HEN laying the foundation of those chapters which from time to time have appeared in THE JOURNAL OF HORTICULTURE, it was part of our plan to sum up with a brief dissertation for the benefit of small growers whose accommodation for plant-culture is of a limited character. Such parties, doubtless, find themselves occasionally not a little perplexed at some unforeseen and unexpected difficulty that may arise when success has all but crowned their efforts. Such difficulties, forsooth, do not always vanish at the bidding of even the most successful cultivator.

"The best-laid schemes of mice and men  
Gang aft a-gae."

The best practical skill at all times will not be surety for the prevention of the inroads of a host of little maladies. All the essays that have flowed from the pens of the best literary and practical gardeners on this or any other subject, all the preventive measures and means and all the cures which have been recommended, supposing they were to be presented to the horticultural and horticultural-loving community in a tabular form, so as to be cognisable at a glance, will not be sufficiently elaborate in detail to come within the range of these little difficulties which perplex the amateur in the management of his pet plants and subjects.

Fully intending, then, to implement our bargain, we shall have something to say on the adaptability of houses containing miscellaneous subjects for the cultivation of the Camellia. In many cases, let it be understood, more depends upon the proper management of the plants located in the house than upon any malformation or inadaptability of the structure itself for retarding their proper development. It is far easier for persons of lymphatic disposition to make excuses for ill success than it is for them to persevere and surmount difficulties, and there is no end to this sort of thing if we allow ourselves to presuppose them.

To be successful in the growth and to promote the blooming propensities of this favourite flower, it requires at least three months' warm and moist temperature during the year towards aiding the perfect formation of the growing shoot. This, then, is the most cardinal point, practically speaking, for the amateur to consider in the annual routine of cultivation; and the first question that naturally arises is how to assist such development with the means at command. Putting your finger upon the map, you could point to a few places in our sea-girt homes, cold as the general character of our climate undoubtedly is, where Camellias grow and bloom out of doors—and accordingly in such a climate there will be little difficulty in inducing bud-formation with very limited means; but to those places where the thermometer descends almost to zero, substantial shelter must be afforded.

The greenhouse viney of the amateur is one of the best mediums for promoting their growth; for the artificial heat requisite to bring away the Vines, especially from the time the branches are partly developed until they are properly set and the berries beginning to swell, suits their wants to a nicety. This sort of house is particularly well suited for a great many of our fine popular foliage plants, which will present a very ornamental appearance under the shade of the Vine during summer, and is as well suited for the cultivation of the Camellia and Azalea, which in their turn, when the Vines are in their deciduous state, will ornament the house during the dull cheerless months of winter. It is worthy of observation that with such plants as these, if the amateur confines himself or herself to them, and a few others, such as Gloxinias, Achimenes, Cockscombs, and even Balsams, which could be put upon the shelves near the glass, and Fuchsias, which could be grown on until the middle of May in such a structure, and afterwards transferred to some arbour or sheltered place out of doors where they would bloom well—one could have a most interesting house during the year, and be nearly as successful in a cultural point of view as many good gardeners are with quadruple accommodation. Of course, it must be under the management of some one who is passionately fond of flowers, else failure will not be long in staring him in the face. If the Camellias, for example, are allowed to get too dry, off go the buds, probably not for some weeks after the damage has been done, and hence arise the surmises and wonder why the failure has occurred. The very same result may occur, but not so very readily, unless there be bad drainage and continual deluging, if they are kept too wet. It is not wisdom, as the most earnest of our amateur friends will not be slow to concede, to get a house stocked with plants, and then leave it at the mercy of some careless person, who may forget to do a great many things which he has been instructed to do. And yet how often is this the case! and how often are the consequences such as may induce the business man to pen some letter of inquiry to his friends at 162, Fleet Street, to know the cause of such mishap and the remedy! Prevention is not only better than cure among the great vegetable family, but is positively one of the smoothest roads to success. To be ever on the alert, and to have the knowledge to administer the proper antidote at the right time, is one of the greatest points in gardening.

Shade is very essential to the well-being of the Camellia, as has been indicated in former chapters, and should be an object of solicitude on the part of the amateur. If they are removed out of doors—a practice which we have abandoned, in consequence of such a continuation of heavy rains—it must be in some place sheltered from the more scorching rays of the sun; and the only attention requisite is to water them when necessary, and to keep their foliage clean so that their stomates may be in perfect working order.

Cleanliness is another very grand point in cultivation. More failures result from inattention to this apparently

simple matter than most people would credit. Sparging must be occasionally resorted to; and if scale should by any means have found their way among them, a little soft soap diluted in water about 180° will soon effect a riddance. Thrips do not often make an attack on *Camellia* collections unless among those which are all but totally miaguided, but frequent syringings and occasional fumigation will effect a remedy. Houses of a mixed character, albeit, are far more liable to be attacked with this pest, especially where *Azaleas* dwell, than any other; and our remarks would almost require qualification, only remember "prevention," and begin to effect a cure forthwith. The mealy bug is by far the most insidious pest of them all, and requires constant vigilance—once allowed to get in amongst a collection of any kind of plants it is very difficult to keep under. Gishurst Compound is one of the best means of reducing these marauders, but it requires to be frequently applied; and, as has been suggested in the pages of this Journal, it should be reduced into a liquid state and allowed to remain twenty-four hours before application, which has the effect of nullifying that peculiar and disagreeable tint which remains upon the plants if applied immediately after liquefaction. In the words of the proverb, "It is a good servant but a bad master," and positively it is a good antidote and preventive to most insects.

In the wintering of the plants in the greenhouseinery, they may be kept as cool as you please, only remember 32°, the freezing-point. It is a great mistake which has been frequently practised by gardeners, and the more ready to be accepted as high-class gardening by amateurs, to allow Vines to be subjected to frost on the plea of giving them a proper rest. No good authority on Grape-growing will maintain that to do so is sound practice; and no good authority on vegetable physiology will maintain that it is necessary towards the resting period to allow the sap, dormant though it be, to become frozen. The temperature suitable for resting the Vine is also suitable for the blooming period of the *Camellia*, only the amateur would require to study that the moisture of the house should never be in excess of proportion to the heat, else sporting of choice flowers will take place, which effectually mars their beauty. This is a rule that ought to be observed throughout the season where flowering plants are in the highest consideration, no matter what the temperature of the house may be. Artificial heat in this miscellaneous house should be given according to the severity or "openness" of the weather. It is a great mistake, which cannot be too loudly proclaimed to all your subordinates, to keep the thermometer at a certain heat all weather. Regulate the amount of heat in proportion to the amount of cold; 33° is a very good temperature in such a house, if the thermometer indicates zero out of doors. Twice within the last two years has it fallen under this point in this locality and many others besides, and this is why we particularise the minimum amount of heat for all in-door ornamental plants.

In the mixed greenhouse proper, a great many hints embodied in the above remarks will be found suitable; and in the general treatise contained in former chapters throughout, much may be deduced by the careful reader and the anxious amateur which will help them over some of their difficulties. A great deal is to be learned by one's own experience in the exact position in which the plants may be individually placed; but, as a rule, more out-of-the-way and anomalous things occur from an infringement of sound practice than from any other cause. In this house it will be requisite at bud-setting time to have all the plants in one position in the house, where ventilation must be only occasional, and where you can ply the syringe without interfering with the flowering plants. It is absolutely necessary, at this time in particular, to keep the young growths from the intensity of the sun, and it is as absolutely necessary to keep the atmosphere at that point as moist as possible to be in the highest degree successful. Once buds are properly formed, a very moderate share of attention will serve; but it is really worth all the extra attention you can give, and all the lecturing we could imagine, to administer to their wants for the sake of the beautiful flowers.

If bud-dropping takes place afterwards it must be the fault either of the drainage, the soil, the moisture, the locality of the plants themselves, all of which it is in your power to prevent if proper means be used.

One more reminder and I have done. Let the plants have all the light at your command, and keep them as near the glass as possible, so that the lower branches may not suffer by comparison with the higher ones. This is sound advice, although

my right-hand neighbour may turn upon me and say that he has flowers and plants quite equal to mine without all this fatherly advice. We have no inclination to rebut the statement, but it is a question whether plants in such a position will always maintain so satisfactory a character.—JAS. ANDERSON, *Meadow Bank, Uddingstone.*

## CRYSTAL PALACE FRUIT AND FLOWER SHOW.

SEPTEMBER 4TH AND 5TH.

THIS was a thoroughly good September show. Dahlias were grand indeed; and the grandest Dahlia there, after Lord "Darby" and Charles Turner, was an immense dark purple one called Donald Beaton. You have only to put Charles Turner in the centre, Lord Derby on his right, and Donald Beaton on his left, and you will have nothing left to desire but that all the world would agree and be as agreeable as these three Dahlias would be when so put. It was in the high collection of Mr. Keynes, of Salisbury; and if it were only for these three noble and most agreeably honourable names and flowers, that collection ought to have had the first instead of the second prize.

The next most remarkable Dahlia there was a light French lilacy flower with pale blue lacing all over the edges, as in Lady Eleho's style of Picotee. This was from Mrs. James Stoddard, the only lady I have ever seen or heard of who by nature a thorough Geranium florist; and Mrs. Stoddard has a stand for these and all her flowers immediately on the right side, or on the west side of the great Handel Orchestra. Only go and see them, and if you do not find them as I say I shall pay for the journey, be it from Caitness or from Cork. And the third most remarkable Dahlia there was mucronate with pure gold, to speak botanically. When a leaf ends in a sharp point or bristle, botanists say it is mucronate instead of it will prick you. Well, the points of all the forets of this most remarkable Dahlia are a little peaked as one might say, and that will do for mucronate. The very peaks are of the colour of refined gold, but the merest specks only—they stand as regularly as anything in Euclid; and the ground colour of the Dahlia is a rich new shade of scarlet with a tinge of cerise or magenta in it. The name is Gem (Stafford), and it was exhibited by Mr. Sladden, of Ash, near Sandwich.

I must next blow the horn and sound "the Campbells are Coming" in the cause and interest of all the best men in the three kingdoms, and in the islands of Jersey and Guernsey, at raising, growing, rearing-up, and dressing the *Chrysanthemum*. The Campbells are coming upon them as sure as you or I was ever born. The growers of the China Asters—the Sandford Brothers, and Mr. Betteridge, of Meldon Hill, Steventon, Berks, are on the eve of becoming just as formidable rivals to *Chrysanthemum*-growers as ever the Campbells were to the rest of the clans or to the government of His Majesty the King. I recollect the very night before Mr. Sandford, gardener to T. Thomaset, Esq., Walthamstow, was born, his father being my foreman at the time, and I had to ring the bell and answer it myself for the rest of the day. Well, this is the sixth occasion in succession in which he has taken the first prize for French Asters; and his brother came up this time very hard upon Mr. Betteridge, who has been equally successful with the German or Quilled, or rather, now, honey-combed Asters.

The flat floretless Asters are the French; and now they have them in globes and evenly flat over the face, also recurved, and quite as much so as the globes, flats, and recurves of the *Chrysanthemum*. If you recollect the old *Chrysanthemum Lucidum*, it was about the first and the best recurved flower we had at that time; and the white incurved Asters are, or were, in Mr. Sandford's first-prize collection exactly of the same size, shape, and substance as that *Lucidum*. Like once a boy always a boy, the brothers Sandford are still my boys, and, of course, they tell me all about the Asters, and how they do them; but it is all a natural gift they inherited from their father. They buy the seeds every year from the Messrs. Fraser, of Lea Bridge Nursery; and all who do the like have the chances the same, but not the gift of inheritance, and that makes all the difference.

On the other side of the line of the Asters, comes Mr. James Betteridge aforesaid, whom I have never seen to my knowledge, but I should like a leaf out of his knowledge of German Asters. The busy bee does not more mathematically construct her cells and her royal chambers, than does Mr. Betteridge the floretless tubes of the quilled Asters—all but one row, or

ray of them; and that row is the outside row, which has one-half of the floret to each tube; and these half-florets in a ray all round the flower are technically termed the "guard petals," and the guard petals of the quilled Asters are now of as much importance to them as the Horse Guards are to us and ours.

Gladioluses were the flower of the day for half the thousands who thronged the glades and avenues of the arrangement for fruit and flowers on the present occasion; and it was a game I have often seen played in the theatre at Perth, to which I one winter had a free ticket. The manager of the theatre and his party had flowers and free admission at the Messrs. Dickson and Turnbull's nurseries, and a lot of us both men had these free tickets from Mr. Bell and Mr. Brown, the then foremen. Perth at that time was the natural residence, as it were, of all the best of the half-pay officers and bachelors in Scotland; and when they mustered in full, or bespoke a play, we nursery chaps were sure to be in that night to see that part of the play called "A Bold Stroke for a Wife," and it was that part of the play which was played at this Show: t the Crystal Palace. It made one laugh, of course; but I will just tell you what it is. There is nothing in this world, or in Perth yet, better than a bold stroke for a wife, or for any mortal thing. If you "go in" sheepish about it, you will lose as surely as you ever lost a hand at whist.

Mr. Youell, of Yarmouth, got the first prize for Gladioluses from the best judges of the flower in the land, from merely playing a bold stroke for a first-hand prize. The schedule for Gladioluses was on the free-trade principle, so you might put up ten spikes, or five spikes, or three, or two, or one of each kind. The more usual way was to chance it with one spike only; and when you wanted to make a blaze for fame and for fortune, to put up lots of bunches of spikes, and to send them in gratis for the good of the house or the concern, and all the customers, and say nought about it, which would make the blaze burn the brighter in the scented satin note-books of the well-to-do, and you had your reward, if not an award, for the flowers. I would, therefore, hint to Mr. Houghton, that, as these flowers are the sword Lilies, that each party should know beforehand how many swords he would be allowed in the battle, so that the south and the north of the Thames, or of the Tweed, I mean, should enter the field on equal terms.

Mr. Youell put up his sword Lilies in threes of each kind; and at either end of his collection, on both sides of one corner of the transept, he placed three rows of threes, and eight in a row, of the spikes of Gladiolus Brenehleyensis—that is, three times eight spikes at this end, and ditto at the other—a bold stroke for a prize. The general collection was in three spikes, in addition to the guard array of Brenehleyensis, while the rest had no guard, and only one spike of each kind in the collections. We are all so fond of playing at swords in these days, that the visitors went all in with Mr. Youell, hand and glove, in the sword Lilies.

Then, if I were Mr. Houghton, whose kindness and prompt attention I all so much admire at these Shows, I would take that as an indication of coming events, and I would arrange the schedule for the next throw at swords of Lilies, so that all might put up so many of a sort, not exceeding a certain number. Then be it three spikes, or four spikes, or two only, be it so; and if you or I happened to have but one spike of any new kind, of course we would be entitled to set it up as part of our collection, at our own risk. I would also make it open for each exhibitor to put up in addition a certain number of spikes of two, three, or more kinds of any of the more popular varieties, just as Mr. Youell put up his splendid groups of Brenehleyensis, but not give them a prize as is now given for the baskets of twelve pounds of grapes.

The most royal lady-like Gladiolus there was Mrs. Standish, a pure pearly white flower, but tinged all over from the reflection of the rose-and-crimson markings of the front sepals, to be botanical. The next lady in the land with us all, after Her Majesty the Queen, is Gladiolus Reine Victoria, then Alice Grey, and following it Lady Mary Wood. The four are in the same strain and not much different in their degrees of merit. Miss Howell, a rosy salmon; and Lady E. Seymour, a rosy cream, are the best in the next shade from white. Edith Dombain is a lovely warm colour, a creamy ground colour tinged all over with the blush of bashfulness. Madame Rabourdin is another out-of-the-way colour—a fine flower, the nearest tint to a lilac yet in the family, with a richly-marked front. Mrs. Menzies, Eugène, Basil, Rosenberg, a new colour, a crimson cerise, and Garibaldi, are all splendid flowers. Napoleon III., a bright orange scarlet; and Ensigen, ditto, are two very gay flowers. Pluto seemed the

best of the Ramosus strain bred down from Colvilli. Couranti Fulgens was the darkest there; and Vulcan the next. Vesta, Penelope, Hebe, Madame de Vetry, Isoline, Impératrice, and Ninon de l'Enelos, would make a group or bed of nearly all white sorts; or a bed of Penelope alone for a white might be better. Canary would make a good yellow group, row, or bed. Conite de Morny would also make the same in Cerise Unique colour, well lighted up with white markings; and Galathée would match a rosy Nosegys colour to a T, tinged as it is like them with shades of carmine. All this, recollect, is merely a flower-garden view of the family as there presented. If you want to follow the fancy, go to Deal and you will do well, my word for it. The very sea breeze down at Deal would put you in a better fit than all the fixings I could do for a whole season. But have it your own way, nevertheless, and I shall go on to the French Gladioluses, of which there was a very large assortment; but instead of them I shall put in a note of hand which I received at the last meeting of the Floral Committee, from three of our very best swordsmen in this line, who were over to see them, and who buy them in heaps, and who live by selling them to us and ours. That note begins and ends thus:—"We are all of us here in England just three years behind the French in Gladioluses. What you see brought over to our shores are as milk and water to their best sorts. Our prizes will not cover their expenses, but buy their five-shilling roots, and their roots at 3s. 6d., and you may take them without more ado, and you will be sure to do as you have been done by—you will beat as you were Beaton." I took all this as quietly as I now wrote it. But I want room some day for a paragraph to transfer my experience in crossing pure white flowers with scarlet and crimson ones, for the use and benefit of a rising race which is to go in to beat the Lilies.

This brings me to the best flower at this Show, the great Lilium auratum of Japan, which Mr. Standish brought out here just as Mr. Veitch did over the water. And here Mr. Standish had a second form of the flower—another variety of auratum, with all the spots on it of a bright rosy colour; and roseum punctatum, being a distinguishing name already for a variety of lancifolium, this one should also have roseum punctatum after auratum, so that all may know the extent and the meaning of the application of the name, instead of loading the memory by a new one which could not give the meaning for it one-half so well. But the roseum punctatum of this Auratum Lily is more manifest in the face of the flower than the same is seen in that variety of lancifolium.

Mr. Standish had also my favourite Japan golden netted-leaved Honeysuckle, which I mentioned as at the July Show of the Horticultural—Lonicera reticulata. But, by-the-by, have you seen the September Number of the *Florist and Pomologist*? These identical plants, *Lilium auratum* and *Lonicera reticulata*, are both figured, and the figures coloured in that Number; and instead of puzzling my brains to explain the extraordinary beauties of these plants, just order them to send you that; and the looks of the Lily itself are just worth double the money to any one who can enjoy and appreciate the beauties of a really fine flower. I shall, therefore, do the next best thing on my part, and that is to tell you a fact which is yet known to but a very few practicals. It is this: that this golden netted-leaved Honeysuckle, and all other variegations in climbers, or in permanent wall plants, should be seen on a north aspect, as the best place for seeing the effect, an east aspect the next best, a west aspect the next; and that no such plants should ever be put on a south aspect, as the glare destroys the whole of the effect, and, not only so, but makes it uncomfortable to a good eye, that being the key to what "D., Deal," told us the other day about the French avoiding such bright colours in their glaring atmosphere, as put ours in a tingling of delight in our northern aspect. So you see we are on the right side of the wall, as of the channel, for really enjoying the blessings of Providence.

The Hollyhocks and the Phloxes were not so fully or so well represented as I have seen them. But there were two collections of good spikes of Hollyhocks—the one from the Messrs. Downie, Laird, & Laing, the other from Mr. W. Paul, the author of the best treatise we have of their management; lots and lots of five-bunched trusses of Verbenas; and a bright scarlet Verbena, called Lord Leigh, from Messrs. Perkins & Sons, of Coventry, an excellent sort as far as one could judge from cut blooms. This promises to make a lordly bedder.

#### FRUIT.

We now come to fruit. The largest fruit there was a Cucumber from Mr. Poulter, gardener to G. Hooper, Esq., Lawrie

Park. It was the very Goliath of Lawrie Park. But the best gardening in fruit was a one-bunch-of-Grapes plant in a pot from the Rose Leviathan of Great Berkhamstead—Mr. Lane, and the kind was Mr. Ivery's Buckland Sweetwater. It was more than twice the size of the largest bunch I ever saw in a pot. The battle for the fruit was very severely contested; and our two best generals, Mr. Henderson, of Trentham, and Mr. Hill, Keele Hall, were beaten by a commander from Liverpool—Mr. Meredith, Vine Cottage, Garston, near Liverpool, who took the first sweep with the twelve-pounds basket, and the first for the best three bunches of Black Grapes. The battle was so closely contested that the ruling passion struck me at once, and I went over the field to see what might have led to the decision of the Judges; and I should take it that it must have been the uniform size of all the berries in all the bunches which sent the victory to Liverpool, for better Grapes were never yet exhibited than those from Staffordshire, which were both awarded the second prize.

Mr. Chapman, Hill House, Streatham, had the first prize for Queen Pines. His specimen was remarkable for a Queen, being as much across under the crown as at the bottom—a barrel shape, in fact. And the first-prize Pine, not a Queen, from Mr. Henderson, of Trentham, was also a remarkable fruit, not so much for the size as for the rich colour and for the fullness of all the pips which were next to bursting the skin.

For a Dessert Collection Mr. Henderson was first. For top he had a fine Montserrat Pine; for bottom a Trentham Hybrid whiteflesh Melon; and for the centre Peaches and Nectarines cross-covered one way, and White and Black Grapes crosswise to suit. The Grapes were magnificent Muscats of Alexandria ambered over with richness, and Mill Hill Hamburgs black as you please, and bloom on them to relieve it. The Peaches were *Violette Hâtive*, and the Nectarines *Elruge*. Mr. Bailey, of Shardloes, was the second-best competitor. *Enville Pine*, *Hamburgs* and *Muscats*, *Elruge Nectarines*, *Magdalen Peaches*, and *Moorpark Apricots*; but it would take a blue book to get them all in, and mine was only a brown one.

I saw one new move which pleased me much, and I really wondered that it never occurred to myself.

When I was an experimentalist in fruits twenty-eight years back I used to keep a memorandum of the size of the flowers of the Peaches and Nectarines. In the spring and in the autumn I sent fruit and leaves of them to Mr. Thompson, of Chiswick, with a note of the size of the flowers of each kind to save him trouble, because the size of the flowers and the glands at the bottom of the leaves is just like looking a gift horse in the mouth—you know the sort of the one and the age of the other that way. Mr. Cunningham, gardener to the Lord Bishop of London, sent Peaches and their leaves to this Show, in order that the Judges might not lose time about knowing the kinds; and if ever you have Peaches or Nectarines and want to know their names, do the like, and you will save some one a world of trouble; and if you learn nought else of this review of the Show, pray learn to be on the look-out when you mean to send fruit or flowers to be named. As for the rest of the fruit, it would actually fill an ordinary fruit-room and keep one in Apple-dumplings to May-day.

D. BEATON.

UNMISTAKEABLE proofs of the exceptional character of the season were afforded by the appearance of the flowers exhibited on this occasion. It was not to be expected after such a sunless summer, and the occasional storms and rains that we have experienced, that flowers which are so much influenced by weather as these autumn ones are should be seen in perfection; and although the Dahlias were wonderfully fine, and *Gladioluses* far better than I expected to see them, other flowers were inferior. Asters were certainly not what they have been for the last two years; *Hollyhocks* I never saw so bad, and *Roses* were miserable in the extreme. Yet, taken as a whole, the Exhibition, especially of fruit, was a wonderful one; and while Mr. Beaton discourses of its general features, I must add my impressions of those flowers which come under my own peculiar province. I never saw a season so fatal to the *Hollyhock* as this has been. I do not mean merely as to growth (and many of them have gone off very rapidly), but as to the absolute ruin caused by the rain. About a fortnight ago we had a very heavy and continuous down-pour, lasting, in some places, thirty-six, in others, fifty hours; and after it the splendid spikes of *Hollyhocks* were absolutely melted together. This, which I had observed in my own garden

was confirmed by Mr. Laing, of Stanstead Park, and Mr. George Paul; while my friend Mr. Chater has fared no better. Under such circumstances, it would be only misleading to give the names of flowers; for probably exigency, and not choice, led to the selection. From what I have been able to observe in my own garden, I think Joshua Clarke the finest *Hollyhock* I ever saw, not excepting, perhaps, Stanstead Rival. *Roses*, as I have said, were miserable; and the state of the season can best be judged by the fact of such stands being set up by men who grow them by acres. The best 24, and there were none of them in character, were contributed by Messrs. Paul & Son, of the Old Nurseries, Cheshunt, and contained *Louise Peronne*, *Léon des Combats*, *Souvenir de la Reine de l'Angleterre*, *Souvenir d'un Ami*, *Archbishop of Paris*, *Colonel de Rougemont*, *Gloire de Santenay*, *Comtesse Cécile de Chabillant*, *Dr. Bretonneau*, *Souvenir de la Malmaison*, *Victor Verdier*, *Mademoiselle Eugénie Verdier*, *Pauline Villot*, *Belle de Bourg-la-Reine*, *Duke of Cambridge*, *Céline Forestier*, *Madame Charles Crapelet*, and *Madame Vidot*.

*Gladioli* formed one of the leading features of the Exhibition, and were contributed by Messrs. Youell and Co., of Great Yarmouth; Mr. John Standish, of Bagshot; Messrs. Carter & Co., of High Holborn; Messrs. Paul & Son, of Cheshunt; Mr. W. Paul, of Waltham Cross; and a very large collection by Monsieur Loise, 3, Rue de la Paterie, Paris. The most noticeable of these were the two first; Messrs. Youell's being composed mainly of varieties of foreign origin, and Mr. Standish's of his own seedlings. Some alteration is needed, and, I believe, will be made, in the exhibition of this fine autumn flower; for it is impossible to know how to exhibit, and equally so for any amateur to do so. This has arisen, I know, from the feeling that so few persons grow them, that it was desirable to get as many as could be. But the case is altered now, and the increased popularity of the flower will enable the authorities to divide them into two classes—for amateurs and growers for sale, as in other flowers; and we shall then, I believe, see a much more numerous and varied selection than at present is exhibited. When a grower advertises having three acres under *Gladioluses*, what hope can a poor amateur have of competing with him when he is enabled to cut such "wisps" of blooms as Messrs. Youell did yesterday? My own taste is decidedly against such a method of exhibiting them. One bunch hides the other, and there is not the same possibility of judging of the individual merits of a flower. What would be thought of exhibiting *Asters*, *Hollyhocks*, or *Dahlias* in bunches?

The most remarkable in this large collection were *Brenchleyensis* (by-the-by, I do not think this is half so brilliant as I recollect it when it used to be shown as an intense glowing scarlet without any green in it), *Advocate*, *John Bull* (why name a light-coloured flower with a name so redolent of fresh colour and portly person?) *Hebe*, *Linné*, *Mademoiselle Eugénie Verdier*, *Pegasus*, *Don Juan*, *Madame Binder*, *Princess Mathilde*, *Clemence*, *Lælia*, *Dr. André*, *Egerie*, *Achille* (a lovely flower, the colour an exquisite currant colour), *Duc de Malakoff*, *Pegasus*, *Othello*, *Vulcan* (very dark, but badly shaped), *Isoline*, *Striped Queen*, *Galathée*, *Penelope*, *Mons. Keteleer*, *Helen*, *Daphne*, *Aristotle*, *Endymion*, *Comte de Moray*, *Vesta* (white, with violet purple blotches), *Le Poussin* (clear red, lower petals blotched with white), *Madame Rabourdin* (white, with large blotches of rosy carmine), *Pluton* (deep scarlet), *Isoline*, *Goliath*, *Solfaterre* (bright yellow), *Madame Leseble* (pure white, striped with carmine), *Courant*, *Fulgens*, *El Dorado* (pure yellow, lower petals striped with red), *Aglæa*, *Osiris* (violet purple, a curious shade of colour).

Mr. Standish had a fine collection mainly of his own seedlings, including *Basil*; *General Cabrera*, dark red; *Lady E. Seymour*, pale buff; *Guido*, vermilion red, yellow throat; *Mr. Menzies*; *Eugène Domage*, rich crimson, dark-coloured throat; *Lady M. Hood*; *Daphne*; *Whipper-in*; *Mrs. Standish*, pure white, with feathers; *Rosenberg*, deep scarlet blood colour; *Mrs. Peach*; *Belle of Bagshot*, beautiful white; *Elfin*; *Earl Carlisle*, bright rose, deep lake feathers; *Adèle Souchet*; *Bacchus*, light crimson; *Rose of England*; *Adam Bede*, peach, deep scarlet lower petals; *Don Juan*; *Mrs. Siddons*; *Reine Victoria*, large and fine white; *Sir I. Newton*; *Edith Dombrain*, beautiful delicate fawn colour; *Alice Gray*; *The Cardinal*; *Donald Beaton*; *Lady Marhead*, very dark; *J. W. Lane*, fine; *The Ensign*; *Miss Howell*, beautiful light peach; *Miss Glegg*; *Oberon*; *The Dauphin*, and *Mademoiselle Patti*.

Amongst the other stands were some very fine flowers; while

the French collection before alluded to was remarkable for its great variety. The flowers were small, and by no means so well done as our English ones.

Dahlias were exhibited in considerable numbers. There being in the class for 12 blooms (Amateurs), twenty-nine competitors the higher numbers had, of course, fewer entries. The best flower in the Show I thought to be Pope's Lord Derby. It was exhibited in many of the stands, and some of the blooms were of surpassing excellence, while the most taking flower was a fancy Stafford's Gem, a lovely light crimson with a golden tip to each petal, which gave it a most attractive appearance, and made it very distinct in character.

In 48 Dahlias (Nurserymen), the race was of a neck and neck character, Mr. Turner winning by half a length. His flowers were Bob Ridley, Delicata, George Brown, Golden Drop, Andrew Dodds, Umpire, Warrior, Juno, Lord Dundreary (new seedling), Norfolk Hero, Mrs. H. Vyse, Cherub, Marquis of Bowmont, Chairman, Jenny Austin, Mr. Stocken, Mrs. Pigott, Mr. Boshell, Sir George Douglas, Lord Eversley, Miss Pressley, Lord Derby (a glorious flower), Duke of Wellington, Perfection, Hugh Miller (very fine), Dinorah, Pluto, Hope, Volunteer, Pioneer, Lady Elcho, Lord Cardigan, Ivy, Capt. Harvey, Cygnet, Chieftain, Sidney Herbert, Model, Commander, Hon. Mrs. Trotter, Madge Wildfire, Goldfinder, Earl of Shaftesbury, Lord Palmerston, Lady Franklin, Criterion, and Lady Popham.

In 24's Mr. Turner was again first with Earl of Shaftesbury, Marquis of Bowmont, George Brown, Mr. Stocken, Golden Drop, Bob Ridley, Mrs. H. Vyse, Mrs. H. Pigott, Model, Hugh Miller, Andrew Dodds, Lady Popham, Lord Derby, Umpire, Chieftain, Norfolk Hero, Mrs. Bush, Lord Dundreary, Lord Palmerston, Cygnet, Capt. Harvey, Criterion, Pioneer, and Delicata.

In 12 Fancies Mr. Keynes, of Salisbury, was first with fine blooms of Harlequin, Elegance, Miss Jones, Countess of Bective, Queen Mab, Mrs. Crisp, Pauline, Confidence, Nora Creina, Starlight, Lady Paxton, Madam Sherrington.

In class of 24 blooms (Amateurs), Mr. Corp, of Milford, Salisbury, was first with Jenny Austin, Lady Elcho, Sidney Herbert, Hugh Miller, Andrew Dodds, Lady Popham, Baron Taunton, Earl of Shaftesbury, Maria Carter, Donald Beaton, Mrs. C. Waters, King of Sweden, Juno, Lord Palmerston, Chairman, Emperor, Mr. Boshell, Pioneer, Peri, Lilac Queen, Mr. Critchett, Marquis of Bowmont, Lady Franklin, and Sir J. Oatram.

In 12's, the first prize was awarded to Mr. H. Thorneycroft, Floore, near Weedon, for Chairman, Cherub, Earl of Shaftesbury, Hugh Miller, Lord Derby, Jenny Austin, Hon. Mrs. Trotter, Golden Drop, George Elliot, Admiral Dundas, Lord Cardigan, and Umpire; while my friend Mr. Sladden, of Ash, took third with Juno, Mrs. Dodds, Beauty of Hilperton, Hugh Miller, Lord Cardigan, Chairman, Sidney Herbert, Marquis of Bowmont, Lord Bath, Andrew Dodds, Earl of Shaftesbury, and Dinorah. He was also good with 12 Fancies, having good blooms of Queen Mab, Lord Stanley, Jessie, Summeride, Mrs. Crisp, William Corp, Elegance, Gem, Confidence, Madame Alboni, and Lady Paxton.

Phloxes were not first-rate, and I believe never will be anything but rubbishy at a show, as they shatter so soon.

Verbenas were shown, considering the season, in good condition by Mr. Turner, of Slough, Mr. Smith, of Hornsey Road, and others. Mr. Turner took the first prize with Gen. Simpson, Kathleen, King of Verbenas, Madame Herman Steiger, Anglaise, Springfield Rival, Nemesis, Snowflake, Foxhunter, Delicatisimum, Lady Taunton, Firefly, Great Eastern, La Gloire, Lady Seymour, Ariosto Improved, Lady Middleton, Rose Imperial, Prima Donna, Warrior, Lord Elgin, Géant des Batailles, Zampa, and Fireball.

One cannot close without referring to the splendid *Lilium auratum* from Mr. Standish, about which Mr. Beaton will have a say, as there seem to be at least two varieties of it. There was also a collection of *Helichrysum* from Mr. Cattell, of West-terham.

As usual, everything was done to contribute to the comfort of all concerned, and a fine day brought a large number of visitors, the grounds looking very beautiful, and leading consequently to many somewhat caustic remarks on the gardens at Kensington Gore. Certainly there is no place which one can show to our French neighbours with so much real satisfaction (arising, I suppose, from the consciousness that they have nothing like it), as the Crystal Palace.—D., Deal.

## A NEW AMARANTHUS TRICOLOR.

MR. ROBSON has written in praise of *A. melancholicus ruber*, lately introduced by Mr. Veitch from Japan, and now growing in the gardens of the Royal Horticultural Society. He seems to think the name more grave than appropriate. I must say I think it deserves its name, for it is of a very melancholy red indeed.

But leaving *A. melancholicus* to stand on its own merits, I beg to bring to the notice of your readers another *Amaranthus*—viz., *A. tricolor*. It is one of the most beautiful variegated plants I have ever seen. There has been an *A. tricolor* advertised in catalogues, and, doubtless, some of our readers may have tried it and been disappointed. The seed of this of which I am writing was brought from Italy only a year or two ago, and though not always true from seed in the open air, sown in gentle heat sufficient plants can be obtained true. I understand that Messrs. Carter, at whose nursery at Sydenham I saw it, are reluctant to bring it forward, as they have for years advertised an *A. tricolor* in their catalogue—a very dingy affair indeed, and not at all to be compared to the new one. The plants of the new kind which I saw were in pots, about 10 inches high. The leaves are formed of exactly three colours—green veined with red at the tips; middle, blood red shot with green; the base, stalk, and stem of the most delicate cream colour, slightly veined here and there with red, forming one of the most perfect and effective combinations of three colours.

As variegated plants are Mr. Beaton's special *protégés*, he being the person who first drew public attention to them, I hope he will have an opportunity of seeing this one, and I am sure he will endorse all that I have said in favour of the new *Amaranthus tricolor*.—F. W. ADEY, *Merkgate Cell*.

## NOTES WHILST RESTING.

(Continued from page 432.)

THE Roman agriculturists sneered at their brethren of the garden, saying that like bacon it was only fit for perpetual slices—that is, I presume, that there were no great returns. They would have said the same of the Guernsey farming. But this and gardening may retort with the proverb, "Many a pickle makes a mickle;" for the Guernsey farms, like our gardens, return a large annual amount of produce in the aggregate. I believe among that produce no equal space in the world yields so much butter and milk, and that nowhere could so many cows be found upon a square mile.

Now, for the winter keep of those cows a large supply of Parsnips, Mangold Wurtzel, and other moist food is needed, and as the manure the cows produce is deposited almost solely upon the grass whereon they are tethered, the question naturally arises, Whence comes the manure for the root crops; sheep, horses, and pigs being so few that there may be said to be no other stock than cows on the island?

That manure is found solely in the *Vraic*, or seaweed, and it is of such vital importance to these islanders that it is placed under special governmental regulations. Without it the island would be nearly unproductive, and it more deserves from the inhabitants the name of *Corban*—a gift—a providential gift, which they bestowed upon the Vazon peat, rather than the inappropriate name *Vraic*, which means no more than wreckage. So well impressed are the islanders with the value of the seaweeds as a manure, that they have a saying—*Point de Vraic, point de hautgard* (No seaweed, no cornyard).

Whether right or wrong in their conclusion, it is nevertheless certain that these island cultivators value only the brown, or rather olive-coloured seaweeds; they neglect the green-coloured, but this may be only because of their comparative deficiency in quantity.

The olive-coloured seaweeds extend from high-water mark to one or two fathoms beyond low-water mark, and are chiefly of the genus *Fucus*—namely, *nodosus*, *canaliculatus*, *vesiculosus*, and *serratus*. *Laminaria digitata*, Sea Tangle or Oarweed, however, supplies much, its fronds being sometimes 8 feet in length and 2 feet in breadth; whilst *Laminaria bulbosa* is sometimes torn up from its home in deep water, and thrown in stormy weather upon the south-western coast, and is a prize to the vrazier, for its large bulb and wide-spread frond are quite a man's load.

There are two states in which seaweed is obtained. When it is floating and thrown ashore it is called *Vraic venet*, and may be collected whenever found; but when it is reaped or cut with

a small billhook it is called *Vraic scic*, and must be collected only at times appointed by the island regulations.

One load of reaped *Vraic* is considered by the islanders equal as a manure to full two loads of the floating. About two or three loads of the former, and from four to five loads of the latter, are considered necessary for manuring efficiently one *vergee* of land.\*

I copy the following from the published observations of a native Guernseyman. "The *Vraic venant* is used almost exclusively as manure, whilst the *Vraic scic* is first used as fuel; the poorer inhabitants, unable to afford coal or to obtain wood, relying upon this provision throughout the winter. The ashes are used as a manure, twenty bushels of them being the most approved allowance for one *vergee*." The ashes, I may observe, are preferred by the islanders for Barley, and, I think, for other corn crops; but for all other cultivated vegetables the *Vraic* itself is alone applied, and the fresher and wetter with sea-water the more beneficial it is considered.

"The *Vraicing* harvests are fixed by the island legislature, the winter harvest commencing at the spring tide of the first new or full moon after Candlemas Day (Feb. 1), and continuing to the 15th of March. The summer harvest, beginning on the second spring tide after the 24th of June, and continuing during two moons, produces what is considered the most fertilising harvest of seaweeds.

"That every class may share equally the benefit of these harvests, poor persons, possessing neither horse nor cart, are allowed exclusively to cut the *Vraic* during eight days of the first spring tide immediately preceding the summer harvest, provided they carry it on their backs to the beach.

"These restrictions apply only to the *Vraic scic*. The rules relating to the *Vraic venant* allow all persons throughout the year to mark, rake, or cart it away, from sunrise to sunset, with the addition that in the winter months the time is extended till eight o'clock in the evening.

"The manner of cutting and gathering in the *Vraic scic* is amusing even to those who are not strangers to the practice. On the mornings of the days appointed for this harvest, thousands of the country people, old and young, male and female, uniting in companies of two or three families, some with their carts, and others with horses bearing strong panniers, slung on each side, proceed joyously to the beaches, and, as the tide recedes, scatter themselves on the different rocks—the boldest, either in a boat, or on foot or horseback, wading to rocks where they consider the *Vraic* is thickest and longest—and begin to cut away in right good earnest, collecting it in heaps, upon which they place a smooth stone chalked with their initials. Thus they continue collecting the *Vraic* until the tide begins to flow, when the men carry it on horseback at full speed either to the beach above high-water mark, or to the carts belonging to their respective companies, which are in waiting as low down in the bays as the nature of the ground will permit.

"The gathering of the *Vraic venant*, though much briefer, is quite as exhilarating. It may be gathered either by marking or raking. When by *marking*, after a gale has thrown much on the shore, the neighbouring country people hasten to the spot before sunrise, each armed with a three-tined fork, and each posting himself where he thinks the most *Vraic* is to be secured. They wait for the sun's rising, watching until one of the company raises his fork as a signal, when they set to work with all their might, collecting the *Vraic* into little heaps, and cart these away as the tide compels them. The *raking* mode of collecting *Vraic* is adopted when the tide is up at sunrise, or at any other time when it ebbs. This is done mostly in stormy weather. Where the *Vraic* happens to be abundant, sometimes forty or fifty men may be seen in a space of as many yards, up to their middle in the water, extending large rakes as far as they can reach, and dragging ashore by their aid masses of the *Vraic* beyond the reach of the waves.

"It has been ascertained that nearly 24,000 loads of *Vraic venant*, each worth, on the beach, 2s. per load; and about 1200 loads of *Vraic scic*, each worth 12s., are thus obtained annually."

No better testimony of the fertilising powers of seaweed could be rendered than by the entire of the field and garden crops of this island. They are all vigorous and abundantly productive. Especially as evidence let the Mangold Wurtzel, Potatoes, and Parsnips produced around Vazon Bay be accepted. The soil

\* A *vergee* contains 40 perches, and 2½ *vergees* are rather more than an English acre.

there is merely a drifting sea-sand, yet I saw Mangold and Parsnips, a full average in size; and the Potatoes, though small, abundant, the return obtained by a large application of *Vraic*.

As I have already noted, it is preferred to be applied quite fresh, is dug or ploughed-in as long stable dung would be in England, and at the time of inserting the crop next to be grown.

It is not difficult to explain how seaweeds are so beneficial on the light soils of Guernsey. The salts those weeds contain, such as the chlorides of calcium and magnesium, absorb moisture from the air, and keep the soil healthfully damp for vegetation, even in the driest season. Others of the salts which they contain, phosphate of lime and chloride of sodium, enter into the composition of cultivated crops, and so does the carbon of the seaweeds. It is true that their carbon is small in quantity, but it is quite enough for the demands of one crop, and, as to each in succession fresh seaweed is applied, the supply is constantly maintained.

The cows in this island being universally tethered, they have no opportunity of following the example of their order in the Isles of Jura and Skye, where the cows come down regularly at the ebb-tide, and browse on the *Fucus vesiculosus* left uncovered by the water. In Gotthland the peasants boil it, mix with it a little meal, and give it to their pigs. In Jura, and others of the Hebrides, the cheeses are not salted, but are covered with the ashes of this plant, which impart to the cheese a sufficiently saline flavour. I do not find that the Guernseyers apply this *Fucus* to any such purpose; but Mrs. Carey, of that beautiful spot the Vallon, puts the vesicles, or bladders, of the plant into rum, which forms from them a thick jelly, having a high repute among her colder neighbours, as a curative application to wounds, rheumatism, and glandular swellings.

*Rhodomelia palmata*, the *Dulse* of the Scotch, is abundant in places on the Guernsey rocks: indeed, one variety of it was mistaken by Mertens for a species, and called by him *Fucus sartiensis*, or Guernsey *Fucus*. It is not employed here as a food, as it is in Scotland and Ireland, and as it was by Soyer in preparing his "St. Patrick's Soup" for the starving Irish.—*QUIS.*

(To be continued.)

## HOW TO USE LIQUID MANURE.

I SHOULD like to see a few words in your paper on the right use of liquid manure. The drainage of my house and stable is received, together with the rainfall on a yard and part of the house, in a tank. With the liquid contents of this tank, in my first experiments, I managed to kill four trees lately planted in the orchard, and to cauter the survivors. Pyramidal Pears were found to shed their blossom on its approach, and the young shoots of Rose trees had their points scorched. In this way I was convinced of its potency; and, at the same time, learned not to apply liquid manure in April before the growing rootlets have gained a little strength.

Will you tell me during what months it may be safely applied to Roses and small garden fruit trees, Cherries, Pears, Apples, &c.; at what season the dose should be the strongest, and when the supply should diminish? Is it altogether injurious to such trees in winter, or to full-grown orchard trees, or to Asparagus and Strawberries in the same season? Strawberries seem most enriched by it. Six dressings in spring brought a magnificent crop, and the corner which was double-dressed was the most fruitful. Is it of use to Strawberries in September, or to fruit trees after the crop has been gathered? Let us have a lecture, not on the value but on the judicious application of liquid manure.

Two maiden Apples, planted among my Strawberries, have been half killed with aphids. I attribute this attack to the manure water. Some plants there are more capable of benefit in this way than others.

As there is much water carried into the tank with the drainage, I dilute it with water, half and half.—*WYESIDE.*

[There are but two rules requiring attention as guides for applying liquid manure:—1, Do not apply it too strong; 2, Apply it only when the plant is growing.

1. It cannot well be too strong when applied to the soil of Cabbage-beds, Rhubarb, Asparagus, and other plants which cannot be too luxuriant, one bucketful of sewage to two bucketfuls of water would not be too much; but for Roses, fruit trees, and other plants which are required to produce flowers and fruit as

well as vigorous foliage, the liquid manure should be very much diluted. It is quite impossible to state absolutely how much water should be added to the sewage of a house, for this must depend upon the number of the inmates and other circumstances; but we never knew such sewage rendered too weak for either flowering or fruiting plants by mixing four bucketfuls of water to one bucketful of the sewage. For potted plants twice the quantity of water would be nearer correctness—weak and often is the best rule in all cases.

2. It is perilous applying it to newly-planted trees or plants of any kind; and is useless or injurious if applied when they are at rest, as in winter. We will vouch for its not having caused canker in your fruit trees; but applied either too strong or when newly-planted it might make them shed their leaves, or even kill them.

From March to September, or later to growing Cabbageworts, is the period of application to out-of-door plants. If the liquid manure made your maiden Apple trees sickly, it would promote their liability to be attacked by aphides.]

“TIS VERY GOOD, BUT MUST BE  
CIRCUMSTANC'D.”—SHAKSPEARE.

I WILLINGLY give you credit for seeking to make your paper useful as well as entertaining; but it occurs to me that you would more effectively do this, and at the same time avoid creating disappointment, were you to urge upon your contributors and correspondents fulness and precision in their statements.

Not very long ago there occurred a glowing account of the wonderful crop of Peaches which the writer gathered from trees planted the previous season. And in last week's Number there is a similar account of the success attending the efforts of a lady with her Peach trees grown in a beautifully painted and paved orchard-house, where it is stated that the first season she gathered a fine crop. Now, both accounts, in my humble estimation, are calculated to mislead. What do the authors mean by “previous” and “first” season? There is something more than the time of planting involved; there is the age of the trees as well; and no mention is made of that—how old they were from the graft in the one instance, and how long they had been grown in the pots in the other. That I think was an important point to have explained.

Communications such as these are only valuable as they give precise information on all the details affecting the individual cases, and not merely the results, leaving out of view the several previous years of careful culture, which I suspect must have been devoted to the trees before they could possibly yield fine crops.—A SUBSCRIBER.

[We quite agree with our correspondent's opinion that when any great success in culture is attained it would be very beneficial if full particulars of the circumstances were given, because such particulars throw a light on the path to be trod, and point the way to it. At the same time the mere record of such successes is beneficial; for what one man can effect another can imitate, and it rouses others to inquire after the means to be adopted, of which our correspondent himself is an illustration. We shall be glad of more information concerning the Peach culture to which he alludes.—EDS.]

EXPEDITION TO VANCOUVER'S ISLAND AND  
BRITISH COLUMBIA.

At a meeting of gentlemen interested in arboriculture and horticulture, members of the Association and of the Committee of the Oregon Botanical Expedition, held at Edinburgh, on the 21st of July, 1862, George Patton, Esq., of the Cairnies, in the chair, the subject of re-organising the Oregon Association, with a view to the employment of a botanist to collect the seeds of hardy trees and plants, and the seeds and roots of flowers, was brought before the Meeting.

The Committee formerly appointed reported that they were at present enabled to obtain the services of a collector, in every way qualified, in the person of Mr. Robert Brown, a gentleman devoted to natural science, whose merits were attested by high authorities, and whose successful prosecution of science had already been proved by contributions to botanical and various other learned societies. They stated that Mr. Brown was pre-

pared to proceed immediately upon the performance of his duties, and to prosecute the object of the Association in whatever part of the world the Association might direct.

After deliberation, it was unanimously resolved that the Oregon Association be revived, and,

First, That an Association, to be called “The British Columbia Botanical Association,” be formed, for the purpose of having an exploration made of British Columbia, Vancouver's Island, and the countries adjoining the Rocky Mountains, with a view to the transmission of seeds of hardy trees and plants, and the seeds and roots of flowers, to the members; the field of exploration being subject to modification or extension according to the direction of the Committee.

Second, That members should subscribe in shares of £5 each, payable yearly, in proportion to which shares the seeds, &c., sent home should be distributed at the sight of the Committee; it being understood, unless otherwise expressly conditioned, that subscriptions should be continued for three years; and that no member shall be called upon to pay more than the amount of shares subscribed by him.

Third, That Mr. Brown be appointed Collector, and be requested to hold himself in readiness to leave this country for Vancouver's Island so soon as he may be directed by the Committee.

Fourth, That Professor Balfour, with the assistance of Mr. M'Nab and Mr. M'Intosh, prepare such instructions as may be thought necessary to the botanist.

Fifth, That Sir Wm. Gibson-Craig, Bart., of Riccarton, be appointed chairman; Mr. Isaac Anderson-Henry, of Woodend, secretary; and Mr. James M'Nab, of the Royal Botanic Garden, treasurer.

Sixth, That the management of the affairs of the Association be placed under the following Committee, with power to add to their number, and to sub-commit:—Sir Wm. Gibson-Craig, Bart., chairman; the Hon. Viscount Dalrymple; Sir William Jardine, Bart.; Sir David Dundas, Bart.; J. H. Balfour, Esq., Professor of Botany in the University of Edinburgh; Archibald Campbell, Esq., of Blythswood; Colonel Ferguson, of Raith; T. A. Hog, Esq., of Newliston; Humphrey Graham, Esq., of Belstane, W.S.; Isaac Anderson-Henry, Esq., of Woodend, secretary; Charles Lawson, Esq., of Borthwick Hall; Charles M'Intosh, Esq., Murrayfield; James M'Nab, Esq., Superintendent of the Royal Botanic Garden, Edinburgh, treasurer; T. Gambier Parry, Esq., of Highnam Court; George Patton, Esq., of the Cairnies; David Smith, Esq., Manager of North British Insurance Company; Wm. Thomas Thomson, Esq., Manager of the Standard Insurance Company; and W. Ivory, Esq., of St. Roque.

Seventh, That the Secretary be requested to get the foregoing minute and resolutions printed and circulated among the members of the Oregon Association, and others interested in arboriculture and horticulture; and that the parties so written to communicate immediately with the Secretary, and, if desirous of joining the Association, pay to the Treasurer, Mr. James M'Nab, Royal Botanic Garden, the amount of their first year's subscription, so as to enable the Committee to despatch Mr. Brown in time to obtain the seeds of this season.

THE ARCHERFIELD EARLY MUSCAT.

You will, doubtless, have observed, that Mr. Rivers has publicly given it as his opinion, founded on mere description, that the Muscat Précoce du Puy-de-Dôme is identical with the Archerfield Early Muscat. I take the liberty of asking whether you, as an acknowledged authority in pomology, know the Muscat Précoce du Puy-de-Dôme, and whether you consider it the same as the Archerfield Early Muscat?

If the Précoce du Puy-de-Dôme ripens as early as the Royal Muscadine, which Mr. Rivers says it does, my impression, or, in fact, conviction is, that it cannot be the same as Archerfield Early Muscat.—D. THOMSON, *Archerfield Gardens, N.B.*

[We do know the Muscat Précoce du Puy-de-Dôme, and we can state most decidedly that it has not the slightest resemblance to the Archerfield Early Muscat, which we have also seen. We know farther from our own observation, that Muscat Précoce du Puy-de-Dôme, Muscat Eugénie, Muscat de Syrie, and Isaker Daisiko, are synonymous, and that they bear as much relation to Archerfield Early Muscat as a White Frontignan does to a Muscat of Alexandria.]

## WHAT TO LOOK FOR ON THE SEASHORE.

MOLLUSCA—(Continued from page 437.)

We now proceed to notice the ASCIDIÆ, or Simple Ascidie.

These creatures are characterised by being enveloped in a close oval or cylindrical sac, which is called the cloak. This sac is fixed at its base, or by its side, either to rock, shell, or seaweed. It is of a leathery substance, and is terminated by two unequal openings—the one branchial, the other anal. From these openings, if the animal be handled or otherwise disturbed, the sea-water is expelled with very considerable force. These animals are entirely deprived of the power of locomotion; indeed, the principal evidence of vitality displayed by them is the alternate absorption and expulsion of the water. They are by no means attractive objects, save in one particular—they are occasionally found of a very brilliant colour. The leathery sac or cloak in which they are enclosed, is frequently seen covered with small shells and stones, ornamented with pretty little tufts of corallines; occasionally even the thick cloak itself is perforated by certain bivalves, which seem to find their strange lodgment much to their taste. There is an inner as well as an outer cloak, which, however, is only attached to the outer one near the openings above mentioned. The branchix, or gills, form a largish bag, at the bottom of which is placed the mouth, and near this opening lie the viscera.

The sexes of the Ascidiæ are quite distinct. The species are extremely numerous, and are found in all localities; in some places perhaps they are more abundant than in others, but they are so common everywhere that it would be useless to designate any particular places. They are one and all, however, inhabitants of salt water. It is said that in some districts there is a species of Ascidia used as an article of food; this may be possible, but it appears to me vastly improbable.

ASCIDIA INTESTINALIS.—This creature occasionally reaches a length of five or even six inches—its ordinary length, however, being about three. It is common on most parts of our coast, but is found in large quantities in the North. Wherever it is met with, however, it adheres to shells, rocks, or seaweed at various depths. It has a long cylindrical body, with a soft, clear, outer tunic, mostly yellow or of a pale green.

ASCIDIA COMMUNIS.—As this is the commonest of all the British Ascidiæ, it is as well to designate it by that name instead of the scientific one. The body is oblong, having a translucent outer tunic which varies in colour, sometimes being of a pale greenish-white, and sometimes of a dark brown. This creature grows to a length of six inches, frequently more, and is found on most parts of our coast in large quantities, at about fifteen fathoms depth.

ASCIDIA ARACHNOIDEA.—So called from the tunic being "marked with reticulating lines as if it were covered with a spider's web." In form it is oval, like the foregoing specimen; the tunic very thick and smooth, and either quite white or marked as above mentioned. Its length is about three inches. This beautiful species is found on the south coast of England, and is "not uncommon," says Mr. Alder, "on the Cornish and Devonshire coasts."

ASCIDIA PRUNUM is another species common to our coasts, where it is found adhering to the under surface of stones at low water. The body is ovate; the tunic smooth and semi-transparent. Its length is about one inch.

MOLGULA TUBULOSA, or ASCIDIA TUBULOSA.—(*Molgula* representing a little bag of skin, as *Ascidia* represents a little bag of leather.) The body of this creature is quite globular, and is found buried in sand or mud. The outer tunic is semi-transparent, encrusted with sand when found, and of a bluish colour. "This curious species," I quote from Messrs. Forbes & Hanley, "occurs abundantly in muddy lochs and bays on the west coast of Scotland. When it comes up in the dredge it resembles a little ball of sand; when the sand is rubbed off it seems like a little transparent bullet, in the interior of which the viscera are seen winding."

CYNTHIA RUSTICA.—This species is about one or two inches in length. The body is globular or clustered, and generally of a deep rusty red colour. It is common on most parts of our coast, where it is found adhering to seaweed.

CYNTHIA GROSSULARIA.—On Oysters in all localities, and on stones also will be often found disks about a quarter of an inch across, and of a rose-red colour. This is the *Cynthia grossularia*, a creature having a flat, smooth, oval body, adhering

by the entire undersurface. It is supposed generally to be the fry of the previously-mentioned Ascidian, *Cynthia rustica*, but it is said by Messrs. Forbes & Hanley to be probably a distinct species.

We now proceed to the SALPIDE, another order of the Tunicata.

The genus *Salpa* differs in one very material point from those Ascidiæ we have just disposed of. It is *free* instead of fixed; the body is of an oblong shape, and of a gelatinous substance; it has both an outer and an inner cloak or mantle, the one adhering to the other throughout; there is an opening at each end of the tube-like body—the openings, however, are somewhat different; the anterior one being a simple orifice, whereas the posterior one closes with a valve, so that the water which enters from behind, and serves to propel the creature forward, cannot return in a contrary direction; in addition to which, further means of progress are supplied by means of certain muscular bands with which the cloak is surrounded. The gills are in the form of a ribbon, attached by one extremity to the tubular cavity of the cloak in such a manner that the water in its passage through the tube continually strikes against them. Numerous small crustaceans take possession of the cavity of the *Salpa*, and are there lodged and conveyed without trouble or inconvenience. These little creatures constantly emit a phosphorescent light. The mode of reproduction of the *Salpæ* is very remarkable. It had been noticed that the animals were sometimes seen singly, at other times in great numbers united together in long chains. The chains glide along the water with a serpentine motion, each individual of which the chain is composed contracting and expanding with perfect precision, and with a simultaneous movement. Each chain, therefore, seems at a distance but a single individual, and is frequently regarded by sailors as a reptile, and *Salpa* chains get the nickname of *Sea-serpents*. The discovery of the mode of reproduction by the *Salpæ* is due to the German naturalist Chamisso.—W.

## THE INTERNATIONAL EXHIBITION.

(Continued from page 380.)

## VICTORIA.

THE colony of Victoria was formerly a dependency of New South Wales, but was erected into a distinct government in 1851. It occupies the whole of the southern extremity of Australia lying to the south of the Murray river, and east of long. 141° E., the boundary of South Australia on that side, and includes an area of 86,831 square miles, or 55,571,840 acres, of which less than half a million are under cultivation. Certainly no colony has ever risen so rapidly in population and wealth as Victoria, the discovery of the gold fields having determined an unprecedented immigration from all parts. In 1836, the whole population only amounted to 177; in 1851, previous to the discovery of gold, it was a little over 77,000; and 1861, just twenty-five years after the first census, it had reached 540,322; whilst it is computed that the value of the gold which was obtained in the colony up to the end of 1860, was £104,000,000.

Taking Melbourne, the capital, as the representative of the colony generally, the climate may be stated to approach most closely to that of the south of Portugal; the northern parts, however, are considerably warmer, resembling Algiers in temperature. At Melbourne the mean temperature of the year is 57.8 or 8½° warmer than in the neighbourhood of London; but the thermometer frequently rises to a much greater height in summer than here; whilst in winter, except in the hilly districts, it seldom falls much below freezing. The soil, too, is on the average nearly 10° warmer than with us, a circumstance which greatly accelerates the process of vegetation. Being thus favourably situated with regard to climate, Maize, Tobacco, Melons, Cucumbers, Figs, Grapes, and most of our hardy fruits, are cultivated with success. Apples and Pears in particular attain a very large size, and from the strength of the sun a high colour. Vegetables, such as the Potato, Turnip, Beet, Carrot, Cabbages, &c., are also produced in great perfection; but the Gooseberry, Currant, and Raspberry, do not succeed well, the climate being, in most parts, too hot for them.

In order to give a just idea of the character of the fruits and vegetables produced in Victoria, a numerous collection of models has been prepared in gypsum, coated with wax or gum tra-

gacanth, and coloured so as accurately to represent the natural hue of the fruit.

The Apples, of which there are forty-eight models, include many of our best varieties, some, however, not being the true sorts, and are generally remarkable for their large size and high colour, as compared with the same varieties grown in this country. The Blenheim Orange, Alexander, and Lord Nelson, are noticeable in both these respects, and the Holland Pippin, Red Quarrenden, Red Astrachan, Golden Pippin, and some others, are very richly coloured.

Of Pears there are thirty-seven models, among which are fine specimens of Uvedale's St. Germain, Bishop's Thumb, Napoleon, Duchesse d'Angoulême, and Forelle. Cherries are of fair size, and so are Plums, the Quinces very large. A White Ischia Fig, and a few Oranges and Lemons, are likewise shown. Among the vegetables are Vegetable Marrows, Onions, Carrots, Beetroot, Potatoes, and Sweet Potatoes, all of which are of good size.

As Victoria is not a grain-exporting country, but, on the contrary, produces not more than sixty per cent. of the Wheat necessary for her own requirements, we need only mention that from the quality of the samples of grain exhibited, there is no question of the capabilities of the climate and soil as regards the production of cereals.

With respect to other crops, we find from the valuable statistical sketch of the colony prepared by Mr. W. H. Archer, the Registrar-General of Victoria, that "an increased breadth of soil has also been each year devoted to minor crops, such as Maize and Sorghum, Rye and Bere, Peas, Beans, Millet, Turnips, Mangold Wurtzel, Beet, Carrots, Parsnips, Cabbage, Onions, and Tobacco, all of which thrive luxuriantly in Victoria. The demand for fruit and vegetables, and the eminent capabilities of the soil and climate for bringing such productions to perfection, have had the effect of causing about 7300 acres to be laid out as orchards and market gardens, making an increase in three years of nearly 2500 acres, or upwards of a third."

The cultivation of the Vine is as yet in its infancy in Victoria, but it is steadily on the increase; and there were last year upwards of 1100 acres in vineyard, which produced 8000 cwt. of Grapes for sale as such, 11,643 gallons of wine, and 260 of brandy. Several samples of different vintages are exhibited, some of which are said to be very good.

Of the other vegetable productions timber forms the principal feature, about eighty specimens having been collected by Dr. Mueller, the government botanist. The most valuable are the Blue, Red, and White Gums, Ironbark, Box, Stringy Bark, Casuarinus or She Oaks, Myall, and Beech or Myrtle (*Fagus Cunninghamii*), and some others, all of which have been previously noticed. Of the rest there are several species of Acacias which would apparently answer well for cabinet work; the Murray Pine (*Callitris verrucosa*), is an extremely useful wood for the same purpose; and the Sassafras tree (*Antherospermum moschatum*), is capable of taking a high polish.

Barks of Acacias and Casuarinas, of which Victoria exports considerable quantities, with a collection of essential oils and resins obtained from various species of Eucalyptus, Melaleuca, and other plants indigenous to the colony complete the list. Some of the oils are likely to prove of considerable importance in the preparation of varnishes; others are stated to be excellent for illuminating purposes; and a few may be useful in medicine and perfumery. A detailed account of these substances as well as a vast fund of other information respecting the colony, is to be found in the catalogue of the Victorian Exhibition of 1861.

(To be continued.)

## THE PROPAGATION OF CONIFERÆ.

(Continued from page 411.)

The following are the principal kinds of Coniferæ requiring particular modes of propagation:—

*Araucaria*.—The propagation of this genus varies considerably as regards the ease with which cuttings are struck. The species which strikes most readily is *A. Cunninghamii*. To obtain young plants of this, select the cuttings in February or March from half-ripe side shoots about 3 inches long; the terminal shoots of side branches may also be used. Let them lie till they are somewhat dry, and having carefully cleaned the cut end, put them in six-inch pots of clean, moist sand, and keep them covered with a hand-light in a greenhouse. When they have grown a few inches, bend the plants gently down towards the surface of the soil, and secure them in this position by small pegs; this

will induce them to break out at the base. When the shoots which have thus pushed out have grown to a few inches, and have become somewhat strong, it will be necessary to cut off the branch which was bent down, which may be used again as a cutting. This mode of treatment is applicable to all Coniferæ. *A. Cunninghamii* may also be propagated by roots; and if there be any old shabby plant, it is as well to sacrifice it for the sake of obtaining a stock of nice young healthy plants. Cut the roots in pieces of 4 inches or 5 inches in length, and choose those that are the thickness of a common quill; put them in pots filled with sandy peat, keeping the cut level with the surface of the soil; treat them afterwards like cuttings of ordinary plants, but do not cover them with anything. As seeds of *Araucarias* are easily obtained, only the better or more choice sorts should be grafted on seedlings about a year old, which will produce good strong plants in the shortest time—at least sooner than from cuttings, especially if they are grafted as near the roots of the stock as possible. The best mode of grafting *Araucarias* is side-grafting; but the graft must be placed near the roots, and the operation performed in July or August. It is advisable to select only fine young terminal shoots. In nurseries, one good old strong plant should be kept for the purpose of producing cuttings. This may be attained by cutting down the heads of such plants as are less serviceable for any other purpose. This will induce them to send out numerous young shoots near the cut, and on the stem.

*Cephalotaxus*.—This very closely resembles the *Taxus* in habit, and may be readily worked on it. The large-leaved species are best propagated by cuttings.

*Cupressus*.—These are best raised from seeds, as seedlings are found to make the finest plants. *C. sempervirens*, in particular, is not so successfully propagated by any other mode; cuttings grow very slowly. August and September are the most suitable months for grafting the better sorts on seedlings of *C. sempervirens*.

*Dammara*.—All the species of this genus are somewhat difficult to propagate by cuttings; they are, therefore, best grafted on *Araucaria imbricata* or *A. braziliensis*. It sometimes happens that a tenacious substance gathers on the incision made on the stock; and, it may be well to observe here, that such substance is not detrimental in the development of the graft, and it may therefore be allowed to remain.

*Pinus*.—This is a very rich tribe, and includes the following section:—*Pinus*, *Picea*, *Abies*, *Larix*, and *Cedrus*. Propagation by cuttings is very difficult, and they are much more readily raised by grafting on those to which they are allied. They are also freely propagated by seed. *Abies*, *Picea*, and *Cedrus*, however, can be propagated by cuttings more readily than by any other means. The best time for taking cuttings, and performing the operation of grafting, is in February and March, or September and October. The stock and graft should be of equal size, as they then join much better, and sooner than when unequal. Only such *Pinus* as are quite hardy should be selected for grafting on, and the strongest stocks should always be used. *Pinus strobus* and *P. sylvestris* grow very well in the open ground, but *P. Mughus* is the best adapted for exposure in places where the climate is cold. *Cedrus* grows freely from cuttings, and is also readily grafted on the hardy species of *Pinus*. *Larix sibirica*, *L. americana*, and others, can only be propagated well and readily when grafted on *L. europæa*, and its varieties. *Picea* and *Abies* may be readily worked on stocks of each other, but the best stocks to graft upon are *Abies excelsa* and *P. pectinata*.—M. COURTIN, *Bordeaux*.

## THE EFFECT OF CLIPPED TREES IN DECORATIVE GARDENING.

BY H. NOEL HUMPHREYS, ESQ.

THE first attempts at decoration, in many branches of art, consist in simply subduing the irregularity of natural forms to geometric shapes, in the regularity and repetition of which the eye of the most untutored recognises at once the existence of certain laws of order, which are necessarily the earliest steps of every advance in civilisation, whether social, political, or artistic. Thus, the Indian savage pares away the rugged bark of his club, and in its place carves with laborious care a series of zigzag or serpentine lines, the evenness and regularity of which constitute, in his estimation, their greatest merit. But there arises, sooner or later, an epoch in the advance of art when formality in its turn gives way, and a return to natural outline takes

place. It is then that we find another race of artists disdaining the regular patterns of the half-savage, and positively imitating, by laborious and painstaking manipulation, the rugged bark and knots which were pared away by the earlier carver to make way for his symmetrical notching. So in gardening, the first steps in the direction of ornament have always been clipping and cropping; first, merely to obtain regularity of line, squaring and levelling being the highest aim of the earliest practitioners in the art. These simple ends are soon accomplished, and more ambitious views succeed, when temples and amphitheatres, colonades and porticoes of verdure become the great objects of a race of architects in foliage. In Italy the art rarely passed these bounds; but in the north, especially in Holland, Belgium, and England, trees were clipped into human figures, and these leafy monsters became a positive rage: the Yew, the Box, and other trees whose close-growing foliage rendered them most suitable for torturing into these unnatural shapes, being cropped and sheared till it was supposed they resembled shepherds and shepherdesses, dogs, peacocks, and other forms; to add to the reality of which, painted faces and hands, &c., were added—such additions rather increasing the absurdity than aiding the wretched imposture. The return to nature (as in the case of the carver of the club, and his successor of a later period) was as violent as its departure; and a race of "landscape gardeners" arose, who swept away with relentless hand the avenues,

the bowers, and the quaint figures which the foliage of the slow-growing Yew had, with the most careful clipping and tending, been a century in producing. We have in England but few old gardens remaining which can show remnants of this exploded taste; but in Holland many may yet be found revelling in all their pristine formality and stiffness; and in Han-

over the curious gardens created by George the Second for his too famous mistress—mentioned in the entertaining memoirs of Lord Hervey—are still in their original state, a kind of German Trianon, in which all kinds of cropped absurdities are still carefully maintained and trimmed.

But the object of the present article is to suggest the partial revival of the best features of this taste, in proper situations and under suitable circumstances, and it is from some of the best Italian gardens that we shall be furnished with the best hints for the partial re-adoption of architectural and other simple and severe forms in foliage. The garden-seat, from the Villa Strada near Rome, backed by a screen of carefully-cropped Limes, the outlines of which harmonise with that of the seat itself, is a good example of a style, and an extent to which symmetrical cropping may be safely resumed with good effect. Let us imagine a tolerable extent of shrubbery formed of well-grown timber trees, with an undergrowth of Laurels and other evergreens, intersected in various directions by means of winding walks. In the midst of this shrubbery, let us suppose an open space of quadri-

GARDEN-SEAT OF THE VILLA STRADA, NEAR ROME.

THEATRE OF CYPRESSES.

lateral form, each side occupied by a seat and cropped screen of foliage similar to the annexed engraving—a square plot of grass, with a fountain, a sundial, or merely a large vase filled with flowering plants in the centre, surrounded by a broad trimly-kept gravel-walk, and it will be easy to conceive that such a combination of regular forms occurring in the midst of a shrubbery similar to the one described would create a most pleasing contrast, and be a spot often sought during the summer months for quiet meditation; as there would always be one shady side, and the surrounding trees would diffuse a pleasing general coolness.

The engraving, also from a celebrated Italian villa, is termed “the Theatre of Cypresses.” With or without its dressings, in the form of fountains, statues, &c., such a disposition of forms might be made successfully available in an English garden in many ways; but there is one which I more especially wish to suggest. Our modern geometric flower gardens, when of considerable extent, generally produce a same and unsatisfactory effect, from their uniform flatness of surface, few of the plants cultivated for the purpose of producing masses of colour growing to any considerable height. I recollect noticing particularly how conspicuous this defect of flatness appeared to me in the otherwise fine flower garden at Trentham. In addition to the defect of flatness—that of seeing over all the surface at one glance, destroys to a great extent the eagerness and curiosity to examine the more distant parts—which should always be considered a fatal defect in gardenesque compositions. To remedy this, I propose introducing, in a geometrical flower garden, either one, four, or more examples, according to space, of such a composition as the annexed “Theatre of Cypresses.” I will imagine the space only suitable to one group, which, in that case, would of course be central. The hedge might be formed of Privet, or some other quick-growing evergreen—some of the new Ber-

berries for instance; instead of the Cypresses, in our climate some hardy tree of spiral growth, but considerable size, might be selected, as great height is necessary to the effect I wish to produce. In Italy, the “sky-cleaving Cypress,” as Shelley has so picturesquely termed it, attains to the size of the Poplars of the north, and forms a most characteristic feature in Italian scenery; indeed, an Italian landscape without Cypresses, or an English one entirely without Poplars, might be compared to the view of a city without steeples, the monotony of which would be insupportable to an eye seeking artistically for agreeable and striking combinations of form.

From this it will be understood that the writer would prefer a geometrical flower garden, the monotony of which was broken up and varied by a few lofty and finely-grouped objects, to one of uninterrupted flatness, varied only by patches of colour. Other advantages would also be obtained; for instance, within the newly-enclosed circuit of the group of tall trees, there would be a space where certain plants, which suffer from too much sun, might be more successfully cultivated than elsewhere, and even on the north side of these trees certain shade-loving flowers would find an appropriate situation. In addition to these advantages, and the improvement to the first general view, a certain legitimate degree of intricacy would be attained, which is always agreeable. All could not be seen at one superficial glance—something choice would be imagined within the well-hedged circle; and beyond it, and on either side, would be certain partially-concealed portions of garden, which one would be thus tempted to explore. In the midst of an irregularly-planned flower garden I would scarcely recommend such an object as the “Theatre of Cypresses,” but as a good centre to a geometric plan I think it could not be otherwise than effective and agreeable, and at this time, when all effects to be produced by cropping have been so completely abandoned, it would be a positive novelty.

AMPHITHEATRE OF VERDURE.

The above example is also from an Italian garden, and is styled an “Amphitheatre of Verdure,” “*amphiteatro di verdura*.” The introduction of a somewhat similar feature in an English garden might in some instances be very successful, but more especially, as in the former case, in a geometric one. Let us suppose a secluded flower garden terminated on one side, perhaps, by a terrace near the house, and on the three others by shrubberies. From either side of the terrace an arcade of cropped Limes might separate the trim flower garden from the free-growing shrubbery, and at the end, opposite the terrace, the garden might with good effect terminate with the *amphiteatro di verdura*. Trimness of form thus exhibits itself, not only on the ground, in the turf, and the form of the beds, &c., but also above the eye, in the outline of these sculptured Limes, thus giving greater comple-

ness to the geometric character of the general composition. The trunks of the Limes might either be covered with hardy climbing Roses, or, by a little careful management, clothed with their own foliage as in the Italian amphitheatre, above which, as in the garden before described, the trees of the surrounding shrubberies, appear softening the rigid outline of the cropped trees, and forming a soft and irregular “sky-line,” which would gracefully complete the composition.

It will be seen by the above remarks that, in resorting to the abandoned custom of reducing foliage to arbitrary forms, only the most severe and simple are advocated, and even then only in well-considered situations, where the contrast or the harmony of forms would be artistically aided by such means.—(*Gardeners' Magazine of Botany*.)

## WORK FOR THE WEEK.

## KITCHEN GARDEN.

The weather still continues favourable for the growth of the autumn crops, and the whole of such as require it should be kept well earthed-up. As young weeds will now be making their appearance in thousands where they have been allowed to ripen their seeds, the whole of the garden, if possible, should be scuffled over on a fine day with Dutch hoes, to destroy them by exposure to the sun. Exhausted crops, as Peas, Beans, &c., to be cleared away as soon as possible after they are done with, and the ground to be manured and trenched, when it will be in readiness for planting. There is but little in the way of sowing required this month, presuming that all the Cauliflowers, Cabbages, Lettuces, Spinach, &c., had been sown last month. *Cabbage*, prepare ground for the main spring crop; it should be highly enriched with manure. A quarter on which the Onions have been grown would be very suitable for the purpose. *Cauliflowers*, prick-out the young plants as soon as they are sufficiently large to fix properly in the soil; some may be pricked into a sheltered border, and others into frames. *Endive*, plant plenty by the sides of walls or wooden fences to stand the winter. *Lettuce*, plant in a warm, sheltered situation some of the Bath Cos for an autumn supply. *Onions*, pull up those that have done growing, and house them in a dry state; to be sorted before they are stored away, and the thick-necked ones used first. *Spinach*, thin the plants to about 9 inches apart, and work the hoe well between them. *Turnips*, to be thinned as soon as they have made a couple of rough leaves. To prevent the attacks of slugs, sprinkle the ground occasionally with soot or lime.

## FLOWER GARDEN.

At this season the beds of flowering plants will require frequent cutting-back to prevent the free-growing sorts from straggling or sprawling about. Decayed flowers and seed-pods to be removed. By careful attention to these little matters the season of blooming may be prolonged until the plants are destroyed by frost. Lawns to be well swept in dry weather to remove worm-casts, and afterwards to be well rolled. Where worms are troublesome water with clear lime water of full strength. Evergreens of all sorts to be propagated by cuttings in the open ground, also *Wistaria sinensis*, *Virginian Creepers*, *Jasmines*, *China Roses*, *Heartsease*, &c. Beds and borders deficient of *Snowdrops*, *Crocuses*, *Jonquils*, *Narcissus*, and other early spring-flowering bulbs should have some introduced.

## FRUIT GARDEN.

Fruit-gathering should now receive frequent attention. The fruit which ripens rather hastily and that possessing aroma to be gathered somewhat under-ripe, whilst sorts that ripen with difficulty or which are slow in obtaining colour should remain much longer on the trees. When gathered, to be kept in a cool and airy situation to allow the moisture that arises on the fruit for some time after being gathered to evaporate.

## STOVE.

As the nights become cold, a little fire heat may be advantageously given more to assist in ripening any wood that may be still succulent than to promote growth. See that every plant is free from insects, and keep the foliage of *Isoras*, &c., clean by washing with a sponge and soapy water.

## GREENHOUSE AND CONSERVATORY.

Climbers will require frequent attention to keep the shoots in their proper places. When *Japan Lilies*, *Gladioli*, and plants of like habit have done blooming, remove them to the sunny side of a hedge or to the foot of a wall facing the south to ripen their growth. To be watered but moderately until their tops show signs of decay, when they may be laid on their sides till potting time (November) arrives. *Heliotropes*, *Verbenas*, *Scarlet Geraniums*, *Roses*, *Ageratum*, &c., required for decorative purposes to be progressively shifted; stopped and trained, they will be found useful to a late period of the year. The *Pelargoniums* cut back some time ago when they have made shoots an inch or two in length to be shaken out of their old soil, the straggling roots trimmed, and to be repotted into smaller pots. If plunged in a slight bottom heat it will assist to give the roots a fresh start. Continue to shift *Cinerarias*, *Chinese Primroses*, *Calecoularias*, *Humeas*, and other seedling plants for next season's blooming. Attend to *Mignonette* by thinning it in time, and sow another batch. Pot Ten-week Stock for early blooming. *Tropeolums* to be started, and no time must be lost in procuring and potting such *Hyacinths*, *Tulips*, and other bulbs as may be required for forcing.

## PITS AND FRAMES.

Give diligent attention to the propagation of bedding-out stock, and get cuttings that are sufficiently rooted potted-off at once, keeping them close and moist until again established. Those which have been potted-off some time, and are established in their pots to be gradually exposed to the open air, stopping the shoots to keep them dwarf and stocky; they also derive great benefit from exposure to night dews. W. KEANE.

## DOINGS OF THE LAST WEEK.

As a fit of weariness from hard labour comes over us, we would be tempted to say, Read our old friend Mr. Keane's suggestions, and you will not be wrong; more especially as our work for the last week has been chiefly of a routine character, and closely resembling that of the preceding two weeks.

## KITCHEN GARDEN.

The work has been chiefly earthing-up the forwardest Celery, so as to have it fit for use in the second week; planting-out Broccoli, Cauliflower, and Cabbages for autumn and winter; pricking-out Cabbages for spring; sowing Cauliflower for spring under hand-lights; sowing Onions in rows for salads, and others to be transplanted for the first bulbs in summer, preferring for this the Lisbon and the Tripoli; watering late Peas to keep them green, and pulling-up others to make way for Celery-beds and other necessaries in winter; sowing a last crop of Red Top American Turnip, with Radishes between the rows—that Turnip, to our taste, being as yet unapproachable for sweetness in flavour, leaving, in this respect, many a good-looking Melon far behind. Sowed also some Lettuces on hard ground to stand the winter, being persuaded that if the ground is merely hoed for this purpose, and the seed scattered over it and raked-in, the plants will stand so much better than if the ground were dug and pulverised in the usual manner.

Planted-out Endive in the open ground, and a quantity also in turf-pits, where a little protection can be given; watered Lettuce when necessary, though on north banks, to keep them crisp, as, though they are less used than in the dog-days, the users of them get more fastidious as to quality. Note here, that a little fault-finding is not a bad thing for all concerned. My own idea of a first-rate Lettuce is to have a firm heart, the centre seed-stalk scarcely to be seen, and the heart-leaves almost as white as a well-got-up shirt front. This is by no means, however, a general feeling. Some prefer them green but crisp—nay, I have known frequent instances in which greenness was preferred one week, and whiteness in the next, to the great chagrin and mortification of the gardener, "who never knew what to be at!" The man of worry will always find something to worry him; the man of prudence will so far trim his sails to the prevalent gale, and, as receiving money for his services, try to meet the best way he can the varying tastes of his employers. Half, and more than half, of the unpleasantnesses between employer and employed arises from such trifling matters as these. "Employers will be so fickle and changeable." Have you ever, brother of the apron, seriously and closely investigated what a creature of whims and changes you yourself are? If so, you need not expect anything like infallibility or unchangeableness in matters of taste even among the highest in station. The real pith of the matter is just this: If a white, firm Lettuce is preferred for one month, try and get it; if the next hobby should be a crisp, green Lettuce be as anxious to send that to table, waiving all tastes and opinions of your own. A cook, an eminent *artiste*, who disdained to see after the boiling of Potatoes—the only vegetable the employer cared for, found a difficulty at last to have a Potato to boil; and many good gardeners have found their services at a discount, because they did not think it worth while to notice what kinds of vegetables and fruit were taken to their employer's table.

Gathered Tomatoes against walls, and regulated those in a turf open pit by stopping above the blooms and young fruit, and removing a good portion of the larger leaves. These plants have so much succulence in their foliage, that, after the fruit shows, the ripening process is much accelerated by a pretty free disleafing of the larger foliage. Cut Vegetable Marrows before they got too large, as they will keep several days quite fresh if laid on damp moss; and thinned and regulated the plants, cutting down those shoots that were showing little or no fruit. Gathered Gherkins, or pickling Cucumbers; and as the plants were a little dirty, and we had as many as we wanted, pulled

them up. Find that young plants of Cucumbers in one bed, growing and bearing freely, have a little trace of the gum disease; whilst in another bed no traces of it have as yet appeared, and the fruit is large and clean. In this last case the plants have nothing but moderately sandy loam from the roadside. The whole of out-door Cucumbers, if not affected with gum, have had less or more of the dingy yellow spot on the foliage. How these came here I shall never know, as previously Cucumbers were less trouble than Potatoes. All that I can suggest in the way of remedies, as proved here, are frequent successions of plants, and fresh hungry soil until all traces of the malady disappear.

Exposed the Mushroom-beds in the sheds during the day, as they were coming in too plentifully to suit our purpose; and just put in a mixture of straw and droppings to form the first shallow bed in the Mushroom-house. I would advise those thoroughly fond of Mushrooms to grow them. I have seen parcels carried home as rarities that I would have been sorry to touch. When remonstrated with, the possessors said "They will do for catsup at any rate." Well, possibly they may; if it be true, as I once was told by an eminent maker of that article, that a goodly portion came from the thick drainings of dunghills, well boiled up and spiced. No wonder therefore some gentlemen will not touch or meddle with Mushrooms or their produce, unless they come from their own beds.

#### FRUIT GARDEN.

Much the same as previous weeks. Gathering the earliest fruit; packing Peaches in cold house for preserving, as they came in too fast for use; made most of the extra Nectarines come in for tarts, &c., as preserving them is more expensive, requiring the presence of brandy to soak them in, which at 6s. 6d. a-bottle is no joke. Would some friend oblige me with a cheap mode of keeping these fruits—I mean in something like a whole state? Besides the preserving alluded to above, I know they make excellent jam and jellies, when treated much the same as Plums and other fruits. It seems a pity when a glut comes and you do not know what to do with them, whilst, perhaps, a week before, or a fortnight afterwards, there would scarcely have been enough for a party. Employers who wish their tables set off to the best advantage, should condescend to consult their gardeners as to the time they intend to have their chief visitors, as it is often practicable to retard or to accelerate, and those who are above thinking of such things cannot expect to be so well served, especially in moderately-sized places, as they otherwise would have been. Regulated fruit trees, gathered Plums ripe enough for keeping to prevent them being holed by flies, &c. The wasp nuisance is past its worst, and a great number of them and large flies have been trapped and done for by the double hand-light which we described last year. Our small Fig-house, which has given us a daily supply since the 1st of June of fine luscious fruit, is now getting thin, and, therefore, we have forked over the soil, giving a top-dressing of horse-droppings and fresh loam, then a good watering, and shut up the house about two P.M., in order to accelerate and ripen the second crop. A very few have ripened out of doors, and the bulk will come in before the second crop in the Fig-house. The wasps first appeared there, showing that they have no bad taste for what is good. Not one, owing to the precautions taken, has found its way into the vinery, though I have heard of some houses where not a bunch was left but was disfigured or eaten up, and employer and employed looked on with philosophic apathy, considering it as one of those events against which the power and contrivance of man were vain and powerless.

#### ORNAMENTAL GARDENING.

Potted Cinerarias and other plants, but the chief work was keeping the walks firm and smooth, the lawns short and firm like a thick carpet, and the beds clean and trim, and propagating wholesale as we could get at them. For general ideas on the latter subject, so much in unison with my own, allow me to refer to pages 417 and 418, to an article signed "D. T.," but which I could as easily fill up with all the letters, as some of our readers can supplement our own "R. F." Thanks to our own good friend Mr. Beaton for teaching them the way. Now, here, on this propagating business, we wish, if possible, to answer a host of complaints as to our lateness in striking bedding plants. In the first place, we will guarantee success to those who are not later than ourselves, if they adopt means at all similar. The first reason, then, for being rather late in taking cuttings is, that we wish our plants to be small until March, in order that we may house them in little room. Our second reason

is, a great dislike to mutilate in the least beautiful symmetrical beds, which you must do less or more, when as yesterday we took more than two thousand cuttings of Scarlet Geraniums from a row, and it would have required rather close scrutiny to find the places they came from. Now this lateness of propagating is not necessary where the owners start in August for the moors, but it is a matter of importance where the proprietor and his company stay with you all the season through, and there is the constant strain to make the beds and borders better to-day than yesterday. The other day an eminent lawyer, agent for a gentleman, and who like Mr. Hamilton, of Ham Wood, has taken keenly to gardening of late, on seeing this cutting-taking process, stated he had quite made up his mind, that after this season not a single flower or cutting should be taken from the flower-beds. "No sooner," said he, "do the beds begin to look nice than in goes the knife for cuttings, and the symmetry is wholly destroyed. I have plenty of kitchen garden of which I care nothing, and there spare plants must hereafter be grown for what flowers and cuttings that are needed." We find that the double idea is a first-rate one; but we can take little help from them, as, unfortunately, while our flower garden is large, every inch of the kitchen garden is wanted for its legitimate purpose. In all such cases the cuttings should be taken off so carefully as not to injure the general outline of the beds, even if the plants should be gone about several times instead of once.

Had I sufficient room, I would prick-out the greater portion of bedding plants where they might remain until March or April. Many of them, such as Scarlet Geraniums, might be struck in the open air in July and August but for the reason stated above. At this season, we prefer shelter of glass or calico when it can be given. Last week we described the essentials of propagating. This season we use little but soil from the roadside, mixed with drift sand and small charcoal from our charring-heap. When either dung or leaf mould is used at the bottom, there is a risk of fungus annoying you in winter. To prevent this still further, we use a little lime in the compost, because that is the great enemy of all the fungus tribe. This mixture is our great stock in trade.

For small bedders, as Verbenas, we use 48-sized pots—two rows round the sides. The first batch are struck and are hardening-off, with plenty of air night and day. These are chiefly for stock to get cuttings from in spring. The great bulk of other things are pricked-out at once into beds, where they will stand the winter, or into wooden boxes, averaging 3 feet in length, 4 inches deep, and 8 inches wide. These are bottomed with rough pieces of soil, from Walnuts to Peas in size, placed at the bottom, finer-riddled material over, and a little drift sand at top. The cuttings have, as in the stronger Geraniums, about 1½ inch; common ones and variegated ones about 1¼ inch. We thus avoid all trouble of raising cuttings. We give a little protection before struck, and all the air possible, afterwards to make them bushy. As a sort of compromise with work to be done in making these Geranium-cuttings, we size them as large, lesser, least, and put them in boxes in sizes accordingly; and we also remove most of the leaves, except the terminal ones, though something unscientific, just because if we leave more leaves on, there is the trouble generally of picking them off. All these we keep cool, so as not to elongate the tops before roots are produced downwards. We agree with Mr. Thomson in never allowing a cutting to flag, but we use the nozzle of a syringe instead of his fine-rosed pot; and for some time past we insert all cuttings as soon as made, having proved that drying the cut ends was better in theory than in practice. September, for the reasons given, is our great cutting-month for this season, so far as flower-gardening is concerned; and, being pretty successful, we shall be glad to give any information to those who have had less experience.—R. F.

#### TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

CORWERS (*Doodar*).—The spiders are lurking all day on the rods, rafters, or other supports of the climbers, as fishers watch their set nets. Hunt them up and destroy them, and there will be no more cobwebs. We have often been so annoyed with them.

Mr. Fish would wish to heartily thank an unknown friend, somewhere about Springfield, Massachusetts, for American papers and seeds, there just being internal evidence that he owes the honour to the privilege he enjoys as a writer in THE JOURNAL OF HORTICULTURE, and more especially for "Doings of the last Week"—a slip of the paper which seems more thought of at home and abroad than ever he could have supposed it merited himself. Earnestly does he pray that the blessings of peace may soon be enjoyed by brothers across the big water.

**PROPAGATING VARIEGATED IVY (O. F. J.).**—If your plant be in a small pot, turn it out into a shallow box or good-sized seed-pan, and peg the shoots down to the soil, water moderately, and in a short time most of the joints will have rooted into the soil, when the shoots may be half cut through, and a week or two afterwards they may be separated and each one potted. If, however, your plant be creeping against a wall, cuttings of two joints each, put into sandy soil and slightly shaded, will root freely enough; but the first-named method is more expeditious.

**MELONS CRACKING (S. T. F.).**—Your case is far from being a solitary one, as most Scarlet-fleshed Melons of the Persian breed are more or less addicted to splitting, and under circumstances so widely different from each other, that the cause and remedy are alike difficult to make out. Generally speaking, keeping the plants dry at the roots checks it most, with merely sufficient syringing of the foliage to keep it healthy. Shading does not seem to be attended with any benefit; a bright sun, and warm close hotbed or Melon-house are less likely to cause cracking than an airy situation—the variety being more tender than the Green-fleshed varieties of the Egyptian breed. The cracking occurs from some atmospheric cause not allowing the rind to enlarge in proportion with the centre: hence it bursts, and decay sets in before it is quite ripe.

**FASTOLFY RASPBERRY FAILING (Narcisse).**—It is difficult to account for your Raspberries failing so suddenly after a mild winter. Had there been a gradual decline for some years, we should not have been surprised, as in the case of one of our correspondents who grows a considerable quantity, the Fastoff (which was originally the very best he had) is now dwindling away, scarcely producing canes of sufficient length to tie up. He is therefore convinced that the variety is worn out, and last year he procured some seedlings from a hedge or thicket, and amongst them selected one of robust habit and good bearing qualities which the past season has far outstripped the Fastoff. As you say your soil is a stiff deep loam, which is the very soil for a Raspberry, it is difficult to account for the failure from any other cause than constitutional decay, unless some local evil—such as an escape of gas or other poisonous matter into the border, can have given rise to the disease. If not the latter, it would certainly be better to trench the border well, and subject it to other cropping for one year or more before planting again, and then to plant another kind. If, however, you have reason to believe some pernicious matter has recently found its way into the border, it must be remedied before planting again. The Prince of Wales is a good Raspberry, and Carter's Prolific and Cornwell's Victoria are also well spoken of.

**DOUBLE-FLOWERING PEACHES (H. A. D.).**—If they are the old kinds there is no novelty about their fruiting; but if they are the recent ones got over by Mr. Fortune for the Royal Horticultural Society, this is the first time we have heard of their ripening fruit.

**PLUM LEAVES DISEASED (T. L.).**—The leaves are covered with fungoid warts, the result of rich feeding and a deficient evaporation owing to the coldness of the season. Use less water, especially in the orchard-houses, and paint the trees with a paint made of water, clay, and sulphur, during the autumn months.

**FLOWER GARDEN (R. Eastlake).**—Good Scarlet Verbenas are as good for panelling as Tom Thumb.

**LEPIDODACTYLONS (Wyeside).**—Strike them just like cuttings of the blue Lobelias, in a close heat; in sand and peat, of course. We do not understand what Capsicum you mean. All the kinds we know are safe enough to eat in moderation.

**GRAPE CRACKING AND SHANKING (T. T.).**—To remedy the cracking of the Frontignan, you must keep a drier atmosphere and protect the borders from heavy rains. We suspect the cause of shanking in the Muscats is too heavy a crop, or the roots are in too rich a soil, which encourages them to make large roots in autumn which die in winter. Poorer soil, more moderate growth, and a moderate crop would be the remedies. The leaves have the appearance of being blighted and parboiled by a high temperature, extra atmospheric moisture, being placed too near the glass, and not having air given early enough in the morning. If fuel is comeatable, leave air on all night.

**SEEDLING FUCHSIAS (A Young Gardener).**—Not one of them is so good either in size or form as many already in the market. Merely sowing Fuchsia seed which happens to ripen is not the mode offering a good chance of obtaining superior varieties. You must cross-breed, endeavouring to combine the good characteristics of superior parents.

**BOILERS (W. G.).**—If your new boiler will boil with the same fire the same quantity of water in ten minutes that requires thirty-five minutes in the boiler you name, that is a merit; but other merits are required—namely, continuing the heating with a small consumption of fuel, cheapness, and simplicity of form. When we know more particulars we will give our opinion.

**VINES (A Young Hand).**—The Charlsworth Tokay is an excellent Grape. The length of rafters will be an improvement, and the consequent management. The width of the inside border is quite sufficient, and, if properly drained, we would not care about the outside border. If, however, you build your front wall on arches, and contemplate taking a bunch every square foot of glass, we would advise making also a narrow border outside, unless you mean to enrich the inside one with top-dressings of dung, bones, &c. If you take that number of bunches, you must not let them grow large. We have no doubt the border inside would suit all practical purposes. There is nothing gained by mere extent of feeding-ground.

**DROSER A ROTUNDIFOLIA (Nemo).**—This will most likely do well in a north or south looking rockery, planted in cocoa-nut refuse pressed very close together, and kept quite damp with the rose of a watering-pot till the plants get established; and many more of the little gems of our flora and of those of similar habits are more likely to do well in this stuff than in any other way they have ever yet been tried. A thousand alpine plants from temperate zones would most probably succeed in this stuff made up in ridges

and valleys, hoed or held up with stones, provided there were no trees near for their roots to get hold of it. With regard to the charge of 2s. 6d. for the carriage of two bags of cocoa-nut refuse six miles and a half by rail, we think it too much. The South-Western would only charge 6d. per bag for the same distance.

**SCROPHULARIAS (North of Ireland).**—The box was smashed in the post, and the two specimens were in bad condition; but we could see little difference between them. Mr. Williams's stock came from your part of Ireland, from the garden of the Archbishop of Armagh, and the character of it is just the same as in your neighbour's garden, "disposed to grow as a weed;" but there is a kind of it about which is a stiff stinging grower. As to Roses being propagated on the plants in balls of moss, THE COTTAGE GARDENER was the very book which sent a knowledge of the fact to the ends of the earth about twelve or thirteen years since, and we are glad the fact has not been forgotten; but we believe you are the first to tell of Camellias and Rhododendrons being propagated the same way. Your seedling Carnations are all Picotees, and most beautiful; they are too—far better than the plain-faced washy Picotees we see about London. The best is the one in the colour of Rosa Ophire, and you ought to name it Mount Ophir. The true yellow one is a dangerous colour in Ireland. The other two ought to have good names, certainly.

**MORPHOLOGY (W. H. Hatcher).**—Many thanks for the extraordinary specimen of morphology. We never saw anything like it. We sent it to Mr. Beaton to hear if he had, and we have since heard he has been playing sad pranks with it at the Crystal Palace Show, by actually betting that judges, exhibitors, and other practicals, and some better folks if such there be, that none of them could tell the name of the plant he should hold in his hand, till he opened his fist and showed them a Sweetwilliam. But to atone for such levity, he has promised to send the specimen to Dr. Masters, the Botanical Lecturer at (we forget where near Kingston), who is studying this branch of physiology, but he, too, is going to try if the morphologic parts can be increased from cuttings; and, if they can, he will first inquire of you how you would like them to be disposed of.

**NAMES OF PLANTS (M. C. D.).**—It is *Ajuga reptans purpurascens*. (*Nemo*).—Probably *Lactuca dilatata*, but too immature for us to be certain. (*P. P.*)—1, *Phlebodium aureum*; 2, *Gymnogramma tartarea*; 3, *Nothochloa nivea*; 4, *Athyrium strigilloseum*; 5, *Asplenium pinnatum*. (*A Six-years Subscriber*).—1, *Acropera Leddigesii*; 2, *Rhus cotinus*; 3, *Gongora fulva*; the other is not recognisable.

### FATTENING YOUNG FOWLS.

(Translations from *M. Jacque's work on Poultry continued*.)

You must procure a tin funnel holding the quantity necessary for a meal for each sort of fowl. The neck or pipe of it should be  $3\frac{1}{2}$  inches long. The top of the pipe should measure outside measure eight-tenths of an inch, and the end of it four-tenths. This end, destined to go into the gullet of the birds, should be diagonally cut, and turned round so as to form a rounded edge. This edge is also softened by a small layer of pewter carefully placed with the soldering-iron.

On the upper edge of the funnel there should be a small ring destined to receive the first finger of the right hand. It is important this ring should be in the right place, because while one hand holds the head of the fowl, the other should properly introduce the funnel. This is almost naturally accomplished if the ring is properly placed.

The orifice at the lower end of the funnel (which, as we have said, is diagonally cut) should be turned towards the person who is using it, for that reason the ring of which we speak should be soldered on the top edge of the funnel two-tenths inch to the right of the direction of the lowest opening of the neck.

Persons who have much practice use this funnel without danger; but those who are not accustomed to it, are apt to damage the lining of the gullet. For this cause it is an excellent plan to use an indiarubber end to the neck. It scarcely adds to the size, and this precaution will prevent accidents that may end in damage.

All this is very simple, and I dwell on this operation at length, in order that it may be well understood, and because it is most important. The food being prepared, is placed in a vase from which it can be easily taken with a spoon. Then when all is ready, take the bird by the wings close to the body, place its head outwards between your knees, so as to hold it firmly

without hurting or stifling it. It will twist about at first, but soon gets used to it. When it is quite quiet, pass the forefinger of the right hand in the ring of the funnel, take the head of the fowl in the left hand, and stretching out its neck open the beak with the help of the right hand, which holds the funnel. When the beak is conveniently open, manage to maintain it in that position, employing the left hand only; then rapidly introduce the whole of the neck or pipe of the funnel, taking care not to injure the lining of the gullet.

It is easy to hold the head of the fowl in the palm of the hand by means of the three last fingers, while the funnel is held with the thumb and forefinger.

Then fill the funnel with food, not quite to the edge, and be sure to keep the neck well stretched out. Place the right hand under the crop of the fowl till you feel it is full, and you may assist this by gentle manipulations. When this is done put back the funnelled bird, and pass on to another. The quantity of food put into the funnel, and which the fowl should eat, should be about the eighth of a quart; but the half only is given at the first meal, and it is three days before the fowl can take the complete ration, even then care must be taken to augment or diminish according to the strength of the bird.

The meals are given with regularity—three in twenty-four hours, at eight hours' interval; six A.M., two and ten P.M. in private houses; at four A.M., midday, and eight P.M. in farms.

To facilitate the operation of "funnelling," and to avoid accidents of forgetfulness, or handlings, which tire and frighten fowls, there must be a proper organisation, which consists in having two, three, or four cages made of close bars, according to the number of birds to fatten. They should never be more than ten together.

These cages, raised from the ground, should be put in a quiet place—such as a stable or an outhouse, completely sheltered from currents of air, and there should always be an empty one at hand. When everything is ready, the bottoms of the cages should be covered with clean straw, and the process of funnelling begins; each bird, as fast as it is fed, is passed into the empty cage. This is continued till all have passed from one to the other.

The straw should be changed every day, because most of our best breeders contend a bad taste is communicated to meat by contact with dirt.

The progress of the operation must be attentively followed, and if it is perceived a fowl remains stationary it should be killed.

In choosing birds to submit to this treatment, care must be taken to take only robust and healthy ones. It is lost labour to endeavour to fatten weak ones; instead of improving they would fall ill and perish.

The duration of the fattening is from fifteen to twenty days, according to the breed and condition of the fowls; a longer period would only cause fat ones to become thinner.

### POCKLINGTON POULTRY SHOW.

THE annual Exhibition of the Pocklington Poultry and Horticultural Society was held at Pocklington on Tuesday last, the 2nd instant. The weather proving favourable, large numbers of visitors attended, and the Show was successful in every respect. The arrangements of the Committee and Secretaries were very complete, and were carried out satisfactorily. Compared with last year, there was a slight decrease in the poultry department.

Mr. H. Adams showed good *Game* fowls; *Hamburgs* were very inferior; *Dorkings*, *Geese*, and *Ducks* were well represented, although not in great numbers. The show of *Pigeons* was very fair—the *Carriers* were excellent.

Mr. R. Tate obtained the medal for the largest number of prizes.

We subjoin the prize list:—

**SPANISH**—First, G. Robson, Hull. Second, R. Tate, Driffield. Highly Commended, J. Holmes, North Cave. *Chickens*.—First, R. Tate. Second, J. Holmes.

**DORKINGS**.—First, W. Watson, Bishop-Burton. Second, H. Adams, Beverley. Highly Commended, O. A. Young, Driffield. *Chickens*.—First, Messrs. E. & W. Witty, Cottingham. Second, W. Watson.

**COCHIN-CHINA** (Buff, Lemon, or Cinnamon).—First, Messrs. E. & W. Witty, Cottingham. Second, R. Tate, Driffield.

**COCHIN-CHINA** (any other variety).—Prize, J. Bell, Thirsk. *Chickens*.—First, Messrs. E. & W. Witty, Cottingham. Second, R. Tate, Driffield. Highly Commended, A. Cattley, York.

**GAME** (Black-breasted or other Reds).—First and Second, H. Adams, Beverley.

**GAME** (any variety).—First and Second, H. Adams, Beverley. *Chickens*.—First, H. Adams. Second, R. Tate, Driffield.

**HAMBURGS** (Silver-spangled).—First, S. Campling, Cottingham. Second, R. Tate, Driffield.

**HAMBURGS** (Golden-spangled).—First and Second, R. Tate, Driffield.

**HAMBURGS** (Silver-pencilled).—First, G. Robson, Hull. Second, R. Tate, Driffield.

**HAMBURGS** (Golden-pencilled).—First, W. Norwood, Everingham. Second, J. Holmes, Pocklington. *Chickens*.—First, —Pears, Everingham. Second, R. Tate, Driffield. Highly Commended, S. Campling, Cottingham.

**POLISH** (any variety).—First withheld. Second, O. A. Young, Driffield.

**BANTAMS** (Gold or Silver-laced).—First withheld. Second, Messrs. E. & W. Witty, Cottingham.

**BANTAMS** (Black or White).—First, H. Hodge, Hull (White). Second, R. Tate, Driffield (White).

**SPANISH COCK**.—Prize, R. Tate, Driffield.

**DORKING COCK**.—Prize, R. Tate, Driffield. Highly Commended, A. Cattley, York; R. M. Staik, Hull.

**COCHIN-CHINA COCK**.—Prize, J. Bell, Thirsk. Highly Commended, A. Cattley, York.

**GAME COCK**.—Prize, H. Adams, Beverley.

**HAMBURGH COCK**.—Prize, R. Simpson, Kilnwick Percy. Highly Commended, R. Tate, Driffield.

**GAME BANTAM COCK**.—Prize, R. Tate, Driffield. Highly Commended, S. Robson, Brotherton.

**FARMYARD CROSS** (Single Cock).—Prize, R. Simpson, Kilnwick Percy.

**GEESE**.—First and Second, R. Tate, Driffield.

**DUCKS** (Aylesbury).—First, R. Tate, Driffield. Second, O. A. Young, Driffield.

**DUCKS** (any variety).—First, R. Tate, Driffield. Second, O. A. Young, Driffield.

**TURKEYS**.—First, R. Tate, Driffield. Second, Master R. English, Meltonby.

**GUINEA FOWLS**.—Prize, R. Tate, Driffield.

**PIGEONS**.—*Carriers*.—First, H. Hodge, Hull. Second, S. Robson, Brotherton. Highly Commended, A. L. Silvester, Birmingham. *Cock*.—Prize, G. Robson, Hull. *Pouters* or *Croppers*.—First, S. Robson. Second, Messrs. E. & W. Witty, Cottingham. *Tumblers*.—First and Second, A. L. Silvester, Birmingham. Highly Commended, G. Robson; J. W. Edge, Birmingham. *Barbs*.—First, A. L. Silvester. Second, T. Ellington, Woodmansey. *Jacobins*.—First, W. Carlton, Howden. Second, T. Ellington.

*Fantails*.—First and Second, T. Ellington. *Trumpeters*.—First, F. Key, Beverley. Second, H. Yardley, Birmingham. *Owls*.—First, F. Key. Second, J. W. Edge. *Turbits*.—First, A. L. Silvester. Second, J. W. Edge.

*Any variety*.—First, J. R. Trenam, Helmsley. Second, J. W. Edge.

**CAGE OF FOREIGN BIRDS**.—First and Second, G. Haigh, York.

**CANARIES**.—*Yellow Belgian*.—Prize, Miss Small, Howden. *Buff Belgian*.—Prize, G. Haigh, York. *Yellow* or *Buff Common*.—First and Second, G. Haigh, York. Extra, R. Wilkinson, Warter. Extra, A. Wright, Pocklington. *Mule*.—First, R. Gilson, Pocklington. Second, G. Haigh.

**RECAP**.—First, G. Haigh. Second, W. Lawson, Pocklington.

**RABBITS**.—*Longest Ears*.—Prize, P. Wood. *Any variety*.—First, J. Noble, Boston Spa. Second, O. A. Young, Driffield.

A Silver Medal given to the Exhibitor obtaining the greatest number of Prizes for Poultry, Pigeons, Canaries, and Rabbits.—R. Tate, Driffield.

**EXTRA STOCK**.—Prize, J. Bannister, Fridaythorpe (Golden-pencilled).

The Judges were Dr. Boulton, Beverley, and Mr. T. J. Charlton, Bradford.

### POULTRY EXHIBITION OF THE SPARKENHOE FARMERS' CLUB.

AS most of our readers are doubtless aware, the Sparkenhoe Farmers' Club ranks among the oldest and best managed of our Agricultural Societies. The Committee have long made poultry an important feature in their annual gatherings, offering a very liberal prize list to encourage the general competition of amateurs and breeders. The constant result has been the exhibition of most excellent specimens from almost every important poultry-yard in the kingdom, combined with so great an accession of visitors, that from this source alone a very considerable portion of the amount received at the doors is undoubtedly derivable. Their arrangements also, in respect to the public dinner, are as unique as they are invariably successful. The dinner tickets are issued alike to the fair sex as to gentlemen, the result being productive both of the best possible order, combined with an amount of enjoyment unattainable in the old accustomed path of restriction to the male portion of those interested in such matters only. To those who have not witnessed such a meeting, it would indeed be a matter of surprise to view, for the first time, the numbers of ladies who avail themselves of this privilege; nor could they witness, but with approval and satisfaction, the snavity and kindly feeling that everywhere prevails. It is well here to add that this is not the result of a single trial, but during a long succession of years the same unvarying conclusion has been arrived at. At the Meeting just past, the demand for dinner tickets was nearly double that of even last year, and perhaps societies of a like character would do well to give more than a passing thought to this legitimate means of improving their exchequer; for, beyond question, the sum received at the doors for admission, consequent on this arrangement, is threefold what might otherwise be expected.

By parties who have attended most of the previous exhibitions of poultry in connection with the Sparkenhoe Farmers' Club, it was the universal opinion that the present collection was far

superior to any that have been competing in bygone years. The continued influx of visitors to this especial portion of the show-yard proved, too, that poultry had not lost any of its attractions.

For many years past the Society has offered a silver cup for the best collection of three pens, the exhibitor remaining perfectly free from restriction as to the variety of breeds he may select, always providing that no two pens shall be similar. We believe that the greatest amount of competition previously obtained has been four exhibitors; on this occasion, however, sixteen threw down the gauntlet, and the rivalry was most extraordinary. We noticed one entry of Black Red Game, Silver-pencilled Hamburgs, and Buff Cochins; a second exhibitor placed his reliance on Grey Dorkings, Buff Cochins, and Grey Geese; a third tried his luck with Aylesbury Ducks, Partridge Cochins, and Rouen Ducks; another exhibitor (the cup winner) with an entry of Grey Dorkings, Black-breasted Game, and Aylesbury Ducks. Other collections comprised White Game, Black Red Game, and Chinese Geese. A trial for success was made with Silver-laced Bantams, Silver-pencilled Hamburgs, and Grey Dorkings; a more varied trio still consisted of White Guinea Fowls, Golden-spangled Hamburgs, and Chinese Geese; whilst yet another entry comprised a capital pen of common Geese, Turkeys, and Japan Pea Fowls. That unusual difficulty must ever attend the arbitrator when so conflicting varieties all put in alike their claims for distinction will be obvious at a glance, still the decisions both for the cup and also second prize of £2 were carefully arrived at; and this portion of the Exhibition proved of far greater public interest than any other class whatever.

We cannot speak approvingly of the *Spanish* fowls, save of the first-prize pen, the remainder without exception being faulty. The Grey Dorkings, however, were a capital class throughout. The White Dorkings were also especially good.

The Cochins were a fair average collection, and a majority of the Game fowls were most commendable.

In Hamburgs, Messrs. Nutting & Fielding, it will be seen by reference to the appended list, actually took all the prizes in both Golden-pencilled and also Silver-spangled. This was indeed a triumph for Manchester, as the competition was excellent.

The "Variety class" was a good one, the Silky fowls being perfect. The Andalusians were also most praiseworthy. It should be borne in mind, that this class is provided exclusively for varieties that have had no chance of entry in the foregoing classes, and that disqualification is inevitable (however good the specimens), if this monition is disregarded.

The Golden and Silver Chinese Pheasants were well shown.

The Turkeys, Geese, and Ducks were remarkably good. Among the latter were a pen of Shell Ducks worthy of the highest praise. These truly beautiful and extraordinary birds we were told had been actually bred by their parents in confinement—a very unusual occurrence, the original birds being hatched from eggs taken on the coast and tame-reared. The pen of three shown (two females and a male), appeared as domesticated as could be desired, and were in the highest plumage.

The show of Pigeons was superior, and many of the Rabbits were of high merit.

The weather was, unfortunately, the most unpropitious possible—a perfect deluge from earliest dawn until late in the day—yet, even despite this mishap, accompanied as it was with a heavy wind, the attendance far exceeded the anticipations of the Committee. As the inhabitants of Leicester had not spared any pains in the erection of triumphal arches with an unprecedented amount of banners, it was really distressing to see so great an amount of trouble and outlay thus rendered valueless by the continuous downfall; the wind lapping the banners so that the mottoes were quite hidden. Weather, of course, is not controllable by any human foresight, but it is due to the Committee to add, that every comfort both to visitors and poultry that was attainable under the circumstances, was most willingly rendered.

Two prizes were awarded for the three best Pens of Poultry, and second-best of any variety, exhibited by and the property of one person.—Silver Cup, W. T. Everard, Leicester (Aylesbury Ducks, Grey Dorkings, Game). Second, H. Yardley, Birmingham (Buff Cochins-China, Black Spanish, Duckwing Game). Highly Commended, J. Faulkner, Burton-on-Trent (Game, Coloured Dorking, White ditto); J. Martin, Claines, Worcester (Various); Major Hon P. Keck, Leicester (Pea Fowls, Turkeys, Geese).

SPANISH.—First, J. Martin, Claines, Worcester. Second,—Morley, Sapeote, Hinckley.

DORKING (Coloured) — First, A. Guy, Grantham. Second, Major Hon.

P. Keck, Leicester. Highly Commended, H. Warner, Loughborough; J. Faulkner, Burton-on-Trent; Mrs. Wolferstan, Tamworth.

DORKING (White).—First, W. Chamberlain, Leicester. Second, Capt. Buckley, Leicester. Commended, J. Grundy, Nuneaton.

COCHIN-CHINA.—First, J. Martin, Claines, Worcester. Second, H. Yardley, Birmingham. Highly Commended, Capt Buckley; H. E. Emberlin, Leicester.

GAME (White, Piles, and Light Colours).—First, Miss Alkin, Atherstone. Second, W. T. Everard, Leicester. Commended, J. G. Ayre, Ashby-de-la-Zouch.

GAME (Red and other dark Colours).—First, Miss Alkin, Atherstone. Second, J. Martin, Claines, Worcester. Highly Commended, W. T. Everard, Leicester; J. G. Ayre, Ashby-de-la-Zouch; M. Tavernam, Nuneaton. Commended, H. Warner, Loughborough.

HAMBURGH (Gold-spangled).—First, H. E. Emberlin, Leicester. Second, H. Warner, Loughborough.

HAMBURGH (Gold-pencilled).—First and Second, Messrs. Nutting and Fielding, Manchester. Highly Commended, Mrs. Wolferstan, Tamworth. Commended, J. Martin, Claines, Worcester.

HAMBURGH (Silver-spangled).—First and Second, Messrs. Nutting and Fielding, Manchester. Commended, W. Chamberlain, Leicester.

HAMBURGH (Silver-pencilled).—First, J. Martin, Claines, Worcester. Second, H. Marshall, Nottingham.

ANY OTHER DISTINCT BREED.—First, C. Lowe, Atherstone (Blue Andalusians). Second, J. Meredith, Atherstone. Highly Commended, Capt. Buckley, Leicester (Sultans); J. Meredith.

GOLDEN PHEASANTS.—First,—Lenard, Leicester. Second, J. Buck, Leicester. Commended, Miss Alkin, Atherstone.

SILVER PHEASANTS.—First, J. Buck, Leicester. Second,—Lenard, Leicester.

DUCKS (White Aylesbury).—First, W. Carver, Leicester. Second, H. E. Emberlin, Leicester. Highly Commended, W. Carver; H. E. Emberlin.

DUCKS (any other variety).—First, Major Hon. P. Keck, Leicester. Second, C. Lowe, Atherstone. Highly Commended, S. Pool, Melton Mowbray; Mrs. Wolferstan, Tamworth. Commended, J. Choyce, Atherstone; J. Cowlishaw, Leicester; W. Chamberlain, Leicester.

GESE.—First, J. Faulkner, Burton-on-Trent. Second, S. Truelove, Hopesford. Highly Commended, J. G. Ayre, Ashby-de-la-Zouch.

TURKEYS.—First, A. Guy, Grantham. Second, J. Coxon, Lichfield. Highly Commended, J. Cowlishaw, Leicester.

GUINEA FOWLS.—First, J. Johnson, Leicester. Second, J. Cowlishaw, Leicester.

EXTRA.—Commended, Hon. Major P. Keck (Pea Hen and Young). BANTAMS.—First, W. T. Everard, Leicester. Second, W. Parcs, Leicester. Highly Commended, H. Marshall, Nottingham.

PIGEONS.—Pouters or Croppers.—First and Second, J. Langham, Leicester. Carriers.—First, W. Choyce, Atherstone. Second, H. Yardley, Birmingham. Tumblers.—First, W. Choyce, Atherstone. Second, H. Yardley. Commended, H. Yardley; W. Chamberlain, Leicester. Fantails.—First, H. Yardley. Second, J. Langham. Commended, W. Choyce. ANY OTHER VARIETY.—First, H. Yardley. Second, W. Choyce. Highly Commended, H. Yardley; W. Choyce.

RABBITS.—Heaviest Weight.—First, W. Choyce, Atherstone. Second, J. Bowles, Leicester. Greatest Length of Ear.—First, H. Yardley. Second, J. Bowles. Highly Commended, W. Chamberlain, Leicester. Any other Kind.—Prize, J. Bowles.

The Judge was Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, Birmingham.

## HALIFAX AND CALDER-VALE POULTRY EXHIBITION.

THE Halifax and Calder-Vale Agricultural Society held their twenty-fourth annual Show in Clare Hall Park, Halifax, on Saturday last, the 30th ult. It is highly gratifying to find so much interest taken in this Exhibition by the inhabitants of Halifax and neighbourhood. In fact, when we mention that about £260 were received at the gates for admission, some idea may be formed of the success of the Meeting. The show of poultry and Pigeons was decidedly the best the Society has ever had, numbering upwards of four hundred pens, most of our principal exhibitors competing.

Black Spanish stood first in the list. Amongst the old birds there were some good specimens. The hen in Mr. Fletcher's first-prize pen was remarkably good. Mr. Rodbard's second-prize birds were also much admired. The young birds were a nice lot. Game mustered strong. In Black-breasted Red adults, we liked the second and highly commended pens more than the first-prize birds, the cock in the latter pen being rather out of condition and somewhat coarse. Both prizes were awarded to Black Reds. Mr. Firth exhibited good Brown Reds, but in wretched condition. The Game chickens were a good collection, both prizes again falling to Black Reds. Some very young Brown Reds of great promise were also shown. Duckwings, old and young, were capital; Mr. Fell's first-prize chickens especially deserving mention. In any other variety of Game the first in adults went to a good pen of Piles shown by Mr. H. Adams, and second to Blacks. In young birds, very good Blacks were first; and a splendid pen of Piles second. Dorkings and Cochins formed excellent classes, which will be fully borne out by a glance at the prize list. Polanders were in greater force than we have seen them for some time. The first and second prizes

in old were awarded to White-crested Blacks. In chickens the same variety again took precedence, and good Silvers second. A very fine pen of Whites received high commendation. *Hamburgs* were numerous and good, as might be expected from the locality; the Golden-spangled, Silver-spangled, and Silver-pencilled forming most excellent classes. The first-prize pens in old and young Golden-spangled were the gems of the Show. The *Bantam* classes were well filled, containing many valuable birds. Mr. Crossland secured first honours in each class.

*Ducks, Geese,* and the first-prize *Turkeys* were very fine.

The show of *Pigeons* was large and good. Mr. Smith's *Powers* were superb. Mr. Cannon exhibited good *Carriers*. In *Turbits, Jacobins, Trumpeters, &c.*, Mr. S. Shaw as usual sent excellent representative.

The Poultry Cup, value five guineas, for the best pen in the Exhibition, was awarded to Mr. Cannon's celebrated pen of adult Golden-spangled *Hamburgs*.

The Cup for the greatest number of Pigeon prizes was awarded to Mr. Shaw.

The arrangements of the Committee and Secretary (Mr. Irvine), were excellent in every department, and the decisions gave general satisfaction.

**SPANISH.**—First, J. Fletcher, Stoneclough, Manchester. Second, J. R. Rodbard, Aldwick Court, Writington, Bristol. Highly Commended, J. Siddall, Halifax. Commended, E. Brown, St. Phillip's Road, Sheffield. **CHICKENS.**—First, T. Greenwood, Eastfield House, Dewsbury. Second, J. R. Rodbard. Highly Commended, T. Greenwood.

**DORKINGS.**—First, H. W. B. Berwick, Helmsey, York. Second, G. R. Tate, Driffield. Commended, E. Smith, Middleton; T. Burgess, Burleydam, Whitechurch. **CHICKENS.**—First, Rev. J. F. Newton, Kirby-in-Cleveland. Second, G. R. Tate, Driffield.

**COCHIN-CHINA.**—First, T. Stretch, Vine Cottage, Ormskirk. Second, E. Witt, Cottingham, Hull. Highly Commended, E. Mu grove, Aughton, Ormskirk. Commended, J. Fletcher, Stoneclough, Manchester. **CHICKENS.**—First, T. Stretch, Vine Cottage, Ormskirk. Second, H. C. McCrea, the Shaw. Highly Commended, A. Wilson, Forest Cottage, Ovenden; H. Yardley, Birmingham.

**GAME (Black-breasted and other Reds).**—First, J. Firth, Ellen's Grove. Second, R. Parkinson, Preston. Highly Commended, Miss E. Beldon, Park Cottage, Bradford; W. Boyes, Beverley; H. Adams, Beverley; A. Holgson, Ovenden. **CHICKENS.**—First, I. Wright, Ovenden. Second, Miss E. Beldon. Highly Commended, J. Sunderland, jun., Coley Hall, Halifax; J. Firth; T. Dodds, Ovenden.

**GAME (Duckwing, Grey, and Blue).**—First, J. Fell, Adwalton, Leeds. Second, J. Firth, Ellen's Grove. **CHICKENS.**—First, J. Firth, Ellen's Grove. Second, J. Riley, Chickley, Dewsbury. Highly Commended, Miss E. Beldon, Bradford.

**GAME (any other variety).**—First, H. Adams, Beverley. Second, Miss E. Beldon, Bradford. Highly Commended, G. Noble, Stancliffe, Dewsbury; H. C. Mason, Drighlington. **CHICKENS.**—First, G. Noble, Stancliffe, Dewsbury. Second, Miss E. Beldon.

**SINGLE GAME COCK (any colour).**—First, D. Ashworth, Halifax. Second, H. Adams, Beverley. Highly Commended, J. Firth, Ellen's Grove; W. Bentley, Lowmoor. **COCKEREL.**—First, J. Sunderland, jun., Halifax. Second, G. Noble, Stancliffe, Dewsbury.

**POLAND.**—First, Miss E. Beldon, Bradford. Second, J. Dixon, Bradford. Highly Commended, H. Carter, Uppertonge, Huddersfield; J. Dixon, Bradford. **CHICKENS.**—First, J. Smith, Well Lane, Keighley. Second, Miss E. Beldon. Highly Commended, Miss E. Beldon.

**HAMBURG (Golden-pencilled).**—First, J. Dixon, Bradford. Second, S. Smith, Northwram. Highly Commended, F. Hardy, Bradford. **CHICKENS.**—First and Second, W. Cannon, Bradford.

**HAMBURG (Silver-pencilled).**—First, W. Cannon, Bradford. Second, J. Dixon, Bradford. Highly Commended, W. Clayton, Keighley. **CHICKENS.**—First and Second, S. Shaw, Stainland. Highly Commended, J. Dixon, Bradford.

**HAMBURG (Golden-spangled).**—First, W. Cannon, Bradford. Second, G. R. Tate, Driffield. Highly Commended, W. Cannon. **CHICKENS.**—First, W. Cannon. Second, H. & G. Newton, Leeds. Highly Commended, J. Dixon, Bradford; W. Cannon.

**HAMBURG (Silver-spangled).**—First, S. Campine, Cottingham, Hull. Second, W. Clayton, Keighley. Highly Commended, J. Dixon, Bradford. **CHICKENS.**—First, W. Cannon. Second, J. Mitchell, Hipperholme. Highly Commended, W. Cannon, Bradford; S. Shaw, Stainland.

**ANY OTHER DISTINCT BREED (ex cl. Bantams).**—First, Right Hon. Lady Hawke, Womesley Park (Brahma Fowls). Second, S. Shaw, Stainland (Black *Hamburg*). **CHICKENS.**—First, S. Shaw, Stainland (Black *Hamburg*). Second, J. Dixon, Bradford.

**BANTAMS (Game).**—First, J. Crossland, jun., Wakefield. Second, G. R. Tate, Driffield.

**SEBRIGHT BANTAMS (Gold or Silver-laced).**—First, J. Crossland, jun., Wakefield. Second, E. Yearley, Sheffield. Highly Commended, W. Cannon, Bradford.

**BANTAMS (any other variety).**—First, J. Crossland, jun., Wakefield. Second, G. R. Tate, Driffield. Highly Commended, C. Walker, Hopwood Lane, Halifax.

**DUCKS (Aylesbury).**—First, J. Dixon, Bradford. Second, G. R. Tate, Driffield.

**DUCKS (Rouen).**—First, J. Dixon, Bradford. Second, S. Shaw, Stainland. Highly Commended, S. Shaw.

**DUCKS (any other variety).**—First, S. Shaw, Stainland. Second, Master Edwards, Pixby Park (Grey Wild Ducks).

**GEES.**—First, G. R. Tate, Driffield. Second, J. Dixon, Bradford. Highly Commended, H. Ambler, Watkinson Hall.

**TURKEYS.**—First, J. Dixon, Bradford. Second, T. Ward, Whitby.

**EXTRA STOCK.**—Highly Commended, C. T. Rhodes, the Dudwells, Halifax (Golden-pencilled *Hamburgs*); C. Smith, Halifax (Dorking hen); H. Edwards, M.P. (White Swans).

**PIGEONS.—Pouters or Croppers.—Cock.**—First and Second, W. Smith, Beech Hill. *Hen.*—First and Second, W. South. Highly Commended, A. L. Silvester, Birmingham. **Carriers.—Cock.**—First, W. Cannon, Bradford. Second, J. Birstow, Heath Cottage, Halifax (Slate). Highly Commended, J. Wadsworth, Halifax (Black). Commended, J. Birstow. *Hen.*—First, W. Cannon (Slate). Second, J. Wadsworth, Halifax (Black). **Tumblers (Almond).**—First and Second, A. L. Silvester, Birmingham. Highly Commended, S. Shaw, Stainland. **Tumblers (Mottled).**—First, W. Cannon, Bradford. Second, S. Shaw, Stainland. **Balds or Beards.**—First and Second, S. Shaw, Stainland. **Owls.**—First, W. Cannon, Bradford. Second, W. F. Entwistle, Bradford. **Turbits.**—First, S. Shaw. Second, W. Cannon. Highly Commended, S. Shaw. **Jacobins.**—First and Second, S. Shaw. Highly Commended, W. Cannon, Bradford. **Fantails.**—First, W. Cannon. Second, S. Shaw. Commended, T. D. Walker, Liverpool. **Barbs.**—First, A. L. Silvester, Birmingham. Second, S. Shaw. Commended, W. F. Entwistle. **Dragons.**—First, T. D. Walker, Liverpool. Second, J. Wadsworth, Halifax (Blue). **Trumpeters.**—First and Second, S. Shaw. **Jaguars.**—First and Second, W. Smith, Beech Hill. *Any other breed.*—First, S. Shaw. Second, A. L. Silvester. Highly Commended, S. Shaw. Commended, A. L. Silvester.

The Secretary's Silver Cup, value Two Guineas, to the exhibitor who takes the largest number of Pigeon prizes, S. Shaw, Stainland.

The Silver Cup (value Five Guineas), for the best pen of poultry, W. Cannon, with Golden-spangled *Hamburg*.

The Judges were—*Poultry*, Mr. M. Hedley, 2, Sar Court, Bread Street, Cheapside, London; and Mr. T. J. Charlton, 50, Southgate, Bradford; *Pigeons*, Mr. J. W. Thompson, Southwain.

## WAKEFIELD POULTRY SHOW.

On the 4th inst. the first annual Exhibition of the Wakefield and West Riding Floral, Horticultural, and Poultry Society was held at Wakefield. The poultry numbered about 250 pens, and comprised birds from many of the best yards in the district, as well as specimens from a considerable distance.

*Game* were the first in the schedule, and were admirably arranged; each variety, except Blacks, Whites, and Piles (which were shown together), having a separate class in both old and young, all being well represented. In Black Reds Mr. Parkinson's birds merited their position, although closely pressed by several good pens. Mr. H. Adams' first-prize Brown Reds and Mr. Hellewell's Duckwings were excellent. Mr. Smith, of Slough, Bucks, was first in "Any other variety" with very good Piles. The chickens were a splendid lot, more especially the first-prize Duckwings. Black *Spanish* seem to be out of favour in this district, only one pen being shown. *Cochins* and *Dorkings* were good. In *Hamburgs* many choice pens were shown, the Golden-spangled being the most noticeable. *Bantams* were excellent.

The Show of Pigeons was unusually good, Mr. Robson's White *Powers* again taking first in their class. Mr. Shaw and Mr. Sylvester exhibited very good birds.

Great credit is due to the Committee, and more especially to the Hon. Secretary, Mr. John Crossland, jun., for the admirable arrangement of the Show, the only drawback to the complete success of the Meeting being the unfavourable weather preventing so large an attendance of visitors as might have been expected. Another year we trust the Committee may be more fortunate in this respect, and we hope they may attain, as they certainly merit, complete success.

**GAME (Black-breasted Reds).**—First, R. Parkinson, Poulton-le-Fylde. Second, G. Hellewell, Walkley, Sheffield. Third, Miss E. Beldon, Park Cottage, Bradford. Highly Commended, H. Adams, Beverley; J. S. Butler, Poulton-le-Fylde, Preston. **CHICKENS.**—First, J. Sunderland, jun., Coley Hall, Halifax. Second, G. Hellewell. Third, R. Parkinson. Highly Commended, H. Mantle, Collingham, Newark.

**GAME (Brown-breasted).**—First, H. Adams, Beverley. Second, T. West, Ecclestone, near St. Uellen's. Third, G. Hellewell. **CHICKENS.**—First, G. Hellewell. Second, W. S. Smith. Third, J. Sunderland, jun.

**GAME (Duckwing, and other Greys and Blues).**—First, G. Hellewell. Second, J. Riley, Third, J. Fell, Adwalton, Leeds. Highly Commended, H. Adams. **CHICKENS.**—First, J. Fell. Second, W. S. Smith. Third, T. Vickerman.

**GAME (Any other variety).**—First, W. S. Smith, Slough, Bucks (Piles). Second, G. Hartley, Gomersal, Leeds (Black). Third, H. C. Mason (White). Highly Commended, G. Noble, Stancliffe (Black). **CHICKENS.**—First, G. Noble, Stancliffe, Dewsbury. Second, J. Wilders, jun., Croxton Kerial, Grantham. Third, J. Craven, Wakefield. Highly Commended, T. Vickerman. **SPANISH.**—Prize, W. Cannon, Bradford.

**COCHIN-CHINA (Cinnamon and Buff).**—First, R. White, Broom-hill Park, Sheffield. Second, W. Dawson, Mirfield. Highly Commended, S. Pickard, Ditcher House. **CHICKENS.**—First, F. G. McCrea, Halifax. Second, R. White. Highly Commended, S. Pickard; W. Dawson.

**COCHIN-CHINA (Grouse and Partridge).**—Prize, R. White, Sheffield. **CHICKENS.**—Prize, R. White.

**COCHIN-CHINA (White, or any other colour).**—First and Second, W. Dawson. Highly Commended, S. Pickard. **CHICKENS.**—First, W. Dawson, Second, S. Pickard.

**DORKING (Coloured).**—First, S. Pickard. Second, H. Hinsworth, Lup et Hall. **CHICKENS.**—First, S. Pickard. Second, J. C. D. Charlesworth. Highly Commended, T. E. Kell, Wetherby; F. C. H. Hawke, Womersley Park; H. Hinsworth.

**HAMBURGH** (Golden-spangled).—First, W. Cannan, Bradford, Second, N. Marlor, Denton. **CHICKENS**.—First, W. Cannan. Second, H. Carter.

**HAMBURGH** (Silver-spangled).—First, H. Carter, Holmfirth. Second, W. Cannan. Highly Commended, W. Cannan. **CHICKENS**.—First, W. Cannan. Second, N. Marlor, Denton. Highly Commended, H. Carter.

**HAMBURGH** (Golden-pencilled).—First and Second, W. Cannan. Highly Commended, J. Smith, Halifax. **CHICKENS**.—First, W. Cannan. Second, J. Smith. Highly Commended, W. Cannan.

**HAMBURGH** (Silver-pencilled).—First, W. Cannan. Second, G. Hellewell. **CHICKENS**.—First, W. Cannan. Second, G. Hellewell.

**POLANDS** (Any variety).—First, Miss E. Beldon, Bradford. Second, H. Carter, Holmfirth. Highly Commended, F. Hardy. **CHICKENS**.—First and Second, Miss E. Beldon.

**ANY BREED NOT BEFORE MENTIONED**.—First, Hon. F. C. W. Hawke, Womersley. Second, W. Dawson. Highly Commended, W. Cannan. **CHICKENS**.—First, W. Cannan. Second, J. Pares, Binfield, Bracknell, Berks. Highly Commended, T. Chambers, Sheffield.

**BANTAMS** (Black-breasted and other Reds).—First, Master G. H. Crosland. Second, G. Hellewell. Third, J. Camm, Farnsfield, Notts.

**BANTAMS** (Duckwing).—First, W. Lawrenson. Second, Master A. Vickerman. Third, G. Hellewell.

**BANTAMS** (White).—First, Master G. H. Crosland. Second, Mrs. Foster, Beverley. Highly Commended, E. Morrison, Wakefield.

**BANTAMS** (Black).—First and Second, Master C. Crosland.

**BANTAMS** (Gold or Silver-laced).—First, Master J. Crosland. Second, W. Cannan.

**DUCKS** (Aylesbury).—First, T. E. Kell. Second, S. Stott, Rochdale.

**DUCKS** (Rouen).—First and Second, S. Pickard. Highly Commended, J. Birst, Boyne Hill.

**DUCKS** (Any other variety).—First, J. R. Jessop, Hull (Black East Indian). Second, Miss E. Beldon, Bradford (Wild Ducks).

**GESE**.—First, C. H. Mason. Second, F. C. H. Hawke. Highly Commended, J. Fawcett, Wakefield.

**TURKEYS**.—First and Second, J. Fawcett.

**SWEETSTAKES**.—*Game Fantam Cock*.—Prize, R. M. Stark, Hull. *Game Pallets*.—Prize, G. Hellewell.

## PIGEONS.

**CARRIERS**.—First, A. L. Silvester, Birmingham. Second, S. Shaw, Stainland, Halifax. Highly Commended, S. Robson, Brotherton; A. L. Silvester; W. Cannan; J. Deakin.

**POWTERS**.—First, S. Robson. Second, Miss E. Beldon, Bradford. Highly Commended, J. Sunderland.

**TUMBLERS** (Almond).—First, S. Shaw, Stainland. Second, A. L. Silvester. Highly Commended, W. Cannan; R. Oxley, jun.

**TUMBLERS** (Any other variety).—First, W. Cannan. Second, S. Shaw, Stainland. Highly Commended, J. W. Eyde, Liston New Town; R. Oxley.

**BARBS**.—First, A. L. Silvester. Second, S. Shaw, Stainland. Highly Commended, H. Yardley, Birmingham; W. Cannan.

**JACOBS**.—First, S. Shaw, Stainland. Second, Miss H. M. Crosland. Highly Commended, W. Cannan.

**TRUMPETERS**.—First, F. Key, Beverley. Second, F. Else. Highly Commended, F. Key.

**OWLS**.—First, J. W. Edge. Second, W. Cannan. Highly Commended, F. Else.

**TURBITS**.—First, S. Shaw. Second, R. Oxley. Highly Commended, F. Else; F. Key; A. L. Silvester; F. Butterworth.

**FANTAILS**.—First, R. Oxley. Second, F. Key. Highly Commended, S. Shaw; F. Else.

**NUNS**.—First, S. Shaw. Second, F. Else. Highly Commended, J. W. Edge.

**ANY OTHER VARIETY NOT MENTIONED**.—First, Miss H. M. Crosland. Second, S. Shaw. Highly Commended, S. Pickard; F. Butterworth.

**RABBITS**.—*Longest Ears*.—Prize, W. S. Smith, Slough, Buckingham. Highly Commended, J. Sunderland. *Any Variety*.—First, S. Pickard. Second, J. Pope, Biggleswade. Highly Commended, L. Appleyard.

**CANARIES**.—*Belgium*.—Prize, R. Freckleton. *Marked*.—Prize, R. Freckleton. *Any other variety*.—First, R. Freckleton. Second, G. Milthorpe. *Nest of Young* (any number).—Prize, R. Freckleton.

Mr. T. J. Charlton, of Bradford, officiated as Judge, and his awards gave general satisfaction.

## CRAVEN POULTRY SHOW.

THE eighth annual Exhibition of the Craven Agricultural Society took place on the 29th ult., in a field behind the Castle grounds at Skipton. The day was observed as a holiday, and seldom has the old historic town of Skipton had within its precincts so large a number of visitors; thousands having been brought by special trains from various parts, not only of Craven, but from more distant places in the West Riding of Yorkshire.

The prizes gave the large total of £450, and the entries, including every class—cattle, horses, sheep, pigs, poultry, implements, and vegetables, numbered 1119. The excellence of the Show was sustained in every department, with the single exception of roots, for which the season has been unfavourable. The receipts from visitors attending the Show amounted to £240.

The show of poultry was generally good; and the arrangements of the Committee and Secretaries were most efficient, and ably carried out. *Dorkings* only mustered one entry each, in old birds and chickens. *Black Spanish* also seem in little favour in this locality, only three pens appearing in the two classes. *Game* were much better represented. Mr. Grimshaw, of Pendle Forest, exhibited excellent birds, taking both prizes in the class for old Game, the first with Black Red, and the second with Brown Red. The same exhibitor also gained second prize in

chickens with Brown Reds; Miss Emily Beldon securing first honours with good Black Reds in perfection of condition. *Cochins* formed average classes. *Hamburghs* were, however, the principal feature of the Show, the district being noted for this breed. Silver-pencilled, and the two varieties of Spangled were the most meritorious, including several excellent pens, the competition being very close. *Polands* were good; *Bantams* scarcely up to the mark. *Geese*, *Ducks*, and *Turkeys* were well represented, although not in great numbers.

The *Pigeons* were not the least attractive part of the Show, the prize birds having mostly figured conspicuously at larger gatherings; Carriers, Tumblers, Owls, Barba, and Jacobins being more especially worthy of notice.

The following is the prize list:—

**DORKINGS**.—Prize, J. Dixon, Bradford. **CHICKENS**.—Prize, Rev. J. F. Newton, Kirby-in-Cleveland, Stokesley.

**SPANISH** (Black).—First, W. Cannan, Bradford. Second, J. Dixon, Bradford. **CHICKENS**.—Prize, J. Dixon.

**GAME**.—First and Second, N. Grimshaw, Pendle Forest, near Burnley (Black and Brown Reds). Commended, Miss E. Beldon, Bradford. **CHICKENS**.—First, Miss E. Beldon, Bradford (Black Red). Second, N. Grimshaw, Burnley (Brown Red). Commended, J. Wilkinson, jun., Earby.

**COCHIN-CHINA**.—First, E. Smith, Lancashire (Partridge). Second, W. Dawson, Hopton Mirfield (White). Commended, J. G. Sugden, Keighley. **CHICKENS**.—First, J. & G. Newton, East Street, Leeds. Second, W. Mitchell, Keighley. Commended, E. Smith; J. G. Sugden, Keighley.

**HAMBURGHS** (Golden-pencilled).—First, J. Dixon, Bradford. Second, W. Cannan, Bradford. **CHICKENS**.—First, W. Cannan. Second, T. Smith, Halifax. Commended, H. Pickles, jun., Earby.

**HAMBURGHS** OR **CHUTEPRATS** (Silver-pencilled).—First, D. Wilson, Sutton. Second, J. Hoyle, Keighley. **CHICKENS**.—First, H. Pickles, jun., Earby. Second, W. Cannan, Bradford. Commended, W. Canoan; J. Hoyle, Nettle-hole, near Keighley; E. Hindle, Accrington.

**HAMBURGHS** (Golden-spangled).—First and Second, W. Cannan, Bradford. **CHICKENS**.—First, J. Newton, Silsden. Second, W. Cannan, Bradford. Commended, W. Cannan.

**HAMBURGHS** (Silver-spangled).—First, W. Cannan. Second, D. Wilson, Sutton. **CHICKENS**.—First and Second, W. Cannan, Bradford. Commended, J. Newton, Silsden.

**HAMBURGHS** (Black).—First, W. Cannan, Bradford. Second, J. Dixon, Bradford. **CHICKENS**.—First, W. Cannan. Second, W. Harker, Cottingley.

**POLANDS**.—First, Miss E. Beldon, Bradford. Second, J. Dixon, Bradford. **CHICKENS**.—First, J. Dixon (Silver). Second, J. Smith, West Lane, Keighley (White-crested Black).

**BANTAMS** (Game).—First, W. Newsome, Biggley (Duckwings). Second, G. R. Tate, Driffield (Black Red). **CHICKENS**.—First, W. Lawrenson, Poulton-le-Fylde. Second, W. Newsome.

**BANTAMS** (any colour).—First and Second, W. Cannan, Bradford (Gold and Silver Laced). **CHICKENS**.—First, J. Hargreaves, Skipton. Second, J. Dixon, Bradford.

**ANY OTHER VARIETY**.—First, W. Dawson, Hopton Mirfield (Sultans). Second, J. Dixon, Bradford. **CHICKENS**.—First, J. Dixon (Malays). Second, T. Chambers, Sheffield (Ibrahma Pouter).

**SWEETSTAKE** (Game Cocks).—First, R. Whittam, Burnley.

**GESE** (White).—First, G. R. Tate, Driffield. Second, Mrs. M. Green, Todley, Keighley.

**GESE** (Grey).—First, J. Dixon, Bradford. Second, S. Swire, Stainton Cotes.

**DUCKS** (Aylesbury).—First, J. Dixon, Bradford. Second, J. Collinge, Habergham Hall, Burnley.

**DUCKS** (Rouen).—First, J. Dixon, Bradford. Second, J. Collinge, Burnley.

**ANY OTHER VARIETY**.—First and Second, J. Dixon, Bradford (Grey Calls and Black East Indian).

**TURKEYS**.—First, J. Dixon, Bradford. Second, O. A. Young, Driffield.

**PIGEONS**.—*Carriers*.—First, S. Shaw, Stainland, Halifax. Second, H. Smith, Skipton (Black). *Powters*.—First, Miss E. Beldon, Bradford. Second, S. Robson, Brotherton, York. *Tumblers* (Almond).—First, S. Shaw. Second, W. Cannan, Bradford. *Owls*.—First, W. Cannan. Second, H. Smith, Skipton. *Barbs*.—First and Second, S. Shaw. *Jacobins*.—First, S. Shaw. Second, W. Cannan. *Tumblers* (Mottled).—First, W. Cannan. Second, S. Shaw. *Fantails*.—First, W. Cannan. Second, J. Anderson, Ghsburn. *Dragons*.—First, S. Shaw. Second, J. Anderson, Crosshills. *Anticraps*.—First, H. Smith, Skipton. Second, J. Collier, Skipton. *Any other Variety*.—First, S. Shaw (Blue Shields).

The Judges were Mr. James Heywood, Bow Lee, Middleton, Manchester; and Mr. T. J. Charlton, Bradford.

## DEWSBURY POULTRY SHOW.

THE annual Show of poultry took place at Dewsbury, on Wednesday, the 27th ult., when the following prizes were awarded:—

**COCHIN-CHINA**.—First and Second, W. Dawson, Hopton. **CHICKENS**.—First, W. Dawson, Hopton. Second, J. Dixon, Bradford.

**SPANISH**.—First, W. Cannan, Bradford. Second, J. Dixon, Bradford.

**CHICKENS**.—First and Third, T. Greenwood, Eastfield Mills. Second, J. Senior, Batley Carr.

**DORKING**.—Prize, J. Dixon, Bradford. **CHICKENS**.—Prize, F. Hardy, Bradford.

**HAMBURGH** (Golden-spangled).—First, W. Cannan, Bradford. Second, J. Dixon, Bradford. **CHICKENS**.—First, J. Dixon, Bradford. Second, S. Shaw, Stainland, near Halifax. Third, W. Cannan, Bradford.

**HAMBURGH** (Silver-spangled).—First, J. Dixon, Bradford. Second, W. Cannan, Bradford. **CHICKENS**.—First, W. Cannan, Bradford. Second, J. Dixon, Bradford. Third, S. Shaw, Stainland, near Halifax.

**HAMBURGH** (Golden-pencilled).—First, J. Dixon, Bradford. Second, T.

Smith, Northwram, near Halifax. CHICKENS.—First, J. Dixon, Bradford. Second, T. Smith, Northwram, near Halifax. Commended, W. Cannan. HAMBURG (Silver-pencilled).—First, J. Dixon, Bradford. Second, S. Shaw, Stainland, near Halifax. Commended, W. Cannan, Bradford. CHICKENS.—First, W. Cannan, Bradford. Second, S. Shaw. POLAND.—First and Second, J. Dixon, Bradford. CHICKENS.—First, J. Dixon. Second, Miss Beldon, Bradford (White). GAME (Black-breasted and other Feds).—First, Messrs. Noble & Ineson, Heckmondwike. Second, Miss Beldon, Bradford. CHICKENS.—First, Miss Beldon. Second, J. Rylah, Chikley. Third, T. Vickerman, Chikley. GAME (Duckwings and other Greys and Blues).—First, Messrs. Noble and Ineson, Heckmondwike. Second, J. Fell, Adwalton. CHICKENS.—First, J. Fell. Second, T. Vickerman, Chikley. GAME (Black).—First, G. Noble, Staincliffe (Black). Second, J. Brooke, Gomersal. GAME (White).—First and Second, H. C. Mason, Drighlington. Third, J. The Judges were Mr. T. B. Stead, Leeds; and Mr. Isaac Thornton, Heckmondwike.

## TRANSFERRING BEES.

ALLOW me to point out to "A. W. D.," or any one else who may attempt to transfer bees with their combs from a common to a frame-hive, the importance of fixing the middle "partition wall," as the Germans term it, of each comb exactly in the centre of the bar to which it is to be attached. In many combs some of the cells will be found elongated on one side for the purpose of storing honey, whilst those on the opposite side remain the usual length. When "paring down" projecting parts this must be particularly attended to, so as to make sure of cutting down only those cells which have been thus elongated.—A DEVONSHIRE BEE-KEEPER.

[We agree with our correspondent as to the importance of the caution which he gives, and are obliged to him for the hint.]

## EGGS LAID BY A QUEEN BEE NOT HATCHING.

IN page 207 of this volume I described the unexpected issue, on the 4th of June, of a large swarm—so large indeed that I divided it into two, shaking one into the whilom super in which I described several royal cells. Ten days afterwards this swarm threw off another, which left the box nearly deserted with most of the cells empty owing to the brood having arrived at maturity. It being, therefore, necessary to return the swarm, I removed the crown-board; and having caught the young queen and introduced her to a queenless stock, I shook the cluster out of the straw-hive, in which it had been temporarily lodged, on the top of the exposed bars. Between these they immediately disappeared, and the job was complete. In due time a number of eggs were deposited in the worker-cells; and when I looked at the large and very handsome Ligurian queen by which they were laid, I doubted not that I had established a strong colony which had probably a long and prosperous career before it. Weeks passed on, however, and the drones having been got rid of, the workers appeared rapidly to diminish instead of increasing in numbers, so that it became evident that something was wrong. An examination of the interior revealed the mischief. Although innumerable eggs were laid not one in fifty was hatched. Never did I see eggs deposited in greater profusion, every cell in the "brood-nest" was occupied, many by two and even three eggs; but of worms or sealed brood there were but very few indeed. Here was a puzzle! That the queen had been impregnated was evidenced by the sealed worker-cells being only of the usual length,

whilst, though few and far between, one or two recently-hatched and perfectly-developed Ligurian workers placed the fact beyond cavil. Being unwilling to destroy so beautiful a queen without giving her a fair trial, I allowed her to remain until the 20th of last month (August). By this time the population had dwindled very much, and the same state of affairs continuing I handed her over to Mr. Fox, who proposed placing her at the head of a queenless stock with the view of watching the result of so singular a phenomenon. Although I supplied the colony with a sealed royal cell, which in due time produced a handsome Ligurian queen, the bees raised several princesses from the brood left behind by their late semi-fruitful sovereign. Having no desire to perpetuate the breed, I destroyed them all after allowing them to be sealed over, and thus satisfying myself as far as convenient that they were most probably capable of being hatched into queens.

I regret to state that I learned a few days afterwards that Mr. Fox had allowed the queen to perish, not having had the opportunity he expected of placing her at the head of a queenless stock; and thus I lost, what was certainly but a very forlorn chance, the opportunity of attempting to penetrate by means of a *post mortem* microscopical examination what still appears to me a most inscrutable mystery.

I commend the foregoing narrative to the attention of Mr. Edward Fairbrother. It would certainly have figured in my reply to his query as an instance of bees dwindling away in their hives from some inexplicable and irremediable cause had it occurred at an earlier period of my career as—A DEVONSHIRE BEE-KEEPER.

## DO BEES VARY?—DZIERZON'S OPINION ON THE POINT.

BEING willing to elicit the opinions of German apiarians in general, and that of Dzierzon in particular on the above subject, I forwarded Mr. Darwin's inquiry to the Editors of the German *Bee Journal*, by whom it has been inserted together with the following reply from Herr Dzierzon.—A DEVONSHIRE BEE-KEEPER.

"DO BEES VARY IN THE DIFFERENT PARTS OF GERMANY?—To the inquiry of Mr. Charles Darwin I reply with pleasure, although owing to want of time I can do so but briefly, and not so particularly as I wished and the question merited. At various times when speaking of the marks which distinguish the yellow Italian bee from our black or grey bee I have already stated that even among the native bees considerable differences are observable in colour or other qualities. The bees of some stocks are decidedly dark, whilst others are remarkable for their yellow colour, and come nearer to the Italian bee. At the meeting of bee-keepers at Vienna in 1853 I observed in the apiary of Herr Freudenthaler several hives in which a great number of the bees were marked with a yellow ring on the abdomen, as is the case with Italian bastards. This difference in colour is especially apparent in the drones. Whilst these are quite black in some stocks, in others they appear with bright rings on the abdomen, and so like Italian drones that they are scarcely distinguishable from them in a superficial examination. This may also explain why the impregnation of an Italian queen by a native drone produces such various effects. Sometimes the degeneration is soon observable, whilst in other cases queens thus impregnated produce such beautiful offspring that one is scarcely able to distinguish them from true Italians. Bees of lighter colour seem also nearer the Italians in this respect that they appear more good-tempered and diligent, whilst the darker ones seem more ill-natured and more disposed to sting.

"If many stocks with their offspring are more inclined to swarm whilst others are richer in honey, so that some beekeepers even distinguish between swarming and honey-gathering bees, this is a habit which has become second nature, caused by the customary mode of keeping and the pasturage of the district. For example: What a difference in this respect one may perceive to exist between the bees of the Lüneburg heath and those of this country. There even second swarms and parent hives still in the same year make preparations for swarming again; whilst here a young queen of the current year will not lay drone-eggs even under the most favourable circumstances both of weather and pasture. Removing an old queen and substituting a young one of the current year is here an infallible mode of keeping the strongest stock from swarming, and preventing

drone-breeding; whilst the same means if adopted in Hanover would certainly be of no avail.

"With regard to size, I have never been able to perceive a constant difference either between the Italian and native bees or amongst the latter. One may easily delude oneself in this respect, and deem essential what is but casual. As with the same kind of bee, and even in the same hive large and small queens are hatched in consequence either of more plentiful or more sparing food, of a larger or a smaller cell, so may also whole generations of workers hatch either larger or smaller from the cell, according as the brood-combs are new or old, or food plentiful or scanty; and if wild bees are said to have been found smaller than others, this may be explained by the greater age of their combs.

"If the difference in colour, which cannot be denied, be ascribed by many to the influence of climate, this opinion is evidently a mistaken one. The Italian bee, which has been termed only a climatic variety, occurs as is known but in a small district, and both it and the black bee have been kept up in Italy from remote antiquity. The foreboding that this species would soon degenerate in Germany into the common black kind has not been realised. In ten years—that is, since its introduction, it has not degenerated with me. The difference in colour is, therefore, a characteristic peculiarity of the species, and no casualty produced by climatic influence.—*DZIERZON, Carlsmarkt, July 28th, 1862.*"

## HONEY AND WAX AT THE INTERNATIONAL EXHIBITION.

"WELL, what of it? Who would care to waste their attention upon those common matters when so many other more important objects are there to claim attention?" I grant all that, yet there is much of less importance to demand attention also; for, when the manifold productions exhibited in the composition of which honey and wax form a great part are considered, and when the by-no-means-slight search has been made in order to discover the numerous specimens which are sent from all parts of the world, one is prone to set down honey and wax as of much more importance than a mere casual observer might choose to give them credit for. But be this as it may, the Jurors of the English class IX. do not appear to have regarded the apianians and their products as of the least consequence whatever—in fact, they have passed them over entirely, unless, peradventure, the successful gainers of those medals and mentions are blushing to find themselves famous, and are keeping them out of our sight. It is possible, and, as public opinion goes, advisable; but the foreign exhibitors show no such squeamishness. There are the medals and mentions sure enough, showered upon them in heaps, and with an indiscrimination perfectly ludicrous. If I were to offer the majority of those products which are dubbed with honours to our London dealers, they would curtly inform me that "such stuff would not suit their customers," and not condescend even to bow me out of their shops. Knowing this, how is it that Mr. Woodbury's large and beautiful super of Ligurian honeycomb, "first of the throng and foremost of the whole," on Messrs. Neighbours' stand is passed over? The same remark may apply to his bar-and-frame hives; in fact, all the English bee-hives, both of high and low degree, are well worthy to be honourably compared with any of their foreign competitors, yet there is a complicated affair, by no means fit to be placed in our front ranks, which has been given a medal in the Zollverein court. What is fair for one ought to be fair for another. There are English hives exhibited, to which, up to the present time, equals are not to be found, and it is quite annoying to find the British bee-keepers and their inventions thus scurvily passed over.

Let every possible pot of honey succumb to the ivory knob on the tip of my cedar pencil, and let every cake of wax, and every bee-hive, subsolve to what scrutiny and justice I can give them, in order to set ourselves right amongst ourselves in this matter, and with the crinolines also. Effectually to do this, as regards the latter, one must glide—do not lift a foot from off the floor, or you come to grief, and fiery darts to a certainty. A quantum of resistance to the circumferences I find not to be disapproved of, but no stamped. I wore a thinnish easy pair of boots (I speak advisedly) during my apianian search, and in order to escape stamping on the ladies' dresses, I soon "slithered" holes completely through the soles, the mere object of which is nothing to a rip of a skirt.

Well, as regards the catalogue and how to find out what one

wants through its agency, only those who have been making a similar scrutiny can form the least idea. According to its index I will take the nations as they come.

ENGLAND.—Class IX.—My case, No. 2112, and all that is in it, is situated almost at the extreme end of the eastern annex, near the bricks; and in Ormson's conservatory close by are Messrs. Boothman's, Pettit, Munn's, &c., bee-hives, amongst the stones. On the right and left of Mr. Ormson's conservatory, just inside the western half of the eastern annex, are Mr. Marriott's and Messrs. Neighbours' stands, both of whom exhibit hive-bees at work, with a variety of their own, and other hives and bee-implements well worth inspection. The best of the English hives exhibited have been so long and are so recently familiar to the pages of this Journal, that it would be mere repetition to recount them. Mr. Marriott's bees are working in a glass hive carefully covered over, and labelled, "Do not touch on any account." So, according to the spirit of a label I saw on a Swiss stand, I kept my "hands off."

The Ligurian bees exhibited by Messrs. Neighbour in a uni-comb-hive are very fine. They are the first of the sort I have seen, and I was rather disappointed in their colour. I expected to find them more sparkling, but they are really a beautiful sight. They had sealed over a good portion of one side of their combs, and were busily working the last time I saw them—the third week in August at half-past six. I happened to observe the queen and pointed her out to some other persons, and soon collected sufficient people to fill the steps and the rostrum. Of course, a lecture on bees naturally followed, but it was near closing time, and a piteous look from the policeman inclined me to intimate that I was not the proprietor of the stand, which at once broke up the audience. It proves hard work for the policemen in the Exhibition, and it is cruel to keep them on duty one minute longer than is absolutely necessary. Allow me here to express my thanks to them for their uniform civility and attention to my numerous wants and inquiries.

COLONIAL POSSESSIONS.—*Australia, South.*—There is part of a cake of tolerably good yellow beeswax exhibited, which gains an "honourable mention."

*Nova Scotia.*—Two parallelogram deal-box supers of honeycomb measuring about 1 foot 3 inches by 9 inches, from "Down Cape," very good, and a cake of wax turned out from a jelly shape. There is nothing new under the sun: I was nursing the idea that my specimens of wax would be the only ones formed by those culinary aids, and here comes one to match from the farther part of the earth.

*Ceylon.*—Honey is specified in the catalogue. I could find none; but I believe a number of things were lost in this court. There is an ordinary specimen of white wax, and some vegetable wax partaking much in appearance of stale preserved vegetables. There is also a bottle of cocoa-nut honey or sugar, having a combined flavour of very bitter honey and coarse brown sugar. It is like very brown liquid honey, with one-fourth sediment like whity-brown congealed honey.

*Bahamas.*—The Local Commissioners exhibit honey in large glass bottles, and a quantity of cakes of a peculiar brown-coloured wax. The honey is good and ought to have met with its reward. This is a very interesting court.—UPWARDS AND ONWARDS.

(To be continued.)

## OUR LETTER BOX.

SPANISH AND BRAHMA POOTRA HENS LAYING (*S. T. V.*).—Neither of these varieties are such good layers as the Hamburgs, but they lay larger eggs; we should think they ought to lay a hundred eggs in the year if they are well fed and have a good run. This is perhaps more than the highest bred Dorkings will lay, but Hamburgs will almost double that number. In a general way we have found the Spanish hens good layers, and endure confinement better than any other kind. Brahma Pootras are less patient in that respect, and their laying qualities are more enhanced by a good run than often feeding. With plenty of space to ramble about in, they will assuredly lay the number of eggs you speak of.

HENS BREATHING NOISILY (*S.*).—Give each of them a tablespoonful of castor oil, less hard corn, no rice, and more boiled potatoes. It may be that they are too fat, and if so omit the hard corn altogether for a week or two, and mix a little barleymeal with the potatoes.

DISEASE IN LINNETS AND GOLDFINCHES (*Q. T. L.*).—Your birds are most likely suffering from obstruction of the oil gland. If you had pressed out the matter, and anointed the inflamed gland with a little butter, it would have helped the sufferer. The bath is very useful in keeping the birds in health.—B. P. B.

TURTLE DOVES.—*Fantail* Doves are evidently the Collared Turtles (*Columba risoria*); the white ones are a variety of the same species. They might be matched in London without much difficulty. I know of no mark to distinguish the sex; but the cock may be known by his coo and gestures.—B. P. B.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 67.2° and 45.8° respectively. The greatest heat, 84°, occurred on the 17th, in 1813; and the lowest cold, 29°, on the 17th, in 1840. During the period 131 days were fine, and on 114 rain fell.

CULTURE OF SUCCULENTS.

FIND my pot plants take so much time that they starve my mind; I cannot find time even to read your Journal till winter evenings return. My little conservatory is divided into two parts, one well shaded, and in which planted-out Ferns thrive well, and give little labour. In the other I have a collection of

greenhouse plants which I could (although most reluctantly) part with; but I cannot neglect them. I think of leaving this with succulents; and if so, will you kindly give me a selection of such as would thrive at ordinary greenhouse temperature?—H. B.

[We can thoroughly enter into the feelings of our correspondent. We all have our hobbies, which we would wish to gratify; and strong as the love of the naturally beautiful may be within us, there may be yearnings after mental vigour—at least, such a strong desire to hold even distant communion with men of great intellect, that the growing of plants, however delightful, must come in as a secondary consideration. Though gardening be not only our hobby, but that by which we live, we sometimes long for the winter evenings, when we hope to get through several volumes, and thus prevent total starvation of mind; as we candidly confess that in summer we have just as little time to read as our correspondent has to attend to his greenhouse plants. Though, therefore, whether from benevolence true and unalloyed, or mingled as it too often is with a fair portion of selfishness, we would wish every man and woman to be a plant-grower, just because we believe they will be bettered, physically and morally, by such occupations; yet we would be the last to encourage this being done to any such extent as would interfere with the more serious duties of life, and those stern obligations which a man owes to his family and himself. The instance of our correspondent, however, is a very pleasing exemplification of the old proverb, that "Where there is a will there will be found a way," and that the real man with genuine stuff in him, will never give up easily a fondly-cherished object, or allow trifles of obstruction to stand in his way. With little time to attend to greenhouse plants in pots, he has turned the half of his little conservatory into a fernery, the plants being planted out, and thus insuring the engaging and beautiful in form with the minimum of time and labour in attending to their wants. The other half he wishes to appropriate to succulents, and these we presume to be kept in pots, in order that at their different stages they may individually receive the treatment they most want, and yet be independent of any of that minute and regular attention

which is required for a Geranium or a Cineraria. We have reason to be delighted with the idea, as in these pages we have frequently recommended the identical practice to those who were much from home, much engaged, and who, with a strong love for vegetable nature, could not give the attention to plants which they generally require. Such succulents, in general, will take little harm if neglected for days, and sometimes for weeks, though, of course, the greater the amount of a right attention they receive the better they will thrive; whilst in the variety of their shapes, the grotesqueness of their forms, and in many cases the graceful beauty and gorgeous grandeur of their flowers, there will be presented the elements of pleasant study and constant admiration.

We have long had a desire to secure a collection of these beauties, so as to form a small house of them, but have, as yet, failed to make a commencement; and at present so much have they fallen out of favour, that we could not tell our correspondent where to procure them, though, no doubt, a desire to possess will soon let us know where such things suitable for a greenhouse can be freely obtained. Amongst our recollections, besides the splendid collection at Kew there used to be a fine assortment at the Horticultural Gardens at Turreham Green, and a good many at some of the nurseries round London. In the provinces the best collection we recollect having the pleasure of seeing were at the Botanic Gardens at Oxford, and the Botanic Gardens at Bury St. Edmunds; and a hint has come in our way that the commercial is to be added to the requisites of the latter establishment. In such circumstances we would advise our correspondent to procure a few as he can get them, and then gradually weed out, so as to retain only one of a kind. If the room is very limited, we would commence with *Aloe* and *Mesembryanthemum*. But just because it may be difficult to get the most suitable at first, we will give rather a long list, in hopes he will find some at least of each family; and though the time of flowering will depend greatly on the treatment, we will divide them into three classes, as showing the times when they will most generally bloom if any moderate degree of attention be given to them.

- 1st. Spring-blooming succulents for a greenhouse:—  
*Aloe glauca, socotrina, aristata, spinosa, subcordata, tuberculata, verrucosa, and cymbiformis.*  
*Cotyledon coruscans, and canaliculata.*  
*Crassula cordata, obliqua, and punctata.*  
*Globulea lingua, sulcata, capitata, mollis, &c.*  
*Haworthia translucens, aspericaulis, atrovirens, hybrida, parva, &c.*  
*Mesembryanthemum crassicaule, marginatum, microphyllum, versicolor, filamentosum, Scottii, virgatum, aduncum, deuticulatum, &c.*  
*Sempervivum cruentum, glandulosum, and rupifragrum.*  
*Rochea jasminea, and versicolor.*  
 For blooming in summer chiefly:—  
*Aloe perfoliata, maculata, nobilis, tenuifolia, flavispina, and dichotoma.*

*Agave americana*, variegata, glauca, and virginica.  
*Cereus grandiflorus*, speciosissimus, flagelliformis, Ackermani, and many British hybrida.

*Cactus*—a few of the hardier kinds of *Echinocactus*, as acutus, concinnus, Linkii, pulchellus, longifolius, &c.

Of *Mammillaria*, as columnaris, helictaria, prolifera, tenuis, turbinata, &c.; and of

*Melocactus* as pyramidalis, and amœnus, &c.

*Cotyledon jasminiflora*, alternans, cornescans, decussata, ovata, sempervivum, mammillaris, maculata, &c.

*Crassula ciliata*, cordata, filicaulis, acutiformis, imbricata, orbicularis, coccinea, and versicolor.

*Echeveria coccinea*, and grandifolia.

*Haworthia margaritifera*, media, minor, &c., viscosa, setosa, tessellata, &c.

*Mesembryanthemum capitatum*, aurantium, multiflorum, productum, difforme, &c.

*Opuntia fragilis*, mollis, &c.

*Rocrea falcata*, and perfoliata.

*Sempervivum aureum*, Smithii, tabulæforme, canariense, arboreum, aureum, glutinosum, villosum, &c.

For blooming in autumn and winter, such kinds as the following:—

*Aloe depressa*, arborescens, picta, purpurascens, &c.

*Cacalia vicinns*, and articulata.

*Crassula columnaris*, ericoides, revolveus, filicaulis, and lactea.

*Cotyledon clavifolia*, cristata, &c.

*Globulea hispida*.

*Epiphyllum truncatum*, speciosum, &c.

*Mesembryanthemum multiflorum*, depressum, difforme, muciforme, minimum, miniatum, grandiflorum, foliosum, compactum, bifidum, and albiglutatum.

*Sempervivum tabulæforme*, &c.

With the exception of *Cereus*, *Epiphyllum*, *Crassula coccinea*, *Echeveria*, and *Sempervivum arboreum*, &c., most of these plants are of a low, stubby, or trailing character. Unless thoroughly burnt up, or thoroughly soaked so as to make a marsh plant of them, they can scarcely be killed with neglect. On commencing, a sandy loam and a little lime rubbish will grow them all well, and moisture in the shape of watering should chiefly be given when the plants are growing freely or showing bloom; at other times, and especially in winter, if not in bloom, or showing bloom, they should be kept rather dry. In fact, many kinds, if the pots stand on a bottom at all moist, will need no water for months, where there is not much sun. This arises from the fact that the whole of the leaves are, in general, more abundantly supplied with absorbing than perspiring pores. We have had *Haworthias*, *Aloes*, *Mammillarias*, *Melocactus*, &c., flourishing nicely that had not been watered for three or four months, and a week's neglect at any time hardly did them any harm.

So much for our friend commencing with his succulents. He may expect for himself, and his visiting friends, a great amount of gratification at the smallest expense of time and labour, and the general principles alluded to above will apply to all we have maintained; but as soon as we can look round us, we will in a simple way specify for his and others' benefit some of the minutæ of detail, for just now we are all up to the neck with work requiring to be done, demanding from us the exercise of the knife and the potting-bench rather than the quill. But all will be done in good time. Get the plants first, like the cook with the hare. We are sure the growing will be all right. We would just say there are many annual *Mesembryanthemums* and *Portulacas* that are beautiful whilst they last, and always bloom best under glass.—R. F.]

## ROYAL HORTICULTURAL SOCIETY'S AUTUMN SHOW.—SEPT. 10TH.

A SCOTCH-MIST sort of a morning, a speculative forenoon, and a most beautiful afternoon and evening—just enough to put us in mind of the glories of Chiswick, and as it happens fortunately, our own most glorious connection with that alma mater of our pursuits.

Chiswick garden is now, undoubtedly, the most important garden in the three kingdoms in a real gardening point of view. If you only take the great conservatory, the ugliest elevation of a house, perhaps, on the face of the earth, and associate with it

the united geniuses of a McEwen and Thompson, of Dr. Hogg and Mr. Eyles, with the labours of the Pomological Committee, the pillars of our pomological experience, you will find it the most generally useful of all the labours of the Royal Horticultural Society, and that which was the most needed at the present day. At this September Show we had an ample illustration of the use and value of the house, and of the authorities aforesaid, and what I have just said about them.

There was a collection of forty kinds of Grapes there on exhibition from Chiswick garden, for which the whole experience of the united kingdom could not furnish a match. Most fortunately there were no prizes offered for fruit at this Show, else Mr. Eyles would have carried the field right before him. Five, six, and seven-pounder bunches of Grapes from Chiswick, and every berry of them of the same uniform size, will soon put some of our walk-over-the-course exhibitors in the saddle, or else out of it altogether; and before the surface of things is smooth again we shall have such bunches as our fathers and Speechly carried between them, to our comfort and our credit.

Where there was no show intended one feels loth to report or review that part of it devoted for fruit. However, I will just trespass to say that a bunch of the Golden Hamburg in that collection was as fine and as full as any bunch of Grapes the Society ever had before them. There are a good many straws in the wind to indicate the current of this new Grape; but of this I am quite certain, it is first-rate with Mr. Eyles. As far back as twenty-four, twenty-five, and twenty-six years, I have my own self proved that a Grape and Grapes can be had to perfection on some soils, and be not worth a rush on a different soil; and I was the first gun who fired against my own self when the British Queen Strawberry beat me out and out at Shrubland Park, where it was not worth one farthing the ounce—for this very reason, that I never could get an ounce of it there to prove the fact. At this time my equals almost all over the country were in a regular campanology about it, if there is such a word, for the sounding of all the steeple bells in the kingdom. And it may be the like with the Golden Hamburg.

There was a bunch of the Strawberry Grape, which I think I said I tasted last year in Sir Joseph Paxton's garden, where it was grown in a pot and had leaves as much like those of some Fig as a Vine leaf, but it requires to be very ripe to acquire the Strawberry taste in it.

Also, three bunches of the Currant Grapes of the grocers were there, the berries like Juniper berries in size and blue bloom. An Indian black Grape, called Monukka, is longer in the berry than any of the old ones, and I judged the bunch at 5 lbs., but it might be six or four. There was a purplish-scarlet bunch called Chasselas Rose de Falloux. But the most beautiful Grapes for a wedding breakfast I ever saw were a bunch of blush pink berries, a new kind called Albee. Of all the Grapes this is peculiarly the ladies' favourite colour for a fancy dish, and it is impossible to look at it for the first time without thinking who, among your friends, would be the most likely to join hands in matrimony and to get this Grape up at the top and on the right-hand side of the wedding cake.

All the head-gardeners in the country, and all their men ought to see the great International Exhibition and the great Grape-conservatory at Chiswick gardens. A great number of them have had that privilege already; and if I could get at the best chord in the national feeling, there is not a gardener or under-gardener in the three kingdoms who would not see the grand sights ere they were all over.

But I must mention some beautiful seedling Pears from the Royal Gardens at Frogmore by Mr. Ingram; and a most luscious-looking yellow Peach from Mr. Rust, gardener to the Hon. L. Sullivan, Broom House, Fulham, and named Thamea Bank Peach, late as the Chancellor, and as good as any of the mid-season Peaches, according to the judgment of some of the Pomological Committee who told me so; but, of course, as there was no pomology for that day, these good things must stand over for another year, when we shall by ourselves, with no International, obtain the attention of the Council.

The fruit at the Crystal Palace Show the previous week was the great source of attraction to the largest number of the visitors there; and although much of it must have been like the fox's Grapes, somehow or other the public take great interest in such things, and we ought, most certainly, not to be too stingy about the prizes.

The flowers were even grand. The Dahlias, the Hollyhocks, the China Asters, and the Gladioluses were really most surpris-

ing considering the summer's weather. But of all the things on the face of society, and of ours in particular, the most difficult matter of all is to school the florists. But the Roses! Who would have expected Roses this season, when my own have made from three-feet to six-feet-lengths of shoots, on their own roots, in this everlasting cocoa-nut refuse, and no particle of manure, liquid, limpid, or in lumps for the last three years, and all only coming into flower, except the Malmaison Rose, and with it I could beat the globe if bigness and flat-facedness would do?

But I shall have seedling Roses soon. I began with Général Jacqueminot with its own pollen, but only the curious part of the pollen, and my seedlings will be either *Senateur Vaisse* or else *Gloire de Rosomenes*. I sounded Mr. Mitchell, who took the first prize in Roses, "*D., Deal*," and Mr. W. Paul as to the best six Roses for me to grow for myself, and to hold my tongue about them; and there was only one of those which I intended having which they did not recommend because the kind is somewhat delicate in constitution. If I cannot get these on their own roots, I shall take such as are the lowest worked of the dwarfs, and plant them as they do the *Manetti* stock—put the budded part all underground, and in May I shall scratch the bark off the shoots, just within the surface of the soil, to make roots come the sooner; then I shall make layers and cuttings till I have a full stock, and I shall give away most of my old Roses for want of room. I shall follow Mr. W. Paul's system of pruning and disbudding Roses, and the old Scotch gardener's way of doing the Gooseberry bush in summer pruning, and July will be my chief Rose-pruning time for the whole year. It would never do to cut-in such shoots as they make with me by way of winter pruning. I shall only stop my Roses, as it were, in winter, and prune and thin them in the summer.

As to new Roses, there were very few of this year's new seedlings. The best I saw were from Mr. Mitchell, and his best was *Lady Georgina Milner*, a magnificent glossy rosy pink; then *Maurice Bernardin*, a distinct crimson, and *Madame Charles Wood*. And all the names following I take to be of Roses to be most relied on for autumnal bloom:—*Madame Vidot* and *Madame Charles Crapelet*, *Comtesse de Chabillant*, *Général Jacqueminot*, *Pauline Lanzeleur*, *Lord Raglan*, *Senateur Vaisse*, *Eugène Appert*, *Jules Margottin*, *Colonel de Rougemont*, *William Griffiths*, *Madame Knorr*, *Anna Alexieff*, *Reine des Violettes* (seems to do in the autumn, and it is certainly a queer-coloured Rose between slate and violet colour), *Comtesse d'Orleans*, *Auguste Mié*, *Devoniensis*, *Malmaison*, *Gloire de Dijon*, *Céline Forestier*, *Triomphe de Rennes*, *François Premier*, *Bacchus*, *Victor Verdier* and *Louise Odier* (a match pair), *General Washington*, *La Reine*, and *Evêque de Nîmes*. Almost all these were in all the collections, with no signs of flinching in any one of them.

I could not get near the Dahlias, but only looked at them from end to end; but there was a vast deal of improvement in their general appearance both here and at the Crystal Palace, from the fact of those horrid foxy colours having been weeded out of them, which no mortal could or would grow, except he had the proper bump for that.

Hollyhocks have also been strained from all the dregs and sediments of all shade that tended to sadness, and were of the most there were really most magnificent, and were of the most delightful colours. I saw one cut bloom of a Hollyhock in the hands of one of the Judges who was then seeking some other kind to match it. I did not catch the name, but I am much mistaken if a match to the colour is yet to be found under the sun. It was a shade between rosy salmon and magenta, and I must have the name of it the first time I meet that one of the Judges at the Floral Committee.

I took the following as the best of their tints from the first and second prize collections, beginning with that from Mr. Chater, and with his new cottage Hollyhock *Hesperis*, the best of the dark slaty colour. The best deep rose was *Rose Celestial*; the best light rose, *Beauty of Walden*; best blush, *Beauty of Milford*; best scarlet, *Morning Star*; best yellow, *Lizzy King*; best next tint of yellow or orange buff, *Excelsior*; best crimson, *Governor-General*; and the best purple, *Lady King*. These were the best in the very best shades of the Hollyhock. In the second, or that from Messrs. Downie, Laird, & Laing, best canary yellow, *Golden Fleece*; best rose, *Miss Edmeads*; best orange buff, *Prince of Hesse*; best reddish-rose, a high tint in this class, *Stanstead Rival*; the best crimson, a fine one, *Lady Loughborough*; and the best purple, also a very rich tint, *Purple Prince*.

Out of the first and second class cut blooms I noted the following as best, because every one who writes to us wants to know

the best of everything under the sun:—*Hesperis* aforesaid; *Illuminator*, crimson; *Jaune Surpasse*, yellow; *Mrs. Chater*, light rose; and *General Wyndham*, all but black.

The *Asters* were magnificent, but I did not see the growers or the prize tickets.

Mr. Cattell brought *Phloxes* up this time in dwarf little plants not more than from 15 inches to 20 inches high. I took the three best *Phloxes* in Mr. Standish's collection and the three best in that from Mr. Turner. The former had as his very best *Parmentier*, which I must order for myself as the largest and deepest red; *Flora* next, a rosy beauty with a crimson eye; and *Mrs. Standish*, of course the best white with the finest eye. Mr. Turner had two pure white selfs, no eye, and I preferred *Avalanche*. His best red was *Rose Queen*, also a self; *Julie Russell*, a light blush and a deep-coloured eye; and *Sparkler*, a fine reddish-roc. Now, as I do not grow Dahlias, I must have these seven *Phloxes*, if only to be right in the minority.

I passed *Pansies*, *Petunias*, splendid *Verbenas*, to get to the very best cut flowers there—the double *Zinnias* and the liliput Dahlias from Mr. Cattell. You may believe me when I say the double *Zinnias* will soon be as snowy as the *China Asters*. They were so foxy brown at first that I should prefer the single ones. But here we had them imbricated as *Camellias*, and with shades quite as promising if not quite so bright; and the dear little liliput Dahlias want only to be made dwarfs to be the finest bedding plants in the world. Who will hit upon the right ray of florets to get the pygmy-forming pollen from, to subdue this race to the will of man?

Mr. Youell, of Yarmouth, was again the Wellington of the day in *Gladioluses*; and one called after himself is the nearest to a *Scarlet-Geranium* colour of any I have seen, the front is also peculiarly marked in shades. *Mrs. Youell* is a bold bright flower, orange and blush mixture, and a large spike; *Mars* next best. *Achille* is a peculiar flower of a good shade of lake, and a light stripe up the centre of the six divisions of the perianth. *Queen Victoria* was the best white in Mr. Standish's collection this time, then *Mrs. Standish*, and then *Lady Mary Wood*. What they would call *Meg Merlice* colours in *Sir Walter Scott's* days you see in *Colleen Bawn*, the only Gaelic name there, it is a lilac, a red, and a white, all in mixture. *Flora Macdonald*, blush, dashed over with crimson in shades and blotches; *Amelia*, light ground streaked and blushed all over; *Marie Dumortier* ditto—and these were the favourites in the above colours. The rest much the same as the colours at the Crystal Palace.

There was a fine collection from the Messrs. Henderson, of the Wellington Road Nursery, of those fancy-leaved *Geraniums*, after *Mrs. Pollock* fashion, which are deservedly great favourites on account of the beauty and novelty of their leaves, in alternate zones of bronze, purple, crimson, yellow, green, and white, in one or the other of them. The newest and best of these is called *Lucy Grieve*, a brighter foliage than that of *Mrs. Pollock*; *Italia Unita*, the next best; then *Countess*, *Elegans*, *Sunset*, and others, all gems of the first water. Along with them were several *Fuchsias*, single and double, and a new *Calceolaria* called *Ericoides*, from the Messrs. Veitch, the growth and looks of which would remind you of *Fabiana imbricata*; also their hybrid *Orchids*, with one after *Calanthe masuca*, and a most valuable large collection. In the western arcades were beautiful specimens of the lovely blue *Vanda cœrulea*, the summer *Orchids* going out in *Vandas* of the tricolor section, and the winter ones just coming in, as *Vanda cœrulea* aforesaid, and *Odontoglossum grande*; also, the *Lapageria rosea*, the *Hedychium Gardnerianum*, in bloom; and *Eucharis amazonica*.

There the Messrs. Lee and Mr. Bull set up collections of foliaged plants; and Mr. Arthur Henderson, *Pine-Apple Place*, a collection of the finest specimen plants of all the best *Caladiums* which have yet been exhibited. There, also, Mr. Ivery had a select collection of fifty kinds of hardy Ferns, a fine sight, and of *Japan Lilies*, there were whole beds of them against the walls. Mr. Cutbush, of Highgate, was high up there and at the top of the tree in pot *Gladioluses*. Mr. Ivery had two varieties named for him, out of lots of firm sports from *Athyrium filix-femina*. Mr. Bull was by his side with lots of fine things, and some *Petunias*; and Mr. Standish had his turn of the new *Japan Lilium auratum*, the *Lonicera reticulata aurea*, and others. But when I get the harvest in I have some more in store from this and from my Crystal Palace notes.

D. BEATON.

"SPLASH, splash! What is that?" as I heard strange sounds on the roof of the house about half-past five. "Is it rain?"

"Yes; pouring, of course. It is one of the Horticultural Society's show-days, and so of course it rains." And so in cold, and damp, and uncomfortable I wended my way in early morn to Kensington, where one was met on all sides by—"Ah, old Chiswick weather again;" and with every prospect of a wretched day, exhibitors were busy at work. The conservatory was suggestive of cold feet, and the arcades of toothache and stiffnecks; but happily Apollo asserted his supremacy, and about midday burst forth, and during the afternoon the gardens were well filled by a gay and fashionable (considering the season) assemblage.

Of the excellence of many things exhibited there could be no question. Dahlias were magnificent, and notwithstanding all that has been said against them, received the warmest admiration. Gladioli were very good, and are making rapid strides in public favour. But as yet amateurs seem to avoid them; there being no competition among them last year induced the Council, I presume, to punish them for their remissness by excluding the amateur class altogether; but unless there be one made, I fear the growers must have it all to themselves. A man who has three acres to roam over must be a "Triton amongst the Minnows" of those who have, perhaps, a couple of hundred of bulbs altogether; but I believe if the division be made, that next year will see a large increase of exhibitors. Many persons were there with their note-books, and many inquiries were made as to prices.

Hollyhocks were wonderfully good, if not numerous; but then they must have been shaded from the influence of the weather, or they never could have been brought so clean and good.

Asters were certainly inferior to former years both in quantity and quality, though there were some very fine blooms. And singularly enough, Mr. Robert Fortune, no mean judge, remarked to me that no flower had made so great an impression on him as to the improvement a few years had made than the Aster. Verbenas were not in first-rate condition, nor were Phloxes.

Roses were exhibited in wonderful order, considering the weather, the last week having greatly improved them. One of the most noticeable being a bloom of Lord Clyde (Paul & Son), which will, although not a florists' Rose, prove, I think, a useful flower. And now I would ask whose judgment was correct—those who maintained that the Dahlia and the Gladiolus would form the features of an autumn show, or those who lauded up Phloxes and Asters as flowers to take their place? The former never will be an exhibition flower. Mr. Cattell, of Westerham, exhibited a collection grown in pots, and very well grown they were, dwarf and compact; but his was the only response to the invitation. In the cut flowers not only was the wonderful sameness manifested, but long before the afternoon was over they had begun to droop; and complaints were hurled against the flowers as if they were bad of their kind, which certainly was not the case; their bstered appearance solely arising from their extreme liability to fade.

Then as to the Helichrysums, or Everlastings, a good collection of them, doubtless, were there. But "weeds, sir, weeds," was all the notice they received from passers-by.

Pleasant, too, right pleasant it was to meet with old friends, and talk over many things with them—parishioners of twenty years back, old friends of college days, one with whom I had worked in organising a Natural History Society, which still, after twenty-four years of life, exists; another, the able Curator of the Dublin College Botanic Garden, in whose company I have spent many pleasant and instructive hours, and who, with the zipened experience of years, still maintains that true humility which ever accompanies real wisdom; so that altogether it formed as pleasant a day as the whole year has afforded. I heard, too, intimations from more than one quarter that the agitation upon the neglect of the florists is likely to result in good; and one expression which fell on my ear from one of the most influential authorities, if carried out with spirit, would certainly go far to remove the objections which we have against the present arrangements of the Council.

Dahlias, as the prominent feature of the Show, claim our first attention, and those of the growers for sale especially. As usual the contest lay between Mr. Turner, of Slough, and Mr. Keynes, of Salisbury; the latter being first in 48 Selfs and 18 Fancies, and the former in 24's. Considerable difference of opinion was expressed (as there always will be), as to the adjudication, but unquestionably the flowers were fine. I subjoin the names, marking with an asterisk those that specially struck me.

Mr. Keynes had, amongst others, \*Lord Derby, Golden Drop,

Imperial, John Harrison, Juno, \*Donald Beaton, Bob Ridley, \*Hugh Miller, Leopard, Duke of Wellington, Chairman, Pauline, Andrew Dodds, Baron Taunton, Mr. Critchett, \*Mrs. Bush, \*Earl of Shaftesbury, Peri, John Keynes, Black Prince, \*Beauty of Hilperston, Lord Palmerston, Lady Elcho, Souter Johnny, \*Criterion, Mr. Waters, Lady D. Pennant, \*Pandora, and Lilac Queen.

Mr. Turner's were \*Criterion, Norfolk Hero, Captain Harvey, Chairman, Pre-eminent, Jenny Austin, Pluto, Golden Drop, Mr. Stocken, Midnight, \*Lilac Queen, Duke of Wellington, Delicata, Beauty of Hilperston, George Brown, Privateer, Flower of the Day, Charlotte Dorling, Earl of Shaftesbury, Seedling (orange scarlet), \*Lady Popham, Lord Palmerston, Cygnet, Volunteer, Andrew Dodds, \*D'Israeli, \*Lord Derby, Peri, Hope, Hugh Miller, Mrs. C. Waters, Umpire, Pioneer, Lord Dundreary, Sir G. Douglas, Joy, Commander, George Eliot, \*Model, Lady Elcho, \*Mrs. Bush.

In 24's, as I have said, Mr. Turner was first. And in 18 Fancies Mr. Keynes had Carnation, Gem, Lady Paxton, Mary Lauder, Souter Johnny, Le Premier, Garibaldi, Queen Mab, Triomphe de Ronbaix, Starlight, Pauline, Patriot, Harlequin, Confidence, Baron Alderson, Nora Creina, Reliance.

In the class of 24 blooms (Amateurs), Mr. J. Hedge, Reed Hall, Colchester, was first with Heroine, John Keynes, Mr. Crawford, Chairman, Bishop of Hereford, Triomphe de Pecq, Golden Drop, Lord Palmerston, Beauty of Hilperston, Neville Keynes, Lady Popham, Standard Bearer, Emperor, Commander, Cherub, Madge Wildfire, Admiral Dundas, Lord Palmerston, &c.

In 12's Mr. W. P. Barnard took first prize with George Elliott, Mrs. Bailhache, Lilac Queen, Mrs. C. Waters, Chairman, Lady Douglas Pennant, Lord Derby, Jenny Austin, Beauty of Hilperston, and Lady Popham. Mr. Corp's 12 Fancies were Reliance, Gem, Confidence, Gem (Stafford's), William Corp, Elegance, Mary Lauder, Lady Palmerston, Pauline, Queen Mab, and Harlequin.

Mr. Youell's Gladioli, which took the first prize—more, I should imagine, for the vigour of the spikes than the refinement of the varieties—contained a goodly number of the foreign varieties: amongst others, Isoline, Velleda, Mons. Vinchon, Napoléon III., M. Blouet, Penelope, Achille, Ophir, Empereur, Junon, Linné, Branchleyensis, Mrs. Youell, Pegasus, Madame Furtado, Jeanne d'Arc, Calendulaceus, Clemence, Princesse Clothilde, Galathée, Le Poussin.

Mr. Standish had two collections mainly composed of his own seedlings. They contained Marie Dumortier, white spotted; Paul Bedford (s.), rose; Queen of Denmark (s.), peach; Solferino (s), red with yellow; Mrs. Peach (s.), beautiful peach, lower petals shaded and spotted; Miss Foster (s.), peach; Amelia, light spotted rose; Reine Victoria, large, white; Colleen Bawn (s.), light, splashed with rose, in the style of Mrs. Donbrain; Countess of Derby (s.), white; Flora Macdonald (s), light, feathers purple; John Leech (s.), light peach, dark feather, spotted lips; Rosenberg (s), peculiar crimson; Adam Bede (s.); Troubadour (s), rose, curiously spotted with yellow, streaked with crimson; Adèle Souchet, white, lilac stripes; Lady Emily (s.), lemon; Amy Robart (s.), light; Rainbow (s.), like John Leech; Tom Moore, light, petals too narrow; Euphemia (s.), peach; Diana (s.), light; Emelita (s.); light, with carmine feathers; Lurline (s.), light; Charlotte Eflingham, white; Basil (s.), white; Couranti Fulgens; Robin Hood (s.); The Favourite (s.), light; Charles Davis (s.); Sanspareil (s.); Lady Mary Hood (s.), white; Don Juan; Duches of Sutherland (s.); Carnation, rose-striped; Jeannie Deana (s.), light.

Messrs. Paul & Son's contained Ninon de l'Enclos, Florina, Aristote, Daphne, Eugène Damage (very bright), Berenice, Victor Verdier, Madame de Vetry, Hebe, Fanny Rouget, Achille, Mazepa, Janne, Penelope, Solfaterre, Couranti Fulgens, Premices de Montrouge, Madame Vilmerin (new, light with rose splashing). Mr. W. Paul had Couranti Fulgens, Madame Rabourdin, Branchleyensis, Ophir, Penelope, Dr. Andry, Vesta, Oracle, Lord Grenville, Fanny Rouget, Madame Binder, Madme Eugène Verdier, Calendulaceus, Ilicbe, Canary, Louis Van Houtta, Madame Leseble, General McMahon, Ceres, Ninon de l'Enclos, Raphael, Sulphureus, and Mazepa.

In the class for 12 of the style of Branchleyensis, Mr. Youell was first and Mr. Standish second. Mr. Youell's flowers were Mars, Comte de Morny, Napoléon III., Mr. Youell, Don Juan, Star of the East, Rembrandt, Achille, Othello, Dr. Andry, Victor Verdier, and Neptune. The latter gentleman's flowers consisted of Dr. Andry; Richard Heath (s.), rose, with yellow centre;

Garibaldi (s.), brilliant crimson, purple throat; Den Juan; Etna, orange scarlet; Bracelet (s.), rose; Murillo (s.), rose, with dark feather; Samuel Weymouth (s.), crimson, with white throat; Paul Bedford (s.), brilliant rose red; Brencleyensis; General Cabrera (s.); and Wallace.

Two collections were shown in pots; Mr. Cutbush's, which obtained first, contained single bulbs, and Mr. Cattell's two or three bulbs in each pot. Mr. Cutbush had Vesta, Janire, Brencleyensis, Galathée, Impératrice, Gil Blas, Goliath, Hebe, Madame Binder, Othello, Eveline, Byron, and Emperor. Mr. Cattell had Rubens, Solferino, Le Roi d'Oude, Courant Fulgens, Madame Rabourdin, Janire, Monsieur Vinchon, Sulphureus, Adèle Souchet, and Linné.

It will thus be seen that this rapidly improving flower was largely represented, and there is no doubt of a greatly increased demand for it; many fine varieties can be purchased at a moderate rate, and will well repay any trouble bestowed on them. They do not, as some have imagined, require a poor soil, but will bear very liberal treatment.

In Hollyhocks, Mr. Chater, of Saffron Walden, took first prizes both in spikes and cut blooms. Some of the spikes, of which I subjoin the names, were very fine. They were Beauty of Milford; Blush; Princeps (s.), lilac; Imperator, buff; Rose Celestial, rose (s.); Governor General, red (s.); Lady King, dark crimson; Ne Plus Ultra, violet (s.); Excelsior, buff (s.); Beauty of Walden, rosy buff; Miss Lizzie King, yellow; and two others, the names of which I took so badly that I am ashamed to say I cannot read my own writing. In cut blooms, Mr. Chater had Illuminator, dark crimson; Hesperis, lilac; Lady King, dark mulberry; La Dame Blanche, pure white; Monarch, red; Comtesse Russell, blush; Morning Star, crimson; Joshua Clarke, very fine; Lady Dacres, pink; M. Anne, rose; Queen Victoria, rose; General Wyndham, dark brownish-crimson; Imperator, buff, &c. In Messrs. Downie & Co.'s stands, Stanstead Rival was particularly fine.

Roses were very good, especially when the season is considered; Mr. Hedge again taking off the honours, amongst amateurs—Mr. Mitchell and Mr. Turner, amongst growers. Mr. Hedge's flowers were La Reine, Gloire de Dijon, Madame Charles Crapetel, Odeuric Vital, Baronne Prevost, Aurora, Eséque de Nîmes, Triomphe de Rennes, Général Jacqueminot, Sombreuil, Madame de Cambacères, Caroline de Sansal, William Griffiths, Géant des Batailles, Madame Knorr, Orillame de St. Louis, Safrano, Duchess of Sutherland, Madame Bol, General Washington, Comte de Paris, Souvenir de la Reine de l'Angleterre, and Jules Margottin.

Mr. Mitchell had Sénateur Vaisse, Gloire de Dijon, Madame Joigneux, Caroline de Sansal, Triomphe de Rennes, Madame Charles Crapetel, Souvenir de la Malmaison; Baronne de Noirmont; Léon des Combats, General Washington, Lord Raglan, Lady Georgina Milner, Dr. Berthel, Madame Vidot, Pauline Lanzeur, Comtesse de Chabrillant, Général Jacqueminot, Duchesse d'Orléans, Baronne Prevost, Sombreuil, Madame Domage, La Reine, Madame Knorr, Devoniensis, Géant des Batailles, Queen, Madame Halphin, William Griffiths, Adalide, Louise Odier, Jules Margottin, Anna Alexieff, Francis L., Dr. Juillard, Comte d'Orléans, Alexandrine Bachmeteff, Madame Schmidt, Reine des Violettes, and Honêre.

