take the trouble to test unknown kinds for the benefit of the public. For ourselves, after having a fair share of trying Melon and other foreign seeds, we politely decline receiving such seeds from obliging unpractical friends now, as our space is too limited to permit of these trials. There is such a pleasure in giving such things and asking about them afterwards, that we feel that pain is often given by a plain statement of the case. The receiving such packets with thanks, and then getting rid of them by placing them in the fireplace, might be more gratifying to the givers;—the result, "O no! we never mention it;" but in so doing we could hardly keep a clear conscience in the matter. There are so many good Melons, scarlet, white, and green-fleshed, that generally those with little room would do well to keep to these well-tried, well-known kinds.

Altogether in such a little garden there might be quite enough of the general-collection principle; but still Mr. Byrne had the good taste to concentrate his attention upon a selection of articles, and this, as we have often stated, would constitute a great charm in street and suburban gardens, and increase the pleasure of friendly neighbours, be they proprietors or gardeners. We have instanced *Fuchsias*; another plant to which special attention is devoted is the *Chrysanthemum*. These were standing on and by the sides of walks, and undergoing a tying and training process before being placed in the orchard-house to bloom, after the trees were placed outside. The training by hoops, &c., is done much the same as described in Nos. 3 and 4, only that Mr. Byrne, instead of having his plants flattish, gives them more the form of a hemisphere or semicircle. We did not think his plants were so large as those of Messrs. Smith and McNeill; but we had either been mistaken, or the plants had been trained and filled-out well before the exhibition at the end of November, at which Mr. Byrne stood first for six Pompons, and first for the special prize of twelve in pots, where distinctness, health, symmetry, and bloom of the plants, were the tests of success. Some Pompons in these twelve plants were the largest exhibited, measuring 4 feet 6 inches in diameter from side to side, and 6 feet across the arc of the hemisphere formed by the flowers, which on some plants were more than 1000 in number. Some readers may not think this notice is penned in vain, if they are made acquainted with the minutiae of Mr. Byrne's treatment.

Whether for large or small specimens, he prefers suckers to cuttings. For large heads to be bloomed in 13-inch pots he proceeds as follows. At the end of December or the beginning of January he selects three of the strongest suckers from the old plants, picks out all the lower eyes and buds; and if one or more sucker should be longer or more leggy than its neighbours, its centre is nipped out, or it is stopped or shortened. These three suckers are then potted in a 6-inch pot, using three parts turfy loam and one part fine sea sand, in which they soon root freely. These are placed for a fortnight or three weeks in such a stove as has been already referred to, to encourage rooting, &c. Then they are moved to the greenhouse for a similar time. They are then moved to a cold frame, where they continue until about the middle of March, when they will need potting into 9-inch pots. They are then kept in the frame for several weeks, and are then moved to a south border, where they remain until the May frosts have gone. By the 1st of June the plants get their flowering 13-inch pots, and from thence to the 1st of August the plants are kept on the north side of a wall. Then they are moved to the most open parts of the garden, then by-and-by to the front of a south wall, and from thence by the second week in September to the orchard-house. We may be mistaken, but we noticed little plunging of the pots, and to that we attributed the robnerness of the plants partly. The strength of the compost is increased at each shifting, until the last consists of half turfy loam chopped roughly, and half well-rotted stable-dung and sand. Stopping the shoots goes on to the middle of July, not later. When placed in the flowering-pots, two sticks are placed across it, and galvanised iron rings placed round as previously described, the hoop being about 3 feet in

diameter at first, and the size increased as the shoots grow. From that time the shoots are gradually brought down, and tied into shape, taking care not to be too rash at first. Water is given at the root when necessary; and when the flower-buds show, liquid manure is given once a-week, or twice if the weather is sunny and warm. When the plants are moved to the orchard-house each pot is set upon the top of another pot reversed, so as to raise them above the ventilators on each side, which are generally left open night and day, except in very cold and stormy weather. In our opinion the great secret of success under such a course of treatment, so as to secure fine healthy foliage as well as fine and numerous flowers, is the very free use of clear water all over the plants with the syringe morning and evening until the flowers begin to expand.

The same plan is adopted for specimen masses in 9-inch pots, with this difference—that a single sucker is selected, placed in a 4-inch pot, shifted into a 6, and finally transferred to a 9-inch.

If disposed to be critical, we might have wished that the main walks in such small gardens were done with flagstones, or asphalt, or gravel and tar, the latter concealed. Opportunity ought to be given for free motion whenever it is fair abovehead. The walk, if of stone, might be high enough to serve for edging as well, and thus be dry a minute after a shower. No edgings are worse than Box for such places, as it retains the wet and other things besides; and we like to see ladies walk in their own gardens with gracefulness and ease, instead of making frights of themselves by their sole concern about preserving their garments clean. Such places, to yield the greatest amount of pleasure, should be the very pink of cleanliness, order, and neatness.

If we have been somewhat slovenly in the minutiae of details, we feel confident that Mr. Byrne will kindly correct all that is amiss.

R. FISH.

#### RHODODENDRON NUTTALII.

WELL, I have seen a sight at last! but I ought to have seen it two years since at Kew, and in some of the London nurseries. I have just seen a noble specimen of *Rhododendron Nuttallii* in most noble bloom, in the garden of A. Mongredien, Esq., at Forest Hill, two stations from the Crystal Palace on the way from London Bridge, the celebrated garden for the *Spergula pilifera*; and this *Rhododendron* and that *Spergula* are now two good sights, such as you will not see elsewhere round London as far as I know.

I never said one word too much in favour of *Spergula* at all events, and if I say aught too much in favour of *Rhododendron Nuttallii*, it is big enough to bear it. It is the grandest flower in the order to begin with, and it is all but one of the cheapest plants in the country if you take it as a little seedling. I was told by several nurserymen, that they were now selling their seedling plants of it cheaper than the new *Verbenas* and *Nosegay Geraniums*; but the plants will not stand much frost. That which I went on purpose to see is about 8 feet high, and has six noble, if not most noble, trusses of flowers on it just now, and the trusses from six to eight flowers in each, and all the flowers on the same level in each truss. When the flower-bud is opening, the colour inside is a beautiful soft tinge of yellow; but, as the flower expands, it gets lighter and lighter, till at last it is purity itself in whiteness, and looks as firm as a piece of polished ivory. No white Lily is of firmer texture, and few more wide across the opening. When it is just at its prime the flower is 6 inches across, 4 inches deep, pure pearly white inside except at the bottom, where the original soft yellow tint remains to the last; and the back of the flower is tinged most delicately with pink, as in some specimens of *ciliatum*. The anthers are dark grey, and full of pollen; and if there are ten of them in each flower, as there should be, this plant would pay itself well by selling the anthers at one guinea the piece—and I am quite satisfied that no anthers were ever sold so cheap; equally so, that a good crosser could use them till the end of next June if he had bought some and took them home with him this week. But, of course, the gentleman who owns the plant would not think of selling the anthers or anything else that way; and of course, also, he will not think much of me for making the suggestion.

Now, as never was such another opportunity in my day, I will just observe that I would take three of the smallest anthers and shortest stamens I could find, wrap them well up in blotting-paper, and send them down by post to Mr. Anderson, the great Scotch cross-breeder and hybridiser, near the heart of Midlothian.

The anthers of all the flowers of this order, in which also

Heaths and Epacris are included, do not split along the side as most anthers do. The pollen gets out of the anthers by pores or an opening at one end: therefore, all the anthers in all the plants in all this order are the easiest to carry about for the purposes of crossing; and as far back as June, 1837, I put it in black and white, that you might gather the anthers of Rhododendrons on the Alps of Thiber, bring them home to England, just as I would send these to Edinburgh, and cross your own stock with them as freely as if the pollen travelled no farther than from Sydenham to Arthur's Seat. And from that day to this I have not seen any reason to alter or amend that story. See London's "Gardener's Magazine," for 1837. So if the notion of selling pollen or of carrying it about for crossing purposes should seem odd or strange, I should say it is not for its novelty at all events.

Now, the first thing Mr. Anderson would do, on receiving these dark grey anthers, would be to look out one of his medium-sized plants of Rhododendron ciliatum, and pick out the three or four strongest flowers out of so many trusses, and throw them away and prepare the medium and the weakest flowers by taking out their own anthers so as to apply the pollen from Sydenham in order to obtain a new race of Rhododendrons having very large ivory white blossoms, a close, comfortable habit of growing, and a constitution which would, after three more turns of crossing with others, which he well knows, render the new race quite as hardy as the Rhododendron ponticum, and better growers even than ponticum.

On the other hand, I would select half a dozen of the longest and stoutest anthers and send them down to Mr. Standish, of Bagshot, to be crossed with some of the very largest flowers there on the biggest standards they have in these quarters, for another race of close-growing giants; and as Nuttall is deliciously sweetly-scented, I would get a bill from Parliament to put an entire stop to crossing ciliatum or any other sort with Edgworthii, and all the other bare legs of the family.—D. BEATON.

### MY AURICULAS IN 1862.

I HAVE, as yet, only talked and written upon the subject of Auricula-growing, but to such an extent, that I fear that many of your readers have regarded me much as the House does some Hon. Mem. when he annually brings on some favourite motion which it votes an immense bore. "Ah! here is poor —— with his hobby again!" But as my doing so has, I humbly believe, led not a little to its reinstatement in the favour of the public, I may be excused for once more taking my ride; and as I have been permitted this year to show that it is not merely talk with me, but practice, inasmuch as I was enabled to take the first prize for six at the Royal Horticultural, and the small silver medal for twelve at the Royal Botanic, any observations I may make will, perhaps, be taken as having a little more weight. The homely old English proverb is never more true than in flowers—"The proof of the pudding is the eating;" for I know people who are always theorising, always fancying what they can do, always taking up every notion that anybody puts forth, and, of course, always failing. Let a thing be well done, and it is worth all the talking in the world as to what we can do.

It may seem strange after doing this that I should be compelled to say that, taking into account the size of my collection, which has gradually increased each year, I never had a worse bloom than this year. Fortunately for me, some of my earlier plants were the best; but I very much question whether I shall have anything very good for the 30th, when the National Auricula Show takes place. And this is only another example of the very great capriciousness of this flower; for my stock never looked more healthy, the plants are, generally speaking, in excellent heart, and yet the bloom is defective! My own county is famous for growing a crop (Hope), of which it is said you never know what sort of a crop you have had until the money is in your pocket; but I really question if they are more uncertain than this favourite flower. As yet I have not heard much of other collections: I know my friend Mr. Jeans' is not as good as usual, but that he attributes rather to not having potted the plants himself, and its having been done late in the year than to any other cause. My good brother, who, alas! by the fortunes of war, or rather the whims of the War Office, has been ordered off to Gibraltar, was with me last week, and told me that Dr. Plant considered his collection by no means in such fine order as usual. Of the more general

character of the season's bloom we shall most probably hear on the 30th, when we may hope to have a good muster of various growers from all parts of the kingdom, and shall then, perhaps, be able to say whether climatic influences have anything to say to it—whether, in fact, a mild weather is more injurious to a good bloom than a severe one. The general statement last year was, that the bloom was a very excellent one: it will be somewhat strange if the reverse is the case now.

Last year I made a statement as to the little dependance that could be placed on heart or centre blooms, and asked for any *rationale* on the subject. And it is a very singular thing that nearly two-thirds of my blooms this year are centre blooms. But what cause them at one season to run so much in this way, and in another to be quite the reverse, passes my comprehension; or why this centre bloom should not be as good as a side one is equally a puzzle. It may be asked, How is this shown? Here, for instance, is a Waterhouse's Conqueror of Europe with hardly any colour at all in it, and there a Dickson's Duke of Cambridge nearly all colours, both these being centre blooms. Now the ordinary failing of these two flowers runs in that direction—that is, the former is generally deficient in body colour, and the latter has a superabundance; but being centre blooms the fault is exaggerated in both cases. Then, again, here are two plants of Headley's Conductor which sometimes has the fault of producing a little green floret in the centre of the pip. In this centre bloom this is so excessive, that in order to make the flower presentable at all, I must pull these out. Why, again, should this be? The fault of the flower, in a florist's eye, being thus exaggerated by its being a centre bloom. But the strangest thing of all has been the production of flower-stems without a single trace of bloom on them. Two of these I have cut off and sent by post to Mr. Darwin. The plants Dickson's Apollo and Leigh's Colonel Taylor are in excellent health. I have examined their roots, and these I find all right, and vigorous growth being made. In both cases there is apparently an attempt at the formation of the sexual organs, but nothing like a flower. Not being a botanist I may here be perhaps mentioning a very ordinary matter; but it has struck me as odd that it should only have occurred in the case of these centre blooms. In three or four plants I have also had what I think my friend the Vicar of Alford called chlorosis—a deficiency of colour in the leaves. As they have all been subjected to precisely the same treatment, I cannot account for this.

There is yet another point which strikes me as singular (and when one is continually noticing a class of plants you get to see many little things which in wider fields one never thinks of)—viz., that the goodness or otherwise of a bloom affects the individual members of a variety. Thus I have six or seven good plants of Spalding's Blackbird, and I have not one good bloom among them; while in the same number of Fletcher's Mary Anne, even though some be small, yet there the bloom is all equally good. Last year the former were all good, the latter poor. Last year my Waterhouse's Conqueror were all good, this year they are all inferior. Making, however, all these deductions, my bloom is very pretty, and I am quite charmed with the blooming-stage which I erected this year. The plants are all so nicely in the range of the eye, and there is no risk whatever of the cover being forgotten, and, consequently, the bloom spoiled. And I feel quite confident that no one who has anything of a collection will have half as much satisfaction in looking at it as he would by adopting this plan; and I hope also to make it useful by-and-by for other things.

I hope to be able to give, by-and-by, a few notes on the different varieties of Auriculas which have bloomed with me this year; and shall hope to have my say next week on the National Auricula Show.—D., Deal.

### SWEATING APPLES BEFORE STORING.

THE following discussion occurred recently at a meeting of the Missouri State Horticultural Society:—

Flagg.—"I would like to ask whether there is any truth in the popular belief that Apples 'sweat,' and that this is essential before putting them away. I find Apples moist in the piles and in barrels opened in spring. Is this anything more than ordinary condensation from the atmosphere?"

Muir.—"I have seen Apples sent from France with the stems sealed to prevent evaporation, and have noticed that the stems shrivel first."

Mason.—"I do not believe there is any evaporation except

from the stem. I think the sealing of the stem of the Grape prevents evaporation."

Redfield.—"Pear-growers consider the perfection of the stem essential in keeping Pears."

Dr. Claggett.—"It looks reasonable that moisture should leave the Apple where it entered."

Dr. Edwards.—"I think the fact of sealing the stem shows there is no evaporation from the surface of fruit."

Dr. Claggett.—"I do not believe in 'sweating.' It is a mere change of temperature that produces moisture."

Smith.—"An Apple will 'sweat' all the time, and you can wipe off more moisture than the Apple weighs during the course of the winter without diminishing its weight."

Pre-ident.—"The point is whether there is a process of evaporation after picking from the tree."

N. J. Colman.—"I would contend that an Apple does not sweat—sweating is a heating process. The process is one of evaporation. I think the Apple shrivels and passes off moisture, and that it is so with all fruit."

E. B. Colman.—"A shrivelled Apple has no moisture. I believe Apples keep just as well barrelled-up right from the tree."

N. J. Colman.—"I remember that when I was a boy my father used to barrel-up Apples direct from the tree, and they were apt to rot. My uncle put his up-stairs and sweated them first, and his kept well. Such is my own experience also."

Dr. Edwards.—"I put up two hundred barrels direct from the tree, and they kept well."—(Prairie Farmer.)

### CERASTIUM BIEBERSTEINII.

I HAVE now two nice little plants of this Biebersteinii, and we shall soon prove what is said about it by "NICKERBOR." I have my plants from a good practical gardener who knows all our wants and all we possess. His account is this—that *Cerastium Biebersteinii* has been in private collections for a length of time, and as an herbaceous plant it always looked better than tomentosum. It does not spread out so much or look so "thin" as tomentosum, that the leaves are twice the size, and that the plant altogether is much in the way "NICKERBOR" put it. My friend is quite full of it, and is getting it up like steam; for he knows where there is an old plant of it in some private gentleman's garden from which he took his cue of it last season, and was going to write to me about it just when "NICKERBOR'S" account of it appeared.

As I expect, Suffolk like, that my two little plants came out of a tremendous close forcing-atove, I cannot trust them out from my cold pit before they are completely hardened—and they seem to me to have begun a fresh growth naturally—say towards the middle of May.—D. BEATON.

### IDENTIFICATION OF PLANTS.

THE *Yampah* (not Yampa), inquired about at page 64 is, according to Fremont, the same as our common Dill (*Anethum graveolens*), or a very nearly related kind, which he found growing in the bottoms along the north fork of the Laramie River, and to which his attention was first directed by observing the Snake women engaged in digging the roots in the low timbered bottoms along the creeks. The Indians along the Rocky Mountains, especially the Shoshonee, or Snake tribes, in whose territory the plant is very abundant, consider it the best among the roots used by them for food, and take great pleasure in offering it to strangers. It also grows very abundant and in great luxuriance along the tributaries to the Colorado; particularly along that stream to which the Snakes are accustomed to resort every year to procure a supply of their favourite plant, and on which they have bestowed the name of Yampah River, but which the Trappers call Little Snake River. Colonel Fremont says the Yampah forms a very interesting link between a savage and a civilised life; for, he observes, "We had for supper on the shores of the Great Salt Lake, *Yampah*, the most agreeably flavoured of the native roots, and again in the morning we breakfasted on the 'Yampah' and 'Kamass' (*Camassia esculenta*); but a cup of good coffee still distinguished us from our digger acquaintances."

The *Mansonita*, or chocolate-coloured shrub of Fremont, is the *Arbutus procera* of Douglas; a fine hardy kind, which grows from 15 feet to 20 feet high, and one deserving to be more extensively planted than it is, on account of its singular appearance.—G. GORDON.

### NEW JAPANESE CONIFERS.

*ABIES MICROSPERMA*, Lindl., The Small-seeded Spruce.

THIS is one of the Conifers sent home by Mr. J. Gould Veitch, who found it at Hakodadi, and who describes it as a tree 40 feet to 50 feet high. The under side of the foliage very glaucous and resembling the Spruce Fir in point of colour; but the leaves are as long as those of *Abies amabilis*, and perfectly silvered underneath.

Mr. Gordon's description in the Supplement to the "Pinetum" is as follows:—"Leaves solitary, about 1 inch long, and three-quarters of a line broad, more or less arranged on the upper side of the branchlets; linear, narrow, flattened, and terminating in a small prickle, or somewhat blunt point; bright green above, and glaucous below. Cones cylindrical, 2½ inches long, and three-quarters of an inch in diameter, and as broad at one end as the other; scales loose, rectangular, with the apices toothed; bractees very small, ovate, and terminating in a spine or micro. Seeds pale, cinnamon-coloured, one line long, with ovate wings two lines long, sometimes acutely notched on the margins."

Dr. Lindley considers it "a beautiful tree, quite unlike any other Spruce, with slender delicately-toothed cones as broad at one end as the other, and the smallest seeds of the genus."

Our figure was drawn by Mr. Fitch from specimens sent home by Mr. J. G. Veitch.

### THE ARRANGEMENT OF FLOWER GARDENS.

BY MR. JOHN CAIE, GARDENER TO THE DUKE OF ARGYLL, INVERARY CASTLE.

NOTHING can be of greater importance, as regards the ultimate effect to be produced in a geometrical flower garden, than the proper arrangement and distribution of the various plants which are to develop the colours upon which that effect is dependant. This is of far more consequence than the actual shape of the beds; although there is no doubt they should be as void of acute angles as possible. The following practical instructions in these matters will be useful to those of our amateur readers who are in the habit of purchasing their bedding-out plants, and may not as yet have determined how to fill their flower-beds for the present season. This is a kind of procrastination, however, in the case of those who propagate for themselves, which, to say

the least, is blameable; for a due provision of plants can hardly be expected to be made, unless this matter has been duly decided at the propagating season. The annexed lists all refer to the accompanying plan, the figures corresponding with those on the plan.

*Arrangement for February and March.*

- |                                     |   |
|-------------------------------------|---|
| 1 Helleborus niger, white and pink. | 6-6 Erythronium dens-canis, light purple. |
| 2-2 Crocus reticulatus, blue.       | 7-7 Erythronium dens-canis album, white.  |
| 3-3 Eranthis hyemalis, yellow.      | 8-8 Corydalis tuberosa, purple.           |
| 4-4 Galanthus plicatus, white.      | 9-9 Erythronium lanceolatum, yellow.      |
| 5-5 Narcissus minor, yellow.        |   |

*Arrangement for April and May.*

- |                                     |  |
|-------------------------------------|--|
| 1 Anemone apennina, blue.           | 7-7 Tulipa oculus-solis, red and black.  |
| 2-2 Arabis praecox, white.          | 8-8 Polemonium mexicanum, blue.          |
| 3-3 Cibiranthus alpinus, yellow.    | 9-9 Vesicaria utriculatum, light yellow. |
| 4-4 Aubrietia purpurea, dark lilac. |  |
| 5-5 Alyssum saxatile, yellow.       |  |
| 6-6 Iueris saxatile, white.         |  |

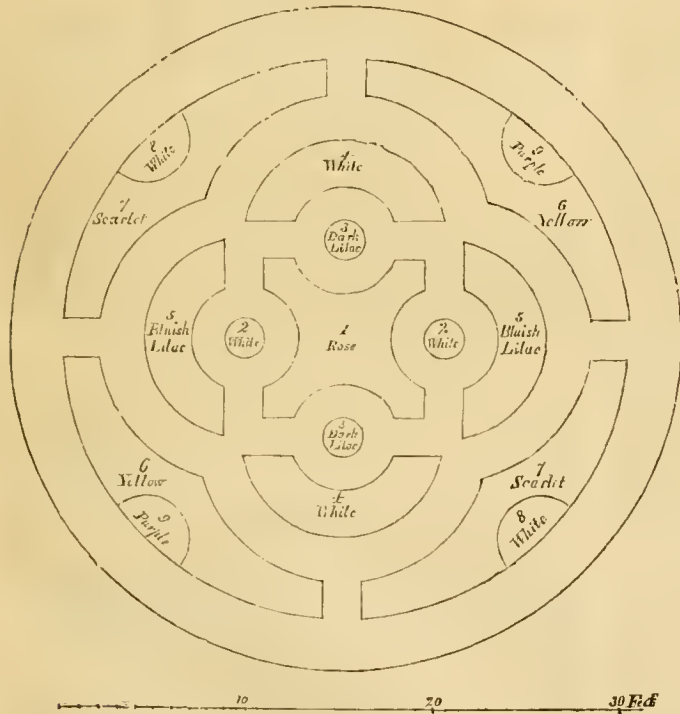

*Arrangement of Hardy Annuals for April and May.*

- |   |   |
|---|---|
| 1 Silene pendula, pink.                   | 6-6 Collinsia bicolor, white and lilac.   |
| 2-2 Nemophila atomaria, white.            | 7-7 Clarkia pulchella alba, white.        |
| 3-3 Nemophila insignis, blue.             | 8-8 Clarkia pulchella, reddish-purple.    |
| 4-4 Eschscholtzia crocea, orange yellow.  | 9-9 Erysimum Perofskianum, orange yellow. |
| 5-5 Collinsia grandiflora, bluish purple. |   |

*Arrangement from May to November, as marked in the figure.*

- |  |  |
|--|--|
| 1 Geranium Lucia Rosea, rose.          | 6-6 Calceolaria viscosissima, yellow.    |
| 2-2 Verbena Princess Royal, white.     | 7-7 Verbena Robinson's Defiance scarlet. |
| 3-3 Verbena Heloise, dark lilac.       | 8-8 Verbena Mont Blanc, white.           |
| 4-4 Verbena White Perfection, white.   | 9-9 Verbena Walton's Emma, purple.       |
| 5-5 Verbena Duc d'Amale, bluish-lilac. |  |

The accompanying figure of a geometrical flower garden is intended to show that it is possible to avoid acute-angled beds to a much greater extent than is generally done; and yet it will be

seen that the beds are not without a good deal of variety in their outline, and also pretty well contrasted in size, as well as expressive of unity throughout the figure, whilst there is a balanced effect conspicuous in every part of it. It will also be observed that the beds are drawn in circles round a central bed, and crossed at right angles, so that the two beds on a line with the centre, or on this side and on that of the centre, are seen to be of one colour, contrasting, of course, with the central mass, but producing of themselves a balanced brightness. When a flower garden is massed, as the present figure is, there is a reflection of one side observed in the other, and, consequently, a uniformity apparent in the arrangement, which gives a dignity of effect to

the figure, that simply contrasting one bed in each circle with the one next it would certainly fail to produce—in other words, planting the four small circles surrounding the centre with four different-coloured plants instead of two colours, as is the case in the annexed figure. The expressiveness of the general arrangement of the beds in the figure, it is possible to work out still more effectively by planting one kind of plant in all the beds forming each circle, taking care that the one circle of beds, in the series of circles of which the figure is composed, contrasts in colour with one another; but in this arrangement it should never be forgotten that what is gained in greatness of expression is so much lost on the side of variety. And although the three modes of planting noticed explain all the principles of massing flower gardens with which I am acquainted, studied care is necessary to a right application of them, so that they may harmonise with the form and features of a place. In a small place, one bed may be planted to contrast with another bed; but, in a larger place, the beds may be contrasted in pairs; and, if larger still, beds completing the whole circuit of the figure, or zones of circles, may be planted with one colour.—(*Gardeners' Magazine of Botany.*)

**ALOCASIA METALLICA AND ALOCASIA MACRORHIZA VARIEGATA.**

THE islands of the Indian Ocean abound in the most extraordinary and gorgeous vegetation. From them we have received the greatest ornaments of our plant-houses, both with respect to flowering plants and plants remarkable for the beauty and richness of the colouring in their foliage. In former times plants were valued by the horticulturist in proportion to the beauty of their flowers; but now none are more highly prized than those with well-variegated leaves. And who can tell what new wonder for the botanist or rare gem for the horticulturist is to be sent us next from these apparently inexhaustible mines of vegetable beauty?

It is not my intention, however, to enumerate the many beautiful things we have received, but to confine my remarks to two plants which stand pre-eminent for decorative purposes—viz., *Alocasia metallica*, from Borneo, and *A. macrorhiza variegata*, from Ceylon. The first from its striking contrast with every other known plant, the splendour of its foliage, which nothing of the kind can excel, if it can equal, and the beautiful metallic lustre which pervades the whole, which must be seen to be appreciated or understood. The blade of the leaf is from 12 inches to 20 inches long, and a foot or more wide, ovate or cordate in shape; the upper surface of a superb bronze colour, richly glossy and metallic; and the under side of a lively purple, if anything more shining and more glossy than the upper. One sight is certainly sufficient to recommend it to any one, and a plant in vigorous health with from ten to twenty such leaves upon it is indeed a glorious sight—an exhibition of itself.

The soil I have found it thrive best in is a mixture of fibry peat, chopped sphagnum moss, and a little dung and sand; being very particular to have my pots well drained to enable me to supply it abundantly with water, and giving it the usual treatment of a moist stove.

*Alocasia macrorhiza variegata* is a plant of a totally different character, but not a degree less beautiful. Naturally a stronger grower, it throws up its splendid broadly-sagittate leaves to the height of 2 feet or 3 feet, which are from 18 inches to 30 inches long and 20 inches broad; the ground colour a beautifully dark green, broadly blotched, and striped pure white, dashed in places with a lighter green and grey, the markings usually extending over fully half the surface. In addition to this, the large bright green footstalks are regularly striped with bands of pure white, running from the base up into the leaf.

In consequence of its being a much stronger grower than *metallica*, a stiffer soil must be used. A mixture composed of equal parts loam, peat, and leaf mould, with a fair addition of sand, I have found to suit it admirably, having the same care to drainage as before mentioned.

So totally different are these two plants, yet withal so beauti-

ful, it is impossible to give the preference to either; but I feel confident they must shortly grace every collection of ornamental foliage plants.—JUVENIS.

### SEEDLING ORCHIDS.

IN reply to "R. C. K." and Mr. Anderson (see JOURNAL OF HORTICULTURE, page 46), may I refer to Messrs. Veitch's catalogue for 1861, wherein, at page 25, three seedling Orchids are described as having been raised at their nursery? They are *Calanthe Dominii*, a hybrid between the purple *C. masuca* and the white *C. furcata*; *Calanthe Veitchii*, a hybrid from *Limatodes rosea* fertilised by *Calanthe vestita*; and *Cattleya hybrida*, from *Cattleya granulosa* and *C. Harrisonia*. All are said to have been exhibited before the Botanic or Horticultural Societies of London.

Mr. Anderson's experiments are exceedingly interesting, and I hope he will succeed in raising seedlings of all the species he names, and let the horticultural world know the result. I have seen ripe seed-pods hanging abundantly from *Broughtonia sanguinea*, from *Angraecum funale*, and from some of the *Oncidiums* and *Epidendrums* in Jamaica; and as we know, of course, that all the species are naturally reproduced from seed, horticultural science ought to be able to solve the problem of their reproduction here. May we not look for seed-packets of the epiphyte Orchids to be advertised for sale before many years as regularly as Balsam and Primula seed, if not quite so cheaply?—P. H. GOSSE, *Torquay*.

### GAS IN HOT-WATER PIPES.

UNDER the above title in the last Volume of THE JOURNAL OF HORTICULTURE, page 473, a correspondent, "JUNIOR," notices a very remarkable circumstance which took place in his hot-water pipes when he applied a light to an air-pipe which he had put on the pipes, the gas bursting in a pale blue flame, and he supposes it to be hydrogen, and you reply, You cannot be certain without more proof as to the gases. Now, to me the proof is positive, because there is no other gas which burns with a pale blue flame but hydrogen; and besides, there is no other gas which was at all likely to be generated in such a place. And it is easily accounted for; but it shows at the same time that there is something radically wrong with the apparatus, and your remedy is not a satisfactory one, as it does not affect the cause. The gas will still be generated, and it is possible that the gas-pipe may not be sufficient to allow the escape of all the gas.

It is well known to all chemists that the first, or among the first, methods adopted to procure hydrogen gas was to heat a gun-barrel red hot in a smith's forge, and pass a current of steam through the gun-barrel. The water was decomposed, the oxygen of the water combining with the red-hot iron of the gun-barrel forming the oxide of iron, and the hydrogen, the other element of the water, being collected at the farther end of the barrel.

Now, it will be seen from this that there is a very great probability of the same operation going on in "JUNIOR's" apparatus. There must be some pipe becoming red hot having but a small orifice for the water to pass through, which enables the fire by its action on the pipe to decompose water, and of course the pipes will soon become oxidised, and wear through.

There is a part of "JUNIOR's" description I do not fully understand, wherein he says, "When the fire draws keen, that in a couple of hours a considerable quantity of water will, if not prevented, boil out, returning through the supply-cistern which feeds the boiler at the bottom of one of the feet." If it means that a small pipe is led from the supply-cistern to the bottom of one of the feet of the boiler, then I can easily imagine that if the fire acts strongly on this pipe that the water will be decomposed, and the result hydrogen; but then the hydrogen would come out at the cistern, and not get into the pipe unless bent in some way to cause it to go there. If it is not caused by the supply-pipe, then it must be by some of the feet, as they are called, of the boiler being too small in their orifice to allow sufficient water to pass through them to keep down the temperature by absorbing the heat generated by the fire.

I would feel obliged if "JUNIOR" would explain it a little more fully how he has it arranged; and would like to know if any other of your numerous readers had experienced anything of the sort with these boilers or any other. But, in fact, there is

no other I am acquainted with which is likely to do so unless the tubular ones. But with "JUNIOR's" experience I must confess that, to me, such an occurrence is likely to happen in others where, from the impurities of the water used and the continual oxidation which is going on in all boilers, the tubes are not unlikely to get partially closed up, and similar results will follow to that of "JUNIOR's."

I would advise "JUNIOR" to be careful, and not light the gas again, as he might have an explosion, because if the hydrogen were to get mixed with the atmospheric air in the pipe, there is a possibility of its doing so, with the ebullitions of the water, in sufficient quantity to blow-up the house. Although I have exploded the gases oxygen and hydrogen from a glass hottle; after having had the bottles blown to dust in my hand, I confess I should not like to light the gas at the tube of "JUNIOR's" boiler, and thence my advice to him to be careful.—ALEX. SHEARER, *Yester*.

[We are glad to have this letter of inquiry and warning from a man so practical yet so scientific as Mr. Shearer, and we hope that "JUNIOR" will afford the additional information he desires. We quite agree with Mr. Shearer in thinking that probably the gas noticed by "JUNIOR" is hydrogen, but we did not, nor do we, think ourselves justified in saying positively that it is that gas, because we do not like to assume as Mr. Shearer has that "there must be some pipe becoming red hot," without which we cannot explain how the hydrogen is formed. It is quite true that hydrogen is the only gas that, when pure, burns with a blue flame; but there are many impurities which tinge a flame blue.—Eds. J. of H.]

### THE ROSE.

*The Amateur's Rosarium, a Manual of Directions Regarding the Culture, Propagation, and Varieties of the Rose.* By the Rev. R. W. THOMSON. London: Hamilton, Adams, & Co. Edinburgh: Paton and Ritchie.

ROSE-CULTURE is one of the most favourite but usually least successful of all the pursuits in the flower garden which amateurs adopt for their own special care. To aid them in escaping from such failures the Rev. R. Wodrow Thomson has just published a cheap little volume, entitled "The Amateur's Rosarium;" and it is an example of what we have often observed—that if an amateur who thoroughly understands his subject writes relative instructions he usually produces a book exactly such as an amateur requires. A professional too readily pools minute details; and the excluding sentence—"Oh! every one knows that!" is accepted too often by his judgment as valid when about to give directions for securing success.

Now, an amateur knows on the contrary that minute details of the commonest practices are just what he wanted to have told him when he was in much ignorance about his subject, and Mr. Thomson has evidently not forgotten what he required to have told him when he began Rose-cultivation. He does not write for the accomplished Rose-grower, but for those who have to become accomplished; and to aid in his instructions being well understood various woodcuts are given of the modes of budding, grafting, and other operations.

We will confine ourselves to one extract.

"A very common cause of annoyance to the amateur, is what is known by the name of the "green centre." In general, this malformation assumes the form of three or four green projections, which occupy the place of the central petals of the flower. In some cases, however, we have seen these develop themselves into little shoots, springing from the centre of the bloom. This tendency is not confined to any particular class of Roses; though it is confined generally to particular varieties. It is found in the vigorous Hybrid Bourbon Great Western, as well as in the dwarf Gallica Ohl, or Boule de Nanteuil. In these, and others, it almost always exists; while in *Coupe d'Hebe*, and *Madame Zoutman*, &c., it is never seen. The class most subject to it is certainly that of the Gallicas. We cannot remember at present one member of this class totally and constantly exempt from this tendency. Kean, Ohl, Boule de Nanteuil, Napoleon, D'Aguisseau, La Tour d'Auvergne, and many others, which are the gems of this family, are all liable to this disease.

"Floriculturists entertain different opinions as to the cause which produces, and the treatment which may cure this disease. So far as our own experience has gone, we agree with those who consider green centres as generally the result of excessive nutrition. We have already observed that the excessive pruning of a naturally vigorous variety of Rose produces in the plant thus overpruned a tendency to increase its individual size, and to diminish its tendency to increase its kind. The way in which this result is effected is this: Overpruning allows the parts which remain to be overfed, and high feeding in the vegetable, as it does in the animal world, induces sterility.

"Now the green centre in a Rose just manifests an effort made by the

plant to increase its size; and if we may be allowed the expression, an unwillingness on the part of that plant, to do anything towards increasing its kind, by the formation of a perfect flower. Such, then, being the apparent cause, let us now consider what may be the probable cure of this disease. This surely cannot be difficult to discover. If the cause is over-nutrition, the cure must be the diminishing of nourishment. We must lessen the quantity of manure, applying what we give in a ripe and well-decayed condition; we must prune the roots unmercifully, and by these means half starve our rebellious protégées. Hunger will influence an obstinate plant as well as an obstinate person."

When another edition is published we recommend something to be said about Rose-stocks, and more about the culture of Roses in pots.

Let us now turn to our note-book for some long-since-accumulated passages in the history of this universally-admired flower. We say universally admired, because though one or two instances are on record of persons who fainted if the perfume of the Rose reached them, yet the only one known to have disliked the Rose, even in a painting, was Marie de Medici, a woman whom it would have been well for if she had loved evil much less and the beautiful much more.

As it is, then, the flower delightful to everybody, so has it been in all ages and in all countries. It is the *Habelzeleth* of the Hebrews, and among them was regarded as the most grateful of flowers. "Come, let us fill ourselves with costly wines and perfumes—let no flower of the spring pass us by—let us crown ourselves with Rose-buds before they are withered," are the words attributed to the sensualist in the Wisdom of Solomon. It is the *Rodon* of the Greeks, and like the Hebrews they chose it for chaplets at their banquets, and as a gift most acceptable to those whom they loved. Anacreon only gave popular customs a poetic dress when he wrote—

"To make the beverage divine  
Mingle sweet Roses with the wine;  
Delicious will the liquor prove,  
For Roses are the flowers of love;  
And while with wreaths of Roses crown'd  
Let laughter and the cup go round."

Sappho joins in adulation of the flower, and our readers will see that the trite epithet of "the queen of flowers" was first bestowed upon the Rose by that "Tenth Muse."

"Would Jove appoint some flower to reign  
In matchless beauty on the plain,  
The Rose (mankind will all agree),  
The Rose the queen of flowers should be;  
The pride of plants, the grace of bowers,  
The blush of meads, the eye of flowers;  
Its beauties charm the gods above;  
Its fragrance is the breath of love."

It is the *Rosa* of the Romans, and though we find less than might be expected in their poetry beyond slight notices of "the twice-blooming Rose-beds of Pæstum," yet passages in Varro and Columella show how assiduously those beds were cultivated; and Horace when he advised his friend Delius to live joyously told him to retire into the country, and

"There bring thy wine, thy odours spread,  
Let blooming Roses crown thy head  
Whilst time, and age, and life permit."

We need not give specimens of what modern poets have written about the Rose, for a volume might be filled with extracts from the works of our own poets, beginning with Chaucer and ending with Tennyson.

Let us turn rather to another phase of the subject, and record some of the emblematic usings of this flower.

With no nation is the Rose a greater favourite than with the Turks; its perfume is especially preferred by them, and they associate with it thoughts of vestal innocence. Lady Montague says, "In the cemeteries of Constantinople the ladies have a simple pillar for a monument without other ornament, except those who die unmarried—they have a Rose at the top of the monument."

"A bed of Roses," used metaphorically for a state of unruffled happiness, is not exclusively a figure of speech, for mattresses filled with the petals of Roses grown in the Jinan Nile, or Garden of the Nile, attached to the Emperor of Morocco's Palace, are used for repose by the nobles of his court. Beds of Roses, however, are not always exclusively luxurious; and the results of effeminate indulgence are well satirised in the Sybarite's complaint that a crumpled Rose petal prevented his repose.

The Rose was dedicated by the Romans to Venus, as well as to Harpocrates, the god of silence—a very fitting association when "the pranks of the goddess be closely thought upon." In 1526 Roses were placed over places of confession as the symbol of secrecy, and they were about the same period adopted, with a similar intent, to overhang the dinner-table. Thus Newton, in

his *Herball* to the Bible, 1587, pp. 223-4, says:—"I will here add a common country custome that is used to be done with the Rose. When pleasaunt and merry companions doe friendly meete together to make good cheere, as soone as their feast or banquet is ended, they give faithfull promise mutually one to another, that whatsoever hath been merrily spoken by any in that assembly, should be wrapped up in silence, and not to be carried out of the doores. For the assurance and performance whereof, the tearme which they use is, that all things there saide must be taken as spoken under the Rose. Whereupon they use in their parlours and dining-rooms to hang Roses over their tables, to put the companie in memorie of secrecie, and not rashly or indiscreetly to clatter and blab out what they heare. Likewise, if they chance to shew any tricks of wanton, unshamefast, immodest, or irreverent behaviour either by word or deed, they protesting that all was spoken under the Rose, do give a strait charge and pass a covenant of silence and secrecy with the bearers, that the same shall not be blowne abroad, nor tattled in the streets among any others."

A relique of this is still to be seen at Lullington Castle, in Kent, the mansion of Sir Percival Dyke. In its hall is a huge representation of a Rose, encircled by this inscription—

"Kentish true blue! take this as a token,  
That what is said here under the Rose is spoken."

In 1453, the White Rose being blazoned on the shield of Richard, Duke of York, and the Red Rose on that of Henry, Duke of Lancaster, their contest for the crown of England was aptly designated the "War of the Roses"—a war so fraught with misery to England before those Roses were united, that Sir Walter Scott's lines are no more than just:—

"Let merry England proudly rear  
Her blended Roses—bought so dear."

Roses are not unassociated with superstitions; for we find it written—"I am told that if I go backwards into the garden, without speaking a word, and gather a Rose upon midsummer-eve, and keep it in a clean sheet of paper without looking at it till Christmas-day it will be as fresh as in June; and if I then stick it in my bosom, he that is to be my husband will come and take it out."

Roses have been adopted for many ages by the Popes as tokens of their good wishes. When a Princess of France was married the Pope then reigning sent her a Rose which he had blessed. Sergius IV., in the year 1009, is said to have been the first on Christmas-night to consecrate Roses and other tokens to be sent to those whom he wished to honour. Leo X. sent a consecrated Rose to Frederic, Duke of Saxony, with a request that he would banish Luther. These Roses were made of gold.

Finally, let us turn to a few jottings relative to the early cultivation of the Rose in England.

When Parkinson wrote his "*Paradisus Terrestria*" in 1629 there were but twenty-four kinds of Roses known, including in that number "the Eglantine, or Sweet Briar Bush," which name we especially quote because it is too usually applied now to the Wild or Dog Rose. Gilbert's "*Florists' Vade Mecum*," in 1693, only enumerates thirty; whereas, now there are about two thousand known varieties, of which every nurseryman who attends specially to their culture keeps three hundred or four hundred.

"I will begin," says Parkinson, "with the most ancient and known Roses of our country, whether natural or not I know not, but assumed by our precedent kings of all others to be cognisances of their dignity, the White Rose and the Red, whom shall follow the Damaske of the finest scent, and most use of all the other sorts." Among the others of his twenty-four sorts is "the Parti-coloured Rose, called of some Yorke and Lancaster;" "the Double Yellow Rose of great account, both for the rarity and doubleness," though "most of them fall or wither away," so that its shy-flowering is not a symptom of declining vigour or of forgotten modes of culture. "It was first procured to be brought into England by Master Nicholas Letc, a worthy merchant of London, and a great lover of flowers, from Constantinople, which, as we hear, was first brought thither from Syria. It perished quickly both with him and with all others to whom he imparted it; yet afterwards it was sent to Master John de Franqueville, a merchant also of London, and a great lover of all rare plants as well as flowers, from which is sprung the greatest store that is now flourishing in this kingdom."

Hakluyt, in his Collection of Voyages, records that the Damaske Rose was brought from Italy to this country by Dr. Linacre physician to our kings Henry VII. and VIII.

The Evergreen Rose was brought from Germany by Sherard, about the year 1727; but it had been cultivated before by Parkinson.

The Dwarf Austrian Rose was introduced about the year 1773 by Messrs. Kennedy & Lee, nurserymen.

The Moss Rose was introduced at the beginning of the last century, for it is not named by Gilbert in 1693, but it is by Furber in 1724; and it is only one among many evidences of the little interest then felt in such pursuits, that neither the time of the introduction, nor the name of the introducer, nor the native country is known of this most beautiful and most fragrant of all the Roses.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

CONTINUE the trenching of ground as it becomes vacant, and during dry weather keep it well forked about. Where Broccoli and Winter Greens are used up, the ground should be deeply trenched, the stumps being laid at the bottom, and quicklime strewed over them; also, if the ground is intended to be again planted with any of the Brassica tribe, it should have some manure incorporated with the soil; but it is best at all times to change the crops as far as practicable. If, however, from circumstances of soil or situation, it is necessary to plant the same kind of crop repeatedly in the same place, such parts should have deep turnings to expose fresh surface to the influence of the atmosphere. *Broad Beans*, sow successional crops, and earth-up the crops above ground. *Broccoli*, sow Early Purple and Myatt's White Cape; also, the Walcheren for late autumn use. *Cauliflowers*, draw the earth well up to the most forward, and give plentiful applications of liquid manure. *Celery*, continue to prick out. This must always be kept well supplied with water, rapid and continual growth being a very essential point in its cultivation if it is required large. Any check from drought is apt to make it run to seed. *Dwarf Kidney Beans*, sow a full crop, and Scarlet Runners. *Lettuce*, repeat the sowings, and thin out and transplant those advancing as occasion may require. *Peas*, sow successional crops, and continue to stake and earth-up the former sowings as they advance in growth. The ground between the rows to be forked-up after the staking is done, even if Spinach is growing between the rows, as that will also receive benefit by having the surface well stirred about it. *Red Beet*, sow a full crop, if not already done. *Savoy*s, prick out the seedling plants of the earliest sowings, and also the seedling plants of *Brussels Sprouts*, to get them stocky for final planting. *Turnips*, sow a good breadth, the ground for which should be well dressed with wood ashes or charred refuse.

### FLOWER GARDEN.

Attend to the pruning of evergreen shrubs. Give standard and dwarf Roses a good soaking with liquid manure, which will excite a vigorous growth and insure an abundant bloom. The autumnal-flowering sorts especially delight in such treatment. The scythe or mowing machine will now be required upon the lawn once a-fortnight. Continue sowing annuals whenever required. The weather is now so inviting that it requires a strong resolution to resist the temptation to begin planting out the half-hardy plants in the flower garden. It is, however, advisable to be cautious on that head, as it is but very rarely that any advantage is gained by planting out before the middle of May, while there is a probability that between this and that time we may have severe frosts.

### FRUIT GARDEN.

The process of disbudding Peach, Nectarine, and Apricot trees will now be in full operation. Watch their growth well and remove but a few of the shoots at a time. Endeavour as far as possible to keep beforehand with the growth in disbudding, and not behind, for if you are behind you are often tempted, I may say obliged, to take off more shoots at once than is proper, and the check thus given to the flow of the sap has very often been the cause of the fruit ceasing to swell, and eventually dropping off. Remove all the foreright shoots, but endeavour to distinguish those which are likely to form short fruit-bearing spurs, which should always be left. Keep a good look-out for the Gooseberry caterpillar. See that the soil is kept well pulverised about the roots of trees, and that all newly-planted trees are sufficiently mulched. Keep a good look-out for the numerous tribe of insects, and apply remedies in time. When Vines have

shot sufficiently to distinguish their fruit-bearing shoots, let all superfluous ones be immediately removed.

### STOVE.

If attended to properly the plants are now growing in earnest, and almost daily will require more room, which must be allowed to the principal specimens or they will sustain injury. Many free-growing plants will now be ready for their blooming-pots, to which they should be removed immediately. Look well to keeping a saturated atmosphere, and shut up early in the afternoon, but keep a free circulation of air with plenty of heat during the early part of the day.

### GREENHOUSE AND CONSERVATORY.

The newly-shifted plants are now beginning to feel the benefit of the new soil, and if properly encouraged will grow rapidly. Do not, however, be in a hurry with them, as elongation is not healthy growth, but endeavour to get clean short growth and strong foliage. Those plants which have got into fresh growth in the new soil and require stopping to make them bushy, should be stopped at once. Use the watering-pot with discretion, and be sure that newly-potted hardwooded plants require water before you give it to them. Keep a moist atmosphere by sprinkling the greenhouse twice or thrice a-day, and keep a sharp look-out for the thrips, red spider, and green fly. Stake and tie-out the Pelargoniums that require such attention in due time. Those that are well established with roots, and are in general good health with the bloom-buds secured, encourage with weak liquid manure. Also, stake and tie-out Heaths and New Holland plants in due time, water them with care, and see that every one has its due space; shade slightly when the weather changes suddenly to a hot arid state. Syringe those plants freely that are making their growth.

### FORCING-PIT.

Another successional sowing of Balsams, Cockscombs, and Amaranths should now be made, and those previously potted should be duly encouraged to make a vigorous and sturdy growth. Another set of Achimenes and Gloxinias may now be started. The cuttings of some of the *Justicias*, *Eranthemms*, and other winter-blooming plants recommended to be put in, will be ready to pot-off.

### PITS AND FRAMES.

The propagation of plants for the summer and autumn decoration of the flower garden should be brought to a close as soon as circumstances will permit. Another batch of cuttings may still be put in this week, but not later. A good deal, no doubt, depends on taking off, making, and putting in cuttings; but, on the other hand, the paying attention to these points alone will not guarantee success, unless they are carefully attended to with regard to light, heat, and moisture. Now is a good time to increase choice collections of Phloxes by cuttings, take off the young shoots when 3 inches or 4 inches in length. Choice alpine plants to be now taken out of their winter quarters and fully exposed to the weather. Large specimens of early-flowering species should be removed to the flower garden and placed in vases or rustic baskets. Clear out some of the hardier bedding-out plants which have been under glass during the winter, place them in some sheltered situation where they can be readily protected in case of frost. This will make room for some of the young stuff lately potted-off. Put a stop to the ravages of mildew by dusting the plants with sulphur vivum.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

FINISHED clipping *Box-edgings*, and getting the walks into their summer livery as the weather would permit. There is nothing after all in fair-sized gardens better to look at for edgings than Box; but tiles of various kinds or even slate is cheapest in the end, and gives little harbour to slugs or other insects. We rarely cut the Box close until at least the middle of April, and for two reasons. First, to save the trouble of giving more than a slight look-over during the season; and secondly, because if done much earlier, the young growth when tender is apt to be blackened by a frosty morning, and then it is a long time before it looks nice and green again. Planted out Cauliflower plants where they would form the second and third succession for heading. Pricked out younger sprig-sown ones, and young Lettuces. Sowed succession Turnips in rows 2 feet apart, with

a row of Radishes between. It is not of so much consequence now, but in early sowing it is advisable to sow some white Turnip Radishes between the rows of Turnips, as they come in for soups, &c., before the Turnips are large enough. In places where Turnips are wanted early, a frame should be sown early in March, and protected from frost. It is of little use sowing before April out of doors, unless some protection is used in frosty nights, as a slight frost causes the plants to bolt into flower, and then the tubers are tough and stringy. Exposed early Carrots and Potatoes in fine days. Sowed the main crop of Carrots and Beetroot, Salsafy, and Scorzonera, &c.; will have a smaller sowing in a month. Staked Peas in dry days, and sowed for succession. Sowed also Scarlet Runners, and a few Dwarf Kidney Beans. Pricked out and potted Chilies and Capsicums, and kept in a warm place; did the same with early Tomatoes, the others for border being left cooler and more hardy. Transplanted Sea-kale, and made cuttings of 4 inches in length of the old roots, forced in the Mushroom-house in winter. Sowed seeds of ditto and Asparagus. Drove the hoe through all crops and borders on a dry day, weeds being easier managed when half an inch high than when half a foot. Planted out the last of autumn-sown Onions, and top-dressed Dwarf Kidney Beans in pots, and gave a surfacing of charcoal-dust, soot, lime, peat earth, and leaf mould to bearing Cucumber plants.

## FRUIT GARDEN.

Regulated Vines, thinned Grapes, shifted Strawberries, keeping the shelves full and moving to greater heat as we wanted the fruit. Drew a dry hand through the flower-stems of Queens to assist the fertilising of the blossoms, the help of the sun being so fitful. Disbudded Peaches and Nectarines in orchard-house, and find the black fly, *Aphis persica*, appearing again; and in addition to syringing, dusted with a little hellebore powder. Watered Fig-house just heavy enough, but we expect no danger from it; but more was given than was intended, as when at all dry a great deluging at once is apt to throw the fruit off. It is better to water round the tree first, in a few days increase the size of the circle and so on; after that, of course, watering all over as required.

## FLOWER DEPARTMENT.

Rolled the lawn, mowed in damp mornings, forked-over borders, sowed hardy annual seeds, removed half-hardy ones up, as Stocks, Zinnias, Asters, &c., to orchard-house, to harden off, sticking little twigs of Laurels in front of them to keep off bright sun. Had here an example of sowing small seeds, which it is worth mentioning, showing that even small seeds should be protected from bright sunlight. Anxious to have a row of *Prince's Feather* rather early, about three weeks ago sowed seeds in small moveable boxes, covered them nicely with fine sandy soil, and placed the boxes under glass on a slight hotbed of leaves. The boxes were at the back of the frame, were forgotten to be shaded, and the dark surface-covering deceived the waterer, as the soil got very dry. No amount of future coaxing has sufficed to bring anything like a regular crop. Four days ago we did what we would not have done except with seeds known to be fresh and good. Other boxes were prepared, the seed sown on the surface, and then watered, and when settled for an hour or two, a covering of fine dryish stuff was thrown over them, and in three days the seedlings were as forward as those few that appeared of those sown three weeks ago. I believe that the dryness and exposure to bright sunshine had deprived the seeds of vitality—in other words, fixed their carbon. The seed when examined looks well enough, but no coaxing will make it vegetate, or if it swells a little it refuses to throw up a healthy plumule. Now, the seed came off the same plant, and was sown from the same saucer. Love-lies-bleeding did not suffer so much as the Feather; but what was sown four days ago is just as forward as that sown as many weeks since, showing that very simple things will prevent good seed from vegetating. I have long proved that large seeds, such as Melons, when well dried, and then exposed to bright sun, especially under glass, so as to be much heated, will lose their vitality. No coaxing will cause them after such treatment to swell and grow kindly.

Pricked-off in wet times Lobelias, Ageratums, &c., and cleared at length our *Calceolaria*-pits, by lifting the plants out and planting them on earth-beds in patches, and will do so with late-struck Geraniums in small pots—say six to nine in a 60-sized pot. When thus turned out ball and all together, the plants increase in size, and can be easily divided at planting time. Gave plenty of water to Azaleas and Cinerarias coming into bloom, and potted other plants as we could get at them.—R. F.

## TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

SLATERS (*J. M., Londonderry*).—These are usually called woodlice. Gas-lime will drive them away if sprinkled occasionally about their haunts. They may be trapped by putting slices of Apple and a little moss between two tiles, kept about a quarter of an inch apart.

MILDEW ON VINES (*Northampton*).—You have kept the air of the house too stagnant. Try Bell's composition—it is highly spoken of, and when we said a short time since that we knew nothing about it, we were confounding it with another composition. When you have removed the mildew, you may prevent its recurrence by a freer and more constant admission of air.

LILY LONGFOLIUM FAILING (*John Tyson*).—You have brought this most beautiful old Lily to the verge of ruin by mismanagement, and you may as well throw the roots away now, for they will never come round or be better, but go on from bad to worse. Your soil is good; but you did not know when a Lily was going wrong for want of water or for too much of it, for red spider, which, by the way, was your enemy from the first, has got the better of your bulbs at last. The leaves of that Lily, and of many mere Lilies, and of all the Gladioluses when they are in pots, ought to be most thoroughly wetted in every part at least twice a-week the whole summer through; and it is easily done with a sponge dipped in water and then squeezed a little, the palm of your left hand being placed behind a leaf, and with the sponge wet the side of the leaf or leaves next to you, drawing the sponge with all your might from the bottom of the leaf upwards six or seven times in succession; then the next side, and so on twice weekly the whole summer through. And the very same thing, and quite as often, ought to be done to every bulb worthy of a pot.

LOAM FOR PINE APPLES (*H. M. K.*).—There is too much clay in the sample sent. Two barrowloads of such loam, mixed with one barrowload of sharp sand, and another of leaf mould might do. It is a raw clayey loam, however, which we should not select for such a purpose.

VARIOUS (*W. G., Ely*).—We do not think the Grapes are injured by an insect. The brown spots look like ulcers, and we think the roots are in fault—either too cold or too dry, or descended into a bad subsoil. The *Cineraria* is a good bold flower, but many of the same colour are far better as florists' flowers. We do not detect any insects on your *Fuchsia* leaves, but there are indications that thrips have been there. We should think your houses would be benefited by a thorough fumigation and more free ventilation.

FLOWER GARDEN (*Young Beginner*).—Your planting is quite correct, but you made a sad mess in describing it. You turned the paper four times and wrote the names of the plants on the beds in four different ways, and on turning your plan round and round to get at the reading, our head got so dizzy that we could not make out if edgings to the beds would improve them, but we think they would. In future write on beds as you would on a page.

TRITELEJA UNIFLORA (*Bulb*).—It is a very pale sky-blue flower at first and turns all but white as it gets older. It was first figured as a blue flower, the plant being under glass in dull weather. Since then the bulb has been proved to be as hardy as a *Crocus*, to come into bloom with the spring *Crocuses*, and to be as desirable a spring flower as *Crocus versicolor* itself. But, unfortunately, no one dares to have cut flowers of this *Triteleja*, for they smell detestably of Garlic.

IMATOPHYLLUM MINIATUM (*Idem*).—No wonder you could not find this name in any Journal. There is not such a name among plants. The plant you mean was first noticed in our pages when Dr. Lindley called it *Valloia miniata*, and we said it was just as much a *Valloia* as an *Imatophyllum*, for it is neither the one nor the other, and it has been mentioned every season since in this Journal.

HYACINTH IN POTS (*L. T. P.*).—You may now plunge the balls in some warm out-of-door place, and see they do not get dry till the leaves turn yellow. They will not do to pot again for two or three years, even although they were not forced, only grown in pots in a cold pit.

TURNING OUT SCARLET GERANIUMS (*Idem*).—All the Scarlet Geraniums, all the *Calceolarias*, and all the *Petunias* may now be turned out into sheltered places, provided there is the means to cover them on cold nights and no more. If the place for them is very well sheltered and they are not set down too close, or allowed to want for water, and if the watering is done the first thing after breakfast, all such plants are now better out than inside, one place out of a hundred. And if all these turned-out pots could be plunged till bedding time, no system could be better, and very little water will be needed; the less water between this hardening and planting out always the better.

FLOWER-GARDEN PLAN (*T. C. G.*).—You have done No. 1 very well except four beds; but 2 and 4, *Gazania splendens*, must not have Geraniums in the middle, nor yet an edging of *Lobelia*. 20 and 21 again will not do together, put both with the *Nierembergia* only. If your house was opposite the centre of this garden, Lady Granville's celebrated Dromore garden, the planting cross-cornerwise, as you have it, would not do; but with one end of it to the house or windows the cross-planting is better. Plan 2 is not so good, and yet not amiss.

SHADING FOR FLOWERS (*A. R., an Old Subscriber*).—We never heard of the sort you mention. Shaw's tiffany of the cheapest kind would answer for the purpose.

**RIBBON-BORDER—DISTANCES BETWEEN PLANTS (A. P. S.).**—Yours is a ridge-and-furrow ribbon-border, with *Ageratum* on the ridge, and Tom Thumb Geranium and *Cerastium tomentosum* on one side of the ridge, and *Calceolaria* and *Cerastium* on the other side, and they will do remarkably well. As to how near Scarlet Geraniums ought to be planted, that depends on the size of the plants. We have planted them as close as 6 inches apart, and from that to 3 feet apart, and the latter were the closest planted of the two sets. A rough guess would say, keep the leaves of small Scarlet Geraniums 6 inches apart, the leaves of medium-sized plants 8 inches apart, and the leaves of ordinary large plants from 10 inches to a foot if the soil is very good; if it is not, reduce the different distances 2 inches, and recollect the distances are not from the stem of one plant to the stem of another, for one could as soon tell how many pieces of chalk would fill an imperial bushel, as tell how far the stem of one plant should be from the next.

**TROPEOLUM CANARIENSE (Idem).**—It would do on the north side of a house in many parts, and in many places it would not do at all. Where is the plant to be grown?

**PEACH AND PEAR BLOSSOMS FALLING (S. W., a Subscriber of Two Years).**—According to your account, if the wood was well ripened, the trees carefully watered, and plenty of ventilation given, we do not see why the blossom on your potted trees should fall, unless Nature was throwing off an extra redundancy, which is not unlikely. Did you examine the blossoms and see if they were perfect? The ventilation in front is high, but that would not injure anything in such a season as this. We have heard of a case where all the blossom dropped with abundance of means of ventilation, but the ventilators remained shut in a sunny morning until eleven o'clock. However, six openings a foot wide and 15 inches long at the base of the front wall, and the back wall too, would be an advantage for securing thorough ventilation in extremely hot weather. The trellis would be desirable, but we think 2 inches from the wall would be enough if there is plenty of ventilation. At 4 inches there would be a strong draught behind the trees, which would be desirable only if the house was apt to be too hot. In fact, at that distance the trees get little benefit of the heat radiated from the wall. See what was said on studding with nails a few weeks ago in "Doings of Last Week." If you heat, you make a hothouse instead of an orchard-house. We do not suppose your trees have suffered from cold. The best mode of heating is by hot water. The cheapest, a brick Arnot's stove.

**DISTANCES BETWEEN GERANIUMS IN A RIBBON-BORDER (Louisa).**—How could you put such a question, and from Hampton, too? It all depends on the size of the plants. You will see our own guess of 6, 8, 10, and 12 inches apart, in another answer to-day.

**FLOWER-BEDS (A Constant Subscriber, North Leach).**—A bed of Golden Chala Geranium, with the *Lobelia speciosa* round it, and another of Bijou Geranium, with the same, will both be as good as any such have ever been—that is, splendid; but they will not make a match pair unless very small plants of Bijou are put against full-sized large plants of the Golden Chain. Your ribbon reads backwards, or else it will be like reading from the bottom of a page, and will never do; but reverse the reading and it is beautiful. 1, Alyssum, next the walk or grass; 2, Purple King Verbena; 3, *Calceolaria*; and 4, *Perilla*. Surely that is how you meant.

**CYCLAMEN SEEDING (Alma Grove).**—The Cyclamens mentioned by "J. A. P." were all red ones, and yours is all white except the eye. The name of yours is *Cyclamen persicum*, of which kind there are now upwards of twenty varieties. You are quite right about the seed-pod, but your plant wants more air and less sun now and until the seeds are ripe. The stalks on which the seed-pods come will presently roll up like a screw, and bring the seed-pod to the level of the bulb, and out of sight from the birds under the leaves. A little before midsummer the seed-pods will get very soft and look ripe; then slit one open a little with a pin, and if the seeds look brown they are ripe for sowing, which do that very day.

**FLOWER GARDEN (A Young Gardener Subscriber).**—We have again to reply that we do not lead people in the way of planting their beds, we only correct the planting of others according to their own style, not our style.

**PRUNING ACACIA DRUMMONDII (J. R. W.).**—Very little pruning indeed is required for a pot *Acacia* with such small leaves, and such good close-growing habit as *Drummondii*. When it and all like it are young the strongest of the shoots need stopping to get up a close bushy plant. After that for the next ten years all the pruning it requires is to thin out the very weakest shoots altogether, and to see that none of the big ones take too much to their own share; and if they do, stop the tops, that is all they require.

**COTTAGE GARDENER'S DICTIONARY (R. Owen).**—The first edition was in 1852, and the last in 1856. (W. Munro).—It cannot now be had in parts. You can have a copy free by post from our office for 5s. 8d.

**VERBENA AS A FLORIST'S FLOWER (Berryburn).**—For five penny postage stamps you can have from our office "Florists' Flowers for the Many," in which are much fuller directions for *Verbena*-culture than we could give in this place.

**DESIGNS FOR SMALL COTTAGES (Rus in urbe).**—You can have from our office for 3s. 4d., free by post, a volume by C. V. Bernard, entitled "Healthy Moral Homes." It contains plans, and estimates, and is a safe guide.

**INK FOR ZINC LABELS (A Lady Subscriber).**—The recipe for it was published no longer since than March 18th, in our No. 51, N.S.

**HEATING A PIT BY TAN FOR MELONS (A Young Beginner).**—You had better get your tan as fresh and well-dried as possible by the first or second week in May, throw it in a heap, and let it ferment for a fortnight, and then put it in your pit; it will thus be warm at once. Then put on your soil at least 15 inches, and when that is warm plant out. Sow the plants at once in a suitable place. It is of little moment whether you train on the ground or on a trellis; but in such a narrow pit, the shoots and leaves should not be more than 15 inches from the glass. When the plants have made two rough leaves nip out the point—a shoot will then come from the axil of each leaf, thin these to two shoots, encourage them to grow to 2 feet, nip out the buds from the axils of the leaves for 20 inches, or so, then nip out the points of the shoots so as to leave four or five leaves, with the buds untouched in their axils. These will soon grow into side shoots, and generally show fruit at the first and second and third joint. Stop these shoots again, a joint before the fruit; fecundate the female blossom. Keep a bottom heat of 75° to 80°, a top heat of 65° at night, 70° during the day, and from 70° to 85° in sunshine with air on. Keep a moist atmosphere when growing at first, a dry air rather when the plants are in bloom, more moisture when the fruit is set and swelling, and a dry air when approaching maturity.

**INDIANRUBBER TUBING (T. W. P.).**—It can be fitted to a water-cart by means of a screw joint. It is dearer than gutta-percha, but much more manageable, being very pliant; but canvas waterproofed tubing would do and is about 6d. per foot. Write to Messrs Warner and tell them what you require and ask for prices. You will see their advertisement in our columns.

**FIGS DROPPING (A Young Gardener, Herts).**—We expect, that in such dull weather as we have had, the Figs have had too much moisture; very likely too much feeding ground, whilst your high stage has kept the light from them. Unless the pipes were very hot which they would not likely be in a greenhouse, we do not think they would harm the Figs. Figs will thrive on such back walls provided they receive a fair amount of light, not otherwise. With a mass of plants in front of them there will be plenty of leaves; but few fruit will show, and fewer still will attain maturity. If Figs will get very dry the fruit will drop. When in a dry state a thorough drenching will often throw them off; they should then be watered by degrees. A full meal at once would be apt to kill a man emaciated by starvation.

**VINES INJURED BY FIRE (Virgo).**—We see nothing after reading your further statement to alter the opinion expressed on your case. It was a misfortune to have the buds injured; it was rendered greater by cutting the Vines back afterwards. If only planted last summer, you should not have taken above a couple of bunches from each at any rate. In alluding to previous replies always point out the page and volume; for we have no time to look over indices, and do for our readers what they ought to do for us and themselves.

**TRIPLETON BLACK CHERRY (W. W. C.).**—We know there is a variety of Cherry so called, but have never seen it, nor are we aware of any one who has. It appears in one or two nurserymen's catalogues, but we do not think it is generally known. We shall be glad if any of our correspondents can enlighten us on the subject.

**PEAS WITH GRANULATED ROOTS (W. W. Bennett).**—The Pea is liable to such granulation on light poor soils. The specimens you have sent show that the plants would be greatly benefited by being watered with liquid manure, and mulching over the roots.

**NAME OF VEGETABLE REQUIRED.**—"Some twenty years ago, in a fashionable locality of this metropolis, I was in the habit of partaking at the dinner-table of a vegetable, the component parts of which had an appearance not dissimilar to light blue starch intermixed with a portion of green pods and a white pearly seed. It was of a glutinous nature, and struck my fancy as being exceedingly nutritious. I have experimented upon Vegetable Marrow in all its forms, and never could bring it to the like consistency. Miss Emma Roberts, in her "Characteristics of Hindostan," vol. i., page 222, refers to an edible named the "ramterye," which approximates nearer to my description than any of the kind I ever met with. Could any of your contributors inform me if it is procurable in this country, or have the seeds been ever imported?—GASTROSOPIST.

[We shall be obliged by information on this subject. We have sought for information in Covent Garden Market and elsewhere. Some suggest that the vegetable was a *Huricot*, and others that it was the *Calavansa Bean* (which we do not know). It certainly agrees very closely with the vegetable mentioned by Miss Roberts, and which we remember partaking of in India, and thought very insipid. It is called also there *ochra*, and is the pod of *Hibiscus esculentus*, and of some other species of that genus.]

**CIRCULAR BED (B. II.).**—Your planting will do very well; *Calceolaria* a *hexiflunda*, in the centre, two rows of *Perilla*, three of *Calceolaria* area *hexiflunda*, and 9 inches of *Lobelia speciosa*. But most people would prefer Punch or Fothergill's Nougay Geranium for the centre, or else put Flower of the Day Geranium instead of the *hexiflunda*; but we can only give fair play to all opinions on planting. We have held, from the beginning, that young plants of *Cineraria maritima* tell best as edgings round all sorts of scarlet, pink, and crimson Geraniums.

**GERANIUM LEAVES TURNING RED (D. C.).**—Your leaves of the Gauntlet forcing Geranium are quite ripe, and no more, or rather they were ready to fall six weeks back; but many, or most plants at that season, are not in such vigour of growth as to cast their done-with leaves, so they turn yellow, or red, or black, or spotted, and still hang on. But good managers effect the autumnal fall for their plants whenever they need it—that is, they pick off every leaf the moment it is of no more use to the plant.

**PETIS ARGYREA (Idem).**—You have grown that *Petis argyrea*, in 5½ feet high and 2½ feet through better than any of the London men; but in London and round it, many people stew their Ferns and roast their bulbs. This *Petis* will do much better in a conservatory than in a stove as you have shown.

**FLOWER-BEDS (Wishful to Learn).**—You have planted very fairly all the beds except 3, which you made of Flower of the Day edged with *Cerastium tomentosum*. That will never do, all edgings being for contrast. The white *Cerastium* is no contrast to the white Flower of the Day. Use the *Cerastium* round the *Calceolarias* instead of the *Lobelia*, and put the *Lobellias* round Flower of the Day Geranium, and you will be as smart as the best of them.

**RENOVATING AN OLD YEW-HEDGE (Verdant).**—The Yew-hedge which was reported by Mr. Beaton from the Highgate Nursery was of the same age as yours, thirty-five years, when every bough and branch of it was cut back to the quick, or old stumps, and which renewed it as close and young-like as a young hedge. Yours will recover in time, but it will be slowly, and we would not touch it any more for some years, not even cut out the dead wood, but tie and train the young wood to it, and stopping in June any shoots that might appear stronger than the rest. What your hedge really wants is a foot depth of the top soil to be removed from it for a space of 4 feet on either side, then to have the bottom forked as deep as a steel fork can go, then to have the top replaced by fresh soil, and to mulch that with good rotten manure liber a couple of inches deep, and let the rains wash down the strength of it by slow degrees. All the old stunted Cedars of Lebanon and any worn-out Conifers could be renewed in a few years by that process, as we can testify from a long experience of it; but very old or injured Yews and Hollies take the longest time to come round.

**TEMPERATURE OF WALTONIAN CASE (T. A. W.).**—Your lamp gives you too much top heat so late as this in the season, and you may let it out from 10 A. M. to 4 P. M. on all sunny days, and leave a little air on at night. 70° to 75° is quite high enough for top and bottom heat now, and for such cuttings as *Verbena*, *Geraniums*, and *Calceolarias*; and the half-inch of sand at the bottom should from this time be kept more damp, or quite damp, and a little air on in the fore part of the day.

**TRITOMA UVARIA SOWING (Manchester).**—If you sow the seeds now—that is, in the beginning of May, 1862, and treat the seedlings just as if they were the seedlings of a first-rate prize Dublin, they will bloom by the middle or end of August, 1861. You can have this Journal at Smith & Co.'s, Railway Station, Manchester, as early as the *Times*.

**PRESERVING GRAPES UNSHRIVELLED (Vinery).**—The way the Grapes were preserved in such good condition, as mentioned in our Numbers for March 11th and April 8th, was by allowing the bunches to remain upon the Vines, in a vinery the air of which was kept dry; cutting them away from the Vine in March with a piece of the spur attached. The end of the spur was stuck into a piece of Mangold Wurtzel, and then the bunch was hung up in a cold dry place.

**ROSES ON THEIR OWN ROOTS NOT BLOOMING (E. M. J.).**—All that is the matter with these Roses is, that they have too much goodness and too much kindness, and too little or no sun at all since they were potted. They should not have had one single "drop" stronger than from the pump the whole of this winter, and till the Rose-buds were all but open. No sort of manure water can be of any use to any plant in our climate, from the 20th of September to the 10th of May following. Giving such liquids is a clear perversion of the plainest facts in natural science.

**NAMES OF PLANTS (J. C. Ireland).**—It is *Orobanchae elatior*, or common Broom-Rape. (S. S.).—Yours is *Tecoma jasminoides*. (C. Drece).—It is Ribes aureum, or Golden-flowered Currant, a native of North America, and very common.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**POULTRY SHOWS.**

MAY 14th and 15th. TAUNTON and SOMERSET. Sec., Charles Ballance, Esq., Taunton. Entries close April 30th.  
 MAY 27th, 28th and 29th. BATH and WEST OF ENGLAND (City of Wells). Steward, S. Pittman, Esq., Manor House, Taunton. Entries close May 1.  
 MAY 28th and 29th. HULL and EAST RIDING OF YORKSHIRE. Sec., Mr. J. Hooton. Entries close May 14th.  
 JUNE 3rd. ESSEX AGRICULTURAL ASSOCIATION. Sec., R. Emson, Slough House, Halstead. Entries close May 10th.  
 JUNE 4th and 5th. BEVERLEY and EAST RIDING. Sec., Mr. Harry Adams.  
 JUNE 12th, NORTH HANTS AGRICULTURAL SOCIETY. Sec., Mr. H. Downs. Entries close May 21st.  
 JULY 9th, 10th, and 11th. LEEDS and WEST RIDING. Secs., E. Holdsworth and J. Wade.

**IMPORTANCE OF PROMOTING FOWL CULTURE.**

WHEN poultry has been kept for a fancy; when a few chickens have been reared; when some prizes have been taken, and when some pens have been sold at high prices; all that could be done has not been accomplished. The *blasé* breeder need not offer a reward for a new pleasure, nor think himself another Alexander lamenting the impossibility of a new victory. There is yet something to be done. Many of our greatest discoveries are due to accident: such things are crotchety and capricious. They escape the combinations of the scientific and studious, while they present themselves to the careless and idle. Such a one has spent days and nights to discover a power or movement, and that which he has failed in has struck another who was playing science to kill time.

The improvements that are to increase the value of stock, or to augment their food-producing qualities, are due to amateurs. Those who keep animals for profit are, with few exceptions, anxious for the main chance, and all are too much interested in the profitable employment of capital to withdraw any part of it for experiments. Such experiments are made by men who live in towns, or small fancy farms, and who labour under every difficulty, *except* want of capital. But as all classes benefit by the discovery of one, it is wise in a government to give every encouragement to those who devote time, capital, or intelligence to such pursuits.

The French Government has not been slow to see the merits of poultry, and we have before us the conditions that have regulated and the motives that caused the Show. Although it will be closed when this paper is in the hands of our readers, still much of it is so good, we think we do well to print it. It is entitled, "A Communication in the name of the Council, by M. Drouyn de Lhuys," President. Sitting of March 14, 1862.

"The Imperial Zoological Society of Acclimatization should, by article 12 of its statutes, contribute to the progress of practical zoology by publications, honorary and pecuniary encouragements, and, if possible, by exhibitions."

**Report,—**

"There are not two opinions on the happy influence exhibitions have exercised on the amelioration and propagation of the great animal classes—horses, cattle, poultry, swine. In all civilized countries these exhibitions take place periodically; they are the great national festivals of our age. They render people familiar with, and inculcate a taste for the best types of the best classes; they stimulate the emulation of amateurs, and impart considerable activity to the trace carried up in these animals."

It is thought such advantages should be eagerly sought for on

behalf of agricultural ornithology, and the lively interest which attempts of this kind have excited in France, England, Saxony, and all over Germany should encourage their increase. A celebrated breeder writes—"Every one is rearing fowls. It is almost a fashion. I see poultry reared in towns, in the gardens of their suburbs, in parks, in rooms, and even on window-sills in the middle of Paris."

"But if this taste has developed itself with all the impetuosity of a fashion, there is also a general complaint that it has been carried out with thoughtlessness and confusion; without considering the properties of the different breeds, the choice of stock-birds, or their purity: hence many deceptions which would at last cause discouragement and disgust. Exhibitions remedy this evil by placing before amateurs the finest specimens of the best breeds. They educate the public."

"These considerations have determined the Council of the 'Société d'Acclimatation,' and that of the 'Jardin du Bois de Boulogne,' to open in the garden, under the auspices of the two societies, an Ornithological Show."

The proper appreciation by the Government of the importance of breeding poultry arises from the fact that they possess in France accurate statistics of the numbers and value of the fowls and eggs consumed; also their weight as food. They also know the number of eggs exported.

Poultry makes more progress in most parts of the continent than it does in England. It is constantly seen at the tables of the middle classes in those countries, while it is a rare luxury here. It forms a very large item of exportation abroad, and many French and Belgian small farmers' families are mainly supported by the produce of the poultry sent to England. They have not one advantage over the English farmer, except that of not pooh-poohing poultry, and with all the costs and risks of exportation they beat him.

Our market supply of poultry becomes smaller every year, and but for the exertions of the dwellers in towns, we should be fast drifting to a state in which we should be dependant on foreign countries for fowls, just as much as for Ortolans. We have but one ray of light—Scotland is sending eggs, and Ireland fowls, to London. Better management on the part of the latter would largely increase the receipts.

**CHANGING PIGEONS' EGGS.**

MR. BRENT states, that if eggs are exchanged between two pairs of Pigeons, and there be above two days' difference or so, that it will be impossible for the young to live. Now, we gave to a pair of Dragoons, the day of laying the latter egg, a pair of eggs from Short-faced Tumblers that they had been sitting six days. They have reared the young, which are in first-rate condition. Now, another Dragoon cock has taken the hen from the cock of the same pair, and she still served the young hatched with the other cock, sitting on them at night, &c.; and, after laying, still continued to sit on them.—J. T.

[Young Pigeons are, as is well known to all fanciers, fed during the first few days with a curdy secretion formed in the crop of the old birds. It is ordinarily produced about the period of hatching. If that be delayed two days beyond the usual time, the old birds seldom sit longer but leave the eggs. On the other hand, if eggs that are to hatch several days sooner are transferred from another nest, the soft food is produced earlier, and the young are nourished. We have often brought it on at the tenth and eleventh days of sitting.]

TAUNTON and SOMERSET POULTRY ASSOCIATION.—We hope our readers will remember that the entries for this flourishing Association will close to-morrow (Wednesday, April 30th). A schedule, including every variety in separate classes, with prizes amounting to nearly £100, with fourteen pieces of plate value £2 2s. each, presents a bill of fare in the West of England not frequently to be met with in the shape of a poultry show. We hope the catalogue will be well filled with entries, and the Directors thereby encouraged on a future occasion still further to increase the value of their prizes. Considerable additions have been made this year, and we observe in the published Report of the Directors for last year, that "they pledge themselves (if well supported) not to relax their efforts until the Taunton and Somerset Poultry Association shall take its stand amongst the leading societies of this kind in the kingdom."

## BIRMINGHAM FANCY RABBIT SHOW.

THIS, the twenty-fifth half-yearly Exhibition, took place on the 21st—24th inst. The following is a list of the prizetakers:—

**LENGTH OF EARS.**—First and Second, J. Guest's Fawn Doe. Length of ears, 21 inches; width, 5½ inches. Weight, 12 lbs. 6 ozs. Age, 10 months 16 days. Yellow and White Buck, Length of ears, 20½ inches; width, 5½ inches. Weight, 9 lbs. 14 ozs. Age, 5 months 22 days.

**BLACK AND WHITE.**—First, J. Hewitt's Black and White Buck, Length of ears, 20 inches; width, 5 inches. Weight, 8 lbs. 4 ozs. Age, 4 months 24 days. Second, J. Guest's Black and White Doe. Length of ears, 20 inches; width, 5 inches. Weight, 8 lbs. 12 ozs. Age, 5 months 2 d. ys.

**YELLOW AND WHITE.**—First, J. Guest's Yellow and White Doe. Length of ears, 20 inches; width, 5 inches. Weight, 9 lbs. 9 ozs. Age, 5 months 22 days. Second, J. Hewitt's Yellow and White Doe. Length of ears, 18½ inches; width, 4½ inches. Weight, 7 lbs. 8 ozs. Age, 4 months 9 days.

**TORTOISESHELL.**—First, J. Guest's Tortoiseshell Doe. Length of ears, 19½ inches; width, 4½ inches. Weight, 6 lbs. 2 ozs. Age, 5 months 2 days. Second, T. Pinchbeck's Tortoiseshell Doe. Length of ears, 17½ inches; width, 4½ inches. Weight, 7 lbs. 8 ozs. Age, 7 months 4 days.

**BLUE AND WHITE.**—First, W. Howell's Blue and White Doe. Length of ears, 19½ inches; width, 4½ inches. Weight, 6 lbs. Age, 2 months 20 days. Second, T. Pinchbeck's Blue and White Doe. Length of ears, 17½ inches; width, 4½ inches. Weight, 7 lbs. 4 ozs. Age, 6 months 7 days.

**GREY AND WHITE.**—First, W. Howell's Grey and White Buck. Length of ears, 20 inches; width, 5½ inches. Weight, 9 lbs. Age, 7 months 1 day. (No Rabbit for the Second Prize.)

**SELF-COLOUR.**—First, J. Guest's Fawn Doe. Length of ears, 20½ inches; width, 5½ inches. Weight, 9 lbs. 6 ozs. Age, 5 months 22 days. Second, J. Coleman's Fawn Buck. Length of ears, 18½ inches; width, 4½ inches. Weight, 8 lbs. Age, 6 months 9 days.

**WEIGHT.**—First, J. Hewitt's Yellow and White Buck. Length of ears, 19½ inches; width, 4½ inches. Weight, 9 lbs. Age, 9 months. Second, T. Pinchbeck's Yellow and White Buck. Length of ears, 19½ inches; width, 4½ in. lbs. Weight, 8 lbs. 8 ozs. Age, 7 months 4 days.

## EXTRA PRIZES.

LONGEST BLUE AND WHITE.—Prize, W. Howell.

LONGEST GREY AND WHITE.—W. Howell. Commended, W. Howell.

**PRAIRIE HENS.**—Fourteen pairs of Prairie Hens have just been sent from Chicago to England. They are intended for Queen Victoria's henery.—(*Boston Cultivator*.)

## THE DOG.

*House Dogs and Sporting Dogs, their Varieties, Points, Management, Training, Breeding, Rearing, and Diseases.* By JOHN MEYRICK. London: J. Van Voorst.

We have before us a small volume entitled "House Dogs and Sporting Dogs," which we recommend strongly to such of our readers as have, or who intend to have any one of the canine breeds, whether they wish to have sound information as to the good characteristics the breed ought to possess, how they ought to manage it, or how to detect and treat the diseases to which it is liable. It is a thoroughly practical, reliable book, and a few quotations will afford a fair criterion of its contents.

"THE SKYE TERRIER.—The varieties of this breed are innumerable. In the island of Islay alone there are four distinct strains of Skye Terrier, all kept distinct and all highly esteemed.

"The general characteristics of this dog are—a long body, very short legs, long neck, and ears which generally stand out slightly from the head. In deciding upon the purity of any breed of Skye Terrier, the following points should be looked to: his coat, which should be long, wiry, and straight; his eyes, which should be bright and keen, but not prominent; his tail, which should be carried in a line with the back; his legs, which should be straight, and not clumsy in the foot; the hair over his eyes, which should be abundant; his colour, which should be either slate-colour or fawn; black is not uncommon, but is objected to in Scotland.\* A cross with the Spaniel or the Maltese Terrier is often resorted to by dog-fanciers; but it is to be objected to, as it makes the hair soft and silky, and spoils the courage.

"There is no pluckier vermin dog than the Skye Terrier. In the Hebrides he is used as an Otter-hound. For this purpose, a pack of from eight to a dozen of these little dogs is employed, which are able, from their small size, to follow the otter and attack him in the crevices of the 'cairns,' or piles of loose rock on the sea-coast, in which he makes his retreat. The otter is quickly driven out, and generally shot in attempting to reach the sea. As there is no harder-biting animal than the otter, the employment of Skye Terriers in hunting him is a sufficient proof of their pluck. I have myself seen two of these little dogs hanging on to the neck of the otter, and thus saving him from the guns of the sportsmen as he scrambled from the rocks into the sea."

"THE BREAKING OF SPANIELS.—The great object in the training of Spaniels is to accustom them to hunt within a radius of twenty yards or so of the shooter, without the necessity of continually hollering and whistling to them.

"The quickest way of breaking a team of Spaniels is to have an assistant to 'whip in' the refractory dogs which hunt too far for the breaker, while the latter should whistle or call to them at the same time. They can also be taught by the use of the check-cord; when a Spaniel hunts too far off he is made to 'down charge,' and the breaker walks up and drags the dog towards him by it. If a dog is too wild, he may have his fore-paw put through his collar, and be hunted in this way for half an hour or so.

"Spaniels should not be hunted in thick covers till they have shown themselves obedient to hunting hedge-rows, bits of gorse, &c., where they can be seen, and rated by name, for any short-comings. They should not, however, be hunted at all until they are perfect in the 'down charge' and in coming to heel; both of which should be taught in the manner recommended for the Pointer or Setter."

"THE CHOICE OF PUPPIES.—A black nose is desirable in every breed of dogs; and as the nose of a young puppy is invariably red, it is important to ascertain whether it is likely to become black or to remain flesh-coloured. It can be foretold as follows: when the puppy is ten days or a fortnight old, a small, indistinct, bluish-black mark will generally be observed on his nose. If this mark is situated in the centre of the slit which divides the nostrils, the nose will be black; if in any other part of the nose, it will be partially black; if there is no mark at all, the nose will be flesh-colour.

"By far the best recommendation to a puppy is fatness; partly because fat is a sign of a good constitution, partly because the being able to get a taller share of milk than the others is itself a sign of greater strength."

## THE BEE SEASON IN DEVONSHIRE.

I HAVE to give a very different report of the comparative seasons for the bees in the springs of 1861 and 1862, to that of your North Lancashire correspondent. In the spring of 1861 most of my hives were in a forward state. Pollen was carried in freely in February. Breeding was proceeded with to an astonishing extent in March and April, and the hives rapidly increased in weight about the middle of April. One hive, which had filled but two-thirds of its space with combs the preceding year, had, by the end of April, completely supplied the deficiency. On the 4th of May the bees were driven out, and a splendid artificial swarm obtained. Its combs were crammed with brood to the bottom, with a very large quantity of newly-sealed honey in the upper part. Several other hives were in an equally forward condition. Many had drones out in April, and all were becoming crowded with population by the end of the month.

In this present spring a very different state of affairs is to be remarked. I consider my hives generally to be at this date (April 23rd) a full month behind what they were last year, although before the winter they seemed in a much superior condition than at the close of 1860. This is not my own experience only, but applies to all the stocks I have seen in the neighbourhood.

I have but just returned from a visit of a few days at Kingsbridge, where I have inspected many apiaries. Without exception the strongest hives are weak indeed compared with what mine were at this time last year. Kingsbridge has always been rather celebrated for bees, and, being considerably to the south of Exeter, is generally favoured with a more forward and genial climate; but at this time it is far behind our own. Vegetation is by no means so advanced; what there is, seems to have suffered a good deal by nipping winds, and bee-flowers are decidedly very backward. Numbers of hives have ceased to exist. Some that have been fed with many pounds of food have died of starvation. We have had a great deal of warm weather this spring, and bees carried pollen perhaps earlier than last; but certain it is that the breeding has been very far behind. It is not because my own bees are less prosperous that I draw these conclusions. They are, so far as I can ascertain, quite beyond the average of those kept in the neighbourhood. The consumption of stores in the stocks has been most remarkable. Had I not liberally supplied all my stocks with artificial food, it is my belief that none of them would have been in nearly so good a state as they are at present, and several of them would most assuredly have come to grief. But there is no cause of alarm. A few weeks of tolerably settled weather will enable the bees to retrieve their lost ground; and I do not despair of seeing my apiary, by the end of May, in as prosperous a condition as at the same period of 1861.

To every rule there is an exception; for two of my stocks present a very different appearance from the remainder. One of these to-day has been, to use a local term, "hanging out," and is so crowded with bees that no combs can be seen from the back window. A second stock in the same garden is, perhaps, equally strong; but, from being domiciled in a very large frame-bar box, does not show such evident signs of prosperity. The other stocks present a beggarly appearance in comparison.

From the first of these two prosperous colonies I obtained 42 lbs. of super honey last summer; and the second is the artificial swarm made, as related above, on the 4th of May. In both, therefore, there are old queens—I should say at least three years of age. The first stock swarmed in 1859, and not since; the second was a first swarm in 1860; consequently then

\* In the Hebrides, the terms blue and yellow are applied, in reference to terriers, to colours which are properly slate-colour and fawn."

at least one year old. This appears to add another proof in confirmation of a theory I have for some time adopted—that the third year of a queen's existence is generally her most prolific period. In all probability, if not renewed naturally or artificially in the fourth year of her life, the hive becomes comparatively worthless. So I hope before the close of the season to substitute young queens in their places.—S. BEVAN FOX, *Exeter*.

APIARIAN NOTES.

SWALLOWS SAID TO DESTROY BEES.—Your correspondent "E. K." charges that innocent bird, the Swallow, with being a devourer of hive bees. I have been a close observer of Swallows for many years, and never destroy their nests; and I am sorry to say, that when a youngster, I foolishly tried my skill in shooting Swifts, Swallows, and Martins in the month of July, more than once. When these birds were shot, their mouths were invariably filled with flies of a very minute description. I never once found a live bee, or even a large fly of any sort, in the mouth or inside of either of the three species of birds I have named. I hope your correspondent "E. K." will "reconsider his verdict," and am sure he will find this assertion of his is a mistake.

"E. K." is quite right in his charge against the large black-headed Tomtit (the *Parus magnus*). He is called the "bee-eater" in Hampshire. As to the House Sparrow, he sometimes kills a few hive bees; but, after all, is only an occasional destroyer. He prefers grubs, butterflies, caterpillars, and ripe wheat when he can get them. I found the garden mice the greatest enemies to bees; and the bees themselves, in spring and autumn, attack each other's hives and plunder without mercy. A good look-out should be kept to prevent this, and instant measures taken. Where there are many hives, a season seldom passes in which this civil war does not more or less take place.

One disadvantage in "E. K.'s" "Insulation" of bees is this—that in wet and tempestuous weather many bees would be driven by the winds into the water, and, unless the temperature were very high, they would perish.

VENTILATION.—Much has been said about ventilation. In severe winters, such as 1860-61, the less the better, as I witnessed the destruction of bees, particularly swarms of the previous summer, where the death of the bees evidently took place from severe cold, the bees being in a very healthy state before the frost, and honey in abundance in numbers of the defunct stocks. At the same time proper ventilation in very hot summers prevents the melting of the combs, which latter event is very little guarded against, particularly by cottagers, many of whom seldom shade their hives, the great heat being an occurrence of perhaps once in six or seven years. The bees do all they can in this case before destruction comes on them, by lying out night and day for some time. The instinctive fear of enemies in bees wars against ventilation a good deal, as they stop up every crevice in the hive to prevent the ingress of all marauders.

THE LUMP-SUGAR-SYRUP ARGUMENT.—I agree with the "DEVONSHIRE BEE-KEEPER" in his views on this subject. It would be equally surprising if an expert chemist were to tell you that he had extracted 20 lbs. weight of excellent honey from the blossoms of the white clover, or from the honeydew on leaves, as to suppose that the syrup in question was not changed in the stomach of the bee. Every experienced bee-keeper knows that pure honey is influenced, both in flavour and quality, by the different pasture from which it is imbibed; the colour is also strongly affected, and the consistency by the state of the weather. In very hot, dry summers it is thick and glutinous, and in a wet season the honey is thin and watery. The honey from the syrup alluded to no doubt will partake of a thin and watery quality, but still it is changed most materially.—H. W. NEWMAN, *Hillside, Cheltenham*.

EARLY SWARM OF BEES.—A rather singular occurrence happened at Steart Bay, in the parish of Stockland, Bristol, on the 29th of March. Mr. G. Silke had in his garden some hives of bees, and on the 29th ult., the weather being extremely hot, a swarm issued from one of the hives and entered an old hive, in which they are now located. It is an exceedingly rare occurrence for bees to swarm at this period of the year.—(*Somerset County Gazette*.)

VENTILATION OF BEE-HIVES.

YOUR correspondent "E. K.," who, in page 57, quotes the opinion of a French bee-keeper in favour of "leaving hives open all round at the bottom," is probably aware that Miner, the American apiarian, recommends this mode of proceeding during summer; but as soon as winter approaches, he lets down his hives and limits ventilation to an entrance 2 inches long by half an inch high in front, and a similar orifice in the rear, which is covered with perforated zinc.

The only instance which has come under my observation in which a stock of bees passed the winter with a free passage all round, occurred early in March, 1850, when, being desirous of increasing my apiary, I purchased five stocks in the neighbourhood of Taunton, in the adjoining county, Somerset. Upon lifting one of them, I was surprised to find it raised from its floor-board by wooden blocks about half an inch thick, and was still more surprised at being informed that it had passed the winter in this state. I may add that this hive showed drones on the 10th of April following, at which time I find by a note in my journal that it was the strongest stock then in the apiary of—A DEVONSHIRE BEE-KEEPER.

WATERPROOFING HIVES.

IN my recipe for waterproofing hives, which you inserted in your Number of the 15th inst., the printer has corrected my punctuation into a mistake (it was correct enough as written), which will deceive any luckless wight who may have tried the recipe. I said, "½ oz. each gums thus, benzoin and guaiacum, &c.," meaning (in a tabulated form)—

- ½ oz. gum thus
- ½ oz. gum benzoin
- ½ oz. gum guaiacum
- 2 ozs. shellac
- 8 ozs. naphtha

A reference to your Number will show the difference it makes, which please correct, or it may get me into hot water.—G. F. B., *Colney Hatch*.

ACCLIMATISATION SOCIETY.

THIS Association has for its objects the introduction, hybridisation, and diffusion of useful or ornamental animals and vegetables, not only in this country but in our colonies. It is a Society proceeding soberly, and, being guided by good sense and sound science, cannot fail of effecting much good. Its funds are in a satisfactory state, because its outlay is regulated by a wise regard to its income; yet it would be able to be more extensively and more rapidly useful if its funds were larger, and we hope that they will soon be increased by the addition of many more subscribers. The annual subscription is but a guinea, and each subscriber has a preference given in obtaining through the Society such animals and vegetables as he covets.

A few extracts from the Society's Annual Report will give a just idea of its proceedings.

"From an official letter from Sir G. Bowen, Governor of Queensland, to His Grace the Duke of Newcastle.

"Government House, Brisbane, Queensland.  
"3rd November, 1861.

"MY LORD DUKE,

"Above all, I would recommend more especially to the notice of the Society:—first, the Bustard, or Wild Turkey of our plains; secondly, the Tallegalla, or Mound-building Turkey of our forests; and, thirdly, the Wonga, the queen of the Pigeon tribe. I am informed by competent judges that all these last-named birds could be easily acclimatised, and even domesticated in England, while I can bear my own personal witness, as a sportsman, that they all afford capital shooting and delicious eatiogs. The Wonga in particular combines, in the most delicate proportion, the flavour of the Pheasant and of the Grouse."

(Signed)

"I have, &c.,  
"G. F. BOWEN."

"CHINESE SHEEP.—The first lot shipped by the 'Wagoola,' from Shanghai, arrived in London a few days ago, and have been temporarily received by Mr. Bush, the Treasurer. One ewe died upon the voyage, after dropping three lambs on board the ship, and one, also in lamb, which was landed in a weak state of health, has died since. We are happy to be able to report, however, that the remaining four ewes and two rams are in excellent health and condition, and that they manifest every sign of thriving, and the ewes are all believed to be in lamb. Mr. Bartlett, of the Zoological Gardens, reports that they breed

twice in the year, and produce four and sometimes five at a birth."

"GUANS.—On the 28th of August four Guans were received by the Hon. G. Berkeley from Mr. Dougall, of Glasgow.\* These birds are now healthy and in good condition. Many interesting facts as regards their food and habits have been recorded by Mr. Berkeley.

"They feed chiefly on barleymeal, mixed as thickly as possible, and only one out of the four will eat maize. They are all very fond of bread, raspberries, blackberries, &c. The food necessary for Pheasants answers very well for Guans. They go to roost after their morning feed, and their nature is to perch and roost a great deal. They are particularly sensible and intelligent, and will live and remain round the house and garden as well as tame fowl. They are fond of roosting in very high trees, but they will easily conform to roosting in a fowl's house. I have placed two of my four with Mr. John Mills, jun., at Bisterne, to breed in his aviary, and kept two myself in my aviary."—(Report from Hon. G. Berkeley.)

"CROSS BETWEEN THE PINTAIL AND THE COMMON DUCK.—The Vice-President of the Society, the Hon. G. Berkeley, has, in pursuance of one of the objects of the Society, been pursuing his experiments on the hybridisation of birds, and has arrived at a valuable cross between the Pintail and common Duck, a hybrid which is not only handsome in its plumage, but forms an excellent variety for the table.

"The following interesting and important communication relative to this experiment has been received from Mr. Berkeley:—

"A circumstance has happened, in regard to the experiment made by Lord Crayke, at Ashdown Park, which bears upon the theory that all species have a common origin. From a Mallard of the Pintailed cross (supplied him by me), and the large tame 'Ronen Duck,' he has bred some beautiful birds, the males carrying the elongated tail-feathers of the sire.

"From a brother of this Mallard, and the large tame black 'Buenos Ayrean Duck,' I also bred a number of birds, not one of which carried the long feathers in the tail, though a slight peculiarity in the curled feathers marked the origin. Had this variety in these two crosses been only occasional, or in an instance or two, it would not have struck me so much; but for a large number to carry so distinguishing an illustration of origin from one species of duck and not from the other, though the parent sires of each were brothers, and precisely alike, is well worthy of remark.

"Lord Crayke finds, in regard to his experiment, precisely that which I have found, that ducks thus bred from the Pintail may be killed all the year round as excellent for the table, never acquiring the hardness to which the meat of the tame duck is liable when grown to maturity."—GRANTLEY F. BERKELEY.

"ARROWROOT.—In compliance with your request, I here give you a short statement in relation to the Arum introduced by me into the island, and which I have been cultivating for the last seven years. It first came under my notice through the means of a plant brought in a pot from the Azores, and given to a brother-in-law of mine, as a plant producing the arrowroot. The first sight I had of it persuaded me at once that it belonged to the arrow tribe, and I at once determined to try its powers of enduring our climate; and the result has been that I have found it perfectly hardy, bearing well the severest of our winters. Growing, however, the winter through, it required the shelter of a walled garden or land otherwise protected from high winds, which break the leaves and thus retard its growth.

"The digging of the crop and the replanting takes place at the end of July or commencement of August. It might be done simultaneously, the smaller bulbs being planted as they are separated from the larger ones destined for arrowroot. They, however, can remain out of the ground for some weeks—a longer time if kept quite dry.

"In planting, I have, after repeated trials of various modes, adopted the following. I dig a trench as for Potatoes, but levelling the bottom with the spade, so as to have a level surface of about 6 inches in breadth, and as much as possible of uniform breadth; then drop into this furrow very thickly the small bulbs. These latter, though not attaining the size of the larger ones, will yet acquire a respectable size. I lay them thick for two reasons: one is that many of the bulbs will not grow the first year, and the second is that it has become evident to me that the bulbs, in increasing their size, require the assistance of each other to get the better of the pressure of the soil, which, after winter rain, gets hard. Between each row I leave a space of 18 inches, or, when I plant in very rich soil, 2 feet.

"The bulbs so planted I leave two years before taking them up. A crop may, however, be obtained yearly by planting bulbs of the size of a good-sized egg; but I prefer the other mode. At the second year, the plants not having been disturbed, are up much earlier, and become much finer and

healthier plants than those planted one year for the other, and produce much finer bulbs for the next planting.

"To obtain a first-rate crop the soil needs to be rich and well manured. If this is done at the time of planting, the more rotten and decayed the manure is, the better. If, however, you prepare your soil early the previous spring, you can turn in manure in its ordinary state. The manure in all cases is spread upon the soil and forked-in.

"This plant seems to delight, like our common Arum, in rich vegetable mould; and, like it, seems to do best in large clumps or close patches. This was what first suggested to me the propriety of planting thick.

"The produce of this plant is enormous. From 1½ perch I manufactured one year 60 lbs. of arrowroot, which I sold at the rate of 1s. per pound, being at the rate of £78 per Guernsey vergée, or £193 sterling the English acre. This was planted with bulbs the size of an egg, in rows 1 foot apart and 3 inches in the rows.

"That was a remarkably good year for bringing the plants to perfection; I have never succeeded so well since. It has never failed, however, in paying me well for the ground it occupied, and the labour required by it.

"In some years it has been attacked with a disease peculiar to the plant. Early in spring I have found the leaves and stalks acquire a rusty appearance, and this gradually spreading until the plant disappeared altogether. On digging the bulb it was perceived that it had stopped its swelling from the time of attack.

"I have observed this same disease in the common Arum, and in another Arum named *serpentaria*, which I have also in my garden.

"With regard to the extraction of the fecula, this operation is performed just in the same way as potato-starch is obtained, and, therefore, does not need any particular explanation here.

"There resides in this Arum, as well as in the common Arum of our hedges, an acrid principle, which would make it very dangerous if eaten in its undried state. By drying, however, its poisonous qualities entirely disappear by evaporation, and in this state it becomes really superior to the Potato. This has led me to believe that if this root was kiln-dried, it might afterwards be stored and used as Potatoes the winter through. I have not yet, however, made the experiment, save with a few roots dried before a fire, and so far proving perfectly successful. This acrid juice becomes very troublesome to those who are occupied in manufacturing the arrowroot; it causes a most intolerable and itching sensation to the hand, and especially between the fingers. Oil of any sort, but particularly oil of cloves or sweet oil, rubbed over the hand soon allays this otherwise unpleasant, if not painful sensation. By great care in avoiding to dip the hand in the water, much of the evil may be averted. Most of the work may be done with instruments having handles.—PETER MARTIN."

## OUR LETTER BOX.

GOLD-PENCILLED HAMBURG HEN (*E. R. Wilton*).—Dragging her leg, hanging her tail, incapacity of standing, are all symptoms of pressure on the brain, and most probably are occasioned by excessive fatness, arising from over-feeding. The hen eating her eggs is also an evidence of a depraved appetite. The only mode of preventing this, is by watching and taking the egg away as soon as laid, and having nest-eggs of white earthenware, which can be purchased for the purpose. Give your hen a table-spoonful of castor-oil twice a-week, and feed her chiefly upon boiled potatoes, with a little oat or barleymeal, until the symptoms abate.

CANKER IN PIGEONS (*W. Choyce*).—The disease affecting your young Pigeons is that known as canker. As it prevails throughout your loft it evidently depends on some general cause. You are either feeding on unwholesome food, or, what is more probable, your loft or pigeon-house is overcrowded, or the dirt is allowed to accumulate, or there is insufficient ventilation. Look well after the general health, and you will have no more canker. The safest application to those birds already cankered is powdered burnt alum, to be applied after removing the white matter.

DRAKE HATCHED UNDER A HEN (*J. R. W., New Forest*).—It cannot be denied that there will exist through life a sort of filial attachment between the Drake and his mother and her family. The indifference with which he would view fowls under other circumstances does not exist, but it is not true he will be a "persecutor of hens." Such may and will be the case sometimes. With proper precautions the use of the hen for hatching is not necessary. The Duck is not allowed her own eggs, because she is said to be a bad mother; but if she is confined and kept from the water, she is as good as a hen.

BEWICK'S BIRDS (*M. L. S.*).—They are very beautiful, but would be too costly. We have had a similar suggestion for drawings of their eggs and nests. We wish we could afford to satisfy all such suggestions. By-the-by, we are glad to see that the French Government have adopted active measures for preventing the destruction of either small birds or their eggs, and on the ground that they are the friends of the cultivators of the soil.

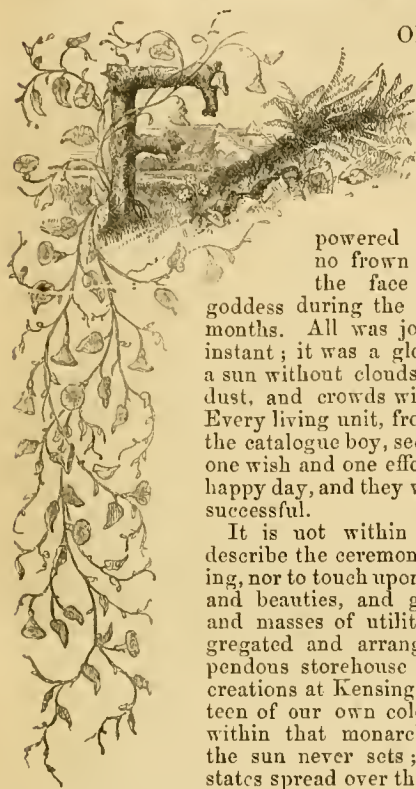

\* These graceful birds were imported by a gentleman from Rio Grande, South America (lat 32° S., long. 62° 12' W.). The American name is 'Jacou'—the 'Turkey of the Woods'. They are from a mountainous and temperate region. The finest poultry known at Rio Grande is a cross between the male Guan and the common domestic Fowl."

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 62.0° and 49.0° respectively. The greatest heat, 81°, occurred on the 6th, in 1830; and the lowest cold, 21°, on the 8th in 1855. During the period 147 days were fine, and on 98 rain fell.

THE INTERNATIONAL EXHIBITION.

ORTUNE smiled on the opening day, and we trust that when the closing day in October arrives, we may be em-

powered to record that no frown has been upon the face of the fickle goddess during the intervening five months. All was joyous on the 1st instant; it was a glorious May-day, a sun without clouds, roads without dust, and crowds without accidents. Every living unit, from the Prince to the catalogue boy, seemed to unite in one wish and one effort to render it a happy day, and they were thoroughly successful.

It is not within our mission to describe the ceremonial of the opening, nor to touch upon the splendours, and beauties, and graceful fabrics, and masses of utilities that are congregated and arranged in the stupendous storehouse for the world's creations at Kensington Gore. Nineteen of our own colonies, comprised within that monarchy upon which the sun never sets; and fifty-seven states spread over the earth's surface with which we are at amity, all have contributed the best examples of their native products and skill, rendering it the most wondrous epitome of the world's wealth and garniture. But we must employ our pen upon none of these. We must drop to what at first sight seems a bathos profound; we must chronicle the beehives, and the mowing machines, and the Potato-diggers, and the spades—yet there is really no bathos here. There hangs a lace shawl in those Courts, which claims in exchange from the purchaser £250; there are golden and silver fabrics, to buy which another cipher must be added to those figures—yet these have no value so real, so wealth-producing, as those bright steel implements by which the flax of that shawl, and the metals of those fabrics were won from the earth. Near those implements, too, are arranged those warlike marvels, the Armstrong guns; and among other Courts ranges of rifles and trophies of swords—but

“Give us the SPADE, 'tis old England's glory,  
That fashioned the field from the bleak barren moor;  
Let us speak of its praise with haliad and story,  
'Tis brightened with labour, not taroished with gore.  
It was not the sword that won our best battle,  
Created our commerce, extended our trade,  
Gave food for our wives, our children, and cattle;  
But the queen of all weapons—the Spade, boys, the Spade.”

No. 58.—VOL. III., NEW SERIES.

Now, having arrived with the poet at this horticultural conviction, let us turn from all that dazzles the eye, and walk to the west side of the eastern annex, and there we shall find the following, upon some or all of which we shall have more to say in future Numbers.

- “2083. BOOTHMAN, J., *Gisburn Coates, near Skipton.*—Observatory bee-hive and feeding-box.
- “2084. BOYD, J., *Lewisham.*—Brush lawn-mower, shaft-roller, and tubular scythe-handles.
- “2099. CRANSTON, W. M., 58, *King William Street.*—Wood's grass-mowing machine.
- “2100. CROSS, T. W. & Co., *Washington Works, Leeds.*—Garden engines.
- “2105. DENNIS, T. H. P., *Chelmsford, Essex.*—Metallic horticultural building.
- “2106. DORE, J., 17, *Ermouth Street, Clerkenwell.*—Garden, watering, rolling, and syringing machine.
- “2107. DOWNIE, R., *Sea, Barnet, Hertfordshire.*—Open bee-hive and uniecomb case.
- “2112. FENN, R., *Rectory, Woodstock.*—Cottager's bee-hive.
- “2113. FERRABEE, J. and Co., *Stroud, Gloucestershire.*—Lawn-mowing and sweeping machines.
- “2114. FERRYMAN, E., *Meadow Place, Oundle, Northamptonshire.*—Patent self-kneading lever churn.
- “2122. GREEN, T., *Smithfield Iron Works, Leeds and London.*—Lawn-mowing machines.
- “2125. HAYWOOD, J., JUN., *Phoenix Foundry, Derby.*—Cast-iron vases and chairs.
- “2127. HEREMAN, S., 7, *Pall Mall East.*—Sir Joseph Paxton's patent hothouses.
- “2133. HUGHES, H., *Regent Street, Loughborough.*—Bee-hive.
- “2139. KAY, T., *Holbeck Moor Pottery, near Leeds.*—Pots, Fern-cases, &c.
- “2141. KENNAN & SONS, *Dublin.*—Iron fences, log saws, lawn-mowers, and root-blasters.
- “2142. KINGSTON, S., *Spalding.*—Rotary cupola bee-hive on Nutt's principle.
- “2144. LEE, C., 12, *Warwick Crescent, W.*—Water-barrow, runner, and greenhouse ventilator.
- “2146. LIPSCOMB & Co., 233, *Strand.*—Improved fountain jets.
- “2147. LOVEY, E., *Ponemooth, Perran Wharf, Cornwall.*—Bee-hives.
- “2150. MARRIOTT, J., *Gracechurch Street.*—Apiary, hives, &c.
- “2153. MUNN, MAJOR, *Throley, Kent.*—Model of a bee-hive.
- “2157. NEIGHBOUR, G. & SON, 149, *Regent Street.*—Bee-hive: bees at work.
- “2159. NIXEY, W. G., 12, *Soho Square.*—Garden labels.
- “2160. ORMSON, H., *Stanley Bridge, Chelsea.*—Conservatory, hot-water tubular boilers, &c.
- “2163. PHILLIPS, G., *Harrow.*—Bee-hives.
- “2169. READ, R., 35, *Regent Circus.*—Horticultural engines, machines, and syringes.
- “2173. ROWLEY, J. J., *Rowthorne, Chesterfield.*—Hedge-clipping machine, grass-mower, and reaper combined.
- “2176. ST. PANCRAS IRONWORK CO., *Old St. Pancras Road.*—Conservatory and glass walls.
- “2182. SHANKS & SON, 18, *Cannon Street, City.*—Lawn-mower.
- “2184. SMITH, G., 31, *St. John's Square, Clerkenwell.*—Ensmelled garden labels.
- “2188. STANLEY, J. M. & Co., *Midland Works, Sheffield.*—Octagon conservatory.
- “2191. TAYLOR, J. & SONS, *Kensall Green, London, W.*—Conservatory, tubular boiler, turnace doors, &c.
- “2192. TEGETMEIER, W. B., *Muswell Hill, N.*—Bee-hives.
- “2197. TYLER, H. & Co., 85, *Upper Whitecross Street, London, E.C.*—Garden engines, conservatory pump, syringes, and fountain-jets.
- “2200. WARNER, J. & SONS, *Crescent, Cripplegate.*—Garden engines, pumps, syringes, fountains, and fumigator for grapes.
- “2201. WEEKS, J. & Co., *King's Road, Chelsea.*—Boiler, heating-stacks, models of conservatories, &c.
- “2204. WILLISON, R., *Alloa, N.B.*—Ventilator for vineries, lift and force pump, &c.”

HUMEA ELEGANS CULTURE.

“A FEW weeks ago a short treatise on the culture of *Humea elegans* was promised in THE JOURNAL OF HORTICULTURE—in other words, this is a breach of promise case so far. Who made the promise it is needless to inquire; the only question now

No. 710.—VOL. XXVIII., OLD SERIES.

is, How best to prevent damages to such specimen plants of *Humeas* as one would like to turn out into the centre of a nice circle of flower-beds, so as not to scare away the birds and butterflies.

I hold it as a firm point of my creed, that flower-bed *Humeas* should never be sown earlier than the first week in May, nor later than from the 10th to the 15th of the month. I hold also, that a score more of other seeds for curious-looking plants, for out-door summer use only, which are sometimes sown as early as February, are best and pay most when this is deferred to the first week in May—say the Castor-oil Plant, which requires exactly the same treatment as *Humea* when it is intended for single specimens out of doors the second season. But let us keep to the *Humea*.

The largest I ever saw was at a Stanmore show, just below Edgware, the last show at which I was one of the judges out of London, in 1838. That *Humea* was 15 feet high, and had three heads to it, 9 feet of the bottom being as bare as a pole, and as big round as a stake for a gap in the hedge. The next biggest *Humea* I have seen was from Sion House at a Chiswick exhibition, about twelve or fifteen years back. I think it had five heads or central stems, and might be from 8 feet to 10 feet high, and 30 feet in circumference, or thereabouts, with only 2 feet of bare bottom. About seven thousand people saw that *Humea*, or might have seen it as well as I did, only I had to book it. And the worst *Humeas* I have seen were in a good flower garden, where the managers knew what *Humeas* ought to be, but failed that year from a change or two among the hands who did the work of the place.

Good gardeners, with sufficient means, can do anything with *Humeas* if they sow the seeds any day from the 1st of February to the last of May; but there is no gardener out of a hundred now-a-days who has the means of nursing such plants as *Humeas* just as they would do Cockscombs or Balsams for three months of the busy spring, so they put off the sowing to the end of April, and make up leeway by a superior first-summer culture, and a kindness over the winter which old *Humeas* in my young days had never given to them: therefore, what I would recommend would be this, To sow the seeds very thin indeed in any light soil, such as you would sow *Calceolaria* or *Cineraria* seeds in; to put the seed-pot or pan in a hotbed where it could be shaded from the sun till the seedlings were all up; but a close frame with little or no bottom heat could then be so managed with sun heat as to do for all seeds that are good for flower gardens. Some people would hardly believe that Black-eyed Susans, the annual *Thunbergias*, treated that way from first-of-May sowings would be by the 10th of June on a par with January-sown seeds for flower-garden purposes; but the plants from the first-of-May sowing have not only the advantage at planting-out time, but a very decided advantage all through the season. Some may recollect the hedges of these *Thunbergias* which I booked as loaded with ripe seeds just like Sweet Peas at the beginning of October not many years back. They were from a late sowing and had no check or stop from first to last, and that is what *Humeas* particularly like—to be on the go, safe and sure, every day from the seed-leaf to the first frost; and the plants next year will be just in proportion to your skill and industry in growing them without any stimulants, and never missing an hour's growth from too much of any one thing.

The reason for sowing the seeds of *Humeas* so very thinly is to be able to let the seedlings remain a little longer than usual without transplanting them, which will be much in their favour; for having acquired a "bottom hold," as gardeners say of nice stocky seedlings and other young stuff, the change will not affect them nearly so much as it would when very young and very close together in the seed-pot. If you do not understand much about rearing seedlings, those of *Humea* will be the best to learn from, as if you come pretty near the mark they will do so far; and if you do not kill them through too much kindness, too much close heat, or too early sowing, you will be sure to have plenty of *Humeas* of some kind. About the end of May the *Humea* seedlings ought to be firm, stocky, with four or five leaves on each, and now comes the greatest point of all for this summer—the properly transplanting them singly into No. 60-pots; or if you have more than you want, it is a safe way to put three seedlings in the first potting, and in the next potting to cut out the two smallest or weakest-looking, thus giving three chances to one for a really good start. These small pots must in that hot season be plunged to the rim in a close cold pit, which is, in fact, a stove all day and a cold pit at night only. Now if you

know anything of Cockscombs and the way they do them, that is just the way for these little *Humeas* for the next two months, only there is no bottom heat. Use the very richest compost you can make—one half loam, the other half very rotten dung and rough leaf mould. As soon as the little balls in the pots are covered with roots, and before the roots begin to coil over each other is the right time to shift into pots one size larger—only one size larger, recollect—and just as soon as the roots are equally forward give them another shift to the next-sized pot. All this will be quick work, for it is the height of the growing season, and you are making up for lost time; as in reality, if one had the chance of sufficient room, the 1st of April ought to be the sowing day; but I prefer a month later, and make up time by superior management. From the first potting that close cold pit, which is now as it were a stove, must never be dry night or day, but by the rose watering-pot or syringe be kept constantly just wet enough for newly-potted-off seedlings and no more; or just damp enough to keep the seedling-leaves from flagging at any time. That is the proper pitch of dampness for all such cold pits in the height of summer, and every kind of pot plant likes that way, and the *Humea* more than most of them.

The third pots, or shifts, ought to be ready for another shift between the 10th and 14th of July, but there must be no shift then, only begin to use a mild liquid manure, giving it every second watering to make up for want of room at the roots. Let air be on night and day from the beginning of July, and a slight shading from ten in the morning to four in the afternoon of all clear hot days, and a little damping be afforded at both times. About the very last of July the third shifts ought to have balls of roots as hard as cricket-balls, so to speak; and now the *Humeas* ought to be planted out of the pots for the next six weeks and more. This, after all, is the grand secret for having splendid *Humeas*.

You may sow in January, in February, in March, or in April, but your plants are nothing worth as compared with these, if you keep them in pots the whole summer. That is the proper age and the right time to put life and blood into your plants, with very little increase of upward growth. Some shading and some syringing will be necessary for a time after planting out, and, of course, if August is broiling hot they must be regularly watered. Choose the first damp day after the middle of September for lifting these *Humeas*, and then you will see the reason for the balls having been got so tight before they were turned out. Lift them with a fork very gently, and when they are out of the ground you may shake almost all the soil of the border from the roots. The original balls will be firm enough to do without more help, and the fresh-made roots in the border will be free for a fresh compost in the next pots; and now the potting should be liberal, for the plants will not cease from the impulse given them by turning out till the other side of Christmas. The best *Humeas* I ever saw were put into No. 16-pots, at nearly the very end of September; in these they stood all that winter, first in a cold pit till Christmas or a little after, then in a very cool greenhouse till the beginning of March, and afterwards in the cold pit again till planting-out time. The bottom leaves hung over the pots and were soft and succulent as *Cineraria* leaves, and the plants were not more than a foot high on New Year's-day. They require constant watering the whole winter when they are in that condition, and to be almost as free as if they were in the open air the whole time; a degree or two of frost being much better for them than 5° of extra heat, or a close house. *Cinerarias* from seeds are the nearest in winter management to these *Humeas*, and also in respect of soil, only that *Humeas* need very strong generous loam. D. BEATON.

#### EXTRAORDINARY RANGE OF TEMPERATURE IN AN ORCHARD-HOUSE.

I do not know whether the severe frosts on the nights of the 11th and 12th ult. were general, but here (Bury, Lancashire), the thermometer registered respectively 21° and 20°. The 13th was a bright morning, hot sun, and cold east wind, with a few heavy thunder-clouds. Upon opening my orchard-house I felt the intense heat, and found the thermometer registering 109°, caused by the action of the sun alone on the closed-up house, which I may say is 30 feet by 14 feet. On looking at the thermometer I found that it had registered 24° as the lowest point during the preceding night, so that in a few hours the plants in the house had experienced the enormous difference of 85° in the

temperature. I have known many extraordinary and rapid changes, but nothing ever to equal the above. I recollect once an outside thermometer registering 12° and 80° in twelve hours.

It may be interesting to some of your readers to know that I had Plum, Peach, and Pear trees, Peas and Scarlet Runners, and my stock of bedding-out Geraniums in this house; but that the only things which suffered seriously were the Beans, the Geraniums escaped with a few scorched leaves.

I should like to know whether any of your readers noticed a similar range at the time I mention.—W. W.

## SUPPLY OF KITCHEN VEGETABLES.

THE TIME WHEN EACH MAY BE IN USE, AND THE CASUALTIES WHICH MAY PREVENT IT.

(Continued from page 78.)

**Endive.**—The white and green Curled may be taken up with balls on some dry day in December, and planted thickly in a frame where they can be defended from frost and blanched as wanted. The Batavian may be allowed to stand in a sheltered place, and will come into use in March when the other is done. In the absence of a frame the Curled varieties will survive medium winters in the open ground, and are often there left to their fate. A dark roof like an open shed will do to preserve them when glass cannot be had. In general Endive is in season from December to March, Lettuce filling up the remainder of the year.

**Lettuce.**—Much uncertainty hangs over this crop, as it is all but impossible to obtain good Lettuce in some soils in very dry seasons: therefore, due allowance must be made if a good, well-blanching article be not forthcoming at all times; but, Lettuce may generally be had very good from the middle of May to the end of November. After the latter time and up to the beginning of May, it is not so good unless glass and other assistance be rendered: its merit depends on a quick growth, and the centre being white and crisp. The Cos varieties as London White, Brown, and Brighton Cos are good; but the cabbaging varieties endure dry weather best. Of the latter kinds the Drumhead, Malta, and Tennis Ball are all good; while the hardy Hammersmith is the best to stand the winter, and next to that the Brown Cos. A good rich soil suits them best, and copious waterings in dry hot weather are essential to success where the soil is very light and dry.

**Leek.**—Few things are more certain as a crop than Leeks, for if the seed is good, there is not much likelihood of any mishap befalling them. Good ground will usually produce this article to perfection where it is not sown too thick, which recommendation will be found amongst many others in the directions for the cultivation of this and other vegetables in preceding Numbers of THE JOURNAL OF HORTICULTURE. Leeks are in use all the autumn and winter months.

**Mushrooms** are somewhat uncertain, but in general they may be expected from November to April or May; after that their novelty ceases, and in the summer and autumn months they are generally to be had in the fields. A good Mushroom-house, with an ample supply of hot dung at all times, will generally insure a supply, and many homely makeshifts in that way are often attended with success; but now and then the eccentric character of the crop will show itself and there is a failure. Due allowance must, therefore, be made for this when it does not occur too often. The general management of the Mushroom has, however, been detailed at length in former articles.

**Mustard.**—See "Cress for Small Salading" to which this is an important adjunct.

**Onion.**—Generally a steady crop, but now and then subject to mishaps, and sometimes not sufficiently ripened to keep well. The Strasburgh and James' Keeping are the best for late use, but the Globe and Brown Spanish for cropping in quantity. The Tripoli stands the winter best when sown in August, while the Silver-skinned is the best for pickling. Onions in one form or another are generally to be had all the year, but good ripened bulbs cannot be obtained in May, nor yet in the early part of June; the half-grown, or half-ripened article, generally suffices for what is wanted then. Sow early, thin in good time, and the result is tolerably certain.

**Orach.**—See Spinach.

**Parsley.**—In hard winters the supply of this may be limited, as, for instance, the spring of 1861, when it was very scarce; in general, however, it is pretty successful. Sow in early spring

and again in July; the latter sowing often standing the winter better than the earlier crop. As a rule Parsley is expected daily; but in extraordinary seasons, unless some plants be protected, they may be all destroyed. This, however, does not often happen.

**Parsnip.**—There is not so much difficulty in obtaining quantity as quality in this root, and the latter is often due to the nature of the ground. A stiff heavy loam does not suit Parsnips, although they will grow there; they do, however, better in a soil of an opposite description when sufficiently deep and not too dry. Winter and spring is the time this root is most esteemed; it may remain in the ground until February, and be afterwards stored away in a cool place.