Mr. Turner had in the best 24, Maxima, Victor Emmanuel, Louise Peronny, Charles Lefebvre, Narcisse, Comtesse de Chabrillant, Louis XIV., Auguste Mié, Général Jacqueminot, Duchesse d'Orléans, Madam Rivers, La Reine, Victor Verdier, La Ville de St. Denis, Madame de Cambacères, Eugène Appert, Souvenir de la Malmaison, Monsieur de Martigny, Gloire de Dijon, Léon des Combats, and Belle de Bourg-la-Reine. Paul and Son were second, and had in their stand a nice bloom of their seedling Lord Clyde.

There was nothing peculiarly striking in Verbenas. There was one stand of double Zinnias from Mr. Cattell, one bloom in which was very double and regular—quite a florists' flower, but not so deep as I have had them myself this year.

Altogether the Show was an excellent one, and evidenced the zeal with which cultivators are endeavouring not only to march with the times, but outstrip them.—D., Deal.

#### FRUIT.

No prizes being offered for fruit on this occasion but little was brought forward for exhibition; we have, consequently, scarcely anything to add to Mr. Beaton's remarks on the subject.

The fine collection of Grapes from the garden at Chiswick formed the chief attraction here; never, probably, at any horticultural show have so many different varieties been assembled at one time, and many were the eager faces anxiously straining to get a glance of the object which detained a four-deep line of lingerers. More fortunate than some, we succeeded in getting near, and taking down the names of the forty varieties shown, which were Black Hamburg, weighing 2½ lbs.; Dutch Hamburg; Frankenthal, 3½ lbs.; Mill Hill Hamburg; Black St. Peter's, and Lady Down's Seedling, two excellent late Grapes; Black Morocco, a well-known large Grape, but generally a bad setter; Esperione, covered with a fine bloom; Black Monrúke, a splendid bunch, weighing 4 lbs., the berries of this are stoneless like the Black Corinth; Black Prince, which can always be depended on for colouring well, 1 lb. 15 ozs.; Morocco Prince, 1 lb. 13 ozs.; Barbarosa, a fine bunch, weighing 2 lbs. 7 ozs., but there are many at Chiswick much larger but not yet ripe; Blussard Noir, a healthy and productive kind of good flavour, but the bunch and berries are not so large as those of the Hamburg; Burchard's Prince, which hangs later than the Black Hamburg; Trentham Black, an excellent sort for hanging long; Late Black (Armagh); Muscat Noir de Jura, a kind having the Muscat flavour of the Black Frontignan; Cassela de Faloux; Chasselas Violet; Prune de l'Hercule; Rouge de Provence; Black Corinth, also known as Zante, which furnishes the currants of the shops; Black, Grizzly, and White Frontignan, all three of which differ chiefly in their colour, and but little in their rich Muscat flavour; Abbe, peculiarly beautiful, looking as if modelled in wax, and having a delicate rosy tinge; Royal Muscadine; Muscat of Alexandria, not ripe; Grouier du Cantal, a large-berried Grape; De Candolle; Cabral; Calabrian Raisin, a showy late kind; Golden Hamburg, a fine bunch, with large, well-ripened berries; Early White Malvasia; Foster's White Seedling; White Nice; Blussard Blanc; Reeves' Muscadine, a Cape variety, and an abundant bearer; Yellow Cabul, and Tokay des Jardins. The above form only a part of the varieties in fruit at Chiswick, where the Vine-pits, and large conservatory in particular, are covered with Grapes. The bunches in the latter reach to the very top, and in many cases are of extraordinary size, constituting a spectacle which it is well worth while going to see.

From M. Chantrier, gardener to the Duc de Levis Vantadour, Noisiel, near Paris, there came several Pine Apples of extraordinary size.—a Smooth-leaved Cayenne, and a new variety called "Charlotte Rothschild," stated to be a fruit of first-rate quality, often attaining a height of a foot, with a circumference of 18 inches, and having the property of ripening well in winter.

Mr. Miller, Combe Abbey Gardens, Coventry, sent two Melons of extraordinary size—the one, a Cashmere, was 26½ inches by 22½ inches round, and weighed 7 lbs; the other, a Beechwood, was a quarter of a pound heavier.

Peaches and a Nectarine, growing naturally on the same branch, formed another interesting object, which was contributed by Mr. F. Moore, gardener to the Earl de Grey, Howick Hall.

Mr. Ingram, of Frogmore, sent a basket of a handsome seedling Pear, the name of which we could not make out.

Messrs. Shaw & Crossland, of Sheffield, had seedling kitchen Apples; and Mr. Rust a seedling Peach.

#### CONSERVATORY TUBS AND GARDEN UTENSILS.

THE very liberal prize which was offered on this occasion for the best conservatory tub, without restriction as to size, form, material, or design, excited the expectation that the specimens offered for competition would be improvements on the forms now in common use, and would fulfil the requisites of fitness, elegance, superior workmanship, and cheapness, which the Society laid down as the test of merit. This anticipation was, however, doomed to disappointment; for not only were the articles brought forward with some exceptions far from ornamental, but they were few in number, and many were in an unfinished state. The Judge, therefore, very properly withheld the prize on the ground that the conditions upon which it was offered were not fulfilled, the exhibitions "not combining utility, elegance, and cheapness, and not being superior to the tubs in common use." We have no doubt that on a future occasion the offer will be repeated, and that something more worthy of attention will be produced.

Two plant-boxes, about 2 feet square, from Mr. Ormson, were among the best. One was constructed of Pitch Pine, so as to

be easily taken to pieces; it was varnished outside and pitched within, and was, undoubtedly, a good useful plant-box, sufficiently ornamental for all ordinary purposes. Its cost was three guineas. The other was made of three different materials, the posts at the corners being of Oak, and the sides Bretton Hall stone with ornamental ironwork above this. It had a neat appearance and seemed well calculated to last.

Mr. Forsyth, of High Street, Camden Town, had a box of wainscot Oak of very solid construction, the front carved and bearing the inscription "Royal Horticultural Society, 1862." Of this it was stated, that it could be taken to pieces in one minute, leaving the plant standing on the bottom, and that being on castors it could be readily moved. It was handsome but its price, £7, without carving, is too high, and it would, probably, lose its good appearance after exposure to the alternate action of water and the air, involved by the necessary watering of the plant which it might contain.

J. Allnut, Esq., of Clapham Common, a well-known lover of plants, exhibited two square tubs tapering inwards towards the bottom, the framework being of wood and the panels of slate. These had an excellent appearance, and were superior in this respect to all others of the same material.

Mr. F. Ransome, of Ipswich, had an octagon of patent concrete stone, with moveable panels at the sides, so that fresh soil might be introduced and the roots examined without turning out the plant; but how drainage was effected we could not perceive, the bottom having only a few crevices, through which water could escape, and which would probably soon be choked up with soil.

Of the others, Mr. Knighton, of Sydenham Hill, showed two rough-looking pots with a bold design, apparently intended to be painted. Their peculiarity consisted in being in three parts, the upper portion or sides being open at bottom, which was formed of a separate piece of potteryware perforated with holes, and the whole was supported on a separate base. The object of this arrangement is, of course, to afford facilities for the examination of the roots; but on a small scale it would be attended with little or no advantage, whilst with large plants the shifting from place to place could not be so safely effected as in the case of an ordinary tub.

Mr. Legge, of Edmonton, had a dodecagon, widest at bottom, in general shape not unlike a distiller's vat, made of Oak, moving on castors, and costing £9; Mr. Braby, of Bangor Wharf, Lambeth, some cheap slate tubs; Mr. Ayres, a cement panel, intended to form one side of a plant-box; and Mr. Pullham, of Proxbourne, two designs in terra cotta, the outline taken from his Fern-stand in the International Exhibition; and about the rest it would be unfair to say much, some being unfinished, and others positively hideous.

Of other garden utensils we noticed nothing particularly worthy of mention, with the exception of a Bijou Plant Case furnished with plants by Messrs. Veitch, which attracted much notice. It has several improvements since it was first suggested in our pages. It is undoubtedly the best adapted to keeping plants through the winter in rooms of any yet suggested. We understand that a leading firm have also purchased one for raising seedlings. The maker is Mr. R. Stocks, 14, Archer Street, Kensington Park. Kistie pots and baskets came from Messrs. Barr & Sugden, who had a large assortment of these, as well as of their flower and Hyacinth glasses, the latter presenting some exquisite designs.

Mr. Watts, of Brompton, exhibited a very good cast-iron flower-basket bronzed and gilt, suitable for windows, and a flower-stand of the same material and ornamentation; and Messrs. Young, Brothers, had some good wire stands, baskets, &c., and a watering-pot called the "Royal Horticultural," no doubt calculated to afford a good shower. The only difference between it and the ordinary form, as far as we could perceive, was, that it had two roses, that not in use being kept on a socket near the base of the spout. All the other articles exhibited have been already noticed in previous reports.

#### AUTUMN TREATMENT OF ORCHIDS.

SOME of my Orchids are in an early stage of growth when most of the others are preparing for rest. For example: Cattleya citrina, suspended from a block, has within these few days put forth three growth-buds, the first attempt it has made for the season. C. Mossia, in pot, has a half-grown pseudo-bulb, which

is just protruding the flower-sheath. C. Loddigesii, in pot, has several growths from 2 inches to 3 inches high. Zygopetalum Mackayi, in pot, has one bulb nearly made, and a growth about 3 inches high besides. Will you please say what is the proper autumn treatment of these?—P. H. G., *Torquay*.

[These starting growth and buds must have a little water given to them, and a little more heat. Most of the Zygopetalums bloom at the end of autumn and the beginning of winter, and if kept dryish then the flowers would be spoiled.]

#### THE ARCHERFIELD MUSCAT GRAPE.

As this is not a seedling Grape raised in England, it is quite necessary that its origin should be known and its synonymes given. I was so much struck with the following description of a Muscat Grape in the "Proceedings" of the Congrès Pomologique du Rhone, Session 1860, that I wrote to Mr. Thomson, telling him that I thought it must be the same Grape. I now give the extract in full, and ask you if I was not justified in thinking the variety described to be identical with the Archerfield Muscat:—

"Muscat de Syrie. Synonymes détruits. Isaker daisiko. Muscat de Smyrne selon M. Hardy père. Grosseur et forme de la grappe, belle, lache. Grosseur, gros. Forme, ovoïde. Couleur, jaune, doré, ambré. Manière d'être, serré. Saveur, croquant, d'un parfum délicieux. Fertilité, fertile. Maturité, mûrit facilement sous la latitude de Paris en même temps que le Chasselas doré (Royal Muscadine). Observations, cette précieuse variété se recommande par sa beauté et ses bonnes qualités. Elle mûrit en même temps qu'un autre Muscat ajourné sous le nom de Muscat Eugénien, mot qui signifie bon."

[Muscat de Syrie—synonymes Isaker Daisiko, Muscat de Smyrne, according to M. Hardy, senior. Size and form of the bunch, handsome, loose. Size large. Form ovate. Colour golden yellow or amber. Berries closely set. Flesh crackling, deliciously perfumed. Bearing, very productive. Ripening.—It ripens readily at Paris at the same time as the Chasselas Doré (Royal Muscadine). Observations.—This valuable sort is recommendable both on account of its beauty and quality. It ripens at the same time as another Muscat called the Muscat Eugénien.]

From the description given of Muscat Précoce du Puy-de-Dôme in a French catalogue, I was induced to think it the same as Muscat de Syrie. I may mention here, that the former kind is of very recent introduction, and has not yet fruited in England; and so I wrote to one of the most celebrated men in Grape lore in France, to ask him if he knew the kinds of Grape above mentioned. I have only recently received his reply, which I give as follows:—

"I hasten to reply to your letter requesting information respecting several kinds of Grapes. As regards the Muscat de Smyrne, or Isaker *Daisiko*, which are the names under which I have received it, I am not aware that it has any other synonymes: it is an excellent Muscat. The Muscat du Puy-de-Dôme is the same as the Muscat Eugénien. I do not know the Muscat de Syrie."

From my extract given of the proceedings of the Congrès at Lyons, it will be seen that Muscat de Syrie is the proper name of the variety; and yet my informant, living near Paris, was not aware that the Congrès of 1860 had adopted it. I have, within these few days, received some fruit of the Muscat Eugénien—it is the same as Muscat Trovère Blanc, which is totally different from Muscat du Puy-de-Dôme—at least from what I think to be it; for I have, judging by their leaves, received from France three varieties under that name. The true one may be Muscat de Syrie, Muscat de Patras, Muscat de Smyrne, or the Archerfield Muscat. The question will, I trust, be set at rest next season; for I intend to send a Vine of each of my suspected sorts to the garden at Chiswick. I must confess that I have felt much interested about the Archerfield Grape ever since Mr. Thomson announced that it was not a seedling. Most of your readers remember the St. Alban's Grape sold at a high price under two names—first as Wilmot's Muscat Muscadine, and then, on a much larger scale, as the St. Alban's; it proving, after all, a very old French variety known as Chasselas Musqué. In these enlightened times such things must not occur. If a new variety of fruit is disseminated, every particle of its history should be given—if from the continent, its continental name should be given—if from seed, its parentage and origin should also be given; in short, the utmost candour should be the rule.

It will be seen from the extracts given at the commencement

of this article what an excellent Grape the Muscat de Syrie, or de Smyrne, must be, and how nearly it approaches the Archerfield Muscat. In your reply to Mr. Thomson, page 451, you assert that Muscat Eugénien, Muscat Précoce du Puy-de-Dôme, Muscat de Syrie, and Isaker Daisko are the same, and you say "we know" this Muscat Précoce du Puy-de-Dôme (Muscat de Patras of some authors) is said to be an old variety. Muscat Eugénien, as I have recently learned from a friend on the spot, was raised at Saumur by the same person that raised the Early Saumur Muscat, and only a few years since. This sort I firmly believe to be perfectly distinct from the first named. The Muscat de Syrie under that name, and the true sort, is not, I firmly believe, in this country.

I mention these matters—first, because I differ from what you say, and, as I think, on sufficient grounds; secondly, because I feel quite certain that at present our knowledge of foreign Muscat Grapes is very limited; thirdly, because I know the evil to pomology of making strong affirmations too hastily.

When the time comes for Mr. Thomson to send out his young Vines of that sort he will, most likely, give its history as far as he knows, which will, perhaps, lead to further inquiries, and make our knowledge of foreign Muscat Grapes more perfect.

I fully trust that you will see my motive for going so lengthily into this Grape question; but that you may not mistake me, allow me to say that any pomological research is to me most agreeable, and I think such discussions when properly conducted are beneficial. As to any business reference, I should no more think of selling young Vines of Muscat de Syrie, Muscat de Smyrne, or Muscat Précoce du Puy-de-Dôme till they have borne fruit than I should think of attempting to fly.—THOMAS RIVERS.

[We shall be better able to give more information on this and other subjects connected with Vines, their varieties and their culture, when Dr. Hogg returns from the south of France.]

### TOWN WINDOW-GARDENING.

WINDOW-GARDENING as practised by the cottager is certainly conducive to real enjoyment. There is something pleasant and cheering in the sight that speaks of a thoughtful appreciation of objects of interest, and shows that amid the cares of daily life some little attention can be given to pets that vary the occupation of the day, as well as afford some little gratification as the result of successful manipulation.

Those who live away from town smoke and dust may well enjoy the result of their labours. Some of the prettiest plants I ever saw have been grown by hard-working people who had no other appliances than their windows in which to grow them. Fuchsias, Pelargoniums, Auriculas, have attained in a small way by such means an excellence that has often surprised me; but then the soil was ready to hand, and other essential matters were in no way unfavourable to the attempt. The surprise, therefore, diminishes, but the effect is still the same—that of unmitigated pleasure that Floriculture has its votaries among the humblest and lowliest in the land. But when we come to think of the inhabitants of the close courts and narrow streets of crowded cities trying to emulate the cottager in this respect—and not only trying, but actually succeeding, in growing plants and flowers about their squalid homes, where every circumstance is as little favourable to the design as can well be imagined, it certainly looks as if the love of flowers were inherent in human nature, and too strong to be resisted under any circumstances.

From what I have actually seen I know that window-gardening is carried on to a large extent in some of the most densely populated parts of London, but should never have thought it had been as described in a late Number of THE JOURNAL OF HORTICULTURE—that there were exhibition plants grown in such places; but there is no disputing what has been done, and my only object now is to offer a few suggestions which may or may not be of use. They may, perhaps, lead others of more experience to offer suggestions that may be useful in the really benevolent work in which the Reverend Mr. Parkes has made himself conspicuous.

As a gardener, I have occasionally had to deal with men who were sent from various workshops of London—men that usually inhabit the crowded dwellings of the metropolis. Most of them, when thus sent into the country to build new houses or do up old ones, leave wives and families, mothers and sisters, in their homes in the crowded thoroughfares, to whom they return once

a-week; and if they can but get a small plant or two, a few cuttings or a bunch of flowers to take with them, they are delighted beyond measure. I have frequently by this means diffused as much pleasure among a number of workmen as though I had done them the greatest service in the world.

There are those who would demur at thus giving away plants when there are many who have to get their living by selling them. But in reality it is a help to the trade; for by this means the foundation is laid for a love of flowers. Those who have had them once will not like to be without them, and will purchase many a plant in order to keep up the supply, especially when they have gained a slight knowledge of the way in which they should be managed. It is also worth doing even for the sake of sending men to their homes the happy possessors of floral treasures from the country, the pleasure of many of them intensified, if possible, in anticipation of the joyful surprise such presents may give to friends at home. It is from the beneficial effects I have seen arise from such instances that I would recommend gardeners and others who have opportunities of doing the same not to begrudge a few stray plants or a few cuttings. They may be doing much good, and can possibly do no harm; nor would employers be in any way opposed to doing so, I am sure, if they do but view it in its true light. The gift of a piece of a Cactus, a few rooted pieces of Chrysanthemums, or a few offsets of any herbaceous plants are carried home with delight. And where is the garden where such would be deemed any loss? Thousands of slips and cuttings are annually thrown away: many gardeners prefer doing so to giving them away, even to the poor cottager, on the excuse that it is hurtful to trade. The sooner they are disabused of such reasoning the better, since the contrary is actually the case.

But what I have chiefly to suggest is, that some attention be paid to the kind of plants most suitable and best adapted to be grown in close courts and smoky thoroughfares. It is evident that all plants will not do alike, nor is it possible that plants will ever be grown in such localities as are shown in all the prime of perfect beauty at first-class flower shows. Specimen Heaths, Azaleas, and New Holland plants can never be grown on window-ledges; and those plants that can be must necessarily be limited in number, for the reason that those who have the management of them are not experienced growers. In the hands of experienced cultivators very many plants are capable of being brought to a certain stage of perfection by window culture, but the chances are reduced in proportion to the unfavourable condition of the locality. Where it may be easy work in the country, it becomes difficult in the midst of dust, smoke, and draught, even in practised hands. What, then, must be the difficulty with those who know little or nothing about the matter? I have often been shown a sooty-looking plant and been asked the cause of its present condition, why the leaves fall off prematurely, why it does not flower, and so on. In ten cases out of twelve the plant happened to be a Scarlet Geranium, a plant little adapted to grow in a dusty place, the downy surface of the leaf being favourable to the lodgment of dust. A glance at the plant showed that the pores of the leaves were stopped and could not perform their functions, that the operation of potting was by no means properly understood, and that it was tortured to the extreme by being made to stand in water, and being subjected to a daily dose of the same whether it liked it or not. It is scarcely to be expected that such florists are going to exhibit good specimens of Pelargoniums, or compete with country growers. But even with such a beginning, knowledge may increase with experience, and practice may point out the best plants to grow, and the best method of growing them. It is too much to say that perfection has been attained when Ivy has been grown in an old box and trained over the window, or that Mustard and Cress has been grown in an old colander.

How far the natural exterior of a plant may fit it for town cultivation I am not prepared to say. Still I think that plants with smooth leaves and stem are the most likely to repay the attention bestowed on them. Those with downy or hairy leaves must of necessity be ill-adapted to grow where a thick dust is perpetually floating in the atmosphere. They sooner take the dust and are not easily cleaned; consequently, they are in no condition to make a healthy growth, nor are they in a position where the syringe or even the watering-pot can be conveniently used: consequently, I think it advisable to discard them for plants that, although they may get dusty, are easily cleaned. The Chrysanthemum is not of the most smooth-leaved plants, yet its adaptability to town culture is well known and fully

established; and even the Geranium under fair treatment may present a creditable appearance. The Fuchsia and the Genista are rather smooth-leaved, and are very good town plants. The Pentstemon is sure to do well; and I think a great deal might be said for plants of ornamental foliage, especially the smooth-leaved ones, as *Farfugium grande*. But, again, I think the chief dependance ought to be placed on herbaceous plants of close habit, which make very neat pot plants. How I should like to see some town grower giving all his spare time and attention to a collection of Saxifrages, than which nothing can be prettier or neater, or even better adapted for the purpose. And why not the commonest among them—the London Pride (*Saxifraga umbrosa*), a plant well adapted to spread over pots and boxes, hanging down and making a verdurous appearance on a window-sill? The Sedums and Sempervivums are both excellent subjects for town culture—that is, if a proper selection of them be made—the common Stonecrop and the common Houseleek, a sample of each often grows luxuriantly on the housetop and window-sill. *Campanula pusilla*, *Alyssums*, *Arabie*, *Vincas*, and *Auriculas* might be added to the list. Indeed, I have known the latter grown, if not to perfection, at least very creditably at a garret window; and what has been done before may be done again, for the person who grew them knew very little of plants or plant-cultivation generally.

The advantage of having plants with hard or smooth leaves is that they are kept clean with very little trouble, as a sponging now and then will accomplish it, and does no injury; and that of ordinary herbaceous plants, that they are less subject to be infested with aphides or other pests, and when grown in the midst of town smoke they are not likely to be eaten by caterpillars or slugs, as such pests are not likely to travel so far out of their way in quest of food. There are still other plants that possess a wonderful property of resisting all the attacks of insects and other counteracting influences. I have known a plant of *Ficus elastica* which for many years kept its place in a window in the heart of London, and it always looked fresh and healthy. Myrtles, and young Conifers, and small evergreen shrubs have also been tried with success.

I have another suggestion which, within certain limits, may be worth attention. In towns, where the light is obstructed by buildings as well as by a perpetual cloud of smoke, it is scarcely possible that plants which in their natural habitat enjoy the full light of the sun can be expected to do well. But happily there are plants that naturally seek the shade of woods. Among these we find the *Oxalis*, the *Wood Anemone*, the *Lily of the Valley*, the *Woodruff*, the *Periwinkle*; and there are besides that neat and still pretty trailing, but rather neglected plant, the common *Moneywort* (*Lysimachia nummularia*), and many more plants that are in reality not the less attractive on account of being found in a wild state in this country. I have an idea that such are likely to be more attractive among the poorer townspeople than exotic plants, on account of their association with the scenes of their holiday rambles: at any rate, I have known a common Primrose prized and cherished with as much or even more regard than the well-to-do has for his choice collection of exotics.

Ferns for the most part like the natural shelter of woods, but how far the shelter caused by smoke, &c., may agree with them without the additional shelter of a glass-case, I can scarcely say; but this I know, that a handy workman can very soon make a Fern-case, and if he be fond of the agreeable recreation of plant-culture, he will want very little encouragement to induce him to make one to suit his convenience. Instances of this I have known; and although such home-made cases have not been all that could be desired with regard to exterior finish, they have answered the purpose and been the means of passing agreeably many a leisure hour. Instances are not wanting where a little of the artistic has been shown in this way, as I once saw a miniature greenhouse with a small stage inside it, and on the shelves were arranged very small plants, mostly succulents. The whole was perfectly in keeping with what one might expect of a skilful horticulturist.

This style of window-gardening cannot be so very rare either, since nurserymen often keep collections of small plants of these succulents in thumb-pots for the purpose, comprising *Cactuses*, *Euphorbias*, *Meembryanthemums*, *Aloes*, &c.; and as they are easily grown, cause very little trouble, and, grown in a case, are very clean, they are well adapted to the purpose.

With regard to the plant-case, we are much indebted to the originator as well as those who have improved it; and although

it is hardly possible that working people can afford to give £4, or even £2 for one, yet with the knowledge that it is in form a double cube, and that the receptacle for the soil is a zinc vessel, they may be enabled to construct one something like it, and thus either enjoy blooming plants in their season, or have it filled with Ferns and enjoy the sight of perpetual verdure. I saw one a short time ago evidently home-made, but, unlike that referred to, it had a ridge top and was rather tall. The bottom was neatly planted with Ferns and Lycopods, and in the body of the case were suspended little baskets containing *Saxifraga tomentosa*, *Linaria cymbalaria*, and common Musk (*Mimulus moschatus*), having a most pleasing effect. It is gratifying to know that such efforts are made even among the industrious poor; and by reporting or exhibiting the results, many others will be induced to follow the example, and thus obtain a means of amusing and also of instructing themselves.—T. CHITTY, *Stamford Hill*.

## PEACH TREE CULTURE.

IN ANSWER to "A SUBSCRIBER" who wishes for a more circumstantial account of the way in which Mrs. Bass's Peach trees had been treated, I will give their history.

The house in which they were grown was only built in the spring of 1861. The trees supplied by me were such as remained unsold—certainly, no one had reason to be proud of them as evidence of good cultivation. The trees had been grown one year in pots, having been potted as maiden plants, and all the best had been sold when this house required furnishing. With the trees Mrs. Bass received a letter cautioning her against expecting much fruit the first season, and a request that if she did me the honour of becoming my pupil she would disregard all other advice on the principle that "too many cooks spoil the broth;" with this letter she received a copy of my "Hints on Orchard-houses."

On visiting Burton the following August, I was much surprised to find a very nice crop of fruit; but from the beautifully clean and healthy condition of the plants, was quite prepared to see a large crop this season.

You will see, Messrs. Editors, why you did not get a more circumstantial account of these trees and their cultivation; it was the native modesty of the writer prevented it; but, through your kind encouragement, I hope the more embarrassing sensation of this distressing malady will pass away. To convince my friends there is hope in my case, I would say to "SUBSCRIBER" "Read my book."—J. R. PEARSON, *Chilwell*.

## NOTES WHILST RESTING.

(Continued from page 450.)

TWO circumstances have struck me most forcibly in Guernsey—the entire absence of beggars, and the plants which grow in the open air without any protection even in winter.

That there are no beggars is explained by the fact that there are no low-class people in the island. Its inhabitants are divided into only two strata—the gentry, or those who live independently; and tradesmen, among whom I include the cottage-farmers and the fishermen.

Of all of them, from the wealthiest to the poorest, I gratefully bear testimony—and, after being a pilgrim in every quarter of the globe it is a testimony of much experience—that nowhere can be met with such marked and undeviating courtesy. Among "the upper hundreds" in all lands such courtesy is rarely absent; but among "the lower thousands" in many countries, courtesy is often too exceptional. In Guernsey I never received a churlish answer; and in many instances, never to be forgotten by me and mine, attentions were paid and services rendered, demonstrative that courtesy is a staple ingredient of the Guernsey character—it is not a mannerism imposed by education, but a birth of genuine heart-kindness.

The fact of the majority of "the lower thousands" being cottage-farmers and fishermen, accounts for the difficulty experienced in obtaining domestic servants from among the islanders. The whole family has full employment upon the cotten-farm; and if a fisherman's family have days not requiring labour at home, it is readily hired by the neighbouring cultivators. The cottage farmer is uniformly a dairy-farmer, and usually on such a small plot that spade-husbandry prevails; and the succession of crops is so constant, the collection of seaweed for manure so

continual, as well as the attention to the cows and the operations of the dairy, that every member of the family has full employment, or, rather, there is always more work than can be completed efficiently.

This deficiency of labour-power may account for the universal badness of the gardening among "the lower thousands." The gardens are well stocked both with fruits and culinary vegetables, but the culture is execrable. So abounding are the weeds everywhere, that I doubt whether a hoe is ever used in a cottage garden—I certainly have never seen such an implement in the whole of the island. Yes, I remember seeing one hanging at an ironmonger's in St. Peter's Port; but as it had evidently been long in stock, it rather confirms me in the opinion that hoeing is not an occupation in the ascendant.

This thrust at the gardening of these worthy islanders passes my pen on to my other topic—the plants which here endure exposure to the open air unprotected even in winter.

The range of the thermometer is remarkably small, not only in the comparative temperatures of the day and the night, but in those of summer and winter. Thus, the average maxima and minima of each month are as follow :—

	Jan.	Feb.	Mar.	Apr.	May	Jun.	Jul.	Aug.	Sep.	Oct.	Nov.	Dec.
Maxima .....	deg. 43	deg. 45	deg. 49½	deg. 50½	deg. 58	deg. 66	deg. 68	deg. 65½	deg. 63½	deg. 57½	deg. 51½	deg. 47½
Minima .....	35½	38½	40½	40½	44½	53½	53½	53½	51½	48½	45	40½

This mildness and uniformity of temperature is evidently very conducive to health, and medicine is consequently not among the golden sciences of the island. Its public records testify that this salubrity is not a result of modern acquirement; for, about a century and a half since, we are told, that "a barber-surgeon having by good fortune come over from France, his arrival was deemed a matter of importance sufficient to occupy the attention of the members of the Island Court, who wisely resolved to keep among them so scarce and valuable a personage. But, then, how to encourage him? It would not do to feign sickness, nor to buy physic in advance. They, therefore, by an ordinance still extant, granted him, for a given period, the exclusive right of bleeding and shaving. Monopolies are usually failures, and this fared but ill. The doctor left them, and they returned to their former state of good health, until another medical and tonsorial visitor appeared. Him they succeeded in retaining, but only by adding to the monopoly given to his predecessor—a pension paid from the various parish rates!"

The uniform mildness and moisture of the air are as favourable to vegetable as to human health, and is the topic from which I have digressed.

The first instance which especially arrested my attention was a *Benthamia fragifera* ripening its fruit as a standard, in the garden of Carey de Jersey, Esq., at Grange Lodge, St. Peter's Port.

Next were the *Camellia* and *Orango* trees in the garden of Beau Séjour, near the same town. It belongs to the Dobree family, but is the residence of Mrs. Whitechurch. These trees are trained on the trellised walls of the garden. One of the *Camellias*, which I was informed is *Lady Hume's Blush*, covers a surface of 16 feet by 14 feet. It is on a N.E. aspect, and does not even approach in size the two trained on the S.W. wall. Of these, one, a double white, has a stem 3 feet in circumference near the ground, and its branches extend over the trellis 30 feet by 14 feet. The other *Camellia* is a striped crimson and white variety, and nearly as large; but the *Orange* tree, their companion, was even still more striking. Its stem near the ground is 2 feet 4 inches round, and its branches cover a space 20 feet by 14 feet. It is a *Seville Orange*, and its fruit is used for making marmalade. Some of the fruit, full-sized, were ripening when I examined the tree at the close of August, and there was not only an abundance of them, but also of green fruit, varying in size from that of large Peas to 1 inch and 2 inches in diameter. Neither this tree nor the *Camellias* have any shelter, yet the winter of 1860 had no injurious effect upon them.

The garden is near the summit of a slope facing the north, and the soil is a stronger loam than in the other parts of the island. The trees, I was informed, had been planted about fifty-two years, which is concordant with the age of the variety *Lady Hume's Blush*, which was named after the late *Lady Amelia Hume*, of *Wormleybury*, in *Hertfordshire*, who imported the first specimen of it in 1806. The *Camellias* begin blooming in winter, and during March are covered with thousands of flowers.

The next plant that I particularly noticed was a *Cianthus puniceus* trained against the north front of *Mont Plaisir*, tenanted by Mr. Robins. It blooms every year, and, like the *Scarlet Geraniums* and *Fuchsias* its companions, is about 20 feet high, and with their united foliage cover the entire house-front.

At another house also near *St. Peter's Port*, and, I think, in what is called the *Queen's Road*, I saw a standard *Magnolia* about 25 feet high, and its branches extending in a circle, the diameter of which was nearly as much. It is a handsome pyramidal growth, and had many flowers upon it still.

In the garden of *Hilary Carré, Esq.*, at *Val Nord*, several of the *Agave americana* have bloomed, planted out in the open ground; and in many gardens by the roadside about *St. Peter's Port* I saw gigantic specimens of the same *Aloe*, with leaves 8 feet or 9 feet long, and proportionately robust.

*Gunnera scabra*, producing its grotesque inflorescence in the open garden, is not uncommon; and there are some very fine specimens of it in the unique grounds of *D. V. Cary, Esq.*, *Le Vallon*.

Among the plants I have already mentioned are some testifying how well the climate suits evergreens, but I have many other evidences recorded in my note-book. Ivy clothes the rocks, the hedges, and the walls: the church of *St. Sampson* is totally enveloped with it. The *Evergreen Oak* is a timber tree in the island, and all the *Hollies* attain a large stature. One of the golden-edged in the garden of *La Fosse* cottage is full 15 feet high, and the trunk nearly a yard in circumference. The *Tamarisk* was in bloom in August; but, as in England, it is very perverse in its selection of places where it will thrive. In *Guernsey* it begins to flourish near *Corbière*, and goes on vigorously round by *Vazon Bay* to the north side of the island's coast, but it will not grow satisfactorily on the more southern side.

This leads me to remark upon the *Coniferous* trees in the garden of *Mr. De Jersey*, which I have previously mentioned. I never saw trees more vigorous or more admirably grown, and they are causes for great surprise when we consider the growth some of them have made in the ten years since they were planted. The *Cupressus macrocarpa* is the most beautiful specimen of a *Conifer* I ever saw.

*Mr. De Jersey* obligingly assented to my request, and furnished me with the following particulars:—

"I obtained the following from *Messrs. Veitch* in 1850, and planted them out from pots in November of that year—viz., *Pinus excelsa*, now about 18 feet high. *P. insignis*, 16 feet high. *Cupressus macrocarpa*, 28 feet to 30 feet. *C. Lambertiana* (?), 16 feet, frequently cut back. *Picea cephalonica*, 14 feet. *Picea motinda* (?), 15 feet.

"In 1855 I planted out from a pot in November, a *Wellingtonia*, now 8 feet high, and a *Picea Nordmanniana*, now 5 feet, after having been transplanted last year." I put a query against *Lambertiana* because that is considered a synonymic of *macrocarpa*.—*QUIS.* (To be continued.)

## WHICH ARE THE WORST OF BADLY-GROWN GRAPES?

MORELLO CHERRIES A DESSERT FRUIT.

FOR the guidance of judges and also exhibitors at provincial flower shows, may I trouble you for an opinion on the following points?

When two dishes of one sort of Grapes are exhibited, the bunches of each being about equal in size, the bunches in one dish being large in berry and perfect in bloom and colour, but not highly flavoured; the other dish small in berry, badly coloured, and without bloom, but very sweet;—which should receive first honours?

Also when prizes are offered for a certain number of dessert fruits, are *Morello Cherries* admissible?—*JOHN STEVENS.*

[If the judges have the power to withhold prizes, they might, in such cases as the Grapes here described, justly exercise that power. If they have not such power, then we think that the prize should be given to the large berries, perfect in bloom and colour, as they are evidence of skill and attention bestowed on their cultivation.

*Morello Cherries*, if perfectly ripened, we should not object to being exhibited among dessert fruits; for we have seen them, in that state, served up at the table of more than one distinguished establishment.]

## ORNAMENTAL PLANTS.

1. *Siphocampylus Orbignyanus*.2. *Fuchsia venusta*.

*SIPHOCAMPYLUS ORBIGNYANUS*, D'Orbigny's *Siphocampylus*. *Nat. ord.*, Lobeliaceæ. *Linn.*, Pentandria Monogynia.—A free-flowering stove perennial, with erect herbaceous stems bearing ovate-acuminate short-stalked leaves, acutely dentate, usually in whorls of three. The flowers are handsome, axillary, on pedicels half their length, one from each axil; the calyx is hemispherical, with five linear subulate lobes; the corolla tube an inch and a half long, furrowed, downy, rose-red with a yellowish-green throat, the segments of the limb linear-lanceolate yellowish-green on the outside, within red with the green continued round the margin. From Bolivia; introduced to the Belgian gardens by M. Van Houtte about 1848. Flowers in spring and summer.

*FUCHSIA VENUSTA*, Beautiful *Fuchsia*. *Nat. ord.*, Onograceæ. *Linn.*, Octandria Monogynia.—A very handsome and distinct greenhouse shrub, having slender, somewhat hairy branches, and lanceolate or acutely elliptic entire glabrous leaves, either opposite, or more usually disposed in whorls of three. From the axils of the leaves grow the pendant flowers 3 inches long, consisting of a slight pendant tapering tube to the base, and divided at the apex into four ovate-lanceolate acuminate sepals; the oblong, lanceolate, undulated petals are of an orange red colour; the calyx, tube, and aepala, salmon red, the latter tipped with light green. From New Grenada: environs of Merida, and on the Paramo of San Fortunato, near Santa Fé de Bogota, at an elevation of nearly 8000 feet. Introduced to continental gardens by M. Linden, through his collectors, MM. Schlim and Funck in 1847. Flowers in summer and autumn.—(*Gardeners' Magazine of Botany*.)

## CULTURE OF LISIANTHUS RUSSELLIANUS.

THE following remarks on this splendid plant were written a few years back, and communicated to the Horticultural Society. I have seen no reason to alter my practice since, and, therefore, the result of it is quite at your service, and I hope your engraving of the plant shown at Chiswick may induce many more to undertake the cultivation of so useful an autumn plant.

This beautiful and much-esteemed plant was introduced into

this country in 1835 from Mexico. Being found to be capable of producing ripe seed in abundance, a large stock of plants was soon diffused among our best cultivators, who hailed it with delight. Nevertheless, strange to say, its successful cultivation, except in a few instances, still remains a desideratum—a fact amply proved by the paucity of really well-cultivated plants produced at our great metropolitan exhibitions.

Having been somewhat more successful than some of my neighbours in growing and flowering this plant, truly magnificent when well managed, I will give my plan, which is as follows:

—I sow early in spring; I first fill a six-inch pot half full of potsherds, over which I place 1 inch of sphagnum moss; I then fill the pot within 1 inch of the top with rich light sandy soil. When all is pressed down equal and firm, and a smooth surface made with the bottom of a small pot, I sow the seed, and cover it very slightly with dry white sand. I cover the pots with bell-glasses, and place them on a shelf in a shady part of an early vinery, keeping the surface constantly moist by pouring water on the outside of the glasses. As soon as the plants have come up, air is admitted, and increased as they advance in growth. When sufficiently strong they are pricked out into small pots, having the same drainage, moss, and mixture as the seed-pots, and are again shaded with hand or bell-glasses until the plants become established. In three weeks or a month they require to be potted-off singly into small pots; and I encourage their growth as much as possible by placing them in a shady part of either a vinery or Melon-pit, whichever is kept at the highest temperature, with a humid atmosphere. As soon as they begin to fill their pots with roots, I give them once a-week a little clarified manure water.

I repot into winter pots about the middle of August, using pots to suit the size of the plants, and replace them in the same growing temperature as before, till their pots are filled with roots. After this I begin to prepare them for winter by giving them less moisture, more air, and a cooler temperature; and finally they are placed on a shelf near the glass, in the coolest part of the stove, and wintered rather dry. Early in February I begin to increase the heat and moisture; and as soon as they begin to grow freely I repot them, which is generally about the second week in March. They receive another shift in April, and those that are intended for large specimens a third in May (using 18-inch or 20-inch pots), and a mixture consisting of equal quantities of good strong maiden loam, peat, or bog mould, burnt clay, leaf mould, and cow-manure, with a little

white sand. These materials are well mixed together, and is dry are moistened to prevent their running too close in the pots. In potting I use a large quantity of drainage, and plenty of rubble stones, small potsherds, and coarse river sand amongst the mixture. I make the mixture just firm, but an very careful to leave it quite porous. I give very little water till the roots reach the sides of the pots: it is increased as the plants and the season advance, giving heat and moisture in proportion. Too much stress cannot be put upon making a proper mechanical arrangement of rich, porous, and well-drained soils, which are essential for the healthy development of plants of the nature of the *Lisianthus*.

When the young shoots have become sufficiently advanced, I stop them immediately above the second joint; each shoot will then produce four; they require stopping about three times. The last stopping for plants required to bloom early should take place in the first week in June, and for plants required to bloom later, in the first week in July. As they advance in growth the branches will require to be tied out with sticks, to make round and well-formed plants.

When the plants are growing freely, they are sometimes attacked with a disease at the base, which is produced by the moist and confined atmosphere that is required for their fine growth. To prevent this I allow the surface to become quite dry once a-week, during which the plants are supplied with moisture from feeders or pans in which the pots are placed for a few hours, being careful not to allow any stagnant water to remain about them. As soon as the blooms begin to expand, I keep a drier atmosphere, and expose them to more air and light, which much improves their colour.

As to the result of the above practice, I may mention, in conclusion, that I grew some seedling plants in 1844, one of which I exhibited at the Horticultural Society's Garden in July, 1845, which was awarded a silver Knightian medal, accompanied with this note by the Judges:—"Had this been exhibited in its proper place, it would have received a higher medal." In July, 1846, a second plant received a large silver medal; and to a third the same award was made in July, 1847. Another plant was also shown in the same year at the Royal Botanic Society's Garden, Regent's Park, and was awarded the first prize as a single specimen of superior cultivation. The plant that I exhibited at the Horticultural Society in July, 1847, had five hundred blooms expanded at once, ten days after the exhibition.—JOHN GREEN, C.M.H.S., *Gardener to Sir Edmund Antrobus, Bart. (Gardeners' Mag. of Botany).*

*Lisianthus Russellianus*, as exhibited.

### DO NOT TAKE UP YOUR GLADIOLUS BULBS.

I PLANTED this spring three dozen of the best hybrid *Gladiolus* to be procured, in the last week of March. Under each, as the ground is rather heavy, I placed cocoa fibre, and worked some into the surrounding mould. Only about half came up, and of these nearly all have turned brown the last month; in fact, the leaves are quite dead. I have dug up some of the roots, and they seem healthy, but very small progress has been made in forming the new corm. A quantity of *Brenchleyensis* that I had by me have done well, as usual, although treated just the same.

My pot Tulips did not please me last spring. I treated them the same as the Hyacinths, which did extra well. Ought the treatment to have differed?—H. B.

[My *Gladioluses* have been grown in cocoa-nut fibre refuse for the last seven years, and those I bloom of them could compete against those grown by Mr. Standish himself, or any other celebrity in the trade. For the last three winters some of them have not been lifted, nor do I intend to lift them for some years. If the ground is rich and light, not less than 3 feet deep, and is thoroughly drained at that depth, every *Gladiolus* now in the trade would go on improving for years in a mixture of the refuse if left in the ground from year to year and never disturbed. Taking up *Gladioluses* is exactly like budding Roses. It is the way required for the trade, and it is the best way where the soil is not suitable; but where the soil is just what they like, *Gladioluses* should not be lifted oftener

than once in six or seven years. A far more tender race of this genus than we now possess have been left out in the beds for the last half of the last generation, and they prospered more, even up in the Highlands, than by any other method. The beds were covered with leaves against frost; there were no roots to be hurt by bad drainage in winter, and the roots, like those of Cyclamens, were kept in a uniform degree of moisture and temperature during the period of rest.

The long succession of unnatural treatment brought on the Potato disease. I should not imagine that twenty years' practice of a wrong principle had much effect yet on the Gladioluses; but let us continue to grow them on the lifting-of-the-potato principle, and their day is coming for the dry rot. Even now the over-drying of unripened bulbs is a serious cause of complaint, and is the very cause of this question being put by "H. B." The one-half of English-grown Gladioluses are only three-parts ripe from the lateness of the present time of planting.—D. BEATON.]

### AJUGA REPTANS PURPURASCENS AS AN EDGING PLANT.

THIS is an herbaceous perennial, and a very old plant of no beauty in itself; but as a low-growing foliage plant in a ribbon-border, or as an edging to a bed, it is, I think, equal to the *Perilla* in colour, and superior to it where a close, low growth is desired. The height also can be regulated in some degree by the richness of the soil.

The blossoms are hardly visible among the leaves, and the few blossoms or flower-stems can be broken off if they are in the way. The gardens here are very old, and I should say the plant is almost out of the floral world. The leaves sent will most likely have lost their metallic lustre before this letter comes to hand. I write this chiefly to call attention to the plant.—M. C. D.

[A very likely plant for the purposes suggested, and well worth proving.]

### BRITISH FUNGUSES.

WELL can most of us remember happy hours spent in child-hood Mushroom-hunting. Few children are insensible to the pleasures of a walk undertaken in search of some object, and still greater is their delight when this object has the merit of usefulness. How eagerly has many a child hunted for the well-known snow white button Mushrooms and the larger ones with their salmon-coloured gills, not to speak of the umbrella-shaped Mushrooms, which are, we are told, so good for catsup! and later in life *entrées* have made us acquainted with the merits of Truffles and Morels. However, notwithstanding happy childish recollections of Mushroom-hunting and the appreciation of Mushrooms in a culinary point of view acquired in after years, there are but few who are even aware of the beauty and variety of this class of plants, and of the interest which they might derive during many an autumnal woodland walk (when the best of the flowers of the field are over), from an inspection of the quaint and varied shapes, and gorgeous or delicate tints of the innumerable Fungi called forth by the damps of early autumn. It is seldom now that in a walking party some are not found lingering in search of Ferns under the hedges, while in a sea-shore ramble the seekers for zoophytes generally number half the party; but few, comparatively very few, ever remark the beautiful productions whose claims for admiration I am now endeavouring to advocate. Of the Agaric tribe alone, to which the Mushroom belongs, there are many hundreds; in another division there are lovely Pezizas, fit drinking-cups for the fairies; in another puff-balls, some good to eat, some to make tinder, some to staunch blood; till, through the larger divisions, we arrive at the Mould, so destructive in the housekeeping department, and the Snout, which is the farmer's terror.

But without descending for the present to the minuter forms, let us turn to some of the best-known and easiest-found of those inhabiting our woods and fields, persuaded as we are that even a slight acquaintance with them will open a mine of enjoyment to the observer. One advantage (and that by no means a slight one), is that no expensive apparatus is needed in the study of mycology; a flat-bottomed basket and a knife being all that is required—unless, indeed, we are in search of Truffles, in which case a little rake in a leathern case must be added. It is true that a certain prejudice attaches to the subject, and that a person

engaged in the search we are advocating will probably be asked what he or she can be doing with "those horrible Toadstools." It is also true that two or three smell very disagreeably, that some few are poisonous, and that in decay many of them present an unpleasing aspect; but these are in the minority. Gorgeous indeed are the scarlet hues of the *Agaricus muscarius* (Fly Agaricus), usually rearing its beautiful head on moss under the waving branches of the Birch. A little farther, perhaps under a canopy of Larches and Scotch Firs, you may come upon the Amethyst Agaric, in contrast with varieties of every shade of yellow, from the brightest orange to the palest lemon. Your next discovery may be a bunch of white or lilac vegetable coral (*Clavaria coralloides*), or a brown Peziza, which I must again pronounce fit only for fairies and elves.

But the most beautiful of the Peziza tribe come in the spring. First that scarlet velvet gem *Peziza coccinea*, which appears upon sticks in hedgerows early in January; then *Peziza reticulata*, spreading itself on the ground and smelling like prussic acid; and thirdly *Peziza acetabulum*, resembling nothing so much as the fonts of the early primitive Church. All the Pezizas may be preserved for some weeks under a Fern-glass; and there cannot be a prettier object than *Peziza coccinea* arranged on a little moss in no more costly an apparatus than a soup-plate covered with a bell-glass.

Having touched upon the beauty and variety of form of this class of plants, I must now add that of late years it has been discovered that there are many more esculent species than was previously supposed, and that to most constitutions Fungi, when eaten in moderation, are nutritious and beneficial. In France and Italy vast quantities are brought to market; and it is not uncommon to see in hotel kitchens a large lithograph of Fungi coloured after nature, showing on one side the edible and on the other the poisonous sorts. It is a singular fact that the Mushroom (*Agaricus campestris*), and its varieties, so much used in our kitchen, are amongst those wholly rejected in some parts of the continent. Dr. Badham has published a beautiful work entitled "The Esculent Fungi of Great Britain." Many of these we have ourselves cooked and eaten, and very good they are. For a person bold enough to try experiments, smell is a safe test. It would be most unwise to taste any Fungus with a disagreeable smell.

My readers are no doubt aware that they are indebted to one species of Mould for the fermentation of liquors. Under certain conditions changes take place in this Mould, the use of which, under the name of yeast, is well known to us all.

There is one other important function in nature performed by Fungi which I must not pass over. They not only decompose and thus get rid of vegetable matter which is cumbering the earth, but in so doing they prepare a rich supply of vegetable mould for future generations. As an example of the beneficial effects arising from the decomposition of vegetable matter, I have only to mention the vigour which we see in grass surrounding what are called fairy rings. These rings are sometimes of very large dimensions, and are caused by a Fungus which destroys all vegetation on the spot where it grows. Each successive year produces a fresh crop; and as the spawn always establishes itself in fresh ground the circle is gradually extended, whilst the dead Fungi, in a state of decomposition, give a stimulus to vegetation, increasing the beauty and vigour of the surrounding grass.

With regard to the nature of Fungi, the Rev. M. J. Berkeley, the celebrated cryptogamic botanist, in his interesting "Outlines of British Fungology," tells us that, taking them as a whole, they are undoubtedly vegetables, although in one point—viz., the absorption of oxygen and the exhalation of carbonic acid when exposed to light, they resemble animals.

It is difficult to imagine any situation in which the existence of Fungi is impossible; for not only are they to be found on vegetable and animal substances, but sometimes on flints, glass, naked walls, and old damp carpets, and in the most poisonous solutions. We even find them on extracted opium—one of those vegetable poisons, which, although not injurious when in their proper cells to the plants by which they are produced, are most destructive otherwise to vegetable life. Most people must have observed the Mould which hangs in black powdery tufts about the walls of wine-cellar, where it is the pride of the merchant, who would not, however, be equally pleased with some species of Fungi, which, after destroying the corks of the bottles, entirely spoil the wine. We all know the disastrous effects of dry rot, and have lately heard of the great curtain of dry rot which

covered the walls of a sandstone railway tunnel in the north of England.

I must not omit to mention the moulds remarkable from being found in situations completely excluded from the air—such as in the interior of the Hazel nut, in an egg, and in some bread a few hours after it is baked. In short, there appears scarcely any limit to the situations in which this class of plants may not be found; and when we consider how small and light are the spores of Fungi, and how rapidly they appear capable of penetrating the closest structures, this fact may appear less surprising. Instantaneous occur of dry rot penetrating not only wood but brick, and Fungi are found in the middle of a solid trunk. In such situations the want of light prevents their proper development, and hence the different forms they assume and sometimes the absence of fruit.

I cannot attempt any account of the structure of Fungi, and will therefore only mention that, with very few exceptions, they consist entirely of cells, and that they are classified under two principal heads—the Sporiferous and the Sporidiferous, according to the organisation of their reproductive bodies. In the former of these primary divisions, the Sporiferous, the seeds are called spores, and are attached on the tips of fruit-bearing threads; in the second, the Sporidiferous, they are produced in sacs called asci, and are distinguished as sporidia. Fungi differ very much in colour. This depends generally upon the contents of the cells, which are of almost every variety excepting pure green. Some Fungi are luminous. This phenomenon has been observed in this country, but it is rare. The most remarkable are found in Brazil, Australia, and Amboyna; and in the south of France also there is one species growing on Olive trees, luminous enough to render it possible to distinguish letters by its light.

In conclusion, I must add that the late Dr. Badham was most anxious to induce the poorer classes to profit by what he calls the vegetable manna scattered about in all directions; and no doubt the great principle which these vegetables contain would make them a valuable addition to the meagre diet of our cottagers. But even supposing them to acquire the skill to distinguish the good from the bad sorts, those who have had anything to do with the poor well know the difficulty, nay, even impossibility, of introducing any improvement into their cookery—it is certainly vexatious. This very spring such masses of the true St. George's Agaric were to be found under every hedge as would have furnished a valuable addition to every cottager's table for miles around. This Mushroom smells of fresh meat, and is excellent eating.

With regard to the works on Fungi, the larger ones, such as Sowerby's, Bolton's, &c., are valuable and expensive, but elementary and reasonable books on this subject are not wanting; and we conclude as we began, Only try the study of these curious vegetables, and we feel assured it will be repaying. For ourselves we have often paused in admiration and wonder at the grace and charm of these humble children of the grove, and felt quite uplifted with gratitude to the Divine Hand which can so clothe "the grass of the field."—LAURA KINGSCOTE.

## SOWING PRIMULA FARINOSA—WHARFDALE AS A BOTANISING FIELD.

YOUR correspondent "W. X. W." inquires if I recommend the seed of *Primula farinosa* to be sown now or to keep it until next spring. My advice would have been, Sow it now; but the season is too far advanced to be certain of success if it be sown in the open border. If it were mine I should divide the seed into three lots, sow two now in pots, plunge one of these in the open border, another in a cold frame, and keep the remaining lot of seed, and sow it in a cold frame next spring. I have a *Primula* which I have been unable to seed until this year, and Nature has given me a hint how to sow it. I bent the flower-stalk down to a pot filled with common soil; the seed-capsules burst and scattered the seed in the soil, and now I have no doubt that my care will be rewarded with a fair supply of seedlings. My father assures me that more than seventy years ago the common Cowslip was very common in our neighbourhood. Now, a wild plant is a rarity, and those in our gardens have weak constitutions. Having a desire to possess a few strong plants, about six years since I brought from the hills above Bolton Abbey a few plants, which I planted in my garden, allowed them to seed and scatter the seed on the ground, but

took good care not to disturb the soil near to the plants. My trouble was rewarded with scores of healthy seedlings, which flower well every year. Since then I have gathered and sown seed in two pasture fields, and hope to see Cowslips plentiful there as my father did when he was a boy.

Has your correspondent "W. X. W." got a genuine British *Cypripedium*, or is it a continental specimen? Most of what are in English gardens are foreign specimens. I am assured that the plants grown at Kew are foreign. The English plants which I have seen are in a garden not more than a mile from where I reside. They were found in the woods near Arncliffe, but they do not increase readily.

A week since I was in the upper part of Wharfedale looking out for this *Cypripedium*, but was not successful, though I got my reward in other varieties. On the top of Barden Moor *Blechnum boreale* grows in the greatest luxuriance. In the woods down in the dale the common varieties of Fern have a beautiful green, which is quite cheering. Near the Strid I found growing in damp peat *Parnassia palustris* nearly half a yard high. *Geranium pratense* was very attractive in the hedgerows. At Addingham I found *Campanula latifolia* growing to a greater height than I remember to have seen it elsewhere. The collector of wild flowers may reap a rich harvest in Wharfedale.

I have long known that *Achillea millefolium rubrum* was in a garden at Todmorden, but the tall variety is still on my list of desiderata. The collector of hardy plants will find in Messrs. Stansfield's nursery a collection of plants worth the trouble of a visit.

I do not possess the antiquarian knowledge of a Whitaker, or even of a Leylands of Halifax: therefore can say little as to the origin of the word Todmorden. I have copied the following from a book which I picked up at a second-hand book-stall:—"Todmorden, a small but thriving town . . . in one of the most picturesque valleys in the north of England, which, taking its name from this place, is called the vale of Todmorden. The ancient orthography of the place was 'Tadmoredenc—the valley of the Fox mere or lake.'—RUSTIC ROBIN.

## ORCHARD TREES PARTIALLY DEAD.

MY orchard has been planted twenty years; the soil being a light loam, of moderate depth, on sand. The bottom was rather wet, but it has recently been drained 4 feet to 5 feet deep. Many of the Apples and Pears contain many branches dead at their extremities; indeed, some of the trees are nearly dead, and others almost unaffected. I suspect the roots getting to the sand is the cause of the decay. What do you advise me to do.—A. B.

[We have seen many such cases in similar soils, and have always found the decay of the points of the branches, and of whole branches, originated in deficiency of nourishment. If you were to give the orchard a dressing with well-decayed stable manure, just pointing it in, keep the surface thickly mulched in summer, and avoid all digging and cropping the ground, you would, we think, soon reinvigorate your trees.]

## BEDDING FUCHSIAS.

WHITE Fuchsias make excellent flower-beds. There is one now on the south side of the Rose Mount at the Crystal Palace of *Fuchsia Queen of Hanover*; and *Smith's Conspicua* will be sure to make a better bed, and there are several more besides, particularly those white-insided Fuchsias with leaves and growth like *gracilis* and *globosa*, or half like the one and half like the other; *globosa minor* or major being yet the best edging plants for many kinds of flower-beds. There are thousands of them getting ready at the Crystal Palace for that work, and there is one whole bed of *globosa minor* there. What I wrote was the best way for common people to get up a cheap stock of plants from cuttings to try one bed first; and I shall now give categorical answers to a correspondent who signs as "IGNORAMUS," and at the same time thank him for putting his questions so methodically and in so few words.

Firstly. The remarks I made were to root *Fuchsia* cuttings in the easiest way in the world; and when the Fuchsias are thus rooted, of course the plants may be used in any way a *Fuchsia* was ever used before.

Secondly. *Fuchsia* cuttings may always and in all ways be made regardless of joints; but as it is a sign of a man's head

being put on in the right way to see him make all his cuttings just under a joint, I would make as many that way as I could for the look of the thing.

Thirdly. It is best to put in the cuttings as soon as they are made. What I had seen kept for so long were bundles of tops of hedges of Fuchsias not intended for cuttings, but to make stakes and flower-sticks of, and the flower-sticks rooted after being dried in the bundles.

Fourthly. It is not too late to put them in on Christmas-eve, or on the last day of next January, or any day from now to then if the frost keep away. The whole month of October is the surest time. But such people as do not know more of cuttings than they learn from books should not put such cuttings in pots before winter, as they would either dry or drown them before the end of winter.

Fifthly. Pruning close on the spurring system is the easiest way to teach close pruning, as most folks know Grape Vines are so pruned. A Fuchsia cut down to the ground or pot would be very close pruning; and if the shoots were all cut close to the big centre shoots, that also would be close. When the cuttings were to be put in in October in the end of a cold pit with a light of glass over them, it was said they would remain so to the 1st of May, and then be planted from there into the beds.

But the best way in gardening is not at all the best way for a great number of people to follow. There is nothing so unwise or more foolish than for such and such people to ask the best way; for, when the best way is told, ten to one if it is not ten times more difficult to do than what would really be the best way under the circumstances. The best plan for the million is not to think of pots or glass at all for this work, but to put their cuttings out in the garden just like Gooseberry cuttings, and only an inch of the cutting out of the ground, and, when frost comes, to cover them with ashes as they do the old Fuchsia plants out of doors.—D. BEATON.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE weather now offers a favourable opportunity for carrying on the war of extermination against the weeds. *Cabbage*, the main spring crop to be planted—the small dwarf sorts at 18 inches row from row and 15 inches plant from plant; the large sort at 2 feet row from row and 20 inches plant from plant. Or a double quantity may be planted in the rows to economise space, but every alternate one to be thinned out in the spring. *Cauliflowers*, prepare the ground for the plants which it is intended to protect with hand-glasses; the soil to be rich. Nine plants may be planted under a good-sized hand-glass, and in the spring five or six of them may be taken up, and planted elsewhere. *Celery*, the ground is in a good condition for earthing it up, the perfection of which depends in a great measure on the care bestowed on this operation. *Endive*, the July-sowing to be pricked-out on a warm border, and as the early plantation attains a proper size, the plants to be tied for blanching. *Mushrooms*, the beds recently made to be spawned as soon as the heat has become moderate; when earthed to be well beaten down, as solidity is one of the principal causes of productiveness. *Potatoes*, when the haulm is ripe they should be taken up, or they are likely to grow again if showery weather occur. Earth-up all plants that require it. Keep a watchful eye for caterpillars; gather by the hand as the most certain method of eradicating them.

### FLOWER GARDEN.

Continue to plant-out Pinks, Cloves, Carnations, and rooted cuttings of hardy herbaceous plants. Look now and then at the lately-budded Roses, and loosen the ligatures; when necessary pinch back to half their length those buds which have made shoots. If left at full length they are apt to be blown out by high winds. If Pansies are to be grown well, the bed must be renewed yearly, and in order to insure a good spring bloom the young plants, obtained as cuttings or side shoots from the old favourites, in addition to any new varieties which may be bought, should be soon planted. It will be requisite that the bed for their reception should be got ready, in order that they may be put out the latter end of this month. Plant-out the biennials and perennials which were sown in the spring.

### FRUIT GARDEN.

As the admission of sun and air to fruit-tree borders is of great service at this season, it would be advisable to have them open and without shade; but as it is but in few places that such

a practice can be adopted, the next best thing to do is to crop with such plants as have small foliage and small roots. Dress Strawberry plantations, and be careful not to injure the leaves of the plants, and avoid deep digging between the rows, as it is apt to injure the roots.

### STOVE.

A certain and gradual reduction of temperature corresponding with the decline of external heat should be commenced, the plants will thus be prepared to withstand the prolonged gloom of the winter season.

### GREENHOUSE AND CONSERVATORY.

As the weather continues favourable many may hesitate in the work of introducing the more tender house plants to their winter quarters; but it is hazardous to expose them to the uncertainty of the weather after this period of the year. Cloudless days are very delightful and most welcome just now, but it not unfrequently happens that they are succeeded by clear, cold nights, accompanied with slight frosts. It is only the more tender sorts that may be housed, as many hard and soft-wooded plants may with advantage be allowed to stand out until the end of the month. The condition of each plant to be examined, and any defects in the soil or drainage to be remedied. Clear off moss, destroy insects, and replace stakes. Violets to be potted or planted in a frame. Mignonette to be thinned. Hyacinths, Tulips, and other bulbs to be potted. The sooner the bulbs are potted for forcing the better. The principal cause of success is to get the pots filled with roots before top-growth commences. The bulbs to be selected for weight or substance in preference to size, to be potted in half leaf-mould or decomposed cowdung and half loam, with a sprinkling of sand; when potted to be placed in a cold frame or pit and covered with 6 inches of dry sawdust. Pinks for forcing to be encouraged. Cyclamens will now be in action, to be shifted if necessary. Roses which have been prepared for early blooming to be housed before the frosty weather arrives, and kept at first in a cold frame, if there is a deficiency of previously-prepared and potted plants for forcing. Healthy young plants of the Perpetuals or Bourbons may be selected and potted; if plunged in a little bottom-heat and kept close for a few weeks they will make fresh roots and be fit for forcing early in spring. W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

EARTHED-UP forward Celery in fine days. Pricked-out Cabbage and Cauliflower getting rather thick in seed-beds, the last Cauliflower just appearing above ground. Watered the late supplies with manure water, as any standing-still now is apt to make the heads come starchy instead of close and compact. Disleafed late Tomatoes to give them more sun; and gave little air to Capsicums planted out in a pit, to get them to ripen. Spawned the first bed of Mushrooms in Mushroom-house to come in as the beds in the thatched shed began to wear out. Regulated Cucumbers, Vegetable Marrows, and kept the hoe moving to cut up weeds before they get any size. Have a great aversion, if it can be avoided, ever to let weeds get so large as to require any raking or other means to get them off the ground. When small the sun will make short work with them, and a man with more ease to himself will go over an acre of ground sooner than he could manage half a rood if the weeds are large, and besides in the latter case he is almost sure to shed thousands of seeds from the stronger weeds.

### FRUIT GARDEN.

Regulated what Melons are left for this season. Owing to the changeable weather they have come more in heaps than we desired them. Protected fruit in the best way we could from wasps and large flies, which for several days have come back again in shoals. Many methods have been tried to palliate the evil. For instance: they made a dead onset on a tree loaded with fine fruit of the Newington Nectarine, Mr. Wasp making a hole and then charitably allowing Mr. Blue Fly to share the spoil, and what surprised me, they preferred this Nectarine mostly as hard as bullets to other Nectarines and Peaches pretty well ripe. We have now got a piece of hexagon netting over this tree and others; but what to do before taking it from Gooseberries getting rather ripe we hardly know, so as to keep off the marauders in the meantime. It struck us that a wasp disliked water as strongly as a finny fish did the dry land, and so an

engine was set to play on the tree, and as soon as the wasp fell or was crippled with his wet wings, a score of them were done for pretty well as fast as I could write the word score, and few were to be seen after several applications of the water-cure. In reality, a number was thus killed that would have made a large nest or two; and though we have been thus troubled, we have been unable to find more than one nest as yet with all our watching and care. Every tree thus secured with netting was well deluged previously, to make sure that none were enclosed in what to them would have been an clysmium of happiness. It is to be hoped that we will have a chilly night or two, and a down-pouring before the Pears and Apples in general get at all ripe, or there will be a dead set upon them when the finer Plums and Peaches cannot be got at. All those injured should be left as traps, as wasps and flies prefer them to sound ones, and a scraggy half-rotten Apple is a good lure for quietly decoying a number of wasps. Some ladies with a dash of the sentimental have been next to horrified at seeing the throngs of large flies, &c., buzzing about under double-topped hand-lights, and as much as hunted that I ought to be punished for cruelly to animals. Well, I do not like to see even a fly starved to death, though if untrapped he would have fed on the finest fruit; but all these very critical on such matters, may destroy the whole at once by burning a little sulphur in the lower glass and throwing a cloth over all. I think this would be a more humane and summary process than is often meted out to flies and wasps by the same ladies, who entice them into bottles half full of some sweets, where the poor things are left to wriggle about until they die, without even the pleasure of getting drunk or gorged over it, as once their wings are immersed in the fluid they seem to share the dread torments of a Tantalus.

#### ORNAMENTAL GARDENING.

Fresh-arranged small stove and conservatory, removing Balsams, &c., from the latter, and supplying with Begonias, pyramidal Cockscombs, Scarlet and Variegated Geraniums; hardening-off stove plants, but shutting-up pretty early and clearing beds. Rolling and cutting lawns, keeping walks firm and smooth, scattering a little salt close to their edges to prevent worms making heaps; and got on as fast as possible with cuttings in the manner detailed in previous weeks, of which more by-and-by.—R. F.

#### TRADE CATALOGUES RECEIVED.

*Floral Guide to Winter and Spring Gardening, Containing Choice Selections of Bulbs, &c., by Barr & Sugden, Covent Garden.*

*A Catalogue of Strawberries Cultivated at Eggescliffe by William J. Nicholson.*

*S. Brown, Sudbury, Suffolk. Bull Catalogue, and Catalogue of Select Herbaceous and Alpine Plants.*

#### TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**CEDERY LEAVES (J. S.).**—The brown withered patches are caused by the grubs of the Celery fly (*Tephritis oporodinis*). These grubs eat away the pulp of the leaf beneath its outer surface. The leaves so attacked should be picked off and burned.

**TROPEOLUM SEEDLINGS (H. B.).**—The foliage was quite fresh, and seemed to be that of plants of very dwarf habit, but the flowers were quite withered. They should be sent in a tin box and packed in damp moss.

**VERBENA SEEDINGS (C. B.).**—The pups enclosed are very bright in colour and of good substance, especially the crimson; but, still, they were only pups, and no judgment can be formed of the merit of a Verbena unless its tresses are seen and its habit known.

**BOOK ON GARDENING (G. K. I.).**—"The Garden Manual" will suit the lady you mention. She can have it free by post from our office for twenty penny postage stamps.

**GRASSES FOR CRICKET-GROUND (M.).**—You should have stated the nature of the soil. We assume it to be a loam of moderately tenacious staple. If the whole field has to be laid down for the first time in grass, it had better be ploughed at once; after the ploughing, thoroughly harrowed-down and rolled. In ploughing it must not be divided into stretches, but be ploughed uniformly. If expense is no object it should be dug instead of ploughed, then rolled, and afterwards the seeds sown. Mr. Robinson considers September the best month for sowing to form a lawn, and there is no difference in that respect between a cricket-field and a lawn. *Cynosuavetata* (Crested Dog's-tail), 12 lbs.; *Festuca duriuscula* (Hardish Fescue), 8 lbs.; *F. tenuiflora* (Fine-leaved Fescue), 6 lbs.; *Poa trivialis* (rough-stalked Meadow Grass), 4 lbs.; *Trifolium repens* (White Clover), 7 lbs.; *Trifolium minus* (Small Yew Clover), 7 lbs. Use the last named in after years for improving the turf and covering worn places.

**MOVING ASPARAGUS (W. Q. C.).**—That planted last spring may, with ordinary care, be moved without injury to a fresh bed next spring.

**WINTERING GERANIUMS AND LOBELIAS (S.).**—Mangled Geranium does not winter well in a cellar as the stems are too hard. Anna and Flower of the Day do better, but not so well as Tom Thumb or Punch. If you have many of them we would advise taking off most of their leaves, packing them closely in a box, or a large pot or two, and placing them where they could get light from a window in good weather, and be covered up in cold weather with a little dry hay and a cloth. The *Lobelia fulgens* and *St. Clair* will keep well in your cellar all the winter. Cut down the stems after the first frost, lift the roots with all the earth that will hang to them, and pack them close together. As soon as fresh growth commences you must give light in spring, and may either divide and plant out, covering with dry ashes, or set the plants out of doors so that you can protect a little if necessary. They will do well planted out about April, and on a cold night you might place a pot over them.

**SMALL STOVE FOR GREENHOUSE (Subscriber).**—A small circular iron stove, which, with pipe to go through the roof, ought not to cost more than 55s. to 60s. will suit your purpose best. Get one with a flat top so as to put a pan of water over it, which kept filled unless in very dull muggy weather. We have seen small ones made by Messrs. Green, of Luton, answer remarkably well when fairly treated.

**INSECT ON FRUITS (G. Thompson).**—Are you sure it is the green fly? Then shut up the house close, and use about three cunecs of the best shag tobacco, burning it slowly in any vessel, placing the vessel on the floor, and covering the tobacco when lighted with 3 inches or 4 inches of damp moss that the smoke may be presented cool. Sprinkle well next day, and most likely the dose must be repeated in three days or so, and if the fly have obtained strong hold they may need a third or a fourth fumigation, as the smoking will kill only what is alive, not the eggs unhatched. If afraid of this, cut a borrow-hole of young Laurel shoots, bruise them and the leaves between a mallet and stone, place them on a mat, spread them out on the floor of the house, and turn them over once or twice. We did nothing better.

**AMARYLLIS CULTURE (A. M. R.).**—As your *Amaryllis* is merely marked sp., it is uncertain whether you can grow it in your window or not, but it is worth trying. Use rather a small pot for the bulb. Use for it chiefly pure loam with a little sand in it—that is, no dung or leaf mould. When growing freely give the plant a little weak manure water. When the leaves begin to get sickly, refrain from watering, and when yellow the plant will want little attention except standing on damp moss and to be kept free from frost until growth commences; then top-dress and water. Most likely the plant will not lose foliage the first year, and, perhaps, not at all, and the treatment must be accordingly.

**HEATING BY GAS (D. C., Manchester).**—A boiler is a needless expense when gas is the source of heat. Two or three circles of jets of gas, the largest circle 18 inches in diameter, burning inside a gas stove with a four-inch tube passing from its top, with a gentle upward slope all round your forty-feet-long pit, would give heat enough.

**WINTERING LOBELIA SPECIOSA (E. K.).**—The old plants now in pots are certainly the best plants to keep. Cut off all their flowers at once, and let no more come, and keep them like *Mignonette* all the winter. The next best plan would be to cut off the flowers of detached plants in the border early in September, to lift them about ten days afterwards, to plant them in the same place again, or some place like it that would cause the roots to make young ones all over them, and the shoots to make such growth as no winter would hurt, then to pot these in October, as late as the frost would allow, and to water them most carefully the whole winter, so as to keep all damp from them.

**WINTERING SEEDLING ANTIRRHINUMS (Idem).**—These, now 4 inches high, and four or five in a pot, should be kept in the same the whole winter; but do not stop them till the water is over. To "pinch" such little things just now, would only make them more difficult to keep. September, to the very last day of it, is the very best time of the year to plant rooted layers of all border Picotees, Pinks, Cloves, common Carnations, and new hybrid Dianthus. None of these, however, are supposed to be florists' flowers.

**SONING CYCLAMEN SEEDS (H. C.).**—The seeds of all *Cyclamen* ought to be sown as soon as they are ripe; but most, if not all, of them will keep as long as Balsam seeds, and come up the first year. We state this on the authority of Mr. Bird, the largest raiser of *Cyclamen persicum* in England, who has raised plants from ten-year-old seed kept in the leg of a stocking all the while.

**PROSEA MEDIA (Idem).**—It is a very scarce plant in Scotland, at least in the highlands, where we have never met with it, while *Uniflora* seems to run over the whole of the grouse grounds up to the limits of the ptarmigan. But some of our readers may be able to point out a habitat for media to a lady correspondent in Galloway. It has been found at Corra Linu near Lanark, and near Forbes in woods belonging to the Earl of Moray.

**WATER LILIES AND BULBS FOR EGYPT (Old Charlton).**—All the *Crinums*, *Paneratiums*, and *Hymenocallis* are most suitable bulbs for planting within the tide-mark of the Nile, but not to be always under water like the Lilies. There are, or were, upwards of one hundred kinds of *Crinums*, half as many of the *Hymenocallis*, and five or six *Paneratiums* for this work, and all the water Lilies we have in England are already in Egypt in abundance.

**JOURNAL OF HORTICULTURE BY POST (A Young Gardener).**—You can have it free by post, posted in London on the day of publication, and it will be at your post town, if in England, the next morning. For twelve months you must *prepay* 17s. 4d., for six months 8s. 8d., and for three months 4s. 4d.

**EDGING PLANTS (Taunton).**—*Gnaphalium lanatum*, *Stachys lanata*, *Cerastium tomentosum*, *Cineraria maritima*, and *Konigia maitima* are not raised from seed, but *Actotis reptans* is; and seedlings of it, we have just discovered, are not one-quarter so good as plants from cuttings. The price of them all, except the *Actotis*, is from half-a-crown to 4s. the dozen, and any nurseryman can supply them.

**STACHYS LANATA (Idem).**—It is hardy as a Russian; and the plant which is called *Gnaphalium lanatum*, and which is really the not useful hedge plant for the flower garden, is not quite hardy—about the same as most of the *Verbenas*. March and April are the best time to propagate it from some old plants taken up and kept over the winter.

**COCA-NUT FIBRE REFUSE (Working Man).**—All the nurseries round Kingston have proved this refuse to be injurious to plants when they could get it by the thousand loads, gratis and welcome; now, however, they find it "a wonderfully good thing" when they have to pay 35s. the truckload for it! It suits every plant and every kind of soil, but the quantity used must depend upon the staple of the soil to which it is applied. That partially decomposed, probably, would be most fertilising the first year, and afterwards both it and the fresh refuse would be equally beneficial.

**WINTERING CALCEOLARIAS (L. G.).**—For most purposes it is better to cut back old plants of *Calceolarias* when they are lifted for the winter, but that is not pruning at all. You may cut off more or less from the tops all round the plant according to your head-room. We have had them doctored so as not to leave a leaf, and we have had them without removing a leaf till the plants were from 3 feet to 4 feet high, and fit for the centre of a very large bed, and both did equally well. Mr. Fish has often stated that he prefers late in the autumn, after the middle of October to the end of November, for these cuttings. We learned the practice from him long since, and we have often proved it to be the best plan of all.

**CUTTING-BACK GERANIUMS (Idem).**—It is even now too late to cut back *Geraniums* if they are of any good sorts. *Pelargoniums* may be cut back as late as one day before the frost, even if it should not come to the end of next January. It is not "better" to winter *Fancy Pelargoniums* in the pots they bloomed in, no matter the size, but much the worst plan; but it is always and in all places the best way with *Scarlet Geraniums* if it could be done.

**SIR JOSEPH PAXTON'S BEDDING PLANTS (B. A. W., Dublin).**—At the page you refer to, we find Mr. Beaton referred to bedding plants in Sir Joseph Paxton's garden. You might have "poked your stick" until now in the beds at the Crystal Palace without finding Sir Joseph's pots!

**FLOWER-GARDEN PLAN (Gardena).**—Your planting is exceedingly well done; 5 and 6 in the chain-border being the only oversight in scores of beds; 6, St. Clair, is the weakest and the lightest-coloured of the bedding *Geraniums*, add that to its variegated foliage and place it next a pure white, like *Madame Vanher*, No. 5, and both are spoiled for effect. Put 7, *Aristo*, one of the darkest of the *Verbenas*, between *Madame Vaucher* and *St. Clair*, and the chain would be much better all round.

**BLUE AMARYLLIS (R. Warner).**—Many plants have been so called, as, for instance, *Xiolorion montanum* from the Caucasus; the blue *Agapanthus* from the Cape; and *Griffithia hyacinthina*, which is the blue *Amaryllis* to this day in the gardens of Rio Janeiro, that part of the Brazils being the native place of that bulb, which grows in strong loam on the Corcovado, and on the hills to the north of Rio, but it requires three-parts of peat in pots with us. Captains of vessels have taken the blue *Amaryllis* of Rio to all parts of the world, and you might now pick it up as a native of Java or Jamaica sooner than even at Rio.

**PIPES FOR FLOEA (Kilworth).**—We have no faith in a metal pipe; unless large, it so soon gets foul. For your house earthenware pipes ought to be from 10 inches to 12 inches in diameter, and to keep the house at all comfortable it would require at least to cross both ends and pass near the front. You would require also to have a brick fire for at least 8 feet from the furnace. Unless you have the pipes at hand, we do not see you will save much, as you should have a brick pillar for the pipes to go into at each corner, which will prevent all necessity of touching the pipes when cleaned.

**PLANTING VINES (Idem).**—It will be best every way to plant the Vines inside your greenhouse. They should be at least 18 inches from the fire. We presume the front wall is ached and the border outside lower than that inside.

**Turf for Sloping Bank (Idem).**—For such a large affair we have no faith in *Spergula*, and such a number of plants would be costly besides; but we own at once that we know little about it, in comparison to Mr. Beaton and others who recommend it so strongly. If you had just given us a section of the slope we should have understood it better—that is, 12 feet wide and 300 feet long, and to have beds cut out on it, and a four-foot ribbon-border in front. If all are the same slope, this will only leave 8 feet for beds, divisions from ribbon-border, &c. Why not ribbon the whole, and need neither grass nor *Spergula*? Perhaps the 4 feet are on the opposite side of a walk, &c. Even then we would prefer balanced symmetry to beds on one side, and border on the other. The *Spergula* may be planted at any time.

**CUTTINGS OF PURPLE UNIQUE GERANIUM (Idem).**—What is called *Rollison's Unique*, strikes best in spring, but pieces, side shoots from 3 inches to 4 inches long, will strike very well now. If you remove most of the leaves, put three cuttings round a 60-sized pot, in light sandy soil, and just keep the soil a little moist, by dropping water in a dibbled hole in the middle of the pot.

**ROSES MILDEWED (E. C.).**—Your heavy soil in Warwickshire, which cracks and bakes in dry hot weather is the cause of your Roses falling. If you mix with the top 9 inches a good dressing of cocoa-nut fibre refuse, mulch the surface, water in dry weather, and have Roses growing on their own roots, you will not have to complain that "everything goes wrong" with them. Remember, that a "stiffish clay" is the most difficult soil for the gardener to subdue to his purposes. We always pare and burn the top spit of the whole surface of such a soil, and work the ashes into the spit below. This permanently improves the staple and destroys the wireworm most effectually.

**NEGLECTED LAWN (J. T. S.).**—Use coal ashes sifted, one-half or one-third, and one-half or two-thirds of any light soil also sifted, mixed and spread over the lawn to fill up the inequalities on your heavy clay lawn. That ought to be the first thing done, and as soon as the mowing is over, spend out all weeds early in the spring as they rise, and in April apply the cocoa-nut fibre refuse to keep the surface cool for the summer.

**SPORT FROM MANGLES' VARIEGATED GERANIUM (D. C.).**—The sport is certainly worth keeping, but is of no money value. Mr. Beaton would like such a sport for crossing.

**WOOLICE ON PEACH WALLS (D. G.).**—You should have trapped your woodlice before the fruit was so near ripe. Now every hole is a harbour to them, and you know just as well as we do the difficulty of getting them out of their hiding-places. The following will alleviate the evil:—Cut a number of bean stalks and stick them in the trees; if cipped in sugar and water all the better, and drive out all that may take shelter in them in the morning. Again, slice up some sweet Apple, put a bit in the bottom of a flower-pot covered with dry hay, and place the pot at the bottom of the wall, after you have syringed it well, so that the Apple and the dryness may alike attract the woodlice; and destroy in the morning in the way you like best. The third mode we have tried successfully with old walls. Gather all the fruit at all ripe, then syringe or rather engine the wall heavily, beginning at the top and coming to the bottom, going over the tree repeatedly three or four times before leaving it, which will wash a great portion of the enemy to the base of the wall; and to prevent those that escape from getting up again, paint a band of 3 inches or 4 inches along the bottom of the wall with a mixture of coal tar and oil—that will be impassable so long as it remains soft and fluid. This is also a good remedy for keeping ants from the fruit; but, in addition, we have had to surround the stem of the tree with a rope so saturated, or they and the woodlice would mount that rapidly. These, however, are only makeshift palliatives when the evil is upon us. The great remedy is fresh pointing so as to fill all the holes in the wall.

**MELONS CRACKING AT THE STALK BEFORE RIFE (Idem).**—How are your Melons grown? If suspended, and no support given, they will often do so. When grown on a bed, unless too much water is given, the cracking there is generally a sign of ripeness. See previous and late remarks on this subject.

**MEDALS (Idem).**—We think much as you do as to the medal affair, but do not see how we can add anything to what was said on the subject of exhibiting lately. It is best when all these matters are settled at the time of engagement, and nothing left to doubt. We knew an instance where the gardener paid his own expenses, and then the master claimed the reward. It was not to be wondered at that such a master was always in the hiring market, and that an actual outlay of some four times the expense of neighbours similarly circumstanced, did not yield him a tithe of the advantage and pleasure which they derived.—R. F.

**THRIPS ON VERBENAS (Wm. Hopkins).**—The thrips have done for your *Verbenas* this year, and the best thing you can do is not to think of caring them, for they seem to have been past a remedy a month ago. Pull them up and burn them, and plant *China Asters* in their place, or even *Chrysanthemums*, tying them down if only to make a green covering to the beds.

**CLIMBERS FOR A CONSERVATORY (Quis).**—To go over the roof in one year, you must either get very fine strong plants, or put up with something more common. Keeping covering the roof in view, we would propose the following:—*Mandarinia Barclayana*, *M. semperflorens*, *Cobea scandens*, *Rhodochiton volubile*, *Passiflora cornea*, *P. racemosa* (crucula), *Tropaeolum pentaphyllum*, *T. polyphyllum*, *Eceremocarpus sabel*, *Lophospermum erubescens*, *L. Hendersoni*, *Tacsonia pinastipula*. Of these the *Tacsonia* and the *Passifloras* may not reach over the house the first season; but they are the only three we would keep permanently. We would get plants of the following, and grow them a year or two in pots before planting them out, and then do away with the other nine, substituting something like the following:—*Habrothamnus clegans*, *Bignonia Chereje*, *B. jasminoides*, *Jasminum odoratissimum*, *Kennedya Maryatta*, *K. nigricans*, *K. Comptoniana*, *K. heterophylla*, and *Soltia heterophylla*. We are sorry about the Vines and Ferns. We expect they have the thrips, though not sure from your description. Your fire was too hot, almost every week we have been cautioning against such a practice. If you consult the reports of the various Exhibitions, you could judge what twelve fine-foliated plants would suit you best. Meanwhile we have two favours to ask; first, the size and height of your house, and then, that one of our successful exhibitors would name the twelve plants most suitable.

**VARIETIES (Kale).**—Your flowers were so jumbled in the letter that no one could tell the one from the other. Fresh soil is better against caterpillars than most nostrums. Soil never fails. We put it on in abundance, and then shake the plants to remove so much of it that dust innumerate itself into all the surrounding parts, and it chokes most things in the crawling line without hurting a leaf. We do not know yet if cocoa-nut fibre refuse will grow *Rhododendrons*. Try the very old refuse which has become like coffee-ground but blacker. We do not know the Pear you saw in Belgium, but take the American Lady Apple and the Red and the White Astrachan, grow them properly and they will be just the very fancy you have now. The Lady Apple is a true cherry cheek. The Red Astrachan will have a bloom on the fruit like a Plum, and the White is transparent. The Parsley-leaved Grape is always best out of doors where it will do, as it once did with us on the south-west slopes of the Malvern Hills. And, lastly, we quite believe you when you say you were ashamed to ask so much at once. Every correspondent should remember, that we have hundreds to reply to and cannot give an hour to each.

**LILIUM LANCIFOLIUM IN POTS (Belladonna).**—Use small pots and the same soil as for *Hyacinths*. It is quite erroneous to talk about these Lilies not liking manure; but unless a grower has full practice in gardening, manure is as dangerous in his hands as any poison whatever. We had some of the original bulbs which were saved from a wreck in a courtyard at Brussels by the French cavalry. The unpacked boxes from Japan by Dr. Siebold were in the court-yard, or some yard or court, when the French were besieging, and we had to bring them round with very decayed cordage nearly one-half, and one-half peat, and a great deal of sand. We have since kept some of them in all soils and composts, and the great secret seems to be to have them cramped for room at the roots, and to supply them with soft rain water as if they were marsh plants. We had then that way in such small pots, that in three years they would burst the pot; and we know a nurseryman who keeps the largest bulbs of them in the smallest pots he can get them squeezed into, for he trusts to the watering alone, and we have no doubt they would grow as well in moss and water as they do in the clay compost in the borders at the Crystal Palace.

**NAMES OF FRUITS (J. Jones, Evesham).**—1, Birmingham Pippin; 2, a very good Apple, with a brisk, aromatic flavour, probably a seedling; 3, not known; 4, one of them is Winter Pearmain, the others are probably local seedlings; 5, appears to be the Nectarine Fruit. (*A. Salsbery*).—1, like Lord Suffolk; 3, Dumelow's Seedling; 4, Round Water Nonsuch; 6, Allis-

ton. Among the others were Court of Wick and Kentish Codlin; but your fruit was not only not sufficiently ripe for proper determination, but it was loosely packed, and the numbers being on detached pieces of paper were mixed together, and some were not to be found at all. In future mark the number with ink on the fruit.

NAMES OF PLANTS (*G. C., Livermore*).—*Pyrus aria*. (X. X.).—Bad specimens of 1, *Tradescantia virginica*; 2, *Epilobium angustifolium*; 3, *Centaurea ruber*, probably; 4, *Cerastium tomentosum*. (*J. D., Forfarshire*).—1, *Echium vulgare*; 2, *Centaurea scabiosa*; 3, *Scabiosa arvensis*; 4, *Sedum telephium*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

SEPTEMBER 25th. STAFFORDSHIRE. *Sec.*, Mr. W. Tomkinson, Newcastle. Entries close August 25th.

SEPTEMBER 25th. MIDDLETON. *Sec.*, Mr. T. Mills. Entries close September 10th.

OCTOBER 28th and 29th. CALNE. *Secs.*, A. Heath and F. Baily. Entries close October 15th.

DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

### OF ILLNESSES.

(Translations from *M. Jacque's work on Poultry continued*.)

I HAVE said this should be a short chapter, and have good reasons for saying so.

Most illnesses are caused by bad constitution, and this is the result of accidents, the causes of which are unknown; sometimes they come from feeble parents, from lack of care and insufficiency of food during growth, or continued ill-treatment. But whatever may be the determining cause of illness in a fowl, it is not less true that if there is a desire to cure it, it will take as much science, as much care, and as much expense as a sick horse. As this is next to impossible, the shortest and simplest of all remedies is to cut the patient's throat; you will thereby get rid of an unproductive animal, capable of only propagating in the poultry-yard the disease with which it is infected. When robust birds become ill, it is almost always caused by dirty water or houses, or by infection bred in the small spaces wherein they are confined, or by the lack of substance they would find if they were at liberty.

It is, then, by the hygienic cares of every description that are pointed out in this work that we must prevent those attacks, which very often become contagious, causing serious damage on large farms, and irreparable loss to amateurs. Some useful indications may in certain cases help to preserve a valuable animal.

The most frequent maladies are nasal catarrh (discharge from the nostrils), canker on the tongue and in the throat, and lastly, ophthalmia. These affections are almost always indications of a bad or vitiated constitution; they may also be caused by draughts, by infected houses or tainted runs, or by unwholesome food or water; and in delicate breeds, such as the Crève Cœur, Ham-burgh, and Dorking by a simple change of locality or habits. In the first case, it is almost incurable, and in the other it is absolutely necessary to isolate the patients or to lot them in ones, twos, or threes in small-floored compartments kept very clean and sanded. The nostrils, the eyes, and the interior of the beak should be washed every morning with slightly acidulated water. If canker produces a thick or hard sticky discharge, it should be removed with a sharp wooden spatula; the place should be washed, and, if possible, cauterised with nitrate of silver. Refreshing food, such as millet, dough made of barley flour, grass, and very clean water, complete the treatment. As fast as the birds are cured they are let out to regain strength and vigour in those places where there is the greatest amount of vegetation.

A barbarous custom, as ridiculous as it is abominable, consists in tearing off the horny tip of the tongue in order to cure the malady called the pip, and which is only canker or *apthe*. This substance is as natural to the tongue as the nail is to the finger. I have seen people take a sick hen, examine the interior of the beak, then, seeing it was suffering from canker or *apthe*, take a pin and tear off the end of the unhappy patient's tongue. As a precautionary measure all the birds in the yard were examined. As they all had the horny tip, it was settled all were about to suffer from canker, and then all hands set to work to mutilate the entire poultry-yard. The wound it causes is long in healing, and sometimes incurable. One of the most dangerous maladies, because in time, and almost imperceptibly, it will invade a whole yard, young and old, is a disease I will call the *white*; it is a

sort of itch, evidently caused by invisible "vegetations," which appear first on the feet, on the combs, on the wattles, on the cheeks, and on the deaf-ears, in the form of small flour-covered patches. These patches extend and thicken till they atop the ear, form crusts on the face, make holes in the legs, raise up the scales, and cause them to fall, and at last invade the whole animal. As soon as the appearance of white is ascertained, a remedy is at hand which is a certain specific. It is merely sulphur ointment, the recipe for which is powdered or flowers of sulphur and lard or hog's fat in equal quantities. These two substances thoroughly kneaded together for a long time will form a very thick ointment, which should be abundantly applied. If the white is of old date and very floury, a cutting instrument should be used, and the parts scraped with it to the quick, even in the most difficult places; the ointment should be abundantly applied, and renewed every third day, till a cure is effected.

The ointment should be applied wherever it is necessary, care being taken to raise the feathers in layers, so that the animal shall not be greased all over. Gout makes a direct appeal to the fatal knife, the same may be said for consumption, chilblains, convulsions, and fractures. To conclude with a general rule, every fowl sick of any malady should, if a cure is desired, be put by itself, and fed as has been described. I have almost always found this successful without any other treatment.

### ALTERING THE DAY FIXED FOR A POULTRY EXHIBITION.

THIS is not so unimportant as it may seem to be until we consider some of the consequences. We will give some examples.

Mr. Hewitt annually awarded the poultry premiums for the Poultry Show of the Manchester and Liverpool Agricultural Society, but having accepted the invitation of the Committee of the Calne Exhibition, therefore, on the after-application of the Manchester and Liverpool Secretary, he was compelled to decline, it being impossible to get from Calne to Warrington in time for duty at the latter Society. Now, the Calne Committee have postponed their meeting until October 28th next. This is unfair to exhibitors as well as to the Judges; for parties who had entered with the Calne Committee were prevented altogether from exhibiting elsewhere at that particular time.

Committees, without doubt, injure their exhibitions in every way by holding their meetings simultaneously, and this must be the case with the Newcastle (Staffordshire) and Melton Mowbray Shows, both held on the 25th instant.

### SPECIMENS AT THE CRYSTAL PALACE POULTRY SHOW.

HAVING made a few notes in my catalogue while at the above Exhibition, I beg to offer them to you, but as you have already published an account of it, I will endeavour to omit repetitions that would only be tiring to your readers. Taking the list in order, I find my first note in the White Dorking class, which I am sorry to see so small, as I consider them the best and most useful fowl for general purposes. The birds are improving in size, but they are getting too leggy—a complaint now often heard of table poultry, too much brown meat and too little breast. Large size is an excellent quality, but long legs and neck are not desirable. One bird I noticed had had his feet plucked, and his toes and comb were not correct, which, of course, would destroy any chance of a prize.

The Shanghaies were a fine lot, but I looked in vain for Black-breasted Red cocks and Partridge-coloured hens. In the Brown class the hens were all dull Grouse-coloured, and the cocks were more black than red, and seemed as if bred from black hens.

Among the odd cocks, No. 113, a white one, had white legs, which I think an improvement.

In Game fowls, No. 130, a pair of the old-fashioned Red-spangle, now rarely seen among the Duckwing cocks, I could only notice one without the red back. That indicates a cross with the Reds. I think the Game fowls are getting too large and much exceed the fighting standard.

Silver-pencilled fowls were generally wanting in depth and regularity of their markings. There is not black enough in the pinions of the cocks. I certainly think Pencilled cocks would match the hens better, and even if not put in the show-pens breeders would find their advantage in breeding from them.

Golden-spangled were all Moonies with black tails and striped hackles, while the Silver-spangled approached the Creels with white tails and hackles, except that some of the hens had black tips to their hackles.

Black Polands with white crests were few but good. No. 286, were blue with white topknots.

The French fowls called Crève Cœurs, La Flèche, and Houdan do not improve on acquaintance. They appear as degenerate Poles.

Mrs. Seamons' Aylesbury Ducks were magnificent, but it does seem a pity to breed those delicious black East Indians so small, if they were larger they would be better for the table.

There were some very fine White Geese. Pen 395 had pale beaks, which, I suppose, gained their honours, as they were not so large-framed as some others.

The Sebastopol Geese were very pretty, medium sized, quite white, and the back feathers long, curled, and wavy.

There were also some hybrids between the China Goose and Canada Goose shown by the Crystal Palace Company.

Among the extra stock there was a pen of birds exhibited as a cross between Golden Pheasant and Game Bantam, but I think it must have been the Pheasant fowl or Hamburg, as I could see no resemblance to a Pheasant. The so-called Breda fowls exhibited by Mr. Charles Bocquet were curious, being without combs or crests like the Guelderlands and of various colours. There were some very excellent Silk fowls, but the novelty of the Exhibition was the Japanese Bantams shown by Capt. F. Martin, R.N. They were small with very large single combs, clean yellow legs, and so short that their breast touched the ground. There were a pen of white and very light ones in ordinary feathers; a pen of black with silky plumage; and a pen of drab-coloured with black tails, in which the feathers were ruffled or reversed as in the Frizzled fowls.

The novelties among the Pigeons were two pairs of White Jacobins with pinks or purls over their heads like Trumpeters. The Jacobins generally were very coarse. Turbits are also in want of improvement. A pair of dun Barbs rather a scarce colour.

The fancy Rabbits were good and plentiful, every class well filled except the Blue and White. But it is a great pity there are no separate classes for the Silver-haired, Ermine, and Angora Rabbits. As it is, no encouragement is offered to the breeders of these useful kinds. The extra class contained two pretty little Piebald Rabbits entered as Egyptians, one Silver-haired Black, two Silver-haired Sandies, and a few Ermine Rabbits, or, as they are improperly called, Himalayan.—B. P. BRENT.

## MANCHESTER & LIVERPOOL AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS Show was held on the 10th inst. There were 180 entries for the prizes offered, and some splendid birds were shown.

Among the prizes awarded were the following:—

- DORKING.**—First, E. Tudman, Ash Grove, Whitechurch, Salop.  
**SPANISH.**—First, J. K. Fowler, Prebendal Farm, Aylesbury.  
**GAME COCK (Black-breasted).**—First, W. Nunnerley, Wellington Place, Latchford, Warrington.  
**GAME COCK (Black-breasted Red).**—First, J. Ho'me, Knowsley, near Prescot.  
**GAME (Brown-breasted Red).**—First, T. Burgess, Burleydam, Whitechurch, Salop.  
**GAME (any other variety).**—First, H. Worrall, Spring Grove, West Derby, near Liverpool.  
**COCHIN-CHINA (Buff or Cinnamon).**—First, E. Musgrove, Aughton, near Ormskirk.  
**COCHIN-CHINA (Grouse and Partridge).**—First, E. Tudman, Ash Grove, Whitechurch, Salop.  
**HAMBURG (Golden-pencilled).**—First, A. Nuttall, Newchurch, near Manchester.  
**HAMBURG (Silver-pencilled).**—First, J. Platt, Deane, near Bolton.  
**HAMBURG (Golden-spangled).**—First, N. Marlor, Denton, Manchester.  
**HAMBURG (Silver-spangled).**—First, J. Fielding, Newchurch.  
**POLANDS.**—First, J. Dixon, North Park, Bradford.  
**BANTAMS (Game).**—First, T. H. D. Bayley, Ickwell House, Eiggleswade.  
**BANTAMS (any other variety).**—First, T. H. D. Bayley, Eiggleswade.  
**ANY OTHER BREED OR CROSS-BREED.**—First, Mrs. M. Seamons, Hartwell, Aylesbury, Bucks (Brahma Pootra).  
**GOSLINGS.**—First, T. Burgess, Burleydam, Whitechurch, Salop.  
**DUCKLINGS (Aylesbury).**—Mrs. M. Seamons, Aylesbury, Bucks.  
**DUCKLINGS (Rouen).**—First, J. Holme, Knowsley, near Prescot.  
**ANY OTHER BREED OR CROSS-BREED.**—First, J. Dixon, North Park, Bradford (Black East Indian).

The Judges were Mr. Richard Tebay, Fulwood, near Preston, and Mr. William Lloyd, Weaverham, near Northwich.

## BLUE OWL PIGEONS.

In your report of the Pigeons exhibited at the Crystal Palace Summer Show, it is said, with reference to the little foreign Owls, that no Blue ones have yet been imported. Will you allow me to state that all three gentlemen whose names appear in the prize list—viz., Messrs. Rake, Morris, and Else, have had Blue Owls of my importation, and that I have Mr. Rake's permission to state that one of his winning birds was bred from a foreign hen purchased of me?—JOHN BAILY, JUN., 113, Mount Street, Grosvenor Square.

## VITALITY OF EGGS.

EGGS for hatching should be as fresh as possible. Some say they should not be over two weeks old—about the time it takes a hen to lay a clutch of eggs. It is no easy matter—in fact, it is impossible, to fix upon any precise period when the vital principle in the egg is destroyed, since it varies from the first, according to the vigour of the parents of the enclosed embryo and the mode of preserving the eggs. A safe rule, however, is to secure fresh eggs. Those who are anxious to secure a valuable variety, one chicken of which would be worth a whole brood of ordinary or common sorts, will run all risks. After seven or eight weeks their chance is not entirely gone—some of the chicks will be found dead in the shell; but those that are hatched, if they survive the first forty-eight hours (the great difficulty), are afterwards no more weakly nor troublesome than others.

Whether for hatching or eating, it is advisable to collect the eggs every afternoon daily. They should be shaken as little as possible, for fear of rupturing the ligaments and mixing the albumen with the yolk. In the meantime, air should be excluded from the eggs as much as possible. They should be carefully packed in oats, bran, cut straw, or any other dry, soft substance. It is best to set them on end, and not suffer them to lay and roll on the side. Set them into a moderately cool, dry room of even temperature. A careful observance of the foregoing rules may save many from disappointments in rearing some of the choicest varieties of fowls.

We have before said eggs for hatching should be as fresh as possible; and, if early in the season, care should be taken that they do not get chilled or frozen, as that would destroy their vitality. As soon as laid they could be marked with a pencil to know their age and stock.

The last week in March, or first in April, will be a good time to set your hens; and the pullets, if well fed from these clutches, will lay through the following winter. Select the eggs of good laying hens, of good shape, and of regular size: by this means you may much improve your stock. Some who are very particular in these matters will only put eggs from one fowl under a sitting hen, in order that no mistake may arise as to the identity of the chicks. In raising Game fowls, this, of course, will be a very important rule; and as the male bird is the object desired in this stock, observe eggs of a good shape that are longest and sharpest at the small end are generally found to produce males, but not always, while the round and large-ended ones produce females. Last year, in a clutch of thirteen long, pointed eggs, there were ten cocks and one pullet hatched.

Many persons are foiled in raising chickens for want of a little attention to them. It is an old but true axiom, that "a thing worth doing at all is worth doing well;" and this will apply to the rearing of chickens as well as to other matters. Convenient nests should be provided for the hens to lay and hatch in. They should be secured in sheltered places, and filled with cut straw, hay, or some soft substance. Old nests or boxes should be cleaned, scalded with boiling lime-water, and the bedding removed and replaced with fresh.

Place all the eggs under the hen at once, and mark with chalk or pencil, in a conspicuous place on the box, a date twenty-one days in advance—the time occupied in hatching.—C. N. BEMEST, New York.

## BEEES ABANDONING THEIR VERMIN-INFESTED HIVES—FORMATION OF ROYAL CELLS.

I OBSERVED at the end of last year several moths flitting about the back window of a strong colony, and excavations made in the brittle edges of the comb next the glass. This season it has got weaker and weaker, till the other day I found the box entirely vacated, a few dead bees on the board, and a little honey

in the combs. I carefully examined all the combs, and with the exception of portions of some of them being eaten into, saw nothing of moths or other depredators. Whether the abandonment arose from the loss of the queen, or disgust at the damage of the combs, I am at a loss to know. The patches destroyed were chiefly in the centre of the combs, which were, of course, tough from being bred in, and I should almost suspect the poor colonists have lately been subjected to attacks from a more powerful foe than the moth. It was almost an impossibility for mice to have got access, as the hive was placed near the top of my dwelling-house, besides there was no appearance of their excrements. We have, however, lots of bats. Do you think they could have popped in and done the mischief? I send you along with this one of the damaged parts of the combs, and hope, therefrom, you may be able to express an opinion.

This wet season has caused the annoyance of an unusual number of snails and earwigs (particularly the former), to intrude themselves into several of my hives, even the strongest. Could you suggest a more lasting preventive than sprinkling soot or salt underneath the boards?

About a fortnight ago I moved the combs from a very strong colony that did not swarm, and sought in vain for an interview with her majesty. The population was so numerous it seemed as hopeless as looking for a needle in a hay-stack, and created such a hubbub and confusion, that I delayed repeating the experiment till the middle of a very hot day, when a great part of the population were abroad; then I was favoured with no better success, but was surprised to see a great many royal cells sealed up, although the colony had slain the greater portion of their drones. Could the queen have been lost or killed in the first overhaul? if so, I am afraid any few drones remaining in my apiary will be insufficient to insure the impregnation of a successor. Suppose this to be the state of matters, when may I expect to see young drones issue, the progeny of the virgin mother? There was no cessation of pollen or honey-gathering after either search.—W. J.

[Neither mice nor bats appear to have been at work upon the combs which accompanied this inquiry, but merely the bees themselves, which have gnawed away, as is their custom, those parts damaged by the larvae of the wax-moth, and which would have, undoubtedly, been replaced had the colony survived until summer. Loss of the queen was the probable cause of its extinction.

A piece of sheepskin nailed with the wool outwards round the supports of hives and saturated with tar, has been recommended as the best means of preventing the ascent of vermin.

You would have done better to commence your investigations with weaker colonies until the eye became sufficiently educated to recognise a queen on obtaining even a momentary glimpse of merely a portion of the royal person. Without some preliminary practice of this kind, it is only by extraordinary good luck that you can ever catch sight of a queen bee amidst the surging population of a strong stock in summer. Great care should always be taken by holding the removed combs over the hive to make sure that her majesty does not fall to the ground during the examination, in which case she would almost certainly be lost. The presence of royal cells may be accounted for in this way, or the queen may have died a natural death or have become superannuated, or swarming may be in contemplation. In either case if a tolerable number of drones remain, impregnation is likely to be effected even now. Should the young queen continue a virgin and escape the great risks attendant upon repeated and long-continued but unavailing "wedding-flights," she will, probably, not commence egg-laying until next spring.]

## A DISCOVERY—INSTINCTIVE FORESIGHT IN THE BEE.

SUCCESSION TO A SUPERANNATED QUEEN, HOW PROVIDED FOR.

IN bringing our minds to the study and contemplation of Nature in any of her wide and varied departments—whether in the vast or the minute, animate or inanimate—whether we direct our studies to the heavens above, and listen to the music of the spheres in the blue ethereal, or explore the minuter but not less wonderful arrangements in this lower world, there is no truth which strikes the reflective mind more than this—that there is an unseen Hand behind directing, superintending, and controlling all with unerring wisdom and almighty power.

From the creation of the world till now how admirably hath Infinite Wisdom provided for the increase and continuance of both animal and vegetable life, each according to its own kind! In all this there is manifested such a wise adaptation of means to ends which is truly wonderful. Mystery and obscurity may hang around many of Nature's ways; but the more we investigate the more shall we know, the more admire.

What a beautiful comment on these remarks is the following incident I give in the history of the honey bee, where, in circumstances of peculiar interest, she wisely provides against an impending loss—the loss of a sovereign superannuated and decrepid from age, by timeously rearing a youthful successor to preserve the community from utter ruin!

Various naturalists and apian writers have hinted at the way in which stocks losing their queens by death in summer must supply themselves with new ones—namely, by the well-known power bees possess of converting a worker-egg or larva into a royal bee; but the manner and time of doing this, if ever observed, have not hitherto, to my knowledge, been detailed by any writer.

Previous to my discovery I entertained no doubts whatever as to the fact of the bees so supplying themselves, but was somewhat sceptical as to the way they did so. I contemplated the possibility of a queen dying from age leaving no eggs or larvae in the hive from which her loss might be supplied—a contingency which certainly might occur unless the bees were guided by a wisdom which never errs, because from heaven sprung. I would, therefore, specially call upon naturalists and apian writers generally to notice how admirably instinct guides the bee in this as in every other case in providing for future contingencies and future wants.

In the summer of 1857 I possessed a Huber leaf-hive, whose queen was a very aged one. While the spring of that year witnessed my other hives progressing fast in strength and population, this hive increased so slowly that in the beginning of July its combs were not more than three-fourths covered with bees, and in which the sealed brood were as yet extremely scanty. I was at no loss to comprehend the cause. The fault evidently lay with the queen. During the preceding summer she had proved very unprolific, and it was more manifest that her ovipositive powers were fast diminishing. She was decrepid and infirm; she had tattered wings, a shrivelled appearance, and was totally unable to fly. She moved slowly over the combs, and was in vain prompted by a circle of bees, which continually gathered around her, to increased energy in her motherly functions. At long intervals she did lay, but laid scantily; and I once observed her laying in the drone-cells. Ultimately, however, she became so feeble that she could scarce hold on by the combs, and on three several occasions I found she had fallen down on the board. Her end was evidently approaching. On replacing her in the hive I observed the bees, though receiving her kindly enough, did not treat her with the same attention as heretofore. Next day I found her again fallen down and crawling on the ground in front of the hive. I again replaced her among the combs: this was on the 17th of July. On the evening of the same day in opening the hive to see if it were still there, how was I struck with wonder and astonishment to find during my search what I failed to discover from want of minute observation before—that the bees had already three royal cells, not only in progress, but one actually sealed up, clearly showing that for a week at least before the queen quitted the hive, the bees, instinctively foreseeing the dire calamity which was impending, had thus been quietly rearing for themselves a youthful successor to their superannuated and decayed sovereign.

Here then was a beautiful discovery, the solution of a problem simple in itself, and insignificant, it may be, in the eyes of many, but to me valuable and long-desired. Here was clearly brought out the manner in which a change in the government of a hive is brought about without swarming, and in circumstances peculiarly interesting. Had the hive been a populous one I might have erred in my conclusions. It might be that the bees were preparing to swarm, but the state, condition, and whole circumstances of the hive precluded such an idea. It relaxed not in its industry by the loss of its queen, feeble though its numerical strength had become. I watched results with extreme interest, and in due time a princess came forth. Shortly afterwards the other royal cells were demolished; but, alas! how sad the sequel to my story! how sad the destiny of this youthful queen! and how fatal to the interests of the community over which she was, after so much foresight, wisdom, and care, intended to

rule! The weather at the time had been unpropitious, but tempted, during a sunny interval, the young princess went forth in an evil hour on one of her aerial excursions, and driven by the wind on her return she mistook her own hive, entered another, and when I visited my apiary I found both the hive which she left and the one she had entered in a state of turmoil and confusion, and a few of the bees of the former deserting into the latter with a humming noise. I at once understood the nature of the catastrophe. I lifted up from its stool the hive the queen had entered, and here a most dismal sight presented itself to my view. On the centre of the board, and amid a small circle of bees, I found the young queen all but lifeless. She was surrounded by a few of her devoted subjects which had traced her out, and which with humming wings and other joyful tokens of recognition thus testified their loyalty and attachment to their sovereign even in her dying moments. I removed her to her own hive, and such was the eldect produced upon the bees that a perfect jubilee of humming sounded throughout the entire colony, and allayed for a time, at least, the commotion which was before observed. The poor princess, however, soon succumbed under her mortal wound, and next morning was found dead upon the stool.—J. LOWE.

### CAN THE WORKING BEE TRANSFORM THE GRUB OF A WORKING BEE INTO A QUEEN BEE IN THE PROCESS OF MAKING ARTIFICIAL SWARMS?

I SHALL feel greatly obliged to any one who may see the above question, to give his views and experience bearing upon this very interesting subject.

I must beg to admit that I am one of those who are still very sceptical in the matter, even after all I have heard and read regarding the various successful operations. That queens have been produced over detached colonies I have not the least doubt; and although this to many may appear conclusive evidence, I still think there is a loophole whereby the means of reproduction is carried on unobserved by the keen and searching eye of the zealous apiarian. If such a process of transformation is in reality accomplished by these industrious insects, we have not another species in the whole list of the animal creation (as far as I am aware), capable of carrying out a similar result.

The sexes are not the production of the will, but the special provision of Nature's laws, guided by the unerring hand of Providence, having both male and female of every kind down to the lowest creatures that have life.

In the case of insects which produce a trio in their own kind—such as bees, wasps, hornets, &c., the egg when laid is the embryo of the future insect that is to come forth, the same as the acorn is true of the oak. Acknowledging such to be the case, does it seem possible that a queen can produce a queen or a brood of drones whenever she pleases? I think not, and take the more plausible view of it, that she must lay her portion of the sexes in due order, and when cells are not in readiness for her wants, she has frequently been found to have laid three or four in one cell, as well as dropped them in quantities upon the board below. Entertaining the view of her majesty being guided and working by Nature's laws (as much so as the hen which lays her portion of eggs before the period of hatching arrives), the queen bee also lays her portion of working bees' eggs before either drones or her own sex, as will always be observed in a new swarm by the young working bee being first seen at the bar of the hive.

Having thus far explained my views upon this very interesting subject, I have just this question to ask before closing. Could it not be possible for some of those supernumerary eggs in the cells or on the boards to have been queens, and been found and placed in royal cells by the working bees when they found themselves minus by the robbery in artificial management? Until this loophole is stopped I cannot put any faith in the power of transformation, but I hope some of your learned bee-keeping correspondents will put me right.—QUANDARY.

[We have submitted your communication to "A DEVONSHIRE BEE-KEEPER," who says, "Although it is somewhat late in the day to discuss a fact which has been indisputably proved by the experiments and observations of innumerable apiarians, from Schirach downwards, I have much pleasure in contributing my mite of information by way of stopping the 'loophole' which your correspondent imagines he has discovered. After removing

the queen from a hive and losing her successor during her 'wedding flights,' and when consequently all chance of supplying her place from the resources of the hive itself was entirely at an end, I have repeatedly cut out a small piece of worker brood-comb, little more than an inch square, from the centre of the 'brood-nest' of another stock where royal cells never exist under ordinary circumstances, and having inserted this in the queenless hive, have in the course of a few days found six or more queen-cells crowded upon it. Now, it cannot be imagined that these royal cells contained other than ordinary eggs or grubs, which, if left undisturbed, would have hatched into worker bees, but which, under altered circumstances, were developed into perfect queens. Take also Huber's experiment, successfully repeated by Kleine, one of the ablest German apiarians, of selecting whatever worker-eggs or young grubs he pleased, and causing the bees to rear them into queens, simply by inserting a small portion of royal jelly in the cells containing the selected ones. There can be no doubt whatever that the queen bee lays eggs of only two sexes, male and female, and that every egg may, by appropriate treatment, be reared into an individual capable of propagating its species. In the case of worker bees, however, the reproductive organs are so stunted as to remain, in all but exceptional cases, entirely in abeyance, whilst the pollen-baskets, tongue, &c., receive such a development as fits them to play their allotted part in creation. With regard to the power of the queen bee within certain limits to lay the eggs of either sex at will, my own observations have perfectly satisfied me that such is really the fact. On this point, however, I can add nothing to the conclusive experiments and observations of Von Siebold, Dzierzon, Von Berlepsch, and others.—A DEVONSHIRE BEE-KEEPER."]

### LIGURIAN BEES AND THE BEE SEASON IN STAFFORDSHIRE.

I HAVE been favoured with the following communication from a friend, to whom I sent a stock of Ligurians last year. It appears that the honey season in Staffordshire has been quite as bad as in the district of—A DEVONSHIRE BEE-KEEPER.

"I have destroyed all my black colonies, and have now only four good Ligurian hives for the ensuing winter; they have, with the assistance of contracted entrances, repelled all the assaults of the wasps, which are exceedingly numerous, and have destroyed the entire stock of some of our oldest bee-keepers.

"The second swarm, made on June 4, ultimately became the strongest hive, and weighed a little over 20 lbs. nett in the middle of last month; the first swarm of May 19 would have been a prime hive but for sending out the two swarms early in July, and also affording two frames of brood-comb and bees to the swarm of June 4. It weighed 15 lbs. nett.

"I have given the four stocks 12 lbs. of lump sugar since that time, which, with the water, has made them a fair weight; and at the end of this month I shall again weigh them, and finish them up for the winter with the honey obtained from my English bees.

"This has been the worst year on record in this district, and the little honey collected in the end of July is very dark-coloured and indifferent.—J. E. B."

### OUR LETTER BOX.

WORMS FOR POULTRY (*H. C.*)—The worms collected from ground to the surface of which they had been driven by a solution of chloride of lime, may be given to poultry with perfect safety.

RING ROUND NECK OF ROVEN DUCKS (*F. H.*)—Roven Ducks of both sexes should be the counterparts of wild Ducks. The Mallard has a white ring; the Roven drake should, therefore, have it. It should be a narrow, but a sharply cut and well-defined purely white ring; there should be no other white on the bird. A white flight is an abomination and disqualification.

DEATH OF BRAHMA POOTRA PULLET (*X. Y. Z.*)—We should say the cause of death was stoppage. You should have given a table-spoonful of castor oil at the beginning of the malady. It is always a safe thing to do, and will cure most ailments if taken at the outset.

FEEDING DUCKS FOR EXHIBITION (*Constant Subscriber*).—It is hardly possible to name quantities for fattening any sorts of birds, as some require far more food than others, although of the same breed. At first Ducks would eat more greaves than they would after they had begun to fatten. One-third to two-thirds of meal should be proper proportions. It is not in any way objectionable for Ducks intended for the table. One treatment in the way of food will fit Ducks for all purposes.

WEEKLY CALENDAR.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 65.4° and 45.1° respectively. The greatest heat, 82°, occurred on the 25th, in 1832; and the lowest cold, 26°, on the 26th, in 1855. During the period 118 days were fine, and on 127 rain fell.

THE PLANTS FOR DINNER-TABLE DECORATION AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW, SEPTEMBER 10TH.

HAVING on a former occasion given my views on the subject of dinner-table decoration in flower-stands, it may seem almost superfluous to repeat many of the same reasons I then gave; but since then another move has been made in the matter. The Royal Horticultural Society has offered a prize for twelve plants in pots applicable to the purpose of dinner-table decorations, and that prize has been

competed for, and the name of the winner, and most likely that of the plants exhibited, will, ere this reach the reader, have gone forth to the world with the various remarks which every one is at liberty to make in such a case. If such remarks when put in print bear any resemblance to those made by the assembled company at the Show, I fear the exhibitor will have little cause to compliment himself on having pleased many; for however unpleasant it may be to repeat it, it is nevertheless true that universal condemnation was passed upon the poor plants. I use the term "universal," as I did not hear any one speak in their favour; and certainly if there were any such they formed a very small fraction in the company present. So general was the disappointment that it is as much in the defence of the exhibitors as it is against the system that I now again call the attention of the readers of THE JOURNAL OF HORTICULTURE to the matter; and those who were not at the Show in question, or have heard of the conditions under which the plants were shown, will have no difficulty in understanding the fettered conditions by which the exhibitors were bound.

The conditions were these: Twelve plants in pots were wanted for the dinner-table, which were to be grown in pots of a small size (48's I believe), and were to have naked stems up to the height of 6 inches, measuring from the bottom of the pot, and the total height of the plant was not to exceed 24 inches. Some remarks followed on beauty of form and adaptability to the purpose.

The plain meaning was that low standards with a well-proportioned head were wanted. How this was answered I need only say that the conditions precluded everything well grown, in the usual sense in which that word is used, from entering the lists, the whole of the plants exhibited numbering only a very few species or varieties. Fuchsias were in every collection, and Coleus Verschaffeltii in most of them; one or two Celosias, a Grevillea, one or two Capsicums, Eugenia Ugni, and some others; the whole being such as few buyers of plants would give any-

thing beyond a mere trifle for. The naked stem was tied up to a single stick, and in the case of some of the Fuchsias some extra tying-in of the head was also adopted.

The only plants in flower were the Fuchsias, Celosias, and a Veronica.

I repeat that a unanimous disapproval was passed on them all. In this general charge of condemnation the exhibitors ought to be exempted, for the conditions laid down limited them to the class of plants shown; certainly there could be no better plea given to aid the views I have before advanced that all table decorations ought to be below the line of vision from one person to another, and the clumsy attempt here made to place the ornamental object above that line has certainly as signally failed in giving satisfaction as anything could possibly have done.

Whether this failure in plant decoration will lead to the floral design taking a dwarfer habit remains to be seen; but certainly no one who saw the plants at South Kensington Show could pronounce them fitting objects to ornament a table, so the promoters of such exhibitions must certainly reconsider the conditions they lay down for the guidance of the public in exhibiting plants fitted for that purpose, or they will incur the censure of all but the eccentric class who pique themselves on differing with everybody else. Whimsical ideas may for a time prevail, and receive a considerable share of public support; but unless based on something more than mere whim, they are sure, sooner or later, to receive their desert. Beauty combined with utility will be found in all cases to maintain its position the longest, and the one without the other may also receive public patronage for a time. It can hardly be expected that objects which lay claim to neither (like the plants alluded to) can be countenanced by any.

J. ROBSON.

KEW GARDENS, SEPTEMBER 16TH.

THIS has been the kind of season to suit the tonchy soil of Kew Gardens, and the consequence is that every tree and plant inside and outside is looking in the most perfect health, and the flower garden was more gay than many good places had been a month earlier. I wanted to have been there in the middle of August, and it is to me a curious incident that I could not get sooner, or until the improvement in the flower gardens, there much needed, had been just effected. The head of the grand centre promenade next the lake is now just as it should be at last, and much better than most of us expected, seeing how difficult it is to get money from Parliament for real improvements.

The flat circle of grass in the centre of the gravelled head of that centre walk is now the bottom of one of the best flower-beds in Kew, or perhaps in all the country. It is 36 feet in diameter, has a rich, massive, and moulded edging of terra cotta 15 inches high or a little more. The bed is raised up to the centre as a pyramid, and in the centre is a very handsome flower-vase with pedestal and plinth, and the planting of the bed reaches up to the very plinth. The upper half of the bed was planted at the usual time, but the edging and the first 4 or 5 feet of the grand circle were only finished in time for me to see the whole in apple-pie order.

This terra cotta vase, of a warm cressy tint, is by Mr. J. M.

Blashfield, the noted manufacturer of these ornaments at Stamford, and, like all the rest of the new works at Kew, it is thoroughly well done, and as if to last for ever.

To suit the finishing round this grand circle, the four large beds of Punch have been converted into panel-beds on the Scottish system of panel-planting—a telling system which I first saw eighteen years ago from a plan which Mr. McIntosh sent me to Shrubland Park from Dalkeith Palace to criticise for him; and this, or these four beds, are the first examples of panel-planting in any of our public gardens round London, and I hope the authorities at Kew will never depart from it while I live.

Knowing more of Punch, however, than most gardeners, and seeing it thus turned out of beds two years before it is come of age, knowing also how scarlet the beds have been made by it, I would suggest that those four beds, to exhibit the system of panel-planting, should be made one-half wider than they are now. Then the extra width would be like two strings to one's bow; the beds would be more in the harmony of proportions to the grand new bed which they embrace, and also be more fitting for the new style of planting which has been adopted, and which is done to the letter of the law all but the outside edging, and that is on a wrong principle altogether for this style of work. But let me give you the pattern.

Each bed has five diamonds of Flower of the Day along the centre or axis, and a single row of Perilla runs round all the diamonds. The rest of the bed is in scarlet Verbenas, and the edge all round is made, as it were, in dots or patches of blue and white alternately. To that I have the strongest objection; besides, it violates a principle—the principle of giving variety, and the principle, too, which I find by my experience in the column for correspondents, is the most difficult to understand. Nine out of ten mistake *mixture* for *variety*. The edging is now a mixture; and as effect is lost by mixing colours, I want variety, each colour to be on its own bottom, as it were; then the different colours make a variety of colours, and as the one colour agrees or contrasts with that next to it, effect is produced. The only effect of mixing colours—as Dahlias and Roses are exhibited, for instance, is to muddle the colours and to make them of none effect. But I shall give you the key some day. Meantime let us take the grand promenade with flower-beds on each side through the centre of Kew Gardens, beginning at the bottom. From this point another great improvement which has been effected this season is very marked.

The upright Junipers and their allies, which stood at regular distances all the way up in the line of the beds, and which set off the beds in "blocks," or groups of pairs of oblong beds with pairs of circular beds at each end of them, are taken away, and the whole line of beds on each side is now free from end to end. One more improvement would finish this part as far as our art of putting flowers in form could do it: I mean the Rose-beds should be entirely remodelled. Every Rose plant in every one of the Rose-beds at Kew, I would up and bundle over Kew bridge at the ebbing of the tide, and I would plant dwarf Hybrid Perpetuals on their own roots in all of them, with a thick band of China Rose Fabvier for so many beds; Cramoisie Superieur China Rose to edge so many more beds; some with the China Mrs. Bosanquet; and some with the old Indica major, as round the outside of the Roses at the Crystal Palace. Then, if it were a bad Rose year, the beds would be full at all events, and look as green as the Rhododendron-beds.

The first pair of oblong beds at the bottom of the arrangement have *Calceolaria amplexicaulis* in the centre, a broad band of Perilla all round, and a splendid edging of the new *Gnaphalium lanatum*, for the first time. The two pairs of circles are in *Ageratum*, with *Tropæolum elegans* round for edging. Next pair of oblongs, Punch, with a row of Brilliant, and a deep mass of Purple King Verbena outside. The accompanying pairs of circles to suit in French Marigolds. The next pair, Lord Raglan Verbena and Cerastium. Then a pair of Rose oblongs; then two pairs of circles with Tom Thumb and variegated Alyssum; and an oblong between them of two kinds of *Calceolaria*, *amplexicaulis* flanked with an orange *Calceolaria*, with Purple King Verbena all round. These two *Calceolarias* are so grouped all over the garden, and look much better than any beds of *Calceolarias* I ever saw, the sulphur yellow of *amplexicaulis* and the orange yellow blend, or combine, most beautifully. The next oblong pair is all of Purple King edged with broad bands of Cerastium; and the two pairs of circles are *Ageratum* with Verbena Géant des Batailles round it. The next oblong pair are all Punch with broad edgings of *Gnaphalium lanatum*, most beauti-

ful. Then a pair of oblongs, Mignonette, accompanied with two pairs of Golden Chain and *Stachys lanata*. Here two walks cross the centre one, and the top half is a reflex of the lower. Accompanying the cross walks are four beds of Flower of the Day, Brilliant, and Purple King Verbena, and four of Zelinda Dahlia edged with *Calceolarias*, all in first-rate style; but equally good are four beds of Brilliant edged with Mangles', and four with *Calceolaria amplexicaulis* and Perilla, edged with *Cineraria maritima*. The grand new raised bed aforesaid is thus planted:—Scarlet Verbenas next the massive edging, then three rows of *Calceolarias*, two rows of *Cineraria maritima*, two rows of Mrs. Vernon Nosegay, three rows of Punch above it, one row of Perilla ditto, and the top part in *Calceolaria amplexicaulis* with the orange *Calceolaria* which suits it so well. Turning to the conservatory-terrace are four beds of Punch and Variegated Mint, and four of *Petunia* Countess of Ellesmere and Alyssum, four of *Ageratum* and dwarf Tom Thumb *Tropæolum*, and two of Zelinda Dahlia edged with *Calceolaria*.

The terrace pattern is very richly planted this year. The principal beds are the centre one with a vase in it, and Perilla round it, the body of the bed being Cerise Unique edged with Flower of the Day. Then four beds of *amplexicaulis* and orange *Calceolaria*. There are two large V-shaped beds across the axis of Perilla, embracing a similar bed all white, with Alyssum on both sides of the centre bed; and between the *Calceolaria*-beds come two beds of Purple King, and outside of them two of Brilliant, and at both ends of the centre bed two of Lord Raglan Verbena. The great outside four corner beds are of Tom Thumb, and one bed in the centre at each end is of Golden Chain. The other half of the terrace and the head of the lake are duplicates of the above. But there is a vacancy in grass on each side of the centre walk across the terrace, which ought to be patterned in flowers to suit the rest, and make a perfect whole of the conservatory-terrace.

The beds on the west side of the conservatory, and in front of the old museum are equally gay and well done, and nothing now seems wanting but a reformation of the Roses, and to festoon in chains the climbing Roses, now at the top of their pillars, beyond the conservatory. But the work which the grand new conservatory, in the pleasure ground, has caused for the last eighteen months is immense.

The building itself is really most splendid, and is the most substantially built house in the kingdom, and yet there are two wings to it not yet begun. Inside it is really a Crystal Palace for plants, with all the arrangements most substantial and complete; no less than eight thousand feet of the largest hot-water pipes to heat its greenhouse range. All the plants are to be planted in beds, these being now in course of preparation with fresh-cut turf, on which the plants are first to be arranged in their pots and tubs to see their effect, and to get them secure before winter, so as not to hurry and to do and undo the final planting; then, when all are safe from the winter, they will begin to trench the turf, and mix it with the natural soil at the bottom, which is a deep bed of gravel, and will require no extra draining.

There are two thousand cubic yards of prepared compost of loam, peat, and leaf mould, and seven hundred cubic yards of peat already on the spot for filling the beds in the conservatory—the four corner beds to be all of Rhododendrons; and the roof above is so ventilated with wheel-and-rack machinery, that one-half of the roof can slide down over the rest, so as to let in the summer rain to the beds as if they were in the open ground. One would think now, the difficulty at Kew would be to find plants to fill this immense space.

But the best part of the story is this: Botanical arrangement is to give place to decorative effect in this planting-out in our most national garden, and one feels a national pride in recording the fact. But would you believe that floristry, in its roughest forms, and smoothest edges, is to be fostered at Kew for the use and gratification of the million? Yet so it is to be.\* I actually looked over eight dozens of the best Scotch Auriculas, gathered from Dundee, through the Carse of Gowrie, Perth, and Stirling to Edinburgh for this very thing. Or would you credit the fact that the very pots for these and for the large specimen plants which are to fill that grand conservatory, are made in Glasgow? The Messrs. Austin and McAslan, once famous for Scotch Roses, are not less so in the present day for supplying flower-pots, and pots of the largest size to Kew Gardens, of better make and material, and at a lower figure than they could be had at any place between Kew bridge and Glasgow.

The first curiosity I met with in the arboretum at Kew is known to some few gardeners and men in the trade—the plant called *Podocarpus Coreana*, throwing off sports like some *Taxus* or *Picea* freely enough; so if your *Podocarpus* of that kind should do the like do not wonder at it, or send it up here as a curiosity. All the Sikkim *Rhododendrons* have now bloomed at Kew—*Ancklandii* is one of the best of them, and is even larger than *Nuttalli*; *argenteum*, not quite pure white or the best habit, as big as either of them; *fulgens*, probably the best scarlet one, and more of a dwarf sort; *formosum*, very good; and for crossing, to bring the race within bounds and proper dimensions, none of them, or of all the races, is preferred before *ciliatum* after all. The first of them all which appeared in public was this *ciliatum* sent from Chatsworth to Regent Street. But the cross of *formosum* and *Dalhousianum*, which was obtained by J. Anderson-Henry, Esq., of Edinburgh, is said to be a first-rate plant, and better at Kew than either of its parents; and from the cut blooms of it at the Floral Committee, I should say better everywhere else.

I had been under the wrong impression for some time about *Abies Mertensii* being rather tender—after another turn among *Abies*, however, I am glad to find the impression altogether wrong; none is more hardy at Kew, and certainly none is more graceful after the *canadensis* section, and it sports amazingly from imported seeds. The Mount Atlas Cedar is still keeping the lead there as the best sort of the Cedar-of-Lebanon look for most people. One bushel of the seeds of *Araucaria imbricata*, from one of Mr. Stevens' sales, has produced from three to four thousand healthy seedlings. They have a collector from Kew in Japan, and almost all the recent Japan plants which were at the exhibitions are to be seen at Kew. Of *Retinospora obtusa*, my own favourite of the Cypress-looking plants of Japan, they have a large number of seeds; also a most extraordinary dwarf from *Cupressus macrocarpa*, which will never get to be a foot high according to present appearances.

The new lake has been full of water several times this summer—they can let it off and on with the tide, and now they have the true China geese there, which are very tame and beautiful birds. These were introduced exactly as the Messrs. Sturgen introduced the Cochinchina fowls, being the remains of a live cargo taken by the captain of a vessel to supply the spit on the way home.

The greenhouses are all show-houses now, and they are as gay with common plants as any conservatory in the country. There is a new house for tree Ferns, in which they all look exotic as they ever have been. But I find I must put off my in-door notes till I get over Hampton Court, when I shall have enough on hand since last May to keep me on for ever so long. I will just end with the grand *Victoria Lily* in two houses, and the *Cissus festoons* round it in that next the conservatory. In that house it is most noble this season, having twenty-five leaves in all, and fifteen flowers in full, with four more coming the day I saw it; and the bow of the *Cissus festoons* is reversed this season by a tie from the middle of the band, pulled up and fastened to the roof—a singularly beautiful arrangement.

D. BEATON.

### GOOD LETTUCES IN WINTER.

It usually happens that the article produced in the greatest abundance during the season is the one most in request; and, in general, Nature so nicely balances the supply to the demand of everything more immediately depending on her, that the oldest and most illiterate inhabitant of rural districts foretels with more certainty than an astro-meteorologist that a severe winter is likely to follow a good crop of hawa on our hedges. This wise provision for the wants of the feathered creation is exemplified in many other ways not necessary here to mention; but as luxury and refinement have added considerably to the number of articles we are accustomed to regard as necessaries, we must not be surprised if Nature leaves the providing of them more to our own management than she does the wild fruits set aside for the other members of the animated creation. Nevertheless, in a certain sense, each country produces the articles of most use to its inhabitants. Fruits are most plentiful in dry, hot climates, where by their delicious juiciness they contribute to the enjoyment as well as the wants of the native population; while in cooler and more moist districts, cereals and vegetables are produced in greater abundance, and form an agreeable article in the bill of fare in everyday life. Habits and modes of living have given

certain classes a preference to special articles, and it would be wrong to find fault with this arrangement; but in the general advancement of society the wants of the community become multiplied to an extent little dreamt of by the more primitive settler in an unexplored district. It is one of the features of that very luxury which has augmented to such an extent the number of useful articles our gardens possess (vegetable as well as floral)—and the ardent admirers of good, useful things at table have no right to despise the floral beauties as being less useful, for, excepting the very commonest of all articles of food, rigid adherents to the maxima of some of the doctrines propounded by certain of the strict sect, whose cognomen is a long unpronounceable, and, therefore, unnecessary name, insist that every article not absolutely wanted to support life in the most frugal way is a luxury, and must, therefore, be eschewed as such in favour of this doctrine. I have nothing to say on the contrary, so long as a temperate course be adhered to, the number of such gratifications as witnessing and admiring the growth of good vegetables, fine trees, and gay flowers, cannot be too much increased, as they all tend to develop that grand lesson which points to their original existence.

Useful, good articles, therefore, being admissible to any extent, let us see how far improvement can be carried in the way of furnishing our tables with an article not always found in the best condition at all times, the subject of the present chapter being one of the most common of garden vegetables, nevertheless, it is one of the most popular, and, in a general way, one of the most wholesome, especially in hot seasons; but as it is not always to be had in good order at all times, let us try to explain how that may be done more effectually than at present, and show that *Lettuce*, which is the vegetable we mean, may be had in good condition in March, as well as in July or August.

Like many things else in the vegetable line, especially such as are eaten uncooked, quickness of growth secures one of the best qualities of this vegetable. Its newly-formed leaves collecting themselves into as small a space as possible to shut out the daylight, are in the most admired condition when their whole previous existence extends over a very short period, as by that the firm, fibry matter which gives this and other plants consistency, has not had time to form: hence a rapid growth accompanied with other points of excellence is what is sought for in the *Lettuce*, and to effect this object the best ground is seldom thought too good for it. This matter is so well understood by the caterers to the great metropolitan family, that the tracts devoted to the growth of this and similar vegetables may be regarded as comprising some of the richest and best lands in the kingdom, and these are rendered still more so by the liberal supplies of dung with which it is treated. The crops are, of course, all that could be desired, and in their way as near perfection as in our present knowledge of such things, we are able to place the point of excellence to be. Good *Lettuce* being, therefore, best had in the way here spoken of, we may be assured that, by following the footsteps of those who produced it, a similar result will meet our endeavours. Unfortunately, however, we are not all favoured with a situation like that of the banks of the Thames, where barge-load after barge-load of dung can be obtained to dress the already rich ground. The demands upon the dung-hill in the distant country place are so great, that some discretion on the part of its managing genius is wanted to apportion each claimant with its due quantum. Unlimited quantities cannot, therefore, be granted without entailing a corresponding deficiency on something else, consequently the country gardener has not the chance of the suburban one in growing this and sundry other vegetables to the perfection that might be wished, although with prudent measures and favourable circumstances united, a good result may be expected, and is often accomplished.

Having shown that this vegetable is a greedy devourer of the fat of the land, let us see how this can be given to it without so much recourse to the dung-cart. The sowing and other features of the cultivation having been gone into in former articles, it needs only to be said here, that although a rapid and luxuriant growth produces the crispest and best article in summer, it by no means furnishes the one capable of withstanding the hardest winter. On the contrary, a more tardy growth, checked by the absence of that food it devours so greedily when in vigorous health, tends to prepare a plant capable of braving the storms of winter better than the more mushroom-like growth of the more delicate article; but circumstances of other kinds also operate on this as well. Cold weather checks vegetation, however favourable the soil may be for it, and, added to this, Nature justly

balances her work with the capabilities of her workers, and growth to a great extent ceases in the autumn, at a proper time, even if a cold atmosphere does not intervene. Vegetation in a measure ceases, and the previous growth hardens to withstand the cold that is to come, and this hardening in the case of the Lettuce becomes, of course, a defect in the article produced. The lesson, therefore, to be taught in the case is simply to place the plant in such circumstances as will insure a more quick and continuous growth than would be the case in winter if only allowed to struggle on in the open ground, unprotected and exposed to all the rigours and changes of an ordinary autumn and winter—say, for instance, such as usually occur in the centre and north of England.

As this article is intended principally to show the means of obtaining a good Lettuce in winter or early spring, the ordinary routine of summer treatment need not be gone into, and that for the winter may be summed up in a few words. In some cold pit which can be covered with glass, plant a good breadth of the best Winter Lettuce in the early part of September, allow it to grow on without any protection until frost or very heavy rains threaten to chill the ground, then put on the glass giving plenty of air, and in very severe weather cover up with mats or straw so as to exclude frost in a great measure, at the same time admit as much light as possible on all occasions, and the growth of the plants not being much checked, the vegetable will have much more crispness than winter Lettuces usually have, when they are merely autumn-grown ones kept alive during the winter. A better way than protecting them in frames would be to keep them in large houses of glass, which by-and-by may become fashionable, as a large amount of light could be admitted and the greater body of moderately warm air would take longer time in cooling down to the freezing-point; besides which the plant would enjoy an atmosphere less loaded with the exhalations of herbage likely to promote disease than when crowded into a frame; but the latter way will do, and until the class of glass structures of which I speak become sufficiently plentiful to meet cases like the above, we must be content with frames, and with careful management good useful Lettuce may be had all through the dark days and up to the time that out-door-grown ones come into use.

J. ROBSON.

### A FEW GOOD BULBOUS PLANTS FOR OUT-DOOR PLANTING.

WHILST continuing my notes upon some of the most attractive of the herbaceous plants, bulbs, annuals, &c., in their respective divisions, I cannot help referring to a numerous amount of queries which I have received as to where the majority of the plants referred to by me in No. 73 of this Journal could be purchased. Judge of my surprise when, upon reference to some of our leading nurserymen's catalogues of the current year, a very small minority of those plants could be found at all—not even the beautiful Lord Anson's Pea (*Lathyrus magellanicus*), could I find. This can only be explained by the nurserymen's supposition, possibly experience, that, if in stock, those varieties which require rather more care than usual are seldom or never a ked for.

In the following list of a few bulbous plants it has often occurred to me, that some of the same could be used most advantageously in the boxes, &c., now so common upon the windowsills of town houses, that there is more variety wanted—a change from the scarlet Geranium, the yellow Calceolaria, Mignonette, and Stocks, which we everywhere so monotonously see. I would not do away with any of these, but mix along the front side of these boxes a few of the many showy bulbs attainable: and would they not be very pleasing, as amid their flag-like leaves, with a back row of scarlet or yellow alternately, their flowers hung over the edge of the box? Whilst alluding to window-gardening, I would remark that I do not ever remember seeing a nicely-sown row of the showy *Nemophila insignis*. Tried in one of those positions, it would seem to be one of the most fitting plants for this purpose.

**COBURGIA INCARNATA.**—When flowering, this plant has a magnificent spike, bearing upon its top four beautiful, pendent, scarlet flowers. It is nearly hardy, but does best planted about 7 inches deep in rich sandy soil in early spring, taking it up just before the first autumn frost when the leaves are decaying, and keeping it quite dry during winter, away from frost. Native of Peru.

**STROPTANTHERA ELEGANS.**—An elegant species, having bold prepossessing flowers. Usual height, between 5 inches and

7 inches. The leaves, a pale green, ending abruptly in a point. Flower, in colour white, having a lovely eye, being red encircled with a ring of dark purple and orange. It requires a little protection in winter—a small heap of tan, ashes, or best of all, cocoa-nut fibre, as so often recommended by Mr. Beaton for all gardening purposes. This plant has a great liking to thorough good loamy soil and sand. Cape bulb. Flowers in June.

**WATSONIA MERIANA.**—A showy scarlet flower, with the merit of requiring no other care than planting out in sandy peat, to be occasionally transplanted. Cape bulb.

**VIRESSEUXIA VILLOSA.**—This, the old purple peacock Iris, may be too well known to need description here. Suffice it to say that it is one of the best, being very showy when four or five bulbs are planted together. It should be planted out in April. Time of flowering, July.

**GEISSORHIZA VAGINATA.**—A showy flower with glaucous leaves, from which the flower-stalk protrudes; the flowers being tri-coloured. Requires the slight protection before alluded to in winter, when it does best planted out. Generally flowers in August. Cape bulb.

**GEISSORHIZA ROCHEANA.**—This, the old plaid *Ixia*, well known, as were most bulbs about the time of the advent of the current century. It has a rather weak stem, having a tendency to droop. I give it a place here as being one of the most useful for window-gardening as before alluded to. To be planted the first week in November, slightly protected. Flowers in May.

**BESSERA ELEGANS.**—A lovely plant, requiring the same or like treatment as the *Crocus*, with the essential provision of a good sandy soil, to be taken up when the leaves have decayed. Generally flowering in September. Native of Mexico.

**ANISANTHUS SPLENDENS.**—A splendid plant when planted and grown *en masse*, throwing up spikes of crimson flowers a foot or so long. It luxuriates in the usual part peat, leaf mould, and sandy loam. It has a decided aversion to excess of wet when dormant in winter; and should be protected properly by having a hand-light placed over it, slightly protected in frosty weather by an additional mat or so. Generally flowers in March and April. Cape bulb.

**HOMERIA SPICATA.**—A fine plant with a jointed stem producing flowers in abundance; perhaps one of the most showy as regards the number of flowers upon one stem fully expanded at once. The bulbs bear a great similitude to the *Crocus*, and require the same treatment in good soil, but *must* be taken up each autumn. Flowers June to August. A Cape bulb.

**SPREKELIA FORMOSISSIMA.**—This flower is in colour the deepest crimson, about 1 foot high. It should be planted 5 inches or 6 inches deep. If left out of doors all the year, it likes a dry border. But the most advisable way is to treat the bulbs like those of Tulips, taking them up in the autumn. Generally flowers in June and July.

**BADIANA RUBRO-CYANEA.**—A splendid variety of this genus, the flowers being exceedingly bright in colour—namely, of a deep blue, with more or less deep or bright crimson. If planted tolerably deep it will do well out of doors, but should be kept as dry as possible: it will then flower better, as each year it becomes more established. Generally flowers in June and July. Cape bulb.

**IXIA PATENS.**—Perhaps this is tolerably well known, as it is by no means a rare kind;—generally detected easily at first sight by the crimson tint upon its leaves. It stands tolerably well in the open ground when once established, but should be grown at least one season in a pot. When turned out in the early spring, to be slightly protected in severe frosty weather and heavy rains. If successful, it will in effect amply repay the trouble taken. Flowers from May to July.

**IXIA CONICA.**—I cannot help giving this a place if only as an excellent one for window-boxes, &c., as it can be planted in the same when the other plants are put in in May. Though this one only expands its flowers when the sun is upon them, they are yet very pretty when closed; the buds being conical in form and of a rich crimson colour, varying materially from the colour of the flower when expanded, being a bright orange with darker centre. Generally flowers in August.

**ANTHOLYZA ETHIOPICA.**—A fine plant, with flower-spikes some 4 feet high or so, requiring but slight protection in winter. Flowering very freely, having expanded occasionally a dozen flowers upon one spike. I have seen no less than thirty fully expanded, but it was a monstrous spike. The leaves are marked prettily, being what may be called semi-striped. Generally flowers from June to August. Cape bulb.

**MILLA BIFLORA.**—A markedly pretty plant, having large, pure white, star-like flowers, requiring a slight protection in winter. Its flowers remain expanded rather a long time. A native of Mexico.

**CHLIDANTHUS FRAGRANS.**—A very sweet-scented yellow-flowered plant, which, when treated in the way we habitually treat the *Belladonna Lily*—planting it under a south wall, or front border of a stove or greenhouse—is a very nice sweet little object; yet it will do in an herbaceous border admirably if taken up before the autumn rains set in. I once in a hurry, when a more severe and earlier autumn frost than usual occurred, dug one of these patches up, and threw it into the corner of an overhead stove-hole-shelf, not thinking to look at it again until required in March for planting-out. I found it in a far better condition than others which I had dried and taken every care of. This bulb is *Zephyranthes* or *Lachenalia*-like in producing so very many small bulbs. They are so numerous as to require almost constant division when being replanted. Generally flowers in July.

**BRODIAEA GRANDIFLORA.**—Three or four bulbs in patches round a *Rhododendron*-bed look very pretty, as it thrives only in peat. In colour a dark purple. From North America.

**GLADIOLUS CUSPIDATUS** is a singular-formed, bright, varied-coloured species, worthy of any trouble that bulbs in general require. It has the merit of being an early flowerer. I have seen it in flower the last week in May.

In conclusion, permit me to make a short dissertation upon the beautiful **GUERNSEY LILY**. From past queries by correspondents of this Journal, I find that the primitive cause as to why this Lily will not flower better when grown here is in practice entirely overlooked, although in theory every one is perfectly conversant with the cause—our summers being too cold and too short. We generally grow or rather flower them in pots; but when once flowered we never repot and give them reasonable opportunities to form fresh flowers in fresh-grown bulbs. We might as well expect the *Hyacinth* after one year's forcing to stand twelve months in the same pot and then flower equally well again. This, as every practical gardener knows, cannot be done. But let us see what can be done with those bulbs when flowered in preference to throwing them away.

Select the warmest spot in the garden—the little border attached to the stove or greenhouse. Dig the soil out 2 feet deep; fill it again with two parts gravelly river sand, one part decayed leaves, and one part good fibrous loam. When the plants have flowered turn them out in this annually. When your Melons and Cucumbers are pulled up in the autumn lean the lights over the plants against the front wall, so protecting the leaves until they begin to decay.—*W. EARLEY, Digsweil.*

## NEAT, INEXPENSIVE, AND SECURE COLD PITS.

THE season is now coming round when cold pits constitute a source of the greatest interest to the majority of your readers, and as I have found the kind I am about to describe all that could be wished, I trust the suggestion may prove of practical use to those who, like myself, are compelled to trust to such appliances for the protection of their plants.

The fact that a double-cased pit is much more secure than a single one is well established, and when the space is filled with such a nonconducting medium as sawdust, I believe the utmost degree of safety possible to obtain is secured. The object I have had in view, then, has been the construction of such frames in the cheapest, and at the same time neatest manner. Boarding is objectionable, as, unless planed and painted, it is always slovenly in appearance, gathers filth and damp rapidly, and, if even done in a rough way, is more expensive than my plan.

To construct then—say a two-light box, first procure the sashes and about 100 feet of battening  $1\frac{1}{2}$  inch thick by 4 inches wide, some four-inch stuff for posts, and half a hundred strong, large slates; the whole, irrespective of the sashes, which may, of course, be new or old, costing about £1.

Having selected the site, excavate to the depth of 18 inches, fill in with stones, brickbats, or other rough drainage, to within 4 inches or 5 inches of the top, level off with coal ashes, and drive your posts, six in number, one for each corner, and two in the centre, after having charred their ends. Drive or cut them to 2 feet high at the back, and 15 inches in front, double rail all round with the battening, leaving the top and bottom rails the

thickness of the sash lower than the side ones, and also cutting the edges to the required bevel. Put in a centre rail flush with the two end ones, and make rebates by nailing on firmly strips an inch thick; repeat the railing close to the ground, and the framework is ready for slating. This may be done by simply placing the slates edge to edge, or by lapping them. A far better plan, however, though it involves an extra half day's work, is, previous to putting the frame together, to have notched out at the width of each slate spaces 2 inches wide and half an inch deep. These having upright pieces nailed into them previous to slating form an admirable break joint, and add materially to the strength of the entire structure.

The slating has now to be accomplished, and though a very simple operation to those who understand it, is a most difficult one to those who do not. The slate having been placed in position, the nail-holes are made where required, by sharply striking the beak of a slater's hammer, or failing that, a blunt-pointed punch through the slate, if the stroke be too gentle the slate will probably be split, and if too hard the resulting hole will be larger than required. A very little practice will, however, render one expert enough for all purposes. The slates of one end being all nailed in place, it becomes requisite to cut them to the bevel, and this is best accomplished with an old saw, but may be done with a slater's knife or a billhook, cutting from the outside and making the edge of the wood act as if it were the part of one blade of a pair of shears.

We will now suppose the whole slated in, and the intermediate space filled with sawdust, all that remains to be done is to board over the space at top and bottom, where the sashes slide, whilst the same spaces at the sides may be slated, and the work is completed. Such a frame as this I do not believe the hardest frost ever experienced in this country could possibly penetrate, and the only fear is of its getting in from below or above. The first might be guarded against by sinking the walls a foot or more, and the second must just be managed as other cold frames are. On this subject, however, a few hints may not be thrown away.

In guarding frames from frost, wetness is the great thing to be avoided. A wet mat is almost worse than no protection. It is, therefore, of great benefit to have an old tarpauling or other waterproof covering to throw over the mats, carpets, or whatever is employed. In the case of frosts of long duration, a layer of sawdust 3 inches thick, and the said covering over it, constitute the most secure protection possible.—*M. G. CUNNINGHAM.*

## TANK-HEATING A SMALL GREENHOUSE.

WILL you be kind enough to inform me if I have a trough 8 feet long, 1 foot wide, and 6 inches deep, would it heat a greenhouse 9 feet long, and 8 feet wide, 5 feet high in front, and 8 feet at back? Also, if three three-quarter-inch pipes will do instead of a boiler, and how low should the fireplace be? The trough to be made of wood with a slate top. Would it do to give the wood a coat of tar or paint before the top goes on?—*T. P. S.*

[Your trough will answer well enough if you get heat enough in it. It had better have no tarring inside or out. If you wish it to last, unless the wood is very old and well seasoned, we would not even paint it. We cannot say so much of your three three-quarter-inch pipes as a boiler, as you do not say how many feet you mean to use, or if you mean merely to bend them, or make a coil of them over or in the fireplace. The latter would be best and most expensive. Then the trough should be divided, except an open space at the farther end, and the upper bend of the coil should join one side of the trough as the flow; and the lower side, the other side of the trough as the return. The coil and furnace should be 3 feet at least below the trough. Unless for some particular object, if you must have a fireplace, we think a small flue would be cheaper and better, and it might be so sunk that the top would be on the level of the floor if desirable. But, for such a small house, a small iron stove with flat top for a water-pan would be the simplest and cheapest, with a smoke-funnel right through the roof or at back.]

**LAW'S PATENT BIJOU DRAINER.**—This simple but most effective cover for the holes of flower-pots is deserving of general use. It is most effective, which cannot be said of crocks, is made of zinc so that it is durable, takes up a very small space, checks

the entry of worms, is always ready for use, and is very cheap. It is made of three sizes, three-quarters of an inch diameter, 1 inch, and 1½ inch.

## NOTES WHILST RESTING.

(Continued from page 473.)

ALTHOUGH in Guernsey the average lowest temperature even of January, is more than 3° above the freezing-point, yet it must not thence be concluded that its winters pass away without the occurrence of frost. Although the majority of its winter and early spring nights have a temperature so high above freezing as to far more than balance the temperatures of those nights when the thermometer sinks below 32°, and, consequently, to raise the average as I have stated, still frosts do occur, and so late in the spring as to be fatal to the blossom of the wall fruit trees. Indeed, so prevalent are these frosts, that a crop from such trees is nearly as uncertain as in England, unless they are efficiently protected.

It is usual, in England, to attribute the sudden dying of the branches of the Moorpark Apricot to the extreme cold and sudden vicissitudes of our winters and springs; but this cannot be the cause, for I noticed in Guernsey that this Apricot suffered there from a similar sudden decay of its limbs. There are no intense colds or violent vicissitudes of temperature there sufficient to destroy a tree's main branch, though the frosts of spring are of sufficient intensity to disorganise its blossom.

I have said that spade husbandry prevails in the island, but it does not do so to the exclusion of the plough; and for what may be termed the crop of Guernsey, the Parsnip, the ploughing has to be very deep. "It is called," says a writer thoroughly conversant with the island, "*la grande charrue* (the great ploughing). The earth has to be turned up to a considerable depth, and this is effected by means of a large plough drawn by four or six oxen, and, sometimes, twice as many horses. So large an array of cattle is not to be found on one farm, and the work is performed, therefore, by a contribution of the neighbours, who are repaid by the like joint-stock assistance, the whole being attended by a sort of holiday bustle, which cannot fail to surprise a stranger. It is, in fact, a holiday, for, besides being regaled with cakes and cider during the work, those who have given their assistance are entertained with a substantial supper in the evening by the proprietor of the field."

In this ploughing a small plough goes first, opening the furrow to the depth of about 4 inches, and this is followed by the larger plough, or *grande charrue*, which increases the depth to nearly four times that depth.

There is a variety of the Brassica in almost every cottage garden, which may be called the Tree Cabbage, for its stem is usually about 5 feet high, many are still taller, and one I saw measured nearly 9 feet. These stems are dried, cut to an appropriate length, painted to imitate cane, varnished, and sold under the name of "Jersey Cabbage sticks."

I must not omit my few notes on the Chaumontel Pear. As in England, so here, the fruit produced on standard trees is small, and so dark bronzy-coloured as to seem a variety altogether different from that which is grown against a wall. The aspect is not a matter of indifference, for Mr. De Jersey told me that he found the finest specimens were produced on a wall facing the east. A western aspect produced the next superior, but a southern aspect is altogether too hot for this Pear.

I confess to not considering it *novum* among our best Pears. If eaten when in perfection its flesh is sugary and melting, but is deficient in that perfumed flavour possessed by such more modern Pears as Williams' Bon Chrétien, and if eaten even just before perfection it is insipid and hard, and if just past perfection it is bitter. I presume that this my opinion is heterodox, and is evidence of a depraved palate, for specimens of this fruit to the extent of 8000 or 10,000, and each weighing from 9 ounces to 18 ounces, are still exported from Guernsey annually, realising, according to the size, from £3 to £6 per 100. Between two and three hundred bushels of smaller-sized fruits are also exported every year, but fetch a much lower price; and I may observe that all good authorities in the island agree that Pears weighing from 12 ounces to 15 ounces are usually superior in flavour to those which are heavier.

Fig trees are abundant in the island, and always growing as standards. Indeed, there are many orchards of them. They are chiefly of the purple variety, but the green-fruited is also fre-

quently met with. The fruit is most abundant in September, and may then be bought in the fruit-market at 3*d.* per dozen. I saw many very large Fig trees, but none equalled one that grew at Mon Plaisier, as late as about the year 1825, when it died. Its trunk was more than 7 feet round, and its height about 20 feet, the branches covering a circle more than 40 feet across. The lesser branches made 187 small faggots, and the trunk, main branches, and roots, filled two Guernsey carts.

I am quite certain that the Fig might be extensively and profitably cultivated as a standard orchard tree in some parts of the Isle of Wight, and other parts of our southern coast. My conviction is founded upon seeing such an orchard some few years ago between Arundel and Worthing. I omitted to make any relative notes at the time, but I will extract some from Mr. Phillips' "Companion to the Orchard."

"There is an orchard of Fig trees at Tarring, near Worthing, in Sussex, where the fruit grows on standard trees, and ripens as well as in any part of Spain; these trees are so regularly productive, as to form the principal support of a large family. Although the orchard does not exceed three-quarters of an acre, there are upwards of one hundred trees, that are about the size of large Apple trees, the branches extending near 20 feet each way from the trunk. Mr. Loud, the proprietor of this little figgery, informs us, that he gathers about one hundred dozen per day during the season, and that he averages the trees to produce him about twenty dozen each. The fruit ripens in August, September, and October, a part of the year when the neighbouring watering-places are frequented with fashionable company, that insures a ready sale for this agreeable fruit, at good prices. Figs were so abundant at Tarring one year, that the inhabitants made wine of them.

"The second crop, we find, has occasionally ripened; the fruit, which, although smaller, is exceedingly sweet, is of the white and purple varieties. Two of these trees are now about seventy-five years old, having been planted in the year 1745 by John Long, who raised them from some old ones in an adjoining garden, near the ruins of the palace of Thomas-à-Becket in that town, who, tradition says, brought these trees from Italy, and planted them himself. The soil of the garden is a deep black loam on chalk.

"The trees are but seldom and sparingly pruned, which we conclude is the cause of their being so prolific, as it is remarked that Fig trees rarely produce much fruit where the knife is regularly used. When they grow too luxuriantly, it has been found better to destroy a part of their roots, and to fill up the space with stones or broken bricks, than to prune the branches too much."—QUIS.

(To be continued.)

## THE USE OF AMMONIACAL GAS IN A HOTHOUSE.

KNOWING that the effluvia of ammonia act healthfully on growing plants, I recently instituted experiments on this substance, by putting half a pound of carbonate of ammonia (common smelling salts) into a wide-mouthed glass jar, and placing the vessel in a small Orchid-house. For some days I had satisfied myself with removing the cork, and allowing the effluvia to escape for an hour or so at a time in the early morning or late in the evening, without any perceptible results, except the strong odour.

But one day I opened the bottle about noon, and allowed the escape of the vapour all the afternoon, while the full sun was on the house, shining, too, directly upon the bottle. The house was shut, and the enclosed atmosphere was at the point of saturation with moisture from the flooded floors. The thermometer under the table, therefore in the shade, rose to 86°.

On opening the door about four o'clock, I found the odour very strong, exactly like that of a newly-turned dunghill, and some of the plants showing damage. The worst case was that of a *Musa coccinea*, which stood so that the leaves stretched over the bottle; of this all the lower leaves, the edges of the foot-stalks, and the leaves and points of suckers in various stages, had turned of a deep brown hue, and were withered.

A wall on the opposite side of the house on which the sun's direct beams fell, had been faced with moss, in which many plants were growing. Of these, a *Tradescantia* (sp.?), widely spreading, showed the evil in a few of its leaves, blackened and curled at the edge. Three young plants of a fine variegated

*Begonia* (*B. Marshalli*) had the outer leaves somewhat injured, but the younger leaves quite killed. *Nephrودیум molle* had one frond partly blackened. Out of about 120 species of Ferns and *Lycopods* growing in the house, this was the only one that suffered.

Of about fifty *Orchids*, none were in the least degree damaged, except a *Calanthe veratrifolia*, of which some leaves were blackened on the edge slightly, and a leaf unfolding had its tip much injured. This plant was standing close to the ammonia-bottle.

In the immediate vicinity there stood, besides, *Caladium argyrites*, *C. tricolor*, *Linum trigynum*, *Gardenia florida*, *Dendrobium nobile*, and *Clitoria ternates* and *Cissua discolor* on wires above. All these, as well as a large number of other plants, including some aquatics, as *Pistia*, *Pontederia*, *Limncharis*, and the delicate little *Marsilea quadrifolia*, enjoyed a perfect immunity.

The plants are, universally (except the scorched specimens), looking very healthy, though I cannot certainly say I have seen any decided deepening of the green hue from the ammonia.

The damage I have recorded above will not prevent my continuing to use it, but it will suggest caution in the mode of application. I attribute the injury to the full sun producing a too rapid and too copious evaporation of the ammonia.

As I think the records of one's failures are often not less instructive than those of one's successes, I submit the above results to the numerous amateur horticulturists, who, like myself, are readers and admirers of your Journal.—P. H. GOSSE, *Sandhurst, Torquay*.

#### PUTTERIDGE GARDENS.

It is always a source of pleasure to notice with approbation any attempt to add to the enjoyments of our business-wearied population. It is so, even when something of the spirit of business enters into the arrangements, and the substantial benefits conferred are accompanied by a certain amount of the darksome shadow incident to most of our earthly joys; much more so is it the case when the gratification bestowed is the effect of pure benevolence, and followed by none of the regrets resulting from indulgence in amusements of a questionable character. Of this better kind is the privilege of visiting the very beautiful gardens at Putteridge, freely extended to all classes in this town and neighbourhood thrice every year, by the gallant proprietor of Putteridge Bury, to whom we desire, at the close of another round of public admissions, to tender our grateful acknowledgments. To those residing in the immediate neighbourhood any description of this lovely spot is quite unnecessary, as there are but few who, by repeated visits, have not become better acquainted with it than they could be made by the best efforts of either pen or pencil. We have, however, reason to believe that our little publication finds its way to many who, owing to distance and other circumstances, can know it only by report. For their sakes we attempt to record what we saw during a recent visit.

The mansion of Putteridge, about four miles north of Luton, is situated on the top of one of the ridges of hills which form so conspicuous a feature in the scenery of this part of the country, and which belong to the range known as the East Anglian Heights. From this commanding elevation views are obtained of Lilley Wood on the north, and portions of the beautiful village beneath, changed from a scene of wretchedness into one of loveliness and comfort—the gilded vane of the church showing above the trees, indicating at once the direction of the wind, and the existence of one of the “bulwarks of our land.” On the north-east is the miniature plateau of Lilley Hoo, whose grassy face, interspersed with Thorns and Hollies, has formed the recreation ground of picnic parties, for aught we know, from time immemorial. On the east side of the mansion there are fine peeps through the trees of the diversified ground, terminating in the heights of Osley; and from the same spot, and other parts of the grounds, rich views to the south-east, terminating in the romantic, Ivy-covered church of Kingswalden, nestling among the trees, as if seeking a peaceful shelter from the rude alarms of the world beyond. On the south the farm-house and village of Mangrove attract the eye. On every side the district gives token of excellent farming, bountiful crops standing upon the arable portions; while here and there on grassy slopes cattle and sheep find ample pasturage, and graze in quiet content. The mansion itself is one of those snug, comfortable residences in

which the utility of a dwelling has not been sacrificed (as is too often the case) to the architectural beauties of the structure. Neat in its outline, it is kept still more so outwardly by frequent painting; it being one of those cemented houses requiring this to be done. The interior, we believe, is also kept with scrupulous care. The buildings attached are painted either white, or of a very light stone colour. The offices are on the west side of the house, and beyond them the kitchen garden and the various other appurtenances extend to a considerable distance—the latter consisting of turf pits, &c., not very beautiful, indeed, but forming a necessary portion of the floriculturist's laboratory. On the south side of the wall separating the offices from the pleasure ground, there is a roofed-in verandah of some length, uniting with a conservatory well filled with the flowering plants of the season. This verandah forms a nice dry promenade in wet weather, and a pleasant shade when the heat makes such a retreat desirable.

The terrace, extending on the east side and on the north and south ends, is bounded by a ribbon-border some 600 feet in length, and planted this season in straight rows, beginning next the grass on the terrace with *Lobelia speciosa*, followed by *Scarlet Geranium Tom Thumb*, yellow *Calceolaria*, *Ageratum mexicanum nanum*, the highest row at the back being *Love-lies-bleeding*, which, though beautiful, we understood did not quite please the planter; as he wished it not only to show above the *Ageratum*, which it does, but to droop with its bell-rope-like racemes of flowers over the banks on the east side of the terrace, the ground on that side being from 3 feet to 6 feet lower than the terrace. Owing, however, to the coldness of the season, this fine old cottage-garden plant has not grown so strong as usual; had it done so, we can scarcely conceive a finer effect than would have been produced by this magnificent border, not only on the terrace side, which is exceedingly beautiful, but also when surveyed from the walk below.

Before entering on the terrace, however, we should have stated that, at the north, or principal entrance to the mansion, there is a large square of gravel, smooth, and without a weed, and that the north end of the terrace abuts immediately on this gravel. We observed here a fine new feature—namely, a row of vases, at regular distances on the turf, filled with *Geraniums*, &c., and connected together by festoons of climbers, so as to form a break between the gravel and the terrace, and so far to serve as a substitute for a low, ornamental wall, which we understood Mr. Fish had long desired. [Would not a similar wall carried round this terrace, and, perhaps, round the south and west sides of the Italian garden, be an improvement?] We cannot help thinking that Mr. Fish has to produce great results from somewhat limited means; in fact, some of the principal lessons to be learned at Putteridge, by a careful observer, are how to make the most of simple materials—never to feel discontented or downcast because you cannot get exactly what you want, and never to scorn the commonest flower—nay, to like it all the better, if beautiful as well as common, because everybody that can lay out a penny for seed may have it. It requires neither powerful spectacles nor much thought to be convinced that Mr. Fish has made the rare discovery that true taste is as economical in its methods as it is beautiful in its results.

Having now got on the terrace and noticed the ribbon-border as above, and seen an extra number of vases by the sides of the walks, we notice, between the walk and the house, thirty small square beds, fifteen in front of the dining-room and fifteen in front of the drawing-room windows, forming two groups separated by a breadth of flagstone, in front of the east entrance by a glass corridor. These beds are themselves separated from each other by narrow stone panels, serving both as a division and a walk. Every time we have seen them these beds have been differently arranged. This season they are filled chiefly with dwarf plants on the crossing system, so that all can be easily seen from the windows. We will endeavour to give an idea of this system of planting, as we thought the effect produced uncommonly beautiful. Form a square of 5 feet or 6 feet; draw two diagonal lines cutting each other in the centre; make the spaces occupied by these lines a foot in width; plant these with one colour, and the four small angles or triangles with another colour. As examples—one bed had the crossed lines filled with yellow *Calceolarias*, and the angles filled with *Purple King Verbena*; another crossed with *Scarlet Globe Geranium*, and the angles filled with white *Ivy-leaved Geranium*; a third crossed with the soft, white, variegated-leaved, scarlet-flowered *Perfection Geranium*, and the angles with the rich pink *Christine*

Geranium; a fourth crossed with the orange *Gazania splendens*, and the angles filled with blue *Lobelia speciosa*. This will serve to show the ways in which these four beds are arranged. With a due regard to the mixing of colours, many very nice effects may be produced. Whether this arrangement is the best we can hardly say. We must confess that our own notions incline to the pyramidal form in which we remember to have seen them planted. On making inquiry, Mr. Fish informed us that that method had been abandoned from its having to some extent intercepted the view from the windows. Most likely another year will present us with a combination not only quite different, but more beautiful than any preceding one. Although these level beds occupy only a small area, they contain flowers sufficient to stock a tolerably large garden.

The ground on the east side of the terrace, which slopes to the level of the park, has a walk through it, and is chiefly planted with varieties of Thorns and a few *apecimen* Laurels. About the middle used to be two groups of Roses divided from each other by a walk and steps leading to the terrace. These suffered so much in the winter of 1860 and 1861 (so disastrous to Roses throughout the country) from the severe frost, that all have been removed, and two groups formed of bedding plants, the one an exact counterpart of the other, and planted on the level. Each group consists of nine beds in the form of a square. The centre bed is a scalloped square, itself centred with white *Hendersoni* Geranium, bounded by red *Compactum* ditto, and a broad edging of *Gnaphalium lanatum*. The four rounded triangular beds consist of two of *Prince of Orange* and two of yellow *Calceolaria*, edged with blue and white *Lobelias*. The four outside beds have patches of lilac *Verbena* in the centre, bounded by low *Scarlet Geraniums*, a border round them of dotted purple *Verbenas*, and an edging all round of white variegated *Alyssum*. These groups have been pronounced by many to be the most beautiful in the garden; and certainly, remembering the old rosery, we were particularly struck with the improved appearance of this part of the grounds.

Turning now to the south side of the mansion, we missed what used to be a very unique style of ornamental gardening. The front of the house is ornamented with a lofty, elegant, glass-covered conservatory, joining to a verandah covered with zinc, which, along with another large conservatory placed in its centre, extends some 300 feet, communicating with the offices and kitchen garden. Part of this verandah next the mansion had also a glass front, and here, and in the loftier building, used to be rows of large plants in vases, with drooping plants hanging over their sides. These, besides their artistic beauty, formed a noble background to the Italian garden in front. We understand that the moisture and the scent were rather too much for these living in the adjacent rooms, so that those places are now nearly empty, and hence is accounted for the increased number of vases by the sides of the walks of which so much notice was taken by the visitors during our recent visit.

South of these corridors, surrounded with a terrace of grass and gravel, is a sunk Italian garden nearly 3 feet below the level of the terrace previously described. The sides of this garden consist of four sloping banks of closely-shaven turf, affording a delightfully quiet contrast to the dazzling brilliancy of the flowers. Broad gravel walks surround all four sides of this garden, with ample grass margins, which are reached by steps at the centre of its sides. The beds, eighty in number, are in circles and squares, divided from each other by grass paths radiating from a fountain in the centre. These beds are filled with contrasting colours of scarlet, white, yellow, purple, orange, and blue, of various shades, and so similar in height that from every point the eye takes in the whole. Perhaps the most conspicuous this season, and showing how advantageously the simplest flowers may be placed in the most important situations, are fine beds of white *Feverfew* and yellow *Calceolarias*. Last year these beds were all bordered; but this season the separate beds are chiefly of a single colour, and every bed full.

Opposite this, and along the sides of a walk, are a series of raised circular beds, about 16 inches above the grass level, with a large hoop over each so as to resemble baskets, the hoops being covered with beautiful creeping plants. Last year each of these beds was filled with three rings of contrasted colour rising from the edge to the centre, the raised edging hidden by masses of pretty small *Nasturtiums* and *Convolvulus minor*. This season two semicircles are drawn from the outside, so as to meet in the centre of the bed. These circular lines are chiefly planted with *Geraniums*, and the two opposite spaces in each bed with

contrasted colours of *Verbenas*. We observed two beds crossed with *Perilla*, two spaces filled with a soft yellow *Calceolaria*, and the other two filled with a scarlet *Nosegay Geranium*, which looked very pretty. Backing these, and at their termination, are four large beds filled with pyramidal *Roses* and *Hollyhocks*, edged with *Dahlias*, *Gladiolus*, &c., and next the grass we could not help noticing that two beds had rings of white *Alyssum* and *Virginian Stock*, which anybody can grow; and that other two had massive edgings of *Fumaria lutea*, which is almost naturalised in many woods and dells, showing that the commonest things are not to be despised.

Among other raised beds are a pair, in front of the verandah and west of the Italian garden, which are very striking. These are circles, some 16 feet in diameter, raised 2 feet above the grass, and covered with *Ivy*. These are crossed much the same way as the baskets! the cross lines planted with *Excellence*, a strong-growing, scarlet, dark horsehoe-leaved *Geranium*, *Perilla nankinensis*, a purple-leaved plant, is planted on each side of these two lines, so as just to be lower than the *Geraniums*. The two opposite larger spaces are filled with variegated *Alma Geranium*; the two smaller with yellow *Calceolaria*; a wreath all round outside consists of *Tom Thumb* scarlet *Nasturtium*, some of which are allowed to hang over and drape the *Ivy*.— (*Luton News*.) (To be continued.)

## REPORT ON THE CABBAGES

GROWN IN THE GARDEN AT CHISWICK DURING THE SUMMER OF 1862. By ROBERT HOGG, LL.D., F.L.S.

OF the sixty-one varieties of Cabbages examined, the following were the only distinct sorts:—*Fulham* or *Early Battersea*, *Atkins' Matchless*, *Sugar Loaf*, *Early Plaw*, and *Early York*.

FULHAM . . . . . F. DANCER, J. JESSOP, C. BAGLEY.

As the type of the *Fulham* or *Battersea* Cabbage, that was selected which is grown by those experienced cultivators Mr. Joseph Jessop, of Chiswick; Mr. Francis Dancer, of Little Sutton, Turnham Green; and Mr. Charles Bagley, of Fulham. The care which these gentlemen bestow upon the selection of their stock, and the skill with which they conduct their gardening operations, are a sufficient guarantee for the excellency of the selection the Committee made by which to compare all the other varieties. There is so distinct a character in the true *Fulham* Cabbage from every other, that it is impossible to mistake it. The leaves are large, round, and broad, of a dark bluish-green, and with a thick succulent midrib. The head is large, round, or roundish-ovate, and very solid. In the purest forms the lower leaves spread out in the form of a sort of ruffle round the head, which stands boldly out, while the leaves occupy the position of the "guard petals" in the flowers of the *Hollyhock*. The plant is set so closely on the ground that there is no space between the latter and the leaves, and the bases of the leaves themselves are so close together that it is impossible to get even a finger between them. Such, then, being the type adopted, all the following were either more or less pure stocks of that form:—

BLENHHEIM . . . . . SUTTON & SONS.

The same as *Fulham* or *Battersea*.

ATKINS' MATCHLESS . . . . . MINIER, NASH, & NASH.

This is a distinct sort, and is a small form of the *Fulham* or *Battersea*, producing a conical head, and with dark green foliage.

BARNES' EARLY DWARF . . . . . CARTER & Co.

The same as *Nonpareil*.

CARTER'S EARLY } . . . . . CARTER & Co.

*Carter's Matchless* }  
These are both the same as *Fulham* or *Battersea*.

CATTELL'S RELIANCE . . . . . HURST & McMULLEN.

A very fine stock of the true *Fulham* or *Battersea*.

COX'S EARLY LONDON . . . . . HURST & McMULLEN.

The same as *Fulham* or *Battersea*.

EARLY CHAMPION . . . . . MINIER, NASH, & NASH.

A fine stock of true *Fulham* or *Battersea*.

EARLY COOMBE . . . . . SUTTON & SONS.

The same as *Early Plaw*.

EARLY EMPEROR . . . . . MINIER, NASH, & NASH.

The same as *Fulham* or *Battersea*.

EARLY NONSUCH . . . . . HURST & McMULLEN.

A remarkably fine stock of the true *Fulham* or *Battersea*, one of the best in the collection.

EARLY PARADISE . . . . .	HURST & McMULLEN.
The same as Fulham or Battersea.	
EARLY PARAGON . . . . .	HURST & McMULLEN.
The same as Fulham or Battersea.	
EARLY LANCASHIRE . . . . .	FLANAGAN & SON.
The same as Fulham or Battersea.	
EAST HAM . . . . .	TURNER.
The same as Fulham or Battersea.	
ENFIELD MARKET . . . . .	MINIER, NASH, & NASH.
This very closely resembles the Fulham, but it grows with rather more leaf, and does not come in so soon.	
HEALE'S IMPERIAL . . . . .	HURST & McMULLEN.
The same as Fulham or Battersea.	
JACON'S EARLY . . . . .	MINIER, NASH, & NASH.
This is a very fine stock of the Fulham or Battersea.	
KING OF THE CABBAGES . . . . .	TURNER.
A good stock of true Fulham or Battersea.	
LITTLE PIXIE . . . . .	NUTTING & SONS.
This bears a very close resemblance to the Dwarf York, and in the opinion of the Committee does not differ materially from a good stock of that variety.	
MATCHLESS DWARF . . . . .	NUTTING & SONS.
The same as Atkins' Matchless.	
MAY'S PARAGON . . . . .	TURNER.
The same as Fulham or Battersea.	
MITCHELL'S PRINCE ALBERT . . . . .	TURNER.
A very fine stock of the Fulham or Battersea.	
MYATT'S ECLIPSE . . . . .	HURST & McMULLEN.
A true stock of the Fulham or Battersea.	
NONPAREIL . . . . .	NUTTING & SONS.
This has evidently been obtained originally from the Fulham or Battersea. It is much smaller in all its parts, and comes in rather earlier, but the general resemblance is very much the same.	
NONPAREIL IMPROVED . . . . .	MINIER, NASH, & NASH.
This is a very beautiful stock of the true Nonpareil.	
PARAGON . . . . .	CARTER & CO.
The same as Fulham or Battersea.	
PEARSON'S EARLY CONQUEROR . . . . .	HURST & McMULLEN.
A very fine stock of the true Fulham or Battersea.	
PRINCE OF WALES . . . . .	HENDERSON.
The same as Fulham or Battersea.	
PRINCE'S NONPAREIL . . . . .	HURST & McMULLEN.
The same as Nonpareil.	
SEALEY'S VICTORIA . . . . .	HURST & McMULLEN.
The same as Fulham or Battersea.	
SHEPPARD'S MARROW . . . . .	HURST & McMULLEN.
A mixed sort, but the best of them are the Fulham or Battersea.	
SHILLING'S QUREN . . . . .	MINIER, NASH, & NASH.
The same as Fulham or Battersea.	
SUPERFINE EARLY DWARF . . . . .	NUTTING & SONS.
A true stock of the Fulham or Battersea.	
SUTTON'S IMPERIAL . . . . .	SUTTON & SONS.
The same as Fulham or Battersea.	
TILEY'S EARLY MARROW . . . . .	MINIER, NASH, & NASH.
This is the same as Atkins' Matchless.	
WHEELER'S IMPERIAL . . . . .	CHARLWOOD & CUMMINS.
The same as Fulham or Battersea.	
WELLINGTON . . . . .	MINIER, NASH, & NASH.
A very pure stock of Fulham or Battersea. The best in the collection.	
WEST HAM . . . . .	TURNER.
The same as Fulham or Battersea.	

### BOUQUETS.

EVERY bouquet is a bunch of flowers, but every bunch of flowers is not a bouquet. Without taste in the selection and arrangement, a bunch of flowers is a bunch of flowers and no bouquet. There are few persons who are really competent to make a perfect bouquet, by which I mean one in which the flowers are well selected, properly arranged, and the effect of the whole the best as regards the harmony of colours, and the perfect exhibition of

each flower. How difficult it is to arrange flowers in a bouquet in such a manner as to satisfy a person of cultivated tastes, many who have tried it know; they are aware that it is a hard matter to avoid getting too many red flowers here, and too many yellow ones there, too many green sprigs or too few, to avoid an undue prominence of one flower, and a too retiring disposition of another, to escape the destruction of the delicate hue of a favourite flower by contact with another of a higher colour, to avoid the loss of the delicious fragrance of the Heliotrope by too close connection with a sprig of Lantana.

There are many flowers which are handsome in the garden but not fit for the bouquet. Many are too large for use except in very large ones for special occasions, the decoration of a supper-table for instance. Some are offensive to the sense of smelling, others to the sense of touch. Some are only open in the broad sunlight, and close in the darkened room.

A better effect is produced by using flowers of decided and high colours than by the use of those delicate and subdued tints. White, crimson, scarlet, deep blue, dark maroon, &c., are the colours which appear to the most advantage.

Double flowers are preferable, as single ones if of large size will have their beauty destroyed by the crumpling of the petals. Small single flowers, however, are unobjectionable on this account, and may be freely used. Regard should be had also to the character of the flowers as regards duration in bloom. Some flowers fade almost as soon as they expand; others lose their petals very soon, and by their fall leave an opening in the bouquet. Too many fragrant flowers can hardly be used. Few persons are satisfied with enjoying the beauty of a bouquet; they must also inhale its fragrance. Heliotrope, Mignonette, Sweet Peas, and fragrant Pinks are not only invaluable for their perfume, but are also beautiful in appearance.

Flowers growing in spikes are not in general well adapted for bouquets, but they may be used in the centre of pyramidal ones. Those with very short stems or no stems at all, as Hollyhocks and Balsams, can hardly be used for bouquets, but may be used by themselves in very flat dishes with a few green leaves between and around them, and thus make very handsome ornaments for a table or stand.

Small bouquets are better than large ones; they are more easily arranged, and individual flowers show to more advantage in them. For the mantel or brackets where they will be level with the eye, they should be arranged in pyramidal form, the flowers with the longest stems and, as far as possible, the larger ones in the centre, and the very small ones on the outside. For tables or stands, take a large, round, rather flat dish, and put a lemonade glass or small tumbler or cup in the centre. Make up your flowers into small, loose bouquets, put one in the centre vessel, and the others around it in the large dish. This is a better way of managing than by putting the flowers in separately, as the water can be changed without any trouble, whereas if the flowers are loose they must be re-arranged every time they are disturbed.

One of the most difficult points in the formation of bouquets is the proper contrast of colours, and it is a pretty difficult matter to lay down rules to regulate this. By a little practice almost any person of good taste will soon learn what arrangement of colours will be the best. You can hardly spoil a bouquet by too many white flowers; and although too many crimson or scarlet flowers make a bouquet too gay for many persons of refined taste, yet they can be used very plentifully, and will make very showy bouquets at all events. A few blue flowers only should be used, and yellow flowers, if used at all, should be introduced very sparingly and ought to be of small size. Rose-buds and partially-opened Roses should be used and not those fully expanded, as they soon decay and the petals fall.

Green leaves and sprigs form an important part of the bouquet. The leaves of the sweet-scented Geraniums are excellent for this purpose. Some of the Ferns and Lycopodiums are good. Many shrubs and perennial plants furnish fresh shoots and leaves, which prove useful. Mignonette may be used profusely for greens.

It is frequently recommended to put salt or charcoal in the water in which the bouquets are to be placed, but I have never discovered any benefit from this practice. Use soft water and change it every day, which will not be much trouble. Some people use wet sand instead of water; this is not as convenient as water, for if the sand becomes dry, the flowers must all be removed before the sand can be wetted, for if sprinkled while the flowers are in the sand, the beauty of many of them will be spoiled.—(Albany Country Gentleman.)

## ARCHITECTURAL FEATURES—THEIR PROPER POSITIONS—TRUE GARDENESQUE STYLE.

BY H. NOEL HUMPHREYS, ESQ.

TOWARDS the close of the last century, an exaggerated taste for the simply natural, or what has been termed the picturesque, banished from English gardens many of their best and most appropriate features—among others, that simple and yet noble adjunct, the terrace. Brown, says Sir Uvedale Price, has been celebrated for the bold idea of taking down Richmond Terrace, and his successor for the still bolder notion of blowing-up the one at Powis Castle; while the fine architectural character of these features was to be replaced by gently undulating turf and serpentine walks, and these winding forms were not merely used to blend the garden into the landscape, but commenced at once, close to the house, where straight lines, in accordance with the form of the building, were so much more appropriate. By this means the landscape features were brought into immediate contact with the residence, making no difference between the arrangement of the ground close to an architectural composition, and that at a distance; "between the habitation of man and that of sheep." The destruction of our fine old terrace-walks by the race of landscape gardeners of the last century, headed by Brown, was partly the result of the extravagant excesses to which architectural gardening had been carried, particularly in France and Holland, where the fine taste of the Italian school had been so

exaggerated as to become caricature—a term which may be fairly applied to the Dutch gardening of the end of the seventeenth century, which was imported into this country with the accession of William the Third. In this Anglo-Dutch school the architectural decorations were over-elaborated, and degenerated into the most wretched taste; trees were cropped into the forms of court ladies; statuary reduced to Dutch shepherds, and these shepherds and shepherdesses painted to imitate Dutch nature; in addition to which were multitudes of pretty terraces connected with endless archways and countless steps. Such abuses of art found, first, satirists to ridicule them, like Horace Walpole, who laughed at the idea of thus "walking up and down stairs in the open air;" and then Kent and Brown, bold innovators, swept them away, leaving nothing in their place—nothing to form, as it were, the setting to the gem—no harmonious concord to accompany the main building, with other tones in the same chord—no framing to set it off—leaving them, in fact, like a picture without a frame, surrounded with nothing but

"Shaven lawns, that far around it creep,  
In one eternal, undulating sleep."

Yet the "natural" style, as it was called, or rather this poor sham of Nature—these artificial slopes, imitative hillocks, and

CASINO SACHETTI AT ROME.

unnaturally winding walks, were yet felt as a relief, after the reign of the over-wrought Dutch and French terrace school, and the fame of these *jardins Anglais* travelled to the Continent, where they were imitated in the grounds of almost every chateau, palace, or villa of importance, but imitated with rather more judgment, for the *jardin Anglais* was almost always placed at a distance from the house, from which its irregular features were concealed by the stately forms of trees cropped into architectural form, or some other arrangement in accordance with the character of the dwelling. Yet this was not always the case; the new English system appears occasionally to have been carried to excess; the Abbé De L'Isle, in his poem "Les Jardins," complains of hills, lakes, and sloping woodlands being crammed into situations totally unfitted for them, either from their position or extent, in the passage beginning with, I think—

"Des lacs et des montagnes sur un arpent de terre."

And I recollect, very recently even, when last in Paris, going to see a furnished house in the *Chaussée d'Antin*, which was adver-

tised, among attractions, to possess its *jardin Anglais*. This interesting feature I found actually existing in a back court of some 60 feet in depth; but the smallness of the space had not caused any of the main features of the *jardin Anglais* to be omitted: there were the undulating lawn and serpentine walks, the belt of Scotch Firs, the winding rivulet with its rocky cascade, and the lake; also the *forêt des Sycamores*, formed by groups of six or seven small and rather miserable specimens of that tree.

In these preliminary remarks, I have endeavoured to show that the school of gardening, in which architectural ornament is overdone, and that in which it is altogether absent, are equally defective; and I shall, therefore, attempt to point out the extent to which architectural features may be used in gardening with advantage. It may easily be conceived that a house of considerable architectural pretension, placed at once in the midst of winding walks or sloping lawns, would appear less complete than when fronted by an esplanade or terrace, however moderate in extent or simple in construction.

Of the old gardens, it has been said that they were formally laid out; but they were laid out to accompany that which was necessarily formal and symmetrical—namely, the main lines of the residence, to which they served as a sort of mounting or frame. The engraving exhibits a rich—perhaps over-rich—example of a villa residence of the high Italian school, surrounded with its legitimate architectural embellishments, its natural framing and accompaniment: it is the Casino of the Sacchetti family at Rome, built from the designs of Pietro Barottini da Cortona, and was once one of the finest specimens of this class of garden and villa architecture in existence, but when Vasi published his engraving it was described as then going to decay. From this imposing composition, it may be inferred that I consider architectural works, on an enormous and costly scale, as necessary to give due effect to a country residence, and blend it properly with the surrounding landscape; but such is not the position I am about to assume. On the contrary, I think that even a simple turfed embankment, surmounted by a low hedge, formed of some hardy evergreen shrub, cropped very square and flat at the top, might, either with or without the addition of a single and simple flight of steps, and a few appropriate pedestals and vases, be sufficient to produce the effect described as suitable, or, at all events, form a very desirable approach to it. In accordance with the more irregular and picturesque forms of cottage architecture, the terrace might be guarded by balustrades of simple rustic work of branches, which would produce a very agreeable and appropriate effect. A principal cause of the agreeable effect of stone or brick terraces is that they harmonise in material, and, consequently, in colour, with the main building, thus carrying out its tone to the landscape; but still another step of modulation is requisite—the perfect blending even of these secondary architectural features with the foreground of the landscape, and this may be judiciously effected by the aid of cropped trees; which, while they agree in colour with the landscape, yet harmonise in forms with the residence and terrace, and so become a link holding harmoniously together with the gardenesque and the picturesque—the artistic and the natural—restricting ourselves in using these phrases to the irregular forms of nature, as the masters of landscape painting have loved to paint them, and not in the extended sense given to the term by Price and others.

The engraving exemplifies this effect, in which the architectural and regular forms of a piece of balustrade and sundial, find a certain degree of analogy in the artificial arches formed by some cropped Limes, while the tone of colour of the latter accords with that of the irregular shrubbery beyond, and thus the blending between art and nature becomes gradual and pleasing.—(*Gardeners' Magazine of Botany*.)

### CUTTING A HEDGE OF AMERICAN ARBOR VITÆ.

WE have a hedge of American Arbor Vitæ about 180 feet long. It has been planted about three years. The plants were rather large when they were put in—the lowest 4 feet and the highest about 8 feet or 9 feet high. It was cut for the first time this spring, and certainly it grew much better in consequence. It was only cut on one side. Ought it to be cut on both sides? and when should it be cut again?—DARRY AND JOAN.

[There is no hedge plant which is more pliable, and less likely to suffer in the least from close pruning, or clipping, or shearing

than the American Arbor Vitæ in deep light loamy, or sandy soil, or on chalk; but is not a very good hedge plant on wet, clayey land. There are hedges of it open to the public behind the new conservatory at Kew, which are from 5 feet to 8 feet or 10 feet high, and not quite 6 inches through at the bottom, and barely an inch thick at the top. We would cut the American Arbor Vitæ on both sides alike, cutting it in by pruning if it needed it, clipping it with the shears if that would do, or switch-cut it with the switching-billhook for making quick work of it, and any of these cuttings we would do any day from the 1st of March to the last of October; but when the hedge was as it should be, one looking-over in April and once again about the end of July would keep it straight and right for a whole year. The Chinese Arbor Vitæ makes a better hedge than the American Arbor Vitæ; but we have seen more than one hedge of it made in one week, and over 12 feet high, and that at one-half of the expense it would cost to make any other evergreen hedge.]

### PORTRAITS OF NEW AND RARE PLANTS.

**AGAVE GLAUDESCENS** (Glaucous Agave).—*Nat. ord.*, Amarillidaceæ. *Linn.*, Hexandria Monogynia. Native of Mexico. Flowers in autumn. Spike of flowers curiously deuced.—(*Botanical Magazine*, t. 5333.)

**PHILADELPHUS HIRUTUS** (Hairy Mock Orange).—*Nat. ord.*, Philadelphiceæ. *Linn.*, Icosandria Monogynia. It has also been called *P. trinervus*. Introduced from Oregon by Messrs. Veitch. The Mock Orange is most popularly known as the "Syringa."—(*Ibid.*, t. 5334.)

**OURISIA COCCINEA** (Scarlet-flowered Ourisia).—*Nat. ord.*, Scrophulariaceæ. *Linn.*, Didynamia Gymnospermia. It has been called also *Dichroma coccinea*. "This truly lovely plant, never yet known in cultivation, and of which no coloured figure (before) has anywhere appeared, was recently imported from the Andes of Chili by those enterprising and eminent nurserymen, Messrs. Veitch & Son (a firm, we believe, of three generations of the family), of Exeter and King's Road, Chelsea." Probably hardy, "but best cultivated in a cold frame."—(*Ibid.*, t. 5335.)

**EPIDENDRUM PRISMATOCARPUM** (Prism-fruited Epidendrum).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. In gardens it is known as *E. Uro-Skinneri*. Native of Chiriqué, Veragua, Central America. Flowers pale yellow, blotched with purple. Blooms in July. Introduced by Mr. Low, Clapton Nursery.—(*Ibid.*, t. 5336.)

**DIMORPHOTHECA BARBERLE** (Mrs. Barber's Dimorphotheca).—*Nat. ord.*, Composite. *Linn.*, Syngenesia Polygamia necessaria. Native of Krellis' Country, Caffraria; a lovely plant with most brilliant purple flowers. Flowers in June.—(*Ibid.*, t. 5337.)

**AZALEA BRILLIANT**.—Raised by Mr. C. Turner, Royal Nursery, Slough. "Finest flower of its class," dark scarlet.—(*Floral Magazine*, pl. 113.)

**TWO-COLOURED BEE LARKSPUR**.—Raised by Messrs. Downie, Laird, & Lsing, of Stanstead Park and Edinburgh. Sepals dark blue, petals creamy white.—(*Ibid.*, pl. 114.)

**GLOXINIA VARIETIES**.—Raised by Mr. W. Bull, Exotic Nursery, King's Road, Chelsea. *Lauretta*, violet lavender; *Beauty*, tube white, limb cerise rose; *Anonyma*, same tint as *Lauretta*, but rather more pinky; and *Fairy*, limb white, throat rose colour.—(*Ibid.*, pl. 115.)

**NEW JAPANESE LILY**.—Species not determined. Sent by Mr. Fortune from Japan, to Mr. Standish, Royal Nursery, Bagehot. Deep bronze red, spotted with black. It has "a double row of petals, the outer row reflexing, the inner row semi-erect."—(*Ibid.*, pl. 116.)

**LILIUM AURATUM**.—"Decidedly pre-eminent among the introductions of 1862, and to Messrs. Veitch & Son belong the honour of having been the first to flower it and introduce it." This gold-banded Lily was brought from Japan by Mr. J. G. Veitch. It grew on hillsides where the thermometer falls to 16°, so that there can be little doubt of its being hardy. It attains a height of 4 feet, has from three to five flowers on the top of its stem, and each flower from 8 inches to 10 inches across! They are white with a broad stripe of golden yellow down the centre of each segment of the corolla, and studded over with reddish-purple, wart-like spots.—(*Florist and Pomologist*, p. 129.)

**LONICERA AUREO-RETICULATA** (Gold-netted-leaved Honey-suckle).—Sent from Japan by Mr. Fortune, to Mr. Standish, Royal Nurseries, Bagehot. "An elegant, slender, climbing shrub. Leaves bright green, with all the veins marked out (like net-

work), with golden yellow." It is a beautiful plant and the Editors may well say, "It is seldom our good-fortune to present two such sterling subjects in one issue," as this Honeysuckle and Mr. Veitch's Lily.—(*Ibid.*, p. 136.)

#### WEST RIDING CONSOLIDATED NATURALISTS' SOCIETY.

THE above Society during last week, held its third quarterly Meeting at Mr. Henry Ashton's, the Queen's Head Inn, Heckmondwike, where upwards of one hundred members of the different local Societies met to discuss the different facts in natural history which had occurred since their last Meeting at Wakefield. There were members from Halifax, Wakefield, Horbury, Huddersfield, Ossett, Cleckheaton, Batley, Dewsbury, Mirfield, and all the surrounding villages. Mr. Samuel J. Swift, of Gomersal, was elected Chairman, and Mr. Fryer, of Heckmondwike, Vice-Chairman. After the preliminary business of the Meeting had been gone through, the Chairman called upon Mr. John Armitage, of Almondbury, to arrange, and Mr. J. Bartlum, of Huddersfield, to name the botanical specimens, which they did in a most efficient manner, showing that, although only working men, they possessed something more valuable than riches in knowledge, gained by diligent study, application, and perseverance, otherwise they could never have gone through such a host of plants giving the local and scientific names to each one. Mr. Armitage exhibited a specimen of *Deilephila Galii*, recently captured in the neighbourhood of Huddersfield, which is the only specimen which has been taken in this locality during the last five years. Mr. Ellis, Secretary to the Society, said that there was one subject which he had been desired to introduce to the Meeting, and this he did with the greatest pleasure, as he knew there were gentlemen there who had a practical knowledge of the subject, and who would, he thought, be able to answer the question whether *Bombyx Callunæ* is a distinct species or only a variety of *Bombyx Quercus*? Some people, he knew, had an idea that the larvæ collected from hedgerows, &c., during the spring months, and which make up and come to perfection during the summer are the larvæ from which come Callunæ, and that those which remain in the cocoon one year are the true Quercus. It so happened that he himself had Quercus which had been collected in the larvæ this summer, and which were now in the store-boxes at home, but he was sorry to say that he had no Callunæ. Mr. Mellor, of Halifax, said, that from what he had seen during his experience, he had no doubt that the Callunæ was a variety of the Quercus, and not a distinct species. The subject was well canvassed over by the Meeting, and it was decided that Mr. Mellor was right in his conclusions. Mr. Swift expressed himself quite satisfied with the result, with which he agreed, and he had no doubt that their Society would from the extensive and varied lands over which it now spread, soon be in a position to answer and settle a great many questions in natural science which were now left open. Mr. Shipstone, of Halifax, spoke on the salutary tendencies the study of nature had upon children and young persons;—how, whilst contemplating the beautiful arrangements and perfection of nature, it was impossible, almost, not to be led to admire the power and wisdom of the Creator. The Chairman read a communication from the Editor of the *Entomologist*, to the Secretary of the Society, and he said he hoped that as the publishing of this weekly paper gave them what they wanted without their having to embark in the printing and publishing business, they would all give it their utmost support both in contributions and subscriptions. A deputation from a Naturalists' Society in Leeds applied to be admitted to join the West Riding Naturalists' Society, which was agreed to. After speeches from several other gentlemen, and passing a resolution that no person should be admitted to their future Meetings without producing his ticket of membership, or by appeal to some of the Presidents of the local Societies present, Mr. Booth, of Huddersfield, moved, and Mr. Ellis seconded, a vote of thanks to the Chairman, which having been duly responded to, the Meeting closed between seven and eight o'clock.

#### WORK FOR THE WEEK.

##### KITCHEN GARDEN.

SUCH ground as is now becoming vacant to be trenched, manure being applied if necessary, and to be ridged or left as

rough as possible, this should always be done whether the ground is wanted immediately or not. *Artichokes, Globe*, cut down the flower-stems of the late plantation as soon as done with, and keep the plants free from decayed leaves. *Cabbage*, continue to plant-out the main crops. Keep the late seed-beds free from weeds. *Capsicums*, the green pods of the large sorts to be gathered if there is any appearance of frost. *Carrots*, slightly thin the autumn sowing, and keep them free from weeds; as soon as the main crop is full grown they should be taken up. *Cauliflowers*, they should be looked over frequently, turning down a few leaves over the hearts, for they are readily spoiled by frost. The young seedlings must not be allowed to stand too thickly in the seed-bed; the thinnings to be planted-out thinly to make good stocky plants. *Celery*, attend to the earthing-up of the crop that is likely to be wanted for use soon, so as to get it well blanched. *Dwarf Kidney Beans*, provision should be made for protecting them from frost lest it should occur shortly. *Onions*, slightly thin the autumn sowing when they are a few inches high. Immediately the main summer crops have done growing pull them up, and house them when dry. *Parsley*, cut down a portion of the spring-sown, so that it may shoot again before winter. Pot some good roots to place in a forcing-house for furnishing a supply during severe weather. Remove or dig-in all decayed leaves, and all litter that affords harbour for slugs. Gravel-walks must come in now and then for a share of attention in weeding and rolling.

##### FLOWER GARDEN.

Cut off the flower-stems of herbaceous plants as soon as they become shabby, and endeavour to prolong the beauty of Phloxes, &c., by keeping them well supplied with water at the root. As cold nights have now set in, scarce plants, or any others which it may be desirable to secure before they are injured by frost, should be taken up and potted at once, or carefully covered where there is the least cause to expect injury. For the formation of a new shrubbery, or the removal of large shrubs, see that the ground is properly prepared by trenching, and draining if the soil be moist or retentive of wet. When a change of weather to rain sets in, evergreen shrubs or trees may be planted. To be successful in the operation four things are necessary—trenching the ground, the preservation and regular distribution of the roots, and shallow planting. The removal of deciduous shrubs should be delayed to the end of next month.

##### FRUIT GARDEN.

Give a final nailing to all fruit trees that there may be nothing to obstruct the perfect maturation of the wood. Fig trees out of doors to be liberally supplied with water to enable them to swell-off their fruit. Every shoot of useless wood on the Vines out of doors to be removed and the branches laid-in close to the wall. Espaliers and dwarf standards, or indeed any kind of fruit trees which exhibit more tendency to produce useless wood than fruit, should be root-pruned when the leaves have fallen; cutting-out any useless shoots at the present time so as to expose the wood as freely as possible to light and air to ripen it.

##### STOVE.

This structure should now be nicely arranged, and both heat and humidity reduced by degrees as we get less solar light. Top-dress any plants that may require it, and see well to the drainage of all, particularly those which are established plants and have not been repotted for a considerable time.

##### GREENHOUSE AND CONSERVATORY.

Keep New Holland plants that have been placed under glass cool and airy, and avoid crowding, especially such plants as are in a growing state. Every plant to be allowed sufficient space that all the foliage may be exposed to light and air. Instead of huddling specimens too thickly together, it would be better to consign some of the least valuable to the dung-heap. As mildew is apt to infest Heaths which have been growing freely in a shady situation in the open air and are in rather a soft state when taken in-doors, apply sulphur freely on the first appearance of the enemy. One of the first things claiming attention at the present time is to get bulbs potted for forcing, as much of the success of early forcing depends upon early potting. Pinks and Violets must also be looked to. The greenhouse should be prepared immediately to receive the plants. It is advisable to have every part of the brickwork limewashed, the woodwork scrubbed with a mixture of soft soap and water, the flues or hot-water apparatus in good order, and, in short, everything in readiness, so that there may be no delay in housing

the plants when a change of weather renders it necessary. Although the dewy nights of autumn are very beneficial to plants exposed to them, it is advisable to guard against the pots being exposed to heavy rains, which would materially affect their safe keeping during the winter. Also tie such plants as may require it, so that there may be no delay in housing them.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

KEPT hoeing all the ground, weeds or no weeds, as if the small things were making their appearance. The scuffle of a hoe, and a little sun, often prevent much work afterwards. Have had a good deal of Sow Thistle this season, and wondered where it could have come from, until we found a very luxuriant patch in a wood at no great distance. The winged seeds had found a nice home in our pulverised ground, and sought to fly no further. I frequently see mounds of Thistles in hedges by the sides of roads, &c. (and good farming beside them, too), with enough of winged seeds to cover the fields all round them. One disadvantage of employing soil from the highway side is, almost the certainty of getting a fair allowance of Thistles and Groundsel in it, which if not cut up or pulled up early, will soon take possession of pots and beds. Proceeded with pricking-out Cabbages and Cauliflowers, for which we as yet can find no room, and planted out the last beds of Celery as we could get the Peas off for the purpose. Planted out Endive and Lettuce in earth-pits, where a little protection could be given them.

### MUSHROOM-BEDS.

Earthed-up the Mushroom-bed in Mushroom-house, as the heat showed no tendency to rise to injure the spawn. Being short of droppings, even for these shallow beds of about a foot in thickness, I use fully the half of that, of rough, shortish litter, mixed with very turfy, half-decomposed soil to firm it. The surface of the bed is chiefly droppings, pretty well dried before being thrown together, and to this is added fully a third of rough, fibry soil. I have thus used more soil than usual, and I do not think I have lost anything by it, as the crops generally are all that could be desired. I dislike the material being violently heated if it can be avoided, and, therefore, however short the bed may be, it is made up at different times—say in two or three layers, and well trodden and beaten each time, to keep out the air, and prevent heating, and consequent decomposition, as we wish the strength of the manure to go with the Mushrooms, and I always find that the fresher the manure on these shallow beds the better the produce. For large beds, well-wrought stable manure does very well, and, perhaps, the very best large beds I ever had, out of doors, or in sheds, were made of half-spent manure, rather caky, that came from linings of hot-beds. These, well shaken and thrown into a heap until they ferment a little, and then beat firmly into a bed of the required shape, will generally produce long and well. But for the shallow beds of which I am speaking, and which independently of the *must*, owing to dearth of materials, I rather prefer for the everyday supply, whatever the bottom of the bed be, I like the top in which the spawn is to be inserted to be chiefly droppings of horses, mixed with fibry turf, and the droppings just so fresh as not to heat violently. Now, here I beg pardon if I answer some half a score of inquiries, the writers wishing me to do so, though writing privately, contrary to orders, which I hope, however, they will attend to in future. 1. "As to the temperature of a bed when spawned." About 80°, if the heat is declining. Make sure of the latter fact, for if rising, it may reach 100° or 140°, and then farewell to the safety of the spawn. In these shallow beds I like to be sure of the declining. Insert the spawn slightly covered, and then if the heat still decline, place 1 inch or 2 inches of the fresh droppings all over the bed, which will set the spawn running, and draw it to the surface. 2. "How thick do you spawn?" Generally pieces rather larger than Walnuts every 5 inches square. If thinner, the beds will long be thin; thicker, the bed will produce more at first, but will soon exhaust itself. On an emergency I have made a shallow bed, sowed it over with spawn about the size of marbles, covered with an inch of soil, kept a moist heat of from 60° to 65°, and gathered in a month; but generally only for a fortnight or three weeks. 3. "Temperature of bed and atmosphere?" The former from the free action of the spawn which will produce heat, may range from 75° to 85°. The surface of the bed or the atmosphere

of the place may range from 55° to 65°, and never higher if you wish for good Mushrooms. 4. "Do you still surface the bed with cowdung?" Not so much as I did, unless the dung in which the spawn runs is wasted, dried, and poor, and for two reasons: first, in winter, Mushrooms were thick and fleshy, which I thought the pink of perfection, but there seemed to be a difficulty in cooking them so as to have them thoroughly done all through; and in the summer time, if the cowdung was at all fresh when used, though the fine Mushrooms looked nice, there was more of a tendency to have maggots in the stalk. For these reasons we often, if the horse-droppings are dry, prefer damping the surface before putting the soil on; but if cowdung can be got, and sheep or deer dung moderately dry, and a couple of months old, these objections will not apply. In fact, with a lot of such materials, and heating above 80° prevented, I have had fine produce even without artificial spawning. Once more—

*Time and Mode of Earthing-up.*—After spawning examine the bed carefully every day as soon as the spawn begins to run. The heat will rise a little, but if not likely to get higher than new milk, the sooner the bed is earthed the better. I generally give about 2 inches, the first rough fibry loam, the second part well-ribbed stiffish loam. This is levelled, beat as firm as possible, levelled nicely, well watered, and a clean spade drawn over it so as to have a clean, smooth, shining surface, which permits of sweeping, &c., nicely afterwards. As soon as the surface is a little dry, and the heat is not too much, we cover with a little straw or hay, which prevents the surface cracking and keeps the bed uniform in temperature. Generally in such beds the Mushrooms show on the surface in about five to six weeks. The bed just earthed-down will most likely yield about the beginning of November, and those in the sheds with a little covering will keep on well till then, and longer if we want them. I find I am mistaken as to lastly. There are two other inquiries, "How to know good spawn?" It is of a whitish nature from innumerable small white threads permeating the mass, each so small as to be next to individually undistinguishable. If there are many white threads as large as sewing cotton the spawn is considerably spent and will not produce so well, unless there are a great number of the smaller ones. 2nd. "Where to procure first-rate spawn?" Here I must decline. All our eminent seedsmen and nurserymen take a pride in keeping it good, but sometimes even they are deceived. I have had bushels sent which were just as much food for the carriage, as the carriage cost more than the spawn was worth as manure; but these are exceptional cases, and respectable firms as a rule make sure of sending out a first-rate article; and my own experience leads me to the conclusion, that there is no reason for delaying supplying their customers because their present season's stock is not ready, if they have a good supply left of what was a good article last year. I have used spawn of my own making four years old, and it showed no diminution of vigour. As previously explained, it was kept cool and dry. Where, however, but little is wanted, it is a waste of time to make your own spawn. When you use barrowloads in the twelvemonth it is a different affair.

### FRUIT GARDEN.

Much the same as last week, with the exception of gathering early fruit, Filberts, &c. I notice that, though Apples are pretty well up to the mark, the early Pears are as yet deficient in flavour; Plums, on the other hand, are good, and some finer in flavour than usual. These are some of the things that are difficult to account for. Some *Bon Chrétien* Pears are, though good in size, more woolly and less aromatic than usual. Fearing we would hardly have enough of Strawberry plants for forcing, took up some that had been pricked-out on a border late last autumn, but do not expect they will do so well as early layers of the present season. Went over all such early-potted ones, giving the pots more room, that the sun might exert more power on them, and cut off every vestige of a runner. All beds and rows in the open garden ought to have been so treated, but we have not got at them all yet. Strawberry plants in pots will, after this, have what watering they want early in the forenoon. As the pots get crammed with roots, well water merely to prevent flagging of the leaves. If the pots are not set on boards, or some hard bottom, they should be lifted frequently to prevent the roots going into the ground; as, for all early work, ripening of the buds is now more important than luxuriant growth.

### ORNAMENTAL DEPARTMENT.

Potted Primroses, Cinerarias, &c.; moved Camellias, &c., where they could be sheltered; moved Pelargoniums, Fancy and florist,

where they could be protected from rains, after they had been pruned-in; planted Pinka, &c., where room could be got; loosened the binding of budded Roses; tied-up and secured Dahlias and Hollyhocks, and will have to do so with Asters if they are to do well, as the heavy rains have beat down their heavy heads; removed a number of large leaves from lines and beds of dwarf Dahlias, to give more room and air, and strength to the flower-buds. The white and purple Zelindas have been as full of bloom as they could be; the Crystal Palace Scarlet has hardly ever been dense with us, whilst, close to the wall in the laundry-yard, under the care of the superintendent of that department, it has been a dense mass of bloom with scarcely a leaf to be seen for two months. The heat reflected from the wall made all the difference—perhaps not quite all; the roots consisted of the large tubers, but little thinned. We are often nonplussed to find that plants thrive better in some of these unlikely places than with us. I have read, with much interest, Mr. Chitty's remarks on "Window-Gardening." For the outside of the window the Sedums and Houseleeks answer well in towns. In a rather close alley, I lately met with a pretty box in the shape of a rough, picturesque basket, with a broad rim, and chiefly filled with Sedums, with long, dependent shoots of the *Lysimachia nummularia*, clothed with their golden blossoms. It quite took away the sombre look of the court. In spring the box held a few Violets, Anemones, Crocuses, and Tulips; and in the autumn two or three Scarlet Geraniums were placed in its centre, and the Sedums acted as a border, and the Moneywort was a graceful fringe or drapery. We like, if we are able, to attend to the inquiries of all such gardeners, as well as those having more space. From several we are requested to give more elucidations as to

#### CUTTINGS.

Thus one says—"You once recommended never to let the cutting feel its removal from the parent plant more than is possible, and that the more leaves you allow to remain on a cutting, the sooner it will make a plant, provided these leaves can be kept from flagging. Now I can place a Geranium cutting in a small pot at once, keep it pretty well from flagging, why, then, should I follow your advice or practice, and leave only a small leaf or two at the point of the cutting?" Why, indeed? Had we the room and the convenience that you have, we might do just as you do, as certainly we should get large plants sooner, with less trouble. But then our circumstances are different from yours. If we allowed all, or nearly all, the leaves to remain, we should want much more room than we have. Again: if these leaves are allowed to perspire much more than they absorb, they waste the strength of the cutting; and they would do so in our case, because we have not the means for making these leaves absorb instead of perspiring; and every leaf that fades would give us the trouble of picking it off, or else endanger the cutting, and other cuttings, by means of damping, &c.

In order to put many cuttings in small space, in the case of Geraniums, we remove the larger leaves, and thus avoid picking off faded and yellow leaves afterwards. We would be inclined to leave more leaves on the smaller Fancy Pelargoniums; but in the case of strong-growing Scarlet Geraniums we think, however unscientific, that at this season a few small leaves at the point to carry on the growth will be sufficient, and secure plants with less trouble than when more and larger leaves are left. The same principle will apply to the propagating of all bedding plants; and in the case of all, just for saving trouble in shading and syringing, and nipping off faded leaves afterwards, I make it a practice to have fewer leaves than I used to do. Thus, a little stubby cutting of Verbena, 2½ inches long, with two or three little leaves at its point, will bear an amount of air, and of light, and even of sun, which would cause a similar slip with two, or four, or more large leaves to droop at once. This reminds me of some inquiries as to keeping the Verbena plants now in beds over the winter. If they are small plants and bloomed little, you may take them up and pot them. If they have bloomed well and have grown strong, it will prove to be labour thrown away before next April, for you may keep them over Christmas and then they will begin to say, Good-bye. You had better even now secure plants from them, first by laying some short pieces, by placing them over some small pots filled with light rich soil, and keeping the shoot in the soil by a stone placed above to keep it down. This is the best for those who have no frame or hand-light. Where either of these is present I prefer such short stubby cuttings even now. From a dozen to twenty may be inserted in a pot of 5 inches in diameter after

it is well drained, filled within half an inch of the top, and surfaced with silver sand. These cuttings should all be drawn through weak tobacco water after they are made before inserting them, holding the root-ends in your fingers, as they are liable to have thrips less or more after September, and one cutting so infested will soon make havoc of a frameful. These must be kept close during the day and shaded from the sun, and hardened-off as soon as struck. If a little bottom heat can be given by plunging the pots in a mild heat, the cuttings will strike sooner. Up to the first ten days of September we would prefer them to be cool. We saw lately bottom heat given to a couple of hand-lights in this simple way. The mowings of a small grass plat and the sweepings of the leaves from beneath two Mulberry trees were placed together firmly, some soil put over them, and then 6 inches of ashes. By having a little air on even during the day, more at night, just dewing the cuttings in a bright day, and shading from sun, the cuttings would be plants in fifteen days; and whether from layers or cuttings, each of these tiny things will be more useful than the largest old plant of Verbena in the garden taken up and kept over the winter.—R. F.

#### TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PRESERVING PEAS GREEN FOR WINTER USE (A. S.).—This desirable result has certainly not yet arrived at the state of perfection we expect of it, and we have heard of many failures; but the following mode has been reported to us by a person well qualified to judge of such matters as being very successful.—Carefully shell the Peas—then put them in tin canisters, not too large ones; put in a small piece of alum, about the size of a horsebean, to a pint of Peas. When the canister is full of Peas, fill up the interstices with water, and solder on the lid perfectly air-tight, and boil the canister for about twenty minutes; then remove them to a cool place, and they will be found in January but little inferior to fresh, newly-gathered Peas. Bottling is not so good—at least, we have not found it so; the air gets in, the liquid turns sour, and the Peas acquire a bad taste.

GLADIOLUSES (Hymmn, Aberdeen).—You must not pot any of the Gandavensis breed before the third week in January, but keep them with you! Potatoes till then; after that your own way is right.

PROPAGATING CINERARIA MARITIMA (Idem).—Keep your seedlings till spring, and then the tops will make you more and more cuttings every three weeks, and then they will root like your Verbenas under the same treatment.

OLD PLANTS OF SCARLET GERANIUMS (Idem).—The branches will make you beautiful cuttings, and now you must lose no time in rooting them in pots in or out of doors till the frost comes. These cuttings would do famously to plant out next May, when the north-east winds leave you for the spring.

LOBELIA ERINUS CUTTINGS (Idem).—Nothing comes easier from cuttings than *Lobelia erinus speciosa* in the spring, and in a slight hotbed; but you must keep a few of the old plants over the winter to get cuttings from; and the best way to do that is yet a secret in all places south of the Dee. It is this. To look out in September the most bushy plants, to cut them down half way, to lift them with a little ball of earth about the roots, and to plant them in a sunny spot for a month or six weeks, and then to pot them when they are quite dry, to keep the tops quite dry all the winter, and the roots rather moist. Some people are so foolish, in the south, as to cut down, take up, and pot their Lobelias the same day, in October; and, of course, those of them who have not gardeners lose them from damp, and from not having growing shoots on them at the time of potting.

BEL-BEP TO FLOWER THE YEAR ROUND (Sarah).—The Spanish and English bulbous Irises follow the last of the May Tulips, and last a good while; and the Ramosus section of Gladiolus follow, and continue till the Gladiolus Gandavensis come in, and they and the Tritomas reach down to the Guernsey and Belladonna Lilies. But there are great numbers of small helbs to bloom from May to August, beginning with Anomathca, and on through Alströméria and Allium, to Zephyranthes and Atamasca Lilies.

HYACINTH SNOW IN THE NORTH OF IRELAND (Narcissus).—We think the latter end of March would be a very suitable time for holding a show in the north of Ireland; difference of climate would be hardly appreciable in such a dower.

PLANTAIN ON TURF (A Subscriber).—We know of no mode of eradicating it except by the spud, or, rather, by a knife. We have employed women to effect a similar eradication, and then sprinkled Suckling seed over the bare places. In a week or two all was green again, and very few Plantains appeared the next year. The present month is a good time for the process, and care should be taken to scoop out the roots deeply. A little earth may fill up the holes before sowing the Suckling.

**ROUGHNESS ON GRAPES (J. Hill).**—It is called by gardeners *the rust*, and they consider it is caused by handling the berries, or the head of the gardener rubbing against them in the process of thinning. These may be causes, but we rather incline to think that admitting cold currents of air suddenly upon the berries is the usual cause.

**BALSAM SEED (J. Ring).**—We regret that you are disappointed, but if you knew as much about the vendor as we do you would not be surprised.

**PINE APPLES (G. M.).**—You are no more entitled to exhibit an Enville as a Queen Pine than you are to exhibit a common Nonpareil for a Bradstreet's Nonpareil. They are distinct varieties. We cannot tell the weights you inquire about. They were not published.

**WIREWORMS IN ASPARAGUS-BEDS (A. M. R.).**—There is no mode known to us of destroying the vermin without destroying the Asparagus at the same time. As the beds are not old we should be inclined to take up the plants very carefully with a fork, lay them in the ground, pare and burn the top spit of the beds, manure them, and replant the Asparagus. This cannot be done until early next spring. To avoid disappointment you might insert young plants at the same time, and remove these if the older plants prospered.

**GOLD AND SILVER FISH (T. S. N., Clapham Park).**—They will become dark-coloured, and then much resemble carp, for they belong to the same genus. Are you quite sure a pike is not in the water? We knew a pond where fish could not be retained—at least, they disappeared unaccountably. It was cleaned out, and but one fish found, but that was a pike weighing twelve pounds.

**HOLLYHOCK PROPAGATION (M. G. C.).**—Cut down the stems at once, and manure the ground round the plants liberally. Hollyhocks may be propagated from buds, and although July is the proper season for doing so, yet we should try it now with some of the greenest of the stems. In July the following is the mode of proceeding:—When the Hollyhocks are tied up to the stakes for the last time, all the inferior stalks, or those that are likely to hide the rest too much from the sun, or, indeed, any that are too much crowded or ill-placed, were cut away as useless formerly, but now they are made into cuttings to increase good sorts, or save one the trouble of sowing seeds of them every year. Every leaf on a shoot will make a cutting if you take a part of the stem and the eye at the bottom along with it; but the easiest way is first of all to cut the shoots into as many pieces as there are leaves or joints, then to split the pieces down the middle, so that every half has its own bud and leafstalk; the blade of the leaf is not necessary, but it is best to keep 2 inches of the leafstalk; the soft pith in the centre of the split parts should be scraped out, as it is liable to cause damp or mouldiness; the pieces are then planted an inch deep in sand, under a hand-glass, or a cold, close frame, and sometimes with no better help than the shade or shelter of a north wall; part of the leafstalks are above the sand, and mark the centre of each cutting; the bud at the bottom of the stalk will soon push, make roots, and be in all respects as good as a seedling, besides being true to the sort.

**GERANIUM (A Clergyman's Wife).**—The flowers and leaves were so shrivelled that we are in doubt as to the name, but think it is the Shrubland Pet Geranium, a neat Oak-leaved kind. We do not know how it happened that it kept so badly in winter, unless it was too wet. It will stand a good amount of dryness in a pit. We are glad you succeeded so well with Verbenas. We are at a loss whether the Geraniums or the Verbenas became sickly after August. Very likely a little top-dressing or watering with liquid manure would have made them all right.

**CLIANTHUS DAMPIERI (G. K. J.).**—This plant is very unwilling to be repotted or meddled much with. A very young plant will do better than a large one, even for planting-out. However, we hope yours will do well. We should prefer the cold end of the conservatory. The finest plant we ever saw was at Messrs. Veitch's Exeter Nursery, against a wall out of doors.

**INSECTS (An Old Box Kale).**—The best thing you can do is to fumigate the house twice with the smoke of the best shag tobacco, taking care that the smoke is cool. The leaf was withered, but we noticed two thrips dead, so there can be no mistake as to the enemy. Where they came from is another question, and one more difficult to answer will be how, by constant care, to keep them away.

**VARIEGATED LEAF (M. F.).**—We could not make out your plant from the variegated leaf, fresh, though it was, in that beautiful oilskin-like fabric; but we put it into the hands of a botanical friend, and he was never yet beaten, even by a leaf.

**WINTERING ENOTERA LAMARCKIANA (A Subscriber).**—Take up some of the plants now, and plant them inside a cold frame; but we should think them hardy enough in your locality—at least, that they would do with very little protection. But the long, fleshy, fangs of roots may be kept like Dahlia roots, but not dried, for a whole winter. In a very cool cellar they would keep in sand as well as Carrots, we should think.

**GRAPE PRIZES (J. H.).**—Without having seen and tasted the Grapes it is quite impossible for us to say how the three prizes should have been distributed. There is too much of actual comparing required.

**RIDDELL'S PATENT BOILER (A Constant Reader).**—We believe it effects what the patentee states. We shall be obliged by a report from some one who has employed it.

**FLOWER-GARDEN PLAN (T. S. B.).**—Yours is the most complete, and the most concise plan and reference, and, of course the easiest for us, we have yet received. A beautiful flower garden of thirty-three beds on a space of  $2\frac{1}{2}$  inches by 34 inches, and the figures referring to the thirty-three beds with the names of the plants, occupy the first or top 3 inches of a page of note paper. At this rate all the plans and references for forty or fifty acres of flower garden would not occupy more than one page of common post paper; and of course that would lessen our expense and our trouble just fortyfold. The largest-sized bed need be no bigger on the plan than could be covered by a lady's thimble, with the number beside it; and the centre bed should be invariably No. 1, the plan not to occupy more than one half a post page, and all the references to be on the same page with the plan, and all to read without changing the page, just like a page of this Journal. "T. S. B.'s" garden is exquisitely planted. The only change which would improve it would be to put Brilliant for Golden Chain in 13, 14, 15, and 16—the four outside corner beds, Brilliant being the strongest of all his colours. His whole letter consists of "Please criticise. T. S. B." So that all that we require for giving a judgment on the largest concern might be put in four lines of a page of post paper.

**NAME OF FERN (A Country Curate).**—It is *Pteris hastata*, a native of South Africa. There must be some mistake on the part of whoever states that it was "found in a wood in Staffordshire."

**NAMES OF PLANT (B. A. S.).**—*Artemisia maritima*, or Sea Wormwood, a native of the sandy coasts of Portugal.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

SEPTEMBER 25th. STAFFORDSHIRE. *Sec.*, Mr. W. Tomkinson, Newcastle. Entries close August 25th.

SEPTEMBER 25th. MIDDLETON. *Sec.*, Mr. T. Mills. Entries close September 10th.

OCTOBER 28th and 29th. CALNE. *Secs.*, A. Heath and F. Bally. Entries close October 15th.

DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

### PRESERVATION OF EGGS.

(Translations from M. Jacqué's work on Poultry continued.)

It is known that eggs are generally used in kitchens, and that the means of preserving them in winter are very important. Messrs. Alibert and Mariot-Didieux have classed together nearly all the discoveries made on this subject.

Mr. Alibert writes thus:—

"Next to the meat, eggs are the most important product of the fowl; they constitute a food at once agreeable, salubrious, and very nourishing. In some pursuits, the yolk and the white are employed for different purposes.

"As food, the general use of eggs and their chemical composition prove that their nutritive value is about equal to that of meat. They contain, in fact, the substances destined for the formation of the organs of the chick when under the influence of incubation, and these same substances are found in meat in a state that is only slightly different: such are the albumen, fat, oils, sugar, colouring matter, salts of lime, magnesia, potash, soda, sulphur, phosphorus, &c. In the egg, the nutritive substances which compose it represent, with the exception of the shell, about the quarter of its weight when they are dried up—this is also the proportion of the solid matters of meat; the three other quarters are water, which evaporates by desiccation.

"These being admitted, will lead to the conclusion that the production of 2 lbs. of eggs requires the same quantity of food as the production of 2 lbs. of meat. This has been proved by our observations and our calculations. Laying hens must consume the equivalent of 20 or 24 lbs. of hay, or 12 lbs. of corn, in order to give 2 lbs. of eggs; when non-laying animals are in question, the same quantity of food, consumed in the shortest possible time, produces an increase of 2 lbs. of meat.

"The principal quality of eggs destined for food or for sitting is to be *fresh*—that is to say, recently laid (six days in winter, two in summer); at that age they have suffered no change. Eggs exposed to the open air and the variations of temperature lose by evaporation part of the water they contain; the void resulting from this loss is supplied by air, which penetrates the shell; the air-chamber at the large end increases in size, the internal parts from contact with air absorb it, change in smell and taste, and, according to circumstances, sooner or later arrive at a state of putrid fermentation. The heat of summer, changeable weather, incubation of barren eggs, interrupted incubation of those that are fertile, are the causes that generally bring about these alterations.

"It is easy to perceive the signs that mark freshness, staleness, or alteration in an egg when it is broken. The dimensions of the air-chamber and the smell are signs that leave no room for doubt. But when eggs are whole it requires practice to distinguish fresh from stale.

"The following characteristics belong to a fresh egg:—  
"First, A rosy yellowish look, and freedom from slightly green livid shades.

"Second, If it has great translucency, which can be discovered on examination, by putting the egg between both hands, forming a hollow circle and placing the egg between the eye and the light, or, better still, putting it on a sheet of white paper at some distance from a very light window, and examining it in different positions through a paper rolled like a telescope and blackened inside. If, in this examination, nothing opaque or cloudy can be seen in it, if the air-chamber is not perceptible, or if it is only seen as a small tip or end, the egg may be presumed to be fresh.

"Third, A new-laid egg shaken lengthways gives neither rattle

nor perceptible internal displacement. Stale ones are lighter, and on shaking a shock is felt against the shell.

"Fourth, By the salt-water test. Procure an egg recently laid but quite cold; then in a vessel equal in depth to four or five times the length of the egg, put water in which salt has been melted until the new-laid egg, being laid gently on the surface of the water, falls slowly to the bottom. It will easily be understood this salted liquid will serve to separate the fresh from the stale eggs, since the new-laid, and, consequently, full ones will reach the bottom of the vessel at once by virtue of the relation existing between their weight and their bulk; while the stale, containing more air, and being, consequently, lighter, will either remain on or near the surface, or will have greater difficulty in reaching the bottom.

"When a new-laid egg is put into a quantity of boiling water representing twelve times its own bulk, it cracks and lets out part of its contents. This little accident, which is caused by the fulness of the egg and the sudden expansion of its internal parts, does not occur where there is less water, because the temperature is lowered by the introduction of the egg. Under any circumstances stale ones do not crack, because they contain a larger air-cell which yields to pressure, and then escapes through the shell. The peculiar smell of eggs boiled hard, or decomposed by putrefaction, is due to a combination of sulphur (sulphuretted hydrogen), which, among other properties, has that of blackening silver utensils.

"From what has preceded, the preservation of eggs consists in employing proper means to preserve them from evaporation, from the introduction of air, and from the variations of temperature, which may cause putrefaction."

(To be continued.)

### HASTENING MOULTING AND LAYING.

LAST year I had a Dorking pullet which began laying in December, and laid well up to August 5. She is now slowly moulting. I am anxious to experiment on making her lay this year again—say in December or earlier. Could you assist me with any information, or point out where I could obtain any?—**INQUIRER.**

[Fortunately for you and for your hen, you cannot materially hasten her moulting. All you can do is to keep her warm and well fed, but with cooling food. Stimulating food causes fever, and that prevents the formation of feathers. Let her have plenty of oatmeal mixed with new milk; feed her freely with lettuce. This will assist in moulting. When the plumage is hard and perfect, you can hasten the laying time by feeding on hempseed, raw flesh, or tallow-chandler's greaves. You must calculate the cost. You will get some eggs rather earlier, but you will not have as many as if you had allowed nature to take its course, and you will sow the seeds of disease in your bird. When pullets, fowls lay at a certain age; but, with few exceptions, hens lay at certain seasons. They become subject to the same laws as game and birds that are at liberty. When they vary, it is from different food and different treatment.]

### PONTEFRACT AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE fourth annual Exhibition of this Society was held at Pontefract on the 11th instant. The number of poultry was only meagre, owing to the smallness of the prizes. We understand, however, a much increased list will be offered next year; and we are certain, should this determination on the part of the Committee be carried out, the poultry will form, as at other exhibitions, not the least interesting part of the Show.

The most successful exhibitors were Lady Hawke, Mr. Cannan, Mr. Crosland, and Miss Beldon. Lady Hawke exhibited good *Dorkings*, *Brahmas*, and *Ducks*. Mr. Cannan's *Hamburgs* were excellent. Mr. Crosland was in his usual position in *Bantams* and *Game*; while Miss Beldon sent first-class *Polands* and *Game*.

The following is the prize list:—

**DORRING.**—First, Lady Hawke. Second, W. Pecl. *Chickens.*—First, Lady Hawke. Second, J. Hurst.  
**HAMBURGH** (Golden-spangled).—First, W. Cannan. Second, J. Crosland. *Chickens.*—First, W. Cannan. Second, J. Crosland.  
**PRESANT** (Silver).—First, W. Cannan. Second, J. Huntingdon.  
**CHESTER.**—Prize, W. Cannan.

**HAMBURGH** (Golden-pencilled).—Prize, W. Cannan. *Chickens.*—Prize, W. Cannan.

**POLANDS** (White-crested).—Prize, Miss E. Beldon.

**POLANDS** (Black).—Prize, Miss E. Beldon.

**POLANDS** (Golden-spangled).—Prize, Miss E. Beldon. *Chickens.*—First and Second, Miss E. Beldon.

**POLANDS** (Silver spangled).—Prize, Miss E. Beldon. *Chickens.*—First and Second, Miss E. Beldon.

**GAME** (Black-breasted and other Reds).—First, Miss E. Beldon. Second, Master R. H. Jones. *Chickens.*—First, Miss L. Beldon. Second, J. Crossland.

**GAME** (White and Piles).—Prize, J. Crossland.

**GAME** (Duckwings and other Greys and Blues).—First, J. Crossland. Second, Miss E. Beldon.

**BANTAMS** (White).—First, J. Crossland. Second, H. Robinson.

**BANTAMS** (Black).—First and Second, J. Crossland.

**BANTAMS** (Golden-laced).—First, W. Cannan. Second, J. Crossland.

**BANTAMS** (Any other distinct breed).—First, J. Crossland (*Game*). Second, Lady Hawke (*Game*).

**ANY BREED NOT MENTIONED.**—First, Lady Hawke. Second, W. Cannan. *Chickens.*—First, Miss E. Beldon. Second, Lady Hawke. Commended, W. Cannan.

**DUCKS** (White).—First, Lady Hawke. Second, W. Liversidge.

**DUCKS** (Rouen).—First, Lady Hawke. Second, J. Hurst. Commended, J. Hurst.

**GESE.**—First, Lady Hawke. Second, Mrs. E. Halmshaw.

**TURKEYS.**—First, W. Liversidge. Second, Miss Foules.

**GUINEA FOWLS.**—First, J. Hurst. Second, W. Jefferson. Commended, W. Jefferson.

**PIGEONS.**—*Tumblers.*—Prize, G. Gressy. *Trumpeters.*—First, I. Smith. Second, S. Fairar. *Any other breed.*—First, J. Wigglesworth. Second, B. Townsend.

The Judges were Mr. T. J. Charlton, Bradford; and Mr. Hutchinson, Thirsk.

### KEIGHLEY AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS Society's twentieth annual Meeting took place at Keighley, on Friday the 5th instant. Both in number of entries and quality it exceeded any of its predecessors. The poultry formed one of the chief attractions of the Show; but owing to the Judges getting on so slowly with their work, a great portion of the visitors had not an opportunity of ascertaining to whom the prizes were awarded, the birds being removed almost immediately after the Judges had finished, and even in this the services of two additional gentlemen were obtained to assist in the decisions. We hope next year a different arrangement will be made.

The *Cochin* class stood first on the list, but, with the exception of the prize birds, they were a poor lot. The same may be said of the *Spanish*, the second-prize adults should have been first. The *Hamburgs* came next, and mustered such a show as can only be seen at Keighley, which has been for years the nursery for *Hamburgs*. Mr. Cannan's first-prize Golden-spangled and Silver-spangled chickens deserve special mention, and it has seldom been our lot to see two such pens. Mr. Dixon's Silver-pencilled cockerel was a nice bird, but we did not like the pullets. We thought there were several pairs much better. In adult Gold-spangled the commended pen should have stood first; in fact, we can scarcely imagine how the Judges could make so great a mistake. The old Gold and Silver-pencilled classes were suffering from the moult, but they contained some good pens. The Gold-pencilled chickens were a nice lot, and the prizes as they stood were judiciously awarded. The same may be said of all the *Hamburg* chicken classes. *Polands*, *Golden* and *Silver*, were good; but in chickens we fancied Miss Beldon's *Golden* chickens should have had first position. *Dorkings* were an indifferent lot, four pens only being shown. Amongst the *Game* were some fine birds, Miss Beldon taking three out of the four first prizes with first-class specimens. Mr. A. Hodgson's first-prize *Brown Red* chickens were excellent, and were much admired. *Bantams* were an average lot, the best being Mr. Tate's *Game*, Mr. Crosland's *Blacks*, and Mr. Gerner's *Whites*.

The prizes for "Any distinct breed" went, in adults, to *Sultans* and *Black Polands*; in chickens, to a splendid pen of *White Polands* and a good pen of *White-crested Blacks*.

The *Silver Cup*, presented by the Mayor of Bradford for the best three pens of *Hamburg* chickens—*Gold-spangled*, *Silver-spangled*, and *Silver-pencilled*—was awarded to Mr. William Cannan, of Bradford, who obtained two first prizes and a commendation, against a first prize by Mr. James Dixon, and a second prize by Mr. Shaw, the other competitors.

*Ducks* were very good, especially the first prize *Aylesburys*.

The first-prize *Geese* were capital.

Only one pen of *Turkeys* was shown, to which the first prize was awarded.

There was a good display of *Pigeons*, the most noteworthy being Mr. Shaw's and Mr. Cannan's well-known birds.

The following is the prize list:—

**COCHIN-CHINA.**—First, J. G. Suggden, Eastwood House. Second, J. Firth, Halifax. **Chickens.**—First, F. G. McCrea, Second, W. Supton, Earby.

**SUSSEX.**—First, J. Dixon, Bradford. Second, W. Cannan, Bradford.

**Chickens.**—First and Second, T. Greenwood, Dewsbury.

**CHITTY-PHEASANT.**—First, S. Shaw, Stainland. Second, J. Dixon, Bradford.

**Chickens.**—First, J. Dixon. Second, J. Bird, Ilwroth. Commended, W. Cannan, Bradford.

**PHEASANTS (Golden).**—First, J. Dawson, Bradford. Second, W. Cannan, Bradford. Commended, W. Cannan. **Chickens.**—First, W. Cannan. Second, Messrs. J. Roe & Co., Glossop. Commended, W. Cannan; Messrs. H. & G. Newton, Leeds.

**HAMBURG (Golden-pencilled).**—First, J. Dixon, Bradford. Second, W. H. Dyson, Morton Banks. Commended, W. Cannan, Bradford. **Chickens.**—First, S. Smith, Northowram. Second, Messrs. Parkinson and Kenyon, Acerrington.

**PHEASANTS (Silver).**—First, D. Wilson, Sutton Field. Second, J. Newton, Silsden. Commended, W. Cannan, Bradford. **Chickens.**—First, W. Cannan. Second, S. Shaw, Stainland.

**PHEASANTS (Black).**—First, S. Shaw, Stainland. Second, J. Dixon, Bradford. **Chickens.**—First, J. Dixon. Second, S. Shaw.

**POLARIS (Golden or Silver Pheasant).**—First and Second, J. Dixon, Bradford. Commended, Miss E. Beldon, Bradford. **Chickens.**—First, W. Newsholme, Bingley. Second, Miss E. Beldon.

**DORKINGS.**—First, E. Smith, Middleton. Second, J. Dixon, Bradford.

**Chickens.**—First, T. E. Kell, Wetherby. Second, Messrs. J. Roe & Co., Gussop.

**GAME (Red).**—First, Miss E. Beldon, Bradford. Second, J. Firth, Halifax. Highly Commended, A. Hodgson, Ilwroth. **Chickens.**—First, A. Hodgson. Second, Miss E. Beldon, Bradford. Commended, J. Firth, Halifax.

**GAME (Any other variety).**—First, Miss E. Beldon, Bradford. Second, A. Bell, Burnley. **Chickens.**—First, Miss E. Beldon. Second, J. Hodgson, Bradford.

**BANTAMS (Black, White, or Game).**—First, G. R. Tate, Driffield. Second, W. J. Crossland, Wakefield. **Chickens.**—First, —Goiner, Bowling. Second, W. Newsholme, Bingley.

**ANY DISTINCT BREED.**—First, W. Dawson, Hopton Mirfield. Second, J. Dixon, Bradford. **Chickens.**—First, Miss E. Beldon, Bradford. Second, W. Newsholme, Bingley.

**DUCKS (Rouen).**—First and Second, J. Dixon, Bradford.

**DUCKS (Aylesbury).**—First, T. E. Kell, Wetherby. Second, G. R. Tate, Driffield.

**DUCKS (Black Indian).**—First and Second, J. Dixon, Bradford.

**DUCKINGS.**—First, S. Shaw, Stainland. Second, Messrs. Parkinson and Kenyon, Acerrington.

**GESE.**—First, G. R. Tate, Driffield. Second, J. Dixon, Bradford.

**TURKEYS.**—Prize, J. Dixon, Bradford.

**EXTRA STOCK.**—Cup, W. Cannan, Bradford (Chitteprat, Silver Pheasant, and Golden Pheasant).

**PIGEONS.—Pouter or Cropper.—Cock.**—First, S. Robson, Britherton. Second, J. Sunderland, Coley Hall. Commended, Miss E. Beldon, Bradford.

**Hen.**—First, S. Robson. Second, E. Brown, Sheffield. Commended, H. Smith, Skipton. **Carrier.—Cock.**—First, H. Smith. Second, S. Robson. Commended, J. Parker, Oakworth. **Hen.**—First, W. Cannan, Bradford. Second, H. Smith. Commended, S. Robson. **Tumblers (Almond).**—First, S. Shaw, Stainland. Second, W. Cannan. **Balds, Beards, or Mottled Tumblers.**—First, W. Cannan. Second, S. Shaw. **Owls.**—First, W. Cannan. Second, H. Smith. Commended, W. Cannan. **Turbits.**—First, S. Shaw. Second, Miss E. Beldon. Commended, S. Shaw. **Jacobins.**—First, W. Carlton, Howden. Second, S. Shaw. **Fantails.**—First, S. Shaw. Second, E. Brown. **Barbs.**—Prize, S. Shaw. **Dragons.**—First, J. Collier, Skipton. Second, J. Sunderland. **Trumpeters.**—First and Second, S. Shaw. **Magpies.**—First and Second, S. Shaw. **Archangels.**—First, S. Smith, Keighley. Second, J. Thompson, Eingley. **Any other breed.**—First, J. Thompson. Second, S. Shaw.

**RABBITS.—Long-eared.**—First, G. Bentley, Kirkstall. Second, J. Sunderland, Coley Hall. **Any other description.**—First, J. Spencer, Calver-lyke Hill. Second, J. Dixon, Bradford.

The Judges were Mr. J. O. Jolly, York, Mr. S. Hall, Gargrave; and to assist them, Mr. Baxter, Elslack, and Mr. Elkanah Aykroyd, Bradford; Messrs. Hall and Aykroyd taking the *Game and Pigeons*, and Messrs. Jolly and Baxter the other classes.

## WEAKNESS IN THE LEGS OF YOUNG COCKS.

**Symptoms.**—This disease attacks young birds, and young cocks more frequently than pullets. The bird is more or less incapable of holding itself up, and frequently sinks on the ground; in severe cases it is unable to stand. The health is otherwise good, and so is the appetite, the bird not having as yet suffered from want of exercise. The comb is red.

**Causes.**—This disease, which appears sometimes to attack the finest birds in preference to any others, is caused by a too rapid increase of weight out of all proportion to the development of muscle. It usually attacks the heaviest fowls, but is of rare occurrence in old birds. It is most common among the heaviest varieties, the Cochins being particularly subject to it. Constitutional weakness will also produce it without rapid growth.

**Treatment.**—Local applications are of no use; the best remedy is a dose of *china*,\* dissolved in a spoonful of water, and given every day, or else of *cocculus*.

\* An extract from the root of *Smilax China*.

A good supply of nourishing food must also be afforded, and it should be of a kind calculated to produce flesh and not fat. Barley, oats, worms, or chopped beef are preferable to rice or Indian corn.—(*Maison de Campagne*.)

## BEES VARYING IN THEIR PROCEEDINGS.

LAST July (the first week), I obtained a very fine swarm of bees. All went on well for a short time, but one Sunday there was a good deal of excitement in the hive, but at night they became quiet. Again in a few days there was the same excitement, no work being done but the air filled with bees. Since then my bees have gradually vanished. One time I thought the tomtits were at them, but I have a mousetrap baited with suet on the hive, yet do not catch any. Then I thought there was no queen; but last Sunday in spite of the rain there were many more bees and all very busy carrying pollen. I have been feeding lately. Can that be the cause of their improvement? I do not think Wanstead, Essex, is a favourable place for them, as nobody keeps any.—NEMO.

[A change of *quems* would seem to be indicated by the circumstances you state, but this is by no means certain, as changes of weather and feeding materially influence the deportment of bees. We should fancy Wanstead a good locality, and if no other bees are kept yours have the better chance.]

## LOSS OF A QUEEN.

THE formation of royal cells in the bee-hive referred to having roused my suspicion that the queen had been lost, very likely from falling on the ground during the search, as you guess, it was subsequently strengthened by the bees rather slackening their activity and crowding about the entrance in little knots, possibly discussing the peculiar quandary in which they were placed, and the weather prospects for the marriage tour of their youthful princess; besides, a way was always cleared for the entrance of any stray drone making his appearance, so unusual in the middle of September, those in my other hives having all disappeared some time ago.

The 15th inst., being warm and beautiful, between one and two, by the merest chance, I caught a glimpse of a queen entering this hive, and noticed as she disappeared, the extreme point of her tail had an open, loose, white appearance, similar to what we see in a worker after losing its sting. May I conclude from such an appearance that impregnation had been effected, and, therefore, trouble you again with this query?—W. J.

[What you saw was the undoubted sign of impregnation. The drone does not long survive, but returns to the hive to perish. It would be interesting to know the exact period when egg-laying commenced after an impregnation effected so late in the season.]

## SUBSTITUTING A LIGURIAN FOR A COMMON QUEEN BEE.

WILL you inform me which is the safest and surest method of introducing a Ligurian queen to a stock of the common species, as I am going to supply my stocks with queens of the Italian species—at least some of them, and wish to accomplish it without sustaining the loss of any of the Ligurian queens? My plan which I intend adopting (if it meet with your approval) is to fumigate the bees I intend to introduce the queen to, search out their own queen, and also fumigate the queen I intend supplying, and then bury her in the middle of the stupified bees. Please, also, inform me if there are any particular features in the pure Ligurians, whereby I can be able to recognise whether they are a pure breed.—JAMES BOOTHMAN.

[The substitution of a Ligurian for a common queen is always attended with considerable risk, but we believe that the fumigation which you propose will reduce that risk to its minimum. You are, doubtless, aware that some of our best apiarists\* consider that fumigation when pushed so far as to produce insensibility, is permanently injurious to bees; and if this be really the case, it is a very serious objection to your plan at this season, when the fumigated bees are all you have to rely on to carry your stock through the winter. We believe our correspondents "A. W.," "A NORTH LANCASHIRE BEE-KEEPER," and "SIBERT-

\* Dzierzon, the great German apiarist, also condemns fumigation.

ON-THE-WOLD," adopted fumigation, and that the two first were permanently successful, whilst the Ligurianised stock belonging to the latter perished during the following winter. The reason of this difference in the results may possibly be, that the successful experimenters operated earlier in the season, so that the fumigated bees were pretty well bred out before winter set in. One piece of advice we must give, and that is, on no account to expose the Ligurian queen to the risk of injury by subjecting her to the narcotic smoke. Successful modes of effecting the desired end have been detailed by "A DEVONSHIRE BEE-KEEPER," "B. & W.," and "J. N.," in Nos. 9, 69, and 74, of our New Series.

We consider that a pure Ligurian queen should breed only Ligurian workers, and of these the greater number should have two well-defined orange-coloured rings on the abdomen.]

## BEE'S TREATMENT OF THEIR QUEEN.

### BEE'S IN A SMOKY ATMOSPHERE.

It must be admitted, that with all our long-cherished notions of the loyalty of our little favourites, a more intimate acquaintance with their domestic arrangements compels us to lower the character of the little heroes, and regard them more in the light of matter-of-fact utilitarians, devoted certainly to their queen as long as she can serve them, but devoid of the higher virtues of compassion and benevolence. We shall never find a ward for the sick in a bee-hive. Yet I have heard of an instance in which a queen was allowed to end her days in peace, after being of no further use. An accurate and practical bee-keeper informed me he once had a first swarm which he examined two days after swarming, and was surprised to find that no eggs had been laid. Wishing then to ascertain the state of the queen, on turning out the bees he found the swarm possessed two queens, one evidently very old, and the other very young. The old queen did not survive many days. This was a remarkable instance of amity on the part of both the queens and workers.

That the bees will become the royal body-guard, and defend their sovereign from threatened danger, surrounding and imprisoning her *con amore*, the instance to which I alluded in the communication to THE JOURNAL OF HORTICULTURE of August 5th affords reasonable grounds for such an opinion. With a profound admiration of the general correctness of the deductions of Huber, I had some misgivings as to the result which he described on introducing a strange queen into a hive possessing a recognised sovereign, and tested it by introducing a young queen into the upper part of a uncomb-hive. In an instant she was seized and surrounded by workers, and the most desperate struggle ensued. The queen evidently used her sting freely, as many of her assailants fell around, contorted as when stung. The queen mother pursued her avocations, merely avoiding that part of the comb where the struggle was taking place. After three or four hours the cluster broke up, and as I could not see the captive, I turned to inspect the other side of the hive. There I found another dense cluster had formed, but this was calm and still. In a quarter of an hour this also gave way, and to my surprise I saw, not the stranger, but the sovereign (a marked one) quietly pass from the centre of the mass. Looking at the entrance there lay the body of the victim. I could not then doubt that when she had fallen, some bees unaware of her fate, had rushed to the defence of their own queen, and detained her till assured that danger was past, by the removal of the intruder; and such I think will be found to be the normal sentiment in a hive.

Of all the extraordinary freaks of the workers lately recorded, that seems to be pre-eminent where they were found by "A DEVONSHIRE BEE-KEEPER" to attack their hybrid queen, which had been a few minutes in the hands of assailants. Could it be possible that in those moments she had been stung or even touched by the venom from a sting, which might have exasperated her own bees?

It is singular, that when a queen is stung the effects should be less apparent than in the workers. She merely seems to sicken and sink, while their legs become paralysed, the body distorted, and the neck twisted. Is it that immunity from pain is one of the prerogatives of royalty?

It must, too, be granted that when under the excitement of anger the wise little bee really does very foolish things. A few days ago I saw two or three bees dragging a dead companion out of the hive. Meeting with some obstruction at the entrance,

they became very angry, and one so far lost its temper as to sting the dead bee. The punishment was summary, for the sting could not be withdrawn, and they fell together. The burthen was dragged along by the sting, which I assisted in vain to disengage. I may add here, that I never could provoke a queen to use her sting, or even to bite; but last year a drone bit me so sharply that an inexperienced hand would have let him go.

An inquiry was made a few weeks since if bees would thrive in the vicinity of a smoky town; and to this I can reply in the affirmative, having known an apiary which was always healthy, in the suburbs of a manufacturing and very smoky district, where there was not only the smoky atmosphere from steam engines and manufactories, but the deleterious vapours of alkali works east their blighting influence over trees and evergreens. The bees did pretty well on the garden flowers and fruit trees, and later in the season on the white clover.

One question I would ask of apiarians, Does any one know an apiary enclosed on all the sides in a shed which continues prosperous?—INVESTIGATOR.

## BEE'S EJECTING EGGS FROM THE CELLS.

I HAD a first swarm in June 1860, and, that being a very bad season, had to feed it. I began to feed in August, and continued till October. The last week in October I found two queens—one the old and the other the young queen; and in the first week of November I found another young queen only partly hatched. I kept the hive through winter, with the intention of joining them to another in the spring of 1861. When spring came, the hive worked and loaded as well as any hive I had. I was sure there was a queen in it, and was certain she could not be impregnated, so I was determined to keep it as it was to see the result. Well, it worked and loaded as well as the rest, and when I fed it, it took all I gave; but when taking the feeder away, I found it covered over with eggs about two or three days old, and the bees continued to throw the eggs on the floor-board, even as late as June. I believe there was only one drone hatched, and no young bees, and the hive dwindled away. I expected them to breed drones: according to Huber, if a queen is not impregnated within twenty days her future progeny will be drones only. The question in my mind is, did the bees know the eggs were drone-eggs, and so would not allow them to come to maturity? But what most surprised me was the bees continuing to load till they were all wasted away. I leave it with you, as being better able to clear up the mystery.—C. B. HEMINGWAY.

[We really must profess ourselves unable satisfactorily to explain this mystery. Where so many eggs were dropped on the floor-board, we should fancy some must probably have been deposited in the cells. Our German friends notice a disease which renders a queen bee unable to retain her eggs; and if this were the case in the present instance, it would undoubtedly solve the enigma.]

## STUPIFYING BEES WITH CHLOROFORM.

HAVING a weakly stock of bees in a common straw hive, of which there was no chance whatever that they would survive the winter, and being also unwilling to resort to the match-and-brimstone plan, so justly condemned in THE JOURNAL OF HORTICULTURE, I was determined to take them by means of chloroform as recommended in "Bee-keeping for the Many." My mode of operation was this:—The hive to be taken and a neighbouring strong hive were simultaneously chloroformed with two teaspoonfuls as prescribed. When all was quiet the weak hive was removed, the bees swept carefully into a newspaper, and were gently mingled with the inhabitants of the other hive, which were also lying stupified. Although this operation was attended with a great degree of success, yet I am inclined to think this was not so complete as it ought to have been. The next two days the bees seemed much excited, and a great many, which the chloroform had evidently killed, lay dead beneath the hive. I fancied also that I could discover some fighting going on.

Would any of your apiarian correspondents kindly inform me, First, Whether there was any error in the mode of operation, as "Bee-keeping for the Many" does not enter into details; and whether I was right in chloroforming both hives?

Secondly, Is it usual under such circumstances for some of

the bees to be killed? If not, can they account for the circumstance in the present case?

Thirdly, Should the hive have been slightly propped-up to have allowed the free circulation of air for a few hours to expedite the reanimation of the bees?—R. J.

[When the late Mr. Payne penned the paragraph relating to chloroform in "Bee-keeping for the Many," it had but recently been introduced, and I feel certain he must have written without much, or probably any, practical experience of its effects. What these really are has been well described by Mr. Fox in No. 518 of the Old Series of THE COTTAGE GARDENER. The only mistake which "R. J." appears to have made was in using chloroform at all for uniting bees, instead of the excellent plan of driving described and strongly recommended in pages 45 and 46 of the same little work. My opinion is that Mr. Payne, or in fact any man who has once succeeded in uniting stocks by driving, would never be induced to subject bees to the injurious effects either of chloroform or fumigation.—A DEVONSHIRE BEE-KEEPER.]

## HONEY AND WAX AT THE INTERNATIONAL EXHIBITION.

(Continued from page 464.)

INDIA.—Several specimens are catalogued, but I could only find two or three muddy samples, tasting much about the same as the Ceylon cocoa-nut sugar-honey, which would certainly never be appreciated by the honey-consumers in this country. I was disappointed in not finding more and better samples from India, as I had been recently informed of the excellency of the honey of that part of the world. My own packing-case was among the first to enter the Exhibition, and for reasons not interesting to the public, was about the last to get fixed. It served as a sawing-bench for numerous carpenters during a whole month, and underwent the most trying gyrations for honeycomb, yet, strange to say, only a comb or two in a straw super got smashed. The Indian products, I believe, came in late, so I take it the honey got small by degrees from the long journey, in a similar manner, perhaps, to my own packing affairs on their return to Woodstock. I had gone to some expense for special contrivances in packing my fragile goods; so I made all tight and forwarded my case here by Great Western Railway, to have it ready to return to London and repack my exhibits. It arrived to me gutted—cloths, wrappers, cord, spare labels, &c., all gone.

*Mauritius*.—I read "finest honey," which I could not find; so it is either not in the Exhibition, or I was not sufficiently lynx-eyed to find it out, and to save repetition on this head, it must be my excuse for other countries of which I make no mention.

JAMAICA.—Society of Industry, Lucca, send ordinary specimens of yellow wax; and J. Brass, Esq., honey of "Apis mellifera," which is given a medal—can it be for flavour?

CANADA.—J. Lyman & Co. exhibit some very good yellow wax—a magnificent court in woods. I could scarcely tear myself away.

*New Brunswick*.—A parallelogram box-super of honeycomb (similar to those from Nova Scotia), contributed by R. Jardine, St. John's, with a specification, "not to be opened," "do not touch"—a nice white sample to look at. Some, however, had run out on to a piece of paper, which had to succumb to the knob of my pencil. It was thin and insipid.

*Newfoundland*.—Charles C. Keane sends a nice white sample of Bermuda honey, and some very good white and yellow wax.

NEW SOUTH WALES.—W. Harbottle contributes "native bees-wax;" J. S. Norrie, Pitt Street, also sends a large cake of wax. Both are tolerable as to quality, and to the latter is given a prize medal.

*Queensland*.—Several specimens of indifferent-coloured honey. That exhibited by W. Staughton, sen., "Doughboy Creek," is the whitest and best. He gains a medal for yellow wax; and Mr. Marshall, Brisbane, sends some tolerable white wax, which is also awarded a medal. There are several other very fair samples both of white and yellow wax here.

*Tasmania*.—Reminiscences of "B. & W." led me to inspect this court narrowly; but nothing relative to bee-keeping could I find. It is, however, magnificent in woods. A case of artificial pears and apples, with "honourable mention" appended, gained my high admiration, and if their representatives in the

flesh are as good-looking and good-flavoured to match—sing hey for the pears and apples of Tasmania.

BRAZIL.—A cake of greenish-coloured wax, and one of good white ditto, gained an "honourable mention" to J. M. Dos S. Carneiro. G. A. G. de Albuquerqu shows a cake of black wax, which is black enough to a certainty. Other specimens of various-coloured wax are there, and good for purposes to which they could be applied no doubt; but the chief feature in the case is a collection of bees, with their wax and honey, exhibited by M. F. Lagos, from the province of Ceará, which could not but prove interesting to scientific naturalists. But in the name of sleepless nights, can any pleasant sensation derive from the mosquitoes? Surely M. Lagos could have found a happier class for his case than these irritating, blood-sucking fellows. There are twenty-four species, with sixteen specimens of wax, and sixteen ditto of honey accruing. A label in the case notifies that there should be twenty-three bottles of honey, so I suppose those minus to have been lost. The names of the species are as follows:—

*Lima*.—Very small. The honey is the colour of Scotch heather honey, and it resembles much for flavour that of common English. Wax black.

*Gupira*.—Size of our house fly. Honey dark brown. Wax black.

*Yaty*.—One-third the size of a house fly. Honey inclining to black. Wax dark brown.

*Mandaçaia*.—Size of a small wasp. Honey heather-coloured. Wax inclining to black.

*Gaucho*.—Size of a house fly. Honey heather-coloured. Wax inclining to black.

*Tamos-nos embora*.—Size of a house fly. Honey black. Wax grey.

*Tatara*.—Two-thirds the size of a house fly. Honey very dark brown. Wax inclining to black.

*Tubiba*.—Size of a house fly. No honey. Wax black.

*Buxú*.—Two-fourths the size of a blue-bottle fly. No honey or wax.

*Euxy*.—Size of a house fly. Honey none. Wax none.

*Gapuchu*.—Size of an attenuated wasp. Honey none. Wax none. (We have its fac-simile on the mignonette to-day, working as eagerly as the common bees. Sept. 2.)

*Gabocho*.—Size of a small wasp.

*Arapuá*.—Size of our small black bee. Honey black. Wax dark brown.

*Mombuca*.—Size of a house fly. Honey dark brown. Wax black, though not quite as rare if it belongs to this bee.

*Wrussú*.—Size of a small bee, and of a yellowish hue. Honey black. Wax dark brown.

*Mosquito*.—Size and colour of a just-born sandy bacon weevil. No honey, of course.

*Sanharó*.—Size of a house fly. Honey dark brown. Wax grey.

*Maça-branca*.—Light-coloured, two-thirds the size of a house fly. Honey dark brown. Wax brown. The honey resembled much in flavour the cocoa-nut sugar honey.

*Cutia ou de purga*.—Sandy-coloured, size of a house fly. Honey the colour of rhubarb. Wax black.

*Mondury*.—Sandy-coloured, size of a common bee. Honey colour of rhubarb. Wax black.

*Manoel d'Abreu*.—Sandy, two-thirds the size of a house fly. Honey dark olive green. Wax inclining to black.

*Bocca torta*.—One-third the size, and shape and colour of a wasp. No honey or wax represented.

*Amarello*.—Ditto.

*Chapó*.—Size of an attenuated hornet, and in life must be much the same colour, having also its upper wings much the longest. Honey and wax nil.

This case of bees is given an "honourable mention," and to the honics and wax a medal.

On entering the Brazilian court there is a case exhibited by B. Quintanilha, of pretty gladiolus-looking artificial flowers, made from insects' wings. It deserves and has gained a medal. The getting-up of this court should be retained as a pattern for future Exhibitions.

FRANCE.—*Aisne* sends parallelograms of yellow wax; and some nice samples of honey are sent by M. de Tillancourt.

*Somme*.—Large quantities of yellow wax; some of it by M. Vignor, apiculteur, is especially good, and there are some good samples of honey.

*Seine et Marne*.—Honeycomb middling; and wax by Lelogeais fils, apiculteur.

*Seine et Oise*.—"Miel en rayons et en vase pour la table, par M. Delechenaux."—Honeycomb for the table worked in a salad-bowl, sent by Mr. Youngoak. There are also yellow wax and in carefully closed bottles specimens of honey, which is here classed under the name of each species of flower from which the honey is derived. We found these maxims, "L'abeille charme les loisirs du cultivateur et elle moissonne gratuitement pour lui une récolte qui ne lui coûte rien."—The bee charmeth the leisure hours of its owner, and gathers for him gratuitously a harvest which costs him nothing. Again, apropos to some very-well-done representations of agricultural and horticultural vegetables in wax. "La terre peut être comparée à une machine, et son amelioration est la source la plus féconde de la production à bon marché."—The earth may be compared to a machine whose improvement is the productive source of fruitful markets. The translations are my own, so those who read must run and not stay to criticise.

*Loiret* Collective Exhibition show white and yellow wax, and honey; and *Pelegrin Frères*, Orleans, honey of Catania in pretty little globular glass pots, and white wax. Very good.

*Cher* Agricultural Society send honey of Sologne, dark-coloured; and there is some yellow wax by M. Berton Gault.

*Charante* Agricultural Collective Exhibition contains a great display of hives, honey, wax, &c., which should have a better light, being placed in a dark corner under a gallery. The products are otherwise neglected, and it is the worst-compiled case of any in the French court; it is, moreover, unfinished, and devoid of glass behind, to the temptation of numerous unauthorised tasters—so much so, that some of the supers are emptied completely of their contents, and others in a fair way of soon becoming so. The majority of the honeys have more the flavour of English honey than any I have operated upon, and that which at present suits my judgment best is some clear run honey in those pretty little pots previously mentioned, and called "Miel de Table Catinais"—table honey from Catania; and if any honey deserved a medal this certainly should have had one. Of the congealed sorts here, I considered that the best was from M. Victor Simon, apiculteur, Sequeville-en-Bessin (Calvados), and called "Miel de Normandie"—Normandy honey. Of the numerous specimens of flaked wax shown by M. P. Faivre, apiculteur, Scurre, Côte-d'Or, Nos. 22, white, and 26, yellow; and amongst numerous specimen cakes, a large yellow cake (No. 1), named "Cire de Blé noir, or Sarazin (Calvados) Harcourt de St. Jean," are very good. There is a bottle of what I take to be mead-vinegar, called "Vinaigre d'eau de Miel;" and if that be so, I am not a solitary exhibitor of that stimulative appetiser. I could not get at the bottle! Here is also "Hydromel-mead," or honey-wine, which I did get at; but I would not advise any other person to do so, for the flavour is simply beastly—like bee-bread and water, half and half, and as dark-coloured as catsup. M. Durant and M. Antoine are both exhibitors of Hydromel; but the taste of one was enough for me.

There is a classical glass urn of honeycomb here of tolerably good colour and flavour; but, unfortunately, the lid is broken, which admits the dust, though when the supers are quite emptied it will prove to be in dangerous proximity to the bipeds. Fortunately, the honey-gingerbread is up on high, and protected by the glass. I have been through Downington, and bought gingerbread there, which, on the supposition that I now liked that epicurean production, I much prefer. Here are numerous beehives and a hackle, the workmanship of which no one could complain of: but go and see them. For practical utility, in my opinion, they fall short of those exhibited by our English makers, and having an eye merely to my own country I thus speak. The majority of them are not large enough for England. In a mild winter starvation would soon stare the colony in the face; and in a severe winter the frost would soon penetrate completely through them, unless they were much swaddled-up, and then would come damp and dysentery. There are two, nearly approaching to some Austrian hives, which I mean to speak of; otherwise I do not care to dwell upon them. A "Nourris-cur à cuvette" tin bee-feeder is shown, which may prove to do all that its name implies; but I am wedded to my fig-drum of that ilk. No medal or mention is given to a single production in this extensive collection.

*Drome*.—M. Girard shows some good yellow wax. In special exhibits, Class 4, Gillord, Bres., Paris; and G. Bureau, Bordeaux (Gironde), show wax in cakes, lumps, and scraped, of very fine quality; also, some comb quite black, I suppose for contrast to show what it may be educated to become at last. M. Barton

Gault d'Aubigny, also sends some honey and some yellow wax.

*Algeria*.—Amongst several exhibitors of honey in this French department, Ahmed Charouch (Constantine), sends a very nice sample, which gains a medal. Kada Kelouch à Sidi bon Mediuc (Ozan), has the next best, "Miel de 1861," which also gains a medal; Belog of St. Denis du Sig (Ozan), a fair specimen of virgin honey, 1861, and he gets a medal. Abbé Abram, of Ozan, is next best, and he has a cake of good white wax. Böensch, apiculteur at Kouba, has also a sample of good yellow wax.

In scrutinising the French south-west court, I observed No. 1226, E. d'Orleans, Batignolles, Paris, an excellent kind of straw "matting for vines," against walls I presumed. They would prove one of the best protectives I know of for any sort of fruit tree in blossom against walls in the spring time, or for covering over frames, &c. A machine in miniature for making them is also exhibited. They have got a medal. At the same stand is a capital sort of thatch shown worked (as it is intended on a larger scale), on to the roof of a shed, forming in miniature a "hackle," that I should say would rejoice all lovers of that sort of bee-hive-protecting material. It is given an "honourable mention."

I revisited this stand several times, but was each time unfortunate in not meeting with an attendant who could furnish me with particulars, or give me specifications. A note also refers one to another person's stand close by, which I applied to but could not succeed. It would be worth any gardener's, farmer's, or bee-keeper's while to visit this stand, and take an inkling from those productions.—UPWARDS AND ONWARDS.

(To be continued.)

**BLACKBERRY WINE.**—Over as many quarts as you have of berries, pour so many quarts of cold water which has been boiled. Bruise the berries well, and let the whole stand for twenty-four hours, stirring it occasionally; strain the juice, and put 1½ lb. of sugar to each gallon of liquid; stir it until the sugar is dissolved, and put it into a cask with a quarter of an ounce of isinglass to two gallons of liquid; let it remain open until the next day, when it should be bunged. In two months it may be bottled-off, and will be found a very pleasant wine.

**ANOTHER.**—Measure your berries, and bruise them, to every gallon adding one quart of boiling water. Let the mixture stand twenty-four hours, stirring occasionally; then strain off the liquor into a cask, to every gallon add 2 lbs. of sugar, cork tight, and let it stand till the following October, and you will have wine ready for use, without further straining or boiling.

**HOW TO PRESERVE CUCUMBERS FOR WINTER USE.**—Put 1 lb. of alum and three quarts of salt to one barrel of pickles; water sufficient to cover them, and lay a cloth on top. There will a scum rise on top, which take off with the cloth, and rinse it in cold water. When you wish to use them, soak overnight; or, if you like them pretty salt, just rinse them off, scald the vinegar, and pour upon them.

## OUR LETTER BOX.

**KEEPING A COW** (*Native worth*).—We hope before long to give some particulars relative to the keeping of a cow or cows on a small plot, as is practised in Guernsey. In the meantime we recommend you to buy "How to Farm Two Acres Profitably," by J. Robson. You can have it at our office for a shilling. In that book you will find full directions for cow management. We recommend you to have an Alderney or Guernsey cow, for the two names apply to one and the same variety; but a cow will be dry for about a month annually, just before calving.

**SOVE MILK** (*F. Hayes*).—This will not do your fowls any injury. For profit—that is, for a good supply both of eggs in winter, and chickens for table, you cannot do better than by keeping Partridge-coloured Cochinchina pullets and a coloured Dorking cock, having fresh pullets every year.

## LONDON MARKETS.—SEPTEMBER 22.

### POULTRY.

We have little change to note since last week. Young Partridges have been rather more plentiful; but, at present, the supply would seem to show this one of the worst seasons on record.

Large Fowls .....	3 0 to 3 6	Ducks .....	2 3 to 2 6
Smaller do .....	2 6 ,, 3 0	Partridges .....	2 0 ,, 2 6

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 63.4° and 43.6° respectively. The greatest heat, 80°, occurred on the 4th, in 1859; and the lowest cold, 27°, on the 2nd, in 1853. During the period 120 days were fine, and on 125 rain fell.

NEW FLOWERS OF THE SEASON.

NO. 1.—VERBENAS.

THE high-sounding titles and brilliant descriptions with which "novelties" are introduced are oftener belied than confirmed by the reality; and I do not think that we need be surprised that it is so, or be led into fierce invectives against the honesty of those who give them. I am quite aware that there is a system of dishonest puffing current; but oftener, I think, it is to be attributed to the fact that things about which we are personally interested seem to us so much better and more valuable than other things. Thus, I have met at the great shows many people, strangers to me, who would insist that they had better Geraniums and other things than

those exhibited. One gentleman would contend that the seedlings which had obtained the prize were by no means worthy of it. "Why, sir, I have better here with me?" and he forthwith showed me some blooms immeasurably behind in all points those which he condemned. He had no pecuniary object in lauding his own flowers, as he never (so he told me), sold them; but his eyes could not see clearly, because his own feelings were interested in pronouncing his own to be the best. So, now, exhibitors have always much better flowers at home; and had it not been for "the family" wanting the Grapes and Peaches, they would have sent such fruit as would have completely beaten out of the field those that they were obliged to send. Hence one never does, until flowers are distributed to the public and get into many hands and under many eyes, obtain really the true character of novelties; and then so many prove worthless, that many and loud are the remonstrances and angry exclamations against being taken in. I have, thanks to the kindness of many growers, had opportunities of seeing the leading novelties in my own garden and elsewhere; and the notes which I have jotted down may be incorrect indeed, but they are impartial. I have, therefore, thought it well to set down a few notes of the leading varieties of the season, and commence with Verbenas.

The death of one or two raisers, and the great wetness of the summer of 1861, have been rather against the production of novelties in such large numbers; while the increasing quantity of bad sorts which come from France has led nurserymen on this side of the channel to be very cautious in recommending these productions. The season has not been a favourable one; for a long time after they were planted-out cold, rain, and sunless weather prevailed, and, as a consequence, plants made little or

no progress; and, as is always the case in such a condition, became the prey of green fly, and in some cases thrips, to an alarming extent. In July they began to push; but it was altogether a cheerless month, and the beds were not half filled. A brilliant August, however, brought them on rapidly; but after its close, early in September, some heavy and continuous rain, lasting in some cases forty-eight hours, completely destroyed their beauty and made it difficult to gather a sufficient number of trusses to show on the 4th of September. I am now describing my own experience, and believe it was not unlike that of many of my neighbours. In such circumstances it may be impossible to decide accurately as to the merits of flowers; but in August when they were at their best my notes were made, and must be now taken for what they are worth.

**ARIOSTO IMPROVED (Osborn).**—This is a very excellent plum-coloured variety. Ariosto was raised by my friend Mr. Banks, and remained for long the best in its class. Another seedling of his Zampa is good, but hardly full enough in the truss. Ariosto Improved is large and full and of good habit.

**FOXHUNTER (Millar).**—This flower has proved itself worthy of its high reputation. It is an advance on Firedy, but so like it, that if the two are put up together it would be almost impossible to tell them; but it has a great advantage in the style of its growth, which is strong without being rampant or open in the centre of the plant. It is a very free bloomer.

**LADY VICTORIA SCOTT (Thompson).**—I do not know whether this has been up to the mark elsewhere, but I have not seen in it anything remarkable.

**MASTER CORNET (Wills).**—Crimson, with white eye. With me it has proved to be too small for any good effect, though a very free bloomer.

**MODEL (Wills).**—Carmine lake, with lemon-coloured centre. This also is too small, as far as my judgment goes.

**JENNY LIND (Wills).**—A light lavender-coloured flower, free-blooming, and may prove an effective plant for bedding.

**LITTLE HARRY (Wills).**—A very dwarf habit; may be useful for small beds, but must not be grown with others. Colour a dark crimson.

**MARMION (Newton).**—A beautiful novel shade of carmine, with yellow eye. Truss large and well filled, and likely to prove a very effective flower.

**AMY ROBSART (Elphinstone).**—A good bright rose, with yellow eye. Good habit.

**ORIENT (Elphinstone).**—Rich lake, with white eye. Truss large and good. A very pretty and bright flower.

**SIR PHILIP (Wills).**—My plant of this made very little progress until late in the season, and then certainly did not come up to the character given of it. I have lately seen a few trusses on the plant in better condition, so that probably it may improve. Colour, a bright scarlet crimson.

**LADY GREY EGERTON (Wills).**—A somewhat novel shade of crimson. Truss large and habit good. I think this is likely to prove a good and useful flower.

**DESDEMONA.**—This has been described as of the same habit of growth as Purple King. Nothing could be more different from it than my plant, as it had the awkward habit of running away from the centre, and thus leaving a bare space without flower. I am not sure that it will always do this, for I have found that some sorts will do so one season and not another.

**LE BON NICOLAS.**—A richly mottled pink variety, of continental origin, and very striking. I do not think it is as well known as it ought to be.

**L'AVENIR DE BELLENT.**—This I received from Mr. W. Bull, of King's Road, Chelsea, and it is decidedly in my opinion and that of my neighbour Mr. Banks, one of the best of new Verbenas. It is a light rose or peach, with a brilliant carmine spot in one petal, and a narrower and lighter one in the others. The habit, too, is good, with abundance of bloom.

**ANNIHILATOR (Perry).**—I received, through Mr. Bull's kindness, Mr. Perry's new seedlings; but as I grew them in pots, I should hardly like to say what they are likely to prove out of doors. I have, however, seen those that I mention here in a neighbour's garden, and think Annihilator is an effective and useful flower.

**DECORATOR (Perry).**—The same may be said of this flower.

**BETRICE.**—I do not know whence this flower comes, or whether it is new; but it is a very pretty mottled one, and will be, I think, useful for bedding.

Amongst the productions of the present season, Lord Leigh, Lord Craven, and Rugby Hero, are promising flowers.

Among the older varieties, Great Eastern, Firefly, Madame Herman Steiger, Anglaise, and Ida, are deserving of cultivation more extensively. The three latter one sees but seldom, but they are flowers of good properties. Last season was so favourable for saving seed that there ought to be plenty of new ones, but as yet I have not heard of many. I hope to see the raiser of Foxhunter next week, and to hear whether he has anything very good this season. Doubtless having won a reputation, he will be careful not to risk it by sending out any inferior varieties. There is, I cannot but think, still room for improvement. As a florist I say this, for the rotundity we look for has not been attained, and there is no reason why it should not be.—D., Deal.

#### HAMPTON COURT GARDENS, SEPTEMBER 22ND.

ONE of the very best of the old Nosegay Geraniums—namely, Mrs. Vernon, along with two other kinds, on Harry Moore's system, have stood sentry-like at the outer gate to the entrance of the Palace-yard for the last nine years, and yet Mrs. Vernon, also one of the best bedders for the Dutch style of so many square yards to a bed, has not yet been brought into the bedding-list of the establishment. It is a favourite at South Kensington and at the Crystal Palace; but it is only in a bed like the new great circular bed next the lake at Kew where Mrs. Vernon can be shown off to the best advantage—that is, to be on the face of a slope with a mass of scarlet either below or above it.

During so many years, however, Mr. Donald has been quietly restoring the flower-bed arrangements to their original standing in the true old style of the Dutch school, and it is questionable if there is one place in Holland itself, or in any part of the Low Countries of the Continent, where the true Dutch school of gardening design two or three hundred years back is so well preserved and exemplified at the present day as at Hampton Court; and for that reason I would not alter one bed or one inch of a border in the whole garden, even if by so doing I should propitiate the favours of all the students of all the schools of architecture and of landscape gardening in the world.

Of all the conservatism in this conservative world commend me to the conservatism of the schools of art, and having that I would go with the fashions and follies of an age to the very end of the tether in flowers and in how to do them, and to set them off in any one fashion which might be the uppermost.

It is not yet ten years since you might have got up a shooting party to kill rats or rabbits at the very garden entrance of Hampton Court Palace, and then the original Yew trees all round the great half-moon circle in front of that entrance, together with those running down direct from the front door to the head of the Dutch water-lakes, were, as it were, in the last stages of decay, covered over with ivy to make them look green, and stilled with scrubby herbaceous plants over their roots and lowest boughs—enough to drive all conceit about a garden out of all who had seen them. But look at them now, renewed not only in their looks and strength, but restored to the very idea of the man who ordered them to be planted centuries ago. Yes, every one of them has to occupy a flower "knot"—that is, what we now call a flower-bed. Where they have ceased to be, some substitute will be found; so that now

the whole face of the garden is as flat, and as regular, and fully as expressive of the school which it represents as a Dutch clock.

Then, in just the same unobtrusive way, Mr. Donald has been improving the style of planting the beds, and of matching the colours, cutting according to his cloth, according to the means allowed to him for making both ends meet; and in another year, or at least in two more seasons, the arrangements all over the garden will be complete. The system of running the colours is now perfected all over the flower-beds, beginning with red, then white, then blue, after that a yellow, and then a neuter colour, and so on exactly throughout.

The herbaceous border which is the bed for the wall plants along the whole length of the Palace-side of the garden, is this season for the first time laid down on the ribbon plan, but the first ribbon had also to be cut according to the cloth or stock on hand to do it with. Every row in that ribbon is half a mile in length all but 3 yards. Then suppose you plant all the plants at 14 inches apart in the row, or not quite 15 inches, it would just take two thousand plants to plant one row of this ribbon, and that was the actual number which was allowed and could be spared at the time.

There are many kinds of neutral beds at Hampton Court, but I must not particularise more of them than those called selfs. *Stachys lanata* is a self-bed; *Antennaria*, or the old *Gnaphalium margaritaceum*, is another as good; then *Geranium sanguineum*, divided in the spring, makes a fair self with no lack of flowers for a whole season. *Vinca major variegata* is another which ought to be planted thick enough at once, and never to be trained down, but only to be pinched and stopped occasionally, and it will last for many years without renewing. Indeed, the older the plants and the more crowded, the more variegated they are. There is another excellent move here for enlivening this bed still further—namely, to plant out a regular distribution all over it of the double dwarf yellow French Marigold. Just try that plan next season, but make the cuttings of the variegated *Vinca* this autumn.

Variegated Mint and Variegated Alyssum make self-beds. *Lamium purpureum* and *purpureum variegatum* make two good selfs. Lavender Cotton, or *Santolina chamaecyparissus*, which was lately suggested, is found to make one of the very best self-beds, and none better than the common Lavender, trained down in the spring if the plants are old. *Cerastium tomentosum* is one of the best self-beds there, and to keep so many square yards of it in one uniform mass of height and thickness, they "foot" it all over several times in the season, which was quite new to me. Edgings of it might be done the same way, but to "foot" a thing, in garden language, means that you should tramp it all over with the feet, not missing one inch of it. *Cerastium Biebersteini* is to be done there next season just the same way, and a fourteen-inch edging of it is also to be put round a large bed of *tomentosum*.

Mr. Donald takes the same view as your humble servant of *Biebersteini*. No matter whether they, or we, or you think the one better than the other, for all that is mere fancy; the two are sufficiently distinct to make two beds in the same garden, and not only so, but the one to make a contrast with the other, and being everybody's plants and no trouble, private fancies will not supersede public utility in their instance.

*Alyssum saxatile*, old plants divided early in the spring, and when in the flush of bloom the spikes of flowers thinned-out one-third, continues in second-rate bloom for the rest of the season, and for a spring bed none is better. After that it is even richer than some self-beds. *Alyssum sempervirens* is a fine bed while in flower, and a thorough self or neutral when out of bloom. But what would you say to two large beds of London Pride? They made the pride of this garden this very spring, and two of the best selfs when their pride was over. Mr. Donald has planted the variegated *Vinca*-bed with creeping flowering plants as *Verbena melindres*, *pulchella*, the two *Impératrice* varieties of *pulchella*, *Sabini*, *Hendersoni*, *Seymouri*, and lots of others which my good people missed in the race for novelty. Purple King, Lord Raglan, General Simpson, and Madeleine, were the best *Verbenas* this season at Hampton Court; *Defiance* and *Speedi* (a dwarf scarlet), the next best. Uncle Tom, a large purple *Petunia*, was the best of them. *Lantana erocea* failed as did all the *Lantanas* in most other places. A large bed of *Chrysanthemum coronarium* *alias* *regale*, a double yellow, did very well, as did *Chrysanthemum frutescens*, a flower which is very largely in the Paris market, and which blooms all the year

round. Also, a Pomponne called Frederick Peel, a brown flower, has kept on the whole of the summer. Beauté de Boudoir was the best Heliotrope, and a fine bed it did make.

The best Geraniums were—Alma (Dennis's), certainly the best bedder of the greenhouse class; Old Ignescens, very good; Boule de Feu, the very best of all the Scarlet Geraniums, beating Punch and Crystal Palace, and all the scarlets I ever saw, it has Nosegay flower-stalks, and is without exception the best I have seen; the old Brompton Scarlet was also very good. Lady Middleton was very fine; and Trentham Rose, which is all but the same as Lady Middleton, in most places, is not worth a great here, the same at South Kensington, but is preferred before Lady Middleton at the Crystal Palace, so that Boule de Feu may not be one-half so good in other places as it appeared to me to be at Hampton Court, so much depends on soil and situation that no one can be sure of a Scarlet Geranium except by the proof of growing it; Magnum Bonum is always a good scarlet under trees here; and Rubens is nearly as good. I often wondered that my own Stella, which has been out five years, never took the country by surprise; but now it is getting into repute, and I should think wherever it did suit, no other Geranium could take the shine out of it. But the truth is, all good seedlings are so run upon in propagation, first by the breeder, and immediately after him by the buyer, that there is no life left in them for the first few years. Mr. Donald has a fine variegated Geranium, a seedling of his own, called Lucy Kerr, with Cerise Unique flowers, and a sport from Général Pélissier, which promises well.

Mr. Donald has paid close, practical attention to the question of variegation in plants, and his matured view of it is this: he would induce a disposition to variegation by the use of pollen from a variegated sort only; then, having given the predisposition to variegation to his seedlings, he would convert a green-leaved seedling into a variegated one by manipulation, rather than that the seedling should come variegated in the first instance, and for this reason, a variegated seedling never comes true to the type of either of the parents, but a green seedling is often a true cross, inheriting the good points of both the parents; then, by forcing such a plant to become variegated, the desired type is got hold of. And that is exactly my own idea, only arrived at in a different way. I shall never give up the belief until it is decided by a fact of easy proof, and that proof to come the same in repeated experiments, and my firm belief is, that all the dispositions of all the plants on the face of the earth, whether in degrees of variegations, of fruitfulness or unfruitfulness, of being liable to this or that disease, of being a dwarf or giant of its race, or any other disposition whatever, are stamped on them at the moment the seed is impregnated, and that all such dispositions must be referred to the conditions in which the parents were at that time; also, that no art of man can afterwards alter any one of such dispositions.

Then, how is it that Mr. Donald can alter a green to a variegated disposition by manipulation, and still be in the same track as I am? Nothing is more easy to understand. He places the plant under an unfavourable condition to its active growth—say, he plants it four times deeper in the worst undrained soil, and in the coldest bottom in the garden, and that seems to help on the predisposing cause to variegation which the plant received with its birth. Then suppose the seedling to have been shed in the wilderness. An accident might just as soon, or sooner, have forced on the original predisposition, or whatever you may call the quality which was stamped on the seedling at the impregnation of the ovule. You may as well attempt to prove that chemistry is capable of making, or creating a new plant, as to assert the possibility of giving a new quality to any of the old plants.

The author of all our most beautiful variegated Geraniums, as Mrs. Pollock, Lucy Grieve, and Italia Unita, is of the same mind as we are, and would prefer a sport from a seedling, first having induced the disposition in it to be a variegated seedling from the seed. Then, if you understand all this, would it not appear to be the best way for getting all golden leaves, and zoned leaves, and, perhaps, other kinds of leaves equally remarkable for departing from the normal type? at least, it would be so to me. And, now, there is no practical gardener, as far as I know, who has the least idea that he can originate a variegated plant otherwise than by pollen in the first instance, and that is, certainly, one great stumbling-block being removed. Then, as to the notion of variegation being a disease, the thing is now too childish in the face of all we are acquainted with to the contrary to be entertained in practice or by practical men of the present day.

Neither at Kew nor in Hampton Court Garden could I find any clue to the authority for *Gnaphalium lanatum*. There is only a provisional tally to it in the botanic arrangement at Kew. What has struck me all along is this: that I had known this new and most useful plant forty years back, as a trailing, straggling, and troublesome customer from the Cape, when it was the fashion to grow up all plants one-sided, and this the worst of them to get to do so. I have now traced it to the nursery of the Messrs. Lee, of Hammersmith, from which it first "came out;" and if they did not make £2000 clear profit by it that is not my fault. A more generally useful plant never left that celebrated nursery, and I shall hazard the opinion that it was a companion to the first *Fuchsia coccinea* in the hands of Lea & Kennedy, before the present firm were in long clothes. Miller's Nosegay Geranium, one of the originals, is called sanguineum at Hampton Court, where they are as partial to it as they are at South Kensington; yet, at Kew and at the Crystal Palace they do not seem to have yet discovered its properties.

Strange to say, no *Lobelia speciosa* out of a pot does any good at Hampton Court; but this season Mr. Donald sowed the seeds in the open bed, and now he has it like other people. All the plants of it to the right and left of me, and in my own sanctum, are from a sowing made in the open ground at the beginning of March last. But I must close with a surplus again.

D. BEATON.

### THE PEAR AS AN OPEN STANDARD AND AS A WALL TREE.

THE flavour of fruits has been a subject that has, from a very early period of gardening records, more or less engrossed the attention of cultivators; and although there is no lack of connoisseurs, there are comparatively few who have attempted to throw much light on the cause whereby fruits of the same variety should differ in flavour when grown under similar circumstances. Yet that it does so is an unquestionable fact; and some of the cases are so self-evident that a few examples will suffice to define what is hereby meant by the term "inexplicable," or, in plain language, a case where a reason for the anomaly is difficult to assign.

In an orchard on grass of mixed Apple and Pear trees we have several large trees of the Marie Louise Pear, which in favourable seasons bear well, the fruit being much smaller and more russety than the same kind trained to eastern, northern, or western walls; but they are infinitely superior to the latter in flavour—so much so, that some have doubted their being the same variety. But the difference is entirely due to the conditions under which they are grown, for they were originally from the same stock. Another variety of Pear, Williams' Bon Chrétien, is exactly the same; large, fine-looking fruit grown on the walls being inferior in point of flavour to the same when grown on open standards, the fruit of the latter being much smaller. Now, these examples are difficult to understand on the generally received notions that cultivation, training, and other judicious management, tend to produce good fruit. Certainly it is finer-looking fruit than the other; but being obtained at a much greater cost, in smaller quantities, and of inferior quality, the question naturally arises, Is it prudent to plant Pears against a wall? To this a qualified answer must be given. At such a place as this (Linton), most certainly it is not advisable to plant either of the kinds above mentioned; but at a place less favourable to the growth of Pears as open standard trees it may be different. Still, the question has to be asked, Why are the fruit on the walls so much inferior to the standards, the soil and climate being the same? This involves a question for which the following suggestion may, perhaps, supply an answer.

Assuming the soil on which both the open standard and wall trees above alluded to are growing, to be exactly adapted to the wants of a fruit-bearing Pear tree (and I have reason to believe that it is so), we have here a manifest example of the evil effects of pruning and managing a fruit tree. The wall trees, of course, receive the usual summer and winter treatment; while the standards have had nothing whatever done to them excepting thinning-out the branches more or less severely once in six years or so, and gathering the fruit when ready. With regard to the certainties of a crop I can say but little, the one being as good as the other; and I have never seen much on the wall trees when the other failed, so we must not deduce much from that, but consider the causes of the one being so much better flavoured than the other; and my opinion on this

point is that the wall-tree fruit is overfed. The tree being denuded of branches and shoots to a great extent, both in winter and summer, to make it conform to the situation it is placed in, and the crop of fruit being seldom proportionate to the activity of a vigorous root, an undue amount of food is forced into the cells of the fruit, and it is swelled beyond its proper proportion, while sugar and the other items constituting flavour are not furnished in a like ratio: hence a full-grown but indifferently flavoured fruit is the result.

Perhaps some one will urge that the greater amount of air the standard-grown fruit receives is the cause of its merit. This may, perhaps, have something to do with it; but I am still of opinion that when a fruit grows really well in a state of nature, its quality is rarely improved by cultivation, especially when such severe measures are adopted as those taken by the dresser of the wall-grown Pear tree, cutting off, as he does, nine-tenths or more of each season's growth every year. Some fruits may benefit by a treatment of this kind, but I have much doubt of the Pear doing so, as some consideration is always due to the natural habit of the tree operated on; and when we know that the Pear in a wild state assumes an almost-forest-tree character, we must pause ere we seek to reduce it to the condition of a dwarf. Fruit it may bear in such a condition, and such fruit may now and then assume a more or less unnatural character, just in proportion to the paucity of its numbers; but its true character can hardly be developed in so limited a space, and either extraordinarily overgrown specimens, or sickly diseased ones will be the result where Nature has not been consulted in its production.

The above case is not the only one of a like nature that has come under my notice. Many years ago a new garden was formed in one of the northern counties, and some hothouses were intended to have been built, but something occurred to prevent their being put up at the time, and at the eleventh hour the gardener, who had planted the other walls with trees suitable to their respective places, planted some dwarf Ribston Pippin Apples against the south wall intended for Grape-houses, expecting they would be removed the following year. But delay after delay in the building of the hothouses occurred until the trees came into bearing, and most beautiful fruit was the result—fruit that carried off the prize at a provincial show, and, I believe, would have done so at a metropolitan one also by its appearance; but this fruit was of indifferent flavour: the place was in a certain sense too good for it, in the same manner as the south of Europe is too mild and warm for the Apple in general. Some other instances of a like nature might be adduced; but as my object was merely to call attention to the Pear, it is needless recording more.

It is proper to observe, that in soils and situations less favourable to the Pear than Linton, the differences between the open standard and wall-grown Pear might not be the same as it is here; but where it is similarly suited to the growth of that fruit, I expect the result will be the same. A healthy aged Pear tree is in a more natural condition to bear good fruit, than one that is continually undergoing amputation of full three-fourths of its entire framework. A gouty habit may tend to swell the fruit of the latter to an unnatural size, but it must be at the expense of the sugary matter which gives flavour and quality to it, as it is exemplified in some other fruits that are more gross feeders, atmospheric influences being also at work in both cases alike; but as the Pear is not generally regarded a gross feeder, it is less likely to run into that condition in the enlargement of the fruit as it is to fail in producing that perfect one which meets the palate of the connoisseur. Be this as it may, certain it is that the finest-looking fruit are not always the best flavoured, Pears especially being more deceptive in this respect than other fruits.

If any of the readers of THE JOURNAL OF HORTICULTURE know of a case similar to the above, or one widely different from it, they will do good service to the community by recording it. I should also like to know the quality of the fruit produced on trained pyramid trees, whether it is better than on trees of natural growth, and how they compare in quality. My own convictions are, that when the climate, soil, and other circumstances favour the growth of the Pear, it produces better fruit as an open standard than as a trained tree; but I am not wedded to this opinion, and I only limit my views to the kinds suited to the place. This whole subject, however, is well worthy of being ventilated, and deserves the attention of all.—J. ROBSON.

[It is quite certain that unnaturally large Pears are not so

fully flavoured as those of a natural size. In Guernsey we were told by the Chaumontel growers that those weighing from ten to fifteen ounces were much superior in flavour to those of much larger size. It is the same with the Gooseberry, and probably with all other fruits. The pampered show Gooseberries of Lancashire are infinitely inferior in flavour, not only to the fruit of the smaller-fruited varieties, but to unbloated specimens of the same variety. The bloated berries have been unable to elaborate all the sap forced into them, and, therefore, its watery constituents predominate; for ripening is neither more nor less than converting the watery and gummy parts of the sap into sugar and aroma.—Eds.]

## MANAGEMENT OF SPRING-FLOWERING BULBS.

ONE great merit in spring-flowering bulbs is the ease with which they are made to produce their flowers. This, added to their cheapness, is the reason for which they are eagerly sought after at this time of the year, and certainly they are well calculated to produce a lively appearance in the garden at a time when it would be otherwise comparatively bare of flowers. Those who grow them on a large scale will, most probably, by this time be supplied, and those who fully understand their proper treatment, procure them as soon as possible after they arrive in this country, knowing full well that in such matters delays are dangerous, and that, generally speaking, the first comers have the best choice; but for decorating villa gardens, windows, &c., they are not generally obtained till late in the year, and often not till they begin to grow in the shop windows. Experienced growers well know that in this case the bulbs are injured, although they may produce their blooms properly, because the rudiments of these are already formed in the bulbs; but then it is much better to have them in the ground before this takes place.

In the purchase of bulbs it is advisable to have an eye to the purpose to which they are to be put. For instance: if intended for decorating the borders of a villa garden, it is scarcely worth while to choose the choicer kinds of Hyacinths and Tulips; for of the former there are plenty, usually catalogued as border Hyacinths, priced at about 4s. per dozen, smaller generally than others, but equally good and oftentimes producing as good spikes of bloom as the high-priced ones. The same may be said of Tulips. There are sorts equally showy with the best—as the Van Thol, Double Tournesol, and Rex Rubrum, which are sold at 6s. and 7s. per hundred in ordinary seasons. These answer admirably for planting in borders, and will be found less expensive than better kinds, for it must be observed that a dozen or two of Tulips or Hyacinths may seem enough to enliven a border; but experience will show that their appearance, when planted and in flower, will be very insignificant, and nothing to the fine massive effect produced by a quantity of less expensive but equally showy sorts; and even where they are not massed but only placed about the borders in small patches, it takes a great number to make any effective display. Something may also be said with regard to colour and prolonging the season of blooming. In the former case some would object to the glare of scarlet and yellow presented by the Van Thol and Tournesol Tulips, as wearying to the eye, and certainly it is not advisable to confine oneself to them. But they may be varied by Crocuses of different colours, Snowdrops, and early Narcissus, and also by means of Hyacinths, which vary considerably. As regards the season of flowering, this may be prolonged by using such bulbs as flower successively, beginning with Winter Aconites, followed by Snowdrops, early Tulips, Crocuses, Hyacinths, early Narcissus, medium Tulips, late Narcissus, and late Tulips. These flower during the months of March, April, and May, and by a suitable arrangement they may be placed so that they may all be seen to advantage at their several times of flowering.

I once planted a bed entirely of different kinds of spring-flowering bulbs, both with the object of keeping up the display as long as possible, and of varying the colours, so that the bed while any of the bulbs were in flower presented a massive display of colour. The bulbs were all newly imported, and were planted so that they might grow and increase, which they could not do without having their proper time to form and ripen the bulbs, and as I did not intend to take them up every season the ground was trenched and manured before planting. The

bed was 7 feet wide, and about four times that length. The arrangement of the bulbs was as follows:—They were placed in rows 10 inches apart across the bed; the depth of planting varying according to the size of the bulbs—that is, about 4 inches deep for Snowdrops, a little deeper for Crocuses, about 6 inches for Hyacinths, and the others in proportion. The first row consisted of early Tulips intermixed with Snowdrops; the second, of Hyacinths; the third row, of late Tulips and Crocuses; fourth, of Winter Aconites and early Narcissus; the fifth row, of early Tulips and late Narcissus; sixth row, of Hyacinths and Winter Aconites; seventh row, of Snowdrops, Scillas, and late Tulips; and so on throughout, varying and mixing the colours and sorts as far as was convenient. Not the most scientific arrangement perhaps, but when in bloom the bed had a most pleasing effect.

From the time the earliest began to bloom till late in May when the double Poet's Narcissus was in flower it presented quite a gay appearance. By midsummer the leaves of all but the late Narcissus had died down and were removed, and the surface of the bed was pricked up with a fork and sowed with the seed of Ploex Drummondii. By the beginning of August this began to flower and continued doing so till the following winter, after which the bulbs again came up and flowered, and the bed underwent the same course of treatment. After flowering the third time, the bulbs were taken up, the ground trenched and planted with Verbenas, and the bulbs again planted the following autumn. They had increased very much, and they flowered equally well the following spring.

This method of treating bulbs, I think is preferable to the usual mode of managing them in villa gardens. They are generally put in borders already too crowded with shrubs and miscellaneous plants, are forced-up, just as they begin to grow, in the usual autumn dressing of the borders, and rarely survive the second season. If by any means a piece of ground can be devoted to them, and they are managed in some such way as that described above, it will be not only more satisfactory, but the bulbs will increase instead of diminishing. I certainly would not discourage planting them in mixed flower-borders, but it is necessary for their well-doing that they have every chance of developing the foliage as well as the flowers—that they are not crowded amongst other plants; and although summer and autumn-flowering plants may be grown between them, it should be remembered that they are likely to be injured by the exhaustion of the soil caused by planting too thickly. Another thing to be observed is, the leaves should not be cut off in a green state, as is often practised, because they are said to look untidy; the leaves are necessary to the proper development of the new bulbs—a fact too often lost sight in villa gardens, and this is one great reason why bulbs so soon dwindle away. It is also important to mark them, so that may be known where they are when there is nothing left of them above ground.

Of the adaptability of bulbs for pot-culture much has already been said; and although the necessary materials for the purpose of growing them in pots are very simple, some would seem to imply that materials are necessary which are certainly not within the reach of all. I have grown them very successfully for years, and used different kinds of soil, and covered them with different materials, as coal ashes, sawdust, old tan, and common earth, and all with nearly the same results—in fact, I have come to the conclusion that the material they are covered with after potting is more a matter of convenience to the operator than of consequence to the well-doing of the bulbs, and that the best soil to grow them in is about one-half silky loam, and one-half of dung, rotted to a crumbling state, mixed with an equal portion of leaf mould, from leaves that have been swept up from paths, lanes, &c., and allowed to rot. These are sure to have a large proportion of grit mixed with them, which keeps the soil porous and open. If grit is not thus obtained, a suitable portion of it should be mixed up in the dung. Mix these ingredients well together, and you have a soil in which spring-flowering bulbs will thrive. But if loam is not to be got, the leaf mould as described will do alone, or any common garden soil may be mixed with it; or even if these are not readily obtained there need be no fear of potting the bulbs in any porous soil in which a tuft of grass will grow, for it is a mistake to suppose that Hyacinths, or Tulips, or Crocuses are particularly nice as regards the nature of the soil they are placed in, provided it be sweet, and free from any grubs or other destructive insects. But this much may be observed, that bulbs, in common with any plants that are grown in pots, are limited in the supply of

soil in which they can form roots—that they have not so much room as plants in the open ground: consequently, the soil in the pot should be proportionately richer, or if the soil is not rich, the roots should be fed with liquid manure. But even this is only requisite when it is desired to make use of the bulbs for another year, when they must be sustained during the process of ripening as well as whilst producing the flowers.

My mode of potting bulbs is to use a soil composed of loam, dung, and leaf mould, as before mentioned. This is well mixed, and if there is not quite enough sand in it, add a little more: fine gravel will do as well as anything.

In preparing the pots, which should be perfectly clean and dry, I always place a piece of broken pot over the hole in each pot. This is placed so that it does not stop the exit of water, as it would do if placed the hollow side upwards when the soil had worked down to it. I then place in each pot a handful of crocks broken rather small, and then a layer of rough soil. This method of draining pots I find effectual, and it is important that it should be so. The pots are next filled two-thirds with soil, the bulbs are then placed with a little silver sand under each to encourage the fibres, and the pots filled up with soil. I like to cover the bulb to the crown, but some prefer letting them stand up half out of the soil.

For Hyacinths I like to put one in a four-inch pot, Crocuses about six, Tulips three, and Snowdrops about twelve in the same sized pot; for Narcissus I prefer putting four or five round a larger pot as I think they show so much better in a fine cluster, and Hyacinths the same if they are matched in colour and height; but they sometimes vary so in height as to spoil the effect in a large pot.

When all are potted, they are placed close together on a level piece of ground where there is no chance of the water standing, the labels are then raised on sticks about 8 inches high, and all are then covered with common earth or any loose mould. I prefer this to ashes, sawdust, or any other material, as it leaves no unpleasant appearance on the surface of the soil as ashes and sawdust do if not thoroughly cleaned off. The labels are left just above the soil, so that it is easily seen where each sort is—a matter of importance where they are to be drawn at different times for forcing or otherwise, as one can be taken out without disturbing the others. If they are not wanted for forcing it is not advisable to uncover them till March if they are in a frame. The soil may be scraped away from the crowns a little in February, and the Narcissuses encouraged, and covered up again, as they apt to root over the sides of the pots.

For window decoration these bulbs are invaluable, and in a warm room some may be got on much earlier than others, so that a succession may be kept up for a long time. When grown for window decoration the treatment is the same as if grown for the conservatory, until they are divested of their winter covering, and then the only difference is, that in one case they have a glass roof over them, and in the other they receive the light all on one side, and are apt to get drawn out of the perpendicular. A suitable stick should be provided, or they are apt to break off with their own weight. But in either case, after flowering, they may be planted in the borders, and they will flower there another season, although not so strongly.

All bulbs that have flowered in pots one season can be planted out in the borders, where they are more likely to come up again and flower than if kept in pots. In fact, I have known Hyacinths flower successively for many seasons after being thus turned out of pots in which they have flowered already, and while this can be done there is no need to throw any away, as a few new bulbs may be procured every year for flowering in pots, and afterwards used to replenish the borders, where they will not be lost.

Of the merits of growing, or rather flowering Hyacinths in glasses, I have always had my doubts. It may seem curious to have a plant growing beside one in a room with every part visible; but I do not see any extra beauty in a glass-grown Hyacinth; indeed, I think that the same plant would look better in a suitable-sized flower-pot, and certainly when they begin to topple over it is much easier to support them in a pot than it is in a glass. Nor are they so useful afterwards when grown in glasses, as the bulb has worn itself out in the process of flowering, and has no strength left to prepare for flowering another season. Yet the practice is carried on by a very large class, is honoured by time, and sanctioned by custom, and it may scarcely be proper for one to express an opinion opposed to what is so regularly done as sure as the bulb season comes round.—F. CHITTY, *Stamford Hill*.

## ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 23RD.

**FLORAL COMMITTEE.**—There was a most beautiful *Caladium* from Borneo from the Messrs. Low & Son, of Clapton, named *Lowii*, to which a First-class Certificate was unanimously awarded. The form of the leaf is the same as that of *Alocasia metallica*, or between that and *Caladium Veitchii*. The midrib and strong veins are whitish, and there is a metallic lustre in the bright green of the blade of the leaf. This is much the best of the *Caladiums*. The same firm sent an exquisitely beautiful new *Cypripedium*, also from Borneo, within the last few weeks; this also had a unanimous award—a First-class Certificate. There were two flowers on the scape, the one above the other; the leaves are plain green, 6 inches or 8 inches long, and of great substance. The flowers are remarkably gay, and much more so than any yet known in the genus. The pouch, or slipper, is purplish in front, shading to pure white and some yellow towards the bottom; the two side petals are long, curved, and twisted, with a bright orange ground colour stained with rich purple, and the two back sepals are broad, erect, and with a broad band of white all round within the margin, the centre being deeply stained with purple, but lighter on the inner surface. It is named *Stonii*, after Mr. Stone, gardener to J. Day, Esq., of Tottenham, who first bloomed the plant. They also sent a new Brazilian *Orchid*, in the way of a *Bifrenaria*, with orange flowers; and two plants of an *Ipomæa*, after *limbata*, fine blue flowers, with white edging.

Mr. W. Paul sent three new *Roses* of 1862. *Eugène Bourcier*, a fine dark *Rose*; *Turenne*, a large scarlet, tinged with purple; and *Louise Darzins*, the best white Hybrid Perpetual, and said to make a good bedding *Rose*. Also *Picea nobilis*, and two forms of the silvery *nobilis*, both more handsome than the green species.

Mr. Bull sent some very pretty *Petunias*, and a very handsome new Fern, with the young leaves in the exact shape of a *Caladium* leaf, with a lighter band along the centre just as in some *Caladiums*. It is *Doryopteris nobilis*, and the leaves will yet become palmate-like, and, perhaps, more froun-like than those of *Caladiums*. The Committee were unanimous in their award to it.

Messrs. E. G. Henderson & Son had a unanimous First-class Certificate for the variegated *Solanum capsicastrum*, of which there were two kinds, and both remarkably handsome, for dinner-table decoration or any decorations in-doors.

Mr. Barker, of Godalming, had a First-class Certificate for a handsome weeping *Cupressus macrocarpa*, and he sent a large collection of cut blooms of *Tropæolums*. And the Messrs. Lee had a First-class Certificate for a Golden common *Spruce*, on the supposition that the colour would be permanent as in the Golden *Yew*.

There were many *Dahlias*, *Verbenas*, and *Hollyhocks*, with odds and ends as *camp-followers*; but the most noteworthy of them was Lord Dundreary *Dahlia*, which had been awarded a Second-class Certificate already, and which the judges of it pronounced to be a "constant" flower, having been equally good throughout the season at all the shows. The Committee sent their special thanks to Mr. Turner, of Slough, for sending a large collection of first-class *Dahlias* which were sent out by himself, in order to assist the Committee in comparing the new seedlings with the best of what are now in the market.

A correspondence between the Secretary of the Committee, Mr. Eyles, and the Council of the Society was read, and the gratifying announcement was made out of it that £20 were at the disposal of the Committee to make the best of for a *Chrysanthemum Show* in November!

**FRUIT COMMITTEE.**—Mr. C. Edmonds in the chair. There was a large show of fruit on this occasion, several prizes having been offered; and the Committee had to defer deciding on the merits of several kitchen Apples and other seedlings till a future occasion, their time being fully occupied in awarding the prizes.

In class A, for the best three dishes of dessert Apples, distinct kinds, Mr. D. Cunningham, gardener to the Bishop of London, Fulham Palace, was first with Early Nonpareil, Yellow Ingestrie, and Fulham Pippin, a seedling from the Ribston Pippin, very like the Margil but larger. Mr. Swinerd, Minster Abbey, had good dishes of Cox's Orange Pippin, Ribston Pippin, and Kerry Pippin, with which he gained the second prize.

In class B, for the best three dishes of dessert Pears, distinct kinds, some excellent specimens were shown. The highest award was made to Mr. Spivey, gardener to J. A. Houlton, Esq.,

for Flemish Beauty, Gansel's Bergamot, and Jersey Gratioli. Mr. Turner, of Slough, had also very good fruit of Jersey Gratioli, Belle de Bruxelles, and Fondante d'Automne. To these a second prize was given.

In class C, Plums, three dishes, distinct kinds, Mr. Kaile, gardener to the Earl of Lovelace, exhibited nicely-grown fruit of Coe's Golden Drop, Impératrice, and Reina Claude de Bavay. This collection was considered the best, and, consequently, it received the first prize. Mr. Bousie, gardener to Lord Taunton, Stoke Park, Slough, had Prince of Wales, Magnum Bonum, and an excellent dish of Coe's Golden Drop.

In class D, for the best single dish of Cherries, the only competitor was Mr. Tillery, gardener to the Duke of Portland, Welbeck, who received the first prize for a very good dish of the Morello.

The next class, E, was for the best Melon, and sixteen fruits were brought forward, only two of which were Scarlet-fleshed, the remainder being chiefly Golden Perfection. The specimens exhibited of this fruit were generally handsome and well-grown. Only one prize was offered for Melons in the schedule, and this was awarded to Mr. Bousie, of Stoke Park, for Golden Perfection; but the Committee recommended that extra prizes should be given to Mr. Whiting, gardener to J. Hope, Esq., the Deepdene, Dorking, for the same variety, and to Mr. Curd, gardener to M. G. Thoys, Esq., for Sulhampstead House Seedling, on account of the excellence of their Melons, and their near approach to the one which obtained the prize.

In class F, which was for the best dish of Grapes, there were no entries; and in class G, for the best dish of Figs, the first prize was taken by Mr. Pottle, of Little Bealings, Suffolk, with very good fruit of the White Ischia. Mr. Ross, gardener to C. Eyre, Esq., Newbury, exhibited the Brunswick, for which he received the second prize.

Mr. Rivers, of Sawbridgeworth, had an interesting collection of seedling Peaches, the best of which was one raised from a stone of the Pitmaston Orange Nectarine. He likewise showed the Pitmaston Pine Apple Apple; Belle Agathe Cherry, which is a late kind of Bigarreau; and retarded Moorpark Apricots, which, though shrivelled, were rich and sugary. They were grown in pots, and placed in an orchard-house with hedges for sides.

From Mr. Graham, of Cranford, came a seedling Pear called Graham's Bergamot, a small Pear of good flavour, and a great bearer; also a white Grape resembling the Chasselas Musqué.

## NOTES WHILST RESTING.

*(Concluded from page 490.)*

THE Guernsey Lily was introduced into England between the years 1629 and 1669, for in Parkinson's very full and accurate description of garden flowers in his "Paradise," published during the year first named, this Lily is not mentioned; but Evelyn in his "Kalendarium Hortense," published during the year named secondly, enumerates, without comment, among the flowers blooming during September, "the Garnsey Lilly, or Narcissus of Japan."

It is probable that this flower reached Guernsey between those two years, and would thence soon reach our gardens—such date coinciding with Mr. Bradley's statement, which I accept as much the most probable account of this flower's first introduction.

"There is one thing," says Mr. Bradley writing in 1731, "which I cannot help taking notice of, which relates to this plant's first coming into the island of Guernsey, told me by M. de St. Marets (Saumarez), a very curious gentleman of that place. He says that in his grandfather's time a ship from China came in there, when some of the sailors gave a parcel of these roots to a person who then kept a public house. From thence came the whole stock that is in the island, and that the place is now in being, close by the sea. This story differs, indeed, from that which we have had of a ship's being cast away, and the roots floating to the shore, and there taking root; but I think this traditional account of M. de St. Marets is the more probable of the two."—(*Appendix to New Improvements.*)

About the same time it appears to have reached Paris; for Cornutus, a physician of Paris, in his "Canadensium Plantarum aliarumque nondum editarum Historia," published in 1635, is the earliest writer who mentions it, and does so under the title of "Narcissus Japonicus rutilo flore"—(Japan Narcissus with a red flower). He states that within a few years previously it

had been brought from Japan, and no expense being spared in cultivating it by M. John Morin, at length it was induced to produce flowers on the 7th of October, 1834. Cornutus gives a description and drawing of the plant in flower, both very good.

Pierre Morin, son of the above-mentioned, in his "Remarques Necessaires pour la culture des Fleurs," published at Paris in 1658, mentions the "Narcisæ du Japon" among the flowers particularly susceptible of injury from cold.

Rea, in 1665, mentions it among the flowers known in England as "the Narcisus of Japan, or Garnsey Lily, which there prospers, bearing in October peach-coloured flowers." The first person decidedly mentioned as having cultivated it in England is a General Lambert, of Wimbledon. In a MS. of Dr. Friend's, preserved in the Lambeth Palace library, the General is stated to have sent flowers of this plant to Dr. Friend in 1659.—(*Douglas' Description of the Guernsey Lily.*)

Dr. Douglas, in his monograph just quoted, published in 1737, gives all the traditions about the first introduction of the flower to that island, most of them vague, but those which are more particular, coinciding partly, or entirely, with Mr. Bradley's account. One gentleman evidently had the narrative from Mr. Bradley's informant—namely, Mr. Henry de Saumarez (not St. Marets), author of the "Marine Surveyor." His grandfather had but six roots, but he did not keep a public-house, and he had them about "fourscore years ago," which deducted from the date of Mr. Douglas's book, would assign 1657 as about the date of the introduction of the bulbs to Guernsey.

Kæmpfer, who is the first naturalist who discovered this plant in Japan, was there in 1690, and the two following years, but we have a fuller description of it by Thunberg, in his "Flora Japonica," published in 1784, under the name of *Amaryllis sarniensis* (Guernsey Amaryllis). He says, that in Japanese it is called by the various names of Seki San, Sibito banna, and Doku Symira; that it is native of the hills about Nagasaki; flowers in September, and that the Japanese know the bulb to be poisonous, the name Doku Symira, according to Kæmpfer means "Poisonous Symira."—(*Kæmpfer's Amoenitatum Exoticarum*, published in 1712.)

Japan, however, does not appear to be the sole native country of this bulb, for we have reason to believe that it is also found in China, and it is certain that Loureiro in his "Flora Cochinchinensis," published in 1793, says that the *Amaryllis sarniensis* is cultivated "in Sinis," or China, on account of its beauty, and is there called *Haien tsao* and *Tuyen thao*.

We entirely agree with the treatment of this flower recommended by Mr. Earley, at page 489 of our last Number. So treated, it bloomed year after year in the garden of the Rev. Mr. Butler, at the foot of the Coomb Hills, near Hungerford. In Guernsey it is planted in the light, loamy soil of the gardens, and beneath the shade of tall trees, and with the surface covered with growing grass. In the garden at Le Vallon, and elsewhere, we were assured by Mr. Carey that it blooms from year to year, and its bulbs are never disturbed. As further evidence that Guernsey is not the only place in Europe where it will flourish in the open air, the same gentleman assured me that he had seen it equally excellent in several parts of Spain.

Various have been the genera in which botanists have included this bulb, such as *Narcissus*, *Amaryllis*, and *Lilium*, but in 1821 Dr. Herbert established a new genus *Nerine*, and it included the Guernsey Lily under the name of *Nerine sarniensis*, a happily-applied name, for *Nerine*, or daughter of the sea, aptly alludes to the fondness of the flower to a sandy soil in the vicinage of the ocean.

Dr. Herbert was one of our most successful cultivators of bulbous plants, nor did the Guernsey Lily defy his skill, though residing so far north as Spofforth, in Yorkshire.

He kept the plants under glass whilst their leaves were green, merely taking care to exclude frost from them, and to admit air to them as freely as the season permitted without the reduction of temperature necessary to be avoided. During this period of growth they were also kept moderately moist, and near the glass. The leaves under this treatment decay about midsummer, and no care is needed except to take care, by having the bed of a light soil, and well drained, that the bulbs while dormant do not suffer from excessive moisture. We would have the bulbs unmoved in the same bed from year to year, and merely sheltered by a glass-covered frame, with extra covering during frost, which must be excluded.

It may be objected that it is much less trouble to purchase fresh bulbs annually; and admitting such objection to be valid,

yet there is the countervailing fact that the flowers are never so brilliant, so fine, or so lasting as when preserved unmolested in the bed from year to year.

The flower is paler and weaker from the dried imported bulbs, and I was told by many good authorities in Guernsey that the bulbs become scarcer and weaker from this artificial treatment pursued to supply the demand for exportation.—*QUIS.*

## THE RASPBERRY.

As Mr. Appleby has recently in this Journal so ably set forth all the points in the culture of the Raspberry, I will only make a few remarks in addition, or rather in confirmation of what he has said on the subject, with some practical lessons which the last few years have given on the matter, omitting as far as possible all repetition of what has been previously stated; the culture being so generally well known, that details respecting it are hardly necessary.

Taking, therefore, a cursory history of this fruit, we will see that for many years prior to about 1844 very little attention was paid it in the way of improving the varieties then in use. A red one and a white one were almost all that many gardeners were acquainted with, and these thrust into some obscure abody corner generally succeeded pretty well; but about the above time, a vast improvement was made by the introduction of the Fastolf Raspberry, which for many years was very popular, and in places where it does well I have no doubt remains so yet. A large, well-tasted fruit on a plant of moderate growth, and remarkable for its bearing qualities, the Fastolf Raspberry remained, therefore, for many years at the top of its class, until others envious of its distinction came forward to dispute its position, and at the present time we have a number of aspirants to general fame. In my own case, I felt so satisfied with the Fastolf for several years, that I did not think another was necessary, until the dry seasons of 1857, 1858, and 1859, told seriously against this fruit on the dry ground the stools were planted in; but the failure or partial failure of the crop was set down to the absence of rain, and other causes of a like nature. The following season, though differing widely from those above referred to, did not effect that improvement in the character of the Fastolf Raspberry that was looked for, and the conclusion came to was, that the variety is "worn out," its constitutional debility unfitting it for any longer fulfilling the duties required of it. Every allowance has been made, new plantations formed on ground that has not been so occupied for many years, but all to no purpose, the plant bears profusely, and the fruit is as good as need be wished for; but the plant scarcely makes any wood, and that often only from 2 feet to 3 feet long. Another evil, which to some may appear as a benefit, is that many of the shoots of the current season bear in August and September, and some very useful fruit is thereby obtained, but it impairs the shoot's bearing in the following season. Thus we often have great difficulty in obtaining canes for the next year, and then often very short and weak, with, perhaps, now and then, one of a loose, rampant growth, overtopping everything else; but there are exceedingly few of these, and the plantation has anything but a promising appearance in the autumn.

Now, I believe this is not the case everywhere. On damper or more congenial soil the Raspberry flourishes and bears as well as before; but as the garden here is a dry one, and just the reverse of the one on which this fruit is found in a wild state, its constitutional vigour may be fully expected to give way sooner than when placed in a situation of an opposite character, and I can only account for the lack of success in 1860, 1861, and 1862, from this cause, as there has been no want of moisture for other things. I would, therefore, like to have the experience of other cultivators on this matter. I know there are many who disbelieve in constitutional decay in fruit trees, and certainly there is less reason to expect it in a Raspberry than in an Apple, Peach, or Pear; but I can hardly reconcile myself to any other cause, for the variety which ten years ago was healthy, vigorous, and all that could be wished for, now drags out a wretched existence, bearing itself to death as some compensation for its unkindly appearance; but stools dying that are only three, or, perhaps, four years old, and the shoots for the ensuing year hardly rising above one's knee, give tokens of something amiss, which I am at a loss to attribute to anything else than a wearing-out of the variety in question, not, perhaps, on all soils, but on the one we are obliged to have it grown on.

I would have had some reluctance at coming to the above conclusion had a case not come under my notice, which seems to confirm what I say. On the outskirts of a piece of back garden ground, our kitchen-garden foreman found a wild Raspberry, apparently a seedling, with fruit on of a tolerable size, and flourishing in all the luxuriance which betokened its being at home, and though surrounded by Brambles and other robust herbage, it seemed to be quite able to take care of itself, and bid defiance to all encroaching vegetation. Taking notice where it was, he carefully dug them up the ensuing autumn, and the result is, a row of healthy, vigorous, well-grown plants, which have borne a good crop the past season, and produced canes from 8 feet to 10 feet long. I do not mean to assert that the fruit was better than the Fastolf or other kinds, but it was good, and there was plenty of it, and the plant looks well for another year, the canes presenting a giant-like appearance compared with the other. Now, it is this result which has convinced me that the Fastolf is either "worn out" on our dry soils, or become unfitted for the place, which amounts to the same thing, for the new one above spoken of is planted side by side with the other, so that there are no advantages of situation to account for the difference; and as the seedling was also from dry ground, there is reason to suppose that it may be better adapted to a similar situation than one originating in a position diametrically opposite. Such is my opinion, and how far it meets the approval of others I shall be glad to learn. The above facts certainly help to strengthen my case, and they are not overstrained.

With regard to other varieties of Raspberry I have but little practical experience to report. I have the "Prince of Wales," which is reported to do well in many places, but I have not had it long enough to give a just opinion of its merits. I have, however, but little hopes of any one doing very well for any length of time, on so dry a soil, unless it be a variety raised on such soil, in which case it may be said to be, to a certain extent, acclimated. How far this doctrine will meet the views of those who have previously arrived at a contrary opinion remains to be shown. One thing however must be borne in mind, that reports from a soil more congenial to the Raspberry ought not to be opposed to the above, for with a different soil there is no question but the results above described would have been different. It is more especially, therefore, to those, who, like myself, are obliged to plant the Raspberry on a soil adverse to it, that the above is addressed, and their report if different from mine will be no less agreeably acceptable.—J. ROUSON.

## PUTTERIDGE GARDENS.

(Concluded from page 492.)

WE now come to what we have always considered to be an especially beautiful feature. In the centre of the lawn is an avenue, not of trees, but of flower-beds, formed of circles of 10 feet and 5 feet diameter alternately, there being twenty-four beds on each side of the avenue, the two opposite beds being planted alike. To produce variety, these are all planted in the pyramidal style, and with three or four distinct colours in each bed. To give an idea of the exquisite beauty of these beds, we would mention that the two first you arrive at, going westward, are ten-feet circles, the centre, a dark Fuchsia 4 feet or more in height, fringed with purple and white Pentstemons; then a double ring of dark Victory Calceolaria; a double ring of buff Prince of Orange Calceolaria; and finishing close up to the grass with a double ring of yellow Prince of Orange Calceolaria. The next two, five-feet beds, have an *Acacia pubescens* in the centre, with a plant of crimson Unique Geranium flaunting from its stem; next a broad ring of pink Christine Geranium; then a double ring of *Lobelia speciosa*, and edged close to the grass with *Arabis variegata*. We might go on describing pyramid after pyramid, but will notice only two, about the centre of the avenue. These are centred with *Brugmansia Knightii*, some 8 feet high, with large, double, white flowers hanging down; a Canary Nasturtium clothes the naked stem, and flaunts its yellow flowers through the large leaves. Through the Nasturtium peep fine spikes of a scarlet *Salvia*, followed by a broad ring of *Ageratum*, and that by one of yellow Calceolarias, with a rim of blue *Lobelia* close to the grass. The avenue consists of a wide space of beautiful lawn, and there is plenty of room between each bed in the rows, affording not only an ample area for promenading, but a nice relief to eyes accustomed to streets and

roads, or somewhat overcome by the brilliancy of the beds. Owing to whatever cause, we found this avenue especially patronised by the ladies, probably from the fact that their full-lengthed dresses swept more agreeably over the turf than over the gravelled paths. Many thanks to whomsoever it is owing that no notices are exhibited instructing the visitors to "Keep off the grass." This avenue is terminated by a mound with Roses on pillars and chains enclosing seven beds of low-growing plants, each edged with a contrasting colour. Some of the columns and chains are uncovered, owing to the effects of the frost above mentioned, but the group of beds below prevents this being much noticed. The centre raised bed has white *Feverfew* and *Pentstemons* round the column, edged with large-flowering *Heliotrope*; the upright side of the bed is clothed with *Sedum roseum*. The six surrounding beds are in three pairs, opposite each other: one pair of *Bijou Variegated Geranium*, with a broad baud, densely bloomed, of the old purple *Verbena Charwoodii*; a second pair with crimson *Ivy-leaved Geranium*, with an edging of *Baron Hugel* ditto; and the third pair with yellow *Prince of Orange Calceolaria* in the centre, a broad band round of *Lobelia speciosa*, and a narrow band, next the grass, of *Cerastium tomentosum*. These, as well as the other beds, are quite full.

Nearly opposite to this, and close to some fine Elms, so pleasant for the shade they afford, is another group of beds, in a circular form, consisting of seventeen beds, all planted simply, but differently from last year. The centre is a circle some 9 feet in diameter; this has a yellow *Cassia corymbosa*, 6 feet in height, for a centre, with a thin ring of purple *Pentstemon*; the bulk of the bed is of white *Feverfew*, but the level is broken by white and purple spikes of *Pentstemons*; an edging of grey *Heliotrope* surrounds the *Feverfew*, and one of *Cerastium* close to the grass. The eight beds round this, of rounded squares and triangles, are all centred with tall, dark *Fuchsias*. Four opposite each other are planted with *Scarlet Geraniums*, and edged with the silver plant *Cineraria maritima*, and four with yellow frosted *Calceolaria Aurea floribunda*, edged with *Purple King Verbena*. Of the outside ring, the four smaller beds have each a *Honeysuckle* in the centre, and that is now covered and draped with *Tropaeolum canariense*, the beds being filled with purple *Geraniums*. The four larger beds have each a massive *Scarlet Geranium* in the centre, and a light-flowered *Fuchsia* on each side of it, so as to divide the centre of the bed by these three large plants; the bulk of each bed is then filled with a fine rosy *Horseshoe Geranium Rubens*, and that again edged with a broad baud of variegated *Manglesii Geranium*.

The ribbon-borders on each side of a long walk are a source of great attraction. The longest, backed by a wall of *Roses*, *Myrtles*, *Ceanothus*, &c., is about 340 feet long, and has previously been planted in straight lines of colour—twisted lines, spotted lines, &c. This season, to humour the straight wall and the straight walk, the front and the back rows are straight, and the rest are waved or roughly vandyked. This causes short, arched pieces to be thrown in on back and front. The front line is *Golden Chain*; then a line and arched piece of blue *Lobelia*, backed by white *Variegated Alyssum*, which meets the first waved line of *Brilliant Geranium*; then a similar one of yellow *Calceolaria* very massive; then a line of *Perilla nankinensis*, with its pretty crumpled shaded purple leaves; then, just a little higher, a noble line to suit of the *Trentham Rose Geranium*; and above that, semicircular sweeps of a large white *Chinese Daisy*, the back lines being *Ageratum* and *Prince's Feather*. The opposite side of the shorter border is exactly similar, but the *Prince's Feather*, whose spiral shape, as well as colour, were wanted for the centre, has refused this season, owing to the coldness of the ground, to mount high enough, though few would notice the omission unless pointed out to them. The opposite or lawn side of the shorter border is done in straight lines, beginning at the grass with *Golden Chain Geranium* and orange *Gazania splendens*, in alternate plants, then blue *Lobelia speciosa*, then a fine line of *Scarlet Geranium Brilliant*, followed by yellow *Calceolaria*, then *Perilla*, backed by *Trentham Rose*, and that again by the large *Chinese Daisy*, and what should have been *Prince's Feather*, but the want of which is never noticed. We heard numerous opinions as to the straight and waved styles of planting, and incline to think that the straight is most effective when looked at from either end, and the waved most pleasant as you pass along the walk.

Beyond the Elm trees are other groups of beds, centered and edged in different ways, more rough ribboning of lines of colour in front of shrubberies, masses of *Hollyhocks*, fronted with tall and

dwarf Dahlias, edged with Calceolarias, Geraniums, variegated Arabis, and Cerastiums. In addition to these, alpine gardens and rock and Fern retreats add their sombre attractions to those of their more showy companions, some of these retreats being festooned abovehead with long wreaths of Ivy; but of these, and the enclosed fruit gardens, &c., we must not at present speak.

This somewhat lengthy enumeration will only serve to show how much there is to be seen at Putteridge, giving at the same time but a very faint idea of the splendid reality. We had well nigh said it is "a blending of all beauties." So far as outside gardening is concerned, after making the necessary allowances for area, &c., we have it upon the highest authority that taking "Putteridge as a whole, or the beds individually, it far, very far exceeds either the Kew or the Crystal Palace gardens. Many of the beds cannot be excelled, and the wavy ribbon is almost beyond what could be conceived." Couple with this statement the fact that the cost of Putteridge is as nothing in comparison with that of the others, and the merits of Mr. Fish will at once be seen to be of the very highest order. Were our descriptive powers in any degree commensurate with our sense of admiration, the pleasing task of recording what we have beheld in the grounds at Putteridge would be more adequately performed. Mr. Fish will probably pardon us for questioning even his ability suitably to describe the fair scene which his ideas of the beautiful and his professional skill have called into existence. Of his powers, indeed, we have had many proofs in the numerous articles which he has, during many years, contributed to the leading horticultural journals (especially his description of the salient points in English, Scotch, and Irish gardens, now being brought out in *THE JOURNAL OF HORTICULTURE*), but it would be putting his well-known modesty to too severe a trial to request him to make the attempt.

We may add here that during the three days of admission, nearly 9000 persons availed themselves of the privilege of visiting the gardens, and it may be safely affirmed that not one returned disappointed. Many more, we believe, would visit Putteridge, but from the dread of their horses being placed so thickly in the stables; we can imagine the risk arising from the packing of something like 140 horses in a space properly adapted for the convenience of a few. A place out of doors seems also desirable for carriages. We content ourselves with mentioning this difficulty, not seeing how it is to be remedied very well.

Putteridge Garden was about the first in this country thrown open to the public without any control being exercised over the visitors, or any fee expected or desired, and during the many years they have been so opened, thousands of persons, of all classes, have flocked to behold them; and if "a thing of beauty is a joy for ever," how happy must they be who have thus ministered to the innocent enjoyment of so many human beings! *Apropos* of this, in passing through the grounds during our recent visit, we heard a worthy gentleman say to Mr. Fish, "I envy you and the Colonel to-day." "Why?" "Because of the luxury you must enjoy in being able to contribute to the pleasure of so many." "Yes, it is a luxury and a privilege too," was the reply.

We may, in passing, venture to express the hope that these visits to Putteridge are not without some influence upon the taste of the visitors; and should be glad to know that the neat flower gardens and windows well filled with plants so common in this neighbourhood, are, in some degree, the result of lessons learned from this silent but most eloquent teacher.

We were sorry to perceive that the throwing of paper bags about the grass is threatening to become a nuisance. In spite, however, of these few delinquencies, we have the authority of Mr. Fish for stating that nothing could be more correct and honourable than the general behaviour of the great assemblage of visitors.

And now, once again, thanks, hearty thanks to the gallant gentleman for another series of most delightful treats. We trust that he finds himself in some degree compensated for his pains by the sight of the happy, blooming beauties which on these occasions Luton and other places pour forth to give an additional charm to the scene. We were going to say something about the presiding genius of the place; we know, however, that he needs no praise of ours, after the professional criticism we have before quoted. He must, nevertheless, allow a word of thanks to "the men." We know with what hearty good will and earnest zeal they give themselves to extra toil to prepare for the visitors, while of their courtesy we have had many instances. Let them emulate their chief, not professionally

merely, but in all those sterling qualities which characterise him as a man, eye, as "the highest style of man." "We were instructed at Putteridge," will be to them one of the best passports to honourable positions.—(*Luton News*.)

### THOMAS FAIRCHILD, THE OLD CITY GARDENER.

ON Whit-Tuesday is delivered in St. Leonard's Church, Shore-ditch, a "botanical sermon"—the Fairchild Lecture—for which purpose funds were left by Thomas Fairchild, who had the Ivy-gardens and a vineyard at Hoxton. He wrote the "City Gardener," 1722, and his name appears in the Hoxton rate-books as early as 1703. Dying rich, he left to the parish of St. Leonard's £50 (increased to £100 by the parishioners), the interest to be devoted to a lecture "on the wonderful works of God in the creation; or on the certainty of the resurrection of the dead, proved by the certain changes of the animal and vegetable part of the creation." In 1856, the Fairchild Lecture was delivered at St. Leonard's by the pious and eloquent Bishop of Oxford. It was formerly the custom of the President and several Fellows of the Royal Society to hear this sermon preached. In 1750, the day was Whit-Sunday, when Dr. Stukeley attended, and was afterwards entertained by Mr. Whitman, the vinegar merchant, "at his elegant house by Moorfields, a pleasant place, encompassed with gardens, well stored with all sorts of curious flowers and shrubs."

Fairchild's book is a thin octavo, entitled "The City Gardener," and dedicated to the Governors of Bethlem and Bridewell Hospitals. In the introduction he says, "I have upwards of thirty years been placed near London, on a spot of ground where I have raised several thousand plants, both from foreign countries and of the English growth; and in that time, and from the observations I have made in the London practice of gardening, I find that everything will not prosper in London, either because the smoke of the sea coal does hurt to several plants, or else because those people who have little gardens in London do not know how to manage their plants when they have got them. And yet I find that almost everybody whose business requires them to be commonly in town, will have something of a garden at any rate. I have been, therefore, advised to give my thoughts in this manner, that every one in London, or other cities, where much sea coal is burnt, may delight themselves in gardening, though they have never so little room, and prepare their understanding to enjoy the country when their trade has given them riches enough to retire from business."

For court-yards and close places, he says, "This part of the city-gardening depends upon more skill than all the rest; for here we have little liberty of air." For these places he recommends Lime, Lilac, Jasmine, Fig, Mulberry, Virginian Creeper, Vine, Privet, Angelica, Lilies, Perennial Sunflower, Martagon Lily, Tradescant's Starwort, London Pride, "Currans," Elder, Gelder Rose, to which may be added annuals and biennials of various kinds. To encourage the planting of such places he instances "two large Mulberry trees now growing in a little yard about 16 foot square, at Sam's Coffee-house, in Ludgate Street;" two others at the Hall of the Clothworkers' Company, which "bear plentifully;" Figs in close places about Bridewell; and other Figs in the garden of the Rev. Dr. Bennett, at Cripplegate, which bear well. "At the Rose Tavern, without Temple Bar, there is a Vine that covers an arbour, where the sun very rarely comes, and has had ripe Grapes on it; and at a coffee-house next to Gray's-inn-gate, there is a Vine which grows very well in a small pot, though it is constantly kept in a close room; this year it was full of leaves before Christmas."—(*City Press*.)

PRODUCE OF AN ORCHARD-HOUSE AT HURSTBOURNE PARK.—A lean-to orchard-house 164 feet long, erected by the Earl of Portsmouth in the spring of 1861, at his seat Hurstbourne Park, Hants, has this season been remarkably productive. From six established Peach trees on the back wall 1350 large-sized and fine-flavoured Peaches have been gathered; or, calculating the crop by measurement, the produce of the six trees would amount to 8 bushels and 1½ peck. Besides which the house has produced a full crop of fine Cherries, both from trained and potted trees; a large quantity of Strawberries of fine flavour from pots; also from pots Plums, Peaches, and Figs, of which no record of the number or weight was kept.—*J. L.*

## CULTIVATION OF CLERODENDRONS.

NOT less remarkable for brilliant-coloured flowers, than, when well cultivated, for rich tropical character and appearance, the genus *Clerodendron* certainly stands pre-eminent as "the Glory Tree" of our plant-stoves and exhibition-tables. Being natives of tropical India, delighting in the moist atmosphere of tropical forests, and being subject in their native habitats to a season of rest, and another of active growth, they require treatment peculiar and systematic in this country, where possibly they are yearly seen in finer perfection than in their native wilds. Agreeably to their native habits, *Clerodendrons* must be allowed to go to rest when they cease flowering in the autumn, and care must be taken to get the wood as thoroughly matured as possible, by exposing it to full sun and gradual heat, cautiously withholding water until the leaves are quite ripe and fall off. After this the plants may be placed in a by-corner of the stove, but do not trust them in the greenhouse, or they will probably perish.

About the first week in March the first batch should be started—say two of each kind, by shaking them clean out of the soil, reducing the roots, cutting them down to the lowest bud upon the young wood, and putting them into pots as small as they can be conveniently got into. The best soil to use for them is well-enriched turfy loam two parts, turfy peat one part, and leaf mould one part, liberally intermixed with potsherds, charcoal, and gritty sand. After potting, plunge the pots in a dung-frame, with a bottom heat of 75° or 80°; water cautiously until the plants begin to start, but sprinkle daily, so as to induce them to break as robustly as possible. Should a number of shoots be produced, and one or two of them seem to take the lead, to the detriment of the others, it will be advisable to remove the strongest and weaker ones so as to give those of

equal strength a good chance to grow. This treatment is more especially necessary with *C. Kämpferi*, upon which it is always desirable to get several shoots. As the plants progress in growth, maintain a temperature of from 65° to 75°, and ventilate freely every day, and through the night also, if possible, so as to promote a robust and sturdy habit. It will be necessary to keep the plants growing in the dung-frame as long as possible, and, indeed, if a deep frame or dung-pit, or a pit heated conjointly by hot water and dung heat, can be spared for their growth until the plants show bloom, no fear need be entertained but that they will be produced in a very superior manner.

As the plants progress in growth, they will require to be removed into larger pots, using the same compost, but substituting good rotten dung for the leaf mould after the first potting. Shift liberally, as a thoroughly good specimen cannot be grown in less

than a 13-inch or 15-inch pot, and a plant so grown will well repay the attention devoted to it. *C. paniculatum* is frequently seen with a panicle of a cockscomb form, which increases the size of the flower-head very materially. To induce this habit of growth, it is necessary to give the plant a slight check, by depriving it of bottom heat until it shows flower, and afterwards growing it very vigorously until the cockscomb character is fully developed. By this treatment, we have had the panicle of *C. paniculatum* upwards of 3 feet long; and though less brilliant in colour than some of its congeners, it is, when so grown, a noble-looking plant. Our woodcut represents *C. fallax*, sometimes called *affine* and *squamatum*; but *C. fallax superbum* is a much finer thing, producing, instead of one, several lateral panicles; from the base of each leaf, indeed, we have had this variety with seventeen

panicles of its brilliant scarlet flowers upon one plant at the same time. This variety is very scarce, but those who go to the trouble of hunting it out, will not regret their outlay in procuring it.

*C. splendens*, a climbing species, is a beautiful thing, either as a pot plant or a stove climber, and where, planted at a corner of the tan or tan-bed, it will grow and produce flowers in great abundance. As a pot plant, it requires to be well pruned-in after blooming, but it must not be so closely pruned as some of the kinds, neither is it advisable to reduce the roots quite so much. Give the plant a season of rest; but after it is started, keep it vigorously growing with a brisk bottom heat. This species and *C. macrophyllum* bloom naturally late in the autumn and partly through the winter; and, indeed, by starting some plants about the end of May, most of the kinds may be had in bloom until Christmas, and at that season no flower can be

*Clerodendron fallax.*

more desirable for making bouquets. *Clerodendrons* delight in rich soil, and also, in the growing season, in rich manure water. This should be prepared by placing one bushel of fresh cowdung and the same quantity of sheep's dung, in a hoghead of soft water, taking care to mix them thoroughly, and adding one peck of soot, one peck of guano, and three or four large lumps of lime. This composition must be frequently stirred for a week before using, and then it will be necessary to use it diluted with an equal portion of clean water. Sprinkle the frame or pit with the manure water occasionally, and if it is perfectly clear and sweet, a little from a fine rose or syringe will be beneficial over the foliage of the plants.

*Clerodendrons* are propagated by cuttings, both of the old and young wood; *C. splendens* by grafting and budding upon the roots of the stronger-growing species, and several kinds by seed,

which is plentifully produced. In making cuttings of the old wood, it is sometimes customary, if the wood is very strong, to split each cutting longitudinally, retaining a growing bud or point upon each, and thus two plants are procured in the place of one. Put the cuttings in very sandy loam, and plunge the pots in a brisk bottom dung heat of 80°. Cuttings of the young wood must be inserted in silver sand; and it will also be necessary to cover them with a bell or hand-glass, and to keep them in a moist growing temperature. When they are rooted, pot them off singly, and treat them as before directed. In raising plants from seed, sow in the usual manner early in March, and pot-off singly when large enough. A strong bottom heat is necessary to induce the seed to germinate. Seedlings make excellent plants, and many of them may be bloomed in small pots, which make them very handy for common decorative purposes.

This tribe of plants is very subject to the attacks of insects, especially of the red spider, thrips, and mealy bug. It is, therefore, necessary, to keep a sharp look-out, and by copious syringing and a moist atmosphere, to keep the enemy at bay. The following are the most desirable kinds:—*Clerodendron splendens*, *fallax*, *fallax superbum*, *paniculatum*, *Kämpferi*, *squamatum*, *infortunatum*, *macrophyllum*, *fragrans flore pleno*, *Bethunianum*.—(*Gardeners' Magazine of Botany*.)

ORNAMENTAL PLANTS.

*NUTTALLIA CERASIFORMIS* (Bird-Cherry-like Nuttalia).—*Nat. ord.*, Rosaceæ. *Linn.*, Monadelphia Polyandria. A dwarf, deciduous, hardy shrub, growing 2 feet high, and bearing thin,

half-transparent, oblong, or oblong-ovate leaves, pale green above, and rather glaucous beneath. The flowers—which are small, five-petalled, greenish-white—grow in nodding racemes, which spring from the base of the young shoots, opposite one of the earliest leaves; they are produced before the leaves are developed, and soon fall. From California: woods near Monterey; introduced, in 1818, by Mr. Hartweg. Flowers in February and March.

*CALOCHORTUS PALLIDUS* (Pale-flowered Calochortus).—*Nat. ord.*, Liliacæ. *Linn.*, Hexandria Polygynia. A pretty, bulbous-rooted, half-hardy perennial, producing a tuft of grass-like channelled leaves, and from among them a flowering stem 6 inches or 8 inches high, supporting three or four blossoms, each on a

slender peduncle; these peduncles grow in an umbellate manner from the base of two or three small leaves, which are produced at the top of the common stem. The flowers are hexapetaloid, the three outer divisions small, ovate oblong, obtuse; the three inner much larger, obovate, rounded at the apex, and attenuated

at the base; they are pale yellowish-buff colour, with a broad angular blotch of dark reddish-brown in the centre. From Mexico; introduced to Belgium about 1844. Flowers in the latter part of summer.

WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 452.)

We may pass over unnoticed a very large number of the Headless Lamellibranchiate Molluscs, as, although presenting many features of great interest which would amply repay an investigation, still they are such as would by no means be likely to come under the notice of those for whom these pages are intended. Passing over then in silence a number of tribes, we proceed to notice the *Mytilidæ* or *Mussels*.

Although a few species of Mussels are found in fresh water, they may be considered as a tribe to dwell in the sea, and may be generally described as oblong creatures having the mantle, so often mentioned previously, open in the front, at that end where the mouth is situated, and close behind, an opening being left for the egress of the fluid. They are provided with a foot, which is of sufficient strength to enable them to crawl about, and they usually affix themselves by a byssus, or filament projecting from the shell. Some species of *Mytilidæ* are littoral, and others inhabitants of the deep water. They are sought for in all localities as articles of food, and by many persons are considered far superior to Oysters. There is one drawback, however, connected with them, they certainly cannot be eaten with the same impunity as Oysters are, for we are perpetually hearing of people being half poisoned after partaking of this favourite fish. All attempts to detect the cause of this have hitherto proved fruitless. It appears to have nothing to do either with the freshness or staleness of the Mussel, the mode of cooking, or the season of the year in which it is eaten, but that very serious, and sometimes fatal consequences have resulted is a well-attested fact, and warns us to be on our guard in making so dangerous a meal. Numbness, debility, convulsions, and a species of nettlerash, are among some of the mildest effects of the Mussel poison, whilst paralysis, epilepsy, delirium, and death, have not unfrequently followed in its train.

*MYTILUS EDULIS* (the Common or Eatable Mussel).—The size of the ordinary English Mussel is from two inches and

half to three inches in length, and about the half of that in breadth. It is found indiscriminately, and in profusion, upon all our coasts near the edge of low water. The shell is so familiar as to need no description here. The animal is of a shape similar to the shell, thick, the mantle open in front, its margins furnished in the middle with cirrhi, or fingers, of a yellowish-white colour, occasionally tinged with brown. The foot is narrow and grooved. Pearls are not unfrequently found in the common Mussel, but they are usually small, ill-coloured, and of little or no value. This is by no means, however, universally the case, for in some parts of Great Britain, a trade more or less flourishing is carried on solely with such pearls as are found in these Molluscs. What use the pearls so found are put to remains a mystery, they appear to be bought up by some monopolist, who, we may readily believe, knows how to turn them to very good account. In a letter quoted by Messrs. Forbes and Hauley, it is said "some suppose that the pearls are sent abroad to be manufactured into seed pearls; others more gravely, that they are exported to India to be dissolved in the sherbet of the nabobs."

**MYTILUS MODIOLUS.**—This is a much larger species than the foregoing, and is from its size vulgarly called the *Horse Mussel*. It averages about five inches in length, and about two in breadth. It may be found on all parts of our coast, in various depths of water, and it is extremely common just below low-water mark, so near that women and children wade out and secure it for the table.

The animal itself is oblong, of a dirty red and orange colour, more or less speckled with a yellowish-white. The byssus or projecting filament is very strong, and of a yellowish colour. It is often found completely enveloped with this filament intermixed with gravel.

**CRENELLA.**—This little *Mytilus* is also very common on our shores, and may be found in abundance, mostly among the roots of seaweed, or among the corallines, both in deep water, and near the low-water mark. It measures little more than half an inch in length, and about five lines in breadth. The animal itself is white, and although it generally prefers a stationary life, still it has the power by means of its foot, to move about with some celerity. It is usually found attached to seaweed by its filament, where it remains patiently awaiting such food as may come within its reach.

**CRENELLA MARMORATA.**—This is another little species of the Mussel tribe, measuring about three-quarters of an inch in length, and five lines in breadth. It is common on our coasts, more particularly where *Ascidia* are found; for the *Crenella marmorata*, if not fixed to stones, is generally to be met with buried in the tough skin of an *Ascidian*. The creature is long, thick, and of a pale yellow colour; the foot is white, and of more use as an organ of feeling than of locomotion. The animal has, however, the means of changing its situation—that is, when attached to the rock, but not when it has burrowed into the skin of an *Ascidian*. The method it employs of detaching itself from stone is by throwing off its old filament (byssus), and by throwing out a fresh one.

These specimens include all that are likely to be met with on the coast by ordinary tourists, and, therefore, are the only ones of the *Mussel* tribe we conceive it necessary to specify. We proceed now to the *Ostrea* or *Oyster Tribe*, which may be generally described as *Headless Lamellibranchiate Molluscs*, in which the two halves of the mantle are separated the entire way round, and where the foot is either altogether absent or very small. They are generally attached to solid bodies by the shell.

The first genus of the *Ostrea* we shall mention is the *Pecten* or *Scallop*. *Pecten Jacobæus* was the badge of the Pilgrim in the days of the Crusaders.

**PECTEN VARIUS** is one of the most common and, at the same time, most elegant shells found on our coast, and on nearly every part of it in considerable numbers. It is generally of a chocolate colour, brown, or orange yellow, and red; the young ones being uniformly red. It is equivalve, and of a shortened ovate shape, both the valves being slightly convex. The animal itself is of a similar shape, and of a pale cream colour. The mantle is open, and its margins fringed with short white tentacles, which are most commonly of a pinkish tint. The foot is short, narrow, and white. In size the *Pecten* measures, in ordinary cases, about an inch and a half in length, and an inch and three-quarters in breadth.—W.

(To be continued.)

## SALE OF ORCHIDS.

A HIGHLY important sale of Orchids took place at Mr. Stevens' rooms, King St., Covent Garden, on Thursday and Friday, the 18th and 19th inst., when the first portion of the extensive and valuable collection belonging to G. Reed, Esq., of Burnham, Somersetshire, who, it seems, is giving up the culture of this class of plants, was brought to the hammer. Among the plants sold were some remarkably fine specimens, which brought high prices, and the total proceeds of the two days' sale amounted to upwards of £1030. The following are a few of the prices which were obtained:—*Cypripedium villosum*, a very fine plant, stated to be the largest in the country, was knocked down after a spirited competition to Mr. Veitch, of Chelsea, for £75. *Odontoglossum nævium* was bought for £32 by Mr. Williams, of Holloway, who also obtained a fine specimen of *Epidendrum prismatocarpum* for £15; *Erides quinquevulnerum*, the white variety, £12; *Erides Schrederi*, £15; *Vanda gigantea*, £15 10s.; *V. cristata*, £10 10s.; *Uropedium Lindenii*, £13 10s.; and some others of less value. Mr. Veitch, in addition to the plant first named, was also the buyer of a large *Lælia purpurata*, which brought £19, *Vanda Cathcarti*, £21, a new *Cypripedium*, £10 10s., &c.

The other principal buyers were Messrs. Bewlay, Basset, Day (of Tottenham), Rucker, Turner, Warner, and Wright, among whose purchases were *Lælia Lawrenceana*, £11 10s.; *L. purpurata*, £14; *Cypripedium Fairrieanum*, £12 10s. and £11; *C. barbatum*, £10; *Oncidium sessile*, £13; *Anguloa Clowesii*, £10; *Odontoglossum citrosium*, £11; *Cattleya Mossia Lawrenceana*, £12 10s.; *Vanda Batenanni*, £23; *Erides Reedii*, £15 10s.; *Cypripedium hirsutissimum*, £15; and *Cattleya elegans*, £22.

The remainder of this extensive collection, comprising a large and fine plant of the beautiful *Cymbidium eburneum*, several fine *Phalenopsis*, *Cattleyas*, *Vandas*, and many other valuable Orchids, is to be sold on Thursday next, the 2nd of October.

## THE CUCKOO AND THE FERN OWL.

THE two birds of which I am about to write are of great value, in an economical point of view, and should be strictly preserved, but, unfortunately, ignorance too often dooms them to destruction, for no other reason that I can discover, than that they have a slight resemblance to Hawks when flying.

The Cuckoo is a summer visitant to this island, arriving about the middle of April, when the trees are putting forth the young green leaf, and the fields their gay attire. The food of the Cuckoo consists of—what? Listen, ye gardeners and fruit-growers!

—Of caterpillars—yes, and almost entirely of caterpillars. If you will allow him, he will come at early dawn, and creeping among the Cabbages and fruit bushes make a hearty breakfast every day of these destructive pests; but if disturbed he retires to the woods and copse to hunt up what he can there find, feeding on the caterpillars which destroy the foliage of trees.

His stay with us is short, so short that he has no time to rear a family, or to settle down to an abode, for when caterpillars are transforming he will be off elsewhere, and early in autumn takes his departure for a warmer clime. His mate troubles not herself over household affairs, the few eggs she lays during her sojourn in this country she deposits in the nests of other insect-feeding birds to whose care the rearing of the infant Cuckoo is confided. The young bird when hatched, shoulders all other occupants from the nest, that he may obtain the undivided attention of his nurses. His cry is that common to young birds when very hungry, and thus he attracts any other birds that may chance to be of a philanthropic disposition. Then he makes all haste he can to get on the wing as soon as possible, and follow his erratic parents to a more genial clime.

The Cuckoo, that harbinger of summer, has been accused of sucking little birds' eggs. No doubt the old nursery rhyme is in the recollection of all, yet I believe the same is a gross libel on both male and female Cuckoo, though the young being spoilt children, are not desirable bedfellows for their nurses' progeny. Mrs. Cuckoo sometimes deposits her egg in such nests that it would be impossible for her to do so in the ordinary way, by sitting on it; and it has been observed that in such cases she conveys the egg in her beak. A Cuckoo being shot, and the remains of her egg found in her mouth, may, perhaps, have given rise to the libel above referred to. Some young birds that were late-hatched, or for want of proper nourishment have tarried too long, got benumbed by the chilly

nights, and creeping beneath some bush or logs have occasionally been found in an almost torpid state, which has given rise to the idea of their hibernating, but such fancies are now corrected by better investigation. The food of the Cuckoo being caterpillars is proof of their usefulness, and explains their early departure.

**The Fern Owl.** The bird is known by a variety of sobriquets, as Goat Sucker, Night Hawk, Eve Jar, Night Reel, &c. It, however, more resembles a nocturnal Swallow than either Owl or Hawk. Its food consists of insects, as moths, beetles, and flies, which it catches on the wing during the evening and night. In the daytime the Fern Owl hides in trees or under Ferns or bushes, and only comes forth as the light declines.

It is a strange-looking bird with its large head; the dark, round, and prominent eye; the small beak and wide capacious gape, the edges of the mouth being fringed with bristles. The body is small and rounded; the wings and tail long; the plumage is dull black, the feathers banded with brown, and shaded with grey, having also some spots of a lighter colour; the feet are short; and the nail of the centre toe is peculiar, it is formed like half a pipe bent rather outwards, the inner edge being serrated like a comb. Their manner of perching differs from other birds, as they sit along the bough, and not across as most birds do. Early in the evening they commence making a long-prolonged croak, or rattling noise, and as they glide from their perch, while skimming along they beat their wings together over their backs, causing a clapping sound. As the evening becomes darker they flit past, occasionally uttering a short pipe or whistle, and pass by on noiseless pinions like some shadowy phantom, anon settling on the road in advance of the evening stroller, or wheeling over head like some spirit of the night. It is now they may be seen hovering among a flight of insects, or chasing some unfortunate moth, or droning beetle. They come rather later than the Cuckoo, and stop longer, so that they breed in this country. They lay two eggs on the ground in a wheel rut, or under some Ferns, or a bush, and rear their own young. The eggs are very pretty, about the size of those of the Turtle Dove, and white spotted with dark blotches.

As the Cuckoo feeds on caterpillars, so the Fern Owl feeds on the perfect insect, and both confer much benefit by ridding us of an immense amount of insect pests, that would otherwise increase to such an extent as to defoliate the trees. Possibly the entomologists might like them to be less numerous, for what a valuable collection must pass down their capacious throats! All other men must, I should think, regard them as useful friends.—  
B. P. BRENT.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

FRESH plantations of Cabbages, Lettuces, &c., to be frequently examined, any that droop without an apparent cause to be examined at the roots, where, probably, a grub will be found, which, if not destroyed, will continue its ravages. *Broccoli*, earth-up the plantations, as they will now be growing rapidly. *Cauliflowers*, a warm, sheltered situation should be selected for the plants to be kept under hand-glasses. Fork-in some fresh loam and well-rotted dung, and arrange the glasses 3 feet or 4 feet apart, forming a shallow basin under each, in which, when the plants are sufficiently strong, three or five plants should be placed according to the size of the glasses. *Mushrooms*, keep the out-door beds protected from heavy rains by a good covering of litter. Maintain a regular degree of heat in houses containing beds and guard against aridity. *Potatoes*, continue to take up the crops as they reach maturity. Sort them before they are housed or pitted, as it will save much future trouble and waste. *Radish*, slightly thin the late sowings of the Spanish sorts. If a succession of the common sorts is required, a sowing should be made in a frame.

### FLOWER GARDEN.

The removal and transplanting of evergreens from the present time to the end of November is attended with more chances of success than at any other period of the year. Whether the planting is done in masses or singly, the ground should be well trenched and drained before attempting to put a plant in; for plants put in singly, if they are meant to thrive, a mere round hole just large enough to hold the roots is not sufficient, but the ground for some space round should be well worked-up to facilitate the progress of the future roots, as well as the escape of water. Mulch the surface to prevent evaporation from the soil,

and, besides occasional waterings at the roots when the weather is dry and windy, sprinkle the tops of an evening, wetting the bark and foliage completely. Carnations and Picotees may now be potted in a compost of loam, leaf mould, and river sand, in about equal portions. Plant offset Tulips, and give the soil of the best bed a turn every week. Plant out young plants of Sweetwilliams, Wallflowers, Canterbury Bells, Foxgloves, Hollyhocks, Heartsease, Pinks, Carnations, Picotees, &c., that they may get established before winter. Prick out young plants of Berberis and Rhododendrons. One-year-old Pinuses and Cedars are better kept in small pots in a protected situation than planted out.

### STOVE.

Very little water should now be given to Gloxinias, Gesneras, Achimenes, &c., but, with the exception of the latter, they should not be allowed to get quite dry. The mealy bug generally increases rapidly at this season and proves a troublesome pest, and if not destroyed gives the plant a most disagreeable and dirty appearance. The best system of extirpation is by brushing it off with a painter's small brush.

### GREENHOUSE AND CONSERVATORY.

The climbing plants in these houses to have a careful regulation, shortening-back the shoots going out of bloom and training the remainder in a regular manner. Climbing plants in pots, as Kennedias, Hardenbergias, &c., to be tied neatly to their trellises, giving all the light possible, and a fair share of air to ripen their wood. A portion of the stock of Chrysanthemums to be placed under glass to forward them; thin-out the flower-buds, and water with liquid manure. The Pelargoniums that were cut back late to be shaken from the old soil and repotted, placing them in a slight bottom heat to facilitate their rooting. In arranging Pelargoniums for the winter, allow them the lightest and warmest part of the house, unless there is a separate house for them, when the Fancies should have the best end; keep them close to the glass, and do not allow them to touch each other. The Lilies of the Valley intended for forcing should be potted and plunged overhead.

### PITS AND FRAMES.

The winter stock of bedding-out plants that are well-established should now be arranged and placed in their winter quarters. As his Majesty has paid us many visits in times past before we were prepared for his coming, and as we have no assurance this season that he will not pop in upon us before he is welcome: therefore, it is advisable to have the stock all housed, and everything in readiness to afford protection when required. The young stock to receive careful attention, and endeavour to get it well rooted and strong without keeping it so close or warm as to render it sappy and liable to damp-off on the first approach of wintery weather, as is often the case with stock got-up in haste late in autumn, and then stored away in cold pits for the winter. Cuttings of Scarlet Geraniums, &c., may still be put in where the stock of such things is likely to be deficient. See to securing as many cuttings as possible of any scarce plants which it may be desirable to increase where there is a fair chance of rooting them, and also be prepared to protect Scarlet Geraniums and other plants which it may be intended to take up and winter.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

PLANTED-OUT Cabbages; removed Onions into a dry place, to wait for a wet day for bunching them; tied Garlic and Shallots in bundles; pulled-up Peas where about done, and thrashed them for what little seed they had; sowed Lettuces for the last time at the base of a wall, to give them a chance of standing the winter; planted-out more Endive, Lettuces, and Winter Greens, that had previously been pricked-out; planted-out the last Celery for spring use, earthed-up the most forward for use, using a little coal ashes round the stems after tying them moderately tight, so as to keep them from slugs and worms, either of which spoils the look of this useful vegetable; watered other beds and rows of Celery with manure water, sprinkling the ground first with a little lime, keeping the black water from the farmyard as much from the stems as possible, and then watering with clear water overhead, to remove any of the black which might adhere to the stems or leaves. At such times, when we can get it, we often see the water too strong for going over the foliage, though not too strong for the roots, especially after it has percolated

through some inches of soil. Partly from necessity and partly from choice, I am getting less partial to strong, rank Celery, and prefer it rather smaller and sweeter; and where nothing but a little leaf mould can be got for manure, we must assist it two or three times with manure watering. I am also thus particular as to the mode of applying the water, because last year some Celery was spoiled by using strong black water, from a farmyard, right overhead, and that without any washing with clean water afterwards. As a rule, such waterings with black manure water should never touch a leaf. Somewhat to our sorrow, our small Mushroom-beds in the shed yielded so profusely as to come in for catsup-making; because, when they come so much at a time, these shallow beds do not often last so long, and, unless on occasions now and then, we would rather have a good supply of large ones for broiling, and buttons for many every-day purposes. The hot weather helped to make the beds white from end to end. Here I would answer a correspondent, who inquires as to the best and quickest way of making

#### MUSHROOM SPAWN

by saying that it is not often that the best and the quickest modes are identical, as there may be much speed, and yet not the same amount of success. The quickest mode I ever tried, was to get a bushel of rather dry sheep-droppings, the same of cow-droppings, dried on a pasture, and the same of horse-droppings, to mix them together, and leave them in a heap that they scarcely heated, and in a month they were a mass of spawn, ready to be planted anywhere. This, however, would require a practised hand, and no beginner to look after it. Other and various modes were described last year. One of the easiest would be to get two parts of horse-droppings, one part of cowdung, and half a part of road drift. Mix these as if making the finest mortar, using little or no water if you can do without. When well mixed spread it out regularly  $1\frac{1}{2}$  inch to 2 inches thick on a hard, dry bottom, and beat it smooth on the surface with a clean spade. In a couple of days cut it out into squares—say of 9 inches, with a sharp edging-iron. Make two, or three, or four holes in each piece with a pin, or one of your fingers, not going through the cake; turn these cakes as the one side gets dry, and when about as dry as soil should be for potting, insert a piece of spawn in each hole, covering it over with a little cowdung. Then pack in heaps, and apply heat to cause the spawn to permeate the cakes.

The plan which we generally adopt, is the following: Make a heap of the above ingredients. If the cowdung and horsedung should be rather moist, we add a little straw chopped very fine. We wish the heap to be as dry as it can be made into a tough dough-like substance. We then provide ourselves with a frame of wood, such as brickmakers use, so as to enclose an open space 9 inches long, 2 inches deep, and 4 inches wide. With this we turn our prepared manure into bricks. Thus: a lump of it is placed beside us on a level table or board. The frame is dipped into a pail of water, placed on the board, filled with the mixture, beat down, and made level on the upper side, while it is sure to be so on the lower. Holding the frame up by one end a slight stroke on the other causes the brick to drop out as clean as can be, generally on a board, so that a number can be easily moved where they will dry. One brick thus succeeds another as quick as I could write the word "brick," and though a little more time is used at first, we think, on the whole, all things considered, this is as good and quick a way as any. These dung bricks are generally placed on their broad side. In a few days they will need turning on the other side, then on one narrow side, and then the other, until all are dry enough through. Two holes are made as soon as they are placed on the board or other hard bottom. These when dry enough have a piece of good spawn thrust into them firmly, which is covered with a little cowdung. The holes and the covering are all done with the fingers, we holding that there is no mechanical contrivance like them, and believing that those who are too refined to touch such things had better never think of troubling themselves, or distracting others, by their attempted gentilities in gardening.

The spawn being thus inserted, when the bricks can neither be said to be wet nor dry, but just in the happy medium a Mushroom-bed should be, the next thing is to get the spawn to permeate the whole brick. This it will do of itself in a shady, dry place in summer. In spring and autumn it will need to be helped. We generally make a slight hotbed in a sheltered place of rather dryish litter—say from 15 inches to 18 inches thick, and in width in proportion to the quantity of spawn. On this we place a layer of the bricks with openings between them,

then a layer above that, with pigeon-holed openings, and so on, lessening the layer until we come to a cene at the top. Then the heap is covered with a little long litter, and the warmer litter placed all round and over it, until a temperature of from  $80^{\circ}$  to a few degrees more—say  $83^{\circ}$ , is secured inside. The bricks being laid open the heat permeates among them more easily. This heat must not be exceeded. In a short time the bricks must be examined, and, perhaps, the top placed at the bottom, and *vice versa*, the running of the spawn being seen by the diminutive white threads getting all through the brick. As soon as a brick is thus done it must be removed, and if kept dry and cool it will retain its goodness for a long period.

All this though simple is attended with such nicety, that where only a moderate quantity is wanted, it is best to purchase from a regular tradesman. Where much is made, it pays well for the attention, but where a vast number of other matters are every day demanding attention, the spawn-heap is apt to be forgotten, and a few hours' over-heating will spoil all the labour. We stated last week how good spawn was to be known, and, in conclusion, to those who are far from a maker, we would say that a little spawn must be got from where the Mushroom grows naturally, or in the mill-track of a threshing machine driven by horse power. Even a few horse-droppings placed in a dry corner will often yield a plentiful supply; but when spawn is needed all the year round, it must be made in some regular way, and though the flat-cake mode is most used by dealers, we prefer the above brick mode ourselves, as the best in our circumstances. We will allow others now to describe their system for another twelvemonth at least. Of course, though we have described the dung-bed above for causing the spawn to spread, it was merely as the most likely to be generally comeatable at this season. Any other contrivance where the heat would not be drying too much, nor too high, would suit equally well; but the heat should, if possible, never be higher than from  $75^{\circ}$  to  $83^{\circ}$ .

#### FRUIT GARDEN.

Besides gathering fruit, finishing summer pruning, watering Figs out-doors and in-doors, the chief work has been watering trees in pots after twisting them round, to stop the progress of roots gone beyond the pot. Of course this was done after the fruit was all gathered, and so as to give the now weaker sun more power to ripen the wood. Removed most of the summer shoots from wall and dwarf trees, that were not well stopped back in summer, to give the latter more light and air.

#### ORNAMENTAL GARDENING.

Swept and rolled lawn, the late fine weather having given a fresh polish to the beauties of the flower garden; and keeping lawn and walks and edgings of beds neat and close adds much to their attractiveness. The leaves are now falling, however, as foreshadows of what is coming, and the finest beds of flowers look tame and melancholy when the leaves keep blowing against their stems. In a few days we will finish the bulk of our cuttings—Verbenas, Geraniums, Fuchsias, Salvias, Pentstemons, Ageratums, Lobelias, &c., and we will make preparations in the course of a fortnight to commence with Calceolarias, which will be quite early enough for them. Our first batch of Verbenas in a cold frame had got such a thicket that they have been moved to a cold earth pit, where six times the space is given them to harden them off. Is seed of *Centaurea candidissima* to be got true? It will make a nice neighbour to *Cineraria maritima*. Has any one got that first-rate from seed—I mean with the real frosted silver of the old plants that were first propagated from cuttings? I have seen none quite so good. I had more than five hundred seedlings last season, but though the leaves in other respects were exactly alike, the colour was far inferior. I thought another year might improve them, but cuttings from these seedlings are no better this year, and bear no comparison to the fine frosted appearance of the old plants. Some of these seed-raised plants are, however, of a smaller type; but for edgings there is nothing like cuttings raised every year. These scarcely ever show bloom, and are always compact, or may be kept so, as already detailed. Though we strike them now, spring is the time to get them to strike quickly and easily.

I have mentioned Prince's Feather doing so badly owing to the coldness of the ground. I might also instance another great favourite—Zinnias. These even now do not fill the space allotted to them, and being fine plants when turned out in June, they stood still, if they did not go back, for ever so long. Though flowering moderately they are now not much above a foot or 15 inches in height. Last year they were double the height and

a dense mass of bloom, without which a row or a bed of them is nothing. In some parts even north of this they have, I believe, done well. The best I have are facing the south, with a shrubby behind them. I like the single or semidouble better than the double. In the double we lose the noble coronet in the centre.—R. F.

## TRADE CATALOGUES RECEIVED.

*Descriptive Catalogue of Roses Cultivated by William Paul, Waltham Cross, N.*

*Catalogue of Bulbous Flower Roots, Fruit Trees, &c., by Sulton & Sons, Reading.*

*Autumn Catalogue of Dutch and Other Flower Roots by Edmondson Brothers, 10, Dame Street, Dublin.*

*Catalogue of Dutch Hyacinths, Gladioli, and Other Bulbs, &c., by John Bell, 10 and 11, Exchange Street, Norwich.*

## TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**PYROLA MEDIA** plants may be had by *A Galloway Lady*, if she will send her directions to Mr. Robert Smith, Dewsbury Moor, Dewsbury, Yorkshire, he having most obligingly offered to supply her.

**PEAS WITH DARK CENTRES** (*A Reader*).—Your mossy soil evidently contains something that is injurious to the seed of the Pea, and does not supply the plants with sufficient nourishment. We should manure with lime the soil where you intend to grow Peas. Write to Messrs. Barsham & Co., Kingston-on-Thames, for information about cocoa-nut fibre refuse.

**FUCHSIA BERRIES AS A FRUIT** (*Idem*).—We believe them to be wholesome, and they are, as you say, "very sweet, and would look well in a dessert." Dr. Hogg in his "Vegetable Kingdom," says, "The berries of *Fuchsia denticulata* and other American species are eaten when preserved with sugar. *Fuchsia excorticata*, a native of New Zealand, yields fruit which is pleasant, very sweet, and eaten with great avidity by birds."

**COCOA-NUT FIBRE REFUSE** (*A. B. C.*).—Write to Messrs. Barsham & Co., Kingston-on-Thames, W.C.

**YOUNG TRITOMA UVARIA PLANTS** (*A Suffolk Subscriber*).—Keep them watered as long as they hold green, even if that were to Christmas; and while they are at rest do not allow them to get quite as dry as *Dahlia* bulbs usually do. Plant them out in the open ground next April, and they will grow twice as fast as they would in a pot.

**SEMI-DOUBLE FUCHSIA** (*Kentish*).—Not a novelty. It is only the first departure from a single towards becoming a double flower.

**INSECTS** (*A Subscriber*).—We found a good many specimens of a small pale yellow species of thrips in an immature state upon the leaves of different kinds you sent us, and presume (as you say they skip when disturbed), that they are the cause of the mischief. They must be treated in the ordinary way to destroy the thrips.—W.

**TRAINING A PILLAR FUCHSIA** (*R. M. A.*).—The only way by which you can have pillar *Fuchsias* 8 feet or 9 feet high out of doors in York-shire, is to grow some plants to nearly that height in pots, which you may do in one season in a warm greenhouse. Then winter these plants in a cool place free from frost; prune pretty well to the required shape, either in the autumn or early in the spring, leaving the twigs longer at the base, and narrow at the top in the shape of a cone. As soon as the buds break give light and air, but little or no heat, merely protecting from frost. In fact, the shorter and stabbier you keep the shoots the better until you plant out in the garden, say in the beginning of June. Break the outsides of the ball a little, then surround with rich soil, and mulch with rotten dung, and water at the least sign of distress. These will do well where the wind is not too powerful—a gale with us has often marred the symmetry of their outline. Before much frost comes raise the plants, pot them, and keep them cool in winter as before, and the plants may thus be ornaments for years. Success greatly depends on plants having but little growth before they are planted out. The best darks for this purpose are *Voltegro* and *Banks' Glory*, and the best white *Pearl of England*; but numbers do well.—R. F.

**MANGOLD WURZEL** (*H. S.*).—We can state positively that in most places in England and the Channel Islands it has not bolted, or run to seed excessively. Your seed either must have been from bolted plants, or some violent check in the early growth of the seedlings produced the mischief. We do not think that stripping off the leaves under any circumstances is beneficial to the roots, but the leaves may be taken off without injury late in autumn when the growth of the roots is concluding. When the season for sowing returns, we will give you all our information on the subject if you will remind us.

**PLANTING-OUT BURNED STOCKS** (*An Amateur*).—We do not know what stocks you mean; but there can be no harm in planting-out as soon in the end of autumn as you think your buds are ripe.

**CUTTINGS OF CENTAUREA CANDIDISSIMA** (*Mas*).—This plant from its woolly nature is a little difficult to strike at this season, especially if the plants are out in the open ground. Small side shoots strike easiest—that is, slipped off when about 3 inches long, and inserted round the sides of a small pot, and all the leaves removed except two or three of the smallest at the point. If the plants are in pots it will be best to keep them as they are, prune well back say in the end of February, place the plants in a heat of 60°, and strike the young shoots made, when from 2 inches to 3 inches long, in a little mild bottom heat. Seeds might also be tried, though we should be a little doubtful of their coming quite so white in the foliage as those from cuttings. The best edging of this we have seen is at Cremorne Gardens, and there it looks beautiful.

**ZINC BOXES FOR VERANDAH PLANTS** (*Madeline*).—We think zinc preferable to wood for such a purpose, only we would have the zinc painted outside of a light stone colour in such a situation, to prevent the roots getting too warm. We can hardly say how long such zinc troughs or boxes would be likely to last, but we know that all plants we have tried thrive in them. We make cutting-boxes of every old piece of zinc troughing or spouting we can lay hands on, and even tin and other metals, but zinc answers by far the best. We merely cut such old spouting into handy lengths—say 2½ feet or 3 feet, and put a semicircular piece of wood in each end. Though painting the outside of such boxes, we would not touch the inside. We have never yet met with a root that did not like to cling to a piece of zinc. We believe that in time the roots and the water together will exert a wearing-out influence on the zinc; but so long as it holds together, our limited experience would tend to the conclusion that everything likes it.

**LIME WATER FOR FLOWERS** (*Idem*).—Lime water, as clear to all appearance as the most limpid spring water, will injure some plants with hairy-fibry roots, as many heaths and *Rhododendrons*; but it in general will do no harm to soft-wooded or succulent plants if not too often repeated. The chief use in their case is to dislodge worms, and act as a solvent to an extra stock of organic manure in the soil.

**PEACH TREE BRANCHES DYING** (*An Old Correspondent*).—Are you sure that your Peach-house trees are not yet suffering from the effects of the frost of 1860 and 1861? Many trees that stood over 1861 in a rather sickly state have gone this season. If this is not the case, may you not have over-cropped and given too little assistance to the trees? Without further information we can hardly say more.

**LYCOPIDIUM CLAVATUM** (—).—"This, the Stag's-horn Moss, so beautiful on the mountains of Wales and Scotland, is spoken of by Mr. Moore as making a beautiful object when cultivated in a greenhouse and suspended from the roof or side walls. 'I have seen it,' continues Mr. Moore, 'in such situations with branches from three to four feet long, flowering most abundantly, and having a peculiarly imposing appearance.' Can any of your readers tell me whether they have seen it so grown and describe its cultivation? I have found some gardeners who have tried and failed, but none who have succeeded."

[We have not had the opportunity of trying, but you can place entire confidence in Mr. Moore's statement. We shall be obliged by some of our readers stating their successful mode of cultivating this *Lycopodium*.]

**VARIOUS** (*C. M. Major*).—Would you be so kind as repeat your queries as to Fig-culture and large standard *Laurustinus*, as we have no recollection of them? We would report the *Laurustinus* in September, that the roots may run freely in the new soil before winter. The culture of the Fig must depend on circumstances and position; south or north of London; forced, or out of doors; planted-out, or in pots. The large bulb of the *Lilium giganteum* generally decays after blooming, we cannot say always. We never like to go ahead so much with new things. A little cocoa-nut fibre will do no harm to your Ferns; but with peat and loam at command, we would make them the chief constituents of the soil.

**FRUIT-STORING** (*A. S. T.*).—For general purposes, there is nothing better than open shelves. To keep long and fresh, we have found nothing better than large earthenware pots or little wood barrels; the sound fruit put carefully in, and carefully covered down at top, with something almost impermeable to air. We know where Apples, Pears, Walnuts, Filberts, are kept as fresh, or fresher by this mode than any other, merely placing a thick turf, grass side downwards, over the top of the vessel, with a sheet of paper or a piece of calico between the fruit and the turf, and no packing is used. All our experiments with packing injured flavour; bran and sawdust were perhaps the worst. In an underground dry cellar, nothing is better than open benches. But we shall be glad to learn the experience of others.

**GOLDEN HAMBURGH GRAPE** (*C. N. B.*).—We do not find that this variety is more liable to shanking than others, and those who say it is rejected on that account are certainly misinformed. If your Vines are planted outside your vinery, that is the probable cause of the shanking. Keep the roots warmer, and that disease will be likely to disappear.

**FERNEY** (*Felix*).—If for hardy Ferns it need not have a top, though even they grow the more luxuriantly with such a shelter. If roofed, let the roof be a pitched roof and glazed with Hartley's plate glass. As for the planting, that must be dictated by your own taste. It is usual to have heaps of bricks and clinkers arranged artistically, which act also as the drainage so essential to the Ferns' welfare; and these heaps are covered with the soil, formed of equal parts peat, sand, and light loam. If you refer to some of the back Numbers of our Journal you will find plans, directions, and lists of Ferns. We shall publish at the close of the year a volume on the culture, &c., of Ferns in a fernery, with very numerous illustrations.

**WELLINGTONIA SEEDS** (*A Subscriber*).—We do not think that there is any tree of this species old enough in this country to yield perfect seed. The cones fall when the seed is ripe. Write to Mr. Murray, Secretary Royal Horticultural Society, Kensington Gore, W., for the dimensions you need. We do not know them.

**NAMES OF FRUITS** (*H. D. Paine*).—We cannot say to what variety your Pears belong, and the Fruit Committee, on Tuesday last, were likewise unable to recognise them. They are not any of the sorts you mention. (*G. J. Neal*).—Apple, No. 1, Wormsley Pippin; No. 2, Tower of Glammis; No. 3, Golden Noble. The Pear is Flemish Beauty. The seedling Peach resembles in appearance the Royal George.

NAMES OF SCARLET GERANIUMS (*J. Cox*).—No. 1, Tientham Rose; 2, Kingsbury Pet; 3, Lucia Rosa, or one very near it; 4, Miller's Nosegay, or Old Cimson; 5 and 6, flowers fallen to pieces; 7, like Punch, but flowers fallen to pieces; 8, Rubens; 9, Brilliant; 10, Amazon.

NAMES OF PLANTS (*W. G. B.*).—No. 1 is a young outside leaf of the lighter variety of *Hippeastrum reticulatum*—the *Amyllis striatifolium* of the "Botanical Magazine," vol. xlvii., fig. 213. The same bulb was exhibited a few meetings back, before the Floral Committee by Mr. Eyles, from the Chiswick Garden, and out of some thousand kinds of bulbs in the same order of plants, that is the only one which has a white band down the centre of an ovate leaf. The secret in growing the wild kinds of *Hippeastris* is to give them abundance of water while the leaf is growing, or say from March to June, and no more water than will keep the leaves from flagging for the rest of the summer, and when they are at rest the place can hardly be too hot or too dry for them—that is, for the store kinds like this variety of *reticulatum*. 2, apparently some *Pomaderris*; 3, *Spiraea Douglasii*; 4, *Lonicera Ledebourii*. (*R. M. A.*).—*Pteris hastata*, var. *macrophylla*. (*J. M.*).—A close-tufted form of *Saxifraga hypnoides*. (*A Five-years Subscriber*).—1, *Nasturtium*, apparently an unusual growth of *sylvestre*; 2, *Cedronella cana*; 3, *Cnicus arvensis*; 4, *Cnicus lanceolatus*. (*An Old Subscriber*).—*Asplenium bulbiferum*, and *Phlebodium aureum*. No. 1 is *Platycerium alcicorne*. They are all exotics. (*J. L. S.*).—1, *Selaginella pubescens*; 2, *S. uncinata* (cesia). Neither of them is a Fern. (*Joseph Varty*).—1, *Anomatheca cruceata*; 2, *Nepeta micrantha*; 3, *Chelone glabra*; 4, *Epilobium angustifolium*; 5, *Tradescantia virginica*; 6, insufficient.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

OCTOBER 28th and 29th. CALNE. Secs., A. Meath and F. Bailly. Entries close October 15th.

DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.

### PRESERVATION OF EGGS.

(Translations from *M. Jacque's work on Poultry continued*.)

EGGS laid towards the end of autumn not being as much exposed to a beginning of alteration as those of the summer, are, very justly, considered easier to keep. It seems certain besides, that barren eggs keep better than those that have germs of life in them. Conditions favourable to the preservation of eggs may be obtained in different ways. It has been proposed to cover eggs with different varnishes, with grease, or any plastic substance capable of preventing evaporation or the introduction of air from without; but these means are inconvenient from causing much loss of time, from being expensive, and from frequent failure.

When eggs are only required to be kept for a short time, it is enough to put them in boxes or vessels filled with bran, grain, sawdust, dry sand, coal ashes, &c. These pulverised matters insure keeping, as they prevent evaporation, especially if they are placed in a fresh and dry place where the temperature does not vary.

But the most certain and most durable method of keeping consists in putting the eggs in a vessel filled with newly-made chalk water, and in keeping them in a cool place. Chalk water is prepared by taking quicklime, which is mixed in cold water, in quantity more than enough to cover all the eggs. The chalk-milk which results from the mixture should be allowed to stand some hours. The clear liquid which separates itself from the excess of chalk or lime employed, is the chalk water which should be drawn off for the purpose for which it is required. Not only does this chalk water prevent evaporation, as the eggs are completely covered with it, but the alkaline earth which it holds in solution stops the pores of the shells, and prevents every fermentation whether of the egg or the organic matters that the water may contain.

The following is what M. Mariot-Didieux says on the subject:

"MODE OF ASCERTAINING IF EGGS ARE FRESH.

"A new-laid egg has a white, clear complexion, its varnish shines. Held before the light of a candle its contents appear clear, transparent, and fluid. When this transparency is only partial, the alteration proves they are not fresh. Striking gently on that part of the egg, the sound given will indicate the size of the air-cell, and that will prove its freshness or otherwise. If the egg is turned quickly to one side by a rotatory motion, the movement is regular, if it is fresh and full; but if more or less empty it is hard and irregular.

"OF CLEAR EGGS AND FRUITFUL EGGS.

"Hens alone, left to themselves, can, without any communication with the cock, lay the eggs which are incessantly formed on the ovarian stalk or bunch; they grow there in size, they detach themselves from their stem, enter in a soft state into the egg-duct, form their shell in that organ, and remain there till the moment when the fibres of this reservoir-conduit, incommo-

by the presence of these bodies, contract themselves and push them out large end first, according to Aristotle. The intervention of the male is only necessary to impregnate a small germ or vesicula, which is firmly fixed to the surface of the membrane which envelops the white of all eggs, whether they are fruitful or not.

"The presence of this germ cannot then, in any case, be a sign of fecundation, as it is vulgarly believed. The hens which have been kept separate lay as many eggs as those that run with the cock; we state this as the result of a series of conclusive experiments, but the fact has been long known. But the suppression of the cock is not the only advantage of clear eggs; they are as good as the fruitful ones, and they have the immense advantage of keeping longer, and of being able to suffer any amount of travelling and moving about without other alteration than that which arises from the evaporation of the fluids. The advantage of clear eggs becomes incontestable for those who deal largely in them, because the producer can defer the sale of them till they are scarce and dear. On this subject, let me be permitted a popular saying. St. Augustine says in one of his sermons, that 'popular sayings often contain salutary lessons.'

"A popular saying is, that the eggs laid between the two 'Notre Dames' of August and September are those that should be kept for the winter: a saying acquires value when it is confirmed by reasoning. It is certain that about the 15th August the cock ceases for a time to notice the hens beyond calling to food, &c.; the hens, equally careless, lay only a few clear eggs, which will keep almost any length of time. Towards this period the moult commences—it is an annual sickness, and may contribute to the lack of fecundation.

"In 1849 we placed twelve eggs under a broody hen; six were fertile, or considered such; the six others, laid by two hens that had been by themselves for more than three months, were considered clear: both underwent all the phases of natural incubation. After twenty-two days, the six clear eggs only showed the white become rather more liquid; but the yolk, which was in its natural state, and without any alteration to the eye, the smell, or the taste, became coagulated in cooking, and was eatable, though not good. Four of the fertile eggs produced chickens; but the two others, from causes unknown to us, contained only undeveloped germs, and decomposed humours, having that aspect and smell of rotten eggs which may be well called 'sui generis.'

(To be continued.)

### PENS AT THE BIRMINGHAM POULTRY SHOW.

As the time is approaching for the Birmingham Poultry Show, I am reminded that when I was there last year there was a grave error in the arrangement of the poultry pens. As you are aware, previous to 1860 it was requisite that there should be a cock and three hens in each pen in the generality of the classes, and the pens were of a size to accommodate that number; but the Committee having decided to reduce the number of birds to a cock and two hens, last year the pens were reduced in size. It appears that a certain width was decided upon, but there were a number of main posts in the way which prevented this arrangement being literally carried out, and the consequence was that next to each post there was a pen only about 16 inches wide!

As may be imagined, the unfortunate birds that were the occupants of these narrow lodgings for a whole week had anything but a comfortable time of it; and for any chance they had of being seen, either by the Judges or visitors, they might as well have been at home. You may be sure there was not a little grumbling on the part of the owners of the birds, and not without good reason.

As the Birmingham Show is the largest in point of numbers, so ought it to be the most perfect in its arrangements, and I feel sure that it is only necessary to point out such a defect as I have named to insure its being at once corrected, either by re-arranging the pens or removing the wires from the narrow ones, so as to render them useless for exhibition purposes.—ALPHA.

MANCHESTER EXHIBITION.—We are much pleased to hear that, notwithstanding the much-lamented depression of trade in the surrounding district, the spirited proprietor of the Belle Vue

COCHIN-CHINA.—First, J. Dixon, Bradford. Second, Messrs. H. & G. Newton, Leeds. *Chickens*.—First, Messrs. H. & G. Newton. Second, G. R. Tate, Driffield.

ANY OTHER BREED.—Prize, J. Dixon, Bradford. *Chickens*.—First, C. Lister, Mirfield (Brahma Pootra). Second, J. Dixon, Bradford.

AQUATIC BIRDS (For the best pen in the section).—Prize, J. Dixon, Bradford.

GESE (Light-coloured).—First, Messrs. H. & J. Mason, Drighlington. Second, J. Sheard, Morley.

GESE (Dark-coloured).—Prize, J. Dixon, Bradford.

DUCKS (Rouen).—First, J. Dixon, Bradford. Second, J. Ward, Adwalton.

DUCKS (Aylesbury).—First, J. Dixon, Bradford. Second, G. R. Tate, Driffield.

DUCKS (Any other variety).—First and Second, J. Dixon, Bradford (Grey Calls and Black East Indian).

PIGEONS.—*Carriers*.—First, Miss Hughes, Leeds. Second, J. Firth, Dewsbury. *Antceps*.—First, Miss Hughes. Second, S. Exley, Heckmondwike.

*Owls*.—First, E. Holdsworth, Leeds. Second, C. Lister, Mirfield.

*Turbits*.—First, H. Cautley. Second, E. Holdsworth. *Barls*.—First, H. Cautley. Second, J. Fir h. *Tumblers*.—First, Miss Hughes. Second, E. Holdsworth. *Fantails*.—First, Miss Hughes. Second, S. Exley. *Pouters*.—First, H. Cautley. Second, F. Butterworth, Huddersfield. *Nuns*.—First, E. Holdsworth. Second, S. Exley. *Jacobins*.—First, Miss Hughes. Second, C. S. Tinker, Huddersfield. *Common Pigeons*.—First, F. Butterworth. Second, R. Barron, Morley.

The Judges were Mr. T. Dodds, Ovenden, near Halifax; and Mr. T. B. Stead, Leeds.

### THE VALLIKILI FOWL.

OUR contemporary *La Maison de Campagne*, says, "That this new tailless breed is now at the Zoological Garden of Paris." Some say that it is of Persian extraction, but others assert that it is from Ceylon. To us it seems not unlike a cross between the Sultan and Rumpless varieties, and we more incline to this opinion because this breed is said to be met with in some of the French provinces, where the hens are considered early and abundant layers.

### KEIGHLEY POULTRY SHOW.

I HAVE read your report of the Poultry Show held at Keighley with interest, and quite agree with you that greater expedition on the part of the Judges in arriving at their decisions would have added most materially to the satisfaction of all parties concerned in that meeting. From the fact that the prize cards were only placed upon the pens just before the birds were removed, it prevented many who were willing to be purchasers from attaining their object, as the judgment of buyers is always materially influenced by the success in prizetaking. Besides this, even the casual visitors had, in numbers of instances, to leave Keighley before knowing anything of the decisions. As we exhibitors, when successful, naturally feel a pride in the public knowing of our success, I join with you in the hope that such unnecessary delays may not occur in future.—H.

### NEWCASTLE (STAFFORD) POULTRY SHOW.

The following is the list of awards:—

GAME.—First, G. Cargey, Sandon Farm, Stone. Second, J. Stubbs, Wee on Hall. Highly Commended, G. Cargey; T. Hill, Chateau, Eccleshall.

SPANISH.—First, J. R. Rodbard, Aldwick Court, Wington, Bristol. Second, Duke of Sutherland, Trentham. Highly Commended, J. Clews, Walsall. Commended, G. Cargey, Sandon Farm; G. Fleming, Trentham.

DORKING.—First, Dr. Hewson, Coton Hill Stafford (Coloured). Second, G. Cargey, Sandon Farm (Silver Grey). Highly Commended, G. Cargey (Silver Grey); E. Shaw, Plus Wilmot, Oswestry; Dr. Hewson (Coloured).

COCHIN-CHINA (Any Variety).—First, R. Adams, Harborne Heath, Birmingham (Partridge). Second, T. Stretch, Ormskirk. Highly Commended, G. Lamb, Compton, Wolverhampton (White); H. Bates, Harborne Heath Cottage, Edgbaston, Birmingham (Buff). Commended, C. Baobery, Standon (White).

HAMBURGH (Golden or Silver-spangled).—First, J. Leech, Newcastle (Golden-spangled). Second, G. Cargey, Sandon Farm (Silver-spangled). Highly Commended, G. Cargey (Silver-spangled); J. B. Bruce, Keele Hall Farm (Silver-spangled); W. Cannon, Bradford. Commended, W. Hyatt, Highfields, Wolstanton (Golden-spangled).

HAMBURGH (Golden or Silver-pencilled).—First, T. Lawrence, Cauldon Place, Shelton (Golden-pencilled). Second, W. Cannon, Bradford. Highly Commended, T. Lawrence (Golden-pencilled); J. Martir, Claines, Worcester. Commended, Mrs. E. Tavenor, Aston Hill Farm, Stone (Golden-pencilled).

TURKEYS.—First, J. Coxon, Freeford, (Cambridge). Second, J. Brassington, Barlaston (Bronze).

GESE.—First, Mrs. M. Seamons, Hartwell, Aylesbury. Second, J. Brassington, Barlaston. Highly Commended, Mrs. A. Baker, Grendon, Atherstone. Commended, G. R. Tate, Driffield.

DUCKS.—First, Mrs. M. Seamons, Hartwell, Aylesbury (White Aylesbury). Second, G. Cargey, Sandon Farm. Highly Commended, Mrs. A. Baker, Grendon, Atherstone (Rouen); W. T. Locker, Tillington (Black East Indian); E. Shaw, Plus Wilmot, Oswestry (Aylesbury); G. R. Tate, Driffield (Aylesbury). Commended, G. Cargey, Sandon Farm.