**Pea.**—Popular as this vegetable is, I have no hesitation in advising the cultivator of small means only to sow a few for early use; and if he is in a neighbourhood where quantities are grown for market, to buy what more he wants, for where ground is scarce it can be much better employed. Scarlet Runner Beans produce much more food in a dry sunny situation; but in a moist one Peas do better, and may be more extensively grown. The wants and requirements of a family must, however, determine this. The cultivation and other features of the Pea are given elsewhere. In early situations the first crop may be fit to gather the last week in May, and in cool damp places some may be still in a fit condition for table up to the middle of November; but I have seen whole crops perish with mildew in July and August on dry ground and in a dry season.

**Potatoes.**—If a frame and hot dung or leaves are to be had, young Potatoes may be produced early in April, and later ones in a protected state in succession until those out of doors come in; but where the means are limited—say the 1st May for the earliest, and continue the supply. Where ground is scarce, it is better not to plant more Potatoes than will serve until the middle or end of July, and after that time to buy from more extensive growers; this advice, however, must be received with certain qualifications which every one may make for themselves. In general, however, the Potato can be grown much cheaper by the large grower than by the amateur; and where the latter has a multiplicity of things to furnish as well which cannot readily be had elsewhere, it is better to buy Peas and Potatoes, which are usually sold at a reasonable rate, than to buy the many odds and ends which form so necessary an item of the everyday bill of fare. The Potato culture being given elsewhere need not be repeated here.

**Radish.**—The best are those grown in April and May, afterwards they become hot unless the soil and season are very moist; they may also be had in March in a hotbed, or even earlier than that. In the autumn the Turnip-rooted varieties are also useful; but all the middle part of summer must be regarded as a blank. In many instances Radishes are sown with Onions, but they must not be allowed to crowd on the important crop.

**Rampion.**—A small root used as a winter salad, but little grown, being troublesome to handle; it is, however, of easy culture, and may be had all the autumn and winter months. For its cultivation, see preceding articles.

**Rhubarb.**—Good ground produces this to great perfection; but the largest varieties are not the most esteemed for private use. An old green-stalked variety of no great size is second to none for quality when cooked; but the Linnaeus and Victoria are good varieties. The spring and early summer months are the time when this is in use; it may also be forced so as to have it by New Year's-day, but it is needless to say there is a sacrifice made to have it then. The *modus operandi* and other particulars are recorded elsewhere.

**Sea-kale.**—This most useful vegetable may be had from Christmas to the middle of April, or perhaps the end of it; but is in greatest abundance and perfection at the end of March and beginning of April, as it takes less to force it into use at these times than before. It may either be forced in some warm shed by the roots being taken up, or where it is grown by being covered up with warm dung or leaves; the latest of all being simply covered up with something to obstruct the light. The plant is not subject to many mishaps, but it will require renewing every three years if forced on its own ground, or if taken up for that purpose new plants will be wanted each time.

**Spinach** may be sown every fortnight from very early spring up to 1st September, the last sowing being a more extensive one to stand the winter. In midwinter, however, it must not be expected in any great quantity, nor so good at that time. In summer its growth and quality are regulated by the weather:

if this is very hot it quickly runs to seed. As a second class vegetable it is of easy culture.

*Salsify and Scorzonera*.—Winter roots occasionally called for, but less frequently than others, such as Turnips, Carrots, &c. Their culture is easy, but care must be taken to have seed only from a respectable firm; for, like many things not of everyday use, old seed is occasionally sold, and it comes up badly.

*Shallot and Garlic*.—The first-named is occasionally attacked by a maggot from which it is not easily rescued, it is, therefore, better to plant some in December and again in April, one of these plantings may escape. They are in use all the autumn and winter months.

*Turnips*.—An early sowing of white Turnip Radish will in general produce a few roots before any can be had from the Turnip. The latter, however, if allowed a hotbed will come in sooner. Occasional sowing from the middle of April up to the middle of August will generally produce crops lasting from the 1st of June up to the end of March or later; but April and May must be either blanks, or any old roots must be kept over for the purposes wanted. The very earliest crop is subject to many uncertainties, not the least being its liability to run to seed; and in very hot weather a similar tendency occurs, so that a continuous supply of the very sweetest young Turnips cannot always be had. This subject, however, has been treated on.

*Vegetable Marrow, Squash, Gourds, or Pumpkins*, are all members of one family, the first-named being the most useful. It is likely the present season, 1862, will give some new features to this family. For the present I leave the admirers of fancy Gourds to settle among themselves which is the largest, and which the most handsome; and merely recommend the Custard and the old-fashioned Vegetable Marrow as being both serviceable and useful at table. The curious and ornamental class belongs elsewhere. Mildew often, nay always, attacks the plants towards the end of summer, so that if the cultivator is supplied pretty well for about ten weeks from out-door plants he must be satisfied. Sometimes they last longer, but often not so long.

*Sundries*.—There are many other little et-ceteras which constitute the sum total of a vegetable garden. Herbs of various kinds are wanted, and some of these, as, for instance, Sage, is not easy to keep in stiff wet ground in hard winters. Thyme is also killed in the same way, as likewise is Winter Savory; and sometimes gardeners have a difficulty to coax Basil to grow in cold wet summers. Sweet Marjoram generally thrives well after having obtained a start. Mint requires replanting every two years; while the tender Capsicum requires a hotbed to start it, and either a very warm summer and warm situation to get it into fruit, or the use of glass for that purpose. Many other things might be added to this list, but enough has been said to point out the uncertainties attending the more common vegetables. For their respective culture, former and future Numbers must be consulted.

*Conclusion*.—The above has been written to meet the inquiry of a number of correspondents, whose knowledge of such matters is not extensive enough to enable them to make the necessary allowance for the uncertainties under which all things labour that are cultivated for our use; at the same time they will be enabled to judge of what they may reasonably expect at the season mentioned. The employed will also be able to excuse the lack of certain things which an inexperienced employer may look for at a wrong time, or from sources which it may be impossible to obtain them; for the presence of good vegetables in Covent Garden is no proof that every garden in the kingdom can produce them at the same time. More might be said on this matter; but if the writer claims some indulgence for the hasty manner in which he has been obliged to throw this matter into form, he hopes the general idea laid down will be found in all cases founded on reason and plain common sense.

J. ROBSON.

### CINERARIAS A CURE FOR GREEN FLY.

I CONCLUDE that anything touching the welfare of trees in orchard-houses is interesting to you, and I, therefore, take the liberty of making known one experience of mine on the subject. I think it very probable that you know my cure for green fly already; but I do not remember to have seen it in your book. By accident, three years ago, some Cinerarias were placed in my orchard-house, we had no green fly that year. Last year I had Cinerarias in one house with Peaches in pots, and no Cinerarias in another house similarly filled. In the house with Cinerarias

I had no green fly, in the one without I was devastated with it. This year I had Cinerarias in both houses, and have no fly to speak of in either. From this I conclude that the green fly has (to speak chemically) a greater affinity for the Cineraria than the Peach; and if my method is a cure for it, as I believe it to be, I think it ought to be known. When the blossom first opens, and the leaves first show, the great mischief is done, because you cannot syringe; the Cineraria prevents this. Several of my neighbours have adopted my plan after seeing my houses.—ALEX. C. FORBES, *Whitchurch, near Reading*.

P.S.—The Cinerarias should be placed on the borders before the Peaches are in blossom. I may observe the Cinerarias in both houses are swarming with fly. It seems to me as a rule the more Cinerarias the less green fly. The only tree I have fly on now is a yard from any Cineraria.

### THE GENUS HIPPEASTRUM.

(Continued from page 80.)

THERE is a secret in growing these Hippeasters that has never been published, and that is, to have abundance of water while the leaf is growing, but during the whole summer, after the leaf has reached its full length, no more water than will just keep the leaves from flagging; and if the pots are plunged, which is the best way, no gardener not in the secret could believe on how little water they would live. Too much water after the end of May has been their bane; they never ripen their leaves in the autumn under that, the ordinary system, and then they rot either in the heart or canker from the bottom while at rest. A late vinery where Grapes are kept till February is the best possible place to winter them in, and even the hardiest of them prefer a warmer place for resting than for growing in. Peat is next to poison to them all, and leaf mould, or rotten dung, is the next worse thing to give them. They require very strong loam with a little sand, and nothing else, but the best drainage, and small, deep, upright pots—that is, pots seemingly small for the size of the bulbs, and the more full the pot is with roots the better they do, and as long as the loam keeps from soddening, no matter how long they are kept in the same soil. While the leaf is growing they like as much liquid manure as a Pine-Apple, and quite as strong, and no more liquid manure after the leaf gets to its full size, or what might seem the contrary of good management, if we did not know by long experience that it is the best course to pursue with them. Highclere, Wentworth House, Spofforth, and Colvill's Nursery, in the King's Road, London, were the best places for them in 1831, when I travelled England, and Dropmora was the next place, where Mr. Bailey used to flower two hundred bulbs of vittatum alone in one season, a glorious sight, besides a large collection of crosses. The quickest way to flower the seedlings—say the third season, is to leave the seedlings in the seed-pots the first season, then to plant out the balls entire in strong loam over bottom heat, and to keep them well supplied with water, which will cause them to continue in growth through the winter—say quite as evergreens the first three years. I have seen the seedling bulbs flattened, and some Carrct-like, for want of room, which seemed to do all the better for them, and I have reared them by the thousand for some years, but Sweet's treatment of these seedlings, by putting each into small pots the first season, and turning the balls on dry shelves in winter to save pots, I never could succeed with; but then plant-houses were kept so much more dry in his day than since. They certainly require as much dryness and as much heat in winter, when at rest, as the Museet of Alexandria Grapes. Even then the very tender kinds will rot, if the bulb is above ground. I always had them buried up to the neck, and in deep pots.

The subjoined list of the very best crosses that were raised when these plants were the fashion, will serve to show the best way to pursue now for a second start, seeing they are likely to become favourites. The list has been made more than thirty years, at least most of it, and all the names are in Sweet's "Hortus Britannicus," or most of them are, and this list will last, as a stud list, for the next twenty years certain, unless the second start be by steam, as these bulbs had once been grown. The father and the mother of each kind have been as truly registered in this, my stud list, as ever the parentage was for the Derby and Newmarket. The father in every instance is the first named, the mother next, and the cross the best out of ten or a dozen experiments at least, and your time and trouble

to that amount will be saved by crossing on this model. After the middle of the list the names are not in strict priority, but the first part is thus—

1. Johnsoni, in 1810, from the pollen of regium on vittatum. A well-known sort at the present day.
2. Seymouri „ alicium and vittatum. Had many names, and is yet in some collections, after Dr. Herbert's gardener.
3. Allmani „ calyptarum and vittatum. A good flower by Sweet, and named after a Professor of botany in Dublin.
4. Andersoni „ bulbulosum and vittatum. A fine flower, and variable as the variety of bulbulosum used.
5. Hookeri „ Goweni and vittatum. A very charming flower, named after Sir W. Hooker.
6. Grahani „ Johnsoni and vittatum. Thus, two turns of vittatum give a larger and a more brilliant flower, together with a hardier plant than Johnsoni. After Professor Graham, Edinburgh.
7. Digweedi „ striatifolium and vittatum. The white stripe retained. After a foreman at Highclere.
8. Griffithi „ psittacinum and Johnsoni. Very beautiful. The best cross raised by Mr. Griffith.
9. Sweetii „ reticulatum and Johnsoni, including the crosses from the variety striatifolium, were called Sweet's strain.
10. Brookesi „ bulbulosum and Johnsoni, including three varieties of bulbulosum, such as crocatum, fulgidum, and rutilum. These were the strain of Mr. Brookes, a nurseryman.
11. Benthami „ stylosum and Johnsoni. A good flower, but not a desirable mixture of colours.
12. Danbeai „ Griffithi and Johnsoni. A very beautiful flower, and a hardy greenhouse plant.
13. Carnarvonii „ solandriiflorum and Johnsoni. A magnificent flower, named after the Earl of Carnarvon.
14. Altaclarae „ psittacinum and Griffithi. A very beautiful cross, named after Highclere.
15. Hayloki „ solandriiflorum and bulbulosum. The rutilum variety, an extraordinarily grand flower.
16. Herberti „ solandriiflorum and stylosum. The largest and most beautiful, yet stylosum is but a small flower.
17. Harrisoni „ reticulatum and stylosum. The most lovely, and the nearest to a florist's flower ever raised.
18. Parkeri „ bulbulosum and reticulatum. Perhaps the richest of all in colour. A tender plant.
19. Hoodii „ equestre and regium. A fancy of Sweet's at Colvill's; good colour.
20. Henslowi „ regium and bulbulosum. The fulgidum variety. A most brilliant flower.
21. Batemani „ equestre and bulbulosum. Never saw it, or knew the variety of bulbulosum used.
22. Gawni „ reticulatum and bulbulosum rutilum. A most lovely colour and good form.
23. Munroi „ psittacinum and equestre. Never saw it. Should be both hardy and handsome.
24. Baconi „ psittacinum and regium. Should be a better colour, and as hardy as the last.
25. Colvilli „ reticulatum and regium. This was the finest Sweet ever raised. A rich colour.
26. Cartani „ alicium and Sweetii. The best of all with the alicium breed, and is yet in some collections.
27. Lindseyi „ alicium and reticulatum. Splendid colour, the shape a death blow to a florist.
28. Lamberti „ Cartani and Grahani. Here the wide staghorn shape of alicium in Cartan's is modified to the right pitch by the two turns of vittatum, which is in Grahani.
29. Donni „ Hookeri and Hayloki. A noble flower, still retaining the white stripe from vittatum.
30. Spofforthiæ „ alicium and Carnarvonii. A most magnificent flower, a splendid colour, and the best shape in the blood race from alicium.
31. Lindleyi „ Griffithi and Carnarvonii. Another noble flower, the best ever called after Dr. Lindley.

Now, study that stud list and register, go to work on your friends in Brazil, get the wild kinds thence, if the Royal Horticultural Society should miss any, grow and cross them, and say nought about it till you hear the worst of these before you; and when you hear a fuss about seedling aliciums, with their six staghorn "points," or of equestres, with lop-ears like the Suffolk pigs, just tell the raisers of them to have them sent to India by the overland route, and if you could get the captain to drop them over in the Red Sea, it is the next best thing you could do for the family. For the only good Hippeasters that have been exhibited for the last fifteen years in London, were hardly worth growing, except some few by Mr. Parker and Mr. Williams.

D. BEATON.

CALAVANSA BEAN.—A correspondent writes as follows:—"Calavansa is the name of a pretty little Haricot Bean answering somewhat to your correspondent's description. It was imported in large quantities by Government for the relief of the poor during the Irish famine. I enclose a pod from a forced plant of last spring. I have not tried it out of doors, but think it will succeed.—R. T. CLARKE."

## MR. B. S. WILLIAMS' PARADISE NURSERY, HOLLOWAY.

PERHAPS there is no difficulty which even an experienced writer labours under greater than that of opening-up his subject. If he begins by stating an acknowledged fact all the world will exclaim, "We know that!" At the risk, however, of such an exclamation being made, we may state that at this nursery exists one of the finest collections of Orchids and foliage plants to be found in the kingdom. In connection with the former class of plants, Mr. Williams' name has long been honourably associated not only as a successful cultivator and exhibitor, but also as the author of a carefully written and most useful book, "The Orchid-Grower's Manual" (and we understand he is now engaged in a more extensive work on the same subject); whilst the magnificent foliage plants which he from time to time displays at our horticultural exhibitions, are sufficient evidence of his great resources in this respect also.

Proceeding at once to the Orchid-house, we met directly on entering with an immenso plant, 5 feet high, of the beautiful *Vanda suavis* with large apices of its lovely white and crimson flowers. *Vanda insignis* with its yellow and crimson-spotted sepals and lilac lip, is another very attractive freely-flowering species. *Phalænopsis amabilis*, which has been justly called the queen of Orchids, was of course, as it is nearly all the year round covered with flowers, constituting an object of rare beauty. *Oncidium papilio majus*, another perpetual-flowering Orchid, afforded a great display of its handsome butterfly-like yellow and brown flowers; and the lovely but less known *Chysis Limminghii* was also to be seen in perfection. This, on account of its rose and white flowers with mauve-striped lip, deserves a place in every collection as a really first-class Orchid. Among the more remarkable *Cypripediums* were *C. barbatum superbum*, a very fine variety with larger flowers than the old *barbatum* and a much darker lip, the end of the upper petal being also of a much purer white; and *C. hirsutissimum*, a kind with a pale green lip dotted with brown, and which lasts six or eight weeks in flower. *Trichopilia coccinea*, of which there was a specimen 2 feet across, was covered with flowers; and so was a *Dendrobium* tortile of remarkable size, a species which is rarely seen flowering so freely except when grown with particular care.

In the centre of this house was a number of fine *Cattleyas*, including very large specimens of *Leopoldi*, *labiata*, and *Harrisoni*, together with *guttata*, *crispa*, *elegans*, and other fine sorts, all of which were growing in peat and potsherds, the plants being well elevated above the rim of the pots. On the same table were *Lælia purpurata* and *Warnerii*, both of large size; and along the side shelves were the charming *Calanthe masuca* throwing up its flower-spikes; the scarce *Anguloa Clowesiana*; fine plants of *Argophyllum giganteum*; of the rare *Miltonia Regnelli*, and *M. cuneata* likewise, a rare and pretty species; *Dendrobium Farmeri*, very fine; *Lycaste Skinneri delicatissima*, a truly splendid variety; together with *Cypripediums*, and a host of other interesting species which it would be tedious to particularise.

In a warmer compartment of the same house we noticed remarkably fine specimens of *Ærides odoratum majus* and *purpurascens*, both of which are highly desirable varieties; *Ærides Larpentei*, larger than we have ever before seen; *virens*, with ten or eleven spikes of flower; *Fielcingii*, with a fine spike of bloom; *cornutum*, very rare, showing for flower; a magnificent *Vanda gigantea*, affording the same signs of promise; the original plant of *Angræcum sesquipedale* brought by Mr. Ellis from Madagascar; a large *Saccolabium Blumei majus*, a variety differing from the species in having much larger flowers; *S. retusum*, 2 feet or more in height; *Cattleya Skinneri*, remarkable for its showy colour; and *Calanthe masuca grandiflora*, a variety which has larger and earlier flowers, and remains much longer in bloom than the old kind.

Conspicuous among the many fine plants with which the side shelves were crowded was *Phalænopsis grandiflora*, certainly one of the finest of all Orchids, the plant being literally covered with the large pure white and yellow flowers, which render it such a favourite for exhibition. Another plant of the same beautiful genus, but of more recent introduction, is the *Phalænopsis Schilleriana*, which we believe Mr. Williams was the first to import into this country. When in flower it is one of the finest Orchids in cultivation, and the leaves being much variegated, it is possessed of a double charm, which will make it eagerly sought after by the lovers of exotic vegetation.

On quitting the Orchid-house we could not but remark the

unusual width of the paths, so different from the narrow confined passages which exist in the older forms of plant-houses. Whether fashion has anything to do with this change we cannot say; but should any of our lady readers visit Mr. Williams' collection, they will find a very ample, we dare not say sufficient, allowance of space has been afforded in all the houses.

In the Fernery, which like the other principal show structures is a lofty span-roof, we found a fine collection of the best stove and greenhouse kinds, many of them being very large specimens. Among the more remarkable were *Dicksonia antarctica*, one of the best of our greenhouse Ferns; *Gleichenia dichotoma*, 6 feet across; *Cyathca elegans*, a rare species of very graceful habit; *Marattia elegans*, with fine spreading fronds about 6 feet long, suitable for an intermediate-house; nice plants of *Platycoerium grande* and *stemmaria*; *Nothochlæna Hookeri*, a pretty compact-growing sort; a nice little specimen of the scarce *Gleichenia semivestita*; *Gleichenia rupestris*, another scarce species; a handsome little *Todea pellucida*, with numbers of *Adiantums*; *Gymnogrammas*, including *G. pulchella ramosa*, a distinct variety, and the new and handsome tasselled *Gymnogramma Witenhalliana*; *Doodia aspera pumila*, a variety which makes a handsome specimen when old enough, hanging all over the pot; *Lomaria sinuata*, the fronds sinuated at the base; and *Nephrodium molle corymbiferum*, a nice distinct variety, with curled foliage. Rare *Trichomanes*, under bell-glasses; the newest *Selaginellas*, such as *Lyalli*, *Lobbi*, and *Wallichi*, together with a large quantity of young stock, must complete our enumeration of the contents of this house, in which, however, it may be added, there is a very interesting collection of about 350 *Anæctochils*, among which were *Lowii*, very large; the pretty *querceticola*, and three new kinds—*Bullenii*, *Ruckerii*, and *Nevilliana*.

On entering the house devoted to fine-foliaged plants no one could fail to remark three magnificent *Cyanophyllums* on the centre stage: one of them, at least 8 feet high, was beautifully clothed with its gorgeous leaves, some of which were a yard long and half a yard across. Near this was a handsome specimen of *Croton angustifolium*, 4 feet through, with leaves 2 feet in length; also a noble plant of *Tupidanthus calyptatus*, 6 feet high and as much through; a remarkably fine specimen of the scarce *Theophrasta imperialis*; a Bird's-nest Fern, 6 feet across; and a large plant of *Amherstia nobilis*. Of course *Caladiums*, *Marantas*, *Dracenas*, and *Rhopalas* were to be seen in abundance, along with a good stock of all the usual foliage plants, which we need not here particularise.

Of the more remarkable of the others were *Spærostema marmorata*, which has been called the Frosted Climber from the upper surface of the leaves having a frosted appearance, a plant which has been much admired wherever it has been exhibited; *Alocasia metallica*, of which the culture was given in our last week's Number; *Bertolonia marmorata*, a beautiful little plant not sufficiently known, and which, being velvety green, marbled and veined with white, would make a good associate for *Anæctochils*; *Campylobotrys refulgens* and *pyrophyllis*, with handsome velvety leaves; the new *Phyllagathis rotundifolia*; and *Franciscæ confertifolia variegata*, a nice distinct climber, with leaves marbled and margined with white. We may just add that some very large *Nepenthes*—*lavis*, *Rafflesians*, and others—occupied the further end of the house, to the general effect of which some well-grown and richly-coloured plants of *Colcus Verschaffelti* contributed not a little.

Proceeding next to the large specimen-house, a structure 50 feet long by 24 feet wide, which has been recently added to this establishment, we remarked a noble *Cycas revoluta*, *Dicksonia antarctica*, with fronds 8 feet to 10 feet long; two fine specimens of *Dion edule*, one of them an enormous plant covering a space 30 feet in circumference, and just throwing up a fresh set of leaves; and an immense *Dracena*, said to be a variety of *Draco*, with a clear stem 5 feet high and about 18 inches in circumference, giving the house quite a tropical aspect. At the further end of the house we observed *Gleichenia speluæ*, 6 feet high and 8 feet through, probably the largest plant in the country. It formed a beautifully compact mass of light green, and was supported on each side by nice specimens of two other rare species—*scandens* and *dicarpa*. There were also fine plants of *microphylla* and *fiabellata*, the latter a beautiful species with the fronds of a bright very lively green. Among *Yuccas*, we noticed *aloifolia variegata*, 5 feet high, and well clothed with foliage to the pot; *concarva*, a good hardy species; and *quadricolor*, one of the most compact-growing of the genus, with very handsome variegated leaves.

Another plant that attracted our attention was *Pandanus reflexus*, the spiny dark green leaves of which are beautifully twisted, completely hiding the upper part of the pot. Nice plants of *Rhopala corcovadensis*, *Chamerops excelsa*, and smaller specimens of *Dicksonias* were scattered here and there, and in one corner *Imantophyllum miniatum* beautifully in flower.

The Show and New Holland-house contained *Eriostemons*, *Chorozemas*, *Azaleas*, and a miscellaneous collection of flowering plants, among which were *Tetratheca ericoides hirsuta*, a nice greenhouse plant with lilac flowers in May; *Genetyllis Hookeri*, covered with its large bell-shaped flowers; *tulipifera*, another nice greenhouse plant, just coming into flower; *Reine des Doubles Azaleas*, one of the handsomest doubles we have, the flower being of a rich rosy crimson; and a new kind called *elegantissima*, pure white with a few red stripes, very handsome and free-flowering; also, one striped like a *Carnation* and of quite a novel character. On a back stage was a stock of *Rhododendrons javanicum* and *Nuttallii*, to the flowering of the latter of which, at Mr. Mongredien's, we called attention last week.

It may not be generally known that Mr. Williams has one of the largest collections of *Amaryllises* that exist in this country, comprising about 1500 plants. Among those in flower were *Ackermanni*, and its variety *pulcherrima*, a magnificent crimson and scarlet flower of fine substance; *aulica major*; *Unique*, a fine seedling which flowered this year; and *Williamsi*, a cross between *Ackermanni* and *pulchella*, bearing immense flowers. Before quitting the houses we must not omit to notice a plant of *Libocedrus Doniana*, about 3 feet high and as much through, forming a dense mass of *Lycopodium*-like foliage.

We had here an opportunity of seeing in quantity the new bedding plant, *Scrophularia uodosa variegata*, which has been so much spoken of lately. It is certainly the best hardy variegated plant which we possess for bedding, and its adoption will save the gardener much anxiety in wintering and finding frame-room for the more delicate plants which it will advantageously replace. *Tussilago farfara variegata* is also a good plant for edging large beds and for ornamenting rockwork, and, of course, perfectly hardy.

Neatly arranged in pots was a collection of other hardy variegated plants, together with herbaceous and rock plants of all the kinds usually grown, and many more that are not, and which would doubtless afford a good resource for those in search of such objects for their gardens; for, since the bedding-out system has been so generally adopted, many of these plants are scarcely to be had.

It is but just to add that within the last twelve months the place has been much improved, the borders having been laid out afresh, and planted with the best conifers and other hardy trees and shrubs, and that the general condition of the place reflects the greatest credit on Mr. Williams' skill and industry.

## CULTURE OF THE PINE APPLE.

(Continued from page 391, Vol. II.)

**SUMMER CULTURE.**—As the Pine Apple is a native of the warmest parts of Asia, Africa, and South America, and as our habitations for it are necessarily kept almost at summer heat all the year round, yet even this exotic fruit is benefited by a kind of rest during some portion of the year. That period of rest is the winter for this plant; and as when a plant is at rest, partially or wholly, it requires less stimulants in the shape of heat, water, and light, it follows that the best period to give this partial rest in this country is during our short dark days. I therefore divide the two seasons into summer and winter. The first commencing about the middle of February, and ending about the middle of October. The second from the middle of October to the middle of February. I thus make the Pine Apple's summer eight months, and its winter four months.

The culture required during the summer consists in potting the plants, renewing the heat of the bed, and, where it is practised, planting-out the fruiting plants in a bed prepared for them. The best season for a general repotting is February, though it may be done in March or April. If done in the early part of the Pine summer, the plants have a longer season to grow in previous to the second repotting in July or August. A fortnight previous to commencing potting, see that a sufficient quantity of soil, as prepared in the manner before described, is laid in a warm shed to take the coldness and wet out of it, or, in other words, to warm and dry it. It should not, however, be too dry. To prove it, take up a handful, give it a gentle squeeze, and let it fall upon the bench; if it falls to pieces,

the soil is in a right state for use. In regard to warmth, it should not feel cold to the hand. Also have the broken pots or oyster-shells ready, dry, and aired. If the plants are plunged in tan or leaves, and the heat requires renewing, have the tan from the tanyard some time previously, lay it in a heap to become heated and to drain. Then examine the stock of pots, and have a sufficient number ready; if old ones are to be used, let them be thoroughly washed in hot water and set by to dry.

All these materials and articles being in a fit state for use, then begin to tie-up the plants carefully with bast mat, avoiding any rubbing of the leaves; and, when they are tied-up, lift them out of the pit and place them either in a warm shed, or, if that is not spacious enough, place them in the vacant walks inside the next house.

As soon as the pit is empty, let some of the assistants begin to renew the heating material. If the bark is very much decayed it should be sifted, and what goes through the sieve removed out of the pit. If there are any worms left amongst the rough old bark, mix it with quicklime: then throw a portion of it to one end of the pit, and commence bringing in the new bark. One man should mix the new and the old tan regularly together as the new is brought in, filling up the pit at one end, and continuing to do so till he reaches the other end; then the trench may be filled up either with all new bark, or mixed with a portion of old, reserved for that purpose. The pit should be well filled, rather above the kerbstone, to allow for settling—it is then ready for the plants. When new tan is used altogether, it should be moderately dry and warm before using it.

Where there are plenty of hands, the potting should be going on whilst the pit is being renewed. A sufficient quantity of new compost being ready, a portion will be laid on the potting-bench; the potter will then take a plant in hand, having previously fixed upon the proper-sized pot, drained in the following manner:—Lay first three or four large pieces over the hole at the bottom of the pot, in such a manner that the superfluous water may readily escape, then upon them lay a second layer of less crocks, and upon them a third layer of a smaller size, and lastly a layer of the rougher pieces of the compost, then a thin layer of soil. It is now ready for the plant. I will suppose the plants about to be potted are such as are to fruit the following season. The larger kinds, such as the White Providence and the Cayenne varieties, will require pots from 12 inches to 14 inches wide, whilst for Queens and Black Jamaica varieties, pots of 9 inches or 10 inches diameter will be large enough for fruiting plants. These points in regard to the size of pots being attended to, the operator will take a plant and carefully turn it out of the pot, keeping the ball entire. Whilst it is in hand he should examine the roots, and if there are any that are dead cut all such off to a living part; also pull off the lowest decaying leaves, for at their base he will find young, healthy roots pushing forth, evidently wanting and seeking for soil to strike into. The pulling-off these lower leaves is often done to great excess. No healthy leaf ought ever to be removed.

Some fifty years ago, in many places where Pines were grown it was a barbarous custom to (what the old gardeners called) disroot large plants in autumn, and put them into smaller pots. Now, on examining the plants after turning out the ball, if the roots are healthy and all alive, it certainly would be little short of madness to cut off these healthy roots merely because it was the fashion to do so. I say, preserve all the living roots. If the ball is too large for the pot, reduce it by rubbing off part of the soil and picking out all the old drainage. Another point should be attended to—and that is, to pot first all the largest plants. These will be placed in the back row in the pit, and as each plant is finished potting, it can be taken into the house and set on the bark ready to be plunged when a sufficient number are potted for that back row.

To return to potting the first plants. Set the ball within the pot, observing that it is rather deeper in the new pot than it was in the old one, fill round the old ball with fresh soil, pressing it down with a blunt stick very firmly, put in a little at a time and press that little down, and keep repeating this till the ball is covered, press the soil firmly to the neck of the plant and leave a small space—say about half an inch short of filling up level with the rim. This space is to hold water when the weather is so hot as to render a large supply necessary. The plant is then repotted, and should be taken into the house immediately, and set on the tan-bed as before mentioned. Take the next in hand and repeat the operations of draining, dressing-off decaying leaves, &c., and so proceed till all are finished. Observe the precaution

in plunging not to put the pots more than half their depth in the fresh tan, for it is better to be on the safe side. Experience has proved that bottom heat is advantageous to all exotic plants, and the Pine Apple is undoubtedly benefited thereby. The only difficulty is to avoid extremes. I have repeatedly found that the maximum heat for the roots of Pines should never exceed even in summer 85°, and 5° or even 10° less will grow them well in the earlier and later months of the year. In experienced hands trial sticks thrust into the bed are a sufficient guide, but the safer plan is to procure a thermometer fixed in a hollow tube with an opening in it where the heat may be observed. Such thermometers are kept in stock by the dealers in such articles. The moment the bottom heat rises above the proper temperature, the pots should be moved backwards and forwards to form a cavity round them, and water should be poured in freely, which will cool the bed and cause a fine health-giving moisture to arise among the plants. Should that not lower the heat the second or third day, then the plants should be lifted up entirely and set on the very top of the bark or leaves, and allowed to remain there till the temperature of the bed is reduced to the safe amount of heat. More mischief has been done in Pine-growing from burning the roots than from any other cause. When the heat declines, then in the case of the pots having been set on the surface, let them be plunged, and when they have only been rocked to and fro fill up between with moderately dry warm bark or leaves where the latter article for bottom heat is used. This completes the potting and renewing of the bottom heat for the fruiting-house.

Observe, that the plants of a sufficient size and strength to fruit, potted in spring, will not need repotting in August following. At that season it may be found necessary to renew the bottom heat, and in so doing the plants will have to be tied-up and lifted out of the pit. It will then be a convenient opportunity to top-dress the plants by removing as much of the old soil as can be done without disturbing the roots, and replacing it with fresh compost. The bark need only at this season be partially renewed, just sufficient to raise the heat to the proper height. It should be remembered that the roots of the plants are now close to the bottom and sides of the pots, and, consequently, are in a greater degree liable to suffer from too much bottom heat. Greater care, therefore, is necessary at this time to preserve the roots from being injured. A vigilance, untiring, night and day must be exercised till it is certain all danger of burning is past.

If all has gone on right the fruiting plants will be stout, a good colour, and show a healthy, fresh appearance, and will enter their winter treatment in such a state as will warrant their fruiting early and certainly in the following spring.

(To be continued.)

T. APPLEBY.

## CRANSTON'S PATENT BUILDINGS FOR HORTICULTURE.

HAVING waited till I had an opportunity of perusing Mr. Cranston's doubtlessly beautifully got-up and cleverly-written monograph, I am at length so far in possession of the grounds upon which he has taken out his patent. In this matter, however, there is a question involved of some moment—equally to him, perhaps, as to me, which I feel it my duty not lightly to pass over. That question is as to priority of invention.

Having been, as you and many professional friends are aware, for some time back more or less occupied in originating and carrying out first, at my own cost, two separate ranges of model houses, very remarkably similar in principle both as relates form and ventilation to some of the respected author's sectional outlines and descriptions, I may thus without any, the least, ungenerous imputation, consider myself justified in submitting my case to the profession, the public, and to you in the following precise statement as to dates.

At the same time I admit, that whilst it is possible that two individuals unknown to and widely apart from each other may be simultaneously occupied on the same subject, and to have arrived at exactly corresponding results as to principle, without either one or the other being aware of the fact; yet it is equally possible, as matters may and do sometimes go amongst us, that with an ominous "patent right" over my head, I may have been acting differently, and so have improperly become guilty of an illegal act.

Finally, as to "patent" on my part. I might have taken one out in the winter of 1860, when I had all my plans matured;

but I determined the rather to leave whatever origination there might be in my inventions *free to all*, merely supplying lithographed plans and details professionally at a fixed rate, according to extent and outlay, and I still purpose following up this determination.

I also fully intend, if spared, in due time, when every point

in structure, heating, and cultivation has been thoroughly tested by result, to submit my monograph thereupon to the public. I then hope to be able to prove that in point of suitability, elegance of form, and proportion, be they large or small, or as to ready adaptability for all and every sort of under-glass gardening requiring ordinary medium dimensions, my houses are

EXTERIOR VIEW OF ONE OF MR. NIVEN'S RANGES.

the most economical in point of cost, the most complete in point of finish, strength of fabric, and general compactness that may yet have been constructed.

Then as to the question of dates, and consequently priority of claim, let us look at it in the following form:—

NIVEN.

In December, 1860, his design was matured, and in January, 1861, begun and carried out to completion; his span-roof and sides broken up into four surfaces or planes, corresponding to the lean-to form of fig. 4 (but not numbered), in Mr. C.'s book, plate I.

Also his horizontal-ventilation principle, same as described in page 35 in same book—viz., “by valvular slides in grooves worked simultaneously by a handle.”

In March and April, 1861, his structures fully stocked and occupied.

In April, 1862, richly promising in Strawberries, Grapes, Peaches, Nectarines, Apricots, Plums, Figs, Cherries, &c., in various modes of training.

I trust I may be allowed to hope that the author of the able and interesting work in question will, from his ability and standing as a professional gentleman, kindly and honourably favour me, if he can, with what is evidently wanting in the above columnar statement.—N. NIVEN, *the Garden Farm, Drumcondra, Dublin.*

[As stated at page 7, it is not our province to decide on priority of invention. We could not but see there was much novelty and genius in Mr. Cranston's sketches, and regret that a few errors in printing have left the expression of our opinions more mystified than they were written. For instance, in page 7, first column, fourteenth line from top, the word “deserves”

CRANSTON.

His date of patent appears to have been August 24th, 1861.

His publication of monograph February (no exact date), 1862.

should be “takes;” and the word “credit” that follows should have had the marks of extract before it. Our perhaps-prejudiced opinion is, that the radial rib ventilators are alike the new, the strong, and the weak points of the system. In seeing much to admire, it also struck us that there was a wonderful unison in idea between the modes employed by Mr. Cranston and Mr. Niven, a section of the lines of the last gentleman's houses being given at page 215, last Volume. Mr. Niven does not make the radial rib a ventilator from being pierced with holes, as Mr. Cranston does; but there is a continuous small ventilator from the overlapping of the glass at the junction behind the longitudinal rafter or radial rib, which is not shown in the section, but which will be understood by the position of the subjoined lines. These small ventilators are shut in winter and open in summer, but little dependance is placed on them, the means at sides and doors being ample. We may also mention here that in page 216 the oval holes should be almost as long as the spaces between them. Our impression is, that both gentlemen have hit on a plan for giving almost all the advantages of curvilinear roofs, with the cheapness of using straight glass in the simplest manner. We might also state that though generally not using quite so large squares as Mr. Cranston, Mr. Niven, from black-puttying the joints, hardly ever, or never, has a square cracked.

Our readers will form their opinion of the claims of both gentlemen to originality. For ourselves, we have two strong beliefs on the subject—first, that any discussion between such men will tend to our benefit and instruction; and secondly, that any interchange of ideas or maintenance of claims will be done in the most courteous and kindly spirit.—R. F.]

ARTIFICIAL WATER IN GARDENESQUE SCENERY, FOR GROWING AQUATIC PLANTS.

BY H. NOEL HUMPHREYS, ESQ.

WATER, in a state of repose, produces the best effect when it is introduced in the lower portions of undulating grounds, such seeming the more natural position; and the best artificial effects, though they must be arbitrary to a certain extent, are always most successful when based upon the laws of natural phenomena. Thus, a series of fish-ponds rendered decorative by stone dressings, &c., or shallow canals for the cultivation of aquatic plants in the open air, which may be made very ornamental, as shown in our illustrations, are best suited to the lower levels of an ornamental garden, where also the water plants, some of them of delicate constitution, are more sheltered from the cutting winds of our variable and sometimes bleak climate. In such a situation, for instance, the common Arum (Calla, or Richardia), a native of St. Helena and the Cape, where it grows in the rich soil at the edges of rivers, may be cultivated with success; the roots being secured in concavities formed of cement, of which the

bed of the canal is formed, and which should be about a foot below the surface of the water. Managed in this manner, this plant, rearing its head high above the water, might be made to form a very picturesque contrast to the Water Lily, which rests its graceful head upon the surface, as Mrs. Hemans has beautifully said—

“A sculpture-like, and stately river queen.”

The supply for a canal of this description may be derived from the water of fountains occupying the higher level of the gardens, whence, after having performed its *tour de force* as a jet 20 feet high, or formed a temple of moving crystal, and many other devices, it may be made to descend in properly prepared channels to the lower levels of the garden to feed canals of this description, constructed for the purpose of growing ornamental aquatic plants, particularly such as require the stimulant of running water.

1. Geometric Canal or Tank for Water Plants.

The annexed engraving (No. 1) is a design for a shallow canal or tank of this description. At the upper end the water enters, as shown, from a conduit, falling in a very thin sheet over a lead form contrived expressly to spread it as much as possible, and thus make an exceedingly small supply produce the effect of a continual cascade. In a similar manner it falls at the lower end into a basin, from which an invisible outlet leads to a drain or conduit to carry the waste away, or to conduct it to some reserve-tank for common gardening purposes. On each side of the canal is a shallower channel, contrived expressly for the growth of plants requiring more careful treatment. The receptacles for the soil, sufficiently massive to remain steadily at the bottom of the channel, might be very neatly contrived in the following manner:—A is a hollow receptacle, and B is a lid pierced with holes as marked. The plant being placed with earth in the recep-

table A, the cement lid B, which fits pretty tightly, is fixed on, and the plant throws up its shoots through the apertures prepared for that purpose. By this means the soil is not washed

away by the action of the water, nor is the water rendered muddy on the slightest disturbance, as would be the case were not the soil about the roots of the plants secured in this or some other manner. The water in a canal, the sides and bed of which should be composed of Portland cement, might by these precautions be kept continually limpid, which the gentle supply of fresh water would tend to insure. The addition of gold and silver fish, in water as clear as this would be, would form a great addition to the general effect, furnishing colour in rapid and fantastic motion, as a strong contrast to the still colours of the plants.

A canal of geometric figure of this description should have stone or cement dressings of an architectural character, as shown in the engraving, and should be surrounded by a broad gravel-path of similar form, approached by a straight walk of some length, to prepare the eye for the regular forms of the canal and its appendages; and the entrance to this aquatic parterre might, to aid its semi-architectural character, be marked by two large vases on pedestals; a few flower-beds, and some masses of shrubs, might be the means of partially concealing these symmetrical features from the rest of the plea-

sure grounds, if rendered necessary, on account of their distinct character.

The plants I have shown in the central or deep part of the canal are simply our native Water Crowfoot, the Marsh Marigold, and the white and yellow Water Lilies, &c., to which might be added the Frog-bit, the floating Plantain, the Water Soldier, and many hardy exotics. In the shallow channel at the sides, I have placed the common yellow Iris, and our handsome native plants, the flowering Rush, and the Arrow-head, with the greater and lesser Water Plantain; to these I have added the elegant Cape plant already mentioned, and commonly known among cultivators of window flowers as the "Arum;" which, grown in water in this manner, attains to much greater size and perfection than by ordinary pot culture.

In order to form a canal or tank of this description for the purpose of growing aquatic plants, the first requisite is a supply of water. A small brook or spring, in any part of the grounds, will be sufficient, which may be cheaply conducted beneath the surface, to any spot required, if not higher than the brook or spring itself, by means of a leaden pipe, or gutta-percha tube, which latter is now being used for such purposes. A tolerably level spot in the lower portion of the grounds should be selected, as convertible at the least expense to the purpose required. The excavation must now be dug, of the extent determined on—the one shown in the design is supposed to be about 24 feet wide by 48 feet long, but a canal of half these dimensions would form a very pleasing object in a place of suitable proportions. The excavation should be about 2 feet 4 inches deep in the central compartment, and 1 foot 4 inches in the side compartments. When the bottom and sides have been made as smooth as can be accomplished with the spade, the masonry may be commenced, which is of so simple a character that any country bricklayer may execute it under the directions of an intelligent gardener. First, let a layer of flat tiles be placed against the sides, and laid in Portland cement, which should be done in dry weather, when the soil is not too moist, or the cement will not set well; a second layer of tiles, with cement between the layers, will make a more complete job, but one layer is sufficient; the bottom must then be covered with tiles laid in cement in a similar manner, and the whole left till perfectly dry; the ornamental moulding may be formed, in bulk, by a single row of bricks, which, being covered with a sufficient coating of cement, may have moulding lines run along it with a moulding-tool, in the usual manner known to any plasterer. The parts designed for the entrance and exit of the water may be formed in the same manner as the cement coping, and with but little more complication. The pipe conveying the water from the spring will be conducted to a small reservoir immediately behind the point at which it enters the tank, or to a leaden shape made to spread it into a thin semicircular sheet, in which form it will fall into the tank, as above described; the surplus water at the other end need only be conveyed away in a common brick drain; but, if desirable not to waste any of it, the drain should be lined with cement. Ornamental balls, vases, or other decorations required, may be procured at little cost at any cement works, and can be easily added in the way of embellishment.

The tank being complete in all its parts, and the cement perfectly dry and hard, the aquatic plants may be placed in the vessels shown at A and B, which are intended to be rather more massive, and more broad in proportion to the height, than common flower-pots, in order to keep them steady and secure at the bottom of the water. These pots, with their plants and soil secured by the perforated lids, may now be placed in the desired positions about the bottom of the tank; the Water Lilies, both white and yellow, and other plants, which grow commonly from a considerable depth, in the central compartment, and the Arums, and different species of Water Iris, &c., in the shallower compartments at the sides. The best time for making a tank of this description is either at the end of March or late in September; in the first place, to secure the cement from the effects of frost, which, before it is thoroughly dry, would cause it to become rotten and crumble; and, in the second place, in order to place the plants in their new position after they have finished their summer growth, and are about to enter into their natural period of repose, or just before the spring growth commences. If it is found inconvenient to get the vessels for the plants made in the form suggested, ordinary flower-pots, with moderately-sized stones or pieces of tile placed on the surface of the soil to secure it, will answer the purpose nearly as well.—(*Gardeners' Magazine of Botany.*)  
(To be continued.)

## PRESERVING SEEDS FROM BIRDS.

I SEE Mr. J. Vickary is complaining in your valuable Journal about the birds devouring the sown seeds. He says he has tried all sorts of scarcerows, &c., but in vain. Allow me to state that I have frightened them effectually in the following manner:—I tie a piece of string across the place I wish to preserve, about 4 feet from the ground, and at certain distances apart tie a piece of string, say 3 feet long, and on the end of it I tie a piece of tin about 4 inches to 6 inches square. This spins round with the least air, and when the sun is out is quite dazzling, and somewhat like a looking-glass. The tin plates cost but a trifle, and will last for years.—ARTHUR.

MR. VICKARY, who asks for advice *versus* the birds who devour his seed, may obtain perfect immunity from their attacks if he purchases a newly invented seed-protector, which is, or ought to be, in the hands of all the ironmongers. It consists of an arch of wire netting made of galvanised iron, in three-foot lengths and 3 inches in width, which may be joined end to end for any distance.

In the event of birds being impertinent enough to walk into this tunnel, the ends can, of course, be easily protected.—W. T. GATES, *Peterborough.*

[We recommend Mr. Vickary and all our readers to mix their seeds with red lead. It is said to be an effective protection.—EDS. J. OF II.]

## THE FUCHSIA AS A BEDDING PLANT.

THE precise period when the Fuchsia came into use as a bedding plant would be difficult to ascertain. Certainly the Scarlet Geranium must take precedence of it in that respect; but as an ornament to the flower garden its service extends backwards farther than my individual acquaintance can trace it. Probably, some stunted unhealthy plant was first turned out by way of a trial, and, succeeding so well, others were treated in the same way. Doubtless this was the way in which its value as a plant fitted for the flower garden was first found out, or in precisely the same way as the adaptability of new plants for particular purposes is traced out at the present day. The Fuchsia, however, was far from plentiful in ordinary small collections of greenhouse plants thirty-five years ago; and, to the best of my recollection only two kinds—*F. coccinea* and *F. gracilis*, were then known. Other kinds, however, speedily followed, and about 1830 Fuchsia *conica* became a great favourite, and almost at the same time it was discovered that Fuchsias were obtainable by seed, and that new varieties were likely to reward the careful hybridiser. This, in addition to some other distinct species, led to the list of names being multiplied to a great extent; one of these varieties raised some few years after the above date—*Riccartoni*, is about the best we yet have for bedding purposes. Previous to this, however, the class of Globes was very popular, and deservedly so; and I am not certain yet that the best collections of the present day can boast of anything better than a really good plant of Fuchsia *globosa*. Unfortunately this class consisted of dwarf growers, and could not easily be coaxed into the upright pyramidal form now required by the fashionable plant-growers. About 1842 our greenhouse-shelves contained a better-varied collection of Fuchsias than they do now; for the introduction of *F. fulgens*, a few years before this, and also *F. corymbiflora*, gave quite a distinct character to the family, which had previously been also augmented by the introduction of *F. microphylla* as the small-leaved and small-flowered species was called. Now we rarely meet with the three species last named, all differing widely from the class to which the vagaries of fashion have brought our show collections of the present day. But the greatest stir made on the advent of any of the Fuchsia family was when the first white variety under the name of *Venus Victrix* was ushered forth. This was about 1843 or 1844; and, at that time, the Fuchsia mania may be said to have been at its height. Other pale-coloured varieties were not slow in following, and the advertising pages of garden publications at that time presented a long array of names, few of which have survived to the present day. But it is certainly to be regretted that the channel for improvement has been so narrowed, and it is equally reprehensible that at horticultural shows there should be such a sameness in the collection. The species *Fuchsia fulgens*, *corymbiflora*, *microphylla*, and others which differ widely from each

other are never seen in a collection of eight or twelve plants, while only such varieties as have received the stamp of approval from the florist are to be found there; but, as this is perhaps his own especial province, it may be wrong to find fault, though it is certain that the presence of more distinct species would improve private collections if inadmissible at shows. It is, however, under another form that the Fuchsia is intended to be treated of in this article.

*The Fuchsia as a Bedding Plant.*—I have said that solitary plants in a flower garden were frequent objects from 1830 to 1835. About the latter period they were beginning to be common in mixed beds or borders of choice flowers, and their adaptability for beds by themselves was by degrees found out. Their hardiness being once established, they speedily became popular; and, I believe, there are beds of Fuchsia Riccartoni at the present time which have been planted twenty years. Many attempts were made at the time that the pale-coloured varieties became so plentiful to work them into beds, but they never seemed to thrive so well as the more hardy scarlet varieties. As uniformity of growth was an essential point in Fuchsia-bed management, the uncertainties attending the white section were such as led to their being disregarded in that respect; and, as they are certainly not so hardy, and cannot be depended on for living through the winter, often presenting a gapped, uneven appearance, they were eventually abandoned. But even now, though some growers take the trouble to propagate a certain number of plants and to grow them of a uniform size up to the time of planting out, it is seldom that the uniformity is kept through the growing season, and the critical eye of good taste is offended. Some other kinds, however, may be depended on as presenting a uniform growth and flower, and these look as well as any description of plant can do. Of this class Fuchsia Riccartoni is the best I have, and for habit of growth, good foliage, and abundance of bloom, it cannot well be surpassed. Fuchsia globosa is certainly not so hardy, though much dwarfer; but the liability of the plant's dying out here and there very much diminishes its utility for bedding. Such strong growers as Fuchsia Carolina are only suitable for certain situations; whilst many of the most esteemed florists' varieties which figure at shows, and form so gay a feature in our plant-houses all the summer months are unsuitable for bedding, the long, delicate flower-stem letting the flower droop so much as to be hidden amongst the foliage. I would, therefore, advise the inexperienced planter to reject these, and only plant out such as flower with short rigid stems, showing the flowers in a somewhat oblique direction instead of entirely pendent. A small dark green leaf, healthy and capable of enduring the sun, is also requisite.

*Fuchsia fulgens and F. corymbiflora in beds.*—The popularity which these species at one time attained was such that they were everywhere favourites; but somehow, like the *Salvia patens* and several other plants, they fell into disrepute, and beds of them are far from common at the present day. The truth of the matter is, they are more difficult to manage than many things; and, unlike the hardy varieties of the *gracilis* family, they will not stand the winter excepting in very favoured situations, as against walls and other places similarly sheltered; even there they require protecting. Still a well-managed bed of Fuchsia fulgens is certainly second to nothing I know of in the flower garden. The best beds I ever saw of it were at St. Leonard's Hill, near Windsor, where Mr. Hale, the gardener, had both the above kinds about 8 feet and 10 feet high respectively, and as full of bloom as it was possible for anything to be; and, what was equally important, the flowers all showed themselves, which they do not in a bed from 2 feet to 3 feet high. This, no doubt, is the reason why the plants were abandoned for bedding by those who had not the convenience to winter plants of such large size; for they must be all taken up and housed somewhere. I have not grown Fuchsia corymbiflora as a bedder since 1854 or 1855. Fuchsia fulgens I have occasionally; but the inconvenience of keeping the plants over winter, and, what is equally important, neglecting to take them up early enough in the autumn, was sadly against them. Another reason is that they do not match well with the ordinary plants used in a series of beds in a geometrical garden, as the flowers, though plentiful enough, are not all at the top, and viewed at a distance are not so showy as variegated-foliaged plants, Scarlet Geraniums, yellow Calceolarias, and other favourites.

*Beds Suitable for Fuchsia fulgens and corymbiflora.*—In some detached bed in the shrubbery, or where the bed does not form one in a set where smaller plants are grown, these two noble-grow-

ing Fuchsias may be planted, either both in one bed (*F. corymbiflora* in the centre), or separately; the latter way being the best. In whatever way they be grown the bed ought not to be less than 12 feet wide, and if 20 feet all the better. Large strong-growing plants like this Fuchsia, if allowed space proportionate to their size, will amply repay any trouble they may give. The wintering of the old plants is all that is required; no stopping, pegging, or trimming of any kind being wanted. Some little care must, however, be taken to place the largest plants in the centre and the smallest at the outside. A deep soil not too rich is best for them, and in the late summer months a mass of loam will well reward the cultivator.

*Fuchsia as a Hedge or Ribbon-border Plant.*—Nothing can be more suitable than the Fuchsia for the first-named purpose. For a single row on grass, or as a boundary or background to some other object, the Fuchsia is admirably adapted, its graceful yet sturdy habit and abundance of bloom rendering it available everywhere, more especially where its whole growth from the ground upwards can be seen at once. As a row for a mixed border of stripes it is not so well adapted; for the blooms, being mostly pendent, are hidden by the adjoining row coming in contact with them. The best kinds for single rows or hedges are those previously mentioned as being best for beds.

*Fuchsia as a Standard or Single Plant.*—Many years ago attempts were made, with more or less success, to obtain with Fuchsias straight clear stems with a round-topped head like a standard Rose; but the determination of the plant to throw up suckers marred this attempt at ideal beauty. It was seldom successfully accomplished; but sometimes these standards were worked into good effect in geometrical gardens, or as single specimens on lawns. A much more useful way was to grow them as pyramids, in which mode of growth the habit of the plant was properly represented; and the general abandonment of mop-headed plants led to a more natural way. Pyramids of Fuchsias are now amongst the most ornamental things we have. As the plants are generally grown to a good size in pots before being planted out, the more delicate white or pale-coloured ones may be used with advantage here; and being taken up and wintered in some shed or amongst shrubs where they can be protected from severe frosts, they will live for many years. Most growers, however, prefer planting out some of the old plants that have been ornaments to the plant-house the year before; for these being in pots are easily stored away during the hard winter months. If no portion of the old stem can be secured, the most forward of the spring shoots must be encouraged to form leaders, and the remainder stopped; a good-shaped plant may thus be obtained with little trouble.

*Concluding Remarks.*—The hardiness of the Fuchsia has been already adverted to, and we often hear of instances of the wood having assumed the proportion of a moderate-sized tree, even in latitudes much farther north than might be expected. A lady once sent me some cuttings of a hardy Fuchsia, the stems of which had braved several winters in the Island of Bute, and I have known plants here survive four or five winters in succession; but an unusually severe season always kills them to the ground. This, however, in a general way, is no detriment to the appearance of the plant, as, when the old stems are saved, it does not flower a day earlier, nor is it so neat-looking.

The Fuchsia seems to thrive best on a stony dry soil, where it ripens its wood early in the season, still it likes depth of material as well; for few plants root deeper than the Fuchsia, and in a soil suitable for it, few will outgrow it. I have seen it usurp more than its share of space when growing in a mixed shrubbery—Roses, Rhododendrons, and similar shrubs being all driven aside; and *Berberis aquifolium*, *Laurustinus*, and others had a difficulty to contend against this robust robber. The most fatal place to plant it, with regard to the welfare of the legitimate occupant of the ground, is on a Vine-border: here, if it be allowed to run riot, small berries and shanked bunches will be the result, for which Fuchsia stems of eight to ten feet growth in one season will be but a poor equivalent. Eight feet, however, is not an unusual growth in less-favoured places, where the plant is more appropriately and, it may be said, contentedly at home.

J. ROBSON.

*NARDUO.*—This plant is very plentiful throughout the whole of our portion of the colony (Murrumbidgee), and has long been known as an article of food, although going by different names in different localities. It is a four-leaved Clover, bearing small black

Pods about the size of *Acacia* seeds. These pods are full of very small seeds, at first green and juicy, but when ripe very farinaceous. It is noticeable that the leaves of this plant turn with the sun, facing the east in the morning and the west at night. The blacks here do not appear to eat *Nardoo*, having probably a sufficiency of food without it; but the Aborigines at Mennindie, have always been known to partake of it. This plant only grows in flooded ground, and although the leaves die away during the heat of summer, the seed-pods last a considerable time. Sheep are very fond of *Nardoo*, and when eating it make a curious noise cracking the seeds between their teeth. Mr. Green, the postmaster at Hay, has forwarded specimens from this locality to Professor Mülller, who pronounces them to be genuine *Nardoo*, similar to that eaten by the unfortunate explorers.—(*Sydney Morning Herald*.)

### VINES BEARING AND NOT BEARING IN THE SAME VINERY.

I FEAR I am like many other amateur gardeners always expecting more than our plants or the mode of treatment will produce. I detest regular grumblers, for nothing satisfies them long. Two years ago I came into possession of a garden for the first time in my life, and in it there is erected a lean-to vinery divided into two houses, each about 24 feet by 16 feet. The situation of the house is direct south. Some of the Vines are planted against the wall, their roots being inside; whilst those which run along the sashes of the glass frames have their roots outside. The Vines are all Black Hamburgs with two exceptions, these being a Muscat and a Frontignan. In the latter end of 1860 I reconstructed the border for the roots and fixed a good drain in accordance with the instructions found in your Journal.

Last year, in consequence of the disturbance of the roots I did not expect much fruit, nor was I disappointed—I had only fourteen bunches altogether, the Frontignan bearing only one large bunch.

I consoled myself by the best reasoning I could use, relying upon the present year to make good the deficiencies of former ones.

The show this year is an improvement upon the last, but not at all equal to the apparent strength of the plants nor my expectations. The order of things in some respects is reversed, the weakest plants bearing, the stronger ones being quite barren. This applies particularly to the Frontignan Vine. The force of the plant has enabled it to throw out many strong shoots, equal in thickness to the middle finger of an ordinary man.

The sap appears to move quite in order, and the vigour by which it has thrown out new shoots cannot be questioned; yet there is not a bit of blossom. They are treated according to the best method which I know; they have all the air they can have consistent with their treatment, but there is no reward for time and labour spent upon them. I am in a fix, the man who looks after them looks unutterable things, and both together we feel quite simple. What can you advise should be done? Any idea or suggestion you may think you can give I shall be glad to acknowledge.—AN AMATEUR, *Manchester*.

[You are just one of those hopeful sort of people we would oblige if we could. We can understand the reason why you should have drained your border; but you have not told us why you raised and replanted the roots two years ago. Perhaps it might have been as well to let well alone so far as good heavy crops at once were concerned. Many Vines in the south have broken badly this season, owing to a too-great hardening of the wood from a powerful sun and a dry summer and autumn. Now we believe that in your neighbourhood the summer and the autumn were sunless and wet; and if so that may explain how the weaker Vines are fruitful, and the vigorous-growing ones are barren. In the first case the wood was well but not inordinately ripened; in the others the wood was so vigorous as not to ripen kindly. If the Vines planted inside against the back wall are pretty fruitful, whilst those planted outside are more barren, then the above idea would be more confirmed than otherwise. If this is at all the reason, and the Vines are planted within a foot or so of the surface, we think we can promise you a rare crop next year, and onwards; though perhaps it would be as well to be moderate for one year. The great thing will be to get the wood ripened thoroughly before the end of autumn, by withholding moisture, giving all the sun possible, and extra fire heat in September if the wood is not like heart of Oak. Very

likely a little dry heat in September and October would have given you fine bunches on your Frontignan this year—that heat being applied, and soaking rains kept out of the border. We think we have hit on the cause; but if you can give us more information we would be glad to give more suggestions if we can, as we are anxious that all such experiments should succeed.]

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

TAKE advantage of the dry state of the ground to get manure wheeled upon quarters where it may be soon wanted, and see that there is a good supply being prepared for the Celery crop; for without plenty of old manure large crisp Celery can hardly be obtained. *Broccoli*, as the present warm weather brings it forward so fast, some of it should be pulled-up before it is fully grown and laid in a cool place so as to prolong the season. *Cabbage*, when the soil is very hard between the autumn-planted, it will greatly benefit the plants to fork between them, and after rain to be again earthed-up. *Cauliflowers*, fork-up the soil surrounding them, and afterwards give them a good soaking with water, which should be repeated twice a-week during dry weather. *Celery*, all that is fresh pricked-out to be shaded and watered until the plants get fresh root-hold. *Cucumbers*, trenches should now be prepared for hand-glasses, they may be 2½ feet wide, and 1 foot deep; each should then be filled with prepared dung, leaves, and short grass to 6 inches above the surface, and prepared soil should be put beneath the glasses, the rest of the dung being covered with the soil that came out of the trench. *Dwarf Kidney Beans*, make a good sowing for succession; a few should be sown in a pan at the same time to fill up any vacancies. *Lettuce*, give a few of the earliest plants a good supply of water to bring them forward, some of the Cos to be tied-up to form hearts. *Mushrooms*, continue to form fresh beds for summer and autumn use. *Radishes*, sow both Long and Turnip-rooted kinds. Water those from which they are drawn for use. Embrace every opportunity of destroying weeds. Clear away all old Cabbage and Broccoli stumps as soon as done with, as they harbour insects.

#### FLOWER GARDEN.

Prepare the stations on lawns for large specimens of ornamental plants, such as *Fuchsias*, *Scarlet Geraniums*, &c. Recently-transplanted shrubs will require to be carefully attended to with water, giving the ground where it may be found necessary a liberal soaking, so as to thoroughly moisten it, lightening-up the surface with a fork where it has become firm. If not already done hardy annuals should be sown after the first shower, and do not forget plenty of *Mignonette* and *Stocks*, their fragrance will always render them favourites.

#### FRUIT GARDEN.

The late drying winds and the present clear warm weather will render it necessary to supply water to recently-transplanted trees and even to vegetables, and also the seedling crops which are just making their appearance; otherwise, they had better be allowed to remain in a dormant state until we have rain, as continued waterings bind the surface of the soil into a hard crust impenetrable to air, and very prejudicial to the germination of seeds: this, however, may in some degree be prevented by shading from the sun, or covering the soil so as to prevent evaporation as much as possible. Frequent waterings are not then necessary, and the soil is kept in an open porous state, which is of the utmost importance. When the nights are warm, seeds and herbaceous plants of all sorts should be watered in the evening, so that the soil may gradually imbibe the water; but if cold nights prevail the early part of the morning is the best time for its application. On the first appearance of green fly on Peach and Nectarine trees syringe them with tobacco water two evenings in succession; if done properly it will stop their career for the season. If the trees are subject to the curl, or mildew, syringe with water as soon as the fruit is set, and then dredge them over with road dust, taking care to apply it to the under sides of the leaves as much as possible, to be allowed to remain until washed off by the rain. The trees may look unsightly after the operation, but they will thrive and grow luxuriantly, which will amply repay for the loss of appearance. When applied to Thorn-quicks attacked by mildew, it proves an effectual remedy. Caterpillars and green fly on Gooseberry bushes, and the dolphin, or black aphid, on Cherry trees, can

be destroyed by the application of a couple of dressings in the same manner. The mining grub, so destructive to the Apricot and Plum trees, may be easily detected by the leaves being folded up; the best cure is crushing them between the forefinger and thumb. Clean and loosen the surface about Strawberries. If strong young plants of the Elton Strawberry are lifted now, and planted behind a north wall, they will produce a crop in August and September, and will keep up the succession along with the Alpines to the latest period. A sloping bank should now be prepared and planted with rows of Alpine Strawberries, three plants in a patch, at intervals of 15 inches, the ground to be covered with slates after the plants have become established.

#### STOVE.

See that growing Orchids have due attention with regard to shading and atmospheric moisture. Do not use the syringe too freely among those starting into growth, but keep the atmosphere thoroughly moist. See that specimens on blocks and in baskets are not allowed to suffer for want of water; for when the soil in baskets is allowed to get thoroughly dry, water is apt to run off. If, through any neglect, the soil is allowed to get too dry, the baskets should be immersed in tepid water until it gets thoroughly soaked. Continue to attend to the stopping and training the plants as they may require, and give free-growing plants plenty of pot-room. Achenenes and Gloxinias in luxuriant growth may be supplied with weak liquid manure occasionally. Repot and propagate Begonias. Persevere in keeping down insects, which, if allowed, will now progress with great rapidity.

#### GREENHOUSE AND CONSERVATORY.

See that all climbers and plants of rambling habits are regularly trained, stopped, and watered. When the young leaves of the Camellias that have been excited into wood have attained their full size, the supply of water may be diminished to prevent overluxuriance, and introduce a gradual maturity of growth. Take care of the young leaves, and apply shading the moment it is perceived to be necessary. Examine the plants carefully on the forenoons of bright days, and see that none of them are suffering from want of water; for with bright sunshine, accompanied with drying winds, it will require careful attention to supply them with water, especially specimens that may be pot-bound. Use the syringe freely on those in full growth. Fuchsias, intended for large specimens, will require to be shaded from bright sunshine, and will be benefited by a liberal supply of manure water; and where free growth is expected from them, the atmosphere can hardly be kept too moist. Young specimens of hardwooded greenhouse plants should be kept as warm and moist as can be done without inducing weakly growth; see that they are properly supplied with water at the root, and do not allow them to sustain any check for want of pot-room.

W. KEANE.

#### DOINGS OF THE LAST WEEK.

At last we have "the Dog Days" at the end of April, and trying it is to many plants after the dull cheerless weather. Many things under glass require a temporary shading, just before the roots are able to supply the excessive demand upon them, by increased evaporation from the foliage.

#### KITCHEN GARDEN.

Earthed-up *Cauliflowers* in hand-lights with rich compost. Elevated the glasses over a few earliest ones, removed the glasses from the rest. Gave all the plants a good soaking with manure water. Pricked out Lettuces and Cauliflowers on border for transplanting. Pointed a border over, placed on it 3 inches of rotten dung and an inch of fine soil on the surface, in which to prick out Celery 4 inches apart, the second lot. The first or forwardest was turned out under glass for a few days to get large plants for transplanting next month. The great secret of having good early Celery and not run, is not early or late sowing, but never allowing the plants to have a check from dryness or otherwise until they are fit for table. Sowed main crop of Kidney Beans out of doors, planted some under slight protection, and earthed-up and watered with manure water those in full bearing. Glad to get hold of pots now past their best for other purposes. Gathered Peas from pots, and kept staking the succession crops. *Asparagus* is coming in well notwithstanding the injury done to the forward shoots by the frost. When grown in rows, a simple covering as two boards fastened at the edges would be useful. Sea-kale under exposed pots have done nicely, but a fortnight or three weeks ago the plants were so

frozen inside as to be as hard as a stick. In cases where the sun struck the pot before the frost was thawed the plants were blackened, showing that a little litter over the pots might be advisable, but I could not spare a bit for such a purpose.

#### FRUIT GARDEN.

Ran the hoe through Strawberry-rows. May draw a rough rake between them by-and-by, but am almost afraid to let such a tool out of my own hands unless in a hay field, or raking off grass. Moved the hay thrown over Gooseberry bushes where it had lodged in the centre of the bushes. Planted out Strawberries that had been forced in order to get a few berries from them in the autumn, and a large crop next year. The first full crop though wonderful, is by far the best they will yield. Planted out also young plants of good kinds, not expecting much from them, or nothing this season, but a large crop the next. Turned in some hundred pots into orchard-house, and potted Queens and Keens', pricked out in a border last autumn, squeezing the soil about them as hard as flint, and will plunge them out of doors in a bed of tree leaves just warmer than the earth. If the season be very early, these will not be much wanted, but if a change of dull weather come over the scene, they will keep the Strawberry-basket going, before those in the open air come in.

Removed all Strawberry-pots from houses as soon as done with, and in early houses it is little use having pots of Strawberries now, as if there is much shade the flavour is deficient. Disbudded and stopped trees in orchard-house. Fresh potted some Pears and Plums, and put them in a mild bottom heat out of doors, to set the roots going nicely. These are intended to fruit next season in pots, being now the first season from the bud. Smoked orchard-house to give a finish to the brown beetle, which would have been very bad, if not hunted up. Used tobacco and bruised Laurel leaves, which made them drop, though a few have got up again. Though the heat is high during the day, in these bright days (80° with all air on), nothing seems to suffer from it. If we shut at night, we open the first thing in the morning. Regulated Vines, thinned Grapes, planted out and potted Melons for succession. Watered Figs; Peaches in pots, that previously needed water once in ten days, have required it every other day, and Strawberries sometimes twice a-day. So much as to the question, How often shall I water?

#### FLOWERS.

Here as to bedding plants alone we would have required to have made every day into three, and every man into two, in moving, boxing, planting out, hardening-off, and propagating. We must finish cutting-making this week, for after that the plants would be too small to do much good. We have just thrown up a mild hotbed for lots of plants, eight or ten in a 60-sized pot. The bed is about a foot in height, 9 inches long stable litter and grass from lawn well trod, 3 inches of rotten leaves above it, and 4 inches of soil over all, rather light and rich, and into this the plants are turned out, ball and all, the earth squeezed tight about them. Here they will grow a good deal in three weeks, and will divide easily at planting time. Lots of others have been turned out of small pots into the trenches described the other day, and the pots thus emptied when washed will be used for the finer variegated Geraniums, and various things that do not lift so well as others. Many Ageratums and Lobelias have been turned out in lumps—say six or twelve plants in a piece, and they grow faster than when separated individually. When thus placed close together, they are easily protected, and being turned into soil need little or no watering; and besides there need be no such hurry scurry in turning out into the beds in the flower garden, as the plants are growing where they are. I have now large beds of *Calceolarias* that have had no water for a month, and have never shown a fly. If kept in pots I know something of the tubs of water they would have wanted.

Plants in general received necessary attention as to watering, shifting, syringing, &c.—R. F.

#### TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

GREEN FLY OR APDIS (*A Lady Subscriber, Barnstaple*).—For amateurs who, like you, have the patience to destroy this pest in detail, there is a double brush made between which the leaves and spray of plants can be drawn without injury, but destructively to the insects. Tobacco water, or a solution of Gishurst Compound kept in a bottle as you propose, might be applied by a brush, but it would be very tedious. You had better have a basin full of one of those liquids, and dip the leaves and shoots into it.

CHARRING WEEDS (*Malpas*).—If you refer to No. 7 of our New Series, page 117; or to No. 426 of our First Series, page 131, you will find full directions for charring.

DISA GRANDIFLORA (*Orchid*).—You are wrong in your treatment of this plant, and in your conclusions as to its culture being difficult. It has been grown very successfully in the Chiswick Garden of the Royal Horticultural Society. If it dampens-off it is because the air is not admitted freely enough.

ROLLER SHADE (*A Subscriber, Il.*).—We do not see we can make the matter clearer than at page 426, Vol. I. Let A represent the ridge-board of your house, and B the front in an inclined plane. Fasten the shade at A with tacks and tape, or any other means; fasten the other side in a similar manner to a rod 2 inches in diameter; have a grooved wheel fastened on the end of that rod at P, to hold a stout cord longer than the length of the roof from E to P; fasten the end of the cord at E, roll the rest round the grooved wheel, pull the string and up the glass the roller will go to the apex, or as far as you like by fastening the string to a pin to keep it tight. This is the simplest mode, and answers well for small houses. The farther end of the pole may be 6 inches lower than that at the rope end, but that is of little consequence. With double the quantity of rope, you might take the end of the string from O, and over a pulley-wheel at E, and then pull the roller up from the back, and fasten the string to a stout pin as before. To inexperienced persons this may seem best; it involves more cord and a pulley-wheel.

ROSES IN POTS (*W. A. O.*).—Rose plants will bloom for years in the same pots if the surface soil is removed, and fresh-surfaced with rich compost in autumn. You do not say when you potted. It should be done in September, so as to get the pots well filled with roots before spring. No plant flowers so well in a pot if the roots are not getting to the sides of the pot. Very probably you over-potted, and late-potted, and the balls have either got dried or sodden.

LAPAGERIA ROSEA PRUNING (*Idem*).—The Lapageria, when established, just like a Vine and a Mandevilla, will bloom either from young wood or on spurs—that is, from well-ripened buds. You had better not prune it in much. We hope you have given it a rest in winter.

DESFONTAINIA SPINOSA (*Idem*).—If the Desfontainia was grown well in summer, and kept cool and rather dry in winter, the stubby little shoots should now be showing bloom. It should not be pruned much, unless to form a head and get fresh growth, and then harden it in autumn. It is more difficult to manage than the Lapageria. Get the latter to grow freely, give it plenty of water in summer, all the sun possible in autumn, and comparative coolness in winter.

VINES BREAKING AT TOP ONLY (*Idem*).—Your Vines-buds had been too much dried-up in winter after such a hot summer. You would have had more chance if you had laid the shoots at breaking time horizontally, instead of vertically. We fear there is little chance of the lower buds breaking if you allow the few at the top to grow. If there is nothing much on the Vines when they are in full leaf, you might nip off all the top shoots—not cut but rub, and that would cause shoots to break from the bottom. We can see nothing wrong in the planting.

SHADE FOR FERNS—ARUNDO DONAX (*H. B.*).—For most Ferns thick tiffany would be necessary. The variegated Arundo is not particular as to sun or shade; but it likes strong loam and p. at, and is very impatient of removals. Perhaps the best time is early in autumn.

STRIKING AZALEA INDICA CUTTINGS (*S. S.*).—Good gardeners can do this almost at any time. The best time will be presently, as soon as the plants have done flowering, and young shoots are grown from 2 inches to 2½ inches long; slip these off with a heel of the old wood, insert them in sand, over sandy peat, in a pot three parts filled with drainage; cover with a bell-glass, and set in a mild hotbed, and shade from bright sunshine.

LIMNOCARIS HUMBOLDTII (*A. B. W.*).—We cannot name the plant from the description; there are so many leaves of the same form. If not a water plant, most likely it is a Caladium. We think you had better leave the Limnocarhis alone. We have seen the original plant and runners in succession flowering freely.

STOVE FOR PINES (*R. T. W. Ashton*).—We think the house will do very well, though you will not have much room in it. You seem to have great abundance of heating power. The pipes so far as we see are all on a level. The flow-pipe goes along the back, then twice through the bed, once round the front, and then returns from the front to the boiler. We should have preferred taking the pipe twice round the first, then below the bed, and lastly, finishing at the back. A division of the house would be an advantage, even though there were no division of the pipes. The Pine-pots should be a foot above the pipes, any rubble between would do. Sand or even earth will do for plunging in, good soil for planting-out in; but for mere plunging we would prefer tan if easily to be procured. In such a house, where high temperature is needed, a foot of ventilation at the apex, and the same in front would do, and much less would be required in cold weather.

COTTAGE GARDENERS' DICTIONARY (*C. Jordan*).—The edition of 1857 differs from that of 1851 in having the plants included which were introduced since the latter date, and an alphabetical list of synonymes. We cannot say whca a new edition is likely to be published.

BOOKS (*T. Hardie*).—Hemfrey's "Rudiments of Botany," 3s. 6d.; and Hogg's "Vegetable Kingdom," 8s. You can have both from our office, with 8d. additional to prepay the postage.

COCOA-NUT FIBRE REFUSE (*Sigma*).—The sample of fibres sent is nothing like it. (*T. Lincoln*).—The sample you enclosed is quite right. It will be darker when moister and a little older. (*An Old Subscriber*).—Yours is not at all the right article. We have repeatedly said it is like coarse brown snuff, or mahogany sawdust; and you, like many others, send us a parcel of bristles, and ask, "Is that the right thing?"

VARIATION (*Nickerbor*).—The blotching on the Kidney Bean leaves you sent is a very common thing when the plants are forced; and we have seen such from the "absorption" of too liberal a dose of ammoniacal gas, in which we have very little faith as a source of true variegation.

PEACH LEAVES BLISTERING (*A Lady Correspondent, Armagh*).—We believe that it arises chiefly from the wood being imperfectly ripened—that is, deficient in well-prepared material for growth, in the previous summer. The blistering is always most prevalent and virulent on over-luxuriant branches. Root-pruning and covering the trees with glass, and not manuring the borders would prevent blistering.

LIQUID MANURE (*E. Hinton*).—To a painful of sheep-dung add fifteen pailfuls of water. This liquid manure may be given in moderate quantity to bedded-out Geraniums when the flower-buds are developed, if the plants seem to require it, but which they will not do unless the soil of the bed is poor.

PROPAGATING BEDDING TROPEOLUMS (*Inoranamus*).—All the Tropaeolums you name—Elegans, De Hyris, Cattell's Dwarf Scarlet, Cattell's Dwarf Crimson, Yellow Tom Thumb, Crystal Palace Scarlet, Crystal Palace Gem, must be had from cuttings, except Tom Thumb, the only one of them which comes true from seeds, unless Cattell's Dwarf Crimson and Dwarf Scarlet should follow Tom Thumb in this respect, as they do in stature. All we know of these two is from what we saw of them at one of the exhibitions at South Kensington last summer, and they are certainly very pretty. Elegans is the best of the others you name, and the only one of them that is likely to do well, except in skilful hands.

CYCLAMENS (*G. A.*).—Many thanks for the industry you have shown about Cyclamens, but as the family had been in great confusion in 18 books until very recently, it is now not worth the trouble to republish from old authorities. Miller never mentioned vernum, or any of them by their present names. The editors of editions of his Dictionary were they who supplied the names you read from imperfect sources. Sweet is the first person who mentions vernum, and not one of the other authors you name would know vernum from comum, or either from europaeum, and no good could result from discussing that side of the question any further.

CULTURE OF TRITOMA UVARIA (*R. F.*).—Neither the seedlings of this nor the young plants should have been in "a hot-house," nor yet in a greenhouse, but in the coldest pit; they should not get more than 5° or 6° of frost till they are of a flowering age, and that will be, or should be, the next summer from the first seeds which were on sale. After the seedlings come to flower, the plants in most parts of the kingdom do better treated as the very best Dahlias, but not dried so much in winter. They should be lifted in November, put into damp sand in the dry, and to be planted out in April; but on dry soils it does best out of doors the year round, when treated like Fuchsias with mulchings in winter, and a most abundant supply of water from June to the end of September.

WHITE BEDDING GERANIUMS (*S. M.*).—The best bedder of all the White Horseshoe kinds of Geraniums to contrast with a bed of Tom Thumb, is one called Madame Vaucher, and it blooms as freely as Tom Thumb itself. Hendersonii is the next best white, and Hendersonii nana is the best white for edgings. But this season we shall have coming out the white-flowering variegated Hendersonii, which was mentioned last autumn for the first time.

IMANTOPHYLLUM MINIATUM (*Bulbs*).—This is the correct spelling. Notices of it occur in various volumes, but not giving directions for its culture. The same treatment as mentioned for Clivia in the "Cottage Gardener's Dictionary" will do for this bulb. You can have a copy of Vol. XV. from our office.

NAME OF ANEMONE (*P. C.*).—It is *Anemone hortensis miniata*, and must have escaped from some garden. It is a native of Italy.

NAMES OF PLANTS (*Arthur Cole*).—Apparently Orchis's mascula; but to send one flower of such a plant! The leaf is decaying, but it is impossible for us to say why. In the next Number of "Wild Flowers" a portrait of that Orchis will appear. (*T. P. Albro*).—Doronicum pardalianthes. (*Bolder*).—1, Tecoma australis; 2, Acacia melanoxylon; 3, Polyzala Dalmatiana; 4, Acacia verticillata. (*S. H. G. Liverpool*).—The purple flower is a variety of Bletia verecunda. The Oncidium is Oncidium barbatum.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ROYAL DUBLIN SOCIETY'S SPRING SHOW.

APRIL 22—25.

The poultry formed a very interesting department of the Exhibition; in the judgment of some, indeed, the most so in the yard. The birds were all in high condition, and particularly good of their kinds. The *Dorkings*, especially, put in a splendid appearance. The *Spanish*, also, were very attractive, and well represented in point of numbers. There were some very fine *Game Fowl*. There are many of the adepts in "Game" flesh who will say that the first and second prizetakers ought to have changed places. We were sorry to notice the entire absence of the old *Irish Hen*, of which there was not a single representative exhibited. We think that this is much to be regretted, for, though not a showy bird, we do not know her equal in point of laying qualities.

BRADMA POOTRA OR COCHIN-CHINA.—First, J. Wight, Johnstown House.

Cabintee. Second, Countess of Beective. *Chickens*.—First, R. W. Boyle, Dundrum. Second withheld.

DOMKING.—First, R. W. Boyle. Second, Col. Leslie, M.P. Highly Commended, Mrs. Farrell, Moynalty; R. P. Williams, Hollybrook, Clontarf; G. Langtry, Kilmore House, Lurgan. Commended, Lord Lurgan, Brownlow House, Lurgan; J. Forrest, Roebuck House; Countess of Beective; R. W. Boyle, Dundrum. *Chickens*.—First and Second, Col. Leslie, M.P. Highly Commended, R. P. Williams; G. Langtry; R. W. Boyle. Commended, Mrs. Farrell, Moynalty; G. Langtry.

SPANISH.—First, Miss E. De Courcy Drevar, Rose Hill, Blackrock. Second, C. M'Clintock, Milmount, Randalstown. Highly Commended, R. P. Williams, Commended, E. J. Smith, jun., Rutland Square, Dublin; Col. Leslie, M.P. *Chickens*.—First, E. J. Smith. Second, R. W. Boyle.

GAME.—First, J. Wight, Johnstown House. Second, H. Cusack, St. Douglahs. *Chickens*.—Prizes withheld.

HAMBUAGHS (Spangled).—First and Second, R. R. Williams. *Chickens*.—Prizes withheld.

BLACK FOWL (White-crested).—First and Second, Miss E. De Courcy Drevar. *Chickens*.—First and Second, Miss E. De Courcy Drevar.

ANY DISTINCT BREED.—Prize, R. W. Boyle.

SIX CHICKENS FIT FOR TABLE.—Prize withheld.

DUCKS (Aylesbury).—Prize, A. Fleet, Jialston Street, Dublin.

DUCKS (Rouen).—First, R. W. Boyle. Second, R. P. Williams. Highly Commended, R. P. Williams. Commended, R. W. Boyle.

DUCKS (Any other breed).—No merit.

TURKEYS.—First, G. Langtry, Kilmore House, Lurgan. Second, J. Hyland, North Anne Street, Dublin. *Poultis*.—Prizes withheld.

GANDER AND GOOSE.—First, R. W. Boyle. Second, J. Bourke, Stapoila, Baldyle.

—(Dublin Agricultural Review.)

## TURKEY-CULTURE IN AMERICA.

THE reason why the Turkeys seen in our poultry-yards do not vie in splendour of plumage with their untamed brothers is that we do not let them live long enough. A creature that does not attain its full growth till its fifth or sixth year we kill at least in the second, to the evident deterioration of our stock. But let three or four well-selected black or bronze Turkeys be retained to their really adult state, and well fed meanwhile, and they will quite recompense their keeper by their beauty in full plumage, by their glancing hues of gilded bronze and black, and the pearly lustre that radiates from their polished feathers. In default of wild specimens, birds like these are sought to complete collections of stuffed birds.

The demand for such large birds among the poultry-dealers, the temptation to fat them before they arrive at this stage, are so great, that few farmers can resist sending their fourteen-pound to eighteen-pound cocks to market, while a young cock of the year, they think, will answer every purpose next spring as well. Some even deem it an extravagance to keep a Turkey cock at all, if they have not more than two hens, which they would send on a visit of a day or two to a neighbour who has a male bird.

When the hen has once selected a spot for her nest she will continue to lay there till the time of incubation, so that the eggs may be brought home from day to day, there being no need of a nest egg as with the common fowl. She will lay from fifteen to twenty eggs, more or less. Her determination to sit will be known by her constantly remaining on the nest, though empty; and as it is seldom in a position sufficiently secure against the weather or pilferers, a nest should be prepared for her by placing some soft straw, with her eggs, on the floor of a convenient out-house. She should then be brought home and gently placed upon it. It is a most pleasing sight to witness the satisfaction with which the bird takes to her long-lost eggs, turning them about, placing them with her bill in the most suitable position, tucking the straw around and under them, and finally sitting upon them with the quiet joy of anticipated maternity.

Thirteen eggs are enough to give her; a large hen might cover more; but a few strong, well-hatched poultis are better than a large brood of weaklings that have been delayed in the shell perhaps twelve hours over the time from insufficient warmth. At the end of a week it is usual to add two or three hen's eggs, "to teach the young Turkeys how to peck." The plan is not a bad one; the activity of the chickens does stir up some emulation in their brethren; the eggs take but little room in the nest; and, at the end of the season, you have two or three very fine fowls, all the plumper for the extra food they have shared with the young Turkeys.

In four weeks the little birds will be hatched; and then, how are they to be reared? Some books tell you to plunge them in cold water to strengthen them; those that survive will certainly be hardy birds (an experiment which some women are cruel enough to try upon their own offspring). Air and exercise increase the strength of any growing animal; but cold and hunger only dwarf and weaken. Others say, "Make them swallow a

whole pop-corn;" which is as if we were to cram a Spitzenberg apple down the throat of a newborn babe. Others again say, "Give them a little ale, beer, or wine." We know, unhappily, that some mothers are wicked enough to give their infants gin, and we know the consequences.

Follow nature; give them nothing; do nothing to them; let them be in the nest under the shelter of their mother's wings, at least eight or ten hours; if hatched in the afternoon, till the following morning. Then place her on the grass, in the sun, under a roomy coop. If the weather be fine she may be stationed where you choose, by a long piece of list tied round one leg, and fastened to a stump or stake. But the boarded coop saves her ever-watchful anxiety from the dread of enemies above and behind—the crow, the hawk, the rat, the weazel!—and also protects herself (she will protect her young) from the sudden showers of summer. Offer at first a few crumbs of bread; the little ones for some hours will be in no hurry to eat; but when they do begin, supply them constantly and abundantly with chopped eggs, shreds of meat and fat, and boiled Indian meal mixed with chives or lettuce chopped fine. Mutton suet poured over shorts or middlings, cut up when cold; also liver, boiled and minced, are excellent things. The quantity consumed costs a trifle; the attention to supply is everything.

The young of the Turkey afford a remarkable instance of hereditary and transmitted habits. From having been attended for many generations with so much care, they appear naturally to expect it almost as soon as they are released from the shell. We are told that young pointers, the descendants of well-educated dogs, will point at the scent of game without any previous training; and so Turkey poultis seem to wait for the attention of man before they can have any experience of the value or nature of their attentions. Food which they would refuse from a dish they will peck greedily from the palm of a hand; a crumb, which would be disdained if seen accidentally on the ground, will be relished from the tip of the finger. The proverb that "the master's eye fattens the haro" is applicable to them, not in a metaphysical, but in a literal sense; for they certainly take their food with a better appetite if their keeper stays to distribute it, and see them eat it, than if he merely set it down and left them to help themselves.

We believe this to be the case with more domesticated animals than we are aware of, and appears natural enough if we remember how much more we enjoy a meal in the society of those we love and respect, than if we partook of it in indifferent or disagreeable company.

The Turkeys then are hatched, and we are rearing them. Abundant food for the mother and the young, constant attention to their wants, are the grand desiderata. An open glade in a grove, with long grass and shrubs here and there, is the best possible location. The long grass will afford them cover from the birds of prey; the hen will drive off four-footed enemies with great courage. We have been amused with the fury with which a mother Turkey has pursued a squirrel till it took refuge in the branches overhead; what instinctive fear urged her we know not. Insects, too, will abound in such a situation. When the little creatures are three or four days old they will watch each fly that alights on a neighbouring flower, fix it with mesmeric intensity, and by slow approach often succeed in their final rush. But in the best position you can station them, forget them not for one hour in the day. If you do, the little Turkeys will for a time loudly yelp, "O, then, remember me," in notes less melodious than those of a *prima donna*, and then they will be sulky and silent. When you at length bring their delayed meal some will eat, some will not. Those that will not can only be saved by a method at all other times unjustifiable—namely, cramming; but it must be done most gently. The soft crumb of bread rolled into miniature sausages should be introduced till their crops are full. For drink, many would give ale or wine; we advise milk. The bird wants material, not stimulant. It has been actually wire-drawn. It has grown all the hours you have neglected it without anything to grow from. Like a young plant in the spring season, it will and must grow, but has no roots in the fertile earth to obtain incessant nourishment. The roots which supply its growth are in the stomach, which it is your office to replenish. "Prevention is better than cure." Such a case ought never to occur in a well-cared-for poultry-yard.

The time when the Turkey hen may be allowed full liberty with her brood depends so much on season, situation, &c., that it must be left to the exercise of the keeper's judgment. A safe rule

may be fixed at the season called "shooting the red," a "disease," as some writers call it—being about as much a disease as when the eldest son of the Turkey's master or mistress shoots his beard. When young Turkeys approach the size of a partridge, or before, the granular fleshy excrescences on the head and neck begin to appear; soon after, the whole plumage, particularly the tail-feathers, start into rapid growth, and the "disease" is only to be counteracted by liberal nourishment. If let loose at this time they will obtain much by foraging, and still be thankful for all you can give them. And now is the time that Turkeys begin to be troublesome and voracious. What else can be expected from a creature that is to grow from the size of a robin to 12 lbs. or 14 lbs. in eight or nine months? The only way to keep them from rambling is to feed them well and regularly at home.—C. N. BEMENT.—(*Genesee Farmer*.)

### DEATH OF A QUEEN.

On the 21st of April I had occasion to remove some brood-comb from the hive, the bees of which had manifested so strong a disposition to attack their sovereign, as related by me in pages 74 and 75, when I found the unfortunate queen again a close prisoner; and although I adopted the same course as before, by releasing her and introducing her between a couple of brood-combs, I had the mortification of finding her dead on the ground in front of the hive two days afterwards.

It may, perhaps, be a question whether I may not have myself contributed to hasten this catastrophe by the disturbance produced by frequent examinations; but never having before met with a similar instance, I am more disposed to believe that the bees had detected some evidence of declining powers in their hapless sovereign, which induced them to pursue the same course with her as is adopted with superannuated workers, multitudes of which I have seen expelled from my strongest stocks during the past two months. This hypothesis is strongly supported by the following interesting narrative by Herr Otto Rothe (author of an excellent apian treatise entitled "Die Korb-Bienen-zucht"), which I find in the German "Bee Journal" of the 14th of last month. Herr Rothe says—

"On the 17th of May I was taking brood from one of my best Italian stocks, domiciled in a common straw hive, when I found (besides brood in every stage) royal cells both sealed and unsealed, which I supposed the queen would soon destroy; for although the stock was very populous and well stored with honey, yet the weather (about Whitsuntide) was by no means favourable for swarming. On the following day, however, sentence of death was passed upon the queen herself; but from hereditary respect the bees did not kill her, but turned her out alive, and I found her, apparently in full vigour, running in the sand before the hive. As she seemed to me quite lively, I gave her to a queenless stock. Here she filled cell after cell with brood, and after I had used some of it for rearing queens, I put her into another queenless hive. But what was the result? From all the eggs laid by her at this time only drone-brood was developed, and queen-rearing came to nothing. Vexed about it, I crushed the head of the useless queen.

"Up to the 17th of May she had regularly filled cell after cell with worker and drone brood, and it was a pleasure to look at the strong colony. From the 18th of May, however, she laid only drone eggs, consequently the sperm must have suddenly come to an end. But it is remarkable that the bees immediately observed this, and resolved upon an act of violence which is not carried out in every hive, since many a stock carries until self-help becomes impossible. Last spring I had a colony with a drone-breeding queen which, after she was removed, would not accept a fertile queen as long as a drone egg remained in the cells, and only received her when all the drone eggs were removed. On the other hand, during this spring another stock with a drone-breeding queen readily accepted an inserted royal cell. They injured the vigorous young drone mother and threw her down from the combs to free themselves from her; receiving willingly a fertile queen that was offered to them, although there was much drone-brood in the hive. Why did the bees in one case know what was necessary for them, and not in the other?"

This question is much more easily asked than answered. We may lay down general rules in apian matters, but it is far from certain that bees will invariably follow them. One thing may be learnt from the foregoing, and that is the sudden

nature of the change which takes place upon the contents of the spermatheca becoming exhausted. Up to the 17th of May Herr Rothe's queen appears to have laid worker eggs in profusion, whilst on and after the very next day she proved herself incapable of laying any but those of drones.—A DEVONSHIRE BEE-KEEPER.

### BEE-KEEPING AND CUSTOMS IN CHESHIRE.

It is customary in many parts of Cheshire, and I believe in the adjoining counties of Shropshire and Staffordshire, for the cottagers possessing stocks to place swarms out to their neighbours by parts, on the understanding that at the expiration of two years a division of the issue and produce of such swarms takes place; such division, so far as I can ascertain from those best acquainted with its equity, is for the lender to take his old stock, the borrower the first swarm, and so on until a fair distribution ends the ceremony. Of course, allowances are made for casualties; but, unfortunately, this system is falling into disuse by reason of many of the cottagers not being over-scrupulous in their dealings, which they would not dare to do if a society were formed for the purpose of regulating this amongst other apian matters, such, for instance, as where a swarm straggles away from the apiary of its owner, and can be identified.

There are several superstitious notions respecting bees. Amongst the chief is, that where any member of a family who keeps bees dies, it is considered imperative to tap the hive and inform the inmates of the calamity, otherwise the tenants will all dwindle and die. I think a custom prevails in Worcestershire of draping the hives with mourning. There are very many old dames here who can cite abundant instances of cases where whole apiaries have ceased to exist in consequence of the non-observance of this strange and, I must confess, singular ceremony.\*

Another superstitious notion prevailing with regard to bees, is where a swarm is known to settle on dead wood it is the omen of death in the family; and, last summer, owing to my doubting such a piece of superstition, I got well snubbed by a fussy overblown old dame who elings to all ceremonies of this sort, and which appear to have been handed down from the abbots and monks of old.

I noticed the case of bee-stealing before Sir John Duckworth, at the Devon Sessions. Mr. Carter evidently thought it was doubtful whether a jury would, under such circumstances, convict; and, certainly, I confess that, upon the law of the case, there may be serious doubts whether they are domesticated or fere nature. The Scotch law upon the subject corresponds much with that of England—the stealing of bees being considered larceny at common law; and prosecutions for stealing bees are very numerous in Scotland, although rare in England. It is usual, however, in order to steer clear of an objection on the head of "fere nature," to lay the articles stolen in the hive and honey, sometimes only the hive, which can certainly, in most cases, be identified. For the law upon this subject, see Tibbs v. Smith, "Sir Thomas Raymond's Report," 33; 2 East's "Pleas of the Crown," 607; 2 Russell "On Crime," 151; 4 "Dowling and Ryland's Report," 508; and Alison's "Criminal Law of Scotland."

You are very fortunate in only having lost two out of the numerous stocks you possess. I doubt not you have bestowed great pains on them. I consider it will in the end be found that ventilation at the bottom of the hive will be a preventive against humidity—permitting a thorough current of air to pass continually through the hives. If so few bees in their wild state—i.e., those which tenant old oak trees, buildings, &c.—die of the rot (as it is so termed here), where it is presumed no other ventilation takes place except through the entrance, which is always small, how happens it that such sad devastation occurs annually in our domesticated stocks? and it does appear to me most strange. It is a subject which has often struck me, and does not seem to have been noticed by any of the writers I have perused on the subject of bee-keeping. You will find most works of any note recommend placing bees about 2 feet from the ground, whereas the bees uncontrolled always make high up, and will remain there for years if not disturbed. I recollect at Hough Hall in the parish of Wybunbury, Cheshire, seeing nearly 1 cwt. of honey taken from the roof of the Hall; and it was stated they (the bees) had been there thirty years. The neighbouring bee-keepers had such a dread of this overgrown

\* I should say this custom exists in Ireland.

colony that they rejoiced at the downfall of such a colossal empire; for the bees not only went out as autumnal marauders (verifying the old adage, "much would have more"), but several swarms were annually known to go there: hence the terror and finally the joy of the bee-keepers. And the old sexton of the parish informed me he had known one or two colonies in his time to settle at the church of Wybumbury, which in consequence of both tower and church cracking (the former had been gradually giving way for years to the extent of 6 feet, and was seen for a distance round, but it was brought back to its perpendicular by the process of boring and letting it gradually down on inverted arches; the church, however, was rebuilt), would afford plenty of opportunity for them to domicile themselves in the crack of the old church.

The weather has not at present been favourable for our pets; but I do hope we may have a good season.

In *THE COTTAGE GARDENER*, No. 597, March 6th, 1860, you recommend that the Alp bee should be kept as far from the common bee as possible; but how can this be done when you have friends keeping bees of the common order in close proximity to your own residence? It would be selfish and unjust, if you had the power, to demand their removal; and, consequently, I consider it would under such circumstances be impossible to keep the blood of the Italians solely pure. The drone-stoppers are not available; besides, I have always understood that the embraces of the queen with her paramour take place on the wing in the open air, and were I to introduce a stock of yellow jackets here, according to what I see and read in *THE JOURNAL OF HORTICULTURE* I should expect hybridising. — EDWARD WYNDHAM JONES.

[I believe it will be found impossible entirely to prevent hybridising, at any rate at first. I have already stated in page 57 what I deem the best mode of combating this difficulty. — A DEVONSHIRE BEE-KEEPER.]

### CHEMISTRY OF HONEY.

In the January Number, page 366, there is the following quotation from Taylor's "Bee-Keeper's Manual":—"That the bees have not the ability to change chemically the contents received into their honey-bags, is shown by the saccharine mixture given to them as artificial food, in which I could never detect any alteration after being stored in their combs." Not having seen Taylor's Manual, I am not aware if he offers any proof of how he "could not" detect any alteration. Of course, mere tasting is none, and the Editors seem to think the same, when they refuse to be umpires in the offer of the "DEVONSHIRE BEE-KEEPER," in page 410.

In page 415 Mr. Taylor gives the opinion of a most eminent chemist, "who says that he cannot imagine any chemical agency in the stomach or honey-bag of the bee." I am no chemist, still I think I know as much of it as to say, that I cannot see why there should not be a chemical agency exerted either in the act of the bees taking the sugar syrup into their stomachs, or in the stomach itself. Still that is mere opinion without any proof, but I will now endeavour to prove that it is chemically changed.

Every chemist knows that the term sugar is applied vaguely to any sweet substance of animal or vegetable origin; but such are generally divided into the saccharine or fermentable substances which form alcohol, as cane sugar, grape sugar, milk sugar, &c., and the unfermentable, such as manna, gelatine, glycerine, &c.

The chemical composition of cane sugar, or that which is given to bees, is carbon 12 equivalents or atoms, 11 of hydrogen, and 11 of oxygen. Grape sugar, again, or that which is sometimes called the sugar of fruit, represented by that seen on the dried grapes and figs which come from abroad, is composed of carbon 12 atoms or equivalents, hydrogen 12, and oxygen 12. Honey belongs to this class, and is composed of these elements—Cane sugar, carbon 12, hydrogen 11, oxygen 11; Honey, carbon 12, hydrogen 12, oxygen 12.

Honey, then, it will be seen, contains the elements of one atom more of water than cane sugar. It, therefore, requires no great stretch of the imagination to conceive that the bees may have the power of adding one atom of oxygen, and one of hydrogen to the sugar syrup in the stomach. However short the time it is in the honey-bag, we know how fast the oxygen of the atmospheric air when inspired into the lungs by man or

animals is expired again in the form of carbonic acid gas—we know very well that the carbon is supplied along with the food taken by man; but how the carbon and oxygen combine to form carbonic acid is not so well understood, although the fact remains the same, and the bee has only to convert or decompose the water in the syrup into its elements of hydrogen and oxygen to change cane sugar into grape sugar, or honey, and no one will doubt of the many wonderful powers the Creator has given to the animal kingdom which we never shall be able to understand.

But there is another classification of sugars which throws still more light on the subject, and can be satisfactorily tested by Dubosey's saccharometer, a very ingenious instrument invented for the purpose of testing the kind and also the quantity of sugar in the several sorts of beetroots used in France for the production of sugar. With one of these instruments I went through a pretty extensive set of experiments a few years ago for my employer, to find out the turnip which had the greatest amount of sugar in it, and if possible to improve the feeding properties.

Some of your readers will doubtless, as I did at the time, scratch their heads at the idea of there being any sugar in a turnip; but "seeing is believing" they say, and I have now whiskey or alcohol beside me which I made from both turnips and beet.

It was during these investigations, that I was led to inquire into the nature of honey, or rather to find out what was crystallisable and uncrystallisable sugar. Cane sugar is the representative of crystallisable sugar; and grape or honey sugar, that from turnips, beet, &c., uncrystallisable.

Dubosey's saccharometer is, then, the instrument which infallibly points out whether it is uncrystallisable or crystallisable sugar which is present in the liquid under examination.

It would be difficult without drawings to give a clear idea of the instrument. I may just observe, that the principle on which it is constructed, is the variations in colour which two prisms when moved give to any transparent liquid containing dissolved crystallisable bodies. Those having a polarised microscope with prism for examining the crystals of nitrate of silver, selenite, &c., will have some idea of it.

When examining the juice of the turnip I found the instrument-scale was reversed from that when looking at a solution of cane sugar, not knowing at that time that there was such a thing as uncrystallisable sugar. On making inquiries I was told that treacle was; but on purifying it, I found it gave indications of both crystallisable and uncrystallisable sugar, showing that the manufacturers had not been able to extract all the crystallisable sugar. I was then told that honey was; and to it I went, and found it to be pure uncrystallisable sugar.

A friend of mine, a chemist, was paying me a visit some time afterwards, and he was very much interested in my bees, and their works, but knew nothing about their habits, and he saw me feeding them with sugar syrup, and he said, "Why don't you give syrup of sugar that is sold by the manufacturers, which is uncrystallisable, and the bees will be saved the trouble of converting the crystallisable syrup of sugar into the uncrystallisable sugar syrup?" Neither he nor I was aware that there was any dispute on the subject. I got the syrup of sugar, it being much cheaper, and was rather a little exalted on the hint I had got; but I found the bees were better chemists than my friend, for they would not take it but in very small quantities. Here, then, is a liquid chemically the same as honey, only not so transparent, which they will not take, and which is still like their natural food. So that I was compelled to resort again to that made from pure sugar. And last year, having a glass top on one of Neighbours' hives which was not filled, I gave the bees as much sugar as they would take night and day, and kept the hive well covered to keep them warm, as the weather was cold they could not get any honey out of doors, but they made combs and filled them with honey from the sugar. To test whether it was different from the syrup made from the sugar when in the combs, I took some and placed it in the instrument, and found certainly that the crystallisable sugar had been converted into the uncrystallisable.

The experiment was made when I had not the slightest idea that I should ever require to make it known as I have now done, for I have no doubt as to the fact myself. Others may say that I was not particular to prevent the bees from getting other honey than that from the sugar. I admit it to be a very proper objection; and to set the matter entirely at rest, having the

instrument that will enable me to do so, I shall be very glad to repeat the experiment in any way your apianian friends may suggest.

Since I began to write this, I have been thinking the best way to set the matter at rest would be to give the sugar to some bees and kill one which had just filled itself with the sugar, take the contents of the honey-bag and examine it, which will be quite sufficient to give the result, and surely none will be able to dispute the correctness of that test.—ALEX. SHEARER, *Yester*.

### THE CROSS BETWEEN ENGLISH AND LIGURIAN BEES.

THE various queries on this subject, which were propounded by "W. H." in page 427 of the last Volume of THE JOURNAL OF HORTICULTURE, are, I think, satisfactorily answered by the following communication from Herr Menzel, which I find in a recent Number of the German *Bee Journal*.—A DEVONSHIRE BEE-KEEPER.

"As German and Italian bees are now generally considered not as different species, but as varieties of one and the same species, it may be advisable not to call the offspring of a true Italian queen and a true German drone, and *vice versa* bastards; but according to the proposal of Professor Wagner to call them either hybrids or mongrels as the most eminent nomenclators have named our domestic animals. A queen descended from a pure race but impregnated by a drone of the other species I would call "a cross-mother;" an Italian queen if she be descended from a true Italian mother, and is impregnated by true Italian drones "an Italian race mother;" therefore I would distinguish—1, Italian and German racemother; 2, Italian and German cross-mothers.

"It is known that the drone-offspring of an Italian cross-mother are true Italians, as also the drone-offspring of a German cross-mother are true Germans; but the worker-offspring of both consists of mongrels or hybrids, although in their outward appearance individual bees may sometimes bear the character of the mother, and sometimes that of the father in colour and habit.

"The impregnated daughter of a cross-mother I would call a mongrel-mother, and that of a mongrel-mother a tierce-mother, and in this manner we should get quadroon and quineroon-mothers.

"In like manner the drone and worker-offspring might be called mongrels, &c.; but the drones would always stand one degree behind the workers. It is not, however, easy to pursue the gradations of these minglings beyond the mongrel-mother, neither would the doing so be of much practical importance.—A. MENZEL."

### OVER-FEEDING BEES—BEES AS CHEMISTS.

YOUR correspondent "G. F. B.," seems to think it is a work of extravagance to feed bees where the weight is 10 lbs., having always found hives containing that weight prosper better than those which are made up to 20 lbs. by artificial feeding or otherwise. This opinion I am not able to endorse; twenty years' experience leads me to a contrary conclusion. Bees well fed in autumn and again in spring to make up any deficiency, at which latter period I am satisfied there is an extensive drainage upon their stores, throw off earlier and larger swarms, the first and second week in June, sometimes in May, than those stocks which are but scantily provided, for in the latter case I have invariably noticed the swarms are sent out in July, much too late to do good. True, there is no rule without an exception, but a liberal supply of Mr. Bevan Fox's mixture judiciously given makes a visible improvement in all stocks requiring aid, and I say such is needed where the weight does not exceed 10 lbs. With due deference to your correspondent's opinion, to whom I tender my thanks for having mooted the point, I think he has not taken into consideration the difficulties and dangers a stock of bees left with only 10 lbs. is surrounded. The queen of those hives possessing abundant stores and escaping that curse—damp, for it destroys more bees than any other enemy she has to encounter, commences her work of laying much earlier than one with a narrow stock of provisions, although hives weighing 10 lbs. in autumn would not be in danger of starvation in spring. Plenty, like poverty, acts upon bees in a similar manner as it does in other parts of the creation. The more mouths to fill, the more is required. I examined a stock of bees of a friend in February last, and found them all dying, not an ounce of provisions left. The evil was manifest, and past reparation. I warned the proprietor in the autumn that although it possessed what he thought enough—viz., 12 lbs., yet it would be short in spring,

\* The original German bee is identical with the common English species.

† The use of the plural in this case would appear to indicate that the writer is of opinion that a queen bee may require the services of more than one drone.—A DEVONSHIRE BEE-KEEPER.

as such a population I seldom witnessed, and he had the mortification of discovering a fine colony smitten down for want of timely aid. The bee is a great economist, and does not throw herself open to the charge of prodigality, not a single ounce of food properly administered is ever wasted, and the only want of foresight which I can discover, and I have taken some pains to do so, is the great profusion: she will at certain periods of the year, and for what purpose I am unable to say, gather immense quantities of pollen. A populous hive well stored in spring is much more active than one otherwise situated. I, therefore, recommend all who value these little slaves to care for this important point (as one of magnitude to their welfare), not to leave them with such a scanty supply of food as recommended by your correspondent, assuring him I shall not do so unless I can see more clearly its practicability.

Your intelligent correspondent the "DEVONSHIRE BEE-KEEPER" is very busy on the subject, which at present appears undetermined and engrossing considerable attention—namely, Whether bees effect a change in the liquid they take so as to convert it into honey. Although I am no chemist, my opinion as at present constituted leans against him, and for the following reason:—I lost a hive of bees through the effects of my old enemy "damp," last winter, and which in the autumn had been fed on the syrup recommended by Mr. Bevan Fox; and in order to make an examination of the comb, I cut out one therefrom which was regularly sealed over. My investigation of the comb plainly demonstrated real honey in that which had been gathered from the pasturage, and the syrup which was distinguished by the rum and salt added in the making, and which was as much different as possible from the honey. I kept it for some weeks in separate vessels, and this spring presented it to my bees placing the same before the apiary, when, strange to say, the real honey was preferred before that which I considered nothing but syrup, and which was only taken when every particle of honey was gone. If the hive is not broken up (having given it to a friend for scientific purposes), I will endeavour to procure a piece of the comb, and if Mr. Woodbury desires forward it to him.—BAR-HIVE, *Nantwich, Cheshire*.

### OUR LETTER BOX.

RABBIT-KEEPING (*Rabbit Fancier*).—In the twenty-fifth Volume of our First Series you will find very full directions for making an enclosure for keeping and feeding Rabbits. No breed is more profitable than the Chinchillas. They are excellent for table purposes, and the skins sell for a high price.

YOUNG HIMALAYAN RABBIT (*Lapin*).—The long white-furred young one from the Himalayan doe is merely an evidence that there is some Angora blood in the breed, either the buck or the doe was of a cross-bred pedigree. We can only advise you to advertise what you wish to sell. One of the parties you name you had better be careful in dealing with.

PUTTING A SUPER ON A COMMON STRAW HIVE (*A Labouring Man*).—In order to place a super on a common straw hive, it is necessary first to form a platform on the top of the hive on which to rest the super, and secondly to make an aperture for communication. Prepare first a piece of three-quarter-inch yellow pine 12 inches or 14 inches square, by cutting a hole in the centre 2 inches or 3 inches in diameter, and screw a couple of stout pieces of wood across the grain on the underneath side near the ends to prevent warping. Next fit this square platform to the top of the hive by paring away the wood round the hole on the lower side until the edges are quite thin and fit close to the straw, and screw three or four inch-and-a-half wood screws into the underneath side round the hole at 3 inches distance from it. These screws should not show through on the upper side, but project an inch below. In order to attach this platform to the hive get some mortar well mixed with a little cowdung and plaster over the top, leaving a flat surface to receive the platform which is to be bedded upon it. The mortar when dry will adhere firmly to the straw, and the projecting screws will give it a fast hold to the wood. As soon as it is set, cut a circular hole in the straw crown of the same size as that in the wooden platform, and the job is complete. Supers should not be put on immediately. Get our "Bee-keeping for the Many," price 4d. (free by post from this office for five stamps), and effect antimonial unions in the manner described in pages 42 and 46.

IS ZINC INJURIOUS TO BEES?—TIME FOR PUTTING ON SUPERS (*A Hortfordshire Bee-keeper*).—The perforated zinc over the entrance will certainly do your bees no harm. When the hives appear crowded no time should be lost in putting on supers. If made of zinc and glass they will require efficient external protection in order to moderate changes of temperature.

KEEPING A PONY (*Decrepit*).—We know a pony which is kept through the summer on a quarter of an acre of good grass land, like yours. He is confined in a railed-off sheltered corner, about 20 yards long and 5 yards wide, with a shed to retire under in bad weather. The grass is mown and brought to him, being placed in an old crate for him to take it from. The plot, from which the grass has been cut for the pony's day's consumption, is watered with the house sewage immediately, and the whole is kept irrigated with the same sewage two or three times weekly. The grass is ready for cutting at one end, as soon as it is finished cutting at the other end. As you have half an acre, one quarter acre might be kept for hay; and, if well irrigated, would give two crops annually.

WEEKLY CALENDAR.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 64.9° and 41.9° respectively. The greatest heat, 86°, occurred on the 15th and 17th, in 1835; and the lowest cold, 23°, on the 15th in 1850. During the period 146 days were fine, and on 99 rain fell.

A FEW ADDITIONAL NOTES ON CYCLAMENS.

HAD no intention of intruding further on the columns of THE JOURNAL OF HORTICULTURE, respecting Cyclamens, had I not laid my hands on a document since I last wrote, indicating the native habitat of Cyclamen vernum. This I was satisfied I ought to possess, yet not finding it amongst my other papers at the time I was

writing, did not feel justified in quoting from memory, making it a rule when writing for publication to be as certain as possible of my facts (a caution which I would respectfully submit Mr. Beaton might with advantage impress on his correspondent, in addition to his other good recommendations, when writing on any subject for the information of others).

On the authority of Reichenbach, Cyclamen vernum is a native of the south of Europe; and whilst writing, accidentally turning to Loudon's "Hortus Britannicus," I find he also gives the same locality for it. These testimonies will, I trust, be satisfactory to most, though I may not be able to convince Mr. Beaton, after the strong opinion he has already expressed.

With regard to Cyclamen ibiricum, I cannot see any valid ground for regarding it a hybrid. Its very name points out its native habitat—Iberia (Georgia) N.E. of Palestine—and I have little doubt if Mr. Beaton will send his "commissioner" there, and he be diligent in his search, but he might return with a good supply of it, and probably other good things. I have had repeated importations of the tubers of C. ibiricum, and have not the slightest reason to doubt their coming from the locality indicated. I do not state it as a fact, but consider it extremely probable, that Goldie received it through his Russian friends, as he certainly did some other good and scarce plants. With respect to C. vernum and ibiricum being produced almost, or quite, pure with C. Atkinsii, I think it easily explained by those who know how freely the latter and its varieties hybridise with all this section—so much so, indeed, as to have in a great measure displaced from cultivation the true ibiricum as imported; many of these so crossed having a much larger and broader petal, with more diversity of colour than the original, are by most preferred before it (though some of the native varieties are beautifully clear and dark, and are botanically interesting). I have reason to know that with one party at least, from whom some of the London nurseries occasionally draw part of their supplies, as well as with myself, the varieties thus produced are endless. Amongst others I have the white petal of C. Atkinsii with the pure dark green and shape of

C. coum foliage, though in the first instance Mr. Atkins has stated in the "Garden Companion" for June, 1852, (where C. Atkinsii was first figured), "that he found every plant deviating in the markings from the seed-bearing parent (coum), produce white or blush flowers, whilst those retaining its plain dark leaf invariably bloomed with different shades of the colour of that species."

As the time of blooming seedlings from pet plants is always anxiously looked forward to by amateurs, I am glad to see by the reply to "E. W.," in the Journal for April 22nd, page 71, that the period to bloom those of C. persicum is now reduced. It is but a few years since a writer on this tribe gravely stated six to seven years were necessary; but in the reply above alluded to, about two and a half are mentioned (two years and two months in the seed-pot, and then potted-off singly for blooming). On both of these I have made an advance, blooming them and also other kinds in sixteen to eighteen months from the time of sowing the seed. My plan is to sow the seed as soon as ripe in shallow pots or pans well drained, give a good watering, place a little moss lightly over the surface of the soil to insure uniform moisture, and put them into a cold pit or frame. As soon as the first plants make their appearance remove the moss gradually to prevent the plants being drawn up weakly (which I should fear the inverted pot as recommended by Mr. Beaton would be very liable to do). As soon as the seed-leaf becomes firm enough to handle without danger of bruising, transplant them into nursery-pots or pans about an inch or so plant from plant. Keep them in the cool frame or pit with a moderate supply of water and abundance of air in all favourable weather for the winter, but protect from frost; as the spring advances encourage their growth by more liberal watering, occasionally over the foliage (but I do not mean sodden or drown them). Give plenty of air in all genial weather, and occasionally shade from the hot sun. Keep them thus growing, but as summer advances leave the lights off during the evenings, nights, and early mornings, only using them in unfavourable weather; and in order the more easily to shade them when necessary from the full sun, towards July or August reduce the moisture, and expose them more freely to the full sun and air for a couple of months, then pot them singly, and if they do as well as mine many will bloom the following spring. There are some tubers now growing here sown as soon as the seed was ripe last summer, which at the present time measure fully three quarters of an inch in diameter. By leaving seedlings long and thick in the seed-pot you have another disadvantage. It is well known that many of the choicest varieties of seedlings are frequently the weakest growers: therefore have but a poor chance to escape from being smothered or deprived of their due share of nutriment by their more sturdy brethren.

I believe there remains much to be done with Cyclamens, not only in improving the bloom, but also as foliage plants; some of them are extremely beautiful, and would rival many of the more tender plants in that

respect. I have of late paid some attention to this, and already raised some beautiful varieties. The more hardy ones especially are invaluable during the winter, when their foliage is in the height of its beauty.

I herewith send you a specimen of a seedling which has been growing out of doors in an exposed situation all the winter without the slightest protection, and just now dying down. The size you will see is very large, and when in vigour the substance very thick and wax-like; ground colour an intensely dark holly green with light markings.—[The leaf is marked somewhat like *Begonia Rex*; is heart-shaped, 6 inches long from apex to point of lobes, and 5 inches broad across the lobes.—Eds. J. or H.]

Mr. Beaton must excuse me for saying I fear he does not always practise the advice he gave to his correspondent, when writing for publication, or he would have perceived and corrected what I presume are unintentional errors in his review (April 22nd) of the previous Number. He therein twice speaks of *Cyclamen sibiricum*, though I expect he means *ibericum*, and also of twelve miles beyond *Genoa* instead of *Geneva*, as the locality from whence the tuber of *C. europæum* came, sent to him by "T. C.,"\* though he has once before had to correct the latter error; and, again, I cannot comprehend what he means when he says "no doubt the *vernium*, on travelling as far north as Naples, &c.," whilst he doubts *vernium* having any native habitat, unless it should have been written *C. repandum* (*hederæfolium* of some authors), that inhabiting the districts of country alluded to.

My attention has also been called to the period of flowering of *Cyclamens*, as given by Mr. Appleby in his arranged list of herbaceous plants in the *Journal* of March 11th, page 472, wherein he puts *C. neapolitanum* as an April bloomer, whilst it is universally allowed to be an autumn one, and *europæum* as March, whilst that is essentially a summer species; both kinds being at the periods named just retiring to rest instead of blooming, and I fear *C. vernum* and *repandum* planted for April would disappoint, the former being generally over by that time, and the latter (except under protection) scarcely early enough. These errors uncorrected are much to be regretted, as tending to perpetuate the confusion which has so long prevailed amongst the species of this beautiful tribe of plants.—J. A. P.

### THE GENUS CROCUS.

The following is an alphabetical descriptive list of species and varieties of wild Crocuses, with the authorities for the names, references to published figures of them, and the native places where they have been found:—

1. *CROCUS AERIUS* (Herbert). *Sibthorpianus* (Bot. Reg., 1845, Misc., 5). Native of Bithynian Olympus, in the pass from Trebizond to Stauros, which is choked with snow till June. Only known yet from dried specimens, in which the flower is very rich. Nearly white, with a yellow bottom, and without a sheath. Closely allied to *boryanus* and *ochroleucus*—two beautiful winter or late autumnal-flowering kinds.
2. *C. ANNULATUS* (Herb., Bot. Mag., 1841, 3861, p. 4; Bot. Reg., 1843, Misc., p. 26). Native of the south-east of Europe, from Italy to the Caspian, in ten varieties and four subvarieties. The latter are omitted.
  1. *Biflorus*, Scotch *Crocus* (Miller, Bot. Mag., 845). Native place uncertain.
  2. *Adamicus* (Herb.). *C. Adami* (Gay, in Bulletin de Ferussac, 25, p. 219). Native of Caucasus.
  3. *Nubigena* (Herb., Bot. Reg., 1843; Misc., p. 81). On the top of Mount Gargarus.
  4. *Purpurascens* (Herb.). Sent him from Dalmatia.
  5. *Albus* (Herb.). From Obschina, near Trieste, on the Austrian side.
  6. *Pusillus* (Tenore). There are three subvarieties of it.—Naples, Parma, and the Roman States.
  7. *Cerulescens* (Herb.) From the neighbourhood of Naples.
  8. *Extriatus* (Herb. The *biflorus* of Bot. Reg., 1937). Found near Florence.
  9. *Tauricus* (Herb.). A fine bluish-purple-streaked kind from Odessa.
  10. *Græcus* (Herb., The *biflorus* of Bory de St. Vincent). From Nauplia.

This *Crocus* is best known by the garden plant named Scotch

We have a communication from "T. C.," in which he points out this error. His communication will be published next week.—Eds. J. or H.

*Crocus*. It is easily known by its smooth hard bulb-coats, its yellow throat, and undivided fragrant stigmas; by the deep yellow sheaths which envelope the leaves when it first pushes, by all the sorts having five streaks on the sepals, or three outer petals, except 6, which has three only, and the strong pubescence of the throat and filaments, characters peculiar to all the varieties. The Scotch *Crocus* is quite sterile, and the seeds marked biflorous and sent here from Italy produced the variety 6 only. The variety 2 is a most beautiful flower of a bluer tint in its purple than any *Crocus*. Much variety and beauty in cultivation may be expected from variety 3. A variety from Pisa of 6 is naturalised in Barton Park, near Bury St. Edmonds. They are all spring Crocuses, from deep bluish-purple to pure white.

3. *C. ASTURICUS* (Herb., Bot. Mag., 3998, f. 2). From the maritime hills of Asturia in Spain, near Gijon and Santander. Its offsets are produced on runners like those of *C. pyrenæus*, to which it has been likened, but from which it differs in a bearded throat, a deeper purple, and flowering at least a month later. It was raised by Dr. Herbert from a single seed, which fell out of a specimen in Sir William Hooker's herbarium, which had been mistaken for *pyrenæus*. This is a very beautiful purple October *Crocus*.
4. *C. BORYANUS* (Bory de St. Vincent; Gay, in Bulletin de Ferussac, 25, 220). *Ionicus* (Bot. Reg., 1845, Misc., 3; ditto, 1847, 16, figure 10). *Veneris* of Tappeiner, and *Caspicus* of Fischer's herbarium. This is a most charming little *Crocus* for November, and one of the most easily to be had of all the wild Crocuses, being a native of most of the Greek islands, the Morea, and on to Asia Minor. It is found in Corfu, Sta. Maura, and Zante. The best variety of it is on Mount Skopo, in Zante, producing from the same eye sometimes five flowers, and even three at once; and it is the only *Crocus* known which exposes the seed-pod out of ground while in flower. The flowers at first are cream-coloured, then white, with an orange throat, and in some of the wild forms of it there are purple streaks on the outside; it is one of the few Crocuses which are remarkable for their lily-white anthers. There is a good figure of it in the "Magazine of Botany" for 1850, page 273, and the editor, Mr. Moore, now Secretary to the Floral Committee, gives there the whole treatment of autumnal Crocuses for the drawing-room, and you ought to see it.
5. *C. BYZANTINUS* (Parkinson, Paradisus, 168; Ker, Bot. Mag., 1111, p. 2; Bot. Reg., 1847, 4, f. 5). *Banaticus* of Gay. (Bull. Fer., 25, 220). Native of thickets in the Banat, and in Wallichia near Krajova. Parkinson had it from Turkey. It is the speciosus of Reichenbach, and the *iridiflorus* of the same and of Dr. Heuffel, flowering in October. This beautiful October *Crocus* is very remarkable from its purple style, the size of its spreading sepals, and the smallness of its erect pale petals, with the points a little recurved, and marked with purple lines, which give it the semblance of an Iris: hence the *iridiflorus* name by the Hungarian botanists. A deep violet purple flower.
6. *C. CAMBESSEDEANUS* (Herb.). *Cambessedesii* (Gay, B. F., 15, 220; Bot. Reg., 1845, t. 57., fig. 4). Native of Majorca. A "very remarkable and pretty little autumnal *Crocus*."—Herbert, who described it from dried specimens.
7. *C. CAMPESTRIS* (Pallas, in Lambert's Herbarium). *C. montanus* (2 Cusius). Native of Roumelia, on the hills near the river Marissa, and believed to be a variety of *Cartwrightianus*.
8. *C. CANCELLATUS* (Herb., Bot. Mag., 1841, 3864, p. 2; Bot. Reg., 1843, Misc., p. 30; ditto, 1845, Misc., p. 81). A pale white or violet flower, of which there are three named varieties from different places. 1, *Kotschianus* (Herb.), with a violet limb, named after Mr. Theodore Kotschy, who found it on the summit of Bulgar Dagh, behind Tarsus, and stretching towards Kurdistan; 2, *Margaritaceus* (Herb., Bot. Reg., 1846, Misc., 74, ditto, 1847, 16, f. 4). Native of Nauplia; 3, *Mazziaricus* (Herb., Bot. Reg., 1845, Misc., p. 3, and 82). Flowers in October in Sta. Maura. This very florid *Crocus* "purples the ground" on the ridges of Mount Taurus at the end of summer and early in the autumn. The other varieties are not so fine.
9. *C. CARPETANUS* (Bossier and Reister). Only known by their description in the "Flora Lusitanica."