EXTRA STOCK.—Highly Commended, Mrs. Blay, the Poplars, Gregory Bank, Worcester (Silver Poland and Black and White-Crested). Commended, Mrs. Blay (Andalusians).

The Judge was Edward Hewitt, Esq., Eden Cottage, Sparkbrook, Birmingham.

### MELTON-MOWBRAY POULTRY EXHIBITION.

The following is the prize list:—

SPANISH.—First and Second, M. Brown, Ab-Kettleby. Commended, A. Guy, Eaton; N. Whitechurch, Melton. CHICKENS.—First, Duke of Rutland. Second, N. Whitechurch.

DORKINGS (Coloured).—First, A. Guy, Eaton. Second, J. Smith, Sedgbrook. Commended, N. Whitechurch, Melton. CHICKENS.—First, B. Everard, Bardon Hill House. Second, J. Smith. Highly Commended, N. Whitechurch. Commended, A. Guy.

DORKINGS (White).—First and Second, R. D. Miles, Keyham. CHICKENS.—First, W. Chamberlain, Desford. Second, Captain Buckley, Desford.

DORKINGS (Silver Grey).—First, N. Whitechurch, Melton. Second, J. Smith, Breeder Hills. CHICKENS.—First and Second, N. Whitechurch.

COCHIN-CHINA (Coloured).—Second, H. C. Woodcock, Rearsby. (First prize withheld.) CHICKENS.—First, H. C. Woodcock. Second, Captain Buckley, Desford.

COCHIN-CHINA (White).—First, H. E. Emberlin, Humberstone. Second, Captain Buckley. CHICKENS.—First and Second, N. Whitechurch, Melton. Commended, H. E. Emberlin.

GAME (White, Piles, and light colours).—First and Second, J. Wilders, Croxton Kerrial. CHICKENS.—First, T. Whitaker, Melton. Second, J. Wilders.

GAME (Red, and other dark colours).—First, B. Everard, Bardon Hill House. Second, J. Wilders, Croxton Kerrial. CHICKENS.—First, T. Whitaker. Second, B. Everard. Commended, B. Everard.

HAMBURGH (Gold, Spangled, and Pencilled).—First, J. Smith, Breeder Hills. Second, A. Houghton, Asfordby. CHICKENS.—First, Captain Buckley, Desford. Second, H. E. Emberlin, Humberstone.

HAMBURGH (Silver, Spangled, and Pencilled).—First, A. Houghton, Asfordby. CHICKENS.—First, Capt. Buckley, Desford. Second, H. Marshall, Cotgrave. Commended, Capt. Buckley.

BANTAMS (Game).—First, B. Everard, Bardon Hill House. Second, T. Whitaker, Melton.

BANTAMS (Black).—First, J. Goodyear, Cawthorpe. Second prize withheld.

DORKING COCK (Any colour).—Equal prize, N. Whitechurch, Melton; Capt. Buckland, Desford.

DUCKS (White Aylesbury).—First, N. Whitechurch, Melton. Second, H. C. Woodcock, Rearsby. Highly Commended, J. Smith, Breeder Hills.

DUCKS (Any other variety).—First, H. Marshall, Cotgrave (Rouen). Second, S. Pool, Brentingby (Albridge). Highly Commended, W. Chamberlain, Desford (Buenos Ayres).

GESE.—First, J. Smith, Breeder Hills. Second, W. Kirk, Wymondham. Highly Commended, G. Cooper, Scargave. Commended, Duke of Rutland.

TURKEYS.—First, Duke of Rutland. Second, J. Smith, Breeder Hills. Highly Commended, N. Whitechurch, Melton.

PHEASANTS (Golden).—First, J. Buck, Leicester. Second, no competition.

PHEASANTS (Silver).—First, J. Buck, Leicester. Second, N. Whitechurch.

PIGEONS.—*Pouters* or *Croppers*.—Prize, H. E. Emberlin, Humberstone.

*Carriers*.—Prize, H. E. Emberlin, Humberstone. Highly Commended, H. E. Emberlin. *Tumblers*.—Prize, W. Chamberlain, Desford. Highly Commended, H. E. Emberlin. *Any other distinct variety*.—Prize, F. W. Montgomery, Gadsby (White Trumpeters).

RABBITS.—*Heaviest Weight*.—Prize, W. Chamberlain, Desford. *Length of Ear*.—Prize, N. Whitechurch, Melton. Highly Commended, Mrs. Hubbersty, Eastwell. Commended, W. Chamberlain. *Any other kind*.—Prize, W. Chamberlain. Highly Commended, Mrs. Hubbersty. Commended, N. Whitechurch; C. C. Woodcock, Rearsby.

The Judge was Edward Hewitt, Esq., Eden Cottage, Sparkbrook, Birmingham.

### THE HONEY SEASON IN DEVONSHIRE.

EARLY CESSATION OF BREEDING AMONG BLACK BEES.

DURING the past few weeks I have been collecting all the condemned bees I could meet with within a radius of three or four miles, and having expelled them from their hives by driving,

have applied them to strengthening weak artificial swarms, and such of my stocks as had been too much weakened by repeated divisions. This has afforded me an excellent opportunity of ascertaining the character of the past honey-season in this locality, and has confirmed my impression that it has been most wretched. I find that a great many swarms died of starvation during the wet weather in June, whilst of those which survived few indeed have half filled their hives with comb, and still fewer are heavy enough to stand the winter.

Another circumstance has also forced itself on my attention, and that is the complete and remarkably early cessation in breeding which appears universal among the black bees. In an old, strong, and well-provisioned colony, on which I operated on the 5th inst. (September), I discovered a small quantity of sealed brood just ready to issue from the cells, but not a single egg or young larva; whilst from that time I have not found brood in any stage in one of the numerous stocks and swarms that I have expelled from their domiciles.

In this respect my Ligurians assert their wonted superiority. Although even with them breeding manifests an unusually early decline, I can still show patches of sealed brood as large as my hand, many thousands of young bees just out of their cells, and eggs and larvæ in all stages, and this in stocks which have not been stimulated by recent feeding. This superiority becomes the more striking when it is considered that my stocks are not nearly so well provisioned as many of the black colonies which I have examined, whilst my locality, in the immediate vicinity of a large town, is decidedly inferior to theirs.—A DEVONSHIRE BEE-KEEPER.

### LIGURIAN BEES FOR AUSTRALIA.

THE following paragraph is copied from *The Exeter Gazette* of the 26th inst. We understand that the four hives were sent out by Mr. Edward Wilson, a gentleman who has spared neither trouble nor expense in the cause of introducing new animals of the most improved breeds to the colony of Australia. The same ship which takes out these Italian emigrants conveys also a quantity of the finest breeds of poultry and others of the feathered race resigned, we believe, to the Melbourne Acclimatisation Society. We doubt not the "DEVONSHIRE BEE-KEEPER" has exhausted his ingenuity in the attempt to insure the safety and comfort of his little favourites during their long confinement, and we hope in due time to be enabled to announce that he has been perfectly successful.

"On Tuesday last we saw four hives of bees of the Ligurian breed, which had been selected and packed for exportation to Australia by T. Woodbury, Esq., of Mount Radford. Mr. Woodbury has long enjoyed a high reputation for his knowledge of bees. He was the first to introduce the Ligurian species of honey bee (*Apis Ligustica*), into England; and he has now brought their culture to a high state of perfection. Through the pages of THE JOURNAL OF HORTICULTURE, "The Bath and West of England Society's Journal," and other channels, he has made known his views on these interesting insects. The first honey taken in England from Ligurian bees, being also the two finest suppers in the building, are from his apiary, and are now in the International Exhibition, where they are exhibited by Messrs. Neighbour & Sons, 149, Regent Street, whose stall is in the Eastern Annex. The order for the four hives from Australia was received through that firm, and from the admirable manner in which Mr. Woodbury has packed the hives there is little doubt that they will reach their destination safely. It required no little ingenuity to devise a hive which should at once afford air to the bees, and yet be perfectly secure against accident. This, however, has been accomplished. The hive proper consists of a wooden box filled with frames, in which are inserted the combs after the German fashion. The whole is then mounted on a "nadir" with perforated zinc, bottom and sides, a space being left at the bottom to receive the droppings from the hive, and thus prevent it from becoming choked. The top is also covered with perforated zinc, over which is a covered receptacle, in which is placed a wet sponge (to be redamped every two or three days), so as to afford moisture for the bees. In the hive is a stock of honey sufficient to last until March next, *The Alhambra* by which they will be conveyed left Southampton yesterday, and will, it is hoped, reach Australia in sixty days. The bees have been selected with the utmost care; all of them being less than three months old. We hope that Mr. Woodbury's care and trouble will be rewarded with success."

### HONEY AND WAX AT THE INTERNATIONAL EXHIBITION.

(Continued from page 504.)

PRUSSIA.—F. V. Burchardi, *Hermsdorf*.—Specimen combs, most of them black and dirty-looking, worked on frames in unicomb compartments on artificial wax foundations, which I shall say more about when I arrive at the Swiss court. The complicated unicomb affair here is built up in the shape of a cross, which, to people who could afford the whole of their time to attend to it, might prove interesting. It has got a "prize medal," and that is all I have thought worth while to say about it. A quantity of dirty-looking honeycomb, in dirty bell-glasses, is also exhibited here.

Berlin.—C. Blumer exhibits honey wine, which for colour and fineness looks exactly like my own; though from the thinness of the bottles it is not so effervescing, or it would certainly burst them. It is to be found near the entrance on the ground floor of the south-west tower, and is awarded a "prize medal;" and from the circumstance of there being one bottle less the half-dozen, it is possible the Jurors did taste it. Upon a further inspection, I observed written, "Agent, 20, St. Dunstan's Street, City." I shall procure a bottle on the first opportunity, to try.

WURTEMBERG.—E. Weitzel (Society for Breeding Bees), *Sonnenberg*, exhibits a model storifying, or bee-hive-house in miniature. The wooden hives are packed in tiers, in the shape of a cross, one limb forming a portico, having for its entablature one tier of hives supported by two pillars. A roof is made to clip the whole. The square space, or room, which forms the inside, is entered by a regular doorway. The hives are square, on the bar-and-frame principle, and are made to open for the bee-master's inspection of the inside. They are all numbered, and have their corresponding numbers on the skirting below for the purpose of writing observations against, referring to the state of the hive. The bee-entrances to the hives from the outside are made to close with horizontal slides at pleasure. It is, architecturally, a spirited contrivance for an enthusiastic lover of the craft; and I ought to mention that the lowermost tier of hives is raised from the ground—let us suppose 3 feet, on a frame skirting, but the entrance-door opens down to the ground.

GREECE.—Demos of Salamis, and A. Theodosios, both get "prize medals" for muddy, inferior honey in bottles. There is a bottle of honey with its head off by Demos of Monembasia, which is the whitest and best-flavoured sample; and if any of these honeys deserved a medal the latter is the sample that should have got it. Other honey should be here, according to book, but I could not find it, and no matter, if no better. The wax is good. Demos of Gytheon receives a medal for white; and Demos of Phellias, ditto. For other specimens, which were much the same, the numbers and names were in a confused state, and my time was too limited to allow me to rectify them.

IONIAN ISLANDS.—Cephalonian Committee.—A middling-looking sample of honey from Spartilla, "honourable mention." B. Cerigo, G. Varipati, a muddy sample, "prize medal." A. Caligero, muddy, "prize medal;" and also some honeycomb (*Calamos*) in a large glass jar—a complete mess and dark-coloured, which also gains a "prize medal." The attendant made objections to my request to taste these specimens, and if I may judge from their bad looks he had good reasons. The jars, however, look as if they never have been opened. There are two poor specimens of wax, which took me three-quarters of an hour to find; they gain a "medal and mention."

ITALY.—There are many specimens numbered to this court in the catalogue not to be found, and some numbers to be found which are not specified in the catalogue. "No. 447, honey," for instance, is not down in the catalogue, but it is on an "honourable mention" card with this specification—"for goodness of quality." I found this mention slung around the neck of a bottle in a case numbered 747. At last, thought I, there is a sample of fineness and colour. I sought an attendant to allow me to taste, when, on lifting up the "card," it proved to be natural oil (*olio naturale metazze*). I tired out his patience to find out, if we could, the number of the natural owner of the "honourable mention," and he (the attendant) gave me quite up to my own devices; and any one who has seen that Italian stand of bottles in the gallery may pity me if he can.

At last I did find a bottle numbered 747 (the number of the oil), which proved to be honey. I suspended the card around its neck, and marked, with the attendant's leave, 447, the number on the card, with my pencil over 747, which number he wanted

to erase from the bottle entirely, but I persuaded him not to do that. I have been thus particular in mentioning this circumstance, in order to point out to "unsuccessful" exhibitors the negligent way in which medals and mentions have been tossed to persons, which must tend to bring these honours into contempt and to be valued accordingly, which is a pity; for "Nec quæere nec sperare honorem" was the rare old Bolingbroke motto which I took for my text on becoming an exhibitor, and which ought to be emblazoned on every Jurors' committee table to constantly impress upon their minds the manner in which the importance and value of their decisions are to be taken by the public. There is a bottle of "Hyblean honey" by G. Lavaggi, and others with honeycomb and honey by Majorana Brothers, Catania, both of which have got medals "for excellence of quality." I must say, then, there is no accounting for taste or for looks either, as nastier-tasting or worse-looking honey I never saw—it fairly stinks. The best specimen of the whole was a finite quantity I probed from the bottom of a little bottle which had got emptied somehow or other, and purporting to be "Mont Hebla honey." That single drop was worth the medals and mention given to the rest.

In wax some specimens notified are minus. G. Carobbi, Florence, exhibits samples in a case tastefully got up, for which he gains a "medal;" and Astengo, Brothers, Savona, show some very good manufactured wax. Cav. N. Maffei, Volterra, is named as having models of bee-hives, but these I could not find here. I then descended the grand staircase from the gallery, and struck through the Roman Court by the "Reading Girl." I had read of this sculptural work of art, and now coming upon it suddenly and without design, it rivetted me intensely to the spot. It is very fine. One almost longed for the power to infuse breath and life into the sculptor's work, and to possess it for one's household god.

NETHERLANDS.—Amersfoort, E. E. Visser, sends the largest quantity and most uniform sample of yellow wax to be found in the building; bright and good. M. Wolff, Amersfoort, sends two large round cakes, though not quite so bright in appearance as the above. A glass bee-hive is also catalogued, but "not come."

PORTUGAL.—There are also forty-two entries of honey in the catalogue, thirty-one of which I found. There are some of good quality, some middling, many very nasty, and most are shockingly shown; some samples even are sent in common black wine-bottles, so I shall resort to the art of calligraphy here, for the notes I have, if given *in extenso* would unworthily occupy a whole column of this paper. One specimen, before I attempted to taste it, I booked thus:—"Very fine golden straw colour," but which, upon closer friendship, turned out to be "oil of almonds." I cautioned the attendant that a good sip mistaken for honey might poison a person, and that it would be as well to get it removed from amongst the honeys—a caution he seemed to deem quite unnecessary. The tone of my notes rings thus:—brown, muddy; olive green, pretty good, tolerable, very bad, good. The best specimen, to my fancy, is "wild honey" by F. M. Loureiro, *Serpa*; no medal or mention is given—albeit, there is better-flavoured honey than the Italian, and better-looking than the Ionian. There are several entries for wax. I could find but three only, mixed up with resins and copals, for which they might easily be mistaken. A. J. de Seixás, from *Loanda* and *Benqualla*, and B. J. Brochado, *Mossamedes*, show coarse, dirty-looking, yellow wax. A bee-hive also is mentioned; I could not find it.

SPAIN.—Being next to Portugal, I will mention her now in case any one should feel enterprising enough to go over my notes. There are twenty entries of honey for this court, most of which may be here in bottles, and in barrels, in bladders, jars, and cakes, but they are placed so as to be difficult to inspect. Don Juan Rodríguez, *Lorenzo*, gains a medal for a good-looking sample of white honey; and B. Oliver, *Baleares*, also got a medal for a sample not so good-looking. I regret I could not get to taste them. V. Delgado has a "medal" for white and yellow wax; Carrona, for white wax and candles, an "honourable mention;" and another exhibitor, who I can suppose feels chagrin, has hidden his name and number behind some of his, certainly the best, white manufactured wax in the collection.

VENEZUELA sends white, brown, and yellow wax, very good; and a large cake of vegetable wax—at least, I concluded it to be such from its appearance, for I could see no specification. They are strong in artificial wax flowers and fruit here, over which I dwelt as long as I could—they do look so refreshingly tempting. Passed over, though, without medal or mention.

RUSSIA (Gallery).—Kazan, Prof. Klikevsky, sends crystallised (my term for this description has been "congealed") honey; and the Countess Olga Rochefort, *Ossa Cive*, gains a "prize medal" for some peculiarly flavoured "lime-tree-blossom honey, obtained by cold pressure." No wax; but F. Krause, *Warsaw*, sends its representative in the shape of "compact bees-wax paint for polishing the floors yellow," or any other colour. "Directions for use:—To every pound of this paint take one quart of soft water, into which, after being well boiled, put the paint out into small pieces, and mix it well together till the paint is thoroughly dissolved, and, while still in a hot state, dip a brush in it and paint the floor; then let it get perfectly dry, after which well rub the floors with dry brushes, and a beautiful polish will be produced." This looks feasible, and the composition is cousin German to Ferm's furniture cream. "Models of bee-hives" again I could not find, nor any one to refer to.

SWITZERLAND (Gallery).—F. Beck-Leu sends two little bottles of congealed honey, which I shall call the "cherub," from their being perched aloft in such an excellent position to be seen. The Jurors, furthermore, watched their welfare by giving them a "medal." This honey stands in these notes as being the third best for quality of the run honey in the building. Thus: my virgin honey, to my English palate, first; the "Miel de Table Cstanais," second; and M. Beck-Leu's, third. There is, also, *dos-a-dos* with the cherubs, a small tin canister of "alpine honey," by F. Wassali, Coire, which gains a "prize medal." The top of the tin resisted my endeavours to twist its head off, but having the fear of the flavour of tin before me, I do not think I cared to exert my strength to the utmost. This court possesses some "stereotyped" zinc-lead plates for the forming of worker-comb foundations. Each plate is about 1 foot by 10 inches in diameter, and two-eighths of an inch thick. Melted wax is run upon the face of one of the plates, which is slightly indented with fac-simile basements to honeycomb; then another plate to correspond is pressed flat upon it; these mould the thin foundation-wax, and it is thereto fixed centrally in the frames, to guide the bees, and save them great labour and loss of time and honey; at least, this was my explanation, as I read the *prima facie* idea of the contrivance before me. In a small box there is a specimen of honeycomb completed by the bees from these foundations. There is, also, what I will call for illustration, a kind of grooved impress roller, worked by two handles as you would a horizontal rolling print on the top of a pound of butter, which, when passed over wax on the sides of the bars or frames, forms sections of foundation cells longitudinally. Capital ideas both of them. I send you two specimens of the foundation wax, which I hope will escape the postmaster's impress. No. 1, is that of Professor Menzel and Graburg, Zurich; and No. 2, is a specimen of M. Burchardi's. The Swiss sample gives the bases of the cells most perfect, though I could perceive no difference in the after-workings of the combs of either, in so far as regards regularity, and the size of the cells. There is no medal or mention for these in the Swiss court, which they deserve, so I hope they meant it for the artificial foundation-combs in the Prussian department.

TURKEY.—The honey is decent, though dark-coloured, and there are some specimens of yellow wax, which are placed in a dark corner partly surrounded with skins of animals, which smell none of the sweetest, and may have proved too strong for the nasal propinquities of the Jurors, as I observe no medals or mentions hereabouts.

Thus ends my survey, and insufficient though it may be, I trust it will be sufficient to prove to us English apiarists that we stand in the front ranks, and that we mean to maintain ourselves there.—UPWARDS AND ONWARDS.

## OUR LETTER BOX.

DUCKWING GAME COCK (H. L.).—There are two Duckwings—the Old Duckwing and the Silver Duckwing. We thought this question was set at rest long since. The copper saddle among Duckwings can be found in print or writing a century and a half ago, and is essentially part of the bird. Our notion of a Duckwinged Game Cock is as follows:—Light straw hackle and saddle, black tail, breast and thigh, copper saddle, and duckwing. We believe you are quite right, and that a dark copper saddle is a good point. Spangles, tassels, and Lark-crests are among the eccentricities of Game fowls. They belonged to a past age, and may rank with four-inside post coaches.

PLAGUE OF FLIES (E).—Autumn is the season when flies seek shelter in houses from the chilly night and morning temperatures. The only way to exclude them is to have lace netting before the part of any window that is open; and to destroy them, pour half a pint of boiling water on a quarter of an ounce of quassia chips, sweeten the liquor with sugar, and offer it on plates to the epicurean flies. It is really a "bitter cup" for them.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 60.7° and 42.7° respectively. The greatest heat, 74°, occurred on the 7th, in 1834, and 8th, 1859; and the lowest cold, 25°, on the 11th, in 1860. During the period 115 days were fine, and on 130 rain fell.

A FEW WORDS ON HYACINTHS.

BEGIN to think that that expression "you know," which we are so prone to use in conversation, is a very troublesome and deceitful word — that it implies ignorance and not knowledge—and that many people are foolish enough to give their head a sort of Lord-Burleigh shake and look very wise, when, if they are

really interested in the matter, they would give anything for some information; only it looks so much wiser to be supposed to know all instead of saying, "Pardon me. I do not know." Alas! how much of sham there is even when we least intend that it shall be so. And does not the speaker too do wrong, often unconsciously doubtless, in supposing that people know (because the subject is so familiar to himself), all the little details which after all give their hue to the story or account? The account of a battle may be so skilfully worded by the ingenuity of a Secretary of War, that what was really a disgraceful defeat is only a strategic movement, and what was a doubtful onslaught becomes a glorious victory.

Well, now, what has all this to do with Hyacinths? Why, just this—that I fear in writing on such matters, we (for I desire to include myself amongst the culprits), while giving directions on many points omit the trifling matters of detail, which tend to either spoil or make the matter. How many a careful housewife has brought down on herself ill-deserved reproach, because in preparing the *ragout* she has been told to add a *little* onion or a *small quantity* of pepper; and has thereby (a little being an unknown quantity), been told by one that it was abominably strong of onion, and by another that their throats must needs be made of copper to stand such fire. And so I, the other day, having received through the kindness of some friends a nice lot of Hyacinth bulbs, and distrusting my own knowledge on the subject of their growth, thought I would consult some of the authorities. I had a number of catalogues, the "Proceedings of the Horticultural Society," gardening books, &c., before me; and yet, strange to say, I did not find exactly what I wanted. One mentioned the kind of compost, but said nothing about proportions; another, the material to be plunged in, but nothing of the position or the length of time in which they were to remain there. So, having read all, I bethought myself, Now I will set to work. My task was finished; and then it occurred to me, having freely confessed my ignorance, I may now, perhaps, without presumption, sit down and tell others what I wanted to know myself, and what my own experience in such matters has suggested to me. Leaving, then, out of sight the cultivation of the Hyacinth in moss or water, both of

which we know are practicable, I shall treat of it as to be grown in pots or in the open air.

I. CHOICE OF BULBS.

It cannot be too strongly impressed on those who desire to grow very successfully or to compete, that as soon as the bulbs arrive from Holland they should go to the importer with whom they are in the habit of dealing and select at once their supply. The first and best consignment arrives generally in the latter end of August. Second and third importations are always to be mistrusted; as the market is so sure and the English importers such good customers, that those which are left behind are generally inferior bulbs, and are either disposed of in this way or else sent over to auctions, where they may be purchased at a very low rate. The bulb should be hard and solid and the base sound. Size is no criterion; some sorts, such as Mammoth, being always large, and others, as Prince Albert, always small. Nor can any rule be given as to shape, some being quite conical at all times, and others spherical or flat. Weight is something; but after all much must depend on the character of the person with whom you deal—and honest and trustworthy men are to be found in abundance. It is, however, better to avoid those bulbs which have the appearance of throwing out many offsets, as they will be sure to weaken the parents. Never choose from bulbs in windows "weighed from sample," does not hold good here.

II. COMPOST.

Although it is perfectly true that the Hyacinth will flourish in any strong rich soil, in which its roots can have fair play, yet to grow it well attention must be paid to this point above all others. That which I prefer is about one-third of good rotten cowdung, one-third of old hotbed manure, one-third of good yellow loam, and about one-eighth of silver sand to be added to this mixture. I prefer the hotbed manure to leaf mould, inasmuch as there is more strength in it, and the decomposed straw gives, I think, sufficient of vegetable fibre to it. The materials should be well rotted, although this is not so necessary as in the case of some florists' flowers, a twelve-month being sufficiently long for the manure to have lain. If there is no loam in the neighbourhood, and one lives within a hundred miles of London, I should not hesitate to advise getting some from Mr. Kennard of the Old Kent Road. It will not cost more for a good batch of Hyacinths than the price of a couple of good bulbs, and I would not "spoil the ship for a ha'porth of tar."

III. SIZE OF POTS.

For general purposes—that is, where you wish to simply grow them for decorative purposes, you can have very fine blooms in 32's—that is, about 6 inches across inside measure. To obtain, however, fuller spikes and such as may successfully compete at exhibitions, a larger size, 9 inches across, will be preferable. Where they can be obtained, pots made on purpose of considerably greater depth than usual are to be preferred; but if plenty of room be given, this will not be of so much importance.

## IV. POTTING.

The time for this will depend much on the period when you wish the bulbs to be in bloom. As a general rule the end of September is the best; and the sooner the bulbs get to work, I fancy, after their close confinement, the better they will like it. Should circumstances, however, prevent this being done, they should be kept in a cool place not exposed to the light. Pass the compost above recommended through a coarse sieve, keeping the coarser pieces for the bottom of the pot. Put in two or three pieces of broken pots, then a handful of the coarse compost, and fill the pot up to the top with the sifted compost. Place the bulb firmly in, leaving about one-third of it exposed. Then place a small pot over the bulb; and if the compost is not sufficiently damp, give the pots a gentle watering with a fine rose or syringe. They are then ready for

## V. PLUNGING.

The object of this is to encourage root-growth before the flower-spike begins to grow. Select, therefore, a well-sheltered spot with a good hard bottom. On this lay a good depth of coal ashes to prevent the intrusion of worms into the pots. Rake it smooth, and then place the pots on it close together. The covering material may be coal ashes, old tan, or anything of a similar character; and the object of placing the small pots over the bulbs is to prevent the material touching them, for it is apt to create canker. I use coal ashes. The bulbs are now safe for two or three months. Of course, if you are desirous of bringing them on, you can easily bring them out and introduce them into the greenhouse; but as a general rule they will be better left until the pots are well filled with roots. This can be easily ascertained by taking out one of the pots nearest the edge.

## VI. AFTER-CULTURE.

When they are removed from the bed they should be carefully cleared of all the ashes, &c., that may cling to them, the surface of the soil stirred a little, and to make it neat a little compost may be added, as the ashes are pretty sure to make it untidy. The shoots will be about 2 inches long and quite white (blanched by want of light). They should not be at once exposed to the full glare of day, but placed where a shade can be put over them. They should be gradually inured to the light, and then placed near the glass, where they will not be drawn. Give them abundance of water; and as the time for exhibition draws nigh, if you intend to compete, liquid manure may be added. I have known some exhibitors to stand their pots in saucers in which liquid manure was placed, and let the grass-feeding fellow fatten himself thus. They will do very well in a cold greenhouse, pit, or frame, so that care is taken to exclude all frost, which injures the beauty of the spike. As the spike lengthens a thin piece of galvanised wire may be passed up through it and tied. The great object should be to obtain a good spike, and clean but not drawn foliage, leaves lapping over the sides of the pots being a great drawback. The same care will be amply rewarded where exhibition is never thought of, but where the best growth is desired.

So far for culture in pots as far as the open air is concerned. I had intended to have said something, but have been anticipated in last week's JOURNAL OF HORTICULTURE by Mr. Chitty, of Stamford Hill; only adding that one of the prettiest sights in spring bulbs I ever saw was a large bed of Hyacinths treated precisely as florists' Tulips are, with canvass awning itself. It was grown by Capt. King, of Dane John Terrace, Canterbury, and was a sight well worth seeing. And now as to

## VII. CHOICE OF SORTS.

For ordinary purposes, and, indeed, for exhibition, many of the lower-priced Hyacinths will give most satisfactory bloom. I shall mention a few of these, and then add a few of the scarce ones. Such kinds as Duc de Malakoff (two guineas), and others are too expensive and rare for any one but growers for sale. I merely mention single ones; for although Groot Vorst, Waterloo, Laurens Koster, and others are very fine, single ones are by far the most satisfactory.

## SELECTION NO. 1.

<i>Single Red.</i>	Charles Dickens
Amy	Grand Lilas
La Dame du Lac	Grande Vedette
Madame Hodgson	Nimrod
Norma	Orondates
Sultau's Favourite	Porcelaine Sceptre

*Single White.*

Elfrida  
Grandeur à Merveille  
Mammoth  
Tubæflora  
Victoria Regina

*Single Blue.*

Baron Von Tuyll

*Single Black.*

La Nuit  
Mimosa  
Prince Albert

*Single Yellow.*

Alida Jacoba  
Heroïne

None of these exceeds 1s. each, and can be obtained, I have no doubt, at 9s. per dozen.

## SELECTION NO. 2.

*Single Red.*

Cavaignac  
Cosmos  
Howard  
Lina  
Macaulay  
Reine des Jacinthes  
Von Schiller

Misa Burdett Coutts  
Paix de l'Europe  
Queen of the Netherlands

*Single Blue.*

Argus  
Couronne de Celle  
General Havelock  
Von Humboldt

*Single White.*

Gigantea  
Madame Van der Hoop

*Single Yellow.*

Aurora  
Victor Hugo

These vary from 1s. 6d. to 7s. 6d. each, but by the dozen could be had, I have no doubt, much cheaper. Most of the flowers in both selections have taken prizes at the various exhibitions held last spring, a pretty sure test of their merits.

I cannot close this paper on the Hyacinth without stating that Mr. James Cutbush has materials, I believe, for an interesting paper on "Gardening round Haarlem," gained during a visit paid this last spring. By their annual Exhibition of spring flowers, the Messrs. Cutbush have done much to make the cultivation of the Hyacinth popular, more, perhaps, than any one else; and they will increase the obligations we are under to them, if we gain a little insight into the manner in which our Dutch friends manage the flower.—D., Deal.

## CROCUS SPECIOSUS—RARE BULBS AND CYCLAMENS.

EARLY last week, or say on the 29th of September, I had on my window-sill the first flowers I have ever seen of the very handsomest of all the wild Crocuses which have yet been described, *Crocus speciosus*, and you never yet saw another *Crocus* like it. Indeed, were I to cut the styles and stamens out of one of the flowers and show it to a botanist, perhaps there are not three of them in the three kingdoms who could tell even the generic name, so little is known of this most lovely *Crocus*, and most un-*Crocus*-like flower, to make an expressive term for it: therefore, perhaps the best way to represent it to the mind's eye of a gardener, would be to say what I would guess it to be if a botanist had tried me with it in the same fashion. I should say at a venture it was a new *Leucocoryne*, and judging from the long tube and the peculiar colours that it must be very nearly related to *Leucocoryne ixioides*, or, perhaps, what would be better understood by some of the older gardeners, as *Brodiaea ixioides*, a half-hardy bulb from the extreme southern limits of the Peruvian Andes, and further on. But thousands of our younger gardeners have never seen one of these "white-club" roots, the *Ixia*-like flowers with six stamens instead of three, but with three out of the six barren, and in the shape of a club, a white club, which is the meaning of *Leucocoryne*. But to what else to liken *Crocus speciosus* I know not; but this I do know, that it is as hardy as the Scotch *Crocus*, that it occurs first in the north-east corner of Hungary, and the countries near it to the eastward too, and through the table-lands of the Crimea to the Caucasian range; that it has bloomed abundantly in Yorkshire, with Dr. Herbert, from the end of September and through October, and seeded freely enough; that pulchellus, medius, pyrenæus, and byzantinus are equally free-bloomers at the same time, and that longiflorus and Cartwrightianus follow them and keep on till Christmas. The whole set, as pot plants, are quite as gay as the Dutch seedlings are in the spring.

Now, I will just show you how it could be that we British could completely beat the Dutch in the matter of autumn and winter Crocuses. The Dutch are so pestered with frost over there, with their low lands and cold climate, that they cannot

show a green bough out of doors the whole winter, so that if they were to put those autumnal beauties out of doors, there they would stick the whole winter without making an inch of leaf till their own Crocuses got free in the spring, and then it would be too late to compete with our growth going on the whole time, more or less. But suppose they had a rapid growth in the autumn before the heat was out of the ground, that would only add to their troubles the more, for they have more slugs and snails than we have, and every blade would be gone much faster than it came, till the frost decided which would pitch the most for the rest of the growing season. The people in this country, also, do not mind so much about pretty little flowers out of doors after the bedding plants are in; but some of them are absolutely bent upon having all manner of flowers for them under cover the whole time, and anything new puts them up in the scale, so that you could get any amount of money out of them for keeping up a fashion and the rage for flowers: therefore, we should grow all the breed of autumn and winter Crocuses in pots till the bloom was over, and by that time it would be all up with our snails and slugs, and we might turn out the balls entire close under the walls in the kitchen garden, and behind the rows of Brown Cos Lettuces—a ribbon-border in fact, by Christmas-eve, when the Dutch would be fast as Wexham Lake in ice and snow and no sign of growth about them. There the roots of the Crocuses would ripen and remain till the middle of August again, when the best would be potted and the rest might be sent over to Holland to give the Dutch the chance of a competition which they must soon give up, for we could beat them there at all events, judging from all that I have been thinking, and trusting to what I mean to do to set the ball going.

But I want more wild winter kinds of Crocuses. And I want, over and above all that, four kinds of very pretty bulbs about which Mr. W. Earley, *Digswell*, made my teeth water at pages 488 and 489—I mean *Streptanthera elegans*, which I feared was out of cultivation over thirty years; *Bessera elegans*, which I have not seen since eighteen and something, and quite forgot; *Milla biflora*, the whitest flower among all bulbs; and *Gladiolus cuspidatus*, which I was well pleased to hear was still on the stocks. Now, I would tell a secret to anybody for these four bulbs, or exchange something handsome with Mr. W. Earley if he could send me a flowering root of each.

But, did I ever tell of the last luck I had in rare bulbs? It was last spring I received a noble root of *Cummingia trimaculata* one of the first foreign bulbs I ever knew, and managed it on the old system of very cool treatment, to see how it could best be adapted to the present style of gardening. You are always safe to begin with any kind of bulb, stove, greenhouse, or open air, as if it required only to be allowed to grow naturally. Then, if it does not move to your liking, give it a little more heat, and so on till you come just to the required degree, but if you begin with one or two degrees of more heat than is natural to a bulb, the chances are that you derange it at once. Then it is said to sulk or to resent such treatment, while the fact is, the system is deranged, and bulbs are not like other pot plants in that condition, you cannot bring them round by merely changing the system of heat, soil, or watering, for a very long time; but by beginning a bulb requiring stove heat in a cool frame, you merely fail in exciting it, you cannot derange it, and it is ready for a change of culture or another experiment.

Well, I knew that my *Cummingia* did not require much heat, but how much I could not exactly say, so much depended on how the last growth of the bulb was ripened; besides, there are no bulbs in any part of the world, as far as we know, which are one-half so touchy as those from Chili, and the southern parts of Peru. The least turn seems to affect them either way, for good or for no good, but a great deal of harm. Knowing all that, I began *Cummingia trimaculata* in a cold frame that was left open day and night in April last. It would not move; the frame, or rather the pot, was put into another division, which was kept close for newly-potted-off plants to recover the shift, but no artificial heat. Last May was a fine season for cold-pit work, the days were fine, and the sun would give stove heat, yet the nights were cold, and by the next morning the plants were as cool as could be to be safe. Never did I notice so much the value of having plants so much more cool at night than in the daytime, as last May, with a mere handful of rare bulbs.

Well, stove heat in the day by the sun, and cold pit shelter at night, had the usual effect—a free, vigorous, and natural growth. That once induced, I planted out all the bulbs, including some

young *Cyclamens*, in one end of that range, and kept up the same system through June, with only more air on both day and night, and the *Cummingia* was the first and foremost of all my experimental plants, and by the end of the month I had to tilt the glass to give it head room, and then I thought I had spoiled it with too much heat, for it got higher than all my ideas of *Cummingias*, and I was perplexed. By-and-by, however, the flower-scape appeared, and after another by-and-by, the flowers also, and I was done, for my bulb was *Bravoa geminiflora* instead of *Cummingia trimaculata*. Now, this *Bravoa* is now in the catalogues as a fine thing, but all I can say is, that it is not worth more than about 1s. 6d. or 2s. the bushel, and that only for a botanical collection, and mine being not so, I rooted-up *Bravoa* and destroyed it, and now I want *Cummingia trimaculata* for another start.

The story of that experiment led to many stories in my walk of life. I had a private story about *Cyclamens* over thirty years standing; but I never thought the world would believe it, so I kept it to myself till now. There was a botanical rumpus at the time, between Dr. Lindley and Don, about *Cyclamen repandum*. The one said it was so and so, the other that it was no such thing, and if ever you want to know the real truth about anything which is in dispute between clever men, you ought not to believe, or disbelieve, either of them; but believe a screw wants tightening somewhere, and you must do it for yourself, and then you will be as sure of the truth as I made myself, that both of them were wrong about *repandum*.

The idea at that time was, that all plants which would come true from seeds, were genuine botanical species. The dispute was about *repandum* being or not being a species, and being at work on *Cyclamens* at the time, I undertook to prove to my employer who was right and who was wrong about *repandum*. I had the bulb from Mr. Wheeler, of Warminster, it was in seed at the time by its own pollen, and, of course, if the seedlings came true, the question was decided, and they did come true, every one of them, all white or nearly so. The fact was proved in sixteen months.

In these days, however, if I were to assert that I gathered *Cyclamen* seeds, sowed them, and had the plants or seedlings in bloom in sixteen months, no one would believe a word of it. Well, a reverend gentleman sent me last spring, a batch of seedlings of the red and the white *Cyclamen neapolitanum*, from below Bristol—the gentleman who discovered the virtue of the cocoa-nut refuse for Ferns and bulbs—the seedlings were only a few weeks old, and I put them with the experimental bulbs in natural heat by the sun, but cold at night, and they did the best of the lot.

In the story about *Cummingia*, I began to tell about *repandum*, and how I got it into bloom in sixteen months from seeds, alleging that any of the hardy *Cyclamens*, like these seedlings, might be hurried on after the same manner, if not by a much better system of stove heat, night and day, from first to last. At this some doubted, and some said that it was madness to think of it, for no *Cyclamen* could stand 5° more than a Heath, and all the rest of it.

The Messrs. Henderson, of the Wellington Road, and of the Pine Apple Place Nurseries, treat the *Cyclamens* now as *repandum* was done and flower them in about eleven months, and the Messrs. Carter & Co., of High Holborn, do them in nine or ten months from the seed-sowing to the flowering of the seedlings, yet those gentlemen once called me a slow coach for taking sixteen months to do a thing which I believed no one would believe even if I added six more to the sixteen! It is even so, and there is no question at all about it.

You may if you choose, and have the means to do it, keep the seed-pan with *Cyclamen* seeds at from 70° to 80°, and up to 90° and to 100° from the sowing in the autumn or in the spring; and by that stimulus the seedling bulbs will be as big in ten months as they could be in full four years after the old slow-coach fashion of treating them as if they were Heaths, which is the usual way, and generally they are in bloom and in the market by the end of the twelve months from the time of sowing the seeds. Meantime the seedlings are potted into larger pots from time to time—or say some twice and some few three times in nine months. There is luck, then, for people who did not expect to live to see their last batch of *Cyclamen* seedlings come of age.

Another turn over the stile would bring us into a wide field of *Cyclamens* which I dread to enter from that in which the autumnal Crocuses prevail. But a gentleman I never had seen

before called on me since I began this paper, and the first thing he made an observation on was my *Crocus speciosus* outside the window. "But how did you come to know it so readily?" said I; "for I had only been just writing that I could puzzle a botanist with it if I took out his index from the flower." "Man alive," said he, "did I not see a whole row of it down the centre of the Botanic Garden at Liverpool, in the time of the late Mr. Shepperd?" But what I thanked him most for, was for telling me of a gentleman, near Manchester, who could help me in this field. "And," said he, "of course you know Mr. Niven, of the Hull Botanic Garden," and of course I did, and his father before him; and the hint is enough for

D. BEATON.

### LOBELIA SPECIOSA, AND WHAT MORE IS WANTED OF IT.

LIKE the appetite of a certain heathen deity, the wants of a flower-gardener are never satisfied. No sooner has he been furnished with something he longed for than some other want is announced. That which in years gone by formed a useful standing dish is no longer palatable, and the purveyors are told that something better is wanted. Fortunately it does not always happen that such wants take an extravagant turn, some plain homely article may, perhaps, be quite as fashionable, or an article previously well known is improved, and served up in a different form; but such is the diversity of wants as respects the different members of the flower garden, that it not unfrequently happens there is some dispute as to which article claims the pre-eminence in its particular way. A year or two ago *Geranium Tom Thumb*, which had reigned with undisputed sway for many years amongst the Scarlet family, was threatened with deposition, and some assert his reign is over. Be this as it may, the name will still figure in the flower garden for many years to come, and I shall be satisfied with the flower until I have good proof that a successor has proved superior. But as my purpose is to ask for something fresh in the flower-gardening line, and as it will be imposing too much on good nature to ask for too much at one time, I will pass by the *Geraniums*, both plain-leaved and variegated, on both of which classes I shall have something to say hereafter, and proceed at once to another plant, which I expect to see playing a more prominent part in the flower garden than it has hitherto done, although even now it is one of the most popular accompaniments there.

**LOBELIA SPECIOSA.**—This popular and highly-deserving plant is certainly gaining ground in public estimation, and the *Verbena*, *Salvia*, and *Anagallis* of the same colour are giving way before it in a wholesale manner; and next to variegated *Geraniums* I should think it is the most popular plant in the parterre. But my purpose is not to dilate in its praise, but to ask what more can be done towards employing it in another colour. Assuredly there is no great impossibility in its attaining the plum-coloured hue of some of the *Verbena* family; tolerably good white with a little blue in it has been attained, and all the paler shades of blue have been common enough for some years; but we want some other good dark colours—as deep purple, maroon, and, shall we say? "a good scarlet." I am in hopes of living to see this accomplished, and when these and other similar colours are attained, the *Verbena* may retire from business; for the *Lobelia* very far outstrips it in general utility and effect, and it only requires the same amount of patience and perseverance in raising new seedling varieties to accomplish this desirable result. And when as good a scarlet *Lobelia* is obtained as the blue one we now have, no *Verbena* will be able to compete with it, unless at the same time some one could also furnish us with a scarlet *Verbena* having all the good qualities and habit of *V. pulchella*. But this is digressing from my subject, my object being to call the attention of hybridisers and others to the means of effecting a change in colour. Perhaps a cross between some of the tall scarlet species and the blue *speciosa* may be effected (although I am far from certain that it can be so), and the vivid hue of the one transferred to a plant of moderate height and of unexceptionable habit. The dark colour will, I think, be accomplished without that, and we may in the end obtain all the colours in the *Lobelia* we now have in the *Verbena*, with the advantage of having them on a plant of more compact habit that shows its flowers all above its foliage, and which flowers both earlier, later, and more abundantly than that popular flower. More than this I need not say; but with a request to call the attention of cross-breeders and others to the subject I must leave

it in their hands. And if the wants here put forth seem in the eyes of some to be utopian, I would ask them to look at what has been done with the *Geranium*, *Dahlia*, and similar flowers. Although the full accomplishment of the colour named is asked for, I will be content to have it by degrees, and shall be glad to hear what progress has been made in that way by any one who either by accident or design has advanced a step in the right direction. Full success cannot be expected all at once, I nevertheless look for it some day; and *Lobelias* may hereafter have all the high-sounding names now conferred on *Verbenas*, *Dahlia*s, &c. But I need say no more, only to again call the attention of those anxious to improve the character of flower gardens to try what can be done with the *Lobelia*, feeling assured it will ultimately repay them for their trouble.—J. ROBSON.

### ARCHERFIELD EARLY MUSCAT GRAPE.

At page 470, Mr. Rivers doubts the truth of the statement that we made in reply to Mr. Thomson's communication at page 451 of our present volume, and wherein we stated that *Muscat du Puy-de-Dôme* was not the same as *Archerfield Early Muscat*. The ground upon which he differs from us is the description of *Muscat de Syrie*, which is extracted from the "Bulletin du Congrès Pomologique du Rhône, 1860," from which we presume that Mr. Rivers has never seen the fruit of *Muscat de Syrie*, either under that name or under any of its synonymes—*Muscat de Smyrne* or *Isaker Daisiko*.

When we made that statement, we had not the slightest doubt but that we were correct, as our information was derived from our own knowledge of the facts. Since we published that reply to Mr. Thomson, we have had further opportunities of confirming what we then stated from an inspection of what are, we believe, the largest collections of Vines in France, or even in Europe, and that, too, in situations which afforded every facility for producing the fruit in the finest possible condition. In three separate collections, hundreds of miles apart from each other, we have seen *Muscat de Syrie*, *Muscat de Smyrne*, *Muscat du Puy-de-Dôme*, *Muscat Eugénien*, and *Isaker Daisiko* growing side by side in all of these collections. *Muscat du Puy-de-Dôme*, and *Muscat Eugénien*, are allowed to be synonymes, and distinct from *Muscat de Syrie*, *Muscat de Smyrne*, and *Isaker Daisiko*, which three are also allowed to be synonymous; but when we state that the whole of these are only forms of *Chasselas Musqué*, if not that variety itself, neither of them can certainly be the same as *Archerfield Early Muscat*.

Our own opinion of these is that they resemble so closely *Chasselas Musqué*, that in England, where we do not attach so much importance as to whether a leaf is a little more sharply serrated in one case than in the other, they would be regarded as the same.

In no part of France is there a Grape known which bears any relation to the *Archerfield Early Muscat*. Recently, we have had opportunities of conversing with the most eminent pomologists of that country, and in every instance when we have asked the question whether or not they knew a Grape in every respect resembling the *Muscat of Alexandria*, with the exception that it was six weeks earlier, we were invariably answered in the negative, and with a feeling of curiosity and wonder expressed on hearing that such a fruit existed.

At the great Pomological Congress, which was held at Montpellier on the 7th of September, we were privileged to be present, and to take part in the proceedings. On that occasion the pomology of every department in France was represented, and there were exhibited between 300 and 400 varieties of Grapes. All the varieties which Mr. Rivers supposes to be the same as *Archerfield Early Muscat* were there; and although examples of them came from many different parts of France, in every case they were merely what we have already stated—forms of *Chasselas Musqué*.

We had an opportunity, also, of seeing at Condom a very large exhibition of all the Grapes that could be collected in the southern departments, and neither there nor at Montpellier, nor at the Exhibition at Lyons, nor yet in the great collection of the Luxembourg at Paris, did we see, or could we hear, anything of a Grape at all answering to the *Archerfield Early Muscat*.

We hope that the statement we have now made will be satisfactory to Mr. Rivers as confirming what we stated previously.

Like Mr. Rivers, we are very curious to know something about the origin of the *Archerfield Early Muscat*; the variety itself is

one of so much excellence and value that any information about it would be particularly interesting; and we know that to none will that information be more acceptable than to the pomologists of France, and more particularly to the Muscat wine-growers of the south.—H.

### PROPAGATING AND MANAGING GLOXINIAS.

THERE is quite as much beauty in a well-grown Gloxinia as in a Cineraria, and they are as worthy of a prize at our exhibitions as either Gourds or Pumpkins. When a plant becomes common it loses its hold of exhibition schedules, just at a time when amateurs are beginning to dispute honours with the professionals; but that is the time when a prize should be offered for amateurs, and in no case might the owner of two dozen of plants to be set aside because he refused to compete with those who have a thousand plants to select from. A fair field and no favour, is said to be characteristic of the Saxon; but as far as regards exhibitions, all is too often framed to suit the interest of large growers, whilst a more enthusiastic but humbler aspirant has his claims practically ignored, or a petty prize offered unworthy of the subject and the skill.

Most varieties must have three months' rest to bloom satisfactorily, but by giving a plant a check immediately after blooming, by exposing it to a colder atmosphere and considerably less moisture, it would appear that the juices of the plant concentrate rapidly in the tuber, and the repose or inaction of the roots is hastened, thereby promoting a premature rest. Such plants generally push again in about six weeks, whilst the prior foliage is in a withered condition, and if that be cut off, and the plant repotted, placed in a moist, growing heat of 65°, and watered moderately a second bloom may be obtained, but not equal to the first, and plants so treated give small foliage, few flowers, and little gratification the following season.

*Propagation from Seed.*—Having obtained a packet from any respectable nurseryman, we may expect about half a dozen varieties from it; but that depends, in a great measure, on the mixing of the seed, and if there is a great quantity of it put in the fire, for it is too plentiful to be good, and, as a rule, sow only those packets of seeds that are small in quantity, and high proportionately in price, for choice seed from good varieties is not half so plentiful as seed from inferior varieties. No seedsman can afford to hybridise or cross flowers and sell the seed at the same price as they that collect the seed as nature produces it. For why should he use his brains, and give extra attention if it confers no benefit? There is scarcely a flower in cultivation in this country, that cannot be made to produce seed by skilled judgment, that will amply reward the painstakinger for his trouble and render recourse to a foreign supply unnecessary. Balsam seeds of foreign growth are worthless in comparison to ours (Why cannot Stocks, Asters, &c., be grown for seed in like manner?), and when Roses are added to the list, we think there is proof enough to convince the sceptical that by a little extra pains bestowed, he may rival his coupees on the other side of the water.

Sow the seed moderately thin in a seed-pan three-parts filled, with one large crock on each hole of the pan; an inch of small crocks sifted follows next, then half an inch of siftings (what remains in the riddle) of half leaf soil, one-quarter light loam, and one-quarter silver sand, which compost is put in on riddings 2 inches thick and levelled. The seed is then sown, and the whole covered lightly with silver sand. Give a light sprinkling of water from a fine-rosed syringe or watering-pot, and set the pan in a Cucumber-frame, or anywhere in a heat of not less than 65° by night, the first week in February. If placed in a frame heated by fermenting materials no water will be required until the plants appear; but if placed in a stove evaporation is greater, and it would be advantageous to cover the pan with a bell-glass tilted on one side about half an inch. No more water to be given than just to keep the surface moist until the plants have made two leaves besides the seed-leaves, when they should be potted singly into 60-sized pots, in the same compost as before. When another pair of leaves appear, or the plant gives signs of growth, water should be given more freely, but not over the foliage, and always a few degrees warmer than the temperature by which they are surrounded. The seedlings had better be rather dry at the root than in a soil full of stagnant and superfluous moisture. The latter is fatal to them, and the former retards growth: therefore, enough moisture to insure growth, combined with fresh air on every favourable opportunity, and rapid transitions of heat or

cold, or currents of air to be equally avoided, are all conducive to healthy development.

*MANAGEMENT OF SEEDLINGS.*—If all has gone on right, the plants will need a shift into 48-pots by the end of May or beginning of June, when we employ the following compost—Two-thirds cocoa-nut fibre refuse, one-third light loam, and a sprinkling of silver sand for potting. In case cocoa-nut fibre refuse is not at hand the compost may be formed of one-half leaf mould, one-quarter sandy peat, one-quarter turfy loam, and about one-sixth of cording two years old; and a like quantity of silver sand may be added with advantage. In all pottings of Gloxinias the drainage should be perfect. A large crock on the hole in the pot, an inch of smaller crocks on that, and half an inch of rough refuse or soil-riddings will secure that in ordinary cases, but the plant is not invulnerable by worms: therefore, whenever a plant looks sickly see that the drainage is all right, and, if the soil is sodden, repot in fresh compost. Never put a plant in a dirty pot, not if it is a common one; for if it is worth growing it ought to be grown well. In potting seedlings the operator must discriminate between strong plants and weaker; for all seedlings, though sown at one time and treated alike, do not all thrive alike. Some will require shifting earlier than others; but as a rule the following is applicable to all seedling Gloxinias. Whenever the pot is full of roots repot from a 60 into a 48, and let weaker plants continue in the pots they are in until roots begin to mat round the pot. After potting into 48's the plants should be well watered, placed on a shelf in the stove or any house with a temperature not less than 60° by night. They should be placed about a foot from the glass, slightly shaded from strong sun, watered when the soil is dry, and gently syringed morning and evening in bright weather, but once a-day will be often enough in dull periods.

When the pots are full of roots, which may be expected the first week in July, repot into 32's, and treat in precisely the same manner as before; and occasionally look out for thrips, never heeding that the leaves are healthy, for it is best to discover the insects before the leaves give unmistakable signs of their presence and a considerable amount of the plant's juices are gone to feed the black-coated or white gentlemen, leaving ill-shaped and small flowers, the results of dingy thrips-eaten foliage. Whenever a thrips, black or white, is seen, shut up the house and fill it with tobacco-smoke. Better spend a shilling in killing one than having to smoke every other day for a month before they are thoroughly eradicated. Tobacco is the only cure for thrips, but it sometimes fails: therefore it is well to be on the look-out and smoke on two consecutive nights, for some will escape the first night, but it is few that escape a second dose. Green fly is easily killed by tobacco-smoke.

About the beginning of August the flower-buds will appear, when the plant should not be allowed to suffer for want of moisture in the atmosphere or water at the root; but we would not repot such plants, for they will flower beautifully in September; but should any be growing vigorously and show no flower-buds, we pot them into 24's and grow on, for which trouble they will amply repay by a splendid bloom in October.

The seedlings will flower earlier by stinting them to small pots; but we cannot arrive at any merit or demerit of the flowers the first season, for the foliage will be poor, the flowers small and ill-shaped, and the colours bad.

When flowering is over, gradually lessen the supply of water, expose to the full solar rays, and give a higher temperature by day and colder by night, and we shall find bulbs will lift the soil; and by the time that the foliage is gone the bulbs will measure an inch and more in diameter—just the sort of bulb to make a plant 18 inches across, 9 inches high, with fifty blooms expanded at one time the season following. If such plants are not desired, give seedlings a thumb during summer, let them flag for want of water, keep them 3 feet from the glass, let thrips sap their reservoir, and we have plants with six leaves 6 inches and 8 inches high, a bulb like a marble, and none or very few flowers into the bargain, and it takes another season's growth before we have a plant that appears in character.

In the ripening of seedlings, after the first fortnight no water should be given unless the plants flag, and only a little even in that case, and none at all if the leaves are yellow. The plant may then be placed on a moist floor under the stage of the greenhouse, but not where the soil in the pot will absorb moisture to cause growth or rot—seldom the last; but often the tubers are kept too dry, which causes them to shrivel, and roots so treated generally rot when moisture is absorbed when growth is wanted.

in spring. During rest a temperature of from 40° to 45° suits them best, and the last-named is perhaps the most suitable; but we have kept them in a cold house more than once at 36° and lost very few, and have had them in a temperature of 50°, and found shoots or buds were formed and starting into growth, and did not rot the bulbs in the least—in fact, they seem to thrive better when buds appear during rest than otherwise.

*Propagation from Leaves.*—Many plants besides Gloxinias are readily propagated by leaves, and I have to add another to the list that accidentally attracted my attention. It was in this wise. A Green's mowing machine had thrown a leaf of Yarrow (*Achillea millefolium*) on a border; a worm had pulled that half-way into its hole, in which I found it well rooted and precisely like leaf-propagation, having formed a knot at the lower end of the leaf, and a raised, minute eye at top, evidently the basis of future growth. Of course I made a note of it, and so you have it.

Select early in June leaves that have attained their full size; take them off with a clean cut half an inch below the blade or with half an inch of the leaf-stalk attached. Well drain a cutting-pot, and fill it with compost, one half sandy peat, one quarter turfy loam, and the remainder silver sand, riddled, and in that insert the leaves three-quarters of an inch deep; three round the side of a 48, or six in a 32, will leave each leaf clear of its neighbour, and unless they are clear water will lodge between the leaves, which causes decomposition or damp, and the leaves decay. Place the leaves so potted in a Cucumber-frame, or in the stove, at a temperature of 65°; if in the former plunge them in the bed, which should not be warmer than 85°, and there will be enough moisture to keep the leaves from flagging without using a bell-glass; but if placed in a stove a bell-glass tilted half an inch on one side is advantageous, for few stoves afford moisture so regularly as fermenting materials, though a tank may do so more than anything else; yet evaporating-gutters generating steam at 180°, are not the sort of thing to meet the requirements of vegetation. We grant evaporating-gutters are very good to keep away red spider, and even mildew, but we beg to state, that a great amount of heating surface at a lower radiating temperature, is more suited to vegetable development, than a less amount of heated surface at a higher degree of radiation. All gardeners are aware of that, and I think whilst they are aware of that fact they might naturally expect that evaporation ought to take place at something like the same temperature as that by which the plants are surrounded. Nature gives a beautiful exemplification of this. The mean temperature of the air between 0 and 20 feet from the earth's surface, is equal to the mean temperature of evaporation from the earth's surface. The mean of the air at 4 feet is also equal to the mean of the earth at 1 foot deep, and it never rains (but it hails) unless the temperature of the rain is the same as that of evaporation. A hygrometer shows, in some measure, the extent of evaporation in houses, but in hothouses condensation is continually taking place, except when the solar rays are passing through the glass, whilst in Nature condensation takes place during the night, as a generality; but on dull days in our hothouses a hygrometer shows little or no difference between the wet and dry bulb, whilst outside there is a difference of several degrees. Bear in mind that Nature carries evaporated moisture onwards to the higher regions of the atmosphere, far out of the reach of vegetation, there to be condensed partially when it falls in the shape of dew, or completely when it falls in the shape of rain; but in our hothouses the moisture evaporated is condensed by almost instantaneous contact with the glass, cold by the external air, and it frequently falls in drops like rain, called drip, which is baneful to vegetation; but a certain amount is also condensed in the shape of dew, which falls at the colder end of the house chiefly, though all over to a sensible degree, which materially affects the reading of the dry bulb. However, if evaporation takes place during the early part of the day with a high temperature, and the thermometer attains its highest point about 2 P.M., and from that gradually falls, so that the minimum temperature is attained by 6 A.M., we shall find our plants covered with dew exactly as in Nature, subject to a considerable amount of drip from the roof. Double-roofed houses obviate drip to a great extent, but in a high-roofed house there is little to complain of in this respect, for the moisture is more diffused in its passage upwards, and the condensation induced is more natural than when heated moisture is more immediately exposed to a condensing surface.

The cutting-leaves may be watered so as to prevent flagging;

but in no case should they be saturated above or below, or the leaves will damp, and the footstalks rot instead of forming roots, and they will require shade from strong light and sun. In six weeks they will be well rooted, when they may be placed in a vinery and kept growing for six weeks longer. They may then be gradually ripened-off as for seedlings, and be kept through the winter in like manner, and afterwards treated like established plants. The Gloxinia can be propagated at any time, but we find June best. It can also be increased by cuttings, but they take so much more of the old plant than leaves, form no better bulbs, and give less certainty in striking, that the plan is good for nothing—in fact, it is now abandoned, for horticulture, like agriculture, is bent on obtaining the largest amount of matter from the least consumption of materials.

Occasionally, Gloxinias are increased by *offsets* from the tuber; but, except in the case of old bulbs, it can seldom be done, and never, that we know of, has propagation taken place by division of the tuber, for wounded tubers do not heal readily, and the eyes are mostly centred so closely together that attempted division is rendered impracticable.

*Established Plants.*—It is presumed there is a stock in hand, and that there is the convenience of a stove, in which a little extra bottom heat can be given, if it be for no other purpose than to secure root-action before top-development commences. Select from those that have had the longest period of rest a dozen of erect and a like number of drooping varieties, giving preference to a bulb 3 inches in diameter rather than to one that is 6 inches. The bulbs should be firm to the touch, and, if eyes are visible, we prefer them, for they are certain to start into growth early; but those in which the eyes are not visible, generally shoot the strongest, though considerably later. The middle of December is quite early enough to commence with the first lot to flower in May.

Shake off all the old soil until live roots appear, and then poke it away from between the live roots with a small stick. Use pots twice the diameter of the bulb, securing good drainage, and taking measures to prevent its choking by placing a layer of rough cocoa-nut fibre refuse, or riddlings from compost, half an inch thick, and let the compost be formed of one-half cocoa-nut fibre refuse riddled, one-half light loam, and a little silver sand. In that compost place the tubers half an inch below the surface, water round the sides of the pot, and place in a bottom heat of 85° for a month, giving no more than just enough to keep the soil moist; then place on a shelf near the glass, watering more freely when growth commences, and giving a gentle syringing morning and evening. The temperature should range from 60° to 75° at this stage of growth, and, indeed, this degree of heat is enough at all stages. If the plants do well re-pot into a nine-inch pot early in March in the same compost as before. Though it is not absolutely necessary to use the compost named, yet it is the best; and one-half sandy peat, one-quarter fibry loam, one-eighth cowdung, and a little sand to be intermixed, is a good substitute, but not equal to the first. Early in April the flower-buds will appear, and care should be taken to prevent drought at the root. Ravages of thrips—monstrous idea so early in the season—and green fly, should be guarded against, and steps taken on the first appearance of either, to remove them. We may thus have nice plants at May-day fit for vases in drawing-rooms or to enliven the conservatory, none of the inmates of which will shame a well-bloomed plant of the common Gloxinia. A temperature of 50° will prolong the blooming to six or eight weeks; but the plants must be taken to the conservatory before the blooms are expanded fully, and hardened a little, if possible, in an intermediate-house before exposing them to a lower temperature and drier atmosphere. As a rule, all plants grown for decoration should be removed from a hotter to a colder place when the blooms are half expanded; for if removed when fully blown the sap receives a check, whereas it naturally requires a higher temperature to insure fructification, which is the chief aim of nature, and the bloom is thrown off.

The main stock should be started in February, and may be treated as the first lot, but the shelf of a vinery at work is a good place; whilst the man of humbler means may start them in a Cucumber-frame, where they may remain until growth has fairly commenced, when the shelf of a warm greenhouse or coolish vinery will give nice plants. We have had them in a greenhouse along with Fuchsias, &c., and Achimenes also, by placing them at the warmest end, and giving less air near them, a little shade as that of Vines or climbers, and more moisture

than greenhouse plants generally. However, an intermediate-house is best suited to their general weal, and by attention to watering and placing near the glass, strong healthy plants may be obtained.

The Gloxinia is not a plant that requires constant shiftings like a Fuchsia, but a pot at first twice the diameter of the bulb, a shift into a size larger when the pot is full of roots, and that is generally enough for most plants, for no good attends potting a plant when the flower-buds are swelling. However, if large plants are desired the strongest may be potted into 11-inch, and in the case of large plants into 13-inch pots, and increased heat and moisture given. The result will be plants 2 feet, 2½ feet, and 3 feet in diameter by 15 inches high, having leaves 9 inches long by 6 inches wide, and a bloom that no Allamanda, Pelargonium, or any plant for which a high-figured prize is offered can eclipse. Those started in February will bloom in the end of June or beginning of July, and will continue to give blooms in succession for three months, provided all that are decayed are picked off as they appear, copious supplies of water given, the air not saturated with it or syringed overhead, and shade afforded from scorching sun.

The last lot should be started in April, and if they are treated liberally they will enliven the conservatory in the somewhat scanty months of August and September. The plants of this lot are more liable to the ravages of insects than the others: therefore they should be looked carefully over. Besides thrips, black and white, mealy bug has no objection to harbour on the plant, for which there is no cure like the fingers. Another insect, very much like a black thrips, but quite as easily destroyed as green fly by tobacco-smoke, has lately infested Gloxinia flowers—the flowers only, harbouring in the inside of the flower, discolouring the corolla, and evidently relishing the juices of the organs of fertilisation. I find the same insect this year on Foxglove, Dahlias, and several other flowers in the open ground; it appears to jump with alacrity, and to be as baneful in its effects as black thrips on the leaves.—GEORGE ABBEY.

#### TREATMENT OF UNFRUITFUL TREES.

I SAW, some fortnight since, in your Journal of July 15th, a reply to "G. K., *Seenoaks*," on the treatment of "an unfruitful Pear tree." I would with all deference to you, beg to suggest what I have found a very successful treatment, having practised it for about seven years. I am indebted to Mr. Rivers for it, although it differs from his mode, and I do not begin so early as you advise either; and as to the "trouble" you refer to, I can only say it will well repay for it. I practise it rather largely on 800 or 900 trees of Pears, Plums, Cherries, and Apples, besides Mulberries and Figs, and the average cost is about 6*d.* each.

The method is this. The trees are dug out except a root or two on one side; and then the following year or second year, if they do not make wood the first, they are turned the other way, so that the roots which were before left are cut off and some left on the other side, and so on alternately. The roots are thus brought near the surface, and the check is never so great that you lose your crop. All the roots except those left undisturbed are cut back and laid round as direct from the stem as possible. The lengths at which the roots are left must depend on the size or height of the trees. A well-furnished pyramid 3 feet to 10 feet I generally shorten to 2 feet or 2 feet 6 inches. Those from 12 feet to 15 feet, 2½ feet to 3 feet.

I should have written before, but I get the Journal in monthly parts, and as I was from home the beginning of the month, I did not see it till my return, and since then I have spoken to an artist to photograph some ten or twelve trees, so as to send you some illustrations of growth and fruitfulness. If you would like it, when they are taken I will send you some and a more minute description of the lifting. I find that any tree will do well so treated. One of my Pears was a standard more than 20 feet high, and after being so treated was removed and transplanted, and it has this, the fourth, year borne two sacks of fruit. This will show you the size.—GEORGE LEE, *Clevedon*.

**THE ALANTHUS SILKWORM.**—It is only a few months ago that Lady Dorothy Nevill first called public attention to this hardy breed of Silkworm, and the possibility of the silk proving a remunerative article of production in this country. We are now happy to be able to state that, after the severe test of a cold

and variable summer like the past, the capabilities of the worm's withstanding our climate are now fully established, and that success in its extensive cultivation is no longer problematical. Her ladyship writes:—"My worms have done admirably, but I was obliged to net the trees over, though I think this would not be a necessity were they not in a garden. I placed five hundred worms on the trees in the beginning of August, and I have just picked off 480 or more cocoons, which is a good percentage. A fly came and killed a very few by piercing them through the body, and once a bird got in. I am selling my cocoons at 3*d.* a-piece with the live chrysalis inside. It is much the best way, if you want to obtain good eggs, to buy them in this form. I have got some worms about three weeks old in the open air, and they seem doing excellently, notwithstanding these cold nights."

#### ORCHARD-HOUSE FRUIT LATE AND DEFICIENT IN FLAVOUR.

I HAVE an orchard-house 40 feet by 16 feet, span-roof, with ventilation at top and shutters round the sides, so that I can give plenty of air. The trees are young, and, according to their age, have had a good crop this year; but I find the fruit do not come in ripe sooner than those out of doors, and have not been a good flavour. The trees for the roof are riders trained on wire 18 inches from the glass, and the sides are planted with dwarf-trained trees. I have thought of having the wire put nearer the glass, but I would like your opinion whether it would be a good plan, and how near you would have it put; or if you could throw any other light on it, why the fruit had not a good flavour and was not earlier, I should be greatly obliged. The borders are all inside, as I have no outside border, so that they require a great deal of water. I was afraid the trees had too much, but they had but very little while the fruit was ripening.—ROSE.

[We do not think your trees are too far from the glass; but if you cover the roof, you must not expect much flavour in the fruit you get from plants below. Flavour has been generally deficient this season, and we fear, like us, you have had too many fruit. Much depends on the care in watering. As to time of ripening, we believe we could, if we desired, keep them later in an orchard-house than out of doors; but to have them earlier we must just regulate the air accordingly, and shut up the houses with sun heat in an afternoon. One house with divisions may thus give several successions by merely regulating the amount of air given to each.]

#### GREEN FROGS.

CAN you tell me how to keep green tree frogs? I have them at present under a ventilated glass shade, with *Todesa pellucida*. I fear it will be too much shaded, and too warm in winter. As I shall not be able to procure them flies at that season, will they take any other kind of food? If not, I can give them a place in a cold frame, or if they need more light and warmth, a conservatory. Are they better under a glass shade, or in a wire cage? Should the soil be wet or dry? Do they need water to swim in?—H. B.

[Not having any experience in the management of these reptiles, we applied to Mr. Veitch, of the Exotic Nursery, Chelsea, who obliged us with the following reply:—"We keep our frogs in a large Fern-case where there is good ventilation, and where there are both moist and dry parts, having thrown up artificial rockwork to obtain the latter. We find that they do not require any flies to be given to them, as on several occasions we have put insects into the case, but they have never been eaten. I have no doubt but that they live on small insects, which they find in the moss and soil. I should advise the frogs being kept in a ventilated case in a conservatory, and a saucer of water placed in the case, and as much variety of soil, moss, rockwork, &c., as is convenient."]

**SALE OF MR. REED'S ORCHIDS.**—The remaining portion of this large collection was disposed of by Mr. Stevens on Thursday last, realising between £200 and £300. The large *Cymbidium eburneum* was sold to Mr. Williams, of Holloway, for £12 10*s.*; a *Sobralia Ruckeri* brought £9 10*s.*; good plants of *Phalænopsis*

amabilis £2 6s. and £2 12s. 6d.; and a *Cattleya Mossiæ* £4. Another important horticultural sale is to take place at Leamington on Monday next and following days, when an extensive collection of Conifers and other ornamental trees, amounting, it is stated, to 300,000, will be offered for sale.

### USES OF SEAWEEDS.

THE quantity of *Vraic* collected at Jersey is probably quite equal to that obtained in Guernsey; but it seemed to me, during a recent visit, that the *Vraic* used was not generally so rich, and that more is burnt and less ploughed-in than at Guernsey. In one cottage I found the mother and all her family employed in drying and burning weed composed entirely of the marine plant known as the Grass Wrack, *Zostera marina* (*Nat. Ord.*, Naiadaceæ), one of the poorest and most common of our seaweeds; the best front parlour was given up to its ignition; this was accompanied by an insufferable odour, which the lady informed me was esteemed very healthy. This is a prevalent opinion amongst the peasants wherever seaweeds are burnt, and in this I must confess that her statement was fully borne out by appearances, if I might judge by the rosy cheeks of her little assistants. She was getting the ash ready in a hurry to sow with corn on the following day. The best seaweeds are stacked in Jersey; a dozen stacks of "*Vraic venant*," thatched over, are common objects in a farmyard, and small barns are given up to its storage when dry. The value set on *Vraic* may be judged of by the fact that the inhabitants of Sark, having none on their island, import it in fishing boats from Herm, five miles distant; fifty Guernsey and Sark boats may be seen at once at Herm engaged in this traffic, and those who are acquainted with the precipitous nature of the rocks of Sark and its dangerous currents will appreciate the value of *Vraic* in that island. "*Driftweed*" is also largely used in Ireland as the only manure for the Potato crop; this is interesting, because the Potato requires a considerable supply of potash. This alkali can hardly, however, be required in the Channel Islands, as the granitic subsoil would, in disintegration, furnish it in abundance; it is probably the earthy phosphates that render the weed so fertilising there. This is borne out by the fact that the lixiviated seaweed ash, from which the alkalis have been removed, meets with a ready sale in Guernsey, and is esteemed, indeed, richer, no doubt on account of the increased per-centage of phosphates. The residual seaweed ash from the iodine factories in France is highly valued as a manure, and constantly carried a distance of thirty miles from the factory. The agriculture in the western islands is also enriched by this manure, and some of the tangle is brought into Oban by fishermen in boats, and sold at 1s. per load. On the S.E. coast of Fife it is laid on the stubble at the rate of twenty cartloads an acre, and ploughed-in; the Clover crop never fails, and this is a crop requiring much phosphate of magnesia, an important constituent of seaweed-ash. In the Isle of Lewis, twenty tons of seaweed are considered ample manure for a Scotch acre. The agricultural produce of the Isle of Thanet, in Kent, is said to have been tripled by the use of this manure, and the farms on the Lothian coasts let for 20s. or 30s. more rent per acre where the tenants have a right of way to the seacoast, where the weed is thrown ashore. In England, generally, however, seaweed is little valued by agriculturists as an actual manure, and appears to be regarded rather as an economical and useful covering to protect Turnips and other roots from winter frosts. Farmers object to its bulk and expensive carriage, particularly now so many portable artificial manures are offered for sale, and recommended so strongly by their manufacturers as possessing great fertilising value in a small compass. There can be no question that many of these are worthless rubbish, and perfectly useless, except to line the pockets of the vendor; and the farmer would do well to turn his attention to the composition of seaweed-ash, which really does, as I hope to prove, contain all the constituents of a good manure in a small bulk.

A process has been recommended by Dr. Stenhouse, "*Philosophical Magazine*," for the manufacture of acetic acid from wet weeds by fermentation. His experiments were conducted with some of the *Fuci*; these were mixed with lime, and kept moist at a temperature of 90° Fahr.; he obtained by distillation with sulphuric acid an average of 1.5 per cent. of anhydrous acetic acid! it is contaminated with butyric acid. This might, however, be separated and turned to account in the manufacture of

butyric ether or essence of Pine Apple. I have not heard of this suggestion being carried out, but it might be tried on those weeds intended for manure. In this case the best method would be to ferment them in pits with lime or chalk at the ordinary temperature in the summer, leaving each portion in for two or three months, and supplying its place by a fresh load until the lime was saturated; the liquid would then be pumped out, evaporated to dryness, the residue sold as crude acetate of lime, and the weed carried to the manure-heap. The whole process could be crudely and economically carried on by an agriculturist near the sea.

The ashes of several *Fuci* have been found by M. Malafati to contain silver, as well as lead and copper, in minute proportion. The silver in the ash of *Fucus serratus* is estimated at 1-10,000th of its weight, or about 3½ ozs. to a ton. Other *Algae* probably contain this metal, as it has been found universally present in sea water; but, desirable as it may be to increase our stores of it, this would not be an economical source, and it is probable that the 2,000,000 tons, calculated by M. Tuld to be dissolved in sea water, might be better extracted by the copper sheathing of our ships, in which the copper is gradually replaced by the silver; the sheathing thus becomes, after a time, rich in silver. It has been found in the sheathing to the extent of 17 ozs. in the ton.

The manufacture of paper is so important to a civilised nation—so many sources of the raw materials have been suggested—that we are not surprised to find seaweeds amongst the number. Two patents were obtained in 1855—the first dated June 20th, by Martenoli de Martinoi and others, of San Francisco, for the employment of seaweed in the manufacture of paper; and the second, dated November 29th, by Charles Maybury Archer, for the employment of seaweed in the manufacture of paper, and for the production of textile fabrics. Neither of these was proceeded with; the true *Algae*, in fact, having no fibres in their structure, would appear to be singularly inappropriate for the strength required in paper. Another patent was recently obtained by Ebenezer Hartnall, of Ryder, dated May 31st, 1861, for the application of Grass Wrack, *Zostera marina*, to the manufacture of pulp for paper, to be used alone or in combination with other fibrous materials. This appears more practicable, as this plant is not one of the *Algae*, and it does contain fibre resembling the Grasses. This patent, however, was not proceeded with.

Another patent was obtained in 1858, dated August 5th by Donald M'Crummen, "for the application, use, and treatment of marine plants, beaths, or heather, and other vegetable productions, as well for the manufacture of paper as for the production of alkaline and other salts." According to his specification, the plants are crushed or bruised, and exposed to the action of boiling water or steam until the soluble salts are removed; the insoluble residuum, after treatment with various agents of disintegration, is to be employed in the manufacture of paper, millboard, and papier maché. The solutions obtained to be evaporated to dryness to recover the salts. This is the only patent which has been proceeded with. I have received small specimens of the crude fibre and black salt from Mr. M'Crummen; but in justice to him I am bound to state that they are sent to me as the first crude results, and he has not yet worked the process on a large scale.—E. C. C. STANFORD.—(*Journal of the Society of Arts.*)

### CRYSTAL PALACE.

THE past month has seen no falling-off in the steady progress of the Crystal Palace during the Exhibition season. For September, the number of visitors was more than double within the same month in former years.

It is anticipated that October will form no exception to this successful rule, and that the visitors to London, anxious to get a glimpse of the wonders of science and industry collected within the International Exhibition, will also continue to flock to the Crystal Palace for a day's recreation. This is not to be wondered at, for the two institutions are so dissimilar, and each is so much an object of interest to foreigners and provincial excursionists, that a jaunt to London, taken for the purpose of visiting the International Exhibition, is looked upon as incomplete without a visit to Sydenham. The one therefore aids the other.

The Crystal Palace also possesses the no inconsiderable advantage, at this time of year, of being warmed throughout when

the weather is cold or damp. For this purpose fifty miles of hot water permeate through the pipes laid under the floors, and as all the approaches to the Palace are under cover, it is no more idle vaunt of the managers of the Crystal Palace when they advertise, "wet or dry, equally available at all times."

The late rains have had a wonderfully revivifying effect upon the flower-beds on the terraces, which for the season of the year were never surpassed.

As the hours are now shortening considerably, and as a long day at the Crystal Palace is a desideratum to most persons, provision has been made for illuminating the promenades of the Palace in a brilliant and novel manner.

### SPIRANTHES AUTUMNALIS, NEOTTIA SPIRALIS, OR LADIES' TRESSES.

BY L. LANE CLARKE.

SCARCELY perceptible to the careless eye is the modest beauty of this little Orchid, the last of its family that will unfold for us this year the "Manuscript of God" concerning the Orchis tribe.

Deeply interested as all intelligent readers must be in Darwin's delightful book, for the facts he has recorded, the study of the British Orchids will henceforth be an ever-recurring recreation to the observant eye.

First, in the early spring, the purple Orchis mascula, and last, in the autumn time, this little white Neottia will again and again recall the wonder with which we first learnt the mysterious fertilisation of Orchids.

Of the three thousand species Lindley has numbered, most varied and fantastic in form are the exotics; but scarcely less curious are the Spider, the Bee, the Fly, and the Butterfly Orchids of our own woods and meadows, and a minute examination of those which haunt our path will surely be acceptable to the intelligent observer.

The *Spiranthes autumnalis* is now abundant in dry pastures; it is thickly dotted on the Malvern hills, on the light pastures of the Isle of Wight, and the meadows and cliffs of the Channel Islands.

The spiral cluster of small white flowers is so insignificant in appearance, that more than once I have heard the exclamation of—"That an Orchid?" Even so—gather one, and come and see.

It will require a microscope to discern all its beauty; but a pocket lens will show us much, and we shall learn from this one specimen what it is quite necessary thoroughly to understand before we can appreciate the discoveries of Darwin.

In the flower we observe the plan upon which all Orchids are fashioned, the number three ruling the plant, however modified by the Creator, "for whose pleasure they are and were created." Three sepals, three petals, three pistils, and twice three stamens. These are not discernible at first, because the large lower petal, or labellum, is so prominent, and two upper petals are joined together, and one of the sepals adheres to them so closely as to require particular attention.

Of the three pistils, one is modified into a rostellum or beak; the other two are confluent, and form a cup, the surface of which is the stigma. This stigmatic surface, like all other stigmas, becomes at a particular moment highly viscid, attracting and retaining the pollen grains, which throw their granular tubes down the loosened tissue, to fructify the ovules in the ovary beneath.

Six stamens, according to Lindley and Hooker, are discoverable in the perfect Orchis; only one fertile anther is apparent in *Spiranthes*, which now demands close attention.

In examining a young *Neottia* with a pocket lens, and looking into the flower, we observe two pale yellow spots in the throat; these are the pollen masses or pollinia lying under the anther-cell, and immediately over the stigma attached to the rostellum by a boat-shaped disk in such a position as to render it highly improbable that the pollen grains of that flower can ever touch their own stigma. If a needle is passed into the flower, and this disk touched lightly, it will detach itself, and with it the whole pollinia.

This, on being pressed between thin glass under the microscope, will show the square or oblong pollen grains; or if applied to the stigmatic surface of an older flower, these bright golden grains will adhere to the glistening green cup, and be a beautiful object under a low power.

Some flowers, if stripped of sepals and petals, will show the

anther-cell empty, the stigma untouched, the flower unfructified—where, then, is the pollinia?

This is Darwin's discovery, that *Spiranthes*, like so many of its brethren, is indebted to insect visitors for the perfecting of its seed, depending also on the movement of its labellum, which at one period closes the throat, and protects the young stigma until its hour of maturity has arrived, then drops slowly down, opening its honey-glands to invite the wandering bee, which bears upon its proboscis the pollinia previously extracted from a younger flower.

Resting on the sunny hills above Torquay, Darwin watched the intercourse between insect and flower. The little *Neottia* giving forth a sweet perfume to attract the living "winged things;" he saw the humble bee, as I have seen the hovering Syrphide and Tipule, and small Hymenoptera enter the flower-cup; but these only entered one flower, and then flew away, I know not whither. Whereas he saw the bee always alight at the bottom of the spike, and, climbing up regularly, withdraw the pollinia from the upper and youngest flower, then fly to a next plant, rest for a moment on the labellum, which is moved aside, and whilst the insect sipped the nectar, the pollen mass was received by the expectant stigma. Then again mounting the spike, as the long and flexible proboscis was thrust into the scarcely opened flower, it could not fail to touch the sensitive rostellum, and bear away the disk and its pollinia.

The experiment is easily tried, and you will find that once fertilised the stigma becomes dry, and will receive no more pollen. There is no waste in any of the works of God.—(Extracted from *The Intellectual Observer*, a monthly Magazine of popular science.)

### FRENCH SALADS.

I WILL, for the benefit of all those whom it may concern, enumerate here the kind of salad our jovial Frenchman eats:—

Lettuce, of course, heads the list. Crisper and whiter than our American plants. Longer in season, too, not only by reason of care and extra cultivation, but by the climate, that knows not the abrupt turn into the hot cycle, nor that fierce, steady heat of America. No Frenchman, though, would eat his Lettuce *per se*. Were you to offer it to him pure he would turn his nose up; or, as that is rather impossible in either hemisphere, the nose being the stiffest of our limbs, he would turn up his upper lip, at the same time that he puts a fold in his brow. He would declare it insipid—his palate wants a flavour. That is given our Lettuce in the common way of vinegar, oil, pepper, and salt; and, in the French way, in addition to these, by Parsley, Garlic, young Onion, and Chervil.

Now, how many of the readers of the *Monthly* know the taste and the virtue of Chervil? This Stag-leaf—*cerf feuille*, contracted to the English Chervil, has a pungent, somewhat bitter, and most noble taste, and deserves a row or two in your garden.

The learned ones among you will know the equally illustrious plant called Tarragon—another corruption of the French Estragon, which is old French for the modern French dragon, which means a dragon or a dragoon. I have failed to find a likeness of either in its long leaf, and would not like it any better if I did. What I have found is a most interesting taste of a novel kind, and somewhat like Mint, but greatly superior to it. I bought a couple of sous' worth in the market, and, for the sake of its odour, hung it up in my study. I keep the window open all the time till the room is delightfully scented—not a scent for ladies' noses, but for the nose of a stalwart man.

A half-dead man, in fact, would get alive if he smelt this drying Estragon. When fully dry, your correspondent's best half will put it in vinegar, the vinegar will take the taste of it, possibly also some of its fragrance, and be a delightful relish like catsup, or serve for pickling. This is the law of Estragon on the continent of Europe.

I will mention Endive salad; you have the plant, though not in its perfection. Nor the Dandelion—*dent de lion*, which you have in perfection, but do not understand to make up into salad. He who likes bitter taste will welcome it.

I will mention all the more *bourache*—a thing I could not master to eat. I have, in fact, given it up in disgust; but, as a matter of taste, those who read this perchance will try it, and perchance will like it. I do not know if it is not called Borage, and possibly cheap as weeds, and may have given its name to "porridge." [The Archæological Society is requested to pro-

nounce on it.] A woolly, weedy leaf, of an uncommon taste—bitterish. I will, with so much greater pleasure, mention—

But no, on second and better thoughts, enough of salad for the day. If you like more, the advancing season will bring forth more and different kinds.—(*American Gardeners' Monthly*.)

### GNAPHALIUM LANATUM.

LIKE many other plants of great value, *Gnaphalium lanatum* has for the last twenty years been neglected, and is one of those introductions which if brought forward at the present time would find a ready sale all over Great Britain.

To the re-appearance of this good old sterling plant we are indebted to that cannie old Scotch nurseryman (now dead), Mr. Cunningham, of Comely Bank, Edinburgh. To see all those old greenhouses that he erected one would think he had been daft; but to look at some of the plants which have been hidden there for years, and which are now in the possession of his nephew and successor, Mr. Fraser, will prove the contrary.

*Gnaphalium lanatum* was again brought to light five years ago from one of these houses; as also *Castanea chrysophylla*, the beautiful Golden-leaved Chestnut, and several other plants of equal value.

Three or four years since we had a round bed belted with this *Gnaphalium*, with a scarlet *Verbena* for a background, and it was admired by all who saw it. It is so easy of propagation that the most ignorant in gardening may succeed if they had ever seen a cutting made.

It is not quite hardy, but we have kept it in a cold pit for the last two winters with only a mat to cover the glass; the plants were kept dry. It succeeds in any soil, and will in time, I think, be found useful for a certain manufacturing purpose.—J. E. LANE, JUN., *The Nurseries, Great Berkhamstead*.

### SILENE SCHAFTA.

THIS simple, but very gay and pretty, herbaceous plant, inhabits rocks on Mount Keridach, in the Russian province of Talysh, and was introduced, through Dr. Fischer, from the Botanic Garden, Dorpat, in 1844.

The account is from the "*Journal of the Horticultural Society*:"—"This proves to be a beautiful little herbaceous plant, producing a great number of spreading, slender, downy stems, which form compact tufts, and are terminated, near the extremity, by four or five bright purple flowers, more than an inch long. Of these flowers, that at the extremity of the shoot opens first, and those below it one after the other in succession, so that the branches are, by degrees, covered all over with blossom. Its stems do not rise above 6 inches high, and render it well suited for bedding-out or for cultivating among collections of alpine, or for rockwork, over which it will bend gracefully." The accompanying engraving, representing a well-grown specimen,

*Silene Schafta*, a specimen plant.

fully bears out Dr. Lindley's description, and shows the *Silene* to be a very elegant plant, and suitable for decorative purposes. It strikes very freely by cuttings, under a hand-glass, and is also increased by seed, which it produces in great abundance; but

being a perennial, the plants do not bloom until the second year. Presuming, however, that you can procure seed, and that it is your wish to grow some specimen plants, sow the seed immediately, and when large enough, put them into 60-sized pots, in light, porous soil, not too rich, putting three plants in each pot. When the plants are established, stop them regularly, so as to make them produce abundance of shoots, and when they have formed a compact tuft, remove them into 48 or small 32-sized pots, using the same compost as before. Keep them through the winter in a cold frame; but about March pot them into pots of a suitable size, using loam and leaf mould in about equal proportions, and making it tolerably firm in the pots. After this potting, it will be well to give the plants the protection of a frame; to keep a moist atmosphere, and to encourage the plants to grow as fast, but as robustly, as possible; stop the shoots regularly, and support those in the centre with a few neat stakes, but allow the side branches to droop gracefully round the sides of the pot. Towards June they will begin to blossom, and at that time they may be removed to the vases, and be planted out, and afterwards be regularly supplied with weak manure water. Take care that the plants do not suffer for the want of water; and, to prolong the season of blooming as much as possible,

*Silene Schafta*, the natural size.

remove the seed-pods, which are produced in great abundance as fast as they appear. After blooming the plants must be cut in pretty close, and started afresh, or be thrown away to make room for other plants.—(*Gardener's Magazine of Botany*.)

### MULBERRY TREE FRUITLESS AND WISTARIA FLOWERLESS.

I HAVE a Mulberry tree trained against a south wall, and which grows luxuriantly, and is extremely healthy, but bears no fruit. It has never been touched with the knife: should it be pruned?

I have likewise a beautiful plant of *Wistaria sinensis* which covers a large space of my house (aspect due south); but it does not flower. Here, too, the knife has been spared: should this be pruned also?—A GRATEFUL SUBSCRIBER.

[You must lessen the luxuriance of your Mulberry tree. Proceed thus:—We suspect you have a great many strong shoots hanging out from the walls of this season's growth, cut out all the strongest of them at once. Select a good number of middle-sized shoots—say between the size of a crowquill and a geesequill; just nip off their points, and then fasten them to the wall, between the main branches, so that they may get all the sun possible to harden the wood. This will, however, scarcely be enough if the tree is so luxuriant. Begin 5 feet from the bole of the tree, undermine the roots, and cut those that go down straight; lay the horizontal ones in fresh soil, and mulch with rotten dung to keep the frost out. Very likely in the first summer, and doubtless in the second, you will have the trees bristling all over with little shoots a few inches long coming from those laid in now, and these will produce fruit, and a short stubby growth will continue to do so.

We would thin-out the shoots of the *Wistaria*, and in every well-ripened bud, whether that be on a short spur or a long

shoot, you may expect a bunch of flowers. If the tree is luxuriant and crowded, the buds will not be matured enough to produce flowers.]

PLANTS FOR DINNER-TABLE DECORATION.

In my communication on plants for dinner-table decoration, page 485, I find a mistake is made in describing the conditions laid down for the guidance of exhibitors. The height from the bottom of the pot to the first branch on the stem should have been stated at 20 inches instead of 6 inches; but the following conditions copied from the schedule will explain what was required of exhibitors:—"The plants must be ornamental, either for their foliage, flowers, or fruits, and must be grown in pots not exceeding 6 inches in diameter; the foliage, flowers, and fruit must not be less than 20 inches, nor more than 24 inches clear from the bottom of the pot."

Now, it is not surprising that conditions so stringent should be met by a corresponding disappointment. Standard Reses in miniature are not so easily obtained, and, excepting for special purposes, are less admired than they used to be, and it certainly must be wrong to restore them in a diminished form to the dinner-table.—J. ROBSON.

ORNAMENTAL PLANTS.

CALLISTEMON BRACHYANDRUM (Short-flowered Callistemon).—*Nat. ord.*, Myrtaceæ. *Lim.*, Icosandria Monogynia.—A handsome stiff-growing, evergreen, greenhouse bush, with many round pubescent branches, bearing narrow, linear, pungent, channelled leaves, conspicuously dotted beneath. The flowers grow from the axils of the leaves towards the end of the branches,

forming short, loose spikes; the stamens, little tufts of crimson threads, which form the conspicuous part of the flowers, are short, much shorter than in any other known kind, being not more than twice as long as the small inconspicuous petals; the threads are tipped by golden-yellow anthers. From Australia: north coast; introduced in 1843. Flowers through the summer months.

EPIDENDRUM FUNIFERUM (Thread-petalled Epidendrum).—*Nat. ord.*, Orchidaceæ. *Lim.*, Gynandria Monandria.—A pretty stove epiphyte, having erect, slender, terete stems, 18 inches to 2 feet high, bearing, on the lower part, alternate sheathing, oblong-lanceolate, acuminate leaves; and along the upper part, the numerous, short, drooping racemes of flowers.

These latter are small, rich orange colour, with a white centre, the sepals are ovate, acuminate, spreading; the petals thread-like, as long as the sepals, at first adhering to the sides of the two lateral sepals as far as the middle, but afterwards being separated nearer to the base, and ultimately becoming contorted like a corkcreeper; the lip is three-parted, the side lobes serrated, the central one ligulate, and notched in the middle. From Brazil: St. Catherine; introduced to Belgium about 1847.—(*Gardener's Magazine of Botany.*)

WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 516.)

PECTEN NIVEUS, or *White Pecten*, is a purely English specimen, very similar to *Pecten varius*, with the exception of the shell being rather more circular, and its colour, both externally and internally, being uniformly white. It is also of somewhat smaller size, measuring only about two inches in length, and the same, or the smallest fraction in excess in breadth. The body of the animal itself is also white. It is most frequently taken on the northern coasts.

PECTEN MAXIMUS.—This is a very familiar variety, and is known commonly as the large edible *Scallop*. The shell is large, somewhat circular, and ribbed. The nucleus of the valves is of a pale orange tint, the flat valve of a reddish colour, the convex one very nearly white; internally, both valves are of a palish hue, with a chocolate-coloured border. The shell of the *Pecten maximus* measures in mature specimens about six inches in length, and five in breadth. The body of the animal itself is of a pinkish-white, the mantle being bordered with brown or black.

The *Pecten maximus* is common to all our seas, but is not found in large numbers on any part of the coast. It appears, according to Messrs. Forbes and Hanley, to be most scarce on the eastern coast of England. It is a favourite article of food with many, and considerable numbers find their way to the London markets. It has a peculiar sweet flavour.

PECTEN OPERCULARIS.—This specimen is the *Common Scallop*, and is very similar to the last-mentioned variety, but is of much smaller dimensions, and the ribs on the shell are more numerous, and placed closer together. The colour of the shell varies greatly, being found indifferently white, brown, red, orange, or pink. Sometimes it is clouded by two of these colours running together. The length and breadth of the shell of the *Pecten*

*opercularis* are about equal, and average somewhat more than two inches. The animal is shaped like its shell; the body of a cream colour on its upper surface, and bright red beneath. This variety is found generally on all our coasts, but chiefly at a depth of from fifteen to twenty fathoms, and is particularly abundant on natural Oyster-beds.

*OSTREA EDULIS* (*the Edible Oyster*).—This is the most common and deservedly the most highly-prized of all our bivalves. Its appearance is so familiar as scarcely to need any description. It will be sufficient to state that the shell varies in shape, that the upper valve is in most instances flat, the under one convex; the surface being foliated—that is, consisting of thin flat plates overlapping one another. The animal itself is shaped like the shell, having its mantle freely open, and bordered with short tentacular fringes. There are two varieties of the Oyster—namely, the well-known “Native,” and the “Rock Oyster.” The former has a comparatively smooth exterior, whilst the latter is coarse and rugged; and whereas the “Native Oyster” is of a uniform brown colour, the “Rock Oyster” is very beautifully marked with streaks of a dark crimson or chocolate colour. The breadth of the shell of an ordinary full-sized Oyster is, in general, about four inches. The body of the animal is rather thick and flattened, of a dusky white colour, and has the margins of its mantle bordered with brown. The large adductor muscle, by means of which it closes the two valves of its shell, is white. Oysters, in common with other bivalves, live principally upon animalcules found in the water, and enjoy a pretty considerable lease of existence. Sea Oysters, or those living in natural beds, are not considered fit for the market till they are four years old, whilst the “Natives,” or those reared in artificial beds, have the limit extended, and are not considered in prime condition till they have attained the age of from five to seven years. The age of the Oyster is known by the annual layer of “shoots” on the lower or convex valve. They are said to suffer severely from frost, and great numbers die of a peculiar sickness with which they are visited during the period of spawning. We may add, that though Oysters are very commonly distributed on all the European coasts, they are nowhere found in such quantities, or in such perfection, as in Great Britain. The chief supply of “Native Oysters” is provided from the artificial beds at Whitstable, Burham, Colchester, Milton, Rochester, and Faversham; whilst for our stock of “Sea Oysters,” we are indebted to Falmouth, the Isle of Wight, the coasts of Sussex and Wales, and, to some extent, to Scotland and Ireland.

With the *Ostrea edulis* we close our notice of the *Lamelli-branchiata*, and proceed to the next division, called *Brachiopoda*, so called from two Greek words, one of which signifies “an arm,” the other “a foot.” This class derives its name from having two long spiral arms placed on each side of the mouth, which in many of the species can be protruded to a considerable distance in search of food. This division has also been distinguished by the name of *Palliobranchiata*, from two Latin words, signifying “a mantle” and “gills,” inasmuch as in this class the gills are developed from the mantle. The *Brachiopoda* have small bodies (with the exception of their large tubular arms), are without a foot, and completely deprived of the power of locomotion. Their food is composed of marine animalcules. As these singular creatures are extremely rare in the British seas, our notice of them will be confined to the foregoing meagre and general account; the ordinary tourist being most unlikely ever to meet with any specimens, as they are for the most part resident in very deep water, where they are found adhering to corals and rock. We may, perhaps, add a general and brief summary of the organisation of this group, in order that the type may be recognised. The lobes of the mantle are free anteriorly. From the body, between the lobes, the arms have their origin at the margin of the mouth, and are capable of being folded up spirally. All the species are permanently attached to foreign bodies, and inhabit the sea. Their reproductive and nervous systems have not hitherto received any particular elucidation. The two principal genera of this group are the *Terebratulida*, and the *Craniada*.

This class brings to a close our account of the Headless Molluscs. The next class which comes under our notice, introduces those which are called *Encephala*, or such as have a more or less distinct head. The first division of these is the *Pteropoda*, so called from two Greek words, signifying “a wing” and “a foot.” The Pteropoda, then, consist of small, floating, marine animals, which swim by means of two lateral musculo-cutaneous fins, but are unable to fix themselves, or to creep

about, being destitute of feet. Some of them have shells, others not. All the British species, however, are provided with shells, and are divided by Messrs. Forbes and Hanley into two different families—namely, the *Hyaleada*, from the Greek word signifying “glass,” and so called from the transparency of the shell; and the *Limacinada*, whose bodies are enclosed in regularly spiral shells. Then, *Pteropoda* are very rarely met with in our seas, as they would seem to require a warmer climate; still they are seen on occasions, but these are so rare that it would be mere waste of our space and the reader's time to devote to them any further attention. The next division in order is that of the *Gasteropoda*, which we shall take under consideration in the following chapter.—W.

(To be continued.)

## SMALL BIRDS, THEIR USES AND DESTRUCTIVE PROPENSITIES.

DURING the past spring and early part of the summer most of our newspapers and similar publications complimented the French Legislature for enacting a law for the more effectual protection of small birds, and commented on the desirability of a similar Act of Parliament and its rigid enforcement in this country, at the same time giving some instances where the absence of small birds led to disastrous results. The articles were likewise garnished with a mixture of what I would call a morbid humanity, which affects to shudder at the idea of destroying a small bird's egg, while not a voice is raised against that of the domestic fowl, or the bird itself when cooked and sent to table, being eaten. As it is common for all, or the major portion, of those who advocate a new theory, to call in all the assistance they can, however distantly connected such helps may be with the point in view, I do not find fault with this plea being also taken hold of by the “Small-bird Protection Society,” as they may, perhaps, be eventually inclined to call themselves. On the contrary, I will endeavour to combat their views on the more legitimate grounds they base their claims to attention upon, and will leave the task of reconciling the inhumanity of killing small birds with those who never hesitate to kill a fowl, sheep, or hulloek, or at least to encourage their being killed by others. As enough has been said on this head, it will be better at once to take the relative merits of the small birds as useful servants in one sense and active enemies on another, being convinced that this way of reasoning the matter will be most conducive to the general good.

*Small Birds as Useful Servants, or rather Agents.*—For as we cannot in any way command their services, we must be content to accord them the distinction of a “free agency;” and whichever it is, certainly they do an immense amount of good. Insects that would prey to a frightful extent on our crops and herbage are kept in subjection by them, and the various similar classes of reptiles are also kept within due bounds by the same sagacious balance of power. Worms and many other things are also held in check, and caterpillars, which prey on our fruit trees, no doubt often fall victims to the vigilant eyes of certain members of the feathered creation; and perhaps some will give them credit as cultivators of the soil, for they are often to be seen scratching in heaps of dung, in newly-turned-up ground, or in moist places in dry weather. Unfortunately, I am afraid their operations in this way will receive a verdict the reverse of utility; but they certainly do busy themselves in this operation. I have no doubt but the larvæ of insects deposited on trees and similar places are much diminished by them in winter, and many other good qualities I am prepared to accord them; but will leave these other virtues for others to dilate upon, and will at once proceed to their opposite characteristic, and endeavour to show some of the evils we attribute to them, and consider

*Small Birds as Destructive Enemies.*—In this respect, I expect the great advocates for their entire preservation have neither fruit orchards nor corn fields, in which case it is an easy and agreeable duty to preach about their utility; but let any one go into the fruit-growing districts, and just notice the appearance of the Gooseberry trees, the shoots of which are in most cases stripped entirely of their buds, with the exception of a few small ones at the tip. This evil is far from being a solitary or exceptional one, but has been going on in an increasing manner for some years; and I believe I am speaking within bounds by saying that it has led to the growth of this popular fruit being abandoned in a great measure, many acres having been recently

grubbed-up. It is all very well for those not having any experience in the matter to lecture on the cruelty of destroying small birds; but let them look at the condition of an orchard of Gooseberry trees that have been so ruthlessly disbudded two or three years, and, finding there is no fruit, a change of opinion will come over them. It is no easy matter to suggest a remedy or preventive for such a state of things. Watching with a gun is the best, but is less effectual than could be wished.

The evil is not confined to Gooseberry trees, for Pears suffer in like manner. A few years ago a variety of Gooseberry called the Yellow Rough, a rather small curly sort, the shoots very full of prickles and small buds, was supposed to be exempt from the depredation of the birds in question, and some growers reduced their plantations to this kind. But another evil arose. The birds attacked the embryo of the fruit when a little further advanced; for just at the time the trees are in bloom, and before the fruit makes the least attempt to grow, it is nipped through by the hard and mischievous beaks of some of the members of the feathered creation, and so rendered completely useless. It is difficult to account for this, as the part cut off (as it were with a knife) is always found underneath the tree, the cut being made through the middle of the little swelling lump that forms the future berry. This evil, I am sorry to say, is not one of small extent; and for the last ten or a dozen years has been much on the increase, as likewise has that of picking-out the buds of the trees. Whatever the "Small-bird Protection Society," if there exists such a body, may say to the contrary, I confess I see no effectual remedy but destroying a number of the depredators; for I must say the evil of picking-out buds is threatening to be carried to an alarming height, and will very likely be extended to other trees as well.

In the spring we are sometimes obliged to cover the bloom-bearing spurs of a *Wistaria sinensis* growing against a wall in a very public place, to prevent their being picked-out by the little thieves, as I may so call them, otherwise more than nine-tenths of them would be gone; and many other things suffer in like manner. It is this prematurely attacking the fruit that is to be, that I find so much fault with. Blackbirds and others siezing on Cherries and Strawberries when ripening, or other birds devouring ripe fruit of other kinds, are more excusable and pardonable, except at the precise moment the depredator is caught in the act. But fruit trees disfigured for life is a crime for which the penal code of horticultural law demands some expiation, and I would willingly allow the friends of the little offenders the privilege of transporting them beyond the seas if they would do it effectually; but, in default of that, I see no other mode of dealing with the incorrigibles but sentencing a number of them to death.

*Reasons for Destroying a Number of Small Birds.*—In a state of nature a just and equitable balance is kept up in the animal as well as in vegetable life, by the all-wise decrees of an unerring Providence, which provides the smaller members of the animal world with an almost unlimited means of reproducing themselves, in order to allow for the large number devoured by the next larger class; this class being less prolific in multiplying their species than those below them, but still more so than the next one above them. In a just and equitable ratio, this goes on until the top is reached, the larger and more powerful animals or birds rearing much fewer young ones than any of their subordinates, and by this means the beautiful balance of nature is kept up. Now, some one will be arguing that destroying small birds' nests, or shooting them while they are pilfering, is disturbing this balance. This I am far from being convinced of: on the contrary, I cannot but think that it is tending to restore it, the balance being previously destroyed in another way, as will be shown.

Taking for granted that the proportion of each living bird, insect, and animal, provided by Nature to inhabit a given space of waste ground is a just one, it certainly does not follow that the same number will be the proper one when this space or district is in a high state of cultivation. The disturbance thus created necessitates a change in the character and description of its previous occupants. The largest class of animals are either entirely extirpated or driven to the inaccessible places and very much reduced in numbers by the war waged on them. This matter may be dilated on to a great length, but it is only necessary to consider its bearings in the case of small birds; and its apparent result is easy to account for in the cultivated district, such, for instance, as the central part of the county of Kent and most other counties in the south and middle of Eng-

land, which are well diversified with woods, thickets, and hedges, in addition to corn fields, all of which tend to encourage the multiplication of small birds; while the vigilance of gamekeepers assiduously destroys by wholesale their natural enemies, the birds of prey, whose presence would rectify the evil by limiting the number of our invaders. Now, as the balance is disturbed by the removal of almost all the Hawks, Vultures, and the whole host of birds or animals that prey on eggs, or destroy the smaller ones, the latter have an unrestricted means of propagation, and it is almost beyond the reach of a doubt that they do increase beyond the requirements of the day. I do not, therefore, hesitate to say, that a very considerable number may be sacrificed to the benefit of the community, and whether that be done by the gun, or by the destruction of eggs, is unimportant. The suffering fruit-grower will suit his own purposes that way I have no doubt, and the denizen of the great metropolis or of some manufacturing city, may return to his abode after a sojourn in the country, and write some wrathful epistle against the inhuman practice of immolating the innocents, if he likes to call them such; but he will have much difficulty in convincing the fruit-grower that they are really what he describes. No one thinks of throwing his protecting influence over weasels, rats, stoats, snakes, wasps, and such like, and yet a similar stretching of the humanity garment would include these also. But as the destruction of the natural enemies of the small birds has, unquestionably, tended to their increase, the balance must be restored by the same means as disarranged it, and though extermination would unquestionably be attended with disastrous consequences, a large number may be done away with to restore that balance, and then, perhaps, they would be content to live in a greater measure on the food originally destined for them, and not attack with such vengeance the choicest productions intended for another class. I do not for one moment expect they will ever be prevented from preying on our corn seeds and fruits, but I sincerely hope the growing evil of destroying the buds of our fruit trees, and thereby removing every chance of getting a crop will be checked by the destruction of that superabundant class which are, perhaps, driven to this mode of getting a living by the other sources being exhausted. I do not certainly assume this latter to be the exact case; but as the evil complained of has increased very much of late years, there are many reasons for supposing it to be so to a certain extent. Some may think they have a good plea by pointing out the Gooseberry caterpillar as being likely to increase to a serious extent. To those I may answer that I never knew the caterpillar worse than it has been the past season, and so unchecked did it appear that there are many who believe that birds do not prey on this insect. I certainly do not mean to assert this; but one thing I do know, that a neighbouring fruit-grower, after exhausting all the known remedies, set a number of women and boys to pick them off, and a bushel a-day of caterpillars was the result for some time, the plantation being entirely leafless up to the end of July. So much for the utility of small birds. I am far from denying them the merits of being useful members of the community at large; but let the proper balance of power be maintained, which at the present time certainly gives a preponderating influence to the class here alluded to, that I at once call the attention of the thinking public to the fact of the destruction these little pilferers do in the fruit-growing districts, and I would ask them what they have to advance in their favour. I do not by any means call for an indiscriminate slaughter of all the little warblers, but a pretty heavy thinning is wanted to place them on a proper level with other things.

My observations relate only to small birds: the case of Rooks will, perhaps, be taken up by some one else; but I am not aware of any case for or against them which calls for any especial notice, and will be glad to learn that my views are corroborated by those of others, but if otherwise I shall be equally thankful for being set right. At the same time residents in the fruit-growing districts are the best able to give an opinion, and to them more especially I appeal to certify if I have in the least overstrained the evil.—J. ROESON.

ROYAL HORTICULTURAL SOCIETY'S INTERNATIONAL FRUIT, CEREAL, AND GOURD SHOW.—This commences to-morrow, and, judging from the number of entries and the names of the exhibitors, it promises to be one of the finest and most extensive exhibitions of such productions that has ever been secured.

## EXTRACTS FROM A TOO-MUCH NEGLECTED BOOK.

MIGRATION OF BIRDS.—October 27.—At early dawn this morning, just as the sky was becoming flushed with sun-rise colours, we saw a large flock of wild Geese flying steadily to the southward. They moved in a regular wedge-shaped phalanx, as usual, with their leader a little in advance. Perhaps they had passed the night in our lake; they are frequently seen here, though rarely shot by our "gunners." They seem often to travel by daylight. The Ducks are said to migrate generally at night, especially the Mallard or common wild Duck. It was a beautiful sight to see the flock this morning; it reminded one of Mr. Bryant's noble "Water-fowl," simply, however, because one never sees the wild fowl travelling through the air, spring or autumn, without thinking of those fine verses. In the present case it was morning, and a whole flock were in movement; Mr. Bryant saw his bird in the evening, and it was alone, still the lines would recur to one:

"Whither, 'midst falling dew,  
While glow the heavens with the last steps of day,  
Far through their rosy depths, dost thou pursue  
Thy solitary way."

A flock of migratory birds can never fail, indeed, to be a beautiful and striking sight. The proud ships crossing the vast ocean, with man at the helm, are not a more impressive spectacle than these lesser creature travelling through

"The desert and illimitable air—  
Lone, wandering, but not lost."

Doubtless the flocks which now pass over the valley are as nothing compared with the throngs that went and came when the red man hunted here; still, we never fail to see them spring and fall. Many are the different varieties which come and go, and various are their habits of travelling. Some fly by day, others at night; some are silent, others utter loud and peculiar cries; these move in a regular phalanx, those in a careless crowd; some have leaders, others need none; these move rapidly and directly toward their goal, others linger weeks on the way. Some travel in flocks, others in pairs; with these the males fly first, with those all move together; some follow the coast, others take an inland course.

And how much pleasure the birds give and receive by their migrations! This singular instinct implanted in the breast of the fowls of the air is indeed a very touching instance of the tenderness of Providence, who not only bestows what is necessary on His creatures, but adds to the cup of life so many innocent pleasures. Some birds are stationary, and doubtless it would have been easy to have ordered that all should be so; but now we find that many of the most beautiful and pleasing of the race pass and re-pass annually over a broad expanse of the earth, giving and receiving enjoyment as they move onward. Many of those which are the most cheering and delightful spread themselves over half the earth: among these are the delicate Wrens and Humming-birds, the gay Swallows, those noble singers the Thrushes; while the larger and more dangerous birds of prey are few in numbers, and chiefly confined to particular regions.

No doubt the change of food, of air, of climate, is a source of enjoyment to the birds; nay, the very effort of the journey itself is probably accompanied with that gratification which is usually connected with the healthful natural exercise of the higher powers of every living being. And how much delight do they afford mankind? Their first appearance, with the hopeful hours of spring; their voices, their pleasing forms, their cheerful movements—nay, their very departure in autumn, all bring to our hearts some pleasures, and thoughts, and feelings which we should not know without them. Wanderers though they be, yet the birds of one's native ground are a part of home to us.

Perhaps the birds generally follow the same course, year after year, in their annual journeyings. There are facts which lead one to believe so. It is already proved that the same individuals of various tribes will return to the same groves for many successive seasons. It has also been observed that certain birds are seen to the north and south of a particular region every year; but within certain limits they are never met with; like the house Wren, for instance, which avoids Louisiana, and yet passes farther to the southward every autumn. Other cases of the same kind might be named.

A well-authenticated story is told by Mr. Wilson of a wild

Goose which had been tamed on Long Island, but the following spring flew away to join a passing flock on its way to the northward. The succeeding autumn, as the farmer was standing in his barn-yard, he observed a flock of wild Geese on the wing; one of these left the flock and alighted near him, proving to be his old pet. Now, the party which the Goose joined was probably the same as that with which she returned, and here they were passing directly over the same farm, going and coming.

The flocks that pass over our little lake note it, perhaps, as the last in the long line of inland waters, the thousand lakes of all sizes passed on their way from the arctic seas. There is no sheet of fresh water of any size to the southward and eastward of our own. Possibly, the celebrated Canvas-backs pass us every year on their way to the Chesapeake, for the mouth of our own river is favourite ground with those celebrated birds. Very few of the Canvas-backs remain in this State; only a very small number are seen occasionally in the Hudson.—(*Miss Cooper's Journal of a Naturalist in the United States.*)

## WORK FOR THE WEEK.

## KITCHEN GARDEN.

TAKE every favourable opportunity of clearing the ground from weeds. In the best-kept gardens they are troublesome at this season when the ground is usually too wet for hoeing and raking, but they are more especially so when they have been allowed to seed during the summer, and the late one has been exceedingly favourable for ripening seed. *Asparagus*, when the tops are decayed cut them close to the ground, the beds to be then made clean and afterwards covered 3 inches deep with rotten dung, the alleys to remain as they are, not to be dug out, as many of the roots are thereby injured. *Cabbage*, the main spring crops to be planted out as early as possible. Those which were planted in August for Coleworts to be earthed-up. The plantations of the Brassica tribe to be searched for grubs and slugs, and any blanks that occur to be made good immediately. *Cauliflowers*, it is a practice with some market-gardeners about London to pot their young plants now, and to plunge them in coal ashes, or sand, in a cold pit or frame close to the glass, admitting abundance of air at all times, unless during very severe weather. *Endive*, continue to blanch it as wanted for use. A large quantity should not now be tied up at one time, as it will be more likely to rot. *Lettuce*, continue to plant the Cabbage varieties into frames for winter use. The *Cos* varieties for spring use to be planted in a sheltered border as soon as they are of a sufficient size. *Sea-kale*, as soon as the leaves begin to decay clear them away. It is advisable to do this as early as possible where it is required for early forcing. *Turnips*, thin the late sowing, but it is not necessary to leave them at so great a distance apart as the spring and early summer sowings. Take advantage of favourable mornings for wheeling out old hotbeds and other manures on spare ground, and get the ground well trenched and roughly ridged to receive the beneficial influence of the atmosphere.

## FLOWER GARDEN.

The broom should now be in constant request, and although the varying tints of the autumn are so admirable when contrasted on the trees and shrubs (a subject worthy of more especial attention), yet they are not so much admired on the lawns or gravel walks. A liberal use of the roller is also necessary on all lawns previously to the last mowing, to leave the surface in an even and dressed state for the winter. Crown Imperials, hardy Lilies, bulbous Irises, Narcissi, and other bulbs should now be planted in the borders, and some spare beds got in readiness for the reception of Hyacinths and Tulip bulbs.

## FRUIT GARDEN.

The principal operations in this department are the gathering-in of the fruit as it becomes in proper condition. Continue to keep the runners removed from the Strawberries, and those that have been some time potted for forcing to be placed in a comfortable situation to insure them from being soddened with wet. Strong pricked-out plants may still be potted with good success if placed on a kindly bottom heat.

## GREENHOUSE AND CONSERVATORY.

This should be a busy time in placing those plants which have been out of doors, and of course have had a thorough examina-

tion as respects draining, surfacing, staking, tying, and the encroachments of worms, insects, mildew, &c. As previously advised, see that Epacris and other winter-blooming plants are placed in a light part of the house, where they will be fully exposed to the sun, so as to get the wood well ripened to insure their blooming freely. *Examinus* Heaths and other plants subject to mildew, and apply sulphur immediately the pest can be perceived. On fine mornings such plants as *Ericas*, *Epacris*, *Pimeleas*, &c., should be well syringed; and all possible ventilation both night and day to be given while the weather continues favourable. There is a tendency in the small bulbous-rooted *Tropæolums*, as *tricolor*, *Jarratti*, *brachyceras*, &c., to commence growing during the autumn months; and this is especially the case with plants that have been flowered at the beginning of the season, and brought early to a state of rest. When this tendency becomes manifest it is most impolitic to attempt to arrest it in any way, as the whole system of the plants is at work, and a check will spoil their growth for that season at least. The best plan is to encourage them to grow slowly in a greenhouse, where, if they are kept from frosts and damp, they will continue to advance and will be in bloom early in the spring. Those roots that have not commenced growing should, if possible, be kept inactive till the spring, and this will be best effected by keeping the roots in a cool place and the soil about them quite dry. It is very necessary to guard against mice, which are very fond of the roots, and will soon produce great destruction if they can get at them.

#### PITS AND FRAMES.

Regulate the general bedding stock, and get the majority established in small pots. Give air freely, and restrict the supplies of water to mature the growth as much as possible. Glazing and other repairs should be completed by this time. As common mats afford scarcely sufficient protection to the half-hardy plants in store-pits for such purposes, advantage should be taken of wet weather to make a stock of straw or reed mats.

W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

MUCH the same as preceding weeks. Earthed-up young Coleworts for the winter; planted Cabbages; threw lime and ashes over young seedlings to keep the slugs from them; pricked-out Cauliflowers under glasses, by sides of walls, &c.; sowed Radishes where they could get a little protection; turned leaves over Cauliflower-heads swelling, to keep them white and protect from heavy rains and slight frosts; turned over Onions; dug over ground for late vegetables that had been occupied by Peas; removed all Pea haulm exhausted, as few things give a more melancholy appearance to a garden; covered a Dwarf Kidney Beau-bed with temporary lights to prolong the bearing, as cold nights may now be expected; regulated Cucumbers in a little heat; turned over a heap of horse litter, mowings of lawn, and a few tree leaves, in order to have some heating material at hand as necessary for slight hotbeds, &c. Used a portion of the above for the bottom of a *Mushroom-bed*, and to throw a little extra heat into the first shelf-bed above it in the *Mushroom-house*, which was spawned and covered lately; kept the beds in sheds as cool as possible, as they are coming rather faster than we want them in this muggy thorough *Mushroom* weather. We have had our attention directed to a plan of getting *Mushrooms* without manure, by sowing the spores and watering with nitrate of potassa; but even in the grand discovery, it is said at one place the soil is *solely* sulphate of lime, and, again, that it is damp ground composed of vegetable loam in a cellar, to be covered with 9 inches of sand and gravel, and above that 6 inches of plaster from old walls, watered with so many grains of the nitrate to so many three-feet squares after the spawn is sown. Now, notice the ambiguity about spores and spawn, and nothing about the quantity of water for the two grammes of potassa, and I think we will come to the conclusion, that we can be quite as particular at home. Now, to all who wish to try, we would say that in a shady place in summer, or in almost any place in autumn, before the middle of October, you may expect to get *Mushrooms* by merely inserting spawn in the soil, provided that spawn is not allowed to get *too wet*, or too dried-up. But all such gatherings will be meagre, unless the ground is rich in nitrogenous matter, and hitherto we have had a prejudice that the decomposing organic matter should chiefly be of an animal

nature: hence, though we use tree leaves, and almost anything for the bottom of *Mushroom-beds*, we like dung in the shape of droppings from horses, cows, sheep, and deer, for the upper layer in which the spawn feeds. I have, therefore, some faith in the nitrate of potassa, on account of the nitrogen it contains; but lest I or some readers should burn our fingers with this potassa, I should, until further experiments were instituted, use a fair decoction from sheep and deer dung for watering. In fact, such watering has invigorated many a decaying bed, when applied in not too strong doses at a time. After all these chemical discoveries, we must still depend chiefly on the efficacy of the muck heap for *Mushrooms*; just as the farmer's son when getting home from a course of lectures told the inquirers wishing to know what he learnt, that he found out that dung made *Barley* grow, and he knew all about that before.

#### FRUIT GARDEN.

Gathered fruit when fine; regulated trees; nipped the runners from *Strawberry* plants intended for forcing; gathered *Figs* out of doors before they were dead ripe, and put them in a warm place to prevent flies holing them; watered trees in *Fig-pit* for about the last time, and used a little fire heat to bring on the second crop; find wasps are now pretty well gone, after the wet weather, so that late *Peaches* and *Apples* and *Pears* will be left undisturbed by them. If the weather should get dry and sunny, will be obliged to net *Pears* to keep the birds from them, as one peck destroys the best specimen. Ground should now be prepared for planting fruit trees next month, and any trees that are overluxuriant, to be fruitful enough should not only have all unnecessary wood removed, but the roots pruned, or the trees replanted as soon as possible, so that fresh roots may be formed before winter. Gathered *Filberts* to prevent birds and squirrels getting the lion's share, the latter doing little harm here in comparison to the former, as many of the larger birds easily penetrate the shell before it gets thoroughly hardened. When we want young fruit trees to fruit early and continuously, we should give them no manure at all in the soil, but add what extra strength is necessary by top-dressings or mulchings.

#### ORNAIMENTAL GARDENING.

Made arrangements for having all tender things under protection in order to give us more time for regulating elubers in conservatory, and washing and getting all clear before the winter. Many things want a little regulating, as the time saved from the general routine would permit. Potted *Primulas*, *Cinerarias*, *Tropæolum elegans*, &c., and lots of plants that do not stand well in cutting-pots. Set *Gloxinias*, *Geueras*, and *Achimenes* to dry in their pots, as they will receive enough of moisture if they are in contact with the soil that is standing on a floor. Set also large plants of fine-leaved *Begonias* to dry and rusticate a little, as they will come all the stronger next season, if they get a little rough treatment now. Will collect *Caladiums*, &c., from conservatory to prevent their getting too chilled, which causes them often to rot afterwards when placed in a suitable temperature—about 60°, and dryish when at rest—just on the same principle that many of us get victims to rheumatism when getting up in years, because we were too careless or too ignorant when young. People are slow to learn, that men and plants have the seeds of disease and premature decay sown thick and deep in their systems by improper treatment; though it may take days, months, or years, before the evil shows itself so as not to be overcome. Plenty of work will be found now in wet days, in washing the pots in which plants stand, or giving them fresh ones.

#### FLOWER GARDEN

Now becomes thoroughly tantalising. Given a number of deciduous trees, and the keeping lawns, &c., all nice, is a mere impossibility. Sweep, sweep, roll, clean, are the never-failing directions; but it is just do and begin again. It is bad enough in summer to go over the same grass with the cutters three times in a fortnight; but now to keep clear of leaves, it would be three times in a day, and then the progress would not be much in advance of trying to wash a blackamoor white. Gentlemen who cannot bear to see a yellow leaf at this season, should summon a company of school children to keep running after them. But many think this should be done with the usual amount of strength, and some acres of extra flower-gardening into the bargain. All flower-gardening this month is also thoroughly trying. You get a few days' sunshine, and *Geraniums*, *Calceolarias*, *Gazanias*, *Salvias*, *Hollyhocks* and *Dahlias*, are just in their glory, and the air is so balmy, that you seem to saunter from bed to bed with

as much delight as you could do in the first days of July; but, presto, a couple of days of drenching rains come and you find bushels of *Calceolaria* blooms washed off, and the trusses of flowers looking as wretched as three-parts-drowned rats, and a part of the same wretchedness begins to steal over you. We begin to think that this new style of flower-gardening takes up a vast amount of time, and on the whole is the most expensive of all gardening. I am sure plant-houses, and forcing-houses, and good fruit and vegetable gardens, even if they made no return, which they handsomely do, are much less expensive than a lawn and flower-beds, where there is nothing to be got in the end but the gratification of the eye—and for that, too, we must be dependant on the weather. I keep telling all our suburban friends that a large lawn and a large flower garden are just a large expense, or a large eyesore; and that it is do, continually do, and nothing for it but a nice lawn and a nice lot of flowers in a fine day after all. I prophesy that if this rage for masses of dazzling flowers continue, we will have our flower gardens less, more artistic in form, and covered all over with glass or other medium, so that we shall not run the risk of having their extreme beauty destroyed when most wanted, by a storm of wind and rain. From what little we have seen done this way, we feel sure that the finest beds of *Geraniums*, &c., in the open air, would pale before those protected by glass. The first that has a garden on this system, and the accessories all in unison, will have the satisfaction of producing a sensation in the flower-gardening world.

#### TRANSPLANTING.

There is no time better than the present month for moving and transplanting all kinds of deciduous and evergreen trees, especially if they can be got up near home, and transplanted with large roots, with or without a ball. When we do much this way, we like to go over such trees and prune them a month or six weeks before planting—that is to say, if any pruning is wanted. This concentrates the proper juices of the plant more in the branches, stems, and roots that are left. If balls are not secured, which is desirable, the roots should be traced as long as possible, and never allowed to be dry. When planting after securing the bole, if large, from winds, the roots should be nicely packed among the rich, fresh soil, and fairly watered. If the weather should be sunny, deciduous trees, if the leaves are not all fallen, and evergreen trees, in every case, should be damped over the top twice—say an hour before and one after midday with the garden engine, which will do more good than repeated delugings of the soil, which only make it a marsh, and unkind for the young roots to go into. The more water at the soil, too, the greater the cold by evaporation. If just moist enough to encourage fresh root-action, and a little dry soil is put over all, the roots will be incited to push forth more readily from the increased heat thus secured. In fact, this heat in the soil is the great argument for early-autumn planting, only if we commenced too early the buds, not being matured enough, would suffer from the sun and wind. As soon as the cold weather begins to set in, the rooting process all the winter will be greatly promoted by mulching the ground to keep the frost out of it. Those who still sturdily maintain that roots cannot be made without the development of leaves, should just for amusement, if not conviction, stick a bough of a Mulberry tree firmly into the ground now, and satisfy themselves as to the roots next spring before a leaf has unfolded.—R. F.

#### TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

*ACER PALMATUSM ATRO-PURPUREUM*.—R. S. D. says that he saw this at Kew, and that its crimson purple foliage is much brighter than that of the

best purple Beech." He considers it a great acquisition and wishes to know if any nurseryman has it for sale. He thinks it would be an excellent companion for the variegated *Negundo fraxinifolium*.

**LAWN MOWERS (J. S.).**—We cannot take upon ourselves to say which is the best. They all do their work well if properly managed and taken care of.

**FUNGUS (M. C.).**—We are obliged to decline naming Fungi. They require so much care, and a mistake in a name is so fraught with danger that we cannot incur the responsibility.

**ASPHALT FLOORING WITHOUT LIME (Westmorlander).**—One part coal ashes, and two parts fine gravel, both quite dry, mixed into a mortar with boiling coal tar, would answer. No bullock's blood or oil. There is no fear of its getting too much dried by the fire—it will rather soften it. Asphalt walks become impressive in sunny weather.

**GRAPE VINE DRIED STALKS (A Constant Subscriber).**—These, and with the berries red and acid, are what gardeners call "shanked." We presume the Vines are planted in a border outside the house, and if so, the shanking is probably caused by the roots being too cold. We have repeatedly pointed out the course to be pursued in such cases, which you will find by referring to the indices.

**CINERARIA MARITIMA (Idem).**—Except for gardeners, the spring is always the best time to strike this plant, and no plant is more easy to lift or to keep over the winter. You might take up a whole bed of it, put all the plants in a washtub, and keep them in the back kitchen just as well as in the front parlour, if there was not much damp about the floor. Sanders on the Vine is the right book for you.

**VERBENA CUTTINGS (Virgil, Derby).**—If you cannot strike Verbenas in September, even in the open air, it is not of the slightest use for you to take up old Verbenas for keeping through the winter, because there is not one thing in the round of the season more difficult than that, and very few indeed of our very best gardeners can accomplish it. Can you not get some of the outside runners in Verbena-beds which are just rooted and no more, and put them in pots exactly like cuttings, and keep the pots outside as long as the frost will allow, and also out of the sun for the first three weeks? Of all the other ways put together, this is by far the best way for most people, and also the easiest; but, recollect, never put such pots of runners of Verbenas under glass for the first three weeks—that is the secret, and if you could keep them out two months all the better. (P. B.).—If you had taken the trouble to read "Doings of the Last Week," and other articles on the propagating of bedding plants, you might have avoided all your mischances about the Verbena cuttings. You say nothing of drainage, and perhaps you made your soil too wet before inserting the cuttings, and that added to the evil; but your two great causes of failure were too much heat, and covering with bell-glasses. Until the middle of September we should give no heat to cuttings, except what the soil and atmosphere afforded, and should never think of a bell-glass; but would merely cover with a sash to keep close and shaded in bright sunshine, and give all the light at other times the cuttings would bear, and air at night and morning provided they showed no signs of flagging. In a case where we wished rapidity of root-making we would use a bell-glass, but only during the day, or if left on, tilted-up at night. We expect you left yours on night and day; and the well-watering, and the confined moisture cut up the poor things with damp—and having had no chance to breathe or perspire, they were forced to absorb moisture to the point of rotteness. It would take too long a story to tell why all your cuttings, similarly treated, did not suffer the same fate; but you will get a fair idea of the case if you remember that, of the poor fellows that were shut up in the blackhole of Calcutta, there were a few that survived that horrible confinement.

**MANAGEMENT OF YOUNG QUICK HEDGES (P. B.).**—We like young Quick hedges to be encouraged to grow freely, and then to be cut well down to produce good width and strength for the base of the hedge, which we like best to be trained in the pyramidal or wedge shape; but if you tell us what you particularly desire, we will try our best to oblige you. Meanwhile, as to propagating bedding plants, consult our pages for the last two months.

**MUSHROOM SPAWN (A Subscriber, St. Helen's).**—You were answered last week in "Doings of the Last Week."

**FILBERT PRUNING (A. W.).**—In Kent, where large quantities of Filberts are grown for the London market, they are pruned-in more closely than any fruit tree we know of; all the strong, coarse shoots being taken away entirely, and only short pieces of the small wood left. The coarse laterals of from 3 feet to 6 feet long may be removed at once; but it is better to wait until about Christmas before the general pruning, as the embryo bearing-bud shows itself then. More particulars will be given in an early Number by one of our correspondents from Kent.

**PRUNING A NECTARINE TREE (Idem).**—Your tree must be in a promising condition not to make shoots more than 2 feet long, and if these be well furnished with fruit-buds to their base you may shorten them in one-half; but, if fruit-buds be wanting, do not cut off so much, as the tree may, perhaps, become too gross next year if cut-in too much this season. We hope it will shed its leaves early in the autumn.

**TROPAEOLUM (H. X. W.).**—Your plant is one of the best dark kinds of *Tropeolum*, with a strong, climbing habit, and is a very common plant about London. But that breed of them came first from the continent, and was the second kind named Brilliant; the first Brilliant was an English seedling.

**FEANS FOR A FERN-CASE (E. C. F.).**—The following merely require frost to be excluded in winter:—*Adiantum capillus-Veneris*, *A. cucullatum*, *A. formosum*; *Pteris tricolor*, *P. argyrea*; *Asplenium viviparum*; *Davallia dissecta*, *D. canariensis*; *Leycopodium cerasia*; *Cystopteris fragilis*; *Asplenium filabelliforme*; *Nothochloa vestita*; *Trichomanes reniforme*.

**VINES IN GREENHOUSE (J. S.).**—If your Vine, only planted last April, is not pretty strong, we would advise its being cut down to some half a dozen eyes; but, if it appears vigorous, the side shoot No. 3 may be cut-in to 18 inches, and trained so that its shoots will occupy another rafter from No. 1. No. 2, in like manner, might occupy a rafter on the opposite side; but, in so doing, you must make No. 1, the centre shoot, the shortest, and thereby have three rafters furnished from one plant. But only allow one shoot from each next summer. The Vine may be pruned at any time after the bulk of the leaves turn yellow—say by the end of October. Ingram's Prolific is reported an excellent Grape, but has not been sufficiently tried. The Black Lombardy is good; and if you want a very late one, try West's St. Peter's or Lady Downe's Seedling.

**PRUNING ESPALIER TREES (N. X.).**—It is not an easy matter to obtain a good crop of fruit all over a tree neatly trained and pruned; for it almost always happens that the spurs in the centre of the tree lengthen each year so as to necessitate their cutting-back for appearance sake, and thereby most of the fruit-buds are cut off. We know of no remedy for this, excepting now and then cutting a large limb clean out of an Apple or Pear tree, and training-in young fruitful wood. But this, in some degree, mars the symmetry of the tree, and it is questionable whether it increases the quantity of fruit or not, as the wood of two and three years old at the tip ends bears best, and this, being at the ends, is more fruitful than the same aged wood in the centre. In situations more than usually favourable to the production of fruits, trees will occasionally bear well to the centre; but the merit of their doing so is more owing to natural than artificial causes. Root-pruning is useful in espalier fruit trees; but, excepting for appearance, and the merit of taking up little room, dwarf standards but little pruned bear quite as well, and are superseding espaliers in many instances.

**CALADIUMS IN WINTER (Northumbrian Subscriber).**—The best way to keep Caladiums in winter is to allow them to remain in the pots, giving them little or no water after the leaves have faded, but allowing the pots to stand on a moist bottom, so that they do not get too dry, and keeping them in a temperature not below 60°. We have lost some when below that temperature; if 65° it will be as well. *Tiburnum plicatum* is hardy enough in the south of England. It is a native of the north of China.

**FRUIT TREES AGAINST A SLOPING BANK (C. C. Hunt).**—We cannot say without knowing that the bank has a steep slope. If you took care that the roots did not get down too deep, you might concrete the surface of the bank, and thus insure heat and dryness to the trees. There can be no doubt that Cherries, Pears, Apples, Plums, &c., would do well trained on a trellis on a properly sloping bank. The flue will be an advantage every way.

**INSECT ON ERICAS (An Old Subscriber).**—We are afraid they have nearly bug, and if so the cure will be very tedious, and wholly impossible if existing on the roots and soil as well as the branches. In that case the best cure would be to burn the whole. If not on the roots, lay the plants down and syringe well with water at 80°, holding some sulphur and lime in solution, and when dry dip them several times in gun water as advised today for Azaleas and thrips.

**WARNING A PIT (Sophia).**—If you only wanted to keep out frost, a small Arnott's brick stove, placed in the middle and fed from the outside, would be the cheapest and give heat enough. If you wished for more, a small flue and furnace would be the next cheapest and best, and 4 feet from the furnace being brick, the rest might consist of earthenware pipes 9 inches in diameter. We would have advised better if you said what you want your pit for.

**VARIEGATED ALMA GERANIUM TURNING GREEN (A Two-year-old).**—The most pointed "remark" we can offer on this subject is, that the same has been of yearly occurrence, not only with Alma, but with all other variegated Geraniums old as well as new. The next prominent remark is only the corollary of the first, which is, that it would be extremely difficult to mention any variegated Geranium which has not thrown off a green sport at one time or another. And the third remark will be an observation founded on your Alma, which died down by mishap or ill usage—two conditions which have been laid down by some as the best and most probable conditions for obtaining a variegated disease from a green-leaved plant; but the "conditions" are against the tide in this instance at all events.

**AZALEA LEAVES (E. S. D.).**—We could not make much of the eggs, but there is little doubt that the leaves are eaten up by thrips, and there can be nothing more destructive. We would advise shutting up the plants in a close place, and smoking them well with the best shag tobacco, leaving them for twenty-four hours, and then taking them out and syringing them well with clear soft water, and after a week smoking and syringing again. If that does not settle the thrips, make up a weak solution of gum or glue water, but strong enough to be a little adhesive when pressed between the finger and thumb, and dip the plants in it, or syringe them with it, so that not a leaf is missed. Allow the plants to stand in a shed for two or three days until the gum is dried and begins to crack, run your fingers carefully through the shoots, and most of the matter will fall off; and then syringe well all over several times with water about 90°, but lay the plant so obliquely that the soil receives not the syringing.

**BOWLING-GREEN (An Old Subscriber).**—The best bowling-green we remember was 90 feet long and 60 feet wide, with a ditch 6 inches deep all round. Half these dimensions would suffice; but it is advantageous to be able, at some points of the game, to have the jack far off. There is no better mode of levelling the turf, if already laid, than by beating it with a sod-beater; keeping it well watered in dry weather, and mowed and rolled frequently. A builder's level will enable you to detect inequalities in the surface.

**JAPAN LILIES (Belladonna).**—We did not, nor do we, recommend these Lilies to be grown in such small pots; we merely referred to the practice of some, to show how very simple and how easily the Japan Lilies can be grown. We grow them in pots proportioned to the size of the bulbs, and keep them in the same pots three, four, and five years without disturbing them.

**GRASS IN PAVED YARDS (M. F.).**—We know of no modes of extirpating it except by rooting it out from between the stones by the help of a knife, or by strewing salt thickly over it. Boiling brine might be more promptly fatal to the grass.

**ANATOMISING PLANTS (A Beginner).**—If you mean skeletonising the leaves, we recommend you to apply to Mr. Persac, of Exeter. He charges 5s. for imparting his mode of rapidly effecting the object.

**FLOWER GARDEN (Subscriber, Sunderland).**—Your plan is very good, concise, and to the point, and all on one page—that is, the whole letter, the plan of the beds, and all the numbers and names referring to the plants for the beds are on one single page. The whole is done thoroughly well, and does you great credit.

**BEDDING GERANIUM (J. G.).**—Your Geranium is of the greenhouse bedding class, and is one of the *Ignescens* race, but you packed it in sticking plaster? and we could not undo it without tearing it to pieces.

**WORMS AND DAISIES IN LAWNS (A Subscriber).**—Lime water applied when the casts intimate it is needed will drive away worms. Daisies can only be eradicated by the knife. We usually fill with earth the holes made by thus eradicating them, and sprinkle a few seeds of Suckling on the surface.

**MAGGOTS IN ONIONS (E. Wootton).**—They are the larvæ of the Onion fly, *Anthomyia ceporum*, of which a drawing and full description is given in the *Cottage Gardener's Dictionary*. Be careful to burn all the Onions thus attacked, otherwise the pupæ will give birth to a brood of flies in the spring, which flies will deposit their eggs in next year's crop. Gas lime sprinkled on the surface between the rows of Onions, as soon as these appear above ground, emits fumes which are said to drive away the flies. Never be afraid to ask for information; nothing is trivial which helps to remove an injury.

**VARIOUS (E. H.).**—First, your leaf is of the Algerian Ivy—the largest of all. Catch the earwigs with hollow bean stalks, as gardeners rid them off their wall fruit. They hide themselves inside any hollow stalks or tubes for the day, and are blown out into cans of water and drowned. *Melia sempervirens* is a large forest tree from the West Indies, and requires the same treatment as the trees in the great conservatory at Kew, and is not worth it. *Roses* cannot be made out by leaves, or even by shoots a yard long, and sometimes net by the flowers, as they vary much.

**TERRA COTTA GARDEN-EDGING (Devonians).**—We believe it is manufactured by Messrs. Eastwood, Belvidere Road, Lambeth.

**NAMES OF FRUIT (J. L. A.).**—Your Peach is certainly different from any known good sort; and as you say it is never good, the best thing you can do is to destroy it. *Plums*.—No. 1, Downton Impératrice; 2, is probably the Nectarine Plum. The *Apple*, No. 1, called Barton's Free Bearer is, perhaps, the same as Barton's Favourite. It seems to be a seedling from the Noneseuch, but is not so regularly formed. (*A. Athinson*).—Hawwell Sourling, (*George*).—Your Pear No. 1 is Duchesse d'Angoulême; No. 2, Beurre d'amaoula. The shrubs are No. 1, Acer negundo; and No. 2, Chimonanthus fragrans. The Sweet Potato will not succeed in the open air in this country. (*Fanny*).—Your Pear is Brown Beurré. (*Stonewall Jackson*).—1, Hollandbury; 2, Herefordshire Pearmain; 3, possibly Bredon Pippin. (*Ridge Wood*).—1, Gansel's Bergamot; 2, Beurré Diel; 3, No Plus Meunis; 4, Glout Moreau; 5, Figue de Naples; 6, unknown; 7, Keswick Codlin; 8, unknown; 9, Sussex Scarlet Pearmain.

**NAMES OF PLANTS (Omega).**—1, *Pteris longifolia*; 2, *Nephrodium molle*; 3, *Polystichum angulare*, var. *proliferum*; 4, *Cyrtomium filicatum*; 5, *Platyloma cordatum*. (*B. A. S.*).—*Senecio mikadoensis*. It does flower sometimes, but not freely. (*J. B.*).—1, *Cacalia coccinea*; 2, *Anaëcia* not in flower; 3, *Polygala Dalmaisiana*; 4, *Tetratheca hirsuta*. (*J. S.*).—*Cornus mascula*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

OCTOBER 15th. FROME. Sec., Mr. C. Harding, Grndon Farm, near Frome. Entries close Oct 8th.

OCTOBER 23th and 29th. CALKE. Secs., A. Heath and F. Baily. Entries close October 15th.

DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.

DECEMBER 16th and 17th. LORD TREDEGAR'S, Newport, Monmouthshire. Sec., Mr. J. G. Palling, Newport.

DECEMBER 29th, 30th, and 31st. MANCHESTER.

### PRESERVATION OF EGGS.

(Translations from M. Jacque's work on Poultry continued.)

"FOR more than six months we had to make the same remark respecting the eggs placed in the artificial hatching-machines in use by Messrs. Tricorne & Adrien, jun., at Vaugirard. The result, then, of these facts, and these very conclusive experiments is, that clear eggs such as are laid in the beginning of autumn, keep very long for the causes we have named, and that the same results may be attained at other seasons of the year, by the suppression of the cocks in large yards where the profit is looked for in eggs only.

#### "ALTERATION IN EGGS.

"The fruitful germ organised by nature to produce on certain conditions a living being—that is to say, a chicken, no doubt perishes if kept long. It can also perish from rough shaking, the result of handling or travelling to distant places. These movements may help to destroy the germ by breaking the ramification of the fine and stretched ligatures by which it is attached to the delicate and transparent membrane of the yolk. When life has ceased in this germ, it becomes corrupt as well as everything in contact with it.

"In these organic bodies corruption always begins in the germ. This demonstrates that the most efficacious means of keeping eggs, and of being able to send them long distances without injury, is to prevent their fermentation.

"Humidity communicates to eggs a fermentation which changes them. Frost cracks the shell, and, disorganising the inside, disposes them to putrefaction. Too much heat dries up their moisture and forms the void which constitutes the cell at the large end; the air penetrating by the pores of the shell into it contributes to their decomposition. Eggs changed in any of these ways are valueless, and can only serve for food to hens and chickens.

#### "VARNISHING EGGS.

"Réaumur who thought, not without reason, that by preventing the evaporation of an egg it might be kept a long time, has

advised that the surface of the shell should be covered with a varnish that would resist water. He advises oil, grease, or butter. It is probable this method has been tried unsuccessfully, as it has been abandoned although so simple. There is reason to believe that there are other causes of corruption than the loss of moisture—such as evaporation and the introduction of putrid miasma in exchange.

#### "PRESERVATION OF EGGS.

"The means used for the preservation of eggs are numerous, and have been thought worthy of the attention of many distinguished economists. It is very important to preserve the precious products which abound in summer, to be eaten or sold in the winter when they are scarce and dear. The preservation of eggs is considered so important as a question of domestic economy, that one of our most illustrious learned societies has proposed it as the subject of a prize."

As it will be some time before the result can be known, we will give that of our own researches on the subject.

We have tried the different means proposed by the authors who have preceded us in this endeavour. We have tried those of Réaumur of which we have spoken. We have also tried gum water and alum water. These means which are intended to prevent the introduction of air into the egg are good, but they do not last long enough. Dry or powdered lime or chalk, ashes that have not been used for laundry purposes, barley or oat hulls, communicate an unpleasant taste to the egg. Chalk water preserves eggs for some months, but this also gives a bad flavour. They spoil as soon as they are taken out of this preparation: they must, therefore, be left in it till they are wanted for use. Water strongly impregnated with kitchen salt causes the liquid of the egg to imbibe it, hardens the yolk, and renders it unfit for many culinary uses. Another plan is to cook eggs in boiling water the day they are laid, and just as much as if they were to be eaten boiled—that is to say, the albumen should be milky and slightly set. Every one knows three minutes will accomplish this if they are put in boiling water. This degree of cooking renders the eggs fit for all domestic uses, and to prevent mistake, sand-glasses have been made of perfect accuracy. When they are taken out of the water they should be marked so that they may be sold or used according to the time when they were preserved, and they should be kept in a cool dry place. By this proceeding they may be kept about three months, after which the inner membrane of the shell becomes thicker, and this denotes the beginning of a change. To eat as boiled eggs for breakfast, it is only necessary to warm them.

Eggs boiled hard soon after they are laid may be kept two months, and are convenient food for travellers. If after they are boiled they are covered with paste made with clay, ashes, or marine salt, they may be kept for two years at least.

A method peculiar to ourselves, and which has appeared to us the most certain and most convenient, is to have large boxes or barrels thoroughly lined inside with paper. These are put in a cool but dry place. A layer of fine white salt an inch thick should cover the bottom. New-laid eggs should be laid side by side on this salt, and all vacant spots or places should be carefully filled with it. Successive layers of eggs and salt fill the box, which is then hermetically closed. Fine white salt is preferable to marine salt, this latter often has an unpleasant odour which it communicates to the egg.

On the 1st of August, 1849, we opened a case of six hundred eggs, preserved in September, November, and December, 1848—that is to say, eleven months after they were put away; although they no longer possessed the delicate flavour of a new-laid egg, they were well-kept, and well-tasted; good enough for any domestic use. The evaporation of liquids was hardly perceptible in the air-chamber; but the white was rather more liquid than in a fresher-laid egg.

At the actual price of salt, the preservation of these six hundred eggs costs 3s. 9d.; this outlay becomes insignificant when it is recollected that after this lapse of time the eggs have not absorbed 2 lbs. of salt. The same salt will last for years. The white of the egg preserved in this manner tastes slightly of salt.

#### CHESHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS Society's Meeting took place at Northwich, on Friday, the 26th inst. The poultry formed one of the chief attractions of the Show.

The Judge of Poultry was—Loyd, Esq., whose decisions appeared to give general satisfaction.

DORKING.—First, J. Waddell, Toft. Second, W. Gaman, Thornton-le-Moors.

SPANISH.—First, W. Woodley, Bunbury. Second, J. Sheen, Tilston.

GAME.—First, E. Viggor, Over. Second, J. Groucott, Haughton.

HAMBURGH (Spangled).—First, T. Dale, Middlewich. Second, S. Allen, Acton.

HAMBURGH (Pencilled).—First, D. Harding, Middlewich. Second, Mrs. Cheers, Hartford.

COCHIN-CHINA.—First, Mrs. Cheers, Hartford. Second, Lady G. Egerton, Oulton Park.

ANY OTHER VARIETY.—First, A. Hulme, Knutsford. Second, J. Waddell, Toft.

DUCKLINGS (Aylesbury).—First, T. Johnson, Over. Second, E. Viggor, Over.

DUCKLINGS (Ronen).—First, W. Gaman, Thornton-le-Moors. Second, W. Erdly, Larkton.

TURKEYS.—First, W. Glassford, Lostock, Gralan. Second, J. Waddell, Toft.

GEESE.—First and Second, T. Burgess, Jun., Burleydam.

#### POULTRY FOR A SMALL SPACE.

WHAT do you consider the smallest space in which a cock and two hens could be kept in health, and what kinds would do best, and whether there is any kind which make less noise than others?—N. R.

[Spanish, Brahmas, or Cochins-Chinas may be kept in a very small space, provided it has neither a brick, stone, nor boarded floor. They will do well in a space 12 feet square. Pains must of course be taken to contrive they shall have sunshine, and to provide them with dust, grass, and gravel, which are almost as necessary as food to them. Noise depends much on provocation. If there is no other cock within hearing, the crowing is not much.]

#### NEWCASTLE POULTRY SHOW.

THIS Exhibition of poultry forms an additional subject of interest to the annual gatherings of the Staffordshire Agricultural Society. It has, on every preceding occasion, been exceedingly well supported by our principal amateurs and general breeders of poultry, and it gives us great pleasure to state the fact that there was scarcely an indifferent pen shown this year throughout the whole collection. No doubt this continuous prosperity of the poultry department ensues from the confidence that arises among exhibitors, on account of the great care taken by the Committee of the birds entrusted to them, and the unvarying punctuality of their return at the close of the Show. A very unfortunate mistake, however, this year we cannot, as public journalists, avoid referring to. The pens used were those of Mr. Turner, of Sheffield, and, by some misunderstanding or other, the number provided for the accommodation of the competing fowls proved some twenty short of absolute requirements. We were assured by the indefatigable Secretary they were duly ordered, and this statement was as flatly contradicted by Mr. Turner's man who was present at Newcastle: therefore, at that time to affix blame to either party with certainty was impossible. A peculiar feature in the Poultry Show held the day following at Melton-Mowbray, however (where Turner's pens were also employed), most probably tends to enlighten us on the subject. At Melton, about twenty unused pens lay still folded beneath the coops that were erected, and, strange to say, that although the arrangements between the Melton Committee and Mr. Turner specified particularly that his man should attend to put the pens up and take them down when done with, no man on the part of Mr. Turner had even reached the Melton Show tent at the opening of the Exhibition to the public, and of necessity the Committee had been compelled to engage other parties, as best they could at the last moment, to put up the pens, or a blank must have ensued. It is scarcely needful to say that such careless management gives a hundredfold additional trouble to the officials of a poultry show, besides the inevitable want of future confidence engendered by such proceedings. At the Newcastle Show, the only course that could be pursued under these circumstances was to exhibit about twenty pens of the poultry in baskets of the most open character that could be selected among the wickerwork packages in which others had been received.

The Game fowls were a splendid feature of the Show; and when we say also that Mr. Rodbard's well-known birds in the Spanish class were closely pressed by several competitors, we

could scarcely pass a higher or better-deserved encomium on the exhibitors of that variety. The *Dorkings*, too, were most excellent. The *Cochins* were exhibited (all colours competing), and the precedence fell to a trio of by far the best Partridge-coloured ones we have seen this season. All the varieties of *Hamburgs* were well shown, and proved quite a leading feature of the Show.

With the exception of the first-prize *Turkeys*, the remainder were very common-place specimens.

In *Geese*, the Newcastle Show ranked highly; Mrs. Seamons, of Aylesbury, standing, however, quite a-head of her rivals. They were a marvellously fine pen.

In *Ducks*, too, this lady took first prize with a splendid pen of Aylesburys, and would have, without doubt, cleared the prize list entirely in this division, but from the fact of a "broken-bellied" Duck being, unfortunately for her owner's interests, shown in the best pen of the two (save this defect, which always insures disqualification). A pen of capital Rouens consequently took second position.

In the "Extra Poultry class," Mrs. Blay, of Worcester, exhibited some especially good Silver Polands, Black Polands, and Andalusians. Taking into consideration the heavy rain in the early part of the day, the attendance was a good one.

The Judge was Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham. We published his awards last week.

### ORIGIN OF OUR POULTRY VARIETIES.

SOME ten years since the columns of this Journal contained inquiries as to the natural history of our various breeds of poultry. Poultry-keepers, both for exhibition and table purposes, would be necessarily interested in such an inquiry, for its investigation might have afforded them material assistance. But whatever information may have been thus acquired, it has not yet been given to the public, and hence the present allusion to the subject. Mr. Darwin's admirable work on the "Origin of Species" elucidates the mode in which such inquiries might best be conducted, and would bring most important assistance to its practical discussion.

The first question is, whether all our different breeds of domestic poultry are to be attributed to some one common stock? Now, the existence of undomesticated Galli, such as *G. giganteus* and *G. Bankiva*, however satisfactory they may stand as the respective parents of the Malay and the Bantam families (although there are difficulties as regards the latter), will not account for the parentage of other fowls. In respect of size and general features they may stand at either extremity; but still some connecting link is evidently wanting. It has been therefore considered probable that the bird which occupied this position, since he cannot be now found or traced, has, like the camel, and, in a less degree, the sheep, been absorbed by domestication, and no longer exists in a natural wild state.

The answer, therefore, to this question seems to be in the negative—viz., that there does not exist, and probably never has existed, any one common parent for all the present members of the poultry-yard. Consequent on this I would put a second question—Is there any other wild Gallus, besides *G. giganteus* and *Bankiva*, that would answer the requirements of such a common progenitor?

Again: has the observation of the poultry-breeder furnished him with any instances in the different varieties where a falling-back to a common type has shown itself? Or, on the contrary, has his experience in this respect tended to support the idea of their original specific distinction?

If any of your correspondents could enlighten us on these points it would certainly be a matter of interest, and possibly of profit also.—W.

### MELTON-MOWBRAY POULTRY EXHIBITION.

THE Exhibition of poultry just closed at Melton is the first yet held in this locality, and the arrangements reflect great credit on the management generally. Among the specimens shown were many pens that would have held favourable position at any of even our largest shows; but, as is invariably the case at the first institution of such exhibitions, not a few local competitors had not made the most eligible selections procurable in their respective poultry-yards. It is only experience that can obviate this shortcoming; and, judging from the birds shown, it is evi-

dent poultry-breeding is a pursuit highly favoured in the surrounding district.

The weather for the Melton Exhibition was highly favourable, and, consequently, everything went off gaily as the clang of marriage bells. A profusion of banners, combined with evergreens in all directions, gave the whole affair the appearance of some public fête. The hotels were filled with visitors to repletion; and the dense mass of vehicles that lined the principal streets on both sides, from the aristocratic family carriage down to the dog trap of the tenant farmer, told conclusively that such an attendance was far greater than anticipated by the licensed victuallers of Melton. On reaching the Show, the great number of lady-visitors was most conspicuous, and holiday-gear was evidently the order of the day. About noontide threatening clouds appeared in the south, but very luckily no rain ensued; and, consequently, the Show proved quite a success.

In the tent, the *Spanish* fowls stood first on the list; and, we must say, were the least creditable class throughout the Exhibition.

The *Grey Dorkings* throughout were very excellent, and the *White Dorkings* were equally praiseworthy. In the class for *Silver Grey Dorkings*, it appeared that exhibitors were at a loss in selection; notwithstanding there were many individual specimens of great merit, although a perfect pen throughout could scarcely be found.

Only one pen of *Buff Cochins* fowls was shown, and those so decidedly meagre in quality that the first prize was withheld; and we fancy it must have been rather a strain of leniency in the Judge to allot them even a second position. The *White Cochins* were nearly all of them "vulture-hooked"—a fatal objection.

The *Game* fowls were not nearly so good as we anticipated seeing. The selection by exhibitors in the *Game* classes possessed at least the feature of great novelty, *Brown Red* hens being misted to *Black-breasted Red* cocks; whilst one competitor, evidently having a relish for "going the whole hog," placed a purely white hen in the same pen with a pair of *Black Red Game* fowls. Such irregularities detracted seriously from the merits of many contributions to the *Game* classes.

In the *Hamburgh* classes the greatest deficiency was the want of white ear-lobes, scarcely a pen being perfect in this necessary trait of character.

The *Game Bantams* were mostly good; but the *Laced Sebright's* prizes were withheld altogether, those shown being decidedly inferior.

A prize given by Nathaniel Whitechurch, Esq., of Melton, for the best *Dorking* cock, brought a goodly competition; the donor of the prize taking the first position with decidedly the best cockerel we have seen for years past.

We do not wish to see a better show of *Geese* and *Turkeys* than the one at Melton; they would have added credit to any poultry exhibition in the kingdom.

The *Golden* and *Silver Chinese Pheasants* were very well shown, and richly deserved the special prizes awarded them.

The *Pigeon* classes, though not numerously filled, contained many birds of great merit and value.

The *Rabbits* were numerous and good; the *Silver Greys* were particularly worthy of distinction.

The tent for the accommodation of the poultry was an exceedingly commodious one.

Mr. Hewitt, of Eden Cottage, Sparkbrook, Birmingham, officiated as the Judge. We published his awards last week.

### LIGURIANS IN NORTH LANCASHIRE.

THE doings of these general favourites upon our plains and moorlands may be interesting and instructive to some of the readers of THE JOURNAL OF HORTICULTURE who are doubting whether they will answer in their respective localities.

About the middle of last April a stock arrived in this district in such a state from rough usage by rail, that there was not a single comb in its place. Matters being made right, they commenced their work in good earnest, and soon proved themselves superior to the ordinary bee. The stock flourished as if by magic, and in nine weeks threw off a swarm, and in seven days a second, and, if the season had been favourable, most likely there would have been a third, as there was a queen cast out.

The first swarm was put into a nine-frame hive, which rapidly filled with comb, the old queen again showing her immense fecundity, and the workers their determination to struggle with

the bad season and make up for lost time worked three hours per day longer than the common bees in the same apiary, thus gaining for themselves the good wishes of all.

The second-swarm queen, I think, has outshone her royal parent in fecundity, the hive being at the present time quite as populous, and only being deficient about 6 lbs. in stores.

The old stock is not so strong, being evidently too much drawn upon this bad season. For the satisfaction of the inquirers as to their honey-gathering qualities, the first swarm is double the weight of any one hive of common bees upon the same pasture, and the second not far behind.

The Ligurians are certainly more handsome than the common bees, but not so quiet to handle; but this is nothing, as a little protection is all that is needed. They protect their home with great energy, and you may be sure to find them busy if there is any honey in the locality. In every respect they are superior to the common bee, and I wish that mine were all Ligurians.

I hope they will arrive safe in Australia; if so, their success is beyond doubt if in practical hands.—A NORTH LANCASHIRE BEE-KEEPER.

OLD QUEENS RETURNING TO THE DRONE-LAYING CONDITION OF VIRGINS.

THE BEE SEASON IN EDINBURGH.

By this post I send a couple of live queens, not for the purpose of having them put at the head of two colonies, but in order that "A DEVONSHIRE BEE-KEEPER" may kindly favour me by getting them dissected and communicating the results.

It would be interesting to know in what state he finds their reproductive organs, whether in a normal or abnormal condition. Both are very old, and the more perfect of the two has for some months past ceased to lay workers' eggs—a few drones only appearing in small cells. The tattered-winged one has also ceased laying for some time.

This has been another miserable bee season in this locality (Edinburgh); a great many deaths, few swarms, and little honey collected.—JOHN LOWE.

[Both queens were dead before they reached me, but were nevertheless so fresh that there was no difficulty in making a perfectly satisfactory examination. On dissecting-out the spermatheca, or seminal receptacle, I found that in both cases this organ presented the exact appearance of that of a virgin; and on submitting it to the test of the microscope, this fact was abundantly proved. In neither of them was there the faintest trace of the countless myriads of spermatozoa which are always present in the spermatheca of a young impregnated queen bee; but, on the contrary, nothing was present save a colourless fluid, perfectly clear and pellucid, appearing, indeed, completely identical with the liquid contents of a virgin spermatheca. I am extremely obliged to Mr. Lowe for affording me the opportunity of investigating and recording another fact, which proves to demonstration the correctness of Dzierzon's theory of parthenogenesis in the honey bee.—A DEVONSHIRE BEE-KEEPER.]

QUEEN BEES ASSAILED BY THEIR OWN WORKERS.

SINCE relating the case referred to by "INVESTIGATOR" in the last Number of THE JOURNAL OF HORTICULTURE, in which bees attacked and killed their own queen which had just been hostilely assailed in another hive, I have had another adventure of the same kind, attended, however, with a more fortunate result.

Attempting to introduce a fertile queen to a small stock which had lost its own sovereign a few days before, I found her violently assailed, and therefore removed her immediately, although with some little difficulty, from her exasperated assailants. On returning her to her own hive a similar scene was enacted with, if possible, increased virulence. Bearing in mind the unfortunate result of my former experiment, I extricated her with the utmost despatch, and found myself on the horns of a dilemma with a beautiful Ligurian queen on my hands in a sadly exhausted condition, owing to the violence of the assaults she had sustained, and equally refused admittance either into her parent or the adopted stock. After a little consideration, I determined upon imprisoning her for two or three hours in a small box formed of perforated zinc, and suspended in the centre

of her own hive. At the expiration of that period I withdrew the sliding door of the "queen-eage," and admitted her expectant subjects; they at once rushed in and again subjected her to a rigorous confinement. Further interference appearing useless, I closed the hive and left her, with sad forebodings, to her fate. On examination the next day I was agreeably surprised at finding her quite safe and once more perambulating the combs in all the dignity of undisputed sovereignty.

I am rather doubtful of the correctness of the inference drawn by "INVESTIGATOR," that bees sometimes confine their sovereign out of regard to her safety. In one case, in which I by mistake got two queens into one hive, I found both the native sovereign and the stranger treated with apparently equal rigour, without favour or affection for either, so far as I could perceive. In the majority of instances, however, a stange queen is stung to death without ceremony, nor have I ever seen a queen give such proofs of her prowess as were witnessed by "INVESTIGATOR." In fact, I had the idea that her long body was so unwieldy as to place her at a disadvantage in actual warfare—an impression which once received a strong confirmation by seeing a vigorous queen stung to death in single combat with a worker after a very short contest.—A DEVONSHIRE BEE-KEEPER.

OUR LETTER BOX.

LEEDS AND WAKEFIELD POULTRY SHOWS.—*Minus* inquires if the prizes awarded at these Shows have been paid. Will some of our readers enable us to give an answer?

HEN DROPPING HER EGGS (*Amateur*).—The egg-dropping from the perch proves that there is something amiss with your hen. It is not a common occurrence, but we have often met with it. Give her a table-spoonful of castor oil, feed for a day or two on ground oats mixed with new milk, and give her lettuce leaves.

FOOD FOR CALIFORNIAN QUAILS (*Belladonna*).—Almost every kind of grain, but especially oats and hempseed. They like also bread and lettuce leaves.

POULTRY SHOWS (*S.*).—We insert the announcements sent to us in our list of those forthcoming; but we think that if not of sufficient importance to be advertised, they are rarely worth attending. At all events it is evidence that the foads are not overflowing.

KEEPING CALIFORNIAN QUAILS (*Amateur de Volaille*).—Californian Quails require a pen with a sunny aspect, being also part gravel and part grass. They do not want a house, but there should be a shed to which they can resort, and this should be partly filled with bays or large boughs, among which they like to perch. It should be perfectly dry and sandy under the shed. Their usual food is oats; they are very fond of bread and lettuce, and will eat almost every grain.

TAME PHEASANTS (*Idem*).—We have had, and have now, Pheasants quite as tame as any farmyard fowls. We have had them full-winged, and they have neither gone away nor become wild. Nothing makes a bird wild so thoroughly as banding it; and, as you cannot cut its wings without catching it, we advise you to leave it at large. If you feed regularly, you will keep it tame.

BULLFINCH (*E. C. F.*).—A work will be published by us about the close of the year. Your Bullfinch is over-fed. Give him less of any kind of food, and leave off the millet entirely. If he could be allowed to fly about in a room for a few hours daily, his paralytic symptoms would disappear. Fatness and idleness are the causes of death to most domestic pets.

POINTS IN A POODLE (*Mrs. Fleming*).—The following are given by Mr. Meyrick:—"His shape should be compact, and should possess the general symmetry which marks a combination of activity with strength, and of which it is impossible to convey an exact idea in words. The points most looked to are: his head, which should be large, with a high, broad forehead, and a square muzzle; straight legs; and hair very thick, and falling in long, sharply-twisted curls or ringlets. The colour is either pure white, or pure black, but generally a mixture of the two colours. The height should be between 15 inches and 18 inches."

ROWAN JAM (*Westmoreland*).—Our correspondent wishes that some of our Scotch readers would furnish us, for publication, with a recipe for making jam of the berries of the Rowan or Mountain Ash.

LONDON MARKETS.—OCTOBER 6.

POULTRY.

Partridges remain very scarce, as the corn is now harvested and birds are become wild. We cannot look for any increase in the supply, and we consider, to the present time, it is the shortest supply we have ever seen. The same may be said of Grouse, which are very scarce and dear. Poultry is scarce, but there is little trade.

Large Fowls	3 0 to 3 <sup>00</sup> 6	Ducks	2 0 to 2 3
Smaller do.	2 0 " 2 6	Partridges	2 6 " 0 0
Chickens	1 6 " 1 9	Rabbits	1 4 " 1 5
Geese	6 0 " 6 6	Wild do.	0 8 " 0 9

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 58° and 40° respectively. The greatest heat, 76°, occurred on the 14th, in 1845; and the lowest cold, 22°, on the 19th, in 1843. During the period 131 days were fine, and on 114 rain fell.

THE ORNAMENTAL CHARACTER OF STANDARD FUCHSIAS.

CONSIDERING the very ornamental character of standard Fuchsias, it is really matter of surprise that so very little attention is paid to their cultivation. Standards of from 5 feet to 6 feet in height, planted out singly on the lawn or pleasure ground, have really a grand effect. I well know that many persons have taken a dislike to standard plants of this favourite family, on account of their "moppy" appearance, and from the wretched-looking specimens too often met with we are compelled to admit that this is but too true. But this is the very reverse of what a standard Fuchsia ought to be, and it is quite practicable to have it so, as it does not arise from any inaptness of the plant to form standards, but consists chiefly in the selecting of unsuitable sorts to form heads for standards of the height above mentioned.

Those varieties, the wood of which is of a stubby, short-jointed character, are altogether unfit for forming heads to full standards, and if used for this purpose, as we fear they too often are, failure and disappointment, of course, are the result. But there is a much more valid objection to standard Fuchsias than this, which is their extreme proneness to throw up suckers from the root. This, no doubt, is a great evil, and one that can be combated in no other way than by removing them as they make their appearance. This latter objection is, we believe, the principal drawback to their more extended cultivation, even by those parties who can fully appreciate a fine standard Fuchsia, of the beauty of which, we think, there can scarcely be any difference of opinion, only a difference in the degree of admiration. Any little trouble bestowed in removing suckers is amply compensated by the beauty of the plant.

Notwithstanding the ornamental character of the Fuchsia, very little attention is paid to its cultivation as a decorative plant for the flower garden. This is evidenced by the fact that they are so seldom seen in use for such purpose; and if standards are objected to on account of their "legginess," why not cultivate them as half-standards, dwarfs, or pyramids, which latter form places them amongst the most beautifully artistic things we have.

Half-standards, or plants with from 18 inches to 3 feet of clear stem, are very ornamental, whether planted-out as single specimens on the lawn, or planted at regular distances along a ribbon-border, the plants forming the groundwork of the border, just concealing the naked

stem of the plant. We think they can be very appropriately introduced in the latter case, as they serve to break the flatness, so prevailing a feature in ribbon-borders of any considerable length, on account of the uniform height of the plants.

The red-flowered varieties of Fuchsias are better suited for tall standards than the white sorts—that is, those with white sepals; this, probably, is on account of their being a little more tender—at all events, they seldom make such fine heads as the first-named. There are a few, however, which succeed pretty well if the situation is a little sheltered. Take the following—Madame Sontag, the Bride, Elizabeth, Diadem of Flora, England's Glory, and Pearl of England. This latter being a pretty free grower, and a most profuse bloomer, makes a magnificent head to a standard. How the white-corollaed varieties would succeed in this way we are not prepared to say; but we are afraid not well. In the red-flowered class we would mention, Nil Desperandum, Voltigeur, Clapton Hero, General Williams, Governor-General, and the old Fuchsia gracilis. These are all first-rate for forming heads to standards of 5 feet or 6 feet in height.

The way to secure fine standards is to select some free-growing sort as a stock. Fuchsia corallina is the one we use for this purpose. Strike this latter from cuttings, and grow on as rapidly as possible, and to a single stem, removing the laterals until it has attained the desired height, and then graft. Common whip or tongue grafting is the best, omitting the tongue, however; as, from the pithy nature of the wood of the Fuchsia, we think the tonguing weakens the graft too much, and a union is less speedily effected. We use no clay in grafting; merely a handful of moss (*Hypnum*) tied over the wound, and kept moist by occasional dampings with the syringe. When the stock and scion are firmly united, which will be perceived by the latter beginning to grow rapidly, the moss, of course, may be removed. It is better, however, to do this a little at a time, as, if removed all at once, the graft is apt to show it by the flagging of its leaves.

The after-treatment consists in practising the frequent stoppings and pinchings necessary to form the head, keeping a sharp look-out for suckers, which must be removed immediately they make their appearance. Half-standards, or anything under 3 feet of clear stem, can be had on their own roots by merely removing the side shoots until the desired height is attained, and then stopping the leader, so as to induce laterals, which latter must be stopped as often as is deemed necessary, to secure a well-balanced head.

The training and forming pyramids has already been treated of in this Journal, and need not be recapitulated here.

In conclusion, I would repeat that, in my humble opinion, almost any amount of trouble bestowed upon this beautiful family of plants will be amply compensated by their surpassing beauty.—J. DUNN, *Gardener to A. R. Boulton, Esq., Herrock Hall, Lancashire.*

## THE INTERNATIONAL EXHIBITION OF THE ROYAL HORTICULTURAL SOCIETY.

OCTOBER 8TH.

FORTUNE favours the brave in war and the bold in peace enterprises; but the boldest of our friends could hardly have anticipated such a thorough victory as our first International Exhibition, now on view at South Kensington, has proved by the result. Never in this world, or at all events in this part of it, was there ever seen anything approaching to the magnificence of this display. Many who were at the opening of the grand display had seen at one time or another specimens of all the things which were there, that were quite as good, and some of them better, as those in this international competition; and I have myself seen far better garden stuff sent into the kitchen by the old garden woman than you could pick up on any of the stalls. Yet everything that was there was thoroughly good of its kind; and, what tells more to our credit, there was not a bad lot from one end to the other. As a nation of gardeners, we lost not a hair's breadth in this trial; and, with the exception of the Pears and Apples, and some few Pomegranates, which we do not profess to excel in, from Mr. Solomon, of Covent Garden, there was nothing there much better than our own. The true and genuine old Golden Pippin was there in better flavour, from very nearly the 60° of north latitude, in Jenny Lind's country, than I could find it from any British grower in these collections. And yet, also, Mr. Eyles beat the first kitchen-gardener in Nice in the very article in which the Italians have been said to excel.

The collection of Gourds from the Chiswick garden was the best collection of Gourds there by many degrees, both in the number of kinds and in the looks and lustre of the specimens. They were from the size of six Gourds to the ounce, or say from fifty to sixty Gourds to the pound, grocers' weight, up to 87 lbs. a-piece. There were three or four more from both sides of the Channel which were heavier than that, but not more handsome; and there was the very old trick—the first trick I ever heard of in gardening—of growing their own names on the skin of the fruit, or nature-printing as one might say. Mr. Eyles, though a young man, is an old hand at that trick. He had some of the finest drawings out of the "Illustrated London News" nature-printed on Gourds at Chatsworth years ago; and Sir Joseph Paxton tells an excellent anecdote about them. They were shown to old Joe something, a native, who, on seeing a picture of the Duke stamped on the Gourd in a different colour, raised his eyes and exclaimed, "The Lord be praised, there is nothing like Nature after all!"

There was no lack of the true Custard Marrow, and there were "sharks" or dark rocky Gourds; "Bell-handle," which would really answer the purpose, if the stalk were fastened to a bell-pull, the upper half next the rope being yellow and the other half black; "Powder Horns" exactly in shape as for grouse-shooting; "Swans' Eggs" to the very life; "Bishops' Heads," a pretty little cream-coloured Gourd marked with even, eight, or nine dark ribs, representing the crown rather than the head of his Holiness—one of these in the collection of Mr. Stuart, of Nice, was named Princess Pia, a name that has just been changed to that of Queen of Portugal; "Gooseberry" Gourds, quite green and prickly, and as much like a Gooseberry as anything could be, and fifty of them would hardly make over a pound weight; and American Squashes, far more likely for Pumpkin-pies than any from the south of Europe. Altogether there did not appear to be any better for cooking in England than the Rock Marrows, cream and straw-coloured, rocked all over and of a moderate size. There were a few very large ones, the largest pair of which was the one 91 inches round the bulge, the other 87 inches: this one was marked 154 lbs. I was glad to see a large collection of edible Gourds, including the Bottle Gourd, which we take to be dangerous, from my Sardinian correspondent. But the meaning seems to be that these, or many of them, will not kill a fellow when he cannot get a Potato to stop a gap that is ill to bear in an Italian climate or in any other. But the American Gourds, whether they be Federals or Confederates, seem really to come within Burns' meaning of the pudding race, and to be a great help in filling up a valley in the region of the inner man.

The Messrs. Sutton & Sons, of Reading, were the only firm who made a dash at exhibiting their products in the style of high effect, and they did it most effectually, more in the ancient style of "setting" the walls of an armoury—that of Sir Walter Scott's, at Abbotsford, for instance. The back wall of the western

arcades, the whole length of their collection, was hung with scarlet cloth, firm as paper-hanging, to a height of 12 feet or 15 feet. Against this scarlet cloth they arranged spikes of many kinds of Grasses, from the Pampas downwards, in moon and star shapes, and in fans, peacock tails, and all manner of devices, which looked exceedingly well, and set off the things in a way to make a real impression.

But this Exhibition, from among the nations, must be taken as an experiment—a feeling of our way into the feelings of the kingdoms of the earth; and the Exhibition having proved successful, beyond the most sanguine of our hopes, there can be little doubt but it will be repeated every three years, if not annually. Then we shall turn another leaf, set everything up to the highest effect, or allow, if not request, all parties to do so in the fashion of their own countries; but, above all, we must study geography at last, and set every collection in the right parallel of latitude; for these arcades seem, as it were, to have been made on purpose for such scientific arrangements. Nothing could have been farther from the truth in geography than the way the different collections were disposed; but then, as there was no attempt at putting them otherwise, there was no harm done, but just the contrary.

The best fruits of the earth were the Potatoes; for what could be better than a roasted Kidney 6 inches long, and flat as a flounder, of a cold frosty day? The next best "fruits" were the Red Onions—you could almost see a man's eyes gushing out by merely looking at them. But the "Farmer's Profit" Potatoes were the most unprofitable of them all for the use of man; for their eyes were so big, so full, and so many, that they would hold water enough to steam or boil them in their jackets.

The most curious Potatoes were some beautiful white Kidneys from Mr. Page, farmer, Godalming, which were grown entirely in rotten tan, specimens of which were alongside of them.

And the rarest dish was a remarkably fine lot of Truffles: you will find them in the south-western arcades, black as they are, and as fine as possible. They are from Mr. Wainwright, gardener to W. C. Thornhill, Esq., Kettering, where one would look for some good Beech trees to harbour such Truffles.

The cereals were chiefly in the upper western arcades, and beautifully they were in glass cases of divers makes, and much in the ways you have seen them at the great International; but, as I have just said, the Messrs. Sutton took the shine out of all of them for effect.

All the best dessert fruits were in the conservatory in three rows the whole length of the building and across both ends of it. The tables along the sides held four rows, or dishes in depth, chiefly Apples and Pears; that along the centre was a double setting, Pines and Melons in ornamental high stands along the centre, and three rows on each side of the centre. The Pines were about from forty to fifty in all, and Melons as numerous. A large circle in pyramid in the centre, was occupied with sensation fruit from Covent Garden, the Apples and Pears being quite monstrous; the Glou Morceau, Easter Beurré, Beurré Diel, St. Germain, and Bells Angevine; also the Calville Apples, the Crassane Pears, the Duchesse d'Angoulême, Bon Chrétien, Bon Curé, and such like in Mr. Solomon's collection must have surprised himself when he first unpacked them.

The Flemish Pears on the whole were more sleek-looking than ours. In a large collection of new Pears from M. Nelis, were some very fine-looking specimens, but it is a question if any of them were superior to an English seedling from Mr. Ingram, of Frogmore, named *British Queen*, which was one of the best-looking Pears in the whole Exhibition, for a first-class dessert. It is all very well to have Algerian Goliath-looking Pears and Apples at a Lord Mayor's dinner; but for an aristocratic dinner that is not the fashion, but the moderate in size and the best looking, with the proper names sent up with them, and the *British Queen* Pear is a model size for such a dinner. It is a seedling from Marie Louise, but not quite so long as a full-lengthed Marie, more russet and has a blush over it on one side. I was told on good authority that it will stand among dessert Pears, as the *British Queen* Strawberry among Strawberries; but Sir Joseph Paxton who was on the spot, and who is more practical than most of us, declared he would rather be able to tell the tale than to hear it. There was a match Pear to the *British Queen*, nearly, but not quite so good-looking, from Her Majesty's garden at Frogmore.

The great force and competition for Grapes took ground on the west side, half of the middle row in the conservatory. Here the battle raged the fiercest, but the centre and either wing, nor

the generals were much different from what they have, hitherto, been on either side of the Thames. I did not hear of the dead or missing, but I met some of the wounded, and, of course, I did, as I often have to do, sympathised with them most sincerely.

The three bunches of Muscat of Alexandria which won the day in threes, were the most Golden Muscats that have yet been exhibited before this Society, but they were not so luxuriant-looking as the more russety looks of the Muscats, from Mrs. Cubitt, nor so big as I have seen them from Bowood.

The Black Grapes were all together on one side, and they were, indeed, so "black and all black," that the whole continent of Europe could not improve them a single shade, nor show any to be named the same day with them.

The Messrs. Low, Veitch, Bull, and the Messrs. Downie, Laird, and Laing, and a few others exhibited some fine plants, and the finest of them all, and of all that have been exhibited for the last ten years, is *Caladium Lowii*, from the Clapton Nursery. Nine members of the Floral Committee held up both their hands when the unanimous award of a first-class certificate was being passed for this most remarkable Caladium; but if nineteen of them had been at this Show, and had to do the thing over again, every one of the number might have held up his right leg in addition, to clench it the more firmly and certain. If you recollect, some of us mistook *Alocasia metallica* on its first appearance, to be an unearthly plant from beyond the flood. Well, with a good deal of the make of *metallica*, this *Caladium* looks as if it was the very first plant after the flood, and that the salt water left an emerald metallic lustre all over the plant, with the midrib and all the big veins zebra-like, looking like the milky-way through the glaze on the blade. There were a score of them now shown to prove the fact, and the plant is coming out next week cheap as a new Fuchsia, in comparison to *Alocasia metallica*.

Then there were two little seedlings of a new *Phalenopsis*, from Moulmein, named *Lowii*, from the same firm. It is white and crimson, and Dr. Lindley has just received a dried specimen of it, which he is said to have likened more to the *Phalenopsis grandiflora* than anything else. Then there was a new, strong, woody *Sonerila*, and four kinds of double and no double *Petunias*, from the same firm. The best plant Mr. Bull has yet exhibited was on this occasion a most beautiful glaucous kind of *Araucaria Cunninghamii*, with some others; and lots of the lovely blue *Vanda*, and other fine things, came from the Exotic Nursery. Also, *Stenogaster*, and the pretty variegated *Erionema* something, for Her Grace the Duchess of Cambridge and the Princess Mary of Cambridge swept past me at the time, and thereby I lost the last and best half of the *Melastomad*.

Then I took to a lot of beautiful new *Pentstemons* from the Messrs. Downie, Laird, & Laing, and found Dr. Hogg and Donald Beaton, two of the best scarlets, with open mouths and white throats; but *Clio* would beat the Doctor and his man Sandy. It is so full of cream and silvery markings. *Blue Beauty*, a new colour in purple; and *Novelty* the next; and then a whole generation of *Liliput Dahlias*; and nine large boxes of cut *Roses* from Messrs. Paul & Son. D. BEATON.

SUMMER comes before us with a garland of flowers, and Autumn brings the yellow corn, and a rich treasure of fruit. To the spoils of the one full justice has been done, and it is now our task in this time of falling leaves and dewy evenings, to record the triumphs of the other. The prefixes of "great" and "grand" have been so lavishly bestowed of late on horticultural exhibitions, that they fall as dead sounds on the public ear; but on this occasion the display of fruit at Kensington is not merely great, it is magnificent, and nothing equal to it has ever before been witnessed in this country, or, we feel confident, in the world.

The imposing spectacle presented by the vast array of fruit occupying every available spot in the large conservatory, and along with Gourds, and other productions, stretching far into the arcades, we have left to the graphic pen of our friend, Mr. Beaton, to describe, merely remarking that the entries in the English department alone exceeded 1200.

We will now endeavour to give as full particulars as possible of the most interesting portions of the exhibition, beginning with the fruit.

In Class A, collection of fruit, fruiterers only, there were only three exhibitors. Mr. Lewis Solomon, and Messrs. Webber and Co., of Covent Garden, being respectively first and second. Mr.

Solomon's contribution was superb, particularly of Pears, which were the admiration of every one, on account of their immense size, and that beautiful colour which the sunnier climate of France could alone impart. These Pears comprised magnificent specimens of Uvedale's St. Germain, under the name of Belle Angevine, splendid high-coloured fruit of the Glou Moreceau, and Bon Chrétien d'Espagne, Calabasse, Napoléon, White Doyenné, Duchesse d'Angoulême, St. Germain, Colmar, Crassane, Monsieur le Curé, and Easter Beurré, of extraordinary size; Beurré Diel, magnificent; St. Germain, and Beurré Royal. Of Apples, there were—Reinette du Canada, and Winter White Calville, very large and fine; Pomme d'Api, and Ribston Pippin. The remainder of the collection consisted of Pines, both Queens and Cayenne, the former evidently of great weight, the latter were in pots, but though very large, were very unripe; Royal George Peaches, Black Hamburg and Muscat of Alexandria Grapes, White Marseille Figs, Pomegranates, of remarkable size, Melons, Morello Cherries, and Red Currants; of Vegetables, Asparagus, Artichokes, Purple Aubergine, Tomatoes, Capsicums, and Cardoons.

Webber & Co., had also a very extensive collection, partly of English, and partly of foreign growth. Of Pears, there were large and fine specimens of the Glou Moreceau, Easter Beurré, Beurré Diel, Duchesse d'Angoulême, Triomphe de Jodoigne, St. Germain, highly coloured; also, Monsieur le Curé, Uvedale's St. Germain, and Catillac. Winter White Calville, and Reinette du Canada Apples, were of great size, and very beautiful, and so was a kind called *La Belle des Bois*; Pomme d'Api was beautifully coloured, a point which constitutes the merit of this variety. Besides the above, there were some very good Apples and Pears of English growth, Muscat and Black Hamburg Grapes, Orion and Beechwood Melons, Cob Nuts, Walnuts, Hiccory, Brazil, Monkey, and Pistachia Nuts, Oranges from Naples, Lychee, Quinces, and three Black Jamaica Pines.

The effect of this collection would have been considerably increased, had greater masses of each kind of fruit being exhibited; but as it was, the display was very creditable to the highly respectable firm by whom it was furnished.

Mr. W. White, of Montpellier Row, Brompton, was the remaining competitor, his contribution contained a Black Antigna Pine, said to weigh 4 lbs., a Black Jamaica of the same weight, a very large Smooth-leaved Cayenne, Black Hamburg Grapes, several good dishes of Apples and Pears, and others not up to the mark, either in size and colour.

In Class B, collections from private growers, there was more competition, and several excellent exhibitions were produced.

Mr. Tillyard, gardener to J. Kerk, Esq., Stanmore, showed three handsome bunches of Muscat of Alexandria and excellent Black Hamburgs; Coe's Golden Drop Plum beautifully ripened, and Ickworth Impératrice; White Marseilles and Brown Turkey Figs; Green-fleshed and Scarlet Gem Melons; Eugenia Ugni; Red and Yellow Raspberries; White Dutch Currants; Walburton Admirable Peach, very fine; Moorpark Apricots; Morello Cherries; Glou Moreceau and Chaumontel Pears; and Margil and Cox's Pomona Apples. To this the first prize was awarded.

Mr. Henderson, gardener to the Duke of Sutherland, Trentham, who was second, had a very fine collection which included a good Montserrat Pine, a Black Antigua, Trentham Hybrid Melon; Black Hamburg and White Tokay Grapes, the former very handsome both in bunch and berries; Walburton and Late Admirable Peaches, of large size; Coe's Golden Drop and Diamond Plums; Chaumontel, Louise Bonne, and Williams' Bon Chrétien Pears; Lord Suffield and Calville Blanche Apples; fine Moorpark Apricots; Elruge Nectarines; Morello Cherries; Brown Turkey and White Ischia Figs; Eugenia Ugni; Red Dutch Currants.

Good collections also came from Mr. Young, gardener to W. H. Stone, Esq., Havant; Mr. Allen, gardener to J. B. Glegg, Esq., Withington Hall; and Mr. Kailc, gardener to Earl Lovelace, Ripley.

Pines were not so numerous as we expected, but several very fine fruit were exhibited. In Class C, Queens, the first prize was given to Mr. Green, gardener to Mrs. Honeywood, Kelvedon, for a very handsome fruit of the unusual weight of 6 lbs. 1 oz.; Mr. Young, of Havant, who was second, had a very fine one, certainly nearly 5 lbs.; and Mr. Robinson, gardener to R. Benyon, Esq. M.P., Englefield House, Reading, was third with one weighing 4 lbs. 15 oz. Mr. Moore, gardener to J. C. Wall, Esq., Redland Lodge, Bristol, had two very fine fruit, one of

which weighed 5 lbs., the other 4½ lbs., which would have certainly taken a prize had they not been very far gone. Mr. Bywe, gardener to R. T. Crawshay, Esq., Merthyr Tydvil, had two fruit, one of which was 3 lbs. 7 ozs., the other considerably larger, but the crown was large and the pips small.

The Class D, for Any other kind, also contained some remarkable fruit. The largest was a Smooth-leaved Cayenne, from M. Chantrier, gardener to the Duc de Levis Ventadour, Paris, and weighed 7½ lbs., but its crown was large, and it only received a second prize, the first being given to a very handsome fruit of the same kind, from Mr. Ingram, of the Royal Gardens, Frogmore, and which weighed 6 lbs. 7 ozs. There were also two others from the same source, but not so large. A fine Providence from Mr. Bywe came in third. A Prickly Cayenne, from Mr. Johnson, gardener to the Duke of Wellington, Strathfieldsaye, weighed 6 lbs. 9 ozs., but it was unripe at top and imperfect; Mr. A. Henderson had a good Black Antigua; Mr. Green, of Kelvedon, an Enville, 5 lbs. 6 ozs., but gone very much at the base; Mr. Speed, a Russian Globa, to which there was the same objection; and Mr. S. Windsor, gardener to Sir R. Brooke, Norton Priory, a Black Prince and Black Jamaica.

There was a magnificent display of Grapes, both White and Black, the bunches in some cases being of extraordinary size. Among the White Muscats, Mr. Hill, Keele Hall, had six bunches of Muscat of Alexandria, weighing altogether 17½ lbs., the heaviest three being no less than 10½ lbs. in weight. The bunches were regular and the berries even, though scarcely quite ripe. To these the first prize was given. Mr. Tillyard, who was second, had also large and handsome bunches; and well-grown examples also came from Mr. Meredith, Garston, near Liverpool; Mr. Frost, gardener to E. L. Betts, Esq., Preston Hall; and Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading. But it was in the class for three bunches that the finest Muscats we have seen this season, were exhibited by Mr. J. Drummond, gardener to J. S. Smith, Esq., of Tunbridge Wells. These were not only remarkably fine in point of size, but also perfection in colour. Those from Mr. Tillyard which came next in the prize list, though larger and with handsome shoulders, were not so perfect as regards ripeness. Excellent bunches were likewise shown by Mr. Potts; Mr. Drewett, gardener to Mrs. Cubitt, Denbies, near Dorking; and Mr. Frost. There were several other exhibitors, but the fruit was either deficient in size and colour, or the bunches straggling.

Of other White kinds, Trebbiano, from Mr. Sage, was very fine, one bunch weighing 7½ lbs., and received a first prize, and the same kind was likewise shown in good condition by Mr. Ingram, of Reading, Mr. Tillery, and Mr. Bywe, who had also Tottenham Park Muscats. Three bunches of Marchioness of Hastings, weighing 13½ lbs., were shown by Mr. Hill, of Keele Hall; and the same kind also came from Mr. Bull, of Chelsea.

Of Black Hamburg Grapes, the finest six bunches came from Mr. Henderson, of Trentham, the bunches very large, and the berries perfectly ripe and covered with a beautiful bloom; Mr. Hill, gardener to R. Sneyd, Esq., Keele Hall, who was second, had six fine bunches weighing 11½ lbs.; Mr. Meredith received an equal second; and good examples of this variety also came from Mr. A. Ingram, gardener to J. J. Blandy, Esq.; Mr. Turner, of Slough, and some others. The finest exhibition, however, among the Black kinds was that of Mr. Drummond, gardener to J. S. Smith, Esq., Tunbridge Wells, who has been already referred to as having shown the best Muscats. The three bunches which he exhibited were the Dutch Hamburg, and the berries were of enormous size and beautifully coloured. Mr. Henderson, of Trentham, had three bunches nearly as large, very compact, and beautifully ripened. Fine bunches were also shown by Mr. Omant, gardener to J. Lurch, Esq., Epsom, though not compact. Mr. Meredith's, of Garston, and several other exhibitions were of average merit.

In other Black kinds, Mr. Drummond received the highest award for Barbarossa, which was large, beautifully coloured, and very compact; indeed, it might easily have been mistaken for the Hamburg. Kempsey Alicante, a very fine late variety, weighing, for the three bunches, 8½ lbs., came from Mr. Meredith, and was not only exceedingly handsome, but compact and nearly black. To this was awarded a second prize. The same variety also came from Mr. Cox, of Worcester, the berries being large and handsome, but very different in colour. Mr. Hill, Keele Hall, had three bunches of Lady Downe's Seedling, weighing 5½ lbs., beautifully coloured. Mr. Bywe, gardener to R. T. Crawshay, Esq., Cyfarthfa Castle, exhibited the same kind, as well as

Black Prince and Black Barbarossa; whilst excellent Black St. Peter's were sent by Mr. Tillyard.

The large conservatory at Chiswick furnished an extensive and interesting collection of Grapes, among which were bunches of Barbarossa and Frankenthal 4 lbs. in weight, Black Monukka 3½ lbs., Dutch Hamburg also nearly as large, and excellent bunches of Black Prince, Raisin de Calabre, Golden Hamburg, and Trebbiano. Ahbea looked as beautiful as ever; and there were besides several varieties that were not exhibited at the last Show, such as Siderites, Bidwill's Seedling, Muscat Ottonel, Tokay Noir d'Hongrie, a Deccan Grape (sent home by Colonel Sykes), as well as a basket filled with bunches of the Frankenthal, which, though not remarkable for their weight, possessed large and well-ripened berries.

Of Dessert Pears there was an immense show, and many of the exhibitions contained large, as well as beautifully-coloured specimens. In Class K, twelve dishes, Mr. Dyerrihouse, gardener to Viscount Eversley, Heckfield, was first, his kinds consisting of Beurré Diel and Easter Beurré, very fine; immense, well-coloured fruit of the Flemish Beauty; Brown Beurré, Gansel's Bergamot (large), Vicar of Winkfield, Beurré Rance (fine), Marie Louise, Beurré de Capiaumont, Louis d'Orleans, No Plus Mauris, and Winter Nelis. Mr. T. Ingram, of the Royal Gardens, Frogmore, was next with an excellent collection, consisting of very fine Duchesse d'Angoulême, Kingacssing, Chancellor (large), Beurré Diel, Prince Albert, Beurré Rance, Knight's Monarch (very fine), a large Californian Pear (of a greenish-yellow colour), Van Mons Léon le Clerc, Chaumontel, Beurré Rance, Beurré de Capiaumont, and Conseller de la Cour.

Mr. Frost, of Preston Hall, had Soldat Esperen, Calebasse Grosse (very fine), Glou Moreceau, Beurré Rance (good), Van Mons Léon le Clerc, Duchesse d'Angoulême, Champ Rich d'Italie (a large greenish-yellow Pear with russet specks), Beurré Diel, Beurré Superfin, Marie Louise, and Comte de Flandres.

From Mr. Morris, gardener to T. White, Esq., Wethersfield, there also came some excellent fruit; among which were fine Duchesse d'Angoulême; Bonne d'Ézée, very fine, but generally considered a second-class variety; Beurré Diel, large, good; Beurré Bosc, Léon le Clerc de Laval, Louise Bonne of Jersey, fine, and others of average merit.

Mr. Ross, gardener to C. Eyre, Esq., Newbury, had, among others, highly coloured fruit of Glou Moreceau and Gansel's Bergamot. The rest were generally too small.

Mr. Gale, of Hammersmith, had some excellent fruit of Louise Bonne of Jersey, Beurré Diel, Glou Moreceau, Chaumontel, and other good kinds, which were well ripened; and considering that they were all produced on standards, were of large size, but, of course, they could not compare in this respect with fruit from walls. Mr. Saunders, gardener to Sir H. Meux, Bart., Theobalds, had a very good collection, particularly as regarded the Beurré Diel, Beurré d'Amanlis, and Van Mons Léon le Clerc. Mr. Culverwell, Thorp Perrow, had Hacon's Incomparable, fine, and a good dish of Sackle, a variety of which, it may be remarked, there were but few exhibitions, and yet it was that which, at the great Fruit Show at St. James's Hall some years ago, carried the palm from all others.

Triomphe de Jodoigne and Louise Bonne of Jersey, from Mr. Gilbert, of Ipswich, were both of good size, and his Colmar d'Arèrberg, very fine in appearance; but this is an inferior kind as regards its quality.

Other good exhibitions, mostly of the varieties already named, came from Mr. Sage, gardener to Earl Brownlow, Ashridge; Mr. Harrison, of Oatlands, Palace Gardens; Mr. Ingram, of Reading; and Mr. Park, of Retford.

The next Class, L, being for only six dishes, there was a greater competition. Mr. Snow, gardener to Countess Cowper, West Park, was successful in winning the highest prize with Van Mons Léon le Clerc (very fine), Glou Moreceau, Beurré d'Anjou (or the No Plus Mauris of the French), Maréchal de la Cour, Beurré Diel, and Marie Louise, all of which were very large and fine. Mr. Ford, of Watton, received the second prize for large and fine fruit of Easter Beurre, Glou Moreceau, Beurré Diel, Marie Louise, and Duchesse d'Angoulême. Mr. Tranter, gardener to the Hon. G. Ryder, Hemel Hempstead, sent good Brown Beurré and fine Beurré Diel, Bergamotte d'Esperen, and Beurré Bretonneau. Mr. Bousie, of Stoke Park, Slough, brought some remarkably fine specimens of Beurré Clairgeau; his Hacon's Incomparable and Duchesse d'Angoulême were also particularly good, and he received an extra prize—a similar award being made to Mr. Stroud, gardener to the Hon. Mrs. Finch, Great

Berkhampstead, who had also a very good show. Mr. Frost had Louise Bonne of Jersey and Calbasse Grosse, both large and remarkably fine; Forelle, from Mr. Hutecheson, was also good.

In Class M, three dishes, the finest came from Mr. Ingram, of Frogmore, consisting of Gansel's Bergamot, large, and finely ripened; and Golden Russet and British Queen, two seedlings of his own raising, bearing considerable resemblance in appearance, and probably of the same parentage, but distinct. Their quality is said to be excellent. Mr. D. Lumsden, gardener to Lady Hamilton, Slough, came in second with Gansel's Bergamot, Beurré Bose, and Marie Louise, all very good, particularly the first. Mr. Frost, who received the third prize, had some large specimens of Beurré Clairgeau (brilliantly coloured), Gansel's Bergamot, and very good examples of the Seckel; not, however, equal to those from Mr. Harrison, of Oatlands.

Excellent collections came from Mr. Baldwin, of Turnham Green, whose Beurré de Capiamont was very fine; G. Wilson, Esq., Weybridge, very large but unripe; and Mr. Bousie, of Slough, and Mr. Newton, gardener to J. G. Graham, Esq., Enfield Chase.

Single dishes of Dessert kinds were shown in Class N; and here Mr. Ingram, of Frogmore, was first with his seedling British Queen before referred to. Mr. Bain, gardener to A. Perkins, Esq., of Hanworth Park, was second with a dish of large and well-coloured Seckel; whilst Mr. W. Culverwell, of Thorp Perrow, who showed large specimens of Haeon's Incomparable, came in third. Mr. Salter, of Dulwich Wood, had very good Flemish Beauty; G. Wilson, Esq., Maréchal de la Cour; and Mr. Ralphs, of Walton-on-Thames, Haeon's Incomparable.

In Class O, Kitchen Pears, Mr. Snow was first with Uvedale's St. Germain, a kind which was largely exhibited by others; and Mr. J. Willmot, Roehampton, second with Catillac, large and fine. Mr. S. Ford, gardener to W. E. Hubbard, Esq., Horsham, and Mr. Morris, Wethersfield, had also large specimens of Uvedale's St. Germain. Of Catillac there were some excellent examples; and Mr. W. Chater, of Saffron Walden, had the Verulam or Buchanan's Spring Beurré, the merits of which as a stewing Pear are not sufficiently known.

The heaviest Five Dessert Pears were Calbasse Grosse from Mr. Frost, their total weight being 5 lbs. 10 ozs.; whilst some very large Beurré Diel came from Mr. Morris, Wethersfield. A dish of Duchesse d'Angoulême from Mr. Drewett, of Croydon, weighed 4 lbs.  $\frac{1}{2}$  oz. One of Beurré Diel, from Mr. Spivey, weighed 4 lbs. Beurré Diel, 4 lbs. 4 $\frac{1}{2}$  ozs, from Mr. Hawes, gardener to J. W. Rhodes, Esq., Henley; and Beurré Bretonneau from Mr. Tranter, 3 lbs. 9 ozs.

The best Twelve Dessert Apples came from Mr. Bousie, gardener to Lady Molyneux, Stoke Park, Slough, who had finely-grown fruit of Court Pendu Plat, beautifully coloured; Rosemary Russet, Clark's Pippin, King of the Pippins, finely coloured; Ribston Pippin, Beauty of Wilts, Gravenstein, very fine; Benwell's Pearmain, Devonshire Quarrenden, and Cox's Orange Pippin, Cockle Pippin, and Formosa Nonpareil.

Mr. Whiting, gardener to H. T. Hope, Esq., The Deepdene, Dorking, had in his collection large and well-coloured fruit of Adams' Pearmain, Court Pendu Plat (rather small, but very fine in point of colour), Braddick's Nonpareil (very good), also Franklin's Golden Pippin, and Sweeny's Nonpareil, though perhaps not properly a dessert Apple. Mr. Frost had Court Pendu Plat, fine, but not highly coloured; a beautiful even dish of King of the Pippins; Irish Pesch, large and highly coloured; Fearn's Pippin, very fine; Ribston Pippin; Syke House Russet; and other good kinds. In Mr. Ingram's exhibition there were some very large Golden Pippins; and Nugget, a seedling, with a yellow skin, with broken streaks of red next the sun, and beautiful fruit of the Blenheim. Fine, highly-coloured fruit, also came from Mr. Cox, gardener to W. Wells, Esq., Redleaf; Mr. Butterfield, Basingbourne; Mr. Grover, of Hammersmith; and Mr. C. Ross.

In Six Dessert Apples, Mr. Hall, gardener to Capt. Tyrrell, Ealing, had the finest exhibition, his Court Pendu Plate were of extraordinary size; Blenheim Pippin, large, and finely grown; King of the Pippins, very large, and finely coloured; Ribston Pippin; Braddick's Pippin; and Fearn's Pippin, the last particularly fine.

Among Mr. Lane's six were Ruck's Nonesuch, brilliant in colour; Kerry Pippin, beautifully streaked; and Forge, also very high-coloured.

Mr. Simpson, of Stoke Farm, Slough, Dr. Cooper, of the same

place, Mr. Willmot, Mr. Baldwin, Mr. Frost, and Mr. Cox, of Redleaf, must also be noticed as furnishing excellent collections.

Of three dishes Mr. Wright, gardener to Mrs. Bamsden, Twickenham, furnished the best, which were Golden Russet (very fine), Duchess of Clarence, and King of the Pippins. Mr. J. Newton, who was second, had some beautifully coloured fruit, the kinds being Ribston Pippin, Scarlet Pearmain, and Margil. Single dishes were shown by Mr. Grover, of Hammersmith, who had Kirke's Incomparable, a brilliant dark crimson variety, to which the first prize was given; Mr. Salmon, of West Ham, who showed Cornish Gilliflower, remarkably fine; and Mr. Barnett, of Shiffnal, who had Bull's Golden Reinette, very large and fine.

Kitchen Apples were exhibited by numerous competitors, and were, with some exceptions, large and handsome. The best twelve were from Mr. Butterfield, of Basingbourne, who had fine fruit of the Catshead, Kentish Brooding, Norfolk Beefing, Royal Russet, and Blenheim Pippin; also Golden Noble, Alexander, Nelson Codlin, Normanton Wonder, King's Pippin, Bedfordshire Foundling, and Waltham Abbey Seedling. Mr. Cox, of Redleaf, had some fine Gloria Mundi, very large Dutch Codlin, and Alexander finely coloured. Mr. Moffatt and several other competitors, had excellent collections; and in the next Class V, for six dishes, the competition was equally good. The best here was furnished by Mr. Snow, who was also first with a single dish of Alfriston, which was truly magnificent. Mère de Ménage, of large size and a deep blood red colour, came from Mr. Lee, gardener to Viscount Combermere.

The prize for the heaviest dish of Kitchen Apples was taken by Mr. Snow with Alfriston, weighing 5 $\frac{1}{2}$  lbs; Mr. Parsons, of Danesbury, had the same kind 4 $\frac{1}{2}$  lbs. in weight; and Mr. Smith, of Enfield, Tower of Glamis, another excellent kitchen Apple, 4 lbs. 6 ozs.; whilst Minehall Crab, from Mr. Wicks, was 3 $\frac{1}{2}$  lbs.

In Melons, there was nothing very remarkable. The best was Victory of Bath, from Mr. Alliston; Heckfield Hybrid, from Mr. Johnson, Strathfieldsaye, came next; and Bromham Hall, Trentham Hybrid, Turner's Scarlet Gem, and Golden Perfection, were the best of the others.

Of Plums, the sort principally shown and certainly that exhibited in greatest perfection, was Coe's Golden Drop. The competition was here very close; Mr. Tillyard, Mr. Bousie, Mr. Snow, and Mr. Kaile standing in the prize list in the same order as their names.

Some very good Keens' Seedling Strawberries were shown by Mr. Masters, gardener to the Earl of Macclesfield, at Tetworth; and Alpines came from Mr. Cunningham, Fulham Palace Gardens.

Currants, especially the Red kinds, were very good, the best coming from Mr. Terry, St. Albans; and Mr. Henderson had also an excellent dish.

A few Raspberries and Oranges were exhibited. Some nice Orange trees in pots came from Mr. Bull, of Chelsea; and from Messrs. Lane & Son, of Great Berkhamstead, were some beautiful fruiting Vines in pots, the bunches being of large size.

To the Gourds, Roots, Foreign Fruit, and other subjects, we shall take occasion to advert next week.

## A WORD OR TWO ABOUT A FEW BEDDING GERANIUMS.

A REMARK which Mr. Beaton makes about his own Stella Geranium in his report of Hampton Court Gardens, has led me to express my opinion of this and a few other Geraniums not yet in general cultivation as bedding plants. I may mention that I was somewhat surprised this season at not meeting with beds of such as Stella, Madame Vaucher, Madame Chardine, Paul l'Abbé, Admiration, &c., at some of the leading places for such things about London.

If Mr. Beaton had never done more for flower-gardening than the raising of *Stella*, it would have been worth a lifetime in that line. It took me by surprise the first year I grew it, although I had it with a very high character. A large bed of it here this season, although a field of bloom lay between the eye and it, arrested the eye immediately the garden was entered. It is a grand thing. Yet I am hoping that *Triomphe de Paris* will be an improvement on it.

Madame Vaucher takes quite as prominent a position as a pure white as *Stella* does as a crimson, and is really a white worth growing largely, which is more than I can say for any

of the other whites that I have tried. As a pot plant it is a charming thing.

*Madame Chardine*, as a soft, salmon-coloured variety, is magnificent, it being a most abundant bloomer, throwing well up its large globular trusses of pleasing blooms.

*Paul V'Abbé*, a dark rose, proves to be an extraordinary bloomer, and makes a magnificent bed. The individual trusses remain in perfection for a great length of time.

*Admiral* is particularly fine as a dwarf horseshoe, the best that I have seen. It makes an exquisite bed, and as a pot variety it is superb.

*Rosy Queen*, in the way of *Christine*, proves to be a superior variety, particularly for late blooming. It stands wet weather better than *Christine*, and lasts longer in perfection as the nights get long and damp.

The above are conclusions formed from my experience of the above varieties as bedded on the fine deep open loam of East Lothian. On other soils the results may vary. I was surprised on coming to this place to find that Tom Thumb was superior to New Frogmore; while, on the Middlesex clay, the latter was by far the most effective: hence we find a war of words about the comparative merits of things, without taking into consideration all the varied circumstances under which notes are taken, and, consequently, the war ends in smoke as far as any benefit to lookers-on is concerned.—D. THOMSON, *Archerfield*.

### FRUIT TREES NEAR A MANUFACTURING TOWN.

WILL Pears grow as wall fruit in a large garden, situation high, walls facing south, west, and east, but adjoining a large manufacturing town on one side and the country on the other? If so, what sorts?

Will Filberts grow and bear fruit in such a locality, and Mulberry trees?

I have already *Glou Morceau*, *Napoléon*, and *Louise Bonne* of Jersey, and they all bloom profusely; but only once has even one borne in the same proportion. Aspect west. A Plum on the same wall, *Coe's Golden Drop*, has rarely blossomed, and never borne. Soil clayey. An Apricot, too, thrives, but never blossoms.—A LADY GARDENER.

[You should have told us your position, and whether the smoke is extra troublesome. In the meantime we do not see why success should not attend your efforts. If the Pears bloom so profusely, and yet bear none, it is a sign the wood is fairly ripened, and the buds somewhat perfected in autumn. The blooms, however, may not be quite perfect, and if extra thick, thinning out the smaller flowers, and those with imperfect incipient fruit, might be an advantage. In London we have seen Pear trees barren, though they had abundance of bloom; whilst Apples bore pretty well under similar circumstances, and I attributed the difference to these causes: The Pears bloomed much more early, and from the heated atmosphere of the metropolis, were thus more subject to spring frosts. More fires being then used than when the Apple was in bloom, there was much more smoke, and on examining we found many of the stigmas of the incipient fruit so crusted with soot that the fertilising pollen of the stamens had no chance of acting upon them. At any rate, we managed to set fruit of Pears by using gauze covering over some small trees well supplied with bloom. If the garden is open to the country on one side, we could scarcely think that smoke would be the cause of your failure. There being plenty of blossom, we should ascribe the sterility either to imperfect ripening of the wood, so as to prevent the fruit-buds being perfect, or a want of nourishment and strength to enable the bloom to set freely. It would be worth while on the latter supposition, to examine the state of the roots as to moisture, and if there was enough of that, to give some rich surface mulchings. We think want of strength is most likely to be the cause in your case. You may add *Williams' Bon Chrétien*, *Marie Louise*, *Duchesse d'Angoulême*, *Beurré Diel*, *Knight's Monarch*, *Beurré Rance*, *Seckle*, *Easter Beurré*, *Forella*, &c.

Filberts will be sure to bear if trained open bush form, if the smoke is not extra dense. You would see the other week how to make Mulberry trees fruitful. Unless root-pruned they will not bear well until they get old and bonnet-headed. By regulating the top and the roots, the trees will bear plentifully either against a wall or in the open air; but far north they do not ripen

nice as a standard. We have seldom seen them doing much in the way of fruiting against a wall, because they were encouraged to do nothing but grow, and extra luxuriance and extra fertility are always in opposition to each other. The *Golden Drop Plum*, and the *Apricot* that grow so freely but never blossom, and, consequently, never fruit, we presume to be in a very different condition to your Pears, and you can tell us if the shoots are not strong, and the leaves large, and keeping their green appearance until a severe frost has come. Now, if that is the case, thin out the largest of this summer's shoots, take the points off the middle-sized ones, shorten back the spurs, and leave only as many as the sun can get at, when all is close to the wall. Then take out a trench 5 feet from the tree; if at all old, undermine it, cut any tap roots, and lay the horizontal ones in fresh, poor soil, water a little, mulch to keep out frost, and if the sun should be powerful, syringe the leaves in the middle of the day, that they may ripen-off kindly. If the trees make very little wood next season, give a little manure water several times during the summer over a fresh mulching, and if you get little in 1863, we could almost be certain you would have blossom in 1864.]

### CULTIVATION OF THE FILBERT.

WHATEVER differences of opinion may exist respecting the management of most of our hardy fruits in regard to the amount of pruning they require, there is no question that the knife, or it may be the saw, is more freely used in the treatment of this tree than in that of any other. It is not too much to say that in the case of the Filbert fully nine-tenths of every year's growth are cut away, and often more than that; and, if we except the Grape Vine when pruned on the spur system, there is certainly no other fruit tree on which the knife plays so conspicuous a part. As the Filbert is in general a free and rather fast-growing tree, the abundance of wood to choose from enables the cultivator to select that which is best adapted to give the shape he wants. This is done with so much exactness, that, in a well-managed orchard of this fruit, one tree so much resembles another that the cursory observer might suppose they had all been turned out of one mould. A glance at the way this is done in Kent, where so many acres are under this crop, will assist the amateur in keeping his trees within reasonable bounds, and also in making them more fruitful than if allowed to run rampant amongst other trees less vigorous than themselves. To make this more clear, we will divide this subject into the following heads:—

**SOIL AND SITUATION.**—Although occasional plantations of this fruit may be formed on stiff heavy ground, such plots are the exception, for they rarely prosper and are fast disappearing. A dry stony soil, not too shallow, without anything pernicious in the subsoil, is the one the Filbert likes best; and many hundreds of acres of the best plantations in Kent are on the slopes of hills having limestone at no great depth below. Occasionally they are also planted over chalk, but the result is less satisfactory.

Generally speaking, the soils which overlie Kentish ragstone, or its substitute, which in local language is called "Hassock" (a soft stone unable to endure frost), are the best; and in tillage quantities of such stones as large as a half-brick are turned up and mixed with the surface soil, presenting anything but an inviting appearance. In such soils both the Filbert and Morello Cherry seem to thrive better than in ground of any other description, and, what is equally important, they bear well also. Such a soil is, of course, a stranger to stagnant water; and though the substratum is hard when first broken up, there is nothing in it pernicious to vegetation, as seeds will vegetate in it soon after being thrown to the top. Being of a half-sandy nature, it may with advantage be used as a fertiliser to soils of a contrary description. All the Filbert plantations are not on soil of the above description, but it is generally admitted that on such the best crops of fruit are produced. The nearer, therefore, that it can be imitated elsewhere, the greater the chance of success.

Situation has also something to do in the matter, and when a choice of this exists the western slope of a hill is the best position; but in the valley of the Medway plantations are formed on all inclinations, dryness of bottom being one of the conditions first of all insisted on, and a soil not by any means meagre in regard to depth, is also necessary. The other conditions are all subservient to them. Shelter from very high winds may be

useful, but this is of less consequence than for most other fruits; but very exposed places, as the tops of naked hills, are too cold and ungenial, and, though the tree will thrive there, it is seldom fruitful enough to be satisfactory. Though blooming amongst the earliest of all our fruits, the tree is far from being the hardiest. The beautiful little tufts of crimson which form the female or nut-bearing blossom are very sensible to frost, and are often damaged by it. The long green catkins or male blossoms which hang all the winter are hardy enough; but if destroyed before the others make their appearance, the crop, of course, is bad. Generally speaking, however, the well-being of the crop depends on other conditions more than this; and so many things are necessary to perfect success, that the crop of Filberts is, perhaps, more capricious than that of any other fruit, although when good nothing yields a better return. Upwards of a ton weight per acre has been gathered in favourable seasons; but as Filberts are often planted in conjunction with Apples, Pears, and other fruits, the return is limited in consequence of the ground taken up by these. Nevertheless, the cultivator generally favours his Filbert trees if they do well, and the others are cut away.

**PREPARATION OF THE GROUND AND PLANTING.**—Ground of the above description is generally trenched, and all hard stones that will do for road-making purposes are taken out; but such soft ones as are of no use and likely to be split up into fragments by the winter frost are left in. I think about 9*d.* per rod for trenching the ground, and about the same per ton for such useful stones as are taken out, is often paid, and the increased value of the land well repays this outlay. This being done early in the autumn, the young trees are planted as soon as they can be conveniently got in, taking care to do this, if possible, when the ground is dry.

Many growers raise their own plants; in fact, it is common for most Kentish farmers who grow fruit for market to have a nursery where they rear large quantities of Currants, Gooseberries, and the like, as well as graft and propagate Apple and other trees by the hundred. In such places Filbert trees are plentiful enough, and they are raised from suckers, which are produced in great numbers when required, as will be shown hereafter. Small plants having about 10 inches or a foot of clear collar, and then spread out into branches in all directions are selected. Assuming that the plantation is intended ultimately for Filberts only, they are planted about 12 feet apart each way if the ground is good; but if not so likely to suit them, 10 feet might be substituted. Generally Currant trees, or it may be Hops, or both, are planted between to occupy the ground while the Filbert is growing, and sometimes standard Apple, Pear, or Plum trees are planted at wider intervals to remain as permanent trees; but this plan has been in a great measure abandoned, and everything made subordinate to the Filbert when it is intended to have a first-rate plantation.

If the ground at the time of planting has been recently trenched, and much of the subsoil thrown to the top, it would be better to have a little mellow fine earth that has been long exposed to the atmosphere, and to give each tree a spadeful or two to start its roots into. This is frequently done with Hops, and also other trees where necessity obliges the planting so quickly after the trenching. Treading around the plant when dry weather sets in about April will be necessary. A low-growing crop is sometimes taken off the ground. This, however, will suggest itself to the cultivator, but I have seen plenty of instances where the farmer paid £6 and upwards per acre rent, and where he found it to his advantage to allow the newly-planted trees—Filberts, Gooseberries, Currants, or Hops, the whole of the ground, occasionally stirring it during the summer, and, of course keeping all the weeds down. If the intending cultivator thinks he cannot afford Filberts the whole space, let whatever vegetable crop he takes off the ground be kept clear of the Filbert trees, and remove it as early in the autumn as possible. I may also observe, that if Currants or Gooseberries be planted between the Filbert trees, they may be from 5 feet to 6 feet apart, taking care that those nearest the Filberts are cut away in time to prevent their injuring the more permanent occupiers of the soil.

**PRUNING THE YOUNG TREES.**—It has been remarked that no fruit tree is cut with more severity than this, and long experience has proved that without doing so a good crop of fruit need not be looked for. Some judgment is also wanted to start the tree into the proper shape at first, and a peep at those of mature age will show how this is to be effected. The universal custom in Kent is to train the tree into a sort of basin shape, not unlike

the ribs of an umbrella when inverted; and in the adult tree, the edges or tips of all the branches radiating from the centre being of a uniform height of about 5 feet, a great similarity exists amongst the trees which compose a plantation; and if the ground is level the eye of the spectator will skim over the whole. Their height and uniformity are very striking after they are newly pruned, but, of course, when the summer's growth is going on they are widely different, and show as rampant a growth as that of any plant I am acquainted with, some of the shoots being little short of 8 feet long, straight and tapering like an Osier wand. Those of the young plants are rarely so long, and it is these that we have more especially to direct our attention to.

In the young plants all central and all gross shoots must be removed, and such small ones as are of a spreading tendency are left, being shortened at the tops. It will be as well to describe the Kentish mode by which another gross growth is in a great measure prevented from taking place when the former one was removed, which is very simple and might in some cases be copied elsewhere with advantage. It is simply to cut out the coarse rampant shoot with a coarse-toothed little hand-saw, making a sort of haggling cut instead of the clean one caused by the knife. This rough haggled cut, with its occasional splintering of the top, is less likely to produce another similar shoot from its base next year than if it were an evenly cut one: hence the practice of using the saw, not in pruning the young trees only, but also those of more mature growth.

The pruning of the first year leaving only five or six side shoots, the number will not be much increased the second year, only a fork may be here and there introduced when the space seems wide. The rank, coarse wood being cut away as before, and the small, short-jointed pieces only left, and these shortened to the suitable length. Keep the centre perfectly open so that the sun may shine into it and on the north side as well, or, perhaps, better than on the south side of the tree. In the third year some tiny shoots will indicate, probably, the presence of fruit-bloom, leave a few of these shortened to about 3 inches or less, and keep the remainder of the tree pruned to the shape recommended above, which is that of a basin or bowl, and do not let the permanent branches or ribs be too thick.

**PRUNING TREES OF MATURE GROWTH.**—If the ground is suitable the summer shoots will be long and straight like many of the basket Willows, and sometimes they are used for the same purposes. From 3 feet to 6 feet is the average length. The first thing done when pruning commences in the autumn is to look over all the trees, and pull out by a jerk of the hand all the gross strong-growing shoots in the centre. Generally they will come out pretty well, and bundles of these are very useful for tying-up plants, or such out-door flowers as only require a slender stake. The rest of the pruning is done with the knife and saw, the latter being used to cut off such strong gross shoots as it may be necessary to shorten to a couple of inches or so, and the more slender are cut back with the knife. It is seldom that more than 4 inches are left of any young shoot, and very often much less.

The short-jointed small wood generally produces the most nuts, and those most exposed are the best; but nuts are also grown near the centre of the plant, on spurs of the long main branches, and some on the subsidiary ones. Occasionally a large limb may be cut out, but this is not often the case unless disease or appearance of too much crowding points it out as necessary, or when the tree has exceeded its bounds. In the latter case it must of necessity be cut back, and the occasional bringing forward of young branches from the centre will enable this to be done on the same principle that other fruit trees are pruned; but the Filbert will bear a greater amount of spurring-back than any tree I am acquainted with. The quantity of young wood left on an adult tree each year at pruning is exceedingly small, and in most other fruits would produce disease; but Filbert plantations last a great number of years, and their bearing properties are rather enhanced than diminished by age. Each succeeding year's pruning leaves them in the same uniform shape as before which is an open cup or basin-shaped centre, with the outer edges not more than 5 feet high. Of course, exact training to this cannot well be accomplished without tying, which is rarely adopted; but the cutting at the edges to the height above indicated leaves the tops parallel with the ground surface; and, though there are some branches near the outer edge between the ground and the edge of the basin spoken of, they are of less consequence than the framework of the tree forming the shape here described.

**VARIETIES.**—There are two or three varieties of Filbert bearing local names; one with a thin shell and the covering of the kernel of a deep pink colour, is esteemed the best at table, but it is not the best bearer. Cob nuts are more popular than Filberts, being larger and producing more weight per acre, and they certainly keep longer; but so much depends on public taste, that those who grow them for market of course cultivate those most likely to pay best, taking into consideration the peculiarities of their position and other features. A large variety of Cob, called *Spanish Cob*, was much in fashion a few years ago, but it is less so now in consequence of its lacking the flavour of smaller nuts; but the amateur who wishes to grow a few for his own use might have a few of both Filberts and Cobs. The latter, after being harvested and put away, last longest; but while both are good, the Filbert will be the greatest favourite.

**MANURE FOR FILBERT PLANTATION.**—Very rich manure, as farmyard dung, is seldom used, as tending to too much grossness. In this district where such large quantities are grown, woollen rags, or a sort of mill waste called *SHODDY*, which is a combination of cotton and woollen waste obtained in the carding of the one and dressing of the other, are largely employed. These substances, which to ordinary observers might almost appear "inert," are great favourites with the Kentish farmers. The rags, it is proper to observe, are chopped into pieces not larger than half the palm of the hand, the other separated by tearing it open. Other manures are also occasionally employed.

**PREVENTION OF SUCKERS RISING AT THE COLLAR.**—This is very effectually done by scooping away the earth all around the collar in October, forming a sort of basin about a yard or more in diameter, and exposing the main roots. The action of the frost on these roots is said to prevent the tree exhausting itself with suckers, and certainly none are produced when this treatment is adopted. The ground is again made level at the time of digging in March, the trimmings being all previously conveyed away; and if all go on well a good crop of nuts is looked for. As with all other crops, this is, however, not a certainty, as many extensive plantations did not last year produce on an average more than a bunch of nuts per tree—not sufficient to be worth looking for, while in favourable seasons from 10 to 20 cwt. of fruit per acre has not been uncommon. So much depends on the season, that with all the advantages of situation, skilful management cannot always command success in this instance any more than in many others; but well-directed skill, aided by other favourable conditions, certainly renders success more likely.—J. ROBSON.

### THE CUCKOO.

I HAVE many times had an inkling to scribble a few lines upon subjects you have entered upon, but I have cooled down without doing so; but in *THE JOURNAL OF HORTICULTURE* of the 30th ult., an article on the "Cuckoo and Fern Owl," by Mr. B. P. Brent, has induced me to say a little on behalf of the Cuckoo.

In the spring of last year a Cuckoo paid us a visit, much to the alarm of myself and fowls; believing it to be a Hawk, and I having chickens, it was not hard to believe he was desirous of thinning my small stock. Of course, I was as anxious to prevent it, and a trial was made several times to bring him down, but without effect, he (or they I may presume) passed to and fro frequently during the summer. Autumn came, and their visits became more frequent, when at last success crowned my efforts, when, to my regret, instead of a Hawk it was a Cuckoo; but its mate continued for some time afterwards to visit our little valley, and many times have I watched it fly from a tree down amongst the Cabbages, and return to the tree with (I have no doubt) large caterpillars hanging from its beak.

In course of time it absented itself, and the spring of 1862 arriving, I scarcely need say it would have been welcomed, and as far as I could protect it would have been safe. At last we had a visit or several, and, which did not transpire last year, or it would have saved a life, we heard the well-known call on one or two occasions; but, to my sincere regret, it has not been seen half a dozen times during the summer, and not once during the last three months.—W. BUDD, *Norwich*.

**DEATH OF MR. JOHN CURTIS.**—This occurred on the 6th inst. at his residence, Belitha Villas, Barnsbury Park. Mr. Curtis was one of the oldest of our national naturalists, having attained

to three score and ten years. He was a Fellow of the Linnæan, one of the six honorary members of the French Entomological Society, and of several other Societies for the promotion of natural history. Insects were his especial study, and he had filled the office of President of the Entomological Society. Under the anonymous signature of "Ruricola" he contributed a series of illustrated essays to the *Gardeners' Chronicle* and in the "Journal" of the Royal Agricultural Society, on insects injurious to our cultivated plants, and which he published in a collected form in 1860 under the title of "Farm Insects." He also published in 1829, "A Guide to an Arrangement of British Insects;" in 1830, "An Account of the Fire Fly of the West Indies;" in 1858, "The Genera of British Coleoptera," and "The Genera of British Lepidoptera." But his chief work is "British Entomology: being Illustrations and Descriptions of the Genera of Insects Found in Great Britain and Ireland, Containing Coloured Figures from Nature of the Most Rare and Beautiful Species, and in Many Instances of the Plants upon which they are Found." This work appeared by degrees between 1824 and 1835, being completed in sixteen volumes.

Mr. Curtis may be numbered among the martyrs of science; for his microscopical researches, rendered necessary not only by his own entomological studies but in his employment as a pour-trayer of insects, caused the loss of his eyesight about four years since, and about that period he had deservedly conferred upon him a pension from the civil list fund.

We sincerely hope that his entomological collection will not be dispersed, but will be purchased by Government for one of our national museums.

### MUSCAT GRAPES.

I HAVE little fear of being contradicted when I say the Muscat stands pre-eminent among Grapes. Such is the universally acknowledged fact. I may, however, be called in question regarding my opinion of the distinctness and comparative merits of some of the varieties in cultivation. But, in the hope of being of service to those who may be about to plant Muscats, I will venture to offer what has been my experience of several varieties, and call attention to that which I consider the most desirable of those that shall be referred to, so far as my experience has enabled me to judge.

What is known, and more extensively grown than any other, as the old Muscat of Alexandria, has been long and widely prized as a most excellent Grape. It has, as will be readily acknowledged, its drawbacks or failings—such, for instance, as being an uncertain setter, except under the influence of a very high temperature and dry atmosphere. It is also probably the most difficult Grape in cultivation to ripen thoroughly, and when not ripened thoroughly, it does not hang long without shrivelling. As to the difficulty of ripening it, there has been ample proof afforded this year, for any one who has inspected the great London shows in July would fail to find a thoroughly ripe and well-coloured example, while from the reports of the September Show at the Crystal Palace we gather that few, if any, of the Muscats were ripe.

There is the Bowood Muscat, a distinct and noble Grape, which sets as well as a Hamburgh in a moderate temperature. It grows to a large and splendid berry, ripens early and perfectly, attaining an exquisite amber colour and high flavour, and is a very desirable Grape.

The only other variety that I will name is the Tynningham Muscat. I know this has been pronounced identical with the Bowood variety, an opinion with which I cannot agree, and my conviction in the matter has been confirmed, not by simply seeing them on the exhibition table, or the one variety at one place and the other at another place, but from having narrowly watched them grown and ripened, and kept side by side in the same house for successive years. The Tynningham variety fruits very freely, either on the closest system of pruning or where an eye or two are left. The Bowood has proved with me a precarious fruiter, except when an eye or two are left, then it shows freely and strongly. In the ripening of their wood, the Tynningham ripens freely and as regularly as any Vine. The Bowood ripens its wood in patches and streaks, and, under the same amount of fire heat, it often remains in patches and streaks of green and ripe wood till pruning time. But the most important distinctive feature is, that although ripening their fruit at the same time and equally well, the Tynningham variety hangs much longer in a sound condition than the Bowood. The

Bowood shrivels, while the other hangs fresh and sound. The Tynningham Muscat I consider the best of the three named, it having all the good points of the other two without their faults, and I would strongly recommend it to intending planters of Muscals on account of its freeness in setting, its high flavour, its large berry, high colour, and long-keeping properties.—(D. THOMSON, in *Scottish Gardener*.)

*de Bresson*, white, with a brilliant rosy carmine eye; *Le Vésuve*, beautifully striped; *Eclair*, rich rosy scarlet, with a dark crimson centre, very effective.—(*Ibid.*, 119.)

ROSE LORD CLYDE.—A fine variety, raised by Messrs. Paul and Son, of Cheshunt. The flower is very full in the early part of the season. "The colour a rich crimson, abundantly suffused with a plum-coloured hue, not unlike some of the deeper-coloured Bourbons."—(*Ibid.*, 120.)

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

LILIAM AURATUM (Golden-striped Lily).—*Nat. ord.*, Liliaceæ. *Lin.*, Hexandria Monogynia.—Native of midland provinces of Japan. Flowers ivory white, with a broad golden yellow stripe down the centre of each division of the perianth, with numerous purple spots. Very sweet-scented.—(*Botanical Magazine*, t. 5338.)

ACANTHONEMA STRIGOSUM (Strigose Acanthonema).—*Nat. ord.*, Cytrandaceæ. *Lin.*, Didymia Angiosperma.—Native of tropical Western Africa, found at an elevation of 4000 feet to 5000 feet. It is a small herb, growing epiphytally on trees. Flowers pretty, tubular, mottled with blood crimson. Bloomed at Kew from June till August. More of interest in a botanical point of view than as an ornamental plant.—(*Ibid.*, t. 5339.)

BOTRYCHIUM DAUCIFOLIUM (Carrot-leaved Moonwort).—*Nat. ord.*, Filices. *Lin.*, Cryptogamia Stachyopterides. Native of Nepal, Sikkim, Ceylon, and Java. A little-known Fern, respecting the name of which some confusion has existed, and which is the *B. subcarnosum* of Mr. Moore.—(*Ibid.*, t. 5340.)

MONOCHÆTUM TENELLUM (Slender-branched Monochætum).—*Nat. ord.*, Melastomaceæ. *Lin.*, Octandria Monogynia. Native of Guatemala. A lovely plant with an abundance of rich purple flowers and Myrtle-shaped leaves. Messrs. E. G. Henderson and Co.—(*Ibid.*, t. 5341.)

WAITZIA TENELLA (Slender-stemmed Waitzia).—*Nat. ord.*, Compositæ. *Lin.*, Syngenesia superflua.—Native of the Swan River. Flowers lively yellow, of the kind known as everlasting. Likely to prove very useful for flower-gardening. Introduced by Mr. Thompson, of Ipswich.—(*Ibid.*, t. 5342.)

RHODANTHE MACULATA (Blotched Rhodanthe).—*Nat. ord.*, Compositæ. *Lin.*, Syngenesia superflua.—Native of Western Australia. In general habit resembling *R. Manglesii*, but differing from that well-known species in being of larger growth and having flowers twice as large, whilst the inner series of ray-like involueral scales are rosy pink stained at the base, near the disk, with a deep sanguineous blotch. "The flower-heads are large, the dry involueral scales having an expansion of about an inch and a half, and surrounding a yellow disk. The scales are toothed on the tip; the outer ones silvery and transparent; the inner ones, in several series, striated, rose pink, marked at the base with a crimson blotch, which is stained in the centre with a darker sanguineous hue. The yellow disk is consequently surrounded by a two-coloured deep crimson ring, exterior to which is the broad rose-coloured ray." It is a charming acquisition.—(*Florist and Pomologist for October*.)

RHODANTHE ATROANGUINEA (Dark red Rhodanthe).—*Nat. ord.*, Compositæ. *Lin.*, Syngenesia superflua.—Of dwarfer habit than the preceding. "The flower-heads are numerous, with a dark bronzy red disk, and a self-coloured striated ray of a deep rose colour, expanding to about an inch across; the outer scales being, as in the allied plants, of a transparent silvery hue. While in bloom, the dark-coloured disk becomes speckled with yellow as the florets successively protrude their anthers. Altogether its aspect is very pleasing."—(*Ibid.*)

MITCHELSON'S PLUM.—Raised many years ago by Mr. Mitchelson, of Kingston-on-Thames. It is said to have sprung from the seed of a Damson. Fruit above the medium size, oval, black; flesh yellow, juicy, and sweet. An excellent preserving Plum. Ripe in the beginning of September. The tree is remarkably hardy, and, being an enormous bearer, is much cultivated for market purposes.—(*Ibid.*)

HYBRID ERYTHRINA.—A new hybrid raised by M. Belanger, of Tours, combining brilliant scarlet flowers, with a more dwarf and free-flowering habit.—(*Floral Magazine*, Plate 117.)

PINKS, ATTRACTION AND DEVICE.—*Attraction* is remarkable for the size and smoothness of its guard petals; colour a bright violet purple. *Device* is large, very full; the colour a bright rosy purple, and the petals very smooth.—(*Ibid.*, 118.)

PHLOXES.—Three new French varieties:—*Madame la Comtesse*

GETTING RID OF THE LEAVES.

THE leaves make such a succession of litter upon our lawn, and accumulate so fast in the heap of our rubbish-yard, that I think of having them thrashed off the trees, and the whole burnt. Is there any better mode of getting rid of them?—A. L. F.

[Never did we expect to receive such an inquiry from one of our readers, and we can only reply that whilst leaves are green they are too useful to their parent plants; whilst dying the tints are too beautiful; whilst decaying are too productive of heat; and when thoroughly decayed are too fertilising, for us to adopt or recommend any mode of "getting rid" of them. Even poetry raises her voice from America for their protection:—

"They were washed by the autumn tempest,  
They were trod by hurrying feet,  
And the maids came out with their besoms,  
And swept them into the street,  
To be crushed and lost for ever,  
'Neath the wheels, in the black mire lost—  
The summer's precious darlings,  
She nurtured at such cost.

"Again has come the spring time,  
With the Crocus's golden bloom,  
With the smell of the fresh-turned earth-mould,  
And the Violet's perfume.  
Oh! gardener, tell me the secret  
Of thy flowers so rare and sweet!  
'I have only enriched my garden  
With the black mire from the street.'"]

THE NURSERY TREATMENT OF YOUNG TREES AS TO ROOT-PRUNING.

THE treatment which the roots of trees receive in the nursery, is, in our opinion, of material importance, and may differ much, with equal propriety, according to the object of the planter, who may either desire to induce rapid and luxuriant growth, or to obtain fruit-bearing properties. It is customary, in most nurseries, to cut the roots of seedling Oaks with a spade in the second year of their growth, to transplant frequently afterwards, and, on every occasion of removal, to trim the strongest roots. The plants so treated are generally considered eligible for removal; they are sure to *live*; but instead of sending up good leaders, they mostly produce weak shoots, and grow stunted and forked, having a stronger resemblance to the miniature old trees of the Chinese gardeners than the characteristic vigour of the British Oak. Rapid growth is a condition not to be disregarded in growing trees for timber, provided always that such growth is fully exposed to the influence of solar light, which alone can give solidity to the newly-formed tissues. It appears to us, that, when we contrast the means given by Nature to the Oak for ample development and sturdy growth, we are not taking the proper course to attain our ends, as it is most probable that the finest Oaks now in existence (such, for instance, as the *Pan-shanger*), are the offspring of acorns which accidentally sprang up where they still stand. Such was, doubtless, the origin of the largest Oaks at Windsor; and those magnificent relics of the once royal domain of Woodstock, which are still remaining, the almost imperishable record of past ages. Surely, when we view these noble products of unassisted nature, it should lead us to reflect upon the fitness of our customary procedure, and ask ourselves if it may not be a blind empiricism, rather than rational practice. We require vigour; we take the most effectual means to check it.

The observation we are about to make does not precisely fall within the scope of this article, but as it is collateral with it, we think it not irrelevant to say, that we believe that if our forest trees were sown where they are to remain, or planted permanently when very young, it would tend much to induce those gigantic proportions which we alone see or read of as developed in natural forests.

The axiom that whatever is conducive to luxuriant growth is inimical to productiveness, has been touched upon. We will only

now say that it has also a *vice versa* bearing. It follows, therefore, that although it is not wise to curtail the young roots of our forest trees, it is most sound, sensible, and efficient practice, to control those of our *fruit trees*. We would scrupulously preserve the tap root of an Oak or a Pine, but would utterly annihilate such an organ in the Apple, Pear, Plum, or any other fruit-bearing tree. Moderate growth, abundance of surface roots, and well-ripened wood, are the desiderata to be aimed at with fruit trees; and root-pruning should be commenced in the nursery, and carried on with discretion during the whole course of their existence.

Autumn, early autumn, is the best period for pruning the roots; as soon as the "sear and yellow leaf" appears, it may commence. It is important that the jagged and ragged cuts made by the spade should be smoothed by the knife, and we would carefully remove the soil from the roots, selecting only the strongest for operation. Root-pruning is certainly one of the first principles in the successful culture of fruit trees. Its importance is obvious, when we consider the reciprocal action which exists between roots and branches, and the control which it gives over the energies of the subject so treated. Although it has not been general amongst English gardeners till latterly, it has long been so among the Dutch. It is not difficult to conceive what would have been the fate of such a thing as that of pruning the roots of plants half a century ago. With what zealous indignation would the gardening worthies of that day have scouted the man who had the temerity to make such a suggestion, or to hint at such a horticultural heresy? "Necessity" is said to be "the mother of invention," and our onward progress in this, as in all other arts which minister to the comfort and luxury of mankind, will be in proportion to the increased demand which will arise as we progress in education and refinement. Let us discard prejudice, and believe nothing impossible.

PRUNING THE BRANCHES OF FOREST TREES FOR TIMBER AND PICTURESQUE EFFECT.

Among the various modes of pruning which have had their advocates in the gardening periodicals, I am not aware that any distinction has ever been made between those whose object is simply to produce useful timber, and those whose aim is to produce objects of picturesque beauty. The treatment of such trees is but too generally confided to ignorant workmen, who believe that the nearer approximation trees make to scaffold poles, the greater is their beauty and perfection. But the discriminating manager will make this difference between the marginal and interior trees, that, while he prunes and fore-shortens the latter to throw all their energies into one trunk, he will only seek to obtain in the former a certain height of clear stem,

Fig. 1.

Fig. 2.

leaving the head to diverge and ramify according to its natural habit.

The pruning of forest trees, as commonly practised, is what we consider more properly a mutilation, generally performed in a rough and slovenly manner, by chopping off with a bill branches of considerable size. We protest against the use of this instrument, and recommend, and believe, that all the pruning which timber trees require may be done with a knife, or the finger while young. We would adopt what we have called preventive pruning, allowing no unnecessary growths to require lopping by becoming too large. We think that, in the case of a young tree whose stem we wish to increase, it is desirable to

spur-in the side branches for a year or two, as the nursery-men do with the Pear and the Apple stocks, gradually and annually removing a tier or two of the lower spurs till a sufficient length of clear stem is obtained. It is contended by some, that every branch of a tree is of service to it, and should not be removed. When it becomes *really a branch*, such removal is always attended with mischief. The great point for the pruner to bear in mind is, that the secretions of trees do not depend upon the quantity of shoots and foliage, but more upon the latter having full exposure to the action of light. The quality of timber grown in the dense gloom of the interior of a wood, is, for this reason, inferior to that afforded by the marginal trees.

We would deprecate (unless in very exposed situations) the system of introducing what are called "nurses," but which are rather destroyers as generally employed. We say, Plant forest trees with the roots Nature has given them; plant while very young, or sow the seeds, and commence pruning almost immediately; spur-in the young side shoots, remove rival leaders, and annually remove some of the lower spurs from the stem before they are large enough to cause a wound. In vigorous trees, choose the spring for the operation, when the wound is quickly healed.

In illustration of the good effects resulting from the practice we recommend, we refer to the accompanying figure of a portion of the stem of a young Elm—the stem from which it was taken being about 8 feet in height, and its diameter, midway up it, 4 inches. Fig. 1 represents about a foot of its trunk as taken from the middle; it is cut longitudinally down the middle, and the grain is clear, straight, and free from blemish. Fig. 2 is another section of a similar tree, showing a knot which has resulted from allowing the side shoot to become too large before removal. The benefit of early or preventive pruning, and the evil of late

or remedial pruning, is here plainly shown. Fig. 3 represents the stem of a young tree in process of pruning—the lower branches removed, the upper spurred-in.

In pruning cone-bearing trees (Conifers), it is good practice to fore-shorten the branches before removal. It is impossible, however, to lay down rules for every contingency, and much must be left after all to the judgment of the operator. But of this we may rest assured, that if pruners are mere automatons, and not observers, much that is fundamentally correct in theory may be misapplied in practice.—H. BAILEY, *late of Nuneham, Oxon.*—(*Gardener's Magazine of Botany.*)

Fig. 3.

ORNAMENTAL PLANTS.

ALMEIDEA RUBRA (Red-flowered Almeida).—*Nat. ord.*, Rutaceæ. *Linn.*, Pentandria Monogynia.—A handsome stove shrub, of branching habit, growing 3 feet to 5 feet high, and furnished with broadly lanceolate alternate petiolate leaves, which are acute at the base, acuminate at the apex, and entire on the margin. The flowers come in thyrsoid panicles, and consist of

a short five-toothed calyx and five obovate-spatulate obtuse spreading petals, all of a deep bright rose colour. It is a slow-growing plant; and at Kew has been grown in the Palm-stove, with the benefit of bottom heat. From Brazil. Introduced before 1850, through M. Makoy, of Liege. Flowers in the autumn.

2. Potentilla ochreata.

1. Almeida rubra.

POTENTILLA OCHREATA (Ochreate Potentil).—*Nat. ord.*, Rosaceæ. *Linn.*, Icosandria Trigynia.—A curious and pretty hardy shrub, forming a dwarf, hairy bush, with weak spreading branches. The leaves are short-stalked, pinnate, or digitate, the oblong revolute leaflets varying in number from five to nine; they have a grey coat above, and are whitish and hairy beneath;

some are usually two-lobed. The flowers are terminal, with five-linear-lanceolate very hairy bracts, having a red scabrous keel, triangular sepals, of the same length, yellow inside, and nearly circular petals, of firm texture and a bright yellow colour. From the Himalayas. Introduced, about 1849, by Major Madden. Flowers in September.—(*Gardener's Magazine of Botany.*)

### THE FASTOLF RASPBERRY.

WHAT Mr. Robson says of the Fastolf Raspberry is very true; but the soil here is just the converse to what he describes, and is congenial to the Raspberry without a doubt, which our annual enormous crops of Red and Yellow Antwerps testify to, and so would the birds if they could, for we allow them out of our abundance to revel amongst the fruit to their heart's content to reconcile them to the careful netting of the Strawberries, Gooseberries, and Currants.

Some seven or eight years ago I wished to do better than well, and hankered for Fastolfs on account of their reputed size and flavour. I bought some of the Yellow Bee-hive variety at the same time, the latter fellows soon proved inferior in flavour to the Yellow Antwerps, so their services were dispensed with. But the Fastolfs put me continually on my metal and to the blush. I have tried them under aldermanic diet, fat soil, deep soil, sharp soil, shallow soil, and have them growing palpably before me now with seven-foot canes, and with canes dwarfed and bearing incipient fruit upon them, but whilst the wood and foliage will come of a sickly hue; whilst growing side by side the Antwerp canes are ruddy as a Cherry. The Fastolfs bear an abundance of fruit annually, but the berries are lean and not full-flavoured, and the stools have an unaccountable tendency to die-off like the branches of a Moorpark Apricot. How I should have attempted to manage them next I am at a loss to say, nor do I much care, for if Mr. Robson says they are wearing out, I freely second the motion, and with very good reason too. Their doom is sealed for me, and I shall remain content with my Antwerps, until I have proved a better sort.

This has been the most fruitful season with me I ever remember. True, I had a long and hard stand-up fight with the vermin; but the result—such a crop of Strawberries, Gooseberries, Currants, Plums, Apples, Pears, Quinces, and Grapes. Yes, out-of-door Grapes in this redoubtable season, 1862! and I verily believe by their quick colouring during the last few days that I shall be enabled to make a small barrel of tolerable wine. But I had a great mind to cut the incipient bunches all off in despair in June or July, or some such time.

With Apricots and Peaches I must report failure again, but the trees are healthy and that is more than a great many people can boast of, so I will even yet look forward to another year, though I know I shall never be able to cope with the blasting effects of the cold spring winds from off the waters of the lake in Blenheim Park; but Hope favours us with a small orchard-house, and I hereby call upon Hope to do so. The flatterer!

Of vegetables I have not to complain of a single failure; and of Potatoes never did I reap so rich an harvest. I have had some twenty sorts on trial one against the other, and have taken copious notes of their proceedings throughout, which I shall take an opportunity to let you know all about, and at the present time conclude by saying, that we have had some capital Roses, and that we are very thankful to the Supreme Giver of all good things.—UPWARDS AND ONWARDS.

### STRATHFIELDSAYE.

IN the north-east portion of the county of Hampshire, and situated about midway between Basingstoke and Reading, lies the noble and fair domain of Strathfieldsaye, the seat of his grace the Duke of Wellington.

Though Strathfieldsaye may not be said to possess the princely grandeur of some of the dual residences of "merrie England," still the historical associations connected with it, its extensive and beautifully-wooded parks, and spacious and well-regulated gardens render it worthy of a description in the pages of THE JOURNAL OF HORTICULTURE.

At the period of the Doomsday survey Strathfieldsaye was held by Hugh de Port, and was then known as Strathfield or Stradfelle, which means the field of the road or way, from its close proximity to the great Roman road from London to Silchester—the Vindonum of the Romans, and Caer Segont of the ancient Britons, which passes near the boundary of the park.

It afterwards passed into the possession of the ancient and noble family of Saye or Say, from which the adjunct Saye is derived, to which family it continued to belong till the marriage of the heiress of the Sayes to Sir Nicholas Dabridgecourt, High Sheriff of the county of Hampshire in the fifteenth year of the reign of Richard II. It remained in the hands of the Dabridgecourts till the early part of the seventeenth century, when it was

bought by Sir William Pitt, to whose successors it belonged till purchased by Parliament of Lord Rivers, and presented by the nation as a tribute of gratitude to the great and illustrious Duke of Wellington.

Entering the park by the Basingstoke lodge, which is situated at the south-west boundary of the domain, we proceed onward through an avenue of Oak, which opens on to a broad and elevated situation in the park immediately facing the southern front of the mansion. Below us flows the river Loddon, here forming a broad and majestic stream, on which are several islands; these being covered with trees, tend very much to enhance the beauty of the scene.

On crossing the river we pass the parish church and rectory-house, both situated within the limits of the park. The former is a plain and somewhat curious style of building in the form of a Greek cross, with hexagonal tower. In it are interred several members of the Pitt family.

But we are now approaching the mansion, which is a large and massive building of a plain though bold and unpretending style of architecture, situated almost in the centre of a finely-wooded park of 1500 acres.

The principal approach to Strathfieldsaye House from the north and eastern boundaries of the park is by a noble avenue of Elms one mile in length. Viewed from the western or principal entrance to the mansion this avenue has a very imposing effect. In fact, we fear our attempt to describe it will fall very short of doing justice to its merits, which can only be fully appreciated by a personal view.

In the more immediate vicinity of the mansion, and extending as far as the boundary of the pleasure grounds, the carriage-drive is bounded on either side by large and gracefully drooping Yews, the branches of which sweeping the closely-shaven grass on each side of the road, form both a pleasing and striking contrast to the more lofty grandeur of the Elms. On the outside of this avenue are two noble rows of *Cedrus deodora* some 15 feet in height. These have been planted with a view of taking at some future period the place of the Elms, when the latter shall have fallen victims to the ravages of time.

The western or principal front of Strathfieldsaye House is in the form of a square, having a centre and two wings attached, the entrance to it being through a spacious portico supported by columns of the Tuscan order. The entrance-hall, which is of noble proportions, and elegant in design, is decorated with many fine paintings, some noble statuary, and other works of art. In short, the whole mansion is replete with objects of interest to the visitor, who will not fail to admire the large and valuable collection of paintings, the extensive library, and many other objects of curiosity and interest it contains.

Immediately facing the western front is a spacious courtyard, with buildings on either side, consisting of stables, laundries, &c., also a large tennis court. On the southern side of the mansion, and attached to it, is a noble span-roof conservatory, 60 feet long by 28 feet wide, and 30 feet high in the centre. The floor is constructed of ornamental slate. Among other interesting objects, it contains two fine plants of *Dacrydium cupressinum* reaching to the roof. The leaders of these noble specimens of the Weeping Yew of New Zealand are unfortunately gone, it having been found necessary to remove them to confine the plants within the limits of the conservatory. This is a subject of regret, as they have been stated by one of the ablest authorities of the day to be two of the finest specimens in Europe. In this house, also, are some good examples of *Rhododendron arboreum* and *Noblecanum*, *Camellias*, *Oranges*, *Acacias*, *Indian Azaleas*, &c.; also some very fine plants of *Pinus longifolia*, *Wincesteriana*, and others. The whole was gay with *Chrysanthemums* and other plants used for winter decoration.

Leaving the conservatory, we pass on to the eastern side of the mansion, in front of which is a broad terrace-walk 380 feet in length, leading to the pleasure grounds. From this spot a commanding view of the park and river may be obtained. The pleasure grounds are extensive, and contain many valuable trees and shrubs.

Immediately facing us is a fine specimen of *Diospyros lucida*, 40 feet in height, its branches drooping gracefully to the ground. Farther on we noticed some fine *Cryptomerias* and *Cedars* of Lebanon; the beautiful striped-barked Maple of North America (*Acer striatum*); some fine Plane trees; the rare *Liquidamber*; a noble specimen of Weymouth Pine, *Pinus strobus*, 100 feet in height; and a beautiful silvery-leaved variety of *Cedrus libani*. In a more distant portion of the grounds may be seen

a very fine plant of Hemlock Spruce, *Abies canadensis*, about 60 feet in the spread of its branches, which feather to the ground, forming as it were a natural bower. The base of this noble tree is 12 feet in circumference. At some distance from this is a noble specimen of British Oak, the bleached and barkless trunk, and branches of which are partially covered with Ivy. It forms a very agreeable contrast to the more sombre hue of the surrounding Pines.

Situated midway between the two last-mentioned trees is a healthy young plant of "the giant of the American forests," *Wellingtonia gigantea*. It is about 12 feet in height, and 2 feet 6 inches at the base. A neat and elegantly constructed label bears the following inscription:—

"*Wellingtonia gigantea*,  
Californian Tree.  
Planted by her Grace  
The Duchess of Wellington,  
April 24th, 1857."

Near the extremity of the grounds stands a very tastefully-built summer-house, erected beneath the branches of some overhanging Yews, it forms during summer a very cool and pleasant retreat. Retracing our steps by a broad gravel walk which sweeps gracefully through the whole extent of the grounds, we pass a large clump of Cedars of Lebanon, some of which are over 100 feet in height. They serve as a good illustration of what those noble trees must be when seen in the primal forests of Mount Lebanon. In these grounds also are many other fine specimens of coniferous trees which we have not space to mention. Many, both here and in the park, were killed during the severe winter of 1860 and 1861. There are, however, still remaining, some very fine specimens of *Cedrus deodara*, *Pinus excelsa*, *Taxodium sempervirens*, and others.

Leaving the pleasure grounds and crossing the avenue before mentioned, we pass through what is known as "the American flower garden," and almost immediately find ourselves within the precincts of the kitchen gardens. These gardens are about nine acres in extent, two inside the walls, and seven out. On entering through an archway at the eastern side we at once gain a view of the principal ranges of houses, consisting of two divisions, one having a southern, the other a south-eastern aspect, the two forming a frontage of 400 feet. The first is a Peach-house 60 feet long by 12 feet wide, and 14 feet high. It contains some well-trained trees of Royal George, Noblesse, Grosse Mignonne, and Bellegarde or Brentford Mignonne. The trees are trained to a wire trellis about 15 inches from the glass. They had been pruned, washed, and otherwise put in order for forcing. In front of this house is a lean-to pit 60 feet long by 16 feet wide, used for cultivating plants for greenhouse and conservatory decoration.

The next house is a stove 40 feet long by 16 feet wide, and 16 feet high. It contains some well-grown specimens of Gardenias, *Ixoras*, *Begonias*, *Draenas*, &c.; also, some very good plants of *Cattleya Mossie* and *granulosa*, *Erides Brookii*, *Vanda Roxburghi*, *Dendrobium nobile*, some *Stanhopeas* and others; also a few very good varieties of Ferns.

Leaving this we enter the greenhouse, a neat and elegantly constructed building on the ridge-and-furrow principle. It is 46 feet long, 27 feet wide, and 14 feet high. Ventilation is secured by means of cranks both at the top and bottom of the house, the ventilators being easily opened or shut at pleasure.

The front stage or stand for plants is formed of slate supported by strong iron rods, and being kept polished with oil has a very clean and neat appearance. The principal portion of the plants are cultivated in pots: some being planted out in beds in the centre of the house. These beds are neatly edged with stone similar to that of which the floor is constructed. The plants consist principally of *Heaths*, *Epacris*, *Eriostemons*, *Pimeleas*, *Boronias*, &c., amongst which are introduced variegated *Yuccas* and other plants remarkable for the beauty of their foliage. The back portion of the house is occupied with *Oranges* and *Camellias*.

The next two houses, respectively 40 feet and 60 feet in length, are filled with *Vines*, the latter being the earliest house used for Grape-growing at Strathfieldsaye. In it forcing had already commenced, and though this was in the dark dull days of November, the *Vines* were breaking strongly and bidding fair to produce a good supply of fruit. The sorts were *Black Hamburg* and *White and Dutch Sweetwater*. The front stage was filled with *Dwarf Kidney Beans* in pots; *Strawberries* occupying the back shelves of the house. In front of this

house is a pit 60 feet long by 16 feet wide, used for growing *Peaches* and *Nectarines*. They are trained to a flat trellis on the Dutch system, and the trees are certainly excellent examples of good cultivation, generally producing very fine crops of fruit.

We are now about to enter another range of houses, 150 feet in length, by 12 feet wide, and 10 feet high, having a south-eastern aspect.

It is divided into three compartments, the first of which is a Fig-house containing the following sorts:—*Brown Ischia*, *Blue Turkey*, and *Nerii*. They are trained to a trellis near the roof of the house, and also to the back wall. They annually produce very fine crops of fruit. The other two divisions of this range are *vineries*. The first containing *Canon Hall*, *Tottenham Park*, and *Alexandrian Muscats*; *Charlesworth Tokay* and *Golden Hamburg*. In the latter were *Black Barbrossa*, *Black Prince*, *West's St. Peter's*, and *Trebbiano*, both houses containing a very fine crop of fruit, large bunches, and well coloured; the *Muscats* being remarkably large and fine. The front wall is built on arches. The borders are formed on the most improved principles, and the *Vines* are planted inside the house. On the back wall zinc troughs are fixed for standing *Strawberries* in pots.

Parallel with the southern range of houses is a broad gravel walk 10 feet in width, in front of which are some large circular beds, which, during summer, are gay with flowering plants; these being bounded by a border planted in the ribbon style. In the centre, immediately facing the greenhouse, is a fountain, and from this point another walk, 8 feet wide and 420 feet long, runs through the entire length of the walled kitchen garden. On each side of this walk is a border planted in the ribbon style, these being separated from the quarters or divisions of the garden by espalier *Apple trees* trained to neat supports made of iron.

A wall running from east to west divides the garden into two portions; the southern side being occupied with *Peach trees*. Though every means has been tried that practical skill and judgment could suggest, the result of late years has been for the most part unsatisfactory, the trees gradually dying away, or, at the best, producing little returns for the labour and care bestowed upon them. The cause of this, doubtless, proceeds from the cold, damp situation in which the gardens are placed, suffering as they generally do, severely from the late spring frosts.

The southern side of the boundary wall, 350 feet in length, is planted with *Apricots*, and they are certainly all that the most zealous cultivator could wish, both in point of training, and vigorous and healthy appearance.

On the opposite side of the walk fronting the border in which the *Apricots* are planted, stands a row of beautifully-trained pyramidal *Pear trees*, with pendulous branches. They are 15 feet in height, and viewed from the top of the walk at the south-eastern entrance to the gardens, they have a truly noble appearance, forming with the *Apricot trees* before mentioned, one of the most striking features in the gardens at Strathfieldsaye.

On the outside of the gardens is a paddock, in the eastern corner of which the visitor will notice a small clump of trees, the centre one being a young plant of *British Oak* surrounded by *Cypress*. Beneath them lie the remains of the renowned war horse, "Copenhagen," the charger which carried the late Duke of Wellington through his last great fight at Waterloo.

To avoid repetition, it will be as well at once to state that the whole of the wall fruit trees we saw at Strathfieldsaye (*Peaches* excepted), were excellent examples of skilful cultivation and management. The garden walls are 13 feet in height, surmounted with a good coping of slate.

At some distance in the rear of the hothouses, and divided from the other portions of the garden by a neat *Laurel hedge*, are four ranges of pits, each 70 feet in length. Three of these are occupied with *Pines*. The fruiting-pit, a half-span, is in two divisions, it is 17 feet wide, and 8 feet high at the back. The whole of the plants were in excellent and very robust health. They are grown in pots plunged in a bed of leaves. The sorts consist of *Ripley*, *Moscow*, and *Strathfieldsaye Queen*, *Black Jamaica*, *Black Prince*, *Prickly* and *Smooth-leaved Cayenne*; also, some very fine plants of *Providence*, *Black Antigua*, and others.

In one of the divisions of this house was a good supply of *Cucumbers*, grown in pots, and trained to a wire trellis over the back wall. At the back of these pits is a long range of building, consisting of sheds, store-houses, &c.; also, an excellent fruit-room. Near these is the compost-yard, in the front of which

are four ranges of low pits, each 50 feet in length, heated with hot water. They are used for the purpose of forcing early vegetables, salads, &c.

On the right is the orchard, two acres in extent, divided into four quarters; the larger fruit trees are planted in rows 14 feet apart, the centre of each space being occupied with Gooseberries and Currants. Here, also, are cultivated many of the common sorts of vegetables. Raspberries are trained to two arches formed of strong wire. They are each 190 feet long, 7 feet wide, by 5 feet high. The trees produce good crops of fruit, and trained in this manner they have a very neat appearance.

Strawberries are grown very largely here, both in the open ground, and also in pots for forcing; the sorts being—Oscar, Prince of Wales, British Queen, Sir Harry, Keens' Seedling, Trollope's Victoria, Empress Eugénie, and the Frogmore Late Pine.

The head gardener's residence is situated at the back of the principal range of forcing-houses, and communicating with them by a door leading into the greenhouse. It commands a view of the gardens both back and front. In its erection personal comfort as well as architectural design, have been taken into consideration. The principal portion of the houses, pits, &c., are heated by Ormson's patent tubular boilers, which give very good satisfaction.

The gardens were some years since efficiently drained on the system recommended by Mr. Josiah Parkes, the eminent engineer; the soil being a very tenacious loam, resting on a heavy subsoil of clay.

Proceeding onward by a carriage drive in front of the gardener's residence, we turn to the right and enter an elegantly-designed panel garden, called the "American flower garden." The side and central beds and borders are filled with choice varieties of Rhododendrons, Kalmias, Azaleas, &c. At each end is a roseroy, facing which are beds filled with flowering plants. In the centre of the garden is a fountain, around which are beds and borders for flowers. In this garden are some very fine specimens of *Araucaria imbricata*, and two large plants of *Paulownia imperialis*, presented to the late Duke of Wellington by Louis Philippe, King of the French. They have annually produced a fine show of flower-buds, which unfortunately have invariably been destroyed by the spring frosts.

We have now once more reached the outside boundary of the gardens, but we cannot leave them without paying a tribute of respect to Mr. Johnson, the Duke's head gardener, who for upwards of twenty-four years has successfully conducted the horticultural establishment at Strathfieldsaye. His courtesy, combined with his skill as a cultivator, is well known to all who have the pleasure of being acquainted with him.

Leaving the gardens we enter the park, and taking our route by the noble avenue of Elms, we pass on our way towards the London lodge, situated on the borders of Heckfield Heath. Leaving the avenue and turning to the right we again cross the river, and ascend the hill. Having gained its summit we turn to admire the beautiful scene opened to our view. Before us stretches the park, with its venerable Oaks and Thorns scattered in natural and picturesque beauty around. The scene being enlivened by numerous herds of cattle grazing in the distance. Here and there may be seen glimpses of the silvery Loddon, as its sluggish waters glide through this venerable domain, and as the eye wanders over a vast track of woodland country, which has the appearance of a mighty forest, the hills in the neighbourhood of Kingsclere are distinctly visible. The view is here bounded by those situated near Castle Highclere, the beautiful seat of the Earl of Carnarvon. Passing through a beautiful wood, called Switzerland, we reach the lodge, and our journey being now ended, we bid adieu to "the noble and fair domain of Strathfieldsaye."—W. G. P. G.

### HOUSE-TOP GARDENS.

IN an article on this subject, the *Building News* says:—It is rather odd that the photographers should have furnished a lesson which has not been made much of for horticulture. As you traverse the City streets you may observe that no matter what the pitch of the roof, wherever a photographer haugs out his sign, he also has contrived to crown his habitation with a glass house. If these can be erected with impunity for taking portraits, why not also for the cultivation of plants? We know of one instance of a citizen who has a capacious plant-house on

a roof at the rear of his business premises, and keeps it furnished with blooming plants brought from time to time from his country residence, where they are grown for the purpose, and renewed as occasion requires. It is well known among intelligent gardeners that plants of delicate constitution—such as the Rose, for instance, cannot be grown in the open air in London, but they may be grown anywhere under glass, and the possessor of a greenhouse, on a roof or "leads" in Fleet Street or Cheap-side, could have his roseroy, and exhibit his two dozen "Teas" or "Perpetuals" at the annual Rose fêtes of the Horticultural Society without fear of being laughed at, but with some certainty of at least "honourable mention," and the cultivation of a new surprise to rosarians. Mr. Rivers avers that there is nothing impossible in growing on the roof of a house in any city in the kingdom a good supply of dessert fruits, from Peaches to Golden Pippins, by means of a glass roof, abundant ventilation, and woollen net over the ventilators to keep out the blacks. Perhaps in these remarks some may find the element for a spirited enterprise in this way, and if once the idea be taken up in London it will spread rapidly, and we may at last have some sort of public conservatory and flowery lawn high up above the level of the crowded streets for the recreation of the poor, who, many of them, never get a glimpse of greenness except when a dairyman's cart goes by laden with Rye fodder, and a troop of boys following it to steal the stalks for "aqueakers." But it will be quite enough to see a beginning made, and to that end we hope to hear more of the experiment in Edinburgh.

### WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 536.)

THE *Gasteropoda* (so-called from two Greek words signifying "the stomach" and "a foot") are a class of Mollusca distinguished by the position and structure of the locomotive apparatus, which consist of a muscular disk attached to the ventral surface of the body, and which serves the purpose in two ways—firstly, as used for an instrument in crawling; and secondly, but in rarer instances compressed into a muscular membrane for swimming. The first genus of this class to which we have to draw attention is the genus *Chiton*.

The *Chiton* has an oblong shell, and consists of a series of imbricated (from *imbrea*: a "roof-tile") dorsal plates laid upon the cloak or mantle, which is firm and cartilaginous, and variously marked on the margins. The plates are generally eight in number, and arched. The body is elliptical, and the mouth, which is destitute of tentacula, is surrounded by a curled semi-circular membrane, and is capable of forming a short proboscis. The tongue is also short, and furnished with strong reflected spines. The foot is narrow.

This curious Mollusc is chiefly found attached to stones, shells, or rock, and occasionally, although unfrequently, it may be seen creeping along the sand. It is very common, being distributed generally round the coast. The greater numbers of the species are to be found on the shore, although some of them range to great depths; but the stroller on the seashore will be sure to meet with specimens if he takes the trouble of looking under the stones at low water.

The *Chiton* varies considerably in its colour. The commonest specimen of the British *Chiton*, which is called *CHITON CINEBEUS*, will exemplify this, as its colour is subject to the following diversities, as noted in the account of that creature given by Messrs. Forbes and Hanley:—"Olive is perhaps the most prevalent tint; but no stress can be laid upon colour in this species, since some are orange, some nearly white with patches of a chocolate hue, some crimson red with white markings, some flesh-colour with one or two of the valves of a madder-lake, &c. Many of the greenish varieties are wared with faint brown lines or speckled with paler dots, and the dorsal ridge is not unfrequently pallid, or else painted on either side with a paler stripe. The margin is frequently, but not invariably, banded or spotted with whitish opposite the sutures of the valves."

The next genus to be mentioned is the *Patella*, an animal very familiarly known to frequenters of the sea-shore under the name of the *Rock Limpet*.

The shell of the *PATELLA VULGATA* is entire and conical, of a pale dirty yellow colour, sometimes marked with radiations of a dark grey. It is coloured throughout, and the internal surface presents the same marks as the external. The younger *Patella*

is more richly marked than one which has reached maturity. In the former case the shell is sometimes seen of an orange red colour, the inside being iridescent, and radiated with bright crimson streaks. The animal itself is of a dusky bluish colour. The head is furnished with a large, fleshy snout, supporting at the base two long, pointed tentacles. The eyes which are black are placed on a small elevation at the external base of the tentacles. But the most singular organ of the *Patella* is its tongue, which is longer than the entire body, narrow, and furnished with three rows of short, reflected spines, or little teeth, interrupted longitudinally and transversely. Its fixed end only can be used in deglutition, the free end being coiled up in the abdomen. The cloak is large, of a yellowish-white, and covers both the head and foot. It is united with the shell along its upper margin. The foot is fleshy, and furnished with numerous muscular filaments, which, uniting in the upper part of the cloak, form a powerful muscle, by which the body adheres to the shell, and which serves either to bring the shell close to the surface, to which the foot adheres, or to remove it to a distance from it.

The *Patella* is to be met with on all our coasts, on the surface of rocks and stones between tide marks. It is not, however, so abundant as it was some years since, such incredible numbers having been taken for bait, as to have materially lessened the quantity. The *Patella* has the power of moving about from place to place with ease, but the inclination for such an effort appears to diminish with increasing age, so that it becomes chiefly sedentary, sometimes inhabiting a crevice in the rock until its increased size renders egress impossible. Its food consists of seaweed, and infusories supplied by the water. The *Patella* is frequently, and, in some places, abundantly used as an article of food, but its flesh is too leathery to render it a general favourite.

*PATELLA PELLUCIDA* is another of this species common to our coasts, having a thin semi-transparent shell, frequently marked with bright blue streaks. In other particulars it differs little from the *Patella vulgata*.

The next species we shall notice is the *Fissurella*, vulgarly known as the "Key-hole Limpet," from a small orifice at the apex of the shell. The shell of the *Fissurella* is conical and thick, and opaque. The animal has a thick head, furnished with two tentacles, at the external bases of which are situated two eyes. The cloak is united to the shell by a circular muscle at the perforation or the apex of the shell already mentioned. The colour of the body is a creamy white. The *Fissurella* is generally found adhering to shells, sometimes on the shore, but more frequently in deep water. It is to be met with chiefly on the southern and western coasts, being much less common in the north.

There is a genus of the *Fissurella*, called *Emarginula*, which differs from the preceding in not having the apex of the shell perforated; but, in its stead, a long narrow slit on the anterior margin, which is the entrance to the branchiæ and anus. The animal is white, the head is furnished with long tentacles, at the external bases of which the eyes are supported on short footstalks. The foot is large and strong, and surrounded at its union with the body by a row of filaments. The *Emarginula* is common to all our shores, being found in the largest numbers in the north, where it inhabits shell-banks and clear ground from low-water mark to considerable depths.

*EMARGINULA ROSEA*.—Is another specimen chiefly found on our southern coasts, and derives its name from a beautiful rosy colour occasionally tinting the aperture of the shell. This is not, however, by any means its general appearance, since in the larger proportion, the shell is found to be of a dirty white both externally and internally. The animal itself is white like the foregoing specimen, and differs from it in no material point, save that the foot is much more bulky. The *Emarginula rosea* has been taken at Poole, in Dorsetshire; at Exmouth, in Devonshire; and at Weymouth, in Dorsetshire; but although found on the rocks in some localities, it is in most instances a resident in deep water, averaging from 15 fathoms to 25 fathoms.—W.

(To be continued.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

As it is but rarely that we have such a favourable season as the present for digging and trenching ground, and as there are few gardens but would be benefited by the latter operation, we

trust the fine weather will not be allowed to pass without attention to this subject. *Artichokes*, let the plants be protected from hard frosts, at the approach of which, cut down the stalks and outside leaves to the inner ones, dig between and earth-up the plants to near the tops, and during severe weather to be covered thickly with straw, to be removed when frost goes. The earthing-up need not be levelled down till the spring, when their general dressing will be done. *Carboons*, tie up for blanching when the leaves are quite dry. Twist haybands round so that the earth does not come in contact with the leaves when earthed-up. *Cauliflowers*, continue to prick-out under hand-glasses and into frames. Any that are now fit for use to be preserved in a cool place. *Chives*, to be taken up and replanted every two or three years. *Garlic*, plant in a dry and rich soil on shallow drills 3 inches or 4 inches apart in the drills, and 10 inches between. *Herb-beds*, fill up and dress them for the winter. *Horseradish*, if too thick in the plantation to be taken up and replanted, reserving all the finest for winter use. It will keep fresh if laid in sand. *Lettuce*, to prevent the ravages of slugs mix soot and lime in equal proportions, and dust them over with it once or twice a-week. *Onions*, look over those that have been stored, and remove any that are beginning to decay. When Carrots, Parsnips, Beet, Salsafy, and Scorzonera are liable to injury from grubs, or from a low, damp, or unfavourable situation, it will, of course, be advisable to take them up. The tops to be cut pretty close, and the roots to be stored in dry sand under cover. In favourable situations each of the crops, with the exception of Beet, may remain in the ground for some time longer.

### FLOWER GARDEN.

When the plants in the beds have been destroyed by frost, they may be prepared for the reception of early-flowering bulbs, but if the whole of the surface cannot be covered with bulbs, a few planted round the outside of the beds will have a pleasing effect in the spring. If the spare beds are sown with Californian and other hardy annuals, they will also look gay in the months of May and June. The following are suitable for the purpose:—*Nemophila insignis* (blue), *Nemophila atomaria*, *Clarkia pulchella alba* and *Iberis coronaria* (white), *Silene pendula*, *Lep-tosiphon densiflora*, *Collinsia bicolor*, and *Gilia tricolor* (pink), *Clarkia pulchella* (rose), *Erysimum Peroffskianum* and *Eschscholtzia crocea* (orange), and *Collinsia grandiflora* (purple). Active measures should now be taken to prepare proper materials for protecting tender climbers and shrubs. It is best to have them in readiness so as to be able to apply to the different objects when protection is required. Any choice plants worth saving and still in the ground should now be lifted and placed under cover. The earliest opportunity may now be taken of removing all such plants as *Auriculas*, *Carnations*, *Pansies*, &c., that are growing in pots, to their winter quarters. A cold dry frame where provision is made for a circulation of air beneath and among the plants is one of the best situations for the purpose. But very little water to be given to these plants during the winter, they only require just sufficient to prevent their tissues from drying and shrivelling, and the drier they can be kept without this taking place the safer will they be from injury by frost, and the more healthy and vigorous to produce good blooms in their proper seasons. They should have air admitted to the frame daily, unless in very severe frosts. They will also require a moderate degree of protection in the most severe part of the winter. The most essential point is to guard against making the soil too damp and to prevent a confined damp atmosphere around the plants.

### FRUIT GARDEN.

Continue to collect-in and store away the late varieties of Pears and Apples carefully, and see that those already stored are in good condition. Walnuts, that have been collected and sweated, to be placed in earthen pans that are quite dry and not glazed; to be covered with a piece of canvass or thick brown paper, and about an inch of dry sand over it. It is a good and easy method for keeping either Walnuts, or Filberts, and other nuts. Run a soft broom over the Peach and Nectarine trees with great care, to take off first the very ripest of the leaves. The formation of fruit-tree borders should be in progress; stagnant water must be carried off by drains. A stratum of stones or broken bricks should intervene between the border and a cold, clayey bottom. Although these precautions may not be necessary on a gravelly or porous bottom, there are but few places where they can with propriety be dispensed with.

## GREENHOUSE AND CONSERVATORY.

Persevere in former directions. Remove all dead and decaying leaves. Continue to stop all luxuriant shoots in due time. Apply water in moderation and with due care as we get less solar light, and do not forget that many plants are now requiring rest. At this season the principal part of the watering to be performed in the forenoon, that by evening all superfluous moisture may be dried-up.

W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

KEPT on much the same as last week. Cutting-up *weeds* where spade or fork could not be used, but when small and thick, and room can be had, a slight turn-over with the spade is the best mode of keeping them down, as this can be done more quickly, and leave the ground in a better state than any hoeing and raking; and mere hoeing, if the weeds are small, is now of little use, as the sun is losing power. A good shower or two sends them all growing again. Earthed-up beds of Celery when the plants were dry, using a little coal ashes round the stems, and the earth close to the ashes, which tends to keep worms and slugs at a distance. Planted out more Cabbages, Cauliflowers, Lettuces, &c. Turned over the leaves of *Cauliflower heads* getting ready, to throw extra wet past the head, keep it white, and safer from a sudden frost. Thinned late Turnips, Radishes, &c., and cleared-off all seed-beds of Greens, and Peas, and Beans, when done with, as we could get at them.

## FRUIT GARDEN.

Gathered the ripest of the fruit on fine days. Even the latest Peaches will soon now be over. Rough-pruned Currants, Gooseberries, Raspberries, &c., and will dung the latter as soon as possible. As soon as the leaves all fall, it would be worth the while of those near a tanyard, to put a couple of inches of fresh tan all round the stem of each Gooseberry and Currant bush, extending fully as much as half the diameter of the head of the bush or tree, for destroying the eggs, &c., of caterpillars. We have used, also, a little fresh lime for this purpose, but do not think it so effectual as the tan, the pungent character of which seems to be the property which is not liked. It is some years now since I tried tan. We shall take the Nottingham netting off the Warrington Gooseberries now, as they are getting just rather ripe. Kept up a little extra heat to some late Melons. Removed most of the laterals from a late vinery, to give more light, and to have the wood and fruit more exposed to the sun. Whatever kinds of *Grapes* are intended to stand over the winter, should be getting fully ripe now. The riper they are now, the better they will keep. Such kinds as West's St. Peter's, though they should be black now, need not yet be sweet, but if deficient in colour by this time, they are not likely to have much flavour, or even hang well, as their juices will be too thin and watery. Burnt a little sulphur in an early house, where we were sure the wood was ripe, for the double purpose of arresting all growth, by killing the leaves, and giving a quietus also to any insects, as red spider, that might be in the house, and some thrips which we were sure were there, by the appearance of some of the leaves. When a vinery is constantly in use, and made to serve the office of cold pit, greenhouse, and plant-stove, and general forcing-house, as well as vinery, it requires sharp eyes and sharper fingers, to keep out every vestige of an insect. In our recommendations we cite shag tobacco burnt as the best remedy for the thrips on such occasions in a vinery, as it would be impossible to dip them; but if people were careful, and raised the same amount of cool, thick smoke from bruised Laurel leaves, judging from ourselves, we should say they would find the thrips liked that application the worse of the two.

## MILDEW ON GRAPES.

Though we have not been troubled ourselves, we are sorry to learn that mildew on the Vine, and especially on the bunches, has been rather prevalent this season. For this the great remedy and the great preventive are sulphur and plenty of air; in fact, with plenty of air it rarely manifests itself in-doors. Out of doors it generally is most abundant in warm, moist, sunless seasons. In very bad cases we should powder with sulphur, even if we did not have any great faith in it. We would have more dependance on the fumes of sulphur given off from being placed on hot-water pipes or flues, about 170° in temperature, and as soon as the fumes were felt in the house, giving abun-

dance of air. We were lately told of a failure where such sulphuring was used; but we elicited on inquiry that the atmosphere was moist, and little air given, and not enough of heat applied. There was thus a slow contest between what would nourish and what would injure the mildew. Another singular case was placed before us, in which the man in charge was accused of destroying the bunches by burning the sulphur in the house. Now, so far as the bunches were concerned, they were so thoroughly done for, so completely encrusted with the *oidium*, though the berries were not so large as peas, that the best thing that could be done for them was to pitch them into a furnace; but as to the dispute—the accusation on the one side, the denial on the other as to the burning of sulphur—there could not be a question that the gardener was in the right, as the wood and the leaves were plump and green; whilst if sulphur had been burned in the house both the foliage and the green parts of the wood would have been done for to a certainty. We are sorry to understand that this disease is mostly prevalent among our good friends the amateurs, who may have only one or two small houses altogether, and make them serve for all purposes. I believe that in almost every case a little sulphur in the shape of a paint, with water or milk, spread on the heating medium, and a brisk fire, but not to raise the pipes, &c., higher than 170°, and plenty of air given to neutralise the fire heat in dull and muggy days, would have rendered the unpleasant visitation next to an impossibility. There are many days in July, August, and September, muggy and close, in which a little fire heat, and more air in proportion, would be of general benefit, besides telling this ugly visitor to keep outside. The trouble of lighting the fire, the expense attending it, deters our friends and ourselves from doing it when it would be useful; and which we would be sure to do did we live near a coal-pit. I rather incline to believe that the mildew has never been so bad in coal districts, firing there is of little value, and a gathering coal is generally in the furnace, and more air is thus given. At any rate, now for late Grapes there ought to be a fire every day, except when there is a bright sun; and though the air be reduced in the afternoon, there ought to be constantly at night 2 inches or 3 inches for air open at least at the highest part of the roof all along and all night, except when the atmosphere approaches the freezing-point.

## FLOWER GARDEN.

There has been the usual routine of mowing, machine-cutting, sweeping leaves, rolling, &c., and all to be done over and over again. As the beds now are of less importance, in addition to giving them a rough picking to remove faded flowers, we have taken strong *cuttings* of *Geraniums*, such as Alma, Bijou, Christine, &c., placing five round the sides of a 60-pot, and plunging them in a little bottom-heat, but giving air all night, morning, and afternoon, and only shutting the sash down when the sun shone bright. If these, and many more we are now putting in, will callus and form a short spongiole or two before November, it is all we want, and they will need so little room in winter, and from their size, they will often beat those little tiny pieces taken off earlier, and which, being now struck, are exposed to plenty of air and light, and just protected from heavy rains. We have, as yet, lifted nothing out of the garden but a portion of our Golden Chain where it could not be much missed. I wish to take up, too, what little I have of Beaton's *Stella*, one of the finest things ever he sent out, though I am surprised to hear from a mutual friend that our coadjutor thinks very little of it himself. Its beautiful bright huge trusses have been noticed by every visitor. With Imperial Crimson Nosegay I have done little good, though I think it is true, but certainly with me it was nothing to what it showed itself at Kensington and the Crystal Palace.

*Thrips*.—We have been rather annoyed to find thrips making its way among our stocky pots of struck Verbenas. These had had no heat, farther than being stuck in a cold frame; and as we knew they are liable to this pest in the autumn, we pulled each half-dozen of the cuttings through a saucer of tobacco water before they were inserted in the pots. As soon as struck the pots were set in a cold earth-pit, and merely protected from heavy rains. There is no worse thing to get among plants. It is from such causes that we of the omnium gatherum people in our houses get insects carried there. Besides, if Verbenas are at all bad with thrips in winter, they are almost sure to bid you good-bye when the days lengthen, just when you want them for cuttings. I shall be a little doubtful of these gentlemen, though just now we did what we could for them. About a quart of

tobacco water was put into a pail. A bushel of bruised pulpy laurel leaves was put into a barrel, and four gallons of boiling water poured over them. When cooled to 90°, the liquor was poured clean off and mixed with the tobacco water; and each pot, with the fingers spread over the soil's surface, was reversed, and the Verbenas well washed in the liquid, without letting any of it into the soil. The worst leaves were picked off before this was done. The pots were then laid on their broad sides for the best part of twenty-four hours, and were then well syringed round and round with clear soft water, and were then set upright again. I have not detected any thrips alive since; but they must have another dose or two, and, to make assurance doubly sure, we shall put in a few more cuttings of the most desirable kinds, if these can be got at all in fair order for the beds, as at this season all the Verbena tribe out of doors are more or less subject to the attacks of the thrips. This will enable me here to give a hint to "A READER" who wishes to know the best and easiest way to treat Verbenas to make them strike.

Now, in the first place, for the liability to thrips late in the season, it is always undesirable to propagate Verbenas so late as October. I find to-day that some kinds, as Lord Raglan and Purple King, hardly show the mark of a thrips in the beds; whilst other kinds, as Defiance, are well nigh covered with them. In the second place, I would refer him to a paragraph in page 540, where he will meet with much to suit his case. In relation to taking the runners as cuttings, I would just say the pots will take no harm in a box if plenty of air be given. You may also try another mode—lay these rooted pieces into a pot, either singly in a small pot, or several in a 48-pot, using light sandy soil, and putting a pebble on the shoot to keep it down. Cut the shoots half through in ten days, and altogether in a few days more, and you will have young layered plants that will be far superior to any old plants you could take up out of the beds. Now for the cuttings. At this time they will require a little more care than at an earlier period. Now, this is just what I am doing to-day. First, the position for the cuttings. A wooden box set on the top of an old dung-bed. This well stirred over and a layer of ashes on the surface will yield a bottom heat ranging from 70° to 75° for a fortnight or three weeks. The *Vessels for the Cuttings*.—Some in pots well drained and filled with sandy loam, with a little sand on the surface; but as pots are getting scarce the rest in wooden boxes averaging 30 inches long, 7 inches wide, and 4 inches deep, and filled with similar soil. In both pots and boxes the cuttings will be planted thick, less than an inch apart. Then, as *Cuttings*, we prefer short side shoots about 2½ inches to 3 inches long. If without flower-bud all the better; if there, it is picked out. These are slipped off close to the stem, the lower leaves removed, the pair above them ditto, the next near the top shortened, leaving nothing but the buds and the small leaves at the top to continue the axis of growth. The removal of so much foliage is chiefly to lessen the risk of taking thrips with the cuttings. Then every few cuttings, as made, are washed in tobacco and sulphur water, and allowed to drip before being planted. They are then planted, gently watered, and put into the frame, shaded in bright sunshine—the glass merely shut down close in a little sunshine—the glass frame elevated an inch or two in the evening, and allowed to continue so until the sun begins to reach it next day. This prevents drawing and damping, and in about fifteen days we expect they will be rooted, when more air must be given, and even then a look-out made for thrips, &c.

We have also done the same thing at this season, merely planting at once in sandy soil under a cold frame without pots or boxes at all. If done a fortnight ago, this is the best plan where the frame can be spared until April.

For *bulbs*, see last year, and recent articles in the preceding Numbers. I would merely state, that when I did much with Hyacinths, &c., a 40-sized pot was in general large enough for a fair-sized bulb. I would only add here, that those who mean to do much in the flower garden with bulbs, should plant them as soon as possible in raised borders, in turfy loam and leaf mould, and then if covered they can be lifted with balls, after the beds are cleared and duly prepared for them.

#### CALCEOLARIA CUTTINGS.

My space is more than exhausted, but I have just made a beginning, and I would wish our friends to be as forward as myself. All bedding Calceolarias, with the exception of amplicaulis, perhaps, do best when they never feel fire heat. The very best mode to strike and keep them, is to have a plat-

form a little raised—say 4 inches, above the surrounding soil, a frame, or a pit, facing the south over that, some 3 inches of leaf mould at the bottom, 3 inches above that of sandy loam, and about a tenth part of fine leaf mould, and from half an inch to three-quarters of an inch of drift sand over all. The sand may be about 16 inches from the glass. If nearer than that the cuttings are too much influenced by sudden changes of weather; if farther from the glass they are apt to be drawn up weak; and in severe winters, when long covered-up, they are apt to lose their leaves and damp a little. Now, we could not hit upon such a suitable place; but, as the next best, had recourse to a brick-pit sunk somewhat under the ground, and too deep, and, therefore, objectionable on two accounts. We neutralised both these inconveniences, by putting in the bottom about a foot of litter and leaves that had been accumulating during the summer, tramped it hard, and we dress in a cold morning the trial stick would give a temperature for a fortnight at the bottom of 60° to 65°—scarcely warmer than the ground is now. On this we placed 3 inches of rotten dung and leaf mould, and finished as above. All is well trod and levelled before the sand is put on. This being rather damp is beaten with a spade, and is ready for the cuttings. These are stubby side shoots, from 2½ inches to 3 inches long, the lower leaves are removed, the others are shortened, and after being pulled through tobacco water are planted firmly in rows, 1 inch apart in the row, and the rows being nearly 2 inches from each other. In using such a position, I place some value on the litter below; but our young friends had better find out its use for themselves in the meantime.—R. F.

#### TRADE LISTS RECEIVED.

Louis Van Houtte, Ghent.—*Prix Courant de Plantes de Serres et de Plein Air; Bulbes, Oignons à Fleurs, &c.*

Eugène Verdier fils aîné.—*Catalogue de Roses remontantes, Gladiolus, Iris, Lilium, Phlox, Pœonia, Plantes diverses.*

William Wood & Sons, Woodlands Nursery, Maresfield, Sussex.—*General Catalogue of Ornamental Trees and Shrubs, Conifers, Evergreens, &c. A Descriptive Catalogue of Roses.*

H. Lane & Sons, Great Berkhamstead.—*Descriptive Catalogue of American Plants, Conifers, Trees, and Shrubs. Fruit Catalogue. A Catalogue of Roses. List of Ferns, &c.*

#### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

MANURE FOR SPRING CROPS (Z. A.).—Have your stable manure and its drainage carefully preserved until the spring, and then put it upon the ground just before digging it for the insertion of the kitchen-garden crops. Whether lime will be of service depends upon the nature of your soil. Do not mix it with the stable manure.

THOMSON ON THE VINE (A Young Gardener).—Its price is 5s.

DESIGNS FOR SMALL FLOWER GARDENS (Peter Piper).—You will find some, and how to plant them, in "Flower Gardening for the Many," which you can have from our office free by post if you send five postage stamps with your direction.

PORTABLE GREENHOUSE (Old Calabar).—We cannot undertake to furnish estimates. If you wish to buy one ready made write for their prices to the makers who advertise in our columns. If you would build one by the aid of a builder in your own neighbourhood, buy our "Greenhouses for the Many," choose the plan which you prefer, and ask the builder for an estimate.

REMOVING FORCING-PIT (Rustic).—You must not remove the brickwork, nor the framework of the door attached to the brickwork; but you may remove the lights, the framework screwed on the boiler, and the pipes.

REG SPIDER (T. Hargrave).—If you refer to p. 33 of "In-door Gardening," and read the whole paragraph, you will see how Mr. Keane keeps away red spider from his Vines without syringing after the berries are set.

COCAIA-NUT FIBRE REFUSE (A Subscriber).—The dust you enclose is the darker sort. It is light-coloured because fresh and dry. It would become darker with moisture and age.

FERN CASE (Patelin).—The Ferns and Lycopod you mention will all grow in your Case, but in so small a Case will be crowded.

**VERBENA CUTTINGS** (*A Reader*).—You will find the information you need in "Doings of the Last Week."

**LONDON PUBLIC GARDENS** (*A Yorkshireman*).—Your unmitigated censure of the Kensington Gore Garden, and your seeing "nothing superior either in the bedding or general keeping" of Kew Gardens, is so unjust that we fear you are not a discreet critic, and we are not inclined to think otherwise by your excessive praise of the Crystal Palace. Try your pen at a description of the north country gardens, as you obligingly offer; we know that many of them are admirably arranged and managed.

**FORCING-HOUSE** (*K. R.*).—There is nothing objectionable in the plan of your friend if rightly carried out. Did we suggest anything, it would be that if the front wall was to be 4 feet, the back, instead of 8 feet, would be better to be 10 feet, 11 feet, or even 12 feet, which would give you a good slope for Cucumbers, &c. What you propose will be flat-roofed. Again: part of the front wall had better be glass, especially if your roof is flat. Once more: but for economy in heat, there is little gained by sinking the floor 2 feet, and even then as to warmth it is not all saving, as you will run the risk of having more damp. The Cucumber end should be next the boiler, and it would be as well if you could heat that end with the pipes, independently of the other, by stopcocks or valves. The flue going all round would not signify much, as the hottest end would be next the furnace. The flue in the Cucumber division, as it comes from the furnace, should be brick on bed; the rest, brick on edge well done. The slightest escape of smoke from the flue will injure the Cucumbers. Keeping this in view we would alter the proposed arrangements, carry the flue along beneath the bed, surrounded with stones, for bottom heat, and use the pipes for top heat.

**CAMELLIA FLOWER-BUDS BREAKING** (*Anna Crichton*).—It is possible that you were just too long in exposing your plant. When such plants and tree Rhododendrons are kept too long in a moist atmosphere after a flower-bud is formed, it is apt to break again. So in wet summers out of doors, the axis of growth sometimes commences again and goes right through the flower-bud. A certain amount of sun is necessary to perfect the flower-bud; but any extra excitement after the bud is formed is apt to make fresh growth, or even cause the buds to fall. We think very likely your plants had received rather too much water. Many flower-buds will come all right enough though rather pointed; but of course they will not do so if a green point comes through them. We are not satisfied that all those you describe will fall even now.

**PUTTING PLANTS INTO NEW GREENHOUSE** (*H. T. B.*).—There will be no danger to the plants if you do not put them in until a few days after the paint is dry. Give all the air permissible then, and give a little fire heat to insure a rapid circulation. Even after the plants are put in it would be as well to use a little fire heat, and leave more air on than otherwise would be necessary. Using these precautions, we have filled houses a week after the painting was finished, and never noticed anything affected.

**CEPHALOTUS FOLLICULARIS CULTURE** (*Jane Flowers*).—A common airy greenhouse is too open, dry, and cold for this plant. Plant it in chopped sphagnum, peaty soil, and broken potsherds, well drained. Set the pot in a saucer filled with moss kept moist. Place a handlight or bell-glass over it, tilted up on the side for ventilation. Shade a little from bright sunshine, and do not let the temperature fall much below 50° to 45°. These will insure a moist atmosphere, and the roots will be moist without being deluged.

**STOPPING LEAKING PIPES** (*Quis*).—You say nothing of what the pipes are made. If of iron, the easiest to apply, when the pipes are empty, is red lead mixed with a little tow. Portland cement will also do if you can force a body of it in the socket. Mr. Beale, of Woodhall, and Mr. Lane, of the Berkhamstead Nurseries, use nothing else. When the pipe is cracked, we have used a piece of stout cloth smeared with red lead, placed round and tied firmly with cord, and then painted. Last winter or spring almost the half of the side of a large boiler gave way; but we tinkered that so as to work well ever since, and nobody had the curiosity to ask how. Of course, a new one would be better and surer, but you cannot always get an employer in the mind to spend some £20 or more in getting a fresh boiler. Pipes can be so grown, but with extra care, and would do much better with a turn of the flue below the bed. Good firey loam, rough, and packed up six months previously, is the soil. Lime putty, made with sharp sand, and plenty of elbow grease and little water, tough as dough, is the best thing for pointing flues.

**TREATMENT OF SEEDLING PANSIES** (*S. F. F.*).—We have just cut down two of the best Pansies we know—the *Tornica* Pansy of the gardeners, or the *Maggie* Pansy of the ladies, and a yellow one which never misses to bloom from April to October; and you cannot do better than follow our example and be quick about it. Then, when the spring is fairly set in for fair weather we would lift them carefully, and divide and replant them the same day, and would take no heed to what "some people say."

**PEAR-TREE SCALE** (*A. B.*).—The "disease" is a parasitical insect, *Aspidiotus ostryaeformis*, the Oyster-shaped, or Pear-tree Scale. Painting the stem and branches thoroughly with a creamy paint made by boiling half a pound of soft soap and a pound of flowers of sulphur for about twenty minutes in four gallons of water will eradicate it. Your trees are dreadfully afflicted with this pest, and we should apply this composition now and again in the spring. In fact, you must repeat the application until not a scale insect can be detected.

**NAME OF BEGONIA** (*Top*).—There was no specimen in your letter.

**NAMES OF FRUITS** (*A. M. R.*).—*Apples*.—No. 1, Cackle Pippin; 2, Keddleston Pippin. *Pears*.—No. 3, a small Bourré Rance, rots at the stalk from being in wet subsoil (*C. E. Bridges*).—*Pears*.—No. 1, Marie Louise; 2, Bourré Clairgean; Fondante d'Antoine; 4, Bourré Hardy. *Apples*.—No. 1, Fearn's Pippin; 2, Ruslock Pearmain; 3, not known; 4, Flower of Kent. (*J. E. F.*).—*Apples*.—No. 1, Bedfordshire Foundling; 2, Cackle Pippin; 3, Golden Harvey; 4, Blenheim Pippin. *Pears*.—No. 1, Glou Moreau; 2, Bourré de Rance; 3, Marie Louise; 4, Doyenné Defais; 5, Triomphe de Jodoigne. (*E. Marlow*).—No. 1, Ribston Pippin; 2, Herefordshire Pearmain; 3, Keswick Codlin. (*North Derby*).—No. 1, Hessel; 2, Autumn Colmar; 3, a small Brown Bourré, evidently from a standard; 5, Achan; 6, Bourré Capiaumont; 7, Marie Louise; 8, Fondante d'Antoine; 9, Marie Louise. *Apples*: 1, Hawthorn (?); 2, Cornish Gilliflower; 3, Fearn's Pippin; 4, Alfriston; 5, Golden Winter Pearmain.

**NAMES OF PLANTS** (*W. Wanklin*).—The *Oenothera* is *Lamarckiana*. The small flower is *Nycteria selaginoides*. The *Tropæolum* was noticed last week. (*M. E. L.*).—1, *Pteris hastata*; 2, *Blechnum occidentale* minor, or,

as it is sometimes called, *B. cognatum*; 3, *Selaginella pubescens*. (*C. P.*).—1, *Portulaca Thellusonii*; 2, double yellow *Heliathemum vulgare*; 3, *Plumbago Larpentæ*; 4, *Anemone japonica*. (*C. S., Colchester*).—*Diplazium Wagnerianum*. The plants you mention are indigenous—the *Cyanophyllum* to Mexico, the *Pterides* to India.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

OCTOBER 15th. FROME. *Sec.*, Mr. C. Harding, Graddon Farm, near Frome. Entries close October 8th.  
OCTOBER 28th and 29th. CALNE. *Secs.*, A. Heath and F. Baily. Entries close October 15th.  
DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.  
DECEMBER 16th and 17th. LORD TREDEGAR'S, Newport, Monmouthshire. *Sec.*, Mr. J. G. Palling, Newport.  
DECEMBER 29th, 30th, and 31st. MANCHESTER.  
JANUARY 1st, 2nd, and 3rd. GLASGOW. (Pigeons and Canaries) *Sec.*, Mr. T. Buchanan. Entries close December 22nd.

### COOKING POULTRY.

(Translations from *M. Jacque's work on Poultry continued*.)

ALTHOUGH I do not wish to enter into competition with the "Cuisinier Royal," I must have a few words to say on the different methods of preparing poultry for the table. In every cookery-book there are numerous and varied receipts for dressing fowls, but few, or none, that relate to plain roasting. The combustibles to be preferred, are for cookery in a room or at a stove, wood charcoal quite clear of smoke; and for a fireplace or rather hearth, very dry wood, split small, producing a clear and scorching fire. When either of these combustibles is properly used, there is not the slightest appreciable difference in the flavour of the roasted fowl, though some old and fastidious epicures say wood is preferable.

Before a fowl is put on the spit, it should be scrupulously clean inside and out, and should be singed with white paper, neither with brown, greasy, nor dirty. A young and small fowl should be roasted quickly, and put down to a clear and lively fire. A middle-sized fat fowl, or a small poularde, should be put to a cheerful but moderate fire, and remain at it till a practised eye detects the exact point at which it is done, either by the look, or by skilful punctures made with a pointed knife or fork, to examine the colour of the gravy. A very large and very fat fowl should be put down to a good fire, but a moderate one, that the heat may thoroughly penetrate every part, and it must remain some time that the inner part of the thighs may be done. These parts should have a greater share of the fire, and be more exposed to it than the fillets (breast), in order that these delicious parts be not dried up. Much must depend on the intelligence of the person charged with this really important mission. It will make of the same fowl either delicious meat, or detestable food.\*

Fowls in general, but especially very fat fowls, are preferable when eaten cold, and if I were a gourmand, I would never deviate from the following rules:—According to the season of the year, from twenty-four to forty-eight hours should elapse between the death of a fowl and its being cooked, and at least six hours between its being cooked and eaten.

A fine fatted fowl, a Houdan, Crève Cœur, or La Flèche, or one of the enormous half-breeds, roasted to a turn, thoroughly cold, and served in the company of excellent white wines, of good cheese, and aromatic coffee, to a lot of hungry sportsmen just returned from a successful "first day," is a meal as simple as it is relishing. Cocks or hens from two to three years old, naturally fatted, and placed under sequestration in a very clean place for eight days, also large adult Brahmas or Cochins, merely in fleshy condition, can be made an excellent dish prepared in the following manner:—

The fowl should be drawn very clean, and well singed, no hairs remaining, and should be cut into moderate pieces. The leg into three pieces (femur, tibia, and feet); the wing into two pieces; the neck into three or four; the body divided in halves, lengthways, should be cut into convenient pieces, without detaching the meat from the bones. Fry the whole lightly in butter; the pieces must only have assumed a yellow hue, then add water till the fricasée is covered, more or less, according to the age of the fowl; for a hard one must of necessity remain longer in cooking, and the operation must be so arranged, that although there shall be plenty of gravy, no addition of water

\* I do not admit the turnspit, that unintelligent cook.

shall take place during cooking. It must simmer over a small fire uninterrupted, and be thoroughly closed that there be no evaporation.

When the ragout, spiced according to taste, is nearly done, which will be in one, two, or more hours, according to the age and nature of the fowl, a few excellent yellow potatoes may be cut in half and added, also onions if they are liked.

The potatoes should be placed on the top and cooked without disturbing the ragout in any way. This will avoid a mixture and a blending that are not always agreeable. A quarter of an hour from this time all should be cooked. The meat and the vegetables should be served at the same time, but separate, in order that it may be easy to pick the choice pieces.

There is another ragout that I have never found in any cookery-book, but which I have always thought excellent, it consists in preparing a young fowl of any size in the manner hereafter described.

The fowl or chicken cut in pieces and cooked till it is gilded, not browned, should be taken from the stew-pan, then make a brown sauce by the addition of as much flour as may be necessary for the size of the dish. Take care it does not burn, it would give it a taste of insupportable bitterness. Having done this, put the pieces back in the stew-pan, adding some small pieces of raw bacon, mild and only half fat, some eschalots chopped fine, salt, a good quantity of good pepper, a little nosegay composed of parsley, thyme, and a few bay leaves. Let it simmer over a slow fire and be well covered that there be no escape for half an hour, then, according to the size of your dish, add mushrooms and small delicate onions.

When all is cooked dress it in a dish and decorate according to taste, so that it looks well with chopped gherkins and marinated vegetables, as peas, haricots, chopped dwarf kidney beans, pieces of radish, carrot, gooseberries, &c., and send up hot.

#### MIXING VARIETIES IN ONE CLASS.

As I am well aware there are many committees of poultry exhibitions now about to issue their respective prize schedules, perhaps you will kindly allow me space to point out a failing, that undoubtedly, in many instances within my own knowledge, has of late most materially lessened the number of entries that might otherwise have been readily obtained—I allude to the practice of giving prizes to be competed for by a variety of breeds in the same class. I can assure committees generally that such an arrangement is the very reverse of popular among exhibitors, and places arbitrators in anything but an enviable position. Only a few days back, when engaged in conversation with a number of our most noted breeders, the very liberal prize list just issued by the Glasgow Society became the subject of consideration, and I heard several say they would most willingly exhibit, but all varieties of Cochins competed in one and the same class, which would be the only cause of their declining to do so. I suggested that, perhaps, as being the first Glasgow Poultry Show, the Committee did not feel justified in giving a greater pecuniary amount in prizes until they had proved how far public support would be enlisted. The unanimous opinion expressed in reply was, "Divide the same amount into separate classes, according to usual custom; Buffs and Cinnamon in the one, Brown and Partridge-coloured in the other, and then all our objections are at end." I confess this is the oft-told tale at every Exhibition I ever yet visited where two varieties competed together, and I myself endorse the opinion entirely, that even arbitrators themselves have frequently expressed a dissatisfaction when called upon to decide on the relative excellence of, perhaps, Golden-spangled and Golden-pencilled Hamburgs, entered in the same class; both, perchance, being excellent as pens of their respective varieties, and involving something closely akin to caprice in the eventual decision. It is a mistaken arrangement, and undoubtedly lessens rather than improves the competition; and now the matter is once mooted, probably various amateurs will favour you with their individual views respecting it.—EDWARD HEWITT, *Sparkbrook, Birmingham.*

#### WAKEFIELD POULTRY SHOW.

In reply to "MINUS," I beg to inform him that upwards of twenty-four prizetakers have been paid, and it is not my fault that the other twenty have not been paid at the time appointed.

I have paid about £10 over what I received for entries, as I expected the general Secretary would hand over the amounts due to the poultry exhibitors; but I have not yet received a penny. I have been to the Secretary many times for the amounts, and his reply was that he had not time to attend to it.

I can also inform "MINUS" that no meeting has been called since the Show to let the Committee know how the Society stands. I trust those who have not received their prize-money will apply to Mr. J. Wainwright; he is the proper party. Had it been left to me, every one would have been paid at the time appointed. I took the management of the Poultry Show, because not one of the other members of the Committee understood anything about fowls. As one of the Committee, I took the responsibility to receive all entries, to pen and to return the fowls after the Show. I did all in my power to oblige every exhibitor, and every pen of poultry left Wakefield Station at 8.20 P.M., the day of the Show. I beg to state I shall pay no more of my own money for the above Society; but I have seen Mr. J. Wainwright to-day, and he has promised to pay all next week. Those who are not attended to must apply to him.—JOHN CROSLAND, JUN., *Wakefield.*

#### LICE ON FOWLS—SHOWS NEAR LONDON.

I HAVE some Black-breasted Red Game Cockerels of first-rate breed, hatched the latter end of May, which a short time since showed evident signs of ill-condition, as drooping wings, &c., and on catching them I found them infested with lice, and the nits deposited in large numbers on the feathers, under the throat especially. The birds have a good grass run, and, as I thought, every requisite in food and pure water, being fed on wheat, barley, barleymeal, and potatoes, lettuces and other green food. I have shut them up for a few days, and have let them have plenty of ashes, mixed with road-grit and sulphur, to dust themselves in, and have rubbed a little sulphur in powder in under their throats; and, as they have been growing fast, have added a little hempseed and meat to their former food. They seem to be improving; but as I wish to get some of them ready for the Crystal Palace December Show, have troubled you to know if my feeding and treatment are correct. I cannot make out the cause of their being so affected, and the pullets are not so.

In every Number of your Journal I see interesting accounts of poultry shows held in the north, west, or midland districts—in fact, almost everywhere but in the districts about the metropolis and the home counties. Surely there is great apathy on this point among the poultry-keepers of the latter districts, and as the London market, I should think, can be supplied better from the near counties than those more removed, would not the effect of poultry shows be to give a stimulus in the shape of competition to improvement of breed that would prove a boon both to those who breed for sale and also to amateurs? An article from your pen, if I might suggest it, would cause some stir, I should hope, in private quarters that would give us something more than the Summer and Winter Exhibitions at the Crystal Palace.

Is there any work you can recommend on the breeding and management of Game Fowls especially?—J. J.

[There is no doubt the lice are the cause of illness in your fowls, and they arise from bad condition resulting from the lack of dust. Every bird in creation is fond of a bath—some take it in water, some in dust. Wherever a spring crosses a road, and leaps clear and sparkling over the gravel crosses, you will see sparrows, chaffinches, and such birds washing; where there is a dry, sunny bank, or a bare spot among swedes or potatoes, you will, if you do not see the birds, see the places where plovers, partridges, blackbirds, and others have dusted. Your fowls wanted this, and now it is provided they will get better, but they should have it at liberty. An almost immediate relief is in such cases to drop a little oil under the wings, to put some on the crown of the head and under the throat; but the cure is the dust bath. Discontinue the hempseed, nothing is so bad for plumage, nor is it good food in ordinary cases; give up the meat, it is too heating, and will set them all fighting together. Feed on ground oats mixed with new milk; and give, if they still appear weak, a little stale bread soaked in ale daily.

The south-eastern counties draw a million from Loudon yearly for poultry, but they cannot support a show. The best plan is

to support the Crystal Palace, where every opportunity is given to amateurs both to exhibit and to compare.

We know no hook exclusively devoted to Game fowls.]

## MANCHESTER POULTRY, PIGEON, AND DOG SHOW.

We have been favoured by the receipt of a prize schedule of the Manchester Poultry, Pigeon, and Dog Show, and whether we consider the almost unlimited accommodation the Manchester Zoological Gardens afford for the accommodation of the birds and animals exhibited, or the unprecedented liberality of the prize list, they conclusively tend to strengthen the belief, that the coming Show will be one of the most colossal in its proportions ever yet held in this kingdom. It is stated, that "the Great Hall will accommodate 2,000 pens of poultry without their being placed over each other." Our experience of last year's meeting, proves this matter is not overstated. It may be added also, that independently of the great advantage of all the birds being exhibited on the same level, the light throughout is equally diffused, and in case of severity of weather (the Show falling in the Christmas week), the heating apparatus can be instantly called into requisition. Such are no mean advantages, and the very prompt payment of the prizes last year augurs well for the renewed confidence in the coming event.

The premiums themselves are most liberal, the entrance money (10s. each pen), being added to the winnings of the successful ones. In the leading classes, this augmentation will add most materially to the value of the prizes and their number also. In proof, should thirty-six entries ensue in any one class, the result is, no less than that seven prizes will be awarded, varying from £8 down so low as 10s. But we may speak even more strongly still, should upwards of thirty-six entries arise in any particular class (and we strongly suspect in Game, Cochins, Dorkings, and some other breeds such a result will be inevitable under so strong a temptation to exhibit), than whatever the numerical increase, the prizes will be "increased proportionately." Again, although in case of want of merit, the Judges have the power to withhold premiums, they are also empowered, in event of superior merit, to apportion £2 in poultry, and £1 in Pigeons, even in case, should such arise, of there being but a single entry.

It is very properly enacted that each pen of birds must enjoy a separate package; and that any infringement of this rule will subject the owner to non-competition, his entrance fee being also forfeited. Provision is made, that "no exhibitor, or other person, will be allowed in the room, or to go near to, or in any way, either directly or indirectly, to interfere with the Judges whilst making their awards." We join heartily in the hope this rule will be stringently enforced; for, by referring to the schedule, it appears that the classes for poultry and Pigeons alone embrace no less than 148 classes, in some of which, as before hinted, as many as eight awards, and probably many more will have to be arrived at. The rule will be rigidly carried out that unhealthy birds will not be permitted to compete, and the entrance fees will be also forfeited. It will, undoubtedly, much tend to the comfort of all parties interested if exhibitors will carefully examine the prize lists before making their entries, as, from the unusual number of classes, mistakes are more than generally probable among the negligent; whilst, by Rule XXI., "no alteration whatever can be made in the certificates after they are received by the Secretary."

## WORTLEY AND ARMLEY POULTRY SHOW.

The annual Exhibition of Poultry and Pigeons of the Wortley and Armley Horticultural and Poultry Society, was held in a field kindly lent for the occasion, at Armley. The competition was with one or two exceptions very good.

As might be expected, the class in which was offered a five-guinea cup, kindly presented by the President, produced a good number of entries, and after some hard fighting it was eventually awarded to Miss Beldon's pen of Gold Polands, and very good they were. Duckwing Game and Gold-spangled Hamburgs taking the two money prizes.

In Black-breasted Red Game, otherwise decidedly the best pen, was disqualified, the cock having his legs painted which was fortunately discovered by the Judges, and the attempted fraud exposed. In the class for "Any other variety of Game," there were some good Duckwings. In the *Hamburgh* classes, out of

six prizes Mr. Cannan carried off four, three first and one second. His Golden-spangled and Pencilled were well worthy of note. Mr. Crosland headed the Game *Bantam* list with his well-known pen, but they were rather out of condition having just commenced moulting. This gentleman also showed a good pen of Blacks; and Mr. Holdsworth a very neat one of Whites. *Spanish* were very inferior; but Mr. Newton's two pens of *Cochins* well deserved their honours. We thought the chicken very promising.

The class for *Geese* produced but one pen of Brents, and to them the prize was awarded.

The *Ducks* were not numerous, but there were some very fair specimens.

The show of *Pigeons* was both numerous and good. Miss Hughes and Mr. Silvester being the most successful competitors. Their *Carriers* and *Turbits* being especially good.

The weather was very unfavourable, and we fear the company was not quite as numerous as might have been wished.

GAME (Black-breasted).—First, J. Horne, jun. Second, A. Farrar.

GAME (Any other Variety).—First, R. Turner. Second, A. Farrar. Highly Commended, A. Farrar.

HAMBURGH (Gold-spangled).—First, W. Cannan. Second, G. A. Hepper.

HAMBURGH (Gold-pencilled).—First, W. Cannan. Second, J. E. V. Mussey.

HAMBURGH (Silver-pencilled or Spangled).—First and Second, W. Cannan.

POLAND (Any Variety).—Prize, Miss E. Beldon.

BANTAM (Game).—First, J. Crossland, jun. Second, W. Lawrenson.

BANTAMS (White).—First, E. Holdsworth. Second, A. Farrar.

BANTAMS (Black).—First, J. Crossland, jun. Second, J. E. V. Mussey.

SPANISH.—First, W. Ingram. Second, W. Rain.

COCHIN-CHINA.—First and Second, H. & G. Newton.

GEESE (Any Variety).—Prize, J. E. V. Mussey.

DUCKS (Rouen).—First, W. Iogham. Second, T. Talbot.

DUCKS (Aylesbury).—First, A. Roberts. Second, T. Talbot.

ANY VARIETY.—First (Silver Cup), Miss E. Beldon. Second, R. Turner. Third, W. Cannan. Highly Commended, W. Cannan; Miss E. Beldon; H. Yardley. Commended, E. Smith.

PIGEONS.—*Carriers*.—First, Miss H. Hughes. Second, A. L. Silvester. *Oxys*.—First, Miss H. Hughes. Second, J. Cliff, jun. Commended, Miss E. Beldon. *Turbits*.—First, A. L. Silvester. Second, Miss H. Hughes. Commended, J. Horne, jun. *Barbs*.—First, A. L. Silvester. Second, Miss H. Hughes. Highly Commended, Miss E. Beldon. Commended, H. Yardley. *Tumblers*.—First, Miss E. Beldon. Second, Miss H. Hughes. *Fantails*.—First, J. Wilson. Second, Miss H. Hughes.

The Judges were—Mr. G. Saunders Sainsbury, Devizes, and Mr. J. B. Stead, Leeds.

## PARTHENOGENESIS IN THE HONEY BEE.

My last Ligurian queen for the season was hatched on the 7th September, and was a very dark one; but as there was no longer any chance of another coming to maturity in sufficient time to become impregnated, I allowed her to remain in the hope that she might find a mate among the few Italian drones still remaining in my apiary. She must have commenced egg-laying within the customary period of three weeks, since this day (October 7th), I found drone-brood sealed over. Not being disposed to attempt preserving a drone-breeder through the winter, this circumstance proved her death warrant; and, on a *post mortem* examination, I ascertained that she was undoubtedly still a virgin, her spermatheca being totally destitute of spermatozoa, and containing only a clear and colourless fluid. This is another proof of the correctness of the doctrine of parthenogenesis in the honey bee.—A DEVONSHIRE BEE-KEEPER.

## OUR LETTER BOX.

DOBKING COCK'S COMA DROOPING (J. W.).—A drooping comb is not a disqualification, but it is a great disadvantage in an exhibition pen.

## LONDON MARKETS.—OCTOBER 13.

### POULTRY.

Everything is scarce, and there is a rise in all things save Game. The corn being now cleared everywhere, shooting is become general, and we receive rather more Partridges and Pheasants.

Large Fowls .....	3 6 to 4 0	Ducks .....	2 0 to 2 6
Smaller do .....	2 6 ,, 2 9	Partridges .....	2 0 ,, 2 3

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 56.6° and 39.5° respectively. The greatest heat, 73°, occurred on the 21st, in 1830; and the lowest cold, 26°, on the 21st, in 1842. During the period 125 days were fine, and on 120 rain fell.

FRENCH FOUNTAINS

AT THE ROYAL HORTICULTURAL SOCIETY'S KENSINGTON GARDENS.

CIRCULAR, signed by the Secretary, of which the following is an extract, has been distributed among the Fellows of the Society by the Council:—

"The subscriptions which have been as yet received are not sufficient to warrant the Council in offering to purchase the fountains—but before the opportunity of securing these absolutely passes away, they wish me to recall the matter to your recollection.

"If each Fellow were only to subscribe one guinea, a sufficient sum would be raised—and as the Council have been recommended

by many of the Fellows to adopt this mode of obtaining the necessary funds, a form is enclosed which you can sign and return to me in case you should feel disposed to contribute.

"I am specially to make you aware that the Council do not in any way press this subscription upon the Fellows. It is essentially a matter for the Fellows' own determination. All that the Council feel called upon to do, is to give those who desire to secure the fountains or bronzes, the opportunity of doing so, and to be the medium of carrying out the wish of the Fellows on the subject, whatever that may be."

We are second to none in our admiration of one, if not of both of the fountains, but however desirable it may be to secure either of them for the decoration of the garden, we think the Council are quite right in remaining passive in regard to this movement, as either of the fountains is far too large for the enclosure, which already is more than fully occupied with artistic designs. With hasins, canals, terraces, slopes, polychromic figures, and other still-life ornamentations, we are of opinion that the garden is sufficiently crowded. But, in addition to that consideration, there is no adequate supply of water for such fountains. At present the meagre display verges on the ridiculous, and to have a sufficient supply and impelled by an appropriate power would require a very large expenditure on hydraulic apparatus. We presume this large expenditure is not included in the subscriptions, but would form an item which the Society would have to furnish, and which we think might be more advantageously expended.

GNAPHALIMUM LANATUM—STELLA AND NEW GERANIUMS.

At last I have received a specimen of the flowers of this most useful edging plant, Gnaphalium lanatum, thanks to Mr. Scott, of the Merriott Nurseries, Crewkerne, Somerset. He says, "I think it is an Antennaria, but the differences between the constituted genera of everlasting slide into one another in very close gra-

dations, something in the way of Chicus and Carduus, that it is difficult to determine them. My eyes are not now so good at finding out a hairy pappus, and a smooth pappus, dorsal awns, and such-like distinctions, as they have been, and I must leave these things to the doctors, and to the Editors of THE JOURNAL OF HORTICULTURE, with their big microscopes, and take the outside of things, and their general resemblance to one another, as my guide."

Very good, nothing was ever more to the purpose for practical men. "The outside of things, and their general resemblance," otherwise called the natural affinities of their looks, are all that practice requires, and when practice is tired of pedantry, this is what it will slide into. Then, if I mistake not, cross-breeders and hybridisers will discover a closer affinity in the outside and resemblance of things, in their way, than in the distinctions of the doctors when they disagree among themselves, as to the value and importance of this or that feature for generic distinctions.

Working upon that text, I have come to the conclusion that this is a true Gnaphalium, that it is an unrecorded, or undescribed species of long standing in our gardens, that it is in close affinity with Gnaphalium lasiocaulon on the one hand, and with G. patulum on the other—that is to say, in consecutive arrangement of species, according to their natural looks, this one should find a place between those two species, but not by the name of lanatum, having no more claims to that feature than many others in the same genus. The flower-head is a compound umbel, but whether it is terminal, or axillary, my specimen is not so complete as to decide.

STELLA GERANIUM.—I am much obliged to Mr. Thomson, of Archerfield, first for putting us on the right scent about planting cuttings of Cerastium tomentosum in place of rooted plants, and secondly, to him and to Mr. Fish, for their moral support in the matter of Stella. The following is the only other notice I have heard of Stella these four years last past. Mr. Scott, of the Merriott Nurseries, writing on the 23rd of last June, said, "I have all your seedlings from the Wellington Road Nursery, and if they please me as well as Crimson Nosegay (Crimson Minimum), and G. Stella, they will do you great credit. When I saw Stella first, I jumped for joy, and said I would rather have been the raiser of Stella, than of all the other bedding Geraniums I know put together." And a gentleman, in an arm-chair in London, wrote to say, "You will be vanity daft when you read what Mr. Fish and Mr. Thomson say about Stella."

Well, they say a daft body is not responsible for his sayings and doings. Therefore, under the recognised privilege of a daft body, I would just back what Mr. Fish says about "our mutual friend," not thinking so much about Stella as it deserves. Stella is now only the fifth best of my better seedlings. Lord Palmerston, one of twins, is one degree better than Stella in rose colour. It proved so this season, on the Rose Mount at the Crystal Palace; and in the new garden at Kensington, Mr. Eyles gave it the place of honour, in the south-west embroidered panel, where, however, it was "caught"

by the sun, so that it would seem to need strong soil to bring it out. *Cybister* or *The Tumbler*, is four degrees above *Stella*. I sent a specimen of it along with *Lord Palmerston* to Mr. Eyles, and he says distinctly, and all his men back him, he never yet saw anything like it. But I was daft enough to bring him up, the other day, enough of it to make a bed next summer, and there will be another bed of it on the Rose Mount at the Crystal Palace. But stop till you see *Ossian*, King of the Fingalians, and then tell me all about *Stella*. *Ossian* was the name of the most faithful friend I ever had, a "Sky" terrier, a present from Lady Middleton, when I left Shrubland Park, and *Ossian* is the name of the second best seedling *Geranium* I ever raised, for I have a better one named *Helen Lindsay*. So that *Stella*, in fact, is now only my fifth best, and it was out of my stud-book two years since. I had not a blade of it since, but I must have it again, and, if possible, from Archerfield, for I think I have now another seedling of that race with which I might improve it—that is, improve the *Stellate* section. The distant climate and fertile soil of the Lothians, I think, would tell favourably on the seedlings.

But, it is through an optical illusion that the *Stellate* race will ultimately become the most favourite bedders, a thing which has often been explained to me over twenty years back, when I was just learning the most difficult of the arts, the art of looking at and seeing the power and effect of colours. To a good eye, a *Compactum*-like truss in a bed is the worst of all the forms, it causes just as much shade as it gives in brightness. If the flowers are large and perfectly round—say, florist-like—that makes the shade still deeper than it is made by the *Compactum* truss, which, of course, destroys the effect of the colour the more. The *Nosegay*-shape lets the light in through the mass of petals, so to speak, which improves the tint considerably, but the *Stellate* form of the petals makes a perfect optical illusion. *Stellate* means a star-shape, the petals stand apart equally all round, the light plays in between the petals equally over a mass or a bed; and you cannot tell how it is unless you knew it, but somehow or other the eye is acted on irresistibly. That is the key to what Mr. Thomson says of *Stella*—"A large bed of it here this season, although a field of bloom lay between the eye and it, arrested the eye immediately the garden was entered." Now, if all the flowers in the "field of bloom" had been of *Stellate* form, my lovely *Stella Geranium* would have been unheeded. It would then be only a unit of a whole instead of a unique in the midst of beauties equally telling, but the effect marred by the mere accident of the shape of the flower and the form of truss, no matter what kind of plant the truss or spike was on.

I shall not live to see it, but the inevitable tendency of cultivating the public eye to the effect and value of colours by means of flower-gardening, must necessarily be to produce that form of flower, and that disposition of the flowers on a plant, and against each other, which will give the most effective sensation of pleasure from looking at them. You can have no idea of the real pleasure it gives a florist to look at a round flower. Since I have been on the Floral Committee I have often experienced extra delight myself, at seeing even the pleasure of hope beaming in the florist's eye when turning round and round the favourite object of his anticipation. What a flood of delight then is yet in store for him in the matter of colour.

But see how doctors disagree. *Paul l'Abbé* and *Mrs. Vaucher* with me are no better than they should be. The *l'Abbé* is the best form of flower in creation, and *Madame* is the best white and the best form to the bargain. I would not plant a bed of either if it was ever so easy; but for pot plants no *Pelargonium* was ever one-half so valuable in my estimation; and while I think of it, allow me to say that *Blackheath Beauty* is, perhaps, the most valuable pot plant we have for early and for late work in-doors.

But be sure and bear in mind, that all this, from the paragraph beginning with *Stella*, has been written under the prediction of that "vanity daft," and that I am not, therefore, to be held responsible for one word of it, all I can say is, that I believe every word of it myself. But I am truly sorry for what I said about *Paul l'Abbé*. Doctor Sankey the best flower-gardener of the florists we have on the Floral Committee, to whom I applied privately to know the best florist's flower among the bedders, said, without hesitation, "*Paul l'Abbé* certainly." Then, I took to *Paul* and made a mess of him. But that was not my fault at all, it was this "everlasting goodness" in cocoa-nut fibre refuse which set up my garden to such a rich pitch that no

*Geranium* can ever again be proved in it as I should like, and it was only yestereen that Mr. Gordon, of the Crystal Palace, seeing how enormously *Paul l'Abbé* put out his arms with me, refused to take it as a gift. But he shall have it yet from what Mr. Thomson says of it. *Madame Vaucher* he has already in the condition which is said to be "as well as can be expected," getting it ready for next season. He said, as Mr. Scott, that he would rather be the raiser of *Helen Lindsay* than of all the bedding *Geraniums* put together, except *Ossian* and *Ratazzi*, the succeder of *Ricasoli* here, as beyond the Alps. But he is a lady's man, and runs after the finest colours as they do, providing they are fast colours, which no amount of sun or rain can impair.

*Christine* was the best of the *Lucia Rosea* breed till last year, now there are two above it, *Mrs. Whitty* in the comparative degree, and *Helen Lindsay* in the superlative degree. You recollect how kindly Mr. Kinghorn sent me *Christine* before it came out, along with his other seedlings for the Experimental Garden; how his man came to my door with the horse and cart to deliver them; how he was astounded at finding a windowsill boxful of it at the time; how Mr. Kinghorn and your humble servant laboured to see if there was a difference between my *Victoria Rose* and his *Christine*, and how we failed; how I cancelled the name and the stock in his favour, and how it was that a monument had been suggested in these pages to commemorate Mr. Kinghorn's best contribution to the flower garden.

Then, the next resolve was to "inoculate" the *Lucia* breed with the crimson and the purple which the original *Nosegay* had infused into other sections of the race, beginning with *Imperial Crimson*. But this had been found an up-hill work. The peculiar soft tint brought in by *Lucia Rosea*, was a pure and undefiled sport of Nature, and resisted for a long time all efforts of inoculation by means of the pollen; the only means, as I take it, for changing and for giving new qualities and new colours to all plants whatever. But, if I were to say in so many plain words, how I got the two colours to mix, the one-half of my readers would say I was daft before they made me so about *Stella*, and the other half of my readers that I was stark mad. So the best thing is to pass over that part, and say the thing is done, and *Mrs. Whitty* is the first instance of it, and you yourself will be the judge in your own instance that the thing is so, for I am amazingly indebted to the authorities at the Crystal Palace, for allowing one of their large circular-beds opposite the railway entrance, to prove this fact next summer.

The bed will be planted with *Mrs. Whitty*, with a broad band of *Christine* all round it, and the edging will be this *Arctotis reptans*, of which you heard so much this season, and which is the newest suggestion.

You will see by these sayings, that in all good gardens, the arrangements for the flower garden for next season are always decided upon before the fall of the year. And knowing all that, if I had not applied for space in time, my product would be sent to one of the annexes, and not one out of a score would go that distance to see, or to be seen.

The superlative in the *Lucia Rosea* strain for this year is *Helen Lindsay*, decidedly the most lady-like flower amongst the races of the bedding branch of the family. It will be out next April or May, and if I should live to see it established in the provinces, the chances are that my head will be turned right round, instead of going daft as for *Stella*.

About *Imperial Crimson*, which Mr. Fish says he can do little good with, and about which he says that with him "it was nothing to what it showed itself at Kensington and the Crystal Palace," the case is this: *Imperial Crimson* was the first plant of the new strain by which we obtained the crimson tint into the new race of *Nosegays* from the oldest *Geranium* we now possess, the *Variagated Geranium*, which Miller describes in his Dictionary as being a chance seedling from the original *Zonale*, or *Horse-shoe* from the Cape. The new race improved at every turn of the cross, and *Stella* was obtained at that stage. Just five years back I discarded *Imperial Crimson* altogether, having had a much better kind of the same stamp, and with the same tint of flower, that kind is *Crimson Minimum*, and is the kind which Mr. Fish had seen at the Crystal Palace, for *Imperial Crimson* was never there, or at Kensington either, for I never thought it worth sending to any of my friends. It was a great step in the right direction at the time, and that was all the good we could expect from the first plant of a new strain.

The best thing Mr. Fish can do with *Imperial Crimson* is to discard it, and get hold of *Crimson Minimum*, which is just as good

for edgings and for small beds as Stella is for large ones. As it happens, I cannot supply Mr. Fish with *Crimson Minimum*, although I am in his debt that way, for I took the last batch of my stock of it up for Mr. Eyles the morning of the Grand International Show, along with one half of my stock of *Cybister*, the other half is gone for a "tumbler" at the Crystal Palace, to vie with *Blondin*.

Now, I have only left me room to tell my last secret. It is this: I said all along that I was only one year before the rest of the breeders, for my best seedlings of one year were out the following season, as is well known to many, and I have heard say that Mr. Banks is only one year in the lead with *Fuchsias*, and so on; but the truth is, Mr. Banks is full three years before any of us in that line, and there is only one man who could come within three years of your humble servant in his strain, and that is my secret, and how it is so is the telling of it. Whoever buys one of my seedlings from me may keep within one year of me in crossing it, but those who buy it of him lose two more years, as, after the hard run at propagation none of the plants is ever worth a rush for crossing for the next two years, and often much more.

D. BEATON.

## ROSES IN AUTUMN.

MESSRS. WOOD & SON, WOODLAND NURSERY, MARESFIELD.

MONDAY, October 6th, was a glorious day—one of those bright and summery ones which on our southern coast chest one into the idea that winter cannot be so nigh as the almanack tells us. The "*L'été de St. Martin*" certainly extends itself to these shores, and much obliged we are to his saintship for compensating us for the "vile north-easters" which frizzle our Rose shoots and congest our lungs in April and May. It was pleasant to sit and whistle along by the sea-coast between Hastings and Pevensey, and see the sunbeams glowing on that glorious sea of which one never tires. It was *not* pleasant to sit at the railway station at Lewes for an hour and a half, although I did manage to liquidate, in fact, a debt I owed to my valued friend the vicar of Caunton. It was pleasant, however, to get "away o'er hill and dale" from the sound of the railway-whistle, to come into bye-roads where the "iron horses" never makes his appearance, to watch the varied hues and tints that were beginning to enrich the foliage—a sort of melancholy joy which tells of winter coming on apace. It was pleasant to be met with a kind and cordial welcome, and to know that a few good hours of an autumnal afternoon were left to one to run over so much of sixty acres as one could master, especially those portions of it devoted to Roses.

Woodlands Nursery is aptly so called, for it lies surrounded on all sides by those "Hursts" which so abound in Sussex, and consequently enjoys good shelter from those terrible winds which with me switch and tear my Roses to pieces. A north-easter is bad enough, but for destruction commend me to a stiff south-wester. There is something so fitful and gusty, it comes so passionately and at the same time without nipping cold, that one feels it to be a cheat that it should treat us so. The lie of the land is very undulating (comprising about sixty acres), and with every variety of soil on a general substratum of sandstone—in one part a stiff clay, in another good strong loam, and then again a good piece of peat for American plants, and even in one part of the grounds white sand. It will be thus seen how advantageous this is for nursery purposes, and that each plant cultivated can have the soil appropriate to it without a necessity for its being made. The nursery has been so long celebrated for its Roses, that one was not surprised to find the great space given to them, and the careful manner in which they are cultivated both in pots and in the open air. One house (the principal one), is 120 feet long and 25 feet wide; and when this is filled as it is with Roses in the spring in full bloom, standards occupying the central space, ample height being given to the house for this purpose, one can imagine what a glorious sight it must be. Other houses are also devoted to them, and a very large number of Teas are grown both in them and in pits.

In talking over the soil for Roses, Mr. Charles Wood said that he felt quite persuaded that it did not answer to grow them in the same soil many years together; and that, consequently, their plan was to shift the Rose-quarter of the garden continually. This, I think, seems now to be pretty generally recognised as true with all flowers. Now, I do not pretend to be a philosopher in the matter of flower-growing, but how is it that in my county

for years and years Hops are grown on the same spot? I know one "garden," on which my grandfather grew Hops fifty years ago, which, to this day, is one of the most productive of the famed Hlop gardens of east Kent, and to tell my uncle, who now has it, that he ought to change the crop would seem to him little short of madness; and yet it seems that in a few years, at least so we are told, gardens become *Verbena-sick*, *Rose-sick*, &c., and require to have the soil changed. "'Tis strange, 't is passing strange." Well, however this may be solved, the plan seems to answer, as may be evidenced by some of the *Curiosities of Rose-growing* which I saw there. Some time ago I had a polite note from Mr. C. Wood, saying he had some extraordinary plants of *Duchess of Norfolk*, which would fully prove how thoroughly justified they were in calling it a good pillar Rose. The history of this Rose, by-the-by, is a curious one. Mons. Margottin, of Bourg-la-Reine, some years ago, in taking Mr. Wood round his garden, said "there is a Rose which we do not think quite full enough to send out, but which we think will come more double in your climate," and gave it to him. Mr. Wood, sen., now a veteran of eighty-two, fancied it; and every year it was propagated, and every year it improved, until, in about six years after they had received it, it had become so fine and of such a vigorous constitution, that they sent it out as *Duchess of Norfolk*, and every season we see it figuring in winning-stands. Well, the plants that I saw, not by ones or twos but by tens, were budded last July twelvemonths on *Celine* stocks, close to the ground; the buds remained dormant, and started this season. They have made a clean, straight shoot of from 10 feet to 12 feet! If that is not a pillar Rose what is? And what fine fellows for tying as pyramids! I have never, in my little Rose-growing experience, seen anything like it, and it only shows what is to be done. Then, again, though perhaps this will not be considered so remarkable, there were *Gloire de Dijon*, budded in July, which had made a clean shoot of 4 feet and 5 feet in length! But the *Duchess* was a beat on them, and, indeed, on anything in its way.

Mr. Wood has found, too, that Teas planted-out in peaty soil make wonderful roots and growth. It has always seemed to me they would answer well in such light stuff, where they could have plenty of encouragement to push their roots. The state of these plants, which had been taken up, potted, and placed in the pits, showed how well it had agreed with them.

There were some remarkably fine standards of the best summer Roses, *Hybrid Bourbons*, *Gallicas*, *Hybrid Chinas*, &c., and these, I was informed, were mainly purchased by Scotch growers, their climate being unfavourable to the second bloom which we expect from *Hybrid Perpetuals*; and so, as they are more vigorous in their growth, they content themselves with summer Roses, and, in truth, some of these are still indispensable. Can we do without *Ohl Kean*, *Charles Lawson*, *Coupe d'Hébé*, and *Boula de Nanteuil* yet in our exhibition stands? No! Let those who have entered the field declare *Hybrid Perpetuals* and *Teas* above all, but in most of them we still find some of this now almost discarded class. We passed *Reine des Violettes* with a smile, remembering how much Mr. Wood had been disappointed in her pretensions; but the fair sex does sometimes do so.

It were needless to go over the very beautiful Roses which were then in bloom of old and well-known varieties; suffice it to say that all the stock was in a beautiful and healthy condition, and sugared well for a good bloom next season.

We had a good chat over the new Roses, and came to very much the same conclusion about them, that there was a vast deal that ought never to have come out, while there were many of decided value. Mr. Wood's plants of them were excellent. *Olivier Delhomme* is a plant of very vigorous habit, the flowers very bright and good, but wonderfully like *Senateur Vaisse*. *Comtesse de Seguer*, a purplish-crimson, is large and double. *Madame Charles Wood* will form, I think, a good show flower, with not quite refinement enough to suit some, but with flowers of great size and substance. *Vicomte Vigier*, another dark crimson Rose, looked well, and *Louise Darzins*, a beautiful white, more robust than *Mademoiselle Bonnair* (which is becoming more and more delicate), is the best of white *Hybrid Perpetuals*.

I did not see but Mr. Wood spoke highly both of Professor Koch and *Nôtre Dame de Fourrieres*, one a rich deep crimson, the other something in the style of *Jeanne d'Arc*, bright rose. We both agreed that amongst the best of the new ones, *François Lacharme* must take a high, if not the very highest place, its bright crimson colour and good build, combining to make it a very attractive Rose. I saw, too, a bloom of a Rose I have not

seen elsewhere—*Souvenir de Lady Eardley*, or *Cardley*, as is wrongly put in some catalogues. It is a brilliant crimson scarlet, extremely rich and velvety, of fine form, with petals of great substance. *Charles Lefebvre* was also of a dazzling crimson scarlet, large and double, of fine form, and is, I think, destined to take a high position in the Roses of this season.

Having had our view of the Roses, the shrubs and other plants with which the nursery is well stocked were visited; and a new piece of land which is about to be taken into cultivation, and a good portion of which will be planted with Briars and Manettis, was inspected. I can imagine what fine maiden plants there will be there. Where are the Briars to come from?

Mr. Wood tells me the woods around there are exhausted, and that they are mainly supplied from the western portion of Kent. What a boon the Manetti has been to us! for although I do not believe so extravagantly in it as some do, there is no doubt it is a first-rate stock, and it has been a most opportune introduction for the Rose-growing world.

Our "out-door amusements" terminated by an inspection of an old Camellia, one which has braved the frost of thirty winters, and is now green and flourishing; and we then had a long chat in-doors over Roses and Rose-growers in France. Lists of the Roses forthcoming this autumn were inspected, and the fact elicited that there are already thirty or forty announced—fewer certainly than last year, but still, perhaps, too many, and as the shades of evening came on, I had to make my way on to Uckfield *en route* to Brighton, and was thus compelled to bring to a close our interesting chat. I shall retain for a long time in my mind the memory of as pleasant a day as I have spent for some time, and of a hospitality and kindness which one now looks upon as almost inseparable from a real lover of flowers, but which I have nowhere experienced more fully than at the plant grounds of the Woodlands Nursery.—D., Deal.

I would use this opportunity in correcting an erratum in my paper on the Hyacinth, arising from a mistake of the printer, in the lists of sorts. The words, "single blue," should have been placed over Charles Dickens, and included those flowers under it, and also Baron Von Tuyl, over which it seems placed in mistake alone.

### THE ARCHERFIELD MUSCAT GRAPE.

I HAVE just read the interesting account of your search for this sort in France, and at once admit that you have excellent reasons for believing that it does not exist there, after finding all the varieties you name merely variations of that peculiar and excellent Grape, Chasselas Musqué. I must, however, candidly confess that your admission of this fact strengthens my opinion that you have not seen the true Muscat de Syrie as exhibited at Lyons in 1860; for how can the description of any one of the sorts named by you tally with that given of the Muscat de Syrie, the berries of which are described as "oval, large, and amber-coloured?" in fact, the terms used by the Congress in describing this Grape are exactly the same as are employed in describing the Muscat of Alexandria, the berries of which are described as oval, large, and amber-coloured. The difference in the two sorts is, that in the former the bunch is described as "serré"—i. e., crowded; and in the latter "très peu serré"—i. e., but little crowded. Now this, as you know, is a very accurate description of the Muscat of Alexandria, and I therefore assume that the Muscat de Syrie is correctly described. The great difference between the two sorts is, however, the time of ripening. The former, according to the report of the Congress, ripens in the south of France the end of September and October, the latter at the same time as the Royal Muscadine, which would be about six weeks before the Muscat of Alexandria.

I place a full reliance on the report of the Congress, for, as you well know, men meet at such places to find out the truth, and to make a true report.

I am not surprised to find that you made fruitless inquiries among the French pomologists at Montpellier, about this Grape, for I have always found such a peculiar "insouciance" (to use their own term) among French amateurs, as to what has taken place even in a neighbour's garden, and they seem in a very short time to forget and think old and out of date every flower and fruit that may have been exhibited a year or two since. It is something new, no matter whether in name only, that attracts their attention.

That there is a large, oval, amber-coloured, early Muscat Grape differing in all respects from the Chasselas Musqué race,

we must take as an established fact, and this sort we must introduce to the Chiswick gardens to be compared with the Archerfield Muscat.

I may remark that the descriptions of the well-known varieties of Grape given in the report from which I have quoted, are remarkably correct, and I may add that my Vines received from France under the name of Muscat du Puy-de-Dôme or Muscat de Patras, differ most remarkably in their foliage and habit from Muscat Eugénien.—T. R.

### AIR-ROOTS ON VINE STEMS.

SOME time ago I observed in THE JOURNAL OF HORTICULTURE some remarks of Mr. Fish on the probable treatment which Vines receive to induce them to produce air-roots along their stems. My object in writing the following is not to give my own opinion, but merely to relate a few instances of where I have seen them most abundant, and the circumstances under which the Vines were placed.

I was some time ago in the habit of visiting a garden, the houses of which were low flat-roofed lean-to's, and their floors from 2 feet to 3 feet below the level of the surrounding ground. In the two early vineries were pits filled with fermenting material in order to produce a constant vapour, and induce the buds to burst more regularly. The Vines were planted in an outside border, and trained one rod to a rafter. They had large dark green foliage, bunches large and well proportioned, but the berries did not colour well, and there were some few instances of their shanking. At every spur of these Vines were large tufts of air-roots hanging like goats' beards, only much stronger, and not less than 6 inches in length. Had there not been a few instances of the berries shanking, the want of colour might have been attributed to the want of light, as the interior of these vineries had a very dark and sombre appearance, owing to the large foliage of the Vines, increased by the enormous quantity of air-roots.

I have sometimes observed these air-roots on Vines, although not to the same extent as the above, where they had been early forced and heavily cropped, and their roots dragging out a miserable existence in a cold, wet, deep border, and the inside temperature ranging from 60° to 70° in the cold short days of January and February. The Vines were syringed twice a-day with tepid water, and occasionally water was sprinkled on the flues and passages, but not to that extent to produce what is called a saturated or over-moist atmosphere.

I have also observed some Vines have a tendency to produce air-roots, while others in the same house, and having precisely the same treatment, have their stems as free from air-roots as a walking-stick, which is a proof that some Vines more than others have a tendency to produce air-roots; but the reason why such should be the case I must leave to older and wiser heads than my own.—T. R.

### ROSES FOR THE SEA-COAST.

E. C. will feel obliged if the Editors will inform her what Roses would be likely to succeed best near the sea on the Cheshire coast. The garden is tolerably sheltered, but the high winds of the spring and autumn must be felt by them.

E. C. wishes for the names of the most hardy Hybrid Perpetuals, and any other suggestion that can be given to insure a good bloom in the autumn.

[In your part of the Cheshire coast you ought not to grow Roses on standards, for two reasons—there are strong gales from the sea, and your soil is too light for the Dog Rose stocks. Such a soil grows Roses by fits and starts, being very moist at times, and too dry in the height of the growing season, causing the leaves to get dry and dark, in blotches, by the end of June. The sea air is not injurious to Roses, for they grow as well in the Hebrides, Stornaway, for instance, as they do about London. What you really require is a selection of free, strong-growing Roses, but not rambling growers, all on their own roots, and we have made the following selection on purpose for this very consideration, whether the Roses are to reside on the coast, and anywhere inland. There is not a dwarf, nor a puny grower in the list, nor yet a Rambler. (Those marked with \* make the longest growths.) 1, Anna Alexief; 2, Anna de Diesbach; 3, Baronne Hallez; \*4, Baronne Prevost; 5, Belle de Bourg-la-Reine; 6, Caroline de Sansal; 7, Comtesse Cecile de Cha-

brillant; 8, Due de Rohan; 9, Duchesse of Norfolk; 10, Empereur de Maroc; 11, Evêque de Nîmes; 12, Géant des Batailles; 13, Général Jacqueminot; \*14, General Washington; 15, Gloire de Santenay; \*16, Jules Margottin; \*17, Lord Raglan; 18, Louis XIV.; 19, Madam Boll; 20, Madame Charles Crapelet; 21, Madame Furtado; 22, Madame Vidot; 23, Sénateur Vaisse; 24, Triomphe de Lyona.

The way to manage this class of first-rate kinds would be to cut them down rather close the first two years, or until you had three, or four, or more strong, healthy shoots from the very bottom, so that they would not readily get hide-bound by any sudden check. After that to be very sparing in the winter pruning, but to thin-out the plants well in summer, after the first bloom is over.]

## THE INTERNATIONAL EXHIBITION OF THE ROYAL HORTICULTURAL SOCIETY.

In resuming our account of this great Exhibition, we must, in the first instance, notice some of the fruit shown in the Miscellaneous Class. To Messrs. Lane & Son's magnificent pot Vines, loaded with large and handsome bunches, we have already alluded; but there were several other exhibitions which for want of space we were under the necessity of passing over. From Mr. Meredith, of Garston, there came a collection of twelve bunches of finely-grown Grapes of different varieties, for which he received a first prize. Among them were included a splendid bunch of Muscat Hamburg, Black Barbarossa also very fine, and excellent bunches of Kempsey Alicante, Lady Downe's Seedling, Black Prince, and Nixon's Seedling. M. Chantrier, of Paris, had some remarkably fine Pears, most of which were of much larger size and higher colour than the same kinds grown in this country; and his fruits of Beurré Clairgeau, and Beurré d'Arenberg in particular, were magnificent. He well deserved the equal first prize which was given him, and a similar award was also made to Mr. Young, gardener, to W. H. Stone, Esq., Havant, for a basket containing ten handsomely-grown Pines, a number which but few gardeners in this country could cut at one time.

Mr. Moore, Redland Lodge, Bristol, had also a basket containing six Queens. R. Webb, Esq., of Culham House, Reading, sent several kinds of Nut, some being of his own raising, such as Daviana, raised from the Cosford, Emperor, Webb's Cob Filbert, an improved form of Cob, and Close Hudd, said to be very prolific, growing in clusters of eight or more. In addition to these the Cosford, White Spanish, and Scarlet Filbert were also shown by the same gentleman, the collection receiving a third prize.

Mr. Snow, gardener to Countess Cowper, Wrest Park, to show the comparative hardness of his Muscat Hamburg, exhibited a bunch grown on a pot Vine, in a late vinery without fire heat, and it was well coloured, and, as far as could be judged from appearance, quite ripe. Good exhibitions of Grapes also came from Mr. Tillery and Mr. Bwyne, some excellent Morello Cherries from Mr. Tillyard, and Damsons from Mr. Hall, gardener to Captain Tyrrell, Ealing.

A fruit rarely seen at horticultural exhibitions was exhibited by Mr. Flower, of Stratford-on-Avon, being *Musa Cavendishii*, which was so successfully grown at Chatsworth some years ago, and at some other places, but which is seldom now seen. The fruit-spike was well furnished with the Banana-like fruits, but these were far from ripe.

F. J. Graham, Esq., of Cranford, exhibited Graham's Bergamot, a variety which is supposed to have sprung from the Winter Nelis. It is said to be very prolific, bearing in clusters of twenty and upwards in favourable seasons, and to be rich in flavour, ripening in the beginning of October. In shape it is like the Autumn Bergamot, but longer; and the skin is dark green and russeted, becoming of a pale cinnamon when ripe. It is much heavier than the Autumn Bergamot, two fruits weighing more than six of the latter. It received a first-class certificate.

A seedling Apple, very like the Golden Noble, came from Mr. Reed, of Sydenham Hill; and from Mr. Jesse Thomas, six unnamed seedlings, all of which are said to be great bearers.

The Derby Local Committee forwarded a numerous collection of Apples and Pears, including many of the newer and less-known kinds, as well as some probably of local origin. They were generally fair specimens for the climate in which they were

grown; Beurré de Capiaumont and Louise Bonne of Jersey were of good size; Duchesse d'Angoulême, not so good Autumn Bergamot was small, but highly coloured; and to Gansel's Bergamot, the same remark is equally applicable. Both Blenheim and Ribston Pippin were good. It would be very desirable if the other Local Committees of the Society would on future occasions follow the example set them by that at Derby; for the leading varieties being collected from all parts of the country, the adaptabilities of each, as regards climate, could then be determined, as well as the differences in appearance and flavour which occur in certain kinds when grown in different soils and localities.

From Mr. G. Lee, of Clevedon, Somersetshire, there came several good specimens of Apples, among which were some fine Alexanders, and about forty kinds of Pears, mostly of large size. We particularly noticed some very large and well-grown fruit of Calabasse Grosse, Chaptal (an excellent stewing Pear in use at the same time as the Catillac), and some very large King Edward's Pears. Captain R. Trevor Clarke had a Queen Pine Apple grown near Weedon in a heated border in the open air, being the fruit of a premature sucker turned out early in June; and he has found that with plenty of heating material beneath them, plants so treated make roots and suckers freely. The Pine in question was remarkably heavy for its size, probably weighing about 3 lbs., but of course it was only partially coloured.

Of foreign fruit there was also a large display, the most extensive collection coming from Burdin, Maggioro, & Co., of Turin, who contributed 322 kinds of Grapes, 170 of Pears, and 91 of Apples. The Grapes were chiefly those adapted to vineyard culture, and of small size, and they did not appear to present anything superior to what we already possess. Among the Pears we observed good fruit of several of the new Belgian kinds; on the other hand there were such as Messire Jean, Blanquet d'Hiver, and others which, at least in this country, are worthless.

M. Grégoire Nelis, of Jodoigne, had a numerous collection of Pears, including many new seedlings of his own raising, among which some are likely to prove acquisitions; as yet, however, there are only a few named, the rest being distinguished by numbers. We happened to be present when some of them were tasted, and found that one variety, marked as 17, and which, in outward appearance, bore considerable resemblance to Marie Louise, was considered very good, possessing an abundance of juice; another, 27, was also very juicy and refreshing. Of other varieties, Colmar d'Arenberg was of large size; Calabasse Grosse, likewise large; Uvedale's St. Germain, also of good size, and more yellow than in English fruit; Duchesse d'Angoulême, fine; Beurré Clairgeau, small, and only slightly tinged with red next the sun, whilst many of the English fruit of that variety which were exhibited were not only much larger, but of higher colour; Bergamotte Louvain was a large fine-looking Pear resembling the Gilgil, and bronzy red next the sun; Joséphine Bouvier was a very large fruit of a greenish-yellow colour, and much russeted near the base, but apparently not ripe. We also noticed a large Pear like Calabasse Grosse, but larger; Duchesse d'Orleans appeared to be also a promising sort.

The Horticultural Society of Namur contributed upwards of 200 kinds of Pears, and more than 80 sorts of Apples. Among the latter, Belle du Bois appeared the same as another large Apple under the name of Bedfordshire Foundling; Reioette Grise was very fine; Court-Pendu Plat and Barcelona Pearmain were also good. Of the Pears, Colmar d'Arenberg was very large; Fondante de Noël was remarkable for having a showy bright red cheek; Beurré Diel, under the name of Beurré Incomparable, was of good size, and so was Van Mons-Léon-le-Clerc, Doyenné Comice d'Angers being also very large. The whole of this collection, however, having been previously exhibited at Namur, had suffered considerably from that cause as well as in the carriage.

M. Borchers, of the Royal Gardens, Herrenhausen, Hanover, exhibited 173 sorts of Apples, and 78 of Pears, the whole of the fruit beautifully coloured; indeed, many of the varieties were those cultivated for their beautiful appearance—such as Agatappel rother, Marienapfel schöner, which was yellow in the shade and intense crimson on the sunny side; and Reioette rothe Maus, with a beautiful dark crimson cheek. The Apples, 109 in number, from M. Konzelman, of Wurtemberg, were also very showy, including fruit of many of the best varieties grown in this country. Extensive collections of Apples were also exhibited by M. Müller, Straubourg; M. Jahn, Meiningen; and C. Van

de Putte, Middleburg, who had also 75 varieties of Pears, among which were Beurré Clairgeau, very handsome; Passe Colmar, very small; and Alexandre Lambré, large. Spanish Bon Chrétien was shown as Beau Présent d'Artois, Catillac as Grate Mogul; and another name, Lob den Cours, we may state, to save learned research and profound speculations, was meant for Shobden Court.

Sweden brought forward a very good exhibition of fruit and vegetables, considering the northern latitudes in which they were produced. Among the Apples we observed Red Winter Calville and the Red Astrachan, rather smaller than when grown here; and Alexander and Gravenstein were of good size; and an Apple unnamed was the true Golden Pippin, and another the Court of Wick. The Pears were generally small, not apparently attaining the same degree of perfection as the Apple. We noticed the Swan's Egg and Autumn Bergamot in their number, and a branch of a kind called Monille Bouche, with eighteen fruit in a foot in length. The fruit bore a striking resemblance to and was probably identical with the Achan which is so common in Scotland, where it is considered excellent though found to be worthless farther south. Bonne Rouge was a small Gansel's Bergamot. Jefferson and Green Gage Plums of good size were also shown, as well as some very good well-ripened Oranges, and Black Hamburg and Royal Muscadine Grapes, both bunches and berries being of tolerable size. Of Potatoes there were 92 sorts, the tubers being generally small, but in some cases they were as large as ordinary Potatoes of English growth. The Carrots from Stockholm were, both red and white, of fair size, the Early Short Horn being the best; and some tolerable Musselburgh Leeks were exhibited. The Kohl Rabi, from Stockholm, was not only large but solid; but what struck us most was some good roots of the true Red Castlenaudary Beet, grown in Lapland, in lat. N. 64° 59'; the Kohl Rabi from the same inhospitable climate was of fair size, but the Carrota small.

Norway contributed fruit as well as vegetables from as far north as latitude 63° N.; and this will not be so much a matter of surprise when it is considered, that though the sun may not be so powerful as farther south, he shines for a much longer time in summer days, whilst the gulf stream passing along the coast prevents the temperature falling so low in spring as might be supposed. The fruit consisted of Gravenstein, Ribston Pippin, Requette du Canada, and some other Apples, and Autumn Bergamot Pears. Of course the fruit was small, but it appeared perfect.

Among the vegetables there were very good blood-red Onions, some excellent red Beet, Kohl Rabi, Swedish and Globe Turnips, pretty fair Altrincham Carrots, and Parsnips. A case of well-grown cobs of Maize, containing several very ornamental varieties, was also shown by Dr. Schübler, of Christiania.

Denmark sent Seckle, Flemish Beauty, Easter Beurré, and some other Pears, and a few Apples, among which were the Gravenstein and Borsdorffer, which seem to succeed well, and to be the favourite kinds in the north of Europe; sixty kinds of Potatoes, some very nice White Belgian, and Short Horn Carrots, Celeriac, Yellow Malta, and Yellow Finland Turnips, together with a sort called the Long Yellow Borsfield, almost exactly the shape of a Carrot, and for which without seeing the leaves, it might easily be mistaken. Some roots of the Large-rooted Parsley were very large, and the Blood-red and Spanish Onions were excellent.

Hamburg and Altona exhibited some very fine Apples like the Nelson Codlin; good Chaumontel, Louise Bonne of Jersey, and Duchesse d'Angoulême Pears. The Alexander and Prinzen Apples were very fine. Dutch Mignonne was shown as Requette d'Or. The Vegetables consisted of excellent Onions, Carrots, Cabbage, Beet, and Mangold Wurtzel, Kohl Rabi, upwards of eighty sorts of Potatoes, a good collection of ornamental Gourds, and a few eatable ones.

Victoria, Tasmania, and British Guiana, sent the models of fruits exhibited in the International Exhibition, the two former also contributing their excellent samples of cereal produce.

Of the remaining portion of the Exhibition, the Gourds, from their endless diversity in size, form, and colour, were that which excited the most general interest on the part of the public. It would, however, be a Herculean task to describe the various modifications which were exhibited. Some were as much as a man could lift, others were no larger than a small green Gooseberry, with a prickly appearance; some were smooth, others caruncled all over; some resembled bottle, others tubes, and others, again, serpents. Then there were Pear-shaped and

Apple-shaped varieties, sorts like Oranges, and sorts like Turnips, self-coloured and striped kinds, orange, yellow, and green, and mixtures of all three.

The largest eatable Gourd was the Mammoth, from Mr. Fryer, Chatteris, which weighed 176 lbs., and was an extraordinary and well-grown example of the kind; one from Mr. Rowe, gardener to Mrs. Nicholl, Watford, weighed 120 lbs., and another 103 lbs.; whilst the Potiron Jaune from the Society's Garden, was about two pounds lighter. Messrs. Veitch had the heaviest Gourd of foreign growth, a handsome Mammoth, weighing 154 lbs.

It must, however, be remembered, that large as these weights appear, much heavier have been grown in this country, one having been produced some years at Sutcombe, in Devonshire, weighing 245 lbs.; whilst in favourable seasons 120 lbs. is not uncommon. Making allowance for the unfavourable character of the past summer, it cannot but be concluded that the weights attained were highly creditable for the first competition which has as yet taken place in this tribe.

The finest collections of Gourds eatable when ripe, came from Mr. E. Stuart, Nice, in the foreign class, and Mr. Cattell, of Westerham, in the English; the latter having about 140 kinds. M. Limclette, of Namur, had likewise a beautiful collection, among which we noticed some excellent Pâtissons of various kinds; but the Bottle varieties we should suppose were intended to belong to some other class, at least we should be sorry to eat them at any time. Several other kinds came from the same exhibitor, such as Cucurbita leucantha longifera, the Syphon, and the Powder Flask—a large green mottled variety related to the Bottle kinds, and only eaten when young. The Cyprus Gourd, a large yellow and green kind, is said to be very good. The green and white Spanish Pumpkins are also large and excellent kinds. The Turban Gourds, though sometimes eaten, may be regarded as ornamental rather than useful varieties.

The most extensive collection of ornamental kinds was that from Mr. Cramb, gardener to the Earl of Ducie, Tortworth Court, and it included about 150 sorts. Messrs. Veitch had a hundred or more, among which were a great variety of pear-shaped and apple-shaped varieties, Turbans, Turk's Caps, Fireball (a large dark green and red kind, 10 inches or a foot in diameter), and Argora (dark green striped with white and mottled with light green). Mr. Fleming, of Cliveden, had Potiron Jaune of good size, and about 70 other sorts; one of which, called Nugget, was all over warts, its exterior presenting somewhat of the appearance of a cob of Indian corn. Extensive collections likewise came from Mr. Tillery, of Welbeck, and Mr. Pragnell, Sherborne Castle; whilst Mr. E. Stuart, of Nice, had a fine specimen of Cucurbita leucantha upwards of 4 feet in length, and of the Wax Gourd, Benincasa cerifera, the green surface of which is covered with a waxy bloom, a long Snake Gourd, and some others. In the Class for six ornamental varieties Mr. Stuart was first with an orange and yellow-striped sort of the Turban breed; an oval dark green kind striped with lighter green, and four others; but the whole having no names attached, it would be needless to describe them. Mr. A. Ingram, of Reading, showed Mammoth, Turban, Valparaiso, an Improved Mammoth, and pear-shaped kinds; and good exhibitions also came from Mr. Higgs, Mr. Tillery, and some others. The best and the most really useful collection of Gourds was that from the Society's garden, which included more than 150 kinds, all of which were legibly labelled with their names, a point too generally neglected by the other exhibitors, and to which attention should in all cases be made imperative, and particularly in exhibitions like this where foreigners, who cannot be supposed to be conversant with our productions, come to see and learn.

There was a very good show of roots and vegetables, which were generally creditable, without, however, presenting anything remarkable. The Potatoes in particular were very good, and appeared free from disease. The largest collection came from Mr. Farquhar, gardener to Colonel Gordon, Fyol Castle, Aberdeenshire; it comprised 118 sorts, and would doubtless have received an award had it arrived in time. We may observe that from exposure to light the Potatoes exhibited rapidly greened—a hint to those keeping Potatoes to seclude them from the light—Messrs. Ivery & Son, of Dorking, had some excellent roots of Dioscorea batatas from 12 inches to 16 inches in length. We also noticed an Egg Plant, from Mr. Standish, the fruit of which was about 5 inches long and 4 inches in diameter, violet purple and yellowish-white, but not ripe. It was brought from Pekin by Mr. Fortune; and when subjected to cultivation for size will no doubt produce much larger fruit.

We must not conclude our account without noticing Messrs. Sutton's stall, to the general appearance of which we have previously alluded. Besides Gourds, of which there was an excellent show, the various roots were remarkably fine, particularly the Mangold and the Turnips. Of the former there were fine roots of the Orange Globe, Long Yellow, and Red Intermediate. Of the Turnips, Gray Stone, Dale's Hybrid, White Globe, and Sutton's Green Top Hybrid appear among the best. Of Swedes, the Champion is very globular, solid, and sweet; and the Kohl Rabi, both purple and green, was also remarkably fine. Onions, both Reading and Blood-red, were equally good; and among Parsnips, one called "The Student," raised from the wild Parsnip by Professor Buckman, is said to be of fine flavour. Of Potatoes upwards of a score of varieties were shown, and of these Early Racehorse is said to be a very early kind, and Daw's Matchless to be very productive. About 150 specimens of ornamental and useful Grasses were exhibited, and 60 kinds of seed, among which were some very fine samples of *Anthoxanthum odoratum*, *Festucas*, *Cynosurus*, and *Clovers*. Two large Cabbages of a kind called Robinson's Champion, from Mr. Robinson, of Shaw House, Melbourne, Derbyshire, found a place here. One of these was 56 inches or 57 inches round and perfectly solid.

In closing our remarks on this Exhibition, we cannot but express a hope that similar international displays, which are calculated alike for the advancement of British and foreign horticulture, may be held at least once in three years; and the experience gained on this occasion will, doubtless, enable the Society to render such shows even more interesting and instructive than that which has just been closed. We have only to add, that the arrangements of Mr. Eyles were admirable.

### HELICHRYSUMS.

I PURCHASED seed of these in spring from a celebrated London establishment, and they are truly beautiful, some of them very large, and quite as double as a Pompon Chrysanthemum; the only fault is their unsightly habit of growth. The general run of them are much too tall: cannot they be dwarfed? Scarcely anything is impossible in the hands of our skilful hybridisers. By careful sowing of seed from the dwarfest and most freely flowering kinds from year to year something might be effected in this way. For a late-autumn bed we have scarcely anything to equal them in the way of annuals. For bouquet purposes in winter they are invaluable, as well as for making table bouquets when bloom is an object. I only wonder they are not more extensively grown. Give me a kind distinct in colour, about 8 inches high, good habit, and a profuse bloomer, and I, for one, will employ it for bedding purposes.—JOHN EDLINGTON, *Crom Castle*.

[Quite true, and as you have put your hand to the plough, you can draw the furrows so straight, you are just the most likely man between London and Crom Castle to do that which you want the hybridisers to do for you. But hybridising being the crossing of distinct species the one with the other, will never do the smallest good with these Everlastings. You must do them by cross-breeding in-and-in. Recollect to gather two or three large bunches of cut flowers, just before they open, of every batch of your seedlings; dry them in the shade, and use them for table and drawing-room decoration in the winter, when fresh flowers are few and difficult to procure.]

### ESTABLISHING AN EVERGREEN HEDGE.

I HAVE in my garden a worn-out hedge of Holly, Laurel, and Bay. Some of the shrubs are dead, and others worn out. I propose to grub this up, and beg to ask your advice about planting another of Yew, or Arbor Vitæ, about 80 feet long and 5 feet high. Which will be the best and grow quickest? Will the ground require much preparation? If three-foot-high plants are used will they soon grow up? How many ought I to have for the length of 80 feet?—A SUBSCRIBER.

[For good appearance, or for shelter, or as a blind, Arbor Vitæ is as good a hedge as any, and is the cheapest, and the easiest obtained of all our hedge plants; but it is not so good as Holly and Yew against cattle. Inside a garden it is the least hurtful hedge to anything near it, and it would grow luxuriantly in soil that would starve a Thorn hedge, and in your

case it will be the best succession to the old Hollies, Laurels, and Bays. The roots of Laurels, however, are as bad as any poison, if any of them are left in the ground. Therefore, take good heed that every morsel of the Laurel roots, at all events, and all the other roots, if you can, are taken out, and that will be a sufficient preparation for the new hedge of Arbor Vitæ; but you should plant it in fresh surface soil, and should not use plants under 3 feet high; but 4 feet high is the right size to make a five-foot-high hedge in two years, or at the very farthest in three years. At 3 feet high the plants should stand apart 18 inches from centre to centre, and 4 feet high the plants should be 1 foot 9 inches centre from centre.]

### REMINISCENCES OF DRUMLANRIG PARK AND GARDENS.

FEW noblemen, either in England or Scotland, have contributed more to the success of gardening than the noble house of Buccleuch and Queensberry. Dalkeith Palace and Drumlanrig Castle have been long celebrated as two of the principal seats of first-class gardening in this country; the former especially for its fruit and forcing departments; the latter for its varied landscape and extensive flower gardens; while each of them at the present day appears to have an unlimited supply of all that a gardener requires. All energetic gardeners who estimate their profession aright—not to speak of enthusiastic amateurs, who have an uncontrollable delight and pleasure in seeing the art elevated to the highest degree—lose no opportunity of visiting and inspecting all such places, with the view of estimating and comparing what to adopt, and what to avoid. And there is as much to be learned the one way as the other, in so far as they are more immediately concerned. But it has a tendency to do a great deal more than this, it quickens the perceptions, strengthens the intellect, and imparts a stability to the character and conclusions of a man which is at all times to be admired. Such a person is no victim to prejudice in his own opinions and practice, but, on the contrary, is ever ready and open to conviction, if pressed home clearly to his mind.

It was in one of these beautiful autumnal days of September, remarkable as being one of the finest months of the whole season, when Sol rose in a hazy, humid-like atmosphere, and gathering strength in his onward course dispersed the misty clouds into space, and shone forth in all his regal splendour, that the writer, in company with another companion, dropped in, *vid* Thorhill, to see Drumlanrig Gardens.

We could not help admiring the clean appearance of this picturesque village in the general landscape, very much more enhanced by having broad streets, and a straight line of Limes on either side the cross-roads, of considerable length, planted like the Boulevards, Paris. Crossing the river Nith, we enter by a simple gateway into, and along, a spacious drive exceedingly well kept, with broad grass margins and Thorn hedges, defining the boundary of the woods on the rising ground to the left, and of the splendid pasture, where numerous cattle were browsing, to the right. Onwards we speed admiring the variety of scenery all along the fertile valley in the foreground, in the lowest part of which the Nith meanders, and away in the far background the diversity of hill and dale now rugged and pointed, indicative of barren slopes, and again clad in patches of golden hue, where the hand and head of the agriculturist had been busily engaged reclaiming. We pass, what we learned was the home farm, and a few minutes more we sight the kitchen garden on the right in a hollow square, and on the left a spacious Gothic building, high up on the rising ground, with a lovely steep grassy bank receding therefrom to the spot where we alighted. We were quite as pleased as surprised to find that this was the head gardener's residence, and is only another proof, in fact one of the most convincing, of the value which the noble owner attaches to the head of this department, and to the profession generally.

Finding that Mr. McIntosh had gone to the flower garden, we directed our course thither, passing through pleasure grounds in the highest order of keeping, planted with a goodly number of deciduous trees and evergreen bushes, and the spacious walk so designed as to command now and again extensive views of the surrounding country. There is, seemingly, a great want in this extensive demesne; at least, in so far as came under our own observation, of aged trees. The greater part of those noble representatives of the forest are diminutive in size, and, therefore, lack that venerable and stately appearance which a com-

mination of them always present in the true English landscape. In fact, we are not sure if this part of Dumfriesshire is altogether suited for maintaining that vigour requisite towards promoting a green old age in forest specimens, and the reason why it may be argued so, is, that there appeared to be a superabundance of lichen, that most insidious parasite, overgrowing the trunks and even branchlets of many of the best examples in these pleasure grounds. This remark, however, does not apply to the evergreens, which are luxuriating in the greatest profusion wherever they appear.

After having travelled a good half mile from the kitchen gardens, and noting with an eye of satisfaction the beautiful and broken ranges of hills lying in the far background for three-parts of a circle, to be seen from mere than one stand-point in the route, we dip into a leafy glen, and come upon numerous bushes profusely clad with scarlet berries, giving a character of individuality and gorgeousness which singled them out as one of the most important features of flower-garden decoration we ever saw. This is a ladies' bush out and out, for the titled ladies of the Castle besides using these clusters of berries for all sorts of indoor decoration, deck their hair with the fruit of *Berberis vulgaris*, for this is the identical bush which tradition sets down as being grown in quantities in the hedgerows of England some centuries ago, but banished owing to the foolish, we should say, notion at that time, of "its presence being injurious to the growth of corn."

Another half mile brings us within the precincts of the dress flower garden, and confronts us with the castellated mansion. To do justice to these and to the large kitchen and forcing gardens, besides other adjuncts in connection with this princely establishment, would fill a respectable-sized volume. We shall be content at present in dealing with them in an abstract way, jotting down the general features of the establishment, and detailing anything which particularly took our fancy.

At first sight in coming within the area of the flower garden proper, we anticipated from the impressions conveyed to our mind by those who had gone before us, that it would be of much greater extent; although, be it understood, that it is much larger than any other one that ever came within the range of our observations. Nay more, be it credited, that from the rising character of the ground the series of terraces that necessarily pervade the whole design from the altitude of the ground on which the Castle is built, it is very much larger than it actually appears from the level where we first took our estimate. Again, the landscape gardener from the very nature of the architectural design of this Græco-Gothic building, was compelled to adopt as much of the true English landscape as possible, to correspond with the bronial nature of the residence. It is one of that sort of massive square buildings, having four turrets at right angles, which must be characterised more for beauty of outline and symmetry in all its principal parts, than for any claim to what architects would call æsthetic grandeur. Its position is commanding. The terraces that recede from it are all that could be desired in design and finish, and the flower garden in the blocks below could not positively be seen to better advantage, whether as regards the disposition and form of the beds, or the material with which they are composed.

Taking one's stand then on the highest of the series of terraces immediately contiguous to the south front of the Castle, the scene is one of great beauty, and testifies with far greater power than any verbiage, however powerful, what has been and can be achieved by the landscape gardener, in exchanging natural for artistic beauty, and at the same time blending and rendering the one subsidiary to the other's wants without destroying the reformed landscape.

A broad terrace of grass and a twenty-four-foot gravel-walk run parallel to one another for nearly a quarter of a mile along this front, and both on the east and west side is a chain-border centred with yellow *Calceolarias* and Flower of the Day Geranium, and the outer margin of the design planted with Miss Trotter Verbena. A counterpart of this is on the east side with the margin planted with "Lady Victoria Scott." Both were densely bloomed, much better so than we have seen them elsewhere this season. As we saw them they looked remarkably artistic, owing to the white-sanded walks being nearly on a level with the flowers. The whole of the series of terraced flower gardens were densely in bloom, and standing as we were some 20 feet above the highest of them, and as much more above the lowest, they required to be so to give them a decided effect. The designs were various, and the materials with which they were

filled were as varied. Here was a panel of native Heath, like an immense oblong piece of embroidery, set into grass and relieved with silver white sand. Close beside it is a very chaste design with an elliptic centre, and four circles cross-cornerways surrounded with a handsome curb stone, and filled with yellow, scarlet, variegated, and blue, as represented by *Calceolarias*, Geraniums both plain and variegated, Verbenas in scarlet and purple, and *Lobelias*, intended for speciosa, from seed but not true to name. Farther down again we have designs in scrolls and almost every conceivable form all as full of flower as any one could wish. *Gazania*-beds were as full of flower as their compeers, and as such make most effective beds. Verbenas *Tweediana* and Lord Raglan, were each conspicuous among their fellows, so was Purple King, worthy of its name. *Perilla* looked exceedingly well, so did Flower of the Day. Mangles' Variegated and Trentham Scarlet Geraniums maintain their superiority among a host of incomers. There was no tint of blue equal to *Nemophila insignis*, and no golden yellow equal to *Leptosiphon aureus* for a blaze; neither was there any *Pentstemon* so very effective in masses as it was grown here, as *Tynninghami*. Then, commingled with these in the lower grassy parterre are clumps of *Rhododendrons*, and all sorts of American shrubs, bordered with *Cotoneaster*, *Yews*, &c., all disposed so as to have a good effect; while the banks sloping upwards to the high ground on the west side is one mass of Laurels cut to run on the same slope as the grassy terraces, and terminating in the woods which form an amphitheatre-like sweep all round the north-west.

We cannot enter into details about the Horse-Chestnut avenue and the rosery, the greenhouse, and pits all contiguous thereto. Nor can we even descant upon the great variety of rustic houses that is to be seen in going round. We cannot even touch upon the carriage drives that diverge from the mansion; nor look into the rocky and rookery. One word we have to say before leaving for the kitchen gardens. There is a complete absence of statuary, there are no fountains, and the only representation of the kind is a few seats of Peterhead granite. It would be impossible to suppose a place in a higher order of keeping. It was a pleasure too, to see his Grace taking a lively interest in the disposition of some fine *Arbor Vitas* which Mr. McIntosh was transplanting.

The kitchen garden lies very low, so low in fact, that when the Nith overflows its banks the drains get completely choked up. Between the garden wall and the drive already noticed, is a mixed herbaceous flower garden containing an assortment of many choice plants, and interspersed with *Dahlias*, *Hollyhocks*, and such like. Here the *Roses* were blooming magnificently, the foliage being in the very best of health, and large, fine-formed blooms from these glorious Hybrid Perpetuals, which find so much favour. Here are, also, the finest groups of *Carnations* that the writer ever saw. For health and vigour, both of blooms and of young grass, they are very remarkable. We were amused with seeing the circular mounds round the layers all covered with river stones, and on asking the reason, Mr. McIntosh informed us that the birds were so troublesome with scraping down the mounds, that he used it as a precautionary and preventive measure, and he found that it was not only effective in this respect, but from their being good conductors of both heat and moisture, the plants luxuriated much better. *Gladioluses* were also in fine feather, and *Brenchleyensis*, in groups, were very effective, so was also that gorgeous decorative plant, *Tritoma uvaria*.

Entering within the walls we confronted a range of forcing-houses, with the borders in front of them planted with several varieties of variegated Geraniums, all in fine foliage and profuse bloom. *Bijou* was, undoubtedly, one of the best, then *Countess of Warwick*, Flower of Spring, and Silver Queen, the latter positively a gem of the first water, having elegant foliage, and a fine light shade of rose flowers. Among Verbenas, where numerous varieties were on trial, we noted as the very finest scarlet having a large truss and distinct eye, *Foxhunter*, positively grand, only rather sprawling in habit, I am afraid. Then there was *Firefly*, also a first-rate one, with a less vigorous habit, and less every way. *Ariosto Improved* is the best of the new shades of purple, and will make an effective bed. There was a very good dwarf *Calceolaria* named *Canariensis*.

We had then a peep into the Pine-houses which are extensive. Pines were extra fine, a whole house of them containing not less than eighty fruit was all at the ripening-point. Sixteen had been cut and presented away the day previous to our visit, and

there could not be less than fifty to cut. Many of them would weigh 4 lbs., and all were nearly uniform in size. These were Queens. The latter and Smooth Cayennes are chiefly grown in this establishment. Another house, scarcely a fortnight behind these noted, also contained fine fruit. There were some very fine samples of the Hurst House variety swelling-off large fruit. In a word the whole of the Pines were in excellent health.

Cucumbers and Melons had each a house for themselves, bore fine crops and large individual samples. Among the former we noted Henderson's Champion, Turner's Favourite, Robinson's Black Spine, Kenyon's Favourite, Munro's Rabley, an exceedingly beautiful variety and very large; and Spary's Prize, which Mr. McIntosh has grown here and elsewhere for a period of thirty-eight years.

Then there was a house devoted to Figs, and a good plant of *Psidium Cattleianum* in fine fruit. Another house, some 30 feet or 40 feet long, was completely filled with *Passiflora edulis* hanging as thick as what would be considered a good crop of Peaches, with its rich oval-shaped fruit—quite a sight of itself. Then there were several houses of Grapes, some 100 feet long in all, corresponding with the same length of Peaches in the principal range. In this range also is an Orchid and fine-foliage-house containing some good examples of *Caladiums*, &c.; and among Orchids we noted a very fine variety of *Zygopetalum Mackayi* having very much richer and denser spotting than the common variety; also, good plants of *Dendrobium formosum*, and several other good ornamental Orchids. Then there were housefuls of *Achimenes* in bloom, and a whole house of *Gesnera splendens*, all grown for Castle decoration. To give some idea of the whole of the glass accommodation, we may state that the principal range is about 380 feet long, with shed and other accommodation at the back for garden purposes the same length. Then a broad gravel walk separates this from the next low range of pits some 170 feet long, for Pines and bedding-out plants. Then a range 210 feet long, with Melons, Cucumbers, Pines, &c. Next, comes another sixty-foot house, at back wall for Vines, and adjoining this a one-hundred-and-twenty-foot range for foliage and other decorative plants, and one nearly as long for bedding stock. Had the plan of these fruit and plant houses been all laid down at once, it would have been so arranged as to have a much better effect externally. We had not time to go round the kitchen garden, but we do say that the whole of this immense establishment is in faultless order as to keeping, and the wonder is that such a great variety of subjects is so masterly handled in a practical point of view. We were highly gratified with our day's excursion, and do say to all lovers of gardening who have it in their power, Go and see Drumlanrig.—JAS. ANDERSON, *Meadow Bank, Uddingstone.*

### CULTURE OF ROSE DE MEAUX FOR MARKET.

I HAVE about half an acre of the old Rose de Meaux which I grow for flowers for market, and I find that when they have been planted down two or three years the vigorous suckers they throw up in the summer die about one-third down from the top, which gives the trees a most miserable appearance all the winter. Now, what I wish to know is, Would it injure the trees to cut them down now? The leaves have entirely fallen, and the tops of the trees are beginning to die away. I have treated a piece in that way in the spring and with good results; but while the trees remain healthy I never cut them, as it cuts away so much bloom. I ascribe their dying to the extreme lightness of the soil here. I give them cowdung every autumn when they are dug, and should like to cut them down to a foot of the ground before I do it. They grow about 2 feet to 2½ feet with us.—A MARKET-GARDENER.

[You treat your Rose de Meaux entirely on the wrong principle for supplying the market with cut Roses. In the first place, it is the dwarfest and the weakest-growing Rose of the old race that is now good for anything. In the second place, it is always grown on its own roots, or at least ninety-nine times out of a hundred, and just as often it is propagated on the wrong principle for supplying the market with cut Roses—that is, it is taken up, divided, and replanted, which is equivalent to planting none but suckers, which make ten times more suckers in their turn than need be, far more than if the plants had been raised from proper layers.

Then, you prune at the wrong season for Rose de Meaux, and you prune it on the wrong principle, and under a very wrong though very old idea. Rose de Meaux and all like it, ought, most certainly, to be pruned at the very end of October, and not later in any one year. Then you do not prune the shoots down to but just one-half of the length they require to be cut to for a mass of bloom.

The effect of that wrong system is this—the effort to produce flowers, and the quantities of cut bloom, and the sprigs and stalks with them for market use, is like what we call “sponging.” The last year's wood of this Rose is so sponged by the end of the blooming season, that very little sap goes up for making the midsummer shoot; but suckers come up tall instead, and they having not sufficient time to ripen get frosted-off.

That is exactly your case, and the case of many hundreds. In your extra light soil at Fulham, what you should do with Rose de Meaux is this. Have your stock in three parts, in three successions, one part to be transplanted into the best ground the beginning of every November, and to be close pruned, and in March the ground to be mulched, and nothing is better than the cocoa-nut fibre stuff, then all your stock would be renovated every third year, and so on every year.]

### ORCHIDACEOUS PLANTS.\*

THE second part of this very beautiful and trustworthy work is just published, and is fully equal in every respect to the first part. It contains *Trichopilia crispa marginata*, *Lælia gigantea*, *Odontoglossum nævium majus*, and *Cattleya Warneri*. We wish we could transfer a copy of the exquisite portrait of this last-named Orchid to our pages. Its specific name is well bestowed in honour of Mr. Warner, and he may justly be gratified by being commemorated in association with a flower so pre-eminent among its fellows.

“This,” says Mr. Warner, “is one of the most beautiful of the many *Cattleyas* of the *labiata* section with which our gardens abound. It was first bloomed by ourselves, and was shown in 1860 at the Royal Botanic Society's exhibition in the Regent's Park, on which occasion a silver medal was awarded to it. We have no information as to its introduction, but believe it to have been obtained from Brazil. Our plant, which has now flowered with us three years in succession, has sometimes had more than twenty flowers expanded at one time.” It blooms in “June and July, which makes it very valuable as an exhibition plant.” The directions for the cultivation of this, and, indeed, for every Orchid portrayed, are copious, and such as every Orchid-cultivator may safely follow.

### PLANT FROM NAZARETH.

I SHALL be much obliged if you will tell me the name of the enclosed plant? It was found growing on the walls at Nazareth, and the little green shoots in the summer become covered with those silvery leaves. It makes a very pretty basket-plant out of doors in the summer, but I fear it is not hardy enough to stand our winters.—H. S. A.

[It is *Paronychia arabica*, a native, not only of Palestine, but of Arabia and Egypt. It is a very pretty, interesting, and peculiar-looking plant. If you could spare us a rooted piece of it we should be obliged.]

### THE ALOE FAMILY.

THE family of the Aloes—one of the largest groups of succulent plants—is now so seldom met with in cultivation, that its members fairly rank among what may be called neglected plants. Yet they comprise species of considerable beauty, added to an aspect so strikingly exotic, that their absence from any general collection of greenhouse plants is to be regretted. We propose to explain the leading features of their cultivation, in the hope that the absence of all difficulty in their management, may, in conjunction with the reasons already stated, aid in reviving the taste of amateur cultivators for a selection of them.

\* *Select Orchidaceous Plants.* By R. Warner, F.R.H.S., and E. S. Williams. L. Reeve & Co., London.

First—of propagation. The majority of these plants are prolific of suckers or side shoots, from the base of the plants, which, if taken off any time, during either spring or summer, somewhat dried before planting, and then put into moderate-sized pots, well drained, and filled with sandy loam, or loam mixed with a third part of pounded bricks, will root readily in a few weeks if the soil is just kept moderately damp—neither so wet as to rot the base of the sucker, nor so dry as to exhaust its juices. The pots containing these suckers or cuttings may be set in any part of the greenhouse, on a shelf or stage, or in a window where they will have the full sun; and from the time they are planted, such suckers will present all the appearance of mature plants, on a reduced scale.

In many cases these side shoots, or suckers, may be taken off with roots attached, and then require only to be potted in pots suitable to their size, and at once form established plants. Some of the species, however, do not naturally produce a supply of suckers or side shoots, except in rare instances—some very rarely, or never. Whenever, in the case of such species, suckers or side shoots are produced, advantage should be taken of the opportunity to propagate them, by planting them as already noticed. But when it is required to propagate any kind which obstinately refuses to furnish materials for propagation, the only alternative is to destroy the centre or heart of the plant, when side shoots will be produced, and these, when large enough, must be treated as cuttings.

The after-culture of these plants is as easy as their propagation. The principal features of their treatment may be pointed out under the heads Soil, Watering, and Situation.

The proper situation for them is the greenhouse—that is to say, while they are just protected from frost on the one hand, they do not require more than a temperate degree of heat on the other, as far as artificial heating is concerned. We find them to do well and flower very abundantly, in a small greenhouse having a south-west aspect, the lights of which are never opened for the purpose of "giving air," except, perhaps, in the hottest days of summer; and to which fire heat is only applied with the view of just keeping out the frost. The species which are of suitable size will do well in a sunny window, and may be kept permanently inside, from one year's end to another, without suffering from their confinement, care being taken to remove them if necessary beyond the reach of frost, or, if a slight frost should catch them, to thaw them gradually by the application of the coldest water, before the sun has had an opportunity of breaking their icy chains. The small sorts do admirably in a Wardian case; and any or all the species might be successfully grown in one of those Wardian cases "of a larger growth," which we hope soon to see interesting many an amateur who cannot bestow sufficient time and attention on a greenhouse of the ordinary construction.

As to soil, the Aloes can have no better compost than pure yellow loam, of a free and open texture, intermixed with about a fourth part of pounded bricks broken up quite small, the dust as well as the small lumpy pieces being added to the loam, and the whole intimately blended. All the species which attain a moderate size should have pots in proportion, not only on account of their producing roots freely, but also because their thick fleshy leaves sometimes render the plants awkwardly top-heavy, if they are in too small pots. The pots must, however, be thoroughly drained upon the most efficient plan; and, providing this is done, and the kind of soil above recommended is used, there need be no fear of employing pots of too large a size

for the larger sorts. As with the majority of greenhouse plants, potting may be done any time from early spring onwards through the summer; it is best not done too late in the season, though it may be done at any time if due care is afterwards exercised in the application of water. The small sorts never need large pots.

As to watering, the general rule is to apply water just before the plant reaches that condition in which it would begin to droop or shrivel. In all cases, therefore, it must be less frequently given in winter than in summer, on account of the difference in the amount of evaporation going on at these two periods. Certainly Aloes and other succulent plants require less water within a given period at any season than most other plants, on account of the slower process by which moisture passes away from them. In summer they may need watering once in two days—seldom, if ever, daily; in winter they may not need any attention of this kind for a month, or even two months, at a time. The only danger, however, is that of giving too much in winter; and it may, therefore, be taken as a safe rule to wait for indications of shrivelling in the lower leaves before water is applied at that season. With proper soil, potting, and moderate care, they will not be liable to be over-watered at any other season.

We shall now enumerate a limited selection of distinct kinds which are worth growing, either for their exotic aspect, the curiosity or beauty of their foliage, or for the showiness of their flowers. The flower-stems of most of the larger Aloes form simple upright racemes, which are clothed with drooping tube-like flowers, comparatively large; and these, when highly coloured, are very ornamental:—

**RHIPODENDRON.**—*R. plicatile* has a forked stem, the leaves arranged in two rows, and the tubular red flowers straight.

**PACHIDENDRON.**—*P. africanum*, 8 feet, red; *P. ferox*, 6 feet, yellowish; *P. supralæve*, 5 feet, orange, are some of the larger single-stemmed forms of Aloe, with straight flowers.

**ALOE.**—*A. purpurascens* is a tall forked-stemmed species with reddish flowers; *A. vulgaris*, 12 feet, yellow; *A. lineata*, 5 feet, scarlet; *A. prolifera*, 2 feet, orange; *A. saponaria*, 4 feet, red; *A. suberecta*, 3 feet, scarlet; *A. variegata*, 3 feet, pink; *A. albo-cincta*, 3 feet, has its orange flowers in a branched or corymbose head. These also have the flowers straight.

**GASTERIA.**—*G. nigricans*, 2 feet, red; *G. subcarinata*, 2 feet, orange; *G. verrucosa*, 2 feet, red; *G. maculata*, 2 feet, scarlet. The flowers of these are tubular, curved, and more or less swollen; and they are mostly tipped with green.

**APICRA.**—Small plants, with greenish-white flowers, small, and somewhat two-lipped; they are more curious than showy. *A. spiralis*, *A. pentagona*, *A. imbricata*, are interesting-looking plants.

**HAWORTHIA.**—Small plants similar to the Apicras, and destitute of showy flowers, these being greenish-white. *H.*

*translucens*, quite transparent; *H. stroviensis*; *H. planifolia*; *H. margaritifera*; *H. retusa*; *H. reticulata*, are interesting species.

With the above, or a similar collection, the Aloe-house would be kept gay and interesting from early spring quite through the summer. The Haworthias and Apicras are especially suitable, from their diminutive size and curious structure, for the smaller Wardian cases, usually seen placed in windows.

Some of the species of Aloe are interesting as furnishing the drug Aloes employed in medicine, and which seems to be obtained from several of the kinds having large juicy leaves. Three kinds are prepared; the best by draining the leaves, the next by pressure, and the third or worst quality by boiling.—*M.*—(*Gardeners' Magazine of Botany.*)

*Aloe picta.*

IXORAS.

THIS is exclusively a tropical genus, and almost exclusively from tropical Asia, only one being known as a native of elsewhere, *Ixora odorata* being found in Madagascar. So Asiatic in its residence, the genus has appropriately received an Asiatic name, *Ixora* being a Malabar idiom, to which the flowers of *Ixora stricta* are offered by the natives. This species is the first that was introduced to Europe, in the year 1690, being described and figured by Rheede in his "Hortus Malabaricus" under the native name *Schettii*.

Two of the more recently-introduced species we now place in our columns.

**IXORA GRIFFITHII** is known to many gardeners by the more descriptive name of *hydrangeaeformis*, for both in its heads of flowers and its foliage it has considerable likeness to the *Hydrangea*. It was discovered by Mr. Griffiths at Mergui, and introduced in the year 1845 by Messrs. Low, of the Clapton Nursery. It is a large branching shrub, the branches terete, rich brown. Leaves large, oblong-ovate, acuminate, somewhat cuneate at the base, tapering into a short stout petiole, penninerved, with numerous transverse veinlets, glabrous, as is every part of the plant. Stipulea broad, short, acute. Cyme large, broad, nearly flat at the top, compound, with a great number of salmon coloured (or sometimes yellow and scarlet) flowers, with a pair of leafy bracts at its base. Calyx very small, with four short blunt teeth. Corolla salver-shaped, salmon colour (or at first orange yellow, then red orange); the tube long, slender; the limb of four rotundate, very obtuse, spreading lobes. Anthers sessile, inserted at the mouth of the tube, and lying horizontally between the lobes. Style a little longer than the tube; stigma bifid.

**IXORA JAVANICA** has been called *Pavetta javanica*, but there is no doubt that it is a true *Ixora*. It is portrayed and described in the "Botanical Magazine," t. 4586, and is very different from the *I. javanica* of Paxton's "Magazine of Botany," xiv. 265. The species we are now considering was imported from Java by Messrs. Rollisson, of Tooting, and bloomed first at their nursery in March, 1851.

It is entirely glabrous; branches round, and the young ones coral-coloured; leaves from 4 inches to 6 inches long, pointed, oblong-ovate, leafstalk short; stipules stem-clasping at their base, terminating abruptly in a spinous point; corymbs at ends of the branches, large, peduncle long and coral coloured; calyx nearly turbinate, limb erect and 4-lobed; tube of corolla red, 1½ inch long, its limb orange red, an inch across, lobes egg-shaped; anthers linear, very deciduous; style long as corolla; stigma thickened, bifid.

Of all the newer introductions into this beautiful family, the above occupy no secondary place, though we still give the palm to the old favourite of our youth, the *Ixora coccinea*. The several species as yet found require a high tropical temperature,

but are somewhat different in their habit; some being of thin upright growth, and others of a more bushy character. All are improved by frequent stopping when young, and tying the lower shoots out to the sides of the pot to give them a wide base at bottom. With these preliminaries, to meet various inquiries, I will advert a little to their propagation and general culture.