10. *C. CARTWRIGHTIANUS* (Herb., Bot. Reg., 1843, Misc., 131; ditto, 1844, f. 3; ditto, 1845, f. 37, b.). A very beautiful autumnal Crocus, bloomed at Spofforth as late or as early as January. The flowers are white, suffused all over with purple, more or less starred inside with purple lines. One "root" had a pure white flower. There is a good figure of an intermediate shade of it in the "Magazine of Botany," page 273. It was named after Mr. Cartwright, British Consul at Constantinople, who procured it from the islands Teno and Seyro, where it flowers in October, November, December, and January. Of all the Crocuses this would be by far the most valuable breeder. It is inclined to a considerable degree of variation in these two islands; and there is a variety of it near the town of Canea in Candia, with the sepals pale yellow externally (see Bot. Reg., 1845, 37, fig. 7). The flowers are fragrant, and have the great merit of expanding easily, and not closing again willingly even in cloudy weather. This, then, is the type plant for an entire new race of Crocuses to bloom in the dead of winter, spreading from the shortest day back to October on the left, and advancing on the right to meet the spring-flowering race.
11. *C. CLUSIANUS* (Herb., Bot. Reg., 1845, 37, f. 8; ditto, 1843, Misc., p. 32). *C. montanus* (1 Clusius, Gay, B. F., 25, 220). This is the farthest-west kind of Crocus, being a native of near Cintra in Portugal, blooming here in September, with a dark yellow throat to a purplish flower.
12. *C. CHEYSANTHUS* (Herb., Bot. Mag., 1841, 3862, p. 2; Bot. Reg., 1843, Misc., p. 27). A very early yellow spring Crocus, native of Macedonia and Thrace, on low mountains near Rhodope and the Despoto Dagh, flowering in February about the village of Carleva.
13. *C. DAMASCENUS* (Herb., Bot. Reg., 1845, 37, fig. 1). An autumnal species from limestone mountains near Damascus, where the Arabs cook and eat them. It is rather a pretty purplish flower.
14. *C. FLEISCHERIANUS* (Gay, B. F., p. 219, 1827). A very florid Crocus with white flowers, slightly streaked on the outside. From the limestone hills of Smyrna.
15. *C. GARGARICUS* (Herb., Bot. Mag., 1841, 3860; Bot. Reg., 1843, Misc., p. 30). *Crocus aurea* of Clarke's "Travels," 1812, who called it aureus. A very ornamental species from the top of Mount Gargarus, flowering earlier in the spring than *lagenæflorus*; the flowers deep golden yellow, and produced seeds at Spofforth. Dr. Clarke's specimens were all citron colour. He and others found several fine kinds on the summit of Mount Gargarus.
16. *C. HADRIATICUS* (Herb., Bot. Reg., 1843, Misc., 77). There are two varieties of it—1, *Chrysobelonicus* (Bot. Reg., 1847, 17, f. 8, 9), from Santa Maura, flowering in October; 2, *Saundersianus* (Bot. Reg., 1847, 17, f. 7), from the hill of Bisdon, where the ancient Dodona once stood. The flower is white, with a deep golden throat, which is sometimes stained with dark livid reddish-purple on the outside. A fine species. Var. 2 was gathered by Mr. Saunders in December, near Janina. Var. 1 is from the hill called Chrysobeloni, in Sta. Maura.
17. *C. HEUFFELIANUS* (Herb., after Dr. Heuffel). A species closely akin to *vernus*, from the Northern Banat, flowering in damp wood in February and March.
18. *C. IMPERATORNIUS* (Herb., Bot. Mag., 3871, p. 2). *Imperati Tenore* (Bot. Reg., 1933). A fine species, varying with flowers striped and white. Native of lofty mountains in the south of Italy, as Monte Pollino, in Calabria, at an elevation of 6000 feet.
19. *C. INSLARIS* (Gay, B. F., 15, 221; Bot. Mag., 3871; Bot. Reg., 1843, f. 21). This species varies from yellow to straw colour in the north-east of the island of Corsica. It also occurs in Sardinia and in Capraria, and is akin to *suaveolens* of Italy. It bears seeds freely in England, and varies so much that two kinds cannot be found exactly similar—a good character for a good and valuable parent.
20. *C. INTROMISSUS* (Herb., Bot. Reg., 1845, Misc., 2). This was found with *Damascenus*, and died without flowering.
21. *C. LEVIGATUS* (Bory de St. Vincent, Voyage de la Morée). *Vernus* (Smith's Prod. Fl. Græc.). This species is almost white with a yellow throat, and with purple streaks outside; but it abounds with much variety of colour in the Morea, near the quarantine station of Zeitun; also in Thermia Melo, and on Hymettus.
22. *C. LAGENÆFLORUS* (Salisbury, Parad. Lond., 1805). This beautiful Crocus—branching into a great number of wild local varieties, from deep yellow to white, either unstreaked or with dark blue streaks on the outside of the tube and base of the limb—extends from the Banat of Hungary, over the Balkan, to Rhodosto and Constantinople, thence to Gargarus and Chios and other islands, and to Bithynian Olympus. In all these places all the kinds were found deep in the ground, much deeper than other Crocuses. Dr. Sibthorp found *aureus* deep in sand upon clay. Treated with very light soil, it produces seeds abundantly in England, but upon sandstone, or in a damp situation, it does not thrive, and often perishes. The breed of *versicolor* has well nigh banished from our gardens the yet richer race of this *lagenæflora* (*lagenæ*, a flask), of which there are nine wild varieties and as many subvarieties. The latter are not here enumerated.
1. *Aureus* (Smith, Prod. Fl. Græc., 1, 24; English Bot., 2646, and Bot. Mag., 2986).
  2. *Striatus* (Ker, Bot. Mag., 938).
  3. *Stellaris* (Haworth).
  4. *Syriacus*.
  5. *Luteus* (the *vernus* of Bot. Mag., 25). This is our "Large Dutch Yellow Crocus," which is barren.
  6. *Oliverianus* (Gay). From Chios, and at Rhodosta in Roumelia.
  7. *Hæmicus* (Herb., Bot. Reg., 82). From Mount Hæmus, near Adrianople.
  8. *Landerianns* (Herb.). From the Troad, through Mr. Lander.
  9. *Candidus* (Clarke's Travels, 1812). From Mount Gargarus.
23. *C. MEDIUS* (Gay, B. F., 1827, pp. 8 and 9; Bot. Reg., 1845, 37, fig. 5; Bot. Mag., 3871, p. 4). This is a great acquisition to an English garden. From east and west Liguria. First sent by Sir Augustus Foster, from the Ligurian Varese. The flower is large and very conspicuous, flowering from the end of September. Purple and violet, and ripened seeds at Spofforth.
24. *C. NIVALIS* (Bory, Voyage de la Morée). *C. sublimis* (Herb., Bot. Reg., 1843; Misc., 73; ditto, 1847, 4, fig. 2). On Mount Delphi, in Eubœa, and a larger variety on Mount Corydallus, near Athens. D. BEATON.

(To be continued.)

## ROYAL HORTICULTURAL SOCIETY.

MAY 6TH.

FRUIT COMMITTEE.—Mr. Edmonds in the chair. Prizes were offered at this Meeting for desert Apples, Peaches, Nectarines, Melons, Strawberries, and Cherries, and strange to say there were no exhibitions in either class, except in Peaches, notwithstanding the liberal prizes that were offered. Is it that the competitors for horticultural honours are reserving their strength for the great contests that are forthcoming?

Mr. Hall, gardener to Capt. Tyrrell, Fordhook, Ealing, sent some dishea of kitchen Apples, including Bess Pool, Dumelow's Seedling, and French Crab.

Mr. Thomson, gardener to his Grace the Duke of Buccleuch, again sent a bunch of Lady Downe's Grape, merely to show what like Grapes were that had hung from the autumn and through the winter and spring till May. From the old wood young shoots had begun to appear; the rising sap had flowed equally into the bunches as into the young shoots, and burst the berries, which in consequence had mostly become mouldy; there were some, however, that had resisted the force of the sap, and these were quite sound and excellent in flavour.

Mr. Carmichael, gardener to the Countess Dunmore, at Dunmore Park, near Stirling, was the only competitor for the prize for Peaches. He exhibited a dish of the Stirling Castle Peach. The fruit was very excellent, well grown, and of good flavour to be so early in the season, and the First Prize was awarded to it. This Stirling Castle Peach seems to be a very excellent one for early forcing.

Mr. Melville, of Dalmeny Park Gardens, near Edinburgh, sent three heads of his Late Broccoli, one of which showed a very large head, and the other two were not much developed. The opinion of the Committee was, that this was a very good stock of Invisible Late White Broccoli.

**FLORAL COMMITTEE.**—The Rev. J. Dix in the chair. There was a mass of new plants before this Meeting, and a full attendance of members of Committee. After appointing Sub-committees for judging new plants, the florists' flowers, and garden seedlings at the exhibitions of the Society in May and June, the Committee resolved not to hold their separate Meetings till after the summer exhibitions were over in July. All those, therefore, who intended to submit their novelties for the awards of the Committee will have to take the opportunity of those exhibition days for doing so.

Mr. W. Barnea, nurseryman, Camberwell, sent three plants of a handsome new variegated Azalea, which had a Certificate of recommendation; the redeeming point being the superior style of growth to that of this section of Azaleus.

Mr. Standish began a large assortment with two kinds of Weigelas, Van Houtte and Stelzneri, the latter, which is in the way of *amabilis*, had a Certificate of recommendation. Then his variegated Holly-like plant, called *Eurya angustifolia*, and which was before the Committee last year, from Japan, had a First-class Certificate unanimately; and his more Holly-like *Osmanthus ilicifolius variegatus* had a Second-class Certificate. A very beautiful *Retinospora pisifera aurea*, also from Mr. Standish's Japan collection, had a First-class Certificate. A Fern called a species of *Microlepia*, from China, from Mr. Standish, had a Second-class Certificate; and his *Ancuba picturata*, from Japan, was requested to be sent again, the imported plant being not in a fit condition to judge of its merits properly. He also sent plants of his May Queen *Epacris*, which were not thought to be superior to many others now in cultivation.

Mr. Kinghorn, nurseryman, East Sheen, sent a fine coloured seedling Azalea, called *Laxton's Red*. To be seen again.

Messrs. Veitch & Son came up with a host of very good things, and one collection of very bad things, which they sent on purpose to show that none of their new *Caladiums* are so good as the old ones, unless it may be one of them, which the Committee wished to see again when the plant is larger. They sent three kinds of lovely hardy Maiden-hair Ferns from the upper regions of Chili, approaching the *Arancaria* region. These stood out of doors all last winter at Exeter. The three kinds had each a First-class Certificate by nearly the unanimous voice of the eighteen or twenty members present. The names and the merits, in our judgments, stand thus—*Adiantum sulphureum* the best, *A. chilensis* next, and *A. scabrum* third.

The same firm sent a fine-looking double red *Petunia*, with white edges to the petals, called *Madame Rendatler*, which had a Second-class Certificate, and another not quite so good. Then came their collection of new kinds of *Begonias*, from which the Committee selected two for Second-class Certificates—namely, a comparatively small-leaved kind; the one, *Imperialis*, a dark purple, soft satiny leaf with light veins and markings; and a clear green-leaved kind, called *Smaragdina*, which is the Latin for emerald green.

After these the same firm had a most noble specimen of *Altasia cristata*, which Mr. Beaton described some years since as like a plant from before the Flood.

From Mr. Bunney was a specimen of *Cypripedium Lowii* with two flowers on the scape, and different from the usual state of the species. Then a gay but very small specimen of foreign *Azalea* from M. Verschaffelt, with a deep white margin all round the edges of the petals and half double, for which a Second-class Certificate was given.

Mr. Ferguson, Stowe, sent a most lovely single white *Petunia*, marked with five broad vivid stripes of purplish-red in every bloom. The whole of the Committee held up their hands for a First-class Certificate to that flower, which is called *Madam Ferguson*.

The Messrs. E. G. Henderson & Son, of the Wellington Road Nursery, sent a large assortment of their newest *Geraniums*, but in such small plants that none of them could be properly judged. Also a large specimen of *Rhododendron Dalhousii* in bloom, and a larger specimen of *B. Nuttallii* just going out of bloom; and a new lively low-spreading yellow-flowering plant, said to be a species of *Vella*, a greenhouse plant. Also a noble new *Swainsonia*-looking plant, with long spikes of stout violet purple flowers. Here also the Committee were unanimous in giving it a First-class Certificate. They sent word they had it from Australia as a *Chianthus*, and the specimens looked that way or as half between *Chianthus* and *Swainsonia*. It is the only pea-shaped flower we have ever seen of that shade of colour. They sent another very small specimen of variegated

Lime tree which the Committee thought very promising, and to which they would have readily given a First-class Certificate if the plant had been two years old instead of two-months grafted; as it was they gave it a Second-class Certificate.

Lastly, the Messrs. Lee sent a fine yellow hardy *Azalea* called *Altaclarensis*, a cross between the yellow *Sinensis*, the leaves of which it assumes, and some of the Belgian yellow *Azaleas*. This, on account of its free-blooming and hardiness, and particularly as likely to be one of the best to force early for the conservatory, had a First-class Certificate.

## NORTH AND SOUTH.

NOTWITHSTANDING the expulsion of Mr. Russell from the United States, and the consequent loss of accurate intelligence from the seat of the war, and in spite of the close blockade of the Southern ports, I have been enabled to obtain through a particular channel accurate information of a fierce, though, like most of the American battles, a bloodless fight, which took place no later than the 30th ult. The ground was remarkably well chosen, and the troops were drawn up under experienced commanders. The appearance of the Northern troops was, to an unpractised eye, poor and weak; while in physique the Southerners were remarkable for vigour of appearance and bold and daring countenances. But the result of the contest only showed how varied are the fortunes of war, and how little we can calculate upon results; for it resulted in the ignominious defeat of the Southern forces, one standard only of any importance remaining in the possession of the Southern army.

To drop all metaphor. The National Auricula Show was held on the 30th at the Royal Botanic Society's sixth spring Show, and the result was that the Northern growers carried off all the principal prizes. As a great deal will be said, doubtless, on the matter which ended in such unexpected results, I shall put the matter as it seemed to me. If correct, it will account for everything.

It has always been a great puzzle to me how the flowers which maintained their hold in Lancashire and the North generally did so, but it is no mystery to me now. And if the National Auricula Show (the first, and I fear the last), has done no other service, it has demonstrated this, that, wide apart as northern and southern amateurs are in their opinions as to Tulips and Pinks, they are equally so as to Auriculas—so wide, that I fear there is no possibility of their ever agreeing together. Taking an entirely different standard, they must ever come to opposite conclusions.

I shall not readily forget the burst of astonishment and something more when the gates were again opened, and the result of the adjudicators became visible. Some contending that, as the rules said three pips were to be the lowest number allowed, therefore the Judges preferred those with three.

Let me say at the outset that I never saw more thoroughly conscientious judging than that made at this Show. Nothing could exceed the pains and labour with which each flower was criticised; but, at the same time, it was done on what we in the South consider to be entirely a vicious principle, for with the Northerners the individual pip is everything. The size of the truss, the vigour of the plant, the general contour, in fact, goes for nothing. Thus, for example, in the class of eight varieties, Mr. Turner's plants, which obtained the second prize, were models of growth. They had fine large trusses containing ten, eleven, and twelve pips; while the collection which obtained the first prize had none more than five, some only three pips. The plants were in truth little more than offsets, but the judgment was entirely confined to the pips. Now, had any of the Southern exhibitors been aware of this, they could very readily have supplied very different plants to what they did; but to cut out a truss so as to leave only three never occurred to them as the right way to exhibit an Auricula. Oh, Dr. Plant, what would you have said—you with your Booth's Freedom with ten and eleven fine pips—your fine Conquerors and Glories?—you would never have had a thought bestowed on your fairest productions! I had wished previously that the Doctor would have sent us something to show what Auricula-growing is. I am glad for his own peace of mind that he did not; and for myself I can say (and I had nothing there from which I expected anything), that sooner than spoil my stage of Auriculas by such a barbarian process, I would give up growing them altogether. Let me see a nicely shaped truss, and there I can

recognise beauty, but not in a miserable starveling, like a Manx coat of arms, all on three legs.

I know the reply to this will be that of the three Judges two were Southerners. Most true; but notwithstanding this the judgment was on the Northern principle, and hence the North-crucers carried the day. Had it been reversed—had the Southerners taken off the prizes—I doubt not that the same strong feeling would have been evinced on the Northern side, and so I fear we must agree to differ; but this very fact will, I fear, entirely demolish any hope of such a reunion again until we can see with their eyes or they with ours. It must happen as it has done with other flowers, and the National Auricula Show be confined as much to them as would a Pink Show were such instituted. I do not write this in any feeling of disappointment as far as the mere fact of the prizes being obtained by Northern growers is concerned; for when I heard that the day was fixed for the 30th I felt that Mr. Turner and others had but little hope of success. But had they had ten times the amount of plants, and their plants been in the best possible condition, it would not have availed them one atom—it is the difference of taste, and there is the sum of the matter.

A good deal, too, of the interest belonging to a contest of this kind was spoiled by the owners not attaching the names of their plants to them: hence it is impossible to give (what to growers is over desirable), the names of the winning sorts. One judgment I believe both North and South acquiesced in—the giving of the premier prize in the Show to Mr. Headley's George Lightbody, which I at one time considered inferior to Lancashire Hero—a judgment I now entirely withdraw. It is a fine and excellent flower, although his plant of it was not in the fulness of bloom that he wished. Perhaps had it been so the Judges would not have treated it so well, considered it too large, &c. As it is, one must heartily congratulate so old and valued a florist upon his success. One other flower I must mention—Holland's Southern Star, apparently of the same family as Mrs. Starrock, but a good deal brighter, a real crimson; and when it becomes a larger plant will make a most striking figure on a stage.

The following were, I believe, the awards:—

Class A, FOR EIGHT VARIETIES.—First, Mr. Wilson, Halifax. Second, Mr. Turner, Slough. Third, Mr. Headley, Esq., Stapleford. Fourth, Mr. Douglas, York.

Class B, FOR FOUR VARIETIES.—First, Mr. Pohlman, Halifax. Second, Mr. Headley. Third, Mr. Elliott. Fourth, Mr. Cheetham. Fifth, Mr. C. Turner.

Class C, SINGLE GREEN EDGE.—First, Mr. Elliott. Second and Third, Mr. H. Wilson. Fourth, Mr. H. Stewart, York. Fifth, Mr. Pohlman.

Class D, BEST GREY EDGE.—First and Second, Mr. C. Turner, with Lancashire Hero and George Lightbody. Third, Mr. H. Stewart. Fourth, Mr. Pohlman. Fifth, Mr. Turner.

Class E, WHITE EDGES.—First, Second, Third, Fourth, and Fifth, Mr. Pohlman, Halifax!!

Class G, SELFS.—First, Mr. Elliott. Second, Third, and Fourth, Mr. Pohlman, Halifax. Fifth, Mr. H. Wilson.

PREMIER PRIZE FOR BEST AURICULA.—Mr. Headley for George Lightbody.

One cannot close a notice of the Show, however brief, without tendering one's warmest acknowledgments to Mr. Douglas, of York, for the great care and anxiety with which he has carried out the project, and for the urbanity and kindness he displayed to all who responded to the invitation.—D., Deal.

### GAS IN HOT-WATER PIPES.

WRITING on the above subject, in your Number of April 29th I think, Mr. Alex. Shearer made an error in stating that "there is no other gas which burns with a blue flame but hydrogen." If I mistake not, carbonic oxide does the same, and that gas is also formed when the vapour of water passes over carbon at a red heat, and coal dust is generally used by moulders in finishing a mould off. But is it not more likely to be hydrosulphuric acid gas, which also burns with a blue flame?

The following is a quotation from Gmelin's "Handbook of Chemistry," vol. ii., page 196. Speaking of the formation of that gas, he says it is formed "when organic compounds containing sulphur putrefy or are heated by themselves, or when other organic compounds are heated in contact with sulphur. If the existence of hydrogen-salts of metallic oxides be admitted, it must likewise be supposed that hydrosulphuric acid is generated when a mousulphide of an alkali metal is dissolved in water, and when iron filings are mixed with water and sulphur." Again, in same page—"Hydrosulphuric acid gas is collected over warm water or brine, which absorbs less of it than pure cold

water." Again, on page 200, speaking of its aqueous solution, he says, "Water at ordinary temperatures absorbs its own volume of hydrosulphuric acid gas. When heated it evolves the whole of the gas."

I do not know where the gentleman resides who first wrote to you on the subject, but is it not possible that the water used in the boiler might, like Harrogate water, contain this gas, and on being heated evolve it?—P. O. WHITEHEAD, *Holly House, Rawtenstall.*

### CONVEYANCE TO EXHIBITIONS OF CUT ROSES AND OTHER FLOWERS.

P. P. would feel much obliged by a little information with regard to the conveyance of Roses (cut trusses) by train for exhibiting, and whether the box that contains them should be air-tight or ventilated. The former, P. P. was under the impression, is most beneficial to the bloom, the moist atmosphere in the box causing the flowers to retain their freshness; but reading Mr. Beaton's article on the subject a few Numbers back, P. P. was surprised to find that Mr. Beaton made rather a point of the necessity of ventilation, to allow the perspiration of the flowers to escape. A box 15 inches deep, with 6 inches of moist sand at the bottom, the surface covered with moss, has been found to answer tolerably well, but the blooms get occasionally scratched with the leaves of the Roses, and the distance has been so short that it is scarcely possible to form an opinion as to the desirability of the box being ventilated. A few hints on this point from any reader of the Journal who has had experience in the matter would be thankfully received.

[Taking cut Roses, Dahlias, Asters, Hollyhocks, Gladioluses, and all the rest of them to exhibitions is a branch of packing which is altogether different from the packing of miscellaneous flowers, and leaves, and shoots for drawing-room decoration, and neither of the two ways recently described in these pages is applicable to your case.

When you can carry a box of cut Roses in your hand, or have them immediately under your own eye, such a plan as yours may possibly answer; but I should be very sorry to trust my chance of obtaining a prize to a box so arranged when much surer plans can be adopted. I have had some little experience in such matters—and, although not myself an exhibitor, carried for my friend, the Rev. F. W. Radclyffe, a box of blooms last September from Blandford to London without ruffling a leaf; and I think you will find the following plan effectually to answer your purpose. Your box should be made specially for them, the lid being sunk a little, so as to allow space for a layer of nice moss to be laid on the top. It should be perforated for the number of blooms you intend to show. The size now generally adopted is 18 inches in depth from back to front, and the length dependant on the number of flowers, though a box that will hold twenty-four blooms is the most convenient size. Where three trusses of each are to be exhibited, the holes should be made in triangles (· · ·), so as to allow each bloom a separate place. Each hole should have a zinc tube about 4 inches long with a flange round it, so as to keep it in its place, and the lid of the box should be fitted with hinges which easily slip off. So far from ventilation being required, the more air-tight they are the better; for where air gets in dust will also intrude, and no one knows how this penetrates everything in a railway carriage until they have experienced it. When you are ready for packing have your tubes well filled with water, the moss laid on the box and watered with a fine rose. Defer cutting your Roses till the evening, and then after sundown and before the dew falls, take what you require. Have ready some pieces of rhubarb-stalks cut in narrow strips. Place the stem of your Rose carefully in the tube, and then plug it in with the piece of rhubarb: this keeps it from shaking about, and prevents the water from being jolted out of the tube. Always carry a small watering-pot with a long spout, or an old teapot; and when you arrive at your destination let the first thing done be to look at your tubes, and see that they are filled with water, for a neglect of this is often fatal to an exhibitor. Roses sent in this way might, I think, be even entrusted to the tender mercies of railway porters, who seem to delight, when a box is marked "this side up," to turn it the other way. I took a box of Auriculas last month to Kensington; and at a station where I was obliged to change trains told the porter to wait until I came across the platform, as the box was to be carried straight. I came back

just in time to see it hoisted on his shoulder, and, of course, two of my pots turned over. Fortunately it was on their return journey, or my hope of a prize would have been of a very vague character. I believe that attention to these few rules will enable an exhibitor to convey his Roses without scratching or rubbing. Of course, care must be taken that the lid of the box is not too low, or else they will certainly be rubbed. And do not forget the watering-pot; for however anxious persons may be to oblige you, it is always better to be independent in such matters, and be able rather to help others than require to be helped. There is a glorious prospect for Rose-exhibitors this season; and with such weather as this that we are now experiencing, North and South will both be in time for even the earlier shows. Never had the queen of flowers so glorious a prospect before her.—*D. Deal.*]

I THINK the plans of Mr. Beaton, and "*D., Deal,*" are unnecessarily complicated. My plan is as follows:—Take a box of the depth, length, and width required—say of sufficient length to hold three bouquets. Get some double laths; cut them the exact width of the box; nail in one through the box, and then one end of the other, put in your bouquet, and then press the other end gently before nailing, allowing distance between each two laths according to the thickness of the bouquet-handle, and so proceed with the three. Now, if six are required to be sent in the same box, this may be done by inverting every alternate one, care being taken to reverse them as you proceed, so that the handle of each one inverted comes up between the others without injury, and see that the laths are put at proper distances, so that they do not squeeze too tightly, or they will make the bouquets oval-shaped.—*J. DIVERS.*

### CORNWALL WEATHER AND OPEN-GROUND CROPS.

NOTHING can be more delightful and cheering than the weather and the general appearance of the early garden produce in the district surrounding Mount's Bay. Everything is really early and vigorous. During the last few days early Potatoes have been drawn in the parishes of Paul and Madron for the supply of our markets, as well as by private individuals. A day or two ago a grower remarked that in twenty-four hours after the soil had been loosened about the roots there was an evident growth, and that everywhere the plant looked very promising. Sixteen or seventeen days ago great fears were excited by the prevalence of easterly and north-easterly winds, with an appearance of frost in the air and sky; but, thanks to an All-wise and over-ruling Providence, the crisis appears to be now past. Had frost come a fortnight ago it would have destroyed all the very early crops and entailed a loss of many thousand pounds sterling to the growers. The last few days the weather has been splendid; the sun bright and hot, the wind soft and gentle, and the face of nature smiles on all hands. In a very short time the tables of our tradesmen and better-to-do classes will be supplied with green Peas. Young Onions are strong and healthy. Radishes and Rhubarb have been as plentiful as sticks in a farmyard. Early Cabbages are delicate and tender; and Lettuces and young Onions are becoming quite common. In some favoured localities the grass is a foot high, and in most places there is plenty of good feed. The Apple trees are perfectly covered with bloom, and the Gooseberry and Currant trees are equally promising. Should the weather continue fine this will certainly prove one of the most abundant seasons known in this neighbourhood for years.—(*April 29, Penzance.*)

**TREE FROGS.**—A fresh supply of these interesting little creatures from the South of France has been presented to the Royal Horticultural Society, and as another envoi is promised, the Council think that some of these may be spared for distribution among the Fellows, and they propose to have a ballot for them in pairs in the month of June. They are not only charming from their beauty, and the marvellous similitude which they bear to the leaves amongst which they live, but are most useful in a conservatory in clearing off green fly, and all sorts of insect vermin. Formal notice will be given of the ballot in the "Proceedings" for June.—(*Proceedings of Society.*)

### THE AILANTHUS SILKWORM.

WE are informed by Lady Dorothy Nevill, who has devoted so much attention to the introduction of the Ailanthus Silkworm to this country, that there is now a prospect of a market being opened for the disposal of the silk. Mr. Lister, one of our great manufacturers at Bradford, is prepared to take one million of cocoons a-year at the rate of 1s. per pound; and should it turn out that there is not much waste in the manufacture, the price would be increased to 1s. 6d.

It is very cheering to hear that a method has been discovered for unwinding the cocoon in a continuous thread, as in the case of the Mulberry Silkworm cocoons. This operation is familiar to the Chinese, who have no difficulty in the matter; but hitherto the process has not been known in Europe. We are told that the discovery has been made by a lady in Paris, and as soon as we obtain particulars we shall communicate the information to our readers.

### THE SEASON IN HERTFORDSHIRE.

WHILE I write, May 6th, I have two swarms of bees hived within an hour of each other, quietly settling themselves within the hives prepared for them. The swarms are each abundant and strong; the individual bees are very fine.

I will add a few jottings upon other things as influenced by the season in this neighbourhood. Mushrooms were gathered upon a bank beside a public highway in the middle of April last. Pears are set for a very good crop here, and the embryo fruit seems to promise well. Apple blossom is most abundant, but I infer that a very large majority of the anthers never came to perfection, so that there will be a scarcity of pollen in this neighbourhood. Plums seem to be set very well, and there is a very good show for a crop. Cherries, in some instances, will not be so abundant, unless the diseased pistils in 60 per cent. of the flowers here is an affection purely local. Wall fruits are set very well, as also are the minor bush fruits. I regret to say the caterpillars upon Gooseberries have made their appearance again this season; they should be seen to. I hope the lightning and heavy showers upon the eve of the 6th here will destroy them as also the black fly, which is unusually abundant this year.—*W. EARLEY, Digsweil.*

### KEEPING GRAPES.

THREE days since, a friend brought me about a pound of Catawba and Isabella Grapes. They were about as good as if just taken from the Vine in the proper season, full and plump, but most of the berries had fallen from the stems, in the carriage of about ten miles over a rough road.

Now, the way these Grapes were preserved may not be new to you, though it certainly seemed a novel one to me; but the fact of their keeping until the end of March in fine condition is worthy of publicity.

In the fall, when they are perfectly ripe, they are taken from the Vines, when they are free from anything like moisture, handled carefully and packed in small kegs—nail kegs were the kind used in this instance. Put a layer of green leaves right off the Vines in the bottom, on this a layer of Grapes, then leaves again and Grapes, alternately, until the keg is full. Put in the head, and your cask is ready—for what? Why, to be buried in the ground. Dig a trench so as to admit the casks, deep enough that they will have about 1 foot or 15 inches of soil over them when covered. The ground should be packed rather tight, and a board laid along on the top before the ground is thrown in. They throw some litter on the surface of the ground over those which they wish to take up during the winter, to prevent the ground from freezing so hard as to keep them from getting at them. One important thing must be observed, that they be placed where there can be no standing water about the casks, or they would suffer.—(*Germantown Telegraph.*)

**EARLINESS OF THE SEASON.**—We always consider Asparagus a sure witness to the earliness or lateness of the season, it being a hardy native perennial. It testifies to this year's early spring by being ready for cutting on the 23rd of April. Last year the first cutting was on the 21st of April, whilst in 1860 the first cutting was not until May 22. The very earliest cutting at the same place, Croydon, during the last ten years was in 1859, when it was on the 11th of April.

A FEW DAYS IN IRELAND.—No. 22.

NUTLEY.

THE next place we looked in upon near Blackrock was Nutley, the charming and beautifully-finished residence of Alderman Roe. Entering the place by a somewhat private road from the station, and through part of the grounds of the nursery already referred to, and which we were told formed part of the property, we had a bird's-eye view of the pleasure grounds, the lake forming in the park between it and the kitchen garden, and the

kitchen garden itself before meeting with our new friend Mr. Wright, busily superintending operations in a Potato-field. Before meeting with him, we had ample opportunity, in the passing view, for remarking to ourselves that here, at all events, the right man must surely be in the right place, as every spot seemed to speak of careful supervision, order, and refined taste.

GROUND PLAN OF MANSION AND PLANT-HOUSES AT NUTLEY.

- A. Dwelling-house.
- B. Camellia-house, 34 feet by 7½ feet.
- C. Kitchen yard.
- D. Stove, 43 feet by 28 ft. by 22 ft.
- E. Greenhouse, 79 feet by 14 feet by 14 feet.
- F. Greenhouse entry, 19 feet by 14 feet.
- G. Orchid-house, 19 feet by 14 feet.
- H. Entrance to terrace.

As far as we recollect the beautiful square mansion is placed at the west side of the pleasure ground. Close to it, and their backs in line with the front of the house, are placed, first a Camellia-house, 34 feet by 7½ feet; then a semicircular ornamental wall, some 60 feet in length, built with alcoves for statues, &c., an object of attraction in itself, and concealing all traces of the kitchen and servants' yard behind; then a square plant-stove with hipped roof, 43 feet in length, 28 feet in width, and 22 feet in height, opening into a greenhouse 80 feet long, 14 feet wide, and 14 feet in height, extending to a wider bayed house 19 feet by 18 feet, and terminating in an Orchid and Fern-house 19 feet by 14 feet. It was at this point we entered by a door in a wall leading southwards, that wall being 152 yards in length, and covered with fine things, with a flower-parterre in front of it. From the south end of that wall an ornamental balustrade goes westward until it passes the mansion, and then returns northward so as thoroughly to separate the pleasure grounds from the park in front and behind. The main entrance is south-west of the house, and though the approach is short, the curves and the planting are a pattern for all who would take lessons in landscape gardening, and showing what interest and taste may be concentrated in a small demesne. To this we will shortly again refer.

Meanwhile, standing near the mansion, you are first struck with the compactness and finish of all the arrangements inside the balustrade; then the massiveness of what planting there is without, so relieved by light and shade; then the waters of the lake, as now forming or widening, seem to sparkle in the sunbeams. South-east of these is a sort of prospect-tower in the kitchen garden, now used partly as a dovecot, but which is an attractive object from the grounds; and beyond, and bounding the horizon, the rich massive woods of Marrion (the late Lord Herbert's), and of Mount Anville (the seat of W. Dargan, Esq., one of the best practical patriots that Ireland has ever known), and that fine beautiful prospect Alderman Roe and all his household may call their own—"theirs by right of eye."

The space enclosed by the balustrade is two acres and nearly three roods. From the entrance to the terrace, between the walk and the balustrade, is a fine row of handsome Irish Yews 10 feet apart. The centre of the lawn is graced with groups, some still young, in the massed picturesque style. In front of the mansion facing south-east is a beautiful flower garden clustered round an elegant fountain, the fountain being supplied from a large cistern at the top of the mansion, and that again supplied from a water-ram at a fall in the lake. The beauty of

this garden consisted not merely in the planting, but in the open space of grass all round it and between it and the mansion thus giving relief and breadth, as it were, to the colours.

Another flower garden was placed farther eastward in front of the main range of houses, with another fountain in the centre. The beds were here placed in geometrical order, close together, bordered by Box and divided by narrow gravel paths. This constituted variety, though the ease and the elegance of the first group were wanting. The beds were also planted more in mixtures, Roses, &c., which also gave more variety, which is ever pleasing, but at the expense of unity and grandeur of expression. Such beds would be most telling when each was filled by a low-growing mass-flowering plant, so as the eye could easily take in the whole. However nice they look in summer, massed Rose-beds always spoil a group of bedding plants in autumn. One of the best gardeners in England was loth to remove them from a beautiful parterre, and though with a fine eye for effect, it was long before he could be made to see that the thin, and blackish, and curled leaves of his Perpetual Roses did detract from the gorgeous beds of Verbenas, Calceolarias, &c., beside them. A small Rose garden would secure the variety and obviate all the difficulty. We rather think our friend has left a couple of beds still, though all the rest have been removed. The last time we saw them there was a glorious bed of Scarlet Geranium on one side, and Yellow Calceolarias on the other. The Roses just made the splendid group very common—almost a failure. In each case a mass of Ageratum would have balanced the red and yellow, instead of a few scattered Roses and leaves, which no care would make nice in September. As a return for kindness, may we hint that this pretty garden might be better and more telling without the Roses in autumn?

The plant-houses were rather thin, as most of their usual residents were transferred to other houses, or placed for a time out of doors, and more temporary plants put in thinly to supply their place. In the stove were some fine specimens of Begonias with fine foliage, Achimenes, &c. In the greenhouse were some fine Fuchsias, Balsams, &c. The back of the house was densely clothed, chiefly with three plants—Polygala Laurencana, producing myriads of flowers; Plumbago capensis, also a mass of bloom; and Heliotropium peruvianum, also a mass of bloom. In the centre of a large vase in the greenhouse was Arista Banksii, a strong Sedge-like plant with whitish leaves. At the back of these houses, under the shade of a large tree, were a fine collection of Camellias, Azaleas, Epacrises, Ericas, Rhododendrons, including a fine plant of Nuttallii, Correas, Acacias, &c. Many

plants ranging from 4 feet to 6 feet in height, and from 2 feet to 3 feet and more in diameter of head. All seemed to be in the very highest health. We also noticed a great quantity of the beautiful *Primula denticulata*.

On the long wall which bounds the east side of the lawn we noticed many things quite healthy, which will not live out with us in general years, and others all of which were killed by the winter of 1860 and 1861. Along the wall were fine plants of Tea, Noisette, Bourbon, and Perpetual Roses; Jasmines in every variety; Glycines, including *sinensis*, *alba*, and *magnifica*; Clematis, all the best kinds, including Sieboldi and lanuginosa, the latter seemingly perfectly hardy here; Escallonia, as *rubra*, *montevicensis*, &c.; Ceanothus, all the hardy and half-hardy kinds; Magnolias, all the best kinds and uninjured; Photinia serrulata without a leaf injured; Solanum jasminoides, fine, healthy, and free-flowering, though in a greenhouse it is generally a prey to fly; Mahonia ilicifolia with its fine greyish leaves, and other Mahonias and Berberis, as Bealii, &c.; Garrya elliptica latifolia growing and blooming freely; Lardizabala tritenata, a fine plant; Abelia triflora producing its large bunches of tubular flowers; and Salisburia adiantifolia producing leaves as large as Catalpa.

The whole of this long wall is fronted by a wide geometrical border formed of Box-edged beds, and narrow paths between them, and planted partly in the grouped style, the semi-grouped style, and the old mixed system, so as to permit of dwarf and tree Roses, Dahlias, Delphiniums, and other fine old plants and annuals being freely introduced. The effect was altogether striking, and for cut flowers it must be a rare resort. We should almost be sorry to see such an arrangement altered; but we could see Mr. Wright had a little hankering to devote a part to bedding or grouping entirely, another part to mixtures, &c., and very likely if we said much he would turn our own weapons or words against us.

We did not go through all the kitchen garden, but it seemed full to overflowing with vegetables and fruit trees. Close to the houses was a sight seldom to be seen last season—a good-sized standard Apple tree and loaded with fine specimens of Ribston Pippins. Here are two vineries, each 40 feet long, 14 feet wide, and 16 feet high, with good crops of Grapes. Also, a pit 24 feet long, some 14 feet wide, and 11 feet high, used for propagating and keeping bedding plants, and, when these are all turned out, for Melons. The Melon crop hanging and suspended from the roof was magnificent in the middle of September, and pretty well as regular as if placed by rule and scale. Outside in a yard were also some fine plants of Camellias and Azaleas, many of the former being 6 feet by 4 feet, and though not told, we presumed they had a help in the vinery to forward growth and the setting of the buds, and were rusticated a little out of doors before being taken to the conservatories. From the kitchen garden a nice walk leads westward through a thick belt of trees that here bounds the park to the entrance-gate.

To the beauties of that carriage-road we said we would again refer. Leaving, then, other matters alluded to as well worthy of attention, there are two great distinguishing features at Nutley. The first is, the clear, defined separation of the flower gardens and pleasure grounds from the park scenery, by means of the elegant balustrade. This permits of a free use of the artistic and even geometric inside the balustrade, and a softening-down with the picturesque at a distance from the straight architectural lines. How different is such an arrangement from attempting to hide the boundary by a deep ha-ha ditch, and then taking a walk near it, so that you cannot help seeing what it was professed to be desirable to hide!

Then secondly, the outside open massive grouping we have also alluded to in the park in front of the house. It is even better behind the house, and westward to the main entrance. From the surroundings this park cannot be large; and yet behind the house so thoroughly are all boundaries concealed, so massive and undulating the groups of timber, so much do they advance to and recede in bold sweeps from the approach, throwing the grass into lesser and larger irregular lawns and glades, that you might fancy yourself in a demesne as large as the imagination could revel in, provided mere extent was the object most desirable. Just think of the difference, and the monotony, and the idea of confinement and restraint produced by bringing the trees down to a somewhat regular distance from such a nicely-curved, nicely-kept approach; and many who would do that in order to effect seclusion and repose, might have no idea how much both these objects would be promoted by expanse, room-

ness, and bold graceful sweeps. In some of these open glades were single and detached groups that told well; in others, a fine single specimen alone in its glory, from which the eye went to the dense irregular background. On praising some of these, Mr. Wright was modestly doubtful whether the picture as a whole, would not be more telling without them. Without the experience and the fine pictorial eye of our friend, we could see that on such a spot it would require much study, and looking and relooking from all points before fixing on the removal or planting of a tree. We regretted that our stay was so short; but so delighted were we with that part of the demesne especially, that to any gentleman near Dublin constructing for himself a suburban home, and anxious to secure for it not only seclusion and retiredness, but free expanse and roominess combined with fine picturesque effect, we would say, Apply to Alderman Roe for permission to study the grouping from the lodge past the mansion. We hope neither the worthy Alderman nor Mr. Wright will be offended by the suggestion. A five-minutes walk will unfold more than five-hours writing without plans and views.

R. FISH.

## THE CALCEOLARIA AS A BEDDING PLANT.

HAVING, in preceding chapters of THE JOURNAL OF HORTICULTURE, given a rough outline of the Geranium, Verbena, and Fuchsia, and their uses for flower-garden purposes, I now come to another plant which, supplying a colour differing from anything else we have in that way, seems as indispensable to the flower garden as a bed of Cabbages to the kitchen department. Time, however, and a better acquaintance with other plants likely to become substitutes to this one may, possibly, to a certain extent displace it; but, hitherto, everything that has been introduced with that view has failed to give that satisfaction which a good bed of yellow Calceolaria is always sure to do, so that it is needless making an apology for calling attention to a plant at once so popular, and, usually, so easy of culture. I will begin with a few observations on the original species from which our present race of flower-garden favourites sprung, and follow them down to the present time, with such remarks as may be interesting to the general reader.

ORIGINAL SPECIES.—I am not able from memory to detail all the various advances made in the transition period which was most active from 1830 to 1840; but it may be of some interest to say that the first Calceolaria I became acquainted with was *C. corymbosa*, and that some time about 1829. It was known and cultivated by older gardeners before that time, but I think it was little altered then. Soon after that period the woolly-leaved species with purple flowers created some little stir under the name of *C. arachnoidea*. This very distinct species might, I think, be turned to good account now if again put into the hands of some skilful hybridiser; but I have not seen it for twenty years or more. *C. purpurea*, I think, was an improved variety of *C. arachnoidea*, but my recollections of it are less clear than of the other kind; and all the kinds previously known fell into disrepute when *C. integrifolia*, the old shrubby yellow variety, or rather species, came into general use. The first time I remember seeing it used as a flower-garden plant was in 1831; seedlings, however, of the herbaceous kinds had been known long before, and some had even been sent out with distinct and high-sounding names—one called Kellyana remaining for some years a favourite. But it was many years before a quick and easy mode was found out to propagate the hardwooded *C. integrifolia*, especially when it was confined in a pot, and that often of limited dimensions, so that seedlings of the herbaceous kinds were on the whole more sought after, especially for plant-house decoration; and *C. corymbosa* and *C. scabiosæfolia* being of easy culture, were frequently found in the flower garden amongst other annuals and such perennials as were then thought the greatest ornaments to the garden.

One of the earliest hybridisers amongst our enterprising nurserymen was Mr. Major, of Leeds; and I believe, before him, another grower in the same way at Chester had sent out several good varieties of the herbaceous, or half-herbaceous kind, while Messrs. Gains and Catleugh exhibited well-grown plants at the London shows. But the merit of bringing the Calceolaria to as great a perfection as any, belongs, I believe, to that veteran plant-grower whose contributions still frequently grace our metropolitan exhibition-stands—Mr. Green, gardener to Sir E. Antrobus, Bart. Mr. Green exhibited some plants about 1840, obtained entirely from crossing *C. corymbosa* with *C. arachnoidea*. As

these belong more to the purely greenhouse, rather than the flower-garden class, it is needless to follow them further, suffice it to say that some years before that time, the flower garden was enriched by such dark kinds as Mogul, Majoriana, Superb, and some others; while the blotched or intermediate kinds were represented by Sir Walter Scott, Sunbury Hero, and a host of others, the yellow ones being at that period of less repute. *Calceolaria integrifolia* and *C. rugosa* were the only kinds I remember in cultivation of the yellow class they represented up to 1838, or perhaps later, when *Sulphureum* was introduced; and a red or dark one of the shrubby kind making its appearance at the same time, gave all the kinds that are now so popular in the flower garden, with the exception of *C. amplexicaulis*, which added quite a new class, and previous to its appearance, a white one caused some little stir; and subsequently another white one, not many years ago, was expected to do great things, but it somehow disappointed everybody. These kinds, forming the originals from which our present flower-garden varieties have sprung, have, in their offspring, been much improved in colour, habit, and all the qualities that make them useful, excepting, perhaps, in constitutional vigour, which, as is common in such things, has been in some degree impaired by the change.

**NATIVE COUNTRY OF THE CALCEOLARIA.**—The western slopes of the Andes of about 20° S. latitude furnish this plant, and also that most remarkable of all our imported *Coniferae*, *Araucaria imbricata*. Of the precise character of the soil we have no positive information, but we are told it is moist, and being at a considerable elevation we may with every reason of probability assume the *Calceolaria* to be well inured to frequent and heavy rains, and ranging as it does up to near the limits of perpetual snow, its roots must often be moistened by a melted liquid almost as cold as ice itself: hence we may easily guess that bottom heat is not one of its requirements—at one period of the year at least. Most likely the plant is buried underneath a mass of snow in the short winter months—at least, such plants as reach the line of snow. But the herbaceous class would seem not to be quite so hardy, and probably inhabit a lower and warmer climate. Chili, where this plant comes from, has a greater diversity of climate than most countries, the tropical and arctic regions may be said to be both represented here; but the *Calceolaria* is in an intermediate one, and no doubt it is surrounded by many ornamental plants yet unknown to us, although the enterprise of explorers has furnished us with several, not the least remarkable neighbour to the *Calceolaria* being the Potato, which, in a wild state, inhabits the same territory. Doubtless the *Calceolaria* is also found in the adjacent provinces of Peru, Bolivia, and perhaps as far south as Patagonia; but I am not aware of its being found indigenous anywhere in the old world; though in its cultivated condition in such climates perhaps as that of New Zealand there is every reason to suppose it may ere long establish itself, and that in mountain countries it will do so also.

(To be continued.)

J. ROBSON.

## CONSTRUCTION OF A GAS-HEATED MELON-PIT.

REFERRING to page 65, I am obliged for the hint about ascent and descent. No doubt the stove must be in the front corner of the pit, and the conducting-pipe must ascend. I have already tried the same stove for two vineries, and they answer well. This stove heats my lean-to house about 5 feet wide and 60 feet long. The stove is by Rickett, of Agar Street, price 35s., and burns 6 feet per hour, and gives a good heat. It can be increased if wanted.

If the gas is more costly in point of actual cash for it alone, how much may be deducted for saving of labour in attending to fires? All brickwork for flues, and sweeping of chimney and coal dust and ashes are avoided; also the cost of keeping a boiler in repair, in addition to the brickwork of the fire.

I wish some of your readers would experiment with gas. I think it would even pay to substitute gas for fire heat to existing boilers.—A SUBSCRIBER.

## CULTURE OF THE PINE APPLE.

(Continued from page 101.)

**SUCCESSION PLANTS.**—The fruiting Pines as mentioned in my last paper being all repotted and put into the freshly-renewed bark-pit, the next thing that requires attention is the succession

plants. These should be repotted, and the bark heat renewed exactly the same as the fruiting plants. They should have larger pots; indeed, the largest-sized plants will be in the next size to those used for fruiting plants, for such plants will be large enough for fruiting the autumn following to supply fruit in winter: therefore, let such have a second shift in July into pots large enough to fruit them.

**YOUNG PLANTS.**—After the succession plants are finished potting, &c., then turn attention to the youngest stock. They will not have filled their pots with roots, but the soil will have become poor with frequent waterings, and the loss of nutriment the plants have drawn from it. The young plants should have liberal treatment in regard to rich soil, plenty of pot-room, and free supplies of internal moisture in the air and water at the root. Free growth at this stage is important; for if the reverse is given the plants will be stunted, and will start into fruit prematurely. Let the cultivator, then, keep this constantly in mind. In potting young plants, turn out the ball, and shake off very gently the greater part if not all of the old soil. Preserve the healthy roots entire, and repot into a pot two sizes larger, following the same method of drainage, and filling-in the fresh-sired compost amongst the leaves. Should any of them have sickly or dead roots cut them away entirely, and cut off even the bottom part of the stem if decayed. Fresh roots will soon be emitted owing to the excitement of renewed heat and fresh soil.

When plunging the Pine plants, whether they are fruiting plants, succession, or yearlings, after the second row is plunged the first row should have the bast matting used in tying-up the leaves cut loose, and with a smooth stick arrange the leaves into their proper position. At this stage of the plunging operation the ties can be reached more conveniently than if left till the whole of the pit is plunged. When the third row is plunged then release the second from the ties, and so proceed till the last row is plunged; then cut that row loose, and that finishes the work. Should any leaves hang over the paths, they should be protected by long strings of twine reaching round the pits: these strings will lift up the leaves, and thus preserve them from being broken or cracked. Some to save trouble cut such leaves in; but that is a bad practice, for every healthy leaf should be kept entire if possible.

I am supposing that all these three plantations of the Pine Apple in its three stages of growth are done as early in the spring as possible—certainly not later than the first week in March. Done at that early season, when the sun has not such great power, there is less danger of the plants flagging, and consequently no necessity for shading them.

**TREATMENT OF SUCKERS AND CROWNS.**—When the old stools are removed out of the fruiting-house to make room for a fresh stock of plants from the succession-house, then is a convenient time to take off the suckers. The best and safest way to accomplish this is to turn the old stock out of the pot, shake off the soil, and cut away all the roots, then commence pulling off the lowest leaves one by one till you come to the first sucker. Grasp it firmly, and bend it downwards, till it breaks off from the old stem; lay it on one side, and pull off the next leaves till the second sucker is bare; then detach it also, and so proceed till every sucker on that plant is separated from the old stool. Many of them will have begun to put forth roots, such may be potted immediately, and, according to their size, take their place amongst the succession plants. Previous to potting them pare the bottom of the stem quite smooth, and pull off some of the lowest small leaves, being careful not to injure the young roots just starting out from the base of the stem. Small suckers that have not formed any roots may be stuck in the tan-bed for a month or so till they emit roots.

**CROWNS.**—These will be sent back to the grower from the table, and as the bottom will be soft and full of sap, it is not advisable to either pot them or put them amongst the bark. I generally adopted the plan of first pulling away a few bottom leaves and paring off the bottom of the stem, and then laying them upon a shelf in the stove for a week or ten days till the bottom of the stem became withered, dry, and firm; then the crown may safely be either planted amongst the bark or potted, as may be convenient. Observe, however, never to water these unrooted suckers or crowns till it is certain that they have pushed forth roots. The Pine Apple is a succulent plant, something like an Aloe or a Cactus, and, therefore, water will be equally as fatal to an unrooted Pine Apple plant as it would be to a cutting of an Aloe or a Cactus.

**ROUTINE.**—Whilst the work of potting, renewing the tan or leaf-bed, is going on, a good opportunity offers of cleaning the inside of the houses. Wash the glass inside and out, whitewash the walls, and scour the stoncs. At this season (spring), however, it is not advisable to paint inside, because air cannot be given sufficiently to carry off the offensive effluvia of the paint. When painting inside is absolutely necessary, the best season for it is the middle of summer. The woodwork, however, should be well scrubbed, not only for the sake of cleanliness but also for the destruction of insects which lay their eggs in crevices of the wood.

This early work of potting, &c., being finished, the daily routine of attention commences. It may be summed-up in a short paragraph. The first point is a due amount of heat: this I have already given. The next is atmospheric moisture. This is attained by syringing the pipes or flues, and keeping the troughs full of sweet clear water, by syringing the bark when the surface is dry, and by syringing the plants after a sunny day; observing, however, not to syringe the fruit when it is in flower or changing to a state of ripeness.

**WATERING.**—Attend to the directions already given, observing, however, not to water newly-potted plants for three weeks or a month; by that time new roots will be forming, and the soil will be so dry as to require a good supply to moisten it. For the first two months watering twice a-week will be sufficient; but in June, July, and August three, or even four, waterings a-week may be necessary. When the fruit is swelling rapidly, if a little water is poured into the crowns it will be serviceable. Fruit that is swelling-off, also should be frequently supplied with liquid manure. It helps them wonderfully to swell up to a large size and form handsome fruit.

**GIVING AIR.**—Large crowns are objectionable, and large crowns arise from too little air being given. That point is the next that I will refer to. Excepting in actual frost I would

give air every day—less, of course, in cold wet weather than on hot, dry, sunny days. In the early part of the year give air for two or three hours in the middle of the day, increasing the length of time before shutting-up as the days become longer and warmer, so that in the very height of summer air may be given by eight o'clock in the morning, or even half an hour earlier, and remain on till five in the afternoon—indeed, in very hot weather, I have frequently left on a little air all night. Attention to this point will cause the plants to grow stout and sturdy; whereas, a too great closeness will cause them to make long, thin, narrow leaves, and make them so weak that the fruit they will produce will be small, and the crowns disproportionately large.

**REPOTTING—RENEWING BOTTOM HEAT.**—It is very probable that towards June the young plants and successions will have filled their pots with roots; many, probably, will have sent their bottom roots through the holes at the bottom of the pots into the bark; also the heat in the bed will have begun to decline. In that case it will be necessary to go over the process of repotting, &c., and also to add a small quantity of fresh tan to the bed. The main body of the bed need not be disturbed unless it should be very dry. In such a case a quantity of warm water poured into it will moisten it and cause a fresh fermentation. The bed of the fruiting-house should be renewed also in the same way. On a rough calculation a sixth part of new tan will be sufficient at that time of the year. Though so little is added, yet the effect must be most carefully watched; for a too great bottom heat at this season, would be most peculiarly unfortunate.

The fruiting plants should not be repotted, but only top-dressed; because, if a too great stimulant of growth be applied, that growth will certainly take place, and though the plants will grow larger, they will not be so certain to fruit at the due time. Should they require helping, give them some weak liquid manure instead of fresh compost. T. APPELBY.

## ARTIFICIAL WATER IN GARDENESQUE SCENERY, FOR GROWING AQUATIC PLANTS.

BY H. NOEL HUMPHREYS, ESQ.

(Continued from page 104.)

ARCHITECTURAL FISH-POND AT THE VILLA STRADA, NEAR ROME.

The above illustration shows the architectural treatment of a fish-pond or pescheria in the gardens of an Italian villa. It exists at the Villa Strada, in the Strada Nuova, near Rome. The architectural features are perhaps overdone, but are an excellent example of the highest and most laborious style to which architectural gardening has been carried in Italy.

BIJOU PLANT AND PROPAGATING CASE.

- A Flexible tube for supplying gas.
- B Tap.
- C Circle of gas-jets 3 inches in diameter.
- D Orifice for escape of heated air.
- E Opening in floor of hot-air chamber to admit the gas-circle and supply air.
- F Partition in hot-air chamber to secure equal diffusion of heat.
- G Opening at end of partition.
- H Circle of gas jets, with a peg on each side to retain it in its place. The dotted line shows the course of the heated air from the gas-circle to the outlet at d.

THE accompanying illustrations render only a brief description necessary.

The glazed front slides out partially or entirely, there being a groove in the framework at the top and bottom. By this, any amount of ventilation is attainable, and the plants are readily arranged.

Gas, as a source of heat, is the most powerful and most easily regulated by means of the tap; but if gas cannot be attained an oil lamp will suffice, even in the severest winter, if a woollen cover be put over the glass at night. At other seasons, if a stove heat is required, two or more of Childs' night lights, according to the temperature of the period, will suffice. A thermometer hanging within the Case is a guide by which to regulate the application of more or less heat.

The partition in the hot-air chamber not only secures a regular diffusion of heat throughout the hot-air chamber, but serves to support the floor of the frame containing the sand and potted plants. That frame may be lined either with zinc or block tin, but the hot-air chamber is best lined throughout with galvanised iron.

It is decidedly the most elegant and most useful amateurs' plant case that has yet been produced. It can be kept permanently at any temperature required, and may be employed for striking cuttings, for raising seedlings, for growing either stove or greenhouse plants, or for retaining hardy plants long in full beauty.—W.

CALAVANSA BEAN.—Surely the word "Calavansa," as the name of a Bean, and referred to in your Journals of May 6 and the previous week, is a corruption of the Spanish word "Garbanzo,"

the English equivalent whereof is Haricot Bean, and the Latin, "Cicer arietinum."—A SUBSCRIBER.

[It is certainly not the Chick Pea, but a small white Haricot; we have a pod before us as we write. It is very small, not more than 2½ inches long, and contains four white oval seeds, each the size of a small Pea. We did not know that Garbanzo is a synonyme of Haricot. Is it really so?—Eds. J. of H.]

### IN-DOOR PLANT CASES.

In Mr. D. Beaton's paper on Waltonian Cases, there are some remarks on the In-door Plant Cases which I have patented, seemingly founded on a mistaken idea of my invention; and I am sure you will readily find space for a few words in explanation of them, though, indeed, a moment's reference to my former contributions to your Journal would, I think, make the matter clear.

My invention (which is chiefly for the growth and preservation of stove plants in rooms), claims the principle of keeping up a constant circulation of air in the Case by the peculiar arrangement of the heating apparatus. The idea of "adding hot water to enable the lamp to burn," is quite wide of the mark, since the object of my Cases is to dispense with a lamp entirely, depending on the hot water poured in, which I find gives sufficient heat to flower Gardenias, &c., and to keep very tender stove plants in health. My servants tell me it is far less troublesome to pour in a couple of cans of hot water daily than to trim and refill a lamp with oil; and for a drawing-room the absence of lamps is certainly an advantage.—E. A. MALING.

[No one who compares Miss Maling's and Mr. Walton's Plant Cases can fail to discern that they are totally different. Mr. Beaton only intended to express Mr. Walton's opinion that heating by hot water in a close case was no novelty, and that a patent for that cannot be sustained. No further proof of this is needed than a reference to our "Window Gardening for the Many," where at pages 32, 35, and 81 Mr. Fish, as far back as 1857, suggests a drawer filled with hot water in winter as the mode of preserving plants during winter in a glass case. His words are as follows:—"I had seriously thought of recommending for the proprietors of many of our pretty parlour windows a lilyputian greenhouse, set upon a neat table, only the top was to be iron instead of wood, and the drawer beneath it was to be lined with zinc, but the outside wood in the usual way, with conveniences for filling this drawer with hot water from the kitchen copper, and removing it when cold at pleasure; but I now gladly give any one the right to make a fortune from such an idea, though entertaining no doubt of its answering well." "I may mention that a gentleman who is very fond of plants, but who has nothing in the shape of a hotbed, told me the other day that he raises many cuttings and tender seeds very successfully in a stout old deal box, the bottom part of which is lined with tin, and with a second tin bottom 4 inches above the bottom of the box. This space he fills and empties of water at pleasure by a funnel at one end and a small tap at the other. In general he supplies water every twenty-four hours; in cold weather twice in that time."

Miss Maling, however, says above that her invention claims the principle of keeping up a constant circulation of air in the Case by the peculiar arrangement of the heating apparatus, a claim which we hope she will never be called upon to sustain in a court of law.

The advantage of a lamp, or jet of gas, for heating a glass case is the uniformity of the heat it maintains, and the power of increasing the heat to any elevation desired. Hot water in a tray is constantly declining in heat, and this cannot be increased.—Eds. J. of H.]

**WEIGHT OF MANURE.**—The average weight of a solid cubic foot of half-rotted stable manure is 56 lbs. If it be dry or coarse, about 48 lbs. A load of such manure, or 36 cubic feet, of this second quality, 1728 lbs.; and of the first quality, 2016 lbs. Eight loads of this first quality, weighing 16,128 lbs., put upon an acre, will give 108 lbs. to each square rod, and less than 2½ lbs. to each square foot. An acre containing 43,760 square feet, the calculation is easily made of the pounds per foot, which will be the result from any known quantity per acre put on.

### BIRDS AND THE CROPS.

I PERCEIVED that in a recent Journal you noticed the endeavour of the French Government to prevent the great destruction of small birds, the loss of which is greatly felt by the French agriculturists; but the French are not the only sufferers from the destruction of birds, the Legislature of the United States of America found it necessary to enact laws for their protection. Complaints of the ravages of insects owing to the destruction of small birds reach us from Canada; and Australia is importing our despised and persecuted birds, and acclimatising them there for the protection of their crops from the attacks of insect pests.

When will the English gardeners and farmers understand the value of these little feathered checks to the rapid increase of insect marauders? It is not to be supposed that they are an unmixed good; many do some injury, but it is very trifling in comparison to the benefits they confer. It is true that the injury they inflict is often very annoying, and, though small in amount, is personal and direct; while the good they do is mostly unobserved, and frequently not thought of.

I think I cannot do better than copy for your readers' consideration the opinion of Mr. Loudon, which, coming from such an eminent gardener, may perhaps have some weight with them and induce them to spare the birds, while they protect their crops:—

"2223. The feathered enemies of gardens are numerous but not very destructive, excepting in severe winters, when they eat the buds, and during the coming-up of small seeds. To preserve ripening or germinating seeds where birds are numerous they must either be covered with a net or watched by man. Scores of different sorts as mock men or cats, mock hawks or eagles, miniature windmills, rattles, lines of feathers, the smell of tar or bruised gunpowder, &c., are of some use; but the chief dependance must be on watching, nets, and the frequent use of the gun. P. Musgrave, a practical gardener, who has treated the subject of vermin in a scientific manner has the following observation on this subject:—"It is a too common practice amongst gardeners to destroy without discrimination the birds that frequent their gardens. This is in my opinion a bad policy. Although I am aware some kinds of birds are great enemies to some crops, it certainly must be a trifling evil indeed that will not bear a person to watch it, or a net to protect it, until it is out of danger: thus the gardener preserves the birds to perform a double office, eating up the vermin from the trees, and the seeds of weeds and eggs of insects from the ground. I have often stood and observed the male bird, while the female was sitting upon her eggs or her young, fly to the spot with his bill full of caterpillars to feed his mate or young; and when the young ones become so strong as to accompany their parents in quest of food, it is really astonishing the number of caterpillars they destroy. I can say from my own observation that if it was not the case that the birds destroy a vast number of caterpillars, our trees in general would exhibit nothing but bare stumps; for the insects would become as numerous as the locusts of Spain and America. It is from that circumstance that we find so few flies in comparison of the great number of caterpillars.

"I one day followed a nest of young Oxeyes (*Parus major*), which had just flown in order to see how the old ones acted. I saw them fly from branch to branch and pick from the curled leaves the caterpillars, with which they flew to their young to feed them. From these considerations it is my opinion, that should the gardener, instead of pursuing a system of indiscriminate warfare against the feathered tribes, avail himself of the service of these useful allies, he might, with their exertions and his own united, soon rid himself of those insects that have hitherto set his efforts at defiance."—(*Encyclopaedia of Gardening*, p. 426).

Your apian contributors I would beg to remind that the bee hears a sting, which would prevent the swallow attempting a second: but I think he is unjustly accused. The tomits would peck the bee to pieces before eating it, and so avoid being stung; but they rarely take one except from the entrance of the hive in cold weather, and which may be easily prevented. All the family of tits are too valuable as insect-destroyers to be killed; the bee-hives should be protected from their visits, the birds provided with some food during their time of famine, and preserved on account of the immense amount of benefit they confer on mankind. It is, in my opinion, short-sighted to destroy that which contributes to the public good, because it may happen to cause us some private annoyance or injury.—B. P. BRENT.

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE April Meeting was presided over by F. Smith, Esq. President. The donations to the Society's library were of considerable interest, including the recent publications of the Linnæan and Agricultural Societies, the Royal Society of Munich, the Society of Arts, the Natural History Society of Montreal, &c. A new natural history journal recently commenced at Copenhagen (containing an elaborate memoir on the spines of plants, and on the genus *Parkinsonia*), and the first half of a new work on the Butterflies of South Africa, by Mr.

Trenton, published at the Cape of Good Hope, were also on the table. The President announced that the first part of a new series of the Society's "Transactions" was ready for delivery to the members.

Mr. S. Stevens exhibited a box of insects of various orders, containing some very rare species collected in South Africa by Mr. Trenton. Also a new British species of *Bryaxis* (a genus of minute Beetles allied to the Staphylinidæ), taken in the north of England by the Rev. Mr. Little.

Mr. Newman exhibited a remarkable female specimen of the *Liparis dispar*, the Gipsy Moth, which has both the antennæ pectinated nearly as strongly as in the male, the wings coloured and marked as in the male (excepting rather lighter), but with the abdomen that of the female. Mr. Newman regarded this as the first pseudogynous specimen which had been observed among insects. Dr. Wallace stated that he had observed that when female Moths have been prematurely developed, as by keeping the chrysalids in a warmer position than that in which they are naturally placed, the eggs and worms are found in a very immature condition.

Mr. Stainton exhibited a specimen of one of the Vapourer Moths, *Orgyia erica*, the female of which is destitute of wings, and never quits the interior of its cocoon on assuming the perfect state. Such is also the case with the females of *Orgyia rupestris* and two other European species, whereas the females of the two British species creep out of the cocoon when hatched; they do not, however, leave their old abode, but deposit their eggs on the outside of the cocoon, within which the females of the other species lay their ova.

Mr. Fenn exhibited a specimen of the rare Moth, *Laphygma exigua*, taken on Sallow blossoms on the 24th March.

Mr. Pascoe exhibited three specimens of *Xenocerus* semiluctuosus, belonging to the Anthribidæ, from the Moluccas, remarkable for the variation in size and development of the individuals. One of these was a female, but the two others were males, which satisfactorily proved the occurrence of dimorphism in that sex, the larger having the legs and antennæ greatly elongated, whilst in the other, which was much smaller, the limbs were comparatively very short. This was also stated to be the case with the species of the allied genus *Mecocerus*. Allusion was made to the various forms in certain species of South American Butterflies, of which an account had recently been read by Mr. Bates at the Linnean Society, but these were merely instances of mimetic analogy. Professor Westwood stated that it had long been known that in those species of insects in which the males exhibited greatly developed organs, such as the cornuted *Drynastidæ* and *Copridæ* or the mandibulated *Lucamidæ*, there were also a certain number of males which remained, as it were, stunted in their development, and scarcely to be distinguished from females. How far these were incapable of producing their kind had not been observed; but the specimens mentioned by Mr. Pascoe afforded the first instance in which the antennæ afforded similar discrepancies in the male sex.

Mr. F. Smith exhibited a monstrous specimen of *Chrysomela Banksii*, of which one of the hinder tibiæ was furnished with three distinct tarsi, giving it the appearance of a bird's claw. Also a living specimen of *Endophlens spinulosus*, taken in the New Forest by Mr. Turner.

General Sir J. B. Hearsey exhibited a case containing a number of beautiful insects of different orders from north-western India. And Mr. F. Moore an extensive and highly interesting series of the silk-producing Moths of Asia, with specimens of their cocoons and silken products contained in fourteen drawers, intended as part of the Indian contribution to the Great International Exhibition of 1862. He made some observations on the different species, and on the variations in the silk textures produced by each.

Dr. Schaum communicated a paper containing remarks on the adoption of obsolete specific names in entomology, rather than such as may subsequently have come into more general use. In his observations the author was severe on the works of various English authors—viz., Marsham, Stephens, Hope, and Waterhouse; the former on account of the asserted insufficiency of their descriptions, and the latter for having adopted the law of priority in nomenclature. This memoir led to considerable discussion.

Mr. Fereday read some notes on a variety of the Moth, *Tenocampa munda*, contending that such varieties were the results of pairing between individuals which were not true to

the type of the species, but that where both parents were true, the progeny was also true.

Mr. F. Walker read some notes on the American species of Fritillary Butterflies, *Argynnia cybele* and *aploitea*, which he regarded as varieties of the same species.

The Secretary read a notice of the injuries committed on the Sugar Canes in the Mauritius, by the larvæ of a Moth, known by the common name of the Borer, communicated to the Society of Arts by Mr. Morris.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE recent battering rains will have rendered the operation of continual surface-stirring necessary. The Dutch or scuffle-hoe is good for this work amongst wide open crops; but wherever practicable, a light thin-tined fork is preferable, as it enters deeper into the soil and makes more effectual work. Small crane-necked hoes are best for stirring the soil amongst seedling crops. By all means avoid treading on the soil after this operation is performed, particularly if it is at all moist. Continue to trench-up all ground remaining or becoming vacant. A watchful eye to be kept on the seedling crops that they do not fall a prey to snails and slugs. *Broccoli*, prick-out the seedlings as soon as they are fit to handle, also *Brussels Sprouts*. *Cabbage*, some of the most forward of the early sowing will now be in a fit state for final transplanting, which should be done the first favourable opportunity; and if dry weather should prevail they must be kept well supplied with water. *Cauliflowers*, prick-out the seedlings as soon as they are sufficiently large to enable you to do so, and water the advancing crops with liquid manure; either the drainage from the dung-heap, or guano, pigeons' dung, horse, cow, or sheep dung, dissolved in water, to be applied in a clear state. Draw a little fresh soil to the stems after the operation. *Leeks*, transplant from the seed-bed as soon as they are large enough, in rows 18 inches apart and 9 inches plant from plant; the soil cannot be too rich. *Lettuce*, tie-up for blanching a few of the largest Bath Cos that have stood through the winter; these should be kept well supplied with water if necessary in order to induce rapid growth, which is essential to the production of that tender crispness so much prized in this variety. *Mushrooms*, cellars or cool sheds are the best places for making beds during summer. Prepare a quantity of materials for making a large bed at once, as it will be found to continue in bearing much longer than smaller beds; and, therefore, there will be no necessity for making them so often. It is almost impossible to keep Mushroom-beds free from grubs during summer unless the situation is very cool. *Potatoes*, when they are above ground fork between the rows, which will prove of great advantage to the crops. *Tomatoes*, plant-out a few on the south border against the wall; the main crop had better be delayed. The same remarks apply to *Capsicums*, *Beet*, and *Marjoram*.

### FLOWER GARDEN.

Bring out all the flower-baskets and tubs which have been hosed during winter, and set them in their proper places; these add much to the beauty and general outline of the landscape, especially where the surface is tame and unbroken. See that due attention is paid to the general effect they may have upon the scene, by placing them in situations where they will be seen to advantage; also procure, if not done already, some good rough turfy loam to fill them. Continue to stake plants in borders, and bulbous plants in beds, as they advance in growth, frequently stir the surface of beds and borders, especially after such heavy rains as we have had lately. Go on thinning-out the annuals sown in the borders, they should never be allowed to smother each other by being left too thick. *Dahlias*, *Salvias*, and all plants intended for flower-garden decoration should be gradually inured to the open air by drawing off the lights before finally planting them out. See that standard *Roses* are properly secured against high winds, and the caterpillar and green fly. Those which were budded last season should be again gone over, and all buds and suckers that proceed from the stock destroyed.

### FRUIT GARDEN.

Continue disbudbing and thinning the young wood as it advances on *Peach*, *Apricot*, and *Plum trees*; retain no more wood than can be laid in without crowding. One well-ripened branch that has been well exposed to sun and air is generally

more prolific than half a dozen branches that have been huddled together, and, consequently, are ill-matured. Thin Peaches and Apricots where too thick, leaving double the number required for a crop till they are stoned, when they must have their final thinning. The Apricots, if wanted for tarts, must be left until they are large enough for that purpose. Do not forget to use every available means to keep Strawberries in a free-growing state, by timely applications of water and frequent surface-stirring.

#### STOVE.

A very kindly temperature and healthy humidity should now be kept up, and regular attention be given to the supply of air, to shading the plants, syringing, and bottom-watering. Many free-growing autumn-blooming plants, that have been encouraged to make their growth, should now receive less nourishment in the way of liquid manure, and also a gradually diminished supply of water at the roots. In a short time such plants may be placed in an intermediate-house, where, if they can enjoy light and air, their growth will be properly matured and the flowering buds will set abundantly. Encourage young stock of all kinds to make a sturdy free growth.

#### GREENHOUSE AND CONSERVATORY.

Follow former directions as to airing, watering, &c., and use every endeavour to keep a moist growing atmosphere at all times. Attend in due time to those plants which require potting, and ply the finger and thumb vigorously to those plants of a rambling or loose habit of growth, so as to get them compact and bushy. Some of the most forward of the Azaleas, which were stopped some time back, will now be breaking again, and, if necessary, this is the proper time to give a second shift. Stop those which require it. All Azaleas, as soon as they are out of bloom, should be taken into heat to make their growth, syringing them copiously, and supplying them liberally with manure water.

WILLIAM KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

CLEARED away the remains of most of the Brussels Sprouts, and the stems of the most forward Broccoli. Even the latest of this, owing to the hot sunny days, is coming in too much at once to be long useful, and if taken up and kept in a cold shady place it loses its flavour. Removed the most of the *Winter Greens*, with the exception of variegated Kale, and Scotch Cabbaging Kale, which, as yet, show few signs of flowering. The last is one of the most useful vegetables alike for hardness and continued production. Some of the plants from a row had remained two seasons, and from being cut over were a mass of shoots. Left also a little longer the plain-looking green Asparagus Kale, which is well named, the shoots being little inferior to Asparagus. Finished planting out young plants of the latter, placing them in rows 4 inches apart in the row, and 27 inches from row to row. The plants are placed on a fine pulverised surface, and rich material put over them in the ridge-and-furrow style. Finished also planting out in rows four-inch pieces of the *Sea-kale* forced in houses. With the exception of the crown ends, the next best of the old plants for this purpose are the small finger-like roots about as thick as a lady's little finger. These soon make crown-buds and grow freely. The plants over which pots were placed in the open air, have afforded some fine gatherings, but have at last rebelled against our authority, and notwithstanding our sinking the pot a little, and a spadeful of soil on the top of it, have lifted the pots on their crowns so far as to let in light from below. Have any readers tried the green flower-heads of *Sea-kale* just when opening? If not, then do not fail to do so, for if well cooked they are excellent, and are often carelessly thrown away. Sowed also what little seed we had. These seedlings if well used may be forced the first winter, and always in the second. I now generally sow and plant in rows about 2 feet apart, the plants being left about 9 inches in the row, and then lift the most that I need for forcing. Threw a little rough salt between the rows of the *Sea-kale* and Asparagus, alike to encourage growth, kill snails, and discourage weeds. A good piece of *Sea-kale* is a fine thing to have to go to in a severe winter. Where much is to be raised, a little litter may be thrown over the ground to keep out frost, and to permit of easy lifting, and any person may have it in perfection who can take the roots packed in soil to a cellar or other dark place, with a temperature ranging from 50° to 55°. Sowed a border of dwarf China Beans, and planted out more under glass for the

last crop, taking care to pick those bearing regularly, as otherwise they soon get too old and injure the plants. If close-picked and well nourished there is no difficulty in keeping plants now bearing in a pit from bearing until the frosts come. Find Tom Thumb Pea very useful for early work in pots under glass protection, and in such fine weather as this, the pots may be set out of doors. Potted-off Capsicums and Chillies. A superabundance is useful for serving-out insects, especially when mixed with tobacco paper. Planted a two-light frame with Cucumbers, to prevent cropping those in pit too heavily, and thus prematurely exhausting the plants. Planted out Melons singly, generally two in a light, to be trained on the ground. Can hardly find room for pots this season, though that is a good way to grow them. Pricked out Lettuces, Cauliflowers, Celery, &c., on a border, some 3 inches or 4 inches apart, the latter to rise with balls, the plants having been forwarded in heat. Two lights of the strongest plants were planted under glass to get them early and strong. A little trouble with the border pays all the labour. We prepare it thus: throw on it a little rotten dung—say 2 inches, prick that in with a fork and mix with the soil, moved 2 inches deep. Place over that about an inch or more of rotten leaf mould, and then a couple of inches of light, fresh soil, in which plant. Most things, if at all fibry-rooted, will rise with fine balls, and never feel the moving. We shade with a few spruce branches at first, after thus pricking-out, and besides the shade the branches from their scent help to keep fly, and weevil, and slug, too, at a distance.

#### FRUIT GARDEN.

Disbudded a little of Apricot and Peach trees out of doors, preferring to do it gradually. Ran the hoe through Strawberry-quarters, expecting fully the rain which came so sweetly on Tuesday night, and a thorough drenching now almost secures a fine Strawberry crop. Just as a proof of what a little bottom heat will do, found that the young Strawberry plants raised from the border, potted firmly, and set half plunged in a mild hotbed about a foot high, as described the other week, quite exposed to the air, and otherwise having no protection whatever, were in full bloom before those in the borders had scarcely opened a flower. They may not be wanted, but it is always pleasant in our changeable climate to have a hundred or two hundred pots moveable, where to a certain extent you are independent of the weather. Already the fine roots are getting to the sides of the pots. Now, be it clearly understood, that though this lifting, potting, and slight forcing if desirable, may do very well in spring, it is a great risk to depend on any such plan in December and January. For early work the pots must be full of roots and the buds well ripened. Dusted soot and ashes over some Gooseberry bushes where a few caterpillars had made their appearance. Gave some manure water to Raspberries and Black Currants, both of which suck it pleasantly, if not given too strong. Watered fresh-planted trees with clear water. Hunted insects in orchard-house. Catch them and squeeze them being, after all, the most effectual remedy. Stopped and disbudded as necessary, and find that all things in pots have evaporated much moisture and need supplies pretty constantly; and, what my good assistants say is very strange, if there is a dry pot in the house I am sure to go straight to it at once and find it out. Tied-up the Vines in the late vinery, having hitherto been tied close to the front of the house beneath the roof, and so kept cool by plenty of front air. I was afraid to leave them longer in case the young shoots should be knocked off in fresh-arranging them in their more regular vertical position. Of all the untouchable things in the Vine way I have come across, are the young budding-shoots of the Stockwood Golden Hamburg. I have lost some fine incipient bunches this season, just from treating them, in moving the shoots, something like other Vines. The least touch will cause the young shoot 2 inches or 3 inches long to break from last year's shoot. "To be forewarned is to be forearmed." Treat such shoots tenderly, and all will be well. Regulated, tied, and stopped in second vinery, and took the opportunity of a dry sunny day to pull a dry hand over the bunches of Muscats in bloom.

Flower department much as last week.—R. F.

#### CATALOGUES RECEIVED.

James Carter & Co.'s *Gardener's and Farmer's Vade-Mecum Plant Supplement* for 1862.  
The *Spring List of Soft-wooded Bedding and other Plants*

cultivated and sold by E. G. Henderson & Son, Wellington Road, St. John's Wood, N.W.

A Retail Catalogue of New and Rare Plants offered by F. & A. Smith, Park Road, Dulwich, S.

### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**COLOURED FLOWER-GARDEN PLAN (Rev. A. F.).**—Some months since we had several most excellent coloured plans sent to us, with a forcible representation that such, if published, would be more instructive and be more readily appreciable by gardeners than any uncoloured plans however full and correct the descriptions accompanying them. We promptly assented, but were compelled to add, "There is no sufficiently cheap and correct mode of carrying out the suggestion." Since then a mode has been discovered, and we shall place the results before you and our other readers in the course of a few weeks.

**SEEDS (P. Kane).**—The seed is Fenngreek (*Trigonella foenugraecum*).

**APPLE BLOSSOM (G. H. B.).**—No one can tell the name of an Apple from a specimen of its blossom. It is difficult enough to do so from an inspection of the fruit.

**VINEY-BORDER (J. F., Kidderminster).**—Look back to Irish notes, and see how Mr. McNeill, Mr. Milroy, and Mr. Watts do their Vine-borders. We have no objection to bricking the front to prevent the roots getting beyond their allotted space, nor yet have we any objection to the bricks at bottom to prevent the roots getting down; but we would not have the bottom flat as you show, but sloping, and on that we would place 9 inches of open rubble as brickbats, &c. You would then have plenty of space for soil. The drain in front must be a foot below the brick bottom at least. Good fresh turfy loam is the best compost; and the best mixtures with it would be some tenth part of brick rubbish, and some one-hundredth part of old broken bones. If more strength is required give it by top-dressings and manure waterings.

**VIGOROUS VINES (Trent).**—We think from your description the Vines must be all right, as they are so short-jointed and fruitful. If they are spur-pruned, then stop before the bunch one joint, and keep stopping; and all the laterals behind remove, except those from the two eyes nearest the branch. If you must remove more leaves, do not take them from the buds you want for fruit-shoots next year. We think if you keep clear of laterals it will do.

**ASPARAGUS (An Inquirer).**—Abundance of liquid manure during the growing season, April to September, and not cutting later than the end of May, are cardinal rules for obtaining good heads. If you require all the details of Asparagus culture by our "Kitchen Gardening for the Many," which you can have free by post from our office if you send five postage stamps with your direction.

**HEAT LIQUIFYING SAP (F. H. A. S.).**—Heat does not liquify sap, it merely arouses the roots into action, and they imbibe more moisture from the soil. The moisture imbibed dissolves, as it ascends, the nutritive matters deposited in the sap-vessels during the previous growing season. Such subjects are involved in much uncertainty, and are best left for discussion to men of science and leisure. We shall be glad to receive any notes on practical gardening the results of your own experience.

**FLOWER GARDEN (G. Holmes).**—You have planted the flower-garden plan very well, and the ribbon-border the same. A centre bed of standard Roses, Mignonette, and Variegated Mint to edge with. Six long oval beds all round, with six kinds of Verbenas, a Fuchsia in each, and all edged with *Cerastium*. An outer circle of six beds of bad shape, or rather very bad shape, capially planted with Variegated and plain-leaved Geraniums alternately, and a ribbon of nine rows, with three colours three times repeated, or Purple King, *Aurea floribunda*, and Tom Thumb—all very good.

**MANURE WATER FOR VARIEGATED PLANTS (J. F.).**—Whether it would injure the variegation depends upon what kinds of variegated plants you mean. All the guano in Peru would not turn the colour of one leaf of some variegated plants into a green one, and some variegated plants will turn green if the soil is even a little richer than common. No manure or any medication known in gardening will turn any of the very best of the Variegated Geraniums green. There is no variegated plant which requires guano water once a-week, nor yet once a-month; and there is no such plant in existence which is not ten times better and more safe without guano water at all.

**HUMEA LEAVES BECOME YELLOW (D. C.).**—A majority of all the Humeas in distant counties are just like yours—that is, with three-fourths of all their strength gone through sheer starvation. All that can be done now is to get them planted out as soon as possible, and to look upon them for the rest of the season as the last evidence of the hardest treatment.

**FLOWER-BEDS (Caustic).**—Much depends on the size of the diamond beds. What you are "most inclined" to do is certainly the best—namely a twelve-feet circular bed, Flower of the Day and Brilliant, time about to the edging of Purple King Verbeena; and any one who might wish a better bed than that would be very hard to please.

**CERASTIUM BIEBERSTEINI (T. S.).**—Your specimen looks very much like that kind; but as our own plants of it have not yet got over the effects of the propagating-house we cannot be quite sure. Besides, we have examined two more kinds of *Cerastiums*, which are in the botanic borders at Kew, and one of them comes very near in looks to yours; but the habit of that kind is not at all suited to flower-borders. We must, therefore, warn our readers that there are three or four kinds of *Cerastiums* not worth growing, yet every one of them will be in the market immediately competing with *Biebersteinii*, by three or four different dealers.

**COST OF A PEACH-WALL (Patelin).**—We cannot answer your question, so much depends upon circumstances. It ought to be 7 inches thick. If you have tenders from two or three respectable builders you cannot be much out in your expenditure.

**HOUSE SEWAGE (H. M. N.).**—Mixed with water it may be used both to kitchen-garden crops and flowers. A lawn never wants such applications unless the soil is very poor. One bucketful of sewage will require at least five bucketfuls of water. In our "Muck for the Many," which you can have free by post for four penny stamps, are full details relative to this manure.

**WHITE-SEEDED DWARF KIDNEY BEAN (P. W. T.).**—The Canterbury Dwarf is a kind such as you require.

**CLIMBERS FOR A CONSERVATORY (F. W.).**—The following will suit your conservatory, not heated more than to exclude frost:—*Lapageria rosea*, *Mandevilla suaveolens*, *Ruscus androgynus*, *Habrothamnus elegans*, *Kennedia nigricans*, *Jasminum odoratissimum*, *Passiflora corulea*, *Passiflora racemosa corulea*, *Bignonia chiritare*, *Sollya heterophylla*, *Tacsonia pinnatifida*, *Kennedia Marryatæ*.

**FUCHSIA LEAVES DISEASED (A Constant Subscriber, Burton-on-Trent).**—We can find nothing alive on the leaves, but signs of thrips and red spider. The best remedies for the former are smoking and sponging with weak gum water, and a moist atmosphere. The insect is thin and long, and jumps on the underside of the leaf. The spider is round, like a small dot from a pen. Sulphur fumes, such as produced from a hot-water pipe at 160°, and a moist atmosphere are the best remedies. The Vine leaf is in a bad case.

**APRICOT SHEDDING FLOWERS (Nesio).**—If your Apricot would not fruit against the wall, we have little hope of its succeeding 20 feet to 30 feet from it as an espalier, unless your place is far south and warm indeed; but of that you say nothing. As the tree blooms so freely we would imagine that nourishment was more wanted, and thinness of wood, and more exposure to the sun to thoroughly ripen the bud. We would not be surprised if many of your buds were abortive ones—that is, contained no incipient fruit. In this neighbourhood a great portion of the Apricot blossom was destroyed by constant mug and wet before the frosty Sunday morning came apparently to finish it. A good sound loam without manure suits the Apricot best; and provided vigour is needed it is best to give a top-dressing of leaf mould or very rotten dung.

**VARIOUS (Idem).**—As a much cocoa-nut fibre will be useful; but we have no faith in anything, compost, &c., being wonders without the constant care and unremitting attention. Apply it at any time. Guano is not wanted if there is enough of vigour without it. When applied as a watering two ounces will do for three gallons. It is too late to graft now, unless you have retarded scions yet fresh. Those who advertise in our columns will supply you with proper Grass seeds if you write to them describing soil and space. We know of nothing more likely to master the Daisies and the Moss than Suckling and white Dutch Clover; at least we would have some of them in the mixture.

**GUMMING IN CUCUMBERS (A Subscriber).**—This disease has puzzled our best gardeners; and our own experience only justifies us in saying that we have seen it mitigated by keeping the air of the pit very moist, and the roots of the plant rather drier and cooler than they were kept before the disease appeared.

**APPLE TREES CANKERING (Ibid).**—We conclude that they have not been planted more than a few years. If so, we would take them up very carefully next autumn, prune away the roots descending into the clay soil, and replant upon stations. If the surface is afterwards kept mulched every summer for some feet round each tree, the roots will be induced not to descend.

**ASPARAGUS-BEDS (G. R. T.).**—With a fork remove carefully the sodden turf, &c., which was so ignominiously put on. If every shoot be broken off it will not weaken the plants so much as if they were allowed to grow and were cut for table. But if you cover the bed over with light soil after removing the sodden stuff, and water well with liquid manure, you will have a good crop this summer, and the plants will lay up a good store for next year's growth, which they will not do if left overwhelmed as they are now.

**WORMS IN GRASS-FIELD (E. D.).**—What you call "worms" are the larvae of the common May-Bug or Cockchafer (*Melolontha vulgaris*). The only mode of reducing their numbers next year is by killing as many as possible of the parent beetles during the present summer. We know of no mode of destroying the larvae without destroying the grass at the same time.

**ALYSIUM VARIEGATUM (Louisa).**—If moved with little disturbance to the roots and well watered it may be moved safely still.

**CIRCULAR BEDS OF THREE KINDS OF PLANTS (R. T. M.).**—In No. 1 you must put strong old plants of *Christina* (not *Christiana*) Geranium in the centre, else Purple King will be too high, and the Variegated Mint should be very low with mere roofed cuttings. No. 2 very good, if *Attraction* Geranium does well with you; they have discarded it at the Crystal Palace. No. 3, Flower of the Day, between *Calceolaria Aurea floribunda* and *Lobelia speciosa* either, must be of small plants, or the *Aurea* must be very large old plants. The rule, in all such cases, where circular beds are planted with circular rows of different kinds of plants, is that the plants in the centre must be the highest, even if the surface of the bed is level, and that no row be higher than the row behind it—that is, each row must be a step above the row in front of it. You mistake the universal objection to scarlet centres entirely. There is not the slightest objection to the centre of a bed being in scarlet: it is the putting of a whole bed of scarlet in the middle of a lot of beds which is considered contrary to good taste.

**NAMES OF PLANTS (Helen).**—*Acacia Riciana*, naturally of a drooping habit. Will your plant make a standard? The other plant looks like a *Boronia* rather than a *Veronica*. It requires peat soil, and to be treated like Heaths and Epacris. We should fear yours is hopelessly sickly. (E. Z.)—1, *Erica mediterranea*; 4, *Azalea nemorosa fl. pleno*; 5, *Muscari rance-*

mosum; 2 and 3 are not determinable from the specimens sent; 3 is a *Myosotis*. (*Polypodium*).—You have sent a *Polystichum*, *Lastræa*, *Scolopendrium*, and *Blechnum*, all without numbers. How can we give you the information you seek so as to be understood? They are wretched specimens too. (*W. G.*).—1, *Amelanchier vulgaris*; 2, *Rhodora canadensis*; 3, *Cerasus japonica multiplex* sometimes, but erroneously called *Amygdalus pumila*. It is the dwarf double Almond of the British nurseries. (*Creeping*). 1, *Phlox subulata*; 2, *Iberis sempervirens*; 3, *Fritillaria alba*; 4, not a sufficient specimen. Neefrey's "Rudiments of Botany" will be best for a beginner. Tobacco water is the usual application for destroying the black aphid on Cherry trees. If on a wall, we always have the finger and thumb applied as well.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

MAY 14th and 15th. TAUNTON AND SOMERSET. *Sec.*, Charles Ballance, Esq., Taunton. Entries close April 30th.  
MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). *Steward*, S. Pitman, Esq., Manor House, Taunton. Entries close May 1.  
MAY 28th and 29th. HULL AND EAST RIDING OF YORKSHIRE. *Sec.*, Mr. J. Hooton. Entries close May 14th.  
JUNE 3rd. ESSEX AGRICULTURAL ASSOCIATION. *Sec.*, R. Emson, Slough House, Halstead. Entries close May 10th.  
JUNE 4th and 5th. BEVERLEY AND EAST RIDING. *Sec.*, Mr. Harry Adams.  
JUNE 12th, NORTH HANTS AGRICULTURAL SOCIETY. *Sec.*, Mr. H. Downs. Entries close May 21st.  
JUNE 26th and 27th. SUFFOLK (Woodbridge). *Sec.*, Mr. J. Loder, jun. Entries close June 5th.  
JULY 3rd. PRESCOT. *Sec.*, Mr. James Beesley. Entries close June 21st.  
JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. *Secs.*, E. Holdsworth and J. Wade. Entries close June 21st.  
SEPTEMBER 9th. WORSLEY AND AEMLEY (near Leeds). *Sec.*, Mr. Robert Hoyle, Armley, near Leeds.  
DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

### POULTRY FROM IRELAND.

It is said that the cockney will travel round the world, and see nothing comparable to London. The view from the Pyramids is nought to that from the top of St. Paul's. No river is equal to the Thames; no scenery can compare with Richmond and Twickenham. O'Connell said there were no hills worth mentioning in England, except the Downshire family; and the cockney thinks there is no hill like Primrose Hill. It is well for a man to like the place of his birth or livelihood, and just as the cockney admires everything about London, and makes all things subservient to it in his idea, so are we at no loss to do the same with poultry. The commander of the galley "Ganymede" said, "If it were a calm, the good ship was in perfect safety; if it blew hard, she sailed the faster. If the night were light, a collision was almost impossible; and if it were dark, pirates could not see them." If the weather is cold, dead poultry will keep; if it is hot, live poultry will grow. If the sun is scorching, fowls will bask and enjoy it. If the weather is wet and muggy, the earth will teem with animal life for chickens.

There has been great dearth of poultry in the London market, and in our character of optimists, we would try to find some use and instruction from a fact we have noticed, that although vast numbers of chickens are brought over from Ireland, and although they realise prices that are doubtless remunerating to senders, yet they do not make the return they are capable of; nor are they sufficiently well fed and managed to bear the journey and voyage in warm weather. The tenor of our remarks of late will have shown that we believe much more poultry might be sent to London than we now receive. We also think it would be profitable.

It is hopeless to look to England for great help in the question considered with reference to food. The small farmers who were the poultry-breeders are either disappearing or have disappeared, and large ones must draw the line somewhere. Just as Boz's barber could shave a baker, but must decline a coalheaver, so the large farmer can keep pigs, but he cannot descend to poultry.

The chickens received of late in large numbers from Ireland have proved the climate is favourable to rearing; but the prices they have returned have been little more than half those that go into Sussex. They lack breed, food, and management. Weeding might do much in the first particular. As yellow, green, and black legs take from value, all such should be done away from the stock birds. There is no lack of strength, as they are reared plenteously at a time when they are scarce in England.

Their food is not good enough to fatten them properly, nor are they sufficiently well fed when young. Oats well ground, without taking away any part of the corn or husk, and meal mixed with milk, will fatten a fowl, and, moreover, give such

firmness of flesh and condition that the bird will bear travelling and change of atmosphere without loss of value. Another most important thing to notice, and one that concerns every one who kills chickens in hot weather is, they should be thoroughly fasted before they are killed. This means they should be kept positively without food of any kind or water for at least twelve hours before they are killed. This will render it possible to keep them in any weather long enough to allow the stiffness to go off, if they are to be eaten where they are killed, or to send them away with the certainty of their reaching their destination fit for the table. If the Irish chickens of which we have spoken were fasted, it would increase their value without causing extra expense. We are delighted to come to our last fault-finding. They are very badly packed, they are thrust into an old tea-chest filled up with oat straw, and here they lie and heat while journeying between Wicklow and London. They would travel just as cheaply if they were packed in a stout square hamper, and carefully divided in layers by good stiff wheaten straw their value would be much increased.

We are quite aware the Irish chickens have made enough to satisfy the senders; but we contend, that by following our advice, they will make a larger sum without incurring any more expense. They evidently have a climate that is suitable for rearing early poultry, and there is no reason why some of the hundreds of thousands that go abroad should not remain at home. Much may be done next winter in Turkeys. Immense numbers come from abroad and make good prices; many come from Ireland and sell badly, if they sell at all. The reason is, it is known they are badly fed, and they are, therefore, only saleable to those who buy for a chance market. Better food would remedy this.

### HEN PIGEON DROPPING HER EGGS.

Is it possible to prevent a hen Pigeon dropping her eggs on the floor, and not sitting at all? I have given her a nest, and also let her make one herself, but to no avail. There are only six pair of birds in the room. Can you tell me where I can get a pair of Merles (Antwerp)?—JAMES BARTON, JUN.

[We have always found that the best remedy for any irregularity in the egg-organs of a Pigeon is to give her a pair of eggs, and allow her to hatch and feed off the young, after which she will generally proceed in the regular course; but it must be remembered that Pigeons in a confined space never do as well as those that are permitted to fly.

With regard to the Merles. Some three or four years since Mr. Thomas Townley Parker went to great trouble and expense in importing birds from the best strains in Belgium, including those of Mons. Lejeune, Fernel, Roth, &c. We believe that he has since retired from the fancy, but possibly he may have some flyers left. Mr. Tegetmeier had several pairs of Mr. Parker's birds, but at present we do not think he has any to dispose of. Several of his birds are from M. Simonis, who won the second prize in the great fly from Marseilles to Brussels, eight hundred miles, which was flown in a violent storm, that greatly interfered with the rate of flight.]

### HATCHING CALIFORNIAN QUAILS.

Will you tell me how I shall manage my Californian Quail's eggs? The hen has made her nest in a sheltered spot and lays daily. Will it be safe to allow her to hatch them, or should I put them under a Bantam? In the latter case I fear the eggs may be broken, as they are so small.—BOUGHTON KINGDON.

[Let the hen sit on the last three or more eggs that she lays. If, as is frequently the case, she lays a large number, you may let her have more. Put the others under Bantams, and when they are hatched let them at first be under a Cuenumber-frame or something like it, the larger the better. Let it be filled with dust, sand, and gravel. Feed as you feed young Partridges or Pheasants; and as soon as they are old enough to eat corn, give them buckwheat and oats. They are hardy and easily reared.]

AN EXTRAORDINARY BROOD OF CHICKENS.—On the 1st day of May last a hen, the property of Mr. Thomas Ibb, farmer and brewer, of Hesthote Road, Longton, Staffordshire, produced an unexpected brood. The hen was sat upon seven eggs, and by some chance or other some of the other hens must have laid to

her; for on the day named above there came jumping and chirping forth the most extraordinary number of twenty-one chicks, and I am happy to say that both hen and family are all doing well. The hen is of the Spanish and Game (cross). The above came under my notice on the 4th inst.—HENRY AVINS.

### GOOSE-CULTURE IN AMERICA.

THE chief requisites for keeping Geese are a pond of water and a pasture for grazing. The latter is essential, as the bird is granivorous as well as granivorous. An occasional cabbage-leaf will form an acceptable variety of food, and during the winter any spare vegetables will help to supply the deficiency of the pasture. If fed high, some varieties of Geese will often lay in autumn, but the advantage of a brood of goslings in November is questionable.

In allowing Geese to range at large, it is requisite to be aware that they are very destructive to all garden and farm crops, as well as to young trees, and must, therefore, be carefully excluded from orchards and cultivated fields. It is usual to prevent them getting through the gaps or holes in fences by hanging a stick or yoke across their breasts.

They are accused by some of poisoning the grass, and of rendering the spots where they feed offensive to other grazing stock; but the secret of this is very simple. A horse bites closer than an ox, a sheep goes nearer to the ground than a horse; but after the sharpest shearing by sheep, the Geese will polish up the turf, and grow fat upon the remnants of others. Consequently, where Geese are kept in great numbers upon a small area, little will be left to maintain any other grass-eating creature. But if the commons are not short, it will not be found that other grazing animals will object to feeding either together with, or immediately after a flock of Geese.

It has already been said that Geese are much given to grazing, but we have not said that they improve the pasture. This, however, is the case, although there is an old proverb to the effect that nothing will eat after a Goose—whereas the auxiliary verb should be can, and not will. The fact is, the Goose will thrive on a pasture so short that a goat would starve on it; and the consequence is a short sweet herbage.

Although water is the natural element of Geese, yet it is a curious fact that they fatten much faster in situations remote from rivers or ponds. They should not be allowed to run at large when they are fattening, as they do not acquire flesh nearly so fast when allowed to take much exercise. It is stated that Geese can be raised, in a proper situation, at a profit far greater than almost any other stock. But to do this, more attention is required than is usually bestowed on their keeping and management. Like other fowls, they may be brought by proper management to a great degree of fatness; but the period at which they are the fattest must be chosen to kill them, otherwise they will rapidly become lean again, and many of them would die.

Geese may be fattened at two different periods of their lives—in the young state, when they are termed "green Geese," and when they have attained their full growth. The methods at each period are very nearly the same. A Goose diet, for the first two weeks, is formed of oats and water mixed in a trough; after this the food is gradually changed to barley meal mixed with water, of the same crumbling consistence that has been recommended for the goslings, the water being given separately in small quantities. Steamed potatoes, mashed up with four quarts of buckwheat or oats, ground, to the bushel, and given warm, is an excellent diet, and will render Geese, cooped in a dark place, fat enough in three weeks.

**HABITATION.**—In selecting a situation for a Goose-house, all damp must be avoided; for Geese, however much they may like to swim in water, are fond at all times of a clean, dry place to sleep in. It is not good to keep Geese with other poultry; for when confined in the poultry-yard they become very quarrelsome, and harass and injure the other fowls: therefore it is best to erect low sheds, with nests partitioned-off, of suitable size to accommodate them; and there should never be over eight under one roof. The larger ones generally beat the smaller, in which case they should, of course, be separated one from the other, by partitions extending out some distance from the nests. The nests for hatching should be made of fine straw, of a circular shape, and so arranged that the eggs cannot fall out when the Goose turns them. From fifteen to seventeen eggs will be as many as a large Goose can conveniently cover.

In the event of any one being induced by our account to keep Geese, let us recommend him not to begin with young birds. They are not to be depended upon for breeding till the third year, and do not attain their perfection for a year or two subsequent to that age. When once in their prime they never retrograde, so that, barring accidents, a person possessed of a gander and three or four Geese (no way related to each other, and in their prime of life) may consider himself set up in the anserine for life.—C. N. BEMENT.—(*Genesee Farmer.*)

### "B. & W.'s" APIARY IN 1862.

I MADE my first swarm out of my Italian stock by driving, on the 29th ultimo, and my second out of one of the Anglo-Italian hybrid stocks the next day. In both instances most successfully securing the whole adult population in each case to the swarm. Not a bee offered to sting, nor was there any fighting. I like amazingly this plan of Langstroth—*i.e.*, making one swarm out of two hives. I can scarcely imagine it to fail, and can now recommend it from actual manipulation (experience I can hardly say). The Italian queen, which I have now seen several times, is most unmistakably marked in the Ligurian fashion, although not to the extent of some of her offspring. Some, I say, because a great many are in no way (that I can see) distinguishable from our common hive bee. A few of the drones found in this stock had the Italian colouring, the rest were similar to common drones. There are drones in three or four of my stocks, but, except in the pure Italian stock, I could not detect any sign of colour different from that of our common drone, and in that, I repeat, only a very few showed it. The Italian queen is small, and not remarkable as a breeder. Not so the only Anglo-Italian queen (her offspring) which I have as yet seen. She was large, and is a capital breeder, but has no distinguishing mark of colour whatever, and yet some few of the common bees in the hive are partially marked, but they may be old bees bred last autumn out of the Italian brood given to this stock to breed a queen from.

I cannot say that my apiary is in as forward a condition as usual this spring, although everything is going on promisingly, and I have secured two first-rate April swarms. The season, however, has been late, and I must not forget the rough treatment my bees got last autumn. A neighbour of mine had a fair-sized natural swarm on the 24th April, on which day we began to have real heat, and since then the weather has been everything that could be wished. Such a May-day as to-day we have not had for years. My experience so far tallies with Mr. Fox's, that I have found it necessary to feed to some extent to make up what I failed to give the bees last autumn, but only four hives out of eight required anything. However, no honey was visibly collected before last week. Decidedly, the bees have been very backward this spring where they have not been stimulated by food. But for the plan of Langstroth's I should not have dared to make a swarm for ten days from this time. As it is, the bees are doing splendidly in all hives, the swarms as usual doing most. If this hot weather continues I predict a very poor honey-season later on.—B. & W.

### WOODBURY ON BEE-KEEPING.

#### SECOND NOTICE.

MR. WOODBURY proceeds to advocate a plan for preventing excessive swarming, first, I believe, recommended by myself in the pages of THE COTTAGE GARDENER, and explained more at large in "The English Bee-keeper." This plan, "whilst it adds strength to the first swarm, generally prevents any subsequent issue. As soon as the swarm is quietly settled, which will generally be in from ten minutes to a quarter of an hour after living, it should be put in the place of the old stock, which must be removed to a new position at a little distance. The returning bees will seek their old locality, and generally in sufficient numbers to prevent the issue of another swarm." I may add that subsequent experience encourages me to recommend this plan without hesitation to the special notice of cottage bee-keepers, who still adhere to the natural-swarming system. It can fail only in exceptional cases—fail, I mean, in preventing after-swarming; but it invariably strengthens the first swarm, which should always be plundered at the beginning of August, except in heather countries. I cannot promise the like success

as a rule without unusual caution \* where the artificial-swarming system is adopted. The absence of the queen, and the great consequent migration of the full-grown bees to their old site, will be productive of mischief where great attention to the condition of the hives both before and after swarming is omitted.

As I was writing the above, the post brought in the first Number of THE JOURNAL OF HORTICULTURE for April, where I read with surprise Dzierzon's verdict on the subject of "Divided Hives." Exceptional cases may occur, but I cannot give in my adhesion to the statement that "the profit from undivided hives, even if the bees never want room, will not amount to so much as from those which have swarmed either naturally or artificially"—that is, of course, in any single summer: therefore, from all experience with which I am acquainted, I adhere to my own recommendation by all means to prevent swarming as soon as the apiary is well stocked. In this respect I endorse Mr. Woodbury's statement that, "where ample additional space is afforded, bees will seldom swarm; and when a sufficient number of stocks has once been established, a larger honey-harvest can be secured by working them on the depriving system than by any other means." Mention is, of course, made of the "Woodbury comb-bar," of which Mr. Bevan Fox speaks in high praise. Having always at command a sufficient store of spare guide-comb for affixing to bars, I have never yet adopted this novel invention. Its utility, however, has been proved beyond question. I may make the same remark with regard to frame-hives. The objections to the use of these frame-bars, as stated by Mr. Woodbury, are sufficient in my own case to outweigh the advantages. Their one advantage is, "that every comb may be extracted, examined, and replaced without injury, or endangering the life of a single bee." Their disadvantages are extra expense in construction, and cumbrousness from their large size, whilst the frames block both back and front windows so as to render them almost useless.

The compound bar-frame is a contrivance of Mr. Woodbury's, which, he says, "I have found very advantageous in enabling me to use bar-hives and frame-hives indiscriminately, without departing from the rule before laid down, that 'every bar should fit every hive in the apiary.' It will be best understood by reference to the accompanying sketch, in which the comb-bar is shown slightly raised from its frame. By adopting the compound bar-frame, any bee-keeper using bar-hives may readily introduce frames without forfeiting the advantages arising from the power of interchanging combs throughout all the hives in his apiary."

The description of what Mr. Woodbury considers "the best and safest mode of making artificial swarms when the apiarian has the advantage of either bars or frames" is nearly identical with an article from his pen, which appeared in No. 20, New Series, of THE JOURNAL OF HORTICULTURE.

Another excellent and safe plan is that recommended by Langstroth, the celebrated American apiarian. Perhaps it is the simplest and the safest yet discovered. It may be described as follows:—Let A and B represent two prolific stocks in about an equal state of forwardness. On a fine calm day drive out the whole population of A, hive the bees, and let the new swarm (C) be put in the place of A. Next move B to a distant stand (which it is permanently to occupy) at the hour of the day when most of the bees are abroad; and in its place locate A, out of which the swarm C had been previously driven. The hives will now stand as follows:—C A B. It will be seen that one swarm is thus got out of two hives. Three weeks or a month later B may be driven in the same way, the forced swarm D taking its place, and C removed (as B was before) to make way for B; the hives will then stand—B A D C. Swarms forced out this plan may be made very early in the season, as soon as drones appear, often in April, with no risk of loss (provided the swarms be fed in bad weather), because of the very slight weakening of the several populations. It is my intention to adopt this plan largely this year, particularly in the apiary of a friend, number-

ing two hives, which are under my superintendence. Langstroth improves upon this plan by giving fertile young queens (which he raises artificially for the purpose) to the deserted hives, which otherwise must raise their own queens artificially; by this means two strong stocks may be multiplied to eight in one season. According to his plan he forces a swarm about every ten days: this will be best explained by an extract from his book:—"Let a fertile young queen be given to A as soon as it is forced, and in ten days force a swarm from B, which I shall call D. Put D on the stand of B, and after removing A to a new place set B where A stood, giving to B a fertile young queen. If another colony E is to be formed make it in the same way, by forcing A and transposing with B; and so continue by the transposition of A and B, forcing the new colony alternately from each, to make successively, at intervals of about ten days, F, G, H, &c., A and B being supplied with a fertile queen as often as they are forced."

In concluding my imperfect review of this essay, I cannot help congratulating my brother apiarians on the accession to their number of so perseveringly scientific, and at the same time cautious an associate as Mr. Woodbury, *alias* the "DEVONSHIRE BEE-KEEPER," has proved himself to be. I always read his communications to this Journal with interest. May he long continue to have health and leisure to enable him to pursue his hobby with undiminished vigour.—B. & W.

### HIVING INTO COMBED HIVES.

In hiving a new swarm of bees it is considered advantageous to give them a hive with empty comb in it? I have a set of boxes, of Nutt's construction, with the middle box full of comb down to the floor and perfectly empty. The box is perfectly sweet and clean. I had purposed, when I have a swarm, to take them in one of the end boxes and draw-up the partition-slide, and so let them have the option of taking possession of the middle box furnished ready for them. The comb is two years old, and not very much discoloured.—C. P., *Herts.*

[It is almost impossible to over-estimate the advantage of placing a swarm in a hive ready furnished with combs. If you hive the bees in a side box of your Nutt's hive, and open the communication with the pavilion, they will, probably, soon betake themselves to the furnished apartment. It should, however, be ascertained beforehand that the combs are in good condition, and free from the ravages of the wax-moth.]

### OUR LETTER BOX.

BROKEN SICKLE-FEATHER (*A Subscriber, Monkwearmouth*).—You may safely pull the feather out. It is not impossible that it should become white, but it is unlikely. It is too important to be left in a broken state.

BEES TRAVELLING BY RAIL (*Sutton Abbott*).—Under the circumstances the best mode of conveying them would be to sew the hive up in a thin canvass, and suspend it by a rope either from the roof of a first-class carriage, or from a nail driven into the roof of the guard's van. If this cannot be done, carry them on your lap. Shake them about, or tilt them on one side as little as possible. The price varies from 10s. to £1 in country districts.

PAYNE'S HIVES.—If some country hive-maker would make these and advertise them at a reasonable price, they would sell largely.

BEST KIND OF HIVE (522).—No one can answer such a query. Every one must determine for themselves after examining the drawings, or the hives, and after considering what characteristics they would especially prefer. Price, facility of observation, character in deprivation, ornamental appearance, and many other points have to be considered before any one can say, "That hive is the best for me."

PREPARATION OF RABBIT SKINS.—D. will be obliged by instructions to prepare Rabbit skins, to be made into muffs or other articles of dress. No doubt there are other amateur Rabbit-keepers who would like to use their own skins in preference to selling them if they could dress them in a satisfactory manner. D. has tried alum and salt, also arsenical soap, but the skins are then too dry and stiff for sewing together.

### LONDON MARKETS.—MAY 12.

#### POULTRY.

Our supply is very small, but the trade is less. In the memory of man it was never so dull in the month of May.

	Each—s. d.	s. d.	Each—s. d.	s. d.
Large Fowls	5 0	to 5 6	Ducklings	3 0 to 3 6

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 66.7° and 44.2° respectively. The greatest heat, 89°, occurred on the 23rd, in 1847; and the lowest cold, 29°, on the 25th in 1839. During the period 144 days were fine, and on 101 rain fell.

CYCLAMENS.

ATHER more than three months ago you obliged me by inserting in your Journal (Vol. II., p. 354), an inquiry respecting the Cyclamen, which has been found wild in our country, and to which our most popular floras give the name of *C. hederæfolium*. My object has been to ascertain whether our plant is the same as *C. neapolitanum*

of Prof. Tenore; and from the remarks of Mr. Beaton appended to my inquiry, and from other information subsequently received, I am nearly satisfied that it is the same. That the plant which grows at Sandhurst, in Kent, and blossoms in the autumn, is so there can scarcely be a doubt; and I am now satisfied that the one which grows at Stackpole Court, Pembroke-shire, is the same as the Sandhurst plant, having lately received from that locality dried specimens of the flowers, both purple and white, which were produced in September.

Of the Suffolk plant, I have not till lately doubted that it blossoms in the spring, having relied on the statement of Sir J. E. Smith in "English Botany" and "English Flora;" but I am now somewhat sceptical about it. He does not, that I am aware of, anywhere say that he had seen it in blossom in the spring; but as he evidently considered it identical with the Ivy-leaved spring-flowering Cyclamen of the older botanists, which, as well as *C. hederæfolium* of "Botanical Magazine," 1001, is, I have no doubt, *C. repandum* of recent botanists, he might naturally conclude that it did blossom in the spring. The specimens which he mentions having received from Suffolk may have been of roots only, which he would be likely to plant in his garden; and if he did, his saying that in a cultivated state it sometimes blossoms in the autumn, is readily accounted for. I must not, however, hastily conclude that the Suffolk plant does not, at least sometimes, blossom in the spring; for though the specimens which I have received of seedling descendants from that locality have with me invariably blossomed in the autumn, they were sent to me with the statement that their time of blossoming is the spring; and if those to whom I am indebted for them were mistaken, I can only account for it by supposing that they were led into the error in some such way as I have supposed Smith to have been. Perhaps some others of your readers may possess the Suffolk plant; and if any of them have had it blossom this spring, they would oblige me as well as others by communicating the fact through your pages, and sending you specimens for your opinion as to its identity with *C. neapolitanum*.

In your Number for February 11th, page 388, *C. europæum* is spoken of as a sickly plant under cultivation. So I have found it when grown in pots—at least, in small

pots; in larger ones—say 7 inches or 8 inches diameter, half filled with stones, and filled up with light earth mixed with a few small stones, I believe it would do well. It has done fairly with me in the common open border; but it would no doubt be an improvement to provide for it a raised bed of light earth mixed with stones, such being the kind of habitat in which I have almost invariably seen it in a wild state. But I cannot do better than refer such of your readers as are interested in its cultivation to the excellent paper of "J. A. P." at page 39 of the Number for April 15. If a few large stones were placed on the surface of the bed, especially on the more exposed sides, they would give the kind of shelter which, he remarks, is so congenial to this plant.

My knowledge of this species in its wild state is not nearly so extensive as that of "J. A. P.," being confined to a rocky district about ten miles south of Geneva, and to a few spots on the borders of the road between Geneva and Chamouuy. On these roadside places I observed it but sparingly; but in the rocky district it grows plentifully, especially on the western slopes of Mont Salève. From this locality I have at different times taken up and brought home many of the roots, which are here found for the greater part amongst loose stones—sometimes nearly on the surface, sometimes 6 inches or more deep. Seating myself on the ground for the purpose of removing the stones, I once extricated eight good roots without moving from my seat; and my friend Jas. Atkins, the originator of the beautiful hybrid Cyclamen which bears his name, who was my companion at the time, obtained eleven roots without shifting his position. We found a few roots, perhaps about one in a hundred, bearing pure white flowers, which I do not remember to have seen anywhere else. The leaves, so far as I have observed them, are generally heartshaped, seldom round like those of *C. coum*, and they are as large at least as those of that species, I think for the greater part rather larger; they are so, as I have the two now growing in my garden. They are entire at the edge, or but obscurely crenate; very unlike the crisped and sharply-crenulate leaves of the figure of Sweet's "British Flower Garden." But that figure was drawn from a specimen of Hungarian origin, and "J. A. P." informs us (page 40) that in the more northern localities the leaves are more decidedly toothed. The earliest time of the year at which I have seen this Cyclamen in blossom is the 10th of July, and then it was but partially so; it was in full blossom from about the middle of July to the end of August, and early in September I observed that the blossoms were beginning to fade.

Now that the inquiry about Cyclamens has been so fully opened in your pages, I hope it will not be closed until the several species are better known and more clearly defined than hitherto they have been. Some botanists, and Mr. D. Beaton appears to be of the number, are of the opinion that *C. vernum* is of hybrid origin; others make it a variety of *C. coum*. In the Prodromus of De Candolle it appears as a variety of this species, or as synonymous with it. But "J. A. P." evidently

considers it a distinct species; and from his long cultivation of it, as well as from his knowledge of the whole genus, his opinion is entitled to much consideration. It appears doubtful, however, whether it was known to the old botanists. I cannot find a reference for it to any one of them, except that Sweet quotes Morison's "Hiatoria Plantarum," an old folio of 1650, which I have not seen; but he also quotes Miller's "Dictionary," No. 4, "Cyclamen (vernale) foliis angulosis integris," which appears to agree better with *repandum* than with *vernum*; for, in addition to the "foliis angulosis," the flowers are said to be large, white or pale purple, with a bright red or purple bottom; whereas in Sweet's figure the leaves are nearly round, not angular, and the flowers are nearly of as full a red as those of *C. coum*. If Miller has *C. vernum* at all it is, I think, his No. 2, "Cyclamen (Purpurascens) foliis orbiculato-cordatis, inferne purpurascens." I refer to the eighth edition of the "Dictionary;" Sweet quotes from the third, but I suppose the numbers and descriptions are the same in both editions.

The "Cyclamen vernum" of Gerard's "Herbal" and of Parkinson's "Paradisus" is, I have no doubt, *C. repandum*. Gerard's "Cyclamen orbiculato folio," and Parkinson's "Cyclamen Romanum Autumnale," come the nearest to our *C. vernum*, and except in the time of blossoming, there is not much either in the figures or descriptions to prevent their being received for it. *C. neapolitanum* is well figured and described by Gerard's "Cyclamen folio Hederae," and Parkinson's "Cyclamen folio hederae autumnale."

Another impediment in the way of receiving *C. vernum* as a distinct species is, that no country appears to be known to which it is indigenous. If it can be found wild in any country, that, of course, would settle the question.

Of *C. ibericum*, I see no reason to doubt its being indigenous to the country from which it takes its name. In the "Horticultural Magazine" of August, 1849, where a description is given of it, it is said to be a "native of Iberia;" and a friend has informed me that he has received two parcels of imported roots, which he had every reason to believe were direct from that country.—T. C., *Halesleigh*.

P.S.—At page 61 of your Journal of April 22, there is the same error of "Genoa" for Geneva, as occurs at page 492, Vol. II., in the Number of March 18.

## RAISING EVERGREEN AND DECIDUOUS STANDARDS.

In the early Volumes of THE COTTAGE GARDENER there were long chapters about how to make standards and half-standards of most of the old evergreen and deciduous shrubs, and reasons and arguments were adduced for the application of such plants on terrace gardens, and every inducement was put forth for going that way to work; but, unfortunately, the old Horticultural Society set its face against any such move, and Mr. Appleby was just lucky enough to escape being transported for venturing to exhibit the first standards of *Deutzia gracilis*, and the last that were ever seen at Chiswick Shows. Things are otherwise now, and no plants are more prized by the revived Royal Horticultural Society than standards inside and out its garden structures. I went through the grounds and conservatory the other day, and the standards of the Portugal Laurel seemed to me likely to do there after all. During the winter they and the Cedar of Lebanon looked wretched, but they are breaking strong.

If Mr. Appleby comes up to the Exhibition he could revenge himself now for the vituperation inflicted on his *Deutzias*, for the new Society has a collection of the most ridiculous Tom-Thumb-looking bronze statues about some of the upper steps near the conservatory, which no mortal with a grain of artistic genuine taste would ever put in such places—unless, indeed, they are meant to signify that the Society is now pliant, and that you could do anything in reason with them, and select even standard *Laurustinuses* above all other things for their display of winter flowers in fine glass houses.

The Society patronises every good move in that direction now, and we have this week felt the first pulse of the new move coming back on us who led the storming party against Fort Prejudice a long time ago. That pulse was from an amateur, who wishes to know if the *Laurustinus* is worked on stocks of the *Guedres Rose*.

The question is not so far out as it might seem; for although there is no natural affinity for working between the two—the one

an evergreen, the other not—there is sufficient family affinity to warrant the idea. But standard Laurels of all kinds, from *nobilis* to the last variety of the family, are made ten times better on their own roots than on the roots of their near neighbours; and most fortunately, nothing is more easy of doing than to raise them all on their own roots, just as the old COTTAGE GARDENER said they ought to be done—that is, by cutting down to the ground; even as late as next week would do.

In the case of an old plant of Sweet Bay, of Portugal or common Laurel, or of Phillyrea, or *Rhamnus*, or *Alaternus*, scoop the ground from near the collar of the plant, and with a small hand-saw cut through the stem as low as you can do it; stir the ground all round, and if the stump bleeds let it—but let there be no doctoring, a little blood lost is often more saved; water the stool, and wait awhile. When the suckers come very thick together thin them, and when they are 6 inches high put 4 inches deep of cocoa-nut fibre refuse in a heap all round them, and the damp in that will keep the stems of the suckers as soft as they are then for the next six weeks. By the time the suckers are, any one of them, just 20 inches above the heap of cocoa-nut fibre refuse, open that heap down to the surface of the old stock, and 3 inches above the old-cut stock take off a ring of bark an inch wide from every sucker that is of that length, and before the end of August every one of these ringed parts will have a fringe of roots all round, and the cocoa-nut fibre refuse is then quite full of such fat white luxuriant-looking roots as you never saw before coming above ground, even from a Vine in a wash-house-like temperature.

I said, seven long years since, that there was nothing on the face of the earth or under it, in which the roots of Hollies and *Deodars* and all manner of trees would luxuriate so soon and so much as in this cocoa-nut fibre refuse, just then fully proved in the Experimental Garden, and I repeat the same now, when every one is holding up the hand in its favour. But prove the fact, and secure to yourself such beautiful evergreen standards at the same time as the Royal Horticultural Society are now growing in their splendid new conservatory. All the plants in this do one real good to see how well they thrive, and none of them better than the standard *Laurustinuses*, which have been beautifully in flower there all the winter, and are now left there to make and ripen their young wood, and to be hardened-off in the autumn, just like Chinese *Azaleas* and *Camellias*, for flowering again next winter, even in a more flourishing state than they ever had the chance of being in before they got into such comfortable quarters.

But, about the rooted young standards, which are to be, in that wonderful cocoa-nut fibre refuse, let us now follow them to their final separation from the old stools. In the autumn of the first year, as we have just seen, they have each a mass of roots, and they ought to remain unmoved all that winter, and to the middle of next April if they are evergreens, then to be cut below where they have been ringed for rooting from. Choose a dripping time to separate them, and before you plant them out for nursing up to be what you require, find out all the buds or eyes, which are situated among the matted roots, and pick them out thoroughly so as to do away with the chance of suckers ever rising from them. Disbud also a foot or 18 inches above the roots, and for the next two years only stop the rest of the side shoots that may issue from the stems of those which ultimately are to be the standards, and see that none of the shoots which are to form the head get on faster than the rest; stop them if they do, and bring all of them up on equal terms, and you never could expect to see such beautiful standards as you will have, or may possess, if you keep strictly to these well-known simple rules of obtaining such things.

But, recollect also, if you were to give them plenty of cocoa-nut fibre refuse as others would give them manure, you will gain time and finer roots.

Then, if your stool standards are of deciduous kinds, as Persian and common *Lilacs*, *Guedres Rose*, or any *Spiræas* and the like, they must be parted from the stools by the end of February, and be done exactly as the evergreens. And, moreover, every hardy tree or shrub, deciduous or evergreen, in this country or in any other, will yield to propagation on that plan. The only special and essential proceeding in the whole of the treatment is to keep the bottom part of the young shoot as soft and as succulent as table *Asparagus*, until the shoot is large enough to be ringed near the bottom, and that can be done only by a heap of the cocoa-nut fibre refuse, exactly on the plan here set forth. I have seen suckers of variegated Hollies root that way as freely,

seemingly, as Verbenas, and there is not a shade of doubt in my mind about the young shoots of any plant rooting the same way under similar circumstances.

D. BEATON.

## A FEW DAYS IN IRELAND.—No. 23.

MONTROSE.

THIS beautiful residence of William Jamieson, Esq., is only a short distance from Alderman Roe's, and the demesne is of much less extent as far as appearances go. On entering the lodge and passing along the approach we noticed some nice plants of Hollies and Conifers, and learnt that more, in addition to Thu-jopses and Cypresses, were to be added. By the sides of the approach were little dots of circles of flowering plants, with Roses—thus destroying everything like breadth of view, and giving an undesirable sensation about flowers before reaching the flower garden. On speaking to Mr. Laidley, the gardener, who had only been there a short time, he told us all these circles were to be turfed-up, and we were glad to hear it. Scarcely any other arrangement could so thoroughly break up the massiveness of a place, and lessen and even destroy all sense of dignity as this frittering with flower-beds along a carriage road, and the evil is anything but uncommon. As you get near the mansion a large Portugal Laurel and a Yew-hedge, &c., conceal the offices on the right side of the approach.

As at Nutley, the pleasure grounds are south and east of the mansion, and the kitchen garden more eastward still. A walk runs through a slip of shrubbery on the south side of the lawn, and this walk is thoroughly concealed from view by a combination of rotery and rockery in irregular sweeping lines, and perhaps some 4 feet in height. That on the west side immediately in front of the mansion is so well clothed with Ferns, creeping plants, Moss, Saxifrage, Sedums, &c., and overhung with evergreen Oaks, &c., as to be rather unobjectionable in an artistic point of view. That on the east side is equally well seen from the house and the conservatories, and, whatever may be the material of its chief construction, showed great masses of white flints, yet uncovered in September. In such an elegant place the flints seemed as glaringly out of place as the white flint-mound alluded to in another pretty place a few weeks ago.

The whole gardens would be nearly three acres, and rather more than one-third we should suppose was devoted to lawn and flower garden. On the east side of the lawn there did not seem to be a very good separation between the ornamental and the useful departments. We forget whether the ridge of rockwork was continued there from north to south or not; if so, it was not so high as on the south side.

Notwithstanding the rage for roteries and rockworks, we are unable to see the propriety of such mounds bounding a fine-dressed lawn, and in front of an elegant mansion, unless it be true that the more violent the contrast the greater the pleasure. If desirable to conceal the walk in the slip thoroughly from the pleasure ground, an evergreen shrubbery faced with Rhododendrons would furnish a nice background; and as the south side of that would be screened by the trees farther south still, there might have been no end of rockeries, and roteries, and ferneries, as distinct and separate objects of attraction, and which could not be seen at all from the lawn or the mansion. We may be thoroughly wrong in our idea, though not wrong in expressing it, that such mounds on a fine-dressed lawn and seen from fine sitting-rooms, speaking from every wall and corner of refined taste and artistic skill, are as much in the right direction as setting the most rustic rough-looking three-legged stools as ornaments in a lady's boudoir. Taste, however, is an undefinable thing, and every man has a perfect right to carry out the ideas which he cheerfully pays for. Some love the showy and gaudy; others the neat, the retiring, the small, or even almost microscopical, in vegetable nature. For giving comfortable homes to such little beauties there is nothing so suitable as the crannies and recesses in a rootwork or rockery. When we meet with a thorough enthusiast in this branch of vegetable study, and observe the pleasure and satisfaction which it yields, we seem to catch a portion of the same spirit; and as in the case of the rockwork close to the elegant mansion of Lamport Hall, in Northamptonshire, forget each and every thing about the position.

As to flowers, there seemed to be a nice group of beds close to the principal rooms of the mansion, a nice group in the centre

of the lawn, Roses on each side of the main walk with small circles of flowers round them, which Roses it was proposed to make of even height, with circles of flowers between, or a waved ribbon-border instead; and, besides all this, the borders in front of the houses were filled with bedding plants pretty well up to the wall-plates—a practice perhaps a little too common, not so much for impoverishing the border as riveting the sun's rays from it. The chief thing, however, that kept our attention, and which has been too much neglected in most flower gardens on the grouping system, were two massive stand-points of colour that by their height gave something like repose to the rest of the lawn, otherwise dotted quite enough. The first is on the west or entrance side of the lawn, and consists of a cone-shaped bed some 9 feet in diameter at base, and fully 4 feet in height, forming a pyramid of Scarlet Geraniums. In a line with this, and on the east or farther side of the lawn, is a raised vase basket about 3 feet in height, and 8 feet in diameter, filled likewise with Scarlet Geraniums elevated in the centre, and having a handle across it covered with the Canary Plant. The effect of such stand-points should be seen by those who can see no beauty in a flower garden, but in masses of colour as level as a mown lawn.

The chief range of glass looking on this lawn, commencing at and connected with the mansion, is close on 200 feet. Many of our English gentlemen, and expecting no end of results too, will think and think for years before they decide to erect some little hotbouse. A glass house seems nothing to these worthy merchants of Dublin. Ere long even the neighbourhood of London will have to look to its laurels if it would not be beat in gardening by the suburbs of Dublin. The first conservatory attached to the mansion is a hipped-roof building, 11 feet high at the sides, 21 feet in height in the centre, and 23 feet in width; the back is covered with a trellis, on which were trained Scarlet Geraniums, Clematises, *Lapageria rosea* doing well, &c. A walk passes all round. A platform, 2½ feet in width, goes all round the three sides for retaining smaller flowering plants. The centre is a bed of clean gravel, on which the plants stand. On our visit the house was decorated chiefly with *Fuchsias*; in winter and spring it is filled chiefly with *Camellias*, *Azaleas*, *Cytisus*, &c.—a row of tall *Camellias* in the centre, *Azaleas*, &c., on the sides. Next to this is the greenhouse with wide steps as a stage, and this too was chiefly devoted to *Fuchsias*; but in winter and spring it has a general collection of *Epacris*, *Heaths*, *Geraniums*, &c. In several places we noticed fine specimens for these houses, slightly sheltered out of doors, as *Heaths*, *Epacris*, *Correa*, especially splendid plants of the best of them still, *speciosa*. Among other fine specimens we noticed *Camellias* 6 feet in height by 4 feet in diameter, and *Azaleas* 4½ feet in height and nearly as much in diameter: these will give some idea of the greenhouse plants.

A viney separates the greenhouse from the centre somewhat-domed conservatory. Some of the vineries showed signs of hard cropping for continued years, and perhaps a little of over-cropping the borders. This one was to be excavated to a depth of 4 feet, drains laid across, a foot of brickbats put over them, a thick layer of lime rubbish over that, and the fresh soil mixed with sweet dung and leaf mould; the young Vines to be planted inside, and Vines in pots grown to supply the deficiency at first. Next, the centre conservatory 20 feet in height and about the same width sets off the range. Here were some fine tree *Rhododendrons* and *Azaleas*, and a good place for wintering large *Fuchsias*, &c. The roof is covered and festooned with *Glycino sinensis*, which must be very beautiful in spring. There is one drawback connected with this plant—namely, that when grown over a general collection of plants in a house there is no end to the trouble in getting rid of the faded petals. Next we come to two vineries, 12 feet at back, 12 feet in width, 4 feet in front, one 21 feet and the other 28 feet in length. Both are supplied with pits in the centre about 4 feet in width; and one to be made the earliest-house was to be filled with fermenting material, alike to excite and break the Vines gently, and to bring on *Roses*, *Lily of the Valley*, &c. We wish we had pits in our houses instead of stages, or rather them both. There is nothing that suits Vines better than the gases and vapour from such pits. With plants the fermenting material must be sweet at first; with nothing but the wood of well-ripened Vines the manure at first may be rank enough, provided it is sweetened by the time the buds break. The next pit was chiefly filled with rubble for setting plants on without heat. As far as we recollect, the range is finished with a Peach-house nearly 30 feet by

12 feet, wires placed horizontally about 15 inches from the glass, and the roof covered with a fine specimen of the Noblesse.

Passing from the houses, the same wall continues onward for 300 feet into the kitchen garden. The wall is 10 feet in height, and seems to have been thoroughly renewed, painted of a black colour, trellised with wire longitudinally, 3 inches from the wall, and not long planted with young Peach trees. We should like to hear of this wall and its success. At present, we are inclined to suppose that unless under certain circumstances, the free absorbing of heat by the black colour is greatly counterbalanced by its free radiation. If the wall were covered at night in front of the trees, the radiation would be so far arrested, the heat would be gradually given out for their benefit, and from the absorbing quality there would be no danger of that scorching in a bright sun which is apt to take place when the heat is reflected from a light whitish surface.

The kitchen garden seemed well, extra well, supplied with old and young fruit trees. This is all right enough for an orchard, but scarcely the thing when a proprietor expects good vegetables as well as good fruit from a kitchen garden. Vegetables without sun, however well manured, are apt to be hard, stringy, and without much flavour; and cooks and gardeners are blamed when the fruit trees above them are the sole cause of the evil. We understood a thinning was to take place.

At the end of this main walk stands a rustic house backed and flanked with rockery and rootery, with climbing Roses, &c., clambling over them. At a little distance is an old ice-house, proposed to be converted into a shell house, communicating by rockwork with the rustic house, and the shell house is to have glass openings in the roof, each painted of a different colour, to reflect the colours on the shells. As we lately stated, we are yet novices in the effects that thus may be produced.

In the Melon ground, in addition to a good collection of frames, we found a span-house 25 feet long for Geraniums, with a stage in the centre and narrow stages at the sides; a Cucumber-pit, 31 feet by 6 feet, 7½ feet high at back, and 2½ feet in front, and which Mr. Laidley wished had been span-roofed, a wish many others would join him in, at the risk of gentlemen saying "It is no use trying to satisfy these gardeners; give them an inch good humouredly, and they will tease your life out to obtain the yard, and not be satisfied then." Well, well, a little teasing brought to bear on employer and employed too is no bad thing after all. It helps to keep down the insidious fungus-growth of thorough self-satisfaction—the great bane and drawback to all progress and improvement.

We were told of a nice place belonging to a brother of the proprietor of Montrose, and also of other places in the vicinity well worthy of a visit; but the shades of evening were now falling, and we felt rather pleased with the day's work at Black-rock, &c., since meeting with Mr. O'Brien early in the forenoon. If we did not tire out the courtesy and patience of the gentlemen, superintendents of these gardens, we found we had pretty well exhausted ourselves, and wanted rest before entering on other scenes; hoping, meanwhile, that we have been able to excite a little of the interest for this suburb of Dublin which we ourselves felt.

R. FISH.

### COLEUS VERSCHAFFELTI.

WE are very much indebted to M. Verschaffelt for the introduction of this striking ornament to our plant-houses. What a magnificent colour, and how elegantly lacinate its beautiful foliage, forming a striking contrast to all the various plants with fine leaves that we possessed previously to its introduction! Even without the presence of other variegated plants, how cheerful it makes a place appear by having a plant or two placed among the various tints of green foliage and flowers that usually decorate our greenhouses and stoves at this season of the year. I say greenhouses advisedly, as our old plant from which others had been propagated has, during the past winter, been in a temperature rarely exceeding 45° Fahr. at night, and often much below; so that we may quite set this down as being much harder than its congeners *C. Blumei* and *pectinata*, for these in the same house have completely perished.

Those who remember the immense specimen of *C. Blumei* shown by Mr. Dodds in the first-prize collection at the last great show at Chiswick, may imagine what a splendid thing *C. Verschaffelti* will be, grown to even half that size. I hope the exhibitors will bring it out well this year, as the plant

cannot be too well known, and should be in every collection of plants—not as a single specimen merely, but in half-dozens or dozens, according to the size of the place; as a few of them, even in the absence of many flowers, make a collection look quite cheerful.

I find that it cannot have too much light, air, and "muck pie" to bring up the colour to perfection; plants that have been coddled-up in great heat and shaded looking little better than the older varieties. But what I wanted particularly to ask was, Will it do for a bedding plant? If so, it will soon put *Perilla* out of the field in high gardening. The latter to my mind having such a sombre appearance; while *Coleus*, both in colour and form, looks quite cheerful.

About ten days since, the weather being so mild, we began to bed out here; and having a plant to spare we put it into one of the beds. I have watched it daily since with great interest, and observed up to Saturday that it seemed quite as much at home in the open air as *Geraniums*, &c.; but yesterday (Sunday) we had a very heavy hailstorm here (in Kent), the ground being quite white, as though snow had fallen for some little time. This morning I went quite expecting to see my pet with its head down; but was very agreeably surprised to find that, as far as appearances go, it looks quite as well as before. I hope, therefore, that others may be induced to try it this season as a bedding plant. If the nurserymen will put it at a bedding-plant price—say 9s. or 12s. per dozen, it might be a temptation to try the experiment.—J. A. S.

### THEORY OF COLOUR, AND THE INFLUENCE OF LIGHT ON VEGETABLES.

THERE are, perhaps, no phenomena in nature better calculated to arrest our attention than the gay and varied colours of the vegetable kingdom; they have been the subject of admiration in all ages, and in almost all ranks and conditions of life. From the study and contemplation of these colours have sprung the arts of dyeing and painting. The savage, to whom clothing is a superfluity, tattoos and daubs his body with all the varieties of colour his ingenuity can prepare and his imagination devise. The civilised man, with more refinement, imparts this colour to articles of clothing. The study of the sciences of light and heat—the two subtlest agents in nature—is, indeed, one of unbounded and intense interest, and likewise of much practical importance. They divulge to us Nature's secrets, and make us acquainted with many, if not all, the phenomena witnessed in everyday life. It is with the former of these only—viz., light, that we have at present to do. And in entering upon the subject of the laws of light I am very well aware that it might be carried to an almost indefinite length; but, as neither time nor space will permit of this, I shall content myself by taking a general and brief view of the effects of light on vegetables.

Science has demonstrated that colour has no material existence—it is a mere optical delusion; at least the colour does not reside or exist in the object that appears coloured. All colours depend for their existence on the rays of light. A beam of light is composed of three distinct rays or colours—red, blue, and yellow—and, according to the ray or rays reflected by the particular objects, so will be its colour. When a beam of light falls upon the surface of a body, part of the rays composing the beam are absorbed and become extinguished, and part are reflected or thrown back; these latter enter the eye of the spectator and determine the colour of the object. It should also be mentioned that the power any body has of absorbing rays of light depends upon its chemical constitution: thus, it follows, that when any change takes place in the colour of an object, a chemical change in its constitution also has taken place. If the red ray is absorbed, and only the blue and yellow rays reflected, the object from which they are reflected appears green; if the yellow ray also is absorbed the object appears blue; or if the blue has been absorbed, and red and yellow reflected, the object appears orange; or if the yellow ray only is absorbed the object appears violet or purple: thus from these three distinct colours—red, blue, and yellow—are the various shades of colour in nature produced. Green is unquestionably the dominant colour in the vegetable kingdom: this is well known to be a compound colour produced by a union of yellow and blue. In speaking of the green-colouring matter of plants, Berthollet says:—"The green of plants is undoubtedly produced by a homogenous substance in the same

way as the greater number of hues which exist in nature. This colour, then, owes its origin sometimes to simple rays and sometimes to a union of different rays; and some other colours are in the same predicament. Were the green of plants due to two substances, one of which is yellow and the other blue, it would be extraordinary if we could not separate them; or, at least change their proportions by some solvent." That this idea of Berthollet in regard to the green-colouring matter of plants being a distinct substance is correct, science has long since fully demonstrated, and the method of obtaining this in a separate state is so exceedingly simple that no one need long remain in doubt as to the truth of the matter, but ascertain it for themselves. It may be procured by the following process:—Bruise the green leaves into a pulp with water, and press out all the liquid; then boil the dry pulp in spirits of wine, or good-proof whiskey. When the alcohol has evaporated there remains a deep green substance, which dissolves on being washed with water; this is the green-colouring matter of vegetables, or, as it has been denominated, chlorophyllite. The formation of this substance depends on the action of the solar rays.—J. DUNN.

(To be continued.)

## PRODUCTS OF TOBASCO, MEXICO.

### SINGULAR CHANGE IN APPLES TAKEN HENCE TO MEXICO.

MR. KOCH, a German gentleman resident in the State of Tobasco, Mexico, about six miles from the mouth of the Tobasco River, at a recent meeting of the Farmers' Club of the American Institute, gave a most interesting account of that country and its productions, and, among other things, stated that he could not grow Apples there, though he had no trouble in growing trees from the seed, which came to bearing in three years. The first fruit produced were small Apples, but afterwards the fruit was exactly in character like the wild Guava, the same of which Guava jelly is made, which grows upon a tree somewhat resembling an Apple tree. He had also planted Pear seeds, but only got Guava fruit. Cherries change to a fruit quite unlike the original, being yellow and of a honied sweetness.

He is now preparing to take some grafted fruit trees out with him, to see if he can grow anything true to its kind in that climate and soil. The situation is about latitude 18°, and range of thermometer 65° to 95°. The soil is sandy and very productive—Sugar Cane growing to a height of 36 feet as a common thing, and sometimes 50 feet. Sweet Potatoes grow to a monstrous size, and in the State of Chiapas Corn grows astonishingly. The Coffee tree in Tobasco is very productive, yielding 15 lbs. or 20 lbs. to a tree, while 5 lbs. or 6 lbs. are considered a fair crop in Brazil.

Rice is grown three crops a-year, by the rudest cultivation. The Indians have no farming tools but the machete, which is a long, heavy knife, with which the brush is cut, and when dry, it is burned, and then the seed put in with a sharp stick, for all their crops.

Mr. Koch is about to take out a steam plough, and many agricultural implements, to cultivate that rich and productive soil, where the only drawback that appears is the insects and reptiles, which are truly by his description enough to deter any white man from attempting to live there. There is also a trifle of intermittent fever in the way, but he thinks that comes from getting wet.—(Prairie Farmer.)

CRYSTAL PALACE.—The great Flower Show of the season will be held on Saturday, 24th May. From the number of entries already received it promises to be the most complete exhibition of flowers which has yet been held at the Crystal Palace. Taking place on the Queen's birthday, a day which this year unhappily will be unattended with the usual military displays, drawing-room, or other rejoicings, a large number of distinguished and official personages will have leisure to attend this, one of the most attractive displays of the season. Considerable additional interest is excited on this occasion from the announcement that the great roof over the Handel orchestra, which has been so many months in preparation for the Festival in June next, will be completed before the day of the Flower Show. The orchestral band of the Company will be considerably strengthened, and, aided by military bands, will afford an

opportunity for estimating the effects which will be produced by the 4000 performers who have been so long in training for the Festival, when assembled beneath this gigantic covering. The vast circles of seats in the great orchestra will be thrown open to visitors, and as it is intended to erect in the great transept large circular trophies of flowers of considerable height, thousands of visitors will be enabled to contemplate the blaze of floral beauty dispersed below, while listening to the musical performances.

## THE GENUS CROCUS.

(Continued from page 115.)

25. *CROCUS OCHROLEUCUS* (Boissier, Bot. Mag., 1862, t. 5297). Native of Anti-Lebanon, near Scanderoun, above Sidon, flowering there and in England in the middle of December. Sir W. Hooker calls it a very elegant and charming cream-coloured flower, with a yellow eye and lily white anthers. It must have been known as one of the "Lilies of the field" to the foresters of King Hiram when preparing Cedar wood for Solomon's Temple; and it should be made known to the gardeners of the reign of Victoria as a likely type plant to diversify the aspect of a new race of midwinter-flowering Crocuses, and holding an intermediate position between *C. Boryanum* and *aërius*.
26. *C. ODORUS* (Bivona Bernardi, longiflorus Rafinesque, and serotinus of Bertoloni). This is a very fragrant and desirable Crocus, a native of Italy and Sicily, and another variety is in Malta. The variety *longiflorus* (Bot. Reg., 1844, 3, fig. 4), is a native of Sicily near Palermo, and on Mount Stella near Paestum, also in Calabria. *Melitensis* (Bot. Reg., 1844, 3, f. 5), occurs on Mount Verdala in Malta. It flowers in October and November, and answers well in pots and ripens seeds. The colour is a lilac purple with an orange throat.
27. *C. PALLASIANUS* (Bot. Reg., 1844, 3, f. 2). *Pallasii* of Maréchal von Bieberstein. A native of the Crimea on sunny hills, with a pale purple flower, hairy in the throat; never introduced.
28. *C. PULCHELLUS* (Herb., Bot. Reg., 1843, Misc., 28; Bot. Mag., 1841, 3862, p. 2). A most lovely Crocus, native of the forest of Belgrade, also on the Asiatic side of the Bosphorus and on Mount Athos. The flower is of a pale bluish-pearl colour with an orange throat, and some with a pure white flower, contrasting beautifully with the orange throat and milk white anthers. It is a great acquisition to our gardens, flowering freely at the beginning of October, and ripening its seeds willingly at Spofforth. The bluish-pearl and the pure white flowers will cross and produce quite a new race of autumnal flowers, which will exceed that of *versicolor*.
29. *C. PYRENEUS* (Parkinson, Paradisus, 1629). *Nudiflorus* (Smith, English Botany, 1793, fig. 491, a bad one). *Multifidus* of Ramon, and *speciosus* in Supplement to Eng. Bot., 2, 2765. A fine large purple Crocus, native of the Pyrennees, and naturalised near Warrington, Halifax, and Nottingham. Which is the yellow Crocus that accompanies it in the latter place?
30. *C. RETICULATUS* (Mar. v. Bieb., Bot. Mag., 1841, 3865, at the end; Bot. Reg., 1843, Misc., 30). *Susianus* (Ker, Bot. Mag., 652). The Cloth of Gold is the best known of the Reticulate Crocus. It occurs in five distinct varieties in the south-east of Europe as far as the Crimea. Variety 1, *auritextus*, is the pure Cloth of Gold, the *fulvus* of Pallas, and *susianus* by mistake, *Susa* being farther east than the eastern limits of Crocus. 2 is *variegatus* from Monte Spaccato, Trieste. 3, *Dalmaticus* of Visiani (Flora Daln.). 4, *Albicans* (Herb.), near Odessa; and 5, *Ancyrensis* (Herb.), wild near Angora. *Albicans*, from Bucharest and Odessa, is Parkinson's Cloth of Silver. And the golden variety of Angora is very different from the Cloth of Gold; having no stripes or suffusion on the sepals, but with a purple tube.
31. *C. SALZMANNIANUS* (Herb., Bot. Mag., 3868, f. 2). *C. ditto* (Tingitanus, p. 2; Bot. Reg., 1847, 4, f. 4; Guay, B. F. 28, 220). From hills near Tangiers, and on mountains near Tunis, flowering in the autumn; the flowers are pale violet purple. The only kind hitherto found in Africa.
32. *C. SATIVUS* (Linnaeus). *Autumnalis* (English Bot., 343). The well-known Saffron Crocus, a pale purple flower, and

- deeper purple at the bottom. Its native place is not certain. It has been found wild in Italy in the Ambruzzi, but is believed to have only escaped from ancient cultivation. Dr. Boyle found it in cultivation in Cashmere, which is beyond the eastern limits of wild Crocuses.
33. *C. SEROTINUS* (Paradisa Londinensis, t. 30; Bot. Mag., t. 1267). Native of Pine forests in the south of Spain near Cadiz, and on the Sierra Nevada; flowering in October. The flowers are pale violet purple with a yellow throat. A very acceptable plant for the table in November.
34. *C. SPECIOSUS* (Maréchal von Bieberstein, Bot. Mag., 3861). This is the very finest wild Crocus hitherto known. There are three wild varieties of it. 1, Caucasian (Bot. Mag., 3861, fig. 1), on Caucasus. 2, Transylvanicus (Bot. Mag., 3861, fig. 2; and Bot. Reg., 25, 40), in Transylvania. And 3, Laxior (Bot. Mag., 3861, fig. 3), on the high table lands in the Crimea. They have all bloomed and seeded at Spofforth from the latter part of September to the end of October. Dr. Herbert says that pyreneus, speciosus, pulchellus, medius, and byzantinus flower with equal freedom at the same time, and that longiflorus and Cartwrightianus follow them with equal freedom in blooming, and continue sometimes to January. The sepals, or three outside petals, are of a fine bluish-purple, with a deeper base and three lines up the back; the three petals not quite so deep, but most beautifully veined, and the throat is of a straw colour, and slightly bearded with strong white hairs.
35. *C. SUAVEOLENS* (Bertoloni, Bot. Mag., 3864). A very fragrant Crocus, straw-coloured and streaked, with an orange-spotted throat. A native of the Campagna of Rome, and the Valle d'Inferno in the old kingdom of Naples, and on calcareous hills near Fundi.
36. *C. SUTERIANUS* (Herb., Bot. Reg., 1845, Misc., p. 5). From the mountains of Naupli, and named after Mr. Suter, British Vice-Consul in Caramania, who found it near Angora. The flowers are of a fiery and sometimes reddish-gold colour, and often with a livid blotch at the base of each section of the limb. A very pretty and conspicuous small flower, blooming in the spring, which, if it could be crossed with the pollen of the Cloth of Gold, would produce seedlings to vie with the Jersey Sparaxuses.
37. *C. THOMASIANUS* (Herb., Bot. Reg., 1844, 3, fig. 6). Thomasi (Tenore, Memoria, &c., 12). A purplish flower, streaked on the outside. Allied to astivus, and flowering in the autumn. A native of upper and lower Calabria, where there are two varieties of it: 1, Princeps, with the edges of the leaves and angles of the midrib closely fringed. 2, lævis, all smooth.
38. *C. TOMASINIANUS* (Herb., Visiani, Flora Dalmaticæ). Named after Signor Tomasini, President of the Magistracy at Trieste, who discovered it in the Mountain Biokovo in Dalmatia. It is allied to vernus, from which it differs in not having an involucre.
39. *C. TOURNFORTIANUS* (Gay, Bulletin de Ferrussac, 25, 220; Bot. Reg., 1845, 37, f. 3, H. Misc., p. 6). Native of the Greek Archipelago, as Milo and Thernia. A desirable pot plant in November, as when the flowers are once expanded they keep so even at night. It has lily white anthers and white pollen, and is akin to Boryanus, from which it differs in the pale blue of the limb, the paleness of the throat and filaments, and other technical marks.
40. *C. VALLICOLA* (Herb., Bot. Reg., 1845, Misc., p. 7; ditto, 1847, t. 16, fig. 3). Native of the Alps of Trebizond, near the village Stauros, blooming in October. The flowers white, with two yellow spots at the base of each segment. Filaments and anthers pure white.
41. *C. VELUCHENSIS* (Herb.) Native of the summit and slopes of Veluchi in the Morea, with a violet purple flower, having a white bearded throat, and blooming in the spring. The flower-scape is so short at the time of flowering, that the ovary seems almost sessile—a rare feature in Crocuses.
42. *C. VERNUS* (Linnaeus). Vernus and sativus were the only two Crocuses known to Linnaeus. This is the most widely extended of all the Crocuses, with an alpine range from Spain to Odessa. It is pure white on the Bavarian Alps, purple in the Tyrol, and deeper purple on Calabrian mountains; but the finest of our garden varieties of it are from the Odessa plants, whose flowers are either pure white, beautifully striped inside, or deep purple. The throat of all the wild varieties of vernus is white and hairy, by which they can readily be distinguished from their powerful rivals—the race of versicolor, which is as constantly smooth in the throat. But whether garden seedlings of either race keep constant to that type feature in their generations has not yet been inquired into; the prevailing feature of the best of our present race of spring Crocuses, such as Sir Walter Scott, Queen Victoria, Prince Albert, and the like, is a smooth throat, which would indicate them as referable to versicolor. There are three very distinct varieties of vernus:—1, the vernus communis; 2, neapolitanus (Bot. Mag., 860), from the highest mountain in Calabria, Monte Pollino, flowering there in June and July; 3, nivigina (Bot. Reg., 29, Misc., 130), which grows on the Steppes near Odessa, is the finest of the three.
43. *C. VERSICOLOR* (Ker, Bot. Mag., 1110). A native of Nice. The prevailing colour is white, sometimes suffused with purple, and generally more or less streaked with deep purple on the outside. The throat is smooth, sometimes white and sometimes yellow. The race of versicolor prefer deep planting, 4 inches or 5 inches below the surface, as does the race of lagenæflorus.
44. *C. VISIANICUS* (Herb., Bot. Reg., 1845, Misc., 78). Pallasi-anus of Professor Visiani in "Flora Dalmatica." Flowers in the autumn, the flowers being of a violet purple, with a yellow throat, by which it is distinguished from pallasi-anus of the Crimea, and approaches more nearly to hadriaticus, its nearer neighbour. D. BEATON.

#### PRESERVING DAHLIA TUBERS.

MAY I be permitted to offer a simple suggestion relative to the preservation of Dahlia roots during winter? Though carefully dried before storing away in the autumn, I used continually to lose them by the rotting of the crown, till at length it occurred to me it was occasioned through the decay of the long stalk left attached to the tubers: this becoming partially charged with fluid kept the crown constantly wet. My remedy has been to leave not more than 4 inches of stalk; from this to scrape the whole of the outer covering or bark, and at the base to make a small opening which permits any watery deposit to escape. The result has been I have preserved the whole of my tubers, while experienced gardeners around me have complained of loss, notwithstanding that every precaution from damp or frost has been taken.—B. F. F., *Margate*.

#### THE CALCEOLARIA AS A BEDDING PLANT.

(Continued from page 121.)

THE GRADUAL PROGRESS OF THE CALCEOLARIA AS A BEDDING PLANT.—It has been stated that the old *C. integrifolia* was planted out in mixed flower-borders as early as 1830, or before, and subsequently the half herbaceous ones were planted out in like manner; but as bedding-out in masses of one colour only had not come into fashion at that time, I do not remember seeing a whole bed of any one kind, and as flowers were the more prized in accordance as they disclosed the more beauties by close inspection, the self-coloured ones were regarded secondary to the blotched or clouded varieties. Nevertheless, the sturdy habit of the yellow one gained friends, and a yellow Calceolaria amongst Campanulas, Phloxes, Chelones, and such-like plants was considered an advantage. But as every year brought forth something new in the half-herbaceous line, and new things then as well as now were eagerly sought after, the progress of the old yellow into general repute as a bedder was but slow until 1838, and afterwards. True, some cultivators in advance of the general public might have had beds of it before that time; but in far-away rural districts it had not become common until 1840, when an impulse was given to it, and soon after newer and improved kinds were forthcoming, one of the best being *C. viscosissima*, which though dating in catalogues as far back as 1832, I do not recollect coming into general repute until 1843, and as it still maintains a respectable position in the list, may be regarded as a sort of standard. The appearance of *C. amplexicaulis* a few years later added another tint as well as another habit to the plant, and beds of Calceolaria became as indispensable as beds of Verbenas. The dark ones being also improved were also sought after, though of late they have ceased to be regarded so important as the yellow

section; but the appearance of *C. Sultan* about 1851 was hailed as a boon, and subsequently *C. Beauty of Montreal*, and others, added to the already useful section of dark ones, while *C. Kentish Hero* had a run for some time as an intermediate variety, its large truss of bloom gave it great importance, but it did not afford that succession so much needed in the flower garden, and it fell into disrepute, so that for the last half dozen years, and more, only the more truly shrubby kinds have been in demand. Yellows also have been much improved during the last ten years, the most popular being *C. aurantia*, sulphurea elegans, aurea floribunda, amplexicaulis, Kayii, and two or three others; and more recently *Gaines' King*, as a dwarf yellow, has stood high in public estimation, and with *General Havelock* as a dark one, and *Prince of Orange* as an intermediate one, the list may be said to be complete, not but that there are newer, and, perhaps, some still better than those named; but I only mention such as I am acquainted with.

**THE PROPAGATION OF THE CALCEOLARIA.**—Amongst the many plants which require multiplying, there is none, with the exception of those which rise spontaneously from seed, which are propagated with greater facility than the shrubby *Calceolaria*. Cuttings put into a pan, pot, box, or plain mother earth in the month of October, or even later, and simply protected from the more extreme frosts, rarely fail to make good, useful plants, as no amount of damp seems to injure them, and the amount of protection they require is much less than is generally supposed. For many years I have been in the habit of putting in hundreds of cuttings into a cold pit in the kitchen garden, covered over only in severe weather with wooden shutters, very seldom with glass; at least a part of them only have that luxury, and I rarely lose more than two per cent., excepting of the delicate kinds, as *amplexicaulis*, and *Prince of Orange* is a little more tender than some; but I generally preserve a few of them in another place for fear of losing the whole. Even in the winter 1860-61, which may be regarded as one of the most severe of late seasons, we scarcely lost one, excepting of the two kinds alluded to. So that the trouble of keeping a good batch of *Calceolarias* is an easy matter.

I do not know to whom the honour of first striking them in this way belongs, but I used to treat the kinds grown about 1839 in much the same way, putting them in, however, much earlier, and potting them off before winter, to be kept under glass. A sandy soil suits them best, as it is not so likely to harden and crack with alternate wet and dry weather. We put our cuttings in little more than 2 inches apart, and by the middle of March take out one half of the rows to give the others room, planting out those taken up into another similar place to strengthen before finally planting out where they are to remain. No plant that I am aware of takes up and plants with so much ease and certainty of growing as the *Calceolaria*. The roots being exactly adapted to take up with a ball, a close, compact tuft of roots all of equal length radiating from the base of the cutting, clasp the earth in such a way as to give it more the character of a true ball than that of most plants to which that name is given, for, unlike most plants, the numerous roots of the *Calceolaria* are all of equal length, and, consequently, occupy all the ground they enclose. There are no long, rambling rootlets travelling long distances in search of choice food, as in the *Verbena* and *Geranium*, but a thick-set mass, or tuft, of roots all uniting in one common centre, and well adapted for assisting the plant to endure the ordeal of transportation with little harm to itself. Potting is out of the question with bedding *Calceolarias*, excepting new or choice ones, and amongst several thousand planted out last year, not more than twenty were honoured with a separate pot, and these only in consequence of being scarce. So that the keeping of *Calceolarias* over the winter is within the reach of many who have not, perhaps, even thought of it, as I have shown that both glass and pots may be dispensed with.

**PLANTING-OUT THE CALCEOLARIA INTO BEDS.**—Having shown that the plant takes up with the spade with an excellent ball, and having also pointed out the general hardihood of the plant, it need not be wondered at that I recommend it being planted out before the general mass of bedding plants. For some years I have, therefore, planted them out in April, and given them where practicable a slight covering of laurel boughs—not stuck in the ground, as the wind is so liable to blow them out, but laid over the plants; and though they have sometimes received a little nipping from frosts, they have never suffered to any extent that way. One bed of yellow *Calceolarias* planted out

the last week in March has been the best bed I have had this season. It is not absolutely necessary to plant so soon; only, if the plants are suffering for want of room, it is better to do so than allow them to get drawn. Plants pot-bound, if there be any such, ought to be turned out into some border of suitable soil, and the matted ball will emit a beard of nice useful roots, all eager to embrace the fresh and unexplored earth. It is always a bad plan to allow *Calceolarias* to become pot-bound, as the plants are not unlikely to die after the first flowers are over. And as a temporary shelter is only needed, some makeshift in that way will easily present itself to the anxious cultivator. It is, however, proper to say, that although the *Calceolaria's* roots do not ramify far, it likes a good rich soil and a fair share of moisture: hence it generally does better in showery neighbourhoods than in dry ones. Dry chalky banks are its bane, and wet and marshy places are also unsuited to it; but it is, nevertheless, so accommodating that few places come amiss to it. And as a single plant in a mixed border, its tidy uniform appearance recommends it to notice; and for a single row in a striped border it is also equally applicable; and the shrubby kinds at least require no trimming to keep them in order, while *C. amplexicaulis* can be either pegged-down to the condition of a low plant, or tied-up to represent a tall one.

**CONCLUDING REMARKS.**—It not being my intention to say anything of the herbaceous kinds so ornamental to the greenhouse in April and May, it is, however, proper to say that in some districts the *Calceolaria* has disappointed some of its most ardent admirers by plants of it dying off during the summer without any apparent reason for doing so. Although I have witnessed this I have never experienced it; as even in the driest season of 1857, 1858, and 1859, we scarcely lost a plant, although after the first flowering was over there was not much succession, and the plants only began to grow after the autumn rain came on, it being then too late to expect flowers. I believe, even in those districts where they had been in the habit of dying off, they did not do so during last season, so that we may fairly attribute their doing so in years gone by to their inability to withstand the dry weather, and yet this is hardly compatible with their enduring the dry weather at this place; but it must also be observed that their utility has fallen far short of what was expected, and I for one invited the readers of *THE COTTAGE GARDENER* to turn their attention to something else as a substitute if the *Calceolaria* failed any more. But the revival of last season has reinstated this old favourite; and until we can have something else as good in colour, convenient in habit, and easy of culture, we must content ourselves with the *Calceolaria*. Possibly our hybridising friends may assist us with something still superior to what we now possess. Assuredly the white one may be worked into something more useful than it has hitherto been, and if they can convert some of the reds into bright scarlets, they will confer another boon; and if they would again begin with the old arachnoidea, and see how near a blue they can command its progeny to be, giving them also the other requisites of a good bedder, not forgetting the property of withstanding rain, they will in this have an entire new field for operations, and I see no reason why their efforts should not be crowned with success.

J. ROBSON.

#### IMAGINARY FORMS IN SECTIONS OF FERN STEMS.

WOULD you tell me which Fern is said to present the appearance of the sacred monogram (I. H. S.), on cutting the stem or root?—M. D. P.

[We do not remember about this; but it is probably the rhizome or stipes of *Pteris aquilina* (common Brake) cut in some peculiar direction. The cuttings of this Fern are well known to give fanciful images of the spread eagle and of an Oak tree, and, by the aid of a little imagination, probably the above letters may be discerned. Can any of our readers throw light on the question?]

**SPERGULA PILIFERA.**—It may, perhaps, be interesting to some of our readers to hear that *Spergula pilifera* appears to succeed in this neighbourhood (Edmonton) for a lawn. I planted rather a large piece in the spring of last year, and it is now nearly closed up, and would have done so entirely; but I committed a mistake in having the ground made up from a

field, and have consequently had great trouble in weeding and keeping clean. The ground is a stiff clay, and I think in hot weather the Spergula will have a tendency to turn yellow unless kept well watered.—G. P. NICHOLLS, *Oakfield*.

### THE ROYAL EXOTIC NURSERY, CHELSEA.

To attempt to give in a single article any adequate idea of the vast resources of Mr. Veitch's establishment, replete with all that is ornamental, or useful, or merely interesting, would be vain. It would take a volume to contain an account of the tropical luxuriance that here everywhere abounds, not to mention the grand collection of the more hardy denizens of the garden, which also deserve and receive their due share of attention.

Having thus candidly avowed our inability to do justice to this place in the limited space at our command, we may, perhaps, be permitted to notice as shortly as possible, the fresh attractions which have been added, and the important introductions which have been effected, without being censured for our inevitable shortcomings. The general features of the nursery are so familiar to most of our readers, that we need not pause to describe what has been so often seen and described before. We may state, however, that the large conservatory or show-house through which the visitor passes from the King's Road, at all times gay, is now a blaze of colour, Azaleas, Rhododendrons, Kalmias, Geraniums, Heaths, &c., contributing their varied hues to set off the more modest greenhouse plants which are introduced to swell the general effect, which is rendered all the more striking by the relief of a due amount of foliage.

Near the entrance is placed a collection of large and handsome Japanese vases and trays brought home by Mr. John Gould Veitch, some square, some round, some hexagonal, interesting and beautiful specimens of the potteryware of the country. Several of the finest kinds were executed in alto-relief, the raised pattern exhibiting trees in flower and fruit; and others exhibited on their sides representations of the stork, which is a sacred bird with the Japanese, who never kill it. At the other end is a fine collection of Camellias, ranged on each side of the central avenue, backed up by magnificent specimens of tree Ferns such as are not to be seen elsewhere. Amongst these are especially noticeable noble *Cyathea*s; *Alsophila Macarthuri*; and a majestic plant of *Cyathea dealbata*, the New Zealand Silver tree Fern; and many other specimens of not less remarkable size and beauty.

Passing out of this grand house, in which we might well be tempted to linger, we come to a new feature which has been quite recently added. This is an area of more than 5000 square feet covered with a tiffany roof, supported by light and elegant cast-iron columns, and laid out according to a most elegant design, consisting of four large circular beds, with others of a form which it would belong to the engraver to represent, and which there is no word in the language to express, surrounding and harmonising with the whole. In the middle of each of these four principal circular beds is a handsome vase, containing a plant of *Yucca recurva*, with its leaves gracefully drooping over the edges.

In the centre of the space thus laid out is a large circular cast-iron vase, painted to resemble stone, round which the path passes on each side, filled with hardy Japanese plants brought home by Mr. J. G. Veitch from Japan. The outer row or edging consists of *Enonymus radicans variegata*, a dwarf distinct variety, with bright green foliage blotched with white, which renders it peculiarly well adapted for edgings; and occupying the centre is a larger plant of the same kind.

The intermediate space is occupied by young plants of *Retinospora obtusa*, one of the finest of all the Japanese evergreen Conifers; *R. lycopodioides*, another kind with fine dark green foliage, and of dwarf habit; and *R. pisifera*, a graceful species of more pendulous habit. Besides these are the beautiful *Thujopsis dolabrata*, one of the finest trees in Japan; and the Chilian *Libocedrus tetragona*, also a hardy and very fine Conifer.

The base is encircled with a selection of Chilian and Japanese Ferns, including *Polystichum setosum*, growing almost like a tree Fern when large, which we shall notice elsewhere; *P. flexum* from Chili, also a perfectly hardy and very fine species, suitable for rockwork; and *Lastræa opaca*, likewise hardy, with dark green and olive fronds, adapted for the same purposes as the preceding.

In addition to the above there were *Lomaria crenulata*, a pretty and desirable species from Chili, which answers to its

name in having crenulated dark green fronds; *Woodwardia orientalis*, a perfectly hardy and peculiarly interesting Fern, its spreading fronds bearing on their upper surface numerous young plants; *Woodsia polystichoides Veitchii*, a very distinct dwarf kind from Yeddo; and several others which, being better known, need not be adverted to just now.

Turning to the gay Rhododendrons, which are viewed at great advantage from the conservatory steps, we find many of the old hybrids interspersed with standards of *Blandyanum*, *Victoria*, *Etendard de Flandres* and other splendid kinds, and presenting to the eye dense masses of glowing colours; and a number of seedlings not yet named, which have been raised by Mr. Veitch, of Exeter; also several new and remarkably fine hardy hybrids due to the same source. Such are *Marian*, literally covered with flowers of a shaded pink with dark spots, a kind which it is expected will prove excellent for forcing; *Lady Lopes*, bluish, equally free and rather later; *Ochroleucum*, pale straw, dwarf, compact, and quite distinct in colour from any other kind; *Miss Buller*, a fine purplish-crimson, shading off to a rosy white; *Lord Elgin*, not yet out; *Rubescens*, and some others. This display is a grand feature, which will undoubtedly prove a great attraction during the remainder of the season; and the masses of colour being relieved by the dark green foliage, the eye does not become wearied, as is often the case at the great flower shows.

The COOL FERN-HOUSE, which adjoins, contains an endless variety of all the most interesting species, but we can only notice here a few of the most new and striking. Of such are *Acrophorus affinis*, from Borneo, with large finely-divided fronds, and very beautiful; *Adiantum chilense*, the Chilian Maiden-hair, with very handsome glaucous fronds; *Adiantum sulphureum*, the Golden Maiden-hair, which forms a thick tuft of great beauty, the whole of the under surface being thickly covered with golden powder; and *Adiantum scabrum*, the Silver Maiden-hair, which is likewise of dwarf growth, and being plentifully covered with silvery dust, it forms an admirable contrast with the preceding. *Leptopteris superba*, a most lovely species, with semi-pellucid finely-curved fronds deserves special mention on account of its peculiarly graceful character. It is from New Zealand, and will be an invaluable greenhouse kind. The plant we saw, however, is, we believe, the only one in Europe. *Polystichum setosum*, of which there is a large specimen, is another great acquisition, having very ornamental bristly fronds. It is from Yokohama, and is perfectly hardy. *Cheilanthes mysurensis*, forming a dwarf tuft, is new and elegant; *C. glauca hirsuta*, a beautiful little variety with very finely-divided triangular fronds, is also very attractive; whilst *Microlepia strigosa*, being of a lively bright green and growing about 2 feet high, forms a very desirable addition to the greenhouse.

Hastily glancing at other objects of interest we can merely mention the beautiful *Todea pellucida*; *Dicksonia arborescens*, with noble fronds densely clothed with yellowish hairs; *Lomaria gibba*, a very graceful species from New Caledonia; *Lomaria blechnoides*, and *Notochloa mollis*, the scarce *Trichomanes noronense*; and the Killarney Fern, *T. radicans*, which is here successfully grown uncovered by a glass.

The HARDY FERNERY, which we next entered, is more like an enchanted fairy scene, or an ocean cave in which the sea nymphs wring their briny locks, than the creation of art, the lovely green fronds of the Ferns completely hiding the sides and ends of the house, except here and there where the rockwork is permitted to peep forth for effect, whilst at one end a trickling cascade falls into a pool where a fine *Osmunda regalis* is growing, and giving a most refreshing effect on the ear on a warm sunny day. The rockwork is closely carpeted at its base with various English Mosses, and planted all over with *Lastræas*, *Polystichums*, *Scelopendrimms*, and other hardy Ferns, the central mass being crowned with a fine *Woodwardia radicans*. We also noticed *Woodwardia orientalis*; *Lastræa Sieboldi*, a rather scarce Japanese species; *Lomaria chilensis*; and *Gleichenia microphylla*, which is usually considered tender, but which stood last winter without fire heat.

The STOVE FERNERY also presents a pretty appearance, hanging-baskets filled with various graceful species with pendent fronds being suspended from the roof, whilst *Trelliseæ* covered with different kinds of *Lygodiums* are seen ever so far. Here were pointed out to us *Alsophila contaminans glauca*, a very rare and beautiful tree Fern obtained in Manilla by Mr. J. G. Veitch; *Thyreopteris elegans*, a very rare and graceful species; the new *Asplenium flabellatum*, and *rachirrhina* with its curious

whip-like ends; the rare *Gleichenia pubescens* and *Schizæa dichotoma*; that fine tree Fern *Cibotium princeps*, as well as many other interesting objects.

We next visited a large collection of new plants imported from Japan by Mr. John Veitch, to whose enterprise and botanical knowledge the country is indebted for so many valuable introductions, and which shall all be noticed in due time. Some of them, however, we cannot pass by unnoticed, as the *Abies firma*, one of the finest of the Japan Conifers, the leaves of which are bifurcate at the apex, and which forms in its native country a magnificent tree; *Thuja pygmaea*, a dense, close, dark green tuft, somewhat resembling a Lycopod, and always remaining dwarf; *Pinus koraiensis*, from the north of Japan, with long beautifully-glaucous leaves; the noble *Sciadopitys*; *Thujaopsis late-virens*, a dwarf, erect, exceedingly beautiful species with very light green foliage; the elegant variegated *T. dolabrata variegata*; the handsome *Eurya latifolia variegata*, with laurel-like foliage, variegated with white and pink; and *Osmanthus ilicifolius variegatus*, somewhat like a handsome variegated Holly.

There were, besides, many Bamboos and other new and beautiful introductions.

The INTERMEDIATE-HOUSE was filled with new Begonias and foliage plants, and several new Gloxinias, one of which, named Constance, was particularly remarkable for its large size and beautiful mauve and crimson colour. *Stenogastra concinna*, a singular miniature, covered with white and lilac flowers, also attracted our attention, and on inquiring about it we were informed that it continued in flower all the year. It is a charming little stove plant. *Ficus Cooperi* is also remarkable on account of its large glossy leaves veined with purplish-crimson.

In the GROVE we found *Caladium Veitchi*, with large bronzy leaves veined with white, a grand foliage plant; *Alocasia macrorrhiza variegata*, with bold and striking white variegation, a noble *Caladium*-like plant—a very fine new and formidable rival to *Cyanophyllum magnificum*, which has for the present been distinguished by the provisional name of *Spherogyne*, and many other valuable novelties, of which we shall have to speak on some future occasion.

In other houses were fine plants of, *Alocasia zebrina*, from the Philippines with large, velvety green leaves, the footstalks being yellow with zebra-like markings of dark green; an extensive collection of *Nepenthes*, among which one called *N. Dominiana* is remarkable as the first hybrid Pitcher-plant raised in England; large specimens of Ferns; grand foliage plants of all kinds; *Vandas*, *Dendrobiums*, *Cattleyas*, *Phalenopsis*, *Cypripediums*, and other Orchids in flower, New Holland plants, *Rhododendron Veitchi* exhibiting its large white flowers, and a legion of other plants. One of these, however, we must particularly mention. It is the new *Amaranthus melancholicus ruber*, the handsomest hardy red-foliaged plant we have ever seen, and which will decidedly beat *Perilla* out of the field.

Before quitting the nursery we were privileged to see a remarkable collection of curiosities from Japan, with models and specimens of the industrial and natural productions of the country, including some beautiful specimens of woods brought home by Mr. J. G. Veitch, and for which a large room is fitting up as a museum. When finished, the cases, which pass all round the room, will be filled with these interesting mementos of his visit, and we doubt not the visitors of the establishment will be permitted to view the collection. We observed particularly a plank of *Planera acuminata* upwards of a yard across; the wood of this is so much esteemed that the Chinese will never use it for any common purpose; also two lovely specimens of coral, forming erect silky feathers of snowy whiteness; and some beautiful China cups and vases, almost transparent.

### CATERPILLARS ON FRUIT TREES.

THERE is a very great show of fruit-blossom in this part of the world, and a great promise of fruit; but insects (and amongst them the Gooseberry caterpillar), are beginning to be very busy. In the Apple blossom, more especially, there are two sorts of caterpillars—one a small green, and the other black, hairy, and much larger. They seem to be in the centre of the blossom, and to eat its heart away. Can any of your readers furnish an effectual plan for dealing with them or a more successful one for destroying the Gooseberry caterpillar than tan, which in compliance with your advice I tried, but without success, as I have had two women constantly employed for the last ten days

in picking, and who literally collect bushels of them? Lime plentifully sprinkled on the tree seems to check them.

I observe a statement that a mild solution of chloride of lime applied to any tree will destroy any fly or caterpillar. But as "mild" is a very comparative term, could you give any information as to the comparative strength of this "mild solution?" and so oblige—AN IGNORAMUS, near Liverpool.

[It is difficult to determine the species of moth or saw-fly which gives birth to a caterpillar without first seeing the caterpillar. The "usually green" ones on the Apple blossom are probably the larvæ of the winter moth (*Cheimatobia brumata*), which are grey at first, but become pale green afterwards. But whatever their parentage, their most effective destroyers are the small birds. No application can kill the caterpillars that would not injure the blossom.

The Gooseberry saw-fly caterpillars, we suspect, result from the moths from the underground larvæ having emerged before the tan was put on to the surface of the soil, or it was put on too thinly. Dusting with fresh white hellebore powder will kill the caterpillars, but we believe that hand-picking, which you have adopted, is the cheapest and most effective remedy.

Any solution of chloride of lime sufficiently strong to kill caterpillars, we think, would kill the leaves also. It is very easy to try the experiment. Dissolve a teaspoonful of the chloride in a tumbler of water, dip into it a shoot, and if it kills the caterpillars and the leaves they are on too, then try one teaspoonful to a pint of water, and so on until you have ascertained the whole truth. Then you could not act more wisely and benevolently than by communicating to us a statement of the facts for publication.]

### OUR PRESENT SEASON OF BLOSSOMS.

AT no time previous do I remember seeing such an abundance of bloom upon deciduous trees, and this is not confined to trees under cultivation, but every tree of our hedges and our woods is, and has been, gorgeously decked with flowers. What other counties may have to report upon this subject I am not traveller enough to be in a position to say; but most certainly here on the south coast, the year 1862 is a memorable year for blossom, and one that will not soon escape man's memory. Our fruit-orchards are beautiful in the extreme, every twig to the very extremity is one mass of bloom. Trees that for years past have scarcely retained life enough in them to secure their remaining upon the ground, have this season put forth more vigorously than they were ever known to do before, while others that have yielded but little fruit bid fair to produce an unusually heavy crop, and each one is congratulating his neighbour upon the happy result that may reasonably be expected. Plums, Pears, and Cherries being more advanced than Apples, we can speak with a little more certainty as to a crop. They are all set in abundance. Wall fruit with us is rather above the average, which we are not surprised to see after a season of bloom such as we witnessed here. Gooseberries and Currants are plentiful, and fully a fortnight in advance of other seasons. Strawberries, too, are trussing-up strongly and plentifully, notwithstanding the prognostications of some of your correspondents that we should have a cold, backward spring.—J. C. CLARKE, Wakehurst Place Gardens.

### SUPERSTITIONS RELATIVE TO THE ELDER TREE.

ARE you aware that it is a superstitious opinion among country people in some districts that the cross on which our Saviour suffered was made of the wood of the Elder, and that they object to burn it on that account? It is also said never to be struck by lightning—an opinion founded, perhaps, on the same tradition.—F. A. W.

[We have heard of this before; but Sir John Maudeville says in his description of Jerusalem, that close by what was considered the Pool of Siloam, "is still the Elder tree on which Judas hanged himself for despair." It may have been for one or both of these legends that Boerhaave always took off his hat to an Elder tree when he passed it. He only shared the superstitious feelings of his countrymen; for Grimm says that in Germany the Elen, or Elder, was held in such great veneration

by their forefathers, that when they lopped it they usually addressed it thus—"Lady Elder, give me some of thy wood, then will I give thee also some of mine when it grows in the forest." This address was uttered kneeling, bare-headed, and with arms folded.

The most ancient tradition relative to the cross is that the upright stem was of *Cedar*, the cross-beam of *Cypress*, the inscription tablet of *Olive*, and the foot-block of *Palm*.

In Hildesheim, when any one dies in the country the grave-digger goes silently to an Elder tree, and cuts a wand to measure the corpse with; the man who takes it to the grave does the like, and holds this wand in place of the usual whip. Elder planted before the stall-door preserves the cattle from magic.

There are various other local superstitions relative to this tree prevalent in many parts of England. Thus, the rider on horseback, it is said, will never "lose leather" if he has two small sticks of Elder in his pocket; no one will have erysipelas who wears in a bag hung about the neck a piece upon which the sun never shone. Those on whom the shadow of age is falling may like to know that Lupton is certain that "the flowers of Elder gathered on a midsummer-day, dried and powdered, and a spoonful thereof taken daily will make one seem young a great while."

Many of our ancestors would not allow their boys to be chastised with a rod of Elder, "because it hinders their growth"—a prejudice the boys would willingly have had enlarged to include rods of all kinds.

The ancient name of this tree, according to Turner, was the "Bour-tree," or, as we should spell it, "Bore-tree," alluding to the large bore or hole through each branch containing the pith. Elder seems to be merely a corruption of the old German name referring to the same fact—Holder, or tree with holes.]

## FLORISTS' FLOWERS,

THEIR DISTINGUISHING CHARACTERISTICS, CULTIVATION, AND VARIETIES.—NO. 6.

THE TULIP

THERE are few flowers which have enlisted on their side so much real furor as the Tulip; indeed, we question if there be one in which extravagance in price, and indeed in language too, has been carried to such excess. It is but little use now referring to the oft-told tale of fabulous prices given for them in the gambling days of the seventeenth century in Holland; for it was not so much the intrinsic merit of the flower as the opportunity of gratifying the rage for speculation and gambling that obtained such ridiculous prices for them, just as people will gamble over the drops of rain running down a pane of

glass. But even at the present day a catalogue of Tulips reveals prices for flowers which have been some years in growth which are not to be found in the lists of any other of Flora's favourites; and were one to make a bid for the bed of 100 rows which Mr. Charles Turner, of Slough, offers for sale this month, he would find that it is no easy matter to get together a collection of Tulips.

I, who have only a very small bed and do the flower in a very humble way indeed, asked in my innocence last year how it came to pass that there were so many ill words, such bad language, and nasty feeling on the subject of this flower, and I honestly confessed that I was almost afraid whether there was not something in the flower itself that might bite me. I bethought me of what the old gardener said of horses—"I've noticed all my life that horses seem to spoil anybody that has much to do with them, whether master or man;" and I began to fear whether the Tulip might not be as bad as the poor horse. And, as if to confirm all my previous fears and suspicions, a controversy is even now pending on this subject in which said controversy personalities of all kinds are flying about thick as possible, and one almost even fears to allude to it, lest one should be dragged into and receive a sound castigation; the controversy (into which even microscopical science has been brought), turning on the question as to whether form or marking is to be considered the first point in a Tulip.

It will be necessary to mention here that this is one of those points in which Northern and Southern florists entertain great difference of opinion. And here, as in the case of the *Auricula* and *Pink*, "Northern" must be understood in a restricted sense—Scotland, which is far north, agreeing with us in the more sunny South; while the what-I-cannot-but-call-erroneous view is shared by the Tulip-growers of Lancashire, Yorkshire, and the midland counties. Dr. Horner's idea seems to be that in the South we lay too much stress on colour, which not only is a prominent feature in Tulips, but which, as he says, really distinguishes their classes; flowers being feathered or flamed according to the disposition of the colours on them. Upon this subject the Northern florists we believe to be decidedly wrong; and Dr. Horner, who only partially sides with them, to some extent admits this, the purity of the base of the petals and of the ground colour of the flower having been much overlooked by them, and those flowers whose markings were the most gaudy and distinct being considered the favourites, even though the petals were pointed and irregular (I believe their taste is improving). But at the same time he upholds the marking of a flower as permanent, and contends that marking, combined with purity and brilliancy of colour throughout the petals, constitutes the first property of the Tulip; while form, with substance and smoothness of petal, is but the second. From this I beg most emphatically to dissent, not from my knowledge of Tulips simply, but because I consider that form in every florist's flower constitutes the first point, colour the second, and size the third.

What, then, is the form which we assign to the Tulip? The accompanying drawing will give Mr. Glenny's notion on the subject; and, as I have before said, his ideas of characteristics have now come pretty generally to be considered the standard ones. It will be seen that the six petals of which it is composed form a perfect cup, spreading out a little horizontally from the base and then turning upwards, that the edges are perfectly smooth and rounded at top, and that there are no interstices between the petals to mar the perfection of its shape: the three outer petals being a little larger than the inner ones materially aids this. The cup should be wider, too, at the top than at the base, for where the petals turn in it is a great hindrance to the beauty of the flower. Substance and smoothness are naturally connected with shape; for if a flower be flimsy it is impossible that it can retain its shape for a day, and therefore the petals should be thick and waxlike, and not coarse in the grain, refinement being quite as much an essential in a well-bred florist's flower as in a duchess. As neither the title nor grandeur of the one can make people overlook coarseness of mind, so neither can fine colouring nor even good shape in the other be tolerated if the substance be coarse. So, again, smoothness of the edge is absolutely necessary; jagged and uneven ones thoroughly destroying its beauty.

Colour comes second in the list of properties, and this must be held to comprise both purity and marking. Tulips are divided into three sections—Bizarres, Byblemens, and Roses; in the former the ground colour is yellow, and in the two latter

white. Now, this ground colour should be perfectly pure, a muddy yellow or a creamy white spoiling the beauty of it. The base of the flower inside should be quite clear—that is, none of the marking should run down to the bottom of the petal, nor be stained in any way; the same is to be said of the stamens, which must be white or yellow according to the class. With regard to the marking, each of the above classes has a further double division into flames and feathers. Bizarres having yellow grounds marked with purple scarlet, when confined to the edge is feathered; when with a dark broad stripe down the centre of the petal it is flamed, some flowers being both feathered and flamed. Byblomens, again, have white grounds marked with violet and purple, and are either flamed or feathered. Roses have also white grounds, marked with rose or cherry red.

In no case must the colours be run, or shaded-off; the marking must be distinct and clear—a difficult point to keep to; for some will oftentimes disappoint the most ardent and particular grower by running, and then they are a sad disfigurement to the bed.

Size comes last in the list of properties; and I think a very large Tulip, such as Lord Raglan, is out of place. It seems too commanding for the graceful and elegant forms around it.

Such are my views on the properties of the Tulip, and I have written so much about this one point, that I must defer what I had to say about their cultivation and varieties until another time; hoping, meanwhile, to get a peep at Mr. Turner's bed, which he pronounces to be in first-rate condition this season.—D., Deal.

## ARTIFICIAL WATER IN GARDENESQUE SCENERY, FOR GROWING AQUATIC PLANTS.

BY H. NOEL HUMPHREYS, ESQ.

(Continued from page 122.)

THE engraving exhibits a canal supplied in a similar manner, and for a similar purpose, as in No. 1, but which is treated in a manner precisely the opposite of the symmetrical or architectural. The picturesque, as it is termed, has been the effect aimed at, in the form of a rocky valley, which it is intended should be entirely screened from the rest of the grounds by means of well-disposed shrubberies, leaving only an approach through a tunnel of rock. A completely sequestered spot of such totally distinct character

would form a very pleasing contrast to the more regular portion of the grounds, and the aquatic plants, which may be the same as those in the engraving No. 1, would, in a situation so sheltered, thrive with great luxuriance. In the interstices of the surrounding rocks, Broom and double-flowering Furze should be planted, with hardy Cistuses, and a variety of Ferns; and so completed, the scene would be very original in its general effect.

A tank of rocky character must be prepared exactly in the

PICTURESQUE OR ROCKY TANK FOR WATER PLANTS.

same way as the one previously described as far as its foundations, supply of water, &c., are concerned. The form, however, must of course be irregular, the rocky effect of the sides being produced by bricks irregularly placed, and roughly covered with cement, as also the opening for letting in the water. The detached pieces of rock should, if possible, be rough pieces of real stone, collected in the neighbourhood, which in many places, such as the red sandstone districts, is easily accomplished; such pieces, in picturesque forms, being very abundant. But where real stone is not available, such masses may be formed by bricks roughly covered with cement, and will produce a very good effect if the eye of a tasteful director superintends the formation

of the outline and position. I recommend this latter mode of producing rockwork as very superior to a collection of heterogeneous materials, which always produces a petty, broken, and patchy effect, while the general similarity of colour of the cementwork gives continuity and grandeur to the design, and the forms may, with these materials, be made large and majestic in their character to any extent that the nature of the design admits of.

In the rocky tank I have supposed the waste water to escape in the form of a small open stream among pieces of rock, which, with the addition of a few well-selected pebbles in its channel, would produce a very pleasing feature in such a scene.—(*Gardener's Magazine of Botany.*)

## CYCLAMEN VERNUM.

IF "J. A. P." insists upon the true explanation of the reason why I said *Cyclamen vernum* "on travelling as far north as Naples," after denying it a home anywhere, I suppose I must come out with *peccavi*, and tell the whole truth and nothing but the truth. But, first of all, let me clear the mist of the misfortune in assigning the locality of *C. europæum* to the southward of Genoa, instead of Geneva. I had only the previous week corrected the reading from a manuscript, and said the Po was still the southern boundary of the species: therefore, any one who took an interest in the question, could easily perceive that Genoa was a misprint for Geneva, and if the thing were in a book the first correction would have been enough for the next edition; but in a serial work like this, such corrections are less useful in practice. "The south of Europe" and "the Levant," are very useful places for authors and for compilers who know very little of what they are writing about, for referring the locality of a plant to; but such loose writing will not do now-a-days, and this most useful article from "J. A. P." is a proof of that assertion. Geneva, Genoa, and Gibraltar are in the south of Europe; but if Loudon, or any of the authors from whom he quoted, or who assisted him in his great works, had known which of these places, or which place in the "south of Europe" a certain plant could be found, they surely would have said it. But "J. A. P." has, very obligingly, assisted us in this inquiry, and the conclusion of it is this—that no author since the days of Linnæus has been wholly right on *Cyclamens*, or rather, that every one of them has been on the wrong scent all their lifetime: therefore, I hold it firm as Loudon, that no man now on the earth knows exactly where to look for *Cyclamen vernum* in a wild state.

I have the "root" and the name *vernum* from Italy this very month from my own "Sardinian Correspondent;" and the Messrs. Carter, Butler & McCulloch, and Barr & Sugden may guess if my correspondent be the same person as they had their *Cyclamens* from, when I say my correspondent is *now* farther to the southward than theirs was a short time since.

Specimens of a score of nursery plants of *vernum* from several Sardinian correspondents have been sent to me for the last two or three years for identification, not one of which was true: therefore, I can only go on supposing that I am in the same fix by my own correspondent until I flower the plants. And therefore, also, as *vernum* can be made here by crossing, and *ibiricum* as well, I see no cause to give up the point till we are better informed.

Now for the *vernum* which I supposed to have travelled northwards from the south point of the Peninsula, through the subalpine risings all through Calabria, and wishing to get nearer to the east on approaching Naples. The whole was a fiction founded on fact to provoke discussion, for one never tires of this sort of thing as long as there is a stone left unturned; and the fact on which it was founded is, that the true Ivy-leaved *Cyclamen* of Clusius occupies all that tract of the country, and blooms there constantly in the spring, and the spring is *vernum*, of course. But neither fact nor fiction seems sufficient to turn many people from the wrong way, and who is so universally wrong on the Ivy-leaved *Cyclamen* as the bulk of British gardeners?

I am delighted with "J. A. P.'s" idea of making *Cyclamens fine-foliaged plants*; that is worth trying for most certainly. I once said I could make them all *macrophyllums* like the variety from Algiers, and I succeeded so well that last autumn I passed off, in review, before a first London authority, several sorts in my border as true *macrophyllums*, although I had not that kind then in stock. But I had to trust them to the care of another for some time after that, and had from 300 to 400 frosted to the ground.—D. BEATON.

**CARTER'S CHAMPION BROCCOLI.**—We have received from Mr. Swinerd, gardener to John Swinford, Esq., of Minster Abbey, Kent, two heads of Carter's Champion Broccoli, which are of very large size, even and beautifully grown, and of a fine colour; they were each 2 feet 3 inches in circumference. This is evidently a form selected from the *Wilcove* Broccoli, and appears to be also somewhat later than that variety. Mr. Swinerd states that the crop of *Wilcove* was over on the 2nd of May, and this is now just in perfection and will last another week.

## NEW BOOKS.

*The Orchard House: or the Cultivation of Fruit Trees in Pots under Glass.* By THOMAS RIVERS. Tenth Edition, enlarged and improved. London: Longmans.

LIKE all great things that spring from small beginnings, the orchard-house system of cultivating fruit trees has gradually developed itself until it has become almost a distinct branch of gardening. From time to time Mr. Rivers has furnished us with the progressive steps that have been made in this mode of culture; and now in the tenth edition of his book he brings us down to the latest improvements in these structures and the most recent discoveries in the management of the trees. In this edition we have some instructions on the application of heat to the roots—a subject which in the present day is occupying the attention of gardeners, and it is one upon which there is not a doubt that the success of the cultivation of all exotic fruits depends.

The instructions given for the construction of arrangements for this root-heat are very simple.

## "FORCING WITH ROOT-HEAT."

"The most efficient method of forcing Peaches and Nectarines and also Grapes in pots, is to give them root-heat, forming a hot-air chamber by enclosing two 4-inch hot-water pipes between two 4-inch brick walls, and then placing bars either of iron or wood, across from wall to wall; on these should be placed slates; the heat from the hot-water pipes thus enclosed, will give a surface constantly heated; on this flooring of slates the pots should be placed, not plunged in any material, for if so, the air of the house will not be heated sufficiently. So favourable is this root-heat to the growth of trees in pots, that I have found Vines in pots placed on the brick-work over a boiler, with a surface heated to 130°, make shoots 30 feet in length, and bear very fine fruit. In a house 12 or 14 feet wide, with two 4-inch pipes going round it, the path should be in the centre, and a bed or hot-air chamber, 5 to 6 feet wide on each side; the pipes should be near the ground, but not resting on it, and the brickwork may be from 20 to 24 inches in height. This method will answer well for moderate forcing, so as to have Peaches ripe in June, but if early forcing is practised there should be two 4-inch hot-water pipes above the hot-air chamber, so as to fill the house with warm air. This extra heat may however be dispensed with, if a house is double glazed, which, as compared with a house single glazed or heated with the same apparatus, will give an increase of from 10° to 12° of heat: for example, a house heated with two 4-inch pipes round it in cold weather in spring, may, with a single roof of glass, have a temperature of 60°, but with a double roof, and with the same heating force, it would have a temperature of 72°. This is an enormous gain, and the construction of such roofs for early forcing will ere long be very general."

Then we have instructions "How to form an Orange grove;" and why not? Oranges are as easily cultivated as Vines; and there is no reason why St. Michael's, Tangerin, and other edible varieties should not be grown as those large, worthless, woolly, and abominably acid sorts that have occupied our conservatories for generations past. It is a high flight of fancy certainly, but it is one which after all is far from Utopian, as the following extract will show:—

## "HOW TO FORM AN ORANGE GROVE."

"A large span-roofed house 100 feet long and 24 feet wide would form a grove large enough for a most enjoyable promenade. An amateur living near Clapham, Surrey, has recently built three houses of this size, one of which will most probably be formed into the first Orange grove ever seen near London. There is another mode of forming an Orange grove under glass, more expensive and luxurious, by adopting 'geothermal culture,' and heating the borders as well as the air of the house. A house 24 feet wide under this system would require four 4-inch hot-water pipes under each border (with rubble 4 inches deep over them), placed about 2 feet under the surface; with a path in the centre of the house 5 feet wide, each border may be from 9 to 10 feet wide; the pipes about 2 feet apart; besides these there must be two 4-inch hot-water pipes to heat the air of the house in the ripening season. In a house thus heated those delicious (when first gathered) Maltese blood Oranges may be grown, and the Pernambuco and other tropical varieties of the genus *Citrus*. Tangerin and St. Michael's Orange trees planted in these warm borders would ripen their fruit very early, and it would be more sugary and rich. There seems, indeed, no end to what can be done by Englishmen with the aid of artificial heat and glass. What a beautiful vineyard under glass could be formed by such heated borders as I have described above; and how charming "to make a promenade," as our neighbours say, in such a place. The Tangerin Orange is an abundant bearer when cultivated under favourable circumstances. A correspondent has recently informed me that a tree in his garden at Alexandria, Egypt, not more than 6 feet high, has often given him a crop of 500 fruit."

Our space is too limited to say more than that this edition is much improved, many additions have been made, and that it is a worthy successor to those that have gone before it.

*A Handy Book of the Chemistry of Soils: explanatory of their composition and the influence of manures in ameliorating them, with outlines of the various processes of agricultural analysis.* By JOHN SCOFFERN, M.B. Lond. London: Bell and Daldy.

This is a pleasant book for the tyro, but it is quite misnamed. It is called "A Handy Book of the Chemistry of Soils;" but it

is a fact, that not more than 24 pp. out of 216 pp. strictly relate to that leading title. It is a pleasant book, nevertheless, and much information may be gleaned from its pages; but we recommend that when it comes to a second edition that it be revised by some one who is a master of English as well as of chemistry. As evidence that this is needed, we will give but one quotation out of many we have marked as incorrectly expressed. "The idea was entertained by Lavoisier and his associates that oxygen was the universal acid of any principle," page 8. What Dr. Scofield meant to say is—"that oxygen is the univocal acidifying principle."

It is a more grateful task to quote passages which are evidences of excellence, and these are by far the most numerous; but we can afford space for but two:—

"It is a remarkable fact, in connection with the chemistry of starch, that it frequently exists in exceedingly poisonous plants, but when once extracted, it is always innocuous.

"A facile instance in illustration of this point, is furnished us by the Potato, which belongs to a very poisonous tribe of plants, the Solanaceæ, or Nightshade tribe, and which itself is somewhat poisonous; for, if Potatoes are allowed to sprout in dark places, the pale blanched sprouts are poisonous, even to danger; and every housewife knows that good Irish stew must by no means have in its composition any of the water in which the Potatoes were first boiled, because of the poisonous extract which such water contains.

"A far more striking exemplification of the poisonous agents with which starch sometimes associates, is furnished by Tapioca. The tree which yields this favourite article of food, not only belongs to one of the most poisonous tribes known to botanists, the 'Euphorbiaceæ,' but the *Jatropha manihot*, as it is termed, is one of the most poisonous of the tribe. A little of the juice of this tree, poured on a wound, or inserted by means of a puncture, almost infallibly kills the animal to which it is applied: indeed the natives of regions where the *Jatropha manihot* grows, employ its juice with the object of poisoning their arrows. Taken internally, this juice is equally fatal. Yet, diffused through the whole of the *Jatropha* trunk, and easily separable from the latter, by washing, is Tapioca starch—perfectly harmless—and which is rendered in the commercial form of Tapioca, by a process of torrefaction or partial baking."

"It is a prominent quality of diastase to render starch soluble in water of a temperature insufficient to cause its solution unaided. According to Liebig, the diastase contained in 1 lb. of malted barley is sufficient to dissolve and convert into sugar 5 lbs. of starch. This fact is turned to great practical use in the operation of brewing—especially in the brewing of pale-coloured ales. If the diastase in 1 lb. of malt be sufficient to turn into sugar 5 lbs. of starch, then it follows that we may save our malt to the extent of that quantity which corresponds with 5 lbs. of starch, and use a corresponding quantity of raw grain. By following this plan, we not only economise to the extent of the labour-value, corresponding with the amount of malt saved, but we lower the colour of the resulting beer; inasmuch as even pale malt, at whatever temperature produced, contains a certain amount of colouring matter.

"In Germany, and many parts of Belgium, where a light colour is desiderated for beer, the above-mentioned chemical principle is taken advantage of. The white beer of Louvain is made from a wort, formed of a little malt, added to a large quantity of wheat flour; and, in the manufacture of the celebrated Bavarian pale beer, a large quantity of unmalted barley is employed.

"If starch be baked, it is rendered soluble in cold water; acquiring under this treatment the leading property of a gum. Under the name of British gum large quantities of this material are manufactured for employment in the operation of calico-printing. The chemical term for this substance is dextrine; and it may be regarded as starch advanced, by one stage beyond diastase, towards the condition of sugar. Dextrine is not only the result of the torrefaction of starch, but it is formed when starch is boiled with very dilute oil of vitriol. As before remarked, it is also generated when starch is operated on by diastase."

## PORTRAITS OF NEW AND RARE PLANTS, FLOWERS, AND FRUITS.

**RHODODENDRON ARBOREUM var. LIMBATUM** (Broad-zoned Tree Rhododendron).—*Nat. ord.*, Ericaceæ. *Linn.*, Diandria Monogynia.—A variety raised from seed sent from the Sikkim Himalaya by Dr. Hooker. "Not one is better worth cultivation than this, whether for its early free-flowering habit, or the exquisite delicacy of the broad rose-coloured limb of the corolla gradually fading into the almost purely white throat, marked at the base with a deep blood-red blotch."—(*Botanical Magazine*, t. 5311.)

**LIMATODES ROSEA** (Rose-coloured Limatodes).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Moulmein. Flowers pale rose-coloured.—(*Ibid.*, t. 5312.)

**CLERODENDRON THOMSONÆ** (Mrs. Thomson's Clerodendron).—*Nat. ord.*, Verbenaceæ. *Linn.*, Didynamia Angiospermia.—Native of Old Calabar, on the west coast of tropical Africa, whence it was sent by the Rev. W. C. Thomson, and is named in memory of his wife. It flowered during January in the stove of the Edinburgh Botanic Garden. Branches long and twining, or prostrate and rooting. Flowers in clusters and very showy, the corolla being deep crimson, and its large campanulate calyx white.—(*Ibid.*, t. 5313.)

**HEMANTHUS CINNABARINUS** (Cinnabar-coloured Hemanthus).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. Native of Ambas Bay, western tropical America. Flowers scarlet.—(*Ibid.*, t. 5314.)

**HELICONIA METALLICA** (Metallic-leaved Heliconia).—*Nat. ord.*, Musaceæ. *Linn.*, Pentandria Monogynia. Native of "the wet shady gorges at the foot of the Sierra Nevada of Santa Martha." Stem 6 feet or 8 feet high. Leaves about 2 feet long, rich velvety green above, coppery metallic purple beneath. Flowers scarlet with greenish-white tips.—(*Ibid.*, t. 5315.)

**AMARYLLIS UNIQUE**, raised by Mr. B. S. Williams, Paradise Nursery, Holloway. Colour deep brilliant scarlet, the centre of petals shaded with black, throat marked with white.—(*Floral Magazine*, pl. 97.)

**HYACINTH DUC DE MALAKOFF**.—"A very striking flower, nankeen yellow ground, with broad stripes of crimson in each segment of the corolla."—(*Ibid.*, pl. 98.)

**PELARGONIUMS**.—CELESTE has "an entirely new shade of colour, the lower petals being of a rich orange scarlet, the upper petals deep maroon with a bright scarlet margin, and a clear white centre; altogether a very novel and striking flower." MRS. HOYLE, "a fine light flower, lower petals violet rose, upper petals same colour shaded with red, with a small black spot." PRINCETTA, "a very beautiful dark flower, upper petals glossy black with a fiery crimson margin; lower petals heavily pencilled with dark red and rose, centre clear white."—(*Ibid.*, pl. 99.)

**EPACRISSES**.—Three varieties raised by Mr. Storey, and sent out by Messrs. Henderson, Wellington Road Nursery. FIREBALL, brilliant crimson; BUTTERFLY, white and rose; and EXQUISITE, bright rosy pink.—(*Ibid.*, pl. 100.)

**POMPON DAHLIAS**.—From Messrs. E. G. Henderson, Wellington Road Nursery, St. John's Wood. STAR, flowers bright orange yellow. LITTLE DORRIT, flowers deep purplish-rose.—(*Florist and Pomologist*, i. 65.)

**CHERRY NOUVELLE ROYALE**.—One of the "Duke" race of this fruit. "A first-rate Cherry ripening in the end of July, and continuing in use till the middle or end of August."—(*Ibid.*, 72.)

## CULTURE OF THE PINE APPLE.

(Continued from page 122.)

**PLANTING IN A BED OF EARTH**.—This method is now followed by many cultivators with great success. At Trentham, the Duke of Sutherland's seat, I saw a few years ago a bed of earth in a pit in a lean-to house planted full of Queen Pines; and, at the time of my visit, they were all in fruit, many in a ripening state. I was assured by Mr. Fleming himself, who had the charge of the garden then, that the fruit would average at least 6 lbs. weight each; and certainly I believe they would, for better swelled or larger fruit of that kind I never saw.

Supposing, then, that some of my readers may choose to follow such a successful example, and supposing also that they have the means in the shape of a proper house and a right sort of a pit—that is, one heated under the bed by hot-water pipes running through a shallow tank of water; let that tank be covered with flags, and on the flags place a layer of rubble, such as broken stones or brick ends, 6 inches thick, and on that layer lay a covering of turf, and then fill the pit up to the curb stones with good rough compost such as I prescribed for fruiting plants in pots. Let this bed of earth settle and become warm and moderately dry. Then select from amongst the fruiting plants a sufficient number to fill the bed without crowding. Choose them as nearly as possible all of a size and age. Set the first row on the pit, and commence to plant them by first laying a broad board on the soil to stand upon, and then open a hole at one corner at the north side of the pit; a three-pronged fork with a short handle is a suitable tool for the purpose. Make the hole deep enough to receive the ball, then turn the ball carefully out of the pot and place it in the hole as entire as possible. Fill in around the ball the soil that came out of the hole, which will raise it a sufficient depth to cover the ball an inch or 2 inches deeper than it was in its pot. Press the earth rather firmly to the plant, and then take the next plant in hand and plant it out in a similar manner, and so proceed till the first row is completed. After that is done, remove the board and gently stir-up the soil that has been pressed down by the board; that board, if of a sufficient length, will be a good guide to keep the rows straight

by. Place the second row ready, and then commence again at one end and plant it out in a similar way, only observing to plant them opposite the spaces in the first row in this fashion . . . . . When that row is completed, plant the next, and so proceed till the pit is filled; only observing, that if the plants have been tied-up with bast mat, to cut the ties loose in each row as the work goes on, so that there may be no disturbance afterwards. The outside rows may be loosened from the back and front path. When all is finished, give a good watering with warm water, wash the floors, and leave all sweet and clean. The after-management is much the same as for the pot system, only when planted out in such a large body of earth less water is necessary at the roots.

Where a succession of fruit is required there ought to be two pits, one for summer fruit and the other for winter fruit; that for summer should be planted out in February, and for winter plant out in July.

**TREATMENT OF OLD STOOLS.**—After the fruit is cut the old stocks should have a liberal supply of water, both from the garden-pot and syringe. This will encourage the growth of the suckers very much, and they may be still further encouraged to grow strongly by pulling off a few of the old bottom leaves, and piling up some fresh turfy soil around the old stem. The young roots of the suckers will strike into this, and, of course, draw nutriment from it. When, however, all the fruit in that pit is gathered, then lift out the old plants at once, and take off the suckers and pot them in the ordinary way. It is quite possible that some of the suckers will be so large as to require pots nearly as large as any in the succession-house. Some kinds are shy in producing suckers—such for instance, as the White Providence. When such a one has only one sucker on it, I have taken that sucker off and repotted the old plant, cutting off and shortening the leaves and replanting it in the bark bed. By this method I have, as it were, forced the old plant to throw out two or three more suckers in succession.

#### WINTER TREATMENT.

The winter of Pine culture, as I remarked before, commences in October and ends in January.

**HEAT.**—The internal heat during this season should never exceed 70° at noon, and if it falls to 60° at midnight that will be warm enough. If a higher heat is kept up the centre young leaves will come up thin and bleached in colour, showing evidently a too great excitement. The same remark applies to the bottom heat. During the short dark days, if the bottom heat averages from 65° to 70°, it will be quite warm enough. In fact, what we want in winter is a slow steady growth, and to attain this we must lower all stimulants, whether they be heat, or water, or steam—that is, moist air. Let this principle, then, be borne in mind by the young gardener—namely, feed a plant in proportion to the work it has to do, and let that work be done mostly in the longest and sunniest days. Grow slowly in winter and quickly in summer. There is, however, one objection to this rule, and that is, when you have a house full of fruit, swelling off to ripen about Christmas, these must have 5° or 10° more heat, and a liberal supply of water at the roots, and moisture in the air. Bottom heat should also be kept up by additions of fresh tan, when the heat falls below the minimum, in all pineries, whether in fruit or not.

**AIR.**—Fresh air is as necessary in winter as summer, but, of course, cannot be given to that extent; yet in some days there is sun and a warm soft air, and on such days air may be given freely, even from ten in the forenoon to three in the afternoon. But in doing this great attention must be exercised, and if the weather changes to a cold dampness close all up immediately; hence the cultivator of the Pine Apple should either be constantly in his garden himself, or leave a competent man in charge that he can depend upon. In November, December, and January very little air can be given, and in very hard frost none at all, unless the sun shines, when a small aperture may be opened for an hour or two in the very middle of the day. It is true in our variable climate we have sometimes a short season, lasting, perhaps, for a week or ten days, of fine, clear, sunny weather without any frost. The diligent cultivator will take advantage of such an occurrence, and give air accordingly.

**WATER.**—During these winter months the Pine Apple requires but little water—only just sufficient to keep the soil moist. If the soil becomes wet and sodden the roots will perish, and very likely many of the half-grown plants will start into fruit when more heat is given: hence the grower should be careful not to

give water till the soil is very dry, and even then to give a very moderate supply. Should by chance any water appear lodged in the hearts of the plants, either from drips from the roof or from the watering-pot, that water should be drawn away. I have generally for that purpose used a long, small, tin tube, and sucked it out with my mouth, and so got rid of it entirely.

There are no actual manual operations required during winter, excepting the renewing the heat of the bark-bed when it falls too low in temperature. As it cools and decays most at the sides and ends next the walls, I have sometimes renewed the heat sufficiently by taking out the outermost rows of plants and removing this cold decayed tan, replacing it with fresh tan in a state of fermentation produced by laying it on a heap in the shed.

With close attention to the above points the plants will be carried through these winter months in good health; and will be short, stout, broad-leaved plants, of a good dark green healthy colour, ready for the spring repotting.

T. APPELBY.

(To be continued.)

#### WORK FOR THE WEEK.

##### KITCHEN GARDEN.

THE weather is now favourable for carrying on the various operations of planting and sowing. Where any main crops in the kitchen garden have failed, more seed should be immediately sown; where they have partially failed procure plants, if possible, to fill up. Thin out all seedling crops as soon as they are fit; delay on this point frequently does great injury, the plants get weak and drawn, and never recover the ground they lose as compared with those that have been attended to in proper time. *Beet*, thin the plants to a foot apart while they are small. Fill up vacancies with those that are drawn out; they will produce plants equally good with the others. If the first crop has altogether failed, it is not yet too late to sow again. *Broccoli*, make another sowing of both early and late sorts; the former to come in in October and November, the latter late in the spring. *Carrots*, where young ones are continually in request, another sowing may now be made; and advancing crops of the same must be kept well surface-stirred and thinned-out from 4 inches to 6 inches apart, as very large Carrots are seldom required. *Capsicums*, plant-out on a warm rich border; water them during dry weather throughout the season. *Cauliflowers*, those in a forward state to be supplied with liquid manure, even if the ground is wet. *Chervil*, make a sowing of that, and also a sowing of American Cress. *Dwarf Kidney Beans*, make another sowing. *Endive*, sow a little seed for an early crop. It is advisable not to sow much, as it will soon run to seed. *Leeks*, make a sowing to plant-out for winter use. *Lettuce*, plant-out a few about once a-week. *Parsnips* require to be thinned to 9 inches apart or more if the ground is rich. *Tomatoes*, plant-out in light compost under a south wall, also Chilies and Basil. Let the roots be gently loosened and spread out, if they are at all potbound.

##### FLOWER GARDEN.

As all apprehensions of danger from frost are now over, the planting-out of half-hardy plants for the summer and autumn decoration of the flower garden should now be proceeded with, and carried on as vigorously as circumstances will permit. Select a shady border, and give it a good dressing of rotten dung or leaf mould slightly forked in, for planting with the runners of the different kinds of Violets for forcing. The Neapolitan is the best for frames or pots, and the runners will now be found in a proper state for removal. Plant them 8 inches or 10 inches apart; water them abundantly in dry weather, and pinch off the runners as they appear. If the soil be rich and open they will grow into stout bushy plants by the autumn, and may then be either potted or planted into pits or frames for forcing. The many beautiful climbing plants that are at present in cultivation, make it as easy to produce pleasing effects on walls as in flower-beds; and there is no reason why an interesting variety should not be produced there as well as elsewhere;—Clematis, Tropæolum, Sollya, Passiflora, Cobæa, Lophospermum, Billardiera, with their differently-coloured flowers, as well as some of the Loniceras, Jasminums, &c., which are worthy of notice either for their flowers or the fragrance that they diffuse around them.

##### FRUIT GARDEN.

During the process of nailing-in the shoots of Peaches Nec-

tarines, and Apricots, examine if there are any nails so placed as to be likely to injure the swelling fruit, and if so, remove them. When nailing-in young shoots it is advisable to use strong cloth shreds cut to a sufficient length to allow plenty of room for the young wood to swell, for it frequently happens when short shreds are used, that at the pruning season, many of the shoots will be found to have an indented ring, and very often a large piece of gum. Vines will now require constant attention in stopping and nailing-in.

#### STOVE.

All plants will now be making rapid growth, and will, therefore, require to be treated liberally, both at root and branch, taking care to pot in time all such things as require it. *Stephanotis*, *Gloriosa*, *Allamanda*, *Dipladenia*, and other climbers will now be showing bloom, see that they do not get entangled. Keep up a brisk temperature with plenty of air. Attend to the plants preparing for winter. *Achimenes* to be placed in an airy situation, stake them out neatly as the shoots progress. *Gloxinias* require a partially shaded situation and moist heat. *Gesneras* may be treated in the same way with the addition of more light. *Amaryllis*, &c., to be removed to the conservatory or show-house for blooming, mark any striking varieties for seeding. After blooming plunge them in a little bottom heat, in a frame near the glass, to perfect their growth.

#### GREENHOUSE AND CONSERVATORY.

Remove the inferior specimens and kinds so as to give plenty of room to the best specimens, and do not allow the plants to touch each other during the time they are making their growth. All plants that are getting shabby to have their blooms removed immediately, and, if necessary, to be cut back and started into fresh growth. Look well to watering, but avoid saturation, and give abundance of air at all times, unless when you have occasion to syringe and to shut-up for an hour or two before sunset.

#### PITS AND FRAMES.

As soon as they are clear of bedding stuff they should be occupied with young stock of hard-wooded plants, for the summer growth of which they are more suitable than large houses. Such places will be suitable for late-blooming *Pelargoniums*, *Balsams*, *Salvia splendens*, *S. gesneriflora*, and many other things which are generally grown for blooming in the conservatory in summer and autumn.

W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN AND FRUIT GARDENS.

The general work was much the same as last week, looking after young crops, staking Peas when the weather was suitable, sowing main crops of Scarlet Runners, planting them out of boxes, &c., and keeping an eye on insects among different kinds of fruit trees. The weather was so warm at times that fires were scarcely necessary in the hothouses; sun heat when it can be got and enclosed being for all purposes far superior to any fire or other artificial heat we can give.

In the pleasure ground and flower department the work has been as varied as the weather. The sides of the walks have been fresh cut by the line and edging-iron, the grass ranging from 1 inch to 2 inches above the gravel. This cutting once a year with the iron makes it an easy matter to cut straight with the clipping-shears all the season afterwards. Hating anything like a raw edge to a pleasure-ground walk, nothing is allowed to be cut off except what is necessary for straightness, and a piece of turf is thrust forward at a gap, rather than allowed to go far from the verge at another point, in order to secure a uniform sweep. From the slight elevation of the turf-edgings, all traces of the cutting-iron will be lost in a week or two, and as stated above, the edging-shears will do their work more easily. A more perfect edging would be formed by our friend Mr. Robson's plan of bevelling hard bricks, so as to maintain a continuous edge, and yet to be so covered by the turf as not to be seen, or but scarcely so. We use the common edging-shears, and a certain gentleman was very wroth, because we could not see the great superiority of other kinds with a paraphernalia of wheels and rollers and all the rest of it, vastly nice and amusing for ladies and gentlemen, as the fine new syringes with their bends and sockets are; but the gardener who could not make his arms superior to all such appliances, would never be of much value as a workman. By-and-by such knickknacks will so thoroughly keep under and destroy the faculty of attention, that if the

great results are to depend merely on the turning of a valve, that valve will be left unturned.

#### PLEASURE GROUNDS.

Rolled lawn and mowed in damp weather, and dug in fine days, turning over the flower-beds after getting their edges all straight. In line, sunny days, and again in warm, heavy showers I sometimes wished that a lot of my plants had been out; but then they are growing away where they are, and we may have a cold bluster yet, though I hope to have a fair commencement before this is in print. About the 15th or 18th is the time I generally commence, and, indeed, can scarcely get things square to commence earlier. What is lost in time, as to earliness, I find is made up by a thorough turning frequently, so as to get beds and borders into good order.

For eight days past we have left most of our earth-pits with bedding stuff uncovered, and only kept under glass what was small and just pricked-off. Among such are *Lobelias*, *Perillas*, *Prince's Feather*, and *Love-lies-bleeding*, of which I spoke the other week. The last two generally do well with me sown in April out of doors, but when I want a row in a good principal place, I would rather plant, so as to secure all being uniform. Other things struck in tins and boxes so thick as to injure themselves, and require much trouble in watering, have been divided in lumps, and turned out into *Celery-trenches*—a far better plan from the middle of April than attempting to plant them singly. That can be done in the flower-beds if desirable.

Cleared out all the *Scarlet Geraniums*, *Salvias*, &c., from the conservatory, many of which will come in as centres to flowering pyramids out of doors. Removed also the greater part of *Cinerarias*, early-flowering *Cytisuses*, and the hardier greenhouse plants, and set out afresh with *Azaleas* in bloom, and *Pelargoniums* coming in, &c. Took a good portion of the *Camellias* now nearly over blooming to the floor of a lateinery, where they can be kept closer, and by-and-by more shaded, and in more heat. All these things being done beforehand we have more time to set about bedding, and to concentrate all our strength upon it, so as to get it quickly over. Took to the conservatory, too, the greater portion of the larger and earlier *Fuchsias*, and will now help them on with a little manure water.

Stocks, *Zinnias*, *Asters*, and lots of such things were pricked out about the 10th on a border prepared much as stated last week for *Celery*, and there they will be growing all right until we find it convenient to want them. There is something grand in a bed of *Zinnias* well grown, and the secret of success if not well supplied with glass room, which, of course, few gardeners are, is to sow late enough, never to let the plants get a check when young. If they do, it is all up with them. I shall see what the double will be if I have the seeds true, for there are a good number of plants. Last season not one vegetated. Had it been determined on they should not?

Potted succession *Fuchsias*, put in cuttings of favourites, sliced-up leaves of some favourite *Begonias* as cuttings for young plants, repotted established and older plants of *Begonias*, potted *Achimenes*, keeping them at first under the shade of Vines, repotted Ferns and other stove plants, and did the same with some variegated *Geraniums* desirable to keep in pots and flower in the house in summer and autumn, and potted singly the last stripe of *Golden Chain*, *Alma*, &c., for the sides of beds.—R. F.

#### TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PALEA CIBOTII (X. F. Z.).—We do not know such a plant, but whatever it is, it will have no effect, we think, if used to stop the bleeding in Vines.

The Cauliflower Broccoli you mention is worthless. Of what advantage is it waiting for two years before obtaining that which you can obtain as good in one?

**BERBERIS JAPONICA INTERMEDIA** and **BEALI**, &c. (*M. C. D.*).—These are of the same section of large-leaved evergreen kinds, and all of them should be planted in the shade, where they should hardly ever have the sun on them. A moist deep sandy loam suits them best, or with a little peat mixed if the loam is strong. If you had said what county your garden is in, your account of these and the other plants you name would have been interesting. *Rhododendron Edgeworthii* is always a sad struggler in the way of growth. *Rhododendrons* *Thomsonii*, *barbatum*, and *Campbelli*, are only now beginning to bloom in some few places, and all you can do is to let them do as they are till they come to a flowering age. The *Thermopsis*, or rather *Piptanthus nepalensis*, is a delicate subject, and is soon killed down to the ground in some places; in other places it is a deciduous plant, and in some other situations it is quite an evergreen. All that depends on the country and climate it is in. It has large yellow pea-flowers, and is free in producing them.

**BISHOP'S WEED** (*L. M. H. G.*).—Its botanical name is *Egopodium podagraria*. We know of no other mode of destroying it than by forking out its creeping roots, and mowing down any stems thrown up as fast as they appear. It is very tenacious of life, which may have suggested one of its common names—Masterwort.

**FLOWER-BEDS AND BORDERS** (*T. L., Liverpool*).—There is nothing to alter in your planting, but the system of matching might be improved in beds No. 1 and No. 3. No. 1 is of mixed *Verbenas* edged with *Gazania splendens*; and its yellow, No. 3, "mixed *Pelargoniums*" edged with *Gazania splendens*. We never put *Pelargoniums* in flower-beds at all, we leave them for the florists, and put *Geraniums* instead, but never to match *Verbenas* with. You have a right to do your way, and in that way the planting is very good.

**DANDELION** (*Taraxacum*).—To obtain its efficacious constituents in a condensed form that will keep unspoil—Clean, slice, and dry the roots; then take 4 lbs. of them, and soak them for twenty-four hours in water just sufficient to cover them; then press out the liquor, heat it to the boiling-point, filter while hot, and evaporate the clear liquor by the heat of a water bath, or other gentle heat, until reduced to 16 fluid ounces. Add to this 12 fluid ounces of rectified spirit. If we required *Taraxacum* to keep for use, we think we should clean, wash, and thoroughly dry the root, and then grate it and take it as a powder. When thoroughly dried, and cut into small pieces, would it not grind in a coffee mill? If so, the powder might be kept in a stoppered bottle.

**MATERIALS USED IN GEOMETRIC BEDS** (*W. O. Hammond*).—The yellow and white grits used in the geometric beds of the Royal Horticultural Society at Kensington Gore, are obtained from Mr. T. Masters, Bakewell, Derbyshire. The green slate grit is bought of Messrs. Jones, Bangor Wharf, Pimlico.

**SOIL FOR FUCHSIA-BED** (*A Constant Reader, Sheffield*).—Two parts strong mellow loam, such as the top soil of a fertile pasture; one part thoroughly decayed stable manure, such as that from an old hotbed; and one part of the cocoa-nut fibre refuse would make a good compost for your *Fuchsias*. The drops exuded from the branches and stems of your very vigorous *Vine* growing in a tub have nothing to do with mildew. Give the *Vine* less nourishment to its roots and more air to its leaves and the drops will disappear.

**LABURNUM TREES SPLITTING** (*W. A., Fulford House*).—Have a piece of iron hoop with holes punched half an inch apart at each end. Put a flat-headed nail with its lead next the bark through a hole in one end of the hoop, and bring the other end tightly round the trunk, and pass the projecting nail through one of the holes in the other end of the hoop. If thus braced round where the splitting asunder of the branches is taking place, it will be prevented going farther. The holes in the hoop enable the bracing to be tightened or loosened as may be needed.

**SULPHUR IN HOT-WATER TROUGHS** (*W. C., near Dublin*).—You may put in the sulphur without any fear. The boiling-point of water is 212° of Fahrenheit's thermometer. We should dust flowers of sulphur over the leaves of the *Vines*, and over the surface of the borders as well. The fumes of sulphur raised at such low temperatures are harmless to plants, but fatal to thrips, red spider, and mildew.

**PLANTING VINES LATE** (*Upminster*).—Yes. You may plant a *vine* as late as June, if you keep it up to stove heat through the summer, and cut the *Vines* down to the lowest three eyes next spring.

**GLOXINIAS FOR EARLY BLOOMING** (*Idem*).—You should not let them get dry till they have ripened the leaves—say towards the end of August, and they will not bloom in winter to do much good, and you had much better not attempt it, but let them be dry till January or February.

**GRAFTING RHODODENDRONS** (*A Subscriber from 1856*).—In London they graft these exactly like Apples and Peas, and on the continent many split down the stock, and put in the graft like a wedge. We never would recommend grafting *Rhododendrons* if it could be avoided.

**TREATMENT OF STANDARD LAURUSTINUS** (*Idem*).—The very same treatment lately detailed by Mr. Anderson for *Camellias* suits these. The *Camellia* is more hardy than the *Laurustinus*, but the same treatment suits both of them the year round when *Laurustinus* is used as *Camellia* are. Mr. Eyles has his standard *Laurustinus* now in with his standard *Rhododendrons* and *Camellias* in the large conservatory at South Kensington. Standard *Laurustinus* are not "worked" in the sense you mean—that is, not grafted. The best are on their own roots, and the way to have them so is told by Mr. Beaton to-day.

**BEDDING PLANTS IN POTS** (*N. V.*).—No bedding plants do well in pots all the summer except *Geraniums*, and in most gardens even they do better out of pots.

**VINE LEAVES AND PELARGONIUM LEAVES BLOTCHED** (*A Subscriber*).—You may well say that your greenhouse is badly glazed. The glass must be of very irregular surface, and when the sun shines the rays are concentrated as in a glass lens, and where the concentrated rays fall upon a leaf they scorch it. Whitewash the inside of the glass.

**CUCUMBERS GUMMING** (*E. V. Minster*).—You will have seen what we said last week, and we have no other course to suggest to you. Your plants being "very strong" is usual, for gumming we consider to arise from an excess of sap supplied by the roots to the fruit.

**COCOA-NUT FIBRE REFUSE MIXED WITH SOIL** (*L. F. F.*).—Yours is the right kind, and you may use it exactly as you would peat along with good loam for most pot plants—that is, about one-third of it to two-thirds of loam, and no sand, and it will improve all kinds of garden soil, especially all kinds of clay soil by mixing it with the surface soil; and to much very light soils with it—say an inch thick, but 4 inches thick would not be too heavy a dressing for strong land.

**CONSERVATORY RHODODENDRONS** (*B. H.*).—The "best scarlet *Rhododendron* for the decoration of a conservatory," is still the old favourite *Nepal Rhododendron arboreum*; and the "best white *Rhododendron*" for the same purpose is *Rhododendron Nuttallii*. No white *Rhododendron* can come near it. There is no yellow *Rhododendron* yet, nor yet likely to be in our time such as you contemplate—namely, "a real yellow" without "a dirty tawny shade." These, the best scarlet and the best white conservatory *Rhododendrons*, will not stand much cold, and when grown as conservatory plants they should not be exposed to any degree of frost.

**SWEET-SCENTED VINE** (*A. A. S.*).—It requires just the same culture as any other *Vine* that is hardy. It may be propagated either by eyes, cuttings, or layers.

**WATERING TREES IN ORCHARD-HOUSE** (*Wyeside*).—After fruiting plants for the orchard-house, have the pots (surface) of the soil half renewed late in the autumn. The whole of the soil and roots, from that day to the first appearance of a move in the buds, should be in the condition called neither wet nor dry—that is Mr. Rivers' practice.

**ANEMONES AND TULIPS AFTER FLOWERING** (*Idem*).—The "best way" for all kinds of *Anemones* is to allow them to ripen off all the foliage and "roots" in the bed they flowered in. The next best way is to sow *Saponaria* or other annual seeds between the rows in April to succeed them; and the third best way is to lift them when the flower is over, and to plant the bed with bedding plants. But this third best way, if followed up, will ruin them after a few years. Tulips should not be removed till the new bulbs are perfectly ripe, because all the old bulbs of all kinds of Tulips are merely so many annuals, and die off with the flowering; then if the young fry of new bulbs are disturbed before they are ripe, you must go to market for a fresh lot.

**FUCHSIA LEAVES CURLING** (*E. M. H.*).—The cause is the roots having had some severe check, probably from being too soon in the season watered with the grand water. The *Calceolarias* are "run out" and not worth keeping. The bed with the *Perilla* in the centre and the *Tropaeolum elegans* round it will not want an edging, and the 50 yards of a six-foot-wide border would make an excellent ribbon-border if you had plants enough to fill it. Look over the different arrangements of such a border in former Numbers, and see what you can do.

**CRYSTAL PALACE SCARLET GERANIUM** (*Old Subscriber*).—No. 1 seems the true *Crystal Palace Scarlet*. There is no such variety as "Crystal Palace Gem" that we are aware of. Certainly no such name has yet appeared in that garden. The best of the two arrangements is *Flower of the Day*, *Brilliant*, and *Purple King*, and allow the latter a space of about 14 inches or 15 inches wide.

**WORK ON VINE CULTURE** (*J. Lynch*).—The best is Sanders "On the *Vine*," a new edition of which we shall publish in a few days. Our correspondent wishes to know if there is a market for unripe Grapes for chemical purposes.

**ROSE SHOOTS CUT OFF** (*R. C.*).—You will find a dirty brown grub just under the surface soil near the bottom of the Rose trees. They do the mischief at night and hide themselves through the day in the earth.

**ANT-HILLS** (*B. M. K.*).—Level them, and water them with ammoniacal gas liquor for a few successive days. The insects soon migrate to a locality less offensive.

**NAMES OF PLANTS** (*J. B. P., Gardener*).—*Lastrea Sieboldii*. (*J. P. Shrevesbury*).—1, *Eupatorium fruticosum*? 2, *Pitiosporum Tobira*; 3, *Ameletich vulgaris*. (*J. O. Shrevesbury*).—1, *Cerasus padus*; 2, *Staphylex pinnata*. (*R. B.*).—*Gnidia simplex*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). Steward, S. Pitman, Esq., Manor House, Taunton. Entries close May 1.

MAY 28th and 29th. HULL AND EAST RIDING OF YORKSHIRE. Sec., Mr. J. Hooton. Entries close May 14th.

JUNE 3rd. ESSEX AGRICULTURAL ASSOCIATION. Sec., R. Emson, Slough House, Halstead. Entries close May 10th.

JUNE 4th and 5th. BEVERLEY AND EAST RIDING. Sec., Mr. Harry Adams.

JUNE 12th, NORTH HANTS AGRICULTURAL SOCIETY. Sec., Mr. H. Downes. Entries close May 21st.

JUNE 26th and 27th. SUFFOLK (Woodbridge). Sec., Mr. J. Loder, jun. Entries close June 5th.

JULY 3rd. PRESCOT. Sec., Mr. James Beesley. Entries close June 21st.

JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. Secs., G. Newton and J. Wade. Entries close June 21st.

SEPTEMBER 9th. WORSLEY AND ARNLEY (near Leeds). Sec., Mr. Robert Hoyle, Arnley, near Leeds.

DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.

### TAUNTON POULTRY EXHIBITION.

The exhibition of poultry just closed at Taunton, Somerset, was anxiously looked forward to by the generality of poultry amateurs with far more than customary interest from the fact that it was the first Chicken Show of the present year.

There were not wanting those who foreboded that the Meeting would prove itself a comparative failure, from the combined influences of the fact that many breeders could ill afford to allow the temporary absence of their laying hens; and again, that very few indeed could boast this year of chickens sufficiently

matured for the purpose of competition. In spite, however, of these admittedly cogent drawbacks, it is certain that as goodly a muster of both useful and fancy poultry was gathered together as ever yet was obtained in this locality. We cannot forbear mentioning that various sceptical remarks reached our ears as to the ages of some few pens of chickens; one old joker very bluffly assuring the bystanders "he at once admitted they were like the ladies, all out what was stated; but how much more was only conjectural." Certainly some of the pullets looked unquestionably suspicious. To absolutely prove an error of entry was impossible, however; and we fear that at shows held so early as the beginning of May such differences of opinion will be always entertained respecting chickens.

Last year the Exhibition took place in the barrack-yard, at that time temporarily unoccupied by troops; this season a fresh locality was compulsory, and, therefore, Billet Street was the spot selected; a considerable part of this street was, consequently, carefully enclosed, and proved both comfortable and suitable to most of the parties interested.

It is true, to even a proverb however, that it is a strange circumstance to hit on any plan to please every one, and in this case there proved to be a solitary objection. It was this: from the front of the Exhibition throughout the whole length of the remaining portion of the street to its junction with the main thoroughfare in Taunton, it had been purposed to temporarily plant evergreens on both sides the way, which, with banners and flags of various kinds, tended greatly to enhance the general effect, whilst in no way a hindrance to passers-by. But, as is frequently the result when applied to novelties, there turned up an individual whose impulse was to make himself disagreeable, indeed to so great an extent as to not only prohibit altogether any evergreens whatever being placed on his side the way (which, by-the-by, was only bounded by a blank wall), but actually went so far as to cause a rope bearing a wreath of flowers which spanned simply across the public carriage-way, and to which the town authorities had previously given sanction, to be cut through, and let fall. So much puerile churlishness of course drew down expressions of disapproval from those who were simply idle spectators; but we are glad to say such manifestations were carried no farther, though doubtless it will be long before the unpopularity thus self-earned will be forgotten. In pleasing contrast to such conduct we must mention that Colonel Phipps without a moment's hesitation at once permitted the attendance, on both days, of the 1st Somerset Militia band, which as naturally increased the attraction.

The space occupied by the Exhibition was about 60 yards by 9 yards, a double tier of pens being arranged down either side, and a refreshment-store at each end. The general appearance of the Exhibition was consequently good; nor need we do more than mention that the exertions of the Honorary Secretary were all that could be desired for the safety and welfare of the valuable poultry committed to his care, nor shall we be at all surprised to hear that many of the birds have greatly improved in condition during their visit to Taunton.

We were gratified to find, too, that Mr. Ballance had again pursued the plan he adopted on previous occasions—viz., not to restrict the plate prizes to cups only. The display of such premiums this year was effective and novel, embracing egg-stands, teapots, cream-ewers, candlesticks, waiters, claret-jug, inkstand, fish-knives and forks, card-baskets, flower-vases; whilst of teaspoons and tablespoons there was an effective array. Backed-up by looking-glasses, there was not any lack of curious visitors inspecting these tempting and useful premiums during the whole time the Exhibition remained on view.

*Spanish* were the first class that met the eye on entrance; and as we intend to briefly review the generality of the classes, it shall take precedence in our remarks. Here Mr. Rodhard took both first and second prizes for adults, and also the plate for *Spanish Chickens*—a premium offered to the best pen of any variety of Chickens of this year. All these pens were marvellously good; indeed, a hen shown in the first prize pen is perhaps the very best ever exhibited.

The *Grey Dorkings* were perfect, Lady Julia Cornwallis taking the lion's share by the awards of plate and second prizes for old birds, and first for chickens. Among the unsuccessful *Dorkings* were some very excellent specimens, the Rosy-combed ones coming to muster in rather considerable force. Mrs. Fookes' pen of this variety eventually taking third position on the list of premiums, though pressing very hard on the second-prize birds. It is very long since we saw three pens of such good *White Dorkings*

together as the successful ones on this occasion. They belonged respectively to Mrs. Fookes and the Rev. G. F. Hodson.

The *Bull Cochins* class was especially good, and here again Mrs. Fookes was triumphant with a pen that will doubtless yet add future trophies to her sideboard. Another of this lady's pens took second position. The Grouse-coloured *Cochins* were certainly not equal to our anticipations. The *White Cochins* on the contrary were exceedingly good; Mr. Whitwell's pen, after a long journey from Kendal, heading the list.

Mr. Charles Ballance easily swept the *Malay* premiums. The old male bird, however, bears evident proofs that age and infirmities are creeping on, yet in plumage he is excellent.

Mr. Fletcher, of Manchester, forwarded a first-rate collection of *Game fowls*, and this secured both the plate premiums; it is needless to say they were unexceptionable, the *Duckwing* pen being one of the gems of the Show. There was a close run in the *Black Game* class, but Mr. Dawson, of Selly Oak, managed to maintain the pre-eminence he has now for years enjoyed.

A somewhat singular feature of this year's Show was, that in the *Hamburgh* classes, whilst the *Golden* (whether *Spangled* or *Pencilled*) were decidedly imperfect, the *Silver* varieties proved admirable; indeed they were the two most interesting classes in the yard. By referring to the appended prize list it will be seen new names claimed both the plate premiums for these breeds.

As most of our noted breeders of *Polands* had entered birds, the display was peculiarly good, Messrs. Edwards, Pettat, and Ray dividing the prizes among them.

The class for *Peafowls, Guinea fowls, &c.*, was a good one, the *Peacocks* particularly proved most attractive; but the pens for these birds were too narrow for them to turn easily without injury to their plumage.

In the well-filled "Variety Class," Mr. Ballance exhibited a pen of first-rate (imported) *Silky Fowls*, taking first prize; and in the "Extra Stock" nine very healthy chickens bred from them this season elicited much attention from visitors, and proved remarkably true in every character. *White Spanish* and *Ptarmigan* fowls were also successfully exhibited.

In *Game Bantams* the Taunton Show has been rarely exceeded, and the prize list tells us that the winners came from localities as distant as Biggleswade, Southwell, and even Kendal. The *Sebrights* were very superior; nor must we, as faithful journalists, omit especial mention of the Rev. G. S. Cruwys' pen of *White Bantams*; they were remarkably small, and shown in capital feather.

Mrs. Fookes again supported the high credit of her yard by taking the plate for *Turkeys* and *Toulouse Geese* likewise: this lady was, however, very closely pressed in the *Goose* class by a wonderfully weighty pen of *Empden Geese* exhibited by Mrs. Seamons, but quite heavy in the moult. If shown when both varieties are in equally full condition the result will be very questionable.

Mrs. Seamons had it all her own way in the *Aylesbury Duck* class, taking the plate prize for the best pen of *Ducks* exhibited, backed by the second premium. When entries of these *Ducks* from her yard appear, the result really seems to be as was said on the spot—"always alike."

The collection of *Pigeons* was of the highest character, and perhaps the very best that has ever yet been realised in the west of England; they naturally produced much attraction.

The weather was splendid, and the Show in all respects proved satisfactory.

As on previous occasions, the office of arbitrator was filled by Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, Birmingham, whose awards gave general satisfaction.

**SPANISH.**—Plate and Second, J. R. Rodbard, Aldwick Court, Wrington. Third, Rev. G. F. Hodson, North Petherton, near Bridgewater. Highly Commended, E. Brown, St. Phillip's Road, Sheffield.

**DORKING (Coloured).**—First and Second, Lady Julia Cornwallis, Linton Park, Staplehurst. Third, Mrs. Fookes, Whitechurch, Blandford. Highly Commended, E. H. Garrard, Clopton House, Broadway.

**DORKING (White).**—First, Mrs. Fookes, Whitechurch, Blandford. Second and Third, Rev. G. F. Hodson, North Petherton, near Bridgewater.

**COCHIN-CHINA (Cinnamon and Buff).**—Plate and Second, Mrs. Fookes, Whitechurch, Blandford. Third, Miss V. W. Musgrove, Aughton, near Ormskirk. Commended, B. Johnson, Watford Heath, Herts; H. Yardley, Market Hall, Birmingham.

**COCHIN-CHINA (Grouse and Partridge-feathered).**—First, Mrs. B. J. Ford, Conness Weir, near Exeter. Second, Miss V. W. Musgrove, Aughton, near Ormskirk. Third, Rev. G. F. Hodson, North Petherton, near Bridgewater.

**COCHIN-CHINA (White and Black).**—First, G. C. Whitwell, Kendal. Second, W. Yardley, Market Hall, Birmingham. Third, G. Lamb, Red Hill

Honse, Compton, near Wolverhampton. Highly Commended, Mrs. Herbert, Powick, near Worcester.

MALAY (Coloured or White).—First and Second, C. Ballance, Taunton Third, J. J. Fox, Devizes.

GAME (Black-breasted and other Reds).—Plate, J. Fletcher, Manchester. Second, E. Stamp, Houlton. Third, A. B. Dyas, Madeley. Highly Commended, S. Matthew, Chilton Hall, Stowmarket; C. W. Brierley, Rochdale; G. C. Whitwell, Kendal; G. Burgess, jun., Burleydam, Whitechurch.

GAME (Duckwings and other Greys and Blues).—Plate, J. Fletcher, Manchester. Second, S. Matthew, Chilton Hall, Stowmarket. Third, S. Dupe, Evercreech, Bath. Commended, Rev. G. S. Cruwys, Tiverton; W. Dawson, Selly Oak, Birmingham.

GAME (White, Black, and Piles).—First, W. Dawson, Selly Oak, Birmingham. Second, J. B. Weeks, High Street, Bromyard. Third, Rev. G. S. Cruwys, Tiverton.

HAMBURGH (Gold-pencilled).—First, N. Barter, Plymouth. Second, J. Llewellyn, St. Fagan's, near Cardiff. Third, A. Nuttall, New Church, near Manchester.

HAMBURGH (Gold-spangled).—First, W. Cuff, St. Fagan's, near Cardiff. Second, G. J. Houghton, Barnstaple. Third, no competition.

HAMBURGH (Silver-pencilled).—Plate, J. Fletcher, Manchester. Second, T. Broome, Upper Lambourne, Hungerford. Third, Miss H. M. King, Walford, near Taunton.

HAMBURGH (Silver-spangled).—Plate, G. L. Brown, Chardleigh Green, near Chard. Second, Lady Julia Cornwallis, Linton Park, Staplehurst. Third, Mrs. Pettat, Ashe Rectory, Overton, Hants. Highly Commended, Lady Julia Cornwallis. Commended, Rev. D. Binney, Shirley House, Southampton; Mrs. Pettat.

POLAND (Black, with White Crests).—First and Third, T. P. Edwards, Lyndhurst, Hants. Second, G. Ray, Minstead, Lyndhurst, Hants.

POLAND (Golden).—First, Second, and Third, Mrs. Pettat, Ashe Rectory, Overton, Hants.

POLAND (Silver).—Plate, Mrs. Pettat, Ashe Rectory, Overton, Hants. Second and Third, no competition.

PEA FOWL (Pheasants and Gallinae).—First, C. Ballance, Taunton (Pea Fowl). Second and Third, Capt. Adney, Lympstone (Gallinae and Pea Fowl). Commended, Miss King, Pyraland Hall (Gallinae).

ANY OTHER VARIETY.—First, C. Ballance, Taunton (Silkies). Second, Miss S. H. Northcote, Upton Pym, Exeter (White Spanish). Third, the Countess Poultic, Hilmster (Tarnigan). Highly Commended, Rev. G. S. Cruwys, Tiverton (Black Hamburg). Commended, R. W. Nicholas, Yewberry Cottage, near Newport (Black Hamburg).

SPANISH CHICKEN.—First and Medal, J. R. Rodbard, Aldwick Court, Wrington. Second and Third, no competition.

DORKING CHICKEN.—First, Lady J. Cornwallis, Linton Park, Staplehurst. Second, L. Pattou, Comestrowe House, Trull. Third, no competition.

COCHIN-CHINA-CHICKEN.—First, Miss V. W. Musgrove, Aughton, near Ormskirk. Second, Rev. G. Gilbert, Claxton, Norwich. Third, Mrs. Fookes, Whitechurch, Blandford. Third, G. Lamb, Red Hill House, Compton, near Wolverhampton.

GAME CHICKEN.—First, Capt. Adney, Lympstone. Second, J. G. Price, Wellington. Third, no competition.

SPANISH COCK.—Prize, J. R. Rodbard, Aldwick Court, Wrington.

DORKING COCK.—Prize, Lady J. Cornwallis, Linton Park, Staplehurst. Highly Commended, Mrs. Wolfenstan, Stafford Hall, near Tamworth.

COCHIN-CHINA COCK.—Prize, Mrs. Herbert, Powick, near Worcester.

HAMBURGH COCK (Pencilled).—Prize, T. Broome, Upper Lambourne, Hungerford.

HAMBURGH COCK (Spangled).—Prize, Lady Julia Cornwallis, Linton Park, Staplehurst.

GAME BANTAM COCK.—First, J. Camm, Farnsfield, Southwell. Second, V. Sandford, Mannamed, Plymouth. Highly Commended, E. Pigeon, Lympstone. Commended, M. R. Liscombe, Devonport.

ANY OTHER BANTAM COCK.—Prize, R. H. Nicholas, Newport, Monmouth.

BANTAMS (Gold-laced).—First, T. H. D. Bayly, Ickwell House, near Biggleswade. Second, Rev. G. F. Hodson, North Petherton, near Bridgewater. Third, Rev. G. S. Cruwys, Tiverton.

BANTAMS (Silver-laced).—First, Rev. G. S. Cruwys, Tiverton. Second, Mrs. Pettat, Ashe Rectory, Overton, Hants. Third, S. Mills, Mannamed, Plymouth.

BANTAMS (White).—First and Medal, Rev. G. S. Cruwys, Tiverton. Second, G. A. Beadon. Third, no competition.

BANTAMS (Black).—First, R. Brotherhood, jun., Almondsbury, near Bristol. Second, Rev. G. F. Hodson, North Petherton, near Bridgewater. Third, Rev. G. S. Cruwys, Tiverton.

GAME BANTAMS (Black and Brown Red).—First, T. H. D. Bayly, Ickwell House, near Biggleswade. Second, J. Camm, Farnsfield, Southwell. Third, Capt. Adney, Lympstone. Highly Commended, R. H. Nicholas, Newport, Monmouth.

GAME BANTAMS (Dorking and other Game).—Plate, G. C. Whitwell, Kendal. Second, J. Camm, Farnsfield, Southwell. Third, J. R. Rodbard, Aldwick Court, Wrington. Highly Commended, Master A. S. Altham, Stoke St. Mary, Taunton. Commended, W. S. Forrest, Eagle Cliff, Greenhithe.

TURKEYS.—Plate, Mrs. Fookes, Whitechurch, Blandford. Second, Miss J. Milward, Newton St. Loe, Bath. Third, Rev. F. G. Hodson, North Petherton, near Bridgewater. Commended, Mrs. Seamons, Hartwell, Aylesbury.

GEESE.—First, Mrs. Fookes, Whitechurch, Blandford. Second, Mrs. Seamons, Hartwell, Aylesbury.

DUCKS (Aylesbury).—Plate and Second, Mrs. Seamons, Hartwell, Aylesbury. Third, Rev. G. F. Hodson, North Petherton, near Bridgewater.

DUCKS (Rouen).—First and Third, no competition. Second, Mrs. B. J. Ford, Countess Weir, near Exeter.

DUCKS (Black East Indian).—First, Major W. S. Altham, Stoke St. Mary,

Taunton. Second, Capt. Edgell, Bramford Speke, near Exeter. Third, no competition.

DUCKS (any other variety).—Plate, T. H. D. Bayly, Ickwell House, near Biggleswade. Second, P. W. Brimwell. Third, no competition.

#### PIGEONS.

BARBS (Yellow).—Plate, Major Altham, Stoke St. Mary, Taunton. Second, F. G. Stevens, Fuzley House, Axminster.

CARRIERS.—First, Major W. S. Altham, Stoke St. Mary, Taunton. Second, A. L. Silvester, St. Paul's Square, Birmingham. Third, Major Hassard, Hilsen, near Portsmouth. Highly Commended, — Summerhayes, Taunton.

TUMBLERS.—First, A. S. Silvester, St. Paul's Square, Birmingham. Second, and Third, no competition.

OWLS.—First, F. Else, Westbourne Grove, Bayswater. Second, F. Key, Beverley. Third, Major W. S. Altham, Stoke St. Mary, Taunton. Highly Commended, H. Yardley, Market Hall, Birmingham.

NUSS.—First, J. B. Edge, Aston New Town, Birmingham. Second, F. Else, Westbourne Grove, Bayswater. Third, H. Yardley, Market Hall, Birmingham.

TURBITS.—First, Major W. S. Altham, Stoke St. Mary, Taunton. Second, A. S. Silvester, St. Paul's Square, Birmingham. Third, T. Hiscock, Taunton. Highly Commended, J. G. Price, Wellington; F. Else, Westbourne Grove, Bayswater. Commended, S. Mills, Mannamed, Plymouth.

JACOBS.—First, Miss J. Milward, Newton St. Loe, Bath. Second, F. Else, Westbourne Grove, Bayswater. Third, Major W. S. Altham, Stoke St. Mary, Taunton. Highly Commended, J. Hardwell, jun., Taunton.

FANTAILS.—First, Major W. S. Altham, Stoke St. Mary, Taunton. Second, T. Hiscock, Taunton. Third, F. Else, Westbourne Grove, Bayswater.

TRUMPETERS.—First, J. Silvester, Birmingham. Second and Third, J. Hardwell, jun., Taunton.

POWELS.—First, H. Yardley, Market Hall, Birmingham. Second, Major W. S. Altham, Stoke St. Mary, Taunton. Third, no competition.

RUNTS.—First, F. Key, Beverley. Second, H. Yardley, Market Hall, Birmingham. Third, E. Pigeon, Lympstone. Commended, — Summerhayes, Taunton.

DRAGONS.—First, — Summerhayes, Taunton. Second, J. B. Edge, Aston New Town, Birmingham. Third, A. L. Silvester, St. Paul's Square, Birmingham. Highly Commended, F. Else, Westbourne Grove, Bayswater; H. Yardley, Market Hall, Birmingham. Commended, Major W. S. Altham, Stoke St. Mary, Taunton.

ARCHANGELS.—First, A. L. Silvester, St. Paul's Square, Birmingham. Second, — Summerhayes, Taunton.

MAGPIES.—First, Major W. S. Altham, Stoke St. Mary, Taunton. Second, J. B. Edge, Aston New Town, Birmingham. Third, F. Else, Westbourne Grove, Bayswater. Highly Commended, W. H. Beadon, Cheddon, near Taunton.

ANY OTHER VARIETY.—First, Miss Elliot, Osborne House, Taunton. Second, — Summerhayes, Taunton. Third, no competition.

Silver Medal for the greatest number of First Prizes in Pigeons to Major W. S. Altham, Stoke St. Mary, Taunton.