The propagating is generally done by cuttings. The best time is about the middle of March or the middle of June. By the first time plants may be potted-off, and established in small pots before winter. The best cuttings are short stubby shoots about 3 inches to 4 inches long, getting hard at their base, though the upper part should not be so hard. Those clipped off with a heel close to the older stem are best. Cut clean at the base with a sharp knife, remove the lower leaves, and either take away the second tier of leaves from the base, or shorten them a little. A four-inch pot will hold a number of cuttings. Fill it better than half full of drainage, with a layer of pebbles and small charcoal on the surface. On this place to within 1 inch of the top a mixture of equal parts of heath soil, sand, and charcoal in little bits, and three-quarters of an inch of silver sand over all, water, and allow the pots to

drain. Then insert the cuttings, filling up the dibble holes with sand and water again. When the tops are dry, place the pot, plunged in a sweet hotbed, about 15 inches from the glass, cover with a bell-glass or hand-light; shade only a little in very bright days, preferring to dew the foliage or the soil inside the glass on such days to keeping the cuttings dark; and give a little air at night to prevent damping. When the cuttings are striking, maintain a moist atmosphere, and a temperature by day from 70° to 90°, by night from 65° to 70°, and bottom heat from 85° to 90°.

*After-treatment.*—As soon as the cuttings are well struck, pot-off into small 60's; when filled with roots place in large 60's or 54's, in which they will stand the first winter, and be kept growing slowly in a temperature not below 65°. In spring nip the shoots so as to make them bushy, and when fresh shoots are breaking shift into a larger pot, and keep growing freely all summer in a stove heat. If the plants are strong, they may bloom the next year—that is, the third season from the cuttings; but for strong plants they will require from three to four years to bloom well. The following will be the general treatment according to the size of the plants:—In March, sponge

and wash the plants as a matter of precaution. Tie-out the side shoots, and plunge the pots at least half-way in a hotbed. By June the plants will want another pot—say from a four or five to a six or seven-inch, or from an eight to a ten-inch, according to size. Any shoots threatening to steal strength from the others should also be stopped, to give two or three shoots instead of

*Ixora Griffithii.*

*Ixora javanica.*

one. A high temperature, a moist atmosphere, and plenty of the syringe must now be used to cause free growth, and keep the plants clean. If fly, or thrip, or bug appear, there must be smoking and sponging at once.

This treatment should continue, with a little shade in very bright sun until September. The pots should then be raised out of the hotbed, the plants placed nearer the glass, and in full light, and though syringing may be resorted to at times, it should gradually be discontinued, and water at the roots also lessened, but never so as to cause the plants to flag. The object is to ripen the shoots formed. As October and November come the water must be lessened, and the temperature fall then, and on to February, to 60° and 55°, the roots just kept healthy and no more, and care taken of the leaves by syringing and sponging on a fine bright day. The rest is thus given at the dull season, as the flowers are much more pale when produced in winter. About March, or earlier, the plants are moved into a higher temperature by degrees, and at first the pots are partially, and ultimately three-parts, plunged in a sweet hotbed, with openings below the pot to secure drainage. The temperature may be gradually raised to 75° and 80° with air, and, of course, waterings at the root will be more needed as the temperature rises, and the syringe must be pretty well used before the bloom-trusses show. Then a drier atmosphere should be given, and the plants be lifted out of the bed as the flowers open, and kept cooler and drier to preserve the bloom.

With established plants the same course must be continued year after year if grown on the continuous system—that is, blooming every year; there being, in addition to shoots blooming now, other shoots that will bloom in the following year. For this purpose, as soon as the flowering is over, cut back these flowering shoots with all the remains of bloom; syringe and wash the plants, and place in a moist heat to encourage growth; then harden that growth in September and October, rest in winter, and start again in spring and summer in an increased temperature.

*Soil.*—The best is rich heath mould, and fibry sandy loam nearly equal parts, and a tenth part of bits of charcoal will do no harm. When the heath soil is poor, add a small portion of leaf mould. We have seen fine specimens grown in three-parts fibry loam, and one of silver sand, and one of leaf mould, sweet and aerated before being used.

*Watering.*—Pure rain water is best: a good supply at roots and overhead is needed when the plant is growing. Clear weak manure water will also be of service from the time the flower-trusses show until done flowering, and you wish the wood to grow until September. From thence use no manure water, and lessen the quantity of the common until the following summer.

*Pruning and Resting* have been referred to.

*Hotbeds.*—Few plants when growing rejoice more in the fumes from sweet decomposing organic matter. Dung and leaves do well. Tan is more cleanly. The best of all are dung and leaves below, and a foot or more of sweet tan on the surface. Whatever plunged in, care should be taken that the pots or roots are *not too hot*, that the bed is perfectly sweet, and that no worms can get into the pot. There are various modes for preventing this.

*Drainage* must be well attended to; no plants suffer sooner from being placed in a marsh.

*Insects.*—These are numerous, but will be little trouble if the plants are well grown in summer as advised. If kept in too low a temperature they are sure to be seized with thrips, bugs, and scale, and all other similar enemies. Smoking for fly must be resorted to whenever it appears. For the others nothing is better than tobacco water or size water, and thoroughly washing the plants with the syringe afterwards. When shut up in a moist atmosphere of 80° to 90° on a summer afternoon, well syringed, and the tan-bed stirred-up, there are few insects, or men either, that could long put up with the treatment.

I would particularly allude to this high temperature and moist atmosphere in summer as essential to success, as I have had several complaints that the *Ixoras* cannot be managed in a warm greenhouse temperature, about 50° in winter, and very airy in summer. It is waste of time attempting such plants under such circumstances. I have given them up for a time because I have not enough heat for them. Those who can command a dryish atmosphere of from 55° to 65° in winter, and a fermenting-bed in spring and summer, securing a bottom heat of from 80° to 85° and 90°, and a top temperature of from 70° to 85°, and 5° to

10° more in sunshine, with abundance of atmospheric moisture, will, no doubt, succeed with these lovely plants, which are well deserving all such attention.—R. FISH.

## SMALL BIRDS.

I AM glad to see that those who contend for the thinning of the number of these little thieves have such a powerful ally as your correspondent, J. Robson, whose letter in your last Number, if observation and clear argument go for aught, will, I think, carry conviction to many of his being right. I have often urged myself that a proprietor of a field of Cabbages, or such like plants, is no fair champion of small-bird protection, inasmuch as his experience only tends one way, and that in his favour.

Now, I have only a moderate garden, but I also keep fowls; and the moment they are fed a complete swarm of these little nuisances descend upon the corn to an extent that has often nearly starved my very young chickens. In fact, I always have to wait until the corn is picked up by my fowls to cheat these depredators. I can also bear melancholy testimony to their destructive propensities in the Gooseberry-stem line; while, as for caterpillars, I do not believe their so-called destroyers have troubled themselves at all about them. The advocates for their preservation state that they only pick out the diseased buds; but, if so, the remedy must be similar to that of cutting off one's head to cure the toothache; for my Gooseberry bushes bear little else but leaves through the exertions of these nuisances.

Having shot a number of sparrows, and in nearly every instance, on dissection, discovered nothing in their crops but my corn, I have come to the conclusion that where corn and young shoots abound, the sparrows leave the caterpillars to the gardener's care altogether. Your correspondent's remarks about the balance of birds are, I think, indisputable.—FOREST HILL.

[It is quite true that sparrows will eat the food intended for chickens; but it may be given to the chickens in the outhouse, or under a coop so covered that the sparrows cannot commit a felony. If they were excluded from the chicken food hunger would make them more sedulous after caterpillars, and thus all would go well. Besides, sparrows require caterpillars for their young ones, for which corn and other chicken provender is unsuitable.]

BEING a constant reader of THE JOURNAL OF HORTICULTURE, I have taken particular notice of what has been written about small birds, some even saying that the fruit crops are all depending on them. I, for one, beg leave to corroborate all that Mr. Robson says against them, and beg to prove that he has not overstrained the evil they do here. In the first place, if they are not kept in check, we shall not be able to get any fruit of several sorts. They begin here with the Pear tree fruit-buds as soon as the leaf falls, and these are all gone by Christmas. (By the way, I cannot make out one writer, who says, after all the buds were picked off, he had the best crop on that tree.) Then they begin on the Gooseberries and Currants, and finish with the Plums. Then, as soon as the Cherries are beginning to colour, away they all go, and so on all the summer as the fruit ripens—Strawberries, Raspberries, Currants, Gooseberries, and lastly, the Morello Cherries.

But the greatest grievance is yet to be told. I wonder what the small-bird protectors would say if they saw a wall 200 yards long and 14 feet high of all the finest kinds of Pears, and all a fair average crop, and two-thirds of them spoiled by the small birds? They pick a small hole near the stalk long before the Pears are ripe, and then these fall off half-rotten. All the standards they serve the same, and Apples likewise.

The humane will say, "Why, net all your trees." Now, this is no small cost to net a whole garden, standards and all. Then I find any kind of fruit is never so good netted, not even Strawberries. We want all the sun and air to the fruit we can get without shading with nets. The humane have made out a great plea in their favour by keeping down the caterpillars. I agree the sparrows eat a few; but about a farmyard, where there is always plenty of sparrows, the farmer's Gooseberry bushes are always first attacked by the caterpillar, which proves they do not save his bushes. Two dressings of hellebore powder will do more than all the small birds.

We must keep down the birds, or it is of no use planting fruit trees of any sort here. Blackbirds, bullfinches, willow biters, comits, and many of the sparrows, must be kept in check; and

the robin redbreast is very destructive among small fruits. I shall be glad if Mr. Robson can find out the best way of keeping in check all these fruit-destroyers, and give his experience to the public.—G. M., *Lincoln*.

### MARKET-GARDENING IN WEST CORNWALL.

THE market-gardening district of west Cornwall comprises portions of the following parishes on the shore of Mount's Bay:—St. Paul, Madron, Penzance, Gulval, Ludgvan, and Marazion. In length this tract extends about five miles, while in breadth it varies from half a mile to two miles. Beyond these limits, however, within the last few years, on the east in the parish of Perran-uthnoe, and on the west in the Deanery of Buryan, small patches of ground, sheltered by the cliffs and with a warm southern aspect, have been employed for the cultivation of early vegetables. These, however, are the exceptions, and the district may be thus generally bounded. In breadth, however, it should be observed, several circumstances affect its extent. To the west in St. Paul the cliffs approach close to the sea, and it is only the more sheltered portions of their sides that are available. In Madron, the adjoining parish, a more level formation of the ground permits the gardener to carry on his work for some two miles inland, and the same in Gulval and Ludgvan. But in these two last-named parishes a strip of marsh land, only partially drained, intervenes between the beach and the gradually-rising ground in the cultivation of the market-gardener. In Marazion the cliffs, again approaching the sea, narrow, and, with the partial exception of Perran-uthnoe before mentioned, bound these limits.

The soil of this district is of varied character, its central portion consisting of a rich loam of considerable depth, formed by the decomposition of the subjacent greenstone rock. On the western side it gradually merges into the granite, forming at this point of juncture a belt of soil of more than usual fertility. When this change of strata is complete, and the soil rests entirely on the granite, or, as it is locally termed, the "growan," its fertility varies according to the character of that rock, and the amount of felspar which enters into its composition. Should this mineral predominate, disintegration then freely takes place, and the result is a light clay, which by the intermixture of decayed vegetable matter forms a loam capable of producing large crops of roots, especially of Potatoes, and of Cabbage and Broccoli.

Towards the eastern portion of this district, resting also on greenstone and other trappean rocks, the soil receives a considerable mixture of sand, rendering it light without, however, apparently diminishing its fertility, though slightly varying the character of its produce, which, in addition to Potatoes and Broccoli, consists also of Turnips and Carrots, both of admirable quality, enhanced in value by the very early period at which they become fit for the market.

The Scilly Islands are our competitors, the character of the soil generally resembling that now described, while their sea-girt position secures them in a still more remarkable degree from the ravages of frost.

I should now refer to the circumstances which render this small tract of land so especially suited for vegetable culture.

Of its soil I have already spoken, but that of itself would not account for the extent and profit with which the market-gardener has carried on his business, for in this respect many other parts of England would hold out to him at least equal encouragement. It is true that his position on the sea-shore has enabled him to use the sand and seaweed which every gale from the south throws up in large quantities; and, indeed, in former years these were his great reliance. Latterly, however, as we shall see when manures are spoken of, they have in a great measure been superseded by guano, rags, and other fertilisers.

To the climate, beyond all doubt, the success of his labours must be attributed; the even temperature of Mount's Bay, the result of the warm flood of the gulf stream, supplying him with the most favourable conditions under which his work can be carried on. In winter severe cold is rarely known before Christmas, and although in the early months of the year he shares the common lot of the English farmer in his experience of both frost and snow, a very few days are usually the limit of his trial. When he does thus suffer it is commonly in April, or even in May, when his Potato crops are advancing towards maturity, when in other parts they are usually still beneath the soil. Wind,

however, and especially that from the north-west, is an enemy that, with respect to his main crop, the early Potato, he must carefully guard against; and this is one of the causes that prevent the extension of the gardening district on the higher and more exposed lands.

As regards the convenience of markets, the completion of the Cornish lines to Penzance has of course greatly increased the trade. One delay in transit, however, still exists in the break of gauge at Truro, necessitating a loss of time, which, with such perishable goods, frequently becomes of serious consequences. How rapidly the business has of late years extended will be seen from the fact that twenty years since one small steamer from Hoyle, a port on the Bristol Channel, six miles from Penzance, conveyed everything that west Cornwall had to send eastward, which was not carried by the sailing coaster or by coach. The cost of railway carriage is amply repaid by the higher value of the earlier crops; but of those that follow a considerable portion is still sent by water to Bristol, and is there divided—a part going on to London, while the rest seeks the northern markets of Birmingham, Manchester, and Liverpool, now among our best customers. If we may judge from recently advancing rentals, a still further development of this trade is at hand.

The facility of rapid steam communication being shared by other countries, Portugal and other parts of the south of Europe are found in some degree in successful competition; but the great cost in transit of the heavy crops of Potatoes, and especially of Broccoli, secure for west Cornwall a pre-eminence for the main supply which she seems likely to retain.

Having thus shown that the climate of this district is the main cause to which must be assigned a success in vegetable culture, I will in the next paper explain the mode in which the market-gardener's labours are conducted.—W.

(To be continued.)

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE September Meeting of the Entomological Society was held on the 1st of that month, the chair being occupied by J. Lubbock, Esq., F.R.S., Vice-President of the Society. Amongst the donations received since the last meeting were the publications of the Royal Society of Munich and the Society of Arts, together with a copy of the fine work on the insects of Mozambique collected by Herr Peters, published by the Prussian Government, presented by J. W. Dunning, Esq., Secretary.

Mr. F. Bond exhibited a specimen of the Oleander Sphinx (*S. Nerii*), taken in a garden at Hastings on the 2nd of August last; also a species of *Tinea* new to Britain (although previously taken in Ireland), regarded as *T. confusella* by Mr. Bond, but which Mr. Stainton considered to be the *T. nigripunctella*. The latter gentleman exhibited living specimens of *Zelleria hepariella*, showing its singular attitude in repose—resting on the four anterior legs, the two hind ones being elevated at the sides of the body, and the head downwards like an *Argyresthia*. The insect had repeatedly been referred to the genus *Gracillaria*, although its real relationships had been pointed out, and a new genus (*Zelleria*), formed for its reception. It had, in fact, been described as *Gracillaria rufipennella*; also as *G. Haighii* by Mr. Gregson (*Zool.* 5295); and as *G. Taxella* by Herrick Schäfer. The specimens exhibited were taken on Yew trees on Mickleham Down. Mr. Stainton also exhibited a list of thirty-six entomologists resident in Canada, showing that the science was making progress in that part of the world.

A letter was read from Miss Farington, of Wood Hall, near Preaton, requesting information as to the habits of an insect that had occurred in prodigious numbers in an old grocer's shop in Preaton. It had not been observed previously to the present year; but it now infested the furniture, beds, &c., to a great extent, and was stated to eat holes through the clothes of the inhabitants. The insect proved to be the domestic *Ptinus hololeucus*, which is said to have been imported from Russia about twenty years ago in a cargo of leather.

General Sir J. B. Hearsey exhibited various fine insects from India and China, including a gigantic species of Gadfly, a cotton insect (*Aphis* sp.), &c.

Mr. F. Bond exhibited a species of Tortriadae taken on Poplars near London in June, which had been regarded as a new species and described by Dr. Knagga under the name of *Spilonota Doubledaii*, but which proved to be the *Pædisca oppressana* of Treitschke, and of Stephens' and Doubleday's catalogues.

Mr. G. R. Waterhouse exhibited seven new British species of Staphylinidæ (Rove Beetles), of small size, which had been previously described by Erichson, Kraatz, Mulsant, &c.

The Rev. Hamlet Clark read descriptions of four new species of Water Beetles, one a native of Spain, and three new to the British Fauna—namely, *Hydroporus severus* from Stowmarket, *H. derelictus* from the Orkneys, and *H. relatus* from Bradgate Park, Leicestershire. He also announced *Hydroporus 5-lineatus* of Zetterstedt as a species also new to this country.

Professor Schaum, of Berlin, read the description of a magnificent species of Scaritidæ, recently received from Laos in Cambogis, collected by the late Mr. Mouhot under the name of *Scaritarchus midas*. Only a few specimens of this insect had been captured, which had been sold at the price of £5 each.

The Secretary read a series of proposed alterations in the by-laws, the chief of which had for its object the annual election of the Curator by the Society at large, instead of his appointment by a permanent one made by the Council as heretofore.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

MANURES to be wheeled out of the framing-ground on to the vacant spaces, to be afterwards dug-in. *Beet*, take up the roots carefully, the tops to be twisted-off above the crowns; to be stored away in any dry place free from frost, in sand. *Broccoli*, the Cape varieties which are now heading to be secured from frost. *Lettuce*, give air at every favourable opportunity, more especially to the young plants. The Cabbage varieties intended for winter use will not require it so freely. *Parsnips*, it is sometimes more convenient to have them taken up and stored in the root-cellar, but digging them up as wanted is generally preferred for flavour. *Rhubarb*, clear away the decayed leaves, and cover the crowns of the roots with old tan or any sort of loose litter. *Scorzonera* and *Salsafy* may now be taken up and preserved as are other culinary roots.

### FLOWER GARDEN.

If it is found that the stock of any useful bedding-out plant is insufficient, not a day should be lost in getting-in cuttings. In the case of such things as *Ageratums*, *Heliotropes*, dwarf *Lobelias*, &c., it is useless wintering young stock, as these grow so freely in heat and are so easily propagated from soft cuttings, that a few good-sized old plants which require but little room and attention in winter, will furnish a very large quantity of plants by bedding-out time. Hardy creepers to be examined at this season, and all superfluous shoots removed. All stakes and ties to be examined and secured from the stormy weather of winter. Lay turf; prevent the accumulation of leaves on borders and walks. In situations where peat mould is scarce, its substitute, leaves and sand, may, at this season, be gathered into a hole in any out-of-the-way place to decompose. Proceed diligently with planting trees and shrubs in the pleasure ground and flower garden. Keep the lawn neatly mown at this season, as on this depends, in a great measure, the neatness of it through the next summer.

### FRUIT GARDEN.

Pay every attention to getting the wood of Peaches and Apricots well ripened by exposure, shortening, &c. Proceed with the planting of fruit trees; spread the roots out carefully, and close the soil about them with the hand. Never shake the tree up and down, as it disarranges the roots very much. Root-prune when the trees are growing very luxuriantly, or take them entirely up and replant them. Gather any remaining fruits—such as Quinces, Medlars, Walnuts, &c. Commence pruning as soon as the fall of the leaves tells of the diminished action of the sap. Put in cuttings of choice Gooseberries and Currants, and make fresh plantations of Raspberries.

### STOVE.

When the sun shines out clearly, give air to maintain the plants in a hardened and ripened state, and take care not to increase the temperature with a moist atmosphere, or you will start the plants into growth, which, at this season, would be quite ruinous. The plants under such treatment must, of necessity, be constitutionally injured; the sap cannot, at this season, for the want of light, be properly elaborated, and, consequently, the shoots come weak and spongy, and are liable to damp-off. The art of cultivating exotic plants lies more in studying the

seasons of excitement and rest than is generally imagined. Shading will not now, under any circumstances, be required.

### GREENHOUSE AND CONSERVATORY.

It is sometimes necessary to employ a fire occasionally at this period of the year, as much to produce an active circulation of air, and to remove all superabundant moisture, as to make up for the deficiency of solar heat. However, assistance of this kind must be applied with caution, so as not to interfere with the system previously recommended of gradually reducing the temperature to correspond with the natural decline of the season. Examine Heaths and hard-wooded plants, and when they are found to be dry water thoroughly, so as to moisten the whole of the ball; also, look sharply after mildew, and dress the plot with sulphur directly the enemy is perceived. Get Azaleas tied into form as soon as can be done. Look carefully after red spider on *Bossias*, *Chorozemos*, &c., to be got rid of by laying the affected plant on its side, and well washing the underside of the leaves with the syringe, applying the water with as much force as the foliage will bear. Repot strong-growing *Pelargoniums*; plants that are fairly established, can hardly be too freely exposed to air, or kept too cool. Also, keep *Cinerarias* cool and moist, and attend to repotting such as require it.

### PITS AND FRAMES.

Abundance of air and light to be admitted to these structures. If any of the lights be dirty, take them off, and wash them thoroughly without delay. Be careful in giving plants water, to apply it only to those that require it. Remove all mouldy and decaying leaves, and keep the interior as dry as possible. *Verbenas*, and all early-struck cuttings to have air at night to keep them hardy, but the lights must not be suffered to be off for fear of wet or frost. Watering to be done in the morning, and then as sparingly as is consistent with the safety of the plant.

W. KEANE.

## DOINGS OF THE LAST WEEK.

THESE have, to a great extent, been a repetition of the previous week's works.

### KITCHEN GARDEN.

In addition to slug-hunting and throwing lime and ashes over newly-planted things, some *Sea-kale* and *Asparagus* have been cleared of their leaves and stems to prepare them for forcing. When the stems begin to decay about the end of the month, it is a good plan to raise the roots intended to be first forced and keep them covered in a shed for two or three weeks. They seem to come away more regular and strong when placed in heat, after thus receiving a complete stoppage to growth and a short rest beforehand. Gathered also a lot of *Asparagus*-pods to be kept until spring for sowing, as, where much is wanted for forcing, there must be a sowing every year. *Asparagus*, *Sea-kale*, *Mushrooms*, and *Dwarf Kidney Beans* are four things we always consider to be improved by a little forcing; and where *Sea-kale* is sown every year, or the roots planted, there is no necessity for having mounds of manure over it out of doors, as placing the roots in soil moderately moist, and where darkness and a temperature of from 50° to 55° can be maintained, will furnish it in good condition. The same temperature just suits the *Mushroom-house*—I mean atmospheric temperature; if much higher the *Mushrooms* come leggy. A friend writes us to say, that "you give much too high a temperature for the bed when spawning—about 80°, and that 60° would be better." We only speak as we find. On spawning, were our bed only 60° we would put some fresh droppings on the surface to raise it a little higher. The heat will decline again after that; but as soon as the spawn is freely working the heat will rise again to 75° and 80°. When we refresh an exhausted bed with watering we always use water fully 80°, except in the summer season, when common water is hot enough. We should be glad to know, however, the experience of others as to the beds being cool at spawning time. After fairly set running the heat of the house will give enough of heat to the spawn. Took up portions of *Beet*, *Carrots*, *Scorzonera*, as after this time the worms are apt to seize them. *Artichokes* are still bearing well and are useful. *Jerusalem Artichokes* are with us now little used, so we appropriate an out-of-the-way place for them, and let them stand for years, getting a few roots when wanted. When much used they should be taken up and planted as carefully as *Potatoes*, every year, and then in good deep soil they will yield a good crop.

Pulled some of the best leaves from *Tobacco plants*, and hung them up in open sheds. We fear the tobacco of commerce, shag or otherwise, is getting as much mixed up as cigars; as, when used for destroying insects, it seems to have little of the same effect it had formerly, and much of what is sold as tobacco paper is dangerous to use. Turned-up all empty ground that could be spared to receive the benefits of aëration, but of this as yet we have but little.

## FRUIT GARDEN.

Continued pruning small fruit bushes as they could be got at. Would go over all Pears and Apples (dwarfs) that we could get at, as it is more pleasant doing it now than in cold winter and spring. Gathered most of the hardy fruit, as if not quite ripe the late sorts suffer quite as much by having a touch of frost. Our shelves for fruit are close, but we prefer them open-sparged, as stated some time ago, for fine late kinds. Besides the shelves, it is desirable to use dry, clean jars, and small barrels, well covered, but the fruit not packed in anything. *Walnuts*, *Chestnuts*, and *Filberts* well cleaned and moderately dried, keep well in new garden-pots, covered with clean paper, and a green sod put over the surface. We had the first hint of this from squirrel-preserves, their stores collected in autumn, when found in spring, were generally quite fresh and plump. In addition to them, we believe that a cool, dry cellar would be an excellent place for keeping all late Apples and Pears. Change of temperature is always injurious for keeping fruit. When a higher temperature is necessary to give flavour, the fruit can be moved for a few days to a suitable place. Turned round or lifted all *fruit trees en pots*, and the fruit being gathered. Dwarf Pear and Apple trees rather luxuriant, will have their roots pruned as soon as possible. Those that have borne profusely and made little growth, will have a mulching of something rich, which will keep the roots catering for the most of the winter. Young trees of Peaches, Apricots, Plums, &c., intended to be potted, should now be obtained from the nursery and potted at once, using rather small pots for the size of roots, spreading the roots out nicely, and potting as hard as possible, using soil in a medium state, neither dust dry, nor marsh wet. Any plants of last year in rather small pots may also be repotted, but not giving a large shift, and potting firm. If the leaves hang on after potting, or repotting, so much the better, and a slight sprinkling over the shoots and leaves on a sunny day, will tend to swell the buds, and set the roots running into the fresh soil. The securing this will be one great element of success next season, and this is the reason why planting in the end of this month is likely to be more successful than at any other time, as the roots get the benefit of the heat stored up in the soil.

## FLOWER GARDEN.

Notwithstanding the heavy rains, this is still too good to be meddled with, as nothing yet shows any signs of cold, except the tops of the *Perilla* in exposed places. I am rather surprised to hear that some gardens warmer even than this, were dismantled ten days ago, and the most favoured plants all pitted, and the beds sown with annuals, or made ready for bulbs. When I used to do things thus quickly, I never could please myself. Were I again to do these matters largely, I would take a sheltered border, or a piece naturally sheltered, such as between the rows of Raspberries and Currants, throw the ground into little ridges moderately firm, and there I would, in the end of September or the beginning of October, sow flower seeds rather thickly of *Nemophilas*, of kinds; *Collisias*, of kinds; *Enocheras*, of kinds; *Candytufts*; *Virginian Stocks*, of colours; *Saponaria calabrica*, *Silene pendula*, and others, and as they got up scatter a little ashes and lime about them. If very severe weather came, I would do just as I used to do, lay a few evergreen branches over them, or stick a few beside them, and if these were spruce or yew, vermin would not care for touching them. This would give an opportunity of clearing the bedding plants away properly, digging and levelling, and even previously exposing the beds to the air, and then before the plants got more than an inch or two in height, they could be moved in largish patches, never feel the moving, and grow with a regularity which they rarely do when sown in beds. Take a lesson from the accomplished gardener at Chiveden, add various-coloured Heartsease and spring bulbs, and how nice a spring garden any one might have, and everything get justice.

We have had several inquiries on this subject from those who wish to combine annuals, bulbs, and bedding plants, by just daubing the latter in among the former, and then the former

among the latter, with no regular digging of beds, &c., and telling me that such and such great gardeners do so and that successfully. Well, I cannot help it. We presume that our inquirers are quite as distrustful of their own greatness in gardening as I myself am, and, perhaps, more so; but I must say that I have little faith in anything that overrides system and work. I have seen such plans often followed, and the result satisfied some people; but to me, in general, the poor plants kept crying all the season to their neighbours to shake hands with them, which they resolutely refused to do, each standing stiffly alone in its dignity, if not its glory. All very well if the object had been for every plant to stand by itself as a solitary specimen, but rather out of place when the object was a mass of colour, and not leaves and flowers, alternating with good breadths of bare soil, as a contrast.

Again: we are obliged to a correspondent for telling us we were rather hazy in a short paragraph about *bulbs* last week. Our friend, aware of the importance of the bulbs having the chance of growing before the flower-beds are ready, does not see how he can do better than *pot* them, and cover them over, and then plunge pots and all together in the beds. Well, we have no fault to find, though a vast number of pots would be required if much was to be done; but still there would be an advantage in moving them in spring if the leaves were not matured by the time for planting the bedding plants. I have found, however, that bulbs planted in the free soil lift also pretty freely, and ripen their foliage when transferred to another place. The plan referred to was as a substitute for this potting, and perhaps we were not clear enough about the raised bed, which seems so hazy to our correspondent. Well, then, supposing it should be getting on towards Christmas before the flower-beds are just right for receiving bulbs. We wish to give these pretty well as much advantage in growth as if they were planted-out at once. Now, the raised bed—say 6 inches above the surrounding soil, and say for convenience 4 feet wide, is solely to secure drainage. Some 6 inches of rough rubble over that would do no harm, so as to let the rain pass away freely. Now, the position of this bed is of little consequence, it will do as well on a north border as anywhere else. On this raised bed we would place about 3 inches or 4 inches of roughish leaf mould, mixed with an equal amount of rough sandy loam, many of the pieces being from the size of Peas to Walnuts, and mixed together with lime—say a spadeful to a couple of barrowloads, to kill all worms, &c. This we would pat down, and place half an inch of sand all over, and on that we would set the bulbs; such things as Snowdrops close together, in rows 2 inches apart row from row; Crocus, not so thick in the row; Tulips, from 1 inch to 2 inches between the bulbs; Narcissus, large, 3 inches; Hyacinths, much the same; and cover all over with 3 inches or 4 inches of leaf mould or ashes. When these are wanted for the beds they will rise with good roots and balls, and will at once push away kindly into the well-turned pulverised soil—in fact, we often, from necessity, resorted to this plan of preparing, when we ultimately bloomed the bulbs in glasses, pots, vases, &c.

As the cold, wet nights are coming, Auriculas, Polyanthus, &c., should be got into frames where rains can be excluded and plenty of air given. Neapolitan Violets should be raised and transferred to the winter's bed, every runner being taken away; Chrysanthemums secured and top-dressed; climbers in conservatories and greenhouses regulated, the glass all washed and cleaned, and stages and shelves scoured, to prepare for getting in all the winter residents. We find that though climbers look beautiful in such masses in summer, much time is necessary to trim and regulate them for the winter, so that the plants in pots may receive their due amount of light.—R. F.

## TRADE LISTS RECEIVED.

André Leroy, Angers (Maine et Loire).—*Supplement au Catalogue de l'hiver*. 1860.

Thomas Rivers & Son, Sawbridgeworth.—*A Descriptive Catalogue of Fruit Trees (by Thomas Rivers)*. October, 1862. An admirable catalogue.—*A Descriptive Catalogue of Roses by Thomas Rivers*, 1862. A complete list of all the best kinds, with accurate descriptions, and numerous valuable remarks concerning them.

W. J. Nicholson, Eggescliffe, near Yarm.—*A Catalogue of Strawberries, Plants of which are Cultivated for Sale*. A descriptive catalogue of almost every known variety of Strawberry.

## TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

TO OUR FRIENDLY CRITICS.—One, not an "Ignoramus" though assuming that protecting signature, declares that "not one man in 10,000 would walk ten yards to look at anything on the seashore;" but what about the women-folk? Is Leech wrong in his sketch of the fair marine-shore searchers? "Ellen Gray" we excuse, if only because of her name, for saying—"I wish you would not urge people to keep bees; my uncle has bought Ligurians, and they sting worse than the old sort." One Scotch gentleman complains that we rejected his notes upon "Golf," and says it is quite as amusing as keeping canaries; whilst a second North Briton wishes us to publish three separate papers at a penny each! We are obliged for all this watchfulness over our interests, and we beg for its continuance; but what our opinions on the suggestions may be, following the example of Lord Palmerston on American suggestions, we will not reveal at present.

NECTARINES SHRIVELLING (*A Young Gardener*).—Perhaps your Nectarines were ripe when they commenced shrivelling, or the house might just be rather dry. Some kinds are more apt to shrivel than others when about ripe. Others are more apt to drop, and save themselves the trouble of shrivelling. We have noticed Nectarines, otherwise all right, begin to shrivel when, after several dull, cool days, a very sunny warm day has succeeded. A slight shade, or a sprinkle over the leaves with the syringe, would have kept them right, using the syringe chiefly on the lower side of the foliage or trellis.

CLIMBER ROSE AND OTHER CLIMBERS FOR AN ARBOUR (*S. P.*).—The quickest climbing Rose is not sufficiently good for such an arbour as yours; you must have a better, and less haste about it. Gloire de Dijon seems just a Rose made on purpose for your arbour. It will soon cover it, however, and be green more months than most Roses; and as for blooming, there is no end to it from the first day of the Rose season until the winter is fairly down upon us. There never was a better colour or a sweeter Rose for an arbour. And the Japan Honey-needle must be the second plant. This also is almost an evergreen, a very fast grower, and as to flowers there is no end to them; but it is for their most grateful fragrance they are so highly prized.

PIT-CONSTRUCTING (*An Old Subscriber, The Oaks*).—What you seem to require is a combination of pit with house. The length, 42 feet, we presume faces the south; the width to be 11 feet. You may sink 18 inches or 2 feet in the ground, or have the floor level with the surface. The first would be warmest but dampest, width 11 feet, height of back wall 7 feet, front 4 feet, hip-roof 2½ feet, in which back air can be given, or in openings in the back wall. The roof might be all fixed, and ventilators placed in the front wall, a flue would go along the centre on a level with the floor, a tiled or brick floor could form the top of the flue; a pit would be placed on each side, and for Cucumbers and Melons mature, sweet and hot, could be placed in the bottom, and soil on the top. In winter, a spar trellis could go across for plants, and the space beneath could be useful for roots. The walls could be built 4½ inches thick, or single brick on bed, and strengthened with 9-inch pliers every 4 feet. No steam could go through such walls, and manure, however rank, placed against them would throw much heat inside. But for the appearance no regular lining would be needed; but, if neatness were an object, the house might be sunk 18 inches or more. In such a case, however, there should be no ventilators in the front wall. We are sure that this you could make use of your manure in giving heat; and if you had cross drains, below the bed from the flue, every 6 feet, we do not see what you could not do with such a house. We would make at least one-third the length of the flue brick on bed, the rest brick on edge, with strong covers. The advantage of such a house, with or without lining is, that you can get inside and do what is wanted in all weathers.

OLD STONE WALLS (*A Subscriber*).—We do not know of anything to fill up the holes in such old walls unless by fresh pointing them with the best lime and sand mortar, or covering with a layer of Portland cement. We have seen a thick coat of gas tar and lime used, but it smells bad for some months, and is apt to injure the trees if they cannot be tied out of the way. In either of these cases, it would be advisable either to trellis the wall or stud it with nails, so as to make no holes afterwards.

FANCY GERANIUMS (*A Subscriber*).—All the kinds you name will make pretty window plants, but they will do little good planted-out in summer. The only way in which they will do moderately out of doors, is to put them into 48-sized pots in March or April, and plunge the pots out of doors in the beginning of June. They might stand outside on a windowsill after the 20th of May. If you chiefly want Geraniums for beds in summer, you had better exchange for such kinds as Lady Mary Fox, Sionia, Ronge et Noir, Diadematum, &c., and the plain and variegated Scarlet, Pluks, &c.

REPOTTING A PEACH AND VINE (*J. M. K.*).—They will not suffer much if done at once, but it should have been done in September. If potted now, you must ram the soil as hard as possible. If the case is particular, we would prefer top-dressing to all, and letting the roots go beyond the pots next season.

MANURING SPRING CROPS (*Z. A., Dartmouth*).—Your queries were answered in our last Number, page 561. Applying the manure in the spring need not prevent ridging the ground in the autumn.

HOT-WATER PIPES (*A Man of Kent*).—The rise from the boiler to where the pipe turns off horizontally is of little consequence, provided there is a rise in the flow-pipe. Suppose you go perpendicularly 2 feet, to the beginning of the horizontal pipe, then rise to the end of the flow-pipe a foot more, place an air-pipe at that end, and let the return-pipe come back similarly gradually to the bottom of the boiler. For such an arrangement, you would require a supply-cistern higher than the highest part of the pipes, communicating with the bottom of the boiler, and always kept full.

TANK-HEATING (*An Amateur Gardener*).—We have said so much on tanks, that really we have nothing fresh to offer. Were we going to heat your houses—one for Pines and Grapes, and the other for winter Cucumbers, &c., and late Grapes, we would have a bed—say 6 feet wide, in the centre of each house, and below that bed we would have three four-inch pipes for bottom heat, and three round the fronts and ends for top heat. To heat these independently of each other, we would have the boiler fixed at the back at the centre, the flow-pipe taken to an open cistern, and four pipes joined to it besides, furnished with plugs or valves, one pair to connect the flow of bottom and top in one house, and the other pair to supply the same office in the other house. By such means bottom and top heat in either department could be given at pleasure. You have evidently, however, set your mind on a tank, but expect too much from the fire from your boiler; so much, indeed, that we should expect to get your Cucumbers and Dwarf Kidney Beans destroyed by an explosion some cold severe night in January. Here, for simplicity's sake, and as bricks and lime seem no object, though lime will be of little use for the tank, we would recommend you to have a tank in both houses, and to depend on that for your chief mode of heating; though we have no objection to your running the fire also through part of a house, if so disposed, if built strong. Well, then, for the purposes designed, we would have the tank fully 6 feet wide, outside measure, and from 8 inches to 9 inches deep, in order that the sides may act as a heating medium to the atmosphere of the house. Six inches would be quite deep enough, and from 4 inches to 6 inches of water will be quite enough, or less; the sides will be quite as well heated, though the water does not rise higher than 3 inches. We would build the tank thus:—Ram the floor thoroughly, so as not to sink; place on it a layer of bricks, brick on bed, the best lime being used; another layer, placed in the best cement, and a layer of thin tiles over that, also cemented. This will form the base of your tank. Build the side walls on that, also in cement; run a division down the middle, except at the farther end, where an opening must be left for the flow. The skeleton is now complete, and must be finished with at least half an inch of cement placed carefully all round the side walls, and along the bottom. The better the cement is, the purer the sand, and the quicker the workman, and the more skill in applying the cement, the better will the tank stand. The next thing to insure success is, to have the boiler-top sunk several feet (the more from three to eight or ten the better) below the floor of the tank. A T-piece should be fixed on the flow, and the same on the return; and after getting a yard from the boiler, a lead pipe will do as well for connecting it with the tank as anything else. These flows may have a tap, or a plug, so as to let heat on at pleasure. The flow will go on at one end, and the return be connected with the other. Now, if we left openings in such a tank, it would be for examining it at pleasure, and shutting close up when we wanted a dry atmosphere. The tank, as a whole, we would wish to be securely covered with slate or other material. So much for the tank. The bed formed over it, for holding earth, &c., or plunging materials, might be made with brick ends and sides, or merely with a wooden box set on the sides of the tank. In either case, a little arrangement will be necessary to place the heat completely under control. On the covering of the tank then, be it slate or iron, we would have at least a foot of rough rubble, terminating with a layer of fine washed gravel, to prevent earth, &c., getting among the rough brickbats or rubble. Now, independently of the sides of the tank being exposed for top heat, a couple of slides on each side of the pit, on the same level as the clinkers, would enable you to let out heat from the bottom when there was too much, and to confine it when there was scarcely enough. By building the tank close to the ground, or about a foot above it, there will be more room for Pines and Grapes, and the stems of Cucumbers, &c. There are just several more matters to be alluded to. First: the Vines will do well enough at the back of the Pine-house. If the plants are strong in pots, and you wish them to fruit the first year, we would widen the holes in the bottom of the pots, and plunge the pots in the border. If not intended to fruit, then we would plant-out and spread-out the roots. The border with top-dressing will do well, though only 3 feet wide; if 2½ feet deep, a layer of a foot of rubble below that, and drainage secured. If the stems can be taken out after the fruit is cut, and the wood ripened, all the better. Again: in the Cucumber-house andinery, it will be advisable to turn the Vines out in the end of autumn, but they should be protected in winter. Had you a double front, they would be secure between the two, and be kept dry. We have no doubt such a plan will answer, and hope we have done a little to meet your case.—R. F.

SIR JOSEPH FANTON'S GLAZED HOUSES (*An Irish Subscriber*).—We have had no experience of these, but we think we can understand them thoroughly. The objection against them where early forcing especially is concerned is, that the ventilation between the sashes opens from top to bottom; but this could be easily remedied, though at the expense of simplicity, by having these ventilators in two or three pieces. The chief recommendations are, comparative cheapness and complete moveability of the houses at any time. If you ask us would we resort to that system in building permanent houses, we unhesitatingly say, No. For such a case as yours, to combine alike economy and suitability, we would have large squares of glass and fixed roofs, with ventilation in front and back. If lean-to's, and the walls to be built, we would have the ventilation in the back wall near the top, and the same in front, be it wood or brick. We could not tell which is the best boiler. We find they are all best as best managed, and we would engage to work every kind of boiler well that is advertised in our pages; though, if we would give an opinion, we would say that the simpler they are the better. The great thing is to have a large surface exposed to the fire for the small quantity of water the boiler contains. As to arrangement of pipes, you will find much in answer to correspondents to-day; and if you tell us what you definitely desire, we will give you our opinion on the matter. Did you want to heat the houses—say two, independently of each other, you had better place your boiler in the centre. Did you wish to make three or four or six divisions, you had better place the boiler at one end, take a flow and return from end to end, and have connections for these with each house, to be turned on or off at pleasure. If you want more definite information, refer to the page and volume.

**DIOSCOREA BATATAE (M.).**—Leave them in the ground, and give the another year's trial—the tubers increase in size by so doing; but if you did not trench the ground very deep at the time of planting, there will be no useful tubers. Some good specimens of these have just been exhibited at the Root Show of the Royal Horticultural Society.

**TOM THUMB LEAVES (Anne, Gloucester).**—Your case is a familiar one. A small caterpillar called the leaf-miner attacks them when they are just unfolding from the bud. When we see a leaf so mined we pinch-off the top joint, and look over all the plants and do the same. Sometimes these Geraniums come up with peckered and discoloured leaves, which is far more difficult to subdue than the miner, as every shoot so affected must be cut back to an old leaf. The cause of this disease we do not know.

**PROTECTION FOR WALL TREES (Old Deer).**—As you cannot have glass, we think you will find what you inquire about woollen netting in our advertisements. The frigid demo would also answer well, but it would require to be moved oftener. If you did not dislike the trouble of moving it, we think that for your cold position stout calico or sheeting would be best of all. The woollen netting would need little moving, but we have seen it of no use when of one-inch mesh. The chief requirements with a moveable cover like frigid demo, bunting, or calico, are to put it on early, as soon as the buds show signs of swelling, to keep it on so as to retard the buds, and more especially in a sunny day, in order that the soil may get heated rather than the wall, moving it aside in a cold, dull day; and even when the flower opens, sheltering a little in the middle of the day when there is bright sun, and covering at night, and even in the day when there is a chilly east wind. A great amount of light goes through the calico, and there will be sure to be air enough. A good, cheap material is a want.

**HEATING A PIT (H. B., Victoria Park).**—With or without a screen we have no faith in any stove that does not have a funnel to carry off the smoke and gases made by the combustion of the fuel. In a late volume there was a good deal on stoves and flues by Mr. Fish. A small iron stove with a funnel would answer with care; but there would be trouble in managing it, as you must open a light to get to it. The simplest and the best thing for you, would be a small brick or Arnot's stove, built inside in the middle of the pit, and close to the back wall—say 2 feet 4 inches square, outside measure. This would leave space enough for a grating to be placed about 2 inches from the floor, a fire-box inside, surrounded with fire lumps 8 inches or 9 inches square, height of stove 3½ feet to 4 feet, covered at the top with a thick Welsh tile, or better still, with an iron plate half an inch thick. Nine inches below the plate should be the outlet-funnel for smoke. Of course we presume that as much of the back wall will be removed as will enable you to get at the feeding furnace-door and ashpit-door outside. These should be about the size of the fire-box, 8 inches to 9 inches, and made to fit close. In lighting, leave the ashpit-door open until the fire has got hold, then shut up, or, if necessary, leave just a little air. If the ashpit-door is well managed there will be little use for a damper. Coke broken should be used. We have no doubt this would keep out frost with but little trouble, and would cost less than a small flue round the front and one end, which would be better still.

**MANAGEMENT OF FERN CASES (Osmunda).**—If you will buy our No. 517, first series, you will there find directions for the greenhouse culture of Ferns, and those directions are applicable to Fern cases. At the close of the present year we shall publish a very fully illustrated work on the subject.

**MADAME VAUCHER GERANIUM (M. D. P.).**—The flowers are certainly not those of Madame Vaucher; they are rather from one of a recent race of continental make, and decidedly ugly. No English lady would tolerate such milk-and-water colours; one half pale bluish, the other half a pale watery pink.

**SAVING CROCEUSES FROM MICE (A. P.).**—Nothing is more certain than that a whole border of Croceuses might be planted in a border by the side of a barn full of mice, and be exempt from their botanical propensities; and not only Croceuses, but seeds and roots of all kinds. The mode of preserving them is to keep fresh soot in a bag or barrel, free from air and moisture, and to sprinkle the whole surface of the ground with it after planting or sowing; and as soon as rain, dew, or damp renders the soot unfit to fly about like Scotch snuff, to renew it on the instant. This operates in two ways—the smell of the soot conceals that of the bulbs of the Croceuses, and the mice are thus put on the wrong scent; but mice have the curiosity of cats, and will go and examine any new arrangement made in their usual runs, and, of course, a fresh-made border would take the whole barnful out the first night to see what it all meant. Then they must walk over it to find that out, and at every breathing the soot is inhaled into their throats and nostrils, and away they all scamper just as if a tom cat had that moment come round the corner of the barn. The only secret is to keep the soot on fresh and fresh, like the old woman's salt, till the mice are thoroughly convinced it is done on purpose.

**MUSCAT GRAPES (P.).**—The Tynningham Muscat and Muscat Eschollata are both forms of Muscat of Alexandria, and may be obtained from any respectable nurseryman under these names. By many they are considered distinct forms, and by some as synonyms of Muscat of Alexandria; and until all Muscates are grown together in the same house, and subjected to the same treatment, there always will be a doubt on the subject.

**FLOWER-GARDEN PLAN (F. H. A.).**—This consists of three concentric circles—1, Scarlet Geranium; 2, Yellow Calceolaria; 3, Perilla; all done to a shade. From the outer circle 3, seven loop-beds spring at equal distances all round like rays of a star, to be planted with different kinds of Verbenas, also all good. F. H. A. asks if it is better to have the three circles on the level, or raised in three steps, as it were? The answer is this. If all the beds are seen from a higher level, raising the circles will improve the general effect; but if they must be seen from their own level, they should not be raised, because one half of the figure or garden can only be seen from any one point. Did you not notice how the effect of the great centre figure in the new garden of the Royal Horticultural Society is completely ruined by the raised vase-like bed in the centre of it?

**GUANO (M. F.).**—Lime water would in some respects injure, and in no way improve the guano.

**GLADIOLUSES (—).**—We have just issued the very list you now apply for. Read our reports on the Gladiolus exhibitions, and you will see all you want plainly laid down; but follow "D., Deal's" names as the most useful. In the spring—say next February, put us in mind again if you find any difficulty, and we will publish lists.

**RED CLAY SOIL (W. H. B.).**—No treatment will so effectually and permanently render it a good, friable, flower-garden soil as paring and burning the top spit of the entire garden, and digging in the ashes.

**ROSES (E. M. M.).**—We have asked Mr. Beaton to throw some light upon the subject.

**CATERPILLARS ON CABRAGES (A Subscriber).**—There is no remedy so good as hand-picking. Attention to this for two or three successive days saves the crop of this year and those of future years.

**PLANTS FOR COVERING GATE-PIERS (A Subscriber).**—*Ceanothus divaricatus* would soon cover the massive pillars, and be about the best plant we have for such a place.

**IXIAS, CYCLAMENS, &c. (B. B. T.).**—We are certain you cannot succeed in what you propose. Give up the idea entirely, till you have experience in growing Ixias, Sparaxises, and Cyclamens in pots. Get a bulb catalogue, and select the kinds according to the prices you would like. Every one of all the kinds of fancy bulbs like these is as good as any other, and have nothing to do with Cyclamens for the system you want to adopt.

**PHLOX DRUMMONDI (Cecilia).**—To be in early bloom it must be sown at the end of February in heat, and treated like the blue *Lobellias* in all respects. It will propagate from cuttings as freely as any bedding plant; but it is now six weeks too late for those who need instruction how to treat it. It is difficult, even for professed gardeners, to take up old plants of Phlox Drummondii and keep them over the winter. You must trust to seedlings as above.

**BED OF DELPHINIUM FORMOSUM (Idem).**—You must buy twelve good plants of Delphinium formosum, and make twelve more plants by dividing your four old ones, and when the bed is ready, between this and the new year, plant them all out about a foot or 15 inches both ways, and sow your seed of it next March or April to come in the year following.

**CUTTINGS (Idem).**—It is over now for all sorts of bedding cuttings for amateurs who need instruction. Tom Thumb Nasturtiums are the easiest of all cuttings to root; but you had better trust to seeds at all times, as they come true enough that way, and save the bother of keeping them over the winter.

**PRUNING HOLLIES (A Subscriber).**—This is not a good time to prune Hollies. The whole month of April is the best time to prune Hollies, and the next best time to prune them is May, or June, or July.

**IVY-LEAVED GERANIUM (S. R.).**—Yours is not the common Ivy-leaved Geranium, but the next to it—the variegated variety of Pelargonium petalatum. It was scarce till within the last ten years, and it has failed to be of any use in flower-bedding, on account of the weakness of its constitution. It was named by Mr. Aiton, gardener to George III., and is the twentieth plant that was figured in the first going-off of the "Botanical Magazine."

**A FIX ABOUT VARIFOATED MINT (M. F.).**—In the first place it was not the best plan to have the variegated Mint planted out in pots. Now, the balls must be left just as they are till the end of next March, in some light compost, anywhere out in the garden. Unearth the balls at the beginning of April, put them one by one on some hard dry bottom, and knock them to pieces just as you would do a lump of chalk, and every morsel of the broken fragments will make a ribbon-row plant, if you only make a drill as for a row of Mignonette, and sow the pieces in the drill, and cover as you would seeds.

**NAMES OF FRUITS (J. B., Subscriber).**—Pears: 1, Beurré de Capiaumont; 2, Beurré Rance; 3, Marie Louise; 4, Red Doyenné; 5, Welbeck Bergamot; 7, Duchesse d'Angoulême; 8, Fondante d'Automne; 10, Winter Nellis; 12, Bergamotte de Stryker; 16, Beurré Diel. Apples: 5, Kerry Pippin; 6, Yellow Ingestrie; 28, Lemon Pippin. We happen to know the above by glancing our eyes over them; but how can a correspondent expect us to give up the time required to examine forty Apples and twenty-two Pears? (J. B. Phelps).—1, Blenheim Pippin; 2, Summer Pearmain; 3, Sack and Sizar; 4, Franklin's Golden Pippin. (M. Matfield Green).—Apples: 1, Hughes' Golden Pippin; 3, Beauty of Kent; 5, Summer Strawberry; 6, Christie's Pippin; 7, Round Winter Nonseh; 9, Old Russet; 10, Hicks' Pippin; 12, Golden Knob; 13, King of Pippins; 15, Winter Greening. Pears: 1, Beurré Bose; 2, Marie Louise; 2, Winter Nellis; 4, Bergamotte de Hollande. The others we do not recognise. (D. Binney).—1, Blenheim Pippin; 2, Brown Kenting; 3, Summer Pearmain; 4, Braddick's Nonpariel; 5, Winter Greening or French Crab; 6, Nancy.

**NAMES OF PLANTS (Agricola).**—*Gymnogramma ochracea* and *G. tartarea*. The other specimen is imperfect. (J. Foster).—Not *Lastrea cristata*, but *L. Filix-mas var. incisa*, a very common Fern. (M. D.).—*Celsia betonicifolia*. (D. R. Aston).—1, *Pleopeltis, alias Drynaria ixioideis*; 2, *Sagenia, alias Aspidium macrophylla*; 3, *Cyrtomium falcatum*; 4, *Woodwardia radicans*; 5, *Athyrium Filix-femina*; 6, a form of *Lastrea dilatata*—apparently *grandidens*; 7, *Athyrium Filix-femina crispum*. We cannot go any further this time. (W. B. Marlow).—1, *Pteris scrubulata*; 2, a narrow form of *Polystichum aculeatum*; 3 and 4, two imperfect *Selaginellas*; if No. 3 has a bluish metallic hue on the upper surface, which appears to be the case from some traces on the fragment sent, it is *S. uncinata*. (H. B.).—1, *Zygopeltis Ma kari*; 2, *Adiantum oblongata*; 3, *Veronica arguta*. (H.).—1, *Lastrea Sieboldii*; 2, *Belopone pubescens*; 3, *Pteris serrulata*; 4, *Blechnum brsilense*. The Pansy is no doubt the variety called *Magpie*. The shrub may be an Olive, and may not; there is nothing whereby to determine.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**POULTRY SHOWS.**

OCTOBER 23th. COLLINGHAM. Sec., W. C. Oates, Esq., Besthorpe, near Newark.  
 OCTOBER 28th and 29th. CALNE. Secs., A. Heath and F. Baily. Entries close October 15th.  
 DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.  
 DECEMBER 9th, 10th, 11th, and 12th. CRYSTAL PALACE. (Poultry, Pigeons, and Rabbits.) Entries close November 8th. Sec., W. Houghton.

DECEMBER 16th and 17th. LORD TREDEGAR'S, Newport, Monmouthshire.  
Sec., Mr. J. G. Pallig, Newport.

DECEMBER 29th, 30th, and 31st. MANCHESTER.

JANUARY 1st, 2nd, and 3rd. GLASGOW. (Pigeons and Canaries.) Sec.,  
Mr. T. Buchanan. Entries close December 22nd.

## KILLING AND PREPARATION OF FOWLS.

(Translations from M. Jacqué's work on Poultry continued.)\*

It is not by a massacre we should end the career of the beautiful animals we have given ourselves so much trouble to rear, and that have come to us so often when they have heard our friendly voice. These animals should die nobly, and I have a great respect for the *intention* of the Jews, who cause them to be immolated by a sacrificator. The fact of dooming to death a being so admirably constituted and so full of life, has something in it so terrible, and answers to such a cruel necessity, that the act should be accomplished with dignity, and with a scrupulous conscience—that is to say, by employing the means and utensils most certain to abridge the horrible agony of these poor beings. What atrocious and useless sufferings! What indifference, and I should dare to say, what contempt for all these destructions!

I know nothing more ridiculous than sentimentality; but the humane idea which has guided the founders of the Society for the Protection of Animals is, in my opinion, nobler and more religious than many great and pompous conceptions.

In order to come to our subject, we will say, then, humanity demands that every precaution be taken to avoid submitting to preliminary tortures the unfortunate fowls devoted to death, not to tie them in bundles like vegetables that are sent to market, nor to allow them to be teased by children, &c.; finally, not to adopt the reasoning of cruel and ignorant idiots—it is *only to kill!* as if, before killing, one should torment.

Humanity demands besides, that the instruments destined to cause death should be even and sharpened, so as to act rapidly and certainly, and that the persons who kill should be instructed by competent teachers. We dare to hope that the day will come when such persons only who have studied under practised veterinaries will have a right to kill these beings that die by thousands every day to help to support our existence; and that we shall no longer see on the market places the horrible spectacle of an old woman killing an unfortunate fowl by inches with a knife which, having neither handle nor edge, refuses to cut the throat.

Let us listen to the precepts on this subject given by Messrs. Allibert and Mariot-Didieux, both veterinaries. M. Allibert writes thus—

"Like cattle, fattened fowls should not be killed till they have fasted about twenty-four hours, which allows the crop and intestines to become empty. The extraction of the latter is easier in consequence. Lean, or half-fattened fowls, are killed by cutting the venous conduits near the head, and then holding the bird suspended by the feet; this facilitates the bleeding, and makes the flesh whiter. Choice fowls, however, require more care, and are killed with a sharp, pointed knife, or the fine blade of a pair of scissors, which is thrust through the palate to the brain; then the large vessels inside the throat are cut without injury to the skin; the animal is then suspended by the feet, in order that all the blood may run away, and its beak is then washed.

"As soon as it is dead all the intestines should be withdrawn without making any opening, but drawn carefully out and cut off at their origin close to the gizzard. The liver and gizzard should remain in the abdomen. This operation is indispensable; for, if the intestines remained some time in the bird after death, the smell and even the taste of stercoral substances would invade the meat, would render it detestable, and facilitate its decomposition. The vacuum caused by withdrawing the intestines is filled up with balls of paper, which are put in at the natural opening, through which the intestines have been withdrawn; this keeps up the size and shape of the fowl.

"Fowls should be picked while they are hot. In this operation the greatest care should be taken to avoid tearing the skin, which spoils the appearance and injures the sale; after being picked, the fowl is put in cold water if the weather is hot, in order to become thoroughly cold; if that be not necessary, it is washed, wiped, and wrapped in a cloth. The poultry women of La Bresse sew-up their choice fowls in a fine cloth, taking care to maintain the oval form; then they soak the linen in milk, in order to give more whiteness and softness to the skin.

\* We translate literally, without binding our own opinions. In many parts we prefer our own methods.

"These choice products should not be packed-up till they are thoroughly cold; each fowl should be wrapped in whitey-brown paper, and they are generally packed in hampers."

We will now see what M. Mariot-Didieux says—

### "BLEEDING TO DEATH.

"Much of the poultry brought to divers markets is killed a long way off. That killed by bleeding is cleaner, more saleable, and keeps longer than any other. The operation is generally performed with scissors which have two pointed blades, each *very* sharp. It is at the back of the mouth, behind the palate, that the operator will sever the two carotid arteries. When all the blood has run away, the clots which may remain on the beak and at the back of the mouth should be removed, and the parts where they have been washed with vinegar. This arterial bleeding empties the body of blood without any outward trace. Nearly all the fowls in the Paris market are killed in a different manner. Their throats are cut at the base of the head. The red wound, bloody and ill-looking, is not only a disagreeable object, but brought in contact with the air putrefaction ensues; then it acquires a nasty smell, and often a buyer declines it for that reason alone. Killed as we advise, the animal is cleaner, more saleable, and it keeps longer. This is very important if it has to be sent far."

## MANCHESTER SHOW.

I HAVE just received a prize list of the Manchester Show of Poultry, Dogs, and Pigeons, and quite agree with the favourable remarks respecting its extreme liberality, as detailed in your Tuesday's publication. But there is one item on which I, with many others, should wish to be enlightened. I find it stated in the printed regulations, that exhibitors can forward stock for competition so late as ten P.M., on the 27th of December next; and again the rules specify, "That the Exhibition will be opened to the public generally at eleven o'clock on the morning of the 29th of December."

For the arbitrators with so comprehensive a prize list, however diligent those parties may be, to properly complete their decisions prior to the early hour on the Monday thus appointed, is necessarily impossible; more particularly as that essential duty cannot be commenced on the Saturday at all, from the fact of the exhibitors being privileged to send in their contributions until so late an hour.

Now, it surely cannot be in contemplation to judge the poultry and dogs, either wholly or in part, on the intervening Sabbath, for if this improbable contingency is the actual arrangement, many exhibitors equally with myself must decline sending at all to Manchester for this sufficient reason. But, perchance, the explanation that may yet be offered will clear away what I really trust may prove an erroneous first impression, though, after all, it will be interesting to every exhibitor to know *when* the adjudications will be actually made.—INQUIRER.

[We shall be glad to hear officially upon this point, because we know several parties who will not exhibit at Manchester if the Sabbath is to be thus misemployed.—EDS.]

## MIXING VARIETIES IN ONE CLASS.

I NOTICE in your Journal a communication from Mr. Hewitt, of Birmingham, which I hope will receive the attention it deserves from committees and managers of poultry shows whose prize lists for the coming season have not yet been published. My own experience of upwards of twenty years in connection with poultry of every kind, and the opportunities I have had of ascertaining the opinions of many of our leading amateurs, convinces me that if committees desire to secure a large number of entries (and it has always appeared to me that this is one of the chief elements in a successful show), they cannot possibly adopt a more certain method of obtaining this result than by issuing a prize list so classified that exhibitors of each variety may enter in a class of their own.

I could mention no end of instances which have come under my notice, in which entries have been withheld which would otherwise have been sent had there been facilities afforded for the owners to exhibit their favourites in classes where they would not have to compete for one or two prizes with birds of other varieties; and I am certain the choice of the majority of our fanciers would be in favour of moderate prizes and an extended

classification, rather than high prizes and a limited classification. Upon this conviction I have myself acted in reference to the schedule of the Taunton and Somerset Association, and though our revived Society has held but two exhibitions, our list has received universal commendation; and though our prizes are not so high as some other associations can boast, yet at our show this year we had an increase of forty-three entries over that of last year, and every class with the exception of two (and there were forty-six for poultry alone) was well filled.

I notice in the Glasgow list there are but twenty-five classes, scarcely more than half of ours; yet the total money value offered in prizes amounts to nearly double ours.

I desire also to endorse Mr. Hewitt's expressed opinion as to the impossibility of so awarding prizes as to satisfy exhibitors when two or three prizes have to be distributed amongst as many or more varieties or breeds; and I trust that, attention having been called to a point of so much importance as this confessedly is to amateurs at large, it will receive that consideration it merits from all who desire to promote the welfare of poultry exhibitions throughout the kingdom.—CHAS. BALLANCE, 5, Mount Terrace, Taunton.

### MONMOUTH AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS took place on the 8th instant. The number of birds was not large, but they were generally good specimens. The Judges were Mr. John Hughes, and Mr. James Eiss. Their awards were as follows:—

GEESSE.—First, A. Jones, Priory Farm. Second, Mrs. Gunter, Argoed. *Goatsings*.—Prize, Mrs. Gunter, Penalt.

DUCKS.—First, R. H. Nicholas, Malpas (Aylesbury). Second, C. Elliott, Tretire (Ronen). *Ducklings*.—Prize, J. Pearce, Wyesham (Aylesbury).

TURKEYS.—Prize, W. Williams, Pilstone. *Poultis*.—Prize, W. Williams.

SPANISH.—First, Mrs. E. Pearce, Wyesham. Second, J. Pearce, Wyesham.

*Chickens*.—Prize, J. Pearce.

DORKINGS.—First, Mrs. A. Jones, Priory Farm. Second, F. T. Parker, Rockfield. Commended, R. H. Nicholas, Malpas. *Chickens*.—Prize, F. T. Parker.

COCHIN-CHINA.—First and Second, R. H. Nicholas, Malpas. *Chickens*.—R. H. Nicholas.

HAMBURGHS (Gold or Silver-pencilled).—First, J. Cloud, Monmouth (Silver). Second, H. M. Clifford, Llantillo (Gold).

POLANDS (Gold or Silver-pencilled).—Prize, Mrs. Bagnall, Monmouth (Gold).

GAME.—First, J. Jones, Llwynygaer. Second, J. Cloud, Monmouth. *Chickens*.—Prize, J. Jones.

BANTAMS.—First, Mrs. G. Everett, Gibraltar Cottage (Silver-laced). Second, J. King, Dixton. Commended, R. H. Nicholas (Japanese Silks).

*Chickens*.—Prize, J. King, Dixton.

ANY OTHER VARIETY.—First, R. H. Nicholas, Malpas (Sultans). Second, R. H. Nicholas (Black Hamburgs). *Chickens*.—Prize, R. H. Nicholas (Japanese).

GUINEA FOWLS.—Prize, F. T. Parker, Rockfield. *Poultis*.—Prize, A. Jones, Priory Farm.

PIGEONS.—*Carriers*.—Prize, R. H. Nicholas, Malpas (Belgium Carriers). *Fantails*.—Prize, R. H. Nicholas.

### THE POULTRY PENS AT NEWCASTLE AND MELTON-MOWBRAY.

ON looking over your Journal of the 7th inst., I am greatly annoyed on perceiving that you make use of my name in a very unjust and injurious manner. I allude to your comments on Newcastle and Melton-Mowbray Agricultural Shows, wherein you give the Committees credit for perfection in all their arrangements, and then proceed to detail circumstances in which I am connected, wherein you draw the inference that all their arrangements were ruined by my mismanagement. As such a statement is totally at variance with the truth, I will give you the plain facts of the case, and trust that in common fairness you will give the same publicity to my explanation as you have done to the charges against me.

As regards the insufficiency in number of pens at Newcastle, you are quite correct; but the fault was with the Secretary entirely. He wrote to me complaining that I had not sent the number of pens ordered; but I forwarded him his own letter wherein he gave the order, and he wrote to me acknowledging the fault (I send herewith a copy of his letter). I think I have cleared myself as regards Newcastle Show.

Respecting the Melton-Mowbray Show, you state the terms of agreement, in which you are quite correct; but the cause of the misunderstanding was with the Secretary entirely, on his giving the order for pens. The agreement was that they should

be fixed on Thursday, and, according to their own schedule (a copy of which I enclose), the poultry were to be penned by 9 o'clock on Friday morning; but the Secretary acknowledges that he wrote to the exhibitors requesting them to send their birds a day earlier than originally named, and he forgot to communicate the alteration to me: consequently, when my man arrived on Thursday morning the pens were already fixed; and as to the surplus pens which you state were lying about, that was on account of the Secretary ordering considerably more than they required, and not because they were mis-sent there instead of Newcastle, as you infer. You state that no one on my behalf had reached Melton when the Exhibition opened; but you are quite mistaken, and I beg to refer you to the Secretary for proof. If my statements are not sufficiently explicit, I am prepared to give any further explanation you may require.—JAMES TURNER, *Wire Works, Sheffield*.

[We most willingly insert Mr. Turner's explanation, which fully exonerates him from blame, and shifts the mistakes to the respective Secretaries of the Shows. We are glad that it is so, because the convenience of being able to hire such pens is great, and we should be sorry if any neglect or carelessness on the part of the lender had interfered with their employment.—EDS.]

### BEEES AND BEE-HIVES

#### IN THE INTERNATIONAL EXHIBITION.

TO those apiarians who have already visited the Exhibition with the express intention of seeing all that is there displayed in connection with their favourite pursuit, it may appear superfluous to state that English contributions to apian science are placed on the west side of the eastern annex; but to the casual visitor who may be disposed merely to cast half an eye on the bees and bee-hives, this information can scarcely be deemed unnecessary, since we find many among our own friends who have visited the Exhibition repeatedly, and totally failed to discover that there was anything at all in it relating to our industrious little favourites. To those, therefore, and such as those, we may repeat that on the west side of the eastern annex, amongst agricultural and horticultural machinery and implements, may be found by such as seek for it carefully all that English apiarians have deemed it necessary to exhibit in connection with bees and bee-keeping.

FENN, R., *Rectory, Woodstock, No. 2112*.—On first entering the eastern annex from its north end we meet with a handsome glass case, exhibited by an old and esteemed correspondent, containing two straw hives of a large and useful size (from which, however, we should like to discard the cross sticks), one with a well-filled super, and the other protected by a milk-pan surmounted by a weighty ornament in carved stone, to prevent its being dislodged by the wind. Here are also the "breakfast honey-glass" filled with the most tempting and delicious-looking honeycomb, small glass super, "self-floating feeder," together with run honey and old and new wax, with their various products of mead, vinegar, waterproof dubbing, furniture cream, &c. Of all these we shall give fuller particulars in a future Number.

MARRIOTT, J., *Gracechurch Street, No. 2150*, has a stock of common black bees at work in a bell-glass, carefully shaded from the light by a chamois leather cover, apparently flourishing very well, and presenting a miniature scene of bustle amidst the ceaseless activity on a far larger scale of "The World's Fair." There are also hives of various descriptions, including those termed "improved cottage," two rotary observatory unicomb-hives, neatly got up in mahogany, &c. This is an interesting and well-furnished stall, quite deserving the "honourable mention" which it obtained.

NEIGHBOUR, G., & SONS, 149, *Regent Street, and 127, Holborn, No. 2157*, have a very handsome and complete stall, on ascending the steps of which we found a flourishing stock of Ligurians, apparently not at all a-hamed of the public position which they occupied, and working vigorously in the full light of day. The queen, one of the largest and finest-coloured we have met with, was perambulating the combs and receiving the homage of her subjects, stopping frequently to deposit an egg in every empty cell. The hive itself was a "Woodbury Unicomb," handsomely got up in mahogany, invented as its name implies, by our valued correspondent, "A DEVONSHIRE BEE-KEEPER," the construction of which will be most readily understood by an

inspection of the annexed engraving. Its distinctive features are the adaptation of the moveable-bar system to unicombs-hives, by

which any colony in an apiary of "Woodbury-hives" can be placed in the unicombs-hive in a few minutes, and the use of "outside venetians," or "sun blinds," as they are called, instead of the usual impervious shutters. By this contrivance light is never excluded, so that when the hive is opened for inspection, all its inmates continue their avocations with their accustomed regularity, and a quiet and orderly scene is presented to the spectator, instead of the hubbub and confusion which ensues in ordinary unicombs-hives. On the left-hand side of the unicombs hangs a beautifully-executed drawing of a Ligurian queen bee magnified, together with the queen worker and drone of *Apis Ligustica*, of the natural size. Immediately under the drawing is placed a square glass super containing nearly 40 lbs. of the finest honeycomb. On the right of the unicombs-hive is another super of the same description, containing nearly 30 lbs. of the purest honey. These supers are, undoubtedly, by far the finest in the Exhibition, and are the first worked in England by Ligurian bees, being from the apiary of "A DEVONSHIRE BEE-KEEPER." In addition to these, the most striking objects, are shown Neighbour's improved single box and cottage-hives, Taylor's bar-hives, Woodbury frame and bar-hives, the new bottle-feeder, and bee apparatus of every description. It will be apparent from the foregoing, that Messrs. Neighbours' stall is well worth inspection, although the various novelties it contains appear to have met with but scant appreciation by the Jury, who merely awarded to them that "honourable mention" so lavishly accorded to far less deserving objects.

TEGETMEIER, W. B., *Muswell Hill*, No. 2192.—Passing through the doorway and the court into Ormson's conservatory, we find therein one of Mr. Tegetmeier's frame-hives which that gentleman has already fully described in our pages. It has the Stewarton bars and slides, and the old wide frames, at distances (eight in 13½ inches) recommended by Dr. Bevan and Mr. Golding, but considered too wide apart by German and some of our English apiarians.

LOVEY, E., *Ponsnooth, Perranwharf, Cornwall*, No. 2147, shows a stock-box and super neatly made in oak, the latter having bars with side pieces and slides Dr. Bevan's distance apart. The slides are strips of wood rounded at the edges, about three-quarters of an inch wide, by a quarter of an inch thick, and are pushed in and out through slot holes cut in the sides of the box. We think these slides very liable to become immovably fixed by propolis when in use, and that no stock of bees can prosper very long in a dwelling of such limited dimensions as 10½ inches square by 7½ inches deep. There is also a flat-topped straw hive with glasses, which calls for no particular remark. The Jury, in some whimsical freak of caprice, awarded this gentleman the highest honour which they have accorded to British apiarian exhibitors—viz., "honourable mention," for what reason we are utterly at a loss to discover.

HUGHES, HENRY, *Loughborough*, No. 2133, exhibits a flat-topped straw hive with wooden octagonal case and dome-shaped zinc roof, also a small bar-super and feeder, none of which appeared to us in any way remarkable.

BOOTHMAN, JAS., *Gisburn, near Skipton, Yorkshire*, No. 2093, contributes a glazed case containing a moveable comb-hive, honey-extracting machine, and wax-refining apparatus. Of this

moveable comb-hive we can only say that it is highly ingenious—so ingenious, in fact, and so full of mechanical contrivances, that many of them pass our simple comprehension. Every comb is supported by an elaborate metal framework, and the entire hive forms quite a complex piece of machinery. There is a separate glazed receptacle fitted to receive one of the combs, and intended, we believe, to answer the purpose of a unicombs-hive. The honey-extractor consists of a machine for crushing combs on the principle of a sausage-making machine, and a screw-press to place them in afterwards for the purpose of extracting the honey which they contain. The wax-refiner is a cylindrical copper vessel in which works a piston of double gauze wire. The combs being placed under the piston with a sufficiency of water, the whole is put on the fire; and as the piston sinks the wax rises to the top, whence it can be removed in a solid state when cold.

(To be continued.)

### HONEY HARVEST ON THE MOORS.

CAN you tell the name of the enclosed plant, and whether bees get honey or pollen from the flowers, as they frequent them very much about this part, south Durham? [It is *Centaurea nigra*, Black Knapweed, or Matfellon. We conclude that they get honey from it.] As most of your bee-keepers will have brought their hives home from the moors, I should like to hear what success they have had, as in this part they have done very badly, the heaviest out of fourteen of mine, is only 26 lbs. nett, whilst some have only made 7 lbs. and 8 lbs., and it is the general complaint that they have done very little at the moors this season, and several have died.—A. W.

[We shall be glad if some of our correspondents will reply to this query, as to the success of the honey harvest on the moors.]

### OUR LETTER BOX.

TRIMMING AND PAINTING FOWLS (*Exhibitor*).—In some instances the fowls so treated have a card stating the fact, and their consequent disqualification attached to their pen. We agree with you in thinking it ought to be done always, "as a warning to exhibitors and as a protection to purchasers."

WEIGHT OF A GAME BANTAM COCK (*T. C. H.*).—There is no proper or fair weight for a Game Bantam Cock. White legs are as good and as pure as any others. We believe we may say it is an established fact.

HYBRID BETWEEN BANTAM HEN AND PHEASANT (*Idem*).—It will not breed. We have had many, and although there was sufficient difference of size and appearance to indicate sexes, they were only imaginary. You will not succeed if the bird is really a hybrid.

ILLNESS OF EAST INDIAN DUCKS (*G. C.*).—We have no doubt the water or something in it disagrees with the Ducks. Confine them entirely in an old pigstye or outhouse. Feed on oats put into a shallow vessel, with plenty of gravel and a turf of grass, the whole covered with water. Separate the sound from the unsound birds.

MOths IN BEE-HIVES (*Colney Hatch*).—Moths may easily be extirpated in bar or frame-hives by lifting out the combs, and cutting out the infected parts. With common hives we know of no remedy if the bees are not able to take care of themselves; and, to enable them to do this, every precaution should be taken to keep the stocks vigorous and well populated. Are you quite sure as to the true cause of all this mischief? Moths do not eat honey, nor do they kill bees except indirectly by damaging their combs. Our impression is that the had honey-season is in fault, and that the bees, being weakened by starvation, cannot make head against their enemies, the moths, as they would do if in a prosperous condition. Immediate and liberal feeding is in this case the only possible remedy, and offers the only chance of escaping a fatal catastrophe.

CANARIES DYING (*P. S. B.*).—The disorder among your birds, characterized by baldness, weakness, swelling and blueness of the belly, is "surfeit," caused by gross feeding and bad food. Let their food consist of canary seed and a moderate supply of green meat, and anoint the bald places with perfectly fresh hog's lard.

EGG-PLANT FRUITS (*C. S.*).—Parboil them, cut them in slices, dip them in butter, season with pepper and salt, fry of a light brown colour. You can only keep your Australian birds from pecking the woodwork of the cage by covering it with tin.

### LONDON MARKETS.—OCTOBER 20.

#### POULTRY.

We have still short markets. The supply is, however, better than it was. Trade is very dull.

Large Fowls .....	3 0 to 3 6	Ducks .....	2 0 to 2 6
Smaller do .....	2 0 ,, 2 6	Partridges .....	2 0 ,, 2 3
Chickens .....	1 6 ,, 1 9	Rabbits .....	1 4 ,, 1 5
Geese .....	6 0 ,, 6 6	Wild do .....	0 8 ,, 0 9
Grouse .....	3 6 ,, 4 0	Pigeons .....	0 8 ,, 0 9
Pheasants .....	4 0 ,, 4 6

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 54.2° and 37.3° respectively. The greatest heat, 67°, occurred on the 28th, in 1830, and 31st, 1854; and the lowest cold, 22°, on the 2nd, in 1860. During the period 122 days were fine, and on 123 rain fell.

DISTRESS AMONG THE WORKINGMEN BOTANISTS OF LANCASHIRE.

Ask from our readers to aid these truly worthy men. No sentence shall flow from our pen to enforce this appeal; we will merely state the unvarnished facts, for no urging will be required for the opening of many purses to afford aid to such men nobly struggling against unmerited adversity.

Information reached us that these workingmen naturalists were striving to avoid the necessity of receiving parochial relief, but that their noble striving was ineffectual, though they submitted to extraordinary privations. We wrote to Mr. Hague, gardener to the noble-minded Mr. Mason, whose liberality is reported in another of our columns, suggesting that those naturalists might at this season sell specimens of Mosses, and this is Mr. Hague's reply:—

"I am under great obligations to you and must thank you for the kind suggestion you made on behalf of John Whitehead, and other Lancashire botanists. I have seen Whitehead and others since you wrote to me, and showed him your note. He did not like to fix a price, but we ultimately agreed that he and others would send out, correctly named, any of the Mosses found in this neighbourhood, of which there are about 150 species.

"They will send them at the same price as Wilson advertises them—viz., one guinea per hundred, or 3s. per dozen.

"J. Whitehead and Roger Schofield have duplicates by them of over two hundred species, and have specimens of nearly four hundred.

"Whitehead has earned about 4s. per week for a long time, out of which, with some little savings, he had to keep his mother and two sisters. His stock is done, and he now has been compelled to apply for relief. He is, without exception, the best muscologist we have in this district, and a very steady man. He is prevented from following out his researches, although he has plenty of time on hand, through want of a little help.

"Schofield has a wife and five little children, and I am sorry to say that he, like the others that have been so long without work, has been obliged to accept parish relief; but what they there receive does not allow them to leave the town to seek for specimens. In fact, they are nearly barefooted, and Whitehead

told me he had been out last week collecting, and his shoes being done he got wet feet.

"These cases that I name to you are no impostors or drunkards, they are all willing for you to publish their names, and seemed glad that I had taken the course I have done.

"The address of John Whitehead is Fetland Street, Dukinfield, Cheshire; of Roger Schofield, Church Street, Dukinfield.

"Some of the others who have not made Mosses their principal study are equally deserving, and it is a grief to such men that the parish and relief committees' allowance does not permit them to leave home for a longer time than a few hours at once, for they cannot afford food that they can carry out with them, save dry bread.

"I am well known to the Mayor and most of the Aldermen and Councillors of Ashton-under-Lyne, and if any of your readers felt inclined to send these poor men some portion of their plenty, the Mayor of the borough would gladly receive it and distribute it at different periods to them; or, as the Mayor is so busy with the general distress, it might be taxing that gentleman's time too much, and it would be better to send to Edward Hobson, Esq., Proprietor of the *Ashton and Stayleybridge Reporter*, who is an old friend to botany; or to Mr. Nathaniel Howard, Agent, Stamford Street, Ashton-under-Lyne.

"It is hard to begin begging for one's friends, but there are few here who have not had to make great sacrifices in this time of unparalleled distress. Hoping I have not said too much for you, I remain, &c.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne."

FRENCH FOUNTAINS

AT THE ROYAL HORTICULTURAL SOCIETY'S KENSINGTON GARDEN.

DESPITE what was said last week about these fountains being too big for the size of the garden, and for the garden itself being already fully occupied with artistic designs, the Editors "see no reason why you," or I, or any one else who is of a different opinion, "should not advocate," without fee, every form of opinion which may be brought to bear on the subject.

Now, what I want, and what I longed for from the first day I saw the red-painted fiery horses from France, the horse marines of Neptune, was to get full hold of the biggest of them, and let the little ones go where they list.

If we had the two fountains for nothing we could not allow them to remain as they are, because they are not a match pair, and if we bought one of them at the good bargain they are offered at, we could not use the other one in any part of the garden if we had it for nothing.

But, lest there should be any doubt on the point, the first thing I did before putting down my name for one guinea was to ascertain if the Council meant to keep the two fountains as they are, provided we, the Fellows,

bought them; and I was assured that the Council men only to be the means of doing just what the Fellows require of them in this instance, and I thought that a wise plan and a happy resolve, and I subscribed at once and with the greatest pleasure.

I attended every public meeting of the Society on the subject of the new garden, and I learned everything I know about it from the explanations of that Prince Albert the Good, whom we all miss with so much regret, and I was within four feet of him all the while he was addressing his inaugural speech at the opening of the new garden—the last speech he ever made on the subject in public, and I shall never forget the impression which the vast grasp of his scientific acquirements made upon me, nor cease to urge and advocate what was so dear to his heart—"the attempt at least," as he humbly expressed it, "to reunite the science and art of gardening to the sister arts of architecture, sculpture, and painting. This union existed in the best periods of art, when the same feelings pervaded and the same principles regulated them all; and if the misuse and misapplication of these principles in latter times have forced again upon us the simple study and imitation of Nature, individual arts have suffered by their disjunction, and the time seems now arrived when they may once more combine without the danger of being cramped by pedantic and arbitrary rules of taste."

The italics are my own, on purpose to enable me to put on record that I am in possession of a large amount of private judgment on this garden, which is founded on that "cramped," that "pedantic," and those "arbitrary rules of taste" which "the misuse and misapplication" of our day and the age of our fathers have left us as a legacy.

As far as I have read, the mind of no critic on this garden has yet grasped either the design or the end in view—the "union" which existed in the best periods of art; but we may be allowed to hope with the founder of the reformed "union," "that it will at no distant day form the inner court of a vast quadrangle of public buildings, rendered easily accessible by the broad roads which will surround them—buildings where science and art may find space for development, and that air and light which are elsewhere well nigh banished from this overgrown metropolis."

These were not "cramped," but enlarged principles, those of the Royal Founder of this garden, as expressed by himself before the thousands of the highest intellects of our free and father land, who congregated and crowded on the upper terraces on the opening day—I never shall forget it. If you had seen the marvellous expression of his usually serene countenance when he said that "unrivalled opportunities are here offered for the display of works of art," you could no more forget it than your humble servant, nor believe that the labour of love for the "display of works of art" had yet even begun in the garden.

Taken as a whole, I, on the contrary, take our garden as like a large unfurnished house "to let." The whole of the lower terrace is "just as bald and bare as a cat's face," as I heard Sir Charles Barry once say of a building. The place of entrance by the council-room block is most unfortunate for effect, it mars the first impression entirely; but owing to the position of the grounds, and the ultimate design of the "vast quadrangle," the entrance could not be better than where it is.

The next thing is this "unrivalled opportunity" of placing the biggest of the French fountains on the site now covered with the Sardinian group. That place was, in the original, the site for sustaining a bold impression on first entering the garden until you came up square with it, and with the axis of the "inner quadrangle," where you could turn and receive the full impression. It was a grand idea for getting over an unavoidable misfortune, and it will be a grand opportunity lost if we are so "cramped by pedantic and arbitrary rules" that we must let it slip between our fingers for the mere fleebite of the charity-standard of one guinea a-piece; and then the money not being wanted till the time of the annual subscription, nothing more is required but to sign the printed circular returned, and leave the rest to the ladies, and, my word for it, they will not fail on their part—they never do.

When I wanted something extra to be done or undone about the garden, the first thing I did was to get the lady on my side, or to decide against me, before I said aught about it to the governor. Ladies decide by instinct on the instant, whereas men have to arrive at conclusions by means of reasoning. Then if the lady said Nay, so did I, for it was all up then, certain; but if otherwise what followed is just the receipt which I have never yet known to fail, and which might be of use in a few instances on this occasion.

There are only two periods in the four and twenty hours when a man will bring out his purse without some reasoning about it—just when he has arrived at that point after dinner from which he can see, clear as a fountain, that there is no place like home after all. The other varies with people's different degrees of condition in life. Some go to bed early, some late, and some not till some others are up next morning; so that one is never sure of the exact time, but so it is, and so we must abide by it.

Then as to the sufficiency of the supply of water, I made it a particular point to see and understand that part of the play when they were laying the water on. The case is this: So much water is borrowed from the west-side supply to the cascade over the canal, in a glazed pipe of a certain diameter, for a mere temporary purpose; but let there be two supply-pipes of larger bore, one from the west and one from the east side, and four times the amount which is now in use for the two fountains would be available for the one with little or no expense at all. The fact is, there is sufficient water, and ample power to put double the present quantity in motion; and believe me, when the memorial of the Exhibition of 1851, the result of private subscriptions, is put up and finished, which it will soon be now, we shall all of us see how much the want of balance for the bottom of the garden will be apparent, and we shall never forgive ourselves and one another if we lose the opportunity of restoring that balance and give up so good a bargain. Let us therefore pray with the Prince, the founder of the scheme, that the efforts of the Council "may meet with public approbation! May that approbation give them all the support required, not only further to ornament these gardens, but also to carry out, even on a larger scale than during the last forty-eight years, the useful objects for which we are incorporated." D. BEATON.

[Knowing that Mr. Beaton differs from us as to the fountains in question, we gave him free permission to advocate his opinion, for we only covet a correct decision. He has proved, as usual, a good and subtle advocate. His words, like the supply of water he promises, are copious; and he applies his words with a power which is lacking at present at the gardens for applying water to a lofty fountain. We now leave the subject to the judgment of the Fellows.—Eds.]

### ARCHERFIELD EARLY MUSCAT.

THERE must certainly be some mistake about the Grapes that Mr. Rivers mentions in his last week's communication. He says, "My Vines, received from France under the name of Muscat du Puy-de-Dôme, or Muscat de Patras, differ most remarkably in their foliage and habit from Muscat Eugénien." We have always believed and asserted that these two are synonymous, as no doubt they are; and our object now in recurring to the subject is to prevent the circulation of what may in time become a pomological error, if Mr. Rivers' statement goes uncontradicted. No doubt Mr. Rivers seems to have two sorts under these two names; but to show that the names are really synonymous, the following is the origin of the nomenclature:—Count Odart, who is the greatest authority in France with regard to Vines, received a Grape from Clermont (the chief town of the department of Puy-de-Dôme), under the name of *Chasselas Musqué*. This he conceived was not a *Chasselas Musqué*, because its leaves were not waved or cockled, and the leafstalks were green and not tinged with red. He therefore changed the name first to Muscat Précoce du Puy-de-Dôme, and afterwards, conceiving still that he saw shades of difference both in the leaves and the flavour, he again changed it to Muscat Eugézien, a word borrowed from Pliny, and which signifies the union of all good qualities. It will be seen, therefore, that the author of these two names applied them to the same Grape; and, as we have seen that Grape in the collection of Count Odart, we can assure Mr. Rivers that it bears no resemblance whatever to Archerfield Early Muscat, but is a round Grape, and merely a form of *Chasselas Musqué*.—H.

### JUDGING GRAPES.

THE rules that regulate the awards made to Grapes seem to vary so much in different parts of the country, that it would be well if some general understanding could be come to as to what constituted a perfect bunch of Grapes. This would prevent much disappointment to individuals, and would be a standard

to which judges could appeal when called over the coals, as they often are, for their supposed misdeeds in this matter.

As the primary object in growing Grapes is to please the palate, I would suggest, by way of opening the discussion, that flavour should count two points, size of bunch one, size of berry one, colour one, perfection of bloom one, firmness of flesh one, thinness of skin half a point, perfect thinning half a point. By perfect thinning, I mean that every berry should maintain its natural position when the bunch is laid horizontally, at the same time that every berry should have space enough to swell to its full size, without being jammed by its neighbours. Thus, it would take eight points to form a perfect bunch of Grapes.

That some fixed rule for judging Grapes should be arrived at must be evident to all who have, as I often have, seen the largest bunch get the prize at one exhibition, the best coloured at another, and the best flavoured at a third, irrespective of all other points of excellence. I believe the most prevalent error in judging Black Hamburgh Grapes is the paramount importance attached to colour. In nine cases out of ten, the blackest Hamburgh Grapes are neither the best flavoured nor the thinnest skinned. There is a slightly brown shade of colour in the Hamburgh that nearly always accompanies a thin skin, large berry, firm flesh, and fine flavour; yet I have seen all these qualities go for nought when opposed to a jet black colour, though in the latter case the skin was thick, the flavour second-rate, and the berry watery. Can this be the right way of judging Grapes?—*WM. THOMSON, Dalkeith Park.*

### ROSES THE FIRST TWO YEARS.

ONLY think of a gentleman in holy orders letting the cat out of the bag just at the time I was arranging my own thoughts on how to put "D., Deal," on the right course for growing Roses with all the vigour and freshness of leaf and bloom peculiar to the Hursts of Sussex—but so it is; and that clergyman and Mr. Wood together gave the best chapter of the season about Rose-growing in the very last Number of this Journal. I was going to hint to him something of the way which they have just pointed out to a lady who resides on the coast of Cheshire—that is to say, to give up the practice of having Roses on dry sticks of standards altogether along the coast, to grow Hybrid Perpetuals only, and to have nothing to do with fancy stocks. There is no stock for a Rose equal to its own stem and roots.

It is all fair, however, to make fair use of all means which go to cheapen the supply for the million; and as far as stocks can do so, no one could object to it on a sound bottom. Barring that, except where the soil is proved to suit this or that stock or Manetti, no stocks should ever be indulged in for the general stock of Roses. The grand fault in Roses on their own roots is to be found in the greed of us gardeners. We are too fast, and the more speed the less the distance we get over. That is without the shadow of a doubt the whole secret, from the stunted starving Vine to the black blistering leaves on the crippled Rose, and nothing is more clear than how it is so.

When a Rose, or a Vine, or a Houeysnuckle is first planted, the great aim is to get a certain space filled with the branches thereof as quickly as possible. You will not meet with one man out of fifty who has the heart to cut back such a plant to the last eye next the ground the first season; and yet there are very few plants indeed out of fifty kinds of plants in common use which would not be benefited, for the rest of their course, by being cut down after the first growth to the last link between the shoots and the roots.

If you think it over in your own mind, you will clearly see that leaving three joints or buds on the stump is exactly equivalent to a belief that the roots are not to have more capacity than they had last year. At the last fall the shoot was just in proportion to the then state of the roots and no more: therefore the portion of the stump between your cut and the issue of the roots is not capable of allowing more sap, or more strength, to pass up this season to the new branches than would pass up last autumn, no matter how much the roots may have extended. Then the balance between the roots and the branches is gone the first season, you arrest the progress both ways—that of the roots and that of the branches. What, then, can be the condition of the conducting powers of a shoot or shoots, which are cut a foot or 18 inches above the ground the first season? for it is during the first two seasons the mischief is done.

Then, if you clearly understand that it is possible, by bad

management, to make a young shoot on its own roots as hide-bound as one on a stunted stock, how much more, therefore, it must be so where a foreign stock is sulking at the same time under it, from the want of the balance of head and roots. The young Rose on its own roots (I mean Hybrid Perpetuals), is the most easy to manage of all the plants in the garden, as you can prune it long or short at least three times during the growing season, in order to improve the passages of the sap, and have them enlarged in proportion to the increased length and strength of the shoots.

I pruned fifty young Roses this summer to the very bottom bud at the end of June. They are two years old from cuttings, and were planted last Christmas or later; and I have shoots now on them from 4 feet to 8 feet and 9 feet in length, and of equal bottom proportion. The strongest of these I shall leave at full length till after the first bloom next season, but the weak shoots shall be cut to one bud.—*D. BEATON.*

### ROOT-PRUNING AN OLD PEAR TREE.

I WISH for your opinion as to the safety of root-pruning a large old Crassane Pear tree on the gable end of a cottage facing the south-west. My landlord is afraid of "experiments," but I think your opinion would satisfy both of us. The tree is, perhaps, forty years old, about 20 feet in height, well grown, and perfectly healthy apparently, but for many years it has borne no fruit (this year it had only two or three clusters of blossoms). Is it likely that the roots have penetrated into a sewer which runs within 20 feet or 30 feet of the stem? and would this account for over-luxuriance and unfruitfulness?—*JANE MORICE.*

[It is rather a ticklish subject meddling with Pear trees of that age and size, in the way of root-pruning them. Very probably the roots are luxuriating in the sewer, and if that were stopped it might tend to make the tree fruitful. From failures and successes with such trees, we have even more faith in taking them up than in partial root-pruning. In a tree of such a size, if a strong tap root should be missed, the tree may remain unfruitful and half starved into the bargain. There could be no harm in examining the sewer, and cutting some of the larger roots; but we would have more faith in commencing 12 feet or 15 feet from the tree, taking out the roots to within 4 feet of the stem, undermining it so as to cut all tap roots, then fill up, and lay the roots in fresh soil, rather rich near the top, and keeping the roots within 9 inches of the surface. Such care is not requisite with young trees, pyramids, &c. Even if this tree were so treated, we would expect it to be two years before it told the result.]

### CARROT CROP FAILING—CELERY FLY.

FOR the last two years I have entirely lost my crop of Carrots from, apparently, a grub. Many in this neighbourhood have been equally unfortunate, and I am told it has been the case in many others. My gardener says he is assured that the destructive insects are, in fact, young wireworms, and no other. I can scarcely think so, though I believe they are four years coming to their full growth in the ground, after the eggs are deposited by what are popularly called daddy longlegs. Last year the Carrots were in ground which had been, perhaps, too highly manured; this year in a piece which had been at rest several years, dressed only with lime in the winter, and certainly they were more entirely destroyed than in 1861. The loss is great in its way, and I should be glad to see your opinion of the insect and your advice for the future. When the Carrots were dug-up and burned in July, the ground was dressed with equal parts of salt and soot, and I have upon it now a splendid crop of Broccoli, &c.

Another grievance in my garden, and all others about here, for the last year and this, is the Celery fly. A great deal was lost last year, mine among others, from not being aware in time that the caterpillars destroyed the hearts as well as the tops. I have had the leaves of mine this autumn constantly picked-off and burned; but, though the crop is safe, I think it is small and injured.—*II. A. S.*

[The high manuring was against your Carrot crop, and so was the fresh soil if there was grass on the surface, which we almost presume, as it had been at rest several years. Soil for Carrots cannot be too well stirred in winter, so as to expose it to all the frosts that come. If wireworms, grubs, &c., are appre-

hended, it is a good thing to sprinkle the soil at times with ammoniacal gas water, or to sprinkle the ground very sparingly with gas lime, making a bushel go over about five poles. This, mixed with the earth in frequent ridgings, will lose its virulence before spring, and will either kill or disperse a host of enemies. In old gardens, we have seen extraordinary crops produced by a good dressing of lime and peat, mixing it thoroughly with the soil. We have no doubt, however, but that you know all these matters yourself; but of late we always choose a poor piece of soil for Carrots, and if manure is given at all it is given at the bottom of the trench, and the ground above, if possible, kept ridged all the winter, and turned in the time of frost, so that most of it shall be frozen through.

The Celery grub has been more common of late. The eggs are deposited in summer between the two skins of the leaves, and there the grub feeds securely in a safe house. There is no remedy but picking the leaves off and burning them. A line run along the rows of Celery well smothered with tar, and kept in a moist state, will either catch the fly or help to keep it off by the smell. The grubs when full grown leave the leaves of the Celery and get down to the roots; and though we never knew them do much damage, there they remain in a chrysalis state through the winter, and start as beautiful flies in their work of propagating their kind as the warm days come in. The fly should then be scared out of gardens just as boys are set to knock down butterflies.]

### THE INTERNATIONAL EXHIBITION OF THE ROYAL HORTICULTURAL SOCIETY.

ALTHOUGH both the English and foreign collections of fruits which were exhibited at Kensington have been long since cleared away, a very interesting collection has recently arrived from Nova Scotia, which is well deserving of notice. Before proceeding to do so, however, a few remarks on the geographical position and climate of that colony may not be unacceptable.

Nova Scotia, which forms a portion of the main continent of America, lies between lat. N. 43° 23' and 47°, extending about 350 miles in length, and from 50 to 100 miles in breadth, and including with its dependency Cape Breton, an area of about 21,500 square miles. The climate is considerably colder than that of England, the mean temperature of the year at Halifax being 43°.8, whilst at London it is 49°.3, or 5½° higher. Though the winters are long and severe, and the springs cold and changeable, yet the summers are warmer than here; the mean temperature of that season being 62°, while for about a hundred days the thermometer is above 70°. Thus vegetation, although retarded about a month as compared with England, proceeds rapidly under the stimulus of the summer heat, and cereal and root crops as well as fruits, are ripe at the same time as in this country.

Judging from the specimens exhibited, Apples acquire a high degree of perfection in Nova Scotia, both as regards size and colour, and are, consequently, very extensively cultivated; and it is said that sorts which require a wall in this country succeed well as standards. To illustrate the size which some Apples attain, there are several specimens of Gloria Mundi of large size preserved in spirits, one of which is stated to have measured 15 inches or 17 inches in circumference.

The finest collection of Apples came from R. G. Haliburton, Esq., the Secretary to the Colonial Commissioners, and included some large and very fine fruit of the Gravenstein, Catshead, of good size; Baldwin, rather small; Nova Scotia Codlin, a fine, large, waxy yellow Apple, prominently ribbed, and with a red cheek next the sun; *Æsopus* Spitzemberg, rather small but highly coloured; Hubbardston's Noneseuch; and Alexander, large, and very finely coloured; Chebucto Beauty, a local variety taking its appellation from Chebucto, the Indian name for Halifax harbour, was a rather large but pretty pale yellow Apple, with broken streaks of crimson, and more or less suffused with the same colour next the sun; Morning Star, a rather small kind, dark crimson next the sun, was very like Pomme de Neige; Royal Pippin and Bishop Pippin appeared identical with the Yellow Bellefleur; Ohio Yellow was a medium-sized, roundish, yellow Apple; and Nova Scotia New, a middle-sized fruit, cream-coloured, with numerous broken streaks and dots of crimson, giving it a variegated appearance.

The Ribston Pippins though rather below the middle size, were well coloured; so was the Nonpareil; and Golden Russet,

Gloria Mundi, and King of the Pippins, were fine; Rhode Island Greening was of fair size; Large Yellow Bough, under the name of Early Bough, was large; Corn Apple was a red fruit, very light, and apparently soft; and Cracking Pippin, a heavy, middle-sized, pale yellow Apple; the Hawthornden was rather small, and much flatter than with us, whilst in colour it was white, with a pale red cheek. The Apples called American Russet, Gilliflower, Late Pippin, Fall Red, and Winter Emperor, were probably seedlings raised in the colony; and Hallow Pippin, Blue Pearmain, Rivers' Apple, and Holland Pippin, were large fruits, equally unknown to us; the last-named was not to all appearance the variety known as the Holland Pippin in this country. For the above collection a silver medal was awarded.

From the orchard of R. Starr, Esq., Cornwallis, there also came an excellent collection of the Apples and Pears grown in that fertile district; but from the specimens of the latter fruit it is evident that the Pear does not acquire nearly the perfection that the Apple does in Nova Scotia, a circumstance which is, doubtless, owing to the lateness of the spring retarding the blossom, and, as compared with this country, the consequent shorter period which is available for ripening. Nevertheless, the Marie Louise, Flemish Beauty, Williams' Bon Chrétien, Passe Colmar, and Vicar of Winkfield, are said to bear constantly and well as standards.

Among the Apples we found Gravenstein, Alexander, and Herefordshire Pearmain, well coloured, and of good size; Ribston Pippin, rather small, but apparently well ripened; Rhode Island Greening, below the average; King of the Pippins, rather large, finely coloured, and in one specimen dark crimson next the sun; Rambo, a kind highly esteemed in America, both for kitchen and dessert use; Yellow Bellefleur, good; Flushing Spitzemberg; Calkin's Pippin; English Russet; Gilliflower, not true; and two or three other kinds.

The Pears consisted of Seckle, small, but well ripened; Louise Bonne of Jersey, very small; Vicar of Winkfield, small, and apparently not well ripened; Marie Louise; Beurré d'Amant, of fair size, but too far gone; Black Worcester, and Glou Morcean (?), both very small; Columbia; Flemish Beauty, very fine and highly coloured; Sylrange, apparently a small Belle et Bonne, and Paradise d'Automne, small. The kinds sent as Beurré de Capiaumont, Belle Lucrative, and Bergamot, did not appear to be these sorts, but were too far gone to make anything of. Quinces of good size were also contributed by the same gentleman, whose collection received a bronze medal.

Black Hamburg, White Cluster, and all the hardier Grapes are said to ripen in the western districts against walls out of doors, the Vines, of course, receiving protection in winter. Small bunches of the Black Hamburg, with fair-sized berries, were exhibited from out of doors, as well as small, compact bunches of the Royal Muscadine, but the berries were small. As for the Isabella and Concord Grapes, the former though of good appearance for a hardy kind, we have long known to be of vile flavour, and the Concord we more than suspect to be of the same breed, and no better. A fine bunch of White Nice was exhibited by Mr. Forman, and three very good bunches of Black Hamburg from Mr. Haliburton; in both cases, doubtless, from under glass.

Apricots, Nectarines, Peaches, Isabella Grapes, and Plums, grown in the open air and preserved in spirits, were also exhibited; and Plums, preserved in the same way, came from Mr. J. Thompson, including Reine Claude de Bavay, Washington, Quetsche, and some others, one of which, through the glass, looked like Coe's Golden Drop.

Among the vegetables were some very fine Onions; clean, well-grown roots of Carrots, both of the Early Horn and Long Orange kinds; Parsnips of good size, considering the season at which they had been taken up; and the Potatoes, of which about a dozen sorts were shown, were all remarkably good, both as regards size and freedom from disease, and it appears that they form a very important article of produce, no less than 3,824,864 bushels having been grown last year. Red Beet was very good; both Mangold and Swedes were of good size; and the Kohl Rabi, though small, was well-grown and very solid. Tomatoes were excellent. Cucumbers, we presume from out of doors, were about a foot long; and of Gourds, the Large Yellow was probably about 100 lbs. weight; and the Vegetable Marrows were also of very large size. It appears that Gourds of all kinds are much cultivated in Nova Scotia, where some of them attain the weight of 170 lbs., both for domestic use and as food for cattle. Some excellent samples of Oats, Barley, and Maize were also exhibited,

as well as Rye, Wheat, and Flax, to the cultivation of the last of which attention has been recently directed as likely to prove a remunerative product.

We observed on the same table as the Nova-Scotia collection, several specimens of the "Fine Apple of Amassia," from E. B. Barker, Esq., Her Majesty's Consul at Saisoun. It is a showy, middle-sized Apple of handsome form, pale yellow, with a crimson cheek, covered with white specks. It is fair to look upon, but what its merits may be we cannot say. Several samples of Wheat came from the same gentleman, and among them were some remarkable for their long and very ornamental beard.

## EXTRACTS FROM A TOO-MUCH NEGLECTED BOOK.

November 22.—INDIAN CORN is prepared in many ways by our housewives: we have *sapaen*, or hasty-pudding; griddle-cakes, made with eggs and milk; hoe-cake, or Indian bread, baked in shallow pans; samp or hominy, corn coarsely broken and boiled; Jonikin, thin, wafer-like sheets, toasted on a board; these are all eaten at breakfast, with butter. Then we have the tender young ears, boiled as a vegetable; or the young grain mixed with Beans, forming the common Indian dish of *succotash*; the kernel is also dried, and then thoroughly boiled for a winter vegetable. Again, we have also Indian puddings, and dumplings, and sometimes lighter cakes for more delicate dishes. The meal is also frequently mixed with Wheat in country-made bread, making it very sweet and nutritious. Besides these different ways of cooking the Maize, we should not forget parched or "popped" corn, in which the children delight so much; and a very nice thing it is when the right kind of corn is used, and the glossy yellow husk cracks without burning, and the kernel bursts through, pure, and white, and nicely toasted. A great deal of popped corn is now used in New York and Philadelphia by the confectioners, who make it up into sugar-plums, like *pralines*. Acres of "popping corn" are now raised near these large towns, expressly for this purpose; the varieties called Rice corn, and Egyptian corn, are used, the last kind being a native of this country, like the others.

The word *sapaen* has sometimes been supposed of Indian origin. It is not found in any dictionary that we know of, though in very common use in some parts of the country. Vanderdonck speaks of the dish.\* "Their common food, and for which their meal is generally used, is *pap*, or *mush*, which in the New Netherlands is named *sapaen*. This is so common among the Indians that they seldom pass a day without it, unless they are on a journey, or hunting. We seldom visit an Indian lodge at any time of the day without seeing their *sapaen* preparing, or see them eating the same. It is the common food of all; young and old eat it; and they are so well accustomed to it, and so fond of it, that when they visit our people, or each other, they consider themselves neglected unless they are treated to *sapaen*."

Maize seems, indeed, to have been the chief article of food with those Indians, at least, who lived upon the banks of the Hudson, or in the New Netherlands. Vanderdonck, in describing their food, does not, I believe, once mention the Potato, at least not in the parts of his works which have been translated. He speaks of Beans as a favourite vegetable of theirs, and one of the few they cultivated, planting them frequently with Maize, that the tall stalk of the grain might serve as a support to the vine. He observes, they had several kinds of Beans—probably all the native varieties, of which we have several, were cultivated by them. Squashes he mentioned as peculiar to them, and called by the Dutch *Quaasiens*, from a similar Indian word. Pumpkins were also cultivated by them, and Calebashes, or Gourds, which, says he, "are the common water-pails of the Indians." Tobacco is also named as cultivated by them.

But, as we already have observed, in his account of their field and garden produce, he says nothing of the Potato, which is quite remarkable. The Maize, on the contrary, seems to have been eaten at every meal. "Without *sapaen*," he continues, "they do not eat a satisfactory meal. And when they have an opportunity they boil fish or meat with it, but seldom when the fish or meat is fresh, but when they have the articles dried hard and pounded fine. . . . They also use many dry Beans, which they consider dainties. . . . When they intend to go a great distance on a hunting expedition, or to war . . . they provide

themselves severally with a small bag of parched corn or meal; . . . a quarter of a pound is sufficient for a day's subsistence. When they are hungry they eat a small handful of the meal, after which they take a drink of water, and they are so well fed that they can travel a day. When they can obtain fish or meat to eat, then their meal serves them as well as fine bread would, because it needs no baking."

Speaking of their feasts, he says, "On extraordinary occasions, when they wish to entertain any person, then they prepare bearers' tails, bass-heads, with parched corn-meal, or very fat meat stewed, with shelled Chestnuts, bruised." Not a bad dinner by any means. Thus we see that while they relied on the Maize in times of scarcity and fatigue, it made a principal part of their every-day fare, and entered into their great feasts also; but Potatoes do not appear at all.

In using the word *sapaen*, Vanderdonck leads one to believe it either a provincialism of the New Netherlands, or an Indian word. Very possibly it may have been borrowed from the red man, like the *Quaasiens* or *Squash*. There is, however, a word which corresponds to our English *sup*, to swallow without mastication, which in Saxon is *zupan*; the Dutch are said to have a word similar to this, and *sapaen* may prove a provincialism derived from it. A regular Hollander could probably decide the question for us. *Samp* for cracked corn; *homing* for grain more coarsely cracked; and *succotash* for Beans and Maize boiled together, are all considered as admitted Indian words. *Mush* is derived from the German *Musse*, for pap, and probably has reached us through the Dutch.—(*Miss Cooper's Journal of a Naturalist in the United States.*)

EARLY FROST.—The first frost of sufficient severity to injure the occupants of our flower gardens, occurred on the night of Friday, the 24th inst, when the thermometer fell to 25°. It was what is called a white frost, and owing to the large amount of moisture in the air everything was abundantly covered with rime. As the immediate recurrence of frost of even greater severity is extremely probable, we would advise our readers to be prepared with their protections.

## BRISBANE BOTANIC GARDEN, 1861-1862.

[THE following from the Report on the Brisbane Garden, Queensland, Australia, made in July of the present year, by its Director, Mr. Walter Hill, will be read just now with especial interest, touching as it does upon the production of cotton and other fibre-producing plants.]

"Amongst the improvements effected in connection with the cultivated land, I may state that two plantations of the *Thea Bohea* (Black Tea), consisting of several hundred plants, have been formed on each side of the ridge in the vicinity of the Director's residence; heretofore, there had been but a few isolated and scattered specimens of this valuable plant in different parts of the garden. These plantations were formed with a view of furnishing an example of the cultivation of this product on a large scale, and also for the purpose of making an experiment to ascertain the position best adapted for the growth of the plant, as this is a disputed question. One of the plantations referred to is exposed to the east, and in the other the plants have a western aspect. In both situations the plant thrives admirably, and there is no perceptible difference in the progress of the two plantations.

"This experiment in connection with the cultivation of the Tea-plant is the largest which has been made in any of the Australian colonies. The result proves the perfect adaptation of our soil and climate for the successful cultivation of this product.

"Several rows of timber trees indigenous to this colony have been planted in part of the border at the south-west side of the ground. These trees will prove highly ornamental. A collection of this kind should form a prominent feature in any botanical garden. Future visitors to these grounds will have an opportunity of examining in the Museum specimens of the timber of this colony, worked-up and polished by the hands of the artisan, and also of viewing in the garden, specimens of the trees from which such timber is procured. For the sake of ornament a row of *Laurus australis* (Native Laurel) has been planted in front of these trees. A pleasing effect will thus be produced when the trees attain a more mature growth.

\* In 1653.

"About half an acre of ground in proximity to the Tea plantations has been planted with Bananas, with a view to the suppression of the growth of that noxious weed, the *Cyperus hydra* (Nut Grass). A similar experiment was made in different portions of the garden with successful results on a previous occasion.

"The cultivation of the Cotton-plant continues to be attended with the most satisfactory results. An experiment has been made in order to ascertain the position best adapted for the growth of the Cotton-plant. Several varieties have been planted in the low, flat ground, and several in the higher and undulating ground.

"The result is, that the plants situated on the undulating ground are much healthier, and yield a larger and stronger fibre than those grown in the low ground. The cultivation of the Peruvian variety of this plant has been unsuccessful, and the result of experience indicates that this variety cannot be cultivated with profit in the district.

"The *Coffea arabica* (Coffee Tree), raised from seed obtained from a plant at Newstead, and planted four years ago, is now in a flourishing condition. This plant did not at first thrive so well as could be desired, owing to the unfavourable situation in which it was placed. About eighteen months ago it was replanted and placed on the side of a ridge sheltered from the westerly winds. In this new position the plant has flourished well. The berry is fine and well-flavoured, and at the present time is bearing about two pounds weight of fruit. This experiment in Coffee cultivation fully proves that the soil and climate of the colony are admirably adapted for the growth of this production.

"The cultivation of fibre-yielding plants has attracted of late years a considerable amount of attention in Great Britain, and other colonies. Several species yielding valuable fibre, such as the Manila Hemp, the Jute, the China Grass, the African Hemp, &c., have been introduced into our gardens and thrive well. One of our commonest weeds, however, which grows in profusion in this district—viz., the *Sida retusa*, will, I am certain, eventually be cultivated as a valuable fibre-yielding plant in preference to any of the species above named. This now disregarded plant will in course of time be ranked in this respect as one of the valuable products of the colony. A small sample of the fibre prepared in a rough way have appeared amongst the contributions of Queensland to the Great Exhibition of 1862.

"Several new and valuable plants, for the cultivation of which the colony is admirably adapted, have been added to the garden during the past year. Among them is a *Cinchona Calisaya*, one of the trees yielding quinine. I trust to be enabled to cultivate this product in our garden with success. Amongst the other plants introduced I may direct attention more particularly to the following:—*Urania speciosa*, a magnificent palm-like plant, whose seeds yield an essential oil, and are said to be edible; *Xanthocymus pictorius* (Gamboge Tree), the juice of which produces the brightest of yellow dye; and the *Indigo* (*Indigofera indica*), the leaves of which yield the valuable dye of that name."

### DÜRKHEIM—THE GRAPE CURE.

DÜRKHEIM is the head-quarters of the Grape cure in Germany. Meran, in the Tyrol, and Vevay and Montreux, on the lake of Geneva, have a high reputation, and are much resorted to for the same purpose, but in Germany Dürkheim is the place which enjoys most fame. It is on the left bank of the Rhine, in the Bavarian Palatinate, and is distant about fourteen miles due east from Mannheim. The nearest railway station is Neustadt, a small town on the line from Mayence to the French frontier at Forbach. The drive from Neustadt to Dürkheim, a distance of about nine miles, is very beautiful, and is to be preferred to that from Mannheim. The road is a very good one, and runs along parallel to and at the base of the Haardt range of mountains, on a slope which has been formed by the action of water on the light, sandy, and friable soil of those hills. From a few miles to the north of Dürkheim to about twenty miles to the south, the Haardt range of mountains on its east side runs almost due north and south, leaving an immense flat plain of about twelve to fourteen miles in breadth, intervening between it and the Rhine. This plain is very highly cultivated, and abounds in every sort of crop. The Haardt range is considered to terminate in the neighbourhood of Landau, the mountain on the south side of the stream which flows through that town being properly the Vosges, though the one range is merely a continuation

of the other. A slope of the same character, and due to the same causes as the one on which the road from Dürkheim to Neustadt runs, extends from Neustadt to the southern limit of the Haardt range at Landau. The geological character of this slope is different from that of the great plain which extends to the Rhine, the latter being either tertiary or alluvium, while the slope is formed of the detritus that has been washed down from the hills. The whole face of the slope is covered with Vines. The Vine cultivation is on so enormous a scale that nothing in Germany, not even in the Rheingau, from whence the most celebrated of the German wines come, can be compared to it in extent. For some five and twenty miles the high road passes through the midst of a succession of vineyards, without a trace of any other cultivation meeting the eye of the traveller. Though the wines of this district do not command such high prices as the wines from the Rheingau, and are not much known out of Germany, the cultivation is conducted with as much care as in the Rheingau itself, and the wines produced are more generally consumed by the Germans themselves than any other of their wines. The Deidesheimer and the Förster are the best of these wines, and immense quantities of them are sent to all parts of Germany. The former is usually recommended by the German doctors to their patients as being the least acid of their wines. The vineyard from which these two wines come is in the immediate neighbourhood of Dürkheim. A very good class of wine is made at Dürkheim, but the Grapes grown there are for the most part table Grapes, as the Germans say, to be used in the Grape cure, and for the purposes of export. Immense quantities of them are sent daily to all parts of Germany, and no Grapes enjoy so high a reputation in that country. Grapes differ materially from each other in quality: the Grape which is best adapted for the purpose of making wine is not generally so wholesome and so agreeable to the taste as another which will produce an inferior wine. About twelve to fifteen different sorts of Grapes are grown at Dürkheim. Many of these, if not most of them, may be often found in the same vineyard. A little practice will enable any one in a very short time to distinguish, by the eye, one sort from another; for differences exist between them not only in colour, but also in form and size, as well as in the thickness of the skins. The leaves, also, of the different sorts differ in form and size. To the taste the differences of flavour are at once perceptible. Persons who have not been through a vineyard, and have not had the opportunity of testing one different sort of Grape after another, can hardly believe that there is so great a difference in flavour between the different sorts as does, in fact, exist. The Grapes used in the cure are generally of four or five sorts; the two most commonly employed are called the Gutedel and the Austrian. They are both white, with thin skins, and are both of them sweet and well-flavoured. The Black Burgundy Grape, and the small dark Red Traminer, which has been introduced from the Tyrol, are also much used in the cure, though not nearly to the same extent as the two already mentioned. The Burgundy Grape is a very fine Grape, and is, both in flavour and look, very like what is called in England the Black Hamburgh. The Traminer is a very pleasant sweet Grape, with a scented or aromatic flavour, and a very thick skin. In certain cases, it is found to disagree with patients as being too heating. The Riesling, the Grape from which all the most celebrated wines of the Rheingau are made, is not used in the cure, and is not considered by the Germans as a good table Grape. Chemical analysis shows that it contains more saccharine matter than either the Gutedel or the Austrian Grape; but at the same time its acid properties are stronger. The Burgundy Grape is still sweeter than the Riesling, but its acid qualities, though less than those in the Riesling, are greater than those in the Gutedel or the Austrian, and, therefore, it is not so much used in the cure as they are. The acids which are found in the juice of all Grapes, in greater or less proportions, are tartaric, citric, and malic acids. Much albumen, gelatine, and gum, as well as a considerable quantity of alkaline matter, are always found. Careful analysis has also discovered in all Grape juice traces of tannin, and even oxide of iron. An excess of acids in the Grape is found, not only to interfere with the digestion, but to affect the mouth and the teeth in such a way as to prevent a person from being able to continue the cure for the requisite period.

The Grape cure lasts for from three to six weeks. The regular season commences, on an average, about the middle or the first week in September, and lasts to nearly the end of October. Everything depends on the state of the ripeness of the Grapes.

The amount of Grapes daily taken by persons undergoing the cure varies from about  $4\frac{1}{2}$  to 7 or 8 lbs.; in some cases even as much as 9 lbs. are eaten. They are taken three times a-day, at the same hours at which mineral waters are usually drunk in Germany—before breakfast, at eleven o'clock in the morning, or two hours before dinner, and at from five to six in the evening. Persons generally commence the cure with from 2 to 3 lbs. a-day, and advance daily in quantity till the larger limit is reached. The skins and the seeds should not be swallowed. The largest portion is usually consumed at eleven o'clock. Some doctors do not allow their patients to take any other breakfast than the Grapes, accompanied by a roll of bread. The usual plan, however, is to permit them to take a breakfast of tea or coffee with bread, but no butter, after the Grapes. A strict diet is universally prescribed; all fat, sour, or spiced meats, and pastry, are forbidden; a small quantity of white, light wines is permitted, but red wines, beer, and milk, must be avoided. The evening meal should be a very light one. The system pursued at Dürkheim is the same as the one followed at the other places where the Grape cure goes on; and the Grapes which are used in the cure both at Vevay and Montrenx are, as at Dürkheim, for the most part the Gutedel and the Austrian varieties.

There is a small Kurgarten at Dürkheim, formerly the garden of the castle, where a band plays at the regular hours appointed for the eating of the Grapes. On one side, under the trees, there are tables covered with large baskets full of the varieties used in the cure. As at Ems and other places where mineral waters are drunk, it is the fashion for every one to buy a glass for himself, so here every one must be provided with a basket to carry the Grapes which he purchases from the attendants at the tables. The price of the best Grapes is at present only  $2\frac{1}{2}d.$  a-pound. To a stranger the sight is an amusing one, and very different from anything to be met with elsewhere. Numbers of people are seen walking up and down in the little garden, each with a small black basket, full of Grapes, in his hand, which he is eating with great rapidity, as if he were doing it for a wager. The place is, as may be imagined, covered with Grape-skins, though some of the burly, round-shouldered Germans bolt skins and all.

On the tables where the Grapes are sold, there is generally a small Grape-press, a miniature of the one used in the making of wine, for the purpose of squeezing out the juice or liquor, which is sometimes preferred to the Grapes themselves. Persons whose mouths or teeth have been affected by the acidity of the Grapes are frequently obliged to give up eating them and drink the juice or must instead. The "mueching" one's own Grapes is by no means essential to the cure, but the liquor pressed out is so strange, so unlike the Grapes themselves, and so unpleasant, that few persons will prefer it, except they are obliged to do so.

The disease in which the Grape cure is considered by the German doctors to be most beneficial is in affections of the mucous membrane of the respiratory organs. The secretive powers of this membrane are roused, and it is enabled to throw off obstructions which have assumed a chronic form. Cases of bronchitis and pneumonia are said to have been often cured even in patients of a serofulous constitution; and much benefit is said to have been experienced by persons affected with tubercular consumption in its earlier stages. Where spitting of blood has set in, much caution must be used as to the amount of Grapes taken. Persons affected with any of these complaints are in the habit of coming to Dürkheim yearly from all parts of Germany.

Dürkheim possesses an advantage over other Grape-cure places in having close to it a brine spring, which enables patients to combine the use of salt baths with the Grape cure. The union of the two remedies is said to be especially beneficial in all maladies affecting persons of a serofulous tendency. Complaints of the heart and liver, as well as other internal complaints, gout, and even Bright's disease, are claimed by the Grape-cure doctors as coming within their scope and range.

Whether the efficiency of the Grape cure in the alleviation of disease be as great and as beneficial as it is claimed by its advocates to be, may be doubted, without at the same time impugning the system altogether. In this, as in most other cases, truth lies, perhaps, between the extremes. A free use of Grapes is probably good, and may be beneficial in the alleviation of many complaints. The action of the vegetable juices upon the animal system is a subject most imperfectly understood. Some of them, it is known, have a most powerful action as well

in the prevention as in the cure of disease, but how that action takes place is still one of nature's secrets. The man who prohibits wholesale the vegetable juices, and crams his patients with mutton chops and bread, is a greater charlatan than the Grape doctor who gorges and stuffs them with Grapes. The course of regimen pursued by the latter includes all sorts of light and nutritive diet, whereas the former forbids even the moderate use of articles of food which seem to be especially suited for the wants of the animal system, and which, in many cases, his patients have an eager craving for. Of all the vegetable juices, none seems so well adapted for man as that of the Grape. In times of serious sickness, and especially in cases of fever, Grapes are frequently the only food which is cared for and eaten with pleasure. Nature tells, with an unerring voice, its real wants, and speaks out with an emphasis that cannot be gainsayed. The food which, on occasions of severe crisis, when nature is put to its strain and reduced to the lowest ebb, the human system calls for, must not only be a healthy one, when taken in moderation, but must also be instrumental in the alleviation of disease. Whether the healthy action of Grape juice be due to its tartaric or citric acid, or to its sugar, or to any other of its constituent parts, or to them all in combination, neither chemists nor physiologists can tell. The property which the saliva has of turning cane sugar into Grape sugar, seems to speak in favour of the sugar; but other facts, well known to doctors and physiologists, will support the claims of others of the component parts.

Like hydropathy, homœopathy, or the cure by the drinking of mineral waters, the Grape cure is, perhaps, carried to excess by its own practitioners. There is, however, truth in it, and it must not be treated with levity or ridicule. Much good may and little if any harm can be done by it. The process is well worthy of being tried by those who have failed to derive benefit from other systems of treatment. As an alternative, the Grape cure is probably a sound system, and it deserves more attention at the hands of English doctors than it has hitherto met with. It is as an alternative that it is looked on with favour by many of the most sound and sensible doctors in Germany, and many patients are sent by them from all parts of the country to try it.

Independently of the question of Grape cure, Dürkheim is well worthy of a visit. The position of the place is very charming, and several objects of interest exist in the immediate neighbourhood. The town is an ancient one; but, as it was burnt down during the wars of Louis XIV., it contains no building of any interest. Dürkheim was formerly the capital of the Counts of Leiningen, a family now represented by the Prince of Leiningen, the nephew of our own Queen, and continued their capital till the French revolution, when their castle was burnt down, and the principality and all their property was confiscated. Leiningen, the *Stamm-Schloss* of the family, is a few miles distant, perched most picturesquely on the top of a conical hill. The family possess no longer any property in the neighbourhood. No princely or noble families exist any longer in the Palatinate. The French revolution was the sponge which wiped them all out. Money is now the only nobility, and perfect equality is dominant. Property is much divided. The owners of vineyards are the people of the greatest influence.

Within half a mile from Dürkheim are the magnificent ruins of the Benedictine Convent of Limburg, built of the red sandstone of the country, which is as sound as on the day on which it was taken from the quarry. Like the castle of Leiningen, and many other places in the range of Haardt, the convent was perched on the flat top of a round conical hill. This common characteristic feature in the scenery of the Haardt is clearly due to the erosive action of the water of the great lake, which must at one time have filled the whole plain, before the Rhine had succeeded in bursting its way to the ocean.

Another very interesting object in the neighbourhood of Dürkheim is the Heidenmauer, a circular enclosure on the top of a high mountain, overlooking the whole plain, formed of loose stones, 60 feet in breadth, 12 feet in height, and  $1\frac{1}{2}$  mile in circumference. The ancient Germans were probably its constructors, and its use were, it is thought, of a religious character. Cooper, the novelist, has made it and Limburg the subject of one of his novels. Other objects of interest exist in the neighbourhood, but it would be tedious to enumerate them. The scenery all over the Haardt range of mountains is so picturesque and charming that the patient is seldom at a loss how to while away the time both with instruction and pleasure to himself. Dürkheim is not the only place in the Haardt where the Grape cure is carried on. Both Neustadt and Gleisweiler, in the neighbour-

hood of Landau, are rivals. The latter of these two places is beautifully situated high up in the face of the mountains, and combines a hydropathic establishment with the Grape cure. Persons who cannot find accommodation at Dürkheim are in the habit of going to either of these places. The hotel Löwe at Neustadt, near the railway station, is very good, the cooking is excellent, and the wine faultless.—(*London Review*.)

### POTATO AND CELERY CULTIVATION IN LANCASHIRE.

THERE are a goodly number of shows held on a small scale in Lancashire by cottage gardeners, for the purpose of seeing which can grow the largest Potatoes, Celery, Apples, and other garden produce. I have been round to the various shows this autumn, for the purpose of seeing which were the best and the heaviest of the above; and allow me to say, that so far as Potatoes (unless for cattle) are concerned, I totally disagree with the shows altogether, for of all the ugly things that I ever saw, the Potatoes were the worst.

The kinds they mostly grow here for showing by weight have many local names. For instance, the sort that chiefly wins is called Lumpers, Mangold Wurtzel, and Red Kidneys; Ox-nobles are the next. The Lumpers are like three or four Potatoes joined together, and sometimes like a dozen little ones fixed together. Nobody could ever peel one without cutting one-half away, or even more.

I have on one or two occasions been a judge at some of these shows of the other things shown along with Potatoes and Celery, and I have disappointed some of the lovers of very large stuff, because I have been unwilling to give the prizes to gross, overgrown productions, scarcely fit for cattle, and certainly not for human beings.

Some of these lovers of big stuff have condemned us poor gentlemen's gardeners as judges of cottagers' vegetables. One man said to me at a late show, that had he been a judge, he should have given his largest Turnips the prizes, instead of which they had no prize at all. I quietly told him that it was not an agricultural show, and if he had any doubts which were the best, to boil them after the show. His largest were 3 lbs. or 4 lbs. each, and his prizetakers about half a pound each. I told the man that there was little art in growing such things large; for what was wanted was simply plenty of room and good stimulants.

The heaviest Potatoes I have seen this year at the shows have been 3 lbs. 1½ oz.; 2 lbs. 11¾ ozs.; and 2 lbs. 8 ozs.

The heaviest Celery I have seen or heard of has weighed 15 lbs. 4 ozs., and 17 lbs. 1½ ozs. Without passing any comment myself, I enclose you the remarks of a genuine lover of gardening, and a man who takes many prizes at the Ashton Town Hall Horticultural Show.—JOHN HAGUE.

### OXFORD MILLS COTTAGE GARDENERS' TEA PARTY.

On September 27th afternoon, at half-past four, the above gardeners and their friends, to the number of 200, partook of tea and sandwiches, provided in great plenty and of excellent quality, in commemoration of their Show, which took place a fortnight ago, in the same set of magnificent rooms, built by Hugh Mason, Esq., for the use of his workpeople and tenants, as reading, smoking, and lecture-rooms. Some of the tables were decorated with bouquets of flowers, and there was an abundance of excellent Celery, nicely cleaned. After tea Mr. Wm. Tipping, cashier and general manager of the mills, was called to the chair, and in opening the business of the evening he said he was glad to be present at such a meeting, for he was glad to see that, in the midst of the present gloom and distress by which they were surrounded, the workpeople of Oxford Mills could have an evening's enjoyment, and his earnest wish was that all who were suffering such privations could be made as happy as those present. The workpeople of Mr. Mason had cause to be very thankful for the generous and kind-hearted treatment of that gentleman, for he (Mr. Tipping) could assure them that had Mr. Mason sold his cotton like some of the millowners, he would have been a richer man by ten thousand pounds than he was. (Sensation, and loud applause.) Instead of that he had not only run his mills full time, but had not reduced their wages at the general abatement. Some of his enemies said he did these things for a motive, but he (Mr. Tipping), taking the lowest idea, did not care what motive a man had if he did good to his fellow-

creatures. (Hear, hear.) Some who had not half the ability of the above gentleman were anxious to pull him down by any means, fair or foul; but, dismissing that subject, he would say to them, Go and do likewise. (Loud applause.)

As that was a meeting of gardeners and friends, it was necessary that something should be said about gardening; but he could assure the young people who were anxious to have an hour's amusement in dancing, that he should make his speech in as short a time as possible.

To those who kept gardens he would say that he should like some other plan than giving the first prize to stuff that was not fit to eat, and hardly fit to look at. He had noticed in going round the room at the late show, that the Celery most fit to eat was to receive the lowest prize. Now, it should be the aim of every gardener to produce something not only fit to look upon, but fit to use. They must have noticed the many fine ornamental plants and fruits brought for decoration, that they were grown not only to please the eye but the palate also. After passing some humorous remarks, he said he did not want the greatest amount to be given to one vegetable, but a fair distribution of whatever prizes Mr. Mason might give. He had sometimes walked over the gardens of the winners of the chief prizes, and had found, perhaps, a few sticks of Celery, a few Cabbages, and the rest of the garden up to the knees in weeds. Now, he would advise Mr. Mason to give his prizes in such a manner that he who kept the *best garden* should have a share, for of what use was it having a garden part full of weeds, and the rest filled with something not fit to eat?

The choir, which was, with about one exception, composed of Mr. Mason's mill hands, sang some beautiful pieces between the speeches, and recitations were given with good taste.

Mr. John M. Broadbent, one of the overlookers, was called upon to say a few words upon gardening, and, after giving an interesting outline of the history of gardening, and the rise and progress of many kinds of vegetables, flowers, and fruit, he referred to the part of Mr. Tipping's speech which spoke of weedy gardens and useless vegetables. He (Mr. Broadbent) would undoubtedly join the gardeners' club if prizes were given for the best-kept fences, the best cultivated gardens, and the most useful vegetables. He, for one, did not see why some Oxford gardener should not bring out some new vegetable, fruit, or flower—a thing which they all might do. He did not expect they would have houses for Grapes and for growing and raising exotics, like his friend Mr. Hague (Mr. Mason's gardener), or that they would, like Mr. Hague, have Verbenas by the hundred, and Geraniums and other things by the thousand, but each could have his garden plotted out into beds, and things grown in little patches or beds in some sort of order, without having all sorts of things jumbled up together, as was often seen in cottage gardens.

Mr. Tipping then gave some useful hints on the art of raising new fruits, flowers, and vegetables, and stated some wonderful facts about Grape-growing, showing that cottagers could now have their own Grapes as well as gentlemen, and there was not so much mystery about growing them as some people imagined. After showing how houses could be built for growing such things, he was sure such men as Mr. Hague would put any of them into the way of growing them.

Mr. Hague, in supporting a vote of thanks to the reciters and the chairman, gave a few useful hints on the value of having as many fresh vegetables in winter as possible, for they were quite as necessary as in summer, and many skin diseases would never occur if more fresh vegetables were eaten in winter.

Votes of thanks to the singers, tea-makers, &c., were received with loud applause. The company then divided into two or three lots, one portion occupying the smoking-room, and another the reading-room, where various plays and amusements were carried on by the elder portion of the company; and the young folks danced in the lecture-room until about eleven o'clock, when all separated, highly delighted with the gardeners' tea party.—(*Ashton Reporter*.)

### RED BEET VERSUS PERILLA NANKINENSIS.

I HAVE for three years tried the Perilla, sometimes edged round with Variegated Alyssum, and some other variegated plants; but the last three years have been anything but good for fairly proving bedding plants. Last year I thought I would substitute Red Beets for Perilla, and see how they would look. I have planted three beds in the geometrical garden. They were

the three centre beds of each group, two were planted or rather sown with Red Beets, and the third was planted with Perilla. Now, I have made up my mind to give Perilla "the bag," as we say in Lancashire—that is, to turn it away, but I will give it another trial.

I edged each with the same plant, but "commend me" the Beets. They are not only very ornamental but useful when their growth is finished, and I should feel glad if any other person who has tried them will speak out in behalf of the Beet, for I am convinced it is far more ornamental than Perilla, and everyone who has seen the two with me has said as I say.—J. HAGUE.

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE October Meeting of the Entomological Society was presided over by F. Pascoe, Esq., F.L.S., Vice-President.

Mr. Samuel Stevens exhibited specimens of a blind species of Beetle (*Adelops Wollastonii*), which he had taken in considerable numbers at Hammursmith, under the decayed leaves of Rhubarb. It had, however, only been observed in certain spots which were frequented by one of the species of *Julida*. The connection was, however, probably only accidental, but Mr. Pascoe stated that he had also found a blind species of Beetle in one of the caves in France, in company with a *Scelopendra*. Mr. Ineson, on the contrary, had never met with any *Myriopoda* in company with the species which he had taken.

M. Desvigne exhibited a very remarkable variety of the Painted Lady Butterfly (*Cynthia Cardui*), having the disk of the fore wings almost uniformly flesh-coloured. It was taken on the sands at Margate in July last, by a schoolboy.

Professor Westwood directed attention to the state of the Turnip crop in Oxfordshire and several other midland counties, where in many places the leaves had gradually died off, having been attacked, as he had been informed by Mr. Druce, the distinguished agriculturist of Eynsham, by myriads of small green flies, similar to those which infest the Roses (*Aphides*). On examining the plants of several varieties he had not discovered any living *Aphides*, but the leaves and stalks were thickly covered with a dense white mould as though the plants had been washed with Gishurst Compound. In some instances the roots had thrown up a few small young leaves in the centre, but more generally they had died. He also exhibited an interesting series of specimens illustrating the natural history of different species of insects which, in the larva state, form mines or burrows within the substances of the leaves of different trees and plants, and which were found to belong to several orders, such as minute Beetles (*Coleoptera*), Flies, *Muscidae* (belonging to the *Diptera*), *Hymenoptera*, and *Lepidoptera*, the latter being small and very beautiful species of Moths. This collection had been made by S. Stone, Esq., of Brighthampton, Oxfordshire, and had been kindly presented to the New University Museum, Oxford.

Mr. F. Moore exhibited drawings of the transformation of a very remarkable large Indian Moth (*Epicopeia Polydora*), which from its extreme similarity to *Papilio Polydora*, and from the mutilated condition of the antennæ in the first recorded specimens, had at first been supposed to belong to the Butterfly tribes. The transformation had been observed by Captain Hutton, of Massoree, and fully proved that it belonged to the *Bombycida*, amongst the nocturnal *Lepidoptera* or Moths, the larva being enveloped in a dense coat of flossy silk of dazzling whiteness standing erect, and falling to powder when touched. He also exhibited a specimen of the magnificent *Kolisuris* Silk Moth of the Deccan, which had been hatched in London on the 15th September last.

General Sir J. B. Hearsey exhibited a case of beautiful Homopterous insects from Darjeeling.

Mr. Newman read a communication from Mr. Jenner, of Lewes, on the extensive destruction of young Ash trees grown in Sussex for Hop poles, by the larvæ of *Zenzera Esculi*. Damage to the amount of at least £1000 had been sustained by this means. Dr. Baly stated that Ash poles were also liable to the attacks of *Pachyta collaris*, one of the Longicorn Beetles; and Professor Westwood stated that he had reared *Clytus arictis* from oaken Hop poles received from Captain Cox.

Mr. Stainton gave an account of a visit to Aix-la-Chapelle, for the purpose of inspecting the specimens of *Micropteryx* reared from Hazel leaves, by Herr Kaltenbach, and which proved to be *M. fastuosella*, a species closely allied to *M. subpurpurella*, the

larva of which mines Oak leaves. It is during the month of April that the larva of the former species was found on the Hazel leaves, which would be a guide to English entomologists in search of the species in this country.

Professor Westwood made some remarks on the misapplication of the ordinary rule of priority in nomenclature in the case of insufficient or inaccurate descriptions of insects. He contended that no description ought to be recognised which was not intelligible, or which had been so carelessly drawn up as to be insufficient to enable a student to determine what was the species intended; instancing cases in which a Neuropterous insect had been described as a new genus of *Coleoptera*, and where a species had been described under many separate specific and even under two or three distinct generic names. He maintained on the other hand the value of typical specimens in collections, and the advantages as well as the duty of consulting them when practicable, by subsequent describers.

Major F. Parry read descriptions of a number of new exotic species of Stag Beetles (*Lucanidæ*); and the Rev. Hamlet Clarke described various new species of small Water Beetles, of the families *Halplidæ* and *Hydroporidæ*.

### FLORA OF THE ROMAN CLASSICS.

(Continued from Vol. I., p. 473.)

#### ACER.

"THE *Acer* and other trees delight in watery places upon mountains.—(*Pliny, Nat. Hist.*, xvi., 18.)

"The *Acer* is almost as large as the Cedar, and next to it for beauty and fineness for cabinet work. There are many kinds of it. The *White*, remarkable for the whiteness [of the wood], called the *Gallie* in Trans-Paduan Italy, is a native of the other side the Alps.\* Another kind, spotted and irregularly wavy, takes its name, when very superior, from the tail of the *Peacock*. It grows chiefly in Istria and Rhetia. An inferior kind is called *Thick-veined*. The Greeks distinguish it by its place of growth. That from the level country being neither white nor wavy, they call *Glinon* [perhaps from its pasty colour, *glia*, paste]: but the mountain-grown wood is [esteemed by them], more wavy and harder, the male tree being especially more wavy and suited to the handsomer kinds of work. A third kind they call *Zygia*; the wood is red and easily cleft; the bark is dusky coloured and rough. Others, however, prefer considering this of another genus, and call it in Latin *Carpinus*."—(*Ibid.* xvi., 15.)

"With the first west wind the Cornel buds swell, then the Laurel; then, a little before the equinox the Lime, and the *Acer*."—(*Ibid.*, xvi., 25.)

"The Terebinth, the *Acer*, and the Ash yield seed at harvest-time."—(*Ibid.*, xvi., 26.)

"Trees of which the substance is wavy, as the *Acer*, Palm, and Poplar, become decrepid slowly."—(*Ibid.*, xvi., 28.)

In all these notices there are but few particulars aiding us to identify this tree, but Theophrastus supplies this deficiency. He says—"Some conclude that there are two, others that there are three kinds of *Acer*; one they call by the common name of the genus—*Acer*; the second, *Zygia*; the third, the Stagirites name *Clinatrocton*. *Carpinus* differs from *Acer*, inasmuch as that the wood of *Acer* is white, having straight fibres; and in *Carpinus* it is red and wavy. In both the leaves are large, cut as in the Plane tree, so that the fissure does not extend to the middle, but stops and slopes to a point at the end; they are smooth and shining, more thin, soft, and long: not entirely covered with hairs. Its bark rather more rough than that of the Lime, rather dusky and thick; harder than the Pine, and less flexible. Roots few; lofty; nearly as many red-wooded as white-wooded trees are wavy. It is produced chiefly in watery situations. Trees not very long, and like to that of the *Paliurus*, but longer."—(*Hist. Plant.*, iii., 11.)

The particulars contained in the foregoing extracts when combined point out that various kinds of the Maple are the trees

\* Of this, probably, the Roman writing-tablets were made. In one of his *Elsgies*, Ovid directs that his tablets with what he had inscribed on them should be taken to his beloved Corinna, concluding with

"Subscribam: Veneri, fidas sibi, Nasq. ministras  
Dedicat; at nuper vile fuist. *Acer*."

—(*Ars Amor.*, i., 11. 27.)

(I will thus conclude: Naso consecrates these to be faithful servants to Venas, which not long since were merely *Acer* of small value.)

alluded to by Pliny and Theophrastus. They are all lofty trees, their wood is sometimes white and unveined; sometimes white and wavyly veined; sometimes reddish and wavyly veined; the leaves are lobed, the sections not extending down to the midrib, pointed, smooth, and shining. The bark is exactly as described by Theophrastus.

The Gallic Acer of Pliny seems to be that known to us as the Great Maple, *Acer pseudo-platanus*. Its wood is remarkably white, and, before earthenware was so cheap and well manufactured, was in much request for the making of trenchers, bowls, and other domestic vessels. It is common in Italy in wooded mountains.

The Peacock Maple was probably the *Acer campestre*, or common Maple, for it is native of northern Italy and its neighbouring countries, and the grain of the wood being very firm, and frequently abounding in knots like the eyes of a Peacock's tail, is very highly prized for cabinetmakers' work.

The Maple of the "level country," and called by the Greeks "Glinon," we believe to be that known to us as the Italian Maple, *Acer opalus*. It is a native of Italy, plentiful about Rome, is one of its loftiest trees, and the wood is white.

The "thick-veined" Acer might be that known to us as the *Acer monspessulanum*, or Montpellier Maple. The leaves are thicker than those of the other species. It is common in Italy and France.

The "Zygia," perhaps, was that now called *Acer creticum*.

Being evergreen, it might well be considered in the days of Theophrastus as belonging to another genus. It is a native of the mountains of the Grecian Archipelago.—G.

#### APPLE AND PEAR TREES UNFRUITFUL.

I HAVE some Apple and Pear trees grafted on Paradise stocks which have been planted five years. The former, with a few exceptions, have neither grown nor fruited; they were about five feet high when planted, and are not higher yet. They are hardy and prolific kinds, such as were recommended for this part of the country. Two years ago they were root-pruned and fresh compost was put to the roots without any beneficial change. They are growing in light loam as standards. The Pears are very much the same as the Apples, but a little more vigorous.—HYPNUM.

[From the description of the trees, we do not see that the fruit trees were too vigorous: therefore they did not need root-pruning at all. Are you sure you have not planted the trees too deep? If not, then, as the loam is light, press or beat it somewhat firm, and then mulch with cowdung or any other manure. We would prune none in such circumstances. If there seems a want of vigour in the spring, rake off the mulching, add a little fresh loam as surfacing, and mulch again. We hope you will have fruit next year, and plenty the second season.]

#### THE WARRINGTON PLANT CASE.

WE now subjoin a design for an aquarium, or Warrington Case, with the view to indicate, to some extent, the variety which may be attained by combining this with the Wardian Case. It will be obvious that this combination will afford scope for a

much greater variety of form than would have been brought out by confining them chiefly to the growth of aquatic plants, and this amount of variety will afford opportunity for the display of a greater amount of ornamentation.

THE WARRINGTON PLANT CASE.

The design now submitted, from the pencil of A. Aglio, Esq., jun., is intended to consist of an ornamental zinc framework, a slate bottom, and the whole of the sides to consist of glass, used in plates as large as the fittings will allow. The front and back will thus each consist of a single plate, and the absence of framework of every kind will admit of the whole interior being viewed without obstruction. The convex ends of the basin portion are

also intended to be of glass formed into the exact shape and size required.

The mass of imitation rock in the centre must be formed expressly for the reception of the plants, good drainage being an essential feature, so that the soil may not become soddened. The whole is supposed to be supported by an appropriate and elegant stand.—(*Gardeners' Magazine of Botany.*)

ORNAMENTAL PLANTS.

*VIOLA PYROLEFOLIA* (Pyrola-leaved Violet).—*Nat. ord.*, Violaceæ. *Linn.*, Pentandria Monogynia. This is a very beautiful dwarf, hardy, herbaceous plant, introduced from Patagonia a year or two since, by Messrs. Veitch, of Exeter, and grown by

them and distributed under the erroneous name of *V. lutea*. It produces a tuft of small, cordate-ovate, radical leaves, with ovate or linear-lanceolate fimbriate stipules, and produces very large, bright yellow blossoms, each elevated considerably above the

*Viola pyrolefolia.*

foliages on a slender stalk. The flowers have a short, blunt spur, and the petals are bearded inside with club-shaped hairs; the lower petal is obovate, streaked with red lines. It is found in Chili, as well as in the straits of Magellan; and is the *V. macu-*

*lata* (Cavanilles), *V. glandulosa* (Dombey herb.), and the *V. lutea* megaphyllos (Commerson herb.). It has been figured by M. Van Houtte in the "Flore des Serres."—(*Gardener's Magazine of Botany.*)

MARKET-GARDENING IN WEST CORNWALL.

(Continued from page 577.)

WITHIN the last twenty years the market-gardening of west Cornwall has undergone an entire change both as regards its system and its extent. Potatoes were then its solo export, and of these the greater part went to Falmouth for the supply of the various packets sailing from that harbour. Probably not one-tenth of the ground now cultivated for early Potatoes, and which may be estimated at about seven hundred acres, was then employed for this purpose. The variety, also, was distinct from that in present use, being a smooth white Kidney, of consider-

able size, and a good cropper. It was known as the "Cornish Kidney," and was grown for seed in the "growan," or granite soils of Zennor and some other adjoining parishes. I have not myself seen this Potato for the last twelve or fifteen years, as, for the purpose of the market, it has been superseded by varieties a fortnight or so earlier.

We now come to the preparation of the land for the Potato crops. Old lay would be preferred for this purpose, but that is rarely to be had, since the narrow limits of the district compel

the annual succession of Potatoes and Broccoli year after year. Many acres have been thus occupied for ten or twelve seasons without any apparent falling-off in the produce. No other two crops that I am acquainted with could be thus constantly and without intermission grown on the same land, the Potato appearing to provide the most favourable conditions for the Broccoli, while the latter re-supplies what is again, after a few months, required by the former. Where lay, however, is attainable, it is usually turned with the long-handled Cornish shovel, which here does the work elsewhere executed by the spade. The cost of this operation varies, according to the toughness of the turf, from £2 10s. to £3 10s. per acre,\* and the seed is planted immediately afterwards. Scarifying and the subsequent use of the harrow, roller, and plough would certainly be a cheaper, and, I imagine, not a less efficacious process. But in whatever way obtained, a fine, tilth is essential, and for the earliest crops a situation neither too low nor too high; wind in the latter case, and the late hoar frosts in the former, too often damaging, or even destroying the plant. Such land as was planted with Broccoli after Potatoes in the preceding year is best dug over, the Potatoes having generally to be planted as soon as possible after the Broccoli is cleared off.

After the disease of the Cornish Kidney, the greater part of the seed was of the Axbridge Kidney, imported from the neighbourhood of that town. But this, again, has in a great measure given way to the Springer or Creeper Kidney, and Early Shaws, of which a large quantity is now annually brought down from the country around Glastonbury. It has long been admitted that a frequent change of seed from a different soil is essential to the well-doing of the Potato; but in this district the general failure of home-grown seed has been aided by another cause—and that is, the long period during which the tuber is more or less exposed to atmospheric influences, ripening so early as it does with us, and planted so late.

Sprouting the seed is now universally practised wherever early maturity is desired. This is done in the following manner:—An airy light room or loft, with windows to be closed in severe weather, has tiers of shelves filling up all its available space. These are often, from lack of room, too close to each other, and a foot from shelf to shelf may be given as a good average distance. On these shelves the seed is carefully placed, each on its end; one sack weighing 2 cwt. will thus require about 30 square feet of superficial space. The end of October or the beginning of November should see this done; and there, with a due supply of light and air, and the occasional removal of any tuber showing signs of disease, they remain till planting-time comes, at the close of February. The great object is to secure strong, healthy, and well-coloured shoots about 2 inches in length; the neglect of ventilation and a proper amount of light producing weak colourless shoots, liable both to injury in removing them, and to decay when planted. The earliest crops are now invariably grown from sprouted seed, and they are drawn a good fortnight in advance of former years when autumnal planting was the rule. I speak of the planting season commencing in the end of February; but where the extent is not great, and labour is abundant, the first week in March would, all things considered, be the best period. The soil is then usually in good order, the seed already in active growth, and the manure unexhausted by winter rains, so that from these causes the shoots are frequently above ground in ten days.

Before speaking of the mode in which they are drilled-in, the manures employed must be severally detailed, and to this purpose the next paper must be given.—W.

(To be continued.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE recent heavy rains have somewhat impeded spade operations. The necessity of an examination of all drains and water-courses will be readily suggested by the now frequent recurrence of wet weather. Every facility should be given at this season for the passage of the water from the garden. *Broad Beans*, in soils favourable to vegetation during winter a few *Mazagans* may be planted, either where they are to remain or on a sheltered border for planting-out early in the ensuing year. *Broccoli*, lay the plants for spring use. The operation is performed thus: Open a good trench and plant them almost horizontally, with

\* The Cornish customary acre, by which these calculations are made, exceeds by about one-fifth the common statute acre.

their heads to the north, burying the stems with soil up to, and even amongst some of the lower leaves. This process will protect them very much against a severe winter. *Cabbage*, vacancies in the main plantations to be filled-up immediately. *Cauliflowers*, those in the frames and under hand-glasses to be divested of their dead leaves, and any vacancies that occur to be filled-up. Give air freely every fine day. *Celery*, if severe weather should set in, some long litter should be laid over the most forward crops. *Endive*, when quite dry, a good quantity to be tied-up for blanching; a quantity of it could then be laid-in in pits or frames before severe weather sets in. *Jerusalem Artichokes*, if left to be taken up as wanted for use, to be covered with litter during severe frost. *Onions*, hand-weed the autumn sowing, and stir the ground slightly amongst them. *Shallots and Garlic*, plant in light and dry soil, otherwise they had better not be planted till February.

### FLOWER GARDEN.

Whenever alterations are intended, lose no time in completing the transplanting of evergreens, the present mild, damp weather being most favourable for their removal. Be careful to secure them against wind, especially large plants, which should never be left until they are properly staked or otherwise made fast, for, when this is put off, it frequently happens that the roots get injured through the tops being rocked about by the wind. Lengthy discussions and conflicting opinions as to the proper time for transplanting shrubs and trees have frequently occupied the columns of gardening periodicals; but there is no time better in practice, or more consistent with theory, than early autumn planting. The uniformly moist atmosphere of October and November, and the exemption generally of these months from severe frosts and drying winds are circumstances, together with the natural warmth of the soil, most favourable for the establishment of the trees in their new quarters. As soon as the greater part of the leaves are off the trees, let the pleasure ground be thoroughly cleaned and swept. The present is also a good time for rearranging the herbaceous ground, which is necessary every two or three years on account of many of the free-growing kinds getting too large. The removal of *Geraniums*, *Heliotropes*, and other bedded-out things should immediately follow their destruction by the recent storms or by frost. Where such is the case do not be niggardly in planting out a good stock of spring flowers, especially if a gay spring garden is required; abundance of early *Tulips* and *Crocuses* in variety should be planted-out now. *Hepaticas* to be remembered, their colours, white, red, and blue, form a pleasing variety; *Snowdrops*, *Winter Aconites*, and *Dog's-tooth Violets* are pleasing visitors in early spring. Standard *Roses* to be gone over and all the long shoots to be shortened to diminish the power of the wind over them. *Chrysanthemums* against walls to have their shoots closely tacked to them, with something at hand to protect them in case of frost.

### FRUIT GARDEN.

The planting of fruit trees, either in the open quarters or against walls, may be commenced as soon as all the leaves are off. The present time is likewise the most favourable for relifting and root-pruning such trees as are too luxuriant, and require cheeking to induce a fruitful habit.

### STOVE.

But little moisture will be required at this period even for the growing *Orchids* which may be located here. Keep the temperature progressively on the decline, more especially in dull weather. Ventilate freely whenever the weather will permit.

### GREENHOUSE AND CONSERVATORY.

If unfavourable weather should occur do not hesitate to use a little fire heat at times, especially in the conservatory where many plants are in bloom, and by such means a free ventilation may be given to expel damp and stagnant air.

### PITS AND FRAMES.

Look over the pots of autumn-struck cuttings and wherever indications of damping appear, remove them to drier quarters. It is safest to keep *Scarlet* and other bedding *Geraniums* in houses where fires can occasionally be lighted to exclude frost and damp, reserving the pits and frames for *Calceolarias*, *Lobelias*, and other similar plants which do not suffer so much from cold and damp.

W. KEANE.

## DOINGS OF THE LAST WEEK.

THE excessive wet continuing on to this morning of the 24th, has rendered all work in the kitchen garden very trying indeed;

but opportunity has been taken to string Onions that had been placed there under cover, until we could get at them. Plaiting them in small strings tends to keep them sounder and longer than when lying in heaps, and hung on nails, &c., space under cover is thus economised. When much is required in little room, it is enough to make one's eyes water, thinking of the extent of accommodation in such places as Drumlanrig and Dalkeith. Even without the assistance of Onion-plaiting, provided Onions are kept dry, I never knew them suffer at all from frost, so that all protection in that way is next to labour thrown away.

Placed a covering of hay over the *Mushroom-beds* in the thatched-roof shed, with open sides, as it was getting too cold to have them exposed. Moved the covering of straw from the first bed in the Mushroom-house. Swept the bed clean with a hair broom, and sprinkled a little dry straw over the surface. The Mushrooms are now coming like pin-heads, and will be in a few days earlier than I expected them. This light covering we find useful, not only for drawing the Mushrooms through the soil, but also for preventing the surface of the bed getting too damp, from the moisture rising from other beds in a state of preparation. The second bed was spawned a week ago, and as all was right, was covered with 2 inches of stish turfy loam, well kneaded and beat, levelled on the top, watered, and a clean spade drawn over it, and now the manure that was thrown in below the first bed, as I mentioned some fortnight or three weeks ago, has been lifted to form a third piece, which, probably, will be ready for spawning in a fortnight.

By these successions we keep heat and moisture enough in the house until cold weather in winter.

I have seen many fine Mushroom-houses, ours is a very plain, simple affair, merely a lean-to shed, with a hot-water pipe through it; the walk in the centre being over the pipe. There is space for a bed on each side on the ground, and a wooden latticed shelf on each side above, making four beds in all. From these we generally make a good number of successions, sometimes making only a third, and rarely more than a half of a bed at a time. There is a small ventilator at the apex at each end, and openings also in the north wall of the house. The roof is close-boarded and slated, and the space between the boards and the lath and plaster is stuffed with dry straw. When the smooth plaster inside was dry, it was washed over with boiled oil, so as to prevent all moisture getting to, and destroying the roof. From the packing of the roof little fire heat is necessary, unless in cold weather. Where Mushrooms, as in many families, are a daily want, the expense of a little simple house would soon be made up, in the saving of labour, and covering of beds out of doors.

#### FRUIT GARDEN.

We had made up our mind to scoure our Vine-borders from such a drenching, but have been beat, as it came some days sooner than we expected, and we hardly hope to see them quite so dry as we wish them for the winter. The first house which we smoked with sulphur a short time ago, has had a thorough scrubbing, the glass and woodwork being washed with hot soap water, the Vines pruned, cleaned, washed also with strong hot soap water, and to be painted with clay and sulphur as soon as they are dry enough. Stages, also, were thoroughly scrubbed. About 1 inch or a little more of the surface soil inside taken away, so as to remove all the filth that fell from the washings, and any insects or their eggs that might be lodging there. To make assurance doubly sure, if possible, we will borrow from Mr. Thomson's book on the Vine, and scatter a little sulphur over the floor, and water it besides with water from the rose of a pot; the water being not much below the boiling-point. When that gets settled we will fork it over a little, and put a surfacing of fresh soil. The walls, thoroughly scoured with hard brushes and soap water, will be whitewashed with new lime, sufficiently darkened to take off the glare, and then every conceivable place will have its shelf, where room can be got for one. Most likely these walls will get another touch of lime and sulphur before the Vines break. The house will at present be crammed—the floor with the rougher bedding plants in boxes and pots, the stage and shelves with the finer Geraniums, &c. This job should have been done a week ago, but we were waiting for the wet weather to do it in. Kept a little fire in the Fig-house, and though the fruit are not so large as in summer, they are sweet, and the out-door ones now are about over. Gave fire every day to the late vinery, with a little air on even in this rainy weather, but allow the fire to go out at night. Placed some sashes, &c., over the border to prevent it getting too wet

and cooled. Burnt a little sulphur in an early Peach-house to stop all growth, and destroy any scale and other insects. Will most likely cut and wash house and trees. No sulphur should be burnt, unless the wood is well ripened, or it will kill it to a certainty, and the sulphur and the sawdust should be covered with a heap of damp moss, and too much should not be used. About half a pound for a house 50 feet by 18 feet. Be sure, however, of the ripeness of the wood, or do not attempt it, and if the sun threatens to show next day, open the house early, and sprinkle the trees from the syringe. Of the finer fruit we have now only a few of the Salway Peach, on a small tree in a pot, valuable for its lateness. The trees in pots in the orchard-house though heavily cropped, are not showing yellow leaves so soon as I would wish, and the Peach and Apricot trees outside are yet too green, and little will come off with switching. The shoots have been shortened, and if this wet, mild weather holds on, we will cut and thin a number of leaves.

#### ORNAMENTAL GARDENING.

We have just taken a few of the plants out of the flower-beds, especially a few of the large central ones. We shall pot a good number of the variegated Geraniums—such as Alma, Bijou, &c. The Golden Chain is already done. The best of these will have most of their leaves stripped off, and be squeezed into 60-pots in light, sandy soil. The smaller ones will be put into larger pots as thick as they can be packed. A lot of these will be plunged into an old bed of leaves in a pit, where they will get a little bottom heat, and plenty of air be given to the tops. A few of the best Scarlets will be treated the same way, all the leaves removed, the points of the shoots taken off, and then the roots packed closely together in soil in boxes and pots, the stems looking just like a little faggot. These generally get watered, are allowed to stand in the dry for a day or two, and then are surfaced with dry soil, and are just kept from frost all the winter, and if they can get a little light all the better. We do not care about their making a leaf bigger than a fourpenny-bit until April, and then they must be protected in temporary beds until planting time.

No time should now be lost in doing such work. We have seen the flower-beds here good in November, but, after such heavy rains, that is impossible now; and success with these old Geraniums greatly depends on having them up before they are touched with frost. When frost threatens, therefore, they should be taken up at once, and placed under cover until there is time to arrange them. There is no other plan so good as this for enabling amateurs and cottagers to have a fine display of Scarlet Geraniums in their beds every summer. A friend writes to say, "Tell little gardeners they should keep their Scarlets in pots, plant them out in pots, raise them in pots, prune a little, and keep them over the winter in pots." This is all very well, but where is the room to come from? An eight-inch pot for a single plant is no joke. On the faggot system, a dozen might be kept in such a pot, and would be safe with a little attention in a garret or a wood-house. Two years ago, I saw some scores thus packed in three moveable wooden boxes in a wood-barn. In fine weather the door of the barn stood open; when there was a little frost the door was shut; when the weather was a little colder a little hay and a cloth were put over all the boxes and stems, and more added as the frost continued. They were thus thickly covered for five weeks; but a few days after the frost was over, when uncovered, they were as fresh as fresh could be, and when adorning the flower garden in summer, I can only say I could not beat them.

The wet weather has also set us thoroughly cleaning the conservatory and other places under cover. But I must stop, only expressing a hope that as soon as it is fine, turfing, planting, &c., will be proceeded with as soon as possible, as sward-laying, box-edging, massing, &c., in winter, are, to me, always associated with that terrible scourge to the gardener—rheumatism, a scourge that lashes all the more when we reflect it chiefly visits us as the result of ignorance, carelessness, or inconsideration.—R. F.

#### TRADE LISTS RECEIVED.

André Leroy, Angers (Maine et Loire).—*Catalogue descriptif et raisonné des Arbres, Fruitières et d'Ornement*. 1860. *Supplement* to the same. 1862.

C. Turner, Royal Nurseries, Slough.—*Catalogue of Fruit Trees, Roses, Coniferae, Trees, and Shrubs*. 1862.—*Select List of*

*Pelargoniums, Cinerarias, Azaleas, Carnations, Pinks, Auriculas, &c.* 1862.

W. Paul, Waltham Cross.—*Descriptive Catalogue of Fruit Trees.* 1862.

### TO CORRESPONDENTS.

We cannot reply privately to any communication unless under very special circumstances.

**TUNNINGHAM MUSCAT GRAPE.**—Since the publication of Mr. Thomson's paper on Muscat Grapes, we have had an application from "R. H. C.," and numerous other correspondents to inquire where this variety is to be obtained. Those nurserymen who have it for sale should advertise it.

**VARIOUS (J. E. W.).**—The Easter Beurré Pear is a very capricious sort. Sometimes it is one of the finest late winter Pears we have, and at others it is perfectly worthless and only fit for stewing. It requires a warm well-drained soil, and a warm exposure. *Escallonia macrantha* flowers are borne by the previous year's shoots. Chalk forms a good concrete under Peach trees. We have them on a chalk subsoil in Hants.

**PANSY SEEDLING (L. F. F.).**—You must name it yourself, if it is worth naming. Seedling Pansies do not come like their parent.

**GRAPE SHANKING (J. L.).**—The cause usually is the roots not supplying a sufficiency of sap, they are probably outside the house, and in a temperature too cold in comparison to that in which the branches are growing. The Live Oak of North America is the *Quercus virens*, an evergreen Oak, known as long since in this country as 1739.

**RASPBERRY STAKES (J. M.).**—As the canes are to be shortened to 2½ feet, it is pretty clear that the stakes depicted in No. 73, must be not more than 2 feet from the plant. In height, 3 feet above the surface.

**FUMIGATING APPARATUS (J. Barr).**—Our correspondent says that many gardeners and amateurs have tried and approved that of which we gave a sketch in No. 70, of our Journal. He thinks "T. H." has not tried it, or he would not prefer the old mode. This may be, but no correspondent has a right to abuse another correspondent merely for differing from him in opinion.

**WHITE-LEAVED CELERY (G. Abbey).**—This whiteness, which has come naturally without the plant being earthed-up, will not be permanent we fear. You had better save seed from it, but the seedlings from that seed, we think, will come green. If they do not, it will be a valuable addition to our kitchen-garden stock.

**TREATMENT OF GLADIOLUS (H. C., Ireland).**—For all who need instruction we advise the common trodden path, even if it is the longest to success. We do not take up our own Gladiolus. He you must take up yours and keep them exactly as you do Potatoes.

**TREE ROSES (Idem).**—We never protect tree Roses unless in very severe frost, and then only Teas and some Bourbons. For them and for all protection work out of doors, dried fern is by far the best, and the way to do Roses with it is to put three stakes to each Rose tree, 4 feet from the stem, then bring their top ends together over the head of the Rose tree, next place half a sheaf of fern, root-end uppermost, between the ends of the three stakes and fasten them and the fern stalks in one tie, and then spread out the fern leaves among the Rose shoots and right over them, and remove the fern before active growth comes on in the spring.

**YELLOW BANFESHIRE ROSE (Marietta).**—What is on the wing now? A "yellow Banksian rose." Is it not possible that your Rose may be the yellow Banksian, named after Sir Joseph Banks, instead of the brow town of Banff? If so, the leaves are smooth and shining, there are very few prickles and very long slender shoots; and if it is the Banksian, the reason for its not flowering is, that you prune it, for it should never be pruned, but only trimmed and thinned every year just when it is going out of bloom, and at no other time unless it grows too crowded, and if it does the extra shoots should be cut right out at once.

**LARGE HOLLY INJURED BY FROST (T. C. P.).**—The way to recover the large, fine, frosted Holly tree would be, first of all, to cut out every particle of dead wood down to the next living joint of every branch and twig of it. That would not be pruning in the sense we use the term, and might be done any day of the whole year. But as the winter is coming on us no good could result from the operation till next season, so put off this till you have fine dry weather in the spring. Meantime, take to the second stage of the operation of recovery, and bring the powers of scientific cultivation to bear upon the roots. Increase their numbers and their efficiency, and then give them fresh soil near the surface, and keep them at active work there instead of at the extremities of the old roots, and you effect all that cultivation can do, and your Holly will in time be as good as ever it was, for no tree is more enduring of hardship than the Holly; but, unfortunately, none is more slow of recovery. Uncover a large space over the roots, put 6 inches deep of the cocoa stuff all over this opening down to the roots, and in one season every inch of the stuff will be full of fresh active roots, then put a layer of fresh good soil or compost of the stuff, and mulch that also an inch thick, and then all that summer give large doses of pond water all over this array of fresh top roots, and the tree will assume the green luxuriance of a "Holly bush."

**STATICE HOLFORDI (Tamerlane).**—We think it is very likely that the plant had got dry in the centre of the ball, or that it had exhausted itself by blooming. It would not be wise to repot it now, unless the soil was in bad order. If the shrivelling-up in the centre continue, you had better cut the plant into pieces, and pot the pieces separately, either as plants or cuttings, using small pots, and two parts sandy heath soil, and one of loam, taking care not to over-water, and keeping them in a temperature about 50° to 55° until rooting freely, when 45° will do. Potted again in spring, these will make good plants. They dislike over-dryness and stagnant moisture. A few broken potsherd and bits of charcoal should be mixed with the soil, so as to make a seventh part of the whole. The drainage must also be good. As the plants get larger more loam may be used than is specified above. When growing freely they like a little salt water—say an ounce of salt in three gallons of water, but only given over the soil occasionally. *Berberis repens* is a native of North America; it is in Messrs. Veitch's catalogue.

**PABONYCHIA ARABICA (H. S. A.).**—We are very much obliged by the plant which you have forwarded, and which arrived safely.

**CAMELLIAS RECENTLY GRAFTED (A Young Beginner).**—We would leave the Camellias alone until the spring; but if the scions are coming strong, top the stock. The plants should be kept in a nice, growing temperature all winter, seldom below 50°, unless you are sure the grafts have taken well. It will be advisable to get them in a place where you can give them from 50° to 60° in March. Cut back then all the forwardest, and dab grafting-clay on the cut. You will obtain the supplement to the Encyclopædia of Plants, at Messrs. Longmans, Paternoster Row.

**PEAR TREE LEAVES DISEASED (R. O.).**—We think that the ground retains too much moisture about the roots of the Pear trees, or that the roots are too deep, but we require more information to enable us to decide. We have seen young trees so infested that were cured by being taken up and replanted shallower in poorer soil.

**TREATMENT OF OLD VINES (P. McH.).**—We quite approve of all you have done. We think you act wisely in not starting until February, or even the beginning of March. The stems should have a little more protection than a board, unless the board is a sort of case that fits over them. We would not delay covering the border until a month or six weeks before starting them, there will surely be moisture enough from the late rains, and we would recommend covering the border at once to keep heat in. If you can keep wet out, it will also be an advantage. You might turn the same litter six weeks before you began to force, and put 9 inches or 1 foot of hot leaves and dung next the soil, and the old litter over that; but more depends on early covering to keep the heat in than upon extra hot coverings.

**VINES OVER-CROPPED (F. G.).**—It would have been better if you had been satisfied with 3 bunches, or 4 bunches at most, on each Vine. Perhaps, however, the Vines were two or three years old when planted. All you can do now is, not to be too hard on them next year in the way of cropping. We have known Vines get over such hard cropping. We have known others that never gave their proprietor a second chance. We hope that will not be your case. We think there is quite enough of dung in the border, and were it ours we would give neither cowdung nor night soil. Very likely either would do more harm than good under the circumstances, but we would have no objection to a couple of bushels of crushed bones, or a hundredweight of superphosphate of lime, applying a third now, a third in March, and the rest in May.

**PLANTS FOR BACK OF CONSERVATORY (A Devonian).**—We do not think, that even now, any Geranium would be superior to *Defiance*, and Mrs. Naylor among Scariets. For ourselves, we would have *Defiance*, and *Stella* us a *Nosegay*. There is no difficulty in grafting new Geraniums on old ones, but we cannot say that ever we found them long-lived and healthy. As a strong-growing, free-flowering, sweet-scented *Heliotrope*, we would prefer *Triomphe de Liege*. The trusses are of an immense size, and of a light grey colour. We do not know "John Catell" variety. The *Luculia* will answer well, but if you plant out all these plants, you should have a brick or wooden box for each—that is, divide the border into so many little pits or beds, that the roots of one plant may not rob the roots of its neighbor. *Jasminum grandiflorum*, *ligustrifolium*, or *gracile*, will answer well. The latter is slender, the flowers not very conspicuous, but of sweet odour, and in bloom nearly the whole of the summer. The *Rhynchospermum* will do at the warmest end. Were you not so far south we would recommend a Japan *Honeysuckle* at the coldest end.

**FERNS DISEASED (One in a Fix).**—Your Fern is eaten up by thrips. Instead of in a hothouse at 70°, that species requires to be grown out of doors or in a cold frame. If you have tender sorts in the same condition, you must use sulphur till you get rid of the insects.

**DESERT PEAR FOR A WALL (Berks).**—There are no better "very early, handsome, dessert Pears for a south-west wall" than Williams' Bon Chrétien and *Beurré d'Amanlis*. The former has a powerful musky flavour, and the latter has not; choose which you prefer.

**NAMES OF FRUITS (Eleanor).**—We do not recognise your Apple. It is quite worthless and ought to be grafted with a better sort. (T.)—Court of Wick, and is generally a good bearer. (B. A. S.)—Your Apple appears to be *Downton Pippin*. (Thos. Sherman.)—*Blenheim Pippin* Apple, and *Marie Louise Pear*. (G. Price.)—*Duchesse d'Angoulême*. (R. W.)—Your Pear is *Paradise d'Automne*.

**NAMES OF PLANTS (Patelin).**—1, The *Pelargonium* (not *Geranium*), is apparently *Madame Vancher*. 2, The Fern is *Polypodium phegopteris*. (J. D., *Furfarshire*).—1, *Genm rivale*; 2, *Mentha aquatica*; 3, *Alechilla vulgaris*; 4, *Stachya palustris*. (*Polypodium*).—1, *Polystichum aculeatum*, young; 2, *dilatata*; 3, *Lactrea Filix-inas*; 4, *Blechnum spicatum*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### TREATMENT OF KILLED POULTRY.

(Translations from M. Jacque's work on Poultry continued.)

FATTENED fowls must, even after death, be subjected to a certain preparation, in order to secure all the advantages there may be in the trade. The dealer in them should know the tastes of the localities where he sells. In some parts buyers like to see fowls with long, round bodies, like the natural form of a Duck; in others they want them flattened, so that there shall be no appearance of a breast-bone; and, again, some want short, square, lumpy forms. All these little circumstances of taste should be taken into serious consideration by feeders, and, if the fowls have not naturally the saleable form, most of them know how to give it as soon as they are killed. Almost all the fowls sold at Paris are flattened. This is done by the killer pressing heavily on the breast and breaking the bone. After this preparation they are put in a press, laid on their backs, and loaded with a sufficient weight. This is done while the bird is still warm; when cold it stiffens and preserves the desired form. Under the weight which presses down the fowl, a more or less coarse cloth should be put,

it leaves its impression on the fat, and gives it a look like *shagreen*, which is pleasing to the eye.

"In Bresse," says M. Chanel de Bourg, "there is no idea out of the immediate neighbourhood of all the pains taken by the farmer's wife who fattens the fowls, to kill them properly by bleeding in the palate without leaving any mark, then to pick it without injury to the outer skin, which becomes a *bark*, and takes from its value; after which she wraps it, while yet warm, in a very fine cloth steeped in milk, and which she sews rather tightly to insure an oval form rather lengthened, which being pleasing to the eye is advantageous to the sale."

Fattened fowls sent long distances, are generally picked, except the head, the flight-feathers of the wing, and the tail. They should also be drawn—that is to say, the intestines and the liver should be drawn out naturally, without making any opening or enlarging the natural one. The appearance of the fowl demands this. The liver should not remain in the body, because the gall, which is generally abundant in the bladder, becomes absorbed, and communicates a bitter and disagreeable taste to the meat. If there be any food in the crop, it should also be emptied; if any remain in this first stomach it becomes sour, and this disagreeable taste is also communicated to the meat. Thus prepared, every head of poultry is wrapped, except the head and feet, in a sheet of white paper, then tied, and packed in hampers of open basketwork, which are preferable to close boxes. The fresh, cool air penetrates and circulates in a basket; the poultry keeps better and longer for it.

The consumption of poultry is immense in France, and the producer, by the facility and rapidity of communications, is in some way sure of a sale for his products. Paris alone buys many millions worth annually.

The hampers of poultry, prepared as we have described, are sent to the great poultry market, formerly at La Vallée, now at the "Halle Centrale," addressed to a salesman who sells them wholesale by public auction. The produce of the sale is sent to the seller.

That which Madame Millet Robinet says on this subject may help to complete the two preceding chapters.

"A fowl should never be killed till it has completely digested all food; morning is then the best time, but if that is not convenient, any time may be substituted, provided the bird has fasted ten hours. There is the same rule to observe with cattle; they must fast till the intestines are nearly emptied. I think eight or ten hours' fasting sufficient for poultry, as they digest rapidly. Fowls may be killed either by cutting the jugular in the mouth with scissors, or by cutting the throat with a *very sharp knife*, after removing the feathers, that the animal may not suffer. In either case the bird must be held up by the feet, head downwards, so that all blood shall run away, for on that operation depends much of the whiteness of the flesh.

"As soon as the bird is dead, and has ceased to bleed, the intestines must be taken out. This is only done in those countries where the poultry trade is a special industry, and yet it is absolutely necessary. They give a detestable taste to the bird if they are allowed to remain. At Le Mans, and in those parts where fattening is carried to perfection, as soon as the intestines are taken out, their place is supplied with fine whitey-brown paper. This not only helps to keep the fowl, but it gives it a good shape, because the loss of the intestines makes it flat-sided. When all the intestines are removed, there remains only the gizzard and liver, which do not injure the keeping. These also are useful in the kitchen; the cook takes them out before she trusses the fowl previous to roasting it.

"Fowls must be picked as soon as they are dead; they are difficult to pick after they are cold. Two feathers should be pulled out at a time, in order that the skin be not rubbed, which would diminish value, if it is for sale, and spoil the appearance, if for the table.

#### MANCHESTER POULTRY AND DOG SHOW.

IN reply to the letter of "INQUIRER," and to satisfy yourselves, I should be greatly obliged by the insertion of the following explanation in your next Tuesday's publication. In the first place, I may say it is not intended to judge either the Poultry, Pigeons, or Dogs on the Sabbath. I may also assure exhibitors that every care will be taken to secure the services of experienced gentlemen to act as arbitrators. The meeting of 1861 has shown us what number of prizes may be awarded, without hurrying, in three hours, and as the Judges are not

appointed until the entries are closed, we shall, of course, be guided by the number of birds and dogs to be shown as to what Judges will be required for each department, so as to finish their labours at or near the appointed time.

I think all exhibitors agree in wishing to keep their birds at home as long as possible before each Show, and to oblige them we have arranged to receive the poultry, &c., so late as ten o'clock on the 27th, even to our own inconvenience.

In conclusion, I may add that most of the exhibitors are aware that should the Judges not have completed their awards by eleven o'clock a portion of the Show can be open to the public whilst the remaining awards are made.—GEO. JENNISON, *Secretary*.

[We are very glad to find that the Sabbath is not to be misemployed, but we had information which induced us to believe that the arrangements were of a different character. We hope that a sufficient number of Judges will be engaged to get through uninterruptedly in the three hours specified; but, although Mr. Jennison refers confidently to the number of prizes that may be awarded (without hurrying), in three hours, when speaking of the Meeting of 1861, he appears altogether to have forgotten that the Judges on that occasion had to push on amongst the whole concourse of spectators till late in the day, and that double the time named by him did not see the awards completed. The only way to prevent a repetition of this error, will be to divide the classes among the adjudicators, if the duties are really to be fulfilled in anything approaching the time fixed for public admission. It would occupy a whole day for any number of gentlemen to act together and go through the classes from end to end of a show like the Manchester one. The judging before competitors, either within earshot or sight, is one of the greatest mistakes in arrangement conceivable.]

#### PIED BANTAMS.

I HAVE a very pretty breed of Game Bantams—viz., White and Pieds. The cock bird has a very perfect pretty ginger saddle, hackle, and saddle feathers; and the hens are a creamy colour; in fact, they are Game fowls in miniature. Would you give me your opinion whether they are not something very scarce and particular?—W. CLARK.

[They are very scarce, and the few we have seen of them have been very beautiful. It would clear up some disputed points if you will state whether you bred them, and if you did, by what process—i.e., what colours and sexes you made use of.]

#### DUTY OF JUDGES AS TO DISQUALIFICATION.

I WISH to ascertain through the medium of your Journal your opinion as to a point in poultry-judging that has given our Society no little trouble. At our last Show we had two sweepstakes for Game—the one a sweep for the best Game cockerel, the other for a cockerel and two pullets, all to be under twelve months old. The first and second prize in each fell to the lot of one individual; but the Judges wrote on the two first-prize pens, "Subject to protest on account of age," clearly showing that they believed them to be over age, which opinion was backed by nearly all the breeders of poultry connected with our Society. In fact, the birds were generally believed to be eighteen months old.

As a competitor in the sweeps, I wrote to the Judges, and asked them to give an opinion in writing as to the age of the birds in question; in compliance with which they gave in writing their unanimous opinion that they were over age, and said that they thought that the protest ought to stand good. I referred the matter to the Committee with the Judges' opinion. The only action taken by them was to forward a copy of the Judges' opinion to the party in question, and leave it to his honour, the consequence of which was that he walked off with the prizes. I wish to ascertain from you what, under the circumstances, would have occurred at any of the leading Shows in England? My own opinion is that the Judges were wrong; that if they believed the birds older than stated, they were bound to disqualify.

If you will clear this point, and give us a rule by which to be guided for the future, you will be conferring an act of very great kindness upon our Society.—W. HUTCHINSON, *Commercial Bank, Hobart Town, Tasmania*.

[Under such circumstances there is no middle course for a

Judge. If he is convinced that birds exhibited as chickens are adults he should absolutely disqualify them. If he is not certain he should state his doubt to the Committee, and then the Committee ought to require from the exhibitor satisfactory proof of the chickenhood. It was a shrinking from duty to allow the exhibitor to be his own censor, and the Committee should have reflected that if he gave up the prizes he would publicly confess by so doing that he had attempted to commit a fraud.—*Eds.*]

### HOLDING EXHIBITIONS SIMULTANEOUSLY.

ALTHOUGH the columns of your extensively circulated periodical have so frequently exposed the fatal error of committees of poultry exhibitions holding their meetings simultaneously, or, at best, closely following each other, there appears at the present moment a more total disregard of this praiseworthy warning than ever.

No doubt several circumstances have tended to produce this result, still the inevitable consequences remain unaffected—viz., the widely spread injury of all. During the past summer not a few local committees, doubtful whether the International Exhibition might not absorb nearly the whole of the stray shillings commonly devoted to other sources of amusement, prudently determined to postpone their respective meetings until some more favoured opportunity, and now the closing time of the London attraction is finally determined upon, many of the managers of these poultry shows, wearied by procrastination, appear to think that any further delay would certainly compromise the future well-doing of their society. Hence it is, that arriving at these conclusions, altogether without the knowledge of each other, December next seems an all but universal appointment among them. From these unusual causes, still another hint to parties thus on the eve of committing, so far as their own shows are concerned, an almost suicidal act, will, perhaps, be more beneficial and time-serving than heretofore. It is almost unnecessary to point out, that those committees whose customary time for holding their shows has hitherto been December, look upon newly-regulated appointments in that month as an encroachment of annually-enjoyed privileges, producing a little jealousy of feeling not altogether provocative of benefit to either party interested.

I will not enter now on the prescriptive rights, real or assumed, just referred to, but merely endeavour to point out that a complication of poultry shows invariably tends to injure more or less extensively each one of them; and by directing attention to the fact that our larger shows of necessity carry out their appointments the most popularly, and that, consequently, the minor meetings suffer the most severely by collision of the character referred to. It must recur to many of your poultry readers, and still more forcibly to pecuniary sufferers, that not a few shows beforetime carried out with perfect success, have been so blighted as to be abandoned altogether by the contingency referred to. It must also be remembered that three of the largest shows in the kingdom already date their appointments for December next.

The opinion is, doubtless, a correct one, that Birmingham, the Crystal Palace, and Manchester Shows will provide quite enough confinement to tax to the full the energies of all the best specimens from the yards of our principal poultry-breeders during the month of December. That exhibitors give decided preference to the hope of winning at the largest shows is a fact barely open to dispute, at least in all cases where the superior quality of their birds justifies the anticipation; and, therefore, it of necessity follows, any small show taking place at about the same period is deprived of the advantages of their exhibition, with an exact discount on its future popularity and importance to the less-known show attempting it. Even the most liberal prize-list rarely counteracts this misadventure; whilst after-prudence fails as entirely to refill un replenished coffers. It is impossible to assign any particular reason why December should thus have become so universally selected, unless it be that Committees are assured that without sufficient time for advertising their show it cannot possibly be successful, and that this idea prohibits November being thought of; and again that after Christmas breeders will be more anxious to keep their favourites at home. That truth exists in this argument I freely admit, but my opinions are without qualification that with the three largest Shows just named, three in addition already before the public, to still augment the December shows by seven others now on the *tapis* would injure

all, and at the same time some of the weaker ones permanently. The individual interests of these societies would be far more insured by spreading the time of holding them over the first months of next year; whilst, most probably, the public taste for poultry-culture would not pall as completely as it must do (except to enthusiastic fanciers) if subjected to this continuous repetition.

As in all probability even other committees unknown to myself are now holding the same subject under consideration, if anything I have written should tend to a more wise determination I shall conceive the trouble I have taken in no way misemployed; and return my best thanks for the opportunity you have thus so kindly allowed me to forewarn those who otherwise might possibly have not imagined the difficulty thus made evident.—*EDWARD HEWITT, Eden Cottage, Sparkbrook, Birmingham.*

### BANTAM CLASSES AT THE CRYSTAL PALACE SHOW.

In further confirmation of what Mr. Ballance says at page 582 of your last Number, I would call your attention to the fact that the Crystal Palace Company have but one class for all varieties of Game Bantams, although at their last winter Show there were twenty-three pens of these birds, clearly showing what favourites they have become with the public. The glaring injustice of this will be manifest when I point out to you that the Gold and Silver Sebrights have two classes, though the two classes together mustered only twenty-one pens at the Show referred to. But what makes the matter monstrous, is the fact that there are four classes for Polish fowls, with eleven prizes of the aggregate value of £21, though these same four classes, at the last winter Show, could only muster altogether twenty-four pens. I, for one, certainly will not exhibit a Game Bantam—though I breed both Greys and Black Reds—at this Show, until a more just distribution of prizes is made. I shall send my birds to Birmingham and Manchester, where they can compete fairly.—*P.*

### MIXING VARIETIES OF FOWLS IN ONE CLASS.

AFTER reading the valuable remarks of Mr. Hewitt and Mr. Ballance on the above subject in your Journal, allow me, as a frequent exhibitor of Cochins, to express my conviction that if there were a separate class for Buff and Partridge birds at all shows, as at Birmingham and the Crystal Palace, it would tend very much to their prosperity, as many exhibitors will not show when both varieties are in one class. And how difficult a thing for the Judge to decide which colour to award the prizes to; besides which I see, on reference to the catalogues of several of our principal shows, that the entries for each colour of Cochins are as numerous as that for Gold and Silver Hamburgs, which, in almost every instance, have a class for each colour; so if committees would make the alteration I suggest, it will surely insure them a larger number of entries.—*HENRY BATES, Edgbaston, Birmingham.*

### MIDDLETON AGRICULTURAL SOCIETY'S POULTRY SHOW.

THERE were 266 entries—a greater quantity, and, according to the Judges' report, of a finer quality than has ever been exhibited during the Society's existence. This was evinced by the care and skill it required to select those for the prizes offered. The general arrangement of this large and interesting department was entrusted to Mr. Smith, and elicited commendations from the Judges, the public, and the Committee. The Judges were Mr. R. Teebay, Preston, and Mr. J. Hindson, Liverpool. Their awards were as follows:—

SPANISH.—First, R. Tattersall. Second, R. M. Stark, Hull.  
DORKING (Any Colour).—First and Second, T. W. Hill, Heywood. Commended, T. Stutter; R. M. Stark, Hull.  
GAME (Any variety).—First, R. Parkinson, Poulton-le-Fylde. Second withheld.  
COCHIN-CHINA (Any Colour).—First, T. Stretch, Ormskirk. Second, J. Pith, Halifax. Commended, E. Smith, Middleton.  
HAMBURGH (Gold or Silver-spangled).—First, J. Ashcroft, Waterloo, near Ashton-under-Lyne. Second, J. Dixon, Bradford.  
HAMBURGH (Gold or Silver-pencilled).—First, J. Dixon, Bradford. Second, S. Smith, Northowram, Halifax.  
ANY OTHER VARIETY.—First, Second, and Third, J. Dixon, Bradford.

**GAME BANTAMS (Any Age or Colour).**—First, J. Crassland, Wakefield. Second, N. Cook, Chawbent.

**BANTAMS (Any other variety).**—First, J. Crassland, Wakefield. Second, G. R. Tate, Driffield. Highly Commended, Mrs. Foster, Molesworth Cottage, near Beverley.

**DUCKS (Aylesbury).**—First, T. W. Hill, Heywood. Second, Mrs. M. Seamons, Hartwell, Aylesbury. Highly Commended, R. M. Stark, Hull; Messrs. H. & J. Kenyon, Acerrington.

**DUCKS (Roan).**—First, J. Dixon, Bradford. Second, G. R. Tate, Driffield.

**ANY OTHER VARIETY.**—First, E. Hutton, Pudsey. Second, J. Dixon, Bradford.

**GREEN (Any variety).**—First, G. R. Tate, Driffield. Second, W. Kershaw, Heywood. Third, J. Dixon, Bradford. Highly Commended, W. Kershaw, Commended, J. Marshall, Saddleworth.

**TURKEYS.**—First, S. F. Armitage, Middleton. Second, W. Kershaw, Heywood.

#### POULTRY HATCHED IN 1862.

**SPANISH.**—First, C. J. Samuels, Manchester. Second, J. R. Rodbard, Winton, near Bristol. Third, C. J. Samuels.

**DORKING (Any Colour).**—First, J. F. Newton, Kirby-in-Cleveland. Second, T. Statter, Whitefield. Third, J. Holmes, Knowsley. Highly Commended, J. F. Newton, Kirby-in-Cleveland; H. Hilton, Harpurhey; E. Smith, Middleton.

**COCHIN-CHINA (Any Colour).**—First, T. Stretch, Ormskirk. Second, F. G. McCrea, Halifax. Third, A. Barker, Todmorden.

**GAME (Black-breasted and other Reds).**—First, J. Fletcher, Stoneclough. Second, C. W. Brierley, Rochdale. Third, C. T. Rhodes, Halifax.

**GAME (Any other variety).**—First, W. Bourne, Newton Heath. Second, B. W. Bretherton, Rinchill, Prescott. Third, W. Barstley, Middleton.

**HAMBURGH (Gold-pencilled).**—First, J. Munn, Stacksteads, Newchurch. Second, Messrs. Carter & Valliant, Poulton-le-Fylde. Third, A. Nuttall, Newchurch, Rossendale. Highly Commended, A. Nuttall; M. Isherwood, Radcliffe; T. Parkinson, Acerrington.

**HAMBURGH (Silver-pencilled).**—First, S. Fielding, Birch. Second, J. Firth, Halifax. Third, C. Moore, Poulton-le-Fylde. Commended, J. Dixon, Bradford; J. Wood, Horridge, near Bolton.

**HAMBURGH (Golden-spangled).**—First, N. Marlor, Denton, near Manchester. Second and Third, J. Roe, Hadfield, Derbyshire.

**HAMBURGH (Silver-spangled).**—First, J. Lancashire, Tonge Lane. Second, E. Collinge, Boarshaw, Middleton. Third, J. Dixon, Bradford. Highly Commended, J. Mitchell, Hipperholme, near Halifax. Commended, W. Cannon, Bradford; J. McWilliams, Glossop.

**ANY OTHER VARIETY.**—First, W. Hargreaves, Bacup. Second, C. J. Samuels, Manchester. Third, J. Dixon, Bradford.

**DUCKINGS (Aylesbury).**—First, Mrs. M. Seamons, Hartwell, Aylesbury. Second, Messrs. H. & J. Kenyon, Acerrington. Highly Commended, J. Collinge, Habergham House, near Burnley; J. Dixon; Mrs. M. Seamons; G. R. Tate, Driffield.

**DUCKINGS (Roan).**—First, J. Collinge, Habergham House, near Burnley. Second, G. R. Tate, Driffield. Highly Commended, J. Holmes, Knowsley; F. Hindle, Haslingden.

**ANY OTHER VARIETY.**—First and Second, J. Dixon, Bradford.

**GOSLINGS.**—First, Mrs. M. Seamons, Aylesbury. Second, G. R. Tate, Driffield.—(*Middleton Albion.*)

#### POULTRY-KEEPING ON A LARGE SCALE.

A CORRESPONDENT of the *American Country Gentleman* says—“I keep from 100 to 200 fowls, mostly of the Black Spanish breed, and keep them confined the year round; but disease is not known among them, and I can assure you that they do full as well as those kept by others, who believe that fowls cannot do as well unless they are kept scratching. My yard is only 25 feet by 60 feet, filled 12 inches deep with leached ashes and fine sand. I have a large box containing some thirty bushels of burnt shells and bones, which the fowls have free access to, and when the top becomes too dirty, I take it off and put it around my grape vines. My gardener raises six hundred head of cabbage annually, which are given to the fowls through the winter, and in summer he gives them lettuces, all they want. I have a contract for ten beef heads weekly, and give the fowls plenty of sour milk, in addition to all of which they have free access to a mixture of corn, oats, wheat, and barley, which is kept in a bin holding some forty bushels, so constructed as to regulate itself, and not allow the fowls to waste a grain or to scratch in it. My watering-trough is also so constructed as only to admit the heads of the fowls, and is always full of pure, clean water, which is of more importance than anything else in keeping poultry healthy.

“A barrel of lime, a bucket, and a brush are indispensable articles in a poultry-house, and should be used every rainy day (and oftener during such a drought as we have had lately), white-washing everything but the floor, and using the lime dust on that; but wash the floor first. I have tried all your vermin preventives, and everybody's else, but never succeeded in keeping my fowls free until I found a remedy by experimenting.

“The nests are so constructed as to be all taken apart in two minutes; they are perfectly smooth inside and out, and once in every two months I have them taken down, cleanly washed, and then thoroughly coated with common whale oil, and have never yet seen a single louse near them, nor can one

be found around my premises. The oil we apply with a common brush, and it can be relied upon as being a sure preventive against vermin on fowls.—(*Boston Cultivator.*)

#### QUEEN BEE'S AGE OF FERTILITY.

COULD you inform me through THE JOURNAL OF HORTICULTURE—1st, At what age a young queen bee usually begins to deposit eggs? 2ndly, Is the laying of eggs retarded if the queen is not soon impregnated after being hatched-out; or does she commence laying about one ago generally, whether impregnated or not? 3rdly, Is a queen older before laying when hatched late on in the year—say the 16th to the end of August—than when bred earlier in the season?

I ask the last question, because one or two late-bred Ligurian queens, hatched in the latter half of August, had not become fruitful when more than a month old. I may say there was not any lack of drones in the apiary.—A. T.

[Three weeks is the usual age at which a young queen commences egg-laying during the summer months; but if the weather be very warm, this period is sometimes shortened to a fortnight, or it may under other circumstances be prolonged to thirty days or even more.

Egg-laying is generally retarded when impregnation has not been effected; but this is not always the case, as exemplified in the instance related by me at page 56t. On the other hand, I have several queens hatched on the 30th and 31st of August, which had not commenced egg-laying when last examined, about the middle of this month (October), although I have reason to believe that most of them are impregnated.

Egg-laying is often longer deferred in autumn-bred queens than in those that are hatched earlier in the season. For instance: a queen which was hatched on the 17th of August last laid no eggs until the 19th of September, although she then laid worker eggs, and turned out remarkably fertile.—A DEVONSHIRE BEE-KEEPER.]

#### BEE-HIVES AT THE INTERNATIONAL EXHIBITION.

FENN, R., *Rectory, Woodstock*, No. 2112.—Not long since I wrote you that I had made a discovery about the ascent of the bees from my hives up into the supers, and that I would let you know all about it on the first opportunity; and from the numerous letters I have received requesting particulars about my hives since they have been at the International Exhibition, and as you are about to issue illustrations, I grasp the nick of time and say, Go forth!

It is a great nuisance to the worker bees in small supers to have a lot of drones constantly fussing about in their way, and antagonistic to quick filling of the glasses. Fat people in general consume less, but your big drone will eat you considerably; and for some cause or other I find they do not meet with such rough usage in the supers as they do in the paternal hive: hence their retreat. But I have changed all that.