GAME COCK (any colour or age).—First, J. Camm, Farnsfield, Southwell. Second, J. Hindson, Barton House, Everton, Liverpool. Third, S. Matthew, Chilton Hall, Stowmarket. Fourth, Rev. G. S. Cruwys, Tiverton. Fifth, V. Sandford, Mannamed, Plymouth. Sixth, J. Fletcher, Manchester. Highly Commended, A. B. Dyas, Madeley. Commended, C. W. Brierley, Rochdale.

## WORTH OF POULTRY IN BRITAIN 1000 YEARS AGO.

THE worth of a Goose one legal penny; of a gander two legal pennies. The worth of a brood Goose is as much as the worth of her nest, and there ought to be in her nest twenty-four goslings. [Broods have degenerated since then!] The worth of each gosling is a halfpenny, or a sheaf of barley, until it lays, and after it lays each is one legal penny in value: thus a brood Goose is twelvecence in value.

A hen is one penny in value, and a cock is two hens in value. Every chicken is a sheaf of oats or a farthing in value, until it shall roost; after that a halfpenny until it shall lay or shall crow.—(Ancient Laws of Wales. Record Commission.)

## PARROT LOSING ITS FEATHERS.

I HAVE a very good grey Parrot which is a first-rate talker, but it seems to be losing its feathers and gradually becoming darker in colour. Not knowing what month they generally moult, and having had one which died in the same way, I am desirous of your advice on the subject. It is fed upon hemp seed, and things which we eat ourselves. It seems to be very fond of animal food.—A WEEKLY SUBSCRIBER, Chesterfield.

[The cause of your bird losing its feathers is its having a cold, or being too fat, and being fed on animal food. The autumn is the period for moulting, but when birds take cold they will sometimes shoot their feathers in the spring. The reason why your bird gets darker in plumage is through having too much hemp seed. Give it little or no hemp, and plenty of canary seed, Indian corn boiled or broken, nuts, and any kind of fruit when in season. They are fond of apples, almonds in the shell occasionally, scalded bread, but not until cold. No animal food of any description should be given. Any kind of grease will cause

an irritation of the skin, which makes the bird pick off its feathers. Place a pan of cold water in the cage for the bird to wash in. The bird which died no doubt was seized with apoplexy caused by being fed too well. The usual remedy is bleeding by making a slight puncture near the claw.]

**MODE OF ATTACHING FULL COMBS TO BARS.**

I HAVE some combs which are partly filled with honey extracted from a young hive of last year, and I wish to place them in a bar-hive; but I cannot understand how I am to fasten them to the bars. Shall I, therefore, trouble you to inform me? as the same will be a boon to the swarms lived therein.—BAR-HIVE.

[We attach heavy combs to bars by supporting them on trough-shaped strips of wood of the annexed sketch; these are sustained by binding-wire passed over the bar at each end as represented below—

The top edges of each comb are kept in their places by a couple of zinc clips from a half to three-quarters of an inch in width, and of the size and shape of the annexed sketch slipped over each bar near the ends, and embracing the sides of the comb. In two or three days the bees will fix the combs so firmly to the bars that all artificial supports may be removed.]

**BEEES AS CHEMISTS.**

MR. SHEARER is perfectly correct in stating that bees convert crystallisable into uncrystallisable sugar; and, although I have myself not the shadow of a doubt on the point, I should be much obliged by his applying the test of the saccharometer to the contents of the honey-bag of a bee which has been seen to fill itself with simple syrup, but which should probably be allowed some little time to admit of its effecting the anticipated conversion.

Very numerous observations have satisfied me that bees effect a marked change in the quality of the food with which they are supplied before storing it for winter, but whether that change be sufficient to entitle it to be considered true honey I must leave to wiser heads than mine to determine. In the case of simple syrup, which is what I am most familiar with, I have always found that, besides the loss of its crystallising properties, it acquired a pungent and slightly sub-acid taste, inferior, of course, to the aromatic flavour of honey collected from the nectaries of flowers, but quite sufficiently marked to distinguish it from the mawkish lusciousness by which it was originally characterised.

The alteration effected is, however, so delicate that it cannot be expected to overcome the taste of strongly-flavoured compounds, such as sugared ale, sweet wort, or syrup to which rum and salt have been added. If it were otherwise we should not find the colour, flavour, and aroma of honey so strongly influenced by the pasture from which it is obtained; nor should we probably have had this difference of opinion, which I believe to have originated from apiarists failing to detect any amelioration in the rank flavour of the strange compounds which it has been too much the fashion to inflict upon their little favourites. For this reason I was not surprised at "A NORTH LANCASHIRE BEE-KEEPER" declaring, in page 37, that he could distinctly see the difference between stored syrup and heath-honey, whilst he stated at the same time, that the former "had not undergone any change from the bottle to the cell;" nor is it at all astonishing, that "BAR-HIVE" should find syrup to which rum and salt had been added, "as much different as possible from honey." If either or both of these gentlemen will submit the contents of the combs in question to the decisive test of the saccharometer, or

even to the more simple experiment of comparative evaporation, as suggested by me in page 58, and will make public the results of their investigations, I shall be, indeed, greatly surprised if they do not confirm most decisively the conclusions which have been already arrived at by—A DEVONSHIRE BEE-KEEPER.

**PAYNE'S BEE-HIVES.**

ALLUSION and inquiry are sometimes made in your publication to what are called Payne's hives (as at page 130). It may be well to say to such correspondents, that there is no mystery about them, for they existed before his time, and any straw-hive-maker, if directed, can make one. Straight and cylindrical in form, flat on the top, of any required height and diameter, with a hole in the centre of the crown, through which the bees can pass onwards into a super when needed. In Payne's "Bee-Keeper's Guide" (Newby, Mortimer Street), is an illustration;\* and the same thing is in Taylor's "Bee-keeper's Manual" (Groombridge & Sons, Paternoster Row). The latter remarks (page 31), "Payne saw reasons for altering the dimensions of his hives from 12 inches wide to 14 inches, and 7 inches or sometimes 8 inches in height, inside measure."—A. B.

**AMERICAN BEE-KEEPERS' MEETING IN CLEVELAND, OHIO.**

THE American Bee-keepers' Association held its third annual meeting in Cleveland, commencing on the morning of the 12th of March, and ending on the evening of the 14th. It was more largely attended than any of its previous meetings. Rev. L. L. Langstroth, and other eminent gentlemen were present during its session. Prof. J. P. Kirtland presided.

The following is an epitome of the subjects discussed:—

I.—*The Winter Management of Bees.*—Messrs. Langstroth, Kirtland, Robinson, Merriman of Burton, Twining of Indiana, and S. C. Brown of Portage, took part in the discussion of this topic. Mr. Langstroth had experience with bees in New England, Philadelphia, and Southern Ohio, and said that what would be good management in one climate, would not be in another of different temperature. He is convinced that if bees have plenty of honey, free intercommunication between the combs, and an upward passage from the hive for the escape of the dampness caused by their breath, that bees can be wintered in any climate. Unpainted thin wooden hives are better than thick painted ones. Want of communication between the combs has caused the death of many bees. This can be remedied by boring holes through the sides of the hives, and then running a "butter-tryer" through the combs at right angles to the frames. If this is done late in the fall, the holes will not be filled by the bees. Mr. Langstroth to prevent this, has contrived a passage made of thin circular shavings. Prof. Kirtland thinks bees do best out of doors, in thin wooden hives. He would protect the hives from the northern and eastern winds, and hot suns. Ventilation must be good below and above. In his cellar he had kept some hives which were ventilated at the top, but not at the bottom, and carbonic acid gathered in the hive like damp in a well, and with like results. The past winter he has had forty-five stocks in a bee-house, and all are doing well. Some swarms, merely covered by dry goods boxes, had wintered perfectly. The boxes were thrown over them to hide them from thieves. Mr. Robinson has three hives, without tops to them, which have stood all winter near an open window, and the bees are in good condition. Messrs. Merriman and Twining agreed with Messrs. Kirtland and Langstroth in their views. Mr. Brown, of Portage, said that he had buried bees, which had come out in excellent condition; those so buried consumed only one-half the amount of food that those not buried did. He believed that in this changeable climate it was best to bury bees, and that such come out in better condition than bees which are wintered out of doors. He never lost a swarm so buried, except for want of food. Mr. Langstroth entertained the Association by reading some accounts from the French "Bee Journal" of the calamities to bees in the year 1860-61. It was a dreadful year. Among other statements was one, that out of 470 colonies of bees, 383 died during the winter.

II.—*Winter Feeding.*—Mr. Langstroth feeds with candy, by

\* So there is in "Bee-Keeping for the Many," which had Mr. Payne's last corrections. It may be had free by post from our office for five penny postage stamps.

laying it on the frames before the honey is exhausted, and prefers it to liquid food. A sponge saturated with liquid honey does excellently. Mr. Merriman thought maple molasses best. Mr. Langstroth, Mr. Sturtevant, and Prof. Kirtland, strongly recommended rye flour as spring bee-food. Mr. Langstroth makes it into a paste with syrup. Prof. Kirtland fed his weak hives in the fall on sugar syrup; this was before fall flowers, and those bees were stimulated to work, and added to their stock of food for winter use. The consequence of such feeding was that the weak hives worked upon the latest sprigs of mignonette in November, and after the strongest hives, which he did not feed, had ceased to work. That was all the winter feeding he gave.

III.—*Italian Bees*.—All agreed as to the superiority of the Italian to the common black bee. They deserve all the good things that European bee-keepers had said of them, save one. They are not more peaceable, but more irascible than the black bee, and their sting is more poisonous. Mr. Langstroth gave it as his experience, and that of some of his friends, that the Italian bees, instead of being more peaceable than our common kind, are more irascible (except in the season of honey-gathering), and are more difficult to quiet when once excited.\* The Italian who brought all Mr. Parson's bees, said that our bees are far more peaceable than the black bees of Germany. A German writer, who furnished a valuable article on bee-keeping for the Patent Office Report of 1860, says that our bees are much more easily handled than those of Germany. This accounts for the belief in Germany, that the Italian bees are more peaceable than the black species. The remarks of Prof. Kirtland seemed to sum up all that other gentlemen had said of the Italian bee. The Doctor prefaced his remarks by saying that he had no "axe to grind," and no bees to sell, and would not have until his experiments had been completed, which would be in three or more years. After discussing the good qualities of the Italian bee, he said that it was as much superior to the black bee as Short-horn cows and Chester hogs are to the "scrubs" of the country; and that the Italian bee is—1. Stronger, more active, and resists lake winds and chills better than the common bee. 2. It works more hours every day. 3. It collects more stores. 4. It works upon some flowers which the black bee cannot operate upon. 5. It breeds more freely. 6. It is more irritable, and its sting more painful. 7. It is more beautiful.

IV.—*Improvements in Hives*.—Six or eight hives were then exhibited and discussed. After this exhibition was concluded, the following topic was taken up.

V.—*Is it expedient to destroy queen bees when they have obtained either their third or fourth year of age; and what is the most successful method of raising young queens for supplying their places, and for forming new colonies?*—Prof. Kirtland said, that after the third year, the queen was nearly worthless and should be killed, and a fertile queen put in her place instantly. So thought Mr. Langstroth; he said a vigorous, fertile queen was worth half a swarm. Mr. Sturtevant thought the queen as good in her third year as at any other time; and at four years he would not kill her, unless he knew that he could instantly get a young fertile queen in her stead;—the risk was great, for at that season of the year the loss of a week or two was a serious loss; it was an exceedingly difficult matter to have young fertile queens on hand, ready for any emergency.

VI.—*Is it profitable to attempt to renovate and cleanse mouldy comb for subsequent use, and what are the best methods to accomplish that purpose?*—The unprofitableness of any attempt to renovate damaged comb was generally conceded.

VII.—*Hybridisation of the Italian and Black Bees*.—This was well discussed. The only sure way to prevent hybridisation is by keeping them long distances apart.

VIII.—*Artificial Swarming*.—Prof. Kirtland cautioned bee-raisers against too frequent division of swarms, or they would destroy all their bees. Mr. Twining thought the proper time for dividing a swarm is when the young queen bee commences piping, and is still capped over. If left alone, the old queen bee will probably attack the young queen, kill it, and then swarm. The young queen should be removed while still capped, with a part of the swarm. The bees would probably swarm on the next day of themselves, if this is not done, and, therefore, no injury can be done by thus swarming artificially. Mr. Langstroth said it sometimes happens that in one district bees will swarm abundantly of themselves, while in another district not far distant, artificial swarming is necessary. Mr. Brown related his experience, going to show that artificial swarming by the use of

movable comb-hives, when not overdone, is the best plan. In answer to a question, Mr. Langstroth said, that in this climate, one new stock to two old ones would be about the proper increase. In warmer climates, the increase might safely be much greater. Mr. Langstroth contended that the apiarian who aims at obtaining much surplus honey at any season cannot usually, at the furthest, more than double his stock; nor even that, unless all are strong, and the season is favourable. If in any season that is not favourable he attempts a more rapid increase, he must expect no surplus honey, but must even purchase food to keep his bees from starving. The time, care, skill, and food required in our uncertain climate for the rapid increase of colonies are so great, that not one bee-keeper in a hundred can make it profitable; while most who attempt it will be sure at the close of the season to find themselves in possession of stocks which have been managed to death. Very rapid multiplication of colonies by artificial processes, Mr. Langstroth pronounced to be hazardous speculation, sometimes successful, but ordinarily sharing the fate of such speculations.

IX.—*Artificial Comb*.—Mr. Samuel Wagner, Editor of the American "Bee Journal," sent a specimen of artificial comb made by a process which he has patented, which excited great interest, and which promises important results.

X.—*Bee Moth*.—Mr. Langstroth said that so long as a colony has a healthy queen, and plenty of stores and bees, it is seldom seriously injured by the moth.

XI.—*Milk as a Bee-feed*.—Mr. Langstroth stated that new sweet milk had been recommended as feed for bees. He had not tested its value, but advised a very cautious trial of it. Prof. Kirtland thought that the sugar of milk and albumen might afford nutriment to bees.

The Convention adjourned, to meet in Cleveland the first day of the Ohio State Fair in September, when a very interesting time may be anticipated.—(*Ohio Farmer*.)

OUR LETTER BOX.

DUCKWINGED BANTAMS (*Amateur de Volaille*).—They have made great strides towards perfection, but they are not as perfect as the Black Reds, nor as their full-sized brethren. It is difficult to say whether they are more prized. We should say not. We should advise you if you can keep but one sort to keep the Black Reds. In our opinion they are quite as handsome, and they breed true; the Duckwings do not.

CALIFORNIAN QUAILS (*Idem*).—These, like all live birds, vary in price according to demand, supply, and season. We believe now they are worth about three guineas or 70s. the pair.

BLACK BANTAM COCK'S EAR-LOBES (*Idem*).—The lack of the white ear-lobe is a grave defect in a Black Bantam cock. It would be a disqualification if it came in competition with good birds possessing it. If all were deficient in this particular, prizes would be awarded as though all possessed it.

DESTROYING VITALITY IN EGGS (*A Reader*).—After being punctured with a needle in treatment will give vitality to the egg.

COCK CANARY EATING EGGS (*A Young Fancier*).—Separate him from the hen when she begins to lay, and do not put him back until she has laid and you have substituted an artificial egg for the one laid. He will abandon the cannibal habit after a time when he finds he cannot penetrate the artificial egg.

PARROT BITING OFF ITS FEATHERS (*Fanny Fern*).—As your Parrot will not bathe, try a watering-pot with a small rose, and give it occasionally a shower-bath of warm water on a warm day. The cause of its pulling out its feathers is owing to an irritation of the skin caused by its having been fed on improper food, such as that of an animal or greasy nature. Give the bath mentioned in an answer to another correspondent to-day, and anoint the bird with a salve consisting of plain pomatum and wornwood, the latter being disgusting to a Parrot. Repeat the process as often as the bird pulls out its feathers, and give a very small quantity of Epsom salts dissolved in water to drink about twice a-week. Indian corn broken or boiled is good, but very little or no hempseed should be given. An aviary of an octagon shape for small birds is very good, one say 7 feet diameter with a domed top made with galvanized wire or one of an oblong form—say, 9 feet long by 5 feet wide with an elliptic top.

PARROT MOULTING (*G. P. Derby*).—Canary seed, bread, tapioca, or sago pudding, a white peppercorn or a chili pod, but no meat or fat of any kind is the proper diet for a parrot, and any ripe fruit in season which it will eat. See our previous answer.

LONDON MARKETS.—MAY 19.

POULTRY.

There is still a lamentably small supply of good poultry. Trade is worse than was ever known at this season of the year, or the numbers sent to market would not satisfy half the buyers.

	Each—s. d.	s. d.	Each—s. d.	s. d.
Large Fowls	5 0	5 6	Ducklings	3 0 to 3 6
Smaller do.	3 6	4 0	Pigeons	0 8,, 0 9
Chickens	2 6	3 0	Rabbits	1 3,, 1 4
Guinea Fowls	0 0	0 0	Wild do.	0 8,, 0 9
Goshugs	6 0	6 6	Hares	0 0,, 0 0

\* This is certainly contrary to the experience of English apiarians.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 68.2° and 45.2° respectively. The greatest heat, 91°, occurred on the 28th, in 1847; and the lowest cold, 32°, on the 31st in 1857. During the period 145 days were fine, and on 100 rain fell.

UTILITY OF SMALL BIRDS.

SEND you in a little box what may amuse you. Here there has been, on the part of the farmers and cottagers, great complaints made of the mischief done by small birds to corn-fields and gardens. In vain did some hold the argument that these small robbers did as much good in destroying grubs and caterpillars as harm

to Wheat and Black Currants. For the last two years the township has not only paid for all dead sparrows, but so much a dozen for birds' eggs.

I am afraid to say how many thousand dozens of eggs were taken and paid for, and (as I believe) mainly in consequence of this (aided, perhaps, by the mild winter), we have this year such a plague of caterpillars and grubs as I never remember. Since I last wrote to you I have had three women constantly employed picking over Gooseberry, Apple, and Currant trees, and our destruction of caterpillars has been by bushels.

I felt so convinced that this plague was partly owing to the last two years' destruction of birds, that in my own grounds, and in all the coverts, I ordered the nests not to be molested. I now enclose you the head of a sparrow shot this morning in my garden. This was done to test what food it did take to its nest. I hope the head may reach you in the same state in which it was picked up—namely, with three green caterpillars, and three daddy-longlegs in its beak. If one journey from its nest could collect so many, it is easy to guess how much may be done by them to clear trees.

My trees from hand-picking are now pretty clear; but I am quite sure it would have been done cheaper and better by the birds had they been left alone. I cannot think I am sending you much information, but one fact is better than many theories.—AN IGNORAMUS, near Liverpool.

[We give this brief communication the most prominent position in our pages, because it relates to a subject of far more importance than it is usually believed to possess. The warfare carried on against small birds is a proceeding founded on the most self-injuring ignorance that at present overshadows our farmers and gardeners.

A similar warfare has been carried on in France, and the same result has occurred there which our correspondent records as now scourging the vicinity of Liverpool—namely, a plague of caterpillars and grubs. So serious has the plague become in France, that the Government have interfered, and a strong arm has been outstretched to save the small birds from destruction. We almost regret that a similar power cannot be similarly exercised on this side the Channel.

We have warned our readers again and again that these birds are far more powerfully benefactors than they are injurers by being thieves of seeds and fruits. They can be scared from these at a small expense, even if old women are paid to act as scarers; whereas, if the birds are destroyed, no outlay, however large, can rescue our crops from insect marauders. The destroyer of small birds is one of the most unmistakable illustrations of the old saying, "He is penny wise and pound foolish." It is preventing a small loss and insuring the occurrence of a far greater.

Nor are the services of small birds restricted to the destruction of insects, for they are great consumers of the seeds of weeds. As an evidence how far in advance of us in a knowledge of these facts are our descendants on the other side the globe, we have a letter before us detailing the successful importation into Australia of goldfinches, hedge sparrows, and other small birds. They were bought in this country and sent by steamer to Sydney, for the express purpose of consuming the Thistle seeds! We recorded some time since how a Scotchman had sown some seeds of his national emblem in Australia, and that it was overwhelming the land. The public authorities have paid large sums to children for gathering the seed-heads of the Thistles; but though this has brought in a vast tribute of heads, yet the Thistles are unconquered; so the Australian authorities have allied themselves, like wise men, with the small birds.

The head of the sparrow sent to us by our correspondent is now upon our table, with the green caterpillars and daddy-longlegs, parents of root-injuring grubs, in his mouth, and we wish every gardener and every farmer could see it, for it is a striking though silent rebuke to them all.]

ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.—MAY 21st.

HONEST Old Moore used to put into his weather almanacs ever since I can remember, that such and such weather would be the day before or the day after certain given days throughout the year; but if he had been a Fellow of the Horticultural Society, old or new, reformed or unreformed, he would have hit nearer the mark to have said, not the day before or a day after such and such show days, but the very day of the show itself will be the showery one. And the crowning day of the year of the second great International Exhibition in London was not an exception to the rule—the worse luck. Nothing could be more provoking than the weather after noonday. In the morning the whole scene was most grand and glittering throughout. That was the thirtieth May show at which I had been present, and, as far as I can call to mind, if all the "best" of all that was at all the May shows for that time had been collected together, the whole would be in the wrong side of the scale, if compared with the brilliancy, and with the high artistic effect produced on this occasion.

First of all, Mr. Eyles scooped out a long oval of some 300 feet, or thereabout, in length, and of the usual mathematical width. All round this oval amphitheatre he made turf shelves in three successive rises, as for a plant-stage; then a

walk on a dead level all round, and I counted ninety-nine paces from the one to the other end—that is, one side or one half of the oval, and by doubling that, and taking the three doorways into account, I calculated 300 feet would nearly reach round the oval; but it must be more, and yet one of the best judges there, Mr. Henderson, of Trentham Gardens, declared it could not be quite so much, alleging that your humble servant could not step a yard fully and so often in succession. And, of course, we must have the oval tested by Euclid, else how are we to advise when oval beds come to be planted? Then Mr. Eyles scooped out the centre of the oval, and made a circle bed in the very centre, which is the very lowest part of the scoop. Then from a door at each end of the oval, and one in the centre of it, on one side, a walk slopes down to the centre and circular bed; and the slopes between the walk round the oval and the one through the centre of the scoop, are shelled in turf for stages, and the circular bed in the centre of the scoop is staged also in steps of turf. All that on what was recently a dead level has made the very best exhibition tent that possibly could be in such a garden. But, unfortunately, this season, this huge tent is up close to the feeding place in the International, and we could hear them, in the afternoon, above all the roar of the elements on our dripping canvases, growling and gnashing their teeth.

Another scooped space to make a match pair, is for Mr. John Waterer's grand exhibition of Rhododendrons, Azaleas, and other federates and confederates of that blood. In the opposite angle of the garden boundary, and between the two scoops there is a running avenue of awnings, and the half of that avenue next to the flower show was shelved on both sides and filled with the most rare, most gorgeous, most variegated, and most novel plants ever seen in this country, or in any other country, at any one time.

In practice two things struck me as improvable. The fittings of the canvases. Surely with all the ingenuity of the world next door to us, we might find means to make rain-proof tents, such for instance, as I myself used to sleep in, sound as I did, and dry as a bone, forty years since, up in the wildest parts of the highlands, where one faint squall from the brow of Ben Doran would sweep away every rag of covering at South Kensington, which would not keep out the mildest Scotch mist one ever was out in. The second thing was, that the sides of the entering avenue should not be filled with the most temptation plants in the book. In early afternoon one could no more get up one side of that avenue, or down the other side of it, than he could fly over crinoline. It was as much as His Royal Highness the Duke of Cambridge could do with all his military skill and daring, and he had to take up an extraordinary-looking new Panay he saw half-way down, and had to shout out to another nobleman who himself was in a fix, that that was the prettiest Panay he had ever seen, and that they had given it a prize. When I got up to it I saw it was from the Messrs. Downie, Laird, and Laing. In less than an hour after that I saw the newest of our great English baronets pushing along the enchanting avenue, firm as a thatcher, endeavouring to conduct their Royal Highnesses the Duchess and Princess Mary of Cambridge safely through the throng. The whole three, and three or four more of the same party, seemed in the very best humour and to enjoy the fun amazingly; but it was no fun for Sir Wentworth Dilke to pilot them through and all round so many and such dangerous islands of crinolines. And as like one hailing for help, he was up to the pitch of his lungs, at all the gardeners he could cast an eye on, inquiring if there were such Lilies of the Valley to be seen then as were shown at the Azalea Show, for the Duchess wanted to point them out to some of the party as the London pride of the Lilies.

The *Times* truly says, it would need a supplement to give the names even of all the winners, so I shall merely give the names of all the stove plants, and all the greenhouse plants, and all the Heaths, and as many more out of the new and out-of-the-way-looking plants as are likely to do good in two ways—good to have if one can afford it, and good for trade as well.

Let me first, however, say, that the best gardening-done plant there was a *Hedera tulipifera* in the first-prize collection of stove and greenhouse plants, by Mr. May. I estimated it to be more than 7 feet in diameter across the mouth of the pot, and it was as full of bloom as a *Ventricosa* Heath; but, strange to say, the name of that plant and most of the same all over the Exhibition were wrongly spelled. The old Horticultural Society cast a spell on the spelling of plants, by giving prizes to men for minding their P's and Q's, and now they are on strike and will

not spell the names rightly, vainly thinking, probably, that the new Society will be unwise enough to give prizes for writing out names properly from any nursery catalogue. This *Hedera*, without going further to-day, was thus spelled—*Hederoma*, *Hederedroma*, and *Aaderoma*.

The best-grown Orchids were the *grandiflora* variety of *Phalenopsis* by the Messrs. Veitch, the *Oncidium ampliatum* major by Mr. Green, and *Cattleya citrina* by Mr. Barker in his first-class collection. There were six flowers on the plant, and each of the six was, at the least, quite double the size of any such flowers ever exhibited in my time, and I was "out" before *citrina*. All the *Lælia purpurata*s there, would not number the same quantity of flowers as the one plant of it which Mr. Warner exhibited this time last year. The collection from the Messrs. Veitch was, every plant, in first-rate style, and the Judges must have made a holiday of it over them. All the rest of the Orchids were very well done; but the breed was not nearly so numerous as we had them at Chiswick ten years back. The Heaths were also behind.

The Messrs. Veitch are now pressing hard upon the heels of Mr. Turner at setting their numerous collections for the best effect. Nothing could be more telling than the way they exhibited their great Orchids, and their masses of variegated and new plants on this occasion. Their Orchids began to read from the centre, where the tallest *Vanda suavis* stood at the back; from thence the collection sloped down to each side, and to the front, in matched pairs to the right and left. In the centre of the second row stood a magnificent specimen of *Phalenopsis grandiflora*, the best plant of the kind yet exhibited; and *Saccolabium retusum* with six blooming spikes stood in the centre of the front row. A match pair of *Cypripedium villosum* and *C. barbatum superbum* had forty-six blooms on between them, and all the rest were equally well matched in pairs from the specimen plants in the centre of each row; one specimen of their *Cattleya Skinneri* had sported into more rose-coloured flowers, and was shown together with the original in the same pot.

Mr. Milford and Mr. Baker also made a good stride in the right way of setting. The former had the strange-looking *Cypripedium caudatum*, whose run-wild sepals might puzzle Mr. Darwin himself to account for the origin of those unearthly appendages. His *Lælia Brysiana* was fine, and the nearest to the race. If I recollect rightly it had sixteen flowers; and his *Dendrobium primulinum* was very good. Mr. Baker, who had that fine *Cattleya citrina*, had also his *Dendrobium Devonianum* particularly well trained, the slender shoots perpendicularly up from a wide flat pan or basket; two *Lælia cinnabarinæ*, a fine match pair happily set; and a fine *Anguloa Clowesii*. Mr. Green had a large bush-like plant of *Oncidium apicelatum* for a back centre, and he followed suit in suitable setting. His *O. ampliatum superbum* had four spikes, and two of them were each nearly 4 feet long, and as full of bloom as a branch of "May." In an off-angle on each side of the way from these Orchids, stood collections from Mr. James Burley, nurseryman, Limpsfield, Surrey, and the Rose nursery of Mr. Paul; and both of them might be burley proud of the strain.

At the risk of my knuckles, my fingers itch again to say that *Symmetry* (Turner's), was the best telling *Pelargonium* there; that *Amy* (Dobson?), was the next best, with its soft salmon tint; that *Etna* and *Sanspareil* are not yet beat for effect; and that *Eugène Duval* is still at the head of the fancy-colour class for my book. They may book me to the last page, but the strain will never leave me.

The following were the stove plants in the usual collections of stove and greenhouse plants—*Franciæa eximia* and *conferta*, *Ixora crocata*, *latifolia*, *coccinea*, and *Griffithii*; *Allamanda grandiflora*, *Clerodendron splendens*, *Stephanotis floribunda*, and *Imantophyllum miniatum*; and one from the Messrs. Jackson, of Kington, was the finest ever exhibited, it had fifteen scapes of bloom.

The greenhouse plants in ditto were these—*Hedera*, *Pimeleas* (of sorts), *Polygalas*, *Ericas*, *Aphelxias*, *Eriostemons*, *Epacris*, *Boronias*, and *B. Drummondii* (done to a T at last), *Leschenaultias* (blue and red, or orange), *Leptodactylon californicum* (fine), *Chorozemas*, *Gompholobiums*, *Hovea Celsii*, *Dillwynia splendens*, *Labichæa heterophylla* (the same called *diversifolia*), *Adenandra*, *Tetratheca*, *Acrophyllum venosum*, *Dracocephalum gracile*, *Rhynchospermum jasmimoides*, and *Farfugium grande*, if you please. These were all, and Mr. Chilman's *Acrophyllum venosum* was the best done, after *Hedera* by Mr. May.

There were splendid specimens of *Rhododendrons formosum*

and aureum fulgens, from Mr. Edmonds, of Chiswick, and by them stood a noble standard of Rose Gloire de Dijon, with fine specimens of Paul Ricaut and Général Jacqueminot Roses from Messrs. Lane, who had the most noble Rosea in competition that ever were seen. Then a long flat stand for rare and new plants, and a match stand on the other side of the centre to suit, on which stood Messrs. Veitch and Fortune's harvest-homes from Japan and China.

These were the most interesting collections ever exhibited, and that by the Messrs. Veitch was accompanied by the specimens of wood mentioned the previous week as being at the Exotic Nursery; but the uses for so much novelty, and the characters of the other new and variegated plants from other parts of the world, must occupy a more descriptive account than can be got into a bare report, in order to make it at all of any use far away from London. And, moreover, the great Crystal Palace Show is held the same week, where most of the novelties can be seen without risking one's ribs; but I find my boots were dreadfully scratched in the pushes through and through the avenue where the vast masses of all the different and indifferent miscellanies were stowed away to entice people to keep there while

others get over the scooped oval, and were off to the colonnades above, to see the grand move caused by the well-timed liberality and kindness of Lady Dorothy Nevill, in instituting a reform on the Covent Garden style of cart-loading the drawing-rooms with heaps of cut flowers without heads or tails. But depend upon it, both the peerage and baronetage, as represented by her ladyship and Sir Wentworth Dilke, will have an up-hill work of it to up-root the Covent Garden style of heaping fruit in a dessert, and of bundling flowers for London drawing-rooms. Well, the same ladies who took the first prize last year for setting the dessert, showed equal confidence now in setting flowers on the drawing-room table. The Misses March, St. James's Palace, an engraving of whose baskets we give below, had the first prize of six guineas, the gift of Lady Dorothy Nevill, and Mrs. J. H. Lermite, Knightons, Finchley, was awarded her ladyship's second prize of four guineas.

Now, the reason why the prize went to Mr. March and the Misses March last year has never been explained to gardeners yet, which is not fair dealing on the part of the Royal Horticultural Society. It is of little avail to tell a man that he is a fool, if you do not let him know wherein his folly consists.

The flowers in one of the smaller baskets were Roses de Meaux; those in the centre basket were Lily of the Valley, White Lilac, and Narcissus; and those in the second smaller basket were purple Gloxinias. The baskets and their handles are of glass, and made expressly after a design by Mr. March. The foliage was partly of Fern leaves and sprays of Lycopodium.

It is not the fault of gardeners, but their misfortune, that there never was an acknowledged guide for setting dessert or furnishing rooms with flowers as the high nobility require them. All gardeners can never get into the high places of this earth, how then are they to know more than Covent Garden measure? Without the least hint or knowledge of the parties who won or judged, one class of gardeners could see at the first glance that the prize dessert last year, and the prize for grouping flowers for drawing-room tables this season, were not intended to be the actual things required by the makers, nor judged as if they were. The prize specimens if they could speak would just say, "Do not do as I am done with such common things, and in such small quantities; just provide all that is necessary, as costly as you please, and then but arrange them all in the simple and refined style in which you see all my parts put together." That is what ought to be taught, and not that men did wrong from not knowing better. There is no intention or need to set any limits to prodigality, but only that even profusion may be dealt with in a simple unstrained system. The idea has gone forth, and is rooted in the minds of gardeners, that unless you place the commonest things in this world before your guests, and that in the smallest quantities, you would be called a numskull by the Horticultural. No such thing. The idea is altogether wrong. All that is aimed at is just like all that we have said about planting beds—namely, that flowers and fruit should be arranged for

table on some plan which will give the greatest pleasure to the greatest number of those who know our fashion in artistic display. There is a fashion in everything, and the flowers were arranged better for Lady Dorothy Nevill's prizes this year than the sample dessert was done last year by the very same hands—success emboldened their simplicities, so to speak. Mr. Turner was the winner of the prize for the best setting of a conservatory, and he did it in the grandest and in the most extravagant style at the same time, which I shall explain another time.

D. BEATON.

#### FLORISTS' FLOWERS.

ALAS! It really seems as if the old enemy of the Horticultural Society, not content with the mischief it had done in old days at Chiswick, was bent on following it up with still more determined assault. This is the second fête this year that the "skiey influences" have marred. The lovely weather of the few previous days promised well. But on Tuesday an ominous fall in the glass, and an equally ominous rise of clouds of dust, portended wet; and although in the earlier part of the day gleams of sunshine deluded us with false hopes, in the afternoon the rain poured down as it seems best able to do on horticultural fête days, and completely spoiled what would have been doubtless the most brilliant gathering of the season. The large tent in which the larger portion of the plants was exhibited was a blaze

of colour; and the manner in which the plants were arranged promises, with a few alterations, to make it a most effective place for showing plants. Then the long annex which joined it with Messrs. Waterer & Godfrey's American exhibition was an excellent idea, and an admirable place to exhibit the new things, seedling florists' flowers, &c., in. And here let me say I think the growl from the International refreshment-room was quite out of place. The *habitués* of the Exhibition were not promised the view; and as the latter was brought there, it would be a strange thing indeed if the plans of the Society were to be thwarted on account of the frequenters of the Exhibition.

In the arrangement of the tent one missed the green background; and the centre mound ought, in my opinion, either to have consisted of ornamental-foliaged plants or of some neutral-tinted flowers. The Orchids from the want of green were killed by the brilliancy of the colours in the back rows: but of all this I dare say Mr. Beaton will discourse. I must keep to my own department, the florists' flowers.

The Azaleas were magnificent. Unquestionably the finest lot (although Messrs. Green's and Carson's approached very near to them), were Mr. Turner's nine; and the arrangement was, as is always the case with his flowers, perfect—contrasting in this respect with Mr. Veitch's, which were spoiled by the want of arrangement in the colours. Mr. Turner's stood thus:—

	Chelson (orange scarlet).	
Iveryana (white).	Alba Magna (white).	
	Extrani (red).	Juliana (scarlet).
Murrayana (purple or rosy lilac).		
Præstantissima (light orange red).	Criterion (light salmon pink).	

In this class Mr. Veitch was second, and Messrs. Frazer third.

In the class for 9, for Amateurs, equal firsts were given to Mr. J. Green, gardener to Sir Edward Antrobus, and Mr. S. M. Carson, gardener to J. C. Sim, Esq., Nonsuch Park, with the following:—Præstantissima, Sinensis, Iveryana, Broughtoni, Sir C. Napier, Perryana, Variegata, Symmetry, Coronata; and Speciosa, Broughtoni, Exquisita, Rubra plena, Sir C. Napier, Sinensis, Murrayana, Triumphans, and Carneæ. Second to Mr. Page, gardener to W. Leaf, Esq., Streatham. Third to Mr. Kaile, gardener to the Earl of Lovelace: and Extra to Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood.

In the class of 6 Azaleas (Amateurs), Mr. C. Penny was first with fine plants of Madame Miellez, Juliana, Triumphans, Extrani, Chelson, Iveryana. Second to Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading. Third to Mr. H. Chilman, gardener to Mrs. Smith, Ashted House, Epsom: and fourth to Mr. Peed.

The large Roses in pots of Messrs. Lane and Wm. Paul were, as usual, magnificent immense bushes, with blooms the very perfection of beauty, but offering no variety; the same sorts of course, as in many other things, appearing from year to year. Messrs. Lane's twelve were Lamarque, Triomphe de Paris, Coupe d'Hébé, Louis Peronny, Comtesse Mole, Chénédole, Jules Margottin, Souvenir d'un Ami (very large and fine), Paul Perras, Charles Lawson, Duchess of Sutherland, Baronne Prevost. Mr. Wm. Paul's contained fine plants somewhat smaller of Souvenir d'Elise Vardon, Lord Raglan (very fine), Louise Odier, &c. Mr. Francis, of Hertford, was third, having amongst others a fine plant of Gloire de Dijon, showing its capabilities as an exhibition Rose.

The Pelargoniums were very fine, and evidently Mr. Turner has been teaching his pupils too well; and he must look to it, or his laurels will be plucked from him. As it was, he was beaten in the open class of Fancies; and in the show kinds Messrs. Dobson & Co. came very close to him. I was glad to see, too, that the Clewer Manor plants were there, and that the floral world is still likely to be benefited by the seedlings of that far-famed home of seedling Pelargoniums.

In the class of 9 show Pelargoniums Mr. Bailey, gardener to T. T. Drake, Esq., of Shardeloes, was first with Osiris, Desdemona, Mr. Marnock, Eugène Duval, Etna, Lady Canning, Sir C. Campbell, Monarch, and Ariel. Mr. Nye, gardener to Miss Foster, had Etna, Fairest of the Fair, Rose Celestial, Sanspareil, Flora, Conspicuum, Ariel, Prince of Wales, and Saracen. Of these only two were of Mr. Foster's own raising. Mr. James Shrimpton, of Putney Heath, was third: and Mr. J. Weir, gardener to Mrs. Hodgson, The Elms, Hampstead, fourth.

In the Nurseryman's class of 12, Mr. Turner was first. His Roseum was the most striking plant of Pelargoniums in the

Exhibition; while Fairest of the Fair was badly shaped and nearly lost him the first prize. He had besides Prince of Wales, Viola, Madame Furtado, Sunset, Beadsman, Rose Celestial, Desdemona, Sir C. Campbell, Vestal, and Symmetry. Messrs. Dobson, of Isleworth, were second: and Messrs. Fraser third.

The six Fancies of Mr. Bailey's were Celestial, Aeme, Clara Novello, Madame Sontag, Negro, and Lady of the Lake. They were beautifully grown and well bloomed. Mr. Turner second; Messrs. Fraser third; Messrs. Dobson fourth; and Mr. Weir recommended.

It was too late for Cinerarias. Messrs. Dobson & Son had six:—Queen Victoria, Lady Seymour, Perfection, Brilliant, Madpiece, and Miss Smith. There was a second lot which was a disgrace to the exhibitor and the Exhibition.

There were two sets of Rhododendrons, the first prize being awarded to Mr. Charles Noble. The best were Lady Palmerston, Lord Palmerston, Lord Granville, and Duke of Cambridge. Mr. Standish was second. He had, besides the six, a nice collection of various kinds. Dr. Hogg, General Wilson, Mr. Mangles, Impeatrice, and Madame Titienus were very fine.

It was too late for Tulips, the unusually warm weather of last week having driven them into bloom. But two stands were shown. Mr. Norman's, of Woolwich, were remarkably clean, though a little defective in colour. His blooms of Duchess of Sutherland, General Bamoseld, Anastasia, Triomphe Royal, Lady Denman, and Mrs. Smith (Norman), were excellent. Mr. Turner was second, but many of his blooms were past their prime.

Mr. Bragg, of Slough, had a box of Pansies, and another of Fancy ditto.

There were three stands of Roses. Those of Messrs. W. Paul and Lane securing an extra prize. Mr. Paul's were gathered, he told me, from trees planted out in a house under glass, and some of the blooms measured 5 inches across, remarkably clean and good. Lælias, Souvenir de la Malmaison, Empereur de Maroc, and Cardinal Patrizzi were very good. He had also a bloom of General Zachargersky, a curious crumpled-looking Rose.

Mr. Barley, of Limpsfield, sent some plants of his fine Calceolarias—Victor Emmanuel, Princess Helena, Monarch, Queen of Oude, Lord Raglan, and Primrose Perfection, besides a few plants of that first-rate bedding variety—Angustifolia globosa, which I fancy we shall find to be one of the best yellows grown.

Amongst the novelties in florists' flowers which came under the notice of the sub-committee of the Floral Committee were, in Pelargoniums, Belle of the Ball (Foster), and Improvement (ditto), the latter a flower perfect in shape, and which I did not fail to point out to those who are ever crying out that my friend Mr. Andrews draws too perfect flowers. These obtained First-class Certificates—as did Conflagration, a fine deep crimson, and Royal Albert (Hoyle), an immense flower. The scarlet Pelargonium of Mr. Turner, "Nesfield," received a Second-class Certificate for its free-flowering properties; and a tiny one, Waltham Pet, of Mr. W. Paul's, was awarded the same honour. The greatest novelty there, however, and one which the Duke of Cambridge specially noticed, was a Fancy Pansy exhibited by Messrs. Downie, Laird, & Laing. It was called Aurea marginata, and is one of very fair shape and size—a florist's flower, purple, with a narrow margin of bright gold round each petal. It is an immense acquisition, and opens up a bright prospect to us. Rhododendron striatum formosum of Mr. Standish was awarded a First-class Certificate, and Suwaroff Second. Mr. Bull had two nicely pencilled single Petunias, for which Second-class Certificates were awarded, Ruby and Emma. Mr. George Smith exhibited that fine Petunia Eliza Mathieu; and Mr. B. S. Williams a fine salmon-flowered Zonale Pelargonium which received a Certificate. With the exception of the Pansy referred to, the new things were not very remarkable.—D., Deal.

#### HORTICULTURAL IMPLEMENTS.

The display of horticultural machines, implements, &c., was meagre in the extreme, and quite unworthy of the Exhibition and the present advanced state of the mechanical art, presenting little of novelty. Were it not that our readers would expect some account of this portion of an exhibition, otherwise so interesting, we would willingly pass it over in silence. As it is, a few comments will suffice.

In Class A, heating apparatus, Messrs. Weeks & Co., of

Ohelsea, exhibited a powerful tubular boiler, of a description that has proved highly efficient in many establishments, and which presents 200 feet of surface to the fire. Also a very handsome pedestal, adapted for heating halls, churches, and conservatories, in any of which no fault could be found with its appearance. It was commended.

From Mr. Ormson, Stanley Bridge, came a large jointless tubular boiler; and from Mr. Jones, of Bankside, the well-known cannon boiler, both which need no description here. There was also a small cylindrical upright boiler adapted for heating a room or small greenhouse.

In class B, mowing, rolling, and transplanting machines, &c., Messrs. Green, of Leeds, exhibited mowing machines of various sizes on their well-known mode of construction, in which quiet working is combined with efficient action, and differing from all others in the use of a chain with peculiarly-formed links in driving the cog-wheel attached to the revolving blades. The contrivance in the larger machines for emptying the grass out of the box at front into the large receiver at back by means of a winch, cog-wheel, and cogged-chain, is very expeditious. Highly commended.

The lawn-mower from Kenman & Sons, of Dublin, noticed in our report of the International Exhibition, was also shown, as well as Shanks' machine of different sizes, by Messrs. Brown, of Cannon Street, the latter of which needs no commendation at our hands. Both these exhibitions were commended.

Newton, Chambers, & Co., exhibited their garden roller, the counterpoise to the handle of which is on the outside instead of within the cylinder as in the ordinary form; and Amies & Barford, Peterborough, a roller with a wrought-iron cylinder having closed ends, and which can be weighted more or less by pouring water through a hole left for the purpose in the cylinder, and which is closed by a solid brass plug that can be removed by a key. This application of water, by which a light roller can be made a heavy one at will, and at no more expense, is new to us, and if found to work well in practice would be worthy of general adoption. Commended.

In the same class we find the fumigator, invented by Mr. Spary, of Brighton, and which essentially consists in a cylinder perforated with holes at the bottom, within which is a lamp heating a pan containing the fumigating material, the smoke from which escapes through holes in the lid. It appears to be less generally known than it deserves.

Of garden chairs there were several, but none so good as that of Pickley & Sims, exhibited at the International, and also shown here. Those from Messrs. Brown & Co., have the merit of cheapness combined with good appearance, and the bottom part and back being of wood are not open to the objection so often made to iron chairs—that of being cold to sit upon. The same firm also exhibited portable folding chairs, and garden vases, the latter of cast-iron of a character that would not disgrace any mansion; in fact, there is no comparison between the classic designs which they exhibit, and the miserable imitations of stonework which so often disfigure gardens, in which if statuary and kindred decorations cannot be well done, they are better left alone.

In the other classes we noticed flower-baskets of galvanised iron wire, suspended from erozier-shaped standards, some ornamental garden pots from the Weston-super-Mare potteries, and Read's garden syringes and engines, of various forms and sizes; the former both in principle and practice are excellent, the ball valve with which the aperture that the water is drawn through is closed, being so little liable to get out of order; but the latter, owing to there being no parallel motion or other provision for the same object, must, in consequence of the piston describing a similar curve, but of less radius to that of the handle, be subject to more wear on one side of the forcing cylinder than on the other, and, therefore, in course of time become no longer airtight—a complaint which many other engines are also open to, and which might easily be obviated.

There were also water-barrows from Mr. Nixey, of Slough, one being on the old gravitation principle, the tub being of an elliptical form, and hung over the axle; the other of similar construction, but with the tub fixed and provided with a perforated pipe in front like that of a street watering-cart, and which is intended for watering garden-walks; a model of Cranston's conservatory, and some other articles either well known or which will be described elsewhere.

#### THE TENTS.

SOME weeks since, when it was announced that the Society

were intending to expend a large sum upon tents, we warned the Council against such an expenditure; and expressed our surprise that they had not been taught better by more than a quarter of a century's experience at Chiswick. Largo ridge-and-furrow tents, even from the best of makers, cannot be made proof against heavy continuous rains, and those who are under such tents during such a downfall, require umbrellas and macintoshes. This was quite apparent on Wednesday last, where, in all parts, the moisture came beating through in the form of a thin drizzling mist, and the visitors were compelled to have recourse to their umbrellas and parasols; and this quite independent of the overflows that took place in the furrows. Moreover, tents in wet weather are miserably chilly from the great evaporation from them; and to talk about "enjoying" a flower show under them in wet weather is to talk of what never can be. Let us add, that the consequences to delicate plants need no other illustration than was afforded by the splendid Orchids of Mr. Veitch last Wednesday. In one sentence, tents were a necessity when glass was dear, but now that glass is cheap they are no longer a necessity, and should be banished from the Royal Horticultural Society's exhibitions. If Mr. Eyles were asked to furnish plans for a glass structure on each side of the conservatory, in connection with the arcades, he would have little difficulty in forming a design harmonising with the arcades and the International Exhibition, the only imposing view of which is shut out by the present tents; and let us add, that never was a greater disfigurement than are the present tents, shutting out as they do the only imposing view that can be had of that building.

#### OFFICIOUSNESS OF OFFICIALS.

We will take this opportunity of calling the attention of the authorities of the Garden to the excessive officiousness of the subordinates wearing the Society's livery, which if not checked will become not only offensive as it is now, but positively intolerable. We have had more than one complaint on this subject; but that which induces us to take notice of it now is, the treatment one of our reporters experienced when engaged in the performance of those duties which are equally for the benefit of the Society, the public, and ourselves. Our reporter is a gentleman well known in the horticultural world, and one who is not likely even to cause suspicion of doing anything that is at all objectionable. We shall say nothing more on the subject at present, further than that the procedure is quite a change from the former system upon which the Horticultural Society was conducted, and we trust that it does not indicate the introduction of that high-handed and unbending administration which is sure to prove the ruin of any establishment depending for its existence on public support.—[Eds. J. or H.]

#### GRAFTING VINES.

MOST gardeners are aware of the uncertainty of success in grafting Vines. This seems to be owing to the bleeding or oozing out of the sap from the wounds made during the operation, which greatly tends to prevent the union of the grafts with the stocks or Vines. I have tried several plans commonly practised, but have found none equal to the following:—This spring I was anxious to have some strong Vines of the Golden Hamburgh, and had from a friend a well-ripened shoot of that kind, which afforded several good grafts. These I put on Black Hamburghs, close to the roots, which were previously turned out of pots. When the Vines were repotted the grafted parts were covered with soil, only two eyes or buds of each being left above it. In order to let the wounds heal, and prevent them from the bleeding already noticed, the pots were kept about two weeks in a cold pit, and afterwards in a warm one, where the Vines soon made fresh shoots from their adopted heads, and are now planted into a house and doing well. An experienced gardener may readily perceive that this plan affords a double chance of success, for if the stock does not unite with the graft the latter will strike root like a cutting. I have also grafted Oranges and Roses in spring in the same way, only they were put into a warm pit at once, there being less chance of failure by the wounds or grafted parts not healing, which is the greatest obstacle to Vine-grafting.—J. WIGHTON.

FENCE POSTS.—The *Ohio Farmer* says, "Many years ago we were building a new fence, and when setting our posts we saturated that part which we placed in the ground, and about

1 foot above, with coal tar, resin, and lime. The proportions were about eight parts of tar to one of lime, and sixteen of tar to one of resin. We melted the resin before mixing, but the lime we put in as we bought it from the kiln. Those posts are now nearly all of them sound and good, although the timber was a sorry mixture of Basswood, Beech, Oak, Chestnut, and Maple."

### AIR-ROOTS ON VINE STEMS.

THE air-roots upon the Vines in our first viney are an eye-sore to my employer. He wished me to write and ask your opinion upon the following points regarding them:—

1st. What causes air-roots on Vines?

2nd. Are air-roots injurious or otherwise to Vines?

3rd. Would it injure the Vines to cut the air-roots off at any stage of their growth?

The Vines have been planted five years. This crop, which will be ripe in three weeks, is the fifth, although I think not excessive crop. The Vines make good wood from the spurs; but the stems do not swell so fast as I could wish. I have a command of bottom heat, and the border now averages 76°. A considerable quantity of carrion was used in the original border. But eighteen months ago I partly lifted the Vines and mixed a lot of lime rubbish and rough turfy loam with the old border. Since then the leaves are much thicker, and the Vines are better, but still we cannot get entirely rid of the air-roots.

I keep the atmosphere pretty moist, and give plenty of air upon every favourable opportunity. In fact, the house is only shut up close upon sunny afternoons, when we put them "warm to bed." They have air again at night, which is on less or more till after dinner next day. The roots are not in want of water, but are running crowquill-like near the surface of the border. The berries swell and colour very well, but the bunches do not come very large. They are all Hamburgs.—W. C.

[These air-roots as you call them are the cause of a vexed question. Some gardeners are rather fond of seeing them, others detest them even more than you do. We have known fine bunches extra fed by letting these roots run into balls of earth and moss, and removed only when the fruit was gathered. We have also known Vines propagated successfully by such means. Others dislike their appearance as so many robbers, and we are pretty well inclined to look upon them in this light ultimately; because, though we are well aware that in an early stage they are caterers of nourishment in a damp atmosphere, we also believe that ultimately they are injurious, because their presence to a great extent on the shoots in the house, so far prevents the free development of fresh roots and spongioles in the border. With your precautions of raising the Vines we are rather surprised that you have so many of them. So long as the roots had to run into unwholesome carrion we would not have been surprised at the roots protruding anywhere and everywhere to escape it, and we have no doubt that as the roots rise and run in the calcareous matter you will have less and less of these stem air-roots, unless you keep an extra moist atmosphere.]

A clear understanding of the cause and the effects of such air-roots will lead to much difference of practice. Those who like to see them will no doubt encourage them and feed them, thinking, perhaps, too little of the roots in the border. Not only so, but seeing how thoroughly the Vine is a creeping or running plant, they will, to get strength and increase space, twist and layer the shoots in the ground in order to get masses of such roots in the soil. On the other hand, those who value them little, as I confess I do, will be chary of all such layering, and prefer Vines with their one set of main roots starting from one collar or crown. I have a strong belief that the finest Grapes can only be produced continuously on the latter plan. Some of our best gardeners have made valuable experiments in this direction, and, perhaps, none more so than Mr. McDonald, of Woodstock, in Ireland, to which I hope to allude before long.

In general circumstances, then, we consider it good policy to remove these roots as soon as they appear. For though they imbibe moisture when the house is moist, they dry up when the house is dry when ripening approaches, and the bunches are then deprived of the nourishment which they would have obtained from roots feeding in the border. We may be wrong, but we think the more fresh air-roots inside the house, the fewer new roots will be made in that border.

Now to the three queries.

1st. The Vine being naturally a creeping and climbing plant, these roots will be naturally protruded when resting on any damp surface, such as the ground or a rock, or when placed in such situations that the roots in the ground could obtain but little nourishment. In rocky districts the Vine in its natural habitats will throw roots from the stems into crevices and crannies in pursuit of nourishment, just as naturally as the Strawberry with us throws out its runners. A moist atmosphere in houses, and especially when stimulated with ammoniacal or other rich gases, will ever increase this natural propensity. In cultivation we do not permit thickets of Strawberry-runners; and if our views are at all correct, we would rather take means to lessen the production of these air-roots.

2nd. Are these air-roots injurious or otherwise to Vines? We think ultimately they are, because tending to lessen the production of roots in the soil. Where roots are deep and the soil unsuitable, they may at an early stage enable the plants to go on and set the fruit before the roots in the border come much into operation. But it would be unwise to depend upon such friendly action of theirs.

3rd. As to injuring the Vines from removing them. We think no injury at all would be given in such a case as yours, if done early. Nor do we think much injury would be done by removing them at any time; but as you have allowed them to remain so long, we would as a matter of prudence, if the berries are now colouring, not meddle with them until the crop is ripe. If the Grapes were only set or so, and in such a border as you speak of, and the roots running so nicely near the surface, we would cut off every one of these air-roots as they appear. The better the roots flourish in the border the less you will have of them inside, though a very moist atmosphere will render their production a natural result. With plenty of air and such a calcareous border, with the roots near the surface, you will not afterwards be much troubled with them.

The course of culture seems to be the very best. We are aware that a variety of opinion exists as to the cause and the results of these air-roots from the stems. I should be much obliged either to be confirmed or set right as to the opinions expressed above, as it is always well to hear all sides of a question.—R. FISHER.]

### MESSRS. CARTER & CO.'S., CRYSTAL PALACE NURSERY, FOREST HILL.

MESSRS. CARTER have long held an eminent position among the great London seedsmen, their assortment of seeds, and particularly of flower seeds, being one of the largest that is anywhere to be found, including not only every novelty, but also many kinds which, either from their scarcity or from being little in demand, can hardly be obtained elsewhere. At their extensive seed-grounds in Essex, where Mignonette, Lobelia, and Nemophila, and a multitude of other popular annuals are to be seen in the summer blooming by the acre, scarcely a season passes without their raising some new race, or effecting some improvement on old ones.

Extending their business to that of nurserymen as well, they have taken a nursery near the Crystal Palace, where they grow the large quantities of bedding and other plants required by their customers, and to the notice of this establishment we purpose devoting a brief article.

Perhaps the most striking feature in the place is a lawn of *Spergula pilifera* interspersed with the darker *agrinoides*, and forming a beautiful, close, green carpet, soft as any moss, and notwithstanding the recent heavy rain, dry and elastic to the tread.

If there are any who are still sceptical as to the value of *Spergula* for lawns, which was first demonstrated by Mr. Summers, the intelligent and persevering manager of this place, we would recommend them to view the specimen lawn here, and we are satisfied they will be convinced of the excellent qualities of the plant as a substitute for grass, and its eminent fitness for lawns laid out with geometric beds. The *Spergula* is now just beginning to show its minute star-like blossoms, but where these are objectionable, they can be swept off with the greatest ease.

On either side of the *Spergula*-lawn is a row of geometrical beds, small circular ones alternating with others of larger size, and of an oblong shape, with the ends having a sweep taken out of them concentric with that of the circles. The effect of this constantly repeated was very good, and, we may remark, it

would be an excellent simple arrangement for small suburban gardens with straight outlines, the laying out of which by way of parenthesis is so frequently carried out by the bricklayer's labourer.

These beds were being filled with variegated Geraniums, such as Cloth of Gold, Golden Chain, and Golden Fleeces, for yellow foliage, and Bijou, Alma, Mrs. Lennox, &c., for white variegation, and a variety of other bedders. Among these the handsome new Fuchsia, Carter's Meteor, was conspicuous by its bronzy crimson leaves shading off to a rich yellow, and its brightly-coloured shoots. The specimen we saw being young and only just planted out, could not be taken as giving an accurate idea of the ultimate appearance of the plant, but we were assured that when older the variegation is still more marked, and in that case the variety must be regarded as a decided acquisition. In another bed was *Coleus Verschaffelti*, which Mr. Summers has planted out by way of experiment, and although it has experienced some rough weather lately, it appears to be thriving well at present. Should it succeed out of doors in summer there can be no question that its crimson foliage will render it even a greater favourite than *Perilla* for beds and ribbons.

In the same bed with the *Coleus*, and planted all round it, was *Gnaphalium lanatum*, with very woolly, silvery grey leaves, and which proves to be an excellent hardy bedder for the middle of beds, and for front rows when pegged-down. *Salvia patula argentea*, another nice silvery-leaved plant for bedding, has also been extensively propagated. The Crystal Palace *Lobelia*, which comes true from seed, and is well known to be the finest of all for bedding, being in great demand, is, of course, largely grown; but the favour with which it is universally regarded is likely to be shared by a new and beautiful kind called *Lobelia speciosa kermesina*, purplish-crimson, with a white eye, of which we saw one little flower.

The frames were occupied by Dahlias, Verbenas, and a large stock of other plants, together with a good collection of all the usual occupants of the herbaceous border, several of which were prettily in flower, as *Viola lutea* and *cucullata*, both nice little spring plants, and several British *Orchises*, &c.

In the houses, the shelves and stages were crowded with bedding stuff, of which the stock is very large, and in capital health; and in the warm greenhouses and propagating-glass, *Gloxinias*, *Caladiums*, *Begonias*, &c., are to be seen in abundance, a large space being occupied by *Coleus Verschaffelti* alone, the crimson foliage of which met our eye at every turning. It is found to be one of the easiest of all plants to propagate, every leaf striking root if placed in a suitable temperature. Of *Mesembryanthemums* there is likewise a very extensive collection, comprising about 170 sorts.

Among flowering plants, *Pimelea Nieppergiana* was particularly worthy of note, on account of its free-flowering habit, which should recommend it for more extensive cultivation in the greenhouse; and the same remark will also apply to *Tetranema mexicana*, which from the profusion with which it produces its purplish flowers in long succession, is a pretty addition to any greenhouse. Judging from the fact of *Lapageria rosea* having been propagated here to the extent of 1500 plants, the demand for this, the finest of all greenhouse climbers, must be steadily on the increase, a circumstance which is easily accounted for by its value being now everywhere recognised, and by the low price at which the seedlings can now be obtained as compared with former years.

The Fern-house contained a collection of Gold and Silver Ferns, amongst which were the elegant silver-tasselled *Gymnogramma Wetenhalliana*, *Pteris tricolor*, *argyrea*, and other attractive species. For the growth of these as well as many other plants, Mr. Summers largely employs the cocoa fibre refuse, to which attention has been so often drawn in our columns, and with excellent results as regards the health and vigour of the plants, and he finds many cuttings root more freely in it than in anything else.

Before closing this notice, however, we must not omit to mention *Cerastium Biebersteinii*, of which we noticed a large pan in one of the houses, and which as a hardy silvery-leaved bedding plant must be regarded as a decided gain. The foliage is larger than that of *tomentosum*, and more densely covered with wool, whilst the plant possesses the same dwarf and compact habit, and is far more striking at a distance.

**BIRMINGHAM ROSE SHOW.**—An advertisement of this will be found in another page. The schedule of prizes and regulations

for the Show of Roses, Horticultural Implements, and Garden Ornaments, is now in circulation, and will receive all the attention to which its contents are entitled. We hear that the previous announcements of the undertaking have been received by both amateur and professional florists with most encouraging expressions of approval, and we trust that the support of manufacturers of the articles which it is intended to embrace will not be wanting. If so, the garden ornaments and implements will constitute a most interesting and valuable feature, and will have a beneficial effect upon various branches of industry in the town and district; and the information which will be applied relative to the various contributions—their purpose, special peculiarities, and cost—will render the catalogue, like the one issued from Bingley Hall, an annual publication worthy of being preserved for reference during the ensuing year. It must also be borne in mind that the Committee will stand in need of pecuniary aid in the shape of subscriptions, which we hope will be extended to them in a prompt and liberal manner. Persons who may add their names to the list, will receive admission tickets according to a certain rate, which is specified in the schedule to which we have referred.

## CRYSTAL PALACE EXHIBITION OF FLOWERS AND FRUIT.—MAY 24TH.

It would be impossible to secure a more effective illustration of the immeasurable superiority for a horticultural show of a glass-covered structure over one covered with canvass than was afforded by this Exhibition, compared with that of the very same plants at the Royal Horticultural Society, with but two days intervening. At the Crystal Palace the company, far larger in numbers, really enjoyed the floral luxuries brought together to gratify by their evidence of skill, colours, and perfumes. Every face was smiling; there was no occasion for anxiety to escape from wet feet and spoiled dresses; no chilliness; no dodging about to avoid streams coming from above, or puddles and marshy places formed below, as there was, so subservive of pleasure, at Kensington Gore. It is true the weather was bright and fair, yet no one who thought about the matter but felt that even if the day had been as wet and cold as on the Wednesday preceding, the Show at the Crystal Palace would still have been thoroughly enjoyable and unmarred by the weather. The glass would have excluded the rain and the cold.

The prize list will be found in our advertising pages, and to them we must this week be satisfied with referring our readers.

The chief feature, additional to the attractions at the Royal Horticultural Society's Show, was the fruit. We never saw finer or better-ripened specimens at a May exhibition.

Altogether it was one of the most successful and most effective Shows we ever attended. The statues mingled with the groups of plants especially added to the gracefulness of the arrangement

## RETROSPECTIVE CRITICISM.

HERE is a budget of commentaries on your No. 60. "*Lastræa Sieboldii*, a rather scarce Japanese Fern," page 138. The plant is a common hardy Fern, and has been so for some years. I observe you always spell this generic name *Lastræa*. This is wrong. The name, which was given to the present genus by Presl, is *Lastrea*. In the same page as the foregoing are mentioned two Ferns, "*Leptopteris auperba*" and "*Todea pellucida*." They are congeneric, and should, therefore, be both named *Leptopteris*, as some moderns do, or both *Todea*, which is certainly to be preferred. *T. pellucida*, by-the-by, ought to be called *T. hymenophylloides*. *Palea Cibotii* (page 145) are the scales of the caudex of a species of *Cibotium* (probably the same as the *Barometz*), which occurs in the islands of the east, and which has been for some time past collected, and exported to Europe for use as a styptic. It is believed to act by rapidly absorbing the aqueous particles of the blood, and thus facilitating coagulation. "There is no yellow *Rhododendron* yet," "a real yellow without a dirty tawny shade," page 146. *R. Boothii*, a Bhotan species, which was shown in flower the other day at the Regent's Park, has waxy flowers of a clear yellow, palish certainly, but I think I may say without a tawny shade. My note of it runs thus:—Flowers yellow, waxy, short bell, with reflexed convex lobes.—DELTA.

[The spelling of *Lastrea* is not uniform, and its derivation is uncertain. It is spelt *Lastræa* by Endlicher, Loudon, and

Lindley. They quote Presl as so spelling it, and if so—for we have not his book by us—he ought to know, for he founded the genus.—EDS.]

### SEA-KALE SPROUTS AS A GREEN VEGETABLE.

“HAVE any readers tried the green flower-heads of Sea-kale just when opening? if not, then do not fail to do so, for if well cooked they are excellent, and are often carelessly thrown away.”—R. F., “Doings of Last Week,” page 126.

A most valuable hint, one amongst many derived from the same source. Indeed, if Mr. Fish had never written anything else but these papers, he would have left a legacy to all young gardeners, worth more to them than any money sum. The morning after reading this I went into the kitchen garden and spied out some of the incipient flower-heads that I had promised decapitation and ignominious expulsion on the first convenient occasion. I immediately got what I thought would be a boiling, took them home and got the lady of the house to boil them up for dinner, reading for her instruction Mr. Fish's instructions. She took the hint, and at dinner-time they appeared looking beautifully green; and on trial, without gravy or any other accompaniment, they were deliciously sweet, with a delicate hint of the Kale flavour. The two censors, pater and materfamilias decided that, as a green vegetable, and a relief from the flavour of Broccoli, Cabbage, and the other members of the Cabbage-works, they were a decided acquisition, and at once voted the thanks of the house to Mr. Fish for his addition to the list of esculents. On inquiry I found that they were put on in boiling water, putting a little salt in the water, and hoiled quickly. They were done to a nicety in half an hour.—JOHN.

### COLEUS VERSCHAFFELTI AS A BEDDER.

THE question, “Is *Coleus Verschaffelti* a bedding plant?” was asked in your columns last week by a correspondent. Now, although all opinions on the subject are theoretical, and at present cannot be answered satisfactorily, yet I have myself great faith in its suiting admirably, and am putting it to the proof this season, by using it in place of *Perilla*, which will have to retire upon the half-pay list, and rest upon its laurels already won, if our new pet does well, and I see no good reason to doubt it whatever.

*Coleus Blumei* I have found thrive well when planted out, and I look upon *C. Verschaffelti* as merely a variety of it with a good deal of the pectinate variety in it. I perfectly agree with your correspondent when he says it does not like shade; but I have found the stronger the heat, the brighter and richer the foliage.

The plant by this time should be as cheap as any *Verbena*, as it propagates so freely. I obtained a plant last November, and commenced increasing it directly, and have now several plants upwards of 3 feet in diameter, others somewhat smaller, and a great quantity fit for bedding or other purposes. I never think of taking more than one joint, and as I pinched my plants to make them bushy, I stuck the points in and had them well rooted in about a week; but then I have the finest root-producing material in the world to do it with—namely, cocoa-nut fibre refuse. I wish more would try it for propagating purposes, they would be utterly astounded at the results obtained.—JUVENIS.

### FRUITERERS' COMPANY.

THE Worshipful Company of Fruiterers is a well-known one to every Lord Mayor. From them he has a present of twelve bushels of Apples of various kinds, and of the finest description, which, packed in clean white baskets, covered with white napkins, are carried to the Mansion House by clean-looking porters, headed by the Company's beadle. This is a custom of nearly two centuries' standing, a specimen of the usages of the City guilds in times of yore. When the Lady Mayoress directs the housekeeper to remove the fruit from the baskets, it is the custom to put in each of the same a bottle of wine for the porters' use, who are besides regaled with a substantial meal, and a privilege to take away the remnants of the same. Soon afterwards, the Lord Mayor entertains the Company to a state or “loving cup” dinner at the Mansion House, at which the Fruiterers take precedence before all other guests of whatever denomination present.

Lord Mayor Cubitt duly honours the custom originated 200 years ago.

James I., in the year 1605, incorporated this fraternity as the Master, Wardens, and commonalty of the mystery of Fruiterers, and their arms, granted soon after, has the tree of knowledge, entwined by a serpent, with man and woman on each side thereof. Their motto is “Deus dat incrementum,” God giveth the increase. The Fruiterers are governed by a Master, two Wardens, a Court of Assistants, and a Livery. The Company have no hall.—(City Press.)

### BROCCOLI MANURED WITH HOUSE SEWAGE.

LAST year I told you the results of slop-pail-culture of Broccoli producing 3½ lbs. on a head, when my neighbours had scarcely any. This season the same application of soap-suds, &c., has enabled me to give away more than two dozen heads of Broccoli, besides having it almost every day on my own table. Many of these were very large, and one of them weighed 9 lbs., and measured nearly 1½ yard round. Comparing this large crop with the trifling weight raised by my neighbours, I am desirous to urge upon cottagers, and especially laundresses, the great importance of using and not wasting the materials capable of adding materially to the quantity of food produced in the country.—THEODORE COMPTON, Winscombe, Somerset.

### THE INTERNATIONAL EXHIBITION.

WHEN we first recorded the opening to the world of this wondrous storehouse of the product of man's ingenuity and skill, and of the rough materials which Nature has given him to work with, we expressed our intention of advertising on future occasions to such of its contents as fall more peculiarly within our province. Not for us is it to describe the forms of beauty which spring from the sculptor's art, nor the bright creations of the painter's brain. The marvellous engines and machines by which the inertia of matter is overcome, and the far-off brought near, alike with glittering gem and costly fabric are all forbidden subjects; and, however much we might be tempted to descant upon them, they must pass unnoticed here.

We shall, therefore, confine ourselves to that which belongs to horticulture, whether tree, or fruit, or flower, the appliances by which these are fostered or encouraged, and the implements employed, and architectural decorations which may be introduced in gardens. It will also be our duty to record in another part of our columns anything which may tend to the advantage of the busy workers of the hive.

Taking the well-arranged official catalogue for our guide, we purpose going through the classes as nearly as possible in the order in which they occur. In connection with this, however, we cannot but remark that in consequence of the various exhibitions being placed in utter disregard of the consecutive order of their numbers, it is frequently a matter of difficulty to find any particular exhibition—for instance, 1036 may be alongside 1139; whilst 1037 may be in some nook or corner 20 yards distant, and 1038 far away in a totally different direction. This, notwithstanding a “sharp look-out,” has involved so much personal exertion, and, what is worse, loss of time on our part, and doubtless it has been the same with many others, that we very much question whether the alphabetical order of the names in the catalogue would not have been better sacrificed to the consecutive numbering of the articles according to their juxtaposition. Having the number of the exhibition, the name of the exhibitor could in that case have been found just as easily as at present; whilst if in search for the number under which any particular name exhibited, we should at most have had to run over three or four columns of print, which would have been much easier than hunting about backwards and forwards. In very large classes surely some compromise between the two systems might have been effected.

Classes 1 and 2 present few objects of horticultural interest, being devoted to mining, metallurgy, and chemical products and processes. We may, however, notice—

510. DUNN, A., Dalston.—In this the effects of his indelible marking-ink pencils are exhibited on wood, zinc, linen, parchment, and paper; but the merit of the invention having often formed the subject of remark in our columns, it must now be well known to our readers.

In the succeeding classes we find—

705. BUTLER & McCULLOCH, *Covent Garden*.—192 sorts of flower-seeds, and 24 of vegetable seeds neatly arranged. Vegetable essences, as Almonds, Garlic, Ginger, Lavender, Peppermint, Sarsaparilla, and Vanilla, together with various herbs, Parsley, Sage, Mint, Basil, Marjoram, Savory, and Thyme, bottled so as to preserve the original green colour.

707. CARTER & Co., *High Holborn*.—418 sorts of flower-seeds, and 63 of vegetables, grasses, and agricultural plants. These are arranged light and dark alternately, and produce a very good effect; whilst the upper portion of the case contains the name of the firm, &c., surrounded by ornamental grasses, and everlasting of various colours.

731. SUTTON & SONS, *Reading*.—A collection of agricultural and ornamental grasses, comprising 100 sorts, arranged according to their genera; also cones, nuts, acorns, &c.; and, occupying the upper portion of the case, dried specimens of ornamental and useful grasses. Among the cones were those of several rare Pinuses and Banksias, as well as the fruits of *Adansonia digitata*, or Monkey Bread; *Anona reticulata*, or Custard Apple; *Achras sapota*, or Sapodilla Plum; *Ægle Marmelos*, or Maredoo; *Entada Purshiana*, a flat blade a yard long; *Moringa pterygosperma*; *Lodica sechellarum*; and the *Sapucaia* nut, or rather the large cup in which the so-called *Sapucaia* nuts of the shops are contained, and which are, properly speaking, the seeds. This large cup belongs to a species of *Lecythis*, and is 7 inches or 8 inches long, about 5 inches in diameter, and is furnished with a kind of lid, which drops off when the cup falls, permitting the seeds to escape. The latter are now well-known articles of consumption, but the cup itself is said to be applied to a singular use in Guiana, that of catching monkeys, which is effected as follows:—The cup is filled with sugar and placed on the ground, and the monkeys insert their paws to get at the sugar; and on being startled, make off with the cup enclosing their paw. They are therefore unable to climb, and are, consequently, easily caught; hence the colonists have called the cups monkey-pots.

In the upper portion of the case, there is a collection of dried grasses; but, unfortunately, many of them are situated so far above the level of the eye, that it is difficult to see their characters. Messrs. Sutton, however, have had to make the most of a limited space; for, we are informed, that a collection of 1000 kinds of agricultural, vegetable, and flower seeds which they had prepared could not be exhibited from want of space; and it has, consequently, been set up at the Crystal Palace, where it occupies 500 square feet. Notwithstanding the above disadvantage, Messrs. Sutton have produced a highly creditable and interesting exhibition.

735. WEBB, R., *Reading*.—A collection of 24 varieties of Filberts, including several of his own raising; also Indian and Imperial Bottle Gourds.

739. WRIGHT & SON, *Great Bentley*.—Seeds and dried specimens of grasses, such as *Agrostis*, *Poa*, *Cynosurus*, &c., and a few Ferns.

782. FORTNUM, MASON, & Co., *Piccadilly*.—A large collection of preserved fruits, &c., both European and tropical, nuts of various kinds, &c. This and several similar exhibitions of preserves and pickles may be advantageously inspected by those who wish to see what is an important branch of domestic economy well done.

Class IV. contains a number of models of flowers in wax, many of which are exquisitely moulded and coloured; among these we may mention Miss Pierson, who sends a charming case of Roses, and another containing *Stephanotis floribunda*, Orchids, Fuchsias, and *Convolvulæes*; Mrs. Willes, who sends 12 cases, and Mrs. Trewolla.

925. LAMBERT, E., *Tunbridge*.—A Kentish bank of flowers in July. This is beautifully modelled; the Forget-me-not is not quite so natural as it might be, but the Foxglove, the *Convolvulæes*, and the Ferns are rendered true to nature.

—AUSTIN, *Dalston*.—A large case of Japan and other Lilies, *Passion-Flowers*, &c., is also deserving of great praise.

929. MAKEPEACE, E., *Merton*, and 946. Mrs. SYMONS, *Notting Hill*, are likewise very creditable exhibitions of the same art.

1033. ADANSON, R., gardener, *Balcarras*.—Three willow baskets for carrying fine fruit and flowers, designed and woven by himself. Very neat, small, cross-handled baskets of a kind which is not uncommon in Fifeshire. For carrying fruit we much doubt whether they would prove so efficient as the common punnet, whilst they are not of a character which would

adapt them for the drawing-room. The workmanship, however, is superior to that of most basket-makers.

1036. ALEX, MATILDA.—Models in wax, showing the leaves, buds, blossoms, and seed-vessels of the Tea, Coffee, Flax, and Cotton plants as in a growing state.

—BARSHAM & Co., *Kingston*.—Show Ferns, *Caladiums*, *Begonias*, &c., growing solely in the cocoa-nut fibre refuse, all of which seem to be flourishing admirably.

1080. HAWE, J., 7, *Adelphi Terrace*.—Leaves and seed-vessels anatomised. A truly beautiful exhibition, the skeletons of the leaves being perfect, having the appearance of the finest lacework.

1133. STEVENS, M., *Pimlico*.—Is another of a similar description, and also worthy of high commendation.

1117. RAYNBIRD, H., *Basingstoke*.—Specimens of timber grown at various gentlemen's seats in Hampshire, amongst which are fine specimens of Oak, Ash, Birch, Lime, Walnut, and Yew. Perhaps none present a better appearance for the turner and cabinetmaker than the wood of the "Acacia," *Robinia pseud-acacia*, which, being hard and close-grained, takes a high polish. It is besides a very durable wood, and might be employed advantageously for many purposes notwithstanding its somewhat brittle character. We may also mention that it decays very slowly in the ground.

2106. DORE, J., *Clerkenwell*.—Garden-roller, engine, and waterer combined.

2110. DRUMMOND, P. R., *Perth*.—Revolving rake for cleaning land of stones, weeds, and haulms, also for raking grass and corn. This is mounted on wheels, and is provided with a semi-circular wire-basket or hepper extending from wheel to wheel, and which, being freely suspended, can be emptied at pleasure. Into this a broad-toothed rake, revolving with the wheels, throws all stones and other matters caught by a fixed rake in front, through the intervals of which the revolving one passes; it promises to be useful for cleaning parks and extensive lawns. The model, however, being broken, the action of this contrivance was seen at considerable disadvantage.

2141. KENNAN & SONS, *Dublin*.—Lawn-mower, root-blaster, apparatus for straining iron-fences, and log-saw.

The lawn-mower, which is of excellent workmanship, can be adjusted to cut the grass at any required height, and is very quiet in its working: Its peculiar feature, however, consists in the grass being caught as it is cut in a kind of box in front, which, by means of a lever at back, can be emptied into a large receiver situated between the handles at back. This arrangement works with great ease, and apparently no grass can be spilled over the knives.

The root-blasting apparatus consists in an augur for boring a hole for the charge, a perforated metallic plug with a strong threaded screw worked on its outside, and a lever handle to screw this into the wood. The plug acts as tamping, and the charge is fired through the perforation by a fuse, in the ordinary way. The whole apparatus is very simple, and numerous testimonials were adduced as to its efficiency.

The wire-strainer consists of a frame, which is placed against the post through which the wire to be tightened passes, and a screw worked by a wheel and having at its extremity a jaw into which the end of the wire is fixed. The wheel being turned, the screw with the jaw is worked away from the post, drawing at the same time the wire to the requisite degree of tightness. The apparatus is simple, efficient, and, being easily worked by a common labourer, would be found very useful for erecting wire fences at little cost.

The log-sawing machine consists of an X-shaped horse like that used by carpenters in which the log can be firmly fixed, and to this is fixed an upright with a jointed arm to which one end of the saw-frame is hung. At the joints there are springs which, on the saw being worked from the opposite extremity, give an alternating motion, and thus only one man is necessary instead of two as in the cross-cut saw. The teeth cut both ways.

2164. PICKSLEY, SIMS, & Co., *Leigh, Lancashire*.—Garden chair, lawn-mower, and agricultural implements.

The garden chair is of cast-iron, 4½ feet long, and of an elegant design called the fern-leaf-and-blackberry pattern. It possesses some advantages over other cast-iron chairs in the peculiar construction of the bottom, which is made of longitudinal bars of Bay wood, which, being a nonconductor, is never so cold to sit upon as iron. In addition, the front of the seat is raised higher than the back and then curved downwards, which gives more rest to the spine and legs than in the flat-bottomed kinds. It is very comfortable to sit in.

The lawn-mower is also of excellent construction; it has four revolving blades, which, being worked by machine-cut cogs, make very little noise; and the roller being divided in two the machine can be turned in small compass. By a simple arrangement the revolving blades can be easily raised or lowered to the cutter; and they can be easily sharpened with a little emery and oil, reversing their action at the same time. We could not but remark the form of the cogs as being particularly good, and from their being rounded at the bottom not liable to break off at that part.

In concluding for this week our notice of a portion of the contents of the International Exhibition, in which we regret to

state that horticulture is not so fully represented as she might be, we cannot refrain from making some remarks. We do not do so in a spirit of fault-finding, than which nothing could be further from our inclination; nor is it our wish to detract in the least from the exertions of the many scientific men who have so liberally given their assistance in carrying out this great national undertaking; but the want of arrangement, which it in many places presents, and its still rough unfinished condition in others, we cannot understand. And this remark is particularly applicable to the annexes, temporary buildings it is true, whose far-from-attractive exterior is in no wise redeemed by their internal aspect.  
(*To be continued.*)

## RUSTIC TERRACES.

BY H. NOEL HUMPHREYS, ESQ.

I HAVE endeavoured to show, in a preceding article, the necessity of blending the hard and symmetrical lines of an architectural elevation with the gentle and irregular outline of natural scenery, by means of a terrace, or some feature of the kind attached to the principal front. Even a rustic cottage requires to be accompanied, at all events on its principal side,

by a moderately broad esplanade or terrace, which, however, does not absolutely require any architectural embellishment of an expensive kind; for, when merely raised a few feet above the surrounding garden, by means of a neatly-turfed embankment, a terrace imparts, even in that simple form, a very pleasing air of propriety to the site of a dwelling:—first, it

suggests at once that a sufficiently high situation has been selected, possessing due advantage in height over the surrounding ground; secondly, that an amply sufficient space has been carefully levelled and prepared for the erection of the building; and, in addition to these evident and agree-

able advantages, art, by its means, is carried beyond the mere form of the house itself, in a manner that causes its vertical and horizontal lines to blend by degrees with the accidental outline of the surrounding vegetation, and undulations of ground.

With but trifling increase of expense, a rustic and somewhat more architectural parapet might be formed, of which a suggestive sketch is given in the top engraving on the opposite page. This parapet, calculated to harmonise with a building in the cottage style, is formed by strong stakes, with the bark left on, to which branches, also unbarked, are attached. They must be arranged with that attention to a certain irregular symmetry commonly known as "rustic work." Three or four steps lead from the terrace to the lower ground, which, to accord with the rustic character of the parapet, should not be stone, but merely gravel, faced at each rise by short stakes with the tops cut off flat, as shown in the bottom sketch on the opposite page.

The turf bank may be terminated at the bottom by a narrow flower-border, not above 12 inches wide, in which compact and trim-growing plants alone should be placed. After this modulation from the straight lines of the building, the curved walks of the garden may commence without further restraint.

Although the design for a terrace-fence, here given is formed

of rustic work of an irregular character—effects equally consistent with the style of architecture of a rustic cottage may be produced by a symmetrical disposition of the same materials—the branches might be so arranged as to form interlacing ellipses, which produce a geometric pattern, the repetition of which, at regular intervals, would be extremely pleasing. Or, if the style of the cottage should be Gothic, the interlacings of the branch-work may be easily made to form a pattern of that character, to which, in fact, the style of the work lends itself with great readiness.

The engraving below is a design for a terrace, embellished in a manner to accord with a building of somewhat more regular architectural pretensions than the rustic cottage for which the former design is suited. It supposes a house of moderately small dimensions, built in the modern suburban-villa style, with which *rugged* forms would not agree, but to which a terrace with a decorative parapet might yet be added without great expense by forming the parapet of wooden trellis-work, the neatness of which would accord well with the style of the building, and still more so, if the house happened to be finished with a verandah of similar

character. When the terrace is of sufficient width to allow of it, without appearing to encroach upon its apparent size, a summer-house, as in the sketch, would form a characteristic and pleasing terminus at each end; but such feature must not be allowed to crowd the residence, as the first quality in a terrace is apparent spaciousness—a character which depends more on treatment than even on real space. This terrace, as in the rustic example, I

have bordered, next the parapet, with turf, cut into recesses to receive vases containing plants, by which means the vases appear to enter into the original plan, and form a necessary part of the composition; whilst, without a framing of that description, such features not only lose great part of their importance, but frequently appear unwelcome spots intruding upon space to which they do not seem to belong.

No. 1.

No. 2.

No. 3.

Any vases or architectural ornaments used to decorate the rustic terrace should be of a corresponding rustic character; the outline, No. 1, represents a stand which is now manufactured, and is suitable to such a situation, though it is more frequently used, without regard to propriety, in places in utter discordance with its style. It has the defect also, though picturesque, of being a mere crude imitation of nature, to which obvious and simple process art should not descend;

but the contrast of the rough bark and the smooth Ivy leaves is very suggestive; and I would propose working it into a symmetrical form, which should, like all works of art, bear the evident impress of *design*. The sketch, No. 2, will sufficiently exemplify my meaning. No. 3 is a vase of more even and regular form, the smooth outline of which is suited to the terrace with the trellis parapet.—(*Gardeners' Magazine of Botany.*)

## CULTURE OF THE PINE APPLE.

*(Continued from page 144.)*

## PROPAGATION.

THERE are three ways by which the Pine Apple may be propagated—viz., by suckers, by crowns, and by seeds. The first produces the greatest number and generally the strongest plants; the second forms nice bushy plants, and sometimes just under the crown there are often produced several smaller plants, which have been called gills. Excepting where the kind is scarce or new, these gills on account of their small size are of little use. Seeds are sometimes produced, and whenever discovered should always be saved, as there is a probability that new and improved kinds may be raised from them, though the Pine Apple is a long-living plant. The old Queen was, probably, the first kind imported, and its progeny raised from suckers and crowns is as healthy and produces as fine, if not finer, fruit than the original plants imported upwards of two hundred years ago.

**By Suckers.**—After the fruit is cut the plants should be brought away out of the house and turned out of the pots; shake off the soil and cut away the roots, then begin to pull off the bottom leaves till the first sucker appears. As soon as it is clear of leaves, take hold of it and give it a smart pull—it will come off without difficulty; lay it aside, pull off the next leaf, which will expose the next sucker; pull it off also, and so proceed till every sucker is stripped from the old plant. Then take a sucker up, pull off some of the bottom short leaves, but, not too many, especially if the sucker is green and soft; and with a sharp knife pare off any ragged parts there may be at the base of the sucker. Finish dressing all the remainder, and then pot them in proportionate-sized pots. Make the compost firm about the base of the suckers, and then plunge them in a warm bed of tan or leaves. Give no water for a month, and then only just enough to moisten the soil, and keep the house or pit rather close. In this stage the plants will bear a rather higher degree of heat till roots are produced; also, keep up a kindly moisture in the air of the house. As soon as evident growth is perceived more water should be given, always in a tepid state—that is, about 80°, and also more air will be of benefit, causing a more sturdy growth and broader leaves. Supposing the suckers to be planted in March, they will require repotting in July into larger pots, and many of them will be fit to remove into the succession-house at that time; and, finally, in the spring following, the best plants will be large enough to put into their pots for fruiting the succeeding summer.

**By Crowns.**—It is customary when a fruit is about to be eaten to twist out the crown; but a better plan is to cut off the top of the fruit an inch or two below the crown, and then with a knife cut away that part of the fruit attached to the crown so as to leave a portion at the bottom. This saves the leaves from being crushed or broken, and preserves the base entire. When the crowns come from the table squeeze any juice out that may be left at the base, and lay them on a shelf in the stove to dry-up and harden the base. When they are quite dry and hard then pare off the bottom nearly up to the leaves, strip off a few of the bottom small leaves, and have some nice, dry, rather fine and warm compost ready. Drain pots of a suitable size and pot the crowns in them, and plunge them in a tan-bed similar to that described above for the suckers. Treat exactly the same as regards top heat, giving no water till roots are emitted, and keeping up a warm genial moisture in the air.

When it happens that there are but a few suckers and crowns on hand at a time, they may be planted among the warm bark till they make roots, and the number accumulates to such an extent that it is worth while to lift them carefully out of the bark. In doing this be very careful not to injure the young roots. They run very freely in the warm bark, and, therefore, require extra care to keep them entire and unbroken in taking-up and potting. Like the roots of all other plants they suffer by being exposed to the air, especially if that air is much colder than the bottom heat they have been growing in: hence suckers and crowns that have been rooted in a bark or leaf bed should not be exposed to cold air, and should be potted in warm soil immediately after being lifted out of the bed where they have struck root. Directly such plants are potted they should have a very gentle watering with tepid soft water, and be plunged as soon as possible in a bark-bed in a heat of at least 85°. If that potting should happen to be done in summer when a bright sun prevails during the day, they would be benefited by a slight

shading from ten in the morning to three in the afternoon, the shading to be continued till fresh roots are formed and a decided fresh growth is perceived in the heart of the plants.

**By SEEDS.**—Very few, even of eminent horticulturists, have attempted to raise the Pine Apple from seed. Even that, in his day, the most successful of raisers of new kinds of fruit—the late Mr. Knight, never to my belief either tried or succeeded in raising new varieties of this king of fruits. Perhaps the reason why gardeners in general do not try this point of Pine culture is because the fruit is consumed in the dining-room, and no care is taken of the seeds should any of these be found. There is no doubt, however, if the gardener were to express a wish to have any seeds saved that his employer or his guests might find in the fruit, that desire would be attended to. I see frequently in the market many Pines imported in a decayed state, and I should suppose such would be more likely to yield seeds than fruit grown in our close hothouses. Let some such be examined; and if seed is found, save and sow it. It is very likely that new kinds would spring therefrom. Having from any source obtained seed, let it be thoroughly dried, and in the spring sow it in shallow pans in a light sandy soil, and set on a warm flue or any place where a good bottom heat can be obtained. A Cucumber or Melon-bed would be very suitable. Great care, however, must be taken that the young seedlings do not damp off: hence, as soon as they appear above the surface, let that surface be covered with fine silver sand, and water, without wetting the young leaves of the seedlings. As soon as three or four leaves are made, pot the plants into small pots, and plunge in a sand-bed on the surface of a bark-bed. When they have filled these pots with roots repot into larger, and so continue to encourage growth until they fruit, which will be in about the fourth year. Well-formed good-flavoured fruits though small should be kept for further trial, but such as are otherwise may be cast away at once.

T. APPELBY.

*(To be continued.)*

**PROPOSED DUBLIN EXHIBITION PALACE AND WINTER GARDEN.**  
—Arrangements are in progress for supplying an Exhibition Palace and Winter Garden under auspices which render success a matter of certainty, and on a scale commensurate with the growing importance and requirements of the Irish metropolis. The provisional directory and executive comprise such a list of noblemen and gentlemen as have not hitherto been associated together for carrying out any commercial undertaking; and the outline of the scheme contained in the prospectus of the new Company bears testimony to the enlarged views and sound judgment of the promoters in devising arrangements for what must become one of the great public institutions of the age. The new Palace and Garden will combine the leading features of the Crystal Palace and grounds at Sydenham with the attractions of the Polytechnic Institution in Regent Street; thus supplying the means of providing instruction and amusement to an extent which no other single institution can equal. The monster concert, the musical promenade, and the popular lecture, will in turn engage attention. In the well-laid-out grounds and magnificent halls of the new Company we look forward to horticultural exhibitions on a scale which could not be equalled under existing arrangements of inadequate accommodation; and the tendency of the mass of the people, being familiarised with the richest treasures of the floral world, must be to promote a taste for the growth of flowers even in the humblest dwelling. Notwithstanding the claims of the people of Dublin to rank high as critics in musical art, the Theatre Royal has for years been the only place where first-class music could be enjoyed unless by the aristocratic few who form our musical societies; and those who have been present at one of the people's concerts in St. George's Hall, Liverpool; in the Town Hall, Birmingham; and even in the newly-erected Ulster Hall, in Belfast, not to particularise further, must look forward with satisfaction to provision being made in Dublin for similar entertainments, on the refining influence of which it is needless to dwell. For the more select audiences, what more agreeable entertainment can be provided than the musical promenade, at which parties can meet their friends and acquaintances, and in friendly converse strengthen attachments and remove estrangements, for which such opportunities are of great value? Again, in a fine-art point of view, one department of the new Palace may be regarded as a sort of National Gallery, in which the commerce of art can be carried on. Nor will the least interesting feature of the new institution

be the magnificent grounds by which the Palace will be surrounded, including capacious conservatories, in which the most attractive objects of the vegetable kingdom will be displayed. The promoters of the new Company have been singularly fortunate in obtaining possession of the Coburg Gardens, almost the only piece of ground within the city boundary suited for such a purpose. The progress of the city towards the south makes this situation peculiarly central and of easy access. The space available for the Palace and Grounds comprises an area of no less than sixteen acres.—(*Dublin Agricultural Review*.)

### NEW BOOKS.

*On the Various Contrivances by which British and Foreign Orchids are Fertilised by Insects, and on the Good Effects of Interbreeding.* By CHARLES DARWIN, M.A., F.R.S., &c. London: Murray.

MANY people objected to Mr. Darwin's theory "on the origin of species," and "blamed him for propounding this doctrine" in the absence of sufficient facts to establish what he believes to be "apparently a universal law of nature, that organic beings require an occasional cross with another individual; or, which is almost the same thing, that no hermaphrodite fertilises itself for a perpetuity of generations." And this volume is written to prove that the learned author had not written what he could not have substantiated if he had had sufficient space in his first volume.

The reader, who takes an interest in this subject, may congratulate himself on the fortunate want of space in the first volume, for had Mr. Darwin attempted then to bring forward his authorities from the bosom of nature, he would probably have confined his matter to his own personal knowledge of how fertilisation is effected among our British Orchids only, a branch of the subject which, although highly interesting as a contribution to practical botany, would be of much less value to the gardener and garden amateur than that which "the force of circumstances" induced Mr. Darwin to place before them in this volume.

Mr. Darwin has included the whole order of Orchids in his marvellous grasp, and with his usual patience and research he has not only shown that all the species, with some few exceptions, through the complexity of their parts of fructification, must be artificially fertilised; but his examinations of these parts have enabled him to account satisfactorily for facts which had hitherto eluded all other botanists.

As an instance, we refer to our extract relative to *Catasetum tridentatum*. Mr. Darwin makes it self-evident that Orchids cannot be fertilised even by their own pollen without artificial assistance; that moths and other insects are the natural agents in the work; that few of the flowers can have their own pollen; and that the natural contrivances for assisting fertilisation, and for preventing self-fertility, so to speak, are of vast variety, and of the most complicated construction. Parts and processes which have been hitherto considered useless, or as stumbling-blocks to the student of botany, have been here explained by our author as necessary appendages for some share in the great aim and end of flowers—the fertility of the seeds.

Here another and a very different student will find abundance of fertilising matter for the mind—find the whole secret of the apparatus by which he can fertilise his Orchids under his own roof and eye, and learn more clearly the botanical construction of the parts, from the woodcuts in the book, than from any other source, or all the sources we knew put together.

As a contribution of the very highest order to the practical attainment of seeding foreign Orchids, we would recommend the work, apart from all speculations about the origin and progress of the clothing of our planet.

"At Torquay I watched a number of these flowers (*Spiranthes autumnalis*) growing together for about half an hour, and saw three humble bees of two kinds visit them. I caught one and examined its proboscis; on the superior lamina, some little way from the tip, two perfect pollinia were attached, and three other boat-formed discs without pollen; so that this bee had removed the pollinia from five flowers, and had probably left the pollen of three of them on the stigmas of other flowers. The next day I watched the same flowers for a quarter of an hour, and caught another humble bee at work; one perfect pollinium and four boat-formed discs adhered to its proboscis, one on the top of the other, showing how exactly the same part had each time touched the rostellum.

"The bees always alighted at the bottom of the spike, and, crawling spirally up it, sucked one flower after the other. I believe humble bees generally act thus when visiting a dense spike of flowers, as it is most convenient for them; in the same manner as a woodpecker always climbs up

a tree in search of insects. This seems a most insignificant observation; but see the result. In the early morning, when the bee starts on her rounds, let us suppose that she alighted on the summit of the spike; she would surely extract the pollinia from the uppermost and last-opened flowers; but when visiting the next succeeding flower, of which the labellum in all probability would not yet have moved from the column (for this is slowly and very gradually effected), the pollen-masses would often be brushed off her proboscis and be wasted. But Nature suffers no such waste. The bee goes first to the lowest flower, and, crawling spirally up the spike, effects nothing on the first spike which she visits till she reaches the upper flowers, then she withdraws the pollinia; she soon flies to another plant, and, alighting on the lowest and oldest flower, into which there will be a wide passage from the greater reflexion of the labellum, the pollinia will strike the protuberant stigma; if the stigma of the lowest flower has already been fully fertilised, little or no pollen will be left on its dried surface; but on the next succeeding flower, of which the stigma is viscid, large sheets of pollen will be left. Then as soon as the bee arrives near the summit of the spike she will again withdraw fresh pollinia, will fly to the lower flowers on another plant, and fertilise them; and thus, as she goes her rounds and adds to her store of honey, she will continually fertilise fresh flowers and perpetuate the race of our autumnal *Spiranthes*, which will yield honey to future generations of bees."

"The position of the antennæ in *Catasetum tridentatum* may be compared with that of a man with his left arm raised and bent so that his hand stands in front of his chest, and with his right arm crossed lower down so that the fingers project just beyond his left side. In *Catasetum callosum* both arms are held lower down, and are extended symmetrically. In *C. saccatum* the left arm is bowed and held in front, as in the *C. tridentatum*, but rather lower down; whilst the right arm hangs down almost paralysed, with the hand turned a little outwards. In every case notice will be given in an admirable manner, when an insect visits the labellum, and the time has at last arrived for the ejection of the pollinium, and for its transportal to the female plant.

"*Catasetum tridentatum* is interesting under another point of view: Botanists were astonished when Sir R. Schomburgk\* stated that he had seen three forms, believed to constitute three distinct genera—namely, *Catasetum tridentatum*, *Monachanthus viridis*, and *Myanthus barbatus*, all growing on the same plant. Lindley remarked that "such cases shake to the foundation all our ideas of the stability of genera and species." Sir R. Schomburgk affirms that he has seen hundreds of plants of the *C. tridentatum* in Essequibo without ever finding one specimen with seeds; but that he was surprised at the gigantic seed-vessels of the *Monachanthus*; and he correctly remarks that "here we have traces of sexual difference in Orchideous flowers."

"From these several facts—namely, the shortness, smoothness, and narrowness of the ovary, the shortness of the ovule-bearing cords, the state of the ovules themselves, the stigmatic surface not being viscid, the empty condition of the utriculi, and from Sir R. Schomburgk never having seen *C. tridentatum* producing seed in its native home, we may confidently look at this species, as well as the other two species of *Catasetum*, as male plants."

### ENTOMOLOGICAL SOCIETY'S MEETING.

The May Meeting of the Entomological Society was well attended, the President, F. Smith, Esq., being in the chair. George Robert Gray, Esq., the distinguished ornithologist of the British Museum, and Rev. Messrs. T. H. Browne and A. Haward were elected members of the Society. The President announced that the first part of the new series of the Society's "Transactions" was ready for distribution, and that it contained a general index to the previous series, a catalogue of which had been found to be a great desideratum. A vacancy in the Council, caused by the resignation of Dr. Knaggs, was announced, and that it was proposed to be filled up by the election of Mr. Stainton at the next meeting.

Professor Westwood exhibited a box containing an extensive series of illustrations of the natural history of various species of British insects which had been formed and recently presented to the University Museum of Oxford by Mr. S. Stone, of Bright-hampton. Amongst them were beautiful specimens of *Acronycta Alui*, one of which had been reared in February last; several species of Beetles belonging to the genera *Malachius*, *Dasytes*, and *Anaspis*, reared from mined twigs, as well as various fossorial Hymenoptera obtained from similar situations; the eggs, pupæ, and imago of *Volucella pelluceus*, reared as parasites in the nest of the common Wasp, as well as specimens of the *Anomalus Vesparum* from the comb of the Wasp, some of which had remained three years before arriving at perfection; likewise several

\* "Transactions of the Linnean Society," vol. xvii., p. 522. Another account by Dr. Lindley has appeared in the "Botanical Register," fol. 1951, of a distinct species of *Myanthus* and *Monachanthus* appearing in the same scape: he alludes also to other cases. Some of the flowers were in an intermediate condition, which is not surprising, seeing that in diocious plants we sometimes have a partial resumption of the characters of both sexes. Mr. Rodgers, of Riverhill, informs me that he imported from Demerara a *Myanthus*, but that when it flowered a second time it was metamorphosed into a *Catasetum*. Dr. Carpenter ("Comparative Physiology," 4th edit., p. 633), alludes to an analogous case which occurred at Bristol.

† The "Vegetable Kingdom," 1853, p. 178.

‡ Brongniart states ("Bull. de la Soc. Bot. de France," tom. ii., 1855, p. 20) that M. Neumann, a skilful fertiliser of Orchids, could never succeed in fertilising *Catasetum*.

galls formed by the midges of the genus *Cecidomyia*, &c. He likewise stated, with reference to the exhibition by Mr. Newman at the last meeting of the Society, of a female *Liparis dispar* which possessed the majority of the male characters, and which had been considered as unique of its kind, that Dr. Klug had published a figure of a nearly identical individual of the same species in a memoir on hermaphrodite insects in the "Proceedings" of the Friends of Natural History in Berlin, and which had been copied in London's "Magazine of Natural History."

Mr. F. Moore exhibited a beautiful cocoon formed of pale green silk from Japan, the perfect insect of which remained unknown.

Mr. J. Lubbock, F.R.S., exhibited the curious larvæ of a species of *Pæcus*, which covers itself with sand and dirt, particles of which were even attached to the eyes by means of curious glandular hairs.

Mr. S. Stevens exhibited a box of insects from Oramp Land, South-western Africa, containing two apparently new species of Goliath Beetles, closely allied to *G. Derbyana* and *Eudicella Smithii*. Also a nest of a species of Trapdoor Spider (*Actinopus*), from Afghanistan.

General Sir John B. Hearsey exhibited a large collection of minute nocturnal Lepidoptera, which he had collected in India with the view of showing the great similarity which existed between many of the species and British insects; some indeed being absolutely identical, as in the case of the beautiful *Deiopeia pulchella*, an account of the apparition of which in immense numbers in his garden was related by the gallant General.

Mr. George R. Waterhouse read a memoir on the genus *Tychnis* belonging to the family of the Weevils (*Cureulionidae*), and describing eleven species found in this country, two of which were now for the first time announced as natives, Mr. Walton having only described nine in his Memoirs on this family.

Mr. J. Lubbock read a memoir, accompanied by numerous anatomical illustrations, on the transformations of an anomalous Dipterous genus *Lonchopteryx*, and the true position of which had hitherto been doubtful. He had been so fortunate as to discover the oval-shaped flattened larvæ under logs of wood during the past winter, and had reared the perfect insect *Lonchopteryx leuta*, on the 11th of March last. The larva is remarkable for dilated lateral appendages, with four long setæ in front of the body, and two behind; the latter protected the large terminal spiracle. These larvæ were transformed to pupæ, within the old larvæ skin of which the form did not undergo any change, the pupæ itself exhibiting no trace of limbs. From these considerations Mr. Lubbock inferred that its position was intermediate between the two great divisions of Diptera.

MR. JAMES ALEXANDER, who was some years since head gardener to the Duke of Leinster, at Carton, from whence he went to manage his Grace's extensive farm known as the Heath Farm, near Athy; and then, on the Marquis of Kildare going to reside there, went to fulfil the important duties of steward and gardener to his lordship at his beautiful residence, Kilkea Castle. Having recently resigned his engagement at Kilkea, and removed to the lands of Nurney Castle, which he has lately taken, he has been presented by the Marquis with a handsome and costly service of silver plate; and also by the Marchioness of Kildare with a beautiful drawing-room timepiece of the richest workmanship. These are well-merited testimonials of the esteem in which Mr. Alexander is held by the noble donors for his long, useful, and faithful services as general superintendent at Kilkea Castle during the last eight years, he having been confidentially employed by the Duke of Leinster, at Carton, for fourteen years preceding. Mr. Alexander's departure from Kilkea is regretted sincerely by the numerous persons with whom he had any intercourse in business, and he carries with him into his new sphere of action the good wishes, respect, and esteem of every individual of a large circle in Kilkea and the adjoining districts who enjoyed the pleasure of his acquaintance.—(*Leinster Express*.)

FOUR-BLADED CLOVER.—The good fortune supposed to accrue to the finder of such rarities as a four-leaved Clover, a double-topped Ash (-leaf) or (and) a green-topped Seave, is expressed in the following couplet, heard at Scarborough:—

"With a four-leav'd Clover, double-topp'd Ash and green-topp'd Seave,  
You may go before the queen's daughter without asking leave."

It may be remarked that Seaves are the Rushes of which rush-lights, or rush candles are made. The sharp-pointed ends of the Seave are almost always, if not invariably, brown or withered.—OZMOND.—(*Notes and Queries*.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

ADVANTAGE should be taken of showery weather to transplant and earth-up all crops that require it, for if done when the soil around them is dry, the roots will not receive that benefit from rain which they otherwise would do. In pricking-out or transplanting particular care should be taken to press the soil close to the roots of the plants, for if left hollow and loose about them drought will soon stop their growth, or probably cause them to perish. Wherever it is convenient to plant with a trowel it is far preferable to planting with a dibble, as with the latter the roots are either left hollow, or are crushed up together and rendered incapable of making free growth. *Asparagus*, the beds would be greatly benefited by liberal waterings with manure water from the stable or Melon-yard. *Broccoli*, prick out the Cape and late Cauliflowers, and keep all seedling crops of this sort well dusted with quicklime, or you will have to repine over the loss of them from slugs. *Broad Beans*, make another sowing of the Longpod, if they are much in request, and take off the tops of those in blossom. *Cardoons*, sow a late full crop; plant out the early crop, if it has been sown in a seed-bed; choose a rich piece of ground for the purpose. It will not be advisable to plant largely of the first crops, as they soon run to seed. *Colewort*, sow the old English sort, and also Jerusalem Kale, both very useful for planting after Potatoes. *Cucumbers*, as they advance in growth under the hand-glasses peg them down; water them in the morning when they require it; but this should only be done when it is likely to be succeeded by a fine day. In pruning away any of the shoots or leaves, cut close to the main stem. This, we are aware, is contrary to the practice of some good growers, nevertheless we believe it in no way injures the plants; in fact, the wound heals quicker than if a piece of the stalk is allowed to remain on until it gradually rots away. *Dwarf Kidney Beans*, sow for succession, and transplant those which have been forwarded, if not already done. *Lettuce*, make a sowing of two or three sorts, by this means the season of one sowing is prolonged. The Paris Cos is a very good summer sort. *Peas*, keep the surface well loosened amongst those just coming up; earth-up and stake others as they become ready. *Sea-kale*, thin out the buds so as not to allow them to crowd each other, and water twice or thrice in the season with a weak solution of salt and water, which will benefit the plants, and dislodge snails and grubs. Two ounces of salt to a gallon of water will be sufficient. *Vegetable Marrows*, plant out this very useful vegetable on a rich piece of ground, where there is plenty of room for it to grow.

### FLOWER GARDEN.

The past week has been all that could be desired for the busy operations connected with this department. *Verbenas* and *Petunias* should now be turned out into their summer quarters if not already done. Peg down all the shoots after the planting of the beds. Strong plants of *Phlox Drummondii* to be planted out, it is valuable for forming large masses. The *Lobelias*, *Nierembergia gracilis* and *Campanula Loreyi* are suitable for edgings to baskets. Plant out Dahlias into the flower-borders, fill up the holes with some good compost, and finish with staking each plant. The *Pæonies*, *Phloxes*, *Delphiniums*, and other tall herbaceous plants to be properly staked. Roll, mow and clip the edgings of grass lawns, and use the daisy-rake at intervals. Do not neglect to stir the ground after heavy battering rains. Thin out annuals, remove all decayed leaves and flower-stems.

### FRUIT GARDEN.

Continue to nail-in the young shoots of all kinds of fruit trees as they become sufficiently advanced, and keep the finger and thumb at work amongst superfluous ones. Give the Strawberry-beds a final stirring, and have some available material at hand for laying about them to prevent the fruit from being splashed with grit during heavy rains. Keep a number of figure-four traps constantly set about the beds to catch mice, as in some places they are very troublesome in Strawberry-plantations. Keep the lateral shoots of Vines stopped at the first joint; the practice of removing them entirely is not to be approved of.

We should always endeavour to assist the operations of Nature as well as judiciously check overluxuriance, and in this respect no tree is more tractable than the Vine.

#### STOVE.

Cultivate with all expedition the various young stock intended for blooming through the autumn and winter. The *Euphorbia jacquiniiflora* is a great favourite when planted three in a pot. The *Gesnera elongata* should not be forgotten, nor the *Begonia manicata* and *incarnata*. Some of the *Justicias*, *Geissomerias*, &c., are worthy of attention for the same purpose. The Orchids require a vast amount of moisture in the atmosphere, and their blocks to be syringed frequently.

#### GREENHOUSE AND CONSERVATORY.

Free ventilation, with plenty of moisture, will now be necessary. Give every encouragement to the growth of the *Azaleas* intended for forcing early, watering them freely, especially if pot-bound, with weak and clear liquid manure; stopping unequal or overluxuriant shoots with the hand, in order to render the plants compact. The *Camellias* which have completed their growth to be cooled down, no artificial heat should therefore be given them. If they are luxuriant in growth, a curtailment of water should be resorted to for a month, giving merely sufficient to keep them from flagging. The present is a good time to sow Chinese Primroses for a winter supply; get them potted-off early, and keep them shifted and growing in a cool frame where they can have plenty of air, and secure protection from heavy rains. Use a light, rich, loamy soil. W. KEANE.

#### DOINGS OF THE LAST WEEK.

READERS must now put up with short notes, as the mind gets a sort of racked what to do, and how to do it. What would many of our good old gardeners think if they again came amongst us, and found that in addition to the usual crops in their houses, they were expected to turn out ever so many thousands of strong bedding plants every year? They would then form an idea of the relief that the absence of the family for a week or two would give in clearing a shelf of Strawberry plants, or a pit of Dwarf Kidney Beans, and also the value of every spare sash of glass however old and crazy for helping on something or other.

We did not prophesy right as to our work, especially bedding. The weather up to the 20th was splendid, but now the glass is falling and threatening wet, and owing to the deluges of the week before we were unable to get the ground in good order as we expected, and we deferred bedding-out in consequence, though, if at all dry above head, we hope to turn out many things before the end of the week.

#### KITCHEN GARDEN.

Sowed succession garden Beans, Peas, Kidney Beans, Parsley, various Herbs, Turnips, Radishes, Spinach between Peas, Leeks, Onions for salads, Lettuces of kinds. Stirred the ground amongst Peas and Beans, staked the former according to their height. Watered Cauliflower with diluted water from the dung-hill, and as dung is scarce depend upon this a good deal for good succulent vegetables. Run the hoe among Carrots, Onions, &c. Find that Parsnips have not done as they ought. Threw a little salt over Asparagus-beds, and would have made more plantations only got out of plants, not having so many as I expected. These plantations are best made when the one-year-old seedlings are 3 inches or 4 inches high; but I would prefer planting when the plants were a foot in height, to planting before the buds began to move. In all stiffish ground the best plan is to plant on the surface, and raise a ridge over the rows with leaf mould and some sandy matter, and mulch with what is readiest, as short grass or muck in summer.

#### FRUIT GARDEN.

Much the same as last week, in looking after insects, dis-budding, stopping, and thinning out the fruit, which we have not done half enough as yet. Prepared beds that had helped on bedding plants, &c., for Melons, by getting some heat below them. Grumbling for want of means will do good to no one. Some people with the dung of a stud of horses to go to, have yet nothing to get on with. Others with the dung of three or four beasts effect wonders. We are none of these wonderful folk; but for hastening on anything with *fermenting material*

we must depend chiefly on tree leaves, and our supply was limited this season. The dung of three or four horses is less than a trifle after getting Mushroom-material out of it. However, about this time we get vastly independent. We pass huge heaps of farmyard manure steaming away, with hardly a semblance of covetousness or envy, and all through the mowing of the lawn. Nothing is better for raising a strong heat, the need is to moderate it and keep it from flaring up and out all at once. Well, about this time we collect together old hay that had been used for protecting plants in winter and spring—this in the first case being chiefly secured from the first mowing of part of the lawn that does not come much in sight of the mansion, and which we allow to stand longer than the rest. To this we add old stubble, and litter that had been used for a similar purpose. To this we add about an equal proportion of short grass, and if the litter is at all wet, a cartload or two of the dry litter that comes from the stable horses. We will suppose that the frame stood above a bed—say from 12 inches to 15 inches deep of dry leaves that have already done good service. The frame is moved, the leaves are whipped out, and a bed made of the litter and grass well mixed, so that the latter shall heat and be moderated by the former. In the last layer a few of the leaves are also added, the bed will now be—say 20 inches in height when fairly trodden, on this is placed about 8 inches of the decayed or rather decaying leaves, so that the heat given off will be sweet before reaching the roots. This is not all, the frames are shallow—some 10 inches in front, and 20 inches behind, so that care must be taken, both that steam shall not rise and also that it shall not enter, if linings should require to be given in the autumn from similar materials. Well, then, after securing this layer of leaves we build a wall of these leaves about 9 inches deep all round for the frame to stand upon, leaving the bed all that more shallow inside. Fill that with soil, raise it 2 inches or 3 inches above the bottom of the frame, beat the soil firmly round the sides, and in three or four days no better place could be found for planting out Melons, and getting one fine crop from them, if the season is at all propitious. To insure high success only one thing more is necessary. Insert some small round drain-tiles by which you can moisten the roots without wetting the surface as the fruit approaches maturity. In autumn and winter you will find that the grass has helped to thoroughly decompose or burn out into good manure what otherwise would have been of little use. We are thus particular because many wish to grow Melons after their bedding plants, and many have inquired how they could bring their mowings to help in this and similar purposes. There is no danger provided a sufficient covering of sweet material is put over the grass and litter. Wherever there is a small lawn, a little bottom heat may thus be procured from spring to autumn. The lastingness of the heat will depend on the mixing and skill.

When not so used, such mowings instead of polluting the atmosphere should be covered with the materials of the rubbish-heap, which will be much enriched in consequence. Beds less than half the thickness mentioned above, with 3 inches of half-rotten leaves, 2 inches of leaf mould, and 2 inches of sandy loam and leaf mould, are just the places for pricking out many things for the flower garden in April, and onwards. Of course, we all might like sweet heated dung, or tan, or flax refuse, or spent hops, as being better for all such purposes; but if these things are unobtainable, as they often are, it will always be a better satisfaction to be able to say, "We made the most of the little means at our disposal," instead of doggedly saying, "It is no use trying, it can't be done."

#### PLEASURE GARDEN.

Our ground being heavy we have not yet worked it to please us for going a-head with planting bedding plants. The rains have delayed us. Most of our plants being in the ground in temporary pits, a few days make little difference, and we find that much depends on the ground being well aired and warmed by turning the heated surface down repeatedly. In other words, from digging in sunbeams. We have more faith in such preparation than in early planting, and protecting in the beds. There is nothing we dislike so much as potching the ground and planting such ground as ours when wet. It would not work kindly for the whole season afterwards, and besides what a sorry figure the men cut at the work! and how the walks and grass and everything else get dirtied and out of place. It is much better to put the steam on in a fine day. We expect to be in the thick of it by the end of the week, if the weather is propitious.—R. F.

## TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**FERNS** (*W. B. Burton-on-Trent*).—Messrs. Groombridge, Paternoster Row, are the publishers of the book you mention.

**HEATING GREENHOUSE** (*Patelin*).—Yes. We think one of Riddell's Patent Cottage Boilers will keep your small greenhouse tolerably warm in winter, if you have a three-inch iron pipe for the hot water to pass all round the interior. Write to Mr. Riddell, tell him what you require, and ask him for information.

**THINNING GRAPES** (*Avarus*).—Cut off one of the bunches from each shoot without any reservation. If one bunch is smaller than its fellow, cut off the smaller. If they are of equal size cut off that one which is furthest from the stem.

**SOIL FOR AMARYLLIS BELLADONNA, AND VALLOTA PURPUREA** (*Malpas*).—Good maiden loam, such as you would mix for Pelargoniums, and one-sixth sand with it, and nothing else, is the soil for the *Amaryllis belladonna*, and for *Vallota purpurea*, and both of them will keep better in a cold pit during the winter than anywhere else. But one who really understood how to cultivate bulbs, would be able to grow the *Vallota* rather better in "a warm dry room," the danger being in too much warmth, too much dryness, and too little air.

**ASPARAGUS FAILING** (*An Old Subscriber*).—We have not heard of a general failure of the crop this year. We recommend you to continue abstaining from cutting, and to give abundance of house sewage or other strong liquid manure twice a week throughout the growing season. If no shoots are produced, then, of course, the plants are dead, and you must plant a fresh next spring. There is nothing stated by you which accounts for such a mortality if the plants are dead.

**SEWING FERNS** (*Polypodium*).—The following directions we extract from "The Cottage Gardener's Dictionary":—"Several of the finest Ferns cannot be increased by division; or, if they can, several years elapse. If right means are followed, they may be raised by seed. This requires a constantly humid warm atmosphere, and little, if any, sunshine. Procure a wide earthen pan, a hand or bell-glass that will go within it, and rest on the bottom, and a shallow wide pot that will stand within the glass and above the rim of the pan 2 inches or 3 inches. Fill this pot half full of potsherds, and upon them a sufficient number of small pieces of turfy peat, mixed with small pieces of sandstone, about the size of peas, to come up to the pot. Then take the frond of any Fern that is full of spores or seeds, and, with the hand, brush them off upon the prepared pot, set it in the pan, place the glass over the pot, and fill the pan nearly with water. Place the whole in the warmest part of the stove, shading it from the sun. The small pieces of turf and stone can be easily separated, and the seedlings on each put into small pots, without any danger of destroying them by the process of potting. In the moist atmosphere of the Orchid-house, several species of Fern will come up spontaneously in the pots, baskets, and upon the blocks. These may be carefully detached as soon as they are large enough, and potted in small pots, placed for a time in a shady situation, and they will soon make nice bushy plants. Ferns require a light open soil. A compost of sandy fibrous peat (we parts, turfy loam one part, and leaf mould one part, with a free admixture of sand will suit them well."

**GAS TAR TO APPLE AND PEAR TREES** (*A. F. T.*).—Painting the stems with gas tar is the cause of the deaths among your Apple trees, and of injury to your Pear trees. It is violently poisonous to them, and the poisonous constituent probably is the kresosote.

**VINES FOR A GREENHOUSE** (*Reuben Saxton*).—You had better confine yourself to four Vines in your 16-foot greenhouse, and for your purpose the Black Hamburg will be the best. We think that from such a small house the profits from sale of the fruit would be very limited.

**MANURING ROSES** (*L. C.*).—Yes, a little guano sprinkled upon the soil over the roots is better than liquid manure in wet weather. We do not think that diluted urine alone is equal to guano; but the sewage combining all the house drainage is nearly or quite as good a fertiliser. If we used urine we should add a pint to a gallon of water.

**PLANTING VINES IN VINERY** (*B. W.*).—The Grapes will ripen very nicely if you secure means of giving plenty of air, and yet shut in the sun heat early in the afternoon, taking care to give plenty of air until the Vines begin to break naturally. We would prefer planting the Vines against the back wall; but if you cover the roof very thickly the soil will get little benefit from the sun's rays.

**SEWING CAMELLIA SEEDS** (*Idem*).—Camellia seeds come up best when sown as soon as they are ripe—in fact, when kept long they are made to germinate with difficulty. We would take them out and soak in water at 130° for five hours and then sow; or water with warm water, and cover the pots with a glass square, and moss over it to keep the heat in. See "Names of Plants" for another answer.

**DICKSONIA ANTARCTICA, &c.** (*St. L. R. M. Tighe*).—The tree Ferns you refer to will flourish in a mixture of peat and loam, and in a temperature of from 50° to 55° in winter, up to 80° and 85°, and 90° with sun heat in summer. To established plants, if you have some imported ones, give plenty of heat, a moist atmosphere, but little or no water until leaves and roots break; then pot or tub, and grow and water freely.

**PROTECTING GREENHOUSE GLASS FROM HAIL** (*Medicus*).—If stout glass be employed, 24 ozs. to the foot, it is rarely injured by hailstones. Canvas blinds on rollers are an effectual protection. The Farmer's Insurance Office, Norfolk Street, London, insure against injury by hailstones.

**PEAR BLOSSOM NOT FRUITFUL** (*J. R. W., New Forest*).—If your border had 2 feet or 20 inches of good soil instead of 4 feet it would have been better for them, and means taken to prevent the roots getting down. The excessive wet, not only at the roots, but the constant drizzle and fog when in bloom injured many trees, as the pollen never was dry enough to perform its functions. We found Apricot blossoms were rotting at the core even before the severe frost of the Sunday morning. The orchard-house will keep the bloom dry. You seem to have plenty of ventilation. The heat for such a house would be 1 foot in front, and the same at the ridge, with two or three openings in the back wall level, or a little above the ground level, and doors open in extra hot weather.

**GLASS CAUSING SCORCHING** (*Fitrum*).—Your tradesmen told you quite right, all glass will burn if the free admission of air is not attended to. The cheapest sheet glass called itra is the most likely to do so; but that and 3rds are chiefly used in large establishments, and there is no complaint about burning. If there should be a spot here and there, it is easy to daub it with putty or paint. For such a house as you describe, useful but not ornamental, good cheap glass at 2d. per foot, ranging from 13 ozs. to 16½ ounces, ought to be sufficient. If you prefer 21-ozs. it will cost from 3d. to 3½d. per foot out to the sizes you want if at all moderate—say 20 inches by 10 inches, or 12 inches or so. If you wish finer glass, as all 3rds, 2nds, or 1st, you must pay accordingly. We think the common sheet, ranging from 2d. to 3d. per foot according to weight is quite good enough for your purpose.

**MARIE LOUISE PEAR UNFRUITFUL** (*P. P.*).—We advise your examining the roots in autumn as you suggest; but from the abundance of bloom and the fruit not standing, we have doubts if the roots of the tree have enough of moisture. Such appearances are often produced from extreme dryness and extreme moisture, but the latter can hardly be the case with such a bed of sand beneath. We presume your climate is not good enough for the *Fitrum*. Nonpareil. All you can do is to keep the roots near the surface so as to encourage the making of short-jointed wood, and mulch or cover the ground with tiles to keep it moist as well as warm. Are you sure that enough of moisture is not given? Such cracking is produced by various causes, such as a high dry temperature, and a deficiency of moisture at the roots; and then again by plenty of moisture at the roots, considerable warmth, and a dry cold atmosphere. In the one case the fruit swells too fast for the root-action, in the other it does not swell fast enough.

**FORCING SEA-KALE** (*Idem*).—You would see much about Sea-kale forcing and growing in "Doings of the last Week." We never grew it in pots; but if you have it in large pots and wish to keep it in them, you had better plunge them half in the ground or more during the summer, leaving an open space below the bottom of the pot to let water escape freely. These watered and mulched in summer would be ripened by November, and the leaves removed; you could then take the pots into any dark place in succession, where there was a heat of from 50° to 55°. We should prefer planting out now and taking up as wanted; but provided the plants are well nourished in summer with manure water, and at times with salt water—say a handful to five gallons, and keeping it off the leaves and crowns, we see nothing to prevent growing and forcing in pots.

**PEACHES ON GLASS-COVERED WALL** (*A Constant Subscriber*).—Yours is one of those puzzling cases that even if we knew more we might not be able to decide. Many of us have been disappointed this season with Peaches not standing as we expected after such an autumn as the last. The early ones had far too little sun, and, though they set, many dropped, which showed the foundation incomplete, as the young fruit when cut were black at heart. The only safety in dull weather is to keep the houses airy and cool, and the roots neither too wet nor too dry. We should almost suppose that the roots had been in the one condition or the other. The only thing you can do now is to lessen extra vigour by severe nipping in summer, and root-pruning if necessary early in autumn. In the late-house we would advise a severe thinning at once, and a careful examination of the soil; if dry below the fruit will be sure to drop.

**INSECTS** (*Tom Pounce*).—Your Cerastium tomentosum has been destroyed by the larvae or grubs of the common daddy-longlegs, now full grown. Wait till the perfect insects appear, and set children to catch every specimen, and then your plants will be safe next year.—W.

**PLANTING PERILLA** (*Ben-a-Mucky*).—It grows as tall as moderately-vigorous plants of Tom Thumb, and it may be planted with good effect in the centre, or on the outside of all the plants in all the books and catalogues, provided always that the plant behind it is not of less stature than the *Perilla*. Nothing but the height need keep *Perilla* on a bed, or part of a bed, or any border, or front of trees, or walls, or where flowers are wanted, although its own flowers are not of any account. The next thing depends on taste and practical skill, and is the training down of *Perilla* to cause it to suit lower kinds of plants. Taste and practical skill can do anything with *Perilla* that way, planted from 10 inches to 1 foot apart.

**FLOWER GARDEN** (*D. A. Glasgow*).—The large bed of Roses being permanent should have the edging of the same description—say *Cerastium* instead of *Labellia*; either way Stocks will do capitally inside the edging. No. 1 should be three diameters in length; it is 5 feet across it should be 15 feet long. But 6 feet is the more usual diameter of circles like No. 2, and beds like No. 1, then 18 feet would be the length of the latter.

**HIMALAYA PUMPKIN SEEDS**.—Some years since we had the pleasure of distributing these seeds. We have lost the stock, and having now an application for some, we shall be obliged by any of our readers supplying us with a few seeds.

**PEACH LEAVES DISEASED** (*R. N. M.*).—They are what gardeners term "blistered." It arises apparently from sudden vicissitudes of heat and cold, and discordancy between the temperatures in which the roots and branches are growing. Such blistering never occurs to Peach trees in a peachery.

**RED LEAD MIXED WITH SEED** (*X. Y. Z.*).—It does not destroy the birds, for the best of reasons—they will not eat the seed, nor will the red powder.

**DESIGNS FOR SMALL COTTAGES** (*Rus in urbe*).—No such answers were given at our office. Our reply to your query brought other applicants, and we have no copies left; but we shall have a supply this week.

**NAMES OF PLANTS** (*W. Lilly*).—*Tritoma media*. (*C. P.*).—1, *Celsia*, and apparently, *subinata*; 2, *Barbarea praeox*; 3, *Carex riparia*. (*B. W.*).—*Phlox subulata*. (*B. B.*).—1, *Bignonia picta*, will do in a greenhouse; 2, *Caelyanthus floridus*; 3, *Muscari cosinum*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

MAY 27th, 28th and 29th. BATH AND WEST OF ENGLAND (City of Wells). *Steward*, S. Pitman, Esq., Manor House, Taunton. Entries close May 1.  
 MAY 25th and 29th. HULL AND EAST RIDING OF YORKSHIRE. *Sec.*, Mr. J. Hooton. Entries close May 14th.  
 JUNE 3rd. ESSEX AGRICULTURAL ASSOCIATION. *Sec.*, R. Emson, Slough House, Haulstead. Entries close May 10th.  
 JUNE 4th and 5th. BEVERLEY AND EAST RIDING. *Sec.*, Mr. Harry Adams  
 JUNE 12th, NORTH HANTS AGRICULTURAL SOCIETY. *Sec.*, Mr. H. Downs. Entries close May 21st.  
 JUNE 26th and 27th. SUFFOLK (Woodbridge). *Sec.*, Mr. J. Loder, jun. Entries close June 5th.  
 JULY 3rd. PAKSCOT. *Sec.*, Mr. James Beesley. Entries close June 21st.  
 JULY 9th, 10th, and 11th. LEWIS AND WEST RIDING. *Secs.*, G. Newton and J. Wade. Entries close June 21st.  
 SEPTEMBER 9th. WORSLEY AND ARMLEY (near Leeds). *Sec.*, Mr. Robert Hoyle, Armley, near Leeds.  
 DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

### CRUELTY TO SITTING HENS.

WOULD you allow me to draw the attention of your poultry readers to an error of management, now quite too prevalent among the breeders of valuable fancy poultry—viz., the permitting hens of great value to sit out two or even more sets of eggs in succession, and so doing under the false impression that she obtains rest by incubation. I have known several friends this present season, who have weakened beyond restoration specimens that would not have been disposed of for any price, however great that might have been offered for them, by permitting them to continue nesting for two months in succession, or even a longer period. It is quite foreign to my ideas to prevent hens (however valuable), sitting at all, for, contrariwise, I believe it most beneficial and restorative. It is prolonging unnaturally the fever always attendant on broodiness, that produces after-ill-consequences, and, most probably, paves the way to a consumption that is altogether incurable.

If what I have just written calls to reflection any poultry friend now committing this mistake in poultry-culture, before the effects are irremediable, it will fulfil the wish of—EDWARD HEWITT, *Sparkbrook, Birmingham.*

### CROSS BETWEEN THE WILD AND DOMESTIC GOOSE.

A CORRESPONDENT of the *Prairie Farmer*, speaking of the hybrid between the wild and domestic Goose, says they frequently "pair like other Geese, and lay quite a number of eggs, yet their eggs will not hatch." He has tried them repeatedly, but the eggs were always rotten at the expiration of four weeks—the period of incubation for both the wild and common Goose. He says the mongrels yield more and better feathers, and can be picked oftener in a year than common Geese; that they are larger than either of the parent stocks; that they are stronger and harder than the common Geese, smaller eaters, and more easily reared. In winter "they sit on the snow and ice, and keep up their wild yells night and day." He gives the testimony of his wife, that the eggs of these mongrel Geese "make better pancakes than any other eggs she has tried."

The editor of the *Boston Cultivator* calls attention to this fact, and says he has heard before that these mongrel Geese sometimes lay, but never heard of an instance of their eggs having hatched. C. N. Bement, in an article written for the *Rural Annual and Horticultural Directory* for 1859, mentions the same fact. Speaking of the American wild Goose, he says:—

"This bird by all foreign writers is called the Canada Goose. Most writers on poultry call it a variety of the common Goose; but it is no more a variety of Goose than the Swan, which it greatly resembles. Cuvier seems to doubt whether it is a Goose at all, and says it cannot properly be separated from the true Swans. We once possessed a wild Gander that had been pinioned by a shot in the wing, which mated with a common domestic Goose, and we bred from them for more than ten years; but their produce was not fruitful, although they laid eggs. The hybrids never showed any disposition to pair or mate with either the wild or domestic Goose. They partake largely of the wild habits, and if their wings are not clipped spring and fall (and more particularly in the spring), they are very apt to fly away and not return."—(*Genesee Farmer.*)

### BEE-KEEPING IN CORNWALL—SIZE OF HIVES, &c.

YESTERDAY (15th May), I had a fine swarm from a hive which stands with two others at a distance from my house. I certainly did not expect a swarm, as the day, though fine, was windy, and such as I thought an old queen would not venture out in.

I lived the swarm in a straw hive with nine frames, similar to those used by "A DEVONSHIRE BEE-KEEPER." It is 13 inches by 11½ inches, and 9 inches in depth. I am much pleased with it, and think it will answer exceedingly well, though constructed on a simple plan. I have no glass in it. In fact the space, three-eighths of an inch, allowed between the top of the frame and the crown-board, gives such facility for inspection that there is no occasion for it to any one of moderate experience in the management of an apiary. I wished to have some three or four straw hives of the above description made for my swarms this season, but fear that one more is all I shall be able to get made—my man having so much other work to get through at this season of the year.

When ordinary hives are furnished with the Woodbury comb-bar, what distance should there be between the under part of the bar and the floor-board? I should imagine that the boxes should be something less than 9 inches in depth, so that the combs may fit without cutting into the Woodbury compound-frame. This is indeed an admirable contrivance.

Is the Woodbury ten-framed hive too large for common black bees? It strikes me that it is not; as "B. & W.'s" hives, 13 by 13 by 9 inches, will contain, unless I miscalculate, just as much as your present ones.

I am having Woodbury comb-bars fitted into my common boxes and square straw hives, so that next spring they may be removed early into my new straw hives with compound-frames.—F. W. P.

[Ordinary bar-hives, to interchange combs with frame-hives by means of the compound bar-frame, should be 8 inches deep inside. This (allowing three-quarters of an inch for bars and the space above them), leaves 7¼ inches below the bars, and will admit of free interchange of comb without any cutting whatever.

The Woodbury ten-framed hive is probably not too large for a strong stock of black bees, with a first-rate queen, in a good locality. It is besides always easy to contract it as much as you please, by a moveable partition on one or both sides fitting into the frame-notches.]

### LIGURIAN BEES—SEASON IN STAFFORDSHIRE.

I NOTICE in your Journal of the 20th inst., that Mr. Langstroth is of opinion that the Italian bee is much more irascible than our own indigenous species. This my own experience fully corroborates, although the contrary has generally been affirmed. In performing operations with our own bees, I have seldom considered it necessary to have any covering on the hands, which they very rarely sting unless actually pinched, provided that the operator abstains from flinching or making sudden or hasty movements; but with the Italians it is far otherwise, as they attack the hands without hesitation, so that it is essential for them to be fully protected.

My Italian stock, obtained last year from "A DEVONSHIRE BEE-KEEPER," has far outstripped my stocks of common bees; and on the 19th May I determined to make an artificial swarm on the principle advocated in your Number of the 13th by your valuable correspondent "B. & W.," and this I satisfactorily accomplished. Nearly half of the Italian bees remained in their old hive; so that, with the accession of black bees belonging to the hive whose site it now occupies, it is nearly as strong as before the operation, and will be in condition to give out a very strong second swarm when the young queens come to maturity. The new hive under the old queen is also well peopled, and will, I doubt not, do well.

The driven bees were extremely angry, and for two hours or more attacked every one within a hundred yards of the hives, and are still rather apt to assault persons who approach close to their hive. I succeeded in catching the queen, which is a very fine, distinctly-coloured Italian, and so heavy that I think she would probably fall and be lost if she attempted to lead off a natural swarm.

As the swarm is put into a different sized hive from the old

one, I was obliged to drive the bees into a box the size of their hive, and then transfer them to the bar-and-frame-hive they now occupy. My black bees are three weeks earlier this season than last.—J. E. B.

P.S.—The mortality this winter has far exceeded that of 1860-61 in this district (Wolverhampton).

INOFFENSIVENESS OF LIGURIAN AND FEROCITY OF GERMAN BEES.

I MUST dissent entirely from the statement made at the recent meeting of American bee-keepers to the effect that the Ligurian is more irritable than the common species, and its sting more painful. On the contrary, I have myself proved to demonstration, that the Ligurian bee is by no means an irascible insect, whilst two competent and impartial witnesses have already testified in the pages of THE JOURNAL OF HORTICULTURE, to the fact that its sting is less poisonous than that of the black bee.

The following story from the German "Bee Journal," certainly appears to bear out what was stated at the meeting regarding the ferocity of the ordinary black bee in Germany:—"One day last year a man named Menzel, somewhat above thirty years of age, a landlord in Tizbic, Bohemia, went among his bees in a drunken condition, when thousands of them attacked him and stung him to death. In order to remove the corpse from the neighbourhood of the hives, the people endeavoured to hinder the flight of the bees by means of hand-syringes, and to keep themselves from their rage they had to fetch the bee-dresses which are used when depriving them of honey. The bees would not even quit the corpse, and water had to be poured over it to drive them away. So irritated were they that poultry and other animals were not safe from their rage; dogs were howling with pain, whilst fowls and geese flew screaming through the air."—A DEVONSHIRE BEE-KEEPER.

DZIERZON'S REVIEW OF AN ENGLISH BOOK ABOUT BEES.\*

NEARLY three years ago there appeared a work on bees from the pen of Mr. James Samuelson, a well-known merchant in the town of Liverpool—a gentleman who, in addition to success in commercial pursuits, combines public spirit and scientific attainments of no mean order—forming the second part of a series in which the marvels of natural history were brought before the public in a popular and attractive form. Mr. Samuelson's little work has recently attained the honour of being translated and republished in Germany with the additional statement on the title-page that it is "for bee-keepers and naturalists." In this new form it has come under the notice of Herr Dzierzon, the eminent German apiarian, who in the German "Bee Journal" says:—"Striking is the apposition on the title-page 'for bee-keepers and naturalists.' According to the index of the book the author seems to have written more for the friends of nature. Had the writer dedicated his book to admirers of bees in general, there would be something less striking in it; but to be able to write for bee-keepers one must himself be a practical bee-keeper, which I cannot believe the author to be. . . . How dangerous it is to write for bee-keepers if the writer be not himself a thoroughly practical apiarian is proved in many pages of this book."

Herr Dzierzon then proceeds to point out the following erroneous statements in Mr. Samuelson's work:—

1st. That the larvæ or grubs are fed at first with honey, then, as the days of the young ones increase in number, with honey mixed with a certain quantity of bee-bread. 2nd. That the bees seize upon a worker larva and transfer it into a royal cell hastily constructed for the purpose. 3rd. That the eyes of bees enable them to seek out the appropriate cell in which to store their treasure; while the reviewer remarks, "it is the sense of feeling which directs them, as they can do all in its usual order amidst absolute darkness." 4th. That if the drones driven out into the cold should attempt to return they are mercilessly slaughtered. 5th. That the matrons of the hive relieve the bees on their return home of the bee-bread. 6th. That the bees which accompany the queen from cell to cell for the purpose of oviposition take care that she lays only one egg in each cell, or in case she should deposit more, as sometimes happens, they remove all but one and place them elsewhere. 7th. As soon as

the usual term of sixteen days has expired, and the guardians of one of the royal cells receive intimation by the movement within that a new monarch is about to make her appearance, the queen mother approaches also with the murderous intent of attacking and slaughtering her child as a rival, and foiled in this design she leaves the hive; while Herr Dzierzon says, "it is known that the old mother leaves the hive with the first swarm when but one of the royal cells is covered and the larvæ begins to metamorphose into a nymph."

This list of errors appears quite formidable enough, but the reviewer has yet another crow to pluck with his author, who whilst giving in his adhesion to the truth of parthenogenesis cites one of Huber's experiments as proving Herr Dzierzon himself mistaken in believing that the queen bee has the power of laying either worker or drone eggs at will. Upon this subject the reviewer, who was himself the first discoverer of parthenogenesis says—"The author would not have fallen into the mistaken notion that the queen had certain periods for laying first one and then the other sort of eggs, and was not able to deviate from this procedure, if he as a clever practical bee-keeper knew what drone-breeding signifies, and when it generally commences in the normal state. It is known that drone-breeding is the first step towards increasing the species—i.e., to swarm, and that it begins and is continued when there is a feeling of prosperity and growing strength in the colony, but that even in a strong hive and in the best time the feeling of prosperity may disappear, and a sense of anxiousness arise if the queen be deprived of her liberty to get unmolested to every cell; and that, therefore, the queen will be far from having the intention to continue preparations for swarming—i.e., to lay drone eggs, but that she will rather drop her eggs is apparent to every one who has penetrated the economy of the bee commonwealth. From this it may be seen that as correct practical management requires theoretical knowledge, so also only the most perfect practical knowledge can preserve one from errors and false inferences." Whilst pointing out Mr. Samuelson's mistakes, his distinguished critic does full justice to his undoubted scientific attainments, and the review is written throughout in a fair and impartial spirit.—A DEVONSHIRE BEE-KEEPER.

"MORE HAY."—An old gentleman who was always bragging how folks used to work in his younger days, one day challenged his two sons to pitch on a load of hay as fast as he could load it. The challenge was accepted, the hay waggon driven round, and the trial commenced. For some time the old man held his own very creditably, calling out, "More hay! more hay!" Thicker and faster it came. The old man was nearly covered; still he kept crying, "More hay! more hay!" At length, struggling to keep on top of the ill-arranged heap, it began first to roll, then to slide, and at last off it went from the waggon, and the old man with it. "What are you down here for?" cried the boys. "I came down after hay!" answered the old man, stoutly.

OUR LETTER BOX.

GAME BANTAMS (*Amateur de Volaille*).—There is no longer any necessity for specifying weights. In the days of Bantam clubs the maximum weights were 17 ozs. for the cock, 14 ozs. for the hen. They are properly described when they are called Game fowls in miniature, and it would be fatal to all hope of success if they resemble the Sebright in anything but diminutive size. These latter among their chief merits have double combs, drooping wings, and hen tails; either of these points would disqualify a Game Bantam. Diminutive size is very necessary to make a perfect bird; but it would be fatal to success if that one point were attained by the sacrifice of those properties of shape, carriage, colour, and hard feather, that are insisted upon in the Game classes.

FLOOR OF HEN-HOUSE (*A Subscriber*).—Nothing can be worse for the floor of a hen-house than either bricks or cement; they retain damp, and bruise the feet of the birds. Nothing is better than the earth covered 2 inches or 3 inches deep with sand. The surface of this can be raked free from excrements every morning.

PARROT EATING ITS FEATHERS (*C. S. — Peaston*).—We can recommend no other treatment than that we inserted in our last Journal in answer to "FANNY FERN."

LONDON MARKETS.—MAY 26.

POULTRY.

There is still comparative dearth; but indications are not wanting that a better supply is "looming in the future."

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 70.2° and 47.1° respectively. The greatest heat, 90°, occurred on the 7th, in 1846; and the lowest cold, 33°, on the 5th in 1856. During the period 137 days were fine, and on 105 rain fell.

THE CAMELLIA AND ITS CULTURE.—No. 6.

VARIETIES.

GUIDED by what we have heard verbally and by letters from several correspondents, there seems to be considerable anxiety to see the multitudinous list of varieties advertised in sale catalogues, cut down by some one whose practical experience can be depended upon, so that

both gardeners and amateurs with limited accommodation could fix upon a dozen, or two dozen, or more varieties, according to their respective requirements, and not be so disappointed in the aggregate, as most of us, at least, occasionally happen to be after proving novelties with high-sounding names, and grand certificates of character. It is no part of our plan to inquire who are to blame for this questionable state of matters, for supposing we were ever so captiously inclined, ever so disappointed for the time being, we would hesitate before expressing an unqualified condemnation on any given person or thing, because the longer we live, and the greater the range of our experience, the more fickle and sportive do some of the examples of the vegetable creation appear to our senses. Some of the varieties of Camellias are not at all fixed in their character, and hence the origin of much disappointment and chagrin; and although much can be done by the hand of the experienced cultivator towards reducing the more wayward of them, not only into a flowering state, but by careful attention to their habits into a tendency to produce flowers of the most desirable form. Albeit! the best prescription and the most careful practice often fail to obtain what, for want of a better name, comes under the category of chance, accident, and such like.

There are now and again some beautiful individual examples of flowers or plants which have a greater tendency to produce blooms that possess in an imperfect degree the organs of fructification; but these examples are somewhat rare. Of course, it is almost unnecessary to mention that all double and perfect flowers are but monsters, botanically speaking, and it is a wonderful and an interesting theme to watch, or, rather more correctly expressed, to note progressive development from the old single red, now and for a length of time, largely used as stocks to the more perfect flowers which adorn our green-houses and conservatories during the inclement portion of the year. Here are stamens surrounding the ovary and its adjuncts like little pedestals, clothed where the anthers containing the pollen ought to be, with petals of irregular form, and thus destitute, in so far as they are

individually concerned, of reproductive power; but so long as the pistil and its adjuncts are perfect there are hopes of fructification by applying pollen from other varieties. From this strain varieties have been produced possessing all the characteristics of first-rate flowers, even although subjected to the canon of the florist; but by far the greater number revert to their normal form, and are thus retrogressive in their tendencies, and, unless for purposes of fructification, are worthless in the eyes of all amateurs and cultivators. Of course, there are exceptions, the very best of which, speaking of those with petaloid stamens, is undoubtedly Chandler's elegans, a grand soft rose, large smooth outer petals, and the petaloid masses in the centre blotched with rose and white; vigorous in habit, and an abundant bloomer. It thus differs from Chandleri, Donckelaari, tricolor, reticulata, and corallina, all of which, in large collections, it is desirable to cultivate both for decorative effect and "breeding" purposes, in having its stamens clothed in the manner above described, and is, therefore, difficult, although possessing a perfect ovary, to get to fructify. All the others are perfect, botanically speaking, and seed, by due attention to small matters, somewhat freely.

The most worthless of all sorts are those entirely destitute of the organs of fructification, and imperfect both in form and disposition of petal. Caryophylloides is one of the best of these, and could not be tolerated in any collection were it not for its variegated and blotched petals. Collettii, Colvillii, Francofurtensis, Marquis of Exeter, Napoléon d'Italie, Persio, Althæaflora, Presse's Eclipse, Punctata, Bruceana, and Carbonaria, which is something like the colour and form of Hollyhock Memnon, are all of this cast, and are good only for purposes of inarching better ones upon. Many others could be named, but these are a few that have obtained some notoriety.

In naming a selection we shall be guided entirely by the fruits of our own experience, which must be somewhat circumscribed. It is not enough, we opine, to pass an opinion upon the merits of individual flowers without knowing something of the general habit of the plants from which they are taken, else the characters ascribed to them, at all events for the benefit of small growers, must be taken only for what they are worth. The reports and awards of the Floral Committee since its organisation are certainly entitled to the utmost consideration, and may be reckoned, in general cases, as a safe guide to the purchaser; at all events, any one may rest assured that anything that has passed their ordeal and obtained a first-class certificate, merited such a dignity at the time, however sportive its inclination might afterwards be.

That Camellias are so there cannot be a doubt, for it is possible to exhibit Mathotiana, for instance, a variety of good substance and surpassing brilliancy, with flowers imbricated to the centre, and petals of good formation; and it is also possible, and, indeed, very probable, that if you go and see it the following season, it may not have a single perfect flower. Grow the plant liberally and you may not have an individual bud upon it, although the

plant may be of considerable size. And mayhap, if there were a few buds they would be nearly as large, and infinitely more ugly than the ugliest crimson *Pæonia Rose* growing in the flower-borders.

In the first place we would submit what we have found to be twenty-four of the best decorative varieties—sorts, in fact, which can be depended upon, with ordinary care, to produce quantities of bloom year after year.

*Alba Plena*, or old White, large, and full of petals.

*Fimbriata*, white, with fringed edges; more handsomely built than the other.

\* *Imbricata*, carmine, beautifully blotched with white; a gem when half expanded.

*Hendersoni*, pale rose, large and well-formed petal; extra large flower.

*Saccoi Nova*, rose, deeper in tinge and larger in petal than the above; extra fine.

\* *Henri Farre*, rosy carmine, extra fine form, and abundant bloomer. This variety is almost without calyx, and therefore remains a shorter time in bloom than most other varieties.

*Lady Hume's Blush*, or *Flaves-cens*, creamy white, of great substance, and a free bloomer.

\* *Wilderi*, rich clear rose, perfect-formed petal and flower; first-class in every respect if well grown.

*Jubilee*, whitish ground, dotted and striped with rosy pink, fine-formed petal; at its best when two-thirds expanded.

*Reine des Fleurs*, vivid orange scarlet, fine imbricated flower, exceedingly striking; free in habit and blooming propensities.

\* *Catherine Longhi*, carmine, occasionally striped with white; very fine flower.

*Teutonia*, white ground with carmine stripes, very sportive in its character, sometimes coming half carmine and half white; fine-formed and cupped flower of good substance.

\* *Valtearedo*, charming rose colour, large fine petal; also a cupped flower of the finest proportions.

*Feastli*, pure white ground colour, with chance cerise stripes; petals not so fine-formed, but a noble flower of great depth and size.

*Bothwelliana*, carmine, petals not of so fine formation, but a noble flower of great depth; free and constant.

*Duchess of Buccleuch*, rosy carmine, flowers very large; habit good, and a very free bloomer.

*Alba Imbricata* (Low's), beautiful shade of white, handsome-formed flower, petals rather pointed; one of the very best for chasteness.

*Miniata*, deep rose, fine-formed flower, of medium size, and an abundant bloomer.

*Princess Bacchiocchi*, brilliant carmine, good-formed petals; constant and distinct.

\* *Duchess of Orleans*, white ground, striped and flaked with carmine; petals of the finest proportions, one of the very best flowers, but rather difficult to manage well from having a delicate constitution.

\* *Sarah Frost*, ruby red, occasionally striped with white down the centre of petal; fine form and habit.

*Candidissima*, fine free-blooming white, quite distinct in habit and character from its compeers.

\* *Archiduchesse Augusta*, dull cerise ground colour, veined and shaded with blue; novel, distinct, and constant.

*Beali*, vivid scarlet, large fine petals, scarcely imbricated to the centre; but indispensable for colour, size, and its late-blooming propensities.

We will now name fourteen of the best we have proved, judged after the standard of the florist. These, mark you, in many instances, produce probably a sprinkling of first-rate blooms, which will stand the test of being individualised; although for decorative qualities they are nowhere (unless it be those of them above mentioned), alongside these beautiful new and old varieties for effect. One does certainly incline to cater for the plants producing flowers with nice rounded petals, even although such of them may be but sparingly bloomed; but tell me what would a collection of *Camellias* be without the old white *Fimbriata*, &c. Where quantities of bloom are in request, we must still fall back upon these and such-like varieties, and no jury of ladies in the country would agree to rob them of their high prestige; nevertheless it may be taken for granted that we are all open to grow, prove, and report upon those that are ushered into the market without any sinister motive; to exalt those that merit it, if need be to the pinnacle of fame, and to be equally judicious in forming opinions upon those that turn out after repeated trials to be worthless. Meantime we give the names of twenty-four that have been some time in the market, which may be depended upon for individual blooms, although some of them may not be constant.

Mrs. Abby Wilder, creamy white, occasionally striped with rose; of first-rate excellence, both as to form and quality.

*Cup of Beauty*, white, striped with pink; also extra fine.

*La Maestosa*, fine cherry colour, blotched with white.

*Mathotiana*, crimson, extra large and of fine form; very distinct.

*Monteroni*, white, slightly striped; very fine form.

*Countess of Ellesmere*, white, slightly striped with carmine; fine.

*De la Reine*, pure white, pink striped; good form and substance.

*Archiduchesse Marie*, rich cerise, with a well-defined band of white down the centre of each petal; free bloomer.

*Giardino Franchetti*, rose, blended with carmine; novel and fine.

*Elizabeth Herbert*, salmon, richly marbled with rose; a great improvement on *Admiral Nelson*.

*Emelia Campioni*, carmine, banded with white down the centre of the petal; large and fine.

*Jenny Lind*, pure white, slightly marked with rose; chaste and fine.

*Rubens*, rich rose, good-sized flower, and of good form and substance. *Story*, rosy carmine, fine smooth petal, and good habit.

These, along with those branded with an asterisk in the first selection, are those I have proved best, looked at in this way.

The next best twenty-four in our collection are the following:—

*Alexina*, a pretty mottled light ground flower, of good-formed petals, showing the stamens in the centre.

*Adrien la Brun*, rose, imbricated to the centre; good.

*Amabilis*, red, blotched with white; small but symmetrical.

*Carswelliana*, ruby, with white stripe; good flower.

*Comte de Paris*, cerise; large flower, but rather fleshy in the petal.

*Countess of Orkney*, light ground, striped with cerise; not equal to what was expected of it.

*Duc de Bretagne*, large, rose colour; free both in habit and as a bloomer.

*Halleyii*, dull crimson; a flower of fair proportions.

*Jacksoni*, good bright crimson; showy and distinct.

*Jeffersoni*, bright scarlet, slightly striped, medium size; good.

*Landrethii*, fine pale rose; free and good.

*Optima*, crimson and white; good habit.

*Queen of Denmark*, dullish crimson; good formed petal, rather inconstant.

*Rubini*, ruby red with white stripe; medium size and good form, fine late bloomer, but shy.

Mrs. Carrick Buchanan, fine-formed white; good-sized petal, one of the best late bloomers of Scotch origin.

*Lady Belhaven*, rich carmine; extra fine substance, scarcely imbricated in the centre. Another of the Woodhall seedlings I believe.

*Thomasini*, after the style of *Henri Farre*, but blotched with white; very good form.

*Varischi*, fine shell petal of shining rose colour, occasionally mottled with white.

*Lowii*, good rose; vigorous habit.

*Mania Theresa*, a fine *Cannion*-like flower; extra fine habit.

*Pisani*, good medium-sized white; occasionally striped.

*Centifolia alba*, pure white; large and showy, a good flower.

*Général Zaccari*, soft rose blotched with white; good late bloomer.

*Cruciata*, rose blotched with white; one of the best earlies.

—JAS. ANDERSON, *Meadow Bank, Uddingstone.*

## THE ROYAL HORTICULTURAL SOCIETY'S AMERICAN PLANT SHOW.—MAY 30TH.

The opening-day of this magnificent Exhibition was heralded by a fall of the barometer, which portended no good to those who looked forward to spending a pleasant afternoon among the "Americans," here harmoniously assembled, to promenade the artistically laid-out grounds, and last, and to the great bulk of the visitors at our horticultural exhibitions not least, listening to the admirable music of the Life Guards' band.

The unfavourable presages of the barometer were not altogether unfulfilled, for the morning was ushered in by showers, whilst in the forenoon there fell a thick close rain; but fortunately, about one o'clock the weather began to clear, and though threatening clouds still floated about, the afternoon was tolerably fine.

Of the Exhibition itself, which has been furnished by Messrs. Waterer & Godfrey, of Knap Hill, we can only speak in terms of the highest praise, both as regards the arrangement and the rich expanse of colour that is spread before the eye. On entering the large covered space where the Show is held, we see here a group of white, there a brilliant mass of crimson, deepening at this point to a blood red or purple, or changing at another to a yellow or orange; while a roseate light seems to pervade the whole scene, which, brilliant as it is, is still not dazzling from the quiet green of the leaves peeping forth in places from amongst the clusters of bloom.

The ground, which has been covered over with a kind of canvas, is hollowed out in the middle so as to afford a better view, and is laid out in beds of various shapes, harmonising with each other—some being circles, others more nearly approaching an oval in character, and gently curving outwards in places, and again inwards so as to take off the rectangular outline of the ground.

The centre figure is composed of two circular beds facing the north entrance, with four others of less size forming a line across the tent, encompassed by four clumps larger than any of the rest. Elsewhere, the area is laid out in circles and small beds of suitable outline. The circles, which are mostly planted with standards, are in many cases raised considerably above the surface of the walk, and turfed over all but a small space round the stem; they have thus a very neat appearance.

Directly opposite the side entrance we met with a fine plant of *Kalmia latifolia*, and on the other side another of still larger size with a very thick stem, and certainly 12 feet high. Near this there was a splendid *Barelaynum*, whose large trusses of crimson scarlet flowers were conspicuous among all the rest from every point of view, and especially from a small stage which has been erected at the west end.

Of the many other fine varieties the following are a few of the best:—Everestianum, rosy lilac, everywhere forming a dense mass of bloom, very fine; Curricanum, very large flowers, late, and very good; Brayanum, rosy scarlet, with lighter centre, glowing colour, and fine foliage; Archimedes, bright rose, very brilliant; Album Elegans, bluish, with green spots; Magnum Bonum, very large and showy, rosy lilac, spotted; Onslowianum, bluish, yellow eye; Nero, dark rosy purple, an excellent late sort; Alarm, very distinct, carmine and white, very late; Bylsianum, white and pink; Cessum, deep rose; Prince Albert, a very distinct dark sort with fine foliage; Vandyck, rosy crimson; Lord John Russell, a beautifully spotted rose; Titian, deep rose, one of the prettiest; Voltaire, vivid reddish-crimson; and Purity, quite new, the best of all the whites, being pure white without any blush. Besides these, which are only a few of the most select, there were atrosanguineum, album grandiflorum, Roseum varieties, especially pictum and grandiflorum in fine bloom, as well as two fine beds of hardy Azaleas covered with yellow and orange bloom.

In boxes, Messrs. Waterer & Godfrey exhibited cut flowers of new hybrid Azaleas, as yet unnamed, with large flowers and fine colours, and having the advantage of flowering with the leaves; also some very fine late-blooming Rhododendrons, with large Magnolia-like foliage. Of those which are named, Mrs. Holford is a very fine and distinct salmon pink; Mrs. Milner, a fine rosy scarlet; and Alexander Dancer, a rosy crimson with very large foliage, is particularly good; and so is Celestinum, white, tinged with pale purple. W. H. Sargent is another kind, which on account of its fine foliage, truss, and colour may be considered one of the best.

The only drawback to this otherwise unexceptionable exhibition is the flimsy nature of the canvass with which it is covered—not in one spun, but in two ridges, meeting in a wooden gutter or trough above the central walk. The canvass just reaches the edge of this trough, which appears leaky besides, and the consequence is that during a shower of rain the water comes in the most just where it is wanted the least—above the heads of those passing along the principal walk, which bears unmistakable signs of a considerable inpouring of water at some no very distant period.

Outside, in the gardens, and facing the International refreshment-room, a long border, gracefully sweeping outwards and again retreating at other parts, and taking for its centre the handsome fountains of Barbezat and Durenne, has been filled with Rhododendrons, which produce an excellent effect, especially when viewed from the Exhibition side. Elsewhere the larger beds, where not already occupied by Geraniums and other plants, have likewise been filled with Rhododendrons.

In addition to the horticultural attractions which were offered to the visitors, we may mention that a concert was given in the conservatory by eminent foreign *artistes*; whilst the band of the First Life Guards under Mr. Waddell, and that of the Royal Artillery, enlivened the visitors with their best strains.

The American Show, we may remark, will continue in perfection for a fortnight, and is a sight which no one ought to miss.

### CRYSTAL PALACE FLOWER AND FRUIT SHOW.—MAY 24TH.

By common consent what everybody says must be true, and everybody says there is no place for a flower show like the Crystal Palace. All I can say is, that after being fifteen years on the circuit, and just as many on the woolpack, I have not seen a place yet one quarter so comfortable to judge, to examine, and to see flowers in their element, so to put it, as the Crystal Palace; all but the first show there, when all the light came on the flowers over the shoulders of the visitors—always a circumstance to be avoided as much as possible.

There was a grand improvement in the stages this time. Opposite the Handel orchestra there was a magnificent pedestal, with a vase to match, placed in the very centre with “furnishing” plants in the vase and round the pedestal, done by the authorities solely for effect; and right and left of this “centre piece,” instead of running stages straightwise, the stages were made “pigeon-breasted,” or half-moon-like, with the round side next the eye. The left-hand “breast” was just large enough to hold the two first-prize collections of stove and greenhouse plants, the finest plants of the kind in all the world; and on the right “breast” were the next two collections of the same class.

Then both sides of the great transept were lined with straight stages full of the same description of plants. The four corners of the transept were reserved for Azaleas—and such Azaleas!

Then, under the Handel orchestra another “furnishing” arrangement of Crystal Palace plants was set down as no effect could excel. Verily, if that wedding is to come off in the autumn in or near London, you must certainly employ Mr. Turner, of Slough, to do the furnishing of the flowers, as he did that of the mook conservatory against the back wall of the arcades at South Kensington, or else get a leaf out of the Crystal Palace book on pigeon-breasted arrangements, grand vases, and off-hand setting to suit, which no one, not even the Misses March themselves, can better.

The north and the south naves were set just as you have seen them ever since Mr. Houghton took the book and the staff in hand, and both extended to the very ends of the crystal and bronze fountains. A better immediate effect is produced, of course, when the flowers are all seen at one view, as at South Kensington; but efforts in succession make variety, and also a more lasting impression of a good or a bad quality; and when you add to all that the comfort of a morning’s ramble among the choicest and most varied plants, in perfect security from all weathers, the reasons are obvious why all give the palm to the Sydenham Shows.

In the first-prize collection of sixteen Orchids, Mr. Milford had a fine specimen of *Dendrobium nobile*, *Cattleya amethystina*, two sorts of *C. Mossie*, and a fine *Lycaste Skinneri*. Mr. Woolley next, and his best were the three *Dendrobies*—*fimbriatum*, *densiflorum*, and *Paxtoni*. Mr. Peed next with fair on the face of his collection, of which *Calanthe veratrifolia* was the oldest plant and *Phaius Wallichii* the best grown.

In the next class of ten plants Mr. Milford was again first fiddle. Here his *Lælia Brysiana* could be examined, and it proved to be only a real good variety of *Lælia purpurata*, and all the rest were in Mr. Milford’s best style.

Mr. Lovell, who was next, had the best specimen of *Cyrtocentrum stellatum* that has yet been shown; it was one mass of upright spikes densely set with cream-coloured flowers all in a bush. Mr. Penny and Mr. Wiggins followed with tens of good kinds and sizeable plants; and Mr. Page had an extra in this class, and well deserved it, if only for his *Cattleya Leopoldii*, a grand, proud, purple-looking species of rare proportions.

In the next class of six plants Mr. Milford was again the winner, and his extra kind in it was *Cyripedium hirsutissimum*. Here he and Mr. Green were meriting it, while Mr. Young was looking on, third best and with the only *Sobralia macrantha* that has been out yet this season; and Mr. Bunney had an extra in the run, his best were the two white *Thalassopsea*, and a very nice *Oncidium pulchellum*.

Tall Cacti followed, and, of course, Mr. Green was first with all red ones; and Mr. Waters next, all red but the one white crenatum—that is, *Epiphyllum crenatum*.

Heaths were next, and they were much the same as those over the water. The largest Fern there came next, *Cyathea medullaris*, from Mr. Lakeman; then a host of huge plants of fine foliage, Ferns and stove et-ceteras, of which the following were additions to the stoves at South Kensington:—*Hoya bella*, *Vincas*, *Allamanda nerifolia*; and these to the greenhouses—*Pteroma elegans*, *Statice Holdfordi*, and *Kennedyia inophylla*, and if you put the two lots together you have what a long experience has proved to be the best month-of-May plants for the stove, for the greenhouse, and also for the heathery. Then, if we take the June and July shows in the same way, we shall get at the root of all the best summer plants to be in the fashion—but not the best, however, for comfortable privacy.

The next names I took as the most likely to be of the greatest use, were the newer Azaleas in the first-prize collection of Mr. Turner, of Slough. Mais, a fine orange; Comte de Hainault, red and well spotted in the throat; Miltoni, Sir H. Havelock, Duc de Brabant, and Perfection, with Grand Crimson, the deepest in colour; while Dr. Livingstone, Model, and Petuniflora were of the same unusual tint of colour. Then some Roses, Cinerarias, and lots of things; and Burley’s excellent strains of shrubby *Caleolarias*. It is the best breed of public *Caleolarias* yet out.

Here, also, began the cut Roses in boxes, and I was cut to the quick by the very first of them. I was inside the barrier going against the stream of people, and a gentleman asked me the name of a yellow Rose in the last box to him and the first to me, and as bad luck would have it, Mr. Lane, the great Rose

monarch, was just up behind and heard me saying it was Cloth of Gold, as far as I could judge, for I could see no name. At that instant I caught the card of Mrs. Stodart in front of the stage, and, of course, I blushed like a maiden at being taken in a third time by that lady, and on this occasion in the presence of his majesty of Roses. Her Roses are made of rice paper, and so are all she had there—as Cloves, Carnations, and Picotees with which the florists have no chance, the artificial flowers being much more after nature than some of their seedlings.

Then followed a bed of Carter's bedding Fuchsia Meteor, and it is only when out of pots and out in the beds that the true tricolor Amaranth-like looks are at their best. The beautiful *Coleus Verschaffelti* for bedding-out against purple Spinsch and *Perilla* this summer, was there also in the form best calculated for bedding—that is, stout, standing, and stunted for want of pot-room, and that is just as the best bedders should be at the middle of May. The next was a pot specimen of *Petunia inimitabilis*, the double variety, 5 feet in diameter, from Mr. Salter, gardener to A. Setzens, Esq.; then a large mass of novelties from Mr. Bull, of King's Road, Chelsea, who has come out and come it this season very strong indeed.

Then the Messrs. Lee, who are the best growers of the best of all the Caladiums, the Queen's favourite—*Caladium agryrites*. Mr. Hally next, with lots of his Geranium seedlings, and one of them, the White Lady, is against the variegated doctors by hand entirely; but another cross seedling Geranium, between Bijou and Mountain of Light, by the Messrs. Downie, Laird & Laing, is enough to check all ideas on the subject, save one, and you must guess it. The cross was here represented by two of the seedlings, with the clearest white variegation yet obtained in Geraniums, and more of it than in most of them, but the batch is what is unswallowable, every one of the seedlings of that cross came equally well marked in variegation, and not a single plain green or horseshoe leaf among them all. Now, Mr. "OLD SHOW-MAN," and Mr. "NICKERBOB," it is just about the right time to bring out your ways of making both ends meet if you can do it, and why, if you cannot, let us have no more words about it; but I shall follow the fortunes of the cross in hand from the Messrs. Downie, Laird & Laing aforesaid.

Then a fine lot of variegated and fine-leaved plants from Mr. Williams, of the Paradise Nursery, and lots of the variegated *Scrophularia nodosa*, which struck me as being one of the very best flower-garden plants we have of that stamp, and now that I have got near to examine it I find it is altogether a different thing from the old *nodosa* of that form; but Mr. Williams has the two kinds, and you can judge, perhaps, better than the Floral Committee, who might have mistaken the one for the other. At all events, I hold to my first opinion of it as recommended for Sir Joseph Paxton's garden last summer.

Mr. Bunney had one of the newest plants there—newest to the shows I mean. It is a *Melastomad* of the same section as *Medinilla*, and called *Phyllagathis rotundifolia*, a very fine-ribbed purple leaf after the way of *Cyanophyllum*; and the Messrs. Jackson and Standish were equally as full of fine things as they were at South Kensington, where you will find their share of the space in my notes.

The fruit-stand was loaded with fine Grapes, Pine Apples, Peaches and Nectarines, and pot Strawberries. All the Black Grapes were along one side of the span-roofed-like stage, and the White Grapes on the other side; and rare fruit, such as *Musa* and several varieties of Citrons from Mr. Young, who succeeded Mr. Scott at Leigh Park; a fine bunch of Grapes in a No. 24-pot from Mr. Standish; and a fine dish of Green Limes from the open wall of J. Luscomb, Esq., of Combe Royal, Devon, who has been noted for his Orange, Lime, and Citrons for many a day.

D. BEATON.

### FLORISTS' FLOWERS.

YES! there can be no question about it; for comfort, independence, and facilities for seeing, there is no place for an exhibition equal to the Crystal Palace. Not that I agree with the observations in last week's *JOURNAL OF HORTICULTURE* about the tents at South Kensington. The Botanic Society has for years held theirs in such structures, and I suppose they are in healthy financial condition, and, taking one year with the other, I dare say a fair proportion of fine days would be obtained. The Royal Horticultural Society has, I fear, in the tent matter been penny wise and pound foolish. More wretched structures were never put up; and the maker could not have

had a better notice to all comers to avoid him for the future. It was certainly an odd sight to see a man running about with a spade to make holes to let the water run off; and umbrellas, macintoshes, and goloshes eagerly appreciated at a flower show. At the Crystal Palace all this was avoided, and for some sorts of flowers the atmosphere seemed well suited; but the Geraniums and Roses, however, felt it, and the blooms of the former could be swept up in handfuls. Yet withal, I believe both exhibitors and the public thoroughly appreciate the comfort of the Great Glass House and all its accessories on such an occasion as this. The arrangements which have held good for the past two years have been altered, and the flowers were distributed according to the views entertained by Sir Joseph Paxton: the passage was kept more clear, and a better opportunity for seeing the flowers given. Coming so soon after the Kensington Show, the plants, which in the main were sent by the same exhibitors, were of course very much those of which I gave some notes last week.

In Azaleas Mr. Turner held the first place. His ten plants were the finest that were, we think, ever exhibited; in fact, as one of the Judges said, so good that it was impossible to say where better could come from. Those which were dissimilar from his group of Wednesday were *Alba Magna*, *Præstantissima*, *Sir C. Napier*, *Gem*, *Magnifica*, *Variegata*, *Gledastænesii*, *Formosa*, and *Stanleyana*, thus showing only two of his former group. He had, moreover, a very interesting set of the newer kinds—viz., *Salmonea albacineta*, striped salmon rose, very like *Due d'Aremberg* figured in the *Floral Magazine* for June; *Comte de Hainault*, very large; *Etoile de Gand*, a beautiful variety, the salmon so disposed on the white as to make a perfect star—in a large plant it will be a grand thing—its habit like *variegata*, from which it evidently comes; *Due de Brabant*, salmon pink; *Mars*, a fiery red, a seedling of Mr. Kinghorn's, very fine; *Perfection*, large bright rose, spotted and veined with dark crimson; *Sir H. Havelock*, bright salmon, a flower of great substance and smoothness; *Milton*, rosy lilac, a fine flower.

Mr. Ivery was second in this class. Some of his flowers the same as Mr. Turner's. He had besides *Flower of the Day*, large white, striped with rose occasionally; *Tricolor*, a striped flower, but inconstant; *Rosea Alba*, rosy pink, white margin; *Leviathan*, a very large white semidouble flower; *Gloire de Belgique*, a white but rough; and *Rubens*, large orange scarlet. Mr. Turner was third. *President De Clove*, something like *Etoile de Gand*; and *Leopold I.*, immense rosy crimson flower, were in the collection.

In *Pelargoniums* there were very much the same plants as at Kensington. Mr. Turner's were *Vestel*, *Festus*, *Prince of Wales* (a fine dark-veined flower), *Sunset*, *Fairest of the Fair*, *Rose Celestial*, *Roseum*, *Beadsman*, *Sir Colin Campbell*, and *Desdemona*. Mr. Dobson second, Messrs. Fraser third, and Mr. Burley, of Limsfield, fourth. Amongst Amateurs Mr. Bailly, of Shardeloes, was first with *Desdemona*, *Sanspareil*, the *Belle*, *Mr. Marnock*, and *Sir C. Campbell*. Mr. Shrimpton second. Mr. Turner's six *Fancies* were perfection. Nothing could be more exquisite than his plants of *Modestum* and *Acme*. He had besides *Claudeana*, *Roi des Fantasies*, *Madame Rongière*, and *Lady Craven*.

Roses in Pots were the same as at Kingston, and the prizes in the same position. Mr. Lane first, and Mr. Wm. Paul second. But I was greatly surprised to find that no better attempt was made to show Roses in small pots; the only collection there being of a very mediocre character indeed.

*Calceolarias* were shown in fine condition by Mr. Burley, of Limsfield. His plants (which he told me had not been shifted since last year), were the perfection of growth, and comprised *Angustifolia Globosa*, *General Havelock*, *Primrose Perfection*, *Empereur*, *Lord Derby*, and *Model*. Mr. Bosnie was second with *Howard*, *Jupiter*, *Morning Dewdrop*, *Canary*, and *Livingstone*.

A very good stand of *Verbenas*, and exceedingly well arranged, was shown by Mr. H. Treen, of Rugby. It contained amongst others *King of Verbenas*, *Mrs. Harrison* (like *Souvenir de l'Exposition*, but better), *Magnificent*, *Firefly*, *Apollo*, *Grand Eastern*, *Anreole* (deep plum), and *Fair Star*.

*Pansies* were small and indifferent.

Several seedling *Pelargoniums* were exhibited by Mr. Turner from Mr. Hoyle's, his own, and Mr. Beck's "stud." The first prize was awarded to *Royal Albert* (Hoyle), an immense rose-coloured flower, with a clear white throat, a free bloomer, and destined to make a fine exhibition plant; *Pelides* (Beck), crimson

with a heavy blotch, and spot on lower petals; Rosy Bloomer (Beck), distinct rosy crimson, with purple shading; Loveliness (Turner), light ground, spotted distinctly on lower petals.

Cinerarias were in no way remarkable. Some collections were indeed so from their excessively bad quality, and ought never to have been sent there.

The same may be said of two collections of Pelargoniums which came from Sydenham, and were really an eyesore amidst the trophies of floral art.

Near them in Tulips Mr. Norman had a nice stand of very clean flowers, but it was too late this season for them.—D., *Deal*.

### PEACH TREES DYING—A WARNING.

TEN years ago last autumn my employer, thinking that the south wall of the garden which was bare of trees might be turned to good account, forthwith began to make preparations. A goodly portion of the old soil was taken away to the depth of 3 feet, and the bottom he had paved with tiles. A drain the whole length of the border was put in about 9 feet from the wall: new soil of a mellow loamy nature was added to fill up, and in this the trees were planted. For four or five years they bore moderately; but at the end of that time a considerable curling of the leaf was noticed, and they began to show evident signs of decay. Each year matters got worse, till they ultimately succumbed to the influence of some secret agency, which, if you are able to enlighten us upon, the information will be gratefully received.

It was at this juncture the place came under my charge, and my first job was to renew this wall with Peach trees. I examined the drain, which was in good running order, and the wall itself was limewashed. Again a great quantity of new soil was added, which was made up with sand, leaf mould, sifted cinder ashes, and good rotten dung. These were well mixed with the old soil, and finally the roots of the trees were placed upon the ground level that they might not so soon get down to the bottom, which is of a stiff, cold, clayey nature. This is their second summer, and already the old symptoms of curling in the leaf are perceptible—indeed, in one instance I fear the tree will not survive the summer.—J. C. CLARKE.

[All along, the trees have been fed too well, and been allowed too deep a border. The summer has not been sufficient to ripen the wood. The frost injured them in winter, and hence the leaf-curling, &c. However, there are many places in which, if Peach trees are encouraged to grow large, they will not live above eight or ten years. You do not say where your place is. In general 20 inches to 24 inches of soil are ample; and even then recourse must be had to means for preventing the roots going down. The cinder ashes, and the leaf mould, and the rotten dung were all mistakes. Try your trees in the pure fresh loam, with a little leaf mould over the roots at planting; and then if not strong enough add leaf mould and rotten dung as mulching. In fact, before you are sure what your climate will do, as well as careful preparation of the soil, be satisfied with small trees with well-ripened wood instead of large luxuriant trees—say 10 feet along a wall instead of 20 feet or 40 feet. We would remove some of the rich soil now, and add fresh pure loam, and replant in October.]

### LASTREA v. LASTRÆA.

I MUST trouble you with some further criticisms in reference to the name *Lastrea*. The spelling is indeed not uniform, but *Lastrea* is not the less right on that account. Presl founded the genus *Lastrea*, as you truly say, and he, therefore, ought to know how he meant to spell the name. Now, it was with a full knowledge of his practice that I was bold enough to say you were wrong in writing *Lastreæ*. Presl always spells it *Lastrea*. Then, as to derivation, where did Presl get it? and what is its origin? The answer to this, probably, explains the partial use of the æ in its composition. Bory de St. Vincent, an old writer on Ferns, once proposed a subgroup of *Polypodium*, which he called *Lastreæ* (using, if my memory serves me, the æ; but I have not the book to refer to). Bory's group had very little in common with Presl's *Lastrea*, most of the plants referred to it being true *Polypodies*—e.g., *Phegopteris*, *Dryopteris*, &c.; and in Bory's sense the name had lapsed altogether. Presl revived it under a modified form, for a genus of which *filix-mas* is the type, and this is the modern *Lastrea*. *Lastrea* being the form

given to it by Presl, is, I must maintain, the right one for our use. The word as used by Bory was given to commemorate M. Delatre, a French botanist, as is stated in Mr. Moore's "Handbook of British Ferns;" and Presl's is no doubt taken from Bory's.—DELTA.

[If Presl took his name from Bory, and Bory spelt it *Lastrea*, then, according to botanical etiquette, this orthography ought to prevail, unless it is in defiance of a law of grammatical construction. Let no one conclude that because it is named in honour of M. Delatre, that this is any reason admitted by botanists for adopting that final *e*. So far are these men of science from admitting such trammels, that they seem to have the same rule for spelling as the boy who spelt pig with two g's, and who, when asked "Why?" replied, "Cause I chooses." Let us take as an illustration BOUGAINVILLEA. Now, as this was named in honour of M. Bougainville, according to "DELTA" (and we think so too), this genus should be *Bougainvillea*, there being no reason, except the pig boy's, why it should not; and to show how that boy's sturdy reason prevails with botanists, we find Commerson, who founded the genus, and Jussieu spell it *Buginvillea*. Very well,—but Endlicher has it *Bugenvillea*; and Lindley, not liking to copy Endlicher closely in this, perhaps, spells it *Buginvillea*. That, however, is only in one of his works; for in another, the pig boy's reason still prevailing, he chooses to spell it, as Brongniart also spells it, *Buginvillea*. Humboldt, Bonpland, and Kunth do not like any of those spellings, so they have it *Buginvillea*. Is it possible for any one to choose any other way? Yes, Blanco has it *Buginvillia*! whilst Donn and De Candolle will hold by *Bougainvillea*!

Since the above was written we have referred to what Bory de St. Vincent says in the "Dictionnaire Classique d'Histoire Naturelle," and we find that even he, also, is a disciple of the pig boy. In vol. vi., page 588 of that work, he spells the name which led to our note, *Lastrea*; but in vol. ix., page 252, two years later, he spells it *Lastreæ*. What does "DELTA" say to that?]

### NEW PLANTS AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW.—MAY 21st.

AFTER getting over the first flush of surprise at seeing such masses of flowers all at one view, and such splendid specimens of plants, the next most conspicuous thing to remark on was the bad spelling of the names, and Dr. Lindley was just as bad as any of the gardeners. The florists may have a feast of it against the Doctor, both in spelling and in botanical description. I allude to his account of Mr. Jackson's beautiful *Clerodendron Thomsonæ*, from the "Botanical Magazine." Then, there is *Hederoma* three times running, down in one column, in a way that no seedsman would put it into his annual list. Then comes Mr. Bull with cartloads of novelties; and one of the very prettiest of them, a new variegated form of the very old *Serissa foetida* was down as *Carissa foetida variegata*!

But enough. Let us rather see what the novelties were like, and take the advertisement list for the guide, and that itself is not free from the most amusing errors by the staff of the Society; but let us see. *Sarmienta repens* from Messrs. Veitch, is the first on the list in Class 22. This is an extremely pretty little trailing plant, very near a *Cranberry plant* in looks, with flowers like those of *Mitraria coccinea*, not quite so large, but of a brighter orange scarlet; it is all but a *Mitraria*, is from Chili, and must be as hardy as a *Myrtle*, and one of the first water for a hanging-basket.

The next is Mr. Jackson's *Clerodendron Thomsonæ*, which will make a most conspicuous stove climber when it gets established, and when not in bloom you would take it for *Clerodendron splendens*. It seems to bloom as freely as *Rhynchospermum jasminoides*. It bears clusters of flowers like *splendens*, and looks as if there were two crops of them; one crop, the lower parts of the bunch white and stiff as ivory, the other deep crimson on the top of the white. The reason is, that all the calices are ivory white, and the five lobes of the calyx connive and meet at the points, and out from these come the crimson flowers, which are more elegant in form than those of *splendens*. The Doctor was wrong in supposing the calyx to be inflated and five-angled, which it is not, only five-lobed, the lobes conniving as I have just said.

*Dendrobium Salaacense*, from Manilla, came from Messrs. Low & Co., of Clapton. When this is up to the right pitch it

will make a most conspicuous specimen for a show. It has long wand-like shoots, as in many varieties near to *D. nobile*, and on these come whorls of small orange scarlet flowers, somewhat bottle-brush fashion, and fifty such shoots 2 feet or 3 feet in length, and all half covered in that way, would make some people stare.

*Lælia Schilleriana* is next, and is now pretty well known to all who take an interest in Orchids. It is marbled in the leaves as the old *Cypripedium venustum*, and the flowers are among the loveliest in its most lovely genus.

*Stenogaster multijlora* comes next; but do you happen to know the meaning of that name? It is a polite way of getting over a most disagreeable idea, in the face of this generation. Forty years back nine-tenths of the mothers of young England were mere *Stenogasters*, were actually drawn together in the middle by tight lacing, and that is exactly the meaning of *Stenogaster*; and all the plants and flowers of all the *Stenogasters* we know of are more for children than grown-up people, because they are such pretty little things. You might call this multiflora a baby's *Gloxinia*.

Then came two specimens, well set, of a new *Calceolaria*, from Chili. Not so very new, if you please, for it is only a more alpine form of *C. plantaginæ*, which we had from a lower station thirty years back.

The next novelties are in Class 23, new or rare tender plants not in flower, and *Sphenogyne latifolia* is first, from the Messrs. Veitch, and well deserves to be. It has a splendid dark purple leaf, is *Melastomad*-like, and not unlike a young *Cyanophylle* magnifique, as they say abroad.

*Cibotium princeps* is next, and is under the misfortune of being among the most beautiful of Ferns, of which there are now ten times more than are needed. Botanists have ruined Ferns, as florists have the *Pelargonium*—that is, outside their own circles.

Then there were the Messrs. Veitch, Lee, Low, Jackson, and Bull, all in for a slice of the honour of having had *Musa vittata* from Kew Gardens; but Van Houtte took the wind out of our sails in having it first figured and named, although it was only the other day that it was sent to Kew by their own collector, from the west coast of Africa. At present it stands next to *Alocasia macrorrhiza* in importance.

*Ficus Cooperi*, from the Exotic Nursery, is next. I never saw it before. It is a New South Wales plant, and the very best-looking Fig I have yet seen for a pot specimen. It would remind you of an Indianrubber plant if the leaves had been so thick and shining; but they are not so, and are more purple in the veins and footstalks.

*Serissa fœtida variegata*, from Mr. Bull, next. This is really the very prettiest variegated plant out of the many hundreds which were there. The old *fœtida* is older than I am; but I never saw this till now, and it took my fancy amazingly.

Then came Class 24, which was left open for all comers with new plants, and first was *Thujaopsis late-virens*, a favourite second name with the Prince Salm Dyck. *Læte* means laying it on thick as skin deep, and this *Thujaopsis* is a good example of that kind of deep green: this genus, and that holding all the beautiful kinds of *Retinospora* from Japan, include plants eminently beautiful, and represent the Cypresses of the western world.

*Ourisia coccinea*, Chili, from the Exotic, next. If this had been a perpetual bloomer it would have made an extremely pretty flower-bed. It is a dwarf Figwort (*Scrophularia*), with soft apinacby leaves, and upright stalks clothed with *Pentstemon*-like blossoms, bright scarlet, and not so big as those of *Pentstemon*.

The next is a species of *Dammara*, from Japan, and if it will turn out hardly will be as valuable as an *Araucaria*. Then *Polystickum concavum*, a fine Fern from Mr. Standish, who had some of his very finest Japan introductions there also. Then *Biota pendula*, a Weeping-Chinese-Abor-Vite-like thing. An *Aucuba*, from Japan, quite different in looks to your *Aucubas*, and as dark green as the leaf of a *Phillyrea*. *Osmanthus*, the variegated Holly-like plants of Mr. Standish, and the *Planera acuminata* for the sides of the green drives in the English plantations, all from the rummaging of Mr. Fortune and young Mr. Veitch in Japan; but not one-half of the plants that were now exhibited could have prizes as they had them last year.

I do not think the Pinuses from Japan are worth much, but most of the other evergreens are most likely to be of the very highest order for planting out, and if they prove hardy they will certainly be most valuable additions. I like the *Retinosporas* best, but you must put the accent on the middle o. *Alocasia*

*metallica* and *macrorrhiza*, and *Caladiums*, and *Coleus*, and *Stenogaster* everybody knows by this time; and the only other name in the next, Class 25, not likely to be much known, is *Erioch-nema marmorata*. This was from the Messrs. Veitch, and is a dwarf broad-leaved *Melastoma*-looking plant, with broad light bands on a brown purple ground leaf and some marbling as well.

The next, Class 26, is of florists' flowers which are out of my beat; but I must mention the Duke of Cambridge's favourite new Pansy, which I see is named *Aurea marginata*. It is of a purple ground colour, with a yellow margin all round each division or petal of the flower, as you see the back petals of many *Pelargonium*s. This is quite a new style of Pansy, and the first of a new race of them with belted petals; and it must be in the florists' style, for they have given it a prize, as you will see in the advertised list of the awards in this class.

The last entry in the Second-class Certificates I must also notice, to correct a wrong entry. It is down in the name of Mr. Harland, gardener to J. Bedwell, Esq., Hatfield, *Begonia mutabilis*. This is altogether wrong. I know Mr. Harland, and he is gardener to Sir Cullen Eardley, Bedwell, and he had five seedling *Begonias* there. The prize must have been given to his *mutabilis* for being the newest pattern of leaf. There was a better seedling called after Lady Eardley, of the Rex blood, and it is the best dark ground and best white marking of that race.

All the rest of the awards, not florists' flowers, speak for themselves; but there were many plants which will bear more telling when we have room to particularise them, or when all the busy shows are over. There were two new *Abies* from California, from the Clapton Nursery, and one of them is named *Lowii*, after an old friend. They and many of the Japan plants must be more fully explained some day.—D. BEATON.

#### PAULOWNIA IMPERIALIS FLOWERS.

I HAVE a *Paulownia imperialis* that has been planted several years, and it is now about 18 feet high. The year before last it made an upright growth of more than 6 feet, and last year nearly the same. Late in last summer it threw out for the first time many blossom-buds resembling small brown knobs in a kind of truss at the extremities of the summer shoots, but none of them had matured before winter, when most of them fell off with the leaves. Some, however, remained; and the leaves now first opening I am surprised to see on several of the old trusses dark blue blossoms of about the size and shape of a rather shrivelled Foxglove. Is this the habit of the tree, or when ought it to blossom, and when blossoming well what is the size of the flower?—A SUBSCRIBER.

[The flowers come so late that they are generally destroyed by frost. You may expect seeds from those showing now. Your flowers are just the common appearance, something like those of a *Catalpa* or *Bignonia*.]

CRYSTAL PALACE.—The great Handel festival orchestra, with its vast and imposing roof, is now acknowledged to be a success far beyond the most sanguine expectations. The performance of the International Exhibition music at the great Flower Show, on the 24th ult., demonstrated in a most satisfactory manner its acoustic capabilities—the faintest tone, such as the high notes of a flute or violin, came out with most remarkable distinctness, while the loud thunders of the gigantic organ were concentrated and thrown forward in such a striking manner, as to render it a matter of certainty that when the great forces to be engaged at the Handel festival are heard, the effect will be the most astounding ever produced, even at the Crystal Palace. But it is not alone in increase of loudness that this orchestra is remarkable, but for the clearness and distinctness with which each series of sound falls upon the ear; while, at the same time the ear is delighted with effects which cannot be produced elsewhere, the eye is equally impressed with the sight of the vast arch stretching across the entire width of the orchestra. The 15,000 visitors assembled at the Flower Show last Saturday, testified, in a most unmistakable manner, the gratification and pleasure they experienced at the extraordinary and unprecedented musical treat afforded them. The great stage and scenery which were erected for *Blondin's* performances at Christmas have been cleared away, and visitors may now form some idea of the value of the more distant places. It is believed by competent judges that the seats furthest removed from the orchestra will now be amongst the

best for hearing. Additional seats are now being erected in the gallery, plans of which will be ready for issue in a few days. As the festival will be held concurrently with the great Agricultural Show at Battersea Park, and during the heyday of the shilling days at the Exhibition, there is no doubt the concourse of visitors at the Crystal Palace on the days of the festival will be immense.

### UTILITY OF SMALL BIRDS.

I, as well as many other gardeners in this locality (Bolton-le-Moors), am puzzled as to how we are to maintain a supply of vegetables whilst what is commonly termed the *black bot* is actually destroying our Peas, Beans, and Cauldlowers; and now I find they have attacked the Strawberries; and they are so numerous that in removing the soil from around the collars of the plants I can find twelve and sometimes eighteen lurking in the soil.

Any information as to the destruction of this unwelcome pest will be thankfully received.—CARBAGE-HEAD.

[Here is another unconscious testimony to the services small birds can render. What our correspondent calls the "black bot" is the larva of the daddy-longlegs, after which Sparrows and other small birds pursue a most slaughtering chase as a food for their young ones, of which we gave an instance last week. No application is known that will kill the "black bot" without also killing the plants it infests; but if a look-out is kept, and every daddy-longlegs is killed as soon as seen, there will be few or none of the "black bot" next year. We repeat our statement of last week, that no allies the gardener and farmer can have for subduing grubs and caterpillars compares in efficiency with the small birds; and again we urge upon our readers the national importance of saving those birds and their nests from the destruction so ignorantly encouraged against them.—Eds. J. of H.]

### YELLOW RHODODENDRON.

TELL "DELTA" that I have him booked on the yellow Rhododendron as another practical instance of the inefficiency even of facts to turn many from the wrong way. The assertion was in answer to a private letter in which three distinct things were required, and one of them only was a "real yellow without a dirty tawny shade;" and without knowing the rest "DELTA" had no sufficient information to say yea or nay, or to guess whether the yellow of *R. Boothii* would suit the correspondent. Besides, *R. Boothii* is as far off from the yellow of our friend as "DELTA" is from my notions of a careful critic.—D. BEATON.

### THE INTERNATIONAL EXHIBITION.

(Continued from page 160.)

CONTINUING our remarks on Class IX. we find—

2077. BARNARD, BISHOP, & BARNARD'S, *Norwich*.—Portable iron chairs, with galvanised wire seat and back. Neat and light.

2084. BOYD, J., *Lewisham*.—Garden roller and self-adjusting scythes with tubular handles, and aquarius. The scythe-handles are very light, and no doubt nearly, if not quite, as strong as if solid; whilst the facility with which the blade can be adjusted at any angle is extremely convenient, especially for those who do not understand the rather difficult art of setting an ordinary scythe. The "aquarius" is a japanned vase of neat appearance and very light, intended to be used either as a flower-vase, water-jug or, with the addition of a nozzle, as a watering-pot or shower-bath.

2105. DENNIS, T. H. P., *Chelmsford*.—Model conservatory. This is a small span-roofed structure, intended to show the mode of construction adopted by the exhibitor, the materials employed being cast-iron and glass. The framework is fitted together without screws and bolts, and the roof is trussed with slender rods of wrought-iron. It is ventilated by the side sashes, the whole of which are attached by jointed arms to a rod which is worked by a lever handle, to which is attached another small handle belonging to a spring catch. This catch or stop falls into a notched wheel on the end of the rod, securing the sashes in the desired position; and in closing it is merely necessary to liberate the notched wheel, by pressing the two handles together.

2113. FERRABEE & Co., *Stroud*.—Lawn mower. In this the

grass-box is emptied by means of a piece of board with an iron handle reaching to the back of the machine. On pushing this handle, the grass is shoved out at a hinged flap in the front of the box.

2119. GRAY, J., *Danvers Street, Chelsea*.—Conservatory tubular boiler, heating pedestal, and patent valve. The conservatory is a neat span-roofed structure of wood, well put together, and suitable for a garden of small size. The glass on each side of the doors, and in some of the fixed sashes at the sides, is stained according to a quiet pattern, and exhibits none of that vulgar glare which is always so objectionable, and particularly in a garden. For giving air the lower sashes are hinged so as to push out; and air can likewise be given in cold weather through gratings at the sides, the supply in this way being capable of regulation at will. The top sashes can also be let down by means of a winch working a chain.

The boiler, which in other respects resembles ordinary tubular boilers, consists of a double row of upright pipes disposed in an oval instead of a circular form. For this arrangement it is claimed that the fire is brought in closer contact with the tubes, and consequently, that a greater heating effect is produced by the same amount of fuel.

The same exhibitor also shows a handsome pedestal for heating balls and conservatories, with a bronzed cast-iron cover; and Beck's patent stop-valves, which are also exhibited in another part of the building.

2122. GREEN, T., *Leeds*.—Mowing machines and garden roller. The former are of various sizes for large and small gardens, and of the same description as noticed last week as being exhibited at the Royal Horticultural Society's Show; the latter is a cast-iron roller in two halves, so as to allow of turning readily.

2125. HAYWOOD, J., jnr., *Phoenix Foundry, Derby*.—Cast-iron vases, &c. These are mounted on pedestals painted to resemble polished granite and marble, and some of them are very handsome. They would be very appropriate for flower gardens, and especially for giving a finish to terraces.

2127. HEREMAN, S., 7, *Pall Mall East*.—We find here one of Sir Joseph Paxton's patent hothouses of the span-roofed kind, which would be very useful either as an orchard or forcing-house. Being easy of removal and exceedingly cheap, houses of this kind supply a want which has long been felt by those who cannot afford the expense of the more highly-finished and more ornamental structures which are usually erected.

2128. HILL & SMITH, *Brierley Hill*.—Park gates, &c. The large entrance gates erected by this firm are handsome, but also very expensive, no less than 500 guineas being asked for them. They open in two halves, and are provided with side gates for foot passengers, and with the exception of the four cast-iron pillars are wholly of wrought metal.

Though not so large nor so elaborate in their workmanship as the Duke of Devonshire's gates at Chiswick, they would form a fine entrance to a nobleman's grounds. Some excellent specimens of park gates and a self-closing stile are also exhibited.

2135. HUNT & PICKERING, *Leicester*.—Garden chairs and tables. The chairs have the back and seat of wood supported on a wrought-iron framework, and are so light that they can be easily moved from place to place.

They are made with or without arms, and are very cheap. The table is also supported on a wooden pillar resting on wrought-iron scroll feet. The top forms an octagon, and consists of bars of wood with intervals between. It is light, and well adapted for a summer-house.

2151. MESENER, T. G., *Loughborough*.—Triangular tubular boiler and hinge valve. The boiler which is set in brickwork consists of a number of large triangular tubes placed horizontally on all sides of the fire, but principally above it, and communicating freely with each other by means of water spaces at each end. The furnace-bars are also hollow, and the water passes through them on its return, before entering the upper tubes.

The hinged valve, which is made of nearly the same capacity as the pipe, is opened and shut, or set at any angle by turning a wheel which acts on a quadrant working the valve.

2154. MORTON, H. J., & Co., *Leeds*.—Models of corrugated iron roofs and buildings, and galvanised wire fencing with winding straining pillar.

2160. ORMSON, H., *Stanley Bridge, Chelsea*.—Conservatory and heating apparatus.

It is impossible to speak too highly of the fine specimen of

conservatory architecture Mr. Ormson exhibits, and which is altogether novel in character as well as light and elegant in design. The ends consist of two half domes, and from the top of these extends the lofty, long, oval, dome-shaped centre supported by ornamental girders and arches springing from the top of elegant cast-iron columns; whilst the portion of roof between the base of the dome and the upright sides is formed on another curve, arching to meet the base of the girders. The structure thus formed affords abundance of light, and ventilation is amply provided for by every alternate sash at bottom being made to open; whilst in the upper portion there are two rows of sashes which can be opened for the escape of heated air. In the inside are displayed plans and sections of various horticultural buildings. The patent jointless tubular boiler, the peculiarity of which consists in its being cast in one piece, and, therefore, presenting no joinings to the fire is also exhibited, as well as a stack of pipes for heating churches.

2169. READ, R., *Regent Circus*.—Garden engines and syringes of various forms, and of excellent workmanship.

2176. ST. PANCRAZ IRONWORK CO.—Conservatory and glass wall. The conservatory is a small octagon, with the upright sashes in mahogany, opening on three of the sides as folding-doors, the remainder being fixed. There is a provision for ventilation at top; but at bottom air can only be given in quantity by opening the doors, which in sunny but cold weather would be attended by draughts.

The glass wall, which is in fact a wall frame, is the invention of Mr. Scott, of Hornsey, and is stated to be capable of being put up or taken down at the rate of 200 or 300-feet run per day, with the aid of a labourer, and the glass stowed away in boxes till again required. It consists of iron standards rather more than a yard apart fixed to a wooden plate, which is secured to charred wooden stakes driven into the ground. To the wooden plate is attached an iron plate with guttering; and from it iron rafters grooved for the reception of glass pass upwards, and slanting inwards towards the top of the wall, near which they pass at an obtuse angle to meet clips or pieces of iron fastened to the wall, and to these the rafters are secured. The glass at top is fastened down by small screws, but that in front is inserted in the grooves, where it is supported by stops cast in the grooves, small pieces of wood and cork being introduced between the glass and iron to make all tight and prevent breakage. Wooden shutters a foot deep are hinged to the iron standards for the admission of air at bottom, whilst the heated air passes out at top through openings in the back wall.

The prices are—for 10-feet sashes 15s. 6d., and for 12-feet ones 18s. 6d. per foot run.

2178. SAMUELSON, B., *Banbury*.—Lawn mower and agricultural implements. The peculiar feature of the lawn mower is the introduction of a brush which prevents the revolving cutters from becoming clogged with wet grass, and the roller being in halve the machine can be readily turned.

2182. SHANKS & SON, 18, *Cannon Street*.—Lawn mowers of various sizes. The excellent construction of these machines being so well known need not be described here, and equally so their efficient working. We may, however, remark, that the mode of emptying the cut grass from the box in front by means of what is called the side delivery, is simple and remarkably expeditious, obviating the necessity of frequent stoppages for that purpose.

2188. STANLEY, J. M. & Co.—Conservatory. This is a small cast-iron house in the form of an octagon, with a dome-shaped roof surmounted by a vane, and suitable for a small garden. In the centre is an octagonal cast-iron stage for the plants.

The facilities for ventilation appear insufficient, especially considering the shape of the structure, which would tend to concentrate the sun's rays towards the centre, where the plants are intended to be.

(To be continued.)

### IMANTOPHYLLUM v. IMATOPHYLLUM.

You have recently spelt this *Imantophyllum*, and it was so spelt on a label at the Show last Wednesday, but it is not the right way. Herbert and Lindley have it *Imatophyllum*.—K.

[We are well pleased to see that attention is roused, as it ought to be, to correct botanical orthography. We venture to think that the two authorities quoted are wrong, and, moreover, that Sprengel is most correct, because he spells it *Himantop-*

*phyllum*. The name is derived from *imas*, a leather thong, and *phyllon*, a leaf. Now there is an aspirate on the *i* in *imas*, and the genitive case is *imantos*, so that, though we disregard the aspirate, "a leaf of leather thong" would be correctly spelt in our nomenclature *Imantophyllum*.—Eds. J. of H.]

### APHIDES AND THEIR DESTRUCTION.

THERE are few things connected with exotic-plant culture that have given rise to more suggestions or experiments than the destruction of the various insects which annoy the cultivator; and, after all, perhaps there is no feature in the management of plants or fruits that has advanced less the last half century; for the same agents in general use fifty years ago—tobacco and sulphur—are unquestionably the best we have yet, although many schemes have been tried, and numberless other articles brought into use during that time, most if not all to be abandoned, and the old remedies resorted to again. Washes, mixtures, compounds, and compositions have been plentiful enough, and in some cases I dare say efficacious; but they have failed to be so in all cases: hence the general adherence to the old-established remedies. Nevertheless, as this may be justly regarded as the age of invention, I hope to hear of something still more efficacious than the articles we have been treated to yet in the way of destroying insect life, and I here invite the assistance of our chemical friends to suggest something better adapted for destroying aphides than what we now possess (with the exception of tobacco); and at the same time the article ought to be innocuous to the plants. And as I purpose to devote the present article to this subject, I may say that what the gardening world wants is a cheap effectual remedy for the green fly that is of easy application, and not in the least hurtful to the plants operated on. It would also have an additional recommendation if it were not so offensive as tobacco when it has to be used in a plant-house adjoining dwelling-rooms; but this qualification need not be insisted on, for it is likely it cannot well be ensured. It is, however, important that the article used effect the purpose at once, and in cases where it has to be applied to a house with plants in full flower, a syringing or wash is impracticable.

Conceiving, therefore, that a solution to be used by the syringe is objectionable for all in-door purposes, although useful and applicable enough outside, it is, evidently, only in the character of a gaseous vapour or smoke that the efficiency of an insect-destroyer can be ensured; if in the latter way, combustion ought to go on without much attendance. A mixture called Neal's pastils has been recommended for this, as they are easily ignited and burn without any attention—in fact, it would be no easy matter for any one to remain where they are consuming, they being much more offensive than tobacco, even to a non-smoker; but the result on green fly is far from satisfactory. The irritating part of the mixture seems to be a Capsicum, or something of the kind, enclosed in folds of paper that have been steeped in some combustible compound, perhaps a strong saltpetre brine. Had I not witnessed its failure on insect life I could scarcely have credited it, as it is so exceedingly irritant to the human lungs. But the failure of Capsicum as a remedy for green fly was proved some years ago, that our chemical friends must turn their attention some other way in furnishing us with a substitute for tobacco.

Many years ago the paper in which tobacco was wrapped-in to come to this country was used with great effect for the destruction of green fly, and I can remember buying it at about one-tenth of the price paid for tobacco; but the demand for it increasing, its price advanced, and wrapper paper from other packages than tobacco got mixed with it, or was supposed to do so, and its reputation declined. Latterly, however, it has been brought into notice again; and, if pure, is an excellent substitute for tobacco. As the price of the latter is the great drawback to its general adoption, what we really want is something cheaper and equally destructive to insect life; and, as before stated, it ought to be easily used, and require little or no attention. That some other plants contain like destructive properties to the tobacco there can be no question, and for the guidance of those who may be disposed to make some experiments, I may here mention a few that may possibly be turned to account:—

*Monkshood*.—The poisonous character of this plant points it out as a fitting one to the experimentalist for insect-destruction. Its fatal effects when partaken of by any one are well known, and

it is possible it might be destructive also in another manner; at all events it is worth trying. Suppose a very strong decoction of it were made, and this decoction made use of to saturate some material that was previously rendered combustible, would the burning of this emit a smoke fatal to insects, or could it be used in some other way? To burn the green plant would be inconvenient if not impracticable, and I fear it will be difficult to make it give off a sort of gaseous vapour in quantity otherwise than by combustion; but our chemical friends must find this out and tell us how.

*Henbane.*—This virulent poison may possibly be used with equal advantage as the last, and as its powers are of a different character, possibly it may be more useful. I have heard of some extraordinary way in which it is used to cure toothache; but the plan had so much of the marvellous about it that I did not pay much attention to it. Certain, however, it is that it possesses extraordinarily poisonous qualities, and being a plant of native growth it might easily be had in sufficient quantity to use in any way that could be pointed out as effectual for the destruction of insects.

*Stramonium.*—This is, perhaps, not so fatal a poison as the two last named; but it may, nevertheless, be sufficiently so on insect life, and it might have its due share of attention in the experimental way. It can be had in any quantity.

*Deadly Nightshade.*—The frequent fatal effects of this are well known, and point the plant out as one likely to furnish a good substitute for tobacco. Perhaps an infusion of this or some other plant might be applied out of doors when the usual mode of smoking could not be resorted to.

*Forglove.*—This plant is, I believe, extensively used by the druggist, but whether it is suitable for the purpose in question or not I cannot say: nevertheless I mention it as likely.

*Poppy.*—This may also be tried, although I have less hope of it than that of some others above mentioned.

*Potato-tops.*—Many years ago I have seen an infusion of these tried with tolerable success, but I have forgotten the manner in which it was done; and I should think some of the plants first named more likely to prove effective.

Besides the above there are many other plants which might be tried. Perhaps some of those noted for their bitter qualities might be useful, as the Linum, Wormwood, Chamomile, and many other herbs; or it is possible some of the preparations of foreign vegetable matters might have the desired effect. It would be better to restrict the experiments to vegetable substances, although minerals might be used if found innocuous; but there is an unwillingness to engage in them, and it would be better to use them with great caution, although their fumes may be more safe than solutions of them; but the smoke from a soda manufactory is alike fatal to insect and vegetable life, and that of copperas, lead, and I believe many other minerals is also dangerous; something less likely to be attended with bad consequences must therefore be resorted to.

In offering the above hastily-thrown-together notes to the readers of THE JOURNAL OF HORTICULTURE, I by no means find fault with tobacco as a good and certain agent in destroying aphides of all kinds, but it is expensive; and as its home cultivation is fettered by excise regulations I should like to see something else substituted for it, equally useful, and at one-third the cost. That this is practicable I hope some of our chemical friends will speedily show us, and I hope that they will do it in the open manner which enhances the boon, and not impoverish themselves and mystify the public by taking out a patent for the invention; for be assured of it not one patent right in ten has paid the inventor when taken out on such subjects as relate to horticulture. The mystery which hangs over them operates against their use, and something else is soon found out equally good and unfettered by the trammels of the patent law, and the thanks of a grateful gardening world are better than the vexatious losses so often experienced by those securing their inventions by patent.

J. ROBSON.

**CHLORIDE OF LIME AS AN INSECT-KILLER.**—In scattering chloride of lime on a plank in a stable, all kinds of flies, but more especially biting flies, were quickly got rid of. Sprinkling beds of vegetables with even a weak solution of this salt effectually preserves them from the attacks of caterpillars, butterflies, morderls, slugs, &c. It has the same effect when sprinkled on the foliage of fruit trees. A paste of one part of powdered chloride of lime and one-half part of some fatty matter, placed in a narrow band

round the trunk of the tree, prevents insects from creeping up it. It has even been noticed that rats and mice quit places in which a certain quantity of chloride of lime has been spread. This salt, dried and finely powdered, can, no doubt, be employed for the same purposes as flowers of sulphur, and be spread by the same means.—(*Dingler's Polytechnisches Journal.*)

## DOWNTON CASTLE,

THE SEAT OF THE FIRST PRESIDENT OF THE HORTICULTURAL SOCIETY, THOMAS ANDREW KNIGHT, ESQ.

WHILE looking over the grand show at South Kensington in the Royal Horticultural Society's Garden, and the evidence of skill brought to public view, I consider we have much to thank Mr. Knight for, as well as the Horticultural Society—*i.e.*, for the first interest and support he gave it. It may interest others to know also that the present worthy proprietor, Andrew Rouse Boughton Knight, Esq., takes much interest in keeping up this fine old place in accordance with the times we live in: therefore, just now I offer a description that has just been sent me through Mr. John Gribbin, who is now executing plans of embroidery and other works under Mr. Nesfield for Mr. Knight.

Downton Castle is situated in the north-eastern corner of Herefordshire, six miles west from Ludlow, the nearest town to the Castle. The park is approached by a fine Gothic lodge, close to a bridge which crosses a very deep ravine with a rushing stream, the banks being clothed with fine Oak trees, and luxuriant evergreens. Among the rocks many Ferns are quite fine and seemingly at home. After crossing the bridge you enter a fine carriage drive, and at once are struck with the effect of the timber which skirts the drive, particularly a majestic Oak, for symmetry and size but rarely to be met with. Approaching nearer to the dressed part of the grounds you pass belts of Rhododendrons, and Berberis aquifolium planted in large masses, they being well backed up with Portugal Laurels, nice large plants; behind them are clumps of Spruce Fir, with the fine Oak and Beech trees to fill up the background. Spaces are left where fine plants of Deodar and Wellingtonia are planted, with many of the best species of Pinus.

When fairly in sight of the Castle the approach is in a straight line. The north wing of the Castle is the principal entrance. On each side are planted Golden Yews and Juniperis alpina and pendula, alternately placed; each of these is attended by three Irish Yews placed in an angle at 6 feet from the centre plant.

The Castle is a noble pile of architecture in the style of Edward III., with eight towers, three of them entirely new, recently built by the present spirited proprietor, who has put the whole Castle in thorough repair, many masons and others having been employed for the last four years.

On the south front is built a new terrace wall 150 yards in length, with bastions, turrets, loopholes, &c., to correspond with the Castle. The width of the terrace at each end is 90 feet, and at the centre 66 feet. The length of the south front of the Castle is 83 yards. Here Mr. Nesfield commences his operations with a walk 15 feet wide running the whole length of the terrace, a smaller walk leading to the principal entrance to the Castle at right angles with it. Next to the Castle Mr. Nesfield is introducing raised beds with moulded stone edging about a foot higher than the grass. In a line with these are Irish Yews, Yucca gloriosa, and beds of Rhododendron myrtifolium. Between the walk and parapet wall are match beds of Irish Yews, standard Portugal Laurels, &c. In the centre bastion a handsome sundial is to be introduced.

At the east end of the terrace walk is a high tower. At the west end is a very fine Cedar of Lebanon. In the west front is a large basin for a fountain ultimately to be erected, with two sunk panels with stone edging for flowers. Beyond this basin on a raised slope is one of Mr. Nesfield's choicest patterns of embroidery. The principal feature in this figure are two griffins, the bodies forming a volute divided by different-coloured spars and flower-beds.

From this point is a fine view of the new church lately built entirely at Mr. Knight's expense, about half a mile distant, seen through an avenue. Outside the walk that encloses this principal panel of embroidery is a dwarf Yew-hedge, with Golden Yew placed at the angles, and at each side of the openings, steps, walks, &c., forming pyramids, which are much higher than the hedge, the golden tint contrasting well with the dark green of the common Yew.

"Under the upper south terrace is a lower one sloping rapidly down to the valley beneath, some 300 feet below the Castle. This second terrace is also bounded by a parapet wall with turrets placed at regular distances, but taking a curving outline to suit the ground. The ground beneath on this lower terrace has clumps of Portugal Laurel, common Yew, and Thorns, some very large, with immense clumps of Rhododendrons, 17 yards through and 12 feet high, well feathered to the grass, forming most beautiful objects. Close to them is a fine standard Portugal Laurel with an eight-foot stem, and forming a head 15 feet in diameter.

"Through the valley beneath flows the river Teme, forming a most pleasing object from the Castle and terraces. The valley seen from the terrace is about thirty-six acres, appearing as level as a bowling-green. We cross the river here by a bridge of three arches. Immediately beyond the river rises a range of hills parallel with the terrace, extending more than seven miles, east and west, clothed with fine timber, at intervals dotted with handsome Thorns. The summits of the hills being topped with clumps of Scotch Fir, vistas have recently been cut through the densest parts, which open to view beautiful green pasturage. Turning from these hills to the north side of the Castle we view the new church, where much Oak timber has been cut down, giving a good opportunity to leave open views, and single specimens of the finest trees, groups, and numerous vistas from the Castle. Mr. Knight himself superintended this part of the work, aided by his steward and Mr. Landen, the active and intelligent gardener.

"The avenue from the Castle to the church is to be planted on each side with Wellingtonias, and in time to come will be a fine sight.

"A new conservatory is intended to be erected at the east end of the terrace, near the kitchen garden, where the late Mr. Andrew Knight carried on his various experiments in horticulture. Many of the wall trees grafted by his own hands, with various kinds on the same stem, are still, after thirty years, in a fine healthy state; but only one of the old houses where he grew Pines remains.

"The kitchen garden consists of four acres. The walls are well covered with well-trained fruit trees. The quality of vegetables grown shows the ground to be of the best quality. There are five houses—three vineries and two Peach-houses, their contents doing the gardener much credit. Outside the garden is a fine range of pits, a house for Cucumbers, another for Dwarf Kidney Beans and Strawberries. The whole is heated by hot water."—J. N., 30, *Eastbourne Terrace*.

## INJURY FROM LIQUID MANURE UNDILUTED —MELONS IN AN ORCHARD-HOUSE.

I HAVE been much disappointed with my orchard-house this year. The man who works for me, in my absence in April watered all the trees with undiluted liquid manure from the cow-house: consequently, all the fruit and most of the leaves have fallen; also, three dozen Strawberry plants looking well, all killed. Will the trees recover for bearing next year?

In the meantime I have turned them out of the house, and have a space 60 feet by 8 feet quite vacant. Can I grow Melons, Cucumbers, Capsicums, &c., in this ground? and if so, will you give me a hint how to proceed with the two first, and the kinds that would suit the situation? My house is lean-to against a south-east wall.—KATE.

[We are very sorry to hear your tale. Every one of the fruit trees which were spoiled with the strong liquid manure this spring will be just as barren of fruit next year as they are at the present moment. All you can expect of them this summer is to recover themselves partially, not to prepare anything for next year, and it is a question if the effects of that acrid application will be got rid of altogether for the next five years. The plants would recover, however, much sooner if they were turned out of the pots into a warm, light, porous soil, mulched, and left there until next February. You can grow extraordinary crops of Melons in the orchard-house. Such is Sir Joseph Paxton's system in a long span-roofed house he uses all the winter for Kidney Beans and Strawberries. There is a path 3 feet wide down the middle of the house. The borders right and left may be 5 feet wide and 9 inches higher than the path. The whole surface of these borders is covered with an inch deep of coal

ashes, the natural soil below is a strong stony clay. A circular hole 3 feet wide and 10 inches deep is made in these borders, one under each light, in a row down the centre of each border; one-half of the coarse natural soil, and one-half good compost, go to fill the holes till they are a little higher than the coal-ash surface, and three good Melon plants of the true old Egyptian Netted Green-flesh Melon—the only Melon worth eating of all the imported kinds—are planted in each pit, or hillock rather, and a fine, moist, mild, airy temperature is kept up till the fruit is full grown, and then turned gradually and more gradually to the dry climate of a desert to give the proper flavour.

We have seen all this and tasted the Melons, and we shall never taste the like again, unless you succeed as well and give us an invitation for a feast of Melons of from 1½ lb. to 2 lbs.; but we must make terms before tasting a Melon of English growth if it be over 2 lbs. Our lives are too valuable to risk with common Melons.]

## GAS IN HOT-WATER PIPES.

IF I am in error in regard to the gas generated in "JUNIOR'S" hot-water pipes, perhaps it is owing to my accepting too strictly his definition of the colour of the gas when he says it burnt with a pale blue flame. Had he said a bright blue flame, I might have suspected the presence of carbonic oxide gas; or if he had said a blue flame it might have led me to suspect sulphureted hydrogen.

It is true, as Mr. Whitehead says in page 117, that moulders use charcoal dust in moulding, and I suspected that at the time as the cause, along with some of the sand, &c., which they use as a core, being kept in the pipes and causing a stoppage. I was aware, too, that if there was carbon there, and it became red hot, it would pass off as a gas; but how it would get its one atom of oxygen to form carbonic oxide I do not know, unless the decomposition of water takes place. At the same time I know that if a stream of carbonic acid gas is made to pass through a red hot iron tube or gun-barrel, carbonic oxide is given off, the iron having taken one atom of the oxygen from the carbonic acid gas. But I do not understand the chemical change which takes place "when the vapour of water passes over carbon at a red heat" and forms carbonic oxide, as Mr. Whitehead says it does, unless the water is decomposed at the same time. Perhaps he will be kind enough to explain the change?

If the gas is caused then by the charcoal left in the pipes becoming red hot, it will blaze as soon as the charcoal or carbon is consumed. Now, I understood from "JUNIOR'S" letter of inquiry that it was of frequent occurrence, which made me think it was by the decomposition of water, especially as "JUNIOR" said it had a pale blue flame.

Mr. Whitehead asks if it is not more likely to be hydro-sulphuric acid gas, which also burns with a blue flame, not a pale blue flame. If he means sulphureted hydrogen, and it is that that is found in the Harrowgate and other waters, I certainly would never have expected it to be there to trouble "JUNIOR," because the small quantity which these waters contain of that gas, supposing it was all to be liberated at once, would not burn as "JUNIOR" describes; and again, if he lives near Harrowgate, he could not help noticing the strong smell which would arise from his hot-water pipes similar to that from these waters.

The quotation from Gmelin's "Chemistry" proves nothing, neither does it throw any light on the subject whatever, as there can be no organic compound containing sulphur in the pipes to putrefy, unless Mr. Whitehead means the ropeyarn which the pipes are likely to be jointed with, and that is indeed very unlikely.

The quotation again says, "If the existence of hydrogen salts of metallic oxide be admitted, it must likewise be supposed that hydrosulphuric acid is generated, when a monosulphide of an alkali metal is dissolved in water, and when iron filings are mixed with sulphur and water." What hydrogen salt does he mean which is likely to be found in the water? I can account for the metallic oxide. And what monosulphide of an alkali metal when dissolved in water produces sulphureted hydrogen? Hand-books are generally understood to be written in a plain manner; but if that is a specimen of the whole book I must be thankful it never came into my hands. The last part of the quotation is

easily understood—where the water absorbs the gas equal to its own volume. But then at the first heating of the water, it would pass off, and the smell would be almost unbearable, so that I would suppose “JUNIOR” not to be near Harrogate or its waters.

But I am still anxious to know really what gas it is which is

generated in “JUNIOR’s” pipes, and it is a simple matter to test both the sulphureted hydrogen and the hydrogen; and the carbonic oxide is well known by its bright blue flame. None of them are difficult to make, and, therefore, can easily be compared; and I would be very glad to point out to “JUNIOR” how to test them should he feel disposed.—J. A. SHEARER, *Fester*.

THREE HARDY EVERGREENS.

*SYMPLOCOS JAPONICA* (Japan Symplocos).—*Nat. Ord.*, *Styracaceæ*, § *Symplococæ*. *Linn.*, *Polyadelphia Polyandria*. *Syn.*, *S. lucida*; *Furuggi* of the Chinese.—An evergreen shrub, or bush, growing naturally 20 feet in height, and much used by the Japanese for decorating the shrines of their idols. Its hardiness is now proved, and it certainly forms a very lively-looking shrub. The leaves are obovate, cuspidate, light green and shining, with something of the aspect of a Bay; it has small pale yellow flowers in clusters from the axils of the leaves. Thunberg took it for a Myrtle, Fortune for a Holly. From Japan, southern provinces. Introduced by Mr. Fortune in 1850. Mr. Standish, of Bagshot.

*QUERCUS SCLEROPHYLLA* (Hard-leaved Oak).—*Nat. Ord.*, *Corylaceæ*. *Linn.*, *Monœcia Polyandria*.—A very fine evergreen tree, with smooth branches, bearing leathery-stalked leaves, 4 inches to 6 inches long, and about half as much in width, coarsely toothed, shining and bright green above, glaucous, with fine down beneath. The acorns grow in compact spikes 3 inches or 4 inches long, and are small, roundish, downy, almost enclosed within the very deep tomentose, sealy cups. From the north of China. Introduced by Mr. Fortune in 1850. Mr. Standish, of Bagshot, who informs us, that after standing several years, it will be cut by frost, but not killed.

*ILEX CORNUTA* (Horned Holly).—*Nat. Ord.*, *Aquifoliaceæ*. *Linn.*, *Tetrandia Tetragynia*.—A fine hardy evergreen shrub, with oblong coriaceous deep green leaves, obtuse at the base,

1. *Symplocos japonica*.

2. *Quercus sclerophylla*.

3. *Ilex cornuta*.

truncate at the apex, almost always furnished with three strong spines at the end, which in old plants sometimes turn up their ends, and assume the appearance of strong horns. The berries are large, in sessile axillary umbels. From the north of China.

Introduced by Mr. Fortune in 1849. Flowers in spring. Mr. Standish, of Bagshot, says that it stood perfectly until the winter of 1860-61, when it was cut down to the ground, but is now growing again.

### THE BIRMINGHAM ROSE SHOW.

THE prize list of a Rose show can scarcely be expected to afford much opportunity for criticism; but we may notice that an attempt will be made to ascertain if a system of classification can be usefully introduced, so far as regards cupped and expanded varieties. At present we believe nothing of this kind has been done; but there is no reason why the experiment should not be tried. The more perfect the mode of classification with regard to any exhibition, the more valuable will that exhibition become, as affording better means of comparison, illustrating the progress which has been made, and showing what remains to be accomplished. The managers of our agricultural societies are well aware of this; and one of the first objects of the founders of the Bingley Hall Shows was to introduce an improved classification of stock—an example which was soon followed by the Smithfield Club, and which was declared by one of our leading agricultural authorities to be an invaluable reformation. Hybrid Perpetuals, Teas, and Noisettes—cupped and expanded flowers—will never, probably, range themselves as distinctly as Herefords, Short Horns, and Devons, but at the same time it is well not to overlook a principle which has done so much good in other directions.

Another feature in the list is also worthy of notice—namely, that there is no restriction as to the numbers under which nurserymen or amateurs may exhibit in their respective classes; a nurseryman, for instance, may enter under one or all the numbers in the "A" and "C" divisions. Any limit to a particular number—as that exhibitors of ninety-six varieties should not show forty-eight, and so on—might, we think, have been considered objectionable at a show open to all comers; and, in fact, a sort of indirect attempt at handicapping which neither class of growers would require.

It is explained "that by the term 'truss' is meant one shoot cut from the wood of the current year's growth, and having a single or greater number of blooms and buds, as the case may be. Any addition to the truss as cut from the tree will disqualify."

The Committee are also anxious to be favoured with miscellaneous specimen plants in pots, and cut Roses, flowering shrubs, and herbaceous plants, made up in large bouquets to be placed in vases for the decoration of the hall. No prizes will be awarded for these; but it is added that the names of the growers will be attached if desired.

With regard to the exhibition of horticultural implements and garden ornaments, it is intended that it shall, as far as possible, include whatever is required in gardening operations, as the requisite tools used in manual labour; garden cutlery; wirework of all descriptions; ornamental flower-pots; edgings of different materials; figures and vases, whether of metal, glass, porcelain, or other material, for the open garden, greenhouse, terraces, halls, or the decoration of rooms; and ornaments to be used in combination with flowers for dinner-tables; in fact, everything in which flowers are displayed for any purpose. Bee-hives, it is added, will also be admissible. This list is sufficiently comprehensive; and there can be no doubt that ample means exist for making this department one of very great interest to all lovers of a garden. Already, we understand, promises of contributions have been made both from this town and neighbourhood, and also from a distance; and we hope that many of the beautiful productions of the Staffordshire Potteries, Worcester, Coalbrookdale, and other places, will aid in making up the collection. This is the first attempt to establish an exhibition of this kind in Birmingham—occupying, perhaps, the best position of any town in the provinces for the purpose—and we trust that manufacturers generally will give their cordial assistance to the promoters. It will afford an admirable opportunity for displaying the products of skill and industry in connection with gardening operations, and garden and other ornaments, and is certainly deserving of that hearty aid which shall not only make the first experiment a complete success, but give to Birmingham another annual exhibition which cannot fail to increase in value and importance from year to year. With regard to the ordinary garden tools, we shall be glad to see these sent in large numbers; every one must acknowledge how great a boon, both to the working gardener and amateur, has been, for instance, the introduction of the improved forks and spades; carefully manufactured and fitted, with the much lighter weight properly distributed, work can be better done with infinitely less fatigue.

A very fair and liberal arrangement has been made with regard to the issue of admission cards, subscribers of 10s. receiving five of these; of £1, ten; and of larger amounts in the same proportion; the charge for admission until six o'clock on the first

day having been fixed at 2s. 6d. The Honorary Secretaries, Mr. Hallam and Mr. Badger, are now prepared to forward or deliver these tickets in return for subscriptions.

We are enabled to add, that many of the leading growers of Roses, amateurs and nurserymen alike, speak most favourably of their prospects for the present season. The general opinion is that the time for holding the Show has been judiciously fixed, and that there will be a large and brilliant collection of flowers.

### CULTURE OF OPHIOGLOSSUM VULGATUM.

THIS Fern is with me the most difficult to cultivate of any hardy Fern that has come under my care, not excepting *Botrychium lunaria*. Its cultivation is put down in books as a very easy matter; but I would ask those who say so, Have any plants been raised from spores some distance from where the plants grow naturally? I have found the spores vegetate freely where the plant grows wild; but I have failed to propagate or raise plants from the same spore-cases, though under the same hygrometrical condition, and at the same temperature, with soil in the same condition, as far as my eyes and touch could judge. I tried the spores in the identical soil the parent luxuriated in, placing a pot in the open ground, plunged another in a cool greenhouse fernery, and a third in a stove fernery; but all without resulting in the spores vegetating. Those pots were covered with bell-glasses, and fed with water from a saucer in the usual way for raising Ferns from spores. Here a thought struck me, "they wanted a free circulation of air, and not the close confined atmosphere of a bell-glass;" but it turned out upon trial to be a complete failure.

Foiled at every point to get the spores to vegetate, my attention was next directed to the cultivation of the plant itself. Mr. Moore says "there is no difficulty in the matter," and others assert it grows freely in stiff loamy soil, with the constant presence of water to prevent drought; but after many futile attempts I found my plants merely existed for three years but did not thrive, and then died in a galloping consumption. However, looking at the roots I found they were not dead, but in such a state of inactivity as to render the formation of fronds impossible. The crown was gone to all appearance, but the eye, aided by a microscope, discovered a very feeble central crown and a bud that required a high magnifying power to detect its presence. Plants in stiff loamy soil were potted, some placed in a cold frame, others in a greenhouse, and some in a stove; but those efforts, perhaps unnatural, were of no avail, the plants became weaker every year, and finally ceased to grow. On examination the roots were not dead—nevertheless very weak; or, what would be more definite, blind at the crown. Well, those plants were bundled out, and after lying dormant for a couple of years they grew.

That *Ophioglossum vulgatum* has the power of remaining dormant for a considerable time without annual leaf or frond formation is a fact more than once confirmed to my knowledge. I have had plants that have remained dormant for three years, and then have grown when the treatment was changed. In 1858 we had a plant of *Botrychium virginicum* from a nurseryman in the south, which did well that year. In 1859 and 1860 it remained dormant, and in 1861 it put forth its fronds and fructified beautifully; but it seems its luxuriance in 1861 was only the final struggle for life, for the root decayed, and there was an end of the plant. Nature produced annually a fine clump of *Ophioglossum* on an old *Asparagus*-bed, where the fronds appeared about the same time as the *Asparagus* shoots. The first time it was observed was in 1853. Searching the lawn and the fields adjoining no trace of the *Ophioglossum* was to be found, neither in 1858, 1859, nor 1860.

Now, in 1860 we dressed the lawn with rotten cowdung and soil in equal proportions, covering it about half an inch thick: of course that dressing was to alter the colour of the verdure, and to promote a thicker and better turf. In that respect it was a complete success, more grass came off at the first mowing in 1860 than was collected in 1859, though 1860 was a remarkably cold and wet spring; and so luxuriantly did the grass grow that the mowing machine instead of superseding the scythe had to follow after it. Moreover, a run over with the machine was enough every ten days to keep the lawn in order prior to 1860; but in 1860 and 1861 a clip every four or five days was necessary; yet it was not so high as it was thick set, and after ten days' growth presented a staple that defied the machine. Lawn mixtures had been sown upon that lawn without result, except

some £5 loss in throwing grass seeds upon soil that could not support the commonest grasses, and those of a country remarkable for its number of species. With the dressing of cowdung and soil was a fine sward, without the lawn mixture at all, and White Clover, &c. Mention is made of the lawn as we intend to say something about it again, and not to show how to improve a bad turf.

In 1860 I scoured the country round here, but could find no such thing as *Ophioglossum vulgatum*; still my old friends in the Asparagus-bed were stronger than ever, some fronds rising 7 inches and 8 inches above the soil. Their fructification was more developed than I had seen before, and a dressing of salt materially invigorated them.

On the 13th of May, 1861, the lawn was full of the *Ophioglossum*, four or more standing on a couple of square inches. How had it got there? Had it come with the soil in 1860, or were the roots already there in a dormant condition waiting for a proper medium wherein to grow? That it was not there prior to 1860 there cannot be a doubt, as the lawn was scanned minutely for Daisies by one who has a keen eye, and some experience as a botanist.

This year the plants made their appearance on the 10th of May, but in a very weak state, and not half so plentifully as in the year before, the fronds being little more than 2 inches in height; and very few indeed are producing fertile fronds, nothing but a sterile frond appearing on each plant.

Having been so unfortunate at cultivating *Ophioglossums*, I hailed its appearance on the lawn as another starting-point for a new trial, because I could not bear to be defeated by such a common subject. Several plants were potted and divided equally, one for an out-door, another for a greenhouse fernery, and a third for a stove or intermediate-house; for very few Ferns indeed require a high temperature. All were kept well supplied with water, even when dormant, and watered with a lavish hand when growing, which brought about something very singular. Heat is said to be the cause of plants commencing to grow, but of my *Ophioglossums*—those in the open ground appeared on the 10th of May, those in a greenhouse on the 21st; whilst those in the stove have not yet shown themselves, and on examination I find they are only just starting from the crown, which will make them at least a month behind those in the open ground. Perhaps I may add all the plants are weaker than they were when removed, and all are barren-fronded.

Accidentally my pets in the Asparagus-bed were doomed to destruction, as the real occupant of the bed was in such a condition from the wet season of 1860 that its destruction was determined on: this gave me an opportunity of examining the *Ophioglossums* where I found them; 10 inches below the surface were the roots, with shoots 3 inches long, and that on the 10th of March. I left them there, and shall look for their reappearance with no little interest.

Taking a handful of the soil where those *Ophioglossums* luxuriated and squeezing it, water ran through the fingers, and the handful of soil was as sodden as a half-melted snowball. Here was the solution of the difficulty. Immediately an inch of rain fell upon one of the pots in the stove fernery, and the same every day for three weeks, when a remarkably strong plant of *Ophioglossum vulgatum* shot forth, distancing by two months its congeners, which have hitherto been living upon themselves: this explains the mystery about the other plants becoming so soon exhausted. Drought this plant cannot endure; but that it will grow freely in heat I have no doubt, like *Asplenium marinum*, which has taken possession of a stone wall in a stove fernery here, and grows far better there than in a cool house clove by.

I am informed that there is at Kew an *Ophioglossum* from Madeira, that has been cultivated so well there as to warrant a division of the original into fifty plants or more. That is just what I want to be able to do with *Ophioglossum vulgatum*, and any one that has done it and will let out the secret will much oblige me.—GEORGE ABBEY, *Bradford*.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

CONTINUE to thin the crops that require it while they are small, and in all cases where practicable loosen the soil about them; and if dry give them a good watering. It will greatly benefit them after disturbing their roots, and the soil being loose

the effects will be so much the greater. *Basil* and *Marjoram* that were sown in beds to be thinned-out to about 6 inches plant from plant. *Broad Beans*, make another sowing towards the end of the week, and top the most forward crop if not done. *Cabbage*, now is a good time to sow a little seed for autumn produce; any of the small sorts should be preferred for this sowing. *Cauliflowers*, plant-out some from the first sowing in the open ground; a small quantity planted from two or three sowings will keep up a succession better than the small stunted plants of very early sowings. *Cucumbers*, peg-down the plants on ridges as they advance in growth, and when the hand-glasses will no longer contain them set them on three bricks placed edgewise, or on crotch sticks. When they require water give it to them milkwarm early in the day. *Onions*, after thinning loosen the soil between the rows, and if the weather is dry give them a thorough watering. The thinnings of the bed to be planted out to be watered every evening, if the weather is dry, until they take fresh root-hold: this to be particularly attended to, as the roots when planted should be very near the surface. *Peas*, sow Knight's Dwarf Marrow as it is a good sort, and is longer in coming into bearing than many others. *Radishes*, make another sowing of the various sorts. *Savoys*, plant-out some of the early-sown, the dwarf sort to be planted at 1½ foot apart in the row, the rows to be 2 feet apart; the larger sorts to be 2 feet plant from plant, and the rows 2½ feet apart. *Tomatoes*, as they are usually placed under a south wall where they sometimes receive but little benefit from a passing shower, they should be occasionally watered and kept mulched with short litter. Stop and nail-in the shoots as they advance in growth.

### FLOWER GARDEN.

The newly-bedded-out plants will require looking over, as with the best management failures will sometimes occur. Such failures to be made good, and the pegging-down, tying, and staking of everything requiring it to be attended to without delay. Sow hardy annuals to succeed the earliest. Those which are up to be thinned-out, so that not more than from three to four of some plants, and say six to eight of others be allowed to remain in a patch. Gather the seed of *Auriculas* as soon as the seed-vessels appear brown, and before they open. Continue to propagate *Chrysanthemums* by taking off the tops and striking them under a hand-glass in the common border, and cut back those intended for specimens into a proper shape. Those intended for cut blooms must not have any of the tops removed, however unsightly they may grow. The leaves of *Crocuses* to be tied-up; as soon as the foliage turns yellow they may be taken up. Take off the side shoots of *Pansies*, and strike them in the common border under a hand-glass.

### FRUIT GARDEN.

Continue to pay attention to fruit trees; nail-in the strong shoots of those against walls. Vines on walls require much attention to bring the fruit to perfection; indeed, if proper attention is not paid them in stopping, regulating, and nailing-in the shoots, they are not worth retaining.

### STOVE.

All rambling shoots of ordinary stove plants to be frequently stopped. Shift *Clerodendrons*, *Erythrinae*, *Gloriosas*, &c., and give liberal supplies of weak liquid manure. The *Dendrobiums*, *Erides*, *Saccolabiums*, *Vandas*, *Phalenopees*, *Sarcanthus*, *Sobralia*, &c., will require abundant and frequent waterings and syringings. The baskets of *Stanhopeas*, *Gongoras*, &c., to be thoroughly soaked where full of roots.

### GREENHOUSE AND CONSERVATORY.

The principal part of the greenhouse plants may now be safely transferred to an out-of-door situation. Select, if possible, a shady situation, open to the east, and protected from high winds; the plants to stand on a bottom carefully prepared to exclude worms from getting into the pots. When the greenhouse or conservatory is thus partially emptied, a portion of the more hardy stove plants may be introduced. Climbers will require attention to keep the young shoots within proper bounds. Although the young wood may partially be allowed to ramble in its natural habit of growth, still it will require some attention to prevent confusion. *Kennedya*s may be slightly cut back after blooming to produce a new growth; water to be given liberally to the plants in the open borders of the conservatory. The *Balsams* and other annual plants grown for filling-up vacancies in the conservatory or greenhouse to be encouraged by frequent shifts, to be kept in bottom heat and near the glass; the few early-formed flower-buds that appear to be picked off, as it is advisable that

the plants should attain a considerable size before being allowed to bloom. Common and fancy Pelargoniums for late blooming thrive best in cold pits, where they can be protected from heavy rains. Pot Fuchsias into their blooming pots if not done already. An abundance of air to be given to Japan Lilies. Keep a portion in the shade of a north wall for a succession of bloom.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

WRITING this at the end of the month, there has been little done except work of routine, as watering Cauliflowers throwing up their heads with manure water, throwing as much salt among Asparagus-rows as would just slightly whiten the ground, making a last sowing of garden Beans except a few in a sheltered place to come in late, pricking-off Cauliflower plants, sowing them and Lettuces in succession. The latter we mostly transplant from scarcity of room; but when we have got enough of space we by far prefer sowing thinly in rows, and then thinning-out a foot apart as the best plan for obtaining large succulent Lettuces. The Paris Cos is a fine crisp summer Lettuce; and now those who would as soon take poison as Lettuces in winter may enjoy them to the full in hot weather. Sowed also London Coleworts, and a few more Broccoli and other vegetable seeds, and made arrangements for planting out Vegetable Marrows and Gherkin Cucumbers.

### PLANTING.

In planting with the dibber, the roots cannot be squeezed too hard, provided they are not hurt, and one stroke of the dibber after the hole is made, and the plant put in, held obliquely, taking some soil with it, and brought firm up to the roots, is worth a score of fiddle-faddle strokes. We want some of the old gardeners back again to teach the minutiae. Go round and try the plants after planting, and ten to one you find the half of them hung. The slightest exertion with two fingers will bring them to you, and, perhaps, they have had some half a dozen of strokes of the dibber, or even more, and the affair bungled after all. Nothing but repeated waterings will cause such plants to grow. Let the straight line represent the hole made by the dibber, in which the roots are suspended, the dotted line the one oblique stroke of the dibber in planting, bring the dibber vertical at once, and the roots are held as in a vice, and one stroke more with the point of the dibber fills up all of the hole that is necessary.

Three moves of the dibber are thus sufficient for planting in general, and are more effectual than a dozen, and after all leaving the plants suspended (hung), without earth close to the roots. The only thing to be guarded against is not to crush tender roots, which will rarely be the case if the dibber takes from one-quarter inch to one-half inch of soil between the roots and its hard substance. I revert to the subject because not so long ago a gardener could not conceive what was the matter with a small fresh-planted quarter of Cauliflowers. Every plant was hung with plenty of air round the roots. In planting with a trowel the roots should also be firmed, but not so much. If the plants have balls of earth the trowel or the spade must be used.

When on this economical move, I may also mention another by which much valuable time is often lost. I mean the manufacture of small sticks for tying, now often wanted by the thousand. Those bought and made of deal are brought to a point by being planed all round. How often now do we see men whittling small twigs not much larger than straws up to the girth of their fingers in the same manner. If they had been bodkins for their wives and sweethearts they could not shave and whittle and scrape them more nicely. Now, it is essential that there should be a sharp point so that roots be injured as little as possible. But for all such purposes, two strokes of the knife, the first slice taking off half the point of the stick, and the next taking more than half of what is left sideways, leaves a point as good as twenty whittlings. If at all large, a small cut may be necessary on the other side, but in this case two strong and one gentle stroke ought to be sufficient.

### FRUIT GARDEN.

Thinned Peaches, stopped, tied to stud-nails, watered, giving a good soaking of manure water but not all at once, going 18 inches from the tree first, then in three days or so 2 feet further, and in four days as much more. If at all dry a sudden drenching a over is apt to make the fruit drop. Watered

Strawberries with manure water as it could be got, after stirring up the baked surface soil. Threw a little soot and ashes on some Gooseberry bushes that showed a few caterpillars, throwing it on with the hand below the bushes when they were damp. Have as yet seen no more. Perceive caterpillars getting on Cherry trees, which we have commenced picking and squeezing, and observe some black fly appearing on Morello Cherries, which we will dip in tobacco water as soon as possible; but the work and bother of getting out myriads of bedding plants, fill the hands full when they ought to be at liberty for general purposes. Removed a good many Strawberry-pots into cold pits out of houses partly shaded, convinced that by having more air and light they will be firmer and higher flavoured at table. Set a thing in its place and keep it there until done with, will only do for quite-out-of-the-way places where the gardener can wear his kid gloves and enjoy himself as a gentleman. There is nothing wrong, quite the reverse, in the ambition that fosters self-respect, and respect for others whether above or below us; but it would be well for many young gardeners to remember that they are servants, to dress like their fathers before them, and not to imitate their employers in affected gentility, or covering their faces with long hair so as to resemble an officer just come home from a Canadian winter.

### BEDDING.

Plants in pots received their general routine; but the most of the week has been taken up chiefly with bedding. The mania for this style is only rising, if I may judge from the communications that reach me—comparing notes, soliciting advice, &c.—from parties chiefly that have some claim to set aside the excellent rule of our conductors not to write privately to any of us coadjutors. If the rule was much violated, of course answers would be out of the question; and readers should recollect that in sending at once to the office they may have the benefit of the full consideration of many heads instead of one. Well, we have got about half through with our bedding, and the only thing I feel a little timid about will be the Calceolarias. Though the cuttings were planted in October, the plants got too big and rather drawn for want of room to thin them; but I dare say they will do pretty well. We generally change the planting of every part every year, and that saves using or having recourse to fresh soil to any extent. Last season we were rather artistic in our arrangements, some borders being a good deal in the style of the pattern given lately by Mr. Thomson, of Archerfield, whose arrangement of conservatories at Dyrham Park I had the privilege of recording. This season we are going back more to the old plainer styles, just for a change. These matters may not be of much importance to planters in general, who will individually prefer their own styles and systems. Two things we consider of more importance than mere early planting, or even very large plants, except for early blooming, and this we like to have and to cover the beds as soon as possible. As many are delaying their full work until the beginning of June, these two matters will not be yet too late. The first has been already referred to—the frequent turning of the ground so as to dig down the heated surface. Let this be done frequently, and the plants go at once into a sort of hotbed. The second is to give each plant a little fresh compost, which also shall be rich, light, and warm. The lightness is more necessary in our heavy soil. For that we generally depend on scrapings from the highway, clearings from the potting-bench, leaf mould riddled, mushroom-dung riddled; and as that might neither be light enough, nor dry enough, nor warm enough, we add a considerable portion of charred rubbish burned, and half-burned earth in a hot state. We generally commence this heap a fortnight or so before planting-time. All the prunings are kept in a heap. Kale-stalks, Brussels Sprouts, &c., are added; all the turf parings from fresh raising the beds, and walks, and other refuse. Earth is added, and fired, and looked after so that it may not blaze. When pretty well burned we take out a number of barrowloads for mixing as wanted, and in this mixture, with half a handful or so to a plant, the roots run very freely in general. A cartload will do for a great many plants. When the plants are small we spread a little over the bed before planting, and scrape it to the roots with a trowel. When the plants are large a little is thrown round the roots as we go along. This practice is gradually lightening the ground. The only disadvantage is that the road scrapings and drift give a good many little weeds; but as the beds would need stirring at any rate, we put up with this disadvantage for the counterbalancing advantage. We ourselves place much reliance for success on these two measures.—R. F.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**FLORISTS' FLOWERS (S. S. S.).**—The Carnation and Picotee were Nos. 4 and 5 in the Series. No. 1 is the Cineraria, and is our No. 45 New Series. Other flowers will follow, but we cannot specify the order in which they will appear.

**MYOSOTIS AZORICA (B. H.).**—Your seedlings of this spring will flower this summer. Whether or not they will live over the winter depends on where they are growing.

**VIOLETS (C. H.).**—Mr. Beaton says that he is very sorry he did not know whom to thank for the trouble of sending the Violets. He received two little cuttings all but dead, and both died before they could be rooted. The blue one was a common sort; the light one he never saw before.

**COCOA-NUT FIBRE REFUSE (A. B. S. H.).**—The sample sent is the right kind.

**TODACCO (A Young Beginner).**—In our No. 48, New Series, you will find directions for drying the plants, and in No. 293, of our First Series, a full account of the American mode of cultivating it. The blossoms without fruit on your Vegetable Marrows are the male blossoms. Bees and other insects will effect all the needful fertilisation.

**ITALIAN TUBEROSE CULTURE (Micran).**—A cartload of book learning has been written on this plant, and the whole put together is of no use whatever, for the plant will not pay to be grown in this country. The "roots" grown in England would not be worth 1s. the thousand, but grown in Italy they fetch 4s. a-dozen. It is, therefore, needless to waste more paper and patience on English-grown Tuberoses. The very same treatment as for pot Hyacinths or Narcissus will do for imported bulbs of the Tuberosae, all but the time of planting. From the 1st to the end of April is the right time to pot and start with. Like all bulbs that are partially or otherwise forced, the pot should be full of roots before extra heat is given. Tuberoses do very well under the stage of a greenhouse or in any dry warm room till the pots are full of roots. Then some extra heat, but not much, will cause them to bloom sooner; but with the same soil and treatment as a pot Geranium the Tuberoses will flower in the autumn, and by forcing slightly will bloom as early as the beginning of July.

**MANGLES' VARIEGATED GERANIUM (Amateur and Novice, Preston).**—Yes, the four leaves are four different sports, but ere the summer is over they will come to the usual two forms of the species, for that is now the only real wild species of Geranium that is bedded. The plain horse-shoe leaf is from the original wild species from the Cape. Mangles' plant was a variegated sport from that wilding, which turn or sport became all but barren, although the parent is the most inveterate seeder in the whole family. That sport is, in its turn, a sport also, the wilding endeavouring to regain its original form and character. Now, if you take a cutting of the green sport from Mangles' Variegated, and get a stock of plants from a bed then on strong clay land, that bed will bear in brilliancy a bed of Punch; but on light land or poor soil it does not succeed. As to the flowers they will be about double the size, and twice the stoutness of those of Mangles' Variegated, and will represent, at Preston, the true style of the Nosegay action, of which ladies who know all about flowers are so fond. All that we have seen proved twenty years back in the garden of the late Sir Abraham Hume, at Wormleybury; near the Rose Nurseries of the Messrs. Paul, of Cheshunt and Waltham. The Hon. Capt. Cust held that garden then. The soil was "brick earth," and the bed of the mother of Mangles' was, at the end of August, the very gayest bed of Geranium of any sort or kind we have ever seen. Your back-wall greenhouse climber, of which you send a leaf, is a Lophospermum, but which depends on the colours of the flower. It will do no good in a pot unless you can plant it in a border. Send it back to your friend, but out of doors is best for it, but like a Geranium it will not bear frost.

**LAYERED BRANCH OF A VINE (—).**—You may separate from the parent in autumn, if upon examination you find that the layered portion has formed a good amount of roots.

**DAMP ON INSIDE OF FERN-GLASS (—).**—It is caused by the air in the room being cooler than the air inside the bell-glass. Covering the glass with flannel will prevent the damp condensing at night on the glass. During the day you must either keep the Ferns in a warmer room, or wipe the damp from off the inside of the glass.

**ROOF OF ORCHARD-HOUSE (Ignoramus).**—You have got more slope than a common garden frame, and the water does not pour into them as in yours it seems to do. In glazing an orchard-house, we put the highest part of the squares in the centre, alike for strength and to throw the water to the sides; but we have no drip to speak of. Your laps are much the same as ours. We do not see why the panes do not touch at the sides—there must be something wrong there in the glazing. We do not see any remedy unless regulating or putting the laps. You might try putting the laps for 3 inches or 4 inches on each side at first.

**VINE LEAVES BLACK-SPOTTED (Banffshire).**—See that your drainage is all right. Do not use much sulphur in the house, and add some quicklime to the surface of the border before rain. We should judge that the house had been kept rather close, and that there was too much moisture and organised matter in the soil.

**SEEDLING POTATO (S. A. Daintree).**—Your seedling Potatoes "Daintree's Earliest," of last year's crop are large and handsome. We have cooked the sample received, and we must acknowledge they are very fine indeed, both in regard of flouriness and flavour.

**PEACHES NOT SETTING (Idem).**—The dull weather would be against the Peaches setting. Did you give abundance of air? We knew a house where air was neglected on a bright day, and every blossom fell. Of course the decay at the centre of the shoots is so far unsatisfactory (if it is decay); but if the trees are healthy, and making new wood outside, we do not think we would change the trees. Trees will bear well enough though the heart is all gone, if fresh growth continues outside.

**ORCHIDS (W. M.).**—There are not twelve Orchids, nor twelve stove plants of any kind except Cacti, that can be grown in a Melon-house. Melons, when ripening, require to be kept quite dry. The "Orchid Manual" by T. Appleby, can be had free by post for thirty-two penny postage stamps from our office.

**PEAR TREE UNFRUITFUL (A. W.).**—As you have root-pruned the tree, give a little rich mulching, and nip the points of the shoots. We expect next year you will have bloom-buds; but root-pruning tells most favourably on young trees, and on trees very luxuriant.

**MUSHROOMS UNDER A GREENHOUSE STAGE (T. R. W.).**—Mushrooms will grow there as well as in the cellar, or in a corner of the stable, or wood shed; but whether you can grow them there, you must be the best judge. All we can say is, we would not advise any one to attempt such a thing. If there is good earth under the stand, plant climbers in it; if not, drain it and make a capital border for climbers.

**STRIKING HEATH CUTTINGS (A Subscriber).**—This is a very good time to strike Heath cuttings, but they are struck all the year round. We would not advise you to try them, even now, except by way of experiment and amusement; for we fear that you will not rear one plant out of fifty from the first 500 Heath cuttings you make. But look over "Heath cuttings" in former Numbers, and think over the matter in your own mind; and if you require more help here it is, and most welcome. Nothing is more amusing than making cuttings and getting seedlings up, if one lost ninety-nine out of a hundred of them.

**BOX-EDGING (R. F. S.).**—We removed as much Box-edging in October, November, December, January, and February as would reach from one end of a parish to the farthest-off end of the next to it; and we are satisfied that not one blade of your Box was killed by the transplanting, but with the salt alone. But the salt had an easier prey from the recent plating. Salt will kill trees just as readily as tree Box, and it will kill dwarf Box much faster and sooner than any other edging of like substance. We would never allow, upon any consideration whatever, the use of salt, or of liquid manure to any but to the best practical hands.

**PAINTING A FERN-HOUSE (H. B.).**—Very likely the smell of paint would injure the young growth of the Ferns so early as this in the season; but if you were to put off the painting to the middle or end of August, and then opened all the doors and ventilators, and left them so at night for three weeks, it would not only be very likely to save the Ferns from the smell of paint, but do them more good in less time than ever they received in double the time since they were planted out.