My supers are now proof against drones, and, I may say, the queens also, for not the least sign have I seen of any bee majesty in my supers, which cannot be said of others working on the free-admittance system in Woodstock; for, in two instances I know bell-glasses have been half filled with bee-brood and bread this bee-breeding season.

I have so lately shot over the workings of my system, excepting the above recently invented contrivance, in Nos. 639, 650, 652 (old series), and 4, 10, 22, 29, 39, 40, 42, 43, and 46 (new series) of this Journal, that it would be unnecessary to beat the ground all over again; so I will merely for the present illustrations point to where their descriptive features may be found, and also attach the prices to them which they cost me, leaving out of question altogether the daily thought and numerous contrivances of eleven years' cogitation ere I arrived at what I consider to be, up to the present time, a very good natural country system of bee-keeping and bee-apparatus, which any one with a little help from his ingenious village neighbour could set-up for himself. “If I had but a thousand a-year” I cannot say whose or how many systems I should set up. But as it is, my necessity and object has been simplicity, and yet nevertheless so to combine results fit to set in a pleasure ground by going to a moderate expense, and to show how good and saleable samples

of honey in the cheapest manner can be produced agreeably to the means and understanding of the cottager.

No. 1.—Pedestal and block-board. See No. 4, 1861, page 73.

Tradesman's work for getting-up as well as they could be of their kind cost me 4s. 6d. I have some which I manufactured myself. Of course their expense is nominal, and I wish to impress this secondary idea as a primary consideration throughout.

No. 2.—Bee-boards. See No. 10, page 186. 7s. 6d., mahogany; 3s. 6d., deal and dovetailed; and 2s. plain ash.

No. 3.—Hive and comb-support-sticks. See No. 10, p. 188. Sorted straw, peeled withes, and hickory support-sticks, 4s. 6d.; common straw, &c., 2s. 9d.

As the next numbers mix themselves up with the permanent adapting-board, I will next explain away what I will call the flap, which is a thin piece of deal, or any other wood, rounded exactly to fit the central hole of the adapter, and to rest on four pin-supports so as to lie even with the surface of the board. Each piece of pin or wire is forced into the wood of the side hole in the adapter some eighth of an inch, and left to protrude about the same distance. Now measure 2 $\frac{3}{4}$ -inch sections off the opposing ends of the rounded flap, and cut away the edges between each section, so as to leave openings between the flap and the adapter of not quite two-eighths of an inch broad, which will admit the worker bees to ascend upwards but not the queens or drones. Two other openings may be cut out of the flap opposite each other 2 inches long, not quite two-eighths of an inch broad, and three-fourths of an inch from the sides parallel with the others. Bore two rows of holes with a small nail-piercer, or form a slit too narrow for a bee to pass along the centre of the flap to act as an air-passage. Then rest the flap upon the pins, and secure a piece of adhesive label (I use the margins from sheets of postage stamps), on to the adapter and flap, which will form a hinge as it were. Paste another piece of adhesive on at the opposite end of the flap only, of which more anon. When I place this my permanent adapting-board—for it is never removed during the honey-gathering season—upon the hive, I firstly take off the small round piece of plaited straw from the top central hole, and quickly place a glass tumbler inverted over the hole, which effectually prevents a bee from escaping to place itself in jeopardy or to annoy the operator. Then if the top of the hive is at all sunken, which is frequently the case, I have small deal fillets (No. 5), a trifle wider in diameter

No. 5.

than the central hole of the adapter, and of various depths, to slip over the tumbler, and a wind of cotton wadding also to lay nearly around the outside circumference on the top of the hive. Then place on the adapting-board (No. 6), when the tumbler will obtrude itself up through the flap-hole, and no insect will ever be able to pass the cotton wadding one way, nor, by reason of the fillet, will the bees be able to go between the hive and the adapter on the other. Now moisten the end of the adhesive paper, quickly take away the tumbler, down with the flap, press the adhesive paper on to the board, and place the super-board (No. 7), which must have a flap in its centre to exactly correspond with the one below. Two guide pencil marks on each board previously marked will point out their proper positions; and by reason of these duplicate openings in the flaps it will be seen by illustration to admit of two glasses (No. 8), being worked in lieu of one, which is another great point gained in a good and early honey season. Now slip a carpet bag over the glasses to keep them warm, and the super-over-hive over that; and then the pan and sculptured weight will keep all taut, and be far from appearing unsightly into the bargain.

No. 6.—Permanent mahogany adapting-board, circular, three-eighths of an inch thick, 16 inches in diameter, and having a central hole 3 inches in diameter. Three shillings with flap.

No. 6.

No. 7.

No. 7.—Super-board mahogany, circular, two-eighths of an inch thick, a foot in diameter, and having a central hole 3 inches in diameter. One shilling and sixpence.

For a description of a method of setting the honey-glasses to work, see old series, No. 652, page 389.

E.A.S.

Honey-glasses.

No. 9 is a second small super-board to correspond with the above, excepting that the central hole remains without a flap; for, unless double supers are worked throughout the season, a third flap is unnecessary, and the super 3 inches high or so, and of any diameter one likes coming within the measurement of the board, is of wood, glass, or straw.

My second relievers are mostly fig-drums cut in halves, or at least to the required depth, having a piece of glass let in nearest the board, so as to admit of one's seeing when the bees have nearly completed their combs, and are ready for another. Well, we are arrived at the time, let us suppose, when it will be seen by examination that the bees have nearly completed their honey-combs in the glasses, and are in want of more room; so that all one has to do to accommodate them is merely to lift up (Nos. 7 and 8) board and glasses, slip (No. 9) a board and super and fillet on top in its place, and bodily set Nos. 7 and 8 on the top of it, which will then represent No. 10. The narrow fillet will prevent the board from coming flush down on the top of the newly-inserted super, which has a hole of only about 1½ inch in diameter in its top; a second small super-board would answer this same purpose—viz., leave a vacuum there for the bees to ascend to complete the sealing-over of their combs in the glasses, which they will presently do, and till when, of course, the piece of carpeting and super-over-hive is reinstated. My method of taking the honey-glasses or supers can be seen in No. 652, page 390; but, with the newly-invented flap, the messing with the thread or wire is quite superseded.

No. 10.

Payee's straw supers I generally use for my third removes; but these the man here who makes my hives, and a very good hive-maker he is, is not quite up to, so I purchase them in my native county of Mr. Major, in the Traverse, Bury St. Edmonds, Suffolk. They cost there about 1s. each.

No. 11 is the super-over-hive, a foot deep, and about 14 inches inside diameter. I cause holes to be worked in their tops, about

No. 11.

No. 12.

3 inches in diameter, the same as for the bee-hives, to allow the foul air to circulate up and away, or the top may be omitted altogether as per engraving.

No. 12.—A self-floating bee-feeder.—I formed this out of a fig-drum, but I find it is becoming out of the fashion to export figs in drums. Square boxes are now the vogue: therefore, to employ a tradesman to make a machine of the sort, I daresay it would cost 3s., and with a bell-glass to cover it—say 2s. more. But I have lately manufactured another out of an old quarter-of-a-peek measure, and for the method of doing it see No. 639, page 185. My spring-time bee-feeder is made of zinc, see page 186, *ibid.* It cost 9d.

No. 13.—Honey-knife. Consists of a flattened steel handle, some 2 feet long, three-quarters of an inch in diameter, by one-eighth of an inch substance, having a horizontal pibleme 2 inches

long, and tapering to a point at one end, and a vertical spud about the same length flattened-out to 1½ inch broad at the

Spring-time bee-feeder.

No. 13.

other. A blacksmith could make one for 2s. 6d. See manner of using it in No. 40, 1861, page 287. My bee-entrances which

Bee-entrances.

appear on the hive in its winter garb (No. 14, A), are described in No. 10, page 187. Cost me 6d.

No. 14, A.

The bee-pan shelters measure 11½ inches wide across the bottom, with sloping sides 7½ inches deep, and measuring 2 feet for their top inside diameters. See No. 10, page 187. They cost me 2s. each.

The well-doing of my bees again through last winter, leads me still to recommend the shelter of pan. A few bricks placed on his head would prevent an exuberance of spirits in a high wind; but, for the look of the thing, a greater expense is gone to. We have a few old Anglo-Saxon pillars left, which have fortunately escaped the churchwardens' axe, in the church here, and they are garnished with sculptured heads of monks and nuns, from the severest of aspects to right-down-broad-face; so, having an ingenious self-taught mason living in the parish, I caught him by the button-hole one fine day, and, with pen and pencil, sketched a few of those heads which vastly took my fancy. His chisel has perpetuated their physiognomies in their congenial stone, and they now do duty as wind-protectors for my pan-shelters. For conveniently taking off and on they are made separate, and to fit on pivoted busts, No. 16. They cost 5s. each. The nun's head illustrated was furthermore endowed with a wreath of vine

No. 16.

foliage and grapes, just by way of not allowing those old facetious fellows to vanish with all the conceits to themselves. The above is shown in *propria persona* in my case, 2112, in the eastern annex, at the International Exhibition.—UPWARDS AND ONWARDS.

### DO WORKING BEES EVER BECOME FERTILE?

AMIDST the many apparent anomalies which present themselves in the natural history of the bee, no one seems more perplexing to the scientific inquirer than the alleged power ascribed to the worker bee to lay fertile eggs; notwithstanding that, according to all naturalists, it is incapable of being fecundated; indeed, the whole subject connected with reproduction in the bee, notwithstanding the German-Dzierzon theory, as to which I do not now pronounce an opinion, is still shrouded in obscurity, and is still *the* great mystery in apian science.

The merit of the discovery of fertile workers is assigned to the naturalist Reim; and the celebrated Huber has confirmed that discovery by observations and experiments conducted chiefly by his valuable assistant, Francis Burnens. To Miss Ivrine also belongs the credit of having, by aid of the microscope and dissecting-knife, discovered the existence of ovaries in the working bee, and of the presence of eggs in several of them; thus establishing, beyond a doubt, the identity of sex of the worker and queen bee.

Although, however, this discovery has been put beyond the reach of cavil by these eminent naturalists, and been confirmed by subsequent observers, I must yet record my doubts of this strange anomaly being sufficiently and thoroughly investigated, and, consequently, understood. I must, for my own part, candidly confess that in all my experience I have never been fortunate enough to detect fertile workers in the act of oviposition, nor have I been able to identify such as are in that abnormal condition.

Admitting the fact, however, which has been so well authenticated, I should, nevertheless, feel extremely obliged to such of your intelligent correspondents as may have witnessed this strange anomaly of fertile workers depositing eggs which developed into male bees, to state under what peculiar circumstances this happened, to give the antecedents of the stock in which they were produced, and such other particulars connected with their history as may be thought worthy of remark.—J. LOWE.

[We should be glad if any of our correspondents who have observed this remarkable phenomenon would comply with Mr. Lowe's request.—EDS. J. OF H.]

### USE OF EMBOSSED BEESWAX.

AT the beginning of October, the weather being warm and fine, I removed a side-bar from my wooden bar-hive, and carefully substituted a new bar having a sheet of embossed beeswax, with which I had been favoured, firmly fixed to the top.

On the 16th, the day being very bright although rather cold, I carried some food to a straw hive near; and, finding the bees in the bar-hive very quiet, I loosened the slides on each side of the bar introduced a few days before, and on looking in was much pleased to find that the bees had built thick comb on each side of the sheet of wax.

My bees have been working well here until within the last week.—SURREY HIGHLANDER, October 24th.

### ARTIFICIAL COMBS.

I HAVE been favoured with the following letter from a lady correspondent to whom I sent a few "artificial partition walls," and whose experiment with one of them appears to have been quite as successful as those of—A DEVONSHIRE BEE-KEEPER.

"I was much obliged by your favouring me with thirteen sheets of wax; and as the 3rd of this month was a very fine, sunny day here (Haslemere, Surrey), I took out one of the side bars from my frame-hive, and inserted a new frame in its stead,

having previously fastened a waxen sheet firmly in, according to your directions. We had wet and windy weather afterwards, and for a few days I could not look at the hive often; but to-day (16th of October) being very fine and sunny again, I went to give some food to a straw hive, and finding everything very quiet in the wooden-frame hive, I provided myself with a little tobacco smoke, and quietly took off the upper box, loosened two slides at the side, and drew them out. The bees crowded up to the light to see what was the matter, but dispersing them with a little smoke, I had the pleasure of seeing that they had built white comb to a considerable thickness, from the sheet of wax, and from each side. It was not possible for me to ascertain during the short time the hive remained open whether they had entirely covered the sheet of wax with comb, nor whether they had built exactly upon the embossed pattern given. This must remain uncertain until next spring, but I think you will be pleased to hear of the success of one of your waxen sheets."—H. R.

PANAMA HATS.—Dr. Berthold Seemann, in the "Bonplandia," says they are not made on the Isthmus alone, but most of them, and the best, in Manta, Monte Christe, and other places in New Grenada, south of Panama. Panama hats are worn all over the continent of America, and in the West Indies. The best are sold at from 1 dol. 50 cents. to 2 dols., and but seldom sent to Europe. The staple article for exportation is made by negroes in the tropical latitudes. Panama hats excel other straw hats in their pliancy, as they consist of but one single piece, and can be rolled up and even carried in the pocket without much injury being done to them. During the rainy season the Panama hat easily gets soiled; it is then cleaned with soap and water, then with the juice of lemon or some other acid, and when dried in the sun its whiteness is restored. The plant which is used for making the Panama hat is called "Tipijape," and "Porto rice,"—botanical name "Carludovicia palmata," looks much like a Palm tree, and grows along the western coast of Ecuador and New Grenada. The leaves are gathered before they unfold, the ribs and coarse stalks taken out, exposed to the sun for twenty-four hours, soaked in boiling water till they get white, when they bring them up in the shade for bleaching. The plaiting of the straw is hard work. Common quality hats take a day or two, fine ones upwards of three months, hence the great difference in prices. The best time for plaiting is when the straw has a certain degree of moisture—viz., in the damp weather, in the rainy season, and in the early hours of the day.

### OUR LETTER BOX.

WARNING (*E. Hutton*).—We have no reason to doubt all that you say, but we do not think that there is any need to insert a letter warning our readers against lending money to applicants whom they do not know personally. It would be difficult to find another gentleman like him you name, who would so readily part with his money.

RIP OR COOP FOR CHICKENS (*North Lodge*).—A rip in which to put a hen and chickens should be 24 inches high in front, 18 inches at the back, 20 inches square inside. It should be boarded on three sides, but have bars in front. Two of these should slide up and down for facility of putting in or taking out the hen, and all should be wide enough apart to allow the chickens to run through between them. It should have no bottom for any kind of poultry. It should stand on sand or gravel. Out of doors is better than the attic. A washing-tub or anything of that size and depth will be all your Ducks require. Slate and zinc are the best materials for small tanks, a hole and plug the best means of emptying them. It is not very detrimental to cut one wing of a fowl, but it is a disadvantage.

BOOTHMAN'S PATENT BEE-HIVE.—When we wrote last week we were not aware that this hive received *honourable mention* by the Jurors of Class 9, there being no medals awarded in this department; a model of this hive also received the silver medal of the Royal North Lancashire Agricultural Society, at Preston, September 3rd, 1862.

### LONDON MARKETS.—OCTOBER 27.

#### POULTRY.

Miserable weather makes dull markets, and Leadenhall is no exception.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 51.7° and 36.8° respectively. The greatest heat, 63°, occurred on the 6th, in 1834, and 5th, 1852; and the lowest cold, 18°, on the 9th, in 1851. During the period 127 days were fine, and on 118 rain fell.

DINNER-TABLE DECORATION.

NE of the principal duties which a gardener has had to attend to of late years, is to provide plants suitable for the decoration of the dinner-table, and the Royal Horticultural

Society made a step in the right direction when it offered prizes for the above. It is true that the first exhibition of the kind was not so successful as was anticipated, but it has been the means of inducing nurserymen and others to adopt measures for importing and cultivating plants more adapted for the purpose than those we already possess.

The size of pots which the Royal Horticultural Society recommend—viz., 48's, is, I think, most suitable, as pots of that size can easily be placed in either gold, silver, or china vases, without disturbing the balls of the plants—a matter of no small importance with choice specimens.

If this kind of decoration is required five evenings out of the seven, a good collection of plants will be indispensable; as, for instance, should four or six plants be used at once, not less than twenty or thirty will be required for the five days—that is, if any portion of a party should stay that time; and as ladies (to whom we must always refer for good taste) never appear twice in one dress during a visit of a few days' duration, that is a sufficient suggestion for the gardener to change his plants every day, which will not only be good taste, but beneficial to the plants, as many of those mentioned below will not bear too much confinement in dry rooms, and if housemaids are not specially careful as regards dust, the pores of the leaves are soon sealed-up, and that important function, perspiration, is suspended. Indeed, with every possible care on the part of the domestics, it is an impossibility to keep plants in a dwelling free from dust in the autumn and winter months: therefore, those plants with smooth foliage which have to remain in-doors for days in succession, should be carefully sponged every morning.

The following are the best which are used here for dinner-table decoration:—

*Dracena versicolor*, than which nothing to my mind looks better, if small plants are used. *Caladium argyrites*, *Belleymei*, and *Wighti*, the first-named of which is an especial favourite here with the ladies, and deservedly so, as it is a lovely plant either by day or lamp light.

*Gesnera zebrina* and *cinnabarina* are both very good when grown dwarf. *Centradenia rosea* is a neat-foliaged plant, and easily grown to a nice height.

*Poinsettia pulcherrima*, the scarlet bracts of this plant are most conspicuous by lamplight. Cuttings taken in July and August will make nice dwarf plants by the end of October and onward through the winter.

*Croton variegatum*, and *Aphelandra Leopoldi*, are two useful plants for a change. *Cyanophyllum magnificum*, *Eriocnema marmorea*, *Maranta regalis*, and *Sonchila margaritacea*, are all lovely for small vases, and so are *Dieffenbachia picta*, *Cissus discolor*, *Dioscorea discolor picta*, *Sanseveira carnea fol. var.*

*Cyperus alternifolius*, is a very pretty little plant by night. Mr. Dyer, the kind and intelligent foreman at Mr. Veitch's, of Chelsea, informed me that this plant should be always pot-bound, otherwise the foliage, instead of being white, has a tendency to become green.

*Solanum capsicastrum*, *Coleus Verschaffelti*, *Fuchsia Tom Thumb*, *Maranta zebrina*, *Ananassa sativa variegata*, a splendid plant for the dinner-table; *Graptophyllum versicolor*, *Lycopodium Lyalli*, and *Campylobotrys pyrophylla*.

Amongst Ferns, the *Gymnogramma tartarea*, *G. chrysophylla*, and *G. sulphurea*, are good, and so are *Cheilanthes elegans*, *Pteris serrulata*, *P. tricolor*, *Adiantum capillus-Veneris*, and *A. cuneatum*.

I shall be glad if Mr. Robson (to whom I tender my best thanks for his kindness to me at Linton last month), will name a few which he thinks adapted for the purpose.

Mr. Fish, at Hardwick House, near Bury St. Edmunds, and Mr. Blair, of Shrubland Park, near Ipswich, have some very nice berry-producing plants admirably adapted for dinner-table plants, particulars of which (should this meet their eye) would be acceptable to all in search of such plants.—J. PERKINS, *Thornham, Suffolk.*

EUGENIA UGNI AND THE GOURMETS.

HITHERTO this fruit has held no place among the gifts of Pomona, notwithstanding the rich and peculiar flavour with which it is gifted. This may have arisen in consequence of its small size, and possibly, too, because of the very satisfying nature of that rich and peculiar flavour.

At the late International Fruit Show at Kensington a happy thought entered the mind of a gentleman, who has both a name and a place in horticulture, that this rich and peculiar flavour might be applied to some useful purpose, and *Eugenia Ugni* be raised to a pomological position it has never yet occupied. Thoughts are as vapour unless they are interchanged, and this gentleman having communicated them to one or two others interested in such matters, it was determined to test the applicability of this fruit as an ingredient for flavouring ices and other cunningly devised achievements of the confectioner.

Arrangements were made, and one day last week a committee of taste met in the city of London to discuss this all-important subject, under the presidency of a gentleman deeply learned in gastronomic lore. As it is necessary when any momentous question is to be settled

in the city of London, the occasion was celebrated by the usual indispensable preliminaries, after which the business of the evening was introduced. If we were to say that the experiment of introducing the flavour of *Eugenia Ugni* into ices was a complete success we convey no idea of what that success really is. Suffice it to say that it is a new flavour, distinct altogether from what we are accustomed to find in Vanilla, Pine Apple, Strawberry, Raspberry, or any other ingredient with which we are already familiar for the purpose. However slight the flavour may be, it still retains that rich and permanent aroma which is marked in the fruit, and leaves on the palate what we have heard distinguished as "a pleasant farewell." The fruit experimented upon was the new variety called "hybrida," raised by Mr. J. A. Henry, of Edinburgh, and in the possession of Messrs. Veitch, of Chelsea.

Now that a use has been found for this remarkable little fruit, we can imagine that its cultivation will be greatly extended. In the west of England it stands out of doors; but for general cultivation it would require the protection of an orchard-house or some such shelter. In an orchard-house, however, it would be quite at home, and we have no doubt when the fact of its use becomes generally known there will not be a glass protection in the country which will not receive under its shelter a plant of *Eugenia Ugni*.

### THE INTRODUCTION OF THE QUININE-YIELDING CINCHONA TREES INTO INDIA.

In 1859, the Secretary of State for India resolved to cause attempts to be made for the collection of plants and seeds of the quinine-yielding *Cinchona* trees (Peruvian Bark), in South America, and the introduction of their cultivation into India. The duty of superintending the necessary arrangements connected with this important experiment was entrusted to Mr. Clements Markham, of the India Office; and, in spite of some disappointments, all the numerous difficulties of the undertaking were finally surmounted, and the measure has at last been crowned with complete success.

By the latest accounts, dated in the beginning of last September, the number of *Cinchona* plants, on the Neilgherry hills, the cultivation of which is under the able superintendence of Mr. William G. McIvor, was as follows:—

Species.		Number.
<i>C. succirubra</i>	yielding red bark of commerce	30,150
<i>C. calisaya</i>	" yellow bark "	1,050
<i>C. condaminaea</i>	" crown bark "	20,307
<i>C. lancifolia</i>	" Carthagen bark "	1
<i>C. nitida</i>		8,500
<i>C. micrantha</i>		7,400
Species without name	grey bark "	2,340
<i>C. peruviana</i>		2,295
<i>C. pahudiana</i>		425
Total number plants		72,563

Of these, 13,700 plants are placed out permanently in the plantations, and, although only recently transplanted, are in a very promising condition. The number of plants placed out in the nurseries in the open air and in the hardening-off frames is about 18,076 all in the finest possible state of health. The number of small plants under glass, including those used for the production of wood for propagation, is about 40,792.

Extensive clearings are now being prepared for *Cinchona* plantations on the Neilgherry hills. The Denison plantations and the Markham plantation, both at Neddidiattam, on the northern slopes of the Neilgherries, will contain 410 acres. The Wood plantation, a splendid piece of land well watered and protected from the west winds, will cover 250 acres; and another plantation has been formed at a higher elevation called Dodabetta.

Private individuals are anxious to undertake the cultivation, and 22,000 plants have already been bespoken, so that the quinine-yielding trees will soon be widely spread over the hills of the Madras Presidency.

Meanwhile they have not been idle in Bengal. Dr. Anderson, who has charge of the *Cinchona* cultivation in that Presidency, conveyed a stock of plants to Darjeeling, in the Sikkim Himalayas, early last May, and in July he had 246 plants there of valuable species. In Ceylon also they are rapidly increasing their stock of *Cinchona* plants.

In the first week in November, a work on the whole subject will be published by Mr. Murray, entitled—"Travels in Peru

and India, while Superintending the Collection of *Cinchona* Plants and Seeds in South America, and their Introduction into India. By Clements R. Markham."

### PRUNING ROSES UNTIL TWO YEARS OLD.

WHEN a fruit tree, or a flowering plant, trained against a wall or any other structure, makes a shoot here or there which is two, or three, or more times stouter, and more soft, more leafy, and much faster growing than the ordinary summer shoots, it is called a "robber" in garden lore. The gardener is both the executive and the executioner against such robbers; and it would seem unseemly in one of their number, like me, to harbour or to encourage a robber of that kind, or of any other. Nevertheless, I have done it scores of times, and I am not only about doing it again, but to attempt to prove that the practice is not so unseemly as might appear on the face of it.

I said that two-year-old Roses from cuttings were pruned at the end of last June, and so they were, on purpose to obtain robbers of this very description. One of them on a *Géant des Batailles* is over 5 feet in length; another, the next to it in degree of affinity, and on the wall, is over 6 feet; and a third with three more of a feather, on an *Auguste Mié Rose*, is over 9 feet long; and the remainder are in different degrees of robberhood, between these points.

The difference of opinion by practical men on the use, and on the dangers of such robbing shoots, arises from the fact that one set of such shoots is the result of bad management, the other of the necessity of adhering to a principle opposed to general practice. You will not find it in the calendar to cut down a *Glycine*, or a *Jasmine*, a *Honeysuckle*, or a *Rose*, to the last bud at the end of June, and immediately before the "midsummer shoot," and yet cases will arise, every year of our lives, in which the midsummer shoot of one year would need double the robbing power of that of the preceding season. Then, if you can tell me an easier way, or a more effective plan to attain that end than the one which is here set forth, I shall be glad of it, and will follow the prescribed mode in preference to my own; if not, you will follow mine till you meet with a better than the encouragement of thieves and robbers for getting up higher in the world.

If we take the first on my list, a *Glycine*, from the beginning, it will teach us to turn the tune twelve months out of time. The *Glycine* is propagated by layers, and then kept in pots, as Mr. Fish keeps his extra *Geraniums* for beds, or rather on his principle, the plan which takes up the less room, cramped at the roots, so as to make a little bush of it, with the bottom of the bush ripened so as to be as hard and dry as the ribs of an umbrella. You, or they, or we, buy such bush-like *Glycines*, knock off the ball, and let the roots go free in planting, and we might let the branches go quite as free also.

You have often heard of the *Glycine* doing no good for a length of time after planting; which failures all come from that fallacy at the first going-off. All the little wiry branches of a so-cramped *Glycine* ought to be let alone the whole of the first year after planting, in order that each of them might add a few more leaves to operate upon the roots; and it is far better not to prune the shoots next spring, but to let them make another effort, and the roots will be thus set in motion the sooner in the season. Then, as soon as the roots are fairly on the go, and the growing season is safely on the wing, by the turn of midsummer, cut down the scrub of a *Glycine* to the last eye, and by the end of the following week that one eye will come up as the *Asparagus* shoots do in the spring—full, green, and juicy; and, now, nothing intervening, the roots will be able at once to sympathise with the onward movement, and the young growth will thus go on and increase to the end of that season, so that you will have a shoot from 5 feet to 10 feet in length, and as free in the passages of the rising and returning sap, as a "rod," on the rod system of pruning a *Black Hamburg Grape*. If that one rod on the young *Glycine* gets hidebound, it can only be caused by leaving it too long at next pruning.

Now, if I had *Madame Furtado Rose* stunted in a little pot, as was that *Glycine*, I would treat it just as the *Glycine*—let the roots go free in planting, and let go the shoots the first season. But the *Roses* I planted last winter were not stunted plants, they were not big, but they were free and sappy, and they and the roots went to work together, and at once, so that I had been enabled to set them quite freely to work together the first instead of the second season. So you see that by applying a principle, a practice might be wrong: therefore, a man who

applies principle without having the practice to know, at sight, whether his subject is in a condition to bear the application of the principle or not, is not better than if he had no notion of principle at all, for all depends upon the condition of the plant at the time of planting, and you may take the Rose, on its own roots, at one end of the scale and the *Glycine* at the other; the Rose the easiest of all to do, the *Glycine* the most difficult. Every plant must come in at some one point between the two extremes. But a man cannot be taught by book-reading to know the point, or the degree; practice only and long observation can make a man an adept at such niceties.

The pruning of every plant in out-door decoration, for the first three years after it is planted in a young state, should be made on the plan or principle of establishing it in the best possible condition for its future well-doing, rather than for filling-up space or for the sake of the flowers; but, with Roses and many other kinds, the two systems may go on at the same time. What I said last week about leaving long Rose shoots at full length, and the short ones to be cut-in to the last eye, had reference to the two systems of pruning being carried on simultaneously. If the plants were old, or say established, I would cut the long shoots down to various lengths, according to the kinds of Roses, and according to the ripeness of the wood; the middle-sized to a foot or 18 inches, and the smallest to three or four eyes, and very likely some shoots of the three degrees of strength would have to be cut out entirely, rather than be much crowded another year. But the plants were not old, merely beginning to get along comfortably; and the pruning to one eye, and no pruning at all, is a very different way from what one would do with established plants.

Now here is the very point where thousands go wrong with their Roses. They prune and manage their young Roses, and their newly-bought-in or wrought-on-the-place plants, just as established Roses ought to be done, or as if the Duke of Cambridge took to so many schoolboys and expected them to act as veteran soldiers without having had any training.

My intention in leaving the extra long shoots at full length the second year is this: Last summer and autumn their extra size and strength of foliage gave a far greater stretch and capacity to the roots than the common run of summer growth could do, and I am anxious to keep up the full power of the roots another year, in order to obtain the most perfect freedom for the flow of sap from the roots, so that, come what will afterwards, there will always be a free passage at the collar of the plant; and should the plant get wrong by blight, or insects, or frost, or be transplanted, if the shoots are cut down to near the bottom, the next growth is sure of a full flow through the good channels which had been provided when the plant was young and in full vigour: therefore, if you can see the drift of this, you will find no difficulty in understanding how it is that a very different system of pruning is quite essential for a young plant from that which the same plant will need when it comes of age. But Roses on the *Manetti* stock will explain the principle, to some much easier than the practice with Roses on their own roots.

The *Manetti* is a free grower, and when cuttings are made of it for stocks they are 4 inches, 5 inches, and 6 inches in length, and they are ridged-in, as it were, so that one eye only at the top is out in the open air. But do you think, for one moment, that it is essential for the rooting that all above the roots should be buried? *Manetti* will certainly root just as well without being covered more than is usual and good for other cuttings; the reason for covering or burying cuttings of the *Manetti* is exactly, in principle, the same as the reason for my leaving shoots so many feet in length, to keep the part between the roots and where the stock is budded fresh and plump, or from getting hidebound, or the sap-channels so dried-up that very little sap can get up through them, and that is the one thing above all other things on this line which I want you to understand thoroughly.

Gardeners can always, by their superior practical skill, get out of a scrape; it is very different, however, with men who are not practical hands at it. Once let a plant get wrong, and ten to one if it is not all up with it before it can be brought round again. No wonder your Roses on that *Manetti* are going to the dogs, the stock part is not buried as it was when it was a cutting, and it never fails to get so hidebound when a morsel of it is exposed to the open air, that you could not drive up sufficient sap through the collapsed and compressed passages even with steam, and, as a matter of course, the roots push and push till the

whole bottom is one mass of suckers. But bury the whole of the stock, as the people who can do or undo all manner of things with Roses have recommended, and the channels of the sap are kept free, fresh, and effective, just like the channels of those strong or very strong shoots which rise from the very collar of my Roses. If I were to take up my two-year-old Roses with the strong shoots, and plant them 6 inches deeper than they are now, I should have them on a par for rooting afresh with Roses on *Manetti*, and I would eat my hat if I could not cause every one of the shoots to root just within the surface of the ground in one season. I have done hundreds of Roses so in my day, and I maintain that there is no possibility of a Rose getting permanently into an ill condition if it is on its own roots, for you can do anything with them; but a worked Rose getting into a bad state is beyond our art entirely. We may operate upon the stock searching for a cure, but with the Rose itself we can do nothing. Then, as we cannot cure a sickly Rose on a worked stock, how much more essential must it be to have the channels of the sap between the stock and the branches of the Rose in healthy action—that is, free from all obstruction to the flow of the sap.

The way to obtain and to retain that degree of capacity is exactly the same as for Roses on their own roots. When the Rose-bud has started and made one good shoot, there are two ways of managing the passage part, as I shall call the distance from the stock-head to that of the Rose, and one of the ways is the best way for the stock-worked plant; but not the best for the one on its own roots. When a budded Rose bursts with a strong shoot, instead of allowing it to run its length to the end of the season, and then to cut back to so many eyes, the better plan is, for the future welfare of the plant, to stop it when it is 6 inches long; then in ten days there will be three, or four, or more shoots starting from the stopped part, and the best three of them should be kept and the rest rubbed-off. Those three shoots then are to form the head, and the original 6 inches form the collar, or neck, or groundwork of the head of the Rose for the rest of its life; and that part, the most essential part of all plants, having never had a cut or a scar, will last in health under difficulties many times greater than the same part could do if the first shoot had been cut back in the usual way. But it is only when Roses are worked at home that this way can be thoroughly well done. It would never pay a nurseryman to take such pains, and, probably, his plants if so treated would not sell so readily as long as public opinion is as it is now, and that is on the wrong scent for big heads and weak shoulders on worked Roses.

The whole of this story might be put into a lady's thimble. It only runs over the first two years of a Rose's life, the period in which the well-doing of the Rose or the contrary is most likely to be effected. But the principle is applicable to every plant in the garden, and it is simply to obtain a permanent way for the flow of the sap from the roots to the branches of a plant without the smallest check or hindrance. If we could but make the people understand the absolute necessity of a free permanent way for the easy and rapid flow from the roots to the leaves, we should not hear one-quarter of the complaints which flow to our office with every tide. The first thing a medical man will do with any of us when we need his aid, is to see the permanent way is all right; and all plants need it quite as much as we do. Doctors' stuff is of little use to a man while his permanent way is sluggish or constricted, and your doctoring a Rose, or a Juniper, while the seat of life, the collar and the parts next to it, are in any way choked or restricted, is similarly ineffective.

D. BEATON.

#### DISTRESS AMONG THE WORKINGMEN BOTANISTS OF LANCASHIRE.

WE have to acknowledge the receipt of 10s. in postage stamps from "F. H. A." for the above-named deserving men, which we have forwarded to Mr. Hague to apply for their benefit.

Our correspondent says:—

"Many I believe would open their purse-strings if you would state in your next Number that you would receive subscriptions, as probably there are many, like myself, perfectly unacquainted with the names given in your paper."

We shall most readily forward any donations entrusted to us for the same good purpose; but no one need hesitate transmitting their contributions to any one of the gentlemen we named in our last Number.

## NOSEGAY GERANIUM STELLA.

I AM indebted to my friend Mr. Thomson for a breed of the above, and direct from the Lothians, and as far as my humble judgment goes I class Stella A1 amongst the Nosegay section. I am not in a position to give a decided opinion of its merits as a bedder compared with others, as I had only a single plant which I grew under glass all this season. It stood amongst some dozen or more of crack kinds, yet, upon entering the house, Stella was the most conspicuous; at once drawing admiration from the beholder—a most telling colour, fine truss, and excellent habit, leaving nothing to be desired. If spared till another season I purpose employing Stella most extensively.

The best of the Nosegay section in beds, with me, this season was one called Newell. This is truly a good thing—a most profuse bloomer, and excellent habit. But I am inclined to suppose that "Newell" is only a local name, having failed to find it in any of this season's catalogues; I may, it is true, have overlooked it. I think Mr. Fish made some comments upon it in his "Few Days in Ireland" in one of your back Numbers.—  
JOHN EDLINGTON, *Crom Castle, Ireland.*

## RAVENSWORTH CASTLE AND ITS GARDENS.

AMIDST the many changes which the increase or fluctuations of wealth more or less create, it is always a pleasing thing to find that an old well-established place, which has been enriched by the liberality of a bygone generation, still retains an actual supremacy over those of more recent date, although the latter may possess more of the fashionable requirements of the present day. A thousand bedding plants are no equivalent for a noble Cedar of Lebanon; and a whole street of plant and forcing houses is much easier reared than an avenue of old well-grown trees. When, therefore, we come upon a place possessing both the one and the other of these necessary appendages to a first-class place, it may be safely inferred that such a situation is one of no ordinary character; and such, therefore, is the one I am now endeavouring to describe.

Ravensthorpe Castle, the family seat of the Baron of that name, is pleasantly situated in a park of large dimensions, profusely timbered—so much so, that it looks almost as if shut-in with large well-grown trees. The situation of the Castle is a slightly rising ground, that in front of it sloping gently but irregularly to the river Team, which forms an important feeder to the Tyne; and the Team valley, in which Ravensthorpe Castle stands, is certainly not surpassed in fertility by any in the north of England; while the domain here spoken of, though not possessing any of the more rugged features which give a romantic tone to some places, is not destitute of deep and precipitous glens or gullies; but these being in most instances densely timbered, their outline is less distinctly shown than when more sparingly clothed. Suffice it to say that the scenery is more pleasing than romantic; while for the neighbourhood an unusual amount of luxuriance prevails, and its privacy is in no way invaded by the numerous railways by which it is surrounded, some of which I believe I am right in saying are upwards of 150 years old, and of the same gauge, gradient, and material as when first made, and the gauge at least is the one in most general use in the most popular passenger lines in the kingdom. It is, therefore, with no small amount of pride that a Tyneside collier, when traversing the well-formed arteries which unite the great metropolis with the other parts of the empire, and hearing some fellow-passenger descant on the utility of railways and their modern invention, tells them in his mother tongue, which no doubt Johnson or Walker would call "vulgar;" that railways have been in existence in his country for two hundred years or more. I believe, however, that many of these lines in which wooden rails were laid down are fast disappearing, and it is only in declivities that they are used. Engineers, in the present day, would not like to trust a carriage on an incline falling 1 in 15; and that was no unusual thing in this neighbourhood in years gone by—and that, too, without a rope or any other check than that of the break, which, by-the-by, was identically the same here in the last century as it is in the passenger and other carriages of the present day, the latter a little, perhaps, improved in power by the aid of a screw. But we must leave railways and the other features of industry by which the neighbourhood is studded, and shut our ears to the distant clang of iron forges, the sharp ring of some boiler building, or the many other sounds which in a busy industrious neighbour-

hood greet the ear of one fresh from a rural district, and after this digression endeavour to confine our remarks to matters purely professional, if allowed to adopt the term.

Ravensthorpe Castle is one of these commodious dwellings which, as the name implies, combine all the dignity of a baronial residence of the olden time with the comforts that the habits and requirements of the present day render so necessary. The present structure was built on the site of an old one about the beginning of the present century, and presents a good example of what may be called the Norman-Gothic style, massive Norman towers flanking the principal front; the carriage entrance is on the opposite side, where the building retains the same character; and a broad terrace contains a flower garden, which was gay with the fashionable bedding plants of the present day. But the greatest breadth of dressed ground was on the west and north-west sides of the Castle, where Pinuses and other things had been planted with a liberality which the memorable winter of 1860-61 told sadly against. In fact, so severe had been the visitation, that some trees generally regarded as the hardiest we have had succumbed to it; and Mr. Mort, the intelligent gardener, pointed out a standard Portugal Laurel whose stem had been split to the core its whole length, and wide enough to get a hand in, during the frost. But, strange to say, this plant survived this trying ordeal; the opening closed-in, leaving a mark or scar, and a top certainly less healthy than before. Some other trees that had suffered in a like manner subsequently died and were removed, and it is needless to say that most of the Californian and Himalayan Pinuses fell victims to its severity, and even the common Laurel. These disasters of course thinned the grounds of many of their most important ornaments, while many that remained were evidently crippled for many years, if not for life. Amongst the latter were some fine Cedars of Lebanon, which some thirty years ago were regarded as the finest for many miles. The dead tips by which they were surmounted, and that absence of vigour which once characterised them gave unmistakeable tokens that they, too, had been sufferers.

The dressed ground here spoken of gradually blends into the adjoining wood, which is of large extent and varied scenery, Ferns, Hollies, and Yews growing naturally with the majestic Oak. In this wood walks of at least 8 feet wide traverse it in various directions, and now and then an opening has been made and some choice shrub or conifer planted; the latter in most cases surrounded with wire netting to keep rabbits at bay, which with other Game abound here to a great extent. Most of these plots had been in some degree levelled, and were kept mown, as well as the broad margins of the walks; and, when taken in concert with perhaps a rugged bank rising on one side, and an abruptly descending one on the other, with jutting rocks and tumbling streams of water, and ever and anon the waving plumes of the Male Fern, which with some others was growing here in wild luxuriance, it is easy to picture the feelings which such an assemblage of natural and artificial beauties calls forth; and this is rather increased by the vast extent of such walks, from which now and then a peep into the outer world is also obtained. But it is needless dwelling further in this direction. Suffice it to say that the ravages of the severe winter were being made up by the spirited nobleman again planting more novelties; and it is to be hoped they will escape such a visitation as proved fatal to their forerunners.

Having described the dressed ground as extending mostly in a westerly direction from the Castle, it is right to say that it extends northward also, the kitchen garden being in that direction. This garden is surrounded by high and good walls, and, I believe, contains from three to four acres. The range of houses, occupying the north wall, was erected a few years before the commencement of the present century, and for symmetry, appearance, and the good quality of their contents were exceeded by few, if any. Neither has the mode of building been much improved on, notwithstanding the many changes that this particular branch of garden architecture has undergone during that time. The range in question is between 400 feet and 500 feet long, being a lean-to, with a front light about 3 feet high, and about 16 feet wide; the central house, which is a plant-house, is both wider and higher than the others, and faces the central walk crossing the kitchen garden to the pleasure ground. At the time these houses were erected, there were few finer ranges or better adapted for the purposes they were intended for. The glazing was in larger squares than was the fashion to make them some thirty years after they were built,

though they have outlived that period; and since large squares came into use again, even larger than these were employed, which was some 8 inches or 9 inches square. The pitch of roof is about 30°, and the rafters, sash-bars, tie-rods, and other features have been little improved on during the seventy years that have elapsed since the houses were built.

Most, if not all of the Grape-houses, had large central beds in them for heating material, and Pines were grown there for many years, but this has been relinquished; I believe, however, that many of the original Grape Vines are still in full bearing. The Peach-houses have trained trees against the back wall, and a broad trellis curving from the front in a manner that has not been much altered in more-recently-put-up houses, for the same purpose. It was too late to see any of their contents, but the appearance of the wood indicated that the Vines were in an excellent bearing condition; and there were some very good Grapes. Most of the houses were heated on the old flue principle, and whatever may be the merits of hot water elsewhere, the old flue is certainly not without its advantages; and it is even a question if, in a place like Ravensworth, it is not superior to hot water. The expense of fuel (an important item in the south of England), the saving of which the advocates of hot water regard as one of its greatest advantages, is here of very little account; for such coals as are burnt in garden flues (and very good coals they are) do not cost more than 2s. per ton at the pit, and if we add a like sum for carriage, a good many tons may be consumed at no great outlay—in other words, the interest of the cost of a hot-water apparatus for such a range of hothouses as those in question, would pay for all the coals used in the flues. This, of course, is not the case where coals are 24s. per ton instead of 4s., so that general conclusions cannot always be drawn. Sufficient, however, has been said to show, and something like three-quarters of a century has proved, that flues will do their work very well; and Mr. Mort, who has had experience in both, is far from giving all the merit to hot-water which its advocates claim for it. Neither does he condemn the old despised flue, but adduces one or two reasons in its favour which are well worth mentioning here, as perhaps not so often striking the observer as they have him. It is a well-known fact that the smoke emitted from the heating apparatus very quickly discolours the painting of the houses: hence some of the more fashionable ones either have the chimneys carried to a distance, otherwise coke is burnt. Now, though the latter is within easy reach of such a place as this, still it is much more expensive than the small coals generally burnt in the flues, and to use coals to heat a boiler, however carefully the latter may be made to economise heat, there are still large volumes of black smoke emitted, much more so than in ordinary flues; the long journey it has to travel in the latter divests it of much of its impurities, and when it is finally discharged out at the chimney it is much less black, and, consequently, does much less mischief than when the same kind of fuel is used in an ordinary hot-water apparatus. These ideas are those of Mr. Mort, the very worthy gardener at Ravensworth, and I can fully endorse all he says on this matter and for such a situation. Passing, therefore, from this range of houses, we are taken to see some Cucumber, Melon, and Pine-pits, or rather houses, at the back of the garden, which are heated on the hot-water system, and which are snugly ensconced in front of excellent shelter from the north and east. They were variously occupied with the crops required for the season, all of which looked well and reflected great credit on the worthy manager, whose professional abilities are only equalled by his kind-heartedness and hospitality, and the visit to Ravensworth will long remain as one of the red-letter days, not to be forgotten.

J. ROBSON.

### SHRUBBY CALCEOLARIAS.

THE vast improvement which has taken place in this class of flowers has been such as to make them most desirable plants for the decoration of the conservatory and greenhouse during the later summer and the autumn months. I had intended giving a few rough notes on their culture and the best varieties, and had written for that purpose to one whom I believed to have been the great mover in them—Mr. Burley, of Limpsfield, Surrey. A letter received from his son gave me the sad news that he was no more. Many will recollect him and his plants, and I am sure will not be displeased at this tribute to his energy and thorough heartiness in the cause of floriculture. Poor fellow! The last time I saw him at Kensington he was full of

his plans for next year. How well I remember his telling me in the fulness of his heart, when his name was for the first time appended to a collection with first prize, his little history; how, like many others, he had foolishly thrown away good prospects; and how one day the good clergyman of the parish came to him and said he would not be satisfied unless he pledged himself to alter; how he did by the blessing of God; and that from that time he had been rising in life, adding to his nursery and houses, and gaining with this thorough heartiness the good will of his neighbours. He died in harness. He had been out as usual in the day, at night retired to rest, and about half an hour afterwards said he felt strange, fell back, and died—doubtless (for he ever spoke as one who felt the reality of eternal things) to enter into rest. And thus my notes have been changed into an obituary, and I had almost feared it was to record, too, the standing-still in this class; but I am glad to say that his son, an intelligent young man, has taken his father's place, and is preparing to carry on the hybridisation which has resulted in such success.—D., Deal.

### TREATMENT OF GRAPES HANGING ON THE VINES.

I HAVE a very large supply of Grapes, which my employer is anxious to have kept as long as possible. According to the quantity which is used daily since the 8th of August, if nothing happens, they should last till about the 1st of January. The kinds are the Black Hamburg, Royal Muscadine, West's Black St. Peter's, and Black Prince. Please to say what treatment is best: what should the day and night temperature be?—HENRY.

[You will have no difficulty in keeping the Grapes to the 1st of January, as we presume you will not start the Vines before the end of February or March. If much earlier, the Vines might be disbudded, and pruned when in leaf: but we presume in your case nothing of the kind will be required.]

The great point will be to keep a dry atmosphere in the house; not a single plant in a pot should be retained there. In your damp climate you will need a fire every day, and a little at night in cold muggy weather. The fire heat should not raise the house above 40°; but the house may rise 10° or more above that with sunshine. Give air all day, and a little at night, except when frosty; a little air at the top of the house prevents stagnation. Give little or no air on a foggy day; a close house and a little fire heat will keep the fog out, but if it continue several days, a little air must be given. Look sharp after decayed berries.]

### REVIEWS OF NEW BOOKS.

*Hints on the Construction and Management of Orchard-Houses.*  
By J. Pearson. London: Journal of Horticulture and Cottage Gardener Office.

"OH that mine enemy would write a book," is an aspiration that would be next to useless when applied to the fashionable monographs of the day; as it would hardly be possible for a writer to give room for confuting himself in such a useful work as the above, consisting of less than fifty small pages.

With respect to lean-to orchard-houses, of which Mr. Pearson is no friend, though we should never think of building a high wall for such a purpose, but would prefer a span-roof, as the cheapest, if not the best, we would not say a word against covering the border in front of such a wall now existing, it suited the proprietor's pleasure. We thoroughly approve of such lean-to's for early forcing. The objection to them in orchard-houses, that the plants are drawn to one side, is more theoretical than real in houses glazed with large squares of glass. The wall under such circumstances is always sure to be heavily cropped, and if the front border is supplied with pots, they can be easily moved round. Many, looking at the great success from thus fronting an old wall, have been led seriously to inquire whether they might not as well cover such walls, instead of taking up fresh ground with span-roofed houses. Mind, we would not advise building a wall for such a purpose; but with all our admiration of the light, elegance, and economy of span-roofed houses, where no walls exist, the fact still remains, that as fine productions have been obtained from lean-to's as from the finest span-roofed houses.

We would, however, advise all to have solid walls, and the

best style of roof, if they can afford it; but we would not throw a wet blanket over the attempts of the small tradesman or mechanic, to have his little fruit-house, even if he built it all himself, and used the simplest and cheapest materials.

Though, therefore, we do not agree with Mr. Pearson as to the inefficiency of such homely structures, and that without citing what we consider the confirmatory experience detailed at page 28, we do most cordially approve his advocating for orchard-houses in particular, and all glass houses in gentlemen's gardens in general, a style of building that shall be distinguished alike for economy, elegance, and durability. Though necessity often compels many of us to do things merely for the present, it is not because we are insensible to the importance of the axiom that might be taken by Mr. Pearson as his motto, "What is worth doing at all, is worth doing well." As an evidence that the above requisites—economy, elegance, and lastingness, may be combined, we are presented with internal and external views of a large orchard-house, of which *fig. 1* is a section.

This house is 30 feet wide, and "covers 2700 square feet, with 18 inches of brickwork above the surface. The walks are paved with black and buff quarries, and the three walks are bordered by round-headed tiles, which have a very neat appearance. The bricks are laid in Portland cement, and the whole finished in a style fit for any garden, at a cost of £230, or about 1s. 8d. a square foot of ground covered. It is, therefore, unnecessary to have an ugly orchard-house to obtain a cheap one, or one that depends on wooden posts let in the ground for its stability. An orchard-house should not be less than 20 feet, nor more than 30 feet in width. When more than 30 feet it must have a ridge-and-furrow roof, which, though necessary when large spaces have to be covered, is more expensive,

houses for the million were introduced to meet the want, which though no doubt answering well for many purposes, had, so far

FIG. 2. Head of column carrying rafter, and into which the end of the tie-rod is screwed.

FIG. 1.

and much heavier in appearance. No fire being used to keep out frost, a wide house containing a large body of air will cool more slowly than a narrow one; and plants blooming in a twenty-foot house would be safe from frost, when those in one 14 feet wide might be in danger." (Pages 4, 5, and 9.)

There is more importance in the large body of air enclosed in a house than is generally imagined, so far as the heating and cooling of that house slowly are concerned. But space being secured, height comes in as an auxiliary as well as width—so much so, that plants frozen in low houses and pits have escaped being touched in lofty houses. Waving this, however, our readers can scarcely fail to notice a very distinctive novel feature in the section of the house, consisting in the mode of using cross-tie bars between the top of the column and the rafters, as patented by Mr. Foster, of Beeston, and which, we have no doubt, is a very elegant and secure mode of fastening.

"The iron pillars rise out of the beds and carry both rafter and cross-tie bars, as shown in *fig. 2*. The upper part is tapped to receive one end of the tie-rod screwed into it. The other end is fastened into the rafter."

Although when a tenant, or leaseholder, resolves on erecting a glass house it would be sound policy to have a written agreement with the landlord as to his right to remove it, there may be circumstances in which it would neither be pleasant to ask nor yet grant such a favour. In such cases, a house that, from being set on the ground instead of in it, could be as legally moveable as a wheelbarrow, is a desirable consideration. To meet such cases various modes have been noticed in this Journal, such as building on stout blocks; and Sir Joseph Paxton's

as orchard-houses are concerned, the fault inherent in the glass walls, of giving but little room inside for the extent of glass employed. This objection is got rid of by Mr. Pearson having the usual dwarf, upright sides "in a patent moveable house with iron supports. It is as strong as any house can be built, and yet may be taken in pieces and removed without difficulty."

FIG. 5.

"*Fig. 5*, is a section of one of these houses, 14 feet wide, with path in the middle. The iron foot, pillar, and bracket, are cast in one piece. The roof is made in separate lights, and also the ends and sides, so that there is no occasion to break a square of glass in removing the whole structure." A table is given at the end of the book of the expense of such moveable span-roofs. Thus, one 20 feet by 14 feet, £20; 40 feet by 14 feet, £70; 50 feet by 24 feet, £126, and so on of all other sizes. It just

struck us that the spurs of the foot of the pillar are scarcely long enough, unless they stood on stone or some hard substance. We would prefer, if there was no bottom but earth, that these feet should have had a sole, and thus a triangle been formed, which we know stands very secure when well rammed.

Mr. Pearson, on the whole, prefers such trees as Peaches and Apricots, &c., in orchard-houses, to be grown in pots; advocates all potting, repotting, and top-dressing, to be done in the autumn before the leaves fall; gives sound cultural directions as to firm potting, soil to be used, air-giving, pollen-dispersing, insect-preventing and destroying, &c.; objects to using fire heat in orchard-houses, because gardeners would stuff them with tender things; has a word of advice to those gardeners who are opposed to such structures as orchard-houses, though so far as our observation and experience go, most would like to get one, and then use it as a little finger for wriggling the whole hand in, and thus obtain three or four; and concludes by giving marks by which Peaches are known to be true or not true to name, with a descriptive list of the most suitable Peaches and Nectarines for orchard-house culture. But for these and other matters we heartily refer our readers to the book itself.—R. F.

*A Practical Treatise on the Cultivation of the Grape Vine.*  
By William Thomson, Gardener to his Grace the Duke of Buccleuch, Dalkeith Park, N.B. Second Edition. Edinburgh: W. Blackwood and Sons.

WE are glad to see that this admirable work has already reached a second edition. Mr. Thomson says, in his preface, "In preparing a second edition of the 'Practical Treatise on the Grape Vine' I have made additions to several of the chapters which may be found useful. I have also added a chapter on the open-air cultivation of the Vine, having discovered that my excluding that aspect of its culture from the first edition was a source of regret to many." We know of no better authority on the Vine than Mr. Thomson is, and whoever follows his instructions must attain success.

*The Orchid-Grower's Manual, containing Brief Descriptions of upwards of 440 Orchidaceous Plants, with Instructions for their General Culture, &c.* By B. S. Williams, F.R.H.S., Paradise Nursery, Holloway. Chapman & Hall, London. Second Edition.

WHEN we were reminded in the above title-page how numerous are the Orchids now in cultivation, and reflected that these numbers are annually increasing, we had forcibly brought to our recollection how much the cultivation of these beautiful plants is a branch of floriculture created within the memory of many gardeners still living, and that it is an illustration of the superior skill of the present generation when compared with the skill of a generation only just passed away.

*Vanilla aromatica* was the only stove Orchid known to Phillip Miller in 1759—at least it was the only one he described and figured, which he did as *Vanilla mexicana*. Yet he ought to have known *Bletia verecunda*, introduced by Dr. Houston before 1733.

Hernandez, a century before, in his "Mexican Plants," had figured an Orchid under its native name—an Orchid which, perhaps, was that now known as *Peristeria Humboldti fulva*. Plumier, Rheede, Rumphius, and others, all contemporaries of Miller, had portrayed other species of these beautiful flowers of the tropical forests—travellers had described their exquisite forms, colours, and fragrance, yet no one had been able to introduce and cultivate them successfully; so that when the first edition of the "Hortus Kewensis" appeared in 1789, not more than twenty species were there enumerated.

When the eighteenth century closed thirty-four species had been cultivated in this country, chiefly through the exertions of Sir Joseph Banks and Admiral Bligh, whose name is so associated with Bread Fruit and the mutiny of the "Bounty."

Even as late as 1813, when the second edition of the "Hortus Kewensis" appeared, no more than fifty-five species were known to Mr. Aiton. On the continent success had not been superior; for in the catalogue of the Berlin garden, one of the European gardens most rich in plants, Professor Link was only able to enumerate nineteen species as late as 1822.

Individual enterprise and enlightened skill then began to be concentrated on the cultivation of these plants, and foremost among their amateur growers was the late William Cattley, Esq., of Barnet. Circumstances, however, compelled him to abandon his horticultural pursuits in 1826, and nine years after he died; but he had aided effectually to give an impetus to the pursuit, and about 1829 a large expenditure on Orchid-culture at Chiswick was incurred by the Royal Horticultural Society. The results of this expenditure were not commensurate with the outlay, but it threw some light upon Orchid-culture; and since then the efforts of such men as Loddiges, Harrison, Skinner, Warner, Veitch, and others have increased our Orchid-wealth, and enabled such a practical man as Mr. Williams to publish a work like the present.

When they began their efforts to cultivate Orchids, they laboured under great want of information relative to the soils, temperature, and degrees of light most congenial to the different species. "The data," observed Dr. Lindley at the time, "that existed upon the subject were imperfect, and the conclusions that were drawn from them were necessarily proportionately unsatisfactory. All our earliest experiments were consequently unsuccessful; we lost our plants as quickly as we received them, and when we preserved a single species out of an entire collection, we thought we had met with great success." Now, on the contrary, if a cultivator fails in blooming one out of a whole collection of new specimens, he considers that he has been unfortunate, and few will be so unfortunate if they follow the directions given by Mr. Williams. The details he gives are full and founded upon long and successful experience, and we do not think that information is deficient upon any point upon which an Orchid-cultivator might require guidance. As an example, Mr. Williams even begins with the in-gathering of Orchids, and the following is his

#### "ADVICE TO COLLECTORS.

"There are many different ways of importing Orchids to this country. I have seen some that have arrived in good condition, while others have been completely destroyed by not being properly prepared before starting. The first and most important thing is to send the plants away at the proper time; the next thing is to prepare them for their journey. My opinion is, that the plants should be sent away from their native country during the dry season, which is when they are at rest. While inactive their leaves contain little sap; but if sent away when they are growing, the foliage is tender and in danger of being bruised, a circumstance which accelerates decay on their journey. Another fact in favour of dormant importation is that, if sent in a growing state or just as they are starting into growth, the young shoots come weak and dwindling, and very often die outright as soon as exposed to light. I have seen many a fine mass of Cattleyas with all their leading growths completely rotten, of course lessening the plants in value compared with such as arrive perfect and are just ready to start into growth as soon as they get into a warm house. Plants with pushing pseudo-bulbs are also apt to lose their leading eye—an accident fatal to some Orchids, for many do not break well from old bulbs. *Ardises*, *Saccolabiums*, *Vandas*, *Angreecums*, and similar plants that have no fleshy bulbs to support are best imported after they have become established on flat pieces of wood, so that they can be nailed to the side of their travelling cases. I received some from Manila last spring, including *Phalaenopsis Schilleriana*, *P. rosea*, *P. amabilis*, *P. Lobbi*, *Ardises quinquevulnerum*, and *Vanda violacea*, all established and sent off in the way just described; these had evidently been growing some time before starting for this country, for their roots firmly adhered to the wood, and many of their leaves were as green as though they had been in an Orchid-house instead of a glass-topped case. One point of importance is to take care to well secure the plants to the sides of the cases; because if allowed to roll about, they get bruised and soon rot, which is very vexing after all the trouble and expense bestowed in importing them. In the case of *Phalaenopsis Schilleriana*, received last spring, some of the pieces of wood had become loose, rolling about during the journey and causing injuries; if therefore, you find a leaf bruised, the best way is to cut it off at once before decay begins; for if allowed to go on, there will be danger of the whole plant being destroyed. With the cases just alluded to I also had a close box filled with *Phalaenopsis* packed in the dry bark of trees, which I consider a bad material for such tender-leaved plants; when I unpacked this box there was not a green leaf to be seen, the shaking of the long journey, combined with the rough material just named, had destroyed all the foliage. If these had been packed in very dry soft moss they would most likely have come safe. I have received plants in good condition from India, in close boxes, packed in dry set shavings; while on the other hand, I have also seen many spoiled in that way. The cause of failure I attribute to their not being packed in a proper state. The plants themselves, as well as the material employed, should be well dried before packing, and care should be taken to avoid bruises, which often prove fatal. Cattleyas and plants with similar pseudo-bulbs I have received in close boxes from the Brazils packed in dry shavings, and have found them, when opened, in good condition; but care had evidently been taken to pack them firmly in the boxes, so that they did not roll about on their journey.

The best time of year for receiving Orchids in this country is, if possible, the spring, in order that they may have the summer before them to get established.

With *Anectechili* the best way is to tie some moss round their roots and stems to keep them firm, leaving the foliage just above the moss, and they should occupy a small case by themselves; these little things are very tender, therefore they require a great deal of care to keep them tight. On arrival, pot them in some dry soil, and put them in a close place with little heat at first, until they begin to grow; afterwards pot them in small pots, and place them under hand-glasses or in a frame, giving them the treatment usually recommended for this class of plants.

"Cases in which Orchids are sent home ought to be made strong, and roofed with good stout glass not easily broken; for I have often seen plants spoiled by the glass being fractured. Through an accident of this kind, salt water and cold air get in, both of which are very injurious. All cases should be air and water-tight; and to prevent the glass being broken, the best thing to place over it is some strong iron wire; the sash-bars ought also to be made very strong; and the case must not be too near heated surfaces or fires in the vessel. I have seen many boxes of plants spoiled by positions of that kind, the leaves being completely dried-up. They ought to be placed in as warm a situation as you can, but by no means near any fires."

## LILY OF THE VALLEY AFTER TRANSPLANTING.

### MAKING AN OUT-DOOR FERNERY.

Rose will be glad to be informed what should be done to a bed of Lilies of the Valley; they were removed from another part of the garden last autumn, and this year flowered and grew very badly. Was this on account of the removal, or will they require any special treatment, and when? They are planted in a tolerably shady border facing the north. Lilies of the Valley do very well in the same soil in the neighbourhood.

Also, she wishes to know if stumps and pieces of wood, or rough stones, clinkers, &c., are the best materials for making a fernery.

[There is nothing the matter with your Lily of the Valley. The bed and the plants in it could not possibly be doing better. As they were only removed from another part of the garden last autumn, as a matter of course it will take just two more years before the plants will be equal to what they were before the removal. Lilies of the Valley, like common Asparagus, take full three years to establish themselves anywhere in our climate. The only thing they require henceforward is to be left alone entirely, and see that no weeds come up to hurt them.

Stones are the best for a fernery, clinkers are the next best, brickbats the next, and "stumps and pieces of wood" are the very worst materials for a fernery, inside a house or out, and should be used only when the better materials are deficient. A most beautiful Fern rockery could be made with any sort of refuse stones, bricks, or clinkers, with cement and greystone colouring, a pair of tidy hands, and a good eye to guide them.]

## RESTING VINES WHILST MAINTAINING STOVE HEAT.

THE above represents a section of my small stove. It has a border at the south front, 18 inches of which are inside the house and 10 feet outside. There are five Vines planted in the border, and to get them to rest and still keep up the stove heat a temporary screen of glass, A, has been fixed. I think while they rest I might as well force four Vines in pots, and wish to know what kinds you would recommend, one at least growing large berries, and where they can be had?—W. O. P.

[Your plan of wintering and securing the Vines is first-rate. We wish we could have such a plan ourselves, we have often recommended a similar plan. Not only will your Vines be safe, and you may use the house for what you like in winter; but you can keep the Vines back by giving air from the outside, and when you wish to start them gradually you can allow a little heat to reach them from the inside. For four Vines in pots with large berries and good we would select Buckland Sweet-

water, Bowood Muscat, Black Hamburg, and Kempsey Alicante. You may procure them from any of the firms that advertise Vines in our pages.]

## THE LILY OF THE VALLEY AS A CHRISTMAS FLOWER.

THE *Convallaria majalis*, or Lily of the Valley, is now an old inhabitant of our gardens, and still very generally admired, more especially by the ladies, on account of the delicious fragrance of its beautiful bell-shaped flowers. As a companion to Crocuses, Snowdrops, Hyacinths, and other early-flowering bulbs, it well merits a little attention. To have it in flower about Christmas, the tubers should be taken up about the middle of November, or, at latest, the third week; the tubers should not be less than three years old, if more all the better. Previous to potting, it will be necessary to decide upon how they are afterwards to be disposed of when in flower. They are frequently placed in fancy wire or wicker baskets, and, perhaps, still often in ornamental vases. Disposed of in either of the above ways they are very beautiful indeed, and each is a favourite way with many ladies.

If it is intended to remove the tubers when in flower, our plan is to wrap a little bit of moss round each, and then pack them away as closely together as possible in pots, or, what is still better, Mignonette-boxes, previously filled with any light, porous soil, the tubers inserted just deep enough in the soil as to slightly cover the crowns. Over all place a good thick layer of moss, it assists in keeping the soil and tubers moist; and lastly, pots or boxes of the same dimensions as those the tubers are planted in are inverted and placed over them, so as to keep all dark, as darkness is essential to success. The boxes are then removed to a warm pit, where they can be supplied with a little bottom heat, which must be gentle at first, but may be gradually increased as the plants show symptoms of active growth: thus, in three or four weeks, more or less according to the treatment they have received, they will be abundantly furnished with their exquisitely scented flowers. They may then be removed with the greatest facility, on account of the moss in which each tuber is enveloped, and transferred to the vases or wicker baskets. If they are intended to remain and flower where planted, the moss, of course, may be dispensed with, but otherwise the treatment is the same. By adopting this method, we yearly produce the Lily of the Valley at Christmas, and keep up a supply of this lovely little flower all through the dull, dreary months of winter.—J. DUNN, *Harrock Hall Gardens, Lancashire.*

## MARKET-GARDENING IN WEST CORNWALL.

(Continued from page 596.)

THE manures employed for the early Potato crop may be thus arranged:—

Seaweed,	Woolen rags,
Guano,	Farmyard manure.

In former years, as has been already been mentioned, seaweed was almost exclusively used; but the recent great increase of Potato cultivation requires far larger quantities than are now procurable. Fifty loads per acre are usually applied in its fresh state, and at a cost on the beach of 1s. 6d. to 2s. per load, to which 1s. must be added for cartage. Wet seasons are regarded as favourable to this manure, and the tubers are a better sample as regards appearance, but in quality are soft and indifferent.

Guano, when used alone, is applied at the rate of a ton per acre, the whole of which is drilled-in with the sprouted seed when planted in February or March; but if autumn planting is adhered to, half should be reserved for a spring top-dressing after hoeing.

Of woolen rags, four tons per acre are the usual allowance, the cost of which is £3 10s. per ton. But rags vary so greatly in quality, that, until the bales are opened, it is difficult to say how much will be required. Leather, cottons, matting, floor-cloth, and other rubbish are constantly added to give weight, but are of course valueless as manure.

All to whom I have referred on this subject place farmyard manure as lowest on the list for its returns. But this assertion, however true as to its actual results in this district, must be modified by the equally certain fact that the preparation of the farmyard manure is here little attended to, and its value compa-

ratively small. Milch cows, and horses whose mangers are supplied with Mangold Wurtzel and Turnips almost if not entirely to the exclusion of Oats, are too often the only animals for its production, and an unprotected yard with a black fetid stream flowing from it the only place for its reception. In the case of box-fed animals and a covered receptacle a very different conclusion would, I believe, be arrived at.

Of these four manures, therefore, the cost would stand thus—

Seaweed, 50 loads, with cartage.....	£7 per acre.
Woollen rags, 4 tons at £3 10s. per ton.....	14
Guano, 1 ton at £14.....	14
Farmyard dung, 60 loads at 3s.....	9

Such would be the proportions where these manures are used by themselves; but this scarcely ever happens in the case of rags.

The result, however, of many years' experience would show that such a combination of them as the following would be likely to pay for the somewhat greater cost:—

30 loads of dung at 3s.....	£4 10s.
20 loads seaweed at, with cartage, 2s. 6d. per load.....	2 10
10 loads of sea sand at 1s.....	0 10
½ ten of guano.....	7 0
	£14 10

These would be deposited on a pile of earth—first dung, then seaweed, then sand to cover it. After remaining two months, to be well turned and mixed, and so to remain for another two months before using; the guano to be spread on the tubers when planted.

In the case of lay ground first broken up for Potatoes, I have no hesitation in saying that this compost with guano at planting time would give the best crops. But where the land had been for some time in Potato tillage, regard should of course be had to its previous dressings. In the case of woollen rags, for instance, their fertilising powers would continue over two or three years, then guano by itself would be judiciously applied. Seaweed, on the other hand, does not benefit more than the year's crop; while farmyard manure also is nearly expended by the successive crops of Potatoes and Broccoli, or Mangold Wurtzel, taken within the year.

Bones, superphosphate, lime, and salt I have tried, but, on our soil, with anything but satisfactory results. Of salt, which, beyond doubt, is a very beneficial ingredient in any compost for Potatoes, the seaweed and sand seem to supply a sufficiency. But the absence of guano under any circumstances is fatal to the very early maturity on which the profit of the market-gardener so mainly depends.

The ground being in good tilth, and the end of February or the beginning of March having come, the sprouted tubers are taken down from their shelves, cut when larger than required for a single set, and placed in baskets. The drill being opened with the shovel, the seed is then laid on its end in a sloping position with the shoot upwards, covered with earth for an inch or more to prevent its coming in immediate contact with the manure which is then applied, and the operation is completed by the earth from the opening of the next drill being thrown over it to a depth of some 3 inches.

The early sorts are planted very closely together, being not more than 13 inches or 14 inches from drill to drill, and the tubers from 8 inches to 9 inches apart. For an acre from twelve to thirteen bags of seed, of 2 cwt. each, will be required. The crop being drawn before maturity, this close planting is not so objectionable as it otherwise would be; but I have found that in ordinary seasons 2 inches more either way would be well bestowed. Should the weather be favourable, in three weeks the shoots will be well up in rows, and a few days afterwards ready for their first and, generally speaking, their only hoeing, which is done either with the ordinary hoe, or with a three-pronged digger handled as a hoe. The latter is preferable, as it not only loosens the ground more thoroughly, and exposes it to the action of the atmosphere, but is also less liable to injure the young roots. If from a cold spring, or any other cause, growth is slow, this process must be again gone through; but, usually speaking, the plants cover the ground quickly enough to check any subsequent growth of weeds. Banking or earthing-up is never had recourse to.

In early situations ten weeks will frequently bring the crop to a marketable size, and it then rests with the grower to take his chance for the high price for the small quantity, or to wait for the larger produce at a reduced value. By the latter end of May and the beginning of June drawing becomes general, and by midsummer the early crop is cleared off.

Contrary to the practice elsewhere, the tubers, instead of being lifted by the fork, are dug up with the long-handled Cornish shovel; each person, after lifting three or four stems, picking the Potatoes from them, the haulm being thrown in one line, the Potatoes in another. Shallow as has been the planting, too many Potatoes are thus cut by the shovel, and were the use of the fork adopted much waste would consequently be avoided. But adherence to (for such purposes) a very indifferent implement seems in this case to be a general determination. For those first drawn small baskets, containing about 25 lbs., are used; but the use of larger ones, containing about 1 cwt., soon follows.

Packing is by no means so carefully attended to as the delicate nature of the young Potato requires; the sides of the hamper are just lined with paper, and when filled straw is placed over them, and tightly laced down with cord. Heaped one upon another, as happens to them in both the cart and the railway truck, many are thus bruised; while greater care, and especially the use of covers to the baskets, would amply repay the additional cost. The tubers are sized when packed, one hamper of small ones going to every four or five of large, the former selling at about half price.—W.

(To be continued.)

## THE GREAT ORCHARDS OF CALIFORNIA.

ACCORDING to the editor of the *California Farmer*, the orchards of Briggs & Haskell, at Marysville, are on a broad scale. We extract the following from his account:—

"It would be impossible for a stranger to form any possible conception of the extent of these orchards, the immense crop daily gathered, or the wonderful producing power of the trees. Strange as it may appear, with all the disastrous effects of the floods which swept away and destroyed thousands of trees, burying, also, great numbers with the drift-wood, of which more than a thousand cords swept over and upon them, and another thousand cords of Peach-tree firewood will be made from the broken and killed trees; yet, with all this destruction, the crops of these orchards will far exceed any former crop. And this, too, with another singular fact, that with all the energy and attention possible, and with about seventy men, the fruit often ripens faster than it can be gathered, so much so that more than 10,000 bushels will be lost in these two orchards alone. In connection with these there is the Oroville orchard, where about thirty men are gathering and shipping in like enormous quantities.

"That some idea may be formed of the magnitude of the business of these fruit orchards, there was sent from these orchards, the second week in August, from sixteen to twenty tons, or 30,000 to 40,000 lbs. a-day, of Peaches, Apricots, and Plums, of which about two-thirds were shipped to Sacramento and San Francisco."

## THE CULTIVATION OF VANDA.

No genus of Orchids is more deserving of culture than the Vandas, whose noble evergreen foliage, fine vigorous habit, handsome even when not in flower, and, above all, truly splendid and highly fragrant blossoms, render them worthy of being in every collection.

These fine plants, being all natives of the warmer parts of the East Indies, require the same treatment in regard to heat, moisture at the root, moisture in the atmosphere of the house, the material in which to grow them, and in their seasons of growth, flowering, and rest. This similarity of culture renders their treatment uniform and easy. There are, besides, several other genera of these singularly interesting plants, from similar climates, that flourish satisfactorily if subjected to the same treatment; and they are now so numerous, that it is almost necessary to place them in a house devoted to them alone, which structure may very appropriately be named the Indian House, in contradistinction to another devoted to the culture of Orchidæ, from the more temperate climate of Southern America. In the countries from which the Vandas and similar genera are brought, the heat at certain seasons is excessive, especially in the lower parts where these plants are located. It is found necessary, in some degree, to imitate the natural climate in artificial ones provided for tropical plants; and on this point experience has proved that when these plants are growing, a heat of 85° by day, and 70° by night, is the proper temperature for them. The

ason to apply this high temperature, thus encouraging vigorous growth, should be when the heat of our own country is at the highest; for then there is also the greatest amount of light, an element equally necessary for the well-being of the plants as heat. The season of growth, then, should commence in May, and continue till September.

How is this heat and light to be obtained? This question naturally brings us to consider the kind of house best adapted for their culture, and the best mode of heating it. In these enlightened days, science, ingenuity, and skill have brought the art of erecting hothouses and heating to, we might almost say, the utmost perfection; and, like most other essays of art, the most simple and least complicated means are found the best to produce a certain result. The form of house for Orchids cannot be too simple. Its aspect should be east and west—that is, the ends of it should point north and south. The form of parallelogram of any dimension; the roof only need be glass; the sides brick or stone. The angle of the roof should be not more than 36°, or, at the most, 40°. If it is more, there is danger to be apprehended to the plants from drip; but if the angle is rather sharp, the condensed water, instead of dropping upon the plants, will run down the glass on each side to the front where it may be collected and carried off. The best mode of heating yet discovered is, undoubtedly, by means of circulating hot water in pipes of sufficient size or number to give out more heat than is wanted, it being always more safe and easy to reduce the temperature by using less fire, or by the admission of fresh cooler air, than it is to force up a high heat with an insufficiency of pipe. To obtain moisture in the air, it is desirable to run part of the pipes through tanks, so shallow as only, when filled with water, just to cover the pipes. This is a superior method to that of having the tanks supplied direct from the boiler, because when a drier atmosphere is desirable, the tanks may, by means of taps, be easily emptied, and the effect attained.

Moisture in the air should always be in abundance during the growing season. If the weather should be so hot out of doors that artificial heat may be, in a great measure, dispensed with, it will be necessary to moisten the air by other means than the tanks alone. It may be sufficiently given by means of copious floodings on the floors, thoroughly wetting the walls, syringing the plants morning and evening, and shutting-up the house early in the afternoon. Water at the root, an element necessary for the growth of all plants at certain seasons, must also be liberally supplied to Vandas when growing freely. It must be of the same temperature as the air of the house. Rain water is the best.

As to the best material in which to grow them, I believe that baskets made of oak branches or hazel rods, and filled with sphagnum (white bog-moss), mixed with broken potsherds and pieces of charcoal, will be found the most suitable. The baskets may either be hung up to the roof, or if the house is low, placed upon pots to bring them near to the glass.

The season for growth has been mentioned; and as the days shorten, and the heat of the summer declines, the season of rest ought to commence by lowering the temperature to 70° by day and 60° by night. This season of comparative rest should commence at the end of September and continue till March. In the darkest days of winter the temperature should be reduced still further to 65° by day and 55° by night. During this cessation of growth, the plants will not require any water at the roots. Occasional syringing may be given (in the morning only) when there are several sunny days in succession; but moisture must be even then very sparingly applied, and only to prevent the

leaves from shrinking too much. This cessation of growth for a season will, as it were, ripen the wood and cause the buds of the flowers to fill and appear in due course; whereas, if the heat and moisture are continued all the year, the plants will keep growing, and rarely, if ever, flower. The season of flowering will follow the season of rest. As the flower-spikes advance, the heat must be increased; but a very moderate supply of moisture, either in the air or at the root, must be given. In their native country they flower during the dry season that immediately succeeds the cool one. So they will in our stoves, if the system of treatment I have described above be followed. The flowering season, then, will be from March to the end of May, or, perhaps, June, if required. Immediately after that is over, the growing season, with its requisite quantity of heat and moisture, will recommence. Then occurs the proper time to give them a shift, if they require it, by renewing the baskets and the sphagnum. Give them larger baskets as they grow and require more space for their roots.

The following is a selection of the species most worthy of cultivation:—

*V. carulea*. Grows on Gordonia trees among the Khasiyahills of India.—The noblest of the race, remarkable for the size of its whole-coloured bluish-lilac flowers, which measure 3 inches to 4 inches in diameter, and grow in long upright racemes of eight or ten blossoms. It has been erroneously called *V. corulescens* in several publications. The sepals and petals are large, membranous, and oblong; the lip small, leathery, deep blue, and linear-oblong in form.

*V. cristata*. Nepal.—One of the most scarce of the genus, and very beautiful. The flowers are produced on long peduncles, generally singly, but sometimes in pairs; they are large, and of a creamy white; the labellum mottled, and striped with rich dark brown. They last a long time in bloom.

*V. fusco-viridis*. East Indies.—This is a species very little known. As the name implies, the colour is a brownish-green, approaching to yellow. The flowers are of considerable size, lasting in bloom full two months, and are very fragrant.

*V. insignis*. Java.—A well-named species, for it is, indeed, a noble plant, with equally noble flowers. They are large; grow frequently six to ten in a raceme; yellowish, beautifully spotted with crimson, and very fragrant.

*V. suavis*. Java; *V. tricolor*. Java.—These two are very beautiful species, in the way of *Vanda insignis*; and together with it are, perhaps the most beautiful of the species.

*V. Roxburghii*. India.—A handsome-growing plant, but not a free-flowerer; no doubt, because the plants are kept too long in a continued moist atmosphere. The sepals and petals are yellowish, spotted with red inside, and rose and white outside; the labellum is white and pale red. There is a variety with blue spots instead of red or rose.

*V. teres*. Various parts of India.—A very fine species. The petals are deep purple, shading off to the margin; the sepals pale cream colour; the lip large and beautifully variegated with crimson and yellow; a tall-growing species, seldom flowering till 3 feet high.

*V. unicolor*. India.—Not a very handsome species, but a free-flowerer; and the flowers are large and continue fresh a long time. They are light brown, changing to a tawny yellow.

*V. violacea*. Manilla. The sepals and petals of this are white, tinged with violet, the labellum richly striped with rich purple. It is a beautiful species, flowering when very dwarf. The season of blooming is about February, a time when flowers are scarce, even among Orchids.—T. APPLEBY.—(*Gard. Mag. of Botany.*)

*Vanda suavis*.

## ORNAMENTAL PLANTS.

**CAMPANULA VIDALII** (Capt. Vidal's Bell-Flower).—*Nat. Ord.*, Campanulaceae. *Lin.*, Pentandria Monogynia.—A half-shrubby maritime Bell-Flower, probably half-hardy or requiring a greenhouse. It is described to us by a gardener well acquainted with English flower-gardening, as a very ornamental species. Our figure, which serves merely to show its form, is taken from a representation of a poor specimen in "Hooker's *Icones Plantarum*" (vii., t. 684). The plant forms a roundish mass 2 feet high, with dichotomous thickened branches, terminating in a rosette of leaves, of half-succulent, half-leathery texture, smooth, spatulate-oblong, with revolute crenated margins; the few leaves which occur on the flowering stems are lance-shaped and nearly entire. The flowers grow in terminal racemes, which shoot out from the centres of the leafy rosettes; they are nodding, bell-shaped, and contracted in the middle, white or cream-coloured. Mr. Watson describes the leaves and branches as recalling to mind some species of *Saxifraga* or *Sempervivum*; in his dried specimen, shown in our figure, on which about three flowers were developed, several flower-buds appeared abortive, or else would have been developed later and irregularly. We have raised seedling plants.—From the Azores; found on an insulated rock on the east coast of Flores by Capt. Vidal. Introduced in 1851. Flowers through the summer, but beat in August.—(*Gard. Mag. of Botany*.) It requires a mixture of two parts sandy loam and one part leaf mould. It increases freely from seed, but the seedlings do not bloom until the following year. It does well upon rockwork, but is rather tender, and the colour of the flowers is rather dingy. The whole plant has so little the appearance of a *Campanula*, that it has been questioned whether it belongs to that genus, and it is suggested that it is nearer related to the genus *Musschia*.—(*Journal of Horticultural Society*, vol. vii.)

**CHRYSANTHEMUMS.**—The annual display of Chrysanthemums in the Temple Gardens promises this year to be very fine. The flowers will be in perfection during this and the following week.

## BRANCHES OF ORCHARD TREES DYING.

I FIND myself in a similar predicament with regard to some of my orchard trees, as your correspondent "A. B." does who wrote for advice in your *JOURNAL OF HORTICULTURE*, No. 77,

New Series. He complains of many of the branches of his Apple and Pear trees being dead at their extremities, whilst others again, he says, are almost unaffected.

Now, looking at your reply to his query, I presume his orchard has been cropped in some way or other, and I can imagine so far, it would to a certain extent be detrimental to the health and vigour of the trees; but how, then, stands the matter with regard to myself? My orchard is grass land, and, therefore, of course, is not cropped. The soil is of an unctuous nature, and yet several of the branches of the older Apple trees are dead for some length towards their extremities, the younger trees not showing the slightest appearance of any like decay.

Now, should the soil have nothing to do with the decay I am speaking of, perhaps the turf being allowed to grow close round the bases of the trees may. If so, do you think that the turf being removed for some few feet, as a radius, from the base, and the ground then well mulched with good manure and dug in, would be the means of giving new life and vigour to the trees, and so prevent further decay? When should this mulching be done—now or later?—A. K. H.

[Your case is far from being a solitary one, neither is it easy to prescribe a cure; but assuming your trees to be young, and as you say some of them are healthy and vigorous, there is reason to believe that those which are dying at the top are kinds not suited to the soil. In most parts of Kent, where large quantities of Apples are grown for the London market,

the Ribston Pippin is rarely met with in any other condition than that of which you speak. The Hawtbornden is falling fast into the same condition, and in some places the Blenheim Orange, and, most likely, other kinds; therefore, the cause of unhealthiness in your trees arises from the unsuitableness of the variety for the situation. It would hardly be advisable to disturb the turf in the way of renovating the ground, but you may apply liquid

*Campanula Vidalii.*

manure if you like, and a good dressing of dung all over the ground early in autumn. Continuous mowing and carrying off the produce is, of course, hurtful to an orchard, and must be recompensed accordingly. But orchards on grass often do well, and the trees attain a greater age and bear quite as well as when it is in tillage. Grass is more especially advisable for Cherries, but the other fruits bear the spade better. If your trees are covered with moss and full of useless wood, thin out the latter, and some mild damp morning in April scatter them over with quick lime. Some other particulars on orchard culture will, however, be given in a short time.]

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

As a general rule, ground that is deeply trenched should be manured after the trenching, and the manure forked-in, except in the case of fusiform-rooted plants—such as Carrots, Parsnips, &c., which will require the manure to be trenched-in deeply, and not incorporated with the surface soil. Trenching-up all vacant departments to be vigorously followed-up, taking care to trench-in all green and decaying vegetable refuse, which is much better than throwing such materials in a heap to decay, which entails a positive loss of fertilising matter. *Cabbages*, earth-up those planted for Coleworts for winter and early spring use. Look over the principal plantations frequently to see if slugs attack the plants. If they are numerous, lay a quantity of Cabbage leaves on the ground and examine them daily; a pail of hot water or some lime may be taken round at the time they are examined, and the slugs shaken into it: thus many thousands may be destroyed at this time of year by this simple method. *Cauliflowers*, lose no time in taking up those nearly fit for use; lay them in a frame so as not to touch each other, and keep them free from dead and decaying leaves. *Celery*, earth-up that intended for winter use to a good height, as soon as the soil becomes a little dry. It will be necessary to attend to this as early as an opportunity offers, as the frost may set in shortly, which, from the weather preventing the plants being earthed-up lately, will do much mischief. *Endive*, continue to blanch it by tying-up or by wrapping the leaves together, and laying two flat tiles on each plant, so as to form a slight ridge, one tile overlapping the other. *Lettuce*, pay similar attention to the autumn plantations as advised for the Cabbages. Give air to the young plants in frames daily; the Cabbage Lettuces in frames for winter use will not require much air. *Shallots and Garlic*, if not planted in consequence of the wet weather, this should now be done as early as possible.

### FLOWER GARDEN.

Where alterations are in hand, push them forward with all possible dispatch while the weather continues favourable for outdoor operations. Now, when this department is presenting a dreary and desolate appearance, a pleasing and lively effect may be produced by furnishing those beds which are not planted with bulbs, or sown with hardy annuals, with dwarfed specimens of shrubs. The beds next the residence to be filled with *Laurustinus*, *Aucuba japonica*, green and variegated *Holly*, *Arbutus*, evergreen *Berberis*, *Rhododendrons*, and *Box*; those at a greater distance with *Portugal* and common *Laurel*, *Arbor Vite*, *Phillyrea*, &c., filling each bed with one distinct kind. In removing them from their winter to their summer quarters, plant them in prepared beds in the reserve garden, and by regularly pruning-back the summer growth of some, and pinching-off the ends of shoots of others, a compact dwarf shrub will be obtained, and thus be in readiness for another winter. To keep them in pots for the purpose is unnecessary labour.

### FRUIT GARDEN.

When planting wall-fruit trees, it is advisable in the first place that the borders should be thoroughly drained, and not more than 2 feet deep. The soil, a yellowish-hazelly loam, from a sheep pasture, about 4 inches of the top only being used. This is sufficient without the admixture of dung. In planting, the top roots which proceed direct to be kept rather above the surrounding surface, every root to be laid out straight, and to be carefully covered with fine soil, to be slightly trod, well watered, and then mulched. If fresh trees are to be planted on old borders, let it be done with as much care as in new ones; a barrow or two of fresh soil to be put in each hole, and mixed

with the soil of the border. Let the holes be made sufficiently large for the roots when laid out straight. It is by inattention to this that suckers arise, which is in a great measure caused by cramping and twisting the roots. Cast an eye over the trees in the orchard, and see if there is a necessity for a judicious thinning-out of the branches. The work of thinning may be performed at any time from now till March, but the sooner it is done the better.

### GREENHOUSE AND CONSERVATORY.

Look over the plants here frequently, and examine things very closely that are liable to suffer from mildew and damp. The *Boronias*, *Gompholobiums*, and other such New Holland plants are very impatient of exposure to cold drying winds, and if they must be wintered in the same house with the hardier kinds of greenhouse plants, they should occupy a part of the house where they will not be exposed to cold draughts; but air must be admitted by the top sashes freely on fine days. Keep *Cinerarias* and other softwooded plants clear of green fly, and endeavour to secure stocky plants by affording them sufficient pot-room, and admitting fresh air freely whenever the weather permits.

### PITS AND FRAMES.

Expose the stock here freely to air on every favourable opportunity so as to check growth and to get the wood firm, in which state the plants will be less liable to suffer from the confinement which may soon be necessary than if kept close and coddled with too much warmth and moisture. Very little water will be required at the roots, but look over the stock every two or three days, withholding water until indications of flagging appear, and then give a moderate soaking, which is the only safe method of watering at this season.

W. KEANE.

## DOINGS OF THE LAST WEEK.

IN the KITCHEN GARDEN prepared for protecting *Cauliflower*, laying down *Broccoli*, securing *Endive* and *Lettuce* from frost. The frosts have not yet been severe enough after the heavy rains to loosen the hold of the leaves on the fruit trees, though *Dahlias*, &c., have been a little blackened. In-door work has been forwarded considerably, of which at this season I often leave more than we ought to do, in order that there may be always plenty to do, when from wet, &c., it is not pleasant nor profitable for men to be at work outside. When the weather was at all fine did a little draining, &c., and looked after slugs and insects. Looked over our *Mushroom* spawn, and thinking we might run a little short before midsummer, resolved to make a little fresh. Got, therefore, three barrowloads of horse-droppings, nearly one of cowdung, half a barrowload of drishy sandy earth, and two or three bushels of wheat straw cut into chaff, mixed altogether into a toughish dough, and made into bricks, as described some time ago. This is rather late, but we shall have plenty of room in orchard-houses presently to dry it sufficiently. There is no mistake about the spawn keeping well for years, if kept dry and cool. I once surprised a London nurseryman, by refusing to have his new autumn-made spawn at a gift, whilst I paid him for some cast-aside material in a loft, at least two years old. Some of the best spawn I ever handled was in a shed loft at Althorp, and Mr. Judd told me it was getting close on four years of age.

### FRUIT GARDEN.

Looked over the bunches of *Grapes* carefully, for if a single berry damps there will soon be several to bear it company, and, ultimately, the whole bunch would go to a certainty. Made little fires to avoid a moist stagnant atmosphere, and, unless in very severe frost, would leave a little air on the top of the house at night. Although the *Grapes* will hang long after the foliage withers, we think they hang much better if the foliage is kept green a little into the winter. This is greatly promoted by covering the borders early in the autumn when the roots are wholly outside as ours. We stated last week that the rains came and drenched the borders sooner than we expected. Drain as we will, there is a sponge sort of character about the soil here, that leads us to be best pleased when too much wet does not pass through such particular parts as a Vine-border. We waited, therefore, until a fine day had hazelled the surface, then we covered that with a thin layer of cowdung rather moist, and made a smooth surface; and on that surface we spread a thin, filmy layer of gas tar, and threw a lot of dry sand and sawdust upon it. This will prevent any more wet getting directly into

the border, and on this we put loosely from 6 inches to 9 inches of stubble. This so arrested the escape of heat by radiation, that a thermometer 3 inches below the surface that stood at 47°, rose in three days, and after frosty nights, to 51°. A little covering, therefore, of loose material, is of importance, to prevent the heat escaping, and a much safer and more economical proceeding than making huge mounds of fermenting material on the border before commencing to force.

We stated last week that we had burnt some sulphur in a Peach-house, next day all the leaves were limp and dead enough. Almost every year we manage to get a little spider, and, perhaps, scale, about the time the fruit is ripening, when we are debarred giving much moisture for fear of lessening the flavour, which had little need to be lessened this season, as the finest fruit were deficient in that respect as compared with former years. Well, this sulphur-burning with care tends to settle any insects that may be remaining, but it will not settle their eggs if there should be such a thing. After the leaves were brushed-off, removed, and burnt, the trees, rafters, glass, woodwork, &c., were syringed with soap water at about 160° of temperature, using a cloth for the hand on the syringe, and squirting the water into every crevice and cranny. Then the whole of the woodwork and trees were washed, using for the twigs of the latter a soft hair brush. When dry they will be painted with a mixture chiefly of clay and sulphur, and a little soot and soft soap, the main object being to shut-up all imperceptible eggs of insects, and destroy them for want of air. The walls will be whitewashed if wet to-morrow. The earth floor has been scraped, about 1½ inch of the surface removed, and when a fresh tree is planted, and the ground fresh-surfaced, the house will be crammed with bedding plants from top to bottom, until we wish to start the trees, and by that time the vineries will be getting empty. At present the bedding plants are chiefly in cold earth-pits, under old sashes, and will be better to be moved. In relation to insects, I may mention that two Peach trees in pots that had some twigs infested with the black beetle fly, were put into a box about 4 feet square, half a bushel of bruised laurel leaves put in with them, and the door or lid shut; and though the trees were not in the least injured, not a single insect was left with life to annoy us any more. We find that thrips are coming on the under leaves of Cinerarias, though standing on a cool bottom with plenty of air, and we will try the same dose with them. It is a good thing to use the Laurels as soon as bruised, so that none of the acid given off is lost.

#### ORNAMENTAL GARDENING.

Little has been done out of doors. Thinking we might want some more Calceolarias, and frost likely to come with the east wind of the 30th, took off a number of Calceolaria cuttings, and placed them in a shed before we could get time to make them. The Geraniums we thought we might want have been placed under protection before being frosted, and they will take no harm if we do not get at them to dress them as detailed last week, for a fortnight. Many of the tender things have been got into brick pits, &c., and we will move most as we can find room and time, as even the moving does them good. A few things that were not struck were put into a little bottom heat, and where dry heat could also be given when necessary. Any damped leaves have been removed, though few have made their appearance. Pelargoniums have been partially disrooted, and repotted mostly in smaller pots, as we do not wish them to have large leaves before the winter is over. These are placed in the vinery that was thoroughly cleaned, and on the stage they do much better than in pits, with only light above them. The conservatory has been mostly reset. Chrysanthemums have received manure waterings to give strength to the flowers, and stove plants are receiving all the light possible, and the temperature in dull weather allowed gradually to fall. Dahlias have had earth put to their stems to prevent them being injured by frost.—R. F.

#### TRADE CATALOGUES RECEIVED.

Narcisse Gaujard (successeur de Ad. Papeleu), Ghent, Belgium.—*Catalogue général des Cultures.*

J. R. & A. Pearson, Chilwell Nurseries, near Nottingham.—*A List of Plants, Trees, Shrubs, Flower Roots, &c.*

William Chater, Saffron Walden.—*Catalogue of Superb Double Hollyhocks.*

#### TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

BOILER FOR VINERY (*D. G., Ireland*).—You would see the other week that we could work any boiler so as to make it best. A middle-sized conical one would suit you well, but we would not despise a saddle-back. Some of our greatest gardeners are going back to saddle-backs. We do not know what the pits are for, but you ought to have a flow and return in them. You ought at least to have three pipes in the vinery, two flows and one return to begin in February; if earlier, you should have four four-inch pipes.

TEN VINES IN FORTY-FEET HOUSE (*Idem*).—Select three Black Hamburgs, one Mill Hill Hamburg, one Victoria Hamburg, one Lady Downe's Seedling, one West's St. Peter's, one Royal Muscadine (or Golden Hamburg), one Buckland Sweetwater, one Muscat of Alexandria. If the ground is in good order we would plant at once, and keep frost and wet out of the ground all the winter. The roots will then be making way. If you cannot do this, defer planting until March or April, and, if not suitable then, defer it to May, and stand the plants in pots inside; but now, if all is favourable. There is no necessity for taking the Vines out in winter, unless you wish to make a hothouse of the house then.

PLANT CASE (*J. S., Forest Hill*).—We do not know the size of the case, and therefore can only guess that Chrysanthemums, Cytisus, Cinerarias, Primulas, Violets, and bulbs such as Snowdrops, Crocuses, Tulips, Narcissus, Hyacinths, with a dwarf Camellia, Daphnes, &c., would answer. If the case were heated the seeds could be raised very well, and be hardened-off in the greenhouse.

ARBOR VITE HEDGE (*C. Lee*).—The American Arbor Vite is the fastest grower, but not the best for a hedge inside a garden or pleasure ground; and we said it was not so good as Yew against assaults from without. The more dwarf, more regular, and more close-growing Chinese Arbor Vite is the best for an ornamental hedge for screens, up to from 7 feet to 10 feet high. Nothing is more easy now than to devote three whole days to the getting-in of a hedge of Arbor Vite 10 feet high, and not quite 2 feet through at the bottom.

FUCHSIAS IN BEDS DURING WINTER (*S. N. E.*).—It is always the best plan to cut down Fuchsias in beds quite close to the ground, and before they are much frosted. We have cut ours last week. Very little covering will then keep them safe enough, and fern is the best, of which you have abundance at Hampton Court. Work the soil well between the Fuchsias with a fork, and you may put Tulips there and an edging of Crocuses.

GOLDEN CHAIN GERANIUM CUTTINGS (*Idem*).—You did wrong as an amateur to make cuttings of it in the autumn. We have often advised not to do so. Never make such cuttings except in the spring and in the cucumber-bed, and every morsel will root and be ready to put out in May. A Golden Chain will take up as much room in winter though all the tops were made into cuttings, as if all the shoots were left on; then the old plant will carry the shoots through the winter ten times more safely than young roots produced just before the winter sets in.

CALCEOLARIA CUTTINGS (*A. K. H.*).—Some instructions the last two or three weeks will have put you in the way of saving these; but a correspondent of ours, who strikes very little short of 10,000, says he puts them into a cold frame of four-and-a-half inch brick work, 6 feet wide, and about a foot high in front, and double that at back. He puts them in rows about 3 inches by 2 inches, and if the weather be moist, which it often is in the middle and end of October, he leaves them quite exposed; if it be dry and windy, and likely to wither them, he puts on the lights and shades them; but he leaves them fully exposed in all mild weather day and night all through the winter, putting on the lights on frosty nights only, or when it is likely to be so, and he says he does not lose one per cent., except in *C. amplexicaulis*, which he says ought to be put into pans or boxes, and be removed to some place secure from frost. A little frost does not hurt the others, and it is not more than once or twice in an ordinary winter that anything but the lights are over them; and these, he assures us, are often not more than perhaps thirty or forty days or nights in the season.

TWENTY-FOUR STANDARD ROSES (*A Constant Subscriber*).—The very thing you want we published last week, page 568. That, we affirm, is the best selection of twenty-four Roses that has ever yet been made for growing as standards or on their own roots, all but Madame Furtado, and from what Madame seems with us, we should say that she is reverse to being put so high in the air as a full standard. But of all the Roses she holds the highest place in our affections, and we would advise our friends never to work her higher than on eighteen-inch stocks. If we ever worked Roses (which we never do), we would work Madame Furtado no higher than 4 inches from the ground: therefore, for Madame Furtado take Eugène Appert, which, being amongst the stronger, we have marked in the list referred to.

DIVIDING VALLOTA PURPUREA (*H. B.*).—This Vallota may be parted now if you wish to increase it. Were it one, and a fine specimen our object, we would carefully remove the smaller bulbs and keep them by themselves, and the chief bulb we would repot, but in a small instead of a free shift. Your friend will have a better choice of books upon tobacco and cotton-culture when he reaches America. None to suit him have been published in England.

**EATABLE GOUBES** (*R. S.*).—We know of no mode of ascertaining which are eatable except by cooking and tasting them. If any of our readers can point out which are best for kitchen purposes, we shall be obliged by the information being sent to us.

**ASPARAGUS-BEDS** (*Edward Wootton*).—Do not put soil to the beds of either old or young plants until next March. Sprinkle about a pond upon each square rod once a-month from that time until the stems die in the autumn. Remove the earth from over the crowns of the old plants, and replace it with about 2 inches deep of very rotten stable manure; leave this on all the winter, and fork it in slightly in March. Cannot you drain your beds? Wet soil, forking the beds deeply, and burying the plants deeply will ruin any Asparagus-beds.

**COVER FOR HARES** (*Inquirens*).—You and your gardener are equally wrong. Unless you can keep out hares and rabbits for five and twenty years from your proposed "cover," your plan is entirely hopeless. The only way to get up a game cover in such lands (Beau soil) as yours, is to plough it as deep as possible, bring it to a good tilth, and sow it with Barley; but, before sowing the Barley, sow a crop of Broom, Gorse, Bird Cherry, and Privet, or else get up 3000 Privet plants first from cuttings, and 2000 Berberis aquifolium from seeds, both to be put in after the Barley is cut, and when the Gorse is knee deep—say in two years, you can plant any kind of forest or copse trees in the centre of tufts of living Gorse, and no living thing can touch the trees. We would not plant Nuts or Filberts in game covers for the double temptation. Ash, and Spanish Chestnuts, to cut for poles would be the best after the ground was covered with Gorse. The Holly-leaved Laberry and the Privet hares never touch, and Gorse they detest.

**VARIOUS** (*An Old Subscriber*).—*Liliums* may remain many years in the same pots if top-dressed with rich compost every year. If potted, it should be done just before they begin to move in spring. *Achimenes* may be dried-up and shrivelled, but will hardly be so kept in soil in pots, or in saucers covered over with sand in a dry place not below 45°. They should be started by the middle of March to be in perfection in June and July. *Amaryllis* need little repotting, but when done part of the old soil should be removed. The potting is best done with established plants when they are growing. If the pots stand on a dampish floor, the roots will not get too dry when at rest. You must not fumigate ainery with sulphur for red spider unless the fruit is all cut, and the wood hard and ripe. See "Doings of the Last Week." Sulphur, in such cases, is a good servant but a destructive matter. If you have Grapes, dab the heating apparatus with sulphur and lime as a wash, and see the flue or pipes are not above 170°.

**GREENHOUSE LAVENDERS** (*Omicron*).—Our correspondent says that he cannot meet with any of the species requiring greenhouse treatment. Will some of our readers say where they can be procured?

**FRUIT TREES FOR A S.W. WALL** (*J. A. W. P., Glastonbury*).—Your wall, 10½ feet high and 7½ yards long, will give space for twelve dwarf trees of stone fruits. The wall you propose to add another year, 100 yards long and from 8 feet to 9 feet high, facing S.E. and East, will not require the trees to be planted so closely as it is lower. You will be doing quite right by digging-in a liberal dressing of mortar rubbish into the stiff border, and especially about the collar of each tree. If your situation is a favourable one, as the locality indicates, both the present wall and that which is to be built might be planted in a great measure with the best class of Peaches, Nectarines, &c. But if you require Pears and Plums with a few Cherries also from the same walls, you may select from the following kinds, which are all good—viz., Peaches: Noblesse, Early Newtown, Walburton Admirable, Royal George, and Late Admirable. In Nectarines: Pitmaston Orange, Violette Hative, and Elrange. In Apricots: the Shipley, Royal, and Moorpark. In Plums: Green Gage, Jefferson's, Washington, and Golden Drop. In Cherries: Black Tartarian, Elton, and Myrdake; and for a late place, Morello. In Pears: Jargonelle, Calveshase Grosse, Duchesse d'Angoulême, Marie Louise, Glon Morcean, and some others; but if you have the means of growing Pears and Plums as standards, you had better plant the whole of the wall of both seasons with the more tender fruits. Apricots are invariably useful, a few more Peaches may also be had, and one or two Morello Cherries are always worthy a place. Pears and Plums ought to be wider apart than Peaches or Apricots, as they grow to a larger size. Your wall is not high enough to require standards, although alternate standards 4 feet high between the dwarfs would do no harm for two or three years, when they might be cut away as the dwarfs advance. Be careful the roots of the forest trees behind your wall do not penetrate underneath, as we have seen much mischief done that way. The sooner that fruit trees are planted after the leaf is fallen the better. By an oversight your communication was mislaid, or it would have been answered sooner.

**MANETTI ROSE** (*Oates*).—There is but one variety so named, and which can be purchased from any of the large Rose-growers. The Manettia mentioned in the Dictionary is not a Rose but a stove climber.

**TOBACCO RAG**.—*H. H.* wishes to know where this can be had wholesale.

**QUERCUS ILEX INJURED BY FROST** (*T. C. P.*).—The directions we gave last week for treating the Holly will apply to the Quercus Ilex.

**MILL HILL AND DUTCH HAMBURG BLACK GRAPES** (*S. W. G.*).—They require no cultivation different from that needed in forcing other Grapes. You can obtain them from any of the nurserymen who advertise Vines for sale in our columns.

**LAURUSTINES IN TUBS** (*A Subscriber since 1856*).—As the standards are doing so well and the boxes are 18 inches in diameter, we would be inclined to pick away a lot of the surface soil, and top-dress with rich fresh compost. If you prefer shifting into larger boxes, the sooner it is done the better.

**CAMELLIA BUDS BREAKING** (*Item*).—Move the Camellias into the greenhouse—they will be much injured if the soil should be frozen in the pots. Do not trouble yourself about flower-buds starting here and there and chiefly appearing from the wood of the old stems. That is a good sign.

**TROPEOLUM AND MAURANDYA IN A WINDOW** (*Constant Reader, Dublin*).—When the *Tropeolum Lobbianum* is fully established and has a number of healthy shoots it will not need much watering at the root; but it will be greatly benefited in the window of a room where there is constant fire by having the leaves sponged or damped with a syringe or fine rose, and fresh air given, whenever the outside temperature is not below 40°. When lower

than that, give air with care. The *Maurandya* will require three or four times the watering of the *Tropeolum*, and if the pot is rather small it would be better to stand in a saucer, only the water in the saucer should never be allowed long to be deeper than a quarter of an inch. The moistening of the foliage of this will also be eagerly enjoyed, and keeping them free from dust. Are you sure there are no insects that cause the curling of the leaves? Do not hurry *Tropeolum azureum* and *Jarratti*. Let them have their time and give little or no water until the shoots appear, and then very carefully. Before then, to prevent the soil being dried too much, cover the pot, and let it stand on damp moss.

**HEATING A SPAN-ROOFED HOUSE** (*A Subscriber*).—When you ask for information you should write clearly in ink, and not make a mixture of ink and pencil—it gives our eyes unnecessary trouble. We think we know the position, &c., of your house. If all the houses are to be heated separately, we have often mentioned the various modes of doing so. There is just one point on which you need a hint, and that is the brick rubble under and over your pipes for bottom heat. It is of no use having two feet of bats below the pipes; we would be satisfied with 2 inches, and a firm bottom. The rubble or bats above may be from 6 to 9 or 12 inches, the middle thickness perhaps the best, and finished with fine gravel. There ought to be room over that for 18 inches of soil, and then the plants should be 16 inches from the glass. If there is anything else you want, write again.

**GLOXINIAS NOW IN BLOOM** (*E. J. C.*).—With successions *Gloxinias* may be in bloom all the year round. Those that bloom late will naturally start late. Water your plants as long as the leaves keep green; when they begin to get yellow lessen watering and then stop. Cut the leaves off when faded and allow the tubers to remain in the pots, and keep them anywhere out of sight in a temperature of from 45° to 50° and 55°, or thereabouts. Examine them about February, and as the plants begin to grow shake the old dry soil from them, pot afresh, and water as they need it. Give at first about 60°, and increase gradually to 65° and 70°, with a rise from sunshine.

**GERANIUM** (*M. D.*).—Your *Geranium* is *Pelargonium citrodorum*, a wild species from the Cape. Much obliged for the specimen of the new *Gaaphium*.

**LAUREL HEDGE** (*Tyro*).—Our correspondent has Laurel plants of some age, which are bare of leaves for 3 feet from the bottom; and he asks if they would do to remove and be put where he is going to make a bank 3 feet high, and to be buried 3 feet deep, so as to have a hedge of them at once. Now this is a valuable practical question, which practice alone could decide. The Laurels must have been too much crowded, or the soil is desperately poor for them, else they would not go so bare at the bottom. But, if these Laurels were to be left where they are, they might be evergreened to the bottom by the plan which *Tyro* proposes—that is, to raise a bank of good soil round them. But it ought to take two years to make the bank; a foot of earth this winter, 6 inches more next August, and 18 inches at once when the roots were fairly brought up to the fresh soil. Old Cedars, old Yews, and almost all very old trees can be renovated that way, and much easier if cocoa-nut fibre refuse (not the fibre itself) is used in the first instance; but to remove those bare-legged Laurels to another place, and bury the roots 4 feet under the ground and the stems 3 feet, at one time would be folly. And when a bank is made for Laurels, by far the cheapest and the best way would be to plant young healthy plants about a yard high, to plant in October or November, and to mulch them with mild, littery, stable dung.

**LILY OF THE VALLEY** (*M. F.*).—Your bed of this "nice old plant," now leafless requires nothing to be done to it until you see the leaves pushing through the ground in the spring, then stir the whole surface, and put an inch of some light, sandy, rich compost over it—say one-half very rotten leaf mould, the other half of very rotten cowdung and fresh sandy soil in equal parts. The present is the best and proper time for making fresh beds of Lily of the Valley. A shady situation and fresh sandy soil, with a little rotten leaf mould but no dung, makes the best bed; but this flower will do in any garden soil that is not too stiff. The place should be dug very deep, and the soil well broken into a smooth tilth. The best way to get plants is to cut off about 9 inches from one end of an old bed, and shake away the mould from and unravel the roots, and plant the pieces singly all over the surface a few inches apart, and quite flat on the surface; then put 2 inches of soil all over the roots, and they will cover the bed in one season, but they will not flower as they do in an old bed until the second season, and if it is a dry summer they should have abundance of water.

**ARBOR VITAE** (*A Subscriber*).—Your plant is the American *Arbor Vitæ*, and although it makes "a standard tree of considerable size" with you, that size is not one-tenth, probably not one-twentieth, of the size of a Yew tree, and yet the Yew makes a hedge ten times better than the *Arbor Vitæ*, and will take ten times more time to do so. All hedge plants, be they evergreen or not evergreen, are "made to furnish below" by one other method but "by clipping." The Oaks, and the Elms, and all other forest trees could be made hedges of by clipping; and at the beginning every tree was fenced for a hedge, and the Yew was discovered to make the best evergreen fence against man and beast, and the *Arbor Vitæ* to make the cheapest and the readiest hedge, but not against beast or man.

**CALVILLE BLANCHE APPLE**, &c. (*F. H. S.*).—Your Apple is quite correct, but it never acquires the same appearance in this country grown out of doors that it does on the continent. If you try it under glass you will succeed. The Grape vine for it is *Chasselas Rose de Falloux*. Apply to any of the respectable nurserymen who advertise in our pages. The Nova Scotia Seedling is not yet in this country, but the Horticultural Society intend introducing it. Prune the Roses and the Japan Honeysuckles in the spring, because then you will be able to judge where to prune if they should have sustained any damage from a severe winter.

**NAMES OF FRUITS** (*H. N. S.*).—Your Pears are 1, *Beurré Rance*; 2, *Beurré d'Arenberg*; 3, *Bezi Vaet*; 4, *Louise Bonne de Jersey*. (*G. F. W.*).—We are sorry to say we do not know either of your Pears. Neither of them is first-rate.

**NAMES OF PLANTS** (*A Five-years Subscriber*).—1, *Selaginella flabellata*; 2, *S. cuspidata*; 3, *S. Martensii*; 4, imperfect; 5, *Nothochloa nivea*; 6, *Cheilanthes microphylla*. (*B. D., An Amateur*).—Common *Tamarisk*. Plant cuttings of the old wood as you would Curant cuttings. (*A Constant Reader, Dorking*).—*Dracopetalum virginianum*, or *Virginia Dragon's-head*; and *Cornus mascula*, Male Dog-wood, or *Cornel*. (*Polypodium*).—They are slightly varying forms of *Polypodium vulgare*, approaching *acutum*, but neither of them genuine examples of that variety.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BIRMINGHAM AND CRYSTAL PALACE  
POULTRY SHOWS.

"Among useful pursuits must be classed the occupation which consists in rearing poultry, in studying the different breeds, in seeking their amelioration by judicious crosses; and, above all, by seeking to improve those classes that are more intimately connected with agriculture.

"We know that other breeds offer a thousand attractions by the variety of their forms, habits, and plumage, and we are far from advising they should be given up, as they satisfy a natural feeling—that of curiosity. But the more useful breeds are quite as varied, as admirable in their shapes, as curious in their habits; and, besides, they unite the useful and agreeable—they not only provide beautiful animals, but excellent and copious food. Exhibitions develop this attractive taste, and supply all classes with the means of employing their leisure usefully, if not profitably."

So says M. Jacque when writing on exhibitions, and so say we. The above, which met our eyes when we opened the book, appeared particularly appropriate. We wished to speak of the Birmingham and Crystal Palace Shows; they, too, unite the useful and agreeable. It is our duty to inform our readers that if they have not made their entries when this reaches them, they must do so without delay. We are obliged to use the imperative mood to those good, easy, well-disposed, insufferably lazy people, who, when walking round Bingley Hall, Monday, December 1st, will declare they have better fowls at home, that they meant to enter them, that somehow they were too late, or they forgot, or they were busy, or nobody told them the entries were closing, and so they did not. We leave them without excuse.

No one who takes any interest in poultry, cattle, or useful enterprises, should omit seeing Bingley Hall during the Exhibition. Those who have been, are sure to go again; those who have not, have little idea of the beauty or magnitude of the spectacle. In many minds the idea of such a show is connected with close dark buildings and passages where there is scarcely room to move; of animals suffering from painful discomfort, and a place which all are glad to leave. Bingley Hall is as airy and clean as a drawing-room, every animal has a large space to itself. Between the rows there is a very wide and well-kept passage. The building is immense and very lofty, and nothing is omitted that can add to the comfort of the visitors. And the poultry! "Who has not seen Seville has not seen a wonder," says the Spaniard. The speech may be paraphrased, and Bingley Hall substituted for Seville. Whether we consider the numbers, merit, or the value of the birds shown, it is equally marvellous. It is the *fourteenth* annual Show, and with the recollection of past years in our minds we give it hearty greeting, and wish it continued and increasing success.

Time runs round; we are approaching Christmas, and the Smithfield Club Cattle Show tells us by its placards the Crystal Palace Show is at hand. The two Shows are held at the same time, we believe to their mutual benefit. Our predilection for the Crystal Palace is no secret to our readers. It gives to amateurs a show that is altogether *sui generis*. It is a first-rate show of poultry, over and above all the attractions of the Palace, without any increase of admission money. It should have a great claim on all Londoners, as it is the London Show. It is the only important show in the east, or south-east, or south, and the counties to which it belongs almost have the monopoly of the best poultry. They should be liberal contributors. The Crystal Palace caters for all tastes. "Hast thou an ailment or a grievance?" quoth Jock Pudding, incontinently; "My master, the learned Aldovraudo, hath a cure. Is any vexed with hollow teeth, smoky chimney, or scolding wife? he hath a remedy." So the Crystal Palace addresses all classes and all tastes. If tired of the crowing of cocks, music awaits you above; if sick of walking about, seats woo you in every direction; if you have seen enough of animated nature, everything that is beautiful in stateliness is at hand. Gardens, statues, music, courts, and poultry, all for 1s.! Cheap John at the fair is nothing to it.

## GAME BANTAM CLASSES.

In only three or four show lists that I have seen has there been more than one class for Game Bantams, while there have

been separate classes for Gold-laced, Silver-laced, Blacks, Whites, and, lastly, Any other variety. Now, as to the merits of the different breeds, opinions vary, though I must say I infinitely prefer the Game. But I think the numbers shown in a class ought to determine its claim to a prize. As far as I have seen, the classes would be much more equally divided as follows, in respect of number:—

## GAME BANTAMS.

1. Black-breasted and other Reds.
2. Duckwings and other Greys and Blues.
3. Gold-laced and Silver-laced.
4. Any other variety of Bantams.

The Duckwings have reached such excellence that I think they deserve a class to themselves, if any breed do so.

Perhaps, if you do not think this subject worth an article, you would let my letter appear, for I think this opinion is shared by many others, and they might be led to express it.—  
W. LAWRENSON.

[We think the suggestion deserves the attention of committees, for the entries of Game Bantams are usually more numerous than the entries of other varieties.—EDS.]

## CALNE POULTRY AND PIGEON SHOW.

OCTOBER 28TH AND 29TH.

THE second Exhibition held by this Society took place on the 28th and 29th ult., beneath a couple of tents erected on the private grounds of Mrs. Gabriel, a concession this lady kindly permitted also on the like occasion last year. Being very conveniently situated, and the grounds exceedingly well kept (so great a boon to the Committee), drew forth a most unanimous and hearty vote of thanks to the proprietor. The day previous to the opening, as also the first day of exhibition, was unfortunately of a most decidedly unpropitious character, the rain being incessant, and the temperature very low.

As the distance at present from the nearest railway station (Chippenham), is fully six miles, and very hilly, the difficulty of transporting nearly the whole of two hundred pens so far needs scarcely be told; but certainly great credit is due to the management, for with all the adverse circumstances mentioned to contend against, not a pen was wetted or a specimen injured. Neither did any delay ensue, covered spring waggons being called freely into requisition. We hear by next meeting the rail to Calne will be complete. The quality of the birds generally this year shown at Calne greatly surpassed those exhibited at the institution of the Society last year, besides which, the entries proved an increase of about thirty pens. This year two prizes were appointed for Pigeons, resulting in the gathering together of a small but very excellent collection. On turning to the prize schedule, it appears that Classes A and B were reserved especially for the competition of local exhibitors; T. H. Poynder, Esq., and Mrs. Poynder respectively offering five-guinea prizes as an inducement to agriculturists to compete. The result was a good entry. Class A was restricted to Dorkings, Spanish, Cochins, and Game fowls; the latter breed proved successful, our impression being we have seen the same birds exhibited in the northern counties previously; they were Black-breasted Reds. Class B was devoted exclusively to Rouen or Aylesbury Ducks; the Aylesbury breed readily taking precedence. All the remaining classes were open to universal competition.

In *Spanish*, Mr. Lane, of Bristol, had evidently made up his mind to show the strength of his poultry-yard, and certainly so good an entry from any one exhibitor is rarely witnessed; for, notwithstanding he had to cope with Messrs. Rodbard and Fowler, either of whom in the Spanish breed stands as a host, Mr. Lane succeeded in securing all the principal prizes. The condition of all the birds exhibited in the Spanish classes was better by far than we anticipated so early after moulting-time. Lady Holmesdale (formerly Lady Julia Cornwallis), took her accustomed position at the head of the *Dorking* class, with birds closely approaching to perfection. In Class 3, confined to Dorkings of "Any variety or age except Grey or Silver Grey," were some entries of chickens of unusually high worth, but unhappily wrongly entered. So very regular and excellent pens of chickens as those shown by Capt. Seymour, of Crowood, Hungerford, really deserve our highest expression of approval; and we understand the Judges themselves deeply regretted the unfortunate wrong entry made respecting them.

Next in order are the *Cochins*. Here Mr. Bates left anything

approaching competition far in the rear. It proved a complete "walk over," so excellent was the pen, as also to receive at the hands of the arbitrators the additional triumph of the five-guinea prize for the best pen of "Any description of poultry exhibited." The pullets are marvellously good, the "clip" of the wings surpassing anything we have seen for years past, colour and condition being perfection. The colour of the cock's hackle (which was still incomplete from moulting), we hope may improve, although we have grave doubts on this point. Should the next month bring about this desired result, we little doubt we shall find Mr. Bates' name figuring in the zenith of our prize lists for Buff Cochins during December—at least, to see their betters, will be a treat to any breeder of poultry.

In *Brahmas*, though a good entry, nothing of note occurred. Mr. Archer, of Malvern, exhibited some capital *Game* fowls, as did Messrs. Dras, Briery, and Wakefield.

The *Hamburgs* were good, but as yet barely restored from moulting.

In *Polands*, Mrs. Blay, of Worcester, stood far in advance with an almost perfect pen of Silvers; so much so as to run Mr. Bates' Buff Cochins uncomfortably closely for the five-guinea special prize; Miss Milward's Norfolk Turkeys being but slightly behindhand. Such a trio of pens must add to the notoriety of any show.

In *Bantams*, save the Silver-laced Sebrights of Mr. Bayly and Mr. Jones, and not less the single Birchton Grey Pantam cock exhibited by the well-known Mr. Forrest, of Eagle Cliff, nothing of great superiority was shown.

The *Turkeys* were capital, and the pen of Miss Milward's referred to above, contained as good a Norfolk hen as the most anxious Turkey-breeder could desire. Mrs. Fookes' second-prize pen (Cambridge breed), was most excellent, and being entered so low as five guineas would most probably never pass by unclaimed.

In *Geese* Mr. Fowler, of Aylesbury, proved beyond question his yard would still hold their superiority, Mrs. Fookes being but little in the rear. Some good Chinese Geese figured in this class, but against an overwhelming competition with the prize-takers.

Rouen *Ducks* were almost without exception good throughout an extensive class. In Aylesbury Ducks Mr. Fowler's noted pens had to cry second to those of a local exhibitor—Mr. Brinkworth, of Calne. Strange to say, that they stood ahead fully a pound when tested by scale, all three pens being perfect in other respects—so unusual a circumstance, that a second test of weighing was resorted to, as a prevention of the possibility of error, with the like result. As we believe this is the first time Mr. Fowler has fallen before the trial of weight in Aylesbury Ducks, that gentleman will do well to look to his colour; and Mr. Brinkworth, whose birds were entered at only £2 10s., may place additional value on so unexpected a success. In the class for "Any other Variety" of Ducks, Buenos Ayrean were present in strong force, and proved successful; the Decoys, both White and Grey, being very perfect likewise.

Some poultry shown as the Pheasant Malay, being, however, the Indian Game, were the best we have seen for a long time past, and shown in the most perfect possible condition.

The *Pigeons* contained some entries of newly-imported "Toys," at the present unnamed; and their classes throughout seemed very popular among visitors.

In conjunction with the general arrangements we may briefly allude to a new feature, that evidently gave the most ready of all opportunities for reference to those purchasing catalogues—viz., spaces were left in the margin when the catalogues were first printed to be afterwards filled-in when the decisions of the arbitrators were completed: thus at a single glance any intending purchaser might realise all the information he could possibly require. A completed catalogue was also posted to the address of each exhibitor by the same evening's post, and we hope this really-unexpected attention will elicit approval, and that exhibitors will show the Calne Committee how much they value it by preventing a loss to the gentlemen so doing.

Although the opening day proved a drenching rain from day-break to nightfall, the second was one of those lovely days that make all autumnal scenes so covetable; the Show was, consequently, well filled with visitors, and we trust the permanency of this Meeting is now secured.

The following is the list of awards:—

DORKING, SPANISH, COCHIN-CHINA, or GAME (A prize of Five Guineas, given by Mr. and Mrs. Poynder, of Hartham Park, and limited to Farmers).

—Prize, H. Waller, Calne (Black-breasted Red Game). Highly Commended, J. P. Coleman, Beversbrook House (Dorking, and Black-breasted Red Game). Commended, W. Bridges, Calne (Black-breasted Red Game).

ROUEN or AYLESBURY DUCKS (A prize of Five Guineas, given by Mr. and Mrs. Poynder, of Hartham Park, and limited to Farmers).—Prize, J. P. Coleman, Beversbrook House (Aylesbury). Highly Commended.—Gough, Calne (Rouen). Commended, J. P. Coleman (Rouen, and Aylesbury).

SPANISH.—First, H. Lane, Bristol. Second, J. R. Rodbard, Wroughton. Highly Commended, J. R. Rodbard. *Chickens*.—First, H. Lane. Second, J. R. Rodbard. Highly Commended, J. R. Rodbard.

DORKINGS (Grey or Silver Grey).—First, Lady Holmesdale, Linton Park. Second, C. H. Wakefield, Malvern Wells. Highly Commended, Lady Holmesdale.

DORKINGS (Any variety except Grey, or Silver Grey).—*Chickens*.—First, W. T. Everard, Bardon Hill, Leicestershire (Grey). Second, Lady Holmesdale. Highly Commended, Mrs. H. Fookes, Whitechurch (White); C. H. Wakefield. Commended, H. R. Seymour, Crowood, Hungerford.

COCHIN-CHINA.—Special Prize, H. Bates, Birmingham (Buff). Second, C. H. Wakefield, Malvern Wells. Commended, Mrs. H. Fookes, Blandford (Buff). *Chickens*.—First, W. H. Beadon, Taunton (Partridge). Second, Mrs. H. Fookes. Highly Commended, R. Adams, Harborne Heath, Birmingham (Partridge). Commended, Mrs. H. Fookes (Buff); R. H. Nicholas, Malpas (White).

BRAHMA POOTEARS.—First, J. Hinton, Hinton, near Bath. Second, W. Hargreaves, Bacup.

GAME (Black-breasted and other Reds).—First, E. Archer, Malvern (Black-breasted Red). Second, A. B. Dyas, Madely, Shropshire. Highly Commended, C. W. Briery, Roehdale. *Chickens*.—First, S. Matthew, Stowmarket, Suffolk (Black-breasted Red). Second, S. Dupe, Evercech (Black-breasted Red). Third, E. Archer, Malvern (Brown-breasted Red). Commended, J. H. Lamb.

GAME (Any variety except Reds).—First, C. W. Briery, Roehdale. Second, W. Beadon (Duckwing).

HAMBRENS (Golden or Silver-pencilled).—First and Second, C. H. Wakefield, Malvern Wells (Golden). Commended, Rev. C. W. Edgell, Easts Hill, Frome (Golden).

HAMBURGS (Golden or Silver-spangled).—First, Miss E. M. Dansey, Tetbury (Golden). Second, Lady Holmesdale, Linton Park (Silver). Highly Commended, Lady Holmesdale.

POLANDS (Any variety).—First, Mrs. Blay, Worcester (Silver). Second, J. Hinton, Hinton, near Bath (Silver).

BANTAMS (Any variety).—First, T. H. D. Bayly, Ickwell House. Second, E. Jones, Clifton (Sebrights). Commended, R. Brothwood, Bristol (Black); E. Jones (Duckwing).

ANY OTHER VARIETY.—First, P. P. Cother, Salisbury (Pheasant Malay). Second, J. R. Jessop. *Chickens*.—Mrs. Blay, Worcester (Silver). Second, G. Ray, Minestead (White-crested Black Polands). Third, R. H. Nicholas, Malpas (White Silkies). Highly Commended, J. Hinton (Brahmas); J. Pares, Chertsey (Light Brahmas). Commended, J. K. Fowler, Aylesbury (Brahma Pootars); Lady Holmesdale (Silver-spangled Hamburgs); R. H. Nicholas (Black Hamburgs and Coloured Silkies).

TERKEYS (First, Miss J. Milward, Bath (Black). Second, Mrs. H. Fookes, Blandford. Commended, J. Tanner.

GEESE.—First, J. K. Fowler, Aylesbury. Second, Mrs. H. Fookes, Blandford. Commended.—Brown, Blackland Park (Chinese).

DUCKS (Rouen).—First and Second, T. R. Hulbert, Badgenden, Cirencester. Commended, H. Garlick, Chippenham; Mrs. H. Fookes.

DUCKS (Aylesbury).—First, J. O. Brinkworth, Calne. Second, J. K. Fowler, Prebendal Farm. Highly Commended, J. K. Fowler.

DUCKS (Any other variety).—First, E. C. Phillips, Chippenham (East Indian). Second, J. Phillips, Calne (White Decoy). Commended, T. H. D. Bayly, Biggleswade; J. R. Jessop, Hull (East Indian).

GAME COCKS.—Prize, W. T. Everard, Bardon Hill House. Commended, J. Keable, Newbury (Black-breasted Red). *Cockerels*.—Prize, S. Matthew, Stowmarket, Suffolk (Black-breasted Red). Commended, A. B. Dyas, Madeley, Salop.

GAME BANTAM COCKS.—Prize, W. S. Forrest, Greenhithe.

SINGLE COCKS (Any variety except Game, or Game Bantams).—Prize, H. Lane, Bristol (Spanish). Highly Commended, Lady Holmesdale.

POROUS.—*Carriers*.—First and Second, Major F. C. Hassard, Hilska (Dun and Black). Highly Commended, A. L. Sylvester, Birmingham. *Pouters*.—First, H. Yardley, Birmingham. Second, A. Heath, Calne. *Tumblers*.—First, A. L. Sylvester. Second, F. Elsc, Westbourne Grove, Bayswater. *Fan-tails*.—First, P. Elsc. Second, Miss J. Milward, Bath. Highly Commended, H. Yardley. Commended, Hon. and Rev. E. Talbot, Evercech, Somerset. *Any other Variety*.—First, A. L. Sylvester. Second, H. Yardley. Highly Commended, W. H. Beadon, Taunton (Turbits); A. L. Sylvester; A. Heath, Calne (Isabels). Commended, W. H. Beadon (Black Magpies and Porelains); A. Heath (Isabels).

Mr. Edward Hewitt, of Sparkbrook, Birmingham, and Mr. G. S. Sainsbury, of Devizes, were the Judges.

## FROME POULTRY EXHIBITION.

THE third annual Exhibition of poultry in connection with the Frome Agricultural Society's Show was held on Wednesday the 15th ult., and though the number of entries was not large, the quality of the birds exhibited was vastly superior to any previous show. This is in a great measure to be attributed to the competition having been thrown open this year, whereas last it was confined to the district.

Game fowls headed the list, the first prize going to a pen which had travelled from Roehdale, and in spite of their long journey they appeared in good condition and obtained an easy victory; Mr. Elling being second with another pen of Black Reds. In *Spanish* Mr. Rodbard was again triumphant, taking both prizes with two of his well-known good pens. Mr. Muspratt's highly commended pen of chickens are very promising, but scarcely old

enough for competition. *Dorkings* were represented by two pens only, the first prize going to a noble-matched pen of chickens, but they were small. The Silver-pencilled *Hamburghs* were not particularly good, as sufficient attention had not been paid to the selection of birds with good combs and earlobes.

The two prizes given for *Ducks* of "all breeds" produced a very spirited competition, the first prize going to a very good pen of *Rouens*, the second to *Aylesburys*; whilst two beautiful pens of East Indian had to be content with high commendations. The pen of this breed exhibited by Lady Bath were small and of a beautiful colour, but it is hardly fair for these to have to compete with the larger varieties.

The prize pens of *Turkeys* and *Geese* were very fine.

In the "extra class" was exhibited a very pretty pen of Gold-pencilled *Hamburgh* chickens.

The weather was not favourable, the attendance therefore was not quite so large as might have been wished; but, as is usually the case to the most of those who were there, the poultry appeared to be the greatest attraction.

**GAME.**—First (the gift of the Rt. Hon. the Countess of Cork) C. W. Brierley, Rochdale, Lancashire. Second (given by the Society), Miss A. Elling-Sutton Parva. Commended, W. Harding, Marston.

**DORKINGS.**—First (the gift of the Rt. Hon. the Countess of Cork). E. Baily, Caloe. Second (given by the Society), J. Card, Norton Ferris.

**SPANISH.**—First and Second (the gift of the Rt. Hon. the Countess of Cork, and the Society), J. L. Rodhard, Wrington. Commended, J. Muspratt, Hovebury.

**HAMBURGHS.**—(Silver-pencilled).—First (the gift of the Rt. Hon. the Countess of Cork),—Grant, Spring Gardens. Second (given by the Society),—Porteous, Marston.

**DUCKS** (Any breed).—First (the gift of the Rt. Hon. the Countess of Cork),—Coleman, Calne. Second (given by the Society), Marchioness of Bath. Longleat. Commended, Capt. Edgell, Northfield House; The Marchioness of Bath, Longleat; E. Pointing, Whatley.

**GEESE.**—First, Marchioness of Bath, Longleat. Second, I. Cox, Whatley. Commended, I. Cox, Whatley; S. Giblett, Bollow Farm; Marchioness of Bath, Longleat.

**TURKEYS.**—First, Miss Millward, Newton Street, Loc. Second, Marchioness of Bath, Longleat.

The Judge was Mr. George Saunders Sainsbury, of Devizes.

## COLLINGHAM POULTRY SHOW.

THIS Show affords an example of what may be done by judicious management, even in a locality removed from any large or populous town. Collingham is a very large agricultural village, having a flourishing farmers' club and an annual ploughing match. The Poultry Show is held on the same day as the latter, and is always well attended. The tent and pens are the property of the Committee, so that the expenses are not much more than the prizes, and the result is that there always remains a balance on the right side of the ledger. The prizes are open to general competition, and as the birds are kept only one day, very good fowls are entered for competition.

The Show is always strong in the *Game* classes, as might be expected in a locality where so many *Game* cocks are kept, and where they have so often to prove their merits by the most practical of all tests. Amongst the Black and Brown Reds, the first prize was awarded to a Brown Red pen of Mr. Doncaster's. The cock was one of the finest birds we have seen for some time, hard, close-feathered, muscular, the very picture of strength, courage, and activity. The same exhibitor also took first in *Duckwings*. In the *Game Bantams* the competition was remarkably strong, the prizes being divided between two splendid pens, one of Black Red belonging to Mr. Harvey Bayly, and the other of *Duckwings* from Mr. Hawksley. Mr. Cann's highly commended pen of *Duckwings* had one of the best-coloured cocks ever exhibited, but he was somewhat heavier than the winner.

In *Aylesbury Ducks*, the winning pen of Mr. J. Smith's contained two of the largest birds that we have ever seen. They were claimed at six guineas a few minutes after the sale opened.

The single *Game cock* prize was awarded to Mr. Swift, who also took the cup for the *Game Bantam cock*, with one of the best-marked, smallest, and handsomest little Brown Reds that were bred.

In *Pigeons*, Collingham Show has always been superior to every other local country exhibition. Birds that have there gained their first honours have always added to them at Birmingham and Halifax; and this will, doubtless, be the case the present season. The first prize for *Carriers* went to a very good stylish pair of Duns from Mr. Sylvester. The first *Powders* were from Mr. Simpson, of Newark, who, though not a frequent exhibitor, possesses a large and valuable stud of these birds. In

Short-faced Mottles, the first went to Mr. Oates' well-known Reds, that won here last year, and again at Birmingham; in colour, marking, head, and beak, these birds are exceptionally good. Mr. Edge won in *Balds*, with a Short-faced pair of unusual excellence. Ten pens of *Owls* were shown. A pair of *Blacks* were highly commended, but the prize went to an exquisite pen of *Whites*, belonging to Mr. Else, that also took the medal for the best pen in the Show. Mr. Oates exhibited in *Trumpeters*, consequently it is needless to say that the winners were very good. Mr. Key's second-prize *Blacks* were the best we have seen of that colour. In the "Other variety" class there was a very strong entry of first-rate birds. Mrs. Domenichetti's pair, which may be described as miniature White Toy *Owls* with black tails, were excessively pretty and very short in face. Mr. Sylvester won the second with a pair of Short-faced White birds with peculiarly-coloured chequered wings. The third went to a good pair of silver-chequered rock-headed, that under the name of *Icelanders* took first at Sheffield and the Crystal Palace. The fourth to a very good pair of *Blaue Priests* with white bars.

The Judges were Mr. Challoner, of Burnt Leys, and Mr. Tegetmeier, of Muswell Hill.

We append the prize list.

**SPANISH.**—First, A. Brahamon, Swinderby. Second, Miss C. George, Beeston Podge, Notts.

**DORKING** (Any colour).—Prize, H. Child, Birmingham.

**COCHIN-CHINA** (Cinnamon and Buff).—Prize, J. Staley, Collingham.

**COCHIN-CHINA** (Any colour).—First,—Chase, Birmingham. Second, J. Staley (Partridge).

**GAME** (Black-breasted and other Reds).—First, J. Doncaster, Ollerton Hill, Southwell. Second, R. Swift, Southwell. Highly Commended, H. Mantell. Commended, T. Carless, Hoveringham, Notts.

**GAME** (*Duckwings* and other Greys and Blues).—First, J. Doncaster. Second, J. Parker, Barber Nook, Crooke Moor, Sheffield. Third,—Staley. Highly Commended, T. Carless.

**GAME** (White and Pile or any other variety).—First and Second, J. Cann. Highly Commended, J. Smith. Commended, J. Cann.

**HAMBURGH** (Gold-spangled).—Prize, W. Cannan, Adolphus Works, Bradford.

**HAMBURGH** (Silver-spangled).—First, W. Cannan. Second, J. P. Carter, Long Bennington. Highly Commended, J. Cann.

**HAMBURGH** (Golden-pencilled).—First, P. W. Bowne, Bull Bridge, Derby. Second, W. Cannan. Highly Commended, P. W. Bowne.

**HAMBURGH** (Silver-pencilled).—First, W. Cannan. Second, H. Marshall, Cotgrave, Notts. Highly Commended, E. Cope.

**BANTAMS** (Gold and Silver-laced).—First, Master R. Swift. Second, R. M. Stark.

**BANTAMS** (Game).—First and Second divided, T. H. D. Bayly; R. Hawksley, jun., Southwell. Highly Commended, J. Cann.

**BANTAMS** (Black, White, or any other Variety).—First, T. H. D. Bayly. Second, Rev. S. Reynolds Hole (Black). Third, W. Cannan.

**DUCKS** (*Aylesbury*).—First and Second, J. Smith.

**DUCKS** (*Rouen*).—First, W. Cannan. Second, J. Cann. Third, J. Bradwell.

**DUCKS** (Any other Variety).—First, R. M. Stark (Black East Indian). Second, Mrs. Cooper. Third, T. H. D. Bayly.

**BARNDORF FOWLS.**—First, R. Cooper. Second, W. Wright. Third, S. Decket, Collingham.

**GAME COCK** (Any colour).—First, R. Swift, Second, J. Fletcher.

**GAME BANTAM COCK** (Any colour).—First, R. Swift. Second, T. H. D. Bayly. Third, J. Cann. Highly Commended, C. Anklard; J. Cann. Commended, T. H. D. Bayly.

**PIGEONS—Carriers.**—First, A. Sylvester, Birmingham. Second, W. Cannan. *Powders.*—First,—Simpson, Newark. Second, W. Cannan. Highly Commended, H. Yardley, Market Hall, Birmingham. *Almond Tumblers.*—First, A. Sylvester. Second, H. Yardley. Highly Commended, W. Cannan. *Short-faced Moths.*—Prize, W. H. C. Oates, Besthorpe (Reds).

Second, F. Else, Westbourne Grove, Bayswater. Very Highly Commended, J. Percival. *Balds or Beards.*—First, J. W. Edge. Second, W. H. C. Oates. *Tumblers* (Any other variety).—First, Mrs. Oates. Second, A. Sylvester. Highly Commended, J. Percival; W. Cannan. *Barbs.*—First and Second, A. Sylvester. *Jacobins.*—First, W. H. C. Oates. Second, W. Cannan. Commended, F. Else. *Owls.*—First, F. Else. Second, F. Key, Beverley. Highly Commended, W. H. C. Oates, Besthorpe; W. Cannan. *Trumpeters.* First, W. H. C. Oates. Second, F. Key. Highly Commended, W. H. C. Oates. Commended, Mrs. Oates. *Turbits.*—First, W. Cannan. Second, F. Else. Highly Commended, W. H. C. Oates. Commended, F. Else. *Fantails.*—First, W. Cannan. Second, J. W. Edge. Any other variety.—First, Miss Domenichetti (Black-tailed Owls). Second, A. Sylvester. Third, H. Yardley (Icelanders). Fourth, R. Swift (Priests). Highly Commended, A. Sylvester. Commended, Miss Domenichetti (Isabells); F. Key (Dunts); G. Boothby (Victorias); W. Richards (Magpies).

## POWLS ATTACKED BY ROUP.

SEVERAL of my fowls have a running at the nostrils with a frothy appearance at times. When first attacked, they appear very red about the head with much heat there, and they make a sound in their throats as if they were obstructed with phlegm; one so diseased which we killed had scarcely any lungs left. It seems to be infectious, and the young fowls especially suffer from it, and waste away in flesh very rapidly. Food—oats, barley, potatoes, and bran, &c.—J. W. D.

[Your fowls are suffering from roup. Either use Bailey's pills

or give them castor oil freely, a tablespoonful to every bird every other day. Feed on stale crusts of bread steeped in very strong ale, and keep them in a dry warm place. Separate all the sickly from the healthy birds. Feed on ground oats and barley. A few potatoes for a change once per week, not oftener. They do not want brsn.]

## TERMINATION OF THE LEEDS AND WEST-RIDING

### HORTICULTURAL AND POULTRY SHOW.

THIS Society, which was ushered forth as being under the patronage of the distinguished noble and aristocratic families of the county, and of several of the most influential gentlemen of this district, wound up its speculation on Thursday, in the Leeds County Court, before Mr. T. H. Marshall, the Judge, under the following circumstances. An action was brought by Mr. B. W. Sharp, of Briggate, printer, against George Newton, son of Mr. Councillor Newton, and John Wade, the Hon. Secs. of the Association, to recover £6 6s. for the printing done by the plaintiff for the Association, in connection with the Exhibition held in the Music-hall, in July last. Mr. Grainger appeared for the plaintiff, and proved that the order for the work was given by the defendants and a person named Holdsworth, and that the order was executed. Mr. Simpson appeared for George Newton, who pleaded infancy, thus throwing the whole responsibility upon the defendant John Wade. Mr. Ferns, who represented Wade, said, if Mr. Councillor Newton, father of Mr. Simpson's client, and one of the Vice-presidents of the Society, would pay the sum of £15 which had been handed over to him out of the funds of the Association, as he (Mr. Ferns) was instructed, the action would be settled. His Honour strongly urged that, with such a list of patrons, the action should be settled. Although the plea of infancy, if proved, might protect the defendant Newton against the responsibility in law, yet in honour he had entered into the undertaking, and the printer ought to be paid. Mr. Councillor Newton was called, and proved that his son was only eighteen years old. In answer to Mr. Ferns, he said that his son had paid £107, and had only received about £60. This however, was denied by Wade. His Honour said that, as between the plaintiff and the defendant, that was no answer. The verdict must go against Wade for the amount, less 15s. 6d., ordered by a person named Holdsworth, one of the previous Secretaries. Wade stated that he had not received one penny of the funds.—(*Leeds Mercury*.)

[Although we regret very much that the Leeds and West Riding Show was a losing speculation, yet out of that evil, as usual, a good has arisen, for it has afforded an opportunity to a man with sufficient spirit to demonstrate, by obtaining a legal decision in his favour, that the committees of such shows can be compelled to liquidate the debts they voluntarily incur in furtherance of their speculations.

We hope it will teach the committees of such exhibitions, what ought not to require to be taught them—that not only in honour but in law they are bound to pay all just demands connected with such exhibitions, whether such exhibitions are remunerative or unremunerative.—Eds.]

## BEE SEASON IN BERWICKSHIRE.

I PURPOSE giving a brief outline of our bee season in this locality (Berwickshire) with its results. We bee-keeping Britons to the north of the Tweed, after two unfavourable seasons, were rather elated to find the remnants of our stock, which we had fostered and fed with no little care and expense during the last winter, enter the spring generally in a very healthy state. Although in not a few instances slack of bees, yet with the spring so favourable for their increase in the end of May, they were generally in a forward state for the time of year, and in a very few instances swarms issued in the end of May. However, our prospects were doomed to be but shortlived, for early in June the weather suddenly changed, when it set in a continuation of cold ungenial winds, with an almost uninterrupted absence of sunshine, and what with wet and cold, which continued during June, July, and the early part of August, this proved a most disastrous ordeal. At its commencement the hives generally were getting completely filled with brood in an advanced state, besides having their complement of royal larva in the cells,

indicative of their intentions of giving their possessor an addition to their stock. The change of weather, however, overtaking them at this stage, caused a complete cessation of breeding ere a week or two had passed, and the workers got into a very listless state. Those of them which ventured abroad in a great many instances never returned to bring in their report to their respective hives; it being quite a common occurrence for weeks together to find the grounds adjoining the apiary literally strewed with benumbed bees, which had been overtaken with the cold during their flight; and this could not be attributable to weakness from the want of food, as those which happened to be well stored with food shared the same fate. It could easily be foreseen what such a constant thinning of their numbers would result in. Evidently on finding that they could neither supply the brood with warmth nor food, they instinctively commenced an onslaught on the larva at the various stages, including queens, and cast them overboard in great numbers, almost invariably beginning with those at the under side of the combs, and gradually working up as their numbers decreased. Of course bee-keepers who fed liberally partly prevented the brood from being destroyed, but could in no way prevent the constant thinning of the adults. And ere a few weeks passed hives that had been hanging out from overcrowdedness were found to be entirely silent at evening, not even a hum could be heard at the entrance; and owing to the lowering of the atmosphere both internally and externally in not a few instances large quantities of the brood were perished in the combs, the evil effects of which will not be fully ascertained until the ensuing winter. We know of several instances where the combs have been taken out when discovered as the only likely way of saving the hives.

The effects of such a lengthened testing ordeal may easily be conceived; fully one-third of those which promised well at the beginning of June were dead in the end of July, there being neither heat nor food either out or in, both of which are so essentially necessary for their prosperity in midsummer: consequently, the beginning of August found our hives materially lighter than they were ten weeks before, and, as a matter of fact, the most hopeful were beginning to get hopeless now.

It may be stated that in this locality during last summer there was an almost entire absence of clover, as well as a like scarcity of other honey-producing flowers; the bloom on the heath on the Lammemoors was little better, there being little or no new growth on the heath on the open exposed moors, especially where the soil was to any extent composed of moss or other damp soil. To use the expression of a shepherd, who had passed some fifty summers on the moors, in answer to the remark, there is evidently going to be little or no bloom on the heather this season, his reply was, "It's na wonder, for this summer's been over could even fer growin' heather;" and the only exceptions were in the sheltered dells, where the subsoil was more dry than the open mossy moors: consequently hives placed in such localities, with favourable weather, still had the prospect of gaining a supply for winter use, as the idea of looking for an extra supply of honey was now out of the question. However, for about two days, from about the 20th to the 31st of August, a very considerable increase was made in weight. This being the only time during summer in which they might be said to have wrought well. About the above last-mentioned date a strong frost for several nights in succession destroyed the remainder of the bloom, a quantity of which on the tops of the stalks did not open at all. The bees again resumed the lethargic state which they had assumed during the greater part of summer, and bee-keepers consider themselves fortunate under the circumstances who have the remainder of their hives weighing from 20 to 30 lbs., as, with a little care, they still have the prospect of preserving a stock for the future, although there is no doubt but that autumn finds Scotland with fully one-third fewer hives than spring, and the greater proportion of them also but scantily supplied with inhabitants. However, it is to be hoped that with favourable seasons they will again rally, and become as numerous as heretofore.—JAMES SWAN, *Dunse*.

## HONEY HARVEST ON THE LANCASHIRE MOORS.

I AM afraid you will not receive very favourable accounts from Lancashire, as to the amount of honey made this year by hives sent to the moors.

I sent one hive, an early and strong swarm of this year, on

the 12th of August, and received it back on the 22nd of September, only 1 lb. heavier than when it left.

About fifteen hives went from this neighbourhood to the same place (near Bolton), and I do not hear that any of them have done much better. I believe very few have gained any weight, and some have lost as much as 3 lbs. or 4 lbs. I suppose the rain, and the little bloom this year on the heath, is the reason of this bad luck.

The place to where the hives were sent appeared as good as could be desired, for close by was a large extent of moor entirely covered with heather.

I hope others of your correspondents may have a better account to give, and that the same bad fortune may not happen another year to—A LANCASHIRE PARSON.

## HONEY HARVEST ON THE EAST LOTHIAN MOORS.

THE following account of the honey gathered by our bees when at the moors here (East Lothian, N.B.) may be interesting to your correspondent "A. W." and others.

They were taken to the heather on the 16th of August, and brought home on the 17th of September. They were weighed when sent away, and again when they returned, and were as follows, not including weight of hives, only the bees, comb, and honey.

	Weight when sent to the heather.	Weight when they came from heather.
	lbs.	lbs.
No. 1. A Ligurian, received from Mr. Woodbury, and noticed in former Numbers of THE JOURNAL OF HORTICULTURE	25	41
No. 2. Eight-bar combs, taken from No. 1, with common black bees added	20	21
No. 3. Six combs taken from No. 1, with common bees added	14	21
No. 4. Took bees of, for No. 2 had not swarmed	31	37
No. 5. Got two swarms from this	27	33
No. 6. A first swarm of No. 5	22	38
No. 7. A second of No. 5	20	37
No. 8. Did not swarm in 1862. A young queen of 1861	34	50
No. 9. Did not swarm in 1862	33	48
No. 10. In one of Neighbour's cottage hives, and from which we took the bees for No. 3, Ligurian	21	32

It will be seen from the above statement that, notwithstanding the bad season, they have done wonders, and I only know of another person in all this neighbourhood who has done equally well. He had nine at the moors, and got five tops or supers weighing in all 40 lbs., and has now six stocks remaining. I took four supers, weighing 32 lbs. in all, from the above, and had ten stocks remaining, all in good condition, some with more honey in them than I wish, but being in common straw hives I cannot take it out.

With the exception of these, all the others in this district have done nothing, and many have died while at the moors, and of those brought home few will survive the winter. In places on the moors where there used to be four hundred hives in former years, this year there were about sixty. Some old bee-keepers who had a stock of thirty and forty have lost the whole, and say they will not keep them again. It may be asked how it is that ours have been so comparatively successful. I may state that, during the wet summer here, when they could not get out to look for food, we fed them with sugar and honey, and so kept up the breeding. When they got to the moors they were comparatively strong in bees, and were able to take advantage of any fine weather. They made all the excess of honey in ten days. Had the weather and heather remained good they would have increased very much.

It will be seen from the above statement that No. 2, the first artificial Ligurian, has not done so well as No. 3, the second I made, which was ten days later, and had only six combs given to it, while No. 2 had eight, and both about the same number of black bees. The reason of this was that the young queen, which was hatched in No. 2, only laid drone eggs. Seeing this, I added another bar-frame of young brood from No. 1 on the 9th of August that they might rear another queen. On the 23rd of August I introduced other two combs into No. 2 while they were on the moors, not being satisfied with its appearance, and again on the 8th of September other two. When we examined them on the 27th of September we found young brood in No. 3, but none in No. 2. We looked again on the 13th of October,

and found brood in both. In No. 3 numbers were sealed-up in worker-cells, but in No. 2 they were new-laid, so that I cannot be certain yet that they are not drone eggs, as I have found the queen to lay drone eggs in worker-cells, and the weather has been so unfavourable that we could not examine them since.

I have every reason to be satisfied with the Ligurians I obtained from Mr. Woodbury. The queen must be extremely prolific, I having taken such a number of bars from her all full of brood; and I can still bear testimony to all I said in their favour in a former communication, with the exception of their docility—they are perfect savages, especially the old ones, so much so that we are almost afraid to touch them in any way.—ALEX. SHEARER, *Yester Gardens.*

## PUTTING STICKS INSIDE HIVES.

IT has often been recommended in THE JOURNAL OF HORTICULTURE not to put sticks across a hive; but your humble servant once, having but two, lost the best by the comb giving way with the weight of honey, and the bees were completely smothered in their own honey and destroyed, so that all the advice I can receive will not make me adopt the plan again. My way is this: after the bees have commenced making their comb, I thrust one stick crossways of the comb, about 4 inches from the bottom, leaving an inch or two on the outside of the hive, which can be laid hold of with a pair of pincers, turned round, and pulled out.—G. C., *Gloucester.*

[Our correspondent does not state why the combs fell in the case to which he refers, but we may pretty safely assume that the accident arose from one of two causes. They either collapsed from excessive heat, or were shaken down by rough usage. Now, we once lost a stock from the former cause, but instead of resorting to the use of cross-sticks (which, moreover, would not even have palliated the evil), we determined to take care to keep our hives cooler in future. We have also had an occasional comb drop during the removals to the heath. This is, in fact, the only valid reason that can be urged for their adoption. In large apiaries where periodical removals to and from the moors take place, it may be difficult if not impossible to take sufficient care altogether to avoid accidents, and in this case the use of cross-sticks may be admissible as the lesser of two evils. That they are an evil no one can doubt who has been in the habit of observing the proceedings of bees within their hives, and the manner in which an apparently trifling obstacle or irregularity will often interrupt or thwart the breeding powers of the queen. The mode which our correspondent adopts is probably as little obnoxious as any that can be suggested.]

## QUEEN BEE'S AGE OF FERTILITY.

IN reply to the query of "A. T.," at page 601, and in confirmation of the remarks of "A DEVONSHIRE BEE-KEEPER," I believe that the time which intervenes between the birth of a queen and the laying of her first egg, varies very considerably, according to season, and the influence of weather and temperature.

Having raised a large number of artificial queens during the last two seasons, I have been able to notice a great difference in the egg-laying age of the queens, even in cases subjected to the same influences. Three boxes were started with royal cells just sealed-up, and cut out from another stock on the same day. Two of them possessed newly-deposited eggs in about seventeen days; but in the third, after the lapse of a month, no eggs were visible. As, after a searching investigation on two separate days, no queen could be discovered, I determined to unite the hive to another, but when on the point of lifting out the frames for that purpose, I caught a sight of her. The frames were returned to their box, and the intention of breaking-up the stock relinquished. In a few days subsequently, the first batch of eggs was deposited, so that five weeks must have elapsed, in this instance, from the time the sealed cells were placed in the hive until the queen commenced egg-laying.

Again, in another hive, earlier in the season, the weather being warmer, I do not think ten days had elapsed before a young queen, given to me the day after its birth by Mr. Woodbury, had filled a large space of comb with eggs.

But the most singular instance of an opposite character to the last, occurred in a stock which lost its queen on the 20th of

September, 1861. Royal cells were immediately commenced, and a young queen hatched-out some time about the 1st of October. I had not a single drone in my apiary; therefore, the hive was sent out to a garden in the close vicinity of Mr. Woodbury's bees, he having still a few left. Although the hive was closely examined several times between that date and February of the following year, yet never could I discover a single egg, and expected nothing more than to find the bees dwindle away, or the queen take to laying the eggs of drones only. It suggested itself as possible that impregnation might have taken place in the autumn, late as it was, and that the queen had the power of withholding any eggs until the spring; but I must confess it hardly appeared probable that such should be the actual state of the case, and I was very agreeably surprised to find on a subsequent inspection, that she had not only been duly impregnated, but was in reality a very prolific breeder, for in March there was an immense quantity of brood in all stages of development.—S. BEVAN FOX, *Exeter*.

### BIRDS FOR AN AVIARY.

To gratify the taste of a helpless invalid, whose amusements are necessarily very limited, some information respecting aviary birds is earnestly solicited. A roomy, ornamental cage, sufficiently portable to be lifted by two persons, to occupy a stand nearly filling an ordinary drawing-room window, is desired; and the description of such birds as will afford pleasure from their form, colour, and song, is wished. One or two Canaries only could be tolerated, as their song would be too loud, with, perhaps, the same number of Linnets and Goldfinches. Would Lovebirds, Australian Grass Parquets, Java Sparrows, and Bullfinches agree with them? and could Grey and Scarlet Cardinals be safely added? The writer is aware that many interesting but less known birds are to be purchased in London, and descriptions of and information respecting them are desired. The inquirer is not ignorant of the management of birds in separate cages, but fears that a pugnacious character may be developed when many of his favourites are united in one general domicile.

He is induced to take this opportunity of asking if any of the ornithological readers of the *Journal* are acquainted with the St. Helena Canaries. He had three, two cocks and a hen, but has lost all but one of the former; they are charming cage birds, and their soft notes, somewhat resembling a Lark's, would not distract the most sensitive ear. The cock birds are of a subdued greenish-yellow, delicately shaded, the hens nearly as dull as a Sparrow. They refused to breed either with their own mate or a home-bred hen Canary, and appear to be very delicate, as the writer has only one cock bird left. Bullfinches appear to be particularly fond of the seed of the wild hedge mustard, called in Devonshire "charleek;" but, as it is rare in the writer's district, he wishes to know if white mustard seed will answer as well.—A DEVONIAN.

[The forms of aviaries are so numerous, that it would be loss of time to give a description of one most suitable for a room; it must, in a great measure, depend on the size of the window and also of the apartment. One about 7 feet long, 3 feet wide, and high in proportion, with a dome in the centre and at each end, would be a convenient size, and would hold about fifty small birds.

British birds, in our opinion most suitable for such an aviary, are the Goldfinch, Linnet, Redpoll, Siskin, and Canary; and those of the foreign birds most desirable for beauty of plumage and interesting habits, and which would live sociably with the above, are the Diamond bird, South African Canary, Broad-tailed Whidah bird, Australian, African, St. Helena, Orange, and the exquisite Zebra Waxbills and Silverbeaks, and the Firefinch, which is of a most brilliant colour.

There are, also, some very pretty Avadavats, which are very small but most beautifully pencilled: these would all agree together extremely well.

When there is a large number of birds associated, attention is necessary to see if there be any of a pugnacious disposition, and if so they should be taken away immediately. All the birds named can be purchased of Mr. Hawkins in Bear Street, Leicester Square.

The little Australian Grass Parquet might be safely added. The Java Sparrow sometimes turns out mischievous, but by watching it could soon be ascertained if they agree. Lovebirds

and Grey and Scarlet Cardinals would not harmonise with the other small birds.

A variety of food should be given in order to suit the taste of each bird, consisting of canary, hemp, rape, and millet; the last-named is most essential to foreign birds.

The St. Helena Canary is, we believe, the wild Canary of the Canary Islands: it is rarely to be purchased here. White mustard seed is not good for birds, as it is of too hot a nature.]

### MIXING VARIETIES IN ONE CLASS.

ATTENTION having been called to this important point, if you do not consider that enough has been said on the subject, I would add a word on behalf of the Pigeon classes; for, although not so important as fowls in point of utility, they add much to the appearance of a show, and afford an innocent pastime to many, who, from want of space, are unable to keep fowls.

The birds I would speak in behalf of are Blue Carriers. It is well known that they cannot compete in the same classes as the Blacks and Duns, being somewhat inferior in points; and yet, with the exception of Halifax and the Crystal Palace, they never get a chance: consequently, exhibitors must soon give them up. This will be much regretted, especially by the ladies, who, I have remarked, generally prefer the beautiful colour of these birds. I am quite convinced that if a class was added for them it would be well filled, as all Carrier-fanciers had the difficulty of showing in pairs, and prefer the single bird-lists; but as Blue is paired with Blue, this difficulty is overcome. Many splendid specimens of this variety are to be found in England, but it is hardly to be expected they will be continued if no encouragement is given to them at poultry shows.—BLUE CARRIER.

GLUE FOR READY USE.—To any quantity of glue use common whisky, gin, or other spirit, instead of water. Put both together in a bottle, cork it tight, and set it for three or four days, when it will be fit for use without the application of heat. Glue thus prepared will keep for years, and is at all times fit for use, except in very cold weather, when it should be set in warm water before using. To obviate the difficulty of the stopper getting tight by the glue drying in the mouth of the vessel, use a tin vessel with the cover fitting tight on the outside to prevent the escape of the spirit by evaporation. A strong solution of isinglass made in the same manner is an excellent cement for leather.

### OUR LETTER BOX.

WARNING.—We have received several letters giving details of a man calling upon some of our breeders of the best exhibition fowls, representing himself to be some other well-known breeder of poultry. In every instance he managed to assume the name of some one unknown to the gentleman he called upon; and conducted himself so circumspectly, and evinced such a knowledge of poultry, as to deceive, in every instance, those he has called upon, and under various pretences to swindle them out of money. In each case he borrowed the money.

FOOD FOR BANTAMS (*R. B.*).—Your feeding is very good. There is nothing better than ground oats, and the ground barley is a good change. We do not think the cayenne necessary. The only extra feeding should be the scraps from your breakfast, luncheon, and dinner table, and now and then the cooked knuckle of a leg or shoulder of mutton, chopped very fine.

CINNAMON COCKIN-CHINAS (*T. Y.*).—A dark Cinnamon cock can be shown with Silver Cinnamon hens. As the classes are for Cinnamon and Buff, there is no doubt he might be shown with Buff hens. He would not be disqualified, but his chance of success would be very small. A dark Cinnamon cock will breed beautiful chickens with Buff or Silver hens, especially with the former.

WHAT QUANTITY OF FOOD DO POULTRY REQUIRE? (*A. P.*).—This question has been repeatedly answered in our columns by some of the best practical poultry-keepers, and they all agree that no specific quantity can be assigned. Not only do the varieties differ in the amount of food they require, but individuals of the same variety differ in the quantity they need, and the same fowl will eat more during one day than it will during another. The best mode of giving no more food than fowls require is to scatter it before them, a little at a time; and so soon as some of the fowls go away, and the others do not run eagerly after the morsels, or grain, scattered, then have they all had enough at that time.

HOOPED BELGIAN CANARIES (*G. C.*).—First-class birds, such as you require, are about 50s. or 60s. a-pair, with good plumage, fit for showing, can be purchased at Mr. Hawkins, Bear Street, Leicester Square.

PARROT MOULTING (*A Constant Reader, Ross*).—Your bird is moulting. Do not give it at any time hempseed, for it is very heating. Your other food is correct; but you may also give bread softened with milk, and any fruit the bird will eat. Above all let it have a bath daily. Fill a soup-plate with tepid water, and let the bird bathe in it. If the bird does not take to the bath, pour the tepid water over it through the rose of a small watering-pot.

WEEKLY CALENDAR.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 49.2° and 34.7° respectively. The greatest heat, 63°, occurred on the 12th, in 1841; and the lowest cold, 15°, on the 16th, in 1841. During the period 133 days were fine, and on 112 rain fell.

CHRYSANTHEMUMS, AND CALCEOLARIA CUTTINGS.

MR. BIRD'S, GREEN LANES, STOKE NEWINGTON.

HERE is nothing, perhaps, more really and more perfectly attended to, from first to last, than the business of a practical man when he himself superintends it, and can do any turn in it with his own hands as handily as any hand in that line he could hire to assist him. Yes, there is another turn which could make the thing more real still. And pray what may that thing be the reader may inquire. Well, you must ask "D., Deal," what that one thing can be, for he has seen it often over in France. You recollect Madame Laffay Rose, the oldest and yet the very best of all our very late blooming Roses; if you have it on its own roots, and allow it a place near a wall facing the south, and let the yearly shoots attain to 5 feet, 6 feet, or 7 feet, or even more, in the early

part of the season, it will give a crop of as good blooms in November and December as any of the Perpetuals would do in the end of September. Well, when the Rose Madame Laffay came out first, Mr. Rivers declared it would turn out just what it has proved, and told us the reason why it must be so. He said, that over in France the Rose-growers' wives assisted in cultural operations; and as wives all over the world are sharper than their husbands, they can see before their lords which is and which is not to be the best seedling, and, as far as their foresight can go, the best is called Madame so-and-so, as the name may be. All this we have in black and white, on Mr. Rivers' authority, which authority will be a good precedent for me to say that Madame Bird's share in the practical parts of this business makes it "the still more real." And to tell you what I have seen with my own eyes will add a Bird's feather into Mr. Fish's cap—he to whom we are all indebted for the first thorough-going way of propagating Calceolarias properly, and he, too, who has stuck to the real way ever since, till that last ten thousand of last week's correspondence.

Well, Mrs. Bird was putting in the middle number of her ten thousand Calceolaria cuttings of this season, when I called on the 4th inst., the middle day of the month of propagating that part of the stock; so that by adding the four days to the middle of November, we may say Mrs. Bird finishes her ten thousand Calceolaria cuttings by the 20th, and it was about the 20th of October she began them. But her mode is different from our mode—more

like what was familiar to me in my kilt-growing days; two dairymaids going along as fast as two Strawberry-carriers for Covent Garden, with their milk-pails on their heads, gossiping and laughing at the turns of the war in the Peninsula, and their fingers going at a rate you could not count them, knitting stockings. Nor could I count her fingers at putting in Calceolaria cuttings. First of all, she made a row of holes for the cuttings, across the breadth of one light, as quickly as a spinning machine, and as regularly as print, in depth and distance about an inch both ways, then took up as many entings, by guess as I take it, as would fill the one row of holes, dropped one in each faster than saying so, and so left them loose, and went on with the next and next to the last row at the front.

Here, then, were one thousand cuttings in one thousand holes, each an inch deep, and each cutting as loose in the hole as the ramrod in a gun barrel. Then a dash with a rose waterpot filled, fixed, and settled one whole light in one minute, and the next minute she was on to the next light. I took out my watch and reckoned the old slowcoach go of fifteen years since, when it would take just ten of my propagating hands to do the same quantity of work in the time. I did not ask what the master Bird expects, but Madam allows herself only one death in one thousand cuttings.

As long as the weather is damp and muggy the lights are left off day and night, up or down, to the end of February, then the whole are potted into No. 60-pots, and when the balls are as firm as bullets, and each wrapped, without the pot, in a quarter of a page of the Times, with two folds under the ball, and the folds over the plant loose, the whole put into a strong wooden case would go to New York, or New Orleans, as safe as lead balls and bullets, and ten times more safe in the un-packing and handling of them. Fifty thousand General Tom Thumb Geraniums will be ready for the same journey just in the same way of packing, by the time of the April-fooling; and now there are 150,000 Cyclamens ready to go and bloom on the persium model, also 100,000 Crocuses showing well up already, 50,000 Tulips ditto, and 30,000 Hyacinths the same, to say nothing of Narcissuses and Liliums. But of the Liliun lancifolium rubrum, the deepest and the best of the Japan Lilies of Siebold, there are 500 potted for Covent Garden alone, and, perhaps, twice as many of Liliun eximium, which, I believe, we owe to M. Van Houtte; this eximium being none other but a sweet-scented chalice bulb of our dear old Liliun longiflorum of Japan, and the sweetness has not yet departed from any one of the bulbs which have so been obtained either in Belgium or at Yeddo, and thereabouts.

But the Crocuses got over me more than the flying fingers putting in the Calceolarias. Not one of the 100,000 has been potted at all, and now they are all in pots. The pots were first placed where they stand, in brick pits, to save the roots from mice; the bulbs were then placed on the surface of the soil, and no more; the roots soon came and took possession, and one or two kinds had a little of the hempseed husks, in which they pack them in Holland,

thrown over the bulbs when so placed. And it is, also, possible that one pair of hands could work off, at this rate, as many as some ten hands have done this very autumn, in the retail way, as one might say, of garden potting, as compared to wholesale potting and "putting-in."

I forget if it were 1000 or 10,000 plants of Gauntlet Geranium for cut flowers I saw; but the way I do know. The plants are got from cuttings in July, August, and September, and at the beginning of October three plants are put into one No. 12-pot, on what you might call the one-shift system; the flowers begin to come in February, with very little or no forcing, and the same big pots continue to produce flowers for cutting to the end of September, then the plants are thrown away as quite useless. All the scented-leaved Geraniums and Cherry-pies are in the same proportions.

A whole generation of Indiarubber-plants, *Ficus elastica*, from eyes like Vines, for drawing-room decoration, and fancy-leaved Begonias the same the whole of the winter, and full demand for them; and a more full cry after Golden and Silver Ferns, and gynoerankums in that line; and a new house for each kind since this time last year, besides another long lean-to house for more Chrysanthemums, a new propagating-house, and a house just begun to be put up to meet the demands of the market.

Mr. Bird, by his ready-money business and his advertising, has more than tripled his business, his glass, and his hot water in four years. He has all his pipes and the saddle boiler from Mr. Jones; his red deal he buys in the rough, and has it cut to his sizes by the steam mill, brought home, and made into hot-house work in his own sheds to his own liking; his bars are a foot apart, and his glass is thicker than the 16-oz. to the foot; his squares are a foot broad and 14 inches long, all in cases of 100 feet for 11s. 6d., and the putty at so much per cwt. direct from the mills.

All that I learned as no one knows how, while Mr. Bird and his men were packing eighteen specimen plants of his biggest Chrysanthemums for one of the members of our Floral Committee. Every flower was wrapped in a square of wadding at double the usual price of cotton wadding, the whole head then tied to a stake stout as a broom-handle, and all put into a spring van to go with them just eleven miles, all for one set sum of money, and that is just how I should decorate my conservatory here if I had one and could afford the money.

And now the van is off, and I take Mr. Bird by the wing to see the blooming stock of Chrysanthemums. The first thing that struck me was the enormous quantities he had of *Jardin des Plantes* Chrysanthemum, and the next the immense size he had induced the flowers to attain. You may judge what they are like from the fact that Mr. Buck, of Covent Garden, is now selling cut blooms of the "*Jardin*" for 1s. 6d. a-piece as fast as they come to hand. A good strong plant of such kinds is allowed to carry twelve blooms; from five to twelve blooms are the allowance for the very large kinds throughout the collection, the rest are picked-off in the bud. Even then the blooms would not get to the largest size if the plants were grown bushy, as specimen plants, or if they were not stopped at the right time and to the proper bud. This season the plants have been grown on the one-shift system, and the flowers were never so large before, yet there was no liquid manure to give them. The water is now from a water company with a strong pressure from the "main," which pressure, through the hose, will water the grounds, houses, pots, and all, as for a house on fire.

Madame Poggi, which I first had from Mr. Mackie, of Norwich, about twenty years back, has not yet been beaten in size or in its dark purple colour. This year the flowers are enormous, with ten or twelve to a plant. Prince Albert with seven flowers, and *Beauté du Nord* with five flowers to a plant are the next to it in size; and *Jardin des Plantes*, with twelve blooms to a plant, was the most perfect-shaped flower of the same size, and of the very colour of the *Buttercup* of our fields. The *Golden Heronion*, a sport in gold and orange, improves in size as the kind gets older, and is a most perfect flower. The *Queen of England*, with all the sports of it—such as *Alfred Salter*—golden, and pure white, and striped, are all up to the mark of the pure original *Queen*. *Progne* is still the highest-coloured in the family—the nearest to crimson, and *Dr. Rosas* is the next shade to it. *Julia Lagrave* is the nearest to *Madame Poggi*, purple; and *Grand Turk*, new last year, is the next to *Dr. Rosas*, a splendid flower. *Novelty* was very early this season, and of the largest size. It was in Covent Garden, along with double

white *Camelias*, by the middle of October. *Lady Hardinge* this season is the finest of the lilac race, it is also tipped or turned-up with a gold shade; and *General Hardinge*, which is one of the darkest, has also the finest floret, not petal, in the whole family.

The best new ones out this last spring are really very fine, the following in particular:—*Madame Leo*, ivory white; *Little Pat*, a darling bluish white flower; *Queen of Lilacs*; *Nil Desperandum*, a magnificent flower of a rosy amber colour; *Orange Perfection*; *Lady Russell*, very chaste two-shaded flower in lilac; and *Putoni*, one of the largest dark red turned up in a shade of lilac. The three purest whites are *Madame Damage*, *Snowball* or *Gueidres Rose*, and *Virginia*. *White Formosum* is nearly as pure, and *Cassandra*, stopped at the second "show," or bud, is quite as pure a white; so is *Vesta* when stopped at the second bud; but stop both of them at the third show—or say, send their heads higher up, and every bloom on them will come with a rosy tip or shade, when *Cassandra* and *Vesta* are the two most ladylike flowers in the family, and, after *Jardin des Plantes*, are most sought after in Covent Garden. *Amazon* is of a beautiful violet crimson, with a large flat-faced flower. *Rifleman*, which we had new last year, turns out a much finer thing this season, after the shades of *Dupont de l'Èure*; *Pandora*, a soft creamy yellow flower; *Anaxo*, better than I ever saw it.

But as we shall have another turn at them next week from the Exhibition at South Kensington, and that without competition at the Crystal Palace, and, if all be well, also at the *Versaille* Nursery, I shall say nought of the novelties of this season just yet, but go on to say there is a partner here for *Little Harry* called *Little Anne*, a beautiful shade of yellow, next to that of *Jardin des Plantes*, and just such another flower as that of *Little Harry* itself.

The *Pompones* are not much in demand as cut flowers in Covent Garden, and Mr. Bird does not grow them in such numbers as the large kinds, only for country and foreign orders for spring distribution; but the quantity he grows of the best for cut flowers is what surprises most people; and where can they all go to? is the usual exclamation. Why, go to London, which is a bottomless pit for quantities. What would you say to four hundred cut blooms of *Jardin des Plantes* alone in one week? that was just the number for the week I was there, and you could hardly miss them. Wonderful is nearly in as great demand; and if *Cassandra*, *Vesta*, and *Novelty* could be kept to Christmas week, a thousand blooms of each could be sold in four or five days; and if that is not cut-and-come-again I know not what else it can be said to be. D. BEATON.

## HEMSTEAD PARK, ITS FLOWER GARDEN AND OTHER FEATURES.

THIS new and beautiful mansion is situated on one of those gentle eminences which form so pleasing a feature in the landscape of the southern portion of the county of Kent. The undulating country which surrounds it extends some three or four miles northward, where it settles down into the level plain called the Weald of Kent, while a few miles further south is the still more level district washed by the English Channel, called Romney Marsh—a tract more rich in its agricultural produce than picturesque in its landscape. The well-wooded and highly-cultivated district which intervenes between the Weald of Kent and the Marsh is composed of gentle hills with smiling valleys; and if we are to be guided by the general character of the timber, the hedges, and the crops, a more than ordinary share of fertility or good management may be accorded to it. The neighbourhood is well, if not profusely, wooded; and the commanding position of this mansion, and, more especially, the view to be obtained from the more elevated parts of it, must carry the eye in a circle for many miles.

The mansion, which has recently been built by the spirited owner of Hemstead—Gathorna Hardy, Esq., M.P., is near the site of a former edifice, which, in accordance with the mutability of earthly affairs, had in its turn superseded a still older building; thus carrying the antiquity of Hemstead back to a period to which it is not our province to follow it. The liberality of former possessors is exemplified by the quantity and age of the timber by which the park and neighbouring woods are studded. One was pointed out as affording a useful sea mark, and in a sheltered valley some Silver Firs had attained an unusual size.

One is said to have measured, some years ago, 127 feet high, and from their healthy condition a still greater altitude might be looked for. As it is proper always to state the character of the soil and situation where large trees are found, it is right to say that the Silver Firs formed a little group on the side of a damp wooded valley, they being several feet above its lowest level, and the soil is a sort of yellow sandy loam; the sand so very fine as to retain water rather than allow it to percolate, and from its appearance I should think that iron abounded. The healthy appearance of Rhododendron and similar shrubs indicated its presence. There were several other large trees, as Oaks, Ash, &c.; but leaving them alone we will introduce the reader to the pleasure ground, which extends to a considerable distance on the south and west sides of the mansion, and when complete will encircle the whole.

Of late years, the number and size of the various specimens of Coniferae have often been regarded as one of the points of merit in a pleasure ground, and certainly such features ought to rank higher than mere bedding plants. In this respect, therefore, Hemstead is in no way behind situations of similar extent. A

Taxodium sempervirens was 40 feet high, and a Cryptomeria japonica the same. There was also a very fine Cupressus Urdiana: the exact height I omitted to take, but it must have been considerably upwards of 20 feet, as also that of some other Pinuses. But not the least important feature in the grounds were some of the largest specimens I ever saw of hybrid Rhododendrons. Many of them were said to be of the choicest kinds, as likewise were the Azaleas, and both exhibited that luxuriant health which indicates the place they live in as being suitable. They had been planted some years ago to form a sort of irregular frame or back to the dressed grounds, which position they still occupy, though they have been several times thinned.

Several other objects of interest were to be met with, but these must be omitted, and a short explanation given of the accompanying engraving of the flower garden, or rather that part of it which is represented, for some others exist, and the formation of more is contemplated. The design, differing as it does from most that have appeared in THE JOURNAL OF HORTICULTURE, is certainly deserving a place, as being of a character but little known or little brought into use elsewhere.

It is some years since the old-fashioned striped borders of our forefathers received the more fashionable name of "the ribbon-border;" but this title is certainly anything but appropriate in many instances in which it has been applied—so much so, that I am not acquainted with more than two or three places where I would give the name. Cliveden, the seat of her Grace the Duchess of Sutherland, is one; the irregular serpentine form of a long border, of uniform width, displaying the true character of a "ribbon;" and the present case, where the ribbon has been rearranged so as to assume a form adapting it to the space it is wanted to occupy, is another.

The general features of the ground may be thus summed-up. A is a central plot to be occupied as may be deemed best hereafter. Hitherto it has been a basin of water. B is a conservatory in the course of construction, which by its dimensions no doubt will be a noble one. C is a point much further in the straight line of walk, where it abuts against some noble trees, and, doubtless, some suitable summer-house or alcove will be erected hereafter. But the main feature which displays the serpentine-like curves of the long flower-border to advantage, is the declination of the ground on all sides to the central point A. The fall in the space occupied by the ribbon-border I should think is not less than 6 feet. This enables the observer to clearly see the outline of that part of the ribbon which is farthest from him with great exactness, and there being ample space between every part, it shows itself clearly and effectively. The plan given is certainly not to scale, but sufficiently near to convey a good idea of the effect, which was much better on the ground than on paper, which is generally not the case with purely mathematical figures.

The width of the ribbon is about 5 feet, and it was planted very effectively by Mr. Pring, the intelligent gardener. I regret having mislaid a note I made of the different lines of colour; but a continuous line of Perilla in the centre, and one of a white-edged Geranium on each side, were prominent features which could not be improved; and looking in whatever direction you chose, the winding snake-like form of the bed showed these

colours to great advantage. The tri-lobed beds in the recesses were planted with bedding things not found in the stripes, and in all cases lower, so as not to interfere with the outline of the more important part of the display, which, as before stated, could be advantageously seen from all quarters, but, perhaps, best of all from the centre, A, from which the whole rose in an amphitheatre-fashion on all sides.

Having devoted so much space to the above description of the flower garden, I am obliged to merely give a hasty glance at the kitchen garden, which is well sheltered and surrounded by good walls, and contains Grape and other houses all in good condition, and which, it is needless to say, would be well filled when cold weather sets in. Mr. Pring was endeavouring to obtain a quantity of that most useful white-leaved plant, *Centaurea candidissima*, and for that purpose had planted some in the Vine-border, where they formed a number of side shoots, that showed that this plant with liberal treatment may be increased faster than is generally supposed. Some other things not very plentiful were also treated in a similar way, and all seemed equally prosperous and good.—J. ROBSON.

### JUDGING GRAPES.

I MUST confess that I am very much surprised to find by an article in your Number, dated October 28th, that an authority like Mr. Thomson should attach so little importance to the art of Grape-colouring as to assign it only a secondary position in his list of qualifications, when all growers are quite aware that it is the most difficult operation in the successful cultivation of the Vine; as a proof of this, how seldom do we see at any of the principal metropolitan exhibitions more than, at the most, two or three first-rate-coloured dishes of Grapes, though not uncommonly hearing the inquiry, "Are those Red Hamburgs?" If the rich amber of the Muscat and blackness of the Sloe in the Hamburg is wanting, the beauty, "like Othello's occupation," is gone, and the eye does not care to rest on them; and if a

certain want of colour in the Grape produces a better flavour, why should not the same rule hold good with other descriptions of fruit? Premising this theory to be correct, would it become finer, more aromatic, or keep better if its natural hues were undeveloped?

As a cultivator of Grapes, "and I flatter myself not an entirely unsuccessful one," were I to fill the unthankful office of judge, I should consider colour as the first point, size and evenness of berry the second, bloom third, weight and symmetry of bunch the fourth. Were these attributes combined in perfection, I think the possibility of excellent flavour being absent would be very remote indeed.—G. J. O.

I AM glad Mr. Thomson has deemed this subject worthy his consideration, and at the same time given us his opinion as to what points judges should be guided by when deciding the merits of Grapes upon an exhibition table.

Whether all Societies will agree with the eight points time alone will prove. Be this as it may, I consider it the duty of all Societies when printing their schedules to insert a rule to guide the judges when deciding the merits of Grapes. Whether such rule embraces only a portion or all Mr. Thomson's points is not of great importance, so long as they know upon what points to give judgment. Such a rule would be of equal benefit to the competitor, as he would then know upon what points his productions would be judged.

Our schedules are, I consider, somewhat vague. For instance: "the best bunch," "best three bunches," as the case may be, is not sufficient. One may consider colour the principal point; a second, size of berry; a third, size of bunch; and on through the whole of the eight points as laid down by Mr. Thomson.

As far as my experience goes, I am bound to confess that too frequently the best-flavoured Grapes at an exhibition table are passed by without any notice, just for the cause that they were not so highly coloured as the successful ones.

Grapes with a brownish tinge, in my opinion, are invariably highest flavoured and far more fleshy than those which are intensely black. I have a striking instance of such here this season. My earliest house was not so highly coloured as two later houses, but the earliest house is, without any doubt, the highest flavoured, and by far the largest and most fleshy berries, and at table would be considered superior to those with a blacker skin.

As the present judging of Grapes goes it would be most damaging to any judge's reputation to award a prize to Grapes which were slightly deficient in colour in preference to those that were black, if the former were perfect in all other points. But now that the subject is started by such a really practical grower as Mr. Thomson, I hope that something of a definite character will be arrived at, enabling those who take upon themselves the unenviable position of judges to know upon what points to give their decision.—JOHN EDLINGTON, *Gardener to the Earl of Erne, Crom Castle, Ireland.*

### JUDGING GRAPES AND MELONS.

SEVERAL years ago I suggested in the *Gardener's Chronicle* a somewhat similar plan for judging Grapes by points to that recently proposed by Mr. Thomson in your pages. I cannot just now explain the number or nature of the points I proposed, but I know that they did not agree with Mr. Thomson's.

For instance: I did not include flavour, although that is an essential quality in good Grapes, because as Grapes are sent to public exhibitions for the express purpose of being looked at, it is not advisable to mutilate or disfigure them in any way, which must be the case to a certain extent if they are to be tasted. As to firmness of flesh, I believe that judges would differ quite as much on that point as they would about flavour; for while one would prefer a firm-fleshed berry, another would favour a pulpy juicy Grape. As to thinness of skin, I do not see how that point is to be satisfactorily ascertained even by tasting; for when Grapes of one kind compete against each other, as Hamburg against Hamburg, Muscat against Muscat, &c., the difference in the thickness of the skins would scarcely be appreciable. In the matter of colour I differ totally from Mr. Thomson, holding that colour is essential to perfection in a Grape; while Mr. Thomson would seem to be of opinion that a thoroughly black colour indicates inferiority. If a Grape which ought to be black is not black, that surely must be considered a defect.

It will certainly prevent much bickering and unpleasantness between judges and exhibitors if some simple rules can be agreed upon for the judging of Grapes; and I hope that Mr. Thomson's proposal will elicit the opinions of Grape-growers, or, rather, Grape-showers, on this matter.

While on the subject of exhibiting, I will ask why the Melon should be the only fruit to be judged by flavour alone? Of all other fruits, the finest and best-looking gain the prizes; of Melons, it is not uncommon to see the shabbiest little thing upon the table take the first prize, because two out of the three judges happen to be of opinion that its flavour is a degree better than that of the noble fruit which stands beside it. Granted that flavour is the most important quality in a Melon, still I maintain that other properties, such as good growth and beauty, ought to have some weight in the decision. At any rate, it will be a step in the right direction when horticultural Societies fix upon a certain minimum weight (say 2½ ozs.) to make a Melon eligible to compete for a prize.—J. B. W.

### CLAIM OF THE DISTRESSED WORKINGMEN BOTANISTS OF LANCASHIRE

ON THE GARDENING PUBLIC.

IT would certainly be out of place if party politics or subjects of controversy unconnected with horticulture were to find a place in your Journal; but the cause of humanity, being one in which all parties must alike feel equally interested, may with perfect propriety be allowed a place—nay, more than that, it becomes the duty of every one, in so far as he is able, to plead the cause and assist the innocent sufferer. I for one can, therefore, hail with pleasure the design of Mr. John Hague, mentioned in No. 83, of affording some worthy admirers of nature the means of encouraging a study of botany amongst a class in more affluent circumstances, by disseminating amongst them specimens which none but the ardent botanist can have the patience to procure.

Mr. Hague's plan for the Lancashire collectors of wild plants forming collections to be sold at the reasonable rate he speaks of will, I trust, meet with the liberal support it so much deserves, and I have no doubt but the subscribers to a fund for so worthy a purpose will be amply repaid by the receiver in the manner explained; so that, apart from the consciousness of having assisted poor men struggling against a misfortune they had no means of averting, the subscribers are likely to receive each a donation of specimen Ferns and Mosses, in return for the loan of the few shillings they may hand over to the sufferers.

To enable this to be done well requires, like most manufacturing operations, to be done on rather a large scale. The collector of plants could almost as easily procure a dozen or more specimens as one, and these could be assorted, named, and dried by others in the same calling, not, perhaps, so able to undergo the fatigue of a march through a morass or over the moors, and who could, nevertheless, assist in the home arrangement. Care should, however, be taken that every plant sent out from such a source should be correctly named if the numbers were ever so few, as those qualified to give an opinion would be the better pleased if this were well done. But the matter will easily arrange itself into working order if the funds be only forthcoming.

Of the untiring zeal that many of the Lancashire operatives have for gardening and botany we have many examples, and I believe I am right in saying that shows for heavy Gooseberries were held in Lancashire before any horticultural society now in existence was thought of, and most of our popular garden favourites have been largely cultivated there. I have the testimony of a valued friend for saying, that in no district that he was ever in did he meet with so many ordinary labouring men who were so well versed in structural and systematic botany. Though I am but imperfectly acquainted with the habits and customs of the mill hands from not having ever resided amongst them, I have, nevertheless, known young men, ardently fond of following their favourite pursuit of botany, take two or three day holiday, and in a band of three together (never more), make a pilgrimage to the Welsh mountains, climbing and making their way to the almost inaccessible places in the pursuit of some plant that report said was to be found in such a situation, and, perhaps, finding several other plants in their rambles. Some useful treatise on botany, with a small pocket compass and map of the country to guide them on their exploration, was all their luggage, with the invariable bread and cheese, which for tourists is, perhaps, after all the best food that can be carried.

Another time a trip would be taken to the Dorbyshire hills for a similar purpose, the students taking some cheap railway journey as far as they could, and sturdily travelling the rest on foot. I remember some years ago crossing one of the wild bleak mountains to the north of Bolton, with a friend residing in the neighbourhood, who repeated the name of every plant we came in contact with, and assured me that there were plenty of factory people who could do so also. In our journey we came upon the garden of a gentleman connected with the district, in perhaps as uninviting a situation as could well be imagined, but in which I was never more surprised in my life. The gardener, whose age could be little short of sixty, was as great an enthusiast in his calling as the most energetic young man of twenty-five. Florists' flowers of various kinds were done to a nicety, and the little stove he had contained the most select plants that could be obtained, and these too in excellent order, and this on the edge of Bolton Moors. That he follows his calling yet I have no doubt, unless he has been called to his long home. It is not for such as him that I now plead, but for the distressed weaver or cotton-worker whose ordinary calling has been taken away; but who, while under more promising circumstances, patronised the humanising calling of horticulture, or pursued with scientific perseverance the study of botany. That such men should be allowed to starve will, I hope, receive the unanimous verdict, No! and the circumstances of the case admit of no delay.

I at once send my little subscription to the address indicated by Mr. Hague, with whom as well as all others I may say I am totally unacquainted, but in times like these ceremonious observances are out of the question. I hope, therefore, that the remarks of your leading article with those of Mr. Hague will be the means of putting several small sums into the treasury for these deserving sons of toil.—J. R.

I BEG to return the thanks of the humble botanists here for the ten shillings worth of stamps I received through you from "F. H. A.," of Tunbridge Wells. I have handed the money to John Whitehead, R. Schofield, and James Pickering, to be divided in seven parts, there being seven botanists in distress in this neighbourhood. Whitehead has also received twenty-five stamps from a friend at Dewsbury, and I have received two orders, each for two guineas worth of Mosses; one from Lady Cotton Sheppard, and the other from Lady Dorothy Nevill, whose children will also send 5s. to be divided between Whitehead and Schofield.

I will acknowledge in your Journal all sums sent to me, and how distributed.

I may say that Schofield has had no work since last February, and since that time has had twins born to him, so that his distress must be had.

November 7th.—Since I wrote to you about the distressed botanists of Lancashire we have received eight applications for Mosses and other things. Three of the orders have been supplied, and the others will be in a few days. A few of the correspondents wish for other things than Mosses, but it is difficult to get anything now save roots of Ferns. But with your permission we will give a list of a few things they could get—that is, the roots of them, for there will be few of them that could be got now as green specimens. Some of the botanists have fairish collections of Grasses, and some few other things. The following plants are found within a short distance of here—viz., Ferns:—*Polystichum angulare*, *aculeatum*, *lobatum*. *Polypodium vulgare*, *dryopteris*, *phlegopteris*, *calcareum*. *Cystopteris fragilis*, *dentata*, var. *Scolopendrium vulgare*. *Asplenium adiantum nigrum*. *Lastrea Filix-mas*, *oreopteris*, *spinulosa*, *dilatata*. *Asplenium trichomanes*, *ruta-muraria*. *Blechnum boreale*. *Alosoras crispata*. *Osmunda regalis*. *Hymenophyllum Wilsoni*. *Lycopodium clavatum*, selago, and *inundatum*.

There are many other plants; but the botanists, not knowing which are common in the other parts of England, will be happy to tell any lady or gentleman whether they can get the particular kinds of plants they may want; for to give a list of all that grow in this neighbourhood would, I fear, take too much of your space, but I will give a list of the most rare here next week under your permission.—J. HAGUE, 36, Mount Street, Ashton-under-Lyne.

P.S.—The distressed botanists beg to thank you and all the ladies and gentlemen who have put a gleam of sunshine through the dark cloud that now hangs over them.—J. H.

## SEEDLING POT MARIGOLD.

I SEND some flowers and buds in different stages of growth to show its free-flowering character. It is also dwarfer in habit than the common sort, and reproduces itself true from seeds. I have grown it two seasons and find that it makes a good ribbon-border plant, and brings up a colour which is telling, and not very common amongst the modern style of bedding-out plants. You will perceive its early tendency to reproduce flowers by examining the back part of the one full blown.—J. WEBSTEL, Gordon Castle.

[This pot Marigold is the best example we have seen of that form of morphology commonly called "Hen-and-Chickens," from eight to twelve "chicken" flowers on three-inch stalks come round each bloom. We sent it to Mr. Beaton for his opinion of it as a flower-garden plant. He says it is a decided hit, and that it might also be now made a "pot Marigold" in another sense, and come in-doors in pots late in the autumn to push against the Chrysanthemums. The next best strain of pot Marigold known to us is with Mr. Whiting, of Deepdene, near Dorking.]

## GRAPES SWELLING AND KEEPING BADLY.

CAN you tell me why it was that our Lady Downe's Seedling Vine did not do well in our late house, although it succeeded very well in the early one? The berries, in very many cases, did not swell at all, but shrivelled-up, and some are still doing so, thus giving the bunches a very miserable appearance. Will you also say if it is a common complaint this season that Grapes are not keeping well? Ours have kept very ill indeed, the Muscats of Alexandria having become brown before being quite ripe, and the Black Hamburgs have got quite mouldy and soft. There was no fire heat in the autumn, and very little air, except from the back ventilators. Could this be the cause? Fire heat has been given to some extent lately, and plenty of air from the front sashes, but the work of destruction still goes on.—DUMERES.

[We suspect that there is something wrong with the roots of the Lady Downe's Grape in addition to the want of the same care which the early crop obtained. This latter fact alone explains why there is often such a difference in the appearance of late Grapes and early ones, and in some respects that difference is aimed at by the gardener. The very large swelled berries that are delicious to eat in July and August, would not be the best to keep as they lolled on each other as thickly as possible in November: hence not only do late Grapes receive more thinning, but it is found that the berries keep better if they are not extra large, because they have more saccharine matter. This will not do much to explain, except indirectly, why your Hamburgs are rotting, and the Muscats are getting brown before they are ripe, and that giving fire heat now does not stop at once the rotting, moulding, &c. If you have read some notes on this subject in "Doings of the Last Week," and then read over what you state, you will have the clue to the whole mystery. "There was no fire heat in the autumn, and very little air except from the back ventilators," and we might add, perhaps, not too much from them; for we do not often in lean-to houses give a great amount of front air, and very likely the houses were shut up close some sixteen hours out of the twenty-four. Now, though the autumn was a fine one in the south, so far as we make out by the public papers, it was extra dull and wet in your part of the country. The Grapes naturally would be more surcharged with watery matter than was good for them. A fire then and more air would not only have ripened them earlier, but would have made them firmer in consistence. As respects thorough ripening, one bushel of coals then would do more than six bushels now. Autumn Grapes always keep best and longest when thoroughly ripe before November comes. It is the worst of all economy to keep Grapes back as long as possible, and then begin forcing them in the end of October. If you can keep the inside of the house thoroughly dry, and the roots from being soaked with wet, it will be all in the favour of the Vines, and in all dull weather you will need a fire on, and air on night and day, unless in foggy and frosty weather. This will be all you can manage now, except never allowing a spotted or damped berry to be seen twice. The chief causes of your disappointment we believe to be no fires, and too little air in autumn. Of course even in that we may be all at sea; but that is our impression, and at least it points to the course to be adopted in future.]