**GERANIUM WALTHAM PET.**—At the Royal Horticultural Society's recent exhibition at Kensington, this Geranium, raised by Mr. W. Paul, had a First-class Certificate awarded to it, and not a Second-class Certificate as stated in our report; and as the difference between the two amounts to the difference between a first-rate and a second-rate plant—a matter commercially of great importance, we readily correct this error.

**SANDERS ON THE VINE (Grapes).**—The new edition is now published, price 8s.

**JOINTLESS TUBULAR BOILER.**—Mr. Ormson writes to inform us that his is the only one "commended" at the Horticultural Society's Garden show of implements. The omission on our part was unintentional.

**LIQUID MANURE (J. C. Hafod).**—Soapsuds, &c., from the house, may mix with the drainage from the cow-house, and will be one of the best of liquid manures. Do not use it too strong.

**NAMES OF PLANTS (J. D., Forfarshire).**—1, *Veronica hederifolia*; 2, *A. Myosotis*, indeterminate; 3, *Veronica arvensis*; 4, *Arenaria serpyllifolia*; 5, *Cyanostis perfoliata*. (*H. B. S.*)—*Niphobolus lingua*. (*W. Baynes*).—*Clanthus puniceus*. (*A. Robertson*).—The specimens were not numbered. How can we refer to them? Send fresh specimens and numbered. (*B. B. II*).—We paid 6d. for the carriage of your box. Upon receipt of six postage stamps we will publish the names.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

- JUNE 3rd. ESSEX AGRICULTURAL ASSOCIATION. Sec., R. Emson, Slough House, Halstead. Entries close May 10th.
- JUNE 4th and 5th. BEVERLY AND EAST RIDING. Sec., Mr. Harry Adams.
- JUNE 12th, NORTH HANTS AGRICULTURAL SOCIETY. Sec., Mr. B. DOWNS. Entries close May 21st.
- JUNE 26th and 27th. SUFFOLK (Woodbridge). Sec., Mr. J. Loder, jun. Entries close June 5th.
- JULY 3rd. PRAESCOT. Sec., Mr. James Beesley. Entries close June 21st.
- JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. Secs., G. Newton and J. Wade. Entries close June 21st.
- SEPTEMBER 9th. WORSLEY AND ARMLEY (near Leeds). Sec., Mr. Robertson Hoyle, Armley, near Leeds.
- DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.

HULL POULTRY SHOW.

The first Exhibition of poultry in connection with the Floral and Horticultural Society at Hull, was held on Wednesday and Thursday last, May 28th and 29th, and as far as the entries for poultry and Pigeons are concerned, was a most successful one.

The number of pens entered amounted to 253, many of them from some of the most noted exhibitors in the north; and as a certain consequence in many of the classes for poultry, and more especially among Pigeons, the competition was very close indeed. Mr. Turner, of Sheffield, supplied the pens, and the birds showed to great advantage in them. They are far preferable to willow coops, not only in this respect, but also on account of the great economy of space, as they do not take up much more than half the room coops would occupy.

The Show of both poultry and Pigeons was pronounced by competent judges to be the best ever held in the town of Hull; and it is only due to those who had the management of the poultry department to say, that every pen of both poultry and Pigeons was carefully repacked and sent to the railway station before ten o'clock the same night.

The following is the list of awards of the Judges:—

**DORKINGS.**—First, Second, Third, and Fourth, H. W. B. Berwick, Helmsley. Highly Commended, H. Himsforth, Lupset Hall, near Wakefield.  
**SPANISH.**—First, E. Brown, Sheffield. Second, R. Teebay, Fulwood, near Preston. Third, J. Shorthose, Newcastle-on-Tyne. Highly Commended, J. Dixon, Bradford; T. B. Stead, Leeds.  
**COCHIN-CHINA.**—First, E. Smith, Manchester. Second, J. Shorthose, Newcastle-on-Tyne. Third, T. C. Trotter, Sutton. Highly Commended, H. W. B. Berwick, Helmsley; E. Smith, Manchester; H. Yardley, Market Hall, Birmingham.

**GAME** (Black-breasted and other Reds).—First and Second, H. Adams, Beverley. Third, G. R. Tate, Driffield. Highly Commended, W. Boyes, Beverley; H. M. Julian, Beverley; J. Hodgkinson, Hull; H. Beldon, Bradford.

**GAME** (any other variety).—First and Second, H. Adams, Beverley. Third, G. W. Langdale, Beverley.

**HAMBURGS** (Golden or Silver Pencilled).—First, H. Beldon, Bradford. Second and Third, J. Dixon, Bradford. Highly Commended, S. Shaw, Stainland, Halifax.

**HAMBURGS** (Golden or Silver Spangled).—First and Second, J. Dixon, Bradford. Third, H. Beldon, Bradford. Highly Commended, H. W. B. Berwick, Helmsley; S. Shaw, Stainland, Halifax.

**POLISH** (any variety).—First, Second, and Third, J. Dixon, North Park, Bradford.

**ANY OTHER DISTINCT OR CROSS BREED.**—First, S. Shaw, Stainland, Halifax (Black Hamburgs). Second, G. R. Tate, Driffield (Malaya). Third, R. Teebay, Fulwood, near Preston (Brahma Pootra). Highly Commended, J. Dixon, Bradford; T. B. Stead, Leeds (Brahma Pootra).

**CHICKENS OF 1862.**—First, H. Beldon, Bradford (Hamburgs). Second, R. D'Ewes, Knarborough (Cochin-China). Third, J. Dixon, Bradford.

**BANTAMS** (Gold or Silver Laced).—First, E. Hutton, Pudsey, near Leeds. Second, E. Yearley, Wiscwood, Sheffield. Third, S. Shaw, Halifax.

**BANTAMS** (Black or White).—First, Master G. H. Crosland, Wakefield. Second, J. Dixon, Bradford. Third, J. Crosland, jnr., Wakefield. Highly Commended, E. Hutton, Pudsey, near Leeds; J. Gawao, Beverley.

**BANTAMS** (Game).—First, C. W. Brierley, Rochdale. Second, H. Taylor, Chesterfield. Third, J. Shorthose, Newcastle-on-Tyne. Highly Commended, T. G. Glenton, Hull; R. Voakes, Driffield; G. R. Tate, Driffield; E. Holdsworth, Leeds. (A very good class.)

#### SWEEPSTAKES.

**GAME COCKS.**—First, G. R. Tate, Driffield. Second, H. Adams, Beverley. DORRING COCKS.—Prize, Rev. J. G. A. Baker, Biggleswade, Beds.

**SPANISH COCKS.**—First, R. Teebay, Fulwood, near Preston. Second, Rev. E. Smith, Northamptonshire. Third, T. P. Wood, jun., Chesterfield. Highly Commended, W. Houseman, Tadeaster; E. Brown, Sheffield; Rev. E. Smith.

**COCHIN-CHINA COCKS.**—First, R. D'Ewes, Knarborough. Second, E. Smith, Manchester.

**HAMBURGH COCKS.**—Prize, H. A. Hudson, Ousecliffe, York.

**GAME BANTAM COCKS.**—First, J. Crosland, jun., Wakefield. Second, R. M. Stark, Hull. Highly Commended, T. Ripon, Beverley; G. R. Tate, Driffield.

**BANTAM COCKS** (any other variety).—Prize, E. Hutton, Pudsey, near Leeds.

**DUCKS** (Aylesbury).—First, H. Beldon, Bradford. Second, G. R. Tate, Driffield.

**DUCKS** (Ronen).—First, G. R. Tate, Driffield. Second, J. Dixon, Bradford. Third, S. Shaw, Halifax. (The class Highly Commended.)

**DUCKS** (Black East Indian).—First and Second, J. R. Jessop, Hull.

**DUCKS** (any other variety).—First, S. Shaw, Halifax (a very beautiful pen of Carolinas). Second, Miss White, Beverley.

**GESE** (any variety).—First, G. R. Tate, Driffield. Second, J. Dixon, Bradford. Third, J. R. Jessop, Hull.

**TURKEYS** (any variety).—First, J. Dixon, Bradford. Second, G. R. Tate, Driffield. Third, Lady F. Haawe, Womersley Park, near Pontefract.

**GUINEA FOWL** (any variety).—First, H. Merkin, Driffield. Second, H. Beldon, Bradford. Third, H. & G. Newton, Garforth, Yorkshire. Highly Commended, G. R. Tate, Driffield; R. Voakes, Driffield; J. Dixon, Bradford. (A very good class.)

**PIGEONS.**—*Carriers.*—First, W. Cannan, Bradford. Second, S. Shaw, Halifax. Third, G. Robson, Hull. Highly Commended, W. Cannan; A. L. Silvester, Birmingham; J. Firth, Dewsbury. *Almond Tumblers.*—First, W. Cannan. Second, S. Shaw. Third, H. Yardley, Birmingham. Highly Commended, A. L. Silvester. *Tumblers* (any other variety).—First and Second, W. Cannan. Third, R. & J. Bell, Beverley. Highly Commended, J. W. Edge, Birmingham; S. Shaw. *Pouters.*—First, S. Robson, Burton-Salmen. Second, H. Beldon, Bradford. Third, J. Crosland, jun., Wakefield. Highly Commended, S. Shaw. *Jacobins.*—First, S. Shaw. Second, F. Else, London. Third, T. Ellington, Beverley. Highly Commended, W. Cannan. *Fantails.*—First, T. Ripon, Beverley. Second, W. Cannan. Third, H. Key, Beverley. Highly Commended, J. R. Jessop, Hull; T. Ellington; S. Shaw. *Trumpeters.*—First, S. Shaw. Second, H. Key. Third, H. Yardley. Highly Commended, A. L. Silvester; J. R. Jessop; E. Smith, Birmingham. *Bairs.*—First, S. Shaw. Second,

E. Smith. Third, W. Cannan. Highly Commended, A. L. Silvester. *Turbits.*—First, Master G. H. Crosland, Wakefield. Second, S. Shaw. Third, W. Cannan. Highly Commended, W. Catterson, Hull; F. G. Glenton, Hull. *Owls.*—First and Second, W. Cannan. Third, H. Key. Highly Commended, F. Else. *Any other Variety.*—First, H. Beldon. Second, W. Lingard, Hull. Third, H. Yardley. Highly Commended, S. Shaw; G. H. Crosland.

**RACONTS.**—*Best Pair for Longest Ears.*—First, T. Rousby, Hull. Second, G. Jones, Birmingham. *Best Pair for All Properties.*—Prize, T. Rousby.

The Judges were, J. H. Smith, Esq., of Skelton Grange, York; and Samuel Bird, Esq., of Shipley.

## BATH AND WEST OF ENGLAND POULTRY EXHIBITION.

MAY 27TH, 28TH, AND 29TH.

ONE of the most successful poultry shows ever yet held by this Society was the one just concluded at Wells, Somerset. Considering the time of year as being that in which most of the best specimens are breeding, together with the well-known fact that May is undoubtedly too early to hope for a very extensive show of chickens of the current year, the collecting together of three hundred pens of first-rate poultry must be esteemed most satisfactory. The numerous plate prizes unquestionably produce no small portion of this competition, and a perusal of the printed catalogue shows that the exhibitors are widely spread throughout most parts of the kingdom. The arrangements in the showyard admit of no improvements so far as scrupulous care and attention to the wants of the poultry are considered; but there is one regulation we hope to see modified on future occasions, as we feel confident it will secure the good opinions of all parties interested. It is this—by a regulation issued with the prize list it is enforced, that "all the specimens intended for exhibition must be in the showyard before 12 o'clock on the morning of Monday, the 26th of May; otherwise they will not be admitted, &c." As a large number of the fowls belonging to the more distant competitors were not forthcoming at that time, the permission was extended to the same time the day following. Perhaps in the present case it was a wise policy to do so; but as a permanent regulation it is open to much grave objection, being scarcely a fair treatment to those owners, who, in spite of much personal discomfort and exertion, contrived to get their pens on the ground in accordance to rule.

A very simple alteration would accommodate nearly every one, and leave disputation out of the question—viz., to receive poultry to some given hour on the Tuesday, and afterwards rigidly adhere to the time specified. It would without doubt much improve the amount of entries generally; and likewise of necessity add no small income to the revenue of the Society.

Within our own personal knowledge not an inconsiderable number of exhibitors refused "to enter at all, because 12 o'clock on Monday, as the latest date for arrival at Wells, absolutely necessitated the fowls being packed and sent off on the Sabbath, or at the best suggested an alternative of forwarding them on the Saturday, to be possibly delayed and neglected on the rails for some forty-eight hours, or even a longer period." As the future interests of the Society will enforce an alteration on this point, we will simply add, that to run the risk of sending valued fowls to be delayed throughout Sunday is hardly to be expected; whilst the no less objectionable plan of packing and forwarding them on the Sabbath will be as universally admitted.

The showyard was this year admirably chosen, the views being of the most rural and extended character, whilst an inspection of the venerable cathedral and some other public buildings afforded no little satisfaction to visitors.

In *Spanish* fowls Mr. Rodbard, Mr. Fowler, and Mr. Martin were the successful ones. It does not by any means follow, however, that they were the only individuals who exhibited good pens, for the class throughout was far better than ordinary.

In *Dorkings* all colours were admissible. In this class the palm was carried off by a very well-shown pen of "Greys" belonging to Mr. Wakefield, of Malvern Wells; the pens of Lady Julia Cornwallis taking second and third position, but evidently betraying want of condition from frequent exhibition. There were a few capital White Dorkings shown in this class.

Mrs. Pookes easily secured both first and second prizes (with Buffs), in the *Cochin* class. Mr. Chase taking the third prize with a pen of excellent White ones.

In the *Game* classes Mr. Fletcher, of Manchester, was the most successful exhibitor, although Mr. Archer, of Malvern,

Mr. Harry Adams, of Beverley, and some others pressed that gentleman very closely.

Mr. Charles Ballance stood ahead in Malays. His pen has wonderfully improved since the recent show at Taunton.

The *Hamburgs* were first-rate, Mr. Josiah Chum showing the best Golden-spangled; Lady Julia Cornwallis the best Silver-spangled; and Mr. Martin sweeping away the prizes altogether for both Golden and Silver-pencilled ones.

Messrs. Ray, Pettat, and Edwards, divided the prizes for Poland, the classes being small but the birds excellent.

The "Sweepstakes for Coeks" brought but little competition, saving the Single Game Coek class, which was keenly contested.

In the class, a "sweep" for Game *Bantams*, H. D. Bayley, Esq., sent a bird a perfect credit to any breeder. His Bantam's success in any competition would have been equally certain, as in the present one, where he stood without opponent of any kind; but of his pecuniary winnings on this occasion the less is said the better. By rule the prize being the return simply of his own entry-money after deducting expenses.

*Ducks, Geese, and Turkeys* mustered in numbers, and were really excellent, as were also the Peafowls and the Variety class generally.

The *Pigeons* were, without doubt, a most excellent and interesting collection; the Carriers, Powters, Runts, Jacobins, Fan-tails, Owls, and Trumpeters being the most praiseworthy. It is very rarely we have visited a collection of these interesting varieties shown so well throughout.

The most careful arrangements were provided for the prompt return of the poultry exhibited.

**SPANISH.**—First, J. R. Rodbard, Wrington, near Bristol. Second, J. K. Fowler, Aylesbury, Bucks. Third, J. Martin, Claines, Worcester. Highly Commended, R. Teehay, Fulwood, near Preston. Commended, R. Wright, London.

**DORKING (Coloured or White).**—First, C. H. Wakefield, Malvern Wells, Worcestershire. Second and Third, Lady J. Cornwallis, Linton Park. Highly Commended, Mrs. H. Fookes, Whitechurch, Dorset; W. Bronley, Birmingham; E. H. Garrard, Broadway, Worcestershire; Major A. S. Altham, Stoke St. Mary, Somerset.

**COCHIN-CHINA (Coloured or White).**—First and Second, Mrs. H. Fookes, Whitechurch, Dorset. Third, R. Chase, Birmingham. Highly Commended, Mrs. B. J. Ford, Countess Weir, Exeter; J. K. Fowler, Aylesbury. Commended, H. Tomlinson, Birmingham; C. Felton, Erdington, Birmingham.

**GAME (Whites and Piles, Blacks and Brassy-winged).**—First, J. Fletcher, Stoneclough, near Manchester. Second, J. B. Weeks, Bromyard, Worcester. Third, Rev. G. S. Crawys, Tiverton, Devon. Highly Commended, W. Dawson, Selly Oak, near Birmingham.

**GAME (Black-breasted and other Reds).**—First, J. Fletcher, Stoneclough, near Manchester. Second, H. Adams, Beverley. Third, S. Matthews, Stowmarket, Suffolk. Highly Commended, S. Dupe, Bath; R. Cozens, Shepton Mallet, Somerset; Rev. G. S. Crawys, Tiverton. Commended, T. Burgess, jun., Whitechurch, Salop; Rev. G. S. Crawys.

**GAME (Duck-wings and other Greys and Blues).**—First, S. Dupe, Bath. Second, J. Fletcher, Stoneclough, near Manchester. Third, W. Dawson, Birmingham. Highly Commended, G. W. Langdale, Beverley.

**MALY (Coloured or White).**—First, C. Ballance, Taunton. Second, J. Rimes, The Grove, Hackney. Third, W. Mansfield, jun., Dorset.

**HAMBURG (Golden or Silver-Pencilled).**—First, Second, and Third, J. Martin, Claines, Worcester. Commended, E. M. Dansey, Gloucestershire.

**HAMBURG (Golden or Silver Spangled).**—First, J. L. Chane, Coalbrookdale, Shropshire. Second, Lady J. Cornwallis, Staplehurst, Kent. Third, N. Marlor, Manchester. Highly Commended, I. Davies, Harborne, near Birmingham; W. Joshua, Cirencester; T. L. Brown, Somerset.

**POLANDS (Black with White Crests).**—First, G. Ray, Lyndhurst, Hants. Second, T. P. Edwards, Lyndhurst, Hants.

**POLANDS (Golden and Silver Spangled).**—First and Second, Mrs. Pettat, Basingstoke, Hampshire.

**ANY VARIETY NOT COMPRISED IN THE FOREMENTIONED CLASSES.**—First, P. P. Cother, Salisbury, Wilts (Pheasant Malays). Second, Miss S. H. Northcote, Upton Pyne, near Exeter (White Spanish). Third, W. Mansfield, jun., Dorchester (Rumpless). Highly Commended, C. H. Wakefield, Malvern Wells, Worcestershire (Crève Cœurs); R. Teehay, Fulwood, near Preston (Brahmas).

**SPANISH CHICKENS (Black or White).**—First and Second, J. R. Rodbard, Wrington.

**DORKING CHICKENS (any variety).**—First, C. H. Wakefield, Malvern Wells, Worcestershire. Second, Miss J. Milward, Newton St. Lo, Bath. Highly Commended, J. K. Tombs, Langford, Gloucestershire.

**GAME CHICKENS (any variety).**—First, J. Fletcher, Stoneclough, Manchester. Second, W. D. Braginton, Bideford. Highly Commended, S. Dupe, Bath; H. Adney, Lympstone, Devon. Commended, H. Adney.

**COCHIN-CHINA CHICKENS (any variety).**—First, G. Locke, Newport, Isle of Wight. Second, Mrs. Fookes, Whitechurch, Dorset. Commended, J. K. Fowler, Aylesbury.

#### SWEEPSTAKES.

**GAME.**—First, E. Archer, Malvern. Second, J. Fletcher, Stoneclough, near Manchester. Third, J. Camm, Farnsfield, Notts.

**SPANISH.**—First, J. R. Rodbard, Wrington, Somerset. Second, H. Lane, Bristol.

**DORKING.**—First, Lady J. Cornwallis, Staplehurst, Kent. Second, J. G. A. Baker, Biggleswade, Beds.

**COCHIN-CHINA.**—First, P. Cartwright, Oswestry. Second, C. Felton, Erdington, near Birmingham.

**GAME BANTAM.**—PRIZE, T. H. D. Bayley, Biggleswade, Beds.

**BANTAMS (Gold Laced).**—First, T. H. D. Bayley, Biggleswade, Beds.

Second, Rev. G. S. Crawys, Tiverton. Commended, Rev. G. F. Hodson, Somerset.

**BANTAMS (Silver Laced).**—Silver Cup and First Prize, T. H. D. Bayley, Biggleswade, Beds. Second, Rev. G. S. Crawys, Tiverton.

**BANTAMS (White and Black).**—First, T. H. D. Bayley, Biggleswade, Beds. Second, Rev. G. F. Hodson, Somerset. Highly Commended, E. Hutton, Pudsey, Leeds; Rev. G. S. Crawys, Tiverton.

**BANTAMS (any other variety).**—First, J. Camm, Farnsfield, N.tingham. Second, W. A. Deane, Blackford, Devon. Highly Commended, T. H. D. Bayley, Biggleswade, Beds; J. Camm.

**DUCKS (White Aylesbury).**—First, J. K. Fowler, Aylesbury. Second, G. Hanks, Malnesbury, Wilts. Commended, J. K. Fowler; G. G. Barrett, Tiverton.

**DUCKS (Black East Indian).**—First, G. R. Edgell, Brandford Speke, near Exeter. Second, Major Altham, Stoke St. Mary, Somerset.

**DUCKS (Rouen).**—First, Mrs. J. N. Grenville, Glastonbury, Somerset. Second, J. K. Fowler, Aylesbury.

**DUCKS (any other variety).**—Prize, T. H. D. Bayley, Biggleswade, Beds (Call).

**GEESE.**—First, W. Mansfield, jun., Dorchester. Second, J. K. Fowler, Aylesbury. Highly Commended, Mrs. Fookes, Whitechurch, Dorset.

**TURKEYS.**—First, Mrs. Fookes, Whitechurch, Dorset. Second, R. Brand, Great Shelford, Cambridgeshire. Highly Commended, Miss J. Milward, Newton St. Lo, Bath; Mrs. J. N. Grenville, Glastonbury, Somerset.

**PEAFOWLS.**—First, C. Ballance, Taunton. Second, H. Adney, Lympstone, Devon.

**GUINEA FOWLS.**—First, Miss S. H. Northcote, Upton Pyne, Exeter. Second, W. D. Braginton, Devon.

**CARRIERS.**—First, Major Hassard, Hilsa, near Portsmouth. Second, A. L. Sylvester, Birmingham. Highly Commended, A. L. Sylvester; A. S. Altham, Stoke St. Mary, Somerset. Commended, Major Hassard.

**TUMBLERS (Almond).**—First, withheld. Second, A. L. Sylvester, Birmingham.

**TUMBLERS (Any other Variety).**—First, S. Summerhayes, Taunton. Second, F. Else, Westbourne Grove, London.

**POWTERS.**—First, E. Pigeon, Lympstone, Devon. Second, A. S. Altham, Stoke St. Mary, Somerset.

**RUNTS.**—First, F. Key, Beverley. Second, E. Pigeon, Lympstone, Devon.

**JACOBS.**—First, A. S. Altham, Stoke St. Mary, Somerset. Second, S. Summerhayes, Taunton.

**FANTAILS.**—First, A. S. Altham, Stoke St. Mary, Somerset. Second, F. Else, London.

**OWLS.**—First, A. S. Altham, Stoke St. Mary, Somerset. Second, W. H. Beadon, Somerset.

**TRUMPETERS.**—First, F. Else, London. Second, S. Summerhayes, Taunton.

**BARNS.**—First, A. S. Altham, Stoke St. Mary, Somerset. Second, no competition.

**TURNTS.**—First, F. Else, Westbourne Grove, London. Second, A. S. Altham, Stoke St. Mary, Somerset. Highly Commended, E. Pigeon, Lympstone, Devon; J. Adzey, Collympton; S. Summerhayes, Taunton.

**YONS.**—First, unnamed. Second, N. Key, Beverley, Yorkshire.

**DRAGONS.**—First, E. Pigeon, Lympstone, Devon. Second, S. Summerhayes, Taunton. Highly Commended, A. L. Sylvester, Birmingham; J. F. Brand, Newton Abbott, Devon; S. Summerhayes.

**ARCHANGELS.**—First, S. Summerhayes, Taunton. Second, A. L. Sylvester, Birmingham.

**ANY OTHER NEW OR DISTINCT VARIETY.**—First, W. H. Beadon, Cheddon Fitzpaire, near Taunton. Second, S. Summerhayes, Taunton.

The Judges were George Andrews, Esq., of Dorehester, and Edward Hewitt, Esq., of Sparkbrook, Birmingham, both of whom expressed themselves highly pleased with the Exhibition generally.

#### RAISING YOUNG PIGEONS BY HAND.

HAVING a young pair of Almond Tumblers just three weeks old, which I am desirous of rearing by hand from the present time to enable the old ones to have the use of the nest again, there being no other occupied, I shall be much obliged by your telling me whether I might safely venture to feed them by hand on soaked peas or other food. The old ones, which I have recently purchased of Lady Winchester, still feed them well, but cannot go to nest again, as they would very soon do until they are removed; and the season is getting late.—ALFRED HEATH.

[As far as regards the young Almonds it would be much safer to shift them under a pair of common Pigeons, having young not quite so old, as feeders, than to attempt to feed them by hand. And as regards the old ones they would do much better if allowed to feed the young as long as they can than if caused to lay prematurely by removing the offspring. By forcing them, or as the fanciers term it by pumping them, the birds are weakened, and the eggs much more likely to be thin-shelled and sterile.]

#### CANARY HENS SITTING WITHOUT LAYING.

CAN any of your readers inform me if they have had hen Canaries which, after building, have sat without laying a single egg? I have a White-spangled Lizzard which at the beginning of the season made her nest, and for a week sat without laying. I put some eggs under her which she kept for eight days, and would have hatched had I allowed her. After giving her a week's rest she had fresh materials for building; but again she is upon an empty but beautifully-built nest. She paired with a

Lizzard of the same kind. She is well, and eats her seed, and egg, and bread, and green food. Strange to say, I have a green hen which has acted in the same way, but brought up three young birds.—E.C.

[The hen, if old, is no doubt barren. Try her with another cock bird, and if she be a young and valuable bird keep her till next breeding season, and then pair her with another. It occurs occasionally that a young bird will not lay the first season, although she may build and sit on the nest: this is owing sometimes to being placed with a cock bird that is sickly or old and cares nothing about her. In such case the hen (although she be not barren), if it be the first season of her being placed in with a male, will not lay. We know one or two instances in which a hen bird has laid only one egg, and others none at all, the first season, and built and sat on their nests; and during the forthcoming season on being paired with another cock have laid several eggs. In one case the hen became the mother of thirteen birds and reared them all. Try a little hemp and maw seed in with the other food.]

THE HOUDAN FOWL.

If those who read this have ever read "Robert Macaire," we ask them whether the individual figured at the head of the page does not remind them of that worthy. His upright carriage, his impudence mingled with humour, his easy assurance, and the appearance of comfort that lurks around the mouth as it emerges, in one from the ample cravat, and in the other from the beard.

Far be it from us, however, to attribute to the Houdan the vices that have made Robert Macaire famous; and, therefore, as the highest authority on the subject, we will allow M. Jacque to speak.

"PROPORTIONS AND GENERAL CHARACTERISTICS.

"Body rather round, compact, of ordinary proportions, short-legged, and standing firmly on strong feet; pectorals, thighs, legs, and wings well developed; large head; half topknot; whiskers, beard, triple comb, transversal; five toes on each foot;

spotted or splashed plumage, black, white, or yellow white in the adult—in chickens, black and white only.

"An adult will weigh from 6 lbs. to 7 lbs.; flesh abundant; bones light, about an eighth of the whole weight.

"A chicken of this breed is put up to fatten at four months, and killed at four and a half months. If we take away from the weight of the carcase, the liver, gizzard, the flesh of the head, of the neck, and of the feet, indeed, all that constitute the giblets, which find a ready sale, being considered delicacies by some people, there will remain from 2½ lbs. to 3 lbs. of solid compact meat. In this breed the bones of the chicken may be calculated as being hardly an eighth part of the body, while in butcher's meat they weigh a quarter.

"Comb.—Triple, transversal, composed of two elongated and rectangular flattened spirals, opening right and left like the leaves of a book, notched on the sides, and thick and fleshy. A third spiral springs up in the middle of the preceding ones, taking the form of an irregular strawberry, and the size of an elongated nut. Another small spiral detached from the others, and the size of a lentil, should appear above the beak between the two nostrils.

"The Wattles should be united to the comb by fleshy parts which form the face, surround the corners of the beak with apparent notches, and the eye with a naked lid.

"The Ear-lobes short and hidden by whiskers.

"The half Topknot thrown backward, and on the sides a few pointed feathers turning at the points, but sticking up in the air.

"Face.—Naked, surrounded with whiskers formed of short-pointed and up-turning feathers.

"Beard.—Begins under the beak between the wattles, joins the whiskers, and hangs down the neck; wider at bottom than at top.

"Beak.—Strong and rather hooked, black at its insertion, and yellowish at its extremity, depressed towards the beard, and dropping considerably at the corners.

"Physiognomy of the Head.—Differing from many other species by several remarkable features; the head and neck form rather an open angle, so that the drooping beak is seen above it, and takes the appearance of a nose.

"Comb.—The square and flattened comb seems to be a fleshy forehead, the cheeks (in England, face) are surrounded with curling feathers which look like whiskers, the drooping corners of the beak resemble a mouth, and a cravat of feathers joined to the wattles simulates a beard; the topknot is like a rough head of hair, and the entire face at once suggests the idea of that of a man.

"Colour of Legs.—In adults, a leaden grey; in chickens, bluish and whitish grey, with rose-coloured spots.

"Plumage.—It should invariably be composed of black, white, and straw-colour; those fowls that have any mixture of red should be got rid of.

"The plumage of the Houdan is of the variety called splashed or curl-papered. It is irregularly composed of feathers, sometimes black, sometimes white, sometimes black tipped with white, and sometimes white tipped with black.

"THE HEN.

"Body.—Well set, appearing almost as large as that of the

cock, firmly planted on strong legs; breast, thighs, legs, and wings well developed; large head; demi or whole topknot; whiskers and beard very distinct; rudimentary comb and wattles; five claws on each foot; feathers of the abdomen very fluffy, ample, and pendant; other feathers of ordinary length; splashed plumage, black and white with violet and greenish shades.

*“Physiognomy of the Head.*—When the topknot is very developed, the hen is unable to see in front or on either side; she can see only on the ground, because the feathers cover not only the lid but the eye itself; this gives the bird a nervous motion at every noise it hears. It is only by close observation her eyes can be discovered at all.”

#### SKINS OF SILVER GREY RABBITS.

I READ in your paper at the end of February last a very interesting account of the Silver Grey Rabbits, and my attention has been since drawn to the subject by a friend of mine showing me a muff made of the skins of that Rabbit, which he breeds in a confined state. A more handsome and elegant article I have seldom seen. My object in writing this letter is to ask whether any of your readers can inform me why these skins are not made up in England as well as in Russia and China? They are surely much more beautiful than the dyed coarse-looking furs in common use.—INQUIRER.

[We shall be glad of some information in answer to this inquiry; for it does seem extraordinary that nearly all are exported to China and Russia.—EDS. J. OF H.]

#### ARTIFICIAL SWARMING.

I HAVE one good stock of bees, but it is in a cottage-hive. It has flown drones a few days and is very full of bees. Is it possible to make an artificial swarm from it, or would you let it come in the regular way, and if you would make an artificial swarm how could it be managed?—J. W.

[We cannot undertake to determine the point whether you had better trust to Nature for a swarm, or try artificial means. Should you decide upon making the experiment, the best way will be to operate in the middle of a fine day, when the queen and bees of your strong stock should be driven into an empty hive in the manner directed in pages 45 and 46 of “Bee-keeping for the Many.” This must occupy the place of the old stock and will form a very strong swarm. The hive itself should take the place of another good stock, which must be removed to a new position. The returning bees will enter it and raise a young queen from the brood left by their predecessors.]

#### LIGURIAN BEES.

HAVING seen in THE JOURNAL OF HORTICULTURE that Mr. Woodbury was the person to apply to about the Ligurian bees, I took the liberty of doing so, requesting him to inform me if he could warrant the safe carriage of a hive this distance—upwards of 400 miles by rail. He seemed to have not the least doubt as to their safety, and he was kind enough to dispatch one to me on the 8th ult. at seven o'clock, A.M. It reached here the following day at five o'clock, P.M., having been thirty-four hours

on the way; and no doubt it was examined with much interest. I could not help admiring the ingenious way it was made up for the journey, being in one of his own bar-hives. However, when I took off the shutter behind, and looked in through the glass, I saw that the bars had been moved out of their places—the one lying up against the other. My other bees being very busy, I did nothing to the Ligurians, but took off the under perforated zinc shutter, and bound them on the board, which allowed them to get out, when they seemed to enjoy themselves. I covered the hive up for the night to keep them warm. The following day being wet and cold, I could not touch them till eleven o'clock: at that time it had got clearer. Having shut down all my other hives that the Ligurians might not get into them while I was putting the bars into their places, and having taken off the upper board, the whole damage was seen. However, I soon got the bars all into their places, and none of the combs had fallen out of the bars, Mr. Woodbury having had them securely fixed. I then screwed down the top board, and placed the hive in its place, and they soon began to clear away the crumbs of the combs—a good sign that all was right. On the following day they were carrying as well as any of my own black ones, and are doing so still. They seem nothing the worse for the journey. With the exception of carrying out a few young bees, which seemed to be imperfect in some way, they have now ceased doing so.

From the careful way Mr. Woodbury had them secured they must have got very rough usage somewhere, as it seemed impossible the bars could get out of place; but I have no doubt Mr. Woodbury will be able to remedy this in future.

I was astonished at their quietness, they never attempted to sting me; I might have done anything I chose with them. My own black ones would not have allowed me to do as much to them without letting me feel their stings.

I have given the above account of the second colony of Ligurians in the East Lothian, that it may induce other apiarists to get a trial of the Ligurians; they seem active, energetic colonists.—ALEX. SHEARER, *Yester*.

P.S.—On the 24th I took off the cover of the box to see how they were getting on, and I was surprised to find the hive had doubled in weight. They had filled two bars with combs, and other two nearly half, and the others are full of young brood. It is now by far the best hive I have, and I thought I had some good ones; its progress is most extraordinary, far beyond what I could have expected.

#### BEES DESERTING THEIR HIVES.

WHAT can be the reason of my bees leaving their hives? I feel almost ready to abandon them altogether. I have been so repeatedly disappointed by them in this way only. For years past I have attributed their abandoning their homes, so well provided with everything required, to the age of the queen. I have never lost a stock from starvation or any other cause but (to me) this mysterious one. I always make up the full required weight early after the first or second week in August from loaf sugar and water only, boiled into as near as possible the consistency of honey; and they seem to do well till the spring, but afterwards dwindle until there are none left. I have sometimes found the queen a poor little dried thing with a few bees; sometimes I have not found her at all. Once I found her dead, still hanging under the board; but in each case the hive was left with honey, pollen, and much of the syrup which I had given some months previously, and I believe from some cause or other slightly changed. I have been in the habit of hiving my swarms into these hives. I will describe a case.

Last summer I had one stock which swarmed, then afterwards gave a second swarm. In the autumn I fed all three well until they reached the weight mentioned by Mr. Taylor and others. I had no trouble, for they very readily appropriated the syrup. I think they bred well, and from each I hoped to have increased my stock. In the first warm weather after Christmas they worked, but as the spring advanced they seemed to decline. I turned up first the east or second swarm, I should say there were not a dozen bees in it; next, the old stock (which too, be it remembered, had young queens in it last autumn), but this had shared nearly the same fate, and seems to grow worse daily; and lastly, the first swarm (which had the old queen in it). This did not seem quite so bad, and may possibly have a little recovered, as I now and then see a bee go in laden with pollen.

Now, I know mine is not a solitary case, for although kept in a town they have sometimes done well. I have known just the same thing happen to bees placed in the best possible situation for honey collecting. When I was in Oxfordshire some years back, the same complaint was made to me of bees kept at the seat of Lord Churchill, in Cornbury Park. I have had bees by rail out of Oxfordshire, and out of Kent, which have done well for some time and then abandoned their hives as I have deserted, I have dwelt at large on this subject because I know so very many people are interested in it, and I hope you will allow sufficient space to have it well discussed. I can only guess at the cause myself.—E. FAIRBROTHER.

[We must know more of the circumstances before we offer an opinion. Have the bees been located in wooden or straw hives? What are their dimensions, &c.? How are they protected from the weather and from extremes of temperature? Do they appear to have suffered from internal moisture? Are you much annoyed by smoke or ill smells? Full information on all points must be afforded in order to enable us to suggest a remedy.]

REARING CALVES ON MILK AND LINSEED MEAL.

No doubt but the best and most proper food for the calf is its own dam's milk; for it is a true food, in which the components of nutrition are so nicely balanced by the all-wise and beneficent Creator as to set at nought all human compositions; but it is of so much value for human consumption that it becomes necessary to economise it and make imitations of it, though at a very humble distance; and thus it is that science comes to our aid. Professor Johnston says, in his "Lectures on Agricultural Chemistry," "that while the calf is young, during the first two or three weeks, its bones and muscles chiefly grow. It requires the materials of these, therefore, more than fat; and hence half the milk it gets at first may be skimmed, and a little beanmeal may be mixed with it to add more of the casein or curd, out of which the muscles are formed. The costive effects of the beanmeal are to be guarded against by occasional medicine, if required. In the next stage more fat is necessary, and in the third week, at latest, full milk should be given, and more milk than the mother supplies, if the calf requires it; or, instead of the cream, a less costly kind of fat may be used. Oil-cake finely crushed, or linseed meal, or even linseed oil, may supply at a cheap rate the fat which, in the form of cream, sells for much money; and instead of additional milk, beanmeal in large quantity may be tried, and if cautiously and skilfully used, the best effects on the size of the calf and the firmness of the veal may be anticipated."

This scientific note from Professor Johnston has engaged the attention of many stock-masters in Ireland, and amongst the rest, Mr. C. Beamish, of Cork, who adopted it and brought it to a regular system on an extensive scale. His formula for compounding the mucilage is as follows:—Thirty quarts of boiling water are poured on three quarts of linseed meal and four quarts of beanmeal. It is then covered up close; and in twenty-four hours added to thirty-one quarts of boiling water, then put on the fire, pouring it in slowly, and stirring it constantly to prevent lumps, with a perforated wooden paddle, so as to produce perfect incorporation. After boiling thirty minutes, the prepared mucilage or gruel is put by for use, and should be given blood or luke-warm to the calves, mixing it in small quantities at first with the milk, say one-fourth mucilage with three-fourths milk, progressively increasing it, so that by the end of a fortnight it will be in equal parts; by the end of the third week, one and a half mucilage to one part milk; by the end of the fourth week the mucilage may be given in double the quantity of milk, and skim milk substituted for new milk; and by the end of the sixth week, the mucilage will be gradually increased in the proportion of two and a half to one of milk, and from that on till the tenth week the milk may be gradually reduced, so that by that time they may be fed wholly on mucilage till they are fifteen or sixteen weeks old, when they may be weaned.

During all this time, if too early in the season to put out the calves, they should be comfortably housed, well ventilated, and kept perfectly sweet and clean; a little sweet hay tied in bundles and suspended, so that they may play with it and learn to nibble and eat it; and a little pounded chalk, mixed with salt, given in troughs to lick at pleasure, which prevents acidity in the stomach, and the undue formation of cud; small lumps of linseed

cake should also be given in other troughs, which they will soon learn to suck, if a little pains are taken to put a bit in their mouths after they have taken their meals of milk and mucilage. When housed it will be advisable to have a separate pen for each calf of sufficient size to walk about, so that they do not get into the habit of sucking each other and swallowing the hair, which, uniting with the curd by the regurgitating process going on in the stomach, forms round balls which are indigestible, and is the fertile cause of the death of many promising animals. The following scale of quantity of milk or milk and mucilage combined for each calf may be useful, but should be altered according to circumstances:—For the first week the calf may get from three to four quarts daily; for the second week, four to five quarts; the third and fourth weeks, five to seven quarts; fifth and sixth weeks, eight to ten quarts; six to eight weeks, ten to twelve quarts per day, and so on, increasing the quantity about one quart per week per calf till weaning time.

Some parties do not give so much liquid food per day, but make it up by giving them finely-cut roots, dry oatmeal &c.; but the animals are much too young for such food, though they may get the mined roots so as to train them into their use. Hay tea is an admirable thing also to mix with the mucilage and milk, as it contains a large amount of nutriment in a soluble form.

In the summer time the calves may be left out on the grass, both day and night, in a fortnight after they are calved, and fed as already described they should be in the house; but a warm sheltered paddock should be provided for them, and in wet weather they should have access to a covered shed.—(Irish Farmer's Gazette.)

ELDERBERRY CATSUP.—On every pint of ripe elderberries stripped from the stalks pour a pint of boiling vinegar, and let it stand in a cool oven all night. Strain without pressing, and boil the liquor five minutes with half a teaspoonful of salt. To every quart put half a pound of anchovies, half an ounce of mace, half an ounce of whole pepper, half an ounce of ginger, twelve cloves, and four eschallots. Bottle when cold with the spices.

OUR LETTER BOX.

KEEPING POULTRY PROFITABLY (Intending Farmer).—You do not require good land for keeping poultry. It should be a light soil, and that is not the best, generally speaking, for farming purposes. As we told you before, the neighbourhood of a large common would be the best place. Such a one as Woking. We have not the least doubt that poultry may be made profitable, and to play an important part in such a place as you describe, but we still think it should be an adjunct only, and that it would be unwise to take a place for it alone.

SPANGLED HAMBURGH EGGS ANGLE (Inquirer).—We cannot give an opinion upon the question whether any unfair treatment had been adopted, not having seen the eggs. There is no book devoted to the treatment of Ducks.

PRECOCIOUS PULLETS.—I subjoin an account of some unusually precocious chickens for insertion in your Journal if you think it remarkable enough to give it a place. In November last one of my Dorking hens stole a nest behind some wood in our poultry-yard and about a week before Christmas brought out a brood of eight fine chickens. Six of these have survived the cold and incursions of cats; and on Easter-day one of them began to lay. Two others soon after followed her example, and are regularly giving us eggs about every other day. They are very small—about the size of the speckled Hamburg eggs; but the fowls are not more than half grown, and are now only five months old.—BLACKHEATH.

CANARIES (P. Shackleton).—We do not know who are the chief dealers in these birds at Norwich and London, much less the others "anywhere in the United Kingdom." Refer to the county directories.

BLACK CURRANT WINE.—Cesto will be much obliged by an approved recipe for making this wine.

LONDON MARKETS.—JUNE 2.

POULTRY.

There is but one month of May in the year, and in Leadenhall Market it is alone—no other is like it. It is generally the busiest month of the twelve—that in which the largest prices are made; and it is the indicator on the dial-plate. It points out the direction that will be taken afterwards. There has been less trade in the month just passed than in any other known to the present generation. The supply has been unusually small; and although it will now increase daily there is no prospect of any glut. Average prices may therefore be looked for.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 71.9° and 48.7° respectively. The greatest heat, 97°, occurred on the 16th, in 1858; and the lowest cold, 80°, on the 15th in 1850. During the period 141 days were fine, and on 104 rain fell.

BEDDING PLANTS AND GARDENING LESSONS FROM THE DERBY DAY.

HERE are two ways in our practice, as a nation of gardeners, which, if it will not be out of order, might be of some use to us, if they were put up in comparison with the practice of some of those who prepare for the events of the Derby day at Epsom downs. The first of these practices makes an experimental garden of nine-tenths of the best private gardens in the three kingdoms—makes a private trial of new bedding plants annu-

ally, to see if they are what they have been represented, ere they are put out into the flower garden, which is more or less a public garden, as compared with the "back premises"—otherwise, the reserve garden. The stud-book shows the winners for the last many years—shows, also, which was next and next, and which was not worth its keep; the man who knows what is in that book, carries his own book with him in his hat, and without much ado he can tell what stage, or what degree a new plant will attain before it is out of the experimental ground; and although he is judge and jury in the case, in the first instance he knows very well his decision will have no weight beyond his garden gate, unless it is pretty near the mark, and the public at large gain or lose exactly as he may be of the thick or thin-skinned judges. Still the proof is not yet a race all round, and a summer right through, in the face of all the world, must decide the issue.

This season the poor man's best edging plant, the *Cerastium tomentosum*, which needs no glass nor gardeners, is to be run against by *Cerastium Biebersteinii*, from the Russian strain of Carter & Co., Bieberstein himself being one of the highest mettle, in botanical round-abouts, which Russia has yet reared, and, of course, glass is foreign to its nature. As far as table talk, and fable talk go, the two are on a par for the poor man's garden in every respect, save the great superiority in blood and breeding of *Biebersteinii*, which qualities have been heralded and backed up by "NICKERBOR" only; and if all he has stated be true, the Russian *Biebersteinii* ought to, and will, carry the day.

Having the whole private history of *Biebersteinii* in my book, however, with the above limitation, I should not hesitate to venture a fortune on the first competition of the season between these two plants, and if you have a mind to follow suit the new one will not cost you more than the old one did at its first coming out, nor yet nearly so much.

The best pure white-leaved plant now in use for flower

No. 63.—VOL. III., NEW SERIES.

gardens is unquestionably the old *Gnaphalium margaritaceum*, the *Antennaria margaritacea* of newer naming. There is not one plant known to us which is more easily "made up" for use than this one, or more cheaply, or looks better when done well as I have seen it last year both here in our clergyman's garden and in Hampton Court Gardens, where it was first brought out by Mr. Donald, to whom we all owe so much for its use in bedding. It is a master plant for the front of Punch or of old Tom Thumbs, or for the backs of either of them in a young state without tying or training. It is also, by training, a most telling edging plant to many kinds of beds. The way to grow it is in the volumes of the last two years; but now comes a rival to it, the *Scrophularia* something, which was brought out in Ireland in the garden of the Archbishop of Armagh. It strikes me, however, that all Ireland, and England also so far, are off the right scent with this plant. Mr. Donald, of the Hampton Court Gardens, is, perhaps, the very best British botanist among all our gardeners. He knows the name of every plant, and weed, and moss which grows in the British islands, and I believe he has dried specimens of every one of them in his herbarium. I have seen his *Scrophularia nodosa variegata* dead, dying, and in health, last autumn. I have seen, also, the same kind of plant exhibited by Mr. Williams, of the Paradise Nursery, at the May Show of the Royal Horticultural Society, and I have examined the Irish plant under that name which Mr. Williams is now selling, and I am quite satisfied the two are as different in their habits and natures as any two plants can be in the same generic family. Which of them is *nodosa* I am not in a position to say, but they are not both *nodosa* certainly. Well, this *nodosa*, or not *nodosa*, is to serve *Gnaphalium margaritaceum* by all accounts as *Caractacus* served *Marquis* on the Derby-day.

The Variegated Mint is booked to run in the same race, and *Stachys lanata* has been recently booked to run with them. But I protest against such arrangements as the putting of variegated plants, no matter how white they may be, against white plants with no variegation in them. The two *Cerastiums* are fair enough in for it, and so would *Gnaphalium* against *Stachys*; and when you come to think of it, you will see there is no real rivalry from the Irish *Scrophularia*, but against the Variegated Mint.

Well, the Variegated Mint used to be 3 feet high in the Experimental Garden, and last year it was only 3 inches high in the new garden of the Royal Horticultural Society; all that was from the difference in management, and the degrees of the difference would run up at three-inch steps from 3 inches to 33 inches. Therefore, those who can and did grow the Mint, may use that *Scrophularia* for any of the rows of a nine-rowed ribbon-border. On this account, the race between the two will be more closely scanned than any of the others which are to come off this season; and all I can say to guide the course and the judges, is, that in my judgment, the entry of *nodosa* in the stud-book has been as contrary to the rules of cross-breeders, as the attempts to set up natural white-

No. 715.—VOL. XXVIII., OLD SERIES.

leaved plants against whiteness from variegation, whether it be from sport, as they say, or from breeding, is contrary to the good plain common sense of ordinary people who are not easily led by crotchets.

But although *Stachys lanata*, and the much whiter pearly *Antennaria* ought to be free for ever from the rivalry of variegated plants, they must stand the brunt of battles, and run the race with all comers of the natural cast of their own looks. And we shall witness another race of white and all-white plants this season, as well as of the two *Cerastiums*. There has not been much ado about the one which is to challenge *Stachys* and *Co*. The first I heard of it was from seeing it in the plant supplement of the Messrs. Carter, where it is recommended for six, or seven, or more ways of ribboning and bedding arrangements; and seeing also that *Stachys lanata* was in the same list, and not having ever heard of such a name as *Gnaphalium lanatum*, the plant in question, I sent for a sample of it at once, and they sent me half a dozen of it, and it is as white all over as the pearly *Antennaria*, and seemingly quite as easy to manage. This, therefore, is the new racer against the woolly and the pearly *Antennaria* and the swan-down *Stachys*; and three better matched, to all appearance, have not hitherto been booked in one season.

Whether *Gnaphalium lanatum* is rightly entered on the register admits of some doubt; but as a good horse can never be of a bad colour, on the same principle a good bedding plant can never lose much by the naming.

The last run of the season is to be between the purple plants for contrast. *Coleus Verschaffeltii* is to be tested against the *Perilla* and the purple *Orach* plant; and if it stands to the opinion some people form of it, there will be no, or very little, difference in the trouble and expense of keeping up a stock of it from cuttings than has been hitherto experienced in procuring a supply of the other two from seeds.

Speaking of seeds, one of the best flower-gardeners in the country holds to the opinion that the purple *Orach* should be sown on a certain day early in May, or at least within a week of a certain day. But my experience of it for the last three seasons is very different. On the 1st of June my seedling *Orachs*, from seeds self-sown the previous autumn, have been exactly as good and no better than seeds sown by hand in February, or March, or April. I have some now exactly in that condition, after thinking I had got rid of it in one border where it seeded in 1860. The border was fresh dug, and up it came like a weed after the seeds had been in it for two years, certainly. All the difference I find is, that when the seeds come from a greater depth than an inch or so, the seedlings are not so easily transplanted as when they are got out of a row of shallow sowing, and from several turns I have seen with it, I should say the best plan for it and for ordinary people who are not high up in gardening, would be to sow it in rows or rings at the end of April where it was to grow, and not transplant it at all, only to sow thin and after a while to thin out the seedlings. The great point in managing it is to keep it constantly stopped in order to have fresh leaves, and to cut away the old leaves as often as it is stopped. All of this takes up a great deal of time; but, then, people who pride themselves in doing what others cannot afford to attempt, will not give up a thing for the mere expense of having it in first-rate style.

The *Perilla* does not require, and needs no such trouble, care, or expense; so that, properly putting it, the race will have to be run between the *Perilla* and *M. Verschaffelt's Coleus*. Although the Crystal Palace people do not keep more cats than will catch mice in the garden way, they are the most spirited of all our public bodies to allow of this kind of racing being tested; and it was a great loss to the friends of purple *Orach* that no good seeds of it, or any seeds of it at all, could be had there last year, in order to show the great body of the people how to grow it properly.

I saw a new move there of planting on the Rose Mount, the day of the flower show, which will please the ladies amazingly if I am not very much mistaken. It was only like the bursting of the bud, however, and flower-show-days are not the best days for everything, nor for catching at an idea just then starting into form, and I may have misunderstood the thing. The men were then all off after the great waterworks, and I could see no one to explain the new move to me; but you shall soon hear all about it, if I must go on purpose to book the plan.

The second part of our practice, which bears a comparison with the doings for the Derby day, is the race for seedling bed-

ders; and in this thing there is one most important feature, which, at a venture, I shall risk the opinion that not one out of one thousand has ever yet given it a thought. Have you ever had an idea that you yourself have been one of a very large company with limited liability, for ever so long before parliament thought of such a thing? You, or some member of your family, to my knowledge has been in that company ever since I have been a breeder; but how long the company may have been at work before my day I never could make out. The company dealt with the breeders of bedding plants ever since the requirements of the bedding system demanded a change of subject. And, as at the Derby, it has often happened that the best subject at last was the one about which the least was said at the time it was ushered into the world, or when registered in the stud-book of the fancy, if you like that way of it better; whilst the "favourite" went on to oblivion after the fuss and the first start. But the company being on the limited principle there was no more loss beyond what each of them ventured on that run, and perhaps not that; and perhaps, also, the back wall or the pillars of the conservatory, or some part of some man's premises had been enriched at the risk which failed for the beds. But without that company there could be no breeders, no matter what the demand might be. Suppose all the world wanted evergreen climbing yellow Moss Perpetuals, or Hybrid Perpetual Roses, and would buy no more Roses till that strain was in the market, think you how many breeders of Roses would be at crossing just now, and then think how much better than all the world the said company have been, to bear individually their limited risks in order to keep the crosses on the move, and to enable them to improve step by step as the strains would admit of. Depend upon it the company will never come to a crash, and you may be equally certain the Derby day, the very day on which this is written, will gladden and disappoint the hearts and the wishes of each section of that company in its turn to the end of the chapter.

And now, if only to keep up appearances, I am ready to back my own favourite of the season at any odds you please to name. Fifty or five hundred to one that Baron Ricasoli will win at our Derby in the strain of Baron Hugel. D. BEATON.

#### CULTURE OF MYOSOTIDIUM NOBILE.

SOME weeks since we received a note of inquiries relative to some points in the culture of this new "Forget-me-not." We sent the note to its most successful cultivator; but totally disregarding the name, he not only forgot the note but lost it! Upon reminding him of his delinquency he sent us the following, and says that it answers the contents of the note. We print it, therefore, and hope we shall stand forgiven by our correspondent.

"*Myosotidium* should be potted in a very rich porous soil, kept in a gentle heat from the middle of September until it flowers, about the end of February, when it should be kept at not less than 45° at night and in a moist air throughout its growth. As it delights in a moist atmosphere, so does it not like sunshine: therefore it should be kept in a cool shady place after it has done flowering."

#### FLORISTS' FLOWERS,

THEIR DISTINGUISHING CHARACTERISTICS, CULTIVATION, AND VARIETIES.—NO. 7.

#### THE TULIP.

(Continued from page 141.)

I WAS led into somewhat more than usual length in descending upon the properties of the Tulip, and I was therefore unable to enter upon the two latter portions of my subject; and this not from a peculiar predilection for the flower, for there are many florists' flowers which I infinitely prefer to it, but because of the many battles which have been and are being fought over it. The most recent one is not yet finished; and whether the "Hardy" standard, or the "Glenny" standard, or the "Horner" standard should be taken, is, it would appear, a moot question.

The cultivation of the Tulip has been so regularly laid down, and the precise manner and form in which the beds should be planted has been so often given, that I cannot hope to add anything new for the information of the veteran grower; it can

be only of service to those who are novices, and who would desire to know how a few may be grown. Unlike the Auricula, it has not been made the unhappy patient to swallow all sorts of odious messes, in the way of savoury compounds, to increase its growth or add beauty to its colouring. To this, indeed, its own determined obstinacy has not a little contributed. It seems to say, "You may if you like. Try it. Oh, yes! add sheep manure, or guano, or anything else that strikes your sagacity; but see if I don't run if you do." And so one and all of its cultivators say, "Humour this obstinate fellow, and give him good sound loam, and let him do what he can or likes."

A Tulip-bed, we are told (and he would be indeed a venturesome man who would attempt to impugn the universal verdict), should be exactly 4 feet wide, and as long as may suit the convenience or the pocket of the grower. Mr. Groom's bed used, I think, to consist of 220 rows; and one I saw last year at Sevenoaks was of the same length. The bed should be raised a foot or more above the level of the garden, and enclosed either with slate or boards; in fact, a box is formed on the surface of the ground, and the mould is filled in. The aspect selected should, if possible, be open, exposed to the sun, but sheltered as much as possible from violent winds. In my own little garden, where Boreas, and Euroclydon, and all the "rude winds that blow," seem to hold their tryst, I have been forced to be heterodox, and grow my thirty or forty rows without elevating the bed—at least I did so last year. This year I altered my practice, but the bloom has not been so good, and I intend to try next season to do as I did before. The bulbs are arranged in seven rows running the entire length of the bed, and the distance of the rows one from the other should be 6 inches, so that a bed of 20 feet in length will contain 280 bulbs. And as the flower-stems run up to various heights, the different sorts are arranged as to the position they should occupy in the bed. The tallest ones are placed in the centre, and are called fourth-row bulbs, leaving three on each side—first, second, and third rows; the dwarfier varieties being placed next to the edge, and the height running up to the centre: thus a uniformity is gained, which very materially adds to the beauty of their appearance. The bed should be regularly marked out at the distances named; holes for the bulbs made with a blunt dibber and filled in with white sand, the bulb placed in this and then covered up. The point of the bulb ought then to be about 2 inches below the surface. The names of the flowers are regularly entered in a book according to their rows, so that a reference to them is easy enough.

Although the Tulip is very hardy—good Mr. Headley says as hardy as a Swedish Turnip—yet it will not flourish any more than a Turnip in all weathers. Excessive wet or excessive drought are alike injurious to it. The latter there is not much likelihood of in so "pluvius" a climate as ours; but the past season has generally been a bad one for Tulips, owing to the exceeding wetness of the winter months. There should be provided some iron hoops to place over the bed, on which mats may be thrown during very heavy rains; but this ought not to be left on one moment longer than necessary, as Tulips are impatient of confinement. As the flower-stems advance they should be tied to thin stakes, and whenever they show colour the awning should be put up. This where the collection is large is a tremendous affair—a sort of Aldershot hut; for it has to be strongly built, remains a fixture, and is covered in both at top and sides with canvass. In itself it forms a most material item in the expense of growing Tulips, and is moreover a sad eyesore to a small garden; in fact, a Tulip garden would be the very thing for one who desired neatness in his arrangements and could afford the room. Those who are more moderate in their pretensions will be contented with using such a covering as will protect these flowers, and be of a more temporary character.

There is not a greater mistake made than the one which we oftentimes hear, that the bulk of the Tulips grown come from Holland. That has long since ceased to be the case; and the last thirty years have weeded out the old Dutch flowers to an alarming extent, and introduced those of English raisers. Take any well-known grower's catalogue, and the very few foreign names will at once show that "we have changed all that." We are told on the excellent authority of Mr. Slater, that of a catalogue published in 1829 by Mr. Thomas Butler (who was so eminent a grower that he thought it well to demand 1s. admittance to see his Tulip-bed in bloom), which contained 236 varieties, only thirty-three are now grown; and since then the

seedlings raised by Clark, Holmes, Strong, Laurence, Groom, Headley, and others have quite revolutionised the catalogue. I lately had the opportunity of seeing Mr. Turner's extensive and valuable collection, and took some notes of a few that then seemed to me the best; and as I have written mainly for young florists or beginners, I will add now the names of those in their several classes with which any one may begin a small bed, being inexpensive and of vigorous constitution:—

BIZARRES.

- |                              |   |

—D., Deal.

ENDIVE CULTURE.

THE precise period when this vegetable was first introduced into cultivation in this country is not exactly known; but it ranks higher in point of antiquity than many vegetables now extensively used. Most likely the Flemings to whom we owe many lessons in gardening were the first to supply us with this useful article, and it is reasonable to suppose that they themselves received it from a district still more eastward. If our researches in the way of finding out its original abode were industriously carried out, we very likely might trace it to the sunny regions of Italy and Greece, and possibly to Egypt also; but it is not necessary to do this. Suffice it to say that it formed one of the items of a bill of fare in the reign of Queen Elizabeth; and an old writer of that period, Gerarde, gives as good a description of its management as can well be given at the present day.

Gerarde advises the seed to be sown in July, and before winter sets in to take up the plants and let them lie in the sun or dry wind for two hours, and after tying-up the leaves with a string to plant in the ground again, bottom upwards. Now, antiquated as this practice may be, it is certainly not without its merits, and in soils that are free from worms it may be adopted with perfect propriety now. Those who have the means of obtaining dry peat frequently preserve Endive in this manner, and I have seen it thus treated in a cool shed; sand instead of peat being the substance it was buried in, roots upwards. Sand, however, is objectionable, as it is liable to get inside, and is not easily removed, even by washing; but this subject will be treated of further on.

It is only fair to give the old cultivators every credit for the information they have given us, and we need not go further into its history or origin, beyond remarking that its ancient popularity no doubt was enhanced by its being esteemed one of the best antidotes to scurvy. This, when the plant was first introduced, was a more formidable disease than now, and from coming into use in winter when salt meat formed a much greater proportion of the general food than it does at present, Endive no doubt, as well as other plants of its class, speedily became a favourite. At all events we may infer that its property of checking a disease so much dreaded at that time, led to the plant being welcomed to the gardens of all who had the means of cultivating it.

Lettuce, and the means of wintering it in favourable situations in England having become better known, and popular taste preferring it to Endive, the latter certainly does not now hold such

a high position at table as it once did. It may be said that the present century has witnessed a diminution in the popularity of Endive; still it is extensively grown; but it is more for the tables of the affluent than as an accessory to the general store of the community at large. We will now proceed to treat of its cultivation as practised at the present day.

**SOIL AND SITUATION.**—Like many other garden vegetables, Endive likes a rich generous soil and an open situation. Shade is objectionable, and the drip of trees is very bad. In the routine of crops it ought not to follow Lettuce, neither ought it to succeed any of the Cabbage tribe if that can be avoided. If it has to succeed a crop of anything of the Cabbage kind let the ground have a good manuring, and possibly a good result will follow. The same treatment may be observed if Peas, Carrots, or other crops have previously occupied the ground.

The object being to obtain a quick growth, manuring is more especially necessary for crops that are intended for use in the autumn only. Those to stand the winter may be planted on a less rich soil, as the conditions necessary to obtain a fresh crisp growth are not those to enable the plant to withstand the hard weather of a severe winter. More shelter in the latter case is also required—in fact, a south border or some such favoured place should be selected, and the open deep-tilled squares or quarters of the kitchen garden for the autumn crops. Both of these crops are of course for use in what may properly be called winter, only the one comes into use before the other, and the supply is kept up by intervening plantations coming in as wanted.

**TIME OF SOWING.**—Every ten days from the 20th of June to the 1st of August; and a sowing of Batavian Endive may be made a week later than the last-named time. Usually, however, the dwarf hardy Lettuce of the Hammersmith Cabbage breed are preferred to come into use in spring. Endive cannot boast of so many varieties as most other vegetables. A Green Curled and a White Curled form the general autumn and early winter crop; and the plain-leaved variety, or Batavian, is more hardy, and usually planted to stand over the winter. In addition to these, some growers have affixed their names as having produced an improvement in the plant. A hardy useful sort by Mr. Fraser was much admired a few years ago.

The White and Green Curled, however, differ so little on the whole that they may both be regarded as one to the small grower, and sowings of each may be made at the early periods indicated. If the weather is very hot and dry at the time of sowing, the beds should be on the north side of a wall; or, what is still better, sow in an open exposure, and water and shade as directed in THE JOURNAL OF HORTICULTURE for Cabbage and other seeds. If the seed is good it need not be sown too thickly; no vegetable suffers more by being thick in the seed-beds than Endive. As the value and utility of the plant depend on the number of leaves arising from the collar, these cannot well be produced if the plant is closely packed up amongst others suffering equally with itself. Should circumstances, therefore, prevent the bulb being planted out in the proper place at once, when getting thick on the seed-bed, thin-out, for generally there will be a plentiful supply left for consumption.

**PLANTING.**—As before stated, an open piece of ground well manured is best for the main autumn crop, but the shelter of a north wall will be better for such as have to stand the winter. Rows about 18 inches apart, and the plants about 15 inches from each other in the row, will not be too much. Shallow drills drawn with the hoe are advantageous for the plants, as these are then planted somewhat deeper; and the leaves resting on the cool earth derive much benefit during the dry period we sometimes have in September or before.

Watering need not be resorted to, except in peculiar cases where the ground is very dry, and the situation a sort of hot hungry sand. In the latter case water may be an advantage, and the more so if manure water be occasionally administered; but where possible avoid systematic watering, as it induces the roots of the plants to remain near the surface in the expectation of that food artificially given to it at the stated time. Do not, however, let the plants suffer; but a growth which mostly takes place in autumn when the nights are long and dews heavy rarely suffers for want of water.

**BLANCHING.**—Many makeshifts are adopted for effecting this. The best thing is a common pantile; but flower-pots and pans are often used, and sometimes slates or boards, the object being to exclude the light, without at the same time bruising the plant by the weight placed upon it, so as to cause it to decay

and thus perish. It is also essential to have the plant dry at the time it is covered up, as extraneous moisture is hurtful to a plant undergoing a process which deprives it of much of its vitality.

A few days generally suffice for blanching the required number of plants, which must be selected as being the most forward in the plot, and showing symptoms of blanching themselves. So long as the weather keeps open the plants so treated in the open ground where they are growing are the best; but when harder weather sets in another way must be adopted, and some should be taken up and stored away in any sheltered dry place where they can be had at all times. This subject brings us to the next point in the treatment of the plant.

**PROTECTING IN SEVERE WINTER WEATHER.**—As already said, some protection is necessary when several days' frost may be expected in succession. For this purpose a dry, open shed, with one side perfectly open, is as good as anything. Plants which have been previously tied up on a dry day should be taken up with good balls, bedded in here tolerably thick, and, unless the weather be very severe, they will require very little other protection; but if it does, it is easy to place some mats or straw over the plants. Batches of plants may be brought in as required, as it is advisable to have some under cover all the winter.

A frame with glazed lights is also a good place, and such protections are often wanted for something else in winter; but a cold pit, whether of turf sides or brickwork, with wooden shutters instead of glazed lights, answers very well, and such a pit is very useful for other purposes. Sometimes a few thatched hurdles placed over the plants where they are growing will save them to a great extent, but not so well as where more pains are taken to exclude severe frosts. Many other contrivances for providing temporary shelter are likewise resorted to.

**CONCLUDING REMARKS.**—The above means of protection are usually adopted with the Curled varieties, and the plain Batavian may be subjected to the like treatment; but being very hardy, it also does pretty well out of doors. Where there is the accommodation of a frame and lights, or lights for a cold pit, or even only thatched hurdles or wooden shutters for the cold pit, Lettuce instead of Endive is often indulged with the space; still Lettuce never blanches to such a true white colour, so that its appearance at table is not so good as Endive when in first-rate condition. However, the taste of the parties requiring the article will decide the respective claims of the two vegetables, both being useful and both deserving protection.

A dish of finely-blanching Endive set round with slices of Red Beet of the richest and best colour is of itself as ornamental as many vases of flowers are at the dull period of Christmas. Some other adjuncts, as small salading, &c., help the general effect of a dish of salad; but the pure whiteness of Endive and the Red Beet contrast strongly together. Let, therefore, Endive have its due, and by-and-by perhaps the hunters after novelties in the ornamental-plant way may turn their attention to this one, and give its present graceful foliage a variegated or other ornamental form. Though the poetic name of Fern cannot be attached to it, possibly its attractive features may rival those of that popular family; but this is apart from the duties of the kitchen gardener, and need not be entered into here. J. ROBSON.

#### AMMONIACAL LIQUOR A DESTROYER OF CATERPILLARS.

I TRIED the following, eight days ago, as a last shift. I sent for a barrel of ammoniacal liquor from the gas-works. To every gallon of the liquor I put five gallons of water, and boiled it all together; then I syringed my Gooseberry trees all over with the liquor as hot as I could bear my hand in it. The following evening I syringed with warm water, and am very rejoiced to say the trees were not only uninjured but looked refreshed and the caterpillars destroyed. I gave my Roses the same washing, and find them looking well after it.—T. C., *Huddersfield*.

["UPWARDS AND ONWARDS" reported some time since that he had adopted this remedy successfully.]

**STRAWBERRIES.**—The proper plan to follow with forced Strawberry plants is to plant them in rows 3 feet apart. This was the plan adopted here last summer, and I never have seen

anything so magnificent as the promise for this season. As forced plants bear another crop the first season, in October it is as well to pinch off the bloom.—SCRUTATOR.

### LASTREA v. LASTRÆA—RHODODENDRON BOOTHII.

I AM glad to see you are converted to my notions as to the orthography of *Lastrea*. I have rested solely upon the fact that *Lastrea* is the name Presl gave to the genus when he founded it. The fact which you mention of Bory having originally written the word in the same way, and not *Lastrea*, as he did afterwards, which fact, not having the books at hand to refer to, I had forgotten when I first wrote to you, I take, however, as a clincher to the argument.

I must also take exception to Mr. Boston's remark about the yellow *Rhododendron*, so far as it implies a censure on me. I did not say anything about *R. Boothii* suiting his correspondent, or being the right shade of yellow for any particular object; I merely said it was a yellow without the tawny shade, which is the fact.—DELTA.

[If we said anything justifying our correspondent in concluding that he might rejoice in our conversion, we most certainly expressed what is contrary to the fact. So far are we from repentance that we are hardened in our first conviction, that *Lastrea* is the authorised orthography. Bory adopted it as what he considered the more correct spelling—a conclusion he came to two years after he had taken the name for a genus. Presl took the name from Bory, though he included under it different species, and the etiquette of nomenclature decides that Bory's amended mode of spelling should be retained. If asked whether *Lastrea* or *Lastrea* is essentially most correct, we reply we know of no grammatical rule against either, and if there is any rule which ought to govern that case we showed last week how botanists set all such rules at defiance.]

### CULTURE OF THE PINE APPLE.

(Concluded from page 162.)

#### INSECTS AND DISEASES.

THE insects that prey upon the Pine Apple are the white scale (*Aspidiotus nerii*), the mealy bug (*Coccus adonidum*), and the brown turtle scale (*Coccus testudo*). The first and second are the most injurious and most difficult to entirely banish from the plants and houses infested with it. The first adheres closely to the leaves, feeding upon them, the females seem lifeless and never move, though the males are more active, and to all appearance have wings to move about with. The females lay their eggs under their bodies, and then die, the scale protecting the eggs. The mealy bug is not so sluggish, it lays its eggs and then works a covering for them like a mealy woolly powder, which is impervious to water. I have seen Pine Apples infested with this insect so much that the fruit could not be sent to table till it was washed many times in warm water and brushed with a hard brush to clean the nasty-looking filth off the Apple and crown, thus spoiling, in a great measure, the appearance and flavour of the fruit. It is almost omnivorous; feeding upon, besides the Pine Apple, the Vine, the Orange, and almost all the plants inhabiting the stove, concealing itself in the soil of the pots, the bark of the shrubs, and crevices in the woodwork of the houses: hence, where it abounds much labour and persevering attention are requisite to entirely destroy it. Many operators think if they clean the plants once thoroughly they have rid the plants of these pests, but in a very few months they will, to their grief and astonishment, find the insects almost as numerous as ever: hence, they doubt the efficacy of the means used, and in despair the infested plants are destroyed, and the houses thrown open for a year in hopes that with a newly-painted house, and a set of fresh clean plants, the enemies will be completely eradicated, destroyed, and banished for ever. Yet if one pair escapes or is introduced on some new exotic, in the course of a few years even this so-called radical cure will be found to be fallacious. I have had Pine plants under my care as much infested with these insects as any I ever saw; but with untiring perseverance I was in time successful in clearing the plants entirely from them.

The first step I took was to remove every plant out of the house, I then had all the old bark taken out and the walls of the pit

whitewashed with lime slacked with boiling water and laid on as hot as possible. To be doubly sure I had this whitewashing done twice over, so that not a crack or a crevice escaped this, to insects, and even their eggs, destructive fluid. All the other walls were treated in a similar manner. Then the woodwork underwent a hard scrubbing with a stiff brush dipped continually in soft soap and water, and finally the floors were flooded over with boiling water, brushed over, and afterwards mopped-up and dried. The house was then, to use a homely proverb, as clean as a new-scraped Carrot.

The best season for this thorough cleansing is the month of May, because then the Pine plants can be placed in a shed for a few days without sustaining much injury. If, indeed, there are Vines on the rafters that time will be inconvenient, and in such a case the cleaning can only be done when the Vines can be turned out of doors, which in Pine-stoves generally can be managed by the end of August. Before the Vines are brought in again they should be pruned and washed over with the mixture described below for the Pines.

Whilst the whitewashing, &c., was in operation, the Pine plants were subjected to a similar dressing, only instead of hot lime and hot water they were thoroughly washed with the following mixture:—1 lb. brown soap cut in small pieces, 1 lb. soft soap,  $\frac{1}{2}$  lb. flowers of sulphur, and half a gallon of tobacco water. The soaps were dissolved in boiling water till all was made liquid, then I added the sulphur and tobacco water, and as much water as made the whole into five gallons. This mixture was boiled for about a quarter of an hour, and when it had cooled a little a pint of spirits of turpentine was poured into it, for I found if the spirit was boiled its strength partly evaporated. Previous to applying this medicated strong liquid I had every plant carefully looked over, and every visible insect rubbed off cautiously, so as not to scratch or bruise the leaves, with a bast-mat brush made of bast cut into short lengths and tied tightly to a smooth stick about 18 inches long. When this was completed the mixture was applied with a small sponge tied also to a stick, and every part of the plant was thoroughly wetted. The sponge does not scratch the leaves as a hair brush would do.

I have frequently found these insects on the roots of the Pine plants, and also in the soil: therefore, to be certain of getting rid of them entirely, I had the soil all shaken off the roots, and all dead roots cut off. The living roots were then dipped in the mixture in a tepid state, and when they were dry I had them repotted in clean pots and fresh soil, and placed them in a warm room or house till the bed was ready to receive them. That bed was made of all fresh spent tanner's bark, or if leaves were used, altogether of leaves fresh from the heap. Both the tan and the leaves were duly prepared by being kept moderately dry and in a fermenting state at the time I used them. As soon as the pit was filled the plants were set upon the tan, and only half plunged for fear of its becoming too hot and scalding the roots. The house was then kept rather close, and a moist atmosphere kept up to start the Pine plants into fresh growth. They were not syringed for several days, to give the mixture full power on the insects.

As stove plants are generally grown in the Pine-stoves, I subjected them also to this thorough cleansing, washing every hard-leaved one with the mixture. Soft-leaved plants I put under a hand-glass placed on a warm flue, and on the flue within the hand-glass I set a saucer containing spirits of turpentine or spirits of wine. If this was not effectual the first time, I did it a second time, and that was certain to kill every insect.

After this washing and steaming was done I treated the stove plants in a similar way to that adopted with the Pines—that is, I shook off as much of the old soil as I thought safe, and repotted every plant in fresh proper soil, using only very clean pots, and then I placed them in the Pine-stove in the spot where they had been before.

As this somewhat severe treatment naturally gave them a check in their growth, the roof of the house was shaded daily whenever the sun was shining; but the moist air and fresh soil soon set them growing, and then less and less shade was given, and the Pine and stove plants were regularly syringed every warm evening. That syringing soon washed off the mixture, and then the plants looked fresh and green, and as healthy as need be. Afterwards they were watched constantly, and if any insects showed themselves they were instantly destroyed. By this method I perfectly succeeded in clearing the plants of insects

of every kind, and by a careful attention afterwards I prevented their re-appearance.

Some writers have strongly recommended the fumes arising from horsedung in a state of fermentation, as a destructive agent to use against the scale and bug on Pine plants. I have no doubt that agent will answer the purpose, and as ammonia is the main gas that escapes from, or is generated by the manure, it seems probable to me that the ammoniacal gas liquor so abundantly obtained in our gas-works now-a-days, would be better than spirits of turpentine or wine to put amongst my mixture. It has been found destructive to many kinds of insects that prey upon our vegetables, and why should it not be equally destructive to such tenacious insects as infest the Pine Apple?

Worms sometimes prevail both in the pots and amongst the bark in the pit. These I effectually destroyed with lime water, which is made by pouring water upon unslacked lime, and allowing it to stand till it is quite clear. Woodlice and ants are also sometimes troublesome. Both feed upon the ripe fruit. The former may be destroyed by setting traps of Cabbage leaves laid on the tan; and every morning have ready a pan filled with boiling water, and then lift up the leaves and pour on the woodlice the scalding liquid, which kills them instantly. Ants are more difficult: I used to lay fresh bones here and there, and go in of an evening, taking up the bones and throwing them into a vessel of hot water, which effectually finished them. A toad or two kept in the houses devour hundreds of these pests. By persevering in the above remedies the Pine-stores may be kept clear of insects, and thus the plants kept in good health.

Diseases.—The Pine Apple is never diseased, at least I have never observed any.

MONTHLY TABLE OF TEMPERATURES.

For the instruction of the amateur I append a monthly table of the average heat required for the Pine Apple.

	With Sea			With Sun			
	Night.	Day.	heat.	Night.	Day.	heat.	
January .....	55	60	65	July .....	65	75	95
February .....	55	60	65	August .....	65	75	90
March .....	60	65	70	September .....	60	70	80
April .....	60	70	75	October .....	60	65	75
May .....	60	75	80	November .....	55	60	65
June .....	65	75	85	December .....	55	60	65

Whenever the thermometer rises above these figures then give air, unless it is very frosty in the winter months.

T. APPELEY.

DESTROYING THE GOOSEBERRY CATERPILLAR.

THERE has been, and still is, much said respecting the destruction of the Gooseberry caterpillar. It is a universal plague to all gardeners, whether of the mansion or the cottage: therefore, a knowledge of an effectual mode of destroying it must be regarded as a great boon.

Well, when I found the pest on my bushes this spring, I referred to several volumes of THE COTTAGE GARDENER, and to the new series, and in Vol. XX. of THE COTTAGE GARDENER, page 23, I found a most effectual receipt, the efficiency of which has been proved by upwards of twenty years' experience. It is as follows:—Get a tub that will hold 25 gallons or 30 gallons, put into it 2 quarts of tar and 7 lbs. of common washing soda; pour a few gallons of boiling water on it, stir it until the soda is dissolved, when the tar will mix with and be held in solution by the water, then fill the tub with cold water, and it is fit for use.

Having mixed the solution I syringed the bushes affected by the caterpillars, which utterly destroyed them all. This is one amongst the many valuable hints I have received from your publication.—J. CANDLIN, Gardener to C. Fison, Esq., Thetford.

DOUGLAS FIR—GUM TREES.—It seems that the enormous length of the great flag-staff of Douglas Fir from Vancouver's Island, also noticed in last month's "Proceedings," is likely to prove an insurmountable obstacle to its ever reaching these shores. The last advices are to the effect that no vessel at Vancouver's Island was large enough to take it. An equally great curiosity as to length is, however, to be seen in the Western Middle Arcade, in a spar of a Gum tree, from Tasmania, 230 feet long, although it is infinitely inferior in value, and wants a great part of its interest from not being in one piece. It is only about half a foot square at its base, and extends the whole length of one

of the lofty New Holland Gum trees, or Eucalypti, the top portion still retaining its bark; and although its small diameter gives a most inadequate idea of the tree itself, still it serves to impress forcibly enough upon the mind what a tree of 230 feet in length really is. The species which has produced it is Eucalyptus viminalis, or the white swamp Gum. There are two other most amazing logs placed in the ante-garden as seats, also from Tasmania, the one 90 feet in length, 18 inches in breadth, and 6 inches deep, cut from the Eucalyptus globulus, or Blue Gum of Tasmania; the other from the Eucalyptus giganteus, the stringy bark of that dependency, 80 feet in length, 18 inches broad, and 7 inches deep. There are three other immense planks from Western Australia not yet placed, also of the Eucalyptus, or Gum tree tribe, which, although not so long, are scarcely less startling from their breadth, one being 24 feet long, 3 feet broad, by 7 inches deep; another, 28 feet long, 4½ feet broad, 5½ feet deep; and the third, 28 feet long, 3 feet 9 inches broad, by 5 inches deep.—(Royal Horticultural Society's Proceedings.)

ECONOMY OF FUEL.

THE importance of the heading which I have affixed to this communication will, I think, be acknowledged on all hands; and more particularly by those who, in the pursuit of their horticultural tastes, find the item a heavy one. An idea has just struck me by which, I think, a most important saving might be effected.

In all furnaces, and more particularly the boiler furnaces employed in horticulture, a large amount of heat is absorbed by the brick setting, and to utilise that is the object of my idea. I would propose for that purpose the employment of a tubular boiler, such as Ormson's or Weeks', around which, at a sufficient distance to permit of free action to the fire, should pass an iron jacket; and between this again and the brick setting a space of say 6 inches all round, constituting a hot-air chamber, to be employed on the Kiddean plan.—M. G. CUNNINGHAM.

[We are obliged for your idea; but so far as credit is concerned, we fear that what is good in the proposed plan is not new, and what is new is not so simple and economical as it seems. Boilers in general are expensive enough in themselves, but your iron jacket fitted to pass tightly and air-proof over pipes, &c., would pretty well be the expense of a second boiler. Anything like thin iron would be out of the question. It would soon warp and burn out, and where then would be the use of the chamber? In furnaces much used, even furnace-bars soon wear out. Those formed of tubes and holding water will, with fair treatment, last much longer than the common iron bars; but it is questionable if a fire will burn bright so quickly over them. The heated air from such a jacket, when red hot or nearly so, would require much mollifying before it went among any plants whatever. We certainly should prefer a Polmaise or Kiddean furnace to the iron jacket. The more nonconducting the material surrounding a furnace-fire the better. When such substances as fire-brick or Welsh lump are used for containing a fire of any kind, from being slow conductors of heat they do not rapidly convey this away from the fuel, as is the case with iron and other quick conductors of heat: consequently the fire is more easily lighted, and, when once fairly burning, not so liable to go out as when surrounded by metal. Another advantage resulting from the use of nonconducting substances round a fire is that when once red hot they insure, when the fire is getting low, a more perfect combustion of the fuel and gases than metal.

Tredgold in his "Principles of Warming and Ventilating" recommends that the slowest conductors of heat should be used for setting boilers, and that no more metal should be used than is absolutely necessary.

Engineers to economise heat employ a jacket of felt or other nonconducting materials for cylinders much exposed to the air. Why not, therefore, use a fire-brick jacket for the fire instead of an iron one, which is about the very worst that could be used? The interposition of a body of air between an inner and an outer casing would then be very good indeed; but no such air should be allowed to pass into the atmosphere of the house. There is nothing new in having a chamber over and round the setting of a boiler, instead of letting that heat go to ameliorate the general atmosphere. To prevent the heat absorbed by the brickwork passing into the surrounding medium, Mr. Fish has also recommended isolating it by an air-tight chamber some 6 inches wide. Most of the heat then that was absorbed by the brickwork in setting would

be radiated back again on the boiler, instead of being conducted to the surrounding earth or other medium. After all the loss of heat thus sustained is trifling in comparison to what passes through the chimney. It is here that the great robber of heat is to be found. One great saving in a large boiler heating many houses, arises from the fact that there is only one robber instead of many. No boiler can be so set as to prevent this loss altogether. The nearest approach to it is when a flue is taken from the furnace to heat a separate part, or a separate house. Then a great portion of the heat will be absorbed before the smoke gets to the chimney. When the heated air after going round and round the boiler, or through it, and over it, and round it, goes then at once up a shaft, the most careful stoking and regulating of the damper will not prevent much heat escaping. Where fires are pitched on without much consideration, and dampers are left to take care of themselves, pretty well half the heat from the fuel goes to improve the temperature of the general atmosphere. We should be glad if our ingenious correspondent would turn his attention to and devise a remedy for this huge loss. It was lately mentioned how by turning a small air-tap Mr. Beale knew at once if the supply-cistern were attended to. Placing the hand on the chimney or smoke-funnel of a hot-water apparatus, will furnish in its comparative coolness or warmth a test of the care exercised in firing and managing the damper.]

### SKIMMIA JAPONICA UNFRUITFUL.

CAN you tell me the reason of *Skimmia japonica* not setting its berries? I have about fifty healthy plants, which were loaded with bloom about the 15th of May, but it all fell without setting a berry. They have been planted two years, and are at the present time making vigorous growth. Twelve months ago they were loaded with berries, and, thinking they might weaken the plants, I took them off, after which the plants grew with great vigour.—D. C.

[The same failure has happened with many plants this season, chiefly owing to the wet cloudy weather, and the blooms being too thick. Thinning might have prevented the dropping.]

### THE INTERNATIONAL EXHIBITION.

(Continued from page 176.)

2071. AMIES & BARFORD, *Peterborough*.—The water ballast roller, of which we gave a favourable opinion in our report of the Royal Horticultural Society's Show, page 155.

2130. HORNSBY, R., & SONS, *Grantham*.—Improved washing and wringing machine, substantially constructed and apparently very efficient in its action. The improvement principally consists in the introduction of a ribbed hollow bridge at the bottom of the oak box for containing the articles to be washed, by which means they are better inflated, prevented from becoming rolled up, and more effectually rubbed.

2156. MUSGRAVE, BROTHERS, *Ann Street, Belfast*.—Iron piggery with iron feeding-trough. This is made entirely of iron, with an open back for placing against a wall; the roof is of corrugated-iron, and arched, covering in a yard for the pigs, to which a good supply of air is admitted at the front and by lattice openings at the sides. The arrangement for filling the trough from the outside and emptying it of rain water, or for the purpose of cleaning, is excellent, insuring cleanliness and preventing waste.

2159. NIXEY, W. G., 12, *Soho Square*.—Kistell's patent garden labels. Neat and apparently durable, consisting of a cast-iron frame in which the name is painted, and protected from the weather by a piece of glass.

2191. TAYLOR, J., & SONS, *Kensal Green*.—Conservatory, boilers, and furnace-doors. The conservatory is of the span-roofed description, with upright sides and ends. Ample provision is made for the admission of air, the whole of the side-sashes opening by a simple contrivance, and ventilation at top is effected by small moveable sashes on each side of the ridge, worked by a cord and pulley. Altogether it is a neat, plain, useful conservatory of no great size.

Two boilers are shown; one is a modification of the common saddle kind, but with corrugated sides, and composed of two chambers, dividing the boiler horizontally in two; the other is a tubular horizontal boiler having numerous small pipes at the sides of and above the fire, but principally the latter.

2193. THOMPSON, H. A., *Lewes*.—Improved entrance gates. These are constructed of wood and iron, with cast-iron pillars, and no mortice or glue is employed. The whole is braced together by iron bars—the top one an inch, the others half an inch in diameter; and the edges of the woodwork being bevelled, the rain does not lodge upon it. They look much neater than the ordinary form of wooden gates, and appear peculiarly suitable for park entrances.

2197. TYLER, H. & CO., *Upper Whitecross Street*.—Oval tub garden engines of oak and galvanised iron on wheels, pail engines, and syringes of various sizes.

2198. UNDERHILL, W., *Newport, Salop*.—Game and poultry fence, and tree guards. In these the upright wires pass through notches in horizontal straps of iron which extend lengthwise. They are remarkably cheap, and would very well answer the purposes for which they are intended.

2200. WARNER & SONS, *Crescent, Cripplegate*.—These well-known hydraulic engineers exhibit a variety of garden engines, syringes, pumps, watering-hose, and fountain jets of various patterns, all of which are well and solidly made.

We also observed Spary's fumigator noticed last week; an improved water-barrow on cast-iron wheels, the suspended cistern of which is of galvanised iron, and capable of containing about thirty-five gallons of water; and in another part of the building a double-action force pump mounted on wheels. This can be used for pumping water, distributing liquid manure, or as a small fire engine. It will throw a continuous stream of water to a considerable distance; and the price being very low, it would be a valuable addition to any gentleman's house, even if useful for no other purpose than protection against fire.

2201. WEEKS, J. & CO., *King's Road, Chelsea*.—Boilers, heating-stacks, and models of conservatories. The boilers are of the well-known powerful form seen in our advertising columns, consisting either of a double or single row of pipes according to size; and the excellent appearance of the heating pedestal has been already noticed in our report of the Royal Horticultural Society's Show. Of the models of horticultural buildings one is that of their own conservatory at Chelsea, with a number of other houses for various purposes, and the other represents a lofty curvilinear conservatory.

2208. WHITEHEAD, J., *Preston*.—Brick-pressing machine. We mention this on account of the beautifully moulded bricks which it turns out, and which in building would present a very fine joint between the courses. The machine is in the form of a table on wheels, and has in its centre two mould-boxes, the bottoms of which are pistons, and a hinged lid serving to cover each alternately. A piece of clay is put into one of the mould-boxes, and the lid closed; the man gives the wheel by which the pistons are worked a half turn; the clay is pressed into the mould; the lid is lifted, and the brick taken out. The same proceeding is repeated with the other mould-box, and so on alternately. It is stated that a man with two boys to feed the machine with clay and carry off the bricks as turned out can make 6000 bricks a-day, and that with a larger machine differing from this in the mode of feeding and delivery, double that quantity can be produced.

2025. WILLIAMSON, W.—Washing and wringing machines. These differ in principle from Hornsby's and other machines in the articles not being washed by a rotary or rocking motion of the receptacle itself, but by means of an open frame somewhat like louvre boarding. This, receiving an alternate backwards-and-forwards motion, and being jointed, a slight upwards-and-downwards one as well, squeezes and rubs the clothes, as far as we could judge, very effectually, and with but little exertion on the part of the person using the machine. It is made of various sizes differing somewhat in the arrangement of the moving power, and with or without rollers for squeezing the water out of the washed clothes.

2204. WILLISON, R., *Alloa*.—Ventilator for vineries. It is stated that this apparatus was invented by Mr. W. Thomson, of Dalkeith, and that it has been tested by him in a vinery with very satisfactory results. Every practical man is aware of the danger of admitting cold currents of air into hothouses, especially those devoted to early forcing, in which at the same time a constant supply of fresh air is needed. To meet this difficulty the hot-water pipes in the front of the house are surrounded by a light iron or copper sheathing perforated on its upper surface with holes, a space being left between the pipe and sheathing for the circulation of air. In connection with the sheathing a pipe provided with a regulating valve is carried to the outside of the

house; the air, being admitted through a grating at the extremity, passes between the sheathing and the hot-water pipe, and is, consequently, warmed in its progress before escaping by the perforated holes of the casing. The idea is good and is deserving of trial, though we are not aware what the cost of the contrivance, which is to be patented, will be.

2405. TAYLOR, J., JUN., *Parliament Street*.—Among other building contrivances are exhibited a coping of tiles for fruit-tree walls, with the pieces readily joining into each other so as to form a continuous joint. These tiles might not only be used as a temporary shelter in spring, but also as a substitute for a regular coping. Their cost is not stated.

The use of hollow-glazed tiles constituting a damp-proof course in buildings, as shown by this exhibition, is excellent. The tiles being open at both ends permit of a free passage of air through the wall, and thus, no doubt, keep the part subjected to damp much drier than it otherwise would be; whilst from the glazed material of which the tiles themselves are composed the ascent of damp is entirely prevented. The same exhibitor also shows an ornamental tile for permanent copings, which, if cheap and durable, will be useful; and a kitchen-garden drain and edging-tile in one, a gutter for the water being formed in the sole at the base of the upright portion.

(To be continued.)

### PORTRAITS OF PLANTS AND FLOWERS.

**BOLBOPHYLLUM CUPREUM** (Copper-coloured Bolbophyllum).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Manilla and Araucan. Flowers copper-coloured and smelling very like the root of Valerian.—(*Botanical Magazine*, t. 5316.)

**RHODODENDRON FULGENS** (Brilliant Rhododendron).—*Nat. ord.*, Ericaceæ. *Linn.*, Decandria Monogynia. None of the Indian Rhododendrons can vie in colour with this. Dr. Hooker says it is the richest ornament of the Sikkim Himalaya, at elevations of from 12,000 feet to 14,000 feet. Flowers intensely crimson. Bloomed at Kew in April.—(*Ibid.*, t. 5317.)

**PALISOTA BARTERI** (Mr. Barter's Palisota).—*Nat. ord.*, Comelyneæ. *Linn.*, Triandria Monogynia. Found at Fernando Po in a grove of Oil-Palms. Colour of flowers there white, but in the stove at Kew they had a purplish tinge. It is almost stemless and herbaceous.—(*Ibid.*, t. 5318.)

**ANTHURUM SCHERZERIANUM** (Scherzer's Anthurium).—*Nat. ord.*, Onoriaceæ. *Linn.*, Tetrandria Monogynia. Native of Guatemala and Costa Rica. Spadix and spathe brilliant scarlet. Bloomed at Kew in April.—(*Ibid.*, t. 5319.)

**OREODAPHNE CALIFORNICA** (Californian Mountain-Laurel).—*Nat. ord.*, Laurinæ. *Linn.*, Enneandria Monogynia. "Fine evergreen and hardy tree, described by David Douglas as forming the greater part of the forests of California." The camphor-like odour of these trees is so strong as to cause sneezing to those resting under their shade. The hunters make a tea of the leaves, which is stimulating.—(*Ibid.*, t. 5320.)

**ECHINOSTACHYS PINELIANA** (Banded Echinostachys).—*Nat. ord.*, Bromeliaceæ. *Linn.*, Hexandria Monogynia. Native of Rio Janeiro. Peduncle and bracts vivid crimson. The zebra-like stripes on the leaves are alluded to in the name "banded." (*Ibid.*, t. 5321.)

**MUTISIA DECURRENS** (Decurrent-leaved Mutisia).—*Nat. ord.*, Compositæ. *Linn.*, Syngenesia Superflua. Native of the Andes of Chili, sent to Messrs. Veitch & Son, of Exeter and Chelsea, by their collector, Mr. Pearce. Flowers intensely orange. "As a hardy climbing evergreen this plant is a welcome addition to our gardens, irrespective of the interest attaching to its curious structure. Its hardiness seems to be well established, inasmuch as it had withstood without the least injury the severe winter of 1860-61, at Exeter, where it had been subjected to 26° of frost; and at Messrs. Veitch & Son's, Combe Wood Nursery, Surrey, it has since stood unharmed through the last winter. It is stated to be a plant of easy cultivation. The specimen from which the flowers were obtained having been merely planted out in good soil against a north-west wall, where it had made vigorous growth, and had perfected many of its brilliant flowers."—(*Florist and Pomologist for June*.)

**DIANTHUS HYBRIDUS MULTIFLORUS** (Many-flowered Pink).—Flowers rosy, very fragrant, and numerous. It blooms freely and grows freely. In a greenhouse without heat it blooms in April. Raised by Messrs. Henderson, Wellington Road Nursery, St. John's Wood.—(*Ibid.*)

**GERANIUM MRS. POLLOCK**.—One of the zone-leaved varieties.

Centre green, with next to it a crimson zone, and an outside one of bright yellow.—(*Floral Magazine*, Plate 101.)

**DOUBLE-FLOWERED CHINESE PRIMROSE**.—Two varieties of this double form, *Delicata*, white, tinged delicately with flesh-colour, and *Rubra grandiflora*, a deep crimson. Messrs. F. & A. Smith, nurserymen, Dulwich, had a first-class certificate awarded to them for the last-named by the Floral Committee of the Royal Horticultural Society.—(*Ibid.*, 102.)

**NEMOPHILA ELEGANT**, a variety of *N. discoidalis*. Flowers deep purple or maroon, bordered conspicuously with white. Raised accidentally by Messrs. Charlwood & Cummings, Florists, Covent Garden. The Floral Committee of the Royal Horticultural Society gave it a label of commendation, and it is mentioned in their "Proceedings" as "an annual desirable for general cultivation."—(*Ibid.*, 103.)

**AZALEA DUC D'AREMBERG**.—"Flowers of good form and substance, of a delicate salmon pink colour, with a broad distinct margin of white, and dashed with red. Upper petals at their base spotted with red."—(*Ibid.*, 104.)

### PROTECTION OF SMALL BIRDS IN SWITZERLAND.

I MUST thank you and your correspondents for taking up the cause of the small birds so valiantly. It is indeed of national importance. Having resided for some years at Geneva, I know full well the direful effects of killing these useful protectors of the crops. The Genevee were just awakening to a sense of duty; just finding out the use of them, and imploring the people not to kill any more. Edicts in the name of Mare Viridet were on all the walls warning the people; not to much purpose I am afraid.—PATELIN.

[The names of the trees you mention, are *Araucaria imbricata*, and *Sumach*, *Rhus coriaria*.]

### THEORY OF COLOUR, AND THE INFLUENCE OF LIGHT ON VEGETABLES.

(Continued from page 135.)

WE have already mentioned that colours depend wholly upon the reflection and absorption of light by the apparently-coloured object; but it should also be understood that this result depends upon the chemical constitution of the particular substance: hence the inquiry into the cause of vegetable colours becomes also a chemical one; and from certain well-known chemical laws these colours must have a definite constitution: therefore, when any change of colour takes place there must also be a chemical change of constitution.

It was likewise mentioned that chlorophyllite, the green-colouring matter of plants, depends for its formation on the action of the solar rays. Many circumstances concur in leading us to this conclusion. Everybody has observed the difference between a plant growing in the full enjoyment of light, and of one growing in some obscure corner where that agent is partially or totally excluded; the former is of brilliant tints, the other of a pale sickly colour. It is, therefore, quite obvious that a plant kept always excluded from the light must have a difference in its composition.

The function of the leaves and other green parts of vegetables is to absorb carbonic acid, and, with the aid of light and moisture, to appropriate its carbon. These processes are in continual operation; they commence with the formation of the leaves, and do not cease with their perfect development. But when light is absent, or, during night, the decomposition of carbonic acid does not proceed—nay, carbonic acid is emitted, and oxygen gas is absorbed.

The effects of darkness upon some vegetables are very remarkable; so much indeed is this the case that the most common plants have, when they have vegetated in the dark, deceived even the practical botanist. Professor Robinson mentions that in visiting a coal-pit he found a plant with large white foliage, and which was quite new to him. It was left at the mouth of the pit for a few days, when the subterranean leaves died away, and common fanny sprang from the root.

From the facts already noticed it would appear that the green-colouring matter of vegetables depends upon a peculiar substance existing in the vegetable, not absolutely essential to the plant,

nor invariably present, and depending on circumstances, but which is at the same time best for the health and well-being of the plant.

Though green is unquestionably the predominating colour in the vegetable kingdom, and exception to this is found in that freak of Nature—variegation, this variegated form of leaf is particularly observable in the Geranium family, which is now so extensively employed in the present style of flower gardening, producing a fine effect when judiciously arranged in combination with strong colours; but all attempts to trace the cause of variegation to its origin have hitherto proved abortive. Several very interesting papers on this subject have appeared from time to time in the pages of this Journal—papers fraught with instruction, and containing many useful hints to future workers in the same field. By some the cause of variegation has been ascribed to disease; but depend upon it, it is a mistake. As facts accumulate on our hands, the results of actual experiment, and the attentive and careful investigation of these facts as they are presented to us, the more firmly are we convinced that disease is not the cause of variegation. The results of several attempts to produce variegation by artificial means—in which I succeeded to a certain extent, but the results were not sufficiently satisfactory to draw definite conclusions from, and I shall, therefore, try again before saying anything of the means used to produce the diversity of colour in the leaves of plants—from a number of facts elicited in these attempts, I am strongly inclined to believe that an appeal to chemistry would be a step in the right direction towards a solution of this perplexing problem.

We may rest assured that there is more than one operating cause producing this discolouration of the leaf, but I cannot perceive that the disease theory is supported by a single fact. Is it not anomalous to suppose that diseased parents should be capable of producing a healthy offspring? and yet numberless experiments prove this to be a fact. In my experiments I have always had a greater number of plain-leaved varieties from a cross between two variegated-leaved Geraniums than from one between Tom Thumb and a variegated-leaved one.

Now, assuming disease to be the cause of variegation, one would expect the reverse of this to be the case—that by imparting fresh life to a diseased plant by means of a healthy variety we should imagine that the disease would be at least mitigated, if not extinguished. From a batch of seedlings obtained from a cross between *Hendersonii* and the Countess of Warwick, both variegated varieties, three-fourths were as free from variegation as Tom Thumb, and certainly quite as robust, some of them a good deal more so; five more were slightly variegated—just enough variegation to swear by and no more, and even this entirely disappeared with one season's cultivation. Surely these facts bear strongly against disease being the cause of variegation in plants. In the animal kingdom certain diseases are hereditary in some families; and it has been proved beyond a doubt that this peculiar form of disease will descend from one generation to another, still retaining its original character, frequently disappearing in one generation and breaking out again in the next or succeeding one in all its original virulence, making it evident that the taint had been communicated, and, though not showing itself, was still lurking in the system of the individual. Now, if we admit of any analogy between the diseases of plants and animals, it is not unreasonable to suppose that by crossing the progeny of diseased parents one with another, that the disease would become more apparent; but in a majority of instances the reverse of this is the case. But after all that has been said, both for and against disease as being the cause of variegation in plants, they exhibit no symptoms of unhealthiness in growth and habit, unless they are planted in poor soil, and otherwise maltreated. True, they are generally more dwarf than the plain-leaved sorts; but we do not see how dwarfness of habit can be regarded as indicative of disease. In the animal world it is no uncommon thing to see several individual members of a family almost positive dwarfs compared with their parents, and they live in the full enjoyment of health and strength physically and mentally.—J. DUNN.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY'S AMERICAN PLANT SHOW.—We regret to learn that this magnificent exhibition has been brought to an abrupt termination by the tent with which it was covered being blown down by the late high winds. Much

damage has been sustained by Messrs. Waterer & Godfrey's noble specimen plants, the replacing which with plants equally fine will probably take years to accomplish.

On previous occasions we called attention to the insecure and altogether discreditable character of this tent, which caused us to fear a catastrophe such as this. We trust that out of the evil which has occurred good may yet arise, and that the Society will altogether abandon the use of tents.

## NOTES FROM BURMAH.

I AM delighted to tell you that I have shot a rhinoceros, I believe the only one that has been killed by any European either in the Mantaban or Tenasserim provinces. Some have been killed by Col. Fytche, our Commissioner at Moulmein; but he got his up the Irrawaddy river above Bassein. He is a most daring sportsman. He was out after elephants some time since, and came upon one very large one with tusks some 10 feet in length. He got up close to him, but rather behind him; knelt down until he turned a little on one side; when suddenly the elephant smelt him, and, raising his trunk, beat the bush close to the Colonel. The latter, not being enabled to shoot, the elephant caught him with his trunk, and sent him up some 30 feet among the boughs of some neighbouring trees, gun and all. This was considered rather a narrow escape, especially as this particular elephant, which is said by the natives to be more than a hundred years old, is a very cool fellow. He was one day eating a poor man's Sugar Cane, and the owner got a gun and went up into a house close to the Cane plantation on the outskirts of a village, and had a shot at him. But this only enraged the elephant, which entered the village and pulled down ten of the native huts.

But about my rhinoceros. I went towards the sea-coast, about two-thirds down the river, and then to the right across the narrow strip of land, which is about seven miles in width, from the river to the sea. The first two days I was unsuccessful; but on the third day I came upon some fresh tracks, and heard the beasts on the hill above me. I ascended, and started them without getting a shot, but followed; and soon one of the two hiding himself in some thick bushes about 30 yards away, I raised my rifle, and put the ball through the arteries of the neck, when he fell on the spot. He was a fine male, not quite full grown, but very handsome. The Burmese danced round me and pulled me by the arm, saying they had never seen anything done so well before. He was 13 feet 6 inches in length, and the skin was as much as six men could carry, the head being a good load for two. This rhinoceros was of the one-horned species; but we have the double-horned kind in the lower part of the provinces below Unequi. I am going out again after the rhinoceros as soon as the monsoon is well over and the jungle a little thinned by the fall of the leaf. The Burmans are very fond of the flesh of the rhinoceros, and use the blood as a specific in all diseases. I shot him through the neck, and hit both carotids, so that when we went up to him the blood was spouting out from both sides. Pieces of Bamboo were soon cut, and the blood collected for the lame, the halt, and the blind. I shot him on the side of a low range of hills, on the shady side of which they are generally found in the day, but go down to the swamps in the night to wallow in the mud.

The single-horned is by far the handsomest of the two kinds of rhinoceros, the double not having the "coat of mail" skin, but one more resembling that of a buffalo. The horns are only attached to the skin, not to the bone as in other horned animals. I am considered a regular Gordon Cumming amongst the Burmese, and can get any number of them I require.

I have not yet received the Rose-cuttings. I want principally Perpetuals and some of the Tea-scented, as *Devoniensis*, a sulphur colour. I really think any cuttings would live in a small open-mouthed glass bottle, or in six pieces of glass fastened together, forming a miniature Ward's case. With a little moisture, put in a small wooden box and sent through the post, I think *Fuchsia* cuttings may also be tried as well as *Roses*. I am afraid you will think me very troublesome, but it will be a very great success should they grow, as it has never, I think, been tried before. I find the *Pink*, *Carnation*, and *Picotée* will do here. Some seeds of good or first-rate would be most acceptable. The latter is now grown with a white instead of a yellow ground. These would be much prized here.—B. H., *Taoy, Tenasserim Provinces*.

## DISCOVERY OF MUSA VITTATA.

In his report of the Royal Horticultural Society's Exhibition, Mr. Beaton says *Musa vittata* was introduced to Kew by their own collector; but I see by the June Number of the "Proceedings" of the Society, just received, that this beautiful plant was "introduced by Mr. W. Ackerman to the nursery of M. Van Houtte, of Ghent, from St. Thomas, a small island in the Gulf of Guinea," page 361. Who is right—Mr. Beaton, or the authority of the Royal Horticultural Society?—K.

[On referring this question to Mr. Beaton himself, he answers as follows:—"Perhaps we are both right, but the 'Proceedings' are certainly wrong in the statement. M. Van Houtte did introduce the plant to the Continent; but before his collector was aware of its existence, there were a number of plants of it on the way home for Kew Gardens—the very plants I reported on from the different nurseries. I do not think this side of the question needs that I should give the information respecting the way both the collectors discovered *Musa vittata*, but I know it. I also knew something of plant-collecting in many parts, and of the difficulty of having everything as it ought to be in 'Proceedings.'—D. BEATON."]

## KNOBS ON YUCCA RECURVA.

I HAVE some *Yucca recurva* that I wish to increase. One of them has had for two years past three large knobs showing through the ground, but as they do not break into leaf I feel inclined to take away the surrounding mould, and slightly pull them from the old stock, filling-in with the fibre.—H. B.

[Do not pull them off, but cut off clean if you can, and smear the part with charcoal-dust. Most likely these knobs if potted will give you a number of plants.]

## DESTROYING MARCHANTIA CONICA ON TURF.

THE turf, say 40 feet square, in my suburban garden is overgrown with *Marchantia* where always in the shade. Is there any mode of destroying it? I have heard of wood ashes.—M. D. P.

[We have little faith in the wood ashes unless you drained the ground, and that would take away what this Liverwort feeds on—the stagnant moisture. If this were done, and the ground dressed with quicklime, we think you would get rid of the annoyance.]

## SAVING STRAWBERRY PLANTS FROM GRUBS.

A CORRESPONDENT from Bolten-le-Moors complains that the "black bot" (or grub of the daddy-longlegs), is eating up his vegetables. I also find that I have a great quantity in my garden, for about three weeks ago I perceived the flower-stalks of my Strawberries falling down, half eaten off at the bottom. Upon removing the soil from about the roots of a plant I perceived a number of bots. I immediately procured some lime slaked to a fine powder and placed some round every plant, since which they have done them no damage.—A. Q.

DEATH OF MR. JOHN EDWARDS.—By this event, which took place last week, the floricultural world has lost one who, both as a cultivator and a judge, held a very high position. I will remember paying him a visit when he resided at Holloway, in the year 1847, and was much struck with the zeal and energy with which he had carried out his favourite pursuit. I believe he commenced as a florist about seven years before that as a grower of Pinks and Pansies; but, like most of the fraternity, one thing led him on to another, and soon Tulips, Roses, Dahlias, Carnations and Picotees, and Auriculas were added. At one time Azaleas, Orchids, stove and greenhouse plants also received his attention; but, alas! that ever-spreading monster, our great metropolis, coveted his garden, and then devoured it. His collection was sold, and villas occupied the once-blooming garden. He, however, continued a most valuable and active member of the various London horticultural societies; and for many years was the diligent and painstaking Secretary of the

National Floricultural Society, until it became defunct, in consequence of the establishment, on a broad and liberal basis, of the Floral Committee of the Royal Horticultural Society. He also acted as judge at the metropolitan exhibitions in the department of florists' flowers; and having been associated with him in that capacity, I have often been struck with the intuitive perception he seemed to have in looking over a number of stands, where the merit really was. Beyond this I knew but little of him personally; but I have ever heard him spoken of as one whose opinion in his own special line few would gainsay.—D., Deal.

## OXALIS ELEGANS (ELEGANT WOOD-SORREL).

*Nat. Ord.*, Oxalidaceæ. *Linn.*, Decandria Pentagynia.—A very showy, half-hardy, tuberous-rooted perennial, with trifoliate leaves, the leaflets of which are deltoid, or sub-rhomboid, and glabrous. There are two varieties, in one of which the under side of the leaves is a purple tint, in the other green; the latter has the flowers somewhat smaller, but brighter coloured than those of the other variety. The flower-stalks grow 9 inches or a foot high, bearing an umbel of from six to ten flowers, of five broad, oval-clawed spreading petals, rose purple, with a very dark purple eye; in the smaller variety the blossoms are upwards of an inch across. These are likely to become valuable plants for the flower garden. Both varieties are from Columbia: Andes of Loxa, at an elevation of nearly 7000 feet. Introduced in 1848 by Messrs. Veitch & Son, of Chelsea and Exeter, through their collector, Mr. W. Lobb. Flowers throughout summer and autumn.

## ARCHITECTURAL TERRACES.

BY H. NOEL HUMPHREYS, ESQ.

I HAVE, in my last communication, shown how terraces may be produced at an exceedingly moderate expense, suitable to various styles of cottage and villa architecture, and it is on this moderate scale that suggestions for the formation of terraces will interest the greatest number; but this most important feature of decorative gardening would be but imperfectly explained did we finish the series without alluding to terraces in their more palatial form, and in their noblest proportions. It is not always necessary to terrace effects, on the largest scale, that architectural decorations should be introduced; for, by simple embankments, as suggested in our paper on cottage terraces, gardenesque features of a very noble character, and suited to residences of the

highest class, may be obtained. The effects to be produced near main terraces, by deep, massive Box-edgings, have been much neglected, and might be revived with great effect; but this feature must be cautiously used, and not carried too far, as, in that case, the attempts invariably sink into the meretricious—when, for instance, these cropped edgings are tortured into initial cyphers, or even entire epigrams, as in some of the later Italian villas; or to select a more modern instance, in the magnificent gardens of the late Earl of Shrewsbury at Alton Towers—gardens reclaimed by art from land, which some years ago was no other than a barren waste—where, if my memory serves me correctly, a bust has been placed upon a marble column, in a conspicuous part of the ornamental gardens, at the base of which, the ingenious and persevering spectator may decipher, in the cropped Box, the motto, “He made the desert smile,”\* in honour of the late Earl of Shrewsbury, under whose directions the improvements were effected. Such elaborate conceits are apt to make the spectator smile; but they are not, as I have observed, without their precedent, for some of the finest of the Italian villas are disfigured by similar effusions, and to a much greater extent, of which several ridiculous and scarcely credible examples might be cited.

Of the more architectural terrace, with its full complement of statuary, vases, fountains, &c., the villa Panfilo Doria may be cited as an example. Of this magnificent specimen, the engraving will convey a good general idea.

As displaying the true feeling of the palatial terraces of the

school, these Italian villas are the safest, as they are the original models. I find in my Italian journal the following notes on these fine monuments of architectural and gardenesque composition.

The villas of the modern Romans merit the name of palaces, and form one of the most characteristic features of Italian scenery. Of those in the immediate vicinity of Rome, that of the Borghesi family, which is the confiscated domain of the unfortunate Cenci, is the most important; it is open to the public, and forms the Hyde Park of the Romans; but neither Hyde Park, nor Kensington Gardens, nor the Tuilleries, nor Versailles, can convey any idea of the peculiar charms of a Roman villa. There is a freshness of vegetation about the suburban *delizie* of Rome, that the neighbourhood of large towns always tarnishes, except in Italy. But there, close under the walls of Rome, the Appennine Anemone, of various tints, brightly-coloured Scillas, the deep crimson Cyclamen, and many beautiful Orchids put forth their fragrant blossoms in early spring, as in the woody dells of the secluded country. The “sky-cleaving Cypress” shoots aloft its pointed or forked peak to a height equal to the Poplar of the north, and noble groves of Ilices, whose vast trunks spread above with groined branchwork into densely-matted foliage, form

“A pillared shade  
With echoing walks beneath.”

The peculiar character of the tufted heads of the Stone Pines, too, grouping in picturesque masses with terraces, statues, and fountains, tend to invest Roman villas with a charm peculiarly their own.

THE VILLA PANFILI DORIA.

To return to the subject of our engraving. The villa Panfilo Doria is next in importance to that of Borghesi among the villas near Rome; but its somewhat greater distance, and unhealthy situation, cause it to be much less frequented. The palace itself is, on its exterior, almost entirely encrusted with antique *alto-relievi*, some of which are of the highest merit, and most exquisite beauty. This is a luxury which cannot be imitated, except in Italy, where the soil still teems with the fragments of her ancient splendour, many of the finest of these *relievi* having been turned up in digging the foundation of the building. The whole of the composition of this palace and gardens—for the whole forms one harmonious design—is an excellent model for the careful examination of the modern student; but the reduced dimensions of our engraving can convey but a very inadequate idea of the numerous and elaborate details.

I find the following brief notices of one or two other villas in my journal, with which I shall conclude this article, which, though not strictly of a practical character, is yet, I think, cal-

culated to convey my opinion of the styles to be adopted in the higher class of terraces better than more mechanical definition.

The villa Albani, perhaps, realises more than any other the dreams of the Italian villa that haunt the imagination before having seen Italy. It is chaste, and severely classic in its style, yet, withal, richly magnificent—a rare and difficult combination. And to its intrinsic features the charms of position are super-added, the range of views from its marble terraces commanding the finest portions of the picturesque campagna, with its rugged lines of half-crumbling aqueducts, and scattered groups of detached ruins.

The gardens of the Borghesian villa, Mondragone, at Frascati, combine, to an unusual extent, the richness of immediately surrounding features with the result of art. The noblest views over the Appennine range, and the campagna, the latter extending even to Rome, where the vast cupola of St. Peter's are seen describing a dim blue arch upon the horizon. The various and picturesque foreground offered by the rich marble terraces of Mondragone have not been overlooked by artists; many distant views of Rome and of the ever-attractive campagna having been painted from this spot.—(*Gardener's Magazine of Botany.*)

\* I am not certain whether the vegetable literature may not be confined to initial cyphers, and the motto itself engraved on the edging; if so, the cyphers serve the purpose of illustration equally well.

### VINES IN A GLAZED CORRIDOR ENTRANCE.

THE entrance to my villa, now building, is through a glazed corridor (you can hardly call it a conservatory), the size being 29 feet in length by 6 feet 3 inches in width. The aspect of this is due south, and I think a few of the hardiest kinds of Vines, nicely trained to cover the roof, would have a pleasing effect; and likewise form a shade from the sun during the summer months. I do not care about the fruit so much as the effect. If you approve of the plan would you put them into the front, and so train them up the roof? or would they be better put on the back wall and trained in this, and then brought down the sloping glass roof?—A SUBSCRIBER.

[We have no doubt that Vines will answer admirably, and if you have pilasters or anything of that kind in front, the stems should go against them as well. We would in your circumstances not plant them against the back wall, as that might render the walls of the dining-room, &c., damp. We would prefer having them planted in front, and if the ground is well drained, and good soil used, there need be no eyecore, as you do not contemplate forcing. We would use six plants or so, and nothing would suit better than Black Hamburgs; or if you liked variety, say three of that and three of Royal Muscadine. We presume you have upright glass in front; if not, and you did not like to break the ground there, two Vines may be planted at the entrance end, and they would soon go along the roof longitudinally. If the front is glass it would be best to plant in front; if at the end, the roots of Vines in good soil will thrive well enough below the gravel of the drive.]

### WHY SMALL BIRDS SHOULD BE PROTECTED.

I AM really gratified to find you are pleading a little in favour of the utility of small birds, and much wish also the feeling was as general as it should be. Perhaps, then, you will allow me a corner to give my experiences on the subject. For the last thirty years of my life my flower garden has been one of my chief hobbies; and let me add, that the voluntary nesting therein of various small birds has greatly enhanced the pleasure as well as doubled its attractiveness to visitors, independently altogether of that far more important feature—their general utility. For the time named I have never been without several boxes provided expressly for their accommodation, thus to induce their easily-attained nidification on my own premises. Whilst I am writing, a pair of Redstarts are feeding their young ones within sight of my breakfast-room window, and the hundreds of “daddy-longlegs” taken daily to their brood can scarcely be credited, save by witnessing it. From the earliest dawn to the last ray of evening they are continually taking supplies, not only of this most injurious insect during the time it remains a caterpillar, but also any description of butterfly or moth that is comestable. Both the Redstarts and also the Grey Flycatcher have almost annually bred in these boxes, though from some unknown cause the latter have not even been seen in this immediate neighbourhood this summer.

Both varieties of these insectile feeding birds are most amusing in their habits, and when they perceive they are not injured become, as incubation progresses, marvellously familiar. Their delight is to sit perched on a tall standard Rose, or any similar object that affords opportunity for a good look-out, and from this they dart at every insect that approaches. The chase of a butterfly is, perhaps, one of the most amusing of their habits, lasting in bright sunshine frequently for a minute or more, the butterfly dodging its best incessantly, and the old birds repeatedly stooping as hawks will do when in pursuit of their prey on the wing. The colours of the Redstart are under such circumstances seen to the greatest possible advantage. Generally after capture, if by the male Redstart of any large insect, he will alight on the top or footboard of his nesting-box, place the still struggling fly under one foot, and sing a few notes of triumph before feeding his little ones. The Flycatchers are undoubtedly the more beneficial of the two, however, as being by far the greatest feeders. The Robins almost always breed with me likewise; but this season the Redstarts gained prior possession of their favourite box, and the Robins, in extreme dudgeon, betook themselves to some adjacent Ivy; for, most unusually, the Redstarts have even yet maintained the mastery all the season. Some twenty-three years back a pair of those very rare birds, the Spotted Flycatchers, built with me, and reared with

success half a dozen young ones; they proved far more active but much less confiding than the common Flycatcher.

At that time I was collecting specimens for a small museum, still in my possession. After the Spotted Flycatchers had reared their young, the temptation to take the cock proved too strong for me, and he now stands preserved a silent monitor of reproof for an act I even then quickly regretted, and which I still view with like feelings. It is worthy of mention, that though several pairs came for a day or so the following spring—most probably the old hen and her brood of the previous year—they passed on to safer quarters; nor have I seen for many years a single living bird of this description.

The boxes I use are about 6 inches by 5 inches; they are gabled, the one end having a hole to hang on a nail in the wall, the other being provided with a circular entrance about 2 inches in diameter. As the cats this year robbed me of a brood, to which by some alteration in the adjoining premises they unfortunately gained access, I purpose before another breeding-time to place on a single support square boxes to each hold four nests, to be placed in the open sufficiently elevated to be above the leap of a cat, and have but little doubt they will soon be occupied, as for many years the Flycatchers bred within only a few inches of each other without any display of anger or unfriendliness; a Robin also rearing its young within a yard of the same spot, and simultaneously.

The quantity of insects thus consumed by a single brood whilst yet unledged is scarcely credible; and the far-increased amount of sustenance they require for the several months they remain after leaving the nest must be even greater. I am well assured, also, that few individuals could be found who would not be interested in watching their movements; and it should be borne in mind that no personal trouble is required: for the less the birds when resting are interfered with the better. An object of unusual interest to my late sister resulted from a Wren having built in the head of a tall standard Rose, a most unlikely spot certainly, being also close to a path; yet the Wren carried out her purpose successfully, and the young ones proved very familiar up to winter time. Some of my neighbours, who, at the outset, smiled at my hobby, are now following my example; and our comparative freedom from blight I attribute almost exclusively to the increasing efforts of these little pets for hours prior to the generality of persons turning out to their gardening occupations.

To those readers who can give this matter a fair trial in suitable situations, I am sure the results will be both instructive and pleasurable.—EDWARD HEWITT, *Sparkbrook, Birmingham.*

### CUCUMBER MAGNOLIA (MAGNOLIA ACUMINATA).

ONE of the most beautiful trees in America is the Cucumber Magnolia, which grows abundantly in Knox Co., Ohio, in the neighbourhood of Mount Vernon. It is generally found on the higher lands along the ridges. It is tall, of cone shape from the lower limbs to the top. The trunk is straight; bark of dark ash colour. This tree bears a beautiful aromatic fruit, of deep scarlet red, oblong, from 4 inches to 6 inches long, 1 inch in diameter, which ripens about the 1st of September; it opens its cells, and drops its seeds (which are about half the size of Persimmon seed) late in October. The fruit is considered an excellent medicine, being a tonic, antiseptic, and stimulant, and is used successfully in curing intermittants.

Perhaps this is one of the most beautiful trees on the continent. The fragrance of the fruit is delightful, equal to the Clove and other aromatic varieties of the Islands. The leaves are as large as your two hands, of heart shape. As an ornamental tree, this cannot be excelled.—J. LLOYD, in *Valley Farmer (American).*

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

*Asparagus*, to husband the strength of the grass for next year no more of the produce should be cut. Late and close cutting is one of the principal causes of weak grass. *Cauliflowers* which are now forming to be watered and mulched with short litter, it will cause them to come close and compact; the head when fully formed to be shaded from the sun by snapping the midrib of one of the leaves and bending it over the head. *Celery*, continue to plant successional crops into trenches; take up the plants with as much earth about the roots as possible, and do

not shorten any of the leaves. Immediately after planting give them a good soaking with water. *Endive*, make a sowing for the main autumn crop. Plant-out a few of the early-sowing, keep them watered if the weather is dry until they get root-hold. *Herbs*, some of them will shortly be fit for drying, the best time for doing so is just as they are coming into flower. *Lettuce*, keep a quantity tied-up for blanching. Make another sowing in drills where they are to remain. *Potatoes*, earth-up the main crops in the garden immediately after the rain. Keep the ground between the rows loose. *Spinach*, sow a few rows for succession; if the weather be dry water the drills before sowing, and again after covering them.

#### FLOWER GARDEN.

There are two or three important points relating to the flower garden, which are sometimes wholly neglected, and at other times very inefficiently done. In the first place, the thinning of hardy annuals should be more generally performed; one of the chief causes of their remaining so short a time in flower may be traced to their being so thick that it is quite impossible for them to branch out, and, consequently, they have only a flower or two at the end of each single spindling stem. The thinning of the flower-stems of herbaceous plants is also but very rarely done; but it is a necessary operation to insure good flowers. Staking is another operation in which there is not sufficient pains taken, the numerous flower-stems of herbaceous plants, and the mode of tying them up, give them the resemblance of a green faggot set on end rather than a living plant. The different kinds of climbing *Roses* to be carefully tied or nailed to prevent them from being injured by winds. Plant-out *Dahlias*, *Salvias*, *Ten-week Stocks*, *Asters*, *Convolvuluses*, *Campanulas*, *Nolanas*, *Kaulfussias*, *Indian Pinks*, &c., into borders or flower-beds, and likewise a few on rockwork. Pot a portion for planting-out into beds later in the season, to replace such as have gone out of bloom. Divide *Campanula carpatica*, and plant it for edgings or in borders in front of herbaceous plants. *Poly-anthus* require a shady situation, as hot weather is very prejudicial to them. Early-planted beds would be much improved by slightly hoeing them over to loosen the soil after the surface is battered hard by the heavy rains which we have had lately. Mow grass lawns regularly during this growing weather. Clip edgings, and endeavour to render the whole neat in appearance.

#### FRUIT GARDEN.

The leading shoots of *Peach*, *Nectarine*, and *Apricot* trees to be tacked-in, taking care to allow plenty of room in the shreds. When thinning-out superfluous shoots it is necessary to foresee what portions of wood will require to be removed at the winter pruning, and the most appropriate shoots to be accordingly reserved for succession and encouraged throughout the summer. If any shoots laid-in for bearing have failed in producing, they may be gradually removed in order to afford more space for successional young shoots. The shoots of *Pears* should not yet be cut back, otherwise the buds that ought to remain as such to form fruit-spurs will be induced to break into shoots. It is now a good time to scrub the stems of fruit trees infested with scale, for the young broods are issuing from their fastnesses and are as naked and tender as mites.

#### STOVE.

Continue to stimulate the plants, repot any that may again require it. Attend to the training and stopping of such as are making rapid growth, syringing every afternoon. As the weather continues changeable take care that the young shoots do not get checked or injured by cold draughts, or scorched by sudden bursts of sunshine.

#### GREENHOUSE AND CONSERVATORY.

*Camellias* after blooming to be placed in a little warmth to make wood and set their flower-buds. Do not allow them to suffer for want of water. *Indian Azaleas* may also be similarly treated. *Rhododendrons* under glass to be fully exposed to the sun for the production of good foliage and an abundance of buds. Keep the conservatory shaded during bright sunshine, and cool to prolong the blooms of all plants introduced there. Keep down the green fly by fumigation, the red spider by syringing, and the mealy bug with the finger and thumb. The thrips, one of the greatest enemies, may be subdued by constant smoking and occasional syringing with lime and soot water in a perfectly clear state, but this and all other insects when they once make their appearance must be followed up in right earnest until they are completely extirpated.

#### FORCING-PIT.

This pit may be profitably filled with many ornamental plants requiring the aid of additional warmth to bring them kindly into bloom. Among these may be named *Balsams*, *Cockscombs*, *Hydrangeas*, *Gardenias*, &c. The propagation of *Geraniums*, and other softwooded plants, may be also carried on in the same place.

#### PITS AND FRAMES.

Shift specimen plants as often as they require it. Shade a little during the middle of the day if the sun is hot, and attend carefully to watering. Give liquid manure to such plants as have filled their pots with roots, but not too frequently; the liquid to be clean and weak. Some caution is necessary, as plants are frequently injured, and even killed, by frequent applications of strong liquid manure. Put in cuttings of choice greenhouse and herbaceous plants, that they may be rooted before the pits and frames are wanted for other purposes.

W. KEANE.

### DOINGS OF THE LAST WEEK.

ROUTINE in all departments much the same as before.

#### KITCHEN GARDEN

Took occasion of dripping weather to thin *Carrots* and *Beet*, the *Parsnips* having thinned themselves, thinned *Onions*, and where defective transplanted; put others thickly in rows for salads, and pricked-off others on hard ground with about an inch of friable stuff on the surface, in order to get some button *Onions*, as when grown in the usual way our ground is too strong for buttons. In all such planting, when either large or small bulbs are wanted, no more should go in the ground than the true roots. If the base of the bulb is much inserted farewell to all good bulbing: hence transplanted *Onions* often bulb the best. Of course, for pickling *Onions*, they should be sown or pricked-out thick, and on heavy land the ground can scarcely be too poor for that purpose. Sowed *Turnips* and *Radishes*, and a fair breadth of late *Peas*, chiefly *Marrowfats*, of moderate height. Cleared out the remainder of the *Kale*, and most of the *Broccoli*-stalks to the burning and charring-heap, as even the latter is of less value now, when *Cauliflower* is coming in, and *Peas* and *Beans*, somewhat accelerated, plentiful. Turned out more *Cauliflower*, and pricked-out from seed-bed in order that the plants may be a good size before being moved to the quarter, as their natural enemies are not uncommon this season, and soon make havoc of plants when small. Fresh regulated and pruned *Cucumbers* that had been bearing heavily. I am sorry to say that signs of gum on the fruit are appearing, so will plant out again in fresh soil ere long, as soon as the successors are in full bearing. There are many modes of mitigating, but I must own I have never obtained a perfect cure for this disease. Fresh soil is a good preventive, and in autumn and winter heath soil enriched with weak liquid manure will generally give a crop quite free of any malady. Although you may have plenty of fine fruit, it vexes one to see some with these gumming excretions when you feel you cannot eradicate it. If perceived at first, rubbed off, and dusted with a powder consisting of equal parts of sulphur, lime, and charcoal dust, it will generally leave merely a dried-up mark behind it. So much for a palliative. Such fruit would be no use for an exhibition-table. When, however, there is some three or four times the show of fruit at a time that the plants can mature, if a few show any such affection, it is best to cut them off at once. For this and the curling of *Cucumber* leaves, with an unhealthy yellowish tinge along with it, and the yellowing of the points of *Cucumbers*, of which now I have some dozen complaints beside me, I know of nothing but such palliatives as the above, and a pure atmosphere, air back and front, soil in a sweet, healthy condition, not too dry, nor too wet, nor gorged with manurial matters, and, perhaps, most important of all, a temperature at night not much above 60°, with a rise of from 10° to 20° from sunshine, also a gentle, yet not a high bottom heat. I have been as successful as most people with *Cucumbers* in the times that are past, and have seen very splendid crops: perhaps the very best for a small space was at Hatfield House, and there with the exception of a little sweet dung and leaves to start them—say some 15 inches or 18 inches, the plants could have no bottom heat. But of this and other matters there I hope some day to give more details. I am thus discursive, perhaps, more than I ought to be; but my old friend Mr. Keane, gives such excellent directions as to what ought to,

be done, that it would be pretty well lost space to do little but rewrite his remarks.

#### FRUIT GARDEN.

Much the same as last week. Gave some manure water to *Strawberries*, having as yet found no time to put straw or litter between the rows. Will, if possible, throw a little soot and lime between the rows, as that sends the slugs and worms a-field; and it is so annoying, when gathering an extra fine specimen, to find it perforated by a slug-hole. When manure water rather strong can be given in dripping weather, it acts most successfully. If the weather is dry, it is a good plan to put it on carefully with the spout of the watering-pot, and then follow afterwards with clean water from the rose. This clears all impurity from the fruit and leaves. No good *Strawberries* can be got from ground that is parched dry. To have them in fine size and flavour, the ground must be moist, and the atmosphere clear, dry, and sunny. I notice the many nice bits about birds. I like them dearly, and they would be quite welcome to the smaller *Strawberries*, or even a few of the best; but the rascals are never satisfied except with the largest, and these in general they merely bite, going from one best to another best, as a bee goes from flower to flower. Now I should be sorry to see the sootballs (sparrows), and far less the blackbirds and thrushes, anything like overmuch thinned; as, besides their eating the enemies of gardeners, they deserve some recompense for their delicious notes night and morning; but still in many places, where game is rigidly preserved and no nests are ever taken, it is an easy matter to get too much of a good thing. If the preserving of thrushes and sparrows goes on in the same ratio as the preservation of pheasants and hares, the time will come that whole gardens will require to be enclosed with nets at certain seasons, if anything is wanted from them for a gentleman's table. There are a vast number of places where nets now must be liberally used if the birds are to be confined to anything like a fair portion of the supplies—that is, if we wish to keep them as servants, and not to make them thoroughly our masters.

#### INSECTS—LAURELS.

I read with much interest the chapters on insect-destroyers last week, by our friend Mr. Robson. At one time or other I have tried almost everything he mentions, and with varied success. Just as in the case of Neal's Pastils, sometimes they killed everything, and at other times killed hardly anything. The same thing happens with smoking with the best shag tobacco. There seems to be much depending on the state of the insects, the state of the atmosphere, and the care of the operator. One insect-destroyer, however, Mr. Robson overlooks, which I have often used with effect, and I mention it because there are wagonloads of it at Linton, and few gardens are without it. Like other cures, however, its action has been precarious, sometimes very effective, and sometimes not. I allude to the common *Laurel leaves* in winter, and young shoots at this season. A good barrowload of these shoots and leaves bruised between a mallet and stone and put into a small house, will often make short work of every insect in it, and leave a pleasant perfume behind, like a manufactory of custards. I often find that burning such bruised material, provided the smoke that issues from them is cool, will kill green fly when the tobacco smoke has failed to do so. But just like tobacco and pastils, it will not always do so. As a wash from the syringe and garden engine, I consider laurel water next to good tobacco water for efficacy, and most of the stone-fruit trees like it as much as the insects dislike it. A good barrowload of shoots bruised, put into a barrel—say 18 gallons, covered over with 4 gallons or 6 gallons of boiling water, left covered up all night, the barrel filled up with common water in the morning, the liquor poured through a sieve into the engine and used directly will generally do good, and the expense is little where Laurels are plentiful. I by no means insinuate that it would be as effectual as tobacco, but the latter so often fails that frequently a combination of remedies must be resorted to. Laurels and laurel water can generally be had easily enough.

#### BEDDING.

We are anything but finished as yet; but there are two points on which information is asked—First, do these plants, transferred to temporary beds instead of pots, do as well in the flowering beds, and look as well at first as those turned out of pots? In many cases they will not look so well at first. Scarlet Geraniums will be apt to lose some leaves from the check given from lifting and planting; whilst those turned out of pots, if watered

before planting, may be expected to go on without flagging or losing a leaf. If the ball was not at all reduced, those from pots will not grow so well as the others ultimately, as the roots from being loose will cater for themselves more freely. We put up then with a few yellow leaves on Scarlet Geraniums when first turned out of temporary beds, because we believe there will be little difference between the two in a fortnight, but that the advantage is rather with the former, and because the trouble of picking off a few yellow leaves is very little to the trouble of so much watering, if the plants are kept some months previously in pots. Then secondly, I am asked some dozen times this in purport, "How am I to water? copiously, slenderly, at root, or overhead?" Now, this is too large a matter for a cursory note. But keep these things in mind. Every plant when turned out should have enough of water to moisten the roots, and but little more. When inclined to flag, a little more in the same way should be given; a great deal would cool the soil by its attendant evaporation. To check that when the little is given, cover it up with dry soil, or draw a hoe through it shortly after to leave the surface loose. It is a mistake to deluge such plants now, if you wish active growth. In bright days after dull weather the leaves may flag from excessive evaporation, even when there is plenty of moisture at the roots. In that case shading would be best for a little time. The next best is what we have recourse to where shading cannot be thought about. Take the garden engine full of clean water, and set a man who can place his finger or thumb on the nozzle, so that the discharge will resemble drizzling mist rather than rain, and scatter it all over the foliage. So long as the leaves are dampish, the evaporation of moisture from within is arrested. In such cases, surface or leaf sprinkling often does more good than root-deluging, and at a twentieth part of the trouble.—R. F.

#### TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

SEEDLING PELARGONIUMS AT THE CRYSTAL PALACE SHOW.—There was a mistake in the official prize list as first published. The necessary corrections are as follows. Second prize, Mr. J. Wiggins, gardener to W. Beck, Esq., Wootton Cottage, Isleworth, "Pelidea." Third to the same for "Rory Bloomer." Fourth, Mr. C. Turner, Royal Nurseries, Slough, "Loveliness."

EXTIRPATING DAISIES (*A Subscriber*).—Every attempt at ridding lawns of Daisies, save that of spudding them out, has failed. It takes three or four years to extirpate them entirely, and very close and early mowing is the next best help.

LIQUID MANURE—DOVE'S DUNG (*A Subscriber, Manchester*).—The soda in the soapsuds will increase rather than diminish their utility as a manure. One gallon of urine to eight gallons of your soapsuds will be quite strong enough. The dung of turtle doves, like that of pigeons, is very stimulating; 1 lb. of it to four gallons of water would be a good liquid manure.

CLIMBERS FOR A CONSERVATORY (*Anna, Norfolk*).—To bloom in winter and spring:—*Habrothamnus elegans*, *Maurandya semperflorens*, *Fuchsia serratifolia*, *Kennedya Marryatiae*, *K. nigricans*, *Fuchsia microphylla*. The *Fuchsias* are not climbers, but will answer the purpose and bloom. To bloom in summer:—*Kennedya Comptoniana*, *Bignonia Chirere*, *Brachyosma latifolia*, *Jasminum odoratissimum*, *Tacsonia pinnatisetipula*, *Pasiflora caerulea-racemosa*. The chapter you mention will probably be published in a volume.

NERINE FOTHERGILLI (*W. W. B.*).—As the leaves are green we would not lessen the supply of water for a month to come, and then gradually. Let the plant have all the sun possible.

PROPAGATING *WIGELA ROSEA* (*G. S.*).—It is very easy. As soon as the bloom is well over look over your plants, and slip off some short shoots about 3 inches long, taking them close off to the older wood; remove the leaves from the lower part, and insert the shoots in a well-drained shady place in sandy peat, and sand on the surface, placing a hand-light over them. They will soon strike if well managed.

WHITE FOXGLOVES (*W. Elliott*).—Your white Foxgloves are the richest marked in the inside we have ever seen. The whole of the inside surface is as regularly marked with purple spots and blotches as the outside of a magpie's egg is.

PRIZES FOR CONSERVATORY-TUBS (*G. S., Belle-Vue*).—There are two exhibitions of them—one in June, the other in September. *Crocus* seed and

Hyacinth seed should be sown in October, and covered a quarter of an inch deep, in a bed of light rich soil, in an open situation. The seedlings will appear in the spring.

NAMES OF PLANTS (*S. S. Woodlands*).—It is a *Dollehes*, probably *D. purpureus*; but the pods and seeds are necessary to enable us to speak decidedly. (*B. B. H.*).—1, Pennyroyal; 2, Savery; 3, Burnet (*Poterium sanguisorba*); 4, Tarragon; 5, Statice, probably *latifolia*, but not being in flower not certain; 6, *Clematis grandiflora*. Tarragon will endure the winter near London.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**POULTRY SHOWS.**

- JUNE 12th, NORTH HANTS AGRICULTURAL SOCIETY. *Sec.*, Mr. H. Downs. Entries close May 21st.
- JUNE 26th and 27th. SUFFOLK (Woodbridge). *Sec.*, Mr. J. Loder, jun. Entries close June 5th.
- JULY 3rd. PRESCOT. *Sec.*, Mr. James Deesley. Entries close June 21st.
- JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. *Secs.*, G. Newton and J. Wade. Entries close June 21st.
- SEPTEMBER 9th. WORSLEY AND ARMLEY (near Leeds). *Sec.*, Mr. Robert Hoyle, Atmley, near Leeds.
- DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

**THE HOUDAN HEN.**

(Continued from page 187.)

*Leg and Foot.*—Strong, fleshy, and provided with five toes like the cock.

*Colour of the Leg.*—Like that of the cock.

*Laying.*—Abundant and precocious; fine eggs.

*Incubation.*—Ordinary.

**DESCRIPTION OF THE PLUMAGE.**

The entire plumage composed of feathers of the ordinary proportions should be splashed—that is to say, irregularly mixed; some feathers black, some white, some black and white, sometimes black at the quill and white at the end, and *vice versa*; but generally having on the back, shoulders, sides, and tail-coverts splashes more distinct and less mixed than on the thighs, belly, and topknot. The large tail and flight-feathers are also mixed with black, white, or spangled feathers, but it is better they should be entirely black.

**GENERAL CONSIDERATIONS ON THIS BREED.**

It is one of the most beautiful breeds of poultry, and nothing can be richer than the appearance of a poultry-yard full of Houdans; but their good qualities are far more remarkable than their beauty. Beside the small weight of their bones, the quantity and fine grain of their flesh, their fecundity and precocity are admirable. They attain their growth in four months—they fill out and fatten in an entire state.

The pullets make magnificent poulardes, and of all breeds this one approaches nearer than any other to an equal weight between the sexes. The pullets lay early and abundantly; the eggs are very white and large. The pullets lay in January.

This is a rustic breed, and is easier to rear than any other indigenous fowl (in France); it is more sedentary, and less predatory than most others.

Like all hens that are abundant and long layers they are but middling sitters; nevertheless they perform this operation fairly, and are good mothers.

**THE BEVERLEY EXHIBITION OF POULTRY.**

It gives us great pleasure to state that this year's Exhibition of poultry has proved itself not only a far superior collection, but the attendance has greatly exceeded that of any of the four preceding years. We in justice add, the Committee well deserve the success they have attained. It must be admitted, also, that Beverley possesses a building in the Assembly Rooms, Norwood, equal to any in the kingdom, for the perfect accommodation of from five to seven hundred pens. The local attractions, also, are of no mean character, whether we consider the venerable Minster or Saint Mary's Church, both marvellous piles of architecture, raised by the industry in accordance to the religious feelings of our forefathers in honour of Divinity. A most singularly quaint epitaph is attached outside Saint Mary's that called forth the attention of many strangers. It is remarkable rather for its abruptness than for any refinement of

expression. It is surmounted by cross swords, and we append a copy of it verbatim.

"Here two young Danish Souldiers lye.  
The one in quarrell chanced to die;  
The other's Head, by their own Law,  
With Sword was severed at one Blow.  
December 23rd, 1689."

Thus brief, it stands in excellent preservation, but without giving the curious reader any further account of either the names of the disputants, or the locality of the disturbance. Still, in all its primitive rudeness, this stone, by its veritable description, bears favourable contrast to the eulogiums we so frequently see on the headstones in our graveyards of the present day, which in too many cases are surely more descriptive of what we had desired the deceased should have been, than of their actual character when among us.

Burton Bushes is another attraction of Beverley. It contains many thousand hawthorns, both red and white, which were just in perfection of blossom. The woodbine so lavishly growing among these hawthorns were scarcely at maturity. A great boon to free-born Beverley men is this—that each has the prescriptive right of pasturage on this land of some fifteen hundred acres of excellent quality, for a horse during nine months in the year, for an outlay of 10s. only. But we must return to the Poultry Show.

Game fowls were its great gem, nor have we for years past seen so excellent and praiseworthy a competition. Mr. Harry Adams, of Game fowl notoriety, obtained a lion's share of premiums, with birds of condition unsurpassable. It is reported that his stock is almost without limit as to numbers; yet, even so, it is remarkable that never does a bird enter any of this gentleman's exhibition pens, that in other hands could be improved. Here lies the one great secret to success, a success so great, by-the-by, that we were informed eighty-eight prizes had fallen to his lot in one year at our public shows for Game fowls exclusively. The two additional silver medals, it will be seen, were gained by specimens from this gentleman's yard. The Beverley men seemed determined, if possible, to prevent Game prizes going out of the district. Mr. Julian's Game were also highly worthy of every praise. In sustaining condition, however, Mr. Julian must cry second to Mr. Adams; a leaf out of the latter competitor's books on this point would be invaluable to him, for it is but seldom we see better stock than Mr. Julian's.

A *Spanish* class, such as is rarely witnessed, brought into position the pride of the yards respectively of Messrs. Rodbard, Brown, and Fowler. They were all of them triumphs of careful selection, and by their excellence alone placed three pens usually prizetakers among the highly commended only. Few breeds seemed so great favourites with visitors.

The *Dorking* class was a goodly rival, as to perfection, to the foregoing. Seven highly commended pens evince the opinion of the Judges, independently of the prizetakers. Several of these pens were claimed by the visitors.

*Cochins* were really first-rate; and more particularly worthy of our notice were Mr. Dawson's pens (of Hopton Mirfield), of both White ones, and a lovely pen of Silver Cinnamons. They were universally admired. We must add Mr. Stretch's pen of Partridge-coloured ones were equally praiseworthy representatives of that breed.

We very rarely see better classes than the two Spangled varieties of *Hamburghs* shown at Beverley; but both kinds of Pencilled ones were absolutely inferior. Years may pass by before a better "variety" class meets the public than was here shown. Some especially useful farmyard crosses were also shown in a class expressly devoted to them.

In *Bantams*, the Game breeds were the most perfect. In the class for Black or White Bantams, as faithful journalists we must expose the wilful deception practised by the owner of the pen awarded the first prize—viz., blacking the legs of the cock bird. It seems from what we afterwards heard, that only last week the same deceit was practised as successfully on two other judges at Hull by the same owner. The artifice at Hull was discovered from the after-fact that an experienced exhibitor claimed the birds "thinking them a bargain and all right;" but, on handling the cock on removal, he discovered the cheat practised, and consequently, very properly refused taking them; but whether the party who by such disreputable acts had the prize awarded to him, then obtained it, we could not discover. At Beverley, however, the Judges on their own responsibility withheld the prize altogether, on the matter being exposed to them by a party who, knowing the affair at Hull, had looked

toward especially to its repetition at Beverley. There cannot be a question that such tricksters (as is the common rule of most societies), should be not only deprived of their present ill-gotten gains, but also precluded from competing at future meetings of the Society. It is the only reliable remedy, whilst none are to blame but the personal delinquent himself for so luckless an issue.

The classes for pairs of *Hens* were decidedly successful.

In the *Ducks*, the "variety" class was well stored with perfect East Indians, and specimens as fine in feather as wild birds of both Mandarins and Carolinas.

The *Pigeons* were as good as could be met with during a year's visits to poultry meetings—there was not a badly-represented breed among the whole; whilst the "any variety" class for these birds was so good that, at the desire of the Judges, two extra prizes were conferred.

The *Cauaries* and *Mules* were really first-rate specimens: a *Goldfinch*, the father of one of the *Mules*, was very remarkable for its singularity of colour. An involuntary shudder passed over us on our attention being drawn to a poor *Goldfinch Mule*, said to be purposely blinded to improve its song. We much regret to find—we had long indulged the fond hope, even yet it appears a delusion—that the days of punishment for witchcraft by popular outbreak, the splitting of *Magpies'* tongues to make them talk, and lastly the blinding, and thus rendering hapless and solitary for life a poor, unoffending, cage-bred bird to improve its song, were the grave misdoings of a period far bygone to our own, both as regards common humanity, and also general information. We regret most fervently, however, thus to find it is not so; and we consider the mode of operation of darkening the eyes to improve the song, by the use of a heated knitting-needle, is so utterly inhuman, that surely our readers must almost universally endorse our opinions—at least, we feel absolute pity for the mind, if existing, so heartless as to be incapable of so doing.

The *Beverley Committee* were deserving of every praise for their courtesy and directions to all parties during the meeting, and also speedy attention to the removal of the birds at its close.

The *Show* was open, under a revised rule, only one day, and the weather was most favourable; nor do we hardly call to mind so great an attendance of the fair sex at a poultry exhibition as at this one.

**GAME (Black-breasted or other Reds).**—First (also, the Society's Silver Medal for the best pen of Game fowls in Classes 1, 2, and 3), H. Adams, Beverley. Second and Third, H. M. Julian, Beverley. Highly Commended, W. Boyes, Beverley; J. Cann, Farnsfield (Black Reds). Commended, H. Adams.

**GAME (Duckwings and other Greys).**—First, H. Adams, Beverley. Second, G. W. Langdale, Leckonfield. Third, W. Dawson, Selly Oak, Birmingham. Highly Commended, S. Dupe, Everscrech. Commended, G. W. Langdale.

**GAME (any other variety).**—First, W. Dawson, Selly Oak, Birmingham. Second, H. Adams, Beverley. Third, J. Woodhouse, sen., Bampton, (Black Game).

**SPANISH.**—First, J. R. Rodhard, Bristol. Second, E. Brown, Albert House, St. Philip's Road, Sheffield. Third, J. K. Fowler, Aylesbury. Highly Commended, T. B. Stead, Leeds; J. Shorthose, Newcastle-on-Tyne; J. Dixon, Bradford. Commended, T. C. Trotter, Sutton, Hull.

**DORRING.**—First and Third, H. W. B. Berwick, Helmsley. Second, E. Smith, Middleton. Highly Commended, A. O. Young, Driffield; Mrs. G. Boynton, Barmston; H. W. B. Berwick; Rev. J. F. Newton, Kirby-in-Cleveland; R. M. Stark, Hull; H. Crossley, Broomfield, Halifax; J. W. George, Beeston Page.

**COCHIN-CHINA (Buff, Lemon, and Cinnamon).**—First, W. Dawson, Hopton Mirfield (Silver Cinnamon). Second, T. Stretch, Bootle, Liverpool (Buff); Third, C. Felton, Erdington. Highly Commended, T. Stretch (Buff); E. Smith, Middleton (Buff). Commended, H. W. B. Berwick, Helmsley; H. Yardley, Birmingham (Buff).

**COCHIN-CHINA (any other variety).**—First, W. Dawson, Hopton Mirfield. Second, T. Stretch, Bootle, Liverpool. Third, J. Shorthose, Newcastle. Highly Commended, T. Stretch. Commended, C. Felton, Erdington; E. Smith, Middleton.

**HAMBURG (Golden-pencilled).**—First, Mrs. G. Boynton, Barmston. Second, J. Dixon, Bradford. Highly Commended, H. Beldon, Bradford; T. Straker, Beverley.

**HAMBURG (Silver-pencilled).**—First, J. Dixon, Bradford. Second, S. Shaw, Staniland, Halifax.

**HAMBURG (Golden-spangled).**—First, R. Tate, Driffield. Second, J. Dixon, Bradford. Highly Commended, W. F. Entwistle, Bradford; R. Tate, Driffield; H. W. B. Berwick, Helmsley.

**HAMBURG (Silver-spangled).**—First, H. Talbot, Sheffield. Second, J. Dixon, Bradford. Highly Commended, R. Tate, Driffield; H. Carter, Upperthong; J. Dixon, Bradford. Commended, K. Carlin, Cottingham.

**POLAND (any colour).**—First, J. Dixon, Bradford. Second, H. Beldon, Bradford. Highly Commended, J. Dixon; F. Hardy, Bradford.

**ANY OTHER PAIR OR DISTINCT VARIETY.**—First, H. Adams, Beverley (Black Hamburgs). Second, J. Ramsey, Shadwell (Malays). Highly Commended, J. K. Fowler, Aylesbury (Brahma Pootra); Lady Hawke, Womersley Park (Brahma Pootra); T. C. Trotter, Sutton (Rumpless); Messrs. Whitty & Young, Cottingham (Pernigan); S. Shaw, Staniland (Black Hamburg); J. Dixon, Bradford (Black Hamburg).

**ANT FARMYARD CROSS.**—First, Mrs. White, Thearne. Second, J. Bilton, New Village, Cottingham.

**BANTAMS (Gold or Silver-laced).**—First, S. Shaw, Staniland (Silver-laced). Second, E. Hutton, Pudsey, Yorks. Commended, W. H. Boddy, Hull (Gold-laced); J. Dixon, Bradford.

**BANTAMS (Black or White).**—First, J. Gawan, Beverley. Second, J. Dixon, Bradford. Highly Commended, Master W. Laybourn, Beverley; E. Hutton, Pudsey. Commended, J. E. V. Nussey, Wortley, Leeds (Black); E. Holdsworth, Leeds (Black).

\* It having been proved after the First Prize was awarded to Pen 180, that the legs of the cock had been fraudulently coloured, the first prize was withheld, as a punishment for the deception.

**BANTAMS (Game).**—Prize, H. Adams, Beverley (Black Game). Highly Commended, Master H. Laybourn, Beverley; R. Tate, Driffield (Brown Reds). J. Cann, Farnsfield; C. W. Brierley, Rochdale; J. W. George, Beeston Pidge; J. Shorthose, Newcastle. Commended, J. R. Jessop; R. M. Stark, Hull; F. Rippon, Beverley.

**GAME COCKS (Black-breasted and other Reds).**—First, and also Silver Medal as being the most perfect pen shown of any kind, H. Adams, Beverley. Second, H. M. Julian, Beverley. Highly Commended, H. Adams, Beverley; C. W. Brierley, Rochdale; W. Boyes, Beverley.

**GAME COCK (Duckwing and Greys).**—First, H. Adams, Beverley. Second, W. Walker, Lockington Station.

**GAME COCK (any other variety).**—First, B. Boyes, Beverley. Second, W. Dawson, Selly Oak (Black).

**SPANISH COCK.**—First, J. K. Fowler, Aylesbury. Second, T. P. Wood, Chesterfield.

**DORRING COCK.**—First, Rev. J. G. A. Baker, Old Warden. Second, T. H. Barker, Hovingham, York. Highly Commended, H. W. B. Berwick, Helmsley (Grey). Commended, A. O. Young, Driffield.

**COCHIN-CHINA COCK.**—First, T. H. Barker, Hovingham, York. Second, Withold.

**GOLD OR SILVER-PENCILLED COCK.**—First, R. R. Tulip, Monkwearmouth. Second, J. Dixon, Bradford.

**COCK (Gold or Silver-spangled).**—First, A. Hudson, York (Gold-spangled). Second, J. E. Powers, Biggleswade. Highly Commended, H. W. B. Berwick, Helmsley (Gold-spangled); H. Carter, Upperthong; J. Dixon, Bradford.

**GAME HEN (Black-breasted or other Red).**—First and Second, E. Ackroyd, Darlington (Black Red and Brown Red). Highly Commended, H. Adams, Beverley.

**GAME HEN (any other variety).**—First, F. Hardy, Bradford. Second, H. Adams, Beverley.

**SPANISH HEN.**—First, E. Brown, Sheffield. Second, R. Tate, Driffield. Highly Commended, J. Shorthose, Newcastle.

**DORRING HEN.**—First, E. Smith, Middleton. Second, H. W. B. Berwick, Helmsley. Highly Commended, W. Watson, Bishop Burton; H. W. B. Berwick; W. Stanton, Cottingham; Rev. J. G. A. Baker, Old Warden.

**COCHIN HEN.**—First, E. Smith, Middleton. Second, Messrs. Whitty and Young, Cottingham. Highly Commended, T. H. Barker, Hovingham, York; H. W. B. Berwick, Helmsley (Buff).

**BANTAM COCK (Game).**—First, E. Brown, Sheffield. Second, R. Voakes, Driffield. Highly Commended, W. W. Boulton, Beverley; Lady Hawke, Womersley Park; R. M. Stark, Hull; E. Holdsworth, Leeds.

**BANTAM COCK (any other variety).**—First, — Hutton, Pudsey. Second, Mrs. Foster, Molescroft.

**DUCKS (Aylesbury).**—First, J. K. Fowler, Aylesbury. Second, R. Tate, Driffield. Highly Commended, J. K. Fowler.

**DUCKS (Rouen or Rhone).**—First, S. Shaw, Staniland. Second, J. R. Tate, Driffield. Highly Commended, J. R. Tate. Commended, T. H. Barker, Hovingham, York.

**DUCKS (any other variety).**—First, J. R. Jessop, Hull. Second, S. Shaw, Staniland (Carolina). Highly Commended, J. Dixon, Bradford (Mandarin); J. Inghrose, Cottingham.

**SWEEP-STAKES.**

**GAME COCKS.**—First, W. Boyes, Beverley. Second and Third, H. Adams, Beverley. Highly Commended, H. Adams. Commended, G. R. Tate, Driffield.

**BANTAM COCKS (Game).**—First, W. W. Boulton, Beverley. Second, R. Hawkeley, Southwell. Third, J. Crossland, jun., Wakefield.

#### PIGEONS.

**CARRIERS (Black).**—First, W. Cannan, Bradford. Second, S. Shaw, Staniland. Third, A. L. Silvester, Birmingham. Highly Commended, A. L. Silvester.

**CARRIERS (any other colour).**—First, W. Cannan, Bradford (Dun). Second and Third, A. L. Silvester, Birmingham.

**POWERS OR CROPPERS.**—First, H. Beldon, Bradford. Second and Third, S. Robson, Brotherton. Highly Commended, A. Smelt, Beverley; T. Rippon, Beverley.

**TUMBLERS (Almond).**—First, S. Shaw, Staniland. Second, E. Holdsworth, Leeds. Third, W. Cannan, Bradford. Commended, A. L. Silvester, Birmingham; T. Coodron, Sunderland.

**TUMBLERS (Kite).**—First, T. Rippon, Beverley. Second, Mrs. E. Rippon, Beverley. Third, J. Bell, Beverley. Commended, Miss S. Bell, Beverley; H. Yardley, Birmingham.

**TUMBLERS (any other variety).**—First, S. Shaw, Staniland. Second, E. Holdsworth, Leeds. Third, J. W. Edge, Ashton New Town. Highly Commended, Mrs. J. Bell, Beverley (Splashed Tumblers); W. Cannan, Bradford; H. Yardley, Birmingham.

**BARRS.**—First, S. Shaw, Staniland. Second, E. Holdsworth, Leeds. Third, F. Key, Beverley. Highly Commended, Mrs. Craigie, Woodlands.

**JACOUBS.**—First, T. Ellington, Woodmansey. Second, S. Shaw, Staniland. Third, Miss S. Dawson, Woodmansey. Highly Commended, H. Yardley, Birmingham.

**TRUMPETERS.**—First, F. Key, Beverley. Second, F. Else, Bayswater. Third, S. Shaw, Staniland. Highly Commended, A. L. Silvester, Birmingham; H. Yardley, Birmingham.

**OWLS.**—First, F. Key, Beverley. Second, F. Else, Bayswater. Third, E. Holdsworth, Leeds. Highly Commended, J. W. Edge, Ashton New Town.

**TURBITS.**—First, J. W. Edge, Ashton New Town. Second, F. Else, Bayswater. Third, H. Yardley, Birmingham. Highly Commended, Miss S. Bell, Beverley.

**PANTAILS.**—First, J. R. Jessop, Hull. Second, F. Else, Bayswater. Third, Mrs. Ellington, Woodmansey. Highly Commended, W. Cannan, Bradford.

**ANY OTHER VARIETY.**—First, E. Holdsworth, Leeds (Silver Runts). Second, S. Shaw, Staniland (Swallows). Third, Miss L. Turner (spots). Extra Third, A. L. Silvester, Birmingham (Snabians). Extra Third, H.

Beldon, Bradford (Archangels). Highly Commended, F. Else, Bayswater (Yellow Magpies); T. Rippon, Beverley (Blue Horsemen); E. Holisworth (Yellow Magpies); F. Key, Beverley (Silver Runts); W. Lingard, Cottingham (Black Nuns). Commended, A. L. Silvester (White Horsemen); H. Yardley, Birmingham (Black Nuns); Mrs. Craigie, Woodlands (Silver Runts).

The gentlemen appointed as Judges were E. Howitt, Esq., of Sparkbrook, Birmingham; and F. Ferguson, Esq., of Walkington, near Beverley.

**DISTINGUISHING THE SEX IN EGGS.**

T. G. H. (an old subscriber) will be obliged if the Editors can advise him how to distinguish eggs that will produce hens from those that will produce cocks.

[There is an epidemic in questions, the letter above being selected only as the shortest of several which contain the same query.

We never yet met with any one who could foretel what sex the chicken would be that was to be produced by an egg; yet the opinion that it could be so foretold is as old as the days of Horace. He says in his Satires, *Lib. ii., Sat. iv.*

"Lunga quibus faeces oris erit, illa memento,  
Ut succi melioris, et ut magis alma rotundis,  
Ponere: namque marem exhibent callosa vitellum."

That is, "When you would feast on eggs, select the long ones; they are whiter, sweeter, and more nourishing than the round, and would produce cocks."

Francis, in giving the translation in verse, writes thus—

"Long be your eggs, far sweeter than the round,  
Cock-eggs they are, more nourishing and sound."

To show how poets as well as doctors differ, he adds in a note. "This precept is contradicted by experience. The round are male eggs, and their shell is harder than that of the long."

However, as others entertain an opinion contrary to ourselves, and more than one correspondent says that the mode described in the following note is infallible, we reprint it.

"At the large end of the egg there is a circular space or cavity containing air, which country folks call "the crown" of the egg; its proper name I know not. When you examine the egg,

hold it, the large end uppermost, before a candle or gas-light, and in looking through it you will observe a dark circular mark something similar to the moon when partially eclipsed. This dark circular mark is the space filled with air, or "the crown" of the egg, and is to be found in all eggs, situated either in the centre or on the side of the perpendicular dotted line. (See diagram.)

"My method of examining the egg is as follows:—I make use of the thumb and forefinger of my left hand as two points, by placing the small end of the egg on my thumb, my forefinger covering the large end of it, and as near the centre of each end as possible. I then

place the egg in this position steadily before a candle, and gently turn it round; if the crown be in the centre it will be scarcely visible, the forefinger nearly covering it. On the contrary, if the crown be on the side (No. 2) you will only see it on one side of the egg as you turn it round.—RICHD. SMITH, *Wood Green, Witney.*"]

1. Centre-crown, male.  
2. Side-crown, female.

**THE POULTRY SHOW OF THE ESSEX AGRICULTURAL ASSOCIATION.**

This was held at Halstead, on the 3rd inst. In order to afford to those of our readers who may be unacquainted with Halstead, some little idea of its past history, we append a brief sketch of the principal events which have occurred in connection with it in years gone by. It derives its name from the Saxon word Halstede—i.e., healthy place, so called because it stands on a beautiful eminence and commanding a splendid view of the country around. The name of Cheping Hill, which is given to

the old market-place, indicates that a market was established in the time of the Saxons; and the market was retained by the Crown till the year 1251, when it was granted by Henry III. to Abel de St. Martin, who was indicted by Hugh de Vere of the neighbouring Castle of Hedingham, for setting up a market prejudicial to the Earl's market, but Abel producing the Royal grant the matter was adjusted on his agreeing to pay the Earl the sum of half a mark yearly. The market, it appears by the ancient records, continued to be held on Cheping Hill till the reign of Queen Elizabeth, when it was removed to the situation it last occupied in the centre of the town. The lordship of Halstead was held soon after the Conquest under Richard natural son of Richard Duke of Normandy, by a family surnamed De Hausted, who in the reign of King Stephen or Henry II., sold the manor to Abel de St. Martin. It was afterwards conveyed to the De Bouchier family, one of whom Robert, Chancellor of England in the reign of Edward III., obtained a charter of the King for a court-leet and other privileges, and founded a collegiate church for eight priests, procuring the Pope's license to appropriate it to the church of Sible Hedingham. He appears to have occupied a prominent position in the esteem of the Black Prince, for we find he had eighteen lordships in Essex, was chief justice of Ireland, and fought by the side of his King at the famous battle of Cressy, and in the following year went to France as an ambassador from the Court of England to treat with the French on the subject of proposals for peace. He occupied Stansted Hall, which he was permitted by Royal authority to convert into a castle, and many of his posterity acquired great fame in the wars with France. Stoe House was formerly a manor, which was given by the Conqueror to Aubrey de Vere, and remained in that family a considerable time: it was afterwards made part of the endowment of the chantry founded by Robert de Bouchier, and in time came into the possession of the Hunwick family, and subsequently was purchased by Charles Hanbury, Esq., who pulled down the old building and erected in its place the present edifica, in the grounds around which the present Exhibition was held.

The show of poultry, which was larger than in any preceding year, was exhibited, as usual, in the admirable pens invented by Mr. Joseph Cooke, of Colchester, and was a source of great attraction during the day. It included some very first-class birds, and the *Dorkings* were especially fine.

The following is a list of the prizes awarded by the Judges:—

- COCHIN CHINA.**—First and Second, C. Punchard, Haverhill.
- DORKING (Coloured).**—First, G. Griggs, Romford. Second, Lady J. Cornwallis, Kent. Third, J. Frost. Commended, G. Griggs, Romford; W. G. Ranson, Suffolk.
- SINGLE COCK.**—Prize, G. Griggs, Romford. Highly Commended, Mrs. Honeywood, Kelvedon. Commended, G. Griggs.
- DORKINGS (White).**—First and Second, H. Lingwood, Suffolk.
- SPANISH.**—First, R. B. Postans, Brentwood. Second, J. H. Cuff, London. Third, J. H. Craigie, Chigwell. Commended, J. H. Craigie; J. L. Lowades, Aylesbury; J. H. Moore.
- SINGLE COCK.**—Prize, J. H. Craigie.
- GAME (White and Piles).**—First, S. Matthew, Stowmarket. Third, J. J. Hazell, Great Bromley.
- GAME (Blackbreasted and other Reds).**—First and Second, S. Matthew, Stowmarket. Third, T. Hill, jun. [A First extra prize was awarded to Mr. E. Pettitt, Colchester, whose birds were not penned through an error on the part of the Secretary, which was not discovered till after the award had been made by the Judges, who recommended that an extra prize should afterwards be given to Mr. Pettitt, his birds being superior to those to which the first prize had been awarded.] Highly Commended, T. Hill, jun. Commended, J. J. Hazell.
- GAME (Duckwing).**—First, S. Matthew, Stowmarket. Second, W. P. Bognhurst, Frating Abbey. Third, J. J. Hazell.
- GAME COCK (any colour).**—Prize, S. Matthew, Suffolk. Highly Commended, Rev. T. L. Fellowes, Aels, Norfolk. Commended, W. P. Bognhurst, Colchester.
- HAMBURGH (Gold-pencilled).**—Second, Rev. T. L. Fellowes, Norfolk. (No First Prize awarded).
- HAMBURGH (Silver-pencilled).**—Commended, Rev. T. L. Fellowes. (No award of prize.)
- HAMBURGH (Gold-spangled).**—Prize, Rev. T. L. Fellowes.
- HAMBURGH (Silver-spangled).**—First, Lady J. Cornwallis, Kent. Second, Rev. T. L. Fellowes. Commended, J. Cooke.

CREVE CŒUR FOWLS.

PEOPLE are grown wiser since what was miscalled the Cochin mania. Then there was a rush to get some of the fowls regardless of less of expense, and little pains were taken to ascertain purity or excellence in the specimens that were obtained. This year many good judges have decided that the Crève Cœur is worth encouraging as a very useful variety. We are disposed to agree with them, and therefore publish this week a short notice of it. We are indebted for much of the information to the excellent and careful work published in Paris by M. Jacque. That clever and painstaking gentleman thus describes the cock :

“PROPORTIONS AND GENERAL CHARACTERISTICS.

“Voluminous body, squarely built, short, well seated on solid legs; back almost horizontal, and slanting but little towards the tail; pectorals, thighs, legs and wings well developed; short limbs; very large head; topknot, whiskers and beard; doublecomb, shaped like horns; wattles long and hanging down; ear-lobes short and hidden; four toes on each foot; feathers of the abdomen long and thick; large feathers of the wing ordinary length; sickles and large sickles very long; the plumage of the finest specimens quite black—in ordinary ones, partly white and partly yellow.”

*Deposition.*—Grave and proud.

*Weight.*—For an adult, from 6½ lbs. to 8 lbs.

*Flesh.*—Very abundant.

*Bones.*—Very light, less than an eighth of the weight of the bird.

We leave out some comparative statements, as we have to do only with one breed. To follow literally, would not be more useful in gaining information, than to be told by a person whose age we asked that he was just twenty-two months younger than his brother Tom, the latter individual being unknown to us. To continue.

*Topknot.*—Well furnished, voluminous, heavy lancet-feathers falling all round the head in the best specimens. Crown-feathers erect, save some that fall forward.

*Whiskers.*—Very thick.

*Beard.*—Long, ample, and falling below the wattles.

*Comb.*—Variable, but always forming

*Horns.*—Sometimes parallel, straight, and fleshy; sometimes joined at the base, slightly uneven, pointed and divided at the top; sometimes uniting to these last appearances interior ramifications which give them the likeness of the horns of a young stag.

*Physiognomy of the Head.*—Not unlike that of the Houdan; the eyes are almost always hidden under the feathers of the topknot. The comb, when it is shaped like horns, gives to the face of a Crève Cœur the appearance of a devil.

*Plumage.*—Entirely black, relieved by bronzed, bluish or greenish reflections on the hackles, the saddle, the wings, the tail-coverts, the large and smaller sickle-feathers. The rest of the plumage is of a dead black, except those of the abdomen, which are of a brown black. The topknot generally becomes white at the back after two or three moultings. Many specimens have a good mixture of straw-coloured feathers; they are not less pure, and they breed black chickens, but they are less esteemed by amateurs.

*HENS.*—Well shaped square body, well defined, and being in some respects like Cochinchinas, both in bulk and appearance; ample size, though low on the legs; large head; varying topknot, black in a pullet, whitish in a hen after the second moult; bearded; ear-lobes short and hidden; comb and wattles short.

*Appearance.*—Grave and heavy.  
*Average Layers* of very large eggs.  
*Non-sitters.*  
*Food for this Breed.*—Egg paste the first eight days. Barley-meal paste\* to the end of two

months. Then feed on grain all those fowls intended for breeders; the others are fed on the paste till they are fattened. This is the way they are managed in Normandy.

COMB—HORNS.

\* Grind or rather crush barley, to produce a flour in which every part of the grain is preserved. Put in a pail a quantity of water or skimmed milk, according to the quantity of the paste required. Experience will soon teach the necessary proportions. Throw in handfuls of meal, and mix with the hand till all is thoroughly wetted. Throw in more meal and manipulate again, so that there shall not be a dry morsel. Continue thus till a thick paste is formed. Thrust your fist through the paste, and turn it inside out. Keep on till it is firm, then roll it out, and powder the surface with a little dry meal. In an hour or two, it is dry enough to break; it can then be given to the fowls. They are fond of it. In Normandy, it is always made the day before it is required. It takes a slightly fermented flavour, which makes it more relishing.

## DO BEES VARY IN DIFFERENT PARTS OF GREAT BRITAIN?

I SHOULD feel much obliged if the "DEVONSHIRE BEE-KEEPER" or any of your experienced correspondents would have the kindness to state whether there is any sensible difference between the bees kept in different parts of Great Britain. Several years ago an observant naturalist and clergyman, as well as a gardener, who kept bees, asserted positively that there were certain breeds of bees which were smaller than others, and differed in their tempers. The clergyman also said that the wild bees of certain forests in Nottinghamshire were smaller than the common tame bees. M. Godson, a learned French naturalist, also says that in the south of France the bees are larger than elsewhere, and that in comparing different stocks slight differences in the colour of their hairs may be detected. I have also seen it stated that the bees in Normandy are smaller than in other parts of France. I hope that some experienced observers who have seen the bees of different parts of Britain will state how far there is any truth in the foregoing remarks. In the Number of your Journal published May 15, 1860, Mr. Lowe gives a curious account of a new grey or light-coloured bee which he procured from a cottager. If this note should meet his eye I hope he will be so good as to report whether his new variety is still propagated by him.—CHARLES DARWIN.

[We insert this without expressing any opinion, because we wish to have answers from as many of our readers as have paid attention to the subject. We, as well as the well-known writer of the inquiry, will be greatly obliged by any observations upon the subject.—EDS. J. OF H.]

## GREAT FECUNDITY AND PREMATURE DEATH OF A LIGURIAN QUEEN.

"THE old queen leads off the first swarm," is an aphorism enunciated in nearly every bee-book, and is certainly as trustworthy an axiom as any that can be propounded for the guidance of apiarians. That even this universally accepted rule is, however, not altogether without its exceptions, has just been proved to my complete satisfaction, or rather, I should say, to my complete dissatisfaction, since it has cost me the life of a valuable Ligurian queen, besides destroying the hopes I entertained of obtaining a magnificent super of pure honeycomb.

At the commencement of the season I set aside one of my strongest stocks with a beautiful Ligurian queen only one year old, for supering, with the view of proving what could be done with an undisturbed colony of Ligurians. Although the stock-box was a large one (14½ inches square by 9 inches deep, with ten frames) the bees soon took full possession of a super 13 inches square by 7 inches deep, and when this became pretty well filled I raised it on another of the same diameter and 6 inches deep, into which they soon extended their combs, and being in great numbers in wax-working festoons. All appeared going on well until to-day (4th June), when without the slightest premonitory symptoms an immense swarm suddenly issued about half-past twelve o'clock, filling the air in such numbers that they literally obscured the sun, at that time shining most brilliantly. After a little while I found them settled in two clusters on two different gooseberry bushes. Struck by this circumstance occurring with a first swarm, which ought, of course, to have but one queen, and that the old one, I bethought me of examining the ground in front of the hive, and there to my great mortification I found the dead body of the royal mother of all these countless thousands. Although life was perfectly extinct, she had evidently not been dead long, and now all became clear to me. In my mind's eye I witnessed the escape of a young princess from her waxy prison, next followed the duel, *à l'outrance*, ending in the death of the queen regnant, then came the probable escape of one or more young princesses, sisters of the victor, the confusion caused thereby culminating in the tumultuous issue of an enormous swarm.

As it appeared possible that under these circumstances there might really be two queens present, I resolved upon treating the clusters as distinct swarms, and endeavouring to establish them as two independent colonies. With this view I shook the small-est into an empty box, and put it immediately in the old stock's place, removing the latter to a new position, and taking from it the super with the bees and combs which it contained. Into this super I shook the remaining large cluster of bees, and established it at once as a separate stock. About an hour after-

wards I noticed that the first-hived swarm and returning bees from the old stock appeared by no means satisfied with their new habitation; whilst many stragglers were still hovering round the gooseberry bushes. This led me to a closer inspection of the latter, and upon one of them I found yet a third cluster of bees as large as a moderate-sized swarm. Bringing the box of dissatisfied bees close to the bush, and placing it upon a cloth spread under the cluster, I raised its front upon a couple of blocks and swept down the overhanging mass. An immediate rush into the box was the result, and in a short time I was enabled to return the live to its place with a united and contented population. Many hundreds of bees still remaining on the cloth, I remembered the fact that bees from a second swarm\* having only an unimpregnated queen will accept any fertile sovereign that may be offered to them; and having satisfied myself by a careful scrutiny of the laggards that their queen had already sought refuge in the box, I at once availed myself of it by conveying them on the cloth to the side of a hive containing a magnificent Ligurian queen, which had for her subjects only a few young bees scarcely able to take wing. Gently raising the side of the hive upon a couple of wedges, I insinuated under it the edge of the cloth. An almost instantaneous vibration of the wings of the whole party soon proclaimed that they likewise had found a home, and a cordial fraternisation upon terms of mutual accommodation was the result.

Being perfectly satisfied that the first-hived colony was now in possession of a queen, although I had not actually seen her, I turned my attention to those in the super. Not doubting from their behaviour that they had a queen either in *esse* or in *posse*, I was yet willing to obtain ocular demonstration of the fact, and therefore proceeded to shift the bees with their combs into the hive they were intended permanently to occupy. On lifting them out I was astounded at the masses of sealed brood (mostly worker) which met my view. Six combs, 13 inches wide by 9 inches deep, were completely filled; whilst hanging to their edges were royal cells in every stage of progress. Failing to detect a queen among the enormous number of bees which crowded the box, I first shook two or three clusters of the super-abundant population into a weak stock possessing only embryo queens, with the inhabitants of which they immediately fraternised, and then cut out three fully-developed royal cells which I thought could well be spared for queen-rearing operations.

The results of this unlooked-for swarm may be thus briefly summed up:—I have sufficient bees to form three strong colonies, besides some thousands spared to strengthen two weak stocks. Although I have failed in my attempt to obtain honey, I have again demonstrated the amazing fecundity of Ligurian queen bees. When it is borne in mind that this colony was in the outset by no means a particularly strong one, and that breeding did not commence in it until March was pretty far advanced, I think any one who peruses the foregoing simple statement of facts can scarcely fail to participate in the astonishment felt by—A DEVONSHIRE BEE-KEEPER.

## QUEEN BEES DESTROYED BY THEIR OWN WORKERS.

IN page 110 I narrated my own experience of this phenomenon, and quoted a somewhat similar instance related by Herr Rothe. In a subsequent Number of the German "Bee Journal" the subject is referred to by Herr Wallbrecht, who says:—

"Much has already been written about the change of queens, and it may indeed very often happen when even the bee-master does not observe it. This is especially the case with the 'pudelmützen,'\* or bell-shaped straw hives, which are not easily examined; but in boxes with moveable combs it not unfrequently happens. My fellow apiarian, Herr Rothe, ascribes such a revolution to the frequent disturbance of the stock, and believes this to be in most cases, if not always, the cause of hostile attacks upon queens by their own bees. But this is not my opinion. I am much more inclined to believe that when bees are disturbed they are the least likely to think of attacking their queen, but rather endeavour to protect their own property and sovereignty to the utmost of their power. We therefore observe how soon all the bees fill themselves with honey in order to secure as much as possible, and at last attack him hostilely that occasioned the disturbance.

"The true motives of every imprisonment and ultimate destruction of the queen it would be very difficult to discover; but they may be weakness, exhausted fertility, and other causes. Last summer I lost a queen in a box, without having disturbed it; and I think if this happens once it may occur

\* Although this was not a second swarm it possessed only an unimpregnated queen, the old queen having been destroyed as above related.

† Literally "poodle-caps," a kind of fur cap often made of the skin of a poodle dog, and which, fitting close to the head, presents a very exact type of the ordinary straw hive. These caps were formerly much worn in Germany.

several times, and by chance also just when the stock is examined. But the queen may easily be killed during examinations of the stock, owing to want of caution on the part of the examiner, either by falling from the combs, which may not unfrequently occur owing to the unwieldiness of a stout pregnant queen, or by crushing or stifling. For this reason the utmost caution should always be observed during such operations.

"When putting a strange queen into a stock last summer, I found that she, because the bees pursued her, flew into the air. I soon lost sight of her, and did not think of her returning; but, after a few minutes, she came back and flew again into the box which remained open. Upon consideration this appeared to me very natural, since every queen bee longs for her people, and a strange queen, which knows no other hive, flies back to the one she has left. How many, especially Italian queens, may have been lost in this manner? It would undoubtedly have been the case here, if I had closed the hive immediately."

I am myself disposed to coincide with Herr Rothe that examining bees has some effect in disposing them to attack their queen. I have often found young queens imprisoned upon opening their hives, and in the case already referred to I have for some time usually found the unfortunate queen confined in a cluster of workers whenever I opened the hive, until at length she fell a victim to one of their attacks as before related. On the other hand, she may have shown signs of exhausted fertility, which were sufficiently apparent to her subjects, if not to myself. I received her from the continent in 1860, when I believed her to be young, but she might not really have been so, and in this case the bees may have adopted the best course for perpetuating the colony. That they have no inherent disposition to destroy their sovereign is evidenced by the fact that they have raised another fine Ligurian queen, which, having become impregnated, has commenced egg-laying. Although my recent examinations have been quite as frequent as during the reign of her predecessor, the bees have never on any occasion manifested the slightest disposition to molest their present sovereign.

On one occasion I lost an Italian queen just received from the continent in the manner described by Herr Wallbrecht. Whilst attempting her introduction to a colony of British bees, she suddenly took wing, and I never saw her afterwards.—A DEVONSHIRE BEE-KEEPER.

## GENERALLY USEFUL MANAGERS.

(Continued from page 12.)

### PIG-KEEPING.

HAVING touched briefly on the management of the cow and the dairy, we must now say a few words respecting the skim milk and the buttermilk. Of course, a pig must be kept, fattened, and killed, and cured for the use of the family. But as there may not be sufficient wash to keep even one pig all the time, a large tub must be procured (at the oil merchant's, or where oil is used in manufactories such are often to be had cheap), and the milk is put in as it comes to hand, and when it is full, and a smaller one partly filled, then think about getting a pig. The size to get will depend upon the time of year you will be ready for it; but it should be managed to have it ready to kill early in the new year, for an extra joint of pork will be very acceptable after the Christmas beef.

Now, in selecting a suitable one, if you have any experience of the various breeds, and their propensity to fatten, you will require but little advice; but if not, it will be well to learn a little on the subject when opportunities offer, and not go to market altogether a novice, for a chief point to insure success is to get things suitable to your circumstances, not what may suit some one else in quite different circumstances. The chief aim will be to select a pig that will weigh about 200 lbs. when thoroughly fat. The hams must be thick, and they are the best size where it is requisite to dress only half a one at a time; but when dressed whole the pig should be 40 lbs. or 50 lbs. less, still well fattened.

Having purchased one to your satisfaction, and got it home, it is possible it will refuse to eat your stale food. If so, you must give it some fresh skim milk, and put about 2 ozs. of flowers of sulphur in, then let it get thoroughly hungry before you give it any more; when you do mix a little of the stale food with some fresh, and continue to put the fresh into the smaller tub, adding from the larger one as required, and with very little trouble you will find all going on to your satisfaction. After a time I make a point of giving it a few peas once or twice a-day, and continue so till it is fattened, with the addition of barleymeal to finish with. The sty should be swept out every morning, and if there is a boarded stage for the pig to lie on, so much the better. Covers must be kept on the tubs to keep the fowls out, or you will have them drowned.

Respecting fowls you will learn from THE JOURNAL OF HORTI-

CULTURE all the information you will need in getting a stock of pullets for winter laying. We have only just commenced keeping fowls here, and I shall defer saying anything more on that point till I have tested our arrangements.

The weather having been all that could be desired for getting out the bedding plants, the chief point of attraction will be hay-making. There is every prospect of an abundant crop.

Haymaking is a very pleasant thing in fine weather (so sang Hood), even where there is a responsibility on your shoulders; but, unfortunately, there is no dependence on the weather prophets for a continuance of it: therefore, most people that have the responsibility of it are desirous of getting it over as quick as possible. There are people that make a point of commencing on a certain day without any regard to the season or the crop, but I am not of their number; and I would say to all, Wait for a crop, and do not let the grass to mowers until you are ready to begin; if you do you must wait their time, and if the weather is not very favourable the chances are that your hay will be badly made. My usual practice is, when there is a fair crop on the ground, and I am not particular to a few days, either before a full crop or after it is ripe, to look after the weather, and as soon as I feel satisfied with the barometer, I then get it down as quick as possible, and when circumstances will admit, I try to get it cut on a Saturday, and let it lie in swath till Monday; then if the weather is fine get it shaken abroad as soon as possible, and that is the most important point in haymaking. Every cock should be well opened, and all the ground covered. It is better to take a little time and do it well the first time, as it will save time in the end, and not have to stop to open green cocks of grass when time is more precious, and the hay three parts made, or they will be left as they are put in the rick, to make the good hay mouldy. Some will scamper over a lot of grass in no time, and are continually shaking and shaking from morning till night for days together, let the weather be what it may; but without attempting to lay down any rules for haymaking, I will venture to say, that in nine cases out of ten that time is worse than thrown away, for if the sun is scorching, the seeds and the best of the leaves will be left on the ground. After the first shaking about if the weather is anything like favourable, I have very little use for the pick till the hay is made, the hand-rake I consider the chief and best tool for haymaking, there is a knack in using it, and in proper hands one rake is worth three picks. It always leaves it light for the sun and air to go through it, and when pulled up into little light rollers in the evening the night air will season it, and forward it almost as much as the day, for it must be understood to make good and nutritious hay, it is by no means necessary to have all sunshine, a good dry air is of equal importance. Each individual must be guided by local circumstances respecting the state of putting it together. Some grass when it is short and thick at the bottom will require more seasoning than when it is long and coarse, as the latter will not heat in the rick like the former, and is improved by a little warmth. Have some straw close at hand when the rick is made, in case of storms, for a heavy storm has spoiled many a well-made hayrick.—THE DOCTOR'S BOX.

WASPS.—In an old thatch in this neighbourhood forty queen wasps were destroyed this season. Twenty-five queens have also been killed feeding on the sweet excrements of the black aphid, which infest a cherry tree on the north side of our garden wall, and still the wasps come apparently as abundantly as ever. Now is the time to exterminate these pests, or all chance of ripe fruit must be given up. Orchards, fruit gardens, vineries, and orchard-houses, &c., in the vicinity of sixty-five wasps' nests are not a pleasant subject for contemplation.—SCRUTATOR.

## OUR LETTER BOX.

MR. TOMLINSON'S COCHIN-CHINA FOWLS (*Fairplay*).—We see no breach of faith in selling now those birds which were not sold at the previous auction. Nor do we think any one ought to buy birds merely on the supposition that they are the seller's best birds. Every lot should be examined and valued according to its merits.

ROUPEY COCK (*Q. T. L.*).—Wash his head daily two or three times with tepid water. Separate him from the other fowls; feed him only on soft food, such as barleymeal, giving in it daily one grain of powdered sulphate of copper. Once a-day also give him a feed of bread soaked in ale. Let him also have as much green food as he chooses to take.

APIARIAN SOCIETY (*E. B.*).—We believe it is defunct. "How to Farm Two Acres Profitably, Including the Management of the Cow and the Pig," will give the information you need about the dairy. You can have it free by post from our office for fourteen penny postage stamps.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 72.7° and 49.4° respectively. The greatest heat, 93°, occurred on the 19th and 22nd, in 1846; and the lowest cold, 30°, on the 20th in 1855. During the period 131 days were fine, and on 114 rain fell.

GARDENERS' HOURS AND HOLIDAYS.

If your subscribers there must be many who, like myself, would be very glad to know what hours of work daily they have fairly a right to expect their gardeners to keep. Their

working hours seem to me to be growing "small by degrees," judging by my own experience.

I fancied, in this summer time, it would not be unreasonable to expect a gardener to come to his work at six A.M. But often nearer seven than six do I see my man making his way from his cottage to his work; calculating, no doubt, that his master may not be up so early, and so not know at what hour he makes his first appearance.

Then, at eight to a minute, he will be off to breakfast, professing to return at half-past eight; but he does not seem to think a quarter of an hour later in coming back to work of any moment.

Then, again, at twelve home to dinner, returning at quarter to half-past one as it may happen.

At five home to tea, coming back just to water his plants, and then finally off home at six to a minute.

Now, the point I want to know is this: Ought not a gardener's day of work to average ten hours one day with another the year round?—say six to six in spring and autumn, less two hours for meals—viz., half an hour for breakfast, one hour dinner, half an hour tea. And seeing that for some months in the depth of winter the daylight necessarily limits a gardener's work to less than this, ought he not in all reason to work rather longer hours in the busy time when days are long?—say some such hours as these:—November 1st to March 1st, half-past seven to five, less only one hour to dinner, breakfasting before coming to work, and tea after leaving work—that is, eight hours and a half work for four months, or an hour and a half less than his ten hours average. Then to compensate, say from May 1st to September 1st, during the four months of long days and busy time,

6 to 7, work	1 hour.
7 to 7½, breakfast.	
7½ to 12, work	4½ hours.
12 to 1, dinner.	
1 to 5, work	4 hours.
5 to 5½, tea.	
5½ to 7½, work	2 hours.

or eleven hours and a half work in all, being an hour and a half over the ten hours average; and for the remaining months in spring and autumn ten hours work a-day.

I wish you would, as they say, "ventilate" this sub-  
No. 64.—VOL. III., NEW SERIES.

ject, and enable employers to fix on some rule of hours that would be fair both to master and men.

Also, on another point some rule would be desirable.

Ought a master to stop his gardener's wages for any holidays he may wish to take? Or if not, what amount of yearly holiday should a master allow without deduction of wage? My man now and then asks for five or six days holiday at a time, and would think his master very hard if any wages were stopped for his absence.—R. W.

[Unfortunately the subject is one to which no general rule will apply, just because gardening is something more than a mere mechanical art; and the man who takes no more interest in his employment than merely passing over a certain number of hours—becoming, in fact, what the late Joseph Knight, Esq., of Chelsea, would, with his telling irony, have called "a six-o'clock man," never will do great things for himself or those who employ him.

The subject, however, is of such importance, and gentlemen and brothers of the spade have asked my opinion on the matter so often privately, that I readily furnish, as you wish, a few general ideas, which, of course, coming from the gardener's point of view, may be counteracted by the opinions of the Editors and other gentlemen employers of labour.

The first idea suggested, then, is the impossibility of coming to a general decision on such a subject with the one-sided view of the sketch given; no mention being made of the remuneration, the distance of the cottage from the garden, the size and make-up of the garden itself, farther than that there are plants to be attended to. Now, it must be a very small garden indeed, or one containing only the hardiest and commonest objects of culture, in which attention and supervision will not be required beyond all reasonable working hours; and if the employer will insist at all harshly on punctuality to the minute, the gardener may unhappily be led as doggedly to keep as strictly to his hours, and let things take their chance afterwards—a state of proceedings which could not long remain satisfactory to, or endurable by, either party.

Again, I am not so biassed in standing up for my order as not fully to grant the right of every employer to decide upon the terms, the number of hours, &c., in which he is to be served. If he be wise he will stipulate for nothing that is unreasonable or contrary to general custom. So long as that agreement lasts, the servant, if he lays claim to honesty, is bound conscientiously to abide by it. If at all harsh or contrary to custom, it would be unreasonable and unnatural to suppose that a man would continue a day longer in such an employment than he could help himself to a better. Whenever mutual confidence and respect between an employer and servant are lost, it is best for both parties that the connection should cease. Without, therefore, endeavouring to establish a general rule, "R. W." would act more wisely in making arrangements for himself.

Thirdly, I have as great if not a greater dislike to want of punctuality as to time than even "R. W." For

all general work I should soon form a poor opinion of a man who came drawing to his labour at any time. From six to six in summer I consider to be very reasonable hours. In large establishments it is customary to enforce punctuality to the minute by sending those that are late back for a quarter of a day. Few things are more annoying than to stand at the tool-house and find men drawing in at different periods after the clock has struck. With men having families leniency may sometimes be shown with advantage. In the case of lads and young men no cure is so effectual as sending them home for the day. If they are not lost to shame, they will sneak home by some back path to avoid the chaff and scorn of the village. So much for labourers and young gardeners.

Whatever position the gardener of "R. W." occupies, there can be no hardship, when in health, in his being at the garden at six. If very irregular, and he has a man or men under him, they will soon trust to and surpass him in his irregularity. It is rather amusing in such circumstances when asking for the gardener to be told with rather a meaning look, "It is not his time yet, sir." They soon know the times and seasons, and are apt to act accordingly. There is much homely truth in the old adage, "It is the early bird that picks up the worms." Nevertheless, a slight want of punctuality at far intervals should not be construed hastily into eye-service. A conscientious man, worth having, would soon make up for lost time in that respect. Besides, if driven into a corner, and his natural combativeness not mollified by moral principle, he might easily keep working for ten hours, and do no more than he could do in five, or four if his heart was in his work in serving a kind master; or he might, if his cottage was any distance, claim the right of an artisan or a mechanic to consider the time spent in walking to his work as so much of the stipulated labour period. Beyond regular punctuality I have no faith in complicated agreements, but every faith and dependance in mutual forbearance—kindness on the one hand and fidelity on the other.

This leads me to say a few words more on the specific hours mentioned by "R. W." If the cottage is not close to the garden, half an hour is not enough for breakfast. I find that men can manage in that time, if they can walk from the garden into their rooms, and their coffee, &c., are previously all ready; I believe that is the general time about London. When I was in the Exotic Nursery at Chelsea, in Mr. Knight's time, no one could be more particular as to punctuality; but he allowed us neither forty or forty-five minutes for breakfast, and I believe with advantage to himself, as there was time to walk back comfortably from lodgings and commence work at once. As to the other contemplated arrangements for summer and winter, I can only say I should be hard-up before I would agree to them, and that I would break them the first opportunity I had for getting a better place. I should like to know more about the wages given before I could see the justice of the compensation principle spoken of, and likewise to be assured that the gardener had not many things to attend to in overhours for which no compensation was given. Not but that I have often worked much later and earlier too than "R. W." contends for as compensation, but then I did it willingly, because the work wanted doing, and not because I was under obligation to do so; and, also, because I knew that if I wanted a day or two when I had got things pretty square, I had no more to do than say so, and, if going far, receive extra encouragement besides. Why, under such circumstances a man would do pretty well a fair day's work in an evening if not too often repeated, or not too long continued. It would be unnatural to expect such a thing from a mere six-o'clock-time-serving principle of action.

Besides, there is a great error running through this compensatory principle of getting a man to work from five A.M. to half-past seven P.M. in summer to make up for the short days of winter. "R. W." would treat the human worker as he would any other piece of machinery—which the longer it worked would produce the more. This cannot long be the case with human labour. The system may be so enervated with over-exertion that the longer the employment is continued, the less will be the profitable result. A spinning-jenny would do more at equal speed in twelve hours than in ten, and so would a man if the same speed were maintained throughout. To do so there must be an extra stimulus to exertion. A fillip must be given alike to the mental and physical system, and that if too frequently repeated will gradually lose its force, and there will be a wearing-out of physical power.

As a general rule, we hold ten hours to be long enough for a

man to work for an employer. The extra time spent in working is anything but all gain. Without a potent stimulus to extra exertion, such as enthusiasm for his profession, the unpleasantness of seeing things out of order, the desire to gratify kind employers, or extra remuneration to supply extra sustenance, and encouragement for the extra wear and tear, the working the long hours will become a dawdling, drawing occupation. The man who will not do a good day's work in ten hours, will be less likely to do it in eighteen. Not long ago I saw a great number of men pretending to dig in a public park. They must have been filling out *their* time. Four good labourers used to the spade would have done more in the same time than any twenty of them. "R. W." should know that mere long hours is quite a different thing from having a great amount of work done. Without such stimuli as those referred to, the work will be dawdled. When these incentives are present, the gardener who feels a pride in his place will very often work extra time without being bound, and all the better, because he is not bound by agreement to do so.

There are few gardens in which such extra work is not needed at certain seasons, and in which assistants and labourers are not required to do their share. If this is done on the mere compensation principle of making up for the short days of winter, the men will soon do no more in the long day than they would do in a short one. A gross injustice used to be perpetrated on many labouring men in gentlemen's and even noblemen's gardens, of causing them to work long hours without any extra remuneration. One of the first of British gardeners told me not long ago, that it gnawed him to the bone to be obliged to send men to mow at half-past four in the morning all the summer over, because it had been the custom, and that without the smallest extra remuneration, and the wages the year round, 9s. per week! He candidly stated that his conscience would *not* allow him to look much after them in the afternoon, and his conviction, that if the men in such circumstances had been allowed to go home an hour and a half earlier he would have got more work done. In such cases justice requires that extra hours should be extra paid for—that is, that a trifle more should be given for every such hour than the usual rate of the ten hours. Then, if not too long continued, the full value in labour will be returned. I say advisedly, *if not too long continued*.

In this neighbourhood it is customary to work long hours in hay and corn harvest. In the latter, labourers, in general, receive double pay, or thereabouts. Men are often kept regularly employed in winter, in order to retain their services in summer. The long hours with such stimuli applied, permit of the work being done with fewer men, and the men employed are not only satisfied, but we escape the disagreeable necessity we otherwise should be under, of taking on men in summer when work is plentiful, and discharging them when work is scarce. But for this unpleasantness, a close observation of the results of long hours of labour, has convinced me that it would be more profitable, and better for the man, to spend a part of the extra money in paying extra men, and lessening the hours of labour. With the encouragement generally given, the system works well enough, and could not be dispensed with, unless in unfortunate times when labour is superabundant, and the disadvantages are greatly counterbalanced, by the pleasure of not being under the painful necessity of parting with men just when out-door employment is becoming scarce.

On the score of economy, then, sound policy, and obtaining a fair day's work for a fair day's pay, extra long hours are to be avoided, unless on special occasions, and for these occasions extra inducements ought to be presented. Without more knowledge of circumstances, I cannot say whether I think "R. W." has any equitable right to the compensation in extra hours which he seeks. In most gardens of any extent, there is much work in winter not at all tempting, and sweltering in a hothouse, or digging in a quarter for ten hours in summer, will bring fatigue and lassitude with it. Besides, in most places in the shortest days there are duties to be attended to in overhours, of which employers in general know little. Often and often in a mild evening, to save fuel, we have lighted no fires, and yet by ten or eleven o'clock have had to turn out and set every fire agoing, and make up the furnaces, perhaps, at twelve or one o'clock; and, then, there is no end to things that need protection on an emergency. I called early in the morning at a large place this spring; the frost had been severe, and the young men seeing what was coming, had turned out at eleven o'clock the previous night, and netted and covered all the wall trees; thus securing

a crop that otherwise might have been lost. It is just possible that "R. W.'s" gardener had been doing something of the same kind one of those mornings he was seen coming rather late from his cottage. Circumstances thus totally alter cases. The compensation principle is a two-edged sword, and in the case of gardeners, in general, I honestly believe, so far as time is concerned, they would have a claim against the employer. This, however, will make no excuse for laziness, indolence, or want of punctuality. These are cases that must be judged by themselves.

I should be sorry to see advocated any such general rule as "R. W." recommends. I feel certain that among other evils it would destroy the good feeling and mutual confidence and trust that now exist, and that all such extra hours stipulated for would be followed by worse than actual loss as to results. A good man will need no such binding; an unprincipled man may obey it to the letter, and thoroughly break all such trammels by merely seeming to work.

In one word, then, I agree with "R. W." in insisting on punctuality. Nothing can be well done without it. I cheerfully accord to him the right of deciding how and for how many hours he will be served. That is a matter entirely between himself and his servant. If beyond this he would farther appeal to my professional experience, and what little knowledge of human nature I have gained, I would just say, If resolved to make hours of labour depend on the season of the year, make up your mind to have also a clear defined schedule of remuneration according to these hours. If at all liberal this will bring into play a stimulus to continued exertion. Without it, your long hours according to the bond will be a grievance to your servant, and sure to end in loss and disappointment to yourself.

It would be idle to attempt anything like a settled rule for holidays. Some employers are perfectly uneasy if they know their gardeners to be away for a day. Other employers like their gardeners to look about them, believing that they themselves will be benefited by the increased intelligence thus gained, and the stimulus to exertion thus obtained. Good gardeners are generally as reluctant to leave home often, as such employers are anxious they should go. Nothing shakes self-conceit and vanity out of a man so effectually as seeing productions and arrangements superior to his own. If a gentleman wishes the most to be made of his garden, he ought to send his gardener, if at all comeatable, to one metropolitan exhibition every year, and also to some celebrated gentleman's garden. I say this the more, because gardeners, as a body, when they have a holiday, generally make a point to visit some gardens, and I must say that I have seldom looked in upon the smallest and the least pretending without gaining something by the visit. Still, the question as to payment for holidays is a question purely between employer and employed. Abstractedly considered, the workman has no right to wages for which he has not wrought. When he receives them it is as a favour rather than as a right; but a favour which ever, in the case of a man worth having, will spur him on to greater and renewed exertion. So well is this understood in mercantile establishments, as well as the necessity of a little change of scene, to give a bolstering strength to the mental and physical system, that these holidays once a-year or so, are now becoming general, and when extra or common success has been achieved, a small *douceur* often accompanies the leave of absence, as well as the paying of the regular wages. In the case of gardeners engaged by the year, or, at any rate, not considered as mere daily or weekly servants, I have seldom known or heard of holidays being deducted from wages. If they were, a respectable man looked upon it at once as a sign that his services were not appreciated, and would take the first opportunity to act accordingly.

The number of these holidays must be a matter of arrangement. "Five or six days now and then" seems rather going ahead in holiday-making. A day or two now and then would be a more correct idea of the holidays that prevail. Once or twice, or, perhaps, thrice, in a long service, I may have had from a week to ten days to go long distances; but I have been at other times with only a part of two or three days from home for a twelvemonth. There can be no regular rule on such a subject; but if I wanted five or six days, common prudence would say, Do not let that be more than once a-year, or in two or three years. A day or part of a day at a time is a very different affair from being away during the night. I and many more have paid holiday visits, and hardly been a night from home for years.

One thing more is of greater importance to the gardener. Let no such holidays be taken without the knowledge and sanction of the employer. If I have to go out a few hours on business, I do not now think it worth while to mention it; but I should not go from home for a whole day without my employer's knowledge. I have just the feeling that I could not enjoy myself in such circumstances; and what is worth the having is worth the asking for. Some good gardeners have split on this rock; they got above asking, and took as something like a right what they ought to have received as a boon.

After what has been said, I hope that "R. W." and other employers, instead of stopping wages for a moderate holiday, will not only pay the wages cheerfully, but encourage industrious, hard-working men by slipping a present into their hands to defray their expenses to see a metropolitan flower show, and the Grand Exhibition, which I hope myself to behold before long.

I must apologise for the crudeness of these remarks. There is little time just now for condensation and polish, which they no doubt want; but, in their roughness, they may give an idea from the gardener's point of view; and I feel sure the Editors will supplement deficiencies, and kindly show where the ideas are unsound or unsuitable.

R. FISH.

We placed our correspondent's letter in the hands of Mr. Fish, because we knew that however he might have a tendency to make things pleasant for the craft, of which he is so worthy a member, he has too sound a judgment to endeavour to have them pleasant by sacrificing the interests of employers. The result is good as we expected, and, as employers of gardeners ourselves, we need only add that we fully assent to all his statements. A gardener worthy of that name, when he accepts a situation knows, and resolves to give, the attention and labour it will require; and he fully appreciates that at some seasons and on some days far more than the usual number of hours must be occupied in the garden over which he presides. If he did not attend to those extra duties—did not devote to our garden those needed extra hours—we should consider him not up to our estimate of a good gardener, and should supersede him.

On the other hand, there are seasons and days when there is no need for even an attendance strictly for a daily ten hours, and we should consider ourselves harsh masters if we even commented upon an hour or two's unusual absence.

We never deducted the wages of the days which we allowed to our gardeners for holidays, for the plain reason that we allowed the holidays because we thought our gardeners faithful and deserved as well as needed relaxation, and we, therefore, did not wish them to pay for what they deserved and needed. If a gardener asked for leave of absence so frequently, or for such long periods as we considered unnecessary, we should tell him so, and if he persisted in requiring them we should tell him that it must cause our separation.

In conclusion, we are decidedly of opinion that the gardener who requires to be bound to an hour-measured service is unworthy of the profession, and no employer will be gratified by being served by him. So, on the other hand, the employer who thinks that every shilling of wages should have been preceded by twelvemonth worth of labour is indeed a hard task-master, and must never expect that best of all service when the head, heart, and hand work in concert.]

#### ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.—JUNE 11.

As bad luck would have it, the tent for this Show collapsed and hung about in all directions; and a gangway covered with canvass was carefully set up from the grand entrance to the interior of the wreck, signifying a wish that all the well-wishers of the Society might be led unawares to the scene of the disaster, in order the more fully to be able to sympathise with the Council of the Society on their bad luck, under the very eyes and noses of representatives of all the people on the face of the earth who came to the International Grand Show in time to see the splendour of our span new garden in the months of May and June. Well, some did feel very sorry, and I was one of them; some were delighted; and some gave expressions to feelings, such as a generous foe would never entertain towards opponents or rivals. But welcome be the day when no British gardener shall exult in the fall or failure of any member of our family, much less when more than one is in for it. Divided authority is the bane of public or private enterprise; and any number of men,

from any craft or profession, acting together instead of under one head, would be just as liable as our Council to have their schemes "gang aft aglee."

In consequence of the tent-ruin, the Show had to be arranged all up the western arcades, through the most beautiful conservatory, and down along the eastern arcades to very near the end, and there never was a better show, and all that was wanting was more shelter for the plants.

The day was disagreeable, battering, blustering, coaxing, tempting, hot, cold, wet, and dry by turns; and a shocking spectacle it was to a gardener to see hundreds of plants in the eastern arcade, worth from £5 to £50 a-piece, knocked about and against each other just as if they were by the seashore in a gale; while the one-third of the price paid for those stupid and most ugly-looking tents would have paid for temporaries, which would render these arcades as comfortable as a drawing-room to visitors, and just as suitable for all sorts of plants as the conservatory is now for the stove and Orchid ones, and next day or the day after these temporaries could be entirely removed.

The Show was very little different from the May Show; the grand Pelargoniums made up for what the Azaleas lacked of their May lustre; and the competition for the dessert and dinner-table decoration was so imposing as to embrace more than the same amount of the public attention which was given in May to the drawing-room and conservatory, decorations. But the effect was singularly different.

The grand improvement was in the dinner-decoration services. I should think that from two dozen to thirty people competed for the distinction, and, with the exception of three of them, they were very well done indeed, and some of them very superiorly. The idea is most excellent; but people who thoroughly understand it find such a difficulty in breaking through an old and original principle of the dessert-table, that none or hardly any but amateurs have yet attempted to compete, and perhaps that is as well. Strangers, however, to the grand doings of our grandees in their territorial dining-rooms can yet get no glimpse of it from these competitions. Not one of the "sets" of last year or of this has been set on dining-room principles—a fault which I wonder such lady judges have not yet pointed out to the Society, and a fault which might easily be prevented. The dining-table was, say 100 yards long, and if there were thirty competitors there would be just ninety dishes, or thirty "services," which are never called dishes in dining-room language. Every two dishes of each of these thirty "services" were placed wrongways on the table at this Exhibition—that is to say, were set down in the line of the run of the table, instead of *across the table*.

In high private dining arrangements, it is considered either vulgar, or evidence of a want of means, to put any fruit bigger than Cherries in the centre group at all. The bare bones of a private dessert are six dishes, and a centre of three, the middle one being the *centre*, and the other two the *flanks*, and these invariably stand across the dining-table. The "top" and "bottom" are the first and second best dishes of "bare bones," and the "four corners" are the next best, and must be in match pairs. That is the smallest dessert you can place within the letter of the law, and your "centre piece" is the ornamental part of it for flowers, confections, and very fancy things, which the young of the party are sure to amuse themselves with ere all is finished; but if the party is thought to be rather too many for the size of the dinner-table, the bottom of the flanks and centre may be borrowed, as it were, to hold your small fruit, which is seldom touched. But in more ordinary ways, I never could see why the "centre" should not hold, or do for all the fruit and flowers. But I hold it as being perfectly impossible for any one to "set up" fruit and flowers on a centre group, as in this competition, with any degree of confidence, or with much effect either, unless he is to know whether the centre is to be the whole dessert, or merely the ornamental part of it.

The premier prize went last year and this on the supposition that the "centre" was at least the main seat of the dessert, which it never is, except at dinners on a very limited scale, or when a family sit down to enjoy a meal by themselves, which is as different from a dinner party as are a carriage bonnet and French gloves to a garden hat and gardening gloves.

But I must talk about the plants. After the very much improved long row of competitions for the very liberal prizes from Sir Wentworth Dilke, the next lot was also on a long level table in the centre of the space, and the first 17 yards of it were oc-

cupied by the Messrs. Veitch's Japan plants in three rows; then 16 yards of boxes of cut Roses, in double rows, the one side Paul & Son, and the other side W. Paul, who had three other English seedlings, Roses of his own rearing. The best of them a deep rosy crimson all in one shade, and called Multiflora, was marked a "bedding Rose," and if it really will bed it must stand next to a bed of Reynolds Helle, which took the fancy by surprise last summer in that conservatory, and in Mr. Standish's contribution. The other two seedlings of Mr. W. Paul were quite as good to my eye as nine-tenths of the French seedlings.

The next 12 yards of this centre table were wholly occupied by Mr. Standish's new Japanese plants. I heard him discoursing about *Ilex Fortunei*, which is not at all like an *Ilex*, being made into all sorts of topiary work in Japan, as the Yew is here, or has been, and that hedges of it closely kept will bear the weight of a Japanese to walk over it. I once walked as one in three abreast along the top of a Holly-hedge 16 feet high, not two miles out from Edinburgh, on the south side, but I forget the name of the place, and I wonder if that hedge be there now. That was in 1828, and the place was on the right-hand side as you would go to Hawthornden, for I went there to see the original Apple tree of that name the same day.

Against the back wall of the arcades in this part were stands of cut flowers of Ranunculuses, Verbenas, Rhododendrons, Pansies, Pinks, Peonies, and Delphiniums, the last two were very fine, from Mr. Salter. After these, all the arrangements were against the back wall of the arcades, and against the back, centre, and ends of the conservatory in three broad steps, or stages, covered with green baize with canvass screening in front of the west side arcades; but not so on the opposite side of the conservatory where the splendid groups suffered dreadfully from the blowing wind.

The first of the back wall plants were two, a match pair, of the Mrs. Ferguson Petunia. They were 9 feet high and loaded with the gayest flowers you ever saw, every one of them striped with five purple bands; and THE COTTAGE GARDENER of the autumn of 1860, is the godfather of the kind when no one else would hardly venture an opinion on the flowers.

Mr. Williams next with heaps of variegated plants, and amongst them the *Gnaphalium lanatum* that is to run against *Antennaria margaritacea*; also the second kind of variegated *Scrophularia*, called *melifera*. Then a very rich seedling single *Petunia* striped with purple more deeply than Mrs. Ferguson, and named Flower of the Day. I should like to be not only the godfather of this new *Petunia*, but to have been the raiser of it, for, depend upon it, no one who can afford to buy it, will long go without it next year, when it must come out. Here, also, stood lots of other new seedlings, *Petunias* from Mr. Bull; *Pelargoniums* of great beauty, and a whole collection of them from Mr. Turner. Some very poor specimens of, seemingly, good seedling *Tropæolums* in the most wretched condition, and a very fine *Delphinium bicolor grandiflorum*, the latter from the Messrs. Downie, Laird, & Laing, a very good dwarf Scarlet *Geranium*, *Adeline Patti*, with large flowers, from Mr. Macintosh, of Hammersmith. Then a most noble collection of fine-leaved and variegated plants from Messrs. Veitch, of Exeter and Chelsea, occupying 20 yards, including grand specimens of the *Alocasias*, *Caladiums*, the new Fig plant, very much better than in May, grand *Cyanophylls*, and the best *Erica depressa* in that nursery no doubt.

The next 24 yards were of Ferns, and fine-leaved plants from various growers. But the newest plant in that part was an African *Crinum*, without the columnar stem of the Asiatic kinds and very near *Crinum Forbesii*, of the Eastern parts of Natal, but marked just like *Hippeastrum vittatum*, with a deep band of purple up each segment of the perianth. There was no name to it, but a ticket telling it was introduced in 1859 by Capt. Speke, from the centre African lake Victoria (?), and was sent to the show by W. Speke, Esq., Jordans, Somersetshire. That *Crinum* and *Forbesii*, if we could get it, and the common *longifolium* of the Cape, would easily get up a race of *Crinums* as hardy and as varied in aspect as the *Gladioli*, and six times more florid and majestic in looks. But where is Lake Victoria in central Africa? Does it mean the great waters of the Makololos above the great falls of Victoria, beginning the Zambesi, or what? If so, this *Crinum* will need Orchid-house treatment till it is crossed with the hardy race.

Now, up a flight of steps, refreshment arcade, and then the grand curve to the west end of the conservatory, and it was in

that curve that grandeur reposed in comfort. But, first, the only collection of standard Rhododendrons there, Mr. Noble, of Bagshot, being the sender and sustainer; then 12 yards of Roses, Calceolarias, and Heaths, and full 60 yards of the most splendidly-grown Pelargoniums ever staged hereabouts or far away; but I recollect when the oldest of them had, or was refused a certificate.

Now for genealogies. How many of the 60 yards had first or second-class certificates when they were seedlings? and how many kinds which had first-class certificates since 1842, the date of the oldest Pelargonium there in my stud-book are now out of cultivation?

Who can answer that?

And now into the grand conservatory. I admire this house the more I see of it. It was a wise thing not to have planted out in borders in it, yet it lacks the very best part of the furnishing of a conservatory for want of climbers. What a noble effect a right selection and direction of climbers would make in that house! I would not care a fig for flowers, so much as for the living festoons of varied green which might run from side to side, suspension-bridge-like, above the feathery and features of the fairest flowers of our race.

This beautiful house was magnificently "set." The first-prize collections of stove and greenhouse plants, and all of their like. The Orchids, too, and the Azaleas were there, as were many novelties, and the hosts of camp-followers you see at all the great London shows. There were 35 yards of Orchids, some very good specimens; but the kinds and the looks of the plants not to be compared, for one moment, with the Orchids, the "morning Orchids" of ten and twelve years back. I have every one of them booked; and of all the Heaths, stove plants and not stove plants, Vanda Batemanni from the Exotic Nursery, and Cattleya superba with two flowers on it from Mr. Chilman, were the two rarest to the shows which were there; and there was also Dendrobium Falconeri the most delicate of the five-stemmed race from India, with flowers after the way and fashion of noble.

At the west end were many novelties from Messrs. Veitch, which stood the brunt of the Floral Committee, and some hybrid Orchids from the same, with one of which another botanical genus is knocked on the head. I allude to a robust-looking seedling from *Goodyera discolor*, older than I am, and by the pollen of *Ancetochilus Lowi*, so *Goodyera* must merge into the more euphonious name at last. A crossed Pitcher-plant, and several others were also shown; but one from the Fox-brush Orchid, the *Erides Fieldingi*, with affine, shows the two to be too much of a sort for useful breeding. *Lindleyana* and *Schroederi* appear the two most likely to give a better third; but it is most interesting to see and know that Mr. Dominy has really got into this secret of the Orchids, without the aid of moths, like *Scintillaria macroglossa* which crosses them, sings over them, sucks them, and looks at you all the while.

The little hard dark brown *Mimulus cupreus* was there, a really good thing; and there was a freshly-potted *Philadelphus hirsutus*, very much in the way of the *P. mexicanus*, which Mr. Turner exhibited at the Azalea Show. I once had up a batch of crossed seedlings from mexicanus by the common old one, and they went for it in 1836 before I could flower them. They and the *Deutzias* will yet make a fortune to some breeder, and this *hirsutus* is just the very sort of plant to vary and make good the strain.

The pretty little yellow *Oxalis valdiviana* was very pretty indeed, and *Stenogaster speciosa* in the same group would seem to offer temptations to cross some of them with *Streptocarpus*, if only to put with another genus. The most curious plants at the other end of the house were *Alocasia zebrina*, from Messrs. Veitch, and cut specimens of the old Hand-plant of Mexico from C. Dorrien, Esq., Ashdean, Chichester. The long leaf-stems of that *Alocasia* are as the markings of a snake with plain green leaves; and here stood under a glass a fine group of skeletonised leaves by Miss Rubergall, of Heath Farm, Old Brompton, and they were exquisitely prepared.

The eastern arcades began with 17 yards of Azaleas, of which *Constantia rosea* was the darkest purple, *Extrani* next, and then the great mass of various shades of orange scarlet, until they ran into rose and salmon tinted, of which one *Fenella* in Mr. Page's collection was the best example; then 30 yards of huge foliage plants in great distress, followed by 39 yards of collections of stove and greenhouse plants; the whole ended with 5 yards of the newer Azaleas, and a group of twenty-four fine dwarf hardy

Ferns—a very select lot from Mr. Ivory, of Dorking, who also with Mr. Turner, had another turn with these new Azaleas. The fruit-stand was down another flight of steps; it was moderate this time, and the best Black Grapes were from Mr. Henderson, of Trentham, and the Ingram's Hardy Prolific Muscat from Mr. Standish was never seen to such advantage. D. BEATON.

#### FLORISTS' FLOWERS.

A TOLERABLY fine day, the height of the season, and the *éclat* which for a time at any rate attaches to the Horticultural Society (which it is *the thing* to belong to), sufficed to bring together a very large concourse of the fashionable, sight-seeing, and gardening world to behold one of the largest and most interesting collections of plants ever brought together, but shown under disadvantages which nothing but the intrinsic merits of the plants themselves could have overcome. It is quite clear that, as at present laid out, the place is not suited for a flower show. The arcades are draughty and cold to a degree; and when covered-in in the front, and the weather is cloudy, it is like looking at flowers in a vault. The arrangement certainly does not please; and as a matter of taste I should think our French neighbours were not a little astonished to see how little we made of our vast materials. However, as I saw Mr. Beaton with pitying eye beholding the fine-foliated plants in the eastern arcade blown about by the fierce south-west wind, I doubt not he will tell the world what he thought about it, and I shall go on to the florists' flowers, which, I rejoice to say, still attracted the larger number of admirers.

Again the foliated plants were passed by. The collections of stove and greenhouse plants were only favoured with a passing glance; but whenever you heard a "Move on, if you please," from X 21, you might be certain that you had come on a box of Roses, a group of Azaleas, or a stand of Pelargoniums. Orchids will always attract their share of attention and were very fine, but with that exception the most popular subjects are florists' flowers.

Pelargoniums were never finer—in fact, I question if Mr. Turner's were ever so fine as they were to-day. They were not only models of growth and masses of bloom, but there was a character about each individual flower which showed how carefully they had been attended to. In his twelve show plants were—Lord Clyde, a flower of great brilliancy of colour, orange scarlet, and of fine shape; Fairest of the Fair; Lady Canning; Viola; Desdemona; Bacchus; Etna, a fine rich scarlet; Prince of Prussia, good white; Rose Celestial; Sir C. Campbell, and Candidate. Messrs. Dobson & Son, of Isleworth, were second; and had amongst their plants very fine specimens of Carlos, Governor General, and Sanspareil. Messrs. J. & J. Frazer were third; and Mr. Burley, of Limsfield, was fourth. He had a fresh variety, Virginia, very brilliant in colour but indifferent in form.

Amongst Amateurs, Mr. Bailey, of Shardloes, was first. Bianca, Sanspareil, Glowworm, Viola, Carlos, Duke of Cambridge, Lord Clyde, Desdemona, and Rosa Bonheur comprised his plants.

In six Fancies, which were open to all, Mr. Turner was first, with admirable plants of Claudiana, Evening Star, Acme, Delicatum, Modestum, and Crimson Pet. It would be impossible, we think, to bring more perfect plants than those exhibited on this occasion. Messrs. Dobson & Son were second, Mr. Bailey third, Messrs. Fraser fourth, and Mrs. Hodgson had an extra prize.

In Spotted Pelargoniums, Mr. Turner was also first. His plants were Mr. Marnock, Conspicuum, Guillaume Severyns, Bertie, Bracelet, Beadsman, Rembrandt, King of Purples, and Osiris. Mr. Dobson second, Messrs. Fraser third.

Azaleas were not so good as in May, nor was this to be expected; but some very fine plants were staged, especially those of Mr. Turner's. They were, as usual, a mass of bloom, and admirably arranged. Centurion, Lateritia, Petuniefiora, Illustris nova, Stanleyana, Gledanesii, Gem, Symmetry, and Sir C. Napier were the plants; and although I fancied they looked as if they had been kept back a little too long, yet they were very fine. Messrs. Veitch & Son held the second place; their plants were certainly fine. Magnificent, Iveryana, Coronata, Holfordi, Apollo, Barclayana, and Perryana were the best. One plant had unfortunately been left too long without water, and during the early part of the day drooped very much.

In the Amateur's class, Mr. Whitbread, gardener to H.

Colyer, Esq., of Dartford, was first with *Reine des Belges*, *Striata formosissima*, *Juliana*, *Extramii*, *Consolation*, *Chelsoni*, *Gledstanesii formosa*, *Conqueror*, and *Stanleyana*.

In the class of six Azaleas, sent out since 1857, Mr. Turner was again first. His plants were *Etoile de Gand*, *Kinghorni*, *Chameleon*, *Magnet*, *Président de Clèves*, *Comte de Hainault*. I have before spoken of all these varieties, but *Etoile de Gand* was superior to anything I have yet seen in the same way; the individual flowers were so fine, and the marking so very constant. In a few years more, when these new varieties come to be large plants and push aside the older ones, their effect in collections will be very striking.

Roses were shown both in pots and as out blooms, the former by Messrs. Lane and Wm. Paul, but not in such good condition as in May. Mr. Lane's celebrated Paul Ricaut, *Baronne Prevost*, *Coupe d'Hébé*, *Elise Mercœur*, *Madame Plantier*, *Souvenir de la Reine d'Angleterre*, and *Queen*. Some fine boxes of bloom were sent by Messrs. Paul & Son, of Cheshunt, Mr. Wm. Paul, Mr. C. Turner, of Slough, and the Rev. F. W. Radclyffe, of Rushton. No prize was offered for them. Is the Society too poor? or will it never learn that these are the sort of things to encourage? Some of the blooms were exceedingly fine, but there was no means of comparing them. One box was up in the conservatory, and the other a long way down in the arcades—in fact, in the Miscellaneous class there seemed inextricable confusion. The exhibitors were puzzled, the Judges were puzzled, and I am sure the public were puzzled. What "third prize" meant no one knew. Seeing it on a box of Roses, one naturally looked to see what had first, but that was not to be found.

I thought Mr. Turner's the freshest-looking of the stand show. There were such fine blooms of *Senateur Vaise*, *Général Jacqueminot*, *Comtesse de Chabillant*, *Vicomtesse de Cazes*, *Madame Furtado*, *Bacchus*, *Eugène Appert*, *Madam Bray*, *Madam Rivers*, and *Amiral Gravina*. There were in the Messrs. Pauls' stand some new Roses, of which more presently.

Pinks were exhibited by Messrs. Turner, Bragg, and Williams, but here again no prizes were offered, being only "garden things!" Mr. Turner's stand, not as fine as usual, comprised *Elcio*, *Adonis*, *Victory*, *Colchester*, *Cardinal*, *Mr. Hobbs*, *Attraction*, *Mrs. Kingsford (Jeana)*, *New Criterion*, *Pride of Colchester*, *Princess Alice*, *Helen*, *Minnie*, *Annie*, *Unique*, and some seedlings.

Mr. Shenton, of Hendon, had a very good box of Pansies; and Mr. Salter, of Hammersmith, two fine boxes of Pæonies, very showy and varied in their colours.

Two collections of Calceolarias were shown. Mr. Bousic, gardener to Lord Taunton, had well-grown and bloomed plants of *Monarch*, *Lady C. Laacelles*, *Lily*, *Dewdrop*, and *Dr. Livingstone*, and received first prize, though his flowers somewhat lacked variety, being nearly all shades of yellow, spotted with brown, &c. Mr. Burley was second: his plants were thinly bloomed and too formally tied, though the variety in them was greater. They were *Lady Havelock*, *Angustifolia superba*, *Prince of Wales*, *Little Dorrit*, and *King of Prussia*.

Seedling florists' flowers, &c., were sent in in goodly numbers. So fine a bank of seedling Pelargoniums I never saw, but the arrangement was very bad; they were put up so closely and so high, that it was impossible almost to get at anything to see it properly. My notes were taken under these difficulties, nor do I yet know how they stood before the Floral Committee; for when I went again to look at them at three o'clock, there were no cards attached. *Canopus* (Beck's), is a beautiful rose colour, with clear white throat; a decided improvement on *Rose Celestial*. *Monitor* (Forster's), splendid spot, a purplish-crimson ground with very large, intense spot. *Royalty* (Forster's), a beautiful purple, clear white throat, and a decided novelty. *Belle of the Ball* (Forster's), is a beautiful painted flower, in the style of *Princetta*, with intense black upper petals, edged with fiery crimson. *Censor* (Forster's), a purplish-crimson; well-shaped flower. *Illuminator* (Forster's), a Lord-Clyde style of flower, of fine shape and size. *Regina Formosa* (Beck's), a beautiful rosy crimson. *Ferrens* (Beck's), fine, smooth, round, scarlet flower. *Prince Albert* (Hoyle's), a very large flower, but somewhat rough. I was particularly struck with the advance made by Mr. Nye, Miss Forster's gardener, as he has got out of that cupped strain which used to spoil his flowers. Mr. Hoyle was a little behind his usual place.

A fine *Petunia*, *Flower of the Day*, in the way of *Madam Ferguson*, was shown by Mr. Holland, gardener to G. W. Peake, Esq., Springrove. It is regularly marked on each petal,

or segment of the flower, and with a much broader and brighter stripe than *Msdam Ferguson*. This has passed into the hands of Mr. B. S. Williams, of Paradise Nursery.

A very dwarf bedding Calceolaria, called *Golden Dwarf*, was exhibited by Mr. Watson, of the New Zealand Nursery, St. Albans, and is likely to prove an acquisition; as is also a fine *Delphinium*, called *Bicolor grandiflorum*, exhibited by Messrs. Downie, Laird, & Laing, and said by them to come true from seed.

Some interesting seedling Roses of English origin were shown, opening up the question whether we cannot rival our French friends. I know it is said that mildew will beat us, but surely it will be worth trying. Messrs. Paul & Son had a very nice and well-shaped H.P. Rose, apparently of the Lord Raglan type, with a shade of colour in it somewhat of the dark Bourbon Rose, such as *George Peabody*, &c. I hope to see more of this yet. Mr. Paul, jun., informed me that it came out of the same bed of seedlings as *Beauty of Waltham*. Mr. William Paul had *Brilliant*, a Bourbon Rose, an improvement on *Sir J. Paxton*, being higher in colour than that favourite flower. As an autumn climbing Rose it is a very desirable variety, and a branch of it shown at the same time clearly marks it as very vigorous. Then there was *Multiflora*, a very free-blooming seedling of *Général Jacqueminot*, and, like its parent, too thin but pretty; *Robusta*, a rosy crimson, as good as many of the French novelties (?); and "*Wee Pet*," small and somewhat rough. These are all interesting, as showing an advance into ground hitherto untrdden.

Messrs. Veitch exhibited *Mimulus cupreus*, fully confirming the opinion formed of it last year. The plants had been grown in the open air, and had been taken up and put into pans: they were consequently much deeper in colour and very dwarf. I think it will be a very useful plant. Then they had *Nolana lanceolata*, a hardy annual, with blue *Convolvulus*-looking flowers, and likely to be useful for vase-culture.

Messrs. E. G. Henderson & Son sent plants of their *Zonale Geraniums*—*Mrs. Pollock*, *Sunset*, *Gold Leaf*, *Mrs. Milford*, *Glowworm*, *Gold Pheasant*, and some seedlings, amongst which I detected, I fancy, *Lucy Grieve*, an improvement on *Sunset*.

The growls that have been for some time sounding deep in the breast of the great public, have at last burst forth in a peal of thunder from the *Times*, suggesting an answer to the question, Are not the gardens a complete failure? Mr. Eyles, however, is not the person on whom the blame rests—he cannot do impossibilities; but I should not be at all surprised if this be not among the things which are tending to stop us in the extreme length to which the bedding-out system is running. The gardens will look well when everybody is out of town; and as to the "broken bottle" style, who can say a word for it except those *dilettanti* who want to play at gardening? These are matters which will occupy the public mind now that the ball is fairly set moving, and I hope with beneficial results to horticulture generally.—D., Deal.

## FRUIT.

ALTHOUGH the show of fruit, taken as a whole, was scarcely so fine as we have seen at the same period in previous years, yet many of the specimens were very good, particularly the Pines, Peaches, and Nectarines, and some of the Grapes, which, however, in general, were not fully ripe.

To no part of the Exhibition, if we except the dinner-table decorations, did the visitors crowd more constantly, and in none did they manifest a greater interest or linger longer than in the fruit show. Indeed, many persons had to content themselves with a mere glimpse, near approach to the tables being almost an impossibility—a gratifying evidence to the lover of fruits that the twofold claim of his favourites for utility and beauty combined is not neglected for the simply ornamental in leaves and flowers.

In Pines, the first prize for the best Cayenne was withheld, and the second was taken by Mr. Bailey, gardener to T. T. Drake, Esq., of Shardeloes; this was the only exhibition in Class A.

In the open class for any other kind, Mr. Froud, gardener to R. Fothergill, Esq., Aberdare, took the first prize with a very handsome *Queen*, weighing 5 lbs. 2 ozs.; and Mr. Barnes, of Bicton, was second with an excellent *Queen*, weighing 4 lbs. 1 oz. The third was taken by Mr. Speed, gardener to Sir E. Walker, Bury Hill, Mansfield, with a well-grown *White Providence*, weighing 7 lbs. 6 ozs.

Of Black Grapes there was a large display, the Black Hamburgh being the sort exhibited almost to the exclusion of every other. Many of the bunches were badly coloured, and others had the bloom rubbed off by bad packing, whilst the fruit of a few, evidently new exhibitors, was set up in a very unskilful manner. In one instance the bunches rested on a thin blue paper similar to that used by grocers, which had a very bad effect.

Mr. A. Henderson, of Trentham, exhibited three magnificent bunches, the berries being large and regular and covered with a fine bloom. These gained the first prize; and from the same exhibitor were three more fine, well-coloured bunches, which would have also merited a prize if more than one could have been taken in a class by the same person. Mr. Clement, of East Barnet, came in second, his fruit being also very fine, even, and well coloured; whilst the third award was given to Mr. Wortley, gardener to Admiral the Hon. P. Cary, Norwood; his bunches, though not so large as the others, were very good, and the individual berries were large. All the above were Black Hamburghs, and good specimens of the same variety were also exhibited by Messrs. Tillyard, Stanmore Priory; Fleming, of Cliveden; and Robson, of Linton Park, Staplehurst. There were several other exhibitors in the same class, but the bunches though in some cases of good size were either badly coloured, irregular, or with the bloom rubbed off.

In the next class, White Muscats, the first prize was awarded to Mr. Horwood, gardener to G. H. Turnbull, Esq., Bromley, for three fine, well-shouldered bunches of Muscat of Alexandria, and he also exhibited a 12 lb. basket, but the berries though fine were unripe. The second prize was taken by Mr. Standish with the same kind, grown in the vineries mentioned at page 51, the berries being large and fine. Mr. Embery came in third; both the bunches and the individual berries were large but not so regular as in the other two. Fine bunches were also exhibited by Mr. Clement. Those from Mr. Peed, Mr. Mecklenright, and Mr. Moylan were likewise good, but the berries were not perfectly ripe. Mr. D. Thomson, of Archerfield, N.B., showed Archerfield Early Muscat, a new form of the Muscat of Alexandria, but which is six weeks earlier than that variety. It was a large, broad-shouldered, and ovate-shaped bunch remarkably well set; the berries of good size and perfectly ripe. It unfortunately arrived too late, otherwise there is no doubt it would have received some very special notice from the Judges.

In the class for any other White Grape, Mr. Wortley, Norwood, came in first for Diamond Drop, a pale-coloured Grape, with a light brown tinge next the sun. Mr. Alderson was second with Royal Muscadine; and Mr. Edwards, gardener to Lady Langdale, Eyewood, took the third prize with Royal Muscadine.

Peaches were exhibited by Mr. Henderson, of Trentham, Mr. Durrant, and Mr. Boston, who were respectively first, second, and third; those from the former were large and beautifully-coloured specimens of the Royal George, whilst Mr. Durrant's exhibition consisted of the Bellegarde, three out of the six fruits being well-coloured, the remainder not equally good.

In Nectarines Mr. Allen, gardener to J. B. Glegg, Esq., Withington Hall, was first with a dish of beautifully-coloured Elrue; and Mr. Henderson, of Trentham, obtained the second prize for Violette Hâtive, which was also very fine; indeed, there was very little difference in the merit of the two exhibitions. Mr. Horwood likewise exhibited a very good dish of the same kind, but not so well coloured; and that from Mr. Moylan, though the fruit was well grown and some of it properly coloured, was not sufficiently ripe.

In the class for Cherries, the only dishes exhibited were Black Tartarian from Mr. Henderson, of Trentham, and May Duke from Mr. Fleming, of Cliveden, who were respectively first and second.

Strawberries, in single dishes. The successful competitors in this class were Mr. Smith, of Twickenham, who exhibited a dish of very handsome fruit of Sir Charles Napier, which took the first prize; Mr. Widdowson, and Mr. Park, of Retford.

In the next class, three dishes, Mr. R. Smith, Twickenham, was first with Sir C. Napier, British Queen, and Empress Eugénie, the former being large and very fine; and Mr. Widdowson, who had also very good fruit, second.

The first prize for green-fleshed Melons was given to Mr. Meredith, for a hybrid Cashmere; and the second to Mr. MacLaren, for Golden Perfection, both being good specimens. In scarlet-fleshed, Kaile's Scarlet-fleshed, from Mr. Kaile, gardener to Earl Lovelace, Ripley, was first; and Turner's Scarlet Gem, from Mr. Meredith, second.

Vines in pots were well represented by Mr. Smith, of Syon,

who exhibited two pots of the Black Hamburgh, forming a wide arch covered with fruit, and for which a first prize was awarded. Mr. Hutt, gardener to Miss Burdett Coutts, came in second with Sweetwater and Black Hamburgh; the only other competitor was C. W. Alderson, Langley Lane, South Lambeth, who exhibited two plants thickly hung with bunches, but which were disqualified by the Judges, it having been found that the Vines were not *bona fide* grown in pots. The plants were remarkably well grown and luxuriant; the bunches large and very numerous; whilst the pots were unusually small for the size of the Vines. All these circumstances excited suspicion; and, on turning a plant out of its pot, it was found that a shoot had been introduced through the hole in the bottom, and, though some adventitious roots had been formed, the Vines had evidently been nourished by the parent plant, the connection with which had been severed a short time previous to the Exhibition.

The prompt detection which this discreditible expedient met with, will, it is to be hoped, deter others from imitating the example, should there indeed be any so inclined.

In the Miscellaneous class, Mr. Standish obtained a first prize for some fine bunches of Ingram's Hardy Prolific Muscat, a just recognition of its merits as one of our best new varieties. Dr. Trouncer came second for Black Hamburghs, grown on the roof of a house in Mount Street, Grosvenor Square, and which under the circumstances in which they were produced were very good. These were arranged as a dinner-table decoration. A similar award was made to Mr. Lunt, Greenock, for a dish of Moorpark Apricots; also to Mr. Henderson, Trentham, for Elton Cherries. Mr. R. Smith, of Twickenham, exhibited some pots of Sir Charles Napier Strawberry. Mr. Ross, Newbury, a dish of White Marseilles Figs; and Mr. Kaile, Raspberries in pots, all of whom received third prizes.

Mr. Hall, gardener to Captain Tyrell, Fordhook, Ealing, exhibited three dishes of Apples, two of them being the Bess Pool, the other French Crab, all of them sound and firm. From Mr. Smith, of Chertsey, came three rather small bunches of the Golden Hamburgh Grape; and from J. Luscombe, Esq., Combe Royal, Devon, a dish of Limes grown on a south wall without glass or artificial heat, and with merely protection—the protection of a reed covering at night and in very severe weather.

#### HORTICULTURAL IMPLEMENTS, &c.

THE show of these differed little in its general character from that on May 21st, of which it was for the most part merely a repetition, there being with but few exceptions the same exhibitors and the same articles, with only a slight increase in their numbers.

This speaks very little for the enterprise of the manufacturers whom the Society has invited to come forward, and who have thus lost a good opportunity which might have turned greatly to their advantage. That the visitors evinced but little interest in this "exhibition" cannot be wondered at—it was a failure. Horticulture, it is true, requires no massive engines working with giant strength and unerring certainty, impressing the beholder by their movements with a feeling of awe—no complicated machinery that the breaking of a thread or the touch of an infant's hand will stop. And that the public should crowd to these cannot be a matter of surprise; but when we find at the International Exhibition every machine, no matter what its purpose, receives its share of public attention, we are forced to the conclusion that it is not from lack of interest on the part of the public, but from the paucity of the display and the familiar nature of the articles shown that so little attention was paid to this part of the Society's Exhibition.

Three kinds of boilers were exhibited—the tubular ones of Ormson and Weeks, and Monro's cannon form of several sizes, of both wrought and cast iron. Messrs. Weeks also exhibited their large heating pedestal and cast-iron furnace-doors, made to slide backwards and forwards so as to obviate the objection of warping with the heat, which hinged doors are almost sure to do.

Mr. Ormson likewise exhibited furnace-doors of admirable construction. They are faced next the fire with firebrick, so that no loss of heat may take place in consequence of the conduction of the metal, and instead of sliding they are provided with brass rollers which run on a bright case-hardened rod; friction is thus reduced to a minimum, and they can, consequently, be moved with almost a touch. From the same exhibitor there was also an improved stop-valve, the shutter of which was drawn backwards or forwards by a screw working in a kind of female screw on the face.

In addition to the boilers, Mr. Jones had a heating coil with an ornamental round case; single, double, and triple valves for hot-water apparatus; a number of excellent cast-iron vases, and a flower-pot stand of the same material.

Mowing-machines were exhibited by Messrs. J. B. Brown and Co., of Cannon Street, who also had garden chairs, and some handsome cast-iron vases; Green, of Leeds; Ransome and Sims, of Ipswich; and Ferrabee & Co., of Stroud.

Amies & Barford's rollers were again shown, as well as Banks' tree-protectors, pendant basket, and galvanised Verbena-pegs; Nixey's water-tubs, and Read's garden syringes and engines.

Messrs. Barr & Sugden exhibited some pretty flower-pot covers for hiding common garden-pots in drawing-rooms; they are made of card of various colours, and are coated with gelatine to prevent injury from moisture. Also flower and fruit gatherers including Gmelin's patent, which, from grasping the fruit between two Indianrubber discs, cannot bruise. They had in addition rustic terra cotta flower-pots, triple flower-vases, and Yeates' improved zinc tallies.

From Mr. W. Thomson, of Dalkeith, came his newly-invented hot-air ventilator, described at page 195; from Mr. W. P. Ayres, a panel in cement for conservatory-tubs; from Mr. Cullingford, garden netting of various kinds; wooden flower-sticks, tallies, and labels, from Mr. F. A. Haage, of Erfurt, which were remarkably cheap; and lastly, seed-protectors, wire archways, flower-stands, and baskets, from Mr. Reynolds, of New Compton Street. There was also a model of Cranston's conservatory, with a sash showing the mode in which ventilation is effected.

Nearly all the articles exhibited were commended either on this or on the former occasion.

### IMAGINARY FORMS IN FERN STEMS.

I FEAR that I uselessly occupied your time and space in asking in which Fern the "sacred monogram" was imagined. I have since learned that the words used were "the initials of Jesus Christ printed there black as with ink." I have recently cut several roots of the Pteris, keeping the inside or grooved side of the stem uppermost, and making a sloping cut from right to left, and have occasionally, with the eye of faith, seen the letters "J. C." It is more like two J's back to back, but a speck near the top of the letter J can be fancied as making it into a C.—M. D. P.

### VINES AND VINE-BORDERS.

MUCH has been spoken and written on the formation of Vine-borders, and the application of heat to them; and it may appear

presumption in me to attempt to give anything new. This, however, I do not attempt to do. But still, I cannot help thinking that we have much to learn on these subjects, which shall be my apology for occupying your pages. I think nearly, if not quite, all are agreed that it is advantageous to have the temperature of the soil where the roots of the plants are growing, approximating somewhat to that in which the shoots are, especially in cold damp climates, and in early forcing. We know that in the pot-culture of plants, generally speaking, they succeed best when the roots are in advance of the stem, or in a medium, where the shoots can be supplied from the root, with the food suitable for the perfecting of the whole plant: if this be correct, which my experience leads me to think is the case, it follows that the general treatment of the Vine hitherto has not been that which it ought to be; this would appear true, from the different modes that have been adopted to increase the temperature of the soil. The natural habit of the Vine, and our own reason, leads us to conclude that it is seldom treated as it ought to be. True, good Grapes have been, and will be, grown without any artificial heat to the soil; but I think this no reason why those same Vines might not have been better, had the temperature of the soil been higher than it was.

Having to erect new vineries here, the drawing below is the plan which was adopted—it being the desire of my employer to heat the soil by some means or other, he being led to do so from his observations on the temperature of the soil when in India. To do so by means of hot dung thrown under brick arches was objectionable, from the amount of labour required to keep up anything like a steady heat. To cover the surface with dung was still more objectionable, from its unsightliness, its bad effects on the border, and its being opposed to the well-known laws of the conduction and radiation of caloric.

We were led to adopt the Caithness pavement, which is 2 inches thick, and in pieces from 3 feet to 4 feet square; also moderately cheap. With this was constructed a chamber, 2 feet 6 inches high, with 9-inch brick pillars supporting the pavement, and heated with hot-water pipes from the same boiler which heats the houses. We have found it to exceed our most sanguine expectations. In the first place, we have a thorough drainage, and the roots cannot by any means get into the bad soil below; but the most important fact is, that the temperature of the soil in the chamber at 2 feet deep, is, at all times, 9° higher than that of a border of the same aspect, not chambered. When the frost has penetrated into the latter 9 inches, it has only reached 2 inches in the chambered border—that is, without any artificial heat being applied. The increase of 9° was quite unlooked for, when the border was chambered; but being supplied with soil-thermometers, for the purpose of ascertaining the temperature of the soil in various parts in the garden, and in the farm, throughout the year, we had an opportunity of knowing the fact; while, under other circumstances, it might not have been known. It also led his Lordship to cause to be chambered upwards of 300 square yards of wall-borders, for growing early vegetables, which, when made, indicated the same increase of temperature of the soil—viz., 9°.

The question will naturally arise, Can the temperature of the soil be raised to any great extent, by the hot-water pipes, with a single mat covering the border to prevent radiation in any sort of weather, excepting rain? We can raise the temperature of the soil from 50° up to 80° in eight or ten days, with a very small amount of fuel, much smaller than I could have imagined. By this mode of heating, I could keep the soil where the roots are at a temperature of 80°, while the shoots would be at the freezing-point, by merely opening or shutting the valve of the hot-water pipes.

In order to find out correctly what effect a quantity of fermenting dung laid on the surface of a Vine-border not chambered would produce in raising the temperature of the soil at 1 foot 6 inches deep, on the 17th December, 1849 I covered the border 3 feet deep with good fermenting stable-dung and leaves, turn-

ing it occasionally and adding to it. When the dung was put on, the temperature of the soil was 40°; on the 17th January, 1850, it was 42°; 17th February, 53°; 17th March, 53°; 17th April, 53°; 17th May, 58°. Until the end of March the temperature of the dung was from 70° to 90°, when it fell gradually until the end of May, when it was taken off. On the 17th of June, by the heat of the sun, it had risen to 60°; July 17th, 63°. While that quantity of dung raised the temperature of

the soil 13°, the chambered border stood till the 17th February (when the hot water was let on), at 49°, only 4° lower than the unchambered border with all the dung. From this it would appear that the dung has little effect in heating the soil. It only prevents radiation; and a slight covering has nearly the same effect as a greater thickness of fermenting dung. This I have proved by experiments I have made.—A. SHEAREE, *Gardener to the Marquis of Tweeddale, Yester.*

STOVE PLANTS.

1. *Thibaudia macrantha.* 2. *Pleione lagenaria.*

**THIBAUDIA MACRANTHA** (Large-flowered *Thibaudia*).—*Nat. Ord.*, *Vacciniaceae. Linn.*, *Octandria Monogynia*.—A beautiful, but rather straggling evergreen stove shrub, with entire, smooth leaves on short thick footstalks. The flowers are extra-axillary, two or three together; the stalks thickened upwards, and coloured red; they are large, upwards of 2 inches long, and an inch in diameter, pendent, with a small pale yellow calyx and flask-shaped five-angled porcelain-like corolla, contracted at the mouth, with the narrow segments of the limb reflexed, and the stamens and style protruded; the colour is "china white, yellow at the base and apex," the spaces between the angles marked with numerous distinct wavy red lines, generally taking the shape of the letter V. It is stated to be of easy cultivation, and to have flowered when not more than 2 feet high. Mr. Smith, of Kew, suggests that it will probably succeed in a close warm greenhouse. From Kola mountain, Moulmein. Introduced by Mr. T. Lobb, collector for Messrs. Veitch, of Exeter and Chelsea. Flowers in winter.

**PLEIONE LAGENARIA** (Bottle *Pleione*).—*Nat. Ord.*, *Orchidaceae. Linn.*, *Gynandria Monandria*.—A beautiful little epiphytal stove plant, with flask-shaped pseudo-bulbs and lovely flowers issuing from a bract, which is hooded, acute,

and much tapered at the base. The sepals and petals, which are linear-lanceolate and acute, are of a pretty rosy lilac colour, as is the exterior of the rounded, entire, emarginate, rolled-in lip, the inner surface of which at the margin is streaked with carmine on a white ground, and towards the centre is yellow, marked with five crested lines. From the Alps of India. Introduced by Messrs. Veitch's collector, Mr. T. Lobb, in 1849. Flowers in autumn. "The secret of their successful cultivation in England lies in keeping them cool and dry when at rest, and forcing them with heat, moisture, and bright light, as long as they are inclined to grow."—(*Gardeners' Magazine of Botany.*)

### COCOA-NUT FIBRE REFUSE FOR DRAINAGE.

I HAVE used this with the greatest satisfaction in many ways, but would safely recommend it as a safe material for drainage. Plants evidently delight in it from its being filled with roots at every change in repotting. This circumstance, as it appears to me, gives it a decided advantage over moss or potsherds, as their effects are simply mechanical; whereas the fibre seems from some peculiar quality to promote the growth of the roots, and, as a natural consequence, increased vigour in the plant.

I watch the use of the fibre with much interest, and am trying some experiments, of which I hope to send you a favourable account.—JONQUIL.

### BOUGAINVILLEA GLABRA AT THE EARL OF SEFTON'S.

WE have a fine plant of this most magnificent flower in full perfection. It has been in full beauty for the last three weeks, and will continue so for some time to come, which leads me to believe that its flowering will soon be as much a matter of certainty as any other stove plant; and when better known, it will doubtless become a universal favourite.

There cannot be too much said in favour of this beautiful plant, as its colour forms quite an acquisition to our stoves; and I am of opinion that it is too little known, and its culture too much neglected at present.

The plant here seems quite at home, growing in a Cucumber-house, which has a span roof 30 feet by 12 feet, standing east and west or thereabouts. The pot in which this *Bougainvillea* is growing is plunged in a small border at the west end of the house, there being no door at that end.

In 1861, a small plant sent here in January, then no more than 6 inches high, had, by the end of November, completely covered the whole of the house, and from that time it received little or no water at the root, with the exception of a slight syringing now and then until the middle of March; and since then it has had a good supply of water, as the temperature of the house has been kept much higher.

The compost this plant is growing in here is two parts peat and one part of loam, with a little silver sand.—W. B., *Croxeth Gardens, Liverpool.*

### MR. R. S. YATES' NURSERY, SALE, NEAR MANCHESTER.

A REPORT having reached me that Mr. Yates had a fine show of *Rhododendrons* and hardy *Azaleas* in bloom, I was tempted to take a trip over to see. I was induced also to go there to inspect his hardy evergreen coniferous and other kinds of trees and shrubs, for the purpose of examining them to report the effects of the ever-to-be-remembered hard frost of 1860-61, and to note how such trees and shrubs, if any, had recovered from that severe ordeal, or had stood it uninjured.

Entering the gate there is a carriage drive, and on each side broad borders planted with specimen ornamental evergreens. Here I missed the fine *Deodars* and *Araucarias* that I observed there in 1859. Only two had escaped, all the rest were quite dead; and on the lawn in front of the house the noble specimen of *Deodar Cedar* was quite dead also. This dead tree is still standing. It is upwards of 20 feet high, with a trunk 9 inches in diameter; but, alas! not even the lowest branches had a green leaf alive. It was left standing in the hope that it would grow again from the root; but so far there is no such appearance. The *Variegated Hollies*, some of them 12 feet high, are very much injured, but they are pushing again pretty well; but it will take several years before they entirely recover. Amidst all this desolation there is some comfort that all kinds of evergreens are not destroyed. The green *Hollies*, of which there are many hundreds of fine specimens, are very little worse. The following were not injured in the least:—*Cupressus Lawsoniana*, (many hundreds of this very beautiful tree planted in long avenues have not even a leaf browned), I consider the best of the genus both on account of its perfect hardihood, and elegant habit. *Wellingtonia gigantea*, *Picea Nordmanniana*, *P. nobilis* (in cone), *P. pinsapo*, *Pinus Benthiana*, *P. insignis*, *P. Sabina*, *P. excelsa*, *P. cembra*, *Thuja borealis*, *T. gigantea*, *Thuja aurea*, and some others of less note. Most of these are planted on each side of a broad grass walk or lawn kept beautifully

mown. Any lover of beautiful rare hardy trees and shrubs would enjoy, as I did, the sight of so many specimens growing freely on each side of this smooth grass walk.

At the far end of this walk there is a turn round on the right hand, which leads to the *Rhododendron-tent*, which is of this form.

By entering at the south end the visitor has the opportunity of walking up the ascent to the top of the mound, and

D Borders.

then the full view of the bloom of *Rhododendrons* is displayed before him. Every plant was full of flower, excepting a few of the later kinds. The show was truly splendid. The blooms were protected by a covering of Britain's three-fold netting, which shaded them from the sun, kept the bees out, and sheltered them from heavy rains and strong winds. Mr. Yates remarked that this netting was better than any other covering he had tried, the wind having less hold of it than either canvass or tiffany. As a summer protection for greenhouse plants such a tent is invaluable. He states, also, that with care in taking it down off the framework and putting it away quite dry in a dry room, it would last many years. He thus it of great service in protecting the rather tender varieties from frost.