## FURNACE FOR GREENHOUSES.

ABOUT three years since I built a new furnace to heat the flues of my greenhouse, which answers much better, is more economical, and easier to manage than the old furnace I had before built on the ordinary plan.

The ash-pit is 9 inches deep; the furnace is 10 inches square inside, and 18 inches deep; the fire hole that goes into the greenhouse flue is 2½ inches high, and 4 inches wide, one brick from the top of the furnace. There are two iron bars built in, one near each side at the bottom of the furnace, on which a loose grate is supported. The top of the furnace is covered by a cast-iron plate, 13 inches by 13 inches, and half an inch thick, with an iron handle riveted on one side, with a socket in which a piece of wood is inserted in order to lift it by.

Section of the side of furnace, showing a piece of hooked iron fixed to the side of the wall to support the cover while the fuel is put in, which is easier than lifting the cover off.

Bottom of furnace with the grate resting on the iron supports.

The advantages of this new furnace are, that it is more cheaply and simply constructed than the ordinary furnace; there are no hinges, fastener, or cast-iron frame to support the door required; nothing but the simple plate to cover the top of the furnace. The draught is much better than that of the ordinary furnace. The fuel I commonly use is cinders sifted from coal ashes, which answer capitally; coke broken small is still better, but the cinders cost nothing but the labour of sifting—a great consideration with many amateur gardeners who now possess small greenhouses.

Several parties who have seen my furnace have adopted the same plan with perfect success.

My greenhouse is 18 feet by 11 feet inside. During the intense frost in December, 1860, at eleven o'clock P.M. on the 23rd the thermometer was at 8° in the open air. I then filled the furnace with sifted cinders, and attended no more until daylight next morning, when the thermometer was at zero in the open air, and had never been below 40° in the greenhouse. Thus, you see, my simple furnace and cheap fuel kept out one of the most intense frosts we have on record in England.—J. S.

## A SELECTION OF GOOD OLD ANNUALS.

A SCHOOLMASTER asking one of his boys in a sharp winter's morning what was Latin for cold, the boy hesitated a little. "What, sirrah!" said he, "can't you tell?" "Yes, yes," said the boy, "I have it at my fingers' ends." So when writing in this way to THE JOURNAL OF HORTICULTURE we suppose we perceive a little requirement, or we fancy some of the many

readers of our favourite Journal say, "Could you not give us an article on this little wish of ours?—Cannot you make and publish for us a list of good or useful plants for a mixed border? We like the beds upon the gay parterre; but we should so like to know what are really pretty or ornamental of the many we see in every nursery catalogue, called by varied names." We hesitate in the midst of our self-chosen task. We have many at our fingers' ends, but will they suit? will they meet others' wishes as of yore they pleased us? They now again rush with strange force to our mind and thence to our pen, giving us a strange delight—a wish that it were our lot again to join their fair forms and faces as once seen by us, as we plainly trace their outlines with this bit of metallic mechanism now. Moderating our flight, we mean in this, our last paper, to bind ourselves reluctantly to sorts enumerated in catalogues of the current year; yet, though such be the case, many of the few given below are great strangers at the present day.

We will commence with a plant, one of those often wanted, to fill and make look gay a cold wet piece of ground, under or near a shady north-east or west aspect—something that will grow where nothing else will to do well—a plant that if once sown will year by year rise, phoenix-like, from its own decay—and this is no other than the singular *Nemophila*-like

*LIMNANTHES DOUGLASSI*.—It is an exceedingly free-blooming decumbent plant; in habit, form of flower, and partly in its leaf not unlike a *Nemophila*. Colour of the flower white, with a centre ring of yellow. Altogether it is a pretty, interesting, old plant, flowering very prettily in May. It should be sown in July. Native of California.

*SCHIZOPETALON WALKERI*.—This, a white singularly-flowered plant, forms a very pretty companion to *Saponaria calabrica*. It is also very sweet. The singular flowers are cut, and again, apparently, cross-cut across the individual petals. I have used this plant as an edging in the flower garden to *Purple King Verbena*. It looks pretty and is very interesting, but not quite gay enough, perhaps, for this purpose in these days of extremes. It does best treated like *Phlox Drummondii*—either sown in patches where it is to stand, or in pans to be pricked-off into thumb-pots, thence turned out with a ball where it is to flower. Generally flowers from June. Native of Chili.

*CLINTONIA PULCHELLA*.—An exceedingly pretty dwarf annual (half-hardy), being in colour the trio—blue, white, and yellow. General height, 6 inches or 7 inches. I cannot do better than inform the reader, if this plant is a stranger, that it is in habit, form of flower, &c., not unlike *Lobelia speciosa*. Generally flowers June, July, and August. Native of Columbia.

*NOLANA PROSTRATA*, *PARADOXA VIOLACEA*, and *ATRIPLICIFOLIA*.—A very showy genus. Of the two last-named I know not to which to give the preference, as *violacea* is so beautiful and an improvement upon the last. They are *Convolvulus*-like in the form of their flowers: sown in a rich loamy bed in April, or first week in May at latest, they will form a very striking object in August and September. From Chili and Peru.

*DRACOPHALUM CANESCENS*.—A bright-leaved, rather strong-growing plant, having very dark purple flowers, or rather the lip of the same is tipped with deep purple; the exterior of the *Salvia*-like flowers being in colour an indistinct rose. Sow in March, giving each plant at least 2 feet of growing room. It flowers generally in July and August. Native of the Levant.

*DATURA CERATOCALON*.—A fine plant, having very large white flowers striped with purple, running something in the way of *Petunia Madam Ferguson*. It is rather fragrant. Sow in a warm situation (with protection by a hand-light), where it is to flower, first week in April. Generally flowers in July and August. From Mexico.

*SCHIZANTHUS RETUSUS*.—A not-very-frequently-grown plant, with pretty orange and scarlet flowers. When sown in good fibrous sandy loam and leaf mould, about the last week in March, it grows fast, and becomes a splendid object from about the middle of June to October. Native of Chili.

*CALANDRINIA DISCOLOR*.—It does not seem to be generally known that there are other species of this beautiful genus besides *umbellata*. *Dicolor* has beautiful rose and purple flowers, which are large and pretty numerous. The plant is a very fast grower. Generally flowers July to September. Native of Chili.

*CALANDRINIA SPECIOSA*.—Another pretty species, with bright crimson flowers when the true kind is obtained, though I have received in lieu a dull rose-coloured variety. This plant is best suited in fine summers for edgings; generally sown in rocky patches. It has one drawback (being a truer subject of the sun

than of man), that of closing its flowers about noon. It should be sown where it is to flower. Generally flowers June and July. Native of California.

**GILIA TRICOLOR.**—A pretty interesting annual, and one of those tenacious sorts of plants which, when once sown, become seemingly perennial, as it generally comes up each successive season, being self-sown, as 't were

"To recompense the hand, the generous mind,  
That pleasure took to sow its humble kind."

Flowers in July and on to September. Native of California.

**NIQUELLA HISPANICA.**—A fine annual—the so-called Love-in-a-mist. Poor precarious being, what reverses he meets with! Though I cannot explain the complicated ideas which were the original cause of this plant's strange christening, I will endeavour to explain the plant as grown, leaving the reader to conjecture the other. Independent of the pleasing hue of its flowers, it has somewhat singular seed-vessels, which show themselves very prominently before the flower is past its best. Its colour is of a pleasing blue. Sow it thinly in a warm corner, leaving each plant abundance of growing room. The leaves are rather ornamental; in fact, the plant is by some named the garden Fennel-flower. Generally it flowers from June to August. Native of Spain.

**CLEOME SPECIOSISSIMA.**—This is a beautiful flowering plant with light red flowers, doing tolerably well with us at the present date, as it will occasionally ripen seed. It generally grows about 12 inches high. *C. pentaphylla*, a white-flowered species, is also very showy. This latter should be treated as a tender annual. Both flower between June and August. Natives of Mexico.

**LOASA LATERITIA AND OTHER SPECIES.**—This, an ornamental semi-climbing plant, has curiously-formed red flowers, followed by equally singular seed-vessels, which from their very singular mode of growth and formation are very interesting. This, as also two or three other species, will do tolerably well in good garden soil, but best raised in a little warmth, to be turned out of pots where it is to flower. It will cover any space within a compass of 3 feet or 4 feet, and looks well with its lively blossoms amid a decidedly soft green prettily-cut foliage when trained upon any artificially formed object. It should be sown about April, and flowers about the first week in July. Native of Tucuman.

I next refer to the various varieties of the genus **MARTYRIA**, of which I note in our catalogues five distinct sorts. They are each of them showy pleasing plants. In choosing I give the preference to the following, with respective merits corresponding with the order of their names. Well, first, the flower with two-fold merit—namely, fragrant. The name tells you it has at least one good string to its bow. Next (the colour of the above being purple, a sweet purple), lutes, with yellow flowers; proboscidea, light blue with beautiful markings. Now, I am informed that this last should be first, but when I grew it (perhaps badly), it did not do as I inferred it would; but I mean to have a more just settling with it at a future day if possible. They are, I believe, respectively natives of Mexico, Brazil, and North America, and generally expand their first blooms in July, lasting till August.

In conclusion, if a singular, free-blooming, rather original-coloured creeper is wanted to train around an archway or rustic entrance with a north aspect, or even up a solitary pole, amid any of your favourites as contained in my lists as above, give a trial by all means to **CLEMATIS HENDERSONI**. In close companionship plant the little white sweet-scented *Clematis*, with, in spring, a plant of **TROPEOLUM COCCINEUM ELEGANS**; and you will admit the contrast of crimson, white, and purple-blue can vie with any other for effect and pleasing harmony.—**W. EARLEY, Digswell.**

### SMALL PIT FOR VARIOUS USES.

I INTEND building a small pit, of brick, 9 feet long by 5 feet 6 inches wide, and about 3 feet high at back, and I want you to tell me how I can heat it by glazed flue-pipes at the least possible expense, as I am an amateur not overburdened with cash. I want the pit in winter for keeping the less hardy greenhouse plants and cuttings, and in the spring for propagating and growing Cucumbers, so I shall want bottom heat. What sort of stove should I have which will only require being made up once in twelve or fourteen hours? Would brick or iron be the cheaper, and can I have it built into the wall at one end of

the pit (to be fed from the outside), without the heat being too great for the plants on that side? Must the fireplace or stove be below the level of the flue, and should I require for so small a pit top heat as well as bottom?—**A SUBSCRIBER, II.**

[We should only deceive you if we led you to believe you could do so much as you suppose under the circumstances. In the first place you say nothing of fermenting material for bottom heat, and, therefore, we presume you mean to get that from the glazed pipes acting as a flue. In either case you would not have room enough for pipes, covering of pipes, earth, and leaves of Cucumbers, as, if 3 feet at back, it could not well be more than 2 feet in front. Unless, then, your heating pipes and their covering were placed beneath that level, the walls at the very least would require to be from 9 inches to 12 inches higher. Again, for such a small pit to keep out the frost, a small brick Arnott's stove placed close to the middle of the back wall, with a funnel through that wall, and a small furnace-door outside would be quite sufficient; but no such stoves will work well with much length of horizontal piping or flues from them, and the heated air from them will not go down to give you bottom heat. For this purpose, and using pipes, you would have to sink your stove considerably at one end, so that the bars of the stove should be from 15 inches to 18 inches below the bottom of your pipes and the floor; but, then, that would just be the same as a common flue. Again, there is no advantage in having a stove that only wants looking to in fourteen hours. To have one such you must have fuel that will burn very slowly, or that will be prevented doing so by a damper, or the fireplace must be large for the heat wanted so as to retain a quantity of fuel, and this is generally attended with waste, as the combustion is less perfect. And, once more, glazed earthenware pipes do not stand fire best well, common earthenware stands it much better, and Portland cement better still. Now, were we required to do all these things you specify in a nine-foot pit, and use pipes or flues, we would have a little furnace at one end in the usual way, low enough for the flue or pipes on the floor as stated above, that furnace or fireplace 1 foot wide, 18 inches long, and 15 inches to 18 inches high, the whole inside the pit, and the top covered with stone, or better, with brick supported on iron. For a yard from that fireplace we would have a flue of brick on bed, the rest of it going along within 15 inches of the front wall brick on edge, two bricks on each side with a tile for top forming the flue, and returning about 18 inches from the back wall. If it would be much cheaper, which I doubt, after a yard of brick on bed, earthenware pipes not less than 9 inches in diameter might be used, and pipes of iron or of earthenware might form the chimney. You have now the means of heating; the what remains is how to regulate. Well, fill the whole space between the flues as loosely as possible, making a chamber of it, in fact, with clinkers, stones, or anything most convenient, finishing with a layer of some finer pebbles or gravel 6 inches above the top of the flue. Here, now, you have the means of giving bottom heat to whatever you put above that floor, but top heat is wanting. Now, we have used the rubble and stones, &c., as a rough chamber through which the heat of the flues will not only have free passage, but be also kept to a certain extent as a reservoir of heat. For getting top heat when wanted we would fix four earthenware pipes 18 inches in length upright, equally distant from each other in the space between the flues, and so that the heated air would have free access to the openings in their bottoms, and the top could be left open or be stopped by a wooden plug at pleasure. Were this rubble of stones not handy, and strong slabs of wood more comeatable, we would fix these slabs 5 inches above the flue or pipes, leaving 2 inches or so between them, which opening we would fill with small stones and a little plaster, and secure the upright earthen pipes in the same way. For ourselves we would prefer the first mode. You will observe that we do not recommend the upright pipes for top heat being placed over the flue. The reason is, that we not only want top heat from these when desirable, but we want moist heat too. Now, pouring a little water down these pipes, if right over the flue, might not only injure the flue but give off steam at times that would be too hot to suit the plants. When poured on the stones lying loosely between the flues, none of these evils are likely to happen. This is the best way we can think of from our experience, if you are resolved on using pipes, and we go into particulars because it will suit several other cases where the pit is to be double and three times your length.

But, now, for such a small affair as a nine-foot pit, and if, as an amateur, you will bestow a little nicety, we should just have a

two-feet-square brick Arnott's stove, and from 30 inches to 36 inches in height, placed either at the end, or middle, at back, with a funnel from it into the open air furnished with a damper. The top of this stove we would cover with an iron plate, with a layer of bricks above it, and on that a vessel of water, with a door in the wall to examine that vessel at pleasure. Now, in your case, the only singularity that must be in this—the stove must be sunk inside and the doors be outside, that the top of the stove shall not be much above the top of your floor inside, but the whole of the brickwork of the stove free of earth, &c. This done, you may make a rough chamber of clinkers, stones, &c., or a more perfect one with slabs, with the joints between filled with stones, and a more perfect one still with slates; but in either case you must have the upright pipes spoken of, either in the middle or at back and front, and these supplied with plugs, &c.; and with the door that gives access to your evaporating-pan you can have bottom heat or top heat, moist heat or dry heat, pretty well at your command, and little danger of smoke troubling you, as might be the case with earthenware pipes, however carefully managed and well jointed. We prefer greatly brick to iron for such a purpose, as the heat is so much more kindly to plants, and it will also cost less. Very lately we described the mode of making such, and in a previous volume fuller details are given. As far as we recollect, Mr. Rivers first introduced these brick Arnott's stoves. If our subscriber wishes to please himself and astonish his neighbours with what he can do with little expense, we would say, Adopt such a course; but before doing so, let him carefully read what Mr. Beaton said about such arrangements this time last year. We have not a word to say against £20 and £30 for a boiler for doing good work with its great quantity of pipes, but for small pits and houses standing by themselves, not to speak of flues, the most economical of all modes of heating, if much heat is not wanted, is these brick stoves, whether lighted inside or outside of a house. We were lately asked about the heating of a handsome lean-to, and we recommended a good-sized brick stove close to the brick wall, or nearly so, where there was just a nice place for the funnel to come out, and coke being used, as ought to be the case in these stoves, there would hardly have been any smoke. The idea of lighting in the house was an insuperable objection, and a flue was resolved on, which from the peculiar circumstances will cost many times as much, and we are rather doubtful if it will answer as well. The only reason why, in small greenhouses we would prefer a nice iron stove with a flat head for water, is that it can be removed in summer. Against this is the fact, that all these funnels of iron soon wear out. With a stove near a back wall there would be little funnel required, and after all its obvious utility would constitute no great eyesore in summer which could not be hidden by a large plant. Thousands and tens of thousands of little places would be erected to keep, or attempt to keep, plants in winter; but the keeping the frost out is the great drawback. We as yet know nothing so simple as an iron stove, nothing so good combined with economy as a brick Arnott's stove. Many of our experiments even with an iron stove surprised us, though much of the heat escapes up the chimney. The humblest means to secure a desired object is not to be despised, however much we may value heating by hot water, &c.—R. F.

N.B.—“A READER,” “D.,” “AN AMATEUR,” “SIGMA,” and “DELTA,” will find answers in the above to their various queries.]

### POTTED PEACHES AND NECTARINES IN A VINERY.

HAVING eighteen Peach and Nectarine trees in tubs, the only place for growing them is under Vines in a span-roofed house 20 feet wide, and a raised bed 5 feet wide on each side. These beds are planted with Vines. The path is 10 feet wide, and the Peach and Nectarine trees are placed along the centre of this path. The roof is occupied with Vines as before stated, a rod to every 4 feet, so that the trees are quite deprived of sun—in fact, almost of light. We had only a thin sprinkling of fruit on the trees this season, and, worse than all, the wood is very far from being ripe: therefore, I think it quite useless to attempt to grow even Peaches, and much less Nectarines, in such an unfavourable place. This, of course, is very unsatisfactory.

Now, as we have the trees, I shall be ever grateful to you if you can give me a hint what to do for the best and cheapest to construct a more appropriate place for growing the above fruit. We have a good wall 12 feet high, with south aspect. I will

endeavour to give the outlines of a passage suitable to the situation named—say a passage 6 feet wide, and 6 feet high in front from the surface; then excavate 2 feet for a brick wall; build the wall 2 feet 6 inches high—that is, 6 inches above the surface; then have shutters 18 inches deep, hinged in six-foot lengths to work with an iron handle to each (an iron rod from end to end would be much better, but would be too expensive), and the remainder of the front glazed with large panes of glass, say 1 foot wide, the roof to be a fixture also, with a board on the top a foot deep, and hinged in lengths to act as ventilators. We cannot ventilate through the back wall on account of out-houses being on the north side. I think in such a structure Peach trees might be planted against the back wall, and the present trees in the tubs and pots planted out, along the front, as bushes.—A. R. M., *Ireland*.

[Your letter is one of those the subject of which ought frequently to come before gardeners and their employers. We are constantly hearing of cases in which gardeners are getting into trouble, and sometimes forced to leave their places because they cannot perform impossibilities. We walk through some splendid garden where everything is in its place and a right place for everything. Plants ought to flourish in such places as these. Gentlemen, however, do not confine their visits to such places; they go to some where a clever gardener has to make one place serve many purposes. They at once generalise, which is all very well, but after all is of no great value when there is no thorough mastering of particulars. Many things may be grown in one house if attention to their requirements is given, and the shade of the one does not interfere with the well-being of another. There is often such a haste in jumping at conclusions as to be unpleasant to all concerned. Not so long ago a gardener got the promise of some pits to winter his bedding plants. His employer happened to see some of our earth pits filled with such plants, without any covering, in a fine day in the end of March. He came at once to the conclusion that they had stood there all the winter, and went home and told the gardener he might get some earth or turf pits like other folk, but that he should have neither bricks nor glass! Here is another case that came in our way not so long ago, showing how little knowledge exists in such matters. In a rather large vinery, where the fruit was not wanted until July and August, the Vines could be taken out by a mode similar to that described at page 612, and the house was turned into a forcing-house for the winter. There, by the new year, we have noticed Mushrooms, Rhubarb, Sea-kale, Asparagus, bulbs, Privets, &c., and from the end of February and onwards good crops of Strawberries from a number of shelves. These were eaten, and praised now and then as they deserved to be; for a little commendation occasionally gives an earnest worker such a pleasant filip, that he could do ever so much more and not feel so tired either afterwards. But unfortunately, though the Strawberries were liked well enough, they did not come in at the time when they were especially wanted. The great thing was to get an extra fine supply of these about the beginning of May; and this could only be done by having the plants set before the house was rendered dense with the foliage of the Vines, and then the flavour was uniformly complained about. It was long before the proprietor could see he expected impossibilities, and that with a roof densely covered with foliage fine Strawberries could not be had beneath them. It was ultimately arranged that 3 feet at the top of the house—the best part for Strawberries—should be kept free of Vines until the Strawberries came in from pits or the open ground.

A rather singular case, bearing on that of “A. R. M.,” came under our notice some time ago. To the inquiry of a correspondent whether he might not cultivate Figs under Vines in a vinery, we gave the reply that no doubt they would grow well enough; but that if the roof was at all densely clothed with foliage, the Figs would do less and less every year in the way of fruiting, and that to secure good crops of Figs the Vines stems must be from 4 feet to 5 feet apart, and a space left clear between each two Vines from top to bottom, and that the whole of the front glass must be clear. A gentleman, who will read this, wrote stating that he supposed I gave the answer in question, but politely informed me that in the present case I was quite in error; for, whatever else might not do, Figs would not only grow but fruit well in pots under a rather thick shade of Vines, and informing me where he saw this result year after year, and where also I might see the same. Well, I could not go to the place, but I got a friend to go and let me know exactly how the

case was, and he wrote to this effect: "There is no doubt a good crop of Figs every year, at least very fair, in this shady vinery, though the Figs seemed deficient in high flavour; and now I think I ought to make you pay for the secret, which is this:—A great many Figs are kept in pots, more than double of what are seen in this vinery. As soon as they have finished fruiting, the roots are pruned and the plants repotted, plunged in litter, and roots and tops protected for the winter; a good pruning is also given. Next summer they are placed under glass if it can be afforded, but out of doors at the foot of a wall facing the south in summer, mulched, and duly attended to with watering, housed in good time, and then when they show fruit the best are retained. And so the plan is continued, the main features of which are to grow and ripen wood one season and then fruit it the next." As corroborative of the above, I may mention that a friend of mine clothed the back of a lean-to vinery with Fig trees of a prolific character. He never got a fruit on the back wall owing to the dense shade of the roof, but could get plenty at the top where the wood of the Fig was allowed to occupy a little of the space that the Vines claimed as their right.

Now, with respect to "A. R. M.'s" case, we would say that this has been a bad season for deciding what could be done on the floor of that span-roofed house. Our own impression is, that if there is much upright glass at the sides of the span, and the Vine shoots from the stem are so thin as to admit of a clear space of 15 inches or so in the centre of each light, then with frequent moving Peach trees in tubs, with heads not too large, will both ripen fruit and ripen wood underneath the shade of the Vines; but, on the other hand, if such a crop of fruit is taken that the side-bearing shoots meet each other, and the roof during the summer is pretty well clothed all over with foliage, then the trees will become more unfruitful every year, and even if the wood is sufficiently ripened for the bloom-buds to stand, and they should even open and show well, few of them will set, because the great proportion will be imperfect, many wanting anthers, and more wanting germens. With such an extra house as our correspondent proposes, to which the trees could be removed to ripen their wood, crops might be got in this vinery by pruning some of the trees back, because the Peaches would be set before there was much shade from the Vines. The next best would be to choose a shady day, and take the trees out as soon as the fruit was gathered, place them against a south wall that the growth might be perfected, and the wood well hardened by exposure to the sun, along with a diminished supply of water.

Mentioning these last plans more for others than "A. R. M.," we cordially approve of his proposal (see page 609.) There are just two things which we would dare to give a hint on in the way of improvement. The first is the width. We would have it at least 10 feet or 11 feet, or 12 feet. According to the plan there seems to be a great lot of glass for a small space enclosed. We would sooner have less height in front—say 4 feet or 5 feet.

Be assured that the back wall will be one of the best cards in your hand; but if your plants in tubs are any size, and you enclose only 6 feet, they will be apt to shade the wall too much, and give a little of the bother of the vinery over again. The extra roof would cost little more, and the extra width would give you so much more room to move about. The next is, that a wooden ventilator will answer admirably at front as you propose, and so it would at back, a foot wide, but it will look heavy, and if of the same slope as the glass from the apex under the coping, it will shade the top of the back wall. No doubt, however, it will answer; but if going to the expense of brick foundations for such a nice-looking house as it would be, we would recommend glass hinged ventilators at top. We shall be glad to know what you decide upon, as we are sure your plan will answer.—R. F.]

### ROSE CATALOGUES.

There are few things connected with the literature of the garden of more value and interest to the amateur than a collection of good catalogues. They not only keep him well informed as to the progress and popularity of his favourites, but afford a never-failing amusement, whether in the retrospect of past trials and successes, or in the anticipation of future triumphs. They should also be valuable guides and assistants in planning and arrangements, which they too often are not, being mere meagre price lists. As the most favourable season of the year

for planting and alterations is now progressing, perhaps a few words on the current Rose catalogues may not be considered out of place by the patrons of that favourite flower. For the benefit of such, therefore, I shall proceed to point out those which I consider, and in what features, to be most complete and worthy of notice among the lists of the most eminent Rose firms, by consulting which intending purchasers, experienced or beginners, cannot fail to satisfy their requirements, however diverse or extensive these may be. It may be premised that all the under-mentioned have valuable introductory observations and cultural remarks.

Messrs. W. Wood & Sons (Woodlands Nursery, Maresfield, Sussex), have adopted the most desirable plan of affixing the number of the nursery-tally to every variety. This not only saves time in writing orders, but enables a visitor provided with a catalogue to examine and note plants at his leisure without the necessity of taking a man from his regular employment to accompany him for explanations; the consciousness of doing which by no means adds to the pleasure of inspection.

The catalogue of Messrs. J. & J. Fraser (Lea Bridge Road), may be noted for the judicious and copious selections of first-rate varieties, new and old; the prices, too, are moderate for such superior plants as the firm is known for sending out.

Mr. J. Cranston (King's Acre, Hereford), presents the excellent feature of specifying the habit of each variety, a most efficient auxiliary in the arrangement of borders and beds. He has also his very extensive assortment of H.P.'s and Bourbons into two sections according to merit.

Mr. Wm. Paul's catalogue is extensive in varieties, and in addition to describing the habit of each, it points out certain kinds suitable for cultivation in the neighbourhood of towns; and Messrs. Paul & Son (Old Nurseries), besides the above features, have adopted a separate tariff for half-standards, an accommodation and saving to those who prefer that style of plant. Mr. Cant, of Colchester, has most of the above points, with a smaller selection; and Mr. Rivers has much improved upon his last year's list by adding some interesting information upon individual Roses. Unfortunately from its size his catalogue is not suited for binding-up with others.

Now, what an excellent catalogue might be made were all the above good qualities united into one; still would it not be possible to effect a more satisfactory system of classification for the purposes of cultivators? For instance: suppose that certain well-known varieties decidedly distinct in form of flower and habit of growth should be selected as types of classes, and those possessing similar characteristics arranged under them, colour and minor peculiarities would follow as additional details. Every novelty could then be referred to its appropriate section, and those sufficiently novel and distinct might stand by themselves as heads for future divisions. Some few, of course, would at present stand *sui generis*, but this would not materially militate against the principle of the system. By means of some such arrangement amateurs would be enabled to realise something like an accurate idea of any given flower. At present, without actual sight, purchasing is a mere lottery, too often followed by disappointment and discouragement.

The following, I think, might be taken as representative flowers; each has very prominent characteristics, and a great many of the best sorts might be collected under them:—H.P.'s, Baronne Prevost, La Reine, Lord Raglan, William Jesse, Comtesse de Chabrilant, Jules Margottin, Erêque de Nîmes, Général Jacqueminot, and so on. Among Bourbons, George Peabody or Paul Joseph, Louise Odier, Sir J. Paxton, and Souvenir de la Malmaison. Noisettes, Aimée Vibert and Narcisse. I hardly know which to select for types among the Teas, but any of the large globular flowers and strong growers, and the small flowers with weaker growth might be selected for the purpose.

In throwing out these suggestions I must beg they may be taken merely as hints for the consideration of more experienced and skilful adepts than myself: indeed, it would require a long and intimate acquaintance with the Rose, and wide opportunities for observation and experiment to thoroughly carry out the plan.

I would just venture to hint, in conclusion, that whenever a catalogue is applied for through the post a stamp should be enclosed for its transmission. It is too great a tax upon nurserymen, who present gratuitously to applicants such elaborate and well-put-up pamphlets as modern catalogues usually are, to subject them to the expense of postage in addition.—W. D. PRYOR, *Homerton*.

## GREENHOUSE PLANTS.

*SALVIA GESNERÆFLORA* (Gesnera-flowered Sage).—*Nat. Ord.*, Lamiaceæ. *Linn.*, Diandria Monogynia.—A magnificent greenhouse softwooded sub-shrub, growing from 4 feet to 6 feet high, and bearing throughout the winter months a profusion of large brilliant scarlet flowers, which render it very ornamental. It

has been compared with *Salvia fulgens*, which, however, it does not much resemble, except in the general form and colour of its flowers, and in its habit of growth. It is a stouter plant than *S. fulgens*, having cordate-ovate leaves with an acuminate point, a, more bullate than those of *S. fulgens*, the latter being also

*Salvia gesneræflora.*

much narrower, elongate-ovate, but slightly cordate at the base, and not at all acuminate, *b*. The flowers grow in whorled, simple panicles at the ends of all the branches, and are of a brilliant light scarlet, larger than in *S. fulgens*, but nearly of the same form; the upper lip, however, of the corolla flatter, and less

shaggy, the tube longer, and the style less feathery. From Central America. It was introduced about 1847. Flowers through the autumn and the winter. Introduced by Mr. Purdie, and was first flowered at Syon.—(*Gardeners' Magazine of Botany.*)

## THE FRUITS OF GREAT BRITAIN.

No. 1.—CONSEILLER DE LA COUR PEAR.

SYN.—Maréchal de la Cour; Beau de la Cour; Bô de la Cour.

THIS very excellent Pear was raised by Dr. Van Mons in 1841, and is worthy of the origin from which it sprung.

The fruit is generally above medium size, but that from which our figure was taken is an unusually large one. It is pretty even on its surface, sometimes a little undulating. Skin at first yellowish-green, strewed with dark green dots, thickly covered with cinnamon-coloured russet on the exposed side; so much so as to form almost quite a crust, and permitting only a very little of the ground colour to be shown through it. On the shaded side there is not so much. Eye large and open, with long, stout, and somewhat woody segments, set in a moderate depression. Stalk from an inch to  $1\frac{1}{2}$  inch long, inserted obliquely on the end of the fruit without depression, sometimes by the side of a fleshy lip. Flesh yellowish, very tender, melting and buttery, with an abundant, richly-flavoured juice, which is quite sugary and sprightly, with a fine perfume.

This is one of the best Pears in cultivation. It ripens about the end of October and beginning of November, and is well deserving of general cultivation.

Our figure was taken from a remarkably fine specimen grown upon a standard, and sent us by Mr. George Lee, nurseryman, Clevedon, near Bristol, where it seems to succeed to perfection.—H

SYSTEM EMPLOYED BY M. GREGOIRE-NELIS,  
OF JODOIGNE, IN REARING PEAR TREES

FROM SEED.

THE extraordinary collection of new kinds of Pears exhibited by M. Grégoire-Nélis at the International Fruit Show, on October 8th to 18th, must be fresh in the recollection of the Fellows; and many must have been puzzled to comprehend how one individual should have succeeded in raising so many good kinds. Their wonder will certainly suffer no diminution when it is known that M. Grégoire's plants have not been grafted, but raised on their own roots.

It is notorious, that for one good kind raised by seed a forest of bad kinds appear. It is almost equally so, that it takes nearly half a century to bring a fruit tree grown on its own stock into bearing. The mode in which this long-protracted period of expectancy has been shortened by cultivators has been by grafting the young plants on older stocks, and so endowing them with fictitious age. Yet M. Grégoire's life has not been extended beyond the ordinary span allotted to mortals. He is not an old man. No doubt he has been engaged for a considerable period in prosecuting the experiments whose results have now been exhibited, but not for a period greater than many others. His experience extends over thirty-two years. He ought not, therefore, according to rule, yet to have had a single crop from any of his young trees; but the fact is, that he has tried and adjudicated upon tens of thousands, and from among them he has kept 150 kinds as really good and deserving of preservation. That many of these were so is proved not only by the various kinds raised by him which have already acquired celebrity, but also by many of those now exhibited, whose excellence was acknowledged by the International Pomological Congress at Namur, and by those who saw and tasted them at the International Fruit Show at South Kensington.

He has now communicated his system to this Society for publication. His account is short, and to the point—

1, "He chooses his seeds about the middle of December and January—that is to say, when the Pear is at maturity. He takes the largest."

2, "He sows them in boxes (frames) at the end of January or beginning of February, and when the young shoots have shown four leaves—that is, the two cotyledonous leaves and two others, he pulls them up and cuts away the tap root, as far up as the beard of the root (*recoupe le pivot jusqu'au chevelu*), and replants them in good soil."

3, "He then leaves them for two years in the same place; after that he takes them up again, and again cuts the tap roots (*retranche encore les pivots*). The same operation is repeated every two years, and in this manner he has succeeded in making them produce fruit so early as in six, seven, or eight years."

It is curious to see on how many points our British mode of cultivation corresponds with M. Grégoire's system without having touched it. M. Grégoire attaches much importance to choosing large seeds. He finds that large seeds produce healthy strong plants, and small seeds weaklings, or to use an expression of his own, "*Gros pépins, gros sujets—petits pépins, petits sujets.*" So does the English cultivator. Like M. Grégoire also, they adopt the same time for choosing and sowing the seeds. The usual way here is to take up and pot or replant the seedling when it is about a year old, and in doing so the root is trimmed either accidentally or by design—a treatment which comes very near to M. Grégoire's cutting off the tap root. Again, the young plants are very commonly transplanted every two years, but the roots are not again cut. The system, however, of encouraging the surface roots and preventing the descent of the tap root, if not as old as the hills, is at least as old as the monks who placed flagstones below the roots to compel them to spread. But it does not appear ever to have been applied at the early stages and in the stringent fashion adopted by M. Grégoire-Nélis.

M. Grégoire's experience throws light on a variety of points. For example, he finds that the development, size, and shedding of the spines or thorns borne by the young Pear tree varies much in different trees—some ceasing to produce them in six or eight years, while others do not do so for double the time, and some cease to produce them so early as even three years. He compares their presence and absence to the period of puberty in man, only it is shown in a converse fashion. Man gains his beard on his arrival at puberty—the Pear tree loses its spines.

M. Grégoire's great experience enables him to diminish considerably the period of suspense as to the quality of his seedlings.

In many cases he can tell from the appearance of the young plant whether it is worth giving it a trial or not. If the wood is clear and grey it will probably turn out well; if red or yellow, most likely not.

M. Grégoire's investigations have also enabled him to pronounce with authority upon various questions which have agitated the horticultural world; for example, the system of Van Mons, which found its origin and was mainly supported in the district adjoining the residence of M. Grégoire. This, as most of the Fellows know, was founded on the theory that the successive raising of plants by regular descent improved the breed; that the seed of A produced B, a better kind than A; that B produced C, which was still better; that D, the produce of C, was an improvement on it, and so on. For a time this fancy met with general acceptance. It has still some supporters—but M. Grégoire-Nélie is not among them. It has been already pretty well proved to be nonsense, and it will go near to be thought so shortly.

It only remains to add, that M. Grégoire's statements are free from the bias of personal or at least professional interest. He is merely an amateur horticulturist. By profession he is a tanner, by nature an amiable and intelligent gentleman.—(*Proceedings of Royal Horticultural Society.*)

## MARKET-GARDENING IN WEST CORNWALL.

(Continued from page 613.)

SINCE the first appearance of the disease in 1844 the cultivation of the later Potatoes has gradually declined, till at present it is limited to a small quantity of Scotch Kidneys and Flukes, both of which yield well, and, the latter especially, suffer least from the disease. These are grown, however, rather for private consumption than for the local markets, for the supply of which importation is found preferable.

Whatever may be the cause of the Potato blight, certain it is that no part of England has suffered more severely from its ravages than West Cornwall. The earlier maturity of our crops would, of course, lead us to expect its appearance before it fell on other districts; but here it acts with a power and a rapidity that I never saw equalled elsewhere. Many, indeed, have been the strongly-recommended systems for its prevention or mitigation; but here, carefully applied as they have often been, the result has proved throughout one and the same—viz., the failure of all remedial measures. The only general deductions that I am able to draw from a careful observation of many years are as follows:—that a certain height of temperature is requisite for the rapid spread of the disease; and this I infer from the fact that undoubted blotches of the mildew are constantly seen in April, but not till May do they appear to spread over the field at large. Again, after a few days of overcast moist weather a bright sun develops the blight in its most virulent and rapid form. Lastly, where the tubers are so planted as to have some 4 inches of earth above them, they are found on drawing to have far less disease than those nearer the surface, although the haulm would be equally burnt up.

The early Potato crop is now almost invariably followed by Broccoli, the seed of which is sown in March. The young plants should be pricked-out when 3 inches or 4 inches high, and dibbled-in as the Potato crop is cleared off from May till July. Two sorts only are grown, and the distinction between them is merely that of early and late; the former being ready to cut from the middle of November, and the latter keeping up a succession till the end of April. The rapid growth of the Broccoli plant encourages a slovenly habit of tillage, the Potato-haulm and weeds being seldom raked-off before dibbling, or, as it should rather be termed, spitting-in; as one person inserting his shovel opens the ground, and a woman following places the plant in its position, and fixes it by placing her foot upon it. One hoeing afterwards, and sometimes breaking-up with the shovel, completes the work, the rapid growth following on moist weather overpowering all weeds.

Within the last few years the cultivation of the Broccoli crop has rapidly increased, about 1000 acres being estimated as its extent during the past year; many situations, as will easily be supposed, proving suitable for its growth, where early Potatoes would not succeed.

The white or Cauliflower Broccoli is the only description in cultivation. In such cases, as where this crop does not follow Potatoes, lay ground is generally chosen; and frequently a crop

of hay is taken, and the skim-coulter employed, and the Broccoli then put in with guano. Heavy crops are thus obtained.

The market-gardener thus obtains within twelve months a double return; and the following is an approximate calculation, on an average of seasons, as to the respective costs and profits on his Potatoes and Broccoli:—

Land suitable for these two successive crops will not now be obtained for less than £8 or £9 per acre, and even this price is often exceeded; so that when to this is added the cost of seed, manure, and cultivation, less than £30 or £35 per acre, according to circumstances, cannot be put down to the expense of the Potato crop. The Broccoli, however, goes in, and is taken out at a small outlay; seed, dibbling, hoeing, and cutting not exceeding £3 or £4 per acre. The seed, it should be observed, is universally saved by the growers themselves, that which is purchased being seldom found trustworthy.

A very wide calculation must be made for the returns of the Potato in some years, a late frost causing such destruction that even the value of the seed is not returned. But from £50 to £60 per acre is a probable receipt, for as often would the value exceed as it would fall below these limits. The average produce of a good acre of early Potatoes drawn in the end of May or beginning of June would be from seventy to eighty Cornish bushels (each consisting of three Winchesters), at from 20s. to 28s. per bushel. From this must be deducted the cost of hampers and carriage to the London or the northern markets, with commission, in all not less than from 6s. to 8s. per Cornish bushel. The earlier crops would be worth more, the later less than the above. So uncertain, however, is the produce, and so varied the price realised, that this can only be taken as an approximate calculation. Should the grower, however, be merely recompensed for his outlay, he has his Broccoli to fall back upon. But here, again, his returns, though not influenced by the effect of weather on his own crops, are materially influenced by weather elsewhere. In the winter of 1860-61, for instance, when scarce a Cabbage but was destroyed in all other parts of England, the returns were very large—at least double what they had been in previous years. On one acre of ground the calculation of 9600 plants is near the mark; and this at 1s. per dozen, clear of all costs of carriage, gives £40 per acre. Often as this is exceeded, the average must be put below, and £25 per acre would be a price that growers generally would be well satisfied with.

During the last year production was greatly in excess of the demand, the high prices of 1860-61 already alluded to causing an unusual extent of ground to be put into Broccoli, and the markets were consequently thoroughly glutted. In many cases indeed the returns did not pay for the expenses of carriage.

I do not, however, think that this should be taken as any lasting discouragement, inasmuch as early Broccoli from its immense increase of price from the grower's to the consumer's hands, is yet considered a luxury within the reach of the higher classes only. But surely if the producer can sell with profit at 1s. or even less per dozen, increased facilities of carriage cannot be long in rendering it an article of much more general consumption than we now find it. The subjoined table of the quantities of Broccoli and Potatoes carried on the West Cornwall Railway during the last three seasons will throw much additional light on what has been said on this subject.—W.

WEST CORNWALL RAILWAY.—VEGETABLE TRAFFIC, SEASONS OF 1860, 1861, AND 1862.

(To be continued.)

## SMALL BIRDS.

I AM induced to bring this subject forward again, having a word to say in favour of small birds. I do not say they do no harm, but I think the good they do exceeds by far the damage done by them. In Switzerland, where small birds are relentlessly destroyed, caterpillars swarm. Whole trees are covered with caterpillar cocoons, and look as if a net had been spread over them. The fruit is all eaten, and drops long before it is ripe. Hedges also are covered with these cocoons, and present at times a strange appearance. We should all be extremely

sorry to see our beautiful English hedges spoilt in this manner I am sure, and the most effectual mode of keeping them nice is to protect small birds.—PATELIN.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

TAKE the opportunity of bad weather to tie-up mats, prepare label-sticks, store-up roots, and see that a good supply of covering material is at hand. *Artichokes*, immediate steps to be taken to protect the roots from frost if not already done. In some situations this may not be necessary, but it is best to be on the safe side. *Cabbages*, all that are sufficiently grown to admit of being earthed-up should have it done before severe frosts set in. Red Cabbages for spring use may still be planted. *Cauliflowers*, those now producing heads are very valuable: therefore, the greatest care should be taken to protect them from frost, either by digging them up and planting them in frames, or pulling them up and hanging them in a very cool shed. *Endive*, take up and plant in a frame some of the most forward, so that should severe frosts set in, they would afford a regular supply. *Radishes*, these in some places are required the year round. Where such is the case, it will now be necessary to sow on a slight hotbed; after they are up, air to be given at every favourable opportunity. If they are sown immediately, they will be ready to draw about the end of January. *Rhubarb*, a few old roots may be taken up and planted in boxes or pots, which may be placed in a Mushroom-house or any other place where the heat is about 60°. *Small Salad*, keep up a succession by sowing in boxes about twice a-week.

### FLOWER GARDEN.

The weather is still favourable for executing alterations, and where these are in hand they should be prosecuted with the greatest possible dispatch. Get in a stock of Briars for budding upon next season. Tulip-growers may be reminded that people begin to plant their blooming bulbs, and that if they want any particular sorts they must be quick in their application. All offsets should be in the ground now, and the main beds had better not be delayed. Continue to examine Auriculas, taking off dead leaves, and above all things seeing that the plants are well dried, and have no drip from the frames. Plant Anemones and Ranunculuses for early flowering, but the choice kinds for showing are not put in till February. Plant Hyacinths and early Tulips, Narcissuses, &c., in the open ground, and continue to pot and glass them for forcing. As tree leaves are always in request, either as a fermenting material or for leaf soil, they should at this season be carefully collected. If they are required only as a manure they may be stowed away in any by-place and left to rot; but if they are required as a cheap mode of affording bottom heat, they should be secured somewhere under cover until wanted for use.

### FRUIT GARDEN.

Make up all vacancies in the Gooseberry and Currant department. All trees of these kinds should have a clear stem of at least 18 inches high; the old plan of growing them near the ground is objectionable for many reasons. The plan of rearing some, pillar-shape, from 8 feet to 10 feet high is adopted by Mr. Tombs, gardener to Major-General Fox, Addison Road, Kensington, and is one by which a great saving of space is effected. They are kept spurred-in from bottom to top, and bear abundantly. Pruning to be now carried on in earnest with Pears, Apples, Plums, and Cherries, and nailing should be commenced. Lay the wood in regularly, using as few shreds as possible, and adapting the size of the shred to the size of the wood. The standards in orchards will also require attention. If the heads of these were kept well thinned-out, that the air and sun could reach the whole of the branches, there would be much finer fruit—a much cleaner and more healthy appearance.

### STOVE.

Let the resting section of Orchids settle quietly down towards their habitual repose, by withholding water at the root, and by diminishing the amount of atmospheric moisture, by permitting a liberal ventilation in favourable weather.

### GREENHOUSE AND CONSERVATORY.

Very little water will be required here at present, but the plants should be carefully looked over twice or thrice a-week, so as to be sure that no plant is allowed to feel the want of it. If not already done, get the plants tied with the least possible

delay, for it is rather difficult to tie a plant so that it will not look somewhat stiff and irregular, and the sooner such attention is paid to them the better they will look when in bloom. If such things as Geraniums, Cinerarias, and Calceolarias, must be wintered in the same house with Heaths and other hard-wooded plants, they should be kept as much as possible by themselves, as they will require a somewhat closer atmosphere than hard-wooded plants. Roses for early forcing to be pruned by this time, and placed where they will be safe from heavy rain. Where American and other shrubs are used for forcing, they should be taken up and potted without delay, placing them in a cold pit until they are wanted for forcing, or in a turf pit where they can be protected from severe weather by mats, straw, or other covering. Fires to be lighted occasionally in damp weather to dry the house, and air to be given only when it is dry outside.

### PITS AND FRAMES.

All stores intended to be wintered in these structures should now be finally arranged as soon as possible. A dry atmosphere with a liberal amount of ventilation when the external air is dry are the requisites. A useful hint may be taken from the Verbenas in the borders which remain out. How often do we see these plants green through a great portion of the winter. They are well established at the root, and would withstand a moderate dry frost much better than a damp and confined atmosphere.

W. KEANE.

## DOINGS OF THE LAST WEEK.

THESE have almost been a repetition word for word of last week. With the exception of getting Strawberries under cover, sulphuring an orchard-house, &c., little has been done except potting and moving plants so as to make them more secure; getting all flower-pots cleaned and under cover before frost should crack them in their wet state, and in fine days root, pruning a few trees which were rather strong. It has been too wet to do much out of doors. The Dalilias are now levelled, but I like the roots to remain a little in the ground afterwards. We will be at them the first fine dry day, and then clear the beds.—R. F.

## TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

FRUITS FOR JERSEY (*J. Levesque*).—Apples for kitchen use—Dumelow's Seedling, Golden Noble, Bedfordshire Foundling, Alfriston, Rymer, Hambleton Deux Ans, Yorkshire Greening, and Small's Admirable. For dessert use—Kerry Pippin, Cox's Orange Pippin, Golden Russet, and Nonpareil. You will find all the prize Lancashire Gooseberries described in Dr. Hogg's "Fruit Manual," which you can have direct from this office by enclosing forty-six postage stamps.

DIGGING GROUND BY THE ACRE (*W. H.*).—The Hop gardens in Kent are dug by the acre, the usual price being from 16s. to 20s. per acre. They are dug shallow with the fork, and the turned-over part is not touched again by the digger. To dig "very stiff" garden ground, if well done, might be worth nearly double the above amount, especially if dug a fair depth; much depends on the quality of the work done. The fork is a better digging tool than the spade in all soils except the very sandy and light ones.

ASPARGUS CULTURE (*A Constant Reader*).—From your want of success in past years we fear your soil is not suited to the growth of this plant. If it is a stiff clay, through which water will hardly percolate, a thorough draining will be the first thing; afterwards burn a part of the clay, and mix with the top soil, which ought to consist of about 18 inches of good staple soil. Digging in large quantities of sand or lime will be useful, and if you can get anything like a loose, open, sandy soil, you may then improve it much by frequent dressings of salt; but salt is far from possessing all the properties alleged of it when given to ground of a stiff, clayey nature, as it only increases the moisture, and renders the ground sour, and less likely to part with it. By first rendering the ground open and perfectly porous, you may apply salt, which, in addition to improving the plant, will destroy the wireworm you complain of.

head. All have largely increased their value in money. This is not the only advantage. Poultry was formerly thought unworthy the notice of any but those small and needy agriculturists who were driven to any expedient to eke out the rent, or to the happier class who having secured a competency in town, went into the country to spend it. But with exhibitions came different ideas, and men of education and judgment became poultry amateurs. The influx of the aristocracy and the list of names among the competitors proved the pursuit was not a degrading one, and numbers took it up. Professional men found it a pleasant relaxation. It was a relief for the overtaxed brain, or the weary frame; it broke the monotony of business or the office, and first-class men looked at the clock to see if the time was at hand when they were free to attend to their poultry. This could not be without its good effect. Medical men brought their knowledge to bear on cocks and hens; they gave their opinions to others who carried them out, and the result has been evident for years. In the early days of poultry shows it was a published rule that diseased birds would be removed, and we have a vivid recollection of a row of empty pens at the Show at the Surrey Zoological Gardens labelled, "These birds removed, being in a diseased state." Such a thing never occurs now: stock has been more carefully bred, and preventive measures have been adopted, so that it is rare to see a diseased pen at a show; and roup, such as used to call for removal, is never now seen. Fowls have been bred for every climate; gardens and societies of acclimatisation, here and abroad, have sprung up, many of them owing their origin to Bingley Hall. The meeting about to be held may be proud of the part, and fairly ask for continued and increasing support in future.

#### COTTAGERS' CLASSES.

A CORRESPONDENT asks why there are none of these in the Birmingham prize list. We are not in a position to speak in the name of that Council, but we know what the result has been elsewhere. We lately reported the Northamptonshire Show at Stamford: for a liberal cottager's prize list there was but one entry. In the early days of these shows proprietors of "cottage-ornées" thought themselves eligible, and the cottager often paid £50 rent, and inhabited a twelve-roomed house. Then the entries were numerous; but when competition was restricted to those who did not pay more than £6 rent, there were no entries. There are many reasons for it: one is that it is true of poultry shows as of churches—if they are to be devoted to the poor exclusively they will have nothing to do with them. Let there be a mixture, and they like both, but they do not approve of competing only with their fellows. We know in a camp that, owing to a schism, two houses were patronised exclusively, one by non-commissioned officers, the other by privates. The separation lasted but a short time; the privates were less numerous every evening, and those who left all went among their superiors. This may be one reason; another is that English cottagers are not poultry-keepers, with the exception of those who live near commons, and they keep Geese. As a rule they have no space for fowls; they trespass, and neighbours complain. Many employers forbid their men to keep poultry, thinking it a temptation to dishonesty, as the food is lying about, and encourages a beginning of "just a handful." When the prizes were awarded they seldom went to the class for whom they were intended, and for these reasons committees have almost everywhere ceased to offer premiums.

#### MIXING VARIETIES IN ONE CLASS.

HAVING seen several letters in the *Poultry Chronicle* under the above heading, perhaps I may be permitted to say a few words. I believe Mr. Ballance was the first; and as he has been so connected with the poultry exhibitions, one would have thought that he must have been aware of the difficulty a committee has to contend with in trying to please all parties in the drawing-up of their schedule of classes and prizes. Having been through it myself I know, or ought to know, something about it.

My view of the matter is this, that the main objects to be carried out in a poultry show are usefulness for table and egg-laying, and for the committee to give such prizes as shall cause a stimulus amongst breeders of such birds. Now, for instance, a committee (local) meet to draw-up their prize list. We will suppose they have from £50 to £60 to give away in prizes, and, of course, to give liberally. They pass unanimously the first five or six renowned classes of the day, then comes the trial

Mr. A. keeps Minoreas, Mr. B. Andalusians, and Mr. C. Malays. Now, of course, you must have a separate class for each, or else these three worthies will not support our show; but Mr. D. says, "I keep the Silkies, and, of course, you will have a separate class for them;" so that really the committee got so bewildered that they are compelled to throw them all into one class, not having sufficient funds, and not knowing where to draw the line, and finding it utterly impossible to please everybody.

Perhaps the parties who have found fault respecting the classification of shows after they have attended a few meetings may know better.—E. J.

#### POULTRY EXHIBITIONS CLASHING.

WE once more warn committees against holding their exhibitions simultaneously. Doing so diminishes the numbers of entries; the best birds cannot beat two shows on the same day; the most experienced judges cannot officiate at both; amateurs and dealers cannot hurry from one to the other; nor can we provide reporters gifted with ubiquity.

If a committee finds that it has fixed upon days for an exhibition that have also been selected by some other committee or committees, that committee should correspond with them upon the subject, and all should be ready to yield for alterations of date that may be most conducive to the success of each show. This is not only a dictate of common sense, but of self-interest.

#### GLASGOW POULTRY AND PIGEON SHOW.

THE city of Glasgow's first annual Poultry and Pigeon Show took place on the 4th inst. in the Trades' Hall. There was a large number of exhibitors, and the Show was a most excellent one.

The following is the list of awards:—

- DORRING.**—First, Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Second, J. F. Newton, Kirby-in-Cleveland, Yorkshire. Third, C. Whitwell, Tolson Hall, Kendal. Commended, D. Logan, Netherton, Renfrew.
- CHICKENS.**—First and Second (Medal), J. Linning, Glasgow. Third, D. Dougal, M.D. Strathaven. Highly Commended, D. Dougal, M.D.; A. Paterson, Airdrie. Commended, J. Anderson, Meigle; D. Logan, Netherton, Renfrew.
- SPANISH.**—First, W. Wilson, jun., Beith. Second, F. Somerville, Edinburgh. Third, W. Jamieson, Busby. **CHICKENS.**—First (Medal), W. Wilson, jun., Beith. Second, M. Gilmour, Inchinnan, Paisley. Third, A. Paterson, Airdrie. Highly Commended, F. Somerville.
- GAME (Black, Brown, and other Reds).**—First, C. W. Brierley, Rochdale. Second, Miss E. Beldon, Bradford. Third, W. Robertson, Polmadie, Glasgow. Highly Commended, W. Robertson; J. London, aen., Wishaw.
- GAME (Any other variety).**—First, Miss E. Beldon, Bradford. Second, C. W. Brierley, Rochdale. **CHICKENS (Any colour).**—First, J. H. Mc'Nab, South Arthurrie, Barhead. Second, W. Robertson, Polmadie, Glasgow. Third, J. Anderson, Meigle. Medal, G. Baily, Waterloo Road, London. Highly Commended, W. Miller, East Bay, Gourcock.
- OLD SCOTCH BREED.**—First, J. Horner, Bosby. Second, A. Watson, Bosby. Third, T. Clarkson, Newmaids, Wishaw. **CHICKENS.**—First, J. Kilpin, Mearns. Second and Third, W. Thompson, Glasgow. Highly Commended, J. G. Brown.
- COCHIN-CHINA.**—Prize, A. Paterson, Airdrie. **CHICKENS.**—First and Third, A. Paterson, Airdrie. Second, J. Sharp, Johnstone.
- HAMBURGH (Golden-pencilled).**—First and Second, J. Lindsay, Thornhill, Stewarton. Third, J. Holborn, Stewarton, Ayrshire. Highly Commended, R. Cunningham, Stewarton.
- HAMBURGH (Silver-pencilled).**—First, A. Yuill, Airdrie. Second, W. Cannon, Bradford, Yorkshire.
- HAMBURGH (Golden-spangled).**—First, W. Cannon, Bradford. Second, J. Wilson, Glasgow. Third, W. Robertson, Polmadie, Glasgow. Highly Commended, J. Holborn, Stewarton, Ayrshire.
- HAMBURGH (Silver-spangled).**—Second, Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Third, W. Cannon, Bradford. Highly Commended, R. Cunningham, Stewarton.
- HAMBURGH (Any colour).**—**CHICKENS.**—First, W. Robertson, Polmadie, Glasgow. Second, H. Pollock, Rutherglen. Third, J. Lindsay, Thornhill, Stewarton. Highly Commended, W. Robertson; J. Stewart, Springhill, Barhead.
- POLAND (Any colour).**—First, A. Yuill, Airdrie. Second, Miss E. Beldon, Bradford. Third, D. Brown, Glasgow. Highly Commended, J. Stevenson, Chapelhill, Airdrie; W. Robertson, Polmadie, Glasgow.
- ANY OTHER DISTINCT BREED.**—First, Mrs. M. Seamons, Hartwell, Aylesbury. Second, E. Hutton, Pudsey, near Leeds. Third, J. Jamieson, Corsehill, Stewarton.
- BANTAMS (Game).**—First, C. W. Brierley, Rochdale. Second, Miss E. Beldon, Bradford. Third, J. Anderson, Meigle. Highly Commended, M. Linning, Glasgow.
- BANTAMS (Any other variety).**—First, C. W. Brierley, Rochdale. Second, A. Paterson, Airdrie. Third, J. Anderson, Meigle. Highly Commended, E. Hutton, Pudsey, near Leeds; J. E. Linning, jun., Glasgow.
- DUCKS (White Aylesbury).**—First and Third, Mrs. M. Seamons, Hartwell, Aylesbury. Second, W. Robertson, Polmadie, Glasgow. Highly Commended, Miss W. Ogilvie, Meigle. Commended, T. Clarkson, Newmaids, Wishaw.
- DUCKS (Rouen).**—First and Second, Mrs. W. Whitehead, Kingsland Road, London. Third, W. Whyte, Glasgow. Highly Commended, J. Isaac, Drumpeller, Coatbridge.

Ducks (Any other variety).—First, Mrs. W. Whitehead, Kingsland Road, London. Second, J. Anderson, Meikle, Third, E. Hutton, Pudsey, near Leeds. Highly Commended, J. Jamieson, Corschill, Stewarton.

TURKES.—First and Third, W. Robertson, Glasgow. Second, D. Brown, Glasgow.

GESE.—First, J. Jamieson, Stewarton. Second, D. Brown, Glasgow.

SWEETSTARS FOR GAME COCKS.—First, J. Mollison, Meikle. Second, J. London, sen., Wishaw. Third, W. Robertson, Glasgow. Highly Commended, H. Chaworth, Musters, Dunnach, Oban.

FIGHTONS.—*Powers*.—First and Second, J. Miller, Camlachie. Third, J. Paton, Stewarton. Highly Commended, W. Neilson, Johnstone; W. Ranken, Glasgow. Commended, W. Neilson, Johnstone. *Carriers*.—First, W. B. Haansbergen, Newcastle. Second, H. Martin, Glasgow. Third, J. Miller, Camlachie. Highly Commended, J. Sharp, Johnstone; A. S. Sylvester, Birmingham. Commended, J. Miller, *Fantails*.—First, J. Miller. Second, A. Paterson, Airdrie; Third, H. Yardley, Birmingham. Highly Commended, J. Kinloch, Glasgow. *Jacobins*.—First, A. S. Sylvester, Birmingham. Second, A. Morrison, Glasgow. Third, J. Miller, Camlachie, Highly Commended, J. R. Rennards, Helensburgh. *Short-faced Tumblers*.—First, J. Miller, Camlachie. Second, A. Sylvester, Birmingham. Third, W. B. Haansbergen, Newcastle. Highly Commended, H. Martin, Glasgow. *Common Tumblers*.—First, F. Pinkerton, Calton. Second and Third, A. Morrison, Glasgow. Highly Commended, J. R. Rennards, Helensburgh. *Any other variety*.—First and Second, J. Miller, Camlachie. Third, H. Yardley, Birmingham. Highly Commended, A. S. Sylvester, Birmingham. Commended, W. B. Haansbergen, Newcastle.

EXTRA STOCK.—*Game Cock*.—Prize, J. James; also, Highly Commended, for one Silver Hamburg cock; and Commended for two Game hens. *Turbits*.—Highly Commended, J. McGraw; also, one *Powder Cock*. *Golden Pheasant*.—Commended, D. Brown, Glasgow.

JUDGES.—For *Poultry*, Dr. Stevens, Ardrossan; Mr. J. Price, Glasgow; and Mr. W. C. Hardie, Carron Ironworks, Falkirk. For *Pigeons*, Mr. M. Stewart, Glasgow, and Mr. J. Cochrane, Glasgow.

## THE EXHIBITION WEEK IN BIRMINGHAM.

WE have pleasure in stating that the entries for all departments of the forthcoming Show in Bingley Hall are in every respect satisfactory. Of cattle, the number, we believe, are greater, with one exception—the year 1851—than those for any previous exhibition. There will also be an unusually large number of sheep; the classes for fat sheep and for the Silver Cup offered by Messrs. Mapplebeck and Lowe, being well filled; and this is the case also with the classes for single ewes—which form a very useful addition to the other features of the Show. The pigs will muster to about the same extent as last year. There is, however, it will be noticed, a considerable falling-off in the entries of roots, which was to be expected from the peculiarly unfavourable nature of the season.

The collection of domestic poultry will, as usual form an important and most attractive part of the Exhibition; and we believe that there will be so strong a competition in all the principal classes as will prove that amateurs in all parts of the kingdom are pursuing with increased attention that interesting branch of rural economy which has been so greatly benefited by the establishment of the pleasant meetings at Birmingham.

We can also report favourably with regard to the Exhibition of dogs, to be held during the same week. We have not at present received a complete return of the numbers, but we believe the total will not be far short of six hundred. All the principal classes will be well filled; and in the two divisions we may hope to see the finest collection of dogs that has ever been brought together in England. This Exhibition, like the Cattle and Poultry Show, appears to be firmly established in public favour; while its promoters have, by the judicious and honourable manner in which they have carried out all their plans, obtained the full confidence of those upon whom they must mainly rely for success. We may add that the situation of the building now erecting for the purposes of the Show will be in all respects most convenient for visitors, being in the direct line from the railway stations to Bingley Hall.

There is yet another Exhibition in what we usually call "The Cattle Show week," that of Fruits, Chrysanthemums, Camellias, Gourds, &c., in the Town Hall. We have, from the first announcement of this Show, looked upon it as an experiment deserving the utmost encouragement. The increased attention which is now devoted to the cultivation of fruit, both in orchard-houses and in the open garden, renders competitions like that we are about to witness in every way desirable, and especially to show, which they will do, what may be accomplished in particular localities. A more plentiful supply of fruit for sale, and that of a higher quality, is also much needed, and especially by dwellers in towns, who must purchase all they want. With regard to the general supply of the products of the country, there may be but little to complain of in Birmingham, for instance; but as respects fruit we are, we believe, in a worse position than many small

country towns. Applications for space at the forthcoming Show must be made not later than the 20th instant.—(*Midland Counties Herald*.)

## LEEDS AND WEST RIDING HORTICULTURAL AND POULTRY SHOW.

IN your last Journal you copy a paragraph from the *Leeds Mercury*, and comment thereon. I think, in justice not only to myself but others, I ought to offer some explanation through your columns.

About the middle of last spring I was requested by Mr. Edward Holdsworth and Mr. John Wade to become a member of the Committee: this I consented to do, and found upon attending my first meeting that the affairs of the Society were managed by a Committee, Treasurer, and two Secretaries, John Wade representing the horticultural department, and E. Holdsworth the poultry.

In the course of a month or so a list of patrons was obtained, a President elected, and the prize lists printed; when, in consequence of certain circumstances (which I have no need to make public), Mr. Holdsworth was requested to resign, and I, unfortunately, was induced to succeed him.

As your Journal pointed out at the time, the Poultry Show was a great success; but I regret to say that financially it was a miserable failure. In consequence of the combined attractions of the annual fair, and a trip to the International Exhibition, we had a very limited attendance of visitors, receiving only £19 at the doors; and although patronised by the principal nobility and gentry of the county, except in a few instances the loan of the use of their names was all that they would or did do for it.

At the close of the Show I called a meeting of the Committee, and laid a statement of the accounts before them, and explained that if each member of the Committee paid between £5 and £6 everything could be paid at once, and the affair quietly wound-up: this, however, they declined to do, stating that they had paid as much as they intended to do, and that I should either have it all to pay myself, or leave it unpaid. I then informed them that I should take the only honourable course left me—viz., to hold myself responsible to pay everything connected with the poultry department which had been ordered since I became Honorary Secretary, including the prizes, and that I considered it very ungentlemanly of them after inducing me to join their Society to leave me to pay for their amusement; and that I should expect Wade to pay the remainder, as he and his brother (the Treasurer) held all the funds that had been collected previously to the Show.

About a month after this Mr. B. W. Sharp, printer, Briggate, called upon me for the settlement of his account, stating that he had been sent by Wade. I told him that I had already paid more than I had received, and was only going to pay those accounts which had been incurred since I became Secretary, and that Wade had funds in hand, since I could hear of no instance of his having liquidated any of the claims made upon him for prize money, &c., for the floral department; and I advised him, Mr. Sharp, to enter the affair into the County Court, when I should put in a plea of infancy and throw the responsibility upon Wade, and by these means get at least part of the funds out of him. This Sharp agreed to do.

In due course the day came for the hearing of the case, when Mr. Sharp was most distinctly informed by my solicitor that if the law failed to make Wade pay, although I was not in the least responsible, I would see it paid; and the Judge on hearing the particulars ordered Wade to pay the account.

The paragraph which you inserted last week was communicated to the *Mercury*, and is very one-sided, and calculated to throw the disgrace of the affair upon me.

Mr. Ferns' statement that my father had got £15 of the funds is simply absurd, and I should like either Mr. Ferns or Wade to say where he got it from. He did obtain promises of subscriptions for £14 or £15, but succeeded in collecting only about £7 10s., which was handed over to me and paid away long ago.

The report also says that Wade denied that I had paid £107 and received only about £60. I never heard him deny it; and even if he did, I do not see how he could be in a position to do so, because I have had no communication whatever with him since the committee-meeting after the Show, when I left him and his friends in disgust after having failed to induce them to pay their share of the loss.

Wade stated that he had not received one penny of the funds. Now, you will agree with me that it is impossible for a man to be secretary of a flower show, and still never receive a single penny. Allow me to ask Mr. John Wade who received the entrance fees for the floral and horticultural department of the Show? He received the entries, and no doubt received the entrance fees with each entry, as I had nothing whatever to do with that part of the Show. But this is not all. Wade and his brother who officiated, as I said before, as Treasurer, received all the monies obtained up to the day of the Show (excepting only the poultry entry fees), including a £1 subscription from each member of the Committee. I paid my £1 into John Wade's own hands, and yet he says he never received a penny!

I hope I understand you rightly, when you say that the committees of poultry shows are bound in law to pay all just demands connected with such exhibitions. Can I sue each member of the Committee I have to deal with for his share of the loss?

I hope, however, that my case may be a warning to any gentleman who is about to undertake the office of secretary to a poultry show, to make his committee guarantee him something like the expenses before going any further with the affair.

After this I am sure you will agree with me, that although inexperienced it will teach me in future, before I again act as secretary for any society, to ascertain as far as may be the character of the men that form the Committee.—GEORGE NEWTON, *East Street, Leeds.*

[This statement needs no comment. Taking for granted that its particulars are correct, the Committee clearly are bound in honour to bear their proportions of the loss.—EDS.]

### FRAUDULENT EXHIBITORS.

In the article last week we have shown that the committees of exhibitions cannot avoid paying the debts and liabilities they incur as officials, and we will now place before them an example they will do well to follow in resisting and punishing unfairness on the part of exhibitors. In the case which follows, the unfair exhibitor was so indiscreet as to sue the Committee for withholding a prize from him, to which by the letter of the Society's rules he was entitled, but which the Judges withheld from him, and justly withheld from him, on what they considered a fraudulent attempt to deceive. A convicted felon forfeits all his property, and by a parity of justice a fraudulent exhibitor forfeits his title to each and any prize that may have been awarded at that show. We would go further, and advise all committees to add the following to their rules:—

"No one who has been adjudged by a Society's officials guilty of fraudulent practices, can be allowed to exhibit; or, if inadvertently permitted to exhibit, will he be allowed to retain any prize which may be awarded to him."

#### HUGH DICKSON, NEWTOWNARDS, v. THE MEMBERS OF THE DOWNPATRICK HORTICULTURAL SOCIETY.

At the Newtownards Quarter Sessions, on Tuesday last, an action was brought, as the process stated, "for that plaintiff, being a subscriber to a certain body, society, or association calling themselves 'the Downpatrick Horticultural Society,' and also an exhibitor at the Downpatrick Horticultural Exhibition, and, as such, became entitled to, and was duly adjudged and awarded by said society or association at their last exhibition in Downpatrick, for certain agricultural and garden produce exhibited thereat by him, a silver challenge cup, value £10 10s.; ten prize certificates; a barn barrow, value for £1; and 10s. as a first-class prize for six parsnips." The plaintiff averred that the defendants refused to deliver up said prizes, although demanded, and his claim now was for a return of same, or the value thereof.

Mr. Dinnen, in opening the case, said it was an action brought by Hugh Dickson, who is a farmer in Newtownards, against the defendants, the Committee of the Downpatrick Horticultural Society, and also against the Secretary of the Society. It was an action of detinue, in consequence of the defendants withholding from his client certain prizes which were awarded to him by the Judges at the late Show of the Society in Downpatrick. The plaintiff was an exhibitor not only at the last Show, but also at the previous Shows of the Society, and was a competitor for the silver challenge cup on the last occasion. The cup was value for £10 10s., and it should have been awarded to the person

taking the largest number of certificates, two second prizes being of equal value to a certificate. The rules of the Society were to the effect that the cup should be given to the competitor who obtained the largest number of prizes, the competition to be confined to farmers belonging to County Down. As his Worship would see from the rules of this honourable Society, the more successful competitor at the previous Show must have held the cup in his possession during the past year, which his (Mr. Dinnen's) client did; but to become the final holder it was necessary that he should again be the winner of it. The plaintiff was a very successful competitor, and had carried off a great many prizes. The Judges had inspected the produce he exhibited, beans and vetches, and deliberately gave their opinion, awarding to Mr. Dickson the silver challenge cup. The class was open to farmers holding thirty-one Irish acres or upwards, or gentlemen who kept land stewards. After enumerating the different classes in which his client had been successful, Mr. Dinnen went on to say that Mr. Dickson had obtained the majority of prizes at the Exhibition, and that, even if the challenge cup were taken from him, he would still have far outnumbered the other competitors. However, after the certificate had been given by the Judges, when the card was put on the articles it was considered the final decision; it was considered that the prize had been awarded to the article on which it was so placed. On the card being placed on the beans, some rival competitor made an objection to the prize that had been awarded to Mr. Dickson. These beans, it appeared, had been very nicely and very artistically fixed and arranged, so as the better to show them to the Judges and the public. Now, although the thing had been done without his client's knowledge, it appeared that some one in his establishment (he believed his son) used a small wire to fasten on some of the pods which had fallen off the stock. The Judges had examined this article, but the rival, who thought he had discovered a mare's nest, took objection to it. Without any notice, and behind his client's back, the Committee came to an agreement that they would expel him from the Society, and would not give the cup to him, which he had fairly won. Suppose his Worship would hold that these beans had been improperly put up, he would say it was very unfair and very disreputable on the part of the Society to withhold the cup when his client had taken the majority of prizes. He had taken no less than eight or nine over and above his rival. The question, however, would turn on the Society, to which he would claim his Worship's attention. The seventh rule said that the Judges had power to award first and second prizes, according to merit, or withhold prizes altogether, if they did not consider the articles worthy, and that their decision in all cases should be final. He considered, therefore, that the Committee had nothing to do with the matter. The Judges' finding was final and conclusive. If his Worship would hold that the case in question came under the ninth rule, in which it was stated that all disputes and objections should be referred to the Committee, then he would say that the objection or refusal of prizes applied only to the beans; and he, having the majority of prizes, leaving out the beans, was clearly entitled to the cup, however valuable it might be, and however much the Society might wish to retain it in their possession.

Hugh Dickson, the plaintiff, was examined by Mr. Dinnen. He deposed—I was a member of this Society, and paid my subscription. Last year I competed for the challenge cup, which I had in my possession the previous year. I was an exhibitor at the last Downpatrick show. I competed for potatoes and barley, and got first prizes. I got first prizes for the beans and vetches, but they were taken off again. They are the same as those for which I received prizes at the Newtownards Show previously. [The witness enumerated the other prizes which he had received.] With the exception of the beans and vetches, I had eight first prizes and three second prizes. I was not aware that there was any wire used with the beans and vetches. To the best of my knowledge there were no pods on the beans but those which belonged to them. I got no notice that the Committee were going to investigate the matter. Mr. Carter told me on the day of the Show that he would call a meeting, and that he would send me a note.

Cross-examined by Mr. Murland—I believe this paper to be in my handwriting. [This was a certificate that the articles of produce had grown on Mr. Dickson's farm, and that the produce was fairly exhibited.]

Mr. Murland said he would now state what the case of this Society was. His Worship had heard what the rules were, and

he knew that it was impossible for judges going round to detect fraud in the articles exhibited. This and other societies of the same kind were entirely in the hands of the contributors as to whether they honestly brought forward their articles. Indeed such Societies must depend on the honour of their members. The beans were exhibited by Mr. Dickson in a sort of sack, for the purpose of exposing them the better; and in this way the pods appeared very numerous, upon which the awarding of the prizes depended. The Judges went round, never suspecting that the pods upon which they looked had been put on by the competitor's own hands. There were a good deal of articles exhibited by this Mr. Dickson, and by the way in which they were put up depended the prizes. In the course of the day an objection was put forward which called the attention of the Judges to the beans. Upon examining them, they found one of the most ingenious devices that could be contrived for the purpose of showing more pods on the stalk than really belonged to it. The pods, as his Worship could see, could not drop off when the stalk was green. Holes had been cut in the stalk, and beans which had never grown upon it were fixed in; and the Judges found this so fraudulently and so disgracefully made up that they said, "We withdraw this prize," and reported it to the Committee. They were very indignant. That fraud disentitled him to a place in the Downpatrick or any other Society. The Committee met, and said, very properly, "We shall not give the prize to this Mr. Dickson. He is guilty of a gross fraud; and, having been detected, we shall give him no prize." In the vetches there was also a kind of fraud perpetrated. The whole stalk should have been shown; but the bare parts had been cut off. Now, it had been called a disreputable Society for not giving Mr. Dickson all the prizes. If the plaintiff himself did not fix the pods on the stalks, he was liable for the fraud. The Judges at once told the Committee that he was not entitled to any prizes. Mr. Murland read a portion of the Society's rules as to all disputes being referred to the Committee, and concluded—Mr. Dickson, as a member of this Society, is bound by, and a party to, the making of these rules. Now I would say that there was a dispute in this instance whether the cup should be awarded to a member of the Society or not; and it was the unanimous opinion of the Judges and Committee—a very large one—that the cup should not be awarded to him. No punishment that the Society could inflict upon this man would be sufficient for the offence, because it strikes at the root of all honesty. If this be allowed to go unpunished, a man can take his beans in this way and endeavour by means of fraud to make his farm produce far better than his neighbours'. Nobody can tell whether the good produce has got the prize or not. If ever there was a case in which there was a breach of good faith, this is one of them.

His Worship—Do the Judges concur in the views of the Committee?

Mr. Murland—Perfectly. Mr. Murland also read extracts from "Addison's Law of Contracts."

His Worship thought the Committee had a perfect right to investigate the matter, as, by their rules, all disputes were to be referred to them. That was his view of the case, and, if he were correct, it would put Mr. Dinnen out of court.

Mr. Dinnen—If the Judges have rescinded all the awards they have made, then, your Worship, you would be right; but they have not done so.

His Worship considered that the Judges were subject to the Committee; and he did not think it necessary to go into what the Judges had done.

Thomas Taylor examined by Mr. Murland—I was one of the Judges at the late Show in Downpatrick, and my attention was drawn to the beans on the day of the Show. Under the place where the pods grew from the stalk a hole had been put in, and pods were attached with wire where pods never grew. It was a complete fraud. When inspecting, we first look at the stalk generally. They were very artistically put up. I told the Judges the beans were fraudulently made up. Mr. Dickson came up and told us to examine the stalk, and said there was not a solitary pod on it which had not grown on it. He persisted so strongly that I was about to give him into custody. We also examined the vetches, and found that they, too, were fraudulently put up. I directed the Secretary to withhold the cup till such time as the case would be inquired into.

Cross-examined by Mr. Dinnen—Are you not ashamed of yourself now?—No. Are you not ashamed of passing over these, and giving them the prize?—I am not, they were so artistically

put up. I will swear that the pods could not have belonged to the stalk—there were more pods than belonged to the stalk.

His Worship—Were there any places which might have had pods, and had been broken off? Witness—No, I believe not.

Mr. Dinnen—Do you happen to know that the wires would present the beans to the Judges in a better position? Witness—I don't know. We don't grow beans here with wires in them.

Mr. Dinnen—Were you at Newtownards Agricultural Show? Witness—I was not.

Mr. Dinnen—Well, you should have gone to it, for it was a better Show than at Downpatrick. Would you be surprised if the same vetches got the prize at Newtownards? Witness—I would not. I don't know if the plaintiff had the majority of prizes. He had a great many. This card [a prize card produced] was put on some of the articles.

His Worship said—I am still of opinion that we have no right to go into the grounds of the Judges' decision. If they say to the Committee, "Withhold the prize from this man" we cannot go beyond it. In deciding in this way, I could, of course, go on and fortify my decision, because there would be another point—if this is not a case of contract—and we do not want to go into that. The whole matter is an entire contract, and one party coming into this court in this way to sue another would need to do so with clean hands.

Mr. Dinnen—Well, sir, I do not wish to press this case further; but, when the Judges do not withdraw the other prizes, I think they have no control over this challenge cup.

His Worship—I believe, if the Judges think it right to withhold the cup, we have nothing more to do with them.

The case was dismissed.—(Northern Whig.)

## DO BEES VARY?

THE insertion of Mr. Darwin's inquiry in the German *Bee Journal* has elicited the following reply from Herr Kleme, pastor of Lüethorst, in Hanover, and one of the ablest apiarists in Germany.—A DEVONSHIRE BEE-KEEPER.

"DO BEES VARY IN THE DIFFERENT PARTS OF GERMANY?"

As Mr. Charles Darwin desires the apiarist experiences of German bee-keepers on deviations of bees amongst each other, this must induce them not to withhold their observations on this point. I fear, however, that these will not give any particular aid to his known theory. For although we possess in the one species, *Apis mellifica*, two different races\* the distinctions of which have proved constant from antiquity, yet amongst these no essential deviations have appeared.

"No animal has drawn the undivided and continual attention of mankind to itself in the same degree as the bee; and no animal have observations been preserved to us from such antiquity, long before our era, more carefully and extensively than on her; but yet we find no change in her. We find that in every climate and under all circumstances she has always remained the same; has kept shape, character, manners, and customs unaltered; so that it is, therefore, impossible for us to be able even to follow the traces of her extension by degrees over the old world; and although man has brought bees into his own neighbourhood from time out of mind, yet has domestication had no influence on their way of life. In the wild as well as in the so-called tame state, in the garden, forest, and wander-bee-keeping have they remained faithful to their original manners and customs, and departed not one tittle from the way pointed to them by instinct.

"And so it is also with their inner and outer shape. We find them at present exactly the same as Aristotle, Pliny, and Virgil, Reaumur and Swammerdam, have described them to us. I know the bees not only of almost all the provinces of Hanover, but also those of the different countries of Germany, in the east and in the west, in the south and in the north. From my own observation, however, I have not been able to perceive a specific difference in size anywhere. The inexperienced indeed are easily deluded; an empty or a full stomach, more or less hair, makes one bee appear larger or smaller than another without her really deviating in the least from her normal size.

\* By this are meant *Apis mellifica* and *Apis Ligustica*, which are considered in Germany to be mere varieties of the same species.—A DEVONSHIRE BEE-KEEPER.

"Deviations in size happen occasionally, but (which is the main thing), they are not specific—not constant. The reasons thereof may be of different kinds. Sometimes old combs with cells narrowed from the remaining cocoons may prevent the full evolution of the size of the body, so that a stock may contain a whole population of smaller bees than other stocks standing near it.

"But if a swarm issues from such a stock, or if a driven swarm is made from it, the young bees reared in the new combs return beyond doubt to their normal size, although they descend from the same mother as the former generations. Then, also, it may happen that all the brood even in the new combs hatch miniature bees. I have had them of the smallness of large ants—real *liliputians*. Their appearance, however, is very easily explained. It only happens in heavy stocks in which the bees were not able sufficiently to surround an inserted brood-comb with eggs and young maggots, and to feed the latter sufficiently. As the workers increase it certainly ceases; the brood hatched afterwards return to the normal size—proof enough that the remarkable deviation is caused only by accident. It is impossible to preserve and increase such a small kind of bees. The size of the mother has not the least influence upon the size of her offspring. The most decidedly dwarfed queens produce a full-sized offspring. The bees of the south of France I know as little as the so-called small Dutch one. However, I am convinced that the one as well as the other has not any difference in specific size from our common bees, that the variation in size depends only on the illusion of superficial observation. I do not doubt that those bees would accept the combs of our bees as willingly, and continue in the same size as the Ligurians have done, which one would think sometimes larger, sometimes smaller than the German bee, although there has not proved any difference whatever in size. It is quite inadmissible to make a difference between so-called domesticated and wild bees. Both are of the same kind, they do not deviate in anything from one another. If a so-called wild people is brought to its stand, every specific difference disappears even to the most careful observer. A colony living in an oak in a forest was once pointed out to me by an old bee-keeper as such a one, the bees of which would verify themselves as belonging to quite another species by their being covered with more hair. A closer examination, however, proved that they certainly had not any more hair, nor any longer than the bees in my apiary.

"In the colour of the hair also there does not exist any difference, only that of young bees is coloured differently from that of old ones. That of the young ones has for some time a light tinge of grey, which afterwards changes into brown. The inexperienced observer may easily be deceived by this, when he has seen, perhaps, the young bees playing before a hive and compared these with old bees of another stock. A difference in the colour of the abdomen may also occasionally be seen in German bees; but it is not specific nor constant, it depends only on a freak of nature, and maintains itself here as little as with the so-called bastards originated from mingling the German and Italian races.

"Differences in the temper of German bees happen at all events, but they are also only individual differences, often only temporary—at all events anything but constant.

"According to my observations, I, therefore, think myself entitled to pronounce, that amongst the common bees which are kept in different parts of Germany a perceptible and constant difference does not exist.—KLEINE, *Lüethorst*."

## HONEY HARVEST ON THE DURHAM MOORS —LONGEVITY OF WORKING BEES.

I CAN confirm the "DEVONSHIRE BEE-KEEPER'S" account of the miserable state of hives this autumn. I had fourteen hives at the moors and the heaviest (which by-the-by was a Ligurian that swarmed four times last May), was 34 lbs., but some were only 10 lbs. and 12 lbs., and very few bees left in them. I, therefore, joined by fumigation five hives of these to the Ligurians; and it would appear that not one of the fourteen, with the exception of the Ligurian named, have bred since last June and July, and a person that took one of his did not find any bee-bread in it: consequently if bees only live six months, I fancy all the bees in this district will have died out by next year. I also find on examination that none of the swarms have been able to fill their hives with comb. Would you, therefore, be so

good as to say how you would recommend me doing with two Ligurian swarms? One was hived into one of Taylor's dividing band-and-frame hives, and the other into a straw skep, and neither has more than half filled their hives with comb, although one swarmed May 27th, and the other June 2nd. The straw one I have superposed and must let it take its chance, but the dividing-hive I do not mind if they will be able to exist the winter; and, therefore, shall be glad of your opinion what is best to do. I have fed it well with honey, and they have the combs filled, and I am going to put felt round the hive to keep the frost and cold out, but I am afraid they will all be dead by the spring.—A. W.

[With regard to the longevity of bees, Dzierzon says:—"Of bees bred in May or June few live longer than two months if the weather be favourable, so that they can be constantly at work;" but "bees bred in September look just as juvenile in February and March as if they had left their cells only a few days ago. If they pass their time in summer in a similar state of rest, as is the case in stocks without a queen or otherwise inactive, they may, perhaps, survive a year, or even more." We can fully indorse the statement that the life of the worker bee is prolonged by idleness; and we do not, therefore, imagine that the stocks you refer to run any risk of extinction from the death by old age of all their inhabitants, but we very much doubt if any worker bee ever attained, much less exceeded, the age of twelve months.

As you state that the superposed stock must "take its chance," we can offer you no counsel regarding it; and with regard to the dividing-hive, if you have fed it up to a sufficient weight, and are careful to give it efficient protection, we can see no reason why it should not survive the winter, as we have known many to do which were apparently in a far worse condition.]

## CROSS STICKS IN HIVES.

IF I had rushed into bee-print seven years before I did, I should certainly have put my foot down upon a person who recommended cross sticks in a hive. Previous to that time, I had used common-sized, and Payne's straw hives only, which ought never to have crossed support-sticks under proper management, but, for my large-sized hives, I was compelled to adopt them, not from the melting or dislodgement of the combs, for, I never had a misfortune of that sort, but through the cautious instinct of the little workers, which would know better than I what was proper for large domiciles; so they worked their combs quite down to the floor-board, and fastened them there, thus creating a sad difficulty for me when spring-feeding, and again for themselves; for when I moved the hive from off the board, then smash would go the combs more or less—a sad case in the spring, or any other time of year, costing both time and store to repair them. I have never found this to happen since my introduction of the sticks, and it really shows a power almost akin to reasoning on the part of the cunning little fellows, by their thus at once accommodating themselves to my assistance. I seldom "take" a hive until it is four years old, and then the combs are become old and tough, and through the agency of an inch protrusion of each stick laying out from the hive, as your correspondent "G. C., Gloucester," mentioned last week, a twist and a pull with a pair of pincers relieves them. I do not find that the sticks incommode the bees materially in large hives, and at least, of two evils, they are quite a counterbalance of the fastening of the combs on the board. Two bars and frames would obviate both; but I write for the million.—UPWARDS AND ONWARDS.

## FERTILE WORKERS.

IN compliance with Mr. Lowe's request, in page 604, I have much pleasure in relating all I was able to ascertain with regard to the occurrence of fertile workers in the only instance which has come under my observation.

The phenomenon occurred at the commencement of July, in the inclement summer of 1860, and was described by me in *THE COTTAGE GARDENER* of the 10th of that month as follows:—"The queen-cells in one of my small artificial swarms having turned out abortive, owing to the inclemency of the weather, some among the working bees have taken the opportunity of usurping the functions of royalty, by depositing eggs in the

breeding-cells. I presume they will produce drones, although laid in the workers' eradles; two or three being deposited in each cell. The depositing a plurality of eggs in a cell is not, however, peculiar to fertile workers, since a prolific queen will often deposit two or more eggs in one receptacle. I am unable to detect the difference in size which is said to distinguish workers which have assumed the functions of maternity. These fertile workers are Ligurians." To these particulars I may now add that the eggs so laid were developed into small drones as I anticipated, and that, although like Mr. Lowe I was never fortunate enough to detect fertile workers in the act of oviposition, nor could I ever identify such as were in that abnormal condition, the circumstances of the case were such as to establish the fact beyond a doubt. Being perfectly satisfied that the eggs in question were really deposited by workers, and not by a small queen which had escaped my scrutiny, I supplied the colony with another sealed royal cell, which arrived at maturity in due course, and the abnormal laying of drone eggs soon came to an end.

Although it may appear somewhat presumptuous in me to attempt the development of a new theory from this the only instance of the kind which I have ever witnessed, yet, as I did theorise at the time, I now venture with all due diffidence to state the theory, having already proclaimed the small amount of experience upon which it is founded. My idea is that upon the first discovery of their queen's loss, bees sometimes supply an extra quantity of food, and in fact accord a rudimentary royal treatment to a greater number of young larvæ than they afterwards deem necessary to rear into queens, and that the ovaries of the bees proceeding from these larvæ receive thereby a sufficient stimulus to admit of their laying eggs, which, being unimpregnated owing to their inability to copulate with the male bee, can only hatch into drones.—A DEVONSHIRE BEE-KEEPER.

MANAGEMENT OF COWS IN GUERNSEY.

It is usual to speak of "Alderney Cows," but the truth is, that the pure breed can only be purchased in Guernsey, and the breed, whether on those two islands, or in Jersey, are only improved specimens of the Norman variety. Perfection and entire purity of breed in the Channel Island Cow are demonstrated by the animal possessing twenty points of excellence, which are thus assigned—

- The pedigree of the parents being proved to be good, yielding yellow butter (the distinctive marks of which property are ears yellow inside, yellow circle round the eyes, yellow tinge at the root of the tail, and full udder), counts for ..... 7 points.
  - General appearance—colour cream or light red, or both mixed with white; hair smooth and short ... 3 points.
  - Handsome head; handsome horns, slightly curved inwards; eye bright and prominent,..... 4 points.
  - Deep, barrelled-shaped body; flanks well rounded... 3 points.
  - Handsome legs, not knocking together when walking 1 point.
  - Hind quarters flat and right-angled; back straight and level ..... 2 points.
- 20 points.

It is found that to feed Cows well and advantageously, two at the least must be kept, and so managed as to calve at different times.

For their keep three acres of ground must be cultivated; and of these one acre is in grass, and the other two are cultivated on the five-course-rotation system, the two acres being divided into five portions, and each portion growing in its turn—1, wheat; 2, parsnips and mangold wurtzel; 3, wheat; 4, barley; and 5, clover.

From the produce of these two acres the Cows begin to be fed sometimes in September; but if the season be mild, as is usual in Guernsey, not until October. The daily allowance to each Cow is from 10 lbs. to 15 lbs. of hay, from 75 lbs. to 100 lbs. of mangold wurtzel, 10 lbs. of parsnips, and whatever straw they may choose to eat of that with which they are littered. If the fields are sufficiently enclosed the Cows are sometimes allowed to pasture in them untethered from October to December.

During the spring, summer, and until about the end of Sep-

tember the Cows are tethered either upon the acre of grass or the clover. The tether, varying in length from 12 feet to 15 feet, is sometimes entirely of rope, with a running noose to pass over the Cow's horns at one end, and the other is passed over a strong iron pin about 18 inches long, driven nearly its entire length into the ground. The best tethers, however, as in the annexed drawing, have a small chain to pass over the cow's horns, looped round them by means of one large link, which is split on one side in the manner of a key-ring, but with the split

permanently wide enough apart to admit of the easy passage of a link of the chain. The iron pin is shifted from four to six times daily, according to the abundance of the pasturage. It is usually only moved from 3 feet to 4 feet from where it was previously fixed.

Milk and butter being the coveted produce, the calf is taken from the Cow immediately, very few cow-keepers allowing it to remain with its mother even a single day, and no one allows it to remain more than four or five days.

The average quantity of butter a good Cow will produce, is one pound a-day—i.e., at the rate of a pound per day from calving to calving, although some are known to produce 14 lbs. to 16 lbs. a-week, or from four to five hundredweight during the year. From ten to sixteen quarts of milk for a considerable time after calving is what the average are considered to give.

OUR LETTER BOX.

CROSS BETWEEN DORKINGS AND COCHIN-CHINAS (A. B. C.).—Have a coloured Dorking cock, and Partridge or Buff Cochin-China pullets. Have fresh pullets annually, as they lay in winter, which adult hens usually do not. The chickens are equally good, whichever way this cross may be effected.

DROOPING COMB OF DORKING COCK (J. R.).—The comb may have fallen from the action of the frost, or from temporary want of condition. If it has shown no inclination to do so before, we should think it will rise again. A solution of alum in cold spring water may often be used with benefit in such cases. A drooping comb is not a disqualification, but it is a positive disadvantage. The silver wire should be as small as can be consistently with strength to keep up the comb; wire as large as a small pin is sufficiently strong, and the support may be derived from the thick base of the comb.

EAR-LOBES OF WHITE GAME COCK (A. Debor).—The white ear-lobes are immaterial in your White Game cock. No leg is good or bad in a Black-breasted Red. If they are to be the old Knowsley, or Lord Derby's breed, they must have white, as that is characteristic of the breed. All that is necessary to observe is, that all the legs is the pen are the same. The prizes generally go to willow legs, but there are thirty of them to one white.

BIRDS FOR AN AVIARY.—We are informed that "A DEVONIAN" may obtain a large ornamental cage suitable for an ordinary drawing-room window, from "S. B. Fox, Esq., No. 7, Southernhay, Exeter," from whom further particulars may be obtained.

RABBIT GRIPED (R. E. S.).—The symptoms intimate that your doe was violently griped. A teaspoonful of castor oil, and one drop of laudanum, might have relieved her if administered when first attacked. Inflammation of the bowels probably occurred at last.

TEACHING A DOG TO TAKE TO WATER.—A. B. C., South Hants, will be obliged by information of a good method to teach dogs (that are grown up), to take to the water.

LONDON MARKETS.—NOVEMBER 10.

POULTRY.

There is an increase in the supply, but none in the demand. The consequence has been a slight fall in prices. We imagine this will last till the approach of Christmas.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 43.2° and 34.5° respectively. The greatest heat, 59°, occurred on the 20th, in 1814, and 21st, in 1833; and the lowest cold, 9°, on the 23rd, in 1858. During the period 130 days were fine, and on 115 rain fell.

PLANTS FOR DINNER-TABLE DECORATION.

ATELY, as well as on a previous occasion, I gave my views on the subject of dinner-table decoration in the plant or cut-flower way. I should not have troubled the readers of THE JOURNAL OF HORTICULTURE again on the matter but for the invitation of Mr. Perkins, the worthy gardener at Lord Henniker's, who asks, at page 605, for a list of plants suitable for such a purpose. Fortunately Mr. Perkins gives at the same time the names of many of the most suitable ones, thereby rendering it unnecessary for me to repeat them; but before giving the additions that may be prudently made to his list, I will offer a few general remarks on the usual requirements of plants for dinner-

table decoration, and purposes of a like kind. In the first place I will say, that although the views that I have hitherto held—that every plant intended for dinner-table decoration ought either to be below the line of vision from one person's countenance to another, otherwise above that line—have experienced no change; yet, as the general public may not be of the same opinion, I will include the names of a few plants whose height may exceed that of 18 inches, and thereby come in the way of the prescribed line I would otherwise have wished kept clear. Nevertheless, the list of plants that may be kept at the proper degree of dwarfness is by no means a meagre one, so that I still hope my views may receive more general adoption when utility asserts its dominion here, as it has done in so many other cases where appearance was quite as essential as in the attraction of the dinner-table. Leaving, however, the question of using dwarf plants or tall ones to the taste of those requiring them, let us consider which description of plants will suit the purpose best, and what will tell to most advantage in such a place.

I think it may be taken for granted, that more than nine-tenths of the fashionable entertainments in high life take place by lamplight, which exhibits many things in a different manner to what they appear in daylight. Yellows, if pale, look like white; and most pale colours, if not surrounded with a dense green foliage, look badly; and pale blue flowers, however agreeable they may be in bright sunshine, have a washy look by lamplight. It is, then, for these reasons that I would advocate the deeper and what are called warm colours of deep rose,

scarlet, purple, and the like; for apart from the rays of lamplight, these colours tell to most advantage when contrasted with the tablecloth, plate, china, and glass by which they are surrounded, and which all, more or less, require high-coloured plants or foliage as a contrast. As all the accompaniments to a table and sideboard in the way of cloth, china, glass, and precious metals, glitter more or less amongst viands which, in a general way, are either brown, pale brown, or some lighter colour of no particular tint, it behoves the purveyor of plants to furnish the table with colours that will contrast as widely as possible with the other attractions of the place. To do this it is quite legitimate to use plants that are either remarkable for their foliage, their fruit, or their flowers. The list given by Mr. Perkins contains examples of all these; and what additions I make may, doubtless, receive accessions from the ideas and practices of others, as there are many plants which may be available of which one individual can scarcely hope to be aware. Thus the mutual exchange of experience in this matter, as well as in many others, is of the utmost importance to the general manager. Commencing, therefore, with plants in flower, I will mention only such as I have seen used, excepting in cases where it is mentioned otherwise.

PLANTS IN FLOWER ADAPTED FOR THIS PURPOSE.—One of the earliest and one of the best plants I ever saw used for this purpose was a nice little plant of Cactus (now *Epiphyllum*) *truncatus*, and the deep rosy purple blossoms, with the tropical appearance of the plant, gave it a very attractive appearance. It is many years since I saw this used, and modern introductions have not presented us with anything more appropriate for the purpose. Some others of the Cactus family, especially of the dwarfer varieties of *Cereus speciosus*, may be very profitably used, care being taken to have a well-formed plant with flowers on all sides, and not on one side only. A nice compact plant of Indian Azalea of some good scarlet or rose colour is also an admirable ornament to the table, and the adaptability of this plant for such purposes will be apparent to every one who has seen the exhibition specimens at the metropolitan and other shows, although, of course, the plant must be small compared with them. A *Pelargonium* may also be admitted now and then, and some of the dark-flowered varieties of the *Fancy* breed are invaluable, as they can easily be kept within due bounds, and there being great variety of them, changes are easy. *Cinerarias* in like manner look well, and I am not certain if all the *Aster* and star-shaped flowers do not show best in candlelight.

For variety a plant of *Acacia grandis*, *Drummondii*, *armata*, or any of the dwarf class, may be now and then admitted, or, where several plants are wanted at once, one of these kinds may be introduced. Although, in general, yellow does not look so well as some other colours, yet for the sake of variety a *Cytisus* or *Coronilla* may be admitted, and if full of flower they are far from despicable, while the pretty and interesting *Cuphea platycentra* looks best when closely examined.

When flowers, flower-buds, and fine foliage, are all

wanted on one plant, the *Camellia* presents itself as one of the best. Some of the *Veronicas* of the New Zealand breed have also fine foliage, and with a spike of blue flowers look not amiss. Then we have the ever-useful Chinese *Primrose*, both single and double, and now and then a *Chrysanthemum* may be brought in at a time when other plants are scarce, and, as these afford many colours, much variety may be had. A well-flowered plant of double *Petunia* is also good, though not more so than the *Fuchsia*, of which the dwarf-growing varieties are the best, and I should say the old *F. parviflora*, if it is still in existence, would perhaps be as good as any; but some of the florists' varieties are also good, though generally they require to be grown to a greater size than is becoming for the table. Nevertheless, we often use a *Fuchsia*. A *Cockscomb* is likewise an ornamental object, but it seldom can be shown in a pot sufficiently small to meet the requirements of the dinner-table. Perhaps some of the varieties of *Celosia* recently become very popular may be more accommodating, but I have not tried them.

Of *Begonias*, the only flowering class suitable here are the small and shiny-leaved varieties, of which *B. fuchsioides* is the type, and well-grown plants of this look well. Those remarkable for foliage will be mentioned hereafter. Heaths of various kinds are desirable, the winter-flowering kinds especially coming in useful; and as plants in flower in January are far from plentiful, the qualification of colour mentioned above must be relaxed in time of scarcity: it is needless, therefore, mentioning the species. *Epacris* does not look so well; so many wiry loose spikes as they present appear too formal for the freedom here wanted. Occasionally a *Salvia splendens* may be introduced with good effect in winter; and it is possible, although I have never used it, a *Lobelia speciosa* may also show off its blooms to advantage; while there are numerous forced plants that may contribute their quota to the general catalogue.

Perhaps no plant that is used looks more really graceful than *Dielytra spectabilis*, while the lovely *Deutzia gracilis* is an acceptable plant from the quantity and purity of its blossom; the double-flowering Chinese *Cherry* being also showy, yet not more so than the profuse-blooming *Weigela rosea*, which is, perhaps, second to none for general spring decoration.

Of *Orchids* my list is but a meagre one, a *Cypripedium* or two and a *Dendrobium* being all that I have tried. The latter of these makes a nice plant; but the general class of *Orchids*, as the *Bletias*, *Oncidiums*, *Phajus*, &c., are too tall, though a *Cattleya* may possibly be worked in to good effect. With this class, however, I should like to have the opinion of others upon their respective merits.

**PLANTS REMARKABLE FOR THEIR FRUIT.**—This class is a much more limited one than the last, nevertheless there is a variety here. *Solanum capsicastrum* and one or two others may be worked in to advantage, and both the red and white varieties of *Ardisia crenulata* may be used in a similar manner; the sturdy habit of the plant with its dense green leaves making it a pleasing object at all times, and the plant bears profusely, and continues for many months ornamental. The *Capsicum* also affords several varieties, one or two yellow ones as interesting as the red. The varieties of the latter are, however, more numerous, and the habit of some of the plants all that could be wished for.

Perhaps the best of all berried plants is *Skimmia japonica*, the habit and foliage of the plant being as good as the berries are pretty, and the latter being placed in clusters on the top of the plant show to great advantage. If this plant could be made to grow a little faster it would be invaluable, although for the purpose here mentioned its slowness of growth and compact habit are all that could be wished for. One or two stove plants, with which I am not sufficiently acquainted, are also said to be applicable to the purpose.

**HANDSOME GREEN-FOLIAGED PLANTS SUITABLE.**—This is a numerous class, and I am far from arrogating to myself that those here given are the best, but additions from other quarters will be acceptable. First of all stand *Ferns*, and their name is almost legion. I cannot say that I admire the Golden-Fern class so much as many do; but, on the contrary, I like a foliage of a deeper green, when the form is also graceful. Some of the hardy *Ferns* are far from unsightly. Even a compact plant of *Polypodium vulgare*, a *Lastrea*, *Blechnum*, or even *Scolopendrium vulgare*, are as interesting and present as many beauties to the observer as the exotic species, while dwarfier varieties are also represented in other hardy sections. The *Adiantums* are great and deserving favourites with ladies, their wavy graceful foliage displaying a form as lovely as it is interesting; and to those who

admire variegated plants, *Pteris argyrea* and *P. tricolor* look well. Indeed, the *Fern* tribe presents some of its members as ready for use every day in the year: therefore I hope some one well versed in this rising section of plants will give us a more complete list of such as can be conveniently kept within the bounds suitable for the table. Almost equal to the *Ferns* in point of variety and numbers are the *Lycopods*, but these are mostly exotic; although there is no doubt but some of the British species, if cultivated, would present forms as beautiful as the foreigners. Some hints as to these from some of our Lancashire friends will be very acceptable. Some *Grasses* are also good. The horse-mane-like tresses of *Isolepis gracilis* form an agreeable contrast with plants of a bold, broad foliage—as for instance, *Eucharis amazonica*, which, though a flowering plant of great beauty, has also a fine appearance in the tropical-looking character of its foliage. *Grevillea robusta* has also a *Fern*-like form; and I am not sure but a plant of *Arbor Vitæ* would look well, and, doubtless, many others may be added.

**VARIEGATED-FOLIAGED PLANTS SUITABLE.**—This class might, perhaps, be made more numerous than any; but as I mentioned at the beginning of this article, the white-edged foliaged plants are hardly suitable in some respects unless they possess properties of consequence in another way. The whole race of variegated *Geraniums* are, therefore, shut out; and though the beautifully-formed leaves of *Centaurea caudicissima* and *Cineraria maritima* are acceptable in many instances, they do not look so well upon a white tablecloth unless they be separated from it by a foot or stand of some high colour, clearly marking out the distinction. The prettiest of all plants for this purpose, not even excepting the best flowering plant we have, is *Dracæna terminalis*; its graceful form and compact habit, aided by a colour which cannot be excelled, commend it to our notice as the best-adapted of all the plants of high colour. *D. ferrea* and others are also useful in the same way, and, possibly, some plant-collector may have a better one than *D. terminalis*, but I am not acquainted with any. Next to these, and in the opinion of many exceeding them, is *Coleus Verschaffeltii*, than which no plant can exhibit finer colours or a finer form, but the smell is somewhat objectionable. It is, however, perhaps the most conspicuous plant that can be set on the table, and a general favourite then. I have also had Mr. Veitch's new *Amaranthus*, *A. melancholicus ruber*, on the table, and its appearance is good—better than the *Perilla*, which in times of emergency has been used in such manner.

I have never had *Poinsettia pulcherrima* in good condition at the time wanted, although I have seen plants elsewhere that were all that could be desired. Of *Begonias* there is great variety, but I confess admiring all of the plants whose names are previously mentioned more than this; but if one be really wanted I would have that having the least white marking that could be had. The old *B. Rex* has a clearer marking than many of the newer ones; and as green is more wanted than white, it is of consequence to have this. The velvety-looking leaves of some of the *Gesneras* with their dark-veined markings look pretty well; and nice plants of *Maranta zobrina* and *M. vitata* also look well. Many ladies, as Mr. Perkins justly observes, admire the *Caladium*, of which the small-leaved class, as *argyrites* and *Chantini*, are better than *C. Belleymei*; while variety of form is given to a group by such plants as *Pandanus javanicus variegatus*, with its sharply-serrated and long curved foliage gracefully bending over the sides of the pot. More stiff is *Aspidistra lurida variegata*, but equally tropical-looking in aspect; and I have no doubt but *Alocasia metallica* will equal any in its singularity of form and lustre. It has hardly become sufficiently plentiful to be trusted at all times in such places.

A variegated *Hydrangea* is hardly admissible, neither is the variegated *Orange* advisable; and for a like reason the variegated *Duranta Baungardi*, though pretty amongst a group of other plants, is hardly so when placed on a white tablecloth, and I confess having much reluctance to advise plants requiring much framework to support them as suitable for this work, otherwise *Cissus discolor* is a gem that way, and a well-managed plant of *Tradescantia discolor* is also good.

**ORNAMENTAL PLANTS NOT SUITABLE.**—In the lists already given, care has been taken to exclude those requiring many sticks, or otherwise showing much mechanical arrangement; for the plant being placed so close to the observer, such appendages as wirework, sticks, string, &c., are objectionable. In accordance with this rule, creepers are therefore excluded. Perhaps some will be pleading hard for a *Tropæolum* or two, but

I have no particular liking to them; while the more robust growing creepers are decidedly objectionable. Plants also with long naked flower-stems rarely look well, however pretty the flower may be, unless that flower is below the eye. For this reason *Statice Holfordi* and kindred species, though exceedingly handsome in other places, are not so here, as likewise is *Bletia Tankervillei*; and the mechanical combination of sticks and string, by which young gardeners are apt to set-off their *Aphelexes* in porcupine-fashion, is not admissible on any terms. All very strong-smelling plants, as *Hyacinths*, are objectionable; *Roses*, however, need not be included in this, as forced and indoor ones are not so highly scented as those grown in the open air, and no one complains of the perfume of a *Rosa*. *Mignonne* is not sufficiently ornamental to entitle it to a place here; and many other plants, whose claims to attention elsewhere are undisputed, are, for reasons here given, unsuitable for dinner-table decoration.

**CONCLUDING REMARKS.**—The above having extended to a much greater length than was at first intended, I need only say that for general purposes of this kind plants that will bear cramping in small pots are the most desirable, and a suitable covering or stand for such pots is also wanted. At Linton we had some of Messrs. Barr & Sugden's covers, of which favourable mention was made in the gardening papers in the early part of the summer; but, though they are pretty enough, they are open to many improvements, and in point of general adaptability are not so good as a kind which preceded them, consisting of a coloured card folded up in flutes, so as to let-out or take-in to fit any sized pot. Some cheap and useful pan or saucer is also wanted to save the tablecloth, and at the same time not to show itself. Perhaps a few tin stands, exactly the size of the bottom of the pots to be used, or a trifle larger, might be made; and if these were about an inch deep they would retain any moisture that might drain away from the plant, while the ornamental cover would go over all and down to the tablecloth. Perhaps some one also will devise some ornamental stand, but it ought to be low—not more than 3 inches high for the highest plants; and as many desert services are on stands, or, rather, consist of stands not more than the height mentioned, it is easy to find an example, but a more ornamental and better-adapted cover for the flower-pots than those we possess is most wanted. The tin or japanned bottom is an easy affair; and if some enterprising manufacturer puts forth a stand for flower-pots, let it be without any side. I am not sure that even a rim is wanted, as the size of flower-pots cannot always be controlled at the moment, and it is provoking to find the pots too large for the allotted space; for, as it is advisable at all times to exhibit the plant in as small a pot as possible, its bottom is needlessly increased when its pot has to be placed inside another, and that one, perhaps, not close-fitting. It is, therefore, for these and other reasons that I would ask for a class of ornamental card-covers of a kind that will enlarge or contract with ease and expedition, and would leave the highly chased and glittering wine-coolers and other articles of plate and costly china to their more legitimate purposes; for, however well such appendages may be adapted for cut flowers, I cannot say that I admire them for plants, and their liability to get broken or otherwise injured affords another reason for dispensing with them. As for cut flowers, I should like the opinion of some lady on this head; my own ideas have already gone forth, and some one else will, I hope, give theirs.

J. ROBSON.

## CHRYSANTHEMUM EXHIBITION OF THE ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 11TH.

WHAT with the meetings of the Fruit and Floral Committees in the same day and place, we never had an Exhibition in November which drew together so many practical heads and such an amount of downright practical judgment, such opposite views and so much of the harmony of contrasts in opinions, as the French dyer said of so many of his colours when viewed on a dark grey ground in masses, and free from the influence of any other shade in creation. A frosty morning, of from 5° to 7° of keenness, in various situations within twenty or thirty miles of London, and a clear sunny day, a bracing air, and a thorough move in advance in the cultivation of the flower of the season—the *Chrysanthemum*, seemed to gather the craft together to make a pleasant day of it, even in November. But the coming

of age of the Prince of Wales on the day the Lord Mayor got into his new boots and so boosed the people in London on the Monday, caused them to have little relish for fruit and flowers when they arose next morning; so let us gather wisdom from the event, to prevent the like next time.

In the coming year we shall stage five days before the Lord Mayor gets into his stage coach.

This has been the worst season for growing *Chrysanthemum* around London for the last forty years, or, at least, since 1827 and 1828, when this Society had a whole house devoted to them in the Chiswick garden, and had a greater number and variety of more distinct kinds there than the whole of Europe could now produce; and if we balance the loss of three distinct strains at least against the improvements we have made on the two remaining strains, the remainder would just leave us where we stood at the end of 1828 in reference to the *Chrysanthemum*.

Now, however, we had the first of Mr. Fortune's distinct strains from Japan exhibited by Mr. Standish, and the Floral Committee had to decide on the merits of a new strain among them of which we never heard before—the Fringed strain. Every floret is fringed as the frills of a Scottish laird of the seventeenth century, not like the fringe of the Marabout feathers, as in the Pomponne of that name. I put up at once for a first-class certificate for the new strain, and none would second the motion; then, to make up for the mistake of judging one strain from the merits of another, I put up both my hands for a second-class certificate, in which the Committee were unanimous. Now, I look upon a unanimous vote of the Committee to be of more value than a higher award would be on a divided opinion, as that might be carried by one in the majority: therefore I must be satisfied with the result of this vote. The Committee was fully represented; therefore, being unanimous on a new plant of an old favourite family, a second-class certificate was better in practice than a first-class one on a divided opinion.

You will see what seedlings were awarded prizes from the published list; and I may add that we were also unanimous in the opinion that several others of the seedlings were, or would be, worthy of prizes, and possibly of higher ones, when the plants recovered from the effects of this unchrysanthemum season.

But I must mention three of a family caste which will be very much sought after. One is "Her Majesty," a fine blush incurved flower, a good, dwarf, close-growing plant, well adapted for pot culture; Princess Louis of Hesse, a beautiful delicate pink blush, incurved flower, about the same habit as "Her Majesty;" and Princess Alexandra, a beautiful rosy blush flower, incurved. This group possess all the qualities we ascribe to lady-like flowers.

The rest of this collection of seedlings were—*Aspasia*, rosy purple and blush at the back, incurved; a dwarf, good, pot plant. *Ariel*, a delicate pink blush. *Antonelli*, large, dark orange, incurved. *Cardinal Wiseman*, a fine pot plant, and very free bloomer, in nearly the colour of *Madame Poggi*; a capital "decorative" plant, as the florists say. *Duchess of Buckingham*, a fine white incurved flower, which had a second-class award—the highest of the day. *Lord Palmerston* will be out next year amongst the "stunners" from Mr. Bird; the colours are mixed, dark orange, and tipped variously. *Cleopatra*, lilac and blush centre, finely incurved. *Cresus*, a dark golden orange, and finely incurved. *Latona*, pure white, incurved. *Holman Hunt*, a large dark rose, incurved, which will be as big as *Lord Palmerston*. *Gavazzi*, a fine, incurved, orange flower. *Margaret Vatcher*, large rosy anemone. *Oliver Cromwell*, dark red, incurved. *Rev. J. Dix*, a thorough decorative flower in the style of *Little Harry*, orange amber, beautifully incurved; and *Abbé Passaglia*, a large, light cinnamon orange, will be among the "stunners" some day.

After these we had half a dozen kinds of new races from Japan, sent by Mr. Standish, but they were not forward enough to be judged, except the fringed one, as above, which is named *laciniatum*. A remarkably handsome Fern, a seedling from the "Dusty Miller" of Peru, from Mr. Parsons, had a second-class certificate unanimously; and Mr. Bull at last got a unanimous first-class for two plants of exquisite habit and look for high decoration and for show days. The *Cyperus alternifolius variegatus*, which took us all by surprise, will give you a fair idea of the looks and ways of this novelty, which is by Siebold, and was missed both by Mr. Fortune and Mr. Veitch in Japan. The name is *Ophiopogon jaburan variegatum*.

Mr. Parsons sent several cut flowers of *Achimenes*, from the strain of *Meteor*, and of most lovely colours, merely that we

might see the progress in that family and style. Mr. Salter sent a good specimen of *Gunnera scabra*, with a fruit-and-flower cone 2 feet long. This is the best of all the rocky-wilderness plants we have. The one out at Kew is now enormous—I think I counted nine cones on it in September. And the Messrs. Veitch sent a fine complement of Orchids, including the white and the crimson-eyed sorts of *Calanthe vestita*, *Vanda cœrulea*, *Lycaste Skinneri*, and others, with the splendid *Cattleya Pescatori*.

After these was a very pretty addition to hexandrous plants—a new hardy herbaceous plant from Japan, with upright flowers, variegated equally in black and white in bars and stripes. The botany of this plant is most beautiful and most singular in this order of plants, the parts being regularly arranged in whorls of threes, which give the index to the name of it, *Tricyrtis* sp.; and whatever the cyrtis, or number of whorls, the specific ought to be amplexicaulis, for every leaf is so arranged on the stalks, which rise a foot or more, with tassels of these blossoms on the tops. It had a first-class certificate with all consent.

Then came Mr. Bird's big cut *Chrysanthemums*, followed by Mr. Cattell, the only other grower who could cut and come again. The two collections were, or might be said to be, at either pole—the one at the biggest end of it, the other not the farthest from the other end. The largest *Chrysanthemums* of this untoward season for them were *Jardin des Plantes*, *Lady Hardinge*, *Queen of England*, *Alfred Salter*, *Pictoreum roseum*, *Nil Desperandum*, *Anaxo*, *Dupont de l'Èure*, *Old and Golden Trilby*, *Madame Leo*, *Dr. Rosas*, *Alarm*, *Pandora*, *Rideman*, *Golden Hermione*, *Progne*, and *Little Pet*. Mr. Cattell had two collections and one miscellany; but some not more than one-half the size he had them the last two or three years at the Crystal Palace.

The competition collections, on the other hand, showed an immense stride of improvement in the growth, training, and blooming of the specimens. They were just in the size and form of the biggest *Pelargoniums*, all on one stem a-piece, and exquisitely done; even Mr. Salter, who has hitherto presented them pure and simple from the way of Nature, took the inoculation from the "growers," and did them on the country-conservatory model to a shade; but that model being so different from that of the exhibitions, he allowed the "growers" to fight it out amongst themselves, and they did so, *Potomac* fashion; for the Judges could not tell who was conqueror of the two foremost in the fray. It was a complete tie; and as there is no lawful authority yet to untie this knot, they generally "serve" them both alike, as you will see by the list of awards.

The kinds in the two first-class collections were these:—Mr. Glover, gardener to R. C. Lepage, Esq., Brixton, had *Chevalier Domage*, *Dr. Maclean*, *Vesta*, *Alma*, *Trilby*, and *Golden Christine*. These were one shade better in the getting-up. Mr. Ward, gardener to W. Fowler, Esq., Tottenham Green, had the original and the *Golden Christine*, *General Have-lock* (a usurped name for *Insigne*), *Vesta*, *Alma*, and *Annie Salter*. Mr. Turner, of Slough, had an extra in this class with *Alma*, *Chevalier Domage*, *Hermione*, *Golden Christine*, *Christine itself*, and *Golden Trilby*. Mr. Ward had a second prize with *Beauté du Nord*, *Chevalier Domage*, *Bouquet des Fleurs*, *Lucidum*, and *Prince Albert*. Mr. Salter had *Rifleman*, *White Christine*, *Julia Grisi*, *Ariadne*, *Sulphurea superba*, and *Christine*; and in another collection he exhibited ten or twelve more kinds exactly as the best gardeners do them for conservatory decoration. These were the principal:—*Prince Albert*, *Dr. Maclean*, *Dido* (a fine white), *Alma*, *General Slade*, *Lady Hardinge*, *Sparkler*, *Mr. Murray* (a violet purple flower of medium size, and the only one of that particular tint, therefore very desirable for variety), and *Defiance*.

There were twenty-eight specimens of *Pompones* in competition, averaging 4 feet across, and as flatly trained as a dining-room table; although this is the usual way at flower shows, the plan is not worth one straw, looking at it from a gardener's point of view. Nothing has ever been done more artistically than this flat-specimen training; but, like the florists' roundness of flower, the form is of no use whatever out of the circle of that particular fancy, and it seems to me a misuse of our means to give prizes to that which is of no public utility whatever.

There were three specimens of pyramid-trained *Pompones* very much better done than the bedroom-candle-extinguisher-like training we had this time last year. Another trial or two will assuredly bring out shape, size, and bloom that will suit everybody, and be worth all the money ten times over. The

fact is, people will then go to *Chrysanthemum* shows to learn what improvements may be made at home; but now as no home can adopt the "equat system," as Mr. Marnock happily called it, no one seems to care the value of a rush about them. Why, then, continue the waste of money in giving prizes to such forms?

There was a large collection of fruit on view from Canada and Nova Scotia, the specimens as good-looking as could be obtained in Europe. Some of them quite new to our pomologists, and some as old as some of the newest Grapes which composed the order of the day for the Pomological Committee.

But, to go off at a tangent to another theme, the gardener at Buckingham Palace has a most valuable foundation for a new strain of Lilies of the *Lancifolium* and the scarlet *Martagon*; and Mr. Standish is on the high way for a still more magnificent run of gems from the great master Lily of our day, the grand *Auratum* from Japan, now selling at ten guineas a-piece.

Depend upon it that new-crossed Lilies will pay better than new seedling Grapes in a year or two. But Mr. Standish will be able to decide that question before any of us, for he has crossed over sixty or seventy kinds of Grapes this very season; and from his experience with the *Rhododendrons* and with their back pollen, if anything can be made out of pollenising Grapes in our climate to beat the Lilies, we shall first know of it from himself; and the mystery, if such there be, may throw some light on the present mode of cross-breeding Grapes, which at present is surrounded with obscurity. D. BEATON.

## BEDDING TULIPS.

I REMEMBER reading some years ago in a gardening cotemporary the mournful complaint of some young man in the country (young at any rate he must have been as to greenness), who, captivated by the glowing descriptions (and I am not sure but that pictorial beauties were added thereto), of a London firm as to the beauties of spring gardening, expended thereon a large sum of money. Crocuses of various hues, Hyacinths fragrant and beautiful, gay and flaunting Tulips, with the pearly and elegant *Snowdrop*, and various other things, were to make the garden at the Grange the envy of all beholders and the pride of the lady of the manor. In order that there might be no mistake the bulbs were accompanied by their own particular trainer, as horses are, and no sacrilegious hand was to attempt an honour for which he alone was deemed worthy. The bulbs were sound, the beds well prepared. Mr. Oldbuck, the gardener, looked on in mute astonishment—"Well I never! If I had asked for half the money them things cost, wouldn't maaster ha' blowed-up?" "and all went merry as a marriage-bell." When January's snow had melted away, there, sure enough, were the bulbs all peering above ground. But alas! he found—and this his complaint—that the Crocuses were so precocious they wouldn't wait for the Hyacinths; while they in their turn would have nothing to say to those dissolute Tulips, all dressed out in such toggery, as if belles would ever associate with such swells as they were. You may be sure old Master Oldbuck did laugh over master's vexation, and wondered how "that 'ere Lunnun chap would look now;" while master himself fired off an indignant letter about a matter which he ought to have known well enough had he ever so small a garden.

One of those flowers on which he depended is, I am sure, very much overlooked in the decoration of our flower gardens in spring—the Tulip. We are told, though I never had the pleasure of seeing it, how tellingly the Dowager Duchess of Sutherland, has employed them at Clevedon; and many saw and admired them, doubtless, at the Royal Botanic Society's garden in the Regent's Park in the summer. Having been favoured by the politeness of Messrs. Barr & Sugden, of King Street, Covent Garden, with a collection of them last autumn, I have made a few notes thereon, which, as this is a very favourable season for planting, may not be unacceptable to some of your readers. For those who are beginning, the most desirable plan will be, probably, to grow them in clumps; and as they readily increase, in a short time sufficient will probably be obtained to make them up in beds of various colours, for they are to be had in white, yellow, scarlet, and various colours; and if planted early enough, can be taken up in sufficient time for *Verbenas*, *Geraniums*, &c., to occupy their places. I would here say that my decided preference is for the single varieties. I know some of the double ones, such as *Marriage de ma Fille*, are

very fine; but they have this objection—that after heavy rain the flower becomes filled with water, and, from its great weight, is either apt to hang down its head and become dragged, or else to be snapped-off by the first burst of that “blustering railer, rude Boreas,” whereas the single ones readily right themselves again. Again, the Van Thole are pretty for early blooming; but just because they are early they are apt to interfere with such arrangements as I am supposing any one wishes to make; their beauty is over before the others are in bloom.

There is not any difficulty with them as to soil: they will flourish in any tolerably good garden soil that is not too heavy. Where it is likely to be so, the addition of leaf mould to it will both lighten it and be agreeable to the growth and vigour of the bulbs. They do not require any fresh manure, but will succeed best where the ground has been kept in tolerably good heart by the manuring of previous crops.

Nor can much be said as to planting or selection of the bulbs; the beautiful clean manner in which the bulbs arrive from Holland are evidence of their vigour and of the manner in which the Dutch grow all these things to perfection. In planting they should be placed about 5 inches apart, and about 3 inches deep. They require no protection, though, like a great many other things, they fare all the better for having a little.

As to choice of sorts, there seems to be some little difficulty from the catalogues varying so as to names. There are some remarkably fine varieties which are common to all the catalogues, such as Duchesse de Parma, &c., but there are others which seem to be peculiar to each individual importer. I rather fancy that the reason is that the growers in Holland have their own names for many very similar if not quite so to each other, and that we should find many synonyms amongst them as in fruits and other things. I subjoin a list of the kinds which struck me as most desirable amongst those sent by Messrs. Barr & Sugden.

WHITE.		
Pottebakker White, very pure. A striking flower.	Belle Laura, violet crimson, bordered with white.	
Luna, very pure and clear.	Couleur Cardinal, brilliant crimson, tinged with yellow.	
Queen Victoria, French or bluish white.	Feu Rouge, bright red, tipped with orange.	
YELLOW.		
Canary Bird, rich and dwarf-growing yellow.	Yellow and Red of Leyden, bronze crimson. Bottom of cup tinged yellow.	
Pottebakker Yellow, very bright canary colour.	WHITE GROUNDS, STRIPED, BORDERED, &c.	
Yellow Prince, pure yellow, and sweet.	Covent Garden Favourite, white, with rose border.	
RED, SCARLET, AND CRIMSON.		
Garibaldi, dark scarlet.	Prince Charlie, white, bordered with rose.	
Samson Red, bright and brilliant.	Parragon Galdebloem, white, feathered and striped with rosy lilac.	
Vermilion Brilliant, a fine flower of a very dazzling colour.	Silver Standard, pure white, striped with scarlet.	
La Belle Elizabeth, brilliant crimson scarlet.	YELLOW GROUNDS, STRIPED, BORDERED, &c.	
Couronne Pourpre, very dark crimson.	Mary Queen of Scots, yellow, striped with red.	
CRIMSON AND SCARLET GROUND, BORDERED OR STRIPED.		
Annie Laurie, light scarlet, striped with yellow.	Abbesse de St. Denis, delicate primrose, feathered with rich crimson.	
Duchesse de Parma, orange crimson, bordered with yellow.	Franciscus Primus, yellow with crimson border.	
Lord Palmerston, bronze red, flaked with orange.	Marie de Medicis, primrose, feathered with deep cerise.	

—D., Deal.

## ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 11TH.

FRUIT COMMITTEE.—Mr. Edmonds in the chair. At this Meeting there was a very large collection of fruit exhibited, exceeding anything ever before witnessed at a Meeting of this Committee. In addition to the collections that were sent to compete for the prizes which were offered, there were collections from the Local Committees of Derby, Yorkshire, Staffordshire, and Herefordshire. The great majority of the varieties forming these collections were as yet unripe, and have been kept over for examination on future occasions. It is worthy of note that those varieties forwarded by the Staffordshire Committee, of which Mr. Hill, gardener to Ralph Sneyd, Esq., of Keele Hall, is Chairman, and which came from Mr. Hill himself and Mr. Allport, of Doddington Park Gardens, were very correctly named, there being scarcely an instance of incorrect nomenclature in either of the collections. Those from the Derbyshire Committee were very extensive, and contained a great number of local varieties, as did also those from Yorkshire. The fruit from Hereford was the best, and exhibited at once the advantage that old orchard country has over the less-favoured districts. A report

was read of a Meeting of the Committee held at Derby under the presidency of Mr. Cooling, and the thanks of the Committee were awarded to Mr. Cooling, jun., who acted as Secretary, for the assiduity he exhibited in collecting so large a number of specimens, and forwarding them to the Society. The thanks of the Meeting were also awarded to Mr. Hill, of Keele Hall Gardens; C. W. Strickland, Esq., of Hildenley; and Mr. Davis, of Hereford, for the services they had rendered from their various Committees.

A fine collection of Apples, Pears, and Grapes was received from the Horticultural Society of Canada, which will form the subject of a separate report.

At this Meeting prizes were offered for the following exhibitions:—

Class A, for the best three dishes of dessert Apples. In this class there were nine competitors, and several of the collections were remarkably fine. Mr. Webb, of Calcot, near Reading, had some very fine Blenheim Pippins and King of the Pippins. The Blenheims of Mr. Snow, of Wreat Park, were also very fine. Mr. Curd, gardener to M. G. Thoytts, Esq., of Sulhampstead, Berke, had beautiful specimens of Golden Winter Pearmain, Cornish Gullflower, and Ribston Pippin; and Mr. Turner, of Slough, exhibited nice examples of Omar Pacha, Cox's Orange Pippin, and Court-Pendu-Plat; but the awards were reserved for those exhibited by Mr. Whiting, of the Deepdene, whose collection consisted of Braddick's Nonpareil, Eldon Pippin, and Cox's Orange Pippin, and to these the first prize was awarded. The second was given to Mr. Bousie, gardener to Lord Taunton, at Stoke Park, near Slough, for Braddick's Nonpareil, Golden Russet, and Cockle Pippin. These two exhibitions, Mr. Whiting's and Mr. Bousie's, though smaller and not such showy specimens as were exhibited in some of the other collections, were fine of their kind and surpassed all the others in flavour.

In Class B, for the best three dishes of dessert Pears, there was a very brisk competition, there being no less than fifteen entries. Two very excellent collections came from Mr. J. Morris, gardener to T. White, Esq., Manor House, Wethersfield, which consisted of Urbaniste, Soldat Laboureur, Orpheline d'Enghien (Beurré d'Aremberg), Beurré Bachelier, Beurré Diel, Van Mons Léon le Clerc, and Broompark. Mr. Curd, gardener to M. G. Thoytts, Esq., Sulhampstead, also sent good examples of Zéphirin Grégoire, Beurré Diel, and Glou Morceau. Noble fruit came from Mr. Ingram, of the Royal Gardens, Frogmore, of Knight's Monarch, Beurré Diel, and Beurré Bosc; and also from Mr. Spivey, gardener to Mr. Houlton, Hallingbury Place, near Bishop Stortford, of Glou Morceau, Passe Colmar, and Beurré Diel. But the prizes in this class were again carried off by Mr. Bousie and Mr. Whiting, Mr. Bousie being first with Marie Louise, Knight's Monarch, and Glou Morceau; and Mr. Whiting second with Duchesse d'Angoulême, Marie Louise, and Winter Nelis. A very good collection was received from Mr. Wm. Earley, of Digwell, but they arrived too late for the Meeting. Taking the whole of the collections that were exhibited in these two classes, they were all of a most creditable description.

In Class C, for the best dish of White Grapes, the prize was awarded to F. J. Graham, Esq., of Cranford, near Hounslow, for three bunches of his new Grape, called Graham's Muscat Muscadine. This was raised from the Royal Muscadine, and has a brisker flavour than the Chasselas Musqué, and not quite so high a Muscat flavour; but it does not crack in ripening as that variety does, and the Muscat flavour is quite as strong as in the other Frontignans. For Black Grapes the prize was awarded to Messrs. Lane & Son, of Berkhamstead, for three large bunches of Black Barbarossa grown in a house without any artificial heat. The bunches were very handsome, well set, and beautifully coloured.

A seedling Pine Apple was sent by Mr. Andrew Batger, gardener to John Gott, Esq., Arnley House, Leeds. It was of good size, weighing 3 lbs. 14 ozs., tall, cylindrical, and handsome, of a fine golden yellow colour. The pips are large and flat; the whole appearance of the fruit is prepossessing. The flesh is yellow, firm yet tender, and free from fibre, very juicy, and very richly flavoured. It was unanimously awarded a First-class Certificate.

A seedling Grape was sent by Mr. Saunders, gardener to Sir Henry Meux, Bart., Theobald's Park, and which was said to be a Muscat. It is called *Royal Vineyard*. The bunch is large and well set, ovate, not long, tapering, or cylindrical. The berries are large, ovate; the skin white, and somewhat trans-

parent, showing the texture of the flesh through it. The flesh is firm and somewhat crackling, very juicy, and with a fine Sweetwater flavour. From the thickness of the stalks and of the berry-stalks it has all the appearance of being a late-hanging sort; and this quality, coupled with its admirable flavour, will doubtless recommend it. The Committee unanimously awarded it a First-class Certificate as a valuable late White Grape, but are of opinion that it does not possess the Muscat flavour to entitle it to be classed among Muscat Grapes.

Mr. Pottle, gardener to B. D. Colvin, Esq., Little Bealings, Woodbridge, Suffolk, sent a bunch of the Hubsbee Grape, a long brownish-red finger Grape, exactly like the large Black Ferral grown in the large vinery at Chiswick.

Two seedling Apples were sent by Mr. J. Gidley, of Exeter, one a seedling from Cornish Gilliflower, and the other from the old Golden Pippin; but in both cases, although good varieties, they were inferior to their parents.

A seedling Apple was sent by Mr. Harrison, of Ostlands, near Weybridge, which promises to be a very desirable variety for kitchen use. It is of the largest size, green, and striped with broken stripes of crimson all over its surface. The flesh is tender, brisk, and with as much sweetness as will go far to dispense with the use of sugar in cooking. The Committee highly recommended this variety.

Dr. Davies, of Pershore, sent specimens of a large kitchen Apple which proved to be Minchall Crab, a very useful variety extensively grown in Lancashire. He also sent specimens of Lady's Delight, a local variety which was introduced to notice some years ago by Dr. Davies; it is an excellent dessert Apple, and deserves to be more widely known.

Mr. S. Snow, gardener to Countess Cowper, Wrest Park, sent a seedling Pear. It is small and obovate, of a clear yellow colour, marked with cinnamon-coloured russet; but the flesh was coarse-grained and astringent in flavour.

A large seedling Apple was also received from Mr. A. Moffat, Eastern Lodge, Dunmow, Essex; but it was too like the Dutch Codlin to require any special notice.

Mr. Laxton, of Stamford, sent specimens of Stamford Pippin, which, however, were much smaller than usual, but the flavour was excellent.

A very excellent dish of Red Currants was received from Mr. Terry, gardener to Lionel Ames, Esq., St. Albans, and an extra prize was awarded to them.

## STOKE NEWINGTON CHRYSANTHEMUM SHOW.

STOKE NEWINGTON enjoys a well-earned reputation for its Chrysanthemums, and the names of cultivators in that district are frequently associated with the highest prizes at the metropolitan exhibitions where that flower finds a place. Besides, at the annual Show of the Stoke Newington Chrysanthemum Society there is always an excellent display both of pot plants and cut blooms, which, as examples of successful cultivation, are all that can be desired.

The sixteenth annual Show, which was held on Wednesday and Thursday last, was not behind its predecessors in merit; and the objects exhibited were not merely well grown but well arranged, and neatly and distinctly labelled—a point which the Society very properly makes imperative.

In Class 1, six plants, in eleven-inch pots, Mr. Ward, gardener to G. Fowler, Esq., Tottenham, was first with General Havelock, a very fine Vesta, Alma, Christine, Annie Salter, and Beauté du Nord. Mr. Howe, who was an excellent second, had Annie Salter beautifully covered with blooms, Dr. Rosas, Vesta, Golden Christine (very fine), Alma, and Chevalier Douage.

The next, Class 2, was for Pompones, in eight-inch pots, and here again Mr. Ward was first; his kinds being Golden Cedo Nulli, Andromeda, Bob, Durullet (very full of bloom), General Canrobert, and Hélène. Next came Mr. Hasdale, of Lower Clapton, who had Cedo Nulli, Hélène, Dr. Bois Duval, and Général Canrobert, all of which were very good.

In Class 3, single specimens, Mr. Ward was first with Defiance, very full of bloom, and Mr. Howe, second with Christine, which was well covered with blooms, some of them being very large; and in the corresponding class 4, for Pompones, he exhibited a very fine plant of Bob, for which he obtained the first prize, the second being given to Mr. Ward.

In an extra class for pyramids, a nicely-grown Cedo Nulli,

from Mr. Howe, received the first prize; Mr. Moxham taking the second for Golden Cedo Nulli and Salomon, trained on wire.

Cut blooms were well represented, and with but few exceptions the stands were very good. Mr. Slade, of Kingsland, who was first, had White Globe, Jardin des Plantes, Cassy, Beauty, Raymond, Rifleman, Pearl, Alarm, Miss Kate, Yellow Perfection, Dupont de l'Enre, Aimée Ferrière, General Hardinge, Caractaus, Picturatum Roseum, Queen, Anaxo, Cherub, Plutus, Nil Desperandum, Trilby, Golden Trilby, Hermine, and Madame André. Mr. James came second, his stand being likewise very good, Mr. Monk was third, and Mr. Ward fourth.

In Class 6, for twelves, Mr. James received the first prize for Jardin des Plantes, Nonpareil, and Queen of England, all large and fine; and White Globe, Lady St. Clair, Christopher Columbus, Alarm, Hermine, Lady Hardinge, Chernb, Nil Desperandum, and Little Harry. Mr. Moxham was second, Mr. Monk third; the last-named being first in the following Class, 7, for six blooms, and Mr. Snare second.

Class 8 was also for sixes; and here the successful competitors were Mr. Butt and Mr. Williams, Kingsland.

Of Anemone-flowered varieties, which were exhibited under Class 9, the best stand contained a fine Louis Bonamy, Marguerite d'Anjou, Gluck, Margaret of York, George Sand, and Nancy de Sermet. Mr. Monk, who was second, had also a good show.

The best twelve Anemone Pompones were shown by Mr. George, of Stamford Hill, who had excellent examples of Calliope, Antonius, Mr. Astie, Madame Montel, and Astrea. Mr. Butt was second, and Mr. James third.

There was also a class devoted to exhibitors who had never won a prize before, and in which creditable blooms came from Mr. Abrahams and Mr. Bowles. We have only to add that the whole affair reflected credit on the Society and their Secretary, Mr. Howe, who was most assiduous in carrying out the arrangements.

## DISTRESSED WORKINGMEN BOTANISTS OF LANCASHIRE.

I AM happy to inform you that our appeal to the public has been very successful. Of Mosses, two ladies have taken two-guineas' worth each; and two others £1 11s. 6d. worth each; a gentleman one-guinea's worth; a lady three shillings' worth; and we have orders in for three guineas' worth of Ferns and other things. Besides these I have received the following donations on account of the poor botanists—viz, 10s. from "PATELIN;" 5s. from H. T. Greenhalgh, Mansfield; 2s. 6d. from the Rev. Henry N. Ellacombe, Bolton Vicarage, Bristol; and a letter came to R. Schofield's house this week, addressed Robert Schofield: it contained 2s. 6d. in stamps, but no name or matter save "A Mother who can feel for another's distress." It had the Ipswich post mark on, and the postman took it back, and it has gone to the General Post Office, London. If this should meet the eye of the lady who sent it, she might probably get it back. There is no other Schofield in Church Street, Dinkinfield.

I am happy to tell you also, that a lady has sent me the following good clothing to distribute—namely, to John Whitehead and mother and sisters, 12 yards of Welsh flannel, 5 yards of good tweed, and two good new woollen rugs. To Roger Schofield and his family, 14½ yards of grey linsey, 12 yards of Welsh flannel, a good cloak, and two woollen rugs; also, 26 yards of striped linsey, 14½ blue serge, 78½ of calico, 19½ of grey cloth, twenty-four woman's shifts; twenty-four ditto bed-gowns, fourteen nightcaps, four men's shirts, and one pair of drawers, for me to give out amongst the other distressed botanists. I am not at liberty to name the lady. I shall by her benevolence be able to give some good warm clothing to nearly fifty persons.

I have called in two other botanists who are above want to help me to distribute the goods, and on Saturday we shall make a from-house-to-house visit to see who are most in want.

Four other cases have come under my notice since I wrote last week; two of them are men of the highest respectability as working men; both I know very well, and each has a wife and six children. They are men who are very enthusiastic botanists, and have striven hard to give their children the best schooling their means would allow. They were too modest to make application to me, even when they knew I expected something coming. I shall be able to do something towards clothing their little ones with a portion of the gift of the good lady referred to. The names of the two men I have just mentioned are James Kirk

Smith, Turner Lane, Ashton-under-Lyne, and Richard Bird, Tame Valley, Dukinfield.

A kindhearted gentleman here has promised to get the goods made-up for these poor people free of cost, and I purpose to raise a fund to buy stockings, shoes, clogs, and other things for them; and if any of your readers would like to help them through this storm, I should be most happy to receive any sum, however small, which can be sent in postage stamps, and I will acknowledge all donations in your Journal.

I can assure the many kind ladies and gentlemen who have taken up the case of these poor honest naturalists, that they have changed to cheerfulness the gloom of many homes.

Parcels of good warm clothing, either old or new, sent to me would come free if on the label were written, "For Distressed Operatives." If I receive more than will be wanted for the botanists, I will distribute the rest amongst distressed cottage-gardeners, of which there are many here; and I can assure ladies and gentlemen that, in the distribution I shall be as cautious as circumstances will allow, and give to the most deserving and to large families.

I will conclude by thanking you for allowing so much space, and the gentleman who so ably pleaded the cause of these unfortunate people in your last week's Journal.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

[We have received and forwarded for these deserving men, 10s. in postage stamps from "LEX," and the same from "PATELIN."]

## THE DALKEITH EARLY AND LATE GRAPES.

CONSIDERABLE interest has been all along manifested, by the members of the profession, at Mr. Thomson's extraordinary success in being able to place upon his employer's table early forced Grapes on New Year's-day; and the excitement may be said to be only culminating, when those who are disposed to give the theory and its results most credence go and see for themselves. It is easy enough to suppose a house of established Vines compelled, by the will of what might be called a dangerous theorist, to yield to unnatural pressure and produce a bunch here and there which might, or might not, come to maturity; but to see a house containing a good "summer" crop of Grapes in the act of stoning, with dark green foliage rustling to the touch, in the month of November, is something not only unprecedented—for to Mr. Thomson, with due deference to others working in the same direction, belong the honour and credit of reducing such practice to a system—but is something foreign to most of our conceptions altogether. Not only so, but we may place on record, for the information of all those who may be inclined to take credit for the theory after the fact, that Mr. Thomson himself, with commendable modesty, acknowledges that the result has far outstripped his most sanguine expectations; and that, like many other knotty points in gardening, he resolved, however unsuccessful, to give it a trial. Dr. Hogg and his co-editor in the "Florist and Pomologist," were evidently as pleased as surprised at last year's productions; and should similar come before their eye two months hence, I am certain they will be more pleased than ever. I am not a betting man, else I should be inclined to give large odds in favour of Mr. Thomson in the forthcoming interesting competition between him and Mr. Tillery.

The house that the Vines are growing in is a lean-to, 36 feet long and 14 feet wide, with a 2½-feet front sash. It is heated by two flow and two return-pipes, fitted with the open gutter, which not only gives off considerable moisture, but adds considerably to the heating power, and shows also the rate the water circulates. Another important addition to these pipes is a coating of sheet iron regularly perforated with holes, leaving an interval of half an inch wide all round. Air is admitted from the outside by two four-inch sheet-iron tubes, fitted with valves, so as to admit or exclude at pleasure, into this vacuum between the sheet iron and the pipes, and, as will be easily conceived, it is superheated before circulating into the house; fresh air so heated in houses of this kind is an important element towards success. The Vines themselves, as has been told by Mr. Thomson himself, are of considerable age, and were experimented upon three years ago, only prior to young ones taking their place, which, of course, has not been done, and will not likely be until another house is prepared to replace the one in question. The young wood was vigorous, and the leaves, as has been hinted at above, all that could be desired. There was no flabbiness nor want of consolidation about any of their parts—nothing, in-

deed, to indicate that the year was any further advanced than June or July. The bunches were all nearly uniform in size, many of them exceedingly handsome, and, so far as we saw, none of the Vines lightly cropped to prepare for the coming struggle. But will they finish? is the rub. Talk of bringing Grapes up to the mark that have to colour in the dark, dullest days of winter, is the cry of the doubtful; and the part that Mr. Thomson is taking in almost ignoring colour in black Grapes, will probably make them more doubtful still. This, to the looker-on, is certainly the most delicate and difficult point to attain; but Mr. Thomson, with two previous years' experience to back him, says, "There is no fear of colouring: they would astonish you on that point."

The late viney is 110 feet long, by, I think, 15 feet wide, and is full from end to end of a very fine lot of fruit, Lady Downe's Seedling predominating. There are also West's St. Peter's and Raisin de Calabre. The Lady Downe's Seedlings are much finer than they have ever been at Dalkeith, and, indeed, are as fine as any one could possibly desire. The bunches are not large but they are uniform, and the berries far above the average size; they were not ripe, but were gone half way in point of colouring. The West's St. Peter's were also very remarkable for their great size of berry, and the bunches, as is usual with that variety, heavily shouldered. Raisin de Calabre was in beautiful order, and is the best keeping late White Grape at Dalkeith. Some of the bunches were not much under 6 lbs. weight, and the berries were of good size and of good colour; the flavour was rich and vinous. At a moderate estimate, there would be five hundred bunches in this house which one might average, after hanging from Christmas onwards, at 1 lb. the bunch. This anybody who sees them will consider under the mark, and would realise a considerable sum of money at the high prices obtained during that season, and, moreover, would pay in full the £160 which Mr. Thomson disbursed for the erection of the house, in one year. The house is placed towards a southern exposure, against a wall previously in existence, which is not included in the estimate. The large sloping sash is a fixture, and ventilation is provided for with a short perpendicular sash at front, and a small sloping one at back. These are so connected by longitudinal iron rods and transverse ones, jointed arm-like, that by means of a lever, in both cases at one end, they can be opened simply and expeditiously as much as desired their whole length. The process is one of the simplest we know of, and one of the most economical.

There is a house here also devoted to the trial and cultivation of seedling Grapes, of which there was a considerable quantity. The fruit of two "crosses" were then hanging. The one was Lady Downe's Seedling crossed by Muscat of Alexandria, of which there had been a goodly batch, but only one reserved as being thought worthy of further trial. This bunch was as unlike Lady Downe's Seedling as possible, only it apparently possesses its late-keeping qualities, and being a White Grape will be worthy of further trial. It is a round berry of a faint amber colour, and its skin is hard, but so crisp as to leave the mark of any puncture as distinctly as it would do in a green state. It is a firm flesh and far superior in flavour to Lady Downe's. The other is a cross between Barbarossa and Muscat. This has black oblong berries, of a medium flavour, making up a handsome bunch of berries, upon the whole rather below the average. Such trials as these, irrespective of their results, are exceedingly interesting, and show what skilful manipulation can effect.—JAMES ANDERSON, Meadow Bank, Uddingstone.

## GRAFTING VINES.

THERE are two best seasons for grafting the Vine. First, when both stock and scion are in a state of rest, and about ten days or so before you wish to set the sap moving artificially, or leave it to move naturally. The Vine cannot be grafted when the spring sap is flowing freely and thin; and, besides, any incision then would waste the energies of the plant. Suppose, then, you commenced raising the temperature of a viney to incite it into action on the 1st of January, we would graft in the last week in December. If the sap began to run naturally in the end of March, we would graft a fortnight previously. We mention this because, though it may only be a notion of ours, our experience would lead us to the conclusion that the grafts do best when they are put on before, but not long before, the sap is in motion. The modes of grafting are endless, and it matters little

which is resorted to. In small stems I prefer cleft-grafting—that is, cutting the stock straight across, splitting it down the middle for 3 inches or so, and making the scion into the wedge form, and making sure that at one side at least the inner bark of the scion joins the inner bark of the stock. The scions I prefer are pieces of well-ripened young wood containing two buds, and an inch of wood above the upper bud. In cleft-grafting the scion is cut across at the lower bud, much if as you were making a Geranium cutting, and then in forming the wedge a piece of the harder substance across the bud is still left. In the case of larger stems we have cut a triangular piece out to fit a similar triangular shape in the scion, but I do not think there was any advantage gained over the more simple mode of just slicing a piece off one side of the scion and a similar piece off the stock, so that the barks of both should unite. In rather thick stems we prefer placing a scion on each side—that is, two instead of one. The scions will be more secure if tongued, but that I have seldom done. The scion is put on so that the lower bud shall be on the outside. Sometimes we cut this bud through to prevent a shoot coming, and sometimes not. If so done the base will be sure to send out small buds afterwards. The two essentials of success are—clean cuts, on stock and scion to fit each other, and tight, careful tying, so that the liber or inner barks of both stock and scion fit. In order to keep the air from the junction, we generally use a little grafting-clay in the usual way, and over that we tie a little moss, which is kept dampish. As the sap begins to move, the scion and stock are kept moderately moist. For this nothing is better than a small bottle hanging above the graft with a worsted string suspended from it in the shape of a syphon. As soon as the union is effected and growth is going on rapidly, the tying must be loosened, but not wholly removed until all danger is past. In fact, it is as well for the first season to have a rod fastened to the stock and going considerably beyond, to which the scion may also be securely fastened.

The second best season can only be resorted to in a house where the Vines are forced so early that they will be in full leaf before a scion kept in a cool place out of doors has at all commenced to move. Grafting then is often done with great success. As soon as a Vine is in full leaf—that is, when the leaves are nearly their natural size, you may cut and prune as you like without any danger of bleeding. The retarded scion may then be put on; and a little more care given to keep it warm and moist, along with the free action of growth in the stock, will generally cause the scion to start quickly and freely. It will at once be seen that, keeping both modes in view, a person may have two strings to his bow. I on the whole prefer the first, though both myself and many friends have been successful with the second. Inarching differs from the second mode, inasmuch as instead of a scion a growing plant is joined to a young shoot by a splice, or laying, similar to grafting; and when once the union is effected, the root part of the new plant in a pot is removed.

Although not a word too much has been said of the Lady Downe's Grape, which you wish to graft on the Hamburgh, it is chiefly as a late Grape that it has acquired such a good reputation; and though, as you say, Grapes in a greenhouse are a great attraction, it should never be forgotten that if plants in pots are also of great importance, the earlier Grapes that may be cut and used—say before the middle of October, are often the most useful. We rather think that Lady Downe's will stand damp as well as any, but we know that some who planted West's St. Peter's, Barbarosa, &c., in their greenhouses, in order to have late Grapes, found that the damp from these plants began to injure them before they were ripe. Of course, such a state of things would not apply to a house receiving a considerable assistance from fire heat; but then that properly speaking would not be a greenhouse, with which we associate generally no more fire heat than will keep it from 40° to 45°.—R. F.

[The above is in reply to "A SUBSCRIBER OF THE FIRST YEAR." To his other queries, the serial on Orchids is 10s. 6d. per part. There is a drawing of the "Lady Downe's Grape" in the last Number of "The Florist and Pomologist."]

### CHRYSANTHEMUMS.

MR. SALTER'S, VERSAILLES NURSERY, HAMMERSMITH.

THE winter garden this season occupies three houses, and the collection has not hitherto been seen to such great advantage. There were nearly fifty kinds of new Chrysanthemums in bloom on the 10th instant, which I had never seen before; and among

them are flowers for all tastes and fashions, and every kind in Europe that is worth growing may be seen in bloom there every season, and that too in their free natural way as common herbaceous plants. But one whole house was devoted to trained plants of moderate size in the style of country conservatory arrangements, very different, and very much better, and more safe for buyers, than the close compound training for exhibitions. If no man can make out if a plant has one stem only, or one and twenty stems, I say that is not safe work for purchasers. Every leaf and every joint of every one of these plants can be seen and examined. The pots are small, and the plants are rounded up to the centre just as one would choose for one's own house where, in our own eyes at least, there ought to be none like our flowers, like our plants and plant-training, and over all and above all the rest—none like our flower-beds and our arrangement of colours.

Upon that principle Mr. Salter has put himself to the extra expense this season of having a fresh first-class trainer and grower of Chrysanthemums, as his customers choose them, and that will bring him in more money, more custom, more care, and more pleasure than he ever yet had in this plant-family. Every trainer of note has his name entered in the stud-book as regularly as the horse and his rider, and our new trainer must be booked that we may not lose sight of him; but I must beg pardon, for I forgot his first name in the striking coincidence of his being the third great Knight in gardening in my day.

I knew Mr. Keight, of Downton Castle, and first President of the Royal Horticultural Society; I knew Mr. Knight, of the Exotic Nursery, Chelsea; and I know Mr. Knight, of the Versailles Nursery, Hammersmith, who first introduced the domestic style of growing and training the Chrysanthemum into a London nursery, and I would advise every one who can and who values that inestimable treasure—domestic peace and comfort, to go and see that style of growth and training, and to go home and follow the example; and the best way I can impress the injunction is by doing the next best thing myself in the same mood—that is, to give the cream of the best and newest of the seedlings, not naming those which are mentioned in the report of the Show in another page.

Loyalty demands the first turn; and Queen of England, worthy of the name, is a splendid large blush, together with the sports from it—namely, Alfred Salter, Golden Queen of England, Striped Queen, White Queen, and Lady St. Clair, all considered, both as regards form and size, as the finest flowers in cultivation. The original Queen of England was raised from seed by Mr. Salter in 1847, and ten years before that he raised Madame Poggi, which has not yet been exceeded in size or in the deepness of its dark purple colour. It was named after an English lady who married a Spaniard of that name.

The first in my notes is Victor Hugo, a large deep ruby, incurved flower; ruby in this family being a deep shade of Indian red. Pyramidalis, orange and red, hybrid, or one-half large and one-half Pomponne; a foot or 18 inches of every shoot blooms in pyramid fashion: hence the name. Daphne, bright sulphur and darker centre; a fine, conspicuous flower, and very large. Golden Fleece, in the way of Plutus, and the best of that style of flower; the plant is dwarf and remarkably well suited for pots of a smaller size than usual. Hugh Miller, dark red chestnut, and incurved. Jane, the best foliage and habit in the collection, a most delicate pink incurved flower, and an excellent pot plant.

These, together with the eighteen kinds mentioned from the Exhibition, include all the seedlings which have flowered up to the 10th of the month.

The next move was to go over the flowers which were sent out first last spring, and the newest of the last two years. Boadicea, rose and cream, with a high centre, was very large. Caractacus, a blush-tipped carmine rose; Ariades, very large creamy rose, a new shade; Alma, rose crimson, according to Chrysanthemum colour; Dido, sulphur white, one of the best for specimens; Draco, dark; and Dr. Brock, reddish-orange, all first-class for specimens. Also, Dr. Maclean, which is a sport of Minerva, and here it is sporting into quite a different colour; Cherub, a beautiful golden amber; Ion, the purest white of all; Emily, a beautiful blush; Julia Grisi, a fine new shade of rose and pink, and now sporting buff; Leda, large white; Général Dumesnil, very large dark fawn; General Slade, Indian red; Garibaldi, red chestnut; Le Bureau, red, tipped with golden yellow; Pandora, mixed rose, yellow, and nankeen; Prince Consort, next shade to Progne, purple; Miss Prim, a clear yellow hybrid, prim as a Primrose; Miss Slade, paleish

sulphur; Lord of the Isles, large rosy orange; Sparkler, red tipped with orange, after Auguste Mic, a splendid kind; and with Saccoi Vera, rosy lilac; Rifleman, Lord Ranelagh, and White Christine, will finish this division, and it is almost needless to say they are all incurred flowers.

Out of the general collection I give an alphabetical list of the very best kinds, on the joint authority of the Messrs. Salter, father and son, and their humble servant the writer; but to save room I shall refer you to their catalogue for descriptions.

Alfred Salter	Lady Hardinge
Albin	La Belle Blonde, very large white
Alma	Léon Laquay
Annie Salter	Le Trouvère
Ariadne	Little Harry
Aregina	Lord Ranelagh
Auguste Mic	Maréchal Ducoc
Bixio	Miss Slade
Caractacus	Mr. Fleurian
Carissima	Mrs. W. Holborn
Cassandra	Pandora
Cherub	Pio Nono
Christine	Prince Albert
Dido	Princess Maria
Dr. Brock	Princa Consort
Duchess of Wellington	Progne
Emily	Queen of England, and all its sports
Etoile Polaire	Rifleman
General Slade	Seraph
Globe, White	Sparkler
Golden Hermione	Sulphurea superba
Golden Queen	Versailles Defiance
Ion	White Christine
Jardin des Plantes	
Julie Grisi	
Julia Lagravère	

I noted besides some very interesting plants and some new ways of doing them, which for want of room must stand over till our columns are a little relieved.—D. BEATON.

PLEROMA ELEGANS.

THIS splendid Melastomad is chiefly interesting from the fact that it produces abundance of its deep blue purple flowers on comparatively small plants, and may be managed without a plant-stove, which most of its neighbours require. The fact that the large flowers are produced most freely on the points of last year's shoots furnishes the key-note to its culture. The next thing essential to success is that it will not thrive if kept in a plant-stove, nor yet will it thrive if kept in a cool greenhouse. In the one case it will get straggling, and the wood will not

ripen well enough to bloom freely; and in the other the plant will assume a starved appearance, and become brown and unhealthy.

In propagating it by cuttings any time during summer would do, but as a matter of choice we would prefer March or April. The points of shoots getting firm at their base would answer; but we prefer firmish side shoots from 2 1/4 inches to 3 inches long, rather green at the point, but brownish and firmish at the base. These are to be cut across at a joint at the bottom, the leaves there removed; the pair above either removed or shortened, and, if long, a little shortening given to all but the terminal ones. They may then be inserted in a well-drained pot, in silver sand over very sandy peat. The success will be all the more certain if a small pot is reversed in the centre of the cutting-pot, so that the base of the cuttings may abut on the centre pot. Fill any holes made by the dibber with silver sand; water well; and, when the sand is firm and the plants dry, cover the pot with a bell-glass, and plunge the pot in a mild bottom heat, shading the glass in bright sunshine, but giving no shade when cloudy; removing it early in the afternoon, and giving a little air under the glass at night, replacing it before sunshine in the morning, and preferring to keep the atmosphere of the cuttings and the bed round them somewhat moist instead of watering the cuttings much. When struck, pot-off singly in small pots, or three round the sides of a four or five-inch pot, using at first a light soil, as three parts of heath soil to one of loam and one of silver sand, and increasing the amount of loam as the plant gets older.

Under the most favourable circumstances a cutting could hardly be expected to make a show as a flowering plant under three or four years, or even more. Amateurs would therefore be nearer their purpose to procure from a nurseryman a nice, bushy, healthy plant, in a four or a six-inch pot; and though we give the process of propagating, yet with all such things it will be the truest economy to keep in mind the division-of-labour principle and purchase a nice plant, as propagators by profession can do all that sort of thing at half the labour and expense that any amateur, or any gardener with a great variety of plants demanding his attention, could by any possibility do.

Supposing the plant to be obtained, our cultural remarks will chiefly have reference to getting it to bloom early in the summer of the following year. The plant, then, home-raised or purchased, being a nice little stubby plant in the end of March or beginning of April, and occupying a five-inch pot pretty well filled with roots, we would keep the plant in a temperature of from 50° to 55° with a view to promote free growth, and this, especially in a bought plant, for a fortnight or three weeks after obtaining it, so that all the stagnation of the journey might be got over. The next thing to do is to give the plant a larger pot. Unless in skilful hands that will regulate watering to a nicety, very large shifts are to be avoided; but so are very small ones, as the plant seems to need a little nursing after every shift. Well, supposing the plant is in a five-inch pot, we would transfer it to a seven or an eight-inch, draining the pot well, using a little broken sifted charcoal over the drainage—that is, getting rid of the dust; then gently disentangle the roots outside the ball, so that they shall run at once into the new soil, taking care that before shifting the ball is thoroughly and sufficiently moistened, as fresh-potting such a plant dry is next-door to throwing it away. The soil should be in good order, neither wet nor dry, and picked-in pretty lightly among and to the roots.

Soil Used.—What is best for young plants has already been stated. For plants about this size three parts of heath soil to two of loam, should be used; and one part more may consist of silver sand, broken pots, and nodules of charcoal, so as to allow free passage for water. When the plants come to stand in a ten or twelve-inch pot the fibry loam and heath soil may be in equal proportions, and then the loam will insure more sturdiness in the growth. Then, too, a little fine aerated leaf mould may also be used in the soil. A little moss will likewise be an advantage between the soil and the drainage.

First Summer's Management.—After potting it would be well to raise the temperature gradually from 50° to 60°, using a little shade in bright sunshine, and frequent sprinklings overhead, until the roots are working freely in the fresh soil. Until then, water should be given carefully, so as not to deluge the fresh soil until the roots get into it. A skiff from the syringe will be useful in sunny afternoons until the end of July. As soon as you perceive the roots are taking fresh hold, the training of the plant should commence, fastening some shoots nearly horizontally, but letting their points have an upright direction, so that the plant when full grown shall have an orbicular form. Many

of the shoots will need no stopping owing to their comparative weakness; but all the stronger shoots will need to be stopped several times, so as to insure compactness and regularity of growth. When blooming next season is resolved on, no stopping of shoots should take place after the end of June. Water will be required in greater quantity as the sun gains strength; and as the roots get to the sides of the pot, manure water will help to give strength and colour, using it in a clear and weak state. Were we not to think of blooming the plants the following year, we would shift again in June; but wishing to have flowers we will not do so, but will gradually give the plant more air, after July, to consolidate the little shoots.

*Autumn and Winter Treatment.*—In August, in addition to giving more air in a greenhouse, we would prefer the plant to stand in a cold pit, with glass over it, and air back and front. In September we would gradually diminish water, and by the end of the month put the plant in a house where the temperature will not be below 45°, nor above from 50° to 55° with fire heat, during the winter. Water, also, should be given carefully, and the plant will be safer if the pot stand inside of a larger pot, with damp moss stuffed between them. In spring the plant may have from 5° to 10° higher temperature as the sun gains power, and more moisture in proportion, which will cause the flower-buds to show and swell.

*Future Treatment.*—When in bloom the plants will keep their beauty longer in a cooler atmosphere, and with a little shade to break the fierceness of the sun's rays. When done flowering give what little pruning is necessary; encourage the plant to grow, shift into a larger pot if necessary, keep close and moist until there is free, fresh rooting, and in autumn give more air and sunlight, as already described, and house in time for the winter.

*Insects.*—If a little fly appears, smoke in the usual way. The most troublesome customer is the thrips, and the best preventive is a free use of the syringe when growing, and frequent smokings and washings as soon as one is seen. If manure water is used from the droppings of animals, it would be advisable to soak the droppings at first in boiling water, which will destroy all vermin and their eggs, and the water may be reduced enough afterwards.

In watering in winter, the water should be soft, and a few degrees warmer than the atmosphere of the house.—R. F.

*ERRATUM.*—In the fortieth line from top in first column, page 633, the first word, "pruning," should be "moving." Will "A. R. M." correct it?

### INSCRIPTIONS ON EXHIBITION CARDS.

It is the practice with our Dublin Royal Horticultural Society to have on the entry-cards, with the heading of the particular class, also the name and address of the exhibitor. These cards are placed on before the Judges go round, and remain on during the day. It is very satisfactory in this way, as not only the names of those who take the prizes are before the visitors, but the names of all the competitors. It appears to have a good effect, too, in making exhibitors careful—much more careful than they would otherwise be—not to bring forward anything that, even though it shall not get the prize, would not be at least creditable. I have heard, too, that impartial judgment is more likely to be had in this way than when the names are concealed.

Will you be so good as to favour me and other exhibitors in your next issue with your opinion on the subject, and also say is this the practice with your great London and other leading Societies in England?—AN OLD SUBSCRIBER.

[At the Exhibitions of the Royal Horticultural Society, those of the Crystal Palace Company, and at some of our leading provincial exhibitions, the name of the exhibitor is inserted on the exhibition class card before the Judges go round; but each card is turned so that the blank side only is seen, until after the Judges have made their awards.—EDS. J. of H.]

### EASILY-MANAGED HEATING.

MY apology for intruding on your space is the hope that my experience may be of some use to other amateurs, who, I observe, often write for information as to the best means of heating small houses, and on the most economical plan, or that will admit of the removal of the arrangements on the expiration of a tenancy.

I must premise that I have tried flues, gas, and hot water at different times, and have been successful with all; but my pre-

sent plan, I can safely engage, most fully answers the above so often-repeated questions.

The boiler is an upright one, and the pipes are on Truss's patent, which are put together with vulcanised india-rubber bands and screw collars, which are so simple, that, by having a spare length or two at hand, either the master or his man can in half an hour take out and replace any piece in case of accidental flaw.

Since the early spring I have kept a propagating-tank, hot-house, and intermediate-house in full work without any cost for fuel, having only made use of the ashes and cinders of the house and laundry. In five minutes after lighting the fire the flow-pipe becomes warm, and in half an hour the circulation is complete through about 200 feet of two-inch and four-inch pipes. If the fire is made up about ten P.M. it requires no further attention till the next morning, and I generally find it burning. The heat from the upright boiler is sufficient to keep off excess of cold from a greenhouse or range of pits, and the whole apparatus can be removed in a short space of time without the assistance of skilled workmen, and without leaving any traces or causing any destruction of material.

I think that my case will answer many of your correspondents' questions; and should you or they require further information I shall be most happy to afford it, and for this purpose enclose my card.—SUBSCRIBER SINCE 1856.

### LAMBTON CASTLE, ITS GARDENS AND SCENERY.

HAVING, on a former occasion, described Ravensworth Castle and grounds as a place of much consequence in the county of Durham, I now endeavour to give an outline of another nobleman's seat, differing considerably from the former in its general features of landscape scenery and in position; while in its architectural construction there is some similarity, as both are castellated mansions, and both were built about the close of the last and beginning of the present century. Lambton Castle may, perhaps, of the two combine a little more of the ecclesiastical style of building in its construction than the other; but massive Norman towers characterise both, and at Lambton the builders have been fortunate in obtaining a stone that stands well. Much of the building has the same clean light colour it had when first erected, and this is much to say in a neighbourhood where coal smoke abounds so much.

The situation of the Castle is on the precipitous banks of the river Wear, which flows at about a stone's throw from the terrace wall which surrounds the Castle, the bed of the river being some 150 feet or more below the terrace. This great elevation gives the place a fortress-like character; and the opposite side of the river, being also steep, rocky, and abrupt, is planted with trees, which in many places reach into the stream. It is easy to conceive the bold scenery which is here brought before the eye, while occasional cross ravines tumble in their waters into the mother stream, which here shows little signs of the many uses it is put to only a short way lower down; for the busy port of Sunderland is less than ten miles off with its closely-packed-in forests of vessels; and ship-building on the banks of this river has been carried on, perhaps, to a greater extent than on those of any other in England. An almost closely-united string of building-yards extends up the river to near Lambton, giving employment to a busy population; besides which, the surrounding country is dotted over in all directions with coal mines, or intersected by their necessary adjuncts—railways.

It has often been a source of wonder that a demesne like that of Lambton should preserve its retirement, its sylvan beauty, and the other features which form so important a character; for at the distance of two or three miles, or less in some points, we come upon those deep and extensive coal mines which from time immemorial have been regarded as the Durham coal fields. Unfortunately, the workings of these mines in years gone by have been much nearer the mansion of Lambton than was expected, for subsequent events have proved it to have been undermined. To those who are not acquainted with such matters, I may mention that coal is usually found in seams lying horizontally, and from 2 feet to 5 feet or 6 feet thick. Seams less than 3½ feet are seldom worked. These seams lie at various distances—say from 50 yards to 500 yards deep; the latter depth being, I believe, about the lowest-worked seam hitherto

tried. Now, it appears that one or two of the seams nearest to the top had been worked out, and the coal all, or nearly all, taken away from the part immediately underneath the Castle. The result was that some ten years ago the ground sunk in a broken manner, carrying the Castle with it; the irregular shrinkage, creating great fractures and settlements, disfiguring and deranging the whole. This settling of the ground, I was told, went on for some years, creating great alarm, as may be imagined, amongst the inmates. Of course, means were taken to remedy the evil by securely building-up the excavated part underneath, or filling it in with material that will bear the superincumbent weight; but this serious calamity necessarily deranged the mansion as a residence for some years, so much of it had to be taken down entirely, and some alteration or addition will be made. Not the least important, and one that will give the reader some idea of the magnitude of the whole, is an entrance-hall 90 feet long by 60 feet high. The width, I believe, was to be about 60 feet also. A local stone of good quality and of a pale grey was to be used in the interior; outwardly the Castle is built of a light-coloured freestone.

The approach is on the north side. One of the lines of carriage-road, after curving towards the river, is carried over it by a noble bridge of one arch, lofty and well-proportioned, and forming an imposing object from the Castle terrace. The steep bank of the river, with the exception of the strip between it and the Castle walls, is thickly wooded on both sides for some distance, and affords some beautiful drives and walks.

The kitchen garden is to the north-east of the mansion, and at this spot the rise from the river is more easy, giving the kitchen garden a gentle slope to the south-east; nevertheless the garden is formed into terraces by intervening walls running parallel with the river. The north wall is devoted entirely to a range of Grape and other houses, and in length is little short of 500 feet; the houses are also of good width—a central one, higher and broader than the rest, being a greenhouse. They are in good working order at the present day, although they have been in use between sixty and seventy years. In breadth and general character they much resemble those previously described at Ravensworth. On a rising ground behind were some fore-pits of more recent date, and also frames, cold pits, and like structures; while to the south the kitchen garden descended for some distance, a terrace wall retaining the platform upon which the range of houses spoken of were built, a broad gravel walk and the Vine-border being also included. I believe there are upwards of four acres inside the walls. The walks, as well as those leading through the woods and elsewhere, were of a beautiful white gravel; the particles, by carefully sifting, being all of uniform size—a trifle larger than large Peas.

In the immediate neighbourhood of the mansion, the presence of a hundred workmen in the building-way prevented anything in the character of dressed ground just then; but the walks, leading in various directions through the woods and by the side of the river, had many fine and beautiful openings, which were made use of to plant here and there Pinuses of the various popular kinds. Shrubs, especially Rhododendrons, were liberally scattered about; and there were magnificent specimens of native Ferns meeting the eye at all turns. Occasionally a large area had been cleared, and a group of Pinuses introduced, some of which gave promise of becoming useful trees at a future date; but it was evident many others required a warmer climate. The hasty glance I was obliged to take of them prevented my noticing them in particular. Some other objects of interest were also occasionally met with, not the least important being a fancy dairy, which, in addition to being highly attractive as regarded its outward appearance and inward embellishments, was also well adapted for the purposes intended, which is not the case in all fancy buildings of a like nature.

Following the broad and well-kept walks leading through these romantic woods, we often get glimpses of the river; while its rugged banks on the opposite side are also cut into drives and walks of a like nature. Amongst timber trees the Oak seemed to thrive as well as any, and of the evergreens the Silver Fir and its kindred were also in tolerable health; while among shrubs the common Laurel was certainly not so much at home as the Rhododendron: the severe winter of 1860-61, which had been fatal to so many Pinuses here as well as other places, had also severely cut up the common Laurels. The Portugal Laurel was in better plight, the moist soil and climate being more favourable to the one than the other; but, so far as management could be brought to bear on the case, everything

was being done which liberality and skill could suggest to make this fine place as attractive as possible. Mr. Stevenson, the worthy gardener there, often lamented the losses they had sustained by the hard winter of two years ago; still abundance is left to testify to the liberality of a bygone time, and I have no doubt but a place which has been carefully attended to for a century or more will continue to receive all the accessions which its situation and climate render advisable, though more favoured districts may excel in the heights of Wellingtonias, Cedrus decodaras, and the like. Lambton Castle, which, I believe, occupied a proud position in the annals of the country five hundred years ago and more, will, I hope, still continue to do so; and, when under the care of such public-spirited noblemen as the late and present proprietors, there is not much chance of a place of modern growth excelling it.—J. ROBSON.

#### CELERY-GROWING AND FAILURE.

HAVING sown the following varieties of Celery—Ivery's Non-such, Laing's Mammoth, Manchester Large, and Incomparable Dwarf White—on the 15th of February last in seed-pans, and plunged them in a bottom heat of 75°; when the plants were fit to handle I had them pricked-out 3 inches apart on dung-beds with a covering of 3 inches of soil, protected with box frames. The bottom heat was 70°. They grew vigorously, and were hardened-off gradually. Meanwhile the trenches were being prepared as follows in an open quarter of the garden, the soil of which is light, resting on gravel at a depth of 2 feet:—I had a trench taken out 15 inches deep, 12 inches wide, and filled with good rotten farmyard manure to within 5 inches of the ground level, over which 4 inches of soil from the trench was put. Then, with a space of 30 inches from side to side, the next trench was proceeded with in the same way, and so on till the quarter was all ridged. Selecting a damp day, the plants, which came up with good balls, were planted with the trowel, and received a watering with the rose on the pot. Damp weather prevailed for nearly a fortnight after they were planted, so that they never had a check; but, on the contrary, being strong stubby plants when put out, they grew vigorously. During the summer, when they required it, they had a good watering from a tank that drains the stable and cow-shed and receives the rain water from the roofs. This was in every instance followed by water from the pump equal in amount to one-fourth part of the whole of the manure water. The earthing-up was attended to about every three weeks until the 8th of October, when they were attacked by the blight or maggot in the leaf. On its appearance I had the diseased parts picked off and destroyed. The Celery received its last earthing-up on the 14th of October; and now, when we come to use it, it is stringy, bitter, and rotting very fast in the hearts, so that I have to discard about three heads as unfit for one that is good.

In former years I have grown my Celery in four-foot beds; but as it was in precisely the same condition, I tried the single rows this year. If you or any of your correspondents can assign a reason, or prescribe a cure, I shall feel deeply indebted.—P. L. C.

[This is not a solitary instance, and we publish it without comment in the hope that some of our readers will impart some information.—EDS. J. OF H.]

#### DEATH OF MR. GLENDINNING.

WE regret to announce another loss which the gardening community has sustained—that of Mr. Robert Glendinning, of the Chiswick Nurseries, who died on Sunday the 9th inst., after severe and long-continued illness, at the early age of fifty-seven. He was a native of Scotland, having been born at Lanark, September 27, 1805, and took to gardening at an early age. He came to England in 1824, was for three years at a place in Somersetshire, and went from thence to Lady Rolle's, at Bieton, in 1829, where he continued for eleven years, giving during that period ample evidence of his skill as a practical gardener and forester.

After being in partnership with Messrs. Lucombe and Pince, of Exeter, for some while, he took the Chiswick Nurseries, formerly occupied by Mr. Williams, in the spring of 1843. This place, which was then in a very decayed condition, he entirely remodelled, building fresh houses and greatly increasing its extent so as to enable him to meet the requirements of a first-class business. As a cultivator of Heaths he

was unsurpassed, and his collection of these was very complete, whilst for Conifers and fruit trees he always held a high reputation. As a landscape-gardener he was extensively employed, and in that capacity carried out with great skill several important works.

Mr. Glendinning was the author of an excellent treatise on the Pine Apple, and contributed papers on subjects connected

with horticulture to Loudon's "Gardener's Magazine," and other gardening periodicals of the day, as well as to the "Journal of the Horticultural Society," of which body he was a member for upwards of twenty years.

We are happy to learn that the fine nurseries which he may be said to have created will not be broken up, but will be carried on by his sons.

### ORNAMENTAL PLANTS.

**ROGIERA AMÆNA** (Pleasing Rogiera).—*Nat. Ord.*, Cinchonaceæ. *Linn.*, Pentandria Monogynia.—A handsome cool stove or greenhouse shrub, with di- or tri-chotomously divided branches, broadly oblong acuminate, opposite downy, deep green leaves, 2 inches or 3 inches long; the young leaves are faintly tinged with brown. The inflorescence is a many-flowered trichotomously branched terminal cyme, the blossoms of which are

crowded, of a pretty rose colour, deeper on the tube. The corolla is salver-shaped, with a tube about half an inch long, slightly thickened upwards, and a limb of five oblong, emarginate, spreading lobes. The flowers measure about half an inch across the expanded limb. From Guatemala; temperate regions. Introduced to Belgium in 1848. Flowers in summer.

1. Rogiera amœna.  
2. Cuphea verticillata.

**CUPHEA VERTICILLATA** (Whorled-leaved Cuphea).—*Nat. Ord.*, Lythraceæ. *Linn.*, Dodecandria Monogynia.—A pretty half-hardy plant with herbaceous or sub-shrubby hairy stems. The leaves are in whorls of three or four, sometimes opposite, and are nearly sessile, oblong, or ovate-oblong, somewhat rounded at the base, scabrous above, hairy beneath. The flowers are extra-axillary, from opposite sides of the stem, and consist of a

curved calyx-tube, about an inch long, pale yellowish-red, and a very irregular corolla of five to eight deep violet petals, of which the two upper are more than half an inch long, oblong-obovate, and undulated, the rest minute. From Peru and Columbia. Found by M. Linden at Pamplona upwards of 8000 feet above the level of the sea. Introduced to continental gardens in 1848. Flowers in autumn.—(*Gardeners' Magazine of Botany.*)

## TRITOMA UVARIA CULTURE.

I PURCHASED a plant of *Tritoma uvaria* lately, and was directed to keep it in a cold frame during the winter, and plant it out in the spring; but I have ventured to plant it out in the open ground, and covered it with 3 inches or 4 inches in depth of coal ashes, and in addition it is covered at night with a tub and mat, as the leaves are still green. The tub and mat are removed every day, but in case of severe weather I intend to keep these on altogether during the continuance of such weather. I can still take up the plant, pot it, and move it to the cold frame or greenhouse if you recommend it.—COUNTRY CURATE.

[You are treating it particularly well, and much better than in a cold frame or greenhouse. Your mode of protecting it is one of the best contrivances possible for such a plant, but the mat is hardly wanted. About the end of November the leaves might be cut down to the ashes, then another layer of dry ashes from the fireplace put on, and the tub put over it and left so day and night to the end of March.]

## GREENHOUSE PLANT.

*CANTUA BUXIFOLIA* (Box-leaved Cantua).—*Nat. Ord.*, Polemoniaceæ. *Lim.*, Pentandria Monogynia. *Syn.*, *C. ovata* and

*C. tomentosa*, *Cavanilles*; *C. uniflora*, *Persoon*; *Periphragmos dependens* and *P. uniflorus*, *Ruiz and Pavon*.—A most beautiful greenhouse bush, very much branched, the branches downy. The leaves are variable in form, generally oblong-ovate, and either entire or sinuate-serrate, and are downy or glabrous. The very large drooping flowers form a leafy terminal corymb; the thick tube of the corolla is 3 inches long, the limb spreading  $1\frac{1}{2}$  inch across, deep rose, almost crimson, the tube reddish-yellow. It appears to be an easily-grown greenhouse plant, requiring something the treatment of *Fuchsias*. From the Peruvian Andes. Introduced in 1849. Flowers in April and May. Messrs. Veitch & Son, of Exeter and Chelsea.—(*Gardeners' Magazine of Botany*.)

Cantua buxifolia.

heart. Double the produce that this gives might be obtained from better sorts; but the latter are unsaleable.

A severe winter, or the contrary, makes the whole difference with respect to the value of this crop, and in cheap seasons I have little doubt but that the opinion of its not usually proving a productive one is correct. The land, however, is left in excellent condition for whatever may follow.

The large Flatpole or Drumhead Cabbage, commonly grown for the winter food of cattle, is also found in a prominent place on the market-stall. These are sown in September, stand the autumn in their seed-beds, are pricked-out in early spring, and finally planted about the end of June. I have grown considerable quantities of them for some years, and whether sold or consumed on the farm, the return has been satisfactory.

A much larger breadth was formerly sown in Onions than is now the case, and Wales was the market to which what was not required for the home supply was then sent. The small profit of this crop, also, is complained of, and probably correctly, as the weight per acre is undoubtedly far below what is obtained in the districts around London—such as West Ham and its neighbourhood. The cost of weeding, also, in a moist climate like our own, is excessive, and to the same cause the inferiority of the sample may often be attributed. Radishes are sown in considerable quantities in November, the crop being fit for

market by the time that the sprouted Potatoes are ready to go in March.

The White Belgian Carrot finds a place in most occupations for consumption in the stable; but the same expense in hoeing adds considerably to its usual cost elsewhere. Some years since it readily sold at £2 per ton, but the price now rarely exceeds £1 5s., which, probably, as compared with Oats, is its full value. The Altrincham and other red Carrots yield well; but there is a difficulty in keeping them through the winter, from the early period at which worms and grubs attack them.

The warm sandy slopes around Marazion, as already mentioned, are very favourable to the growth of both white and yellow

Turnips, with which the adjoining markets are abundantly supplied almost throughout the year. Swedes are seldom satisfactory on the lands occupied by the market-gardener, and where they used formerly to be planted-out after Potatoes Mangold Wurtzel now takes their place.

Rhubarb was till lately grown largely, but at present it is not in so much favour, though the soil is most suitable, and seaweed the best manure than can be given to it.

Asparagus has a fair share of ground allotted to it, but its quality is not that which would recommend it to the London consumer, who requires so large a proportion of tough white stem to its edible end. Earthing-up the beds and keeping the plants at greater distances would, of course, produce heads fitted for this London requirement; but a large local sale seems to render the growers indifferent to a more extended market.

Sea-kale, with few exceptions, is raised only for private consumption. This vegetable, however, I fully believe, would be a very remunerative speculation to the Cornish grower, if he would study the condition in which Covent Garden requires its production. And the same may be said with respect to early Cauliflowers, which stand our winters without any protection.

This concludes the list of vegetables grown for sale, and it will be observed that several are complained of as giving bad

## MARKET-GARDENING IN WEST CORNWALL.

(Continued from page 636.)

POTATOES and Broccoli are the only vegetables here cultivated for the supply of the London and other distant markets. The growers, however, have a large local demand from the thickly-populated mining districts in the neighbourhood, and their waggons are consequently dispatched as far as Falmouth and Redruth.

Cabbages are next in order with respect to the acreage employed in their cultivation; but all accounts unite in representing them as not giving a good return for the outlay. Woollen rags are the usual manure, and this in larger quantities than for Potatoes. Planting is done in November, and cutting begins in March. Attempts have been repeatedly made to introduce the Fulham and other like Cabbages, but hitherto without success, the only demand being for the Cornish Cabbage, which is a poor variety of the Paington, having large and straggling leaves with thick midribs, and a small

indifferent returns. Such complaints, however, are capable of being, in many instances, sufficiently accounted for. With respect to nearly all of them, for instance, the comparison is commonly made between their habit and that of the combined Broccoli and Potato crops, which latter will be easily understood, as giving a very high average return. Defective cultivation is another cause, and in this respect it would be a useful journey for many of our growers to visit the market gardens in the vicinity of London, and thence try to introduce into their own system the same careful eradication of weeds, attention to the constant occupation of the ground, and the proper rotation of crops, that they would witness around Fulham and Hammer-smith. In all these respects we have much to learn; but what has for a long time done well is only with reluctance altered on the chance of doing better, and where Nature has been as bountiful, both as respects soil and climate, as she has proved here, this difficulty is always increased.

The fruits in cultivation may be shortly summed-up. Apples, especially Codlins, and other early varieties, are extensively planted where the requisite shelter from wind is attainable; but they are not, generally speaking, well managed, standing too close together, and the pruning being carelessly done. Little attention is given to their due succession, so that by Christmas we are generally dependant on importation, the home-grown supply being by that time exhausted. The climate, doubtless, is unfavourable to the late keeping of either Apples or Pears, both of which, in respect of their late varieties, ripen six weeks or two months before that state would be attained in the colder districts of England. But still hardly an effort is made to produce what easily might be provided for the early months of the year.

Few Pear trees are seen in the orchards of the market-gardeners, though in regard of the hardier varieties their average produce is encouraging.

Beneath and between the rows of Apple trees, Black Currants and Gooseberries are largely planted, the produce of the latter being sold green; and it is by no means an unusual practice to grow between the bushes one or more rows of Potatoes; but the constant disturbance of the ground necessitated by this practice is not favourable to the well-doing of the trees.

Plums were formerly in extensive cultivation around Penzance, but are now out of favour, and the supply beyond what comes from Kea, a parish near Truro, is brought down by steamers from Bristol.

Many acres were once given to the cultivation of the Carolina Strawberry; but this has given way in a great measure to the Broccoli and Potato system, so that this fruit has now become an inconsiderable item of production. On the greenstone formation many of the larger varieties of this fruit, such as Keens' Seedling, and the British Queen are too apt to run to leaf, notwithstanding all efforts to check this tendency. Sir Harry and Trollope's Victoria, however, bear well.

Cherries are hardly ever seen beyond a garden wall, and where they have been tried elsewhere the result is far from satisfactory.

Walnuts and nuts generally must be spoken of in the same way, and their failure is, doubtless, in a great measure to be attributed to the mild autumn, which prevent the due ripening of the young wood. Severe pruning of the roots, and their exposure during the winter, have given a small crop from Filberts, which for years have borne nothing; but no system of management is likely in this climate to make them worth the ground they occupy.

Such are the general features of the market-gardening of West Cornwall, and from what has been said, it will be evident that much has yet to be learnt before it is brought to that point of excellence which soil and climate warrant our looking forward to. A great advance has been made within the last few years, and its future progress ought certainly to be maintained at an equal rate, if due care and intelligence be given to the work.—W.

#### PINES NOT SWELLING.

I HAVE now several plants of Black Jamaica Pine in fruit. For this last month they have made very little progress; and on examining them I find a great many of the pips very brown and shrivelling, having the appearance of being bruised or rather scalded, and the fruit not swelling. But the crowns grow fast, and the plants look healthy. The house has been kept at from 70° to 80°, with bottom heat from 80° to 85°, and air given at every opportunity. The plants are syringed in the morning with

water of the same temperature as the house, and the pipes sprinkled in the afternoon, causing a little steam. I should feel obliged if you could enlighten me on this subject.—A SUBSCRIBER.

[In this dull weather, be satisfied with 70° as the maximum for fire heat, with a rise of 5° to 10° in bright sunshine. Let 65° to 70° be the average at night. Place evaporating-pans on the pipes, but neither syringe nor steam. A little skiff of the syringe might be given on a very bright day.]

#### PROPAGATING STRUCTURE IN A GREENHOUSE.

I WISH you would publish a plan for a cheap way of propagating plants that could be used in a corner of a greenhouse. Something 4 feet by 3 feet would do well for most amateurs. If one had gas a small tank could easily be kept warm; but such an auxiliary as gas in the country is out of the question. Could a small stove be used as described in "Greenhouses for the Many," set as in an oven? or would heat sufficient be kept up in a small tank by using a few common paraffin lamps? I have been puzzling my head to try and invent some easy plan of securing bottom heat to strike plants, such as Verbenas, in spring, better than a hotbed, which is very unsatisfactory. I must look for aid to some of your worthy correspondents, as I am sure they are willing to help an amateur in difficulty.

I should also be glad to know whether it is better to keep young rooted plants of Verbenas in a cold pit, or on a high shelf in a greenhouse near the glass?

Would it be advisable to replot Verbenas which are now well established in three-inch pots? I imagine that by letting them grow a little they would run less risk of dying-off than if they were kept standing still in the small pots.—KILWORTH.

[We should have liked to have known how your house was heated. Could you not manage with that? The stove in "Greenhouses for the Many" would do if you could manage it, but we do not like stoves without chimnies. The propagating-case recommended by Mr. Boston, heated by suitable candles, would suit you no doubt. If your greenhouse is near the kitchen boiler, a case such as you mention with a double bottom would be cheap and most useful. Make it of good inch deal, say 15 inches deep at sides and 20 inches at centre. Place in that a water-proofed box of galvanised iron or zinc, 3 inches deep, with a tap or cock-hole at one end, and a hole for a funnel in the other, which thus you can fill with hot water, or remove when cold when you like. Place some bars across the top to equalise the weight, then 2 inches or 3 inches of charcoal finished by sand for the pots to stand on; set the case at the warmest end of the house on the top of pipes or flue. You will be surprised how long the water will keep warm. You can hinge the top or use loose squares of glass: the latter could be easily turned when the damp condensed against them. We know no simpler, cheaper, nor better mode than this when access can be had to a kitchen boiler. The changing of the water will be a trifle to the bother of candles, stoves, &c. In cold nights a cloth could cover the whole. Much could be done with an Arnott's stove (see page 632), and even by a little alteration in heating the greenhouse; but of that at present we say nothing. An idea of this simple case will be found in "Window-Gardening."

We would not touch the Verbenas until the sun was gaining power. If you do, there is more danger of their dying-off than if you let them alone.]

#### LILY OF THE VALLEY FORCING.

IF this should meet the eye of Mr. J. Dunn, of Harrock Hall Gardens, Lancashire, would he kindly tell your readers how long he continues the inverted pots or boxes over those in which the tubers are planted, mentioned at page 612 of this Journal? as every particular in the successful culture of this charming plant for early blooming is desirable.—LILY OF THE VALLEY.

THE WEATHER near London during the past week has fully justified the reputation of gloomy November; fog, more or less dense, having prevailed throughout, accompanied on Tuesday and Wednesday last by frost of considerable severity, the

thermometer falling to 20° on the former date and 19° on the latter. On Thursday night the frost was but slight; but the fog was extremely dense.

### CLOSE-PRUNING VINES.

THE Vines in my house (Black Hamburgh, Sweetwater, Muscadine, and Golden Hamburgh) had made such hideous long spurs from year to year, some of them 4 inches to 5 inches in length before coming to a bud, and so crooked, that in a fit of utter disgust this week, I have pruned them all off close to the rod. Will they "break" next year at the places I have cut off the spurs and bear fruit? One party has told me they will, and another the contrary. Your opinion will be worth both put together. I should mention the first three Vines are about ten years old.—T. T. T.

[Before we could answer your question satisfactorily, we should require an answer to two others. Did your Vines bear well this year? and, another, Was the wood well ripened? If these two questions can be answered satisfactorily in the affirmative, then by leaving no single piece of young wood—not a single bud, mind—the Vines will break and show fruit well. If neither, then you will be disappointed. We attach less importance to appearance than crops. If that, however, disgusted you, unless sure of the fruitful state of your Vines and their ripeness, we would have advised bringing up a strong rod from the bottom, and cutting the old stem away altogether, making the rod the bearing-stem next year. Start the Vines gently this season, keeping them moist; if all is right you will have to thin away a great many shoots.]

### NEW BOOK.

*Travels in Peru and India while Superintending the Collection of Chinchona Plants and Seeds in South America, and their Introduction into India.* By Clements R. Markham, F.S.A., &c. London: J. Murray.

#### INTRODUCTION OF CHINCHONA PLANTS INTO INDIA.

THE volume leading us to this notice is in every respect highly satisfactory. It demonstrates that Mr. Markham's mission was fully successful; it refutes, without the slightest reference to them, the calumnies heaped upon him; and the contents of the volume are replete with interest, not merely for the naturalist, but for the reader who peruses chiefly for amusement.

Those who prejudged Mr. Markham, founded their prejudice upon the fact that he is not altogether a botanist, and a more unsound foundation could not well have been selected. If the mission of Mr. Markham had been to discover in Peru its previously unknown plants, then a more deep acquaintance with botany than he possesses would have been absolutely necessary; but that was not his mission. He had to search for and secure plants already well known, and which the natives themselves knew how to distinguish as well as the best-endowed man of science. The qualifications, therefore, most needed in the director of the proceedings for obtaining and securing these well-known plants, were a good knowledge of the country and its language, sound sense, discretion, and resolution. The task of taking-up and packing the plants could be readily completed by the very able assistants who accompanied him.

Mr. Markham possesses the qualifications we have specified. He had travelled in South America, and the results of his travels had been published in his "Cuzco and Lima." He was in South America during 1852, in which year Dr. Royle was impressing upon the Government that, "after the Chinese Teas, no more important plant than the Cinchona could be introduced into India." "It is a curious coincidence," says Mr. Markham, "that at the very time when Dr. Royle was writing this report I was actually exploring some of the Chinchona forests of Peru. But the object of my travels was of an antiquarian and ethnological character, and I was in ignorance of the desire of the Indian Government to procure supplies of those plants, which I then only admired for their beauty."

That Mr. Markham possesses the other needed qualifications we have mentioned, is testified by the volume before us.

It will be noticed that Mr. Markham has departed from the spelling of the generic name usually adopted by botanists, and this is his defence:—

"The botanical name for the plants which yield Peruvian

bark was given by Linnaeus in honour of the Countess of Chinchon, who was one of the first Europeans cured by this priceless febrifuge. The word has been generally, but most erroneously, spelt Cinchona; and, considering that such mis-spelling is no mark of respect to the lady whose memory it is intended to preserve, while it defeats the intention of Linnaeus to do her honour, I have followed the good example of Mr. Howard and the Spanish botanists in adopting the correct way of spelling the word—Chinchona.\* The Counts of Chinchon, the hereditary Alcaides of the Alcazar of Segovia, do not hold so obscure a place in history as to excuse the continuance of this mis-spelling of their name."

In the Quichna language, when the name of a plant is reduplicated such reduplication usually intimates that the plant has medicinal qualities. In the present instance the native name is *Quina-Quina*, or "Bark of Bark," yet the Peruvians attached little importance to its febrifugal qualities.

"Poeppig, writing in 1830, says that in the Peruvian province of Huancu the people, who are much subject to tertian agues, have a strong repugnance to its use. The Indian thinks that the cold north alone permits the use of fever-bark; he considers it as very heating, and, therefore, an unfit remedy in complaints which he believes to arise from inflammation of the blood. Humboldt also notices this repugnance to using the bark amongst the natives; and Mr. Spruce makes the same observation with respect to the people of Ecuador and New Granada. He says that they refer all diseases to the influence of either heat or cold; and, confounding cause and effect, they suppose all fevers to proceed from heat. They justly believe bark to be very heating, and hence their prejudice against its use in fevers, which they treat with frescos or cooling drinks. Even in Guayaquil the prejudice against quinine is so strong that, when a physician administers it, he is obliged to call it by another name."

Its first notable employment by the Spaniards was in 1638, when its use cured of an intermittent fever the wife of Count Chinchon.

"While the Countess Ana was suffering from fever, in 1638, in her sixty-third year, the Corregidor of Loxa, Don Juan Lopez de Canizares, sent a parcel of powdered Quinquina bark to her physician, Juan de Vega, who was also captain of the armoury, assuring him that it was a sovereign and never-failing remedy for 'tertiana.' It was administered to the Countess and effected a complete cure; and Mr. Howard is of opinion that the particular plant which had this honour, and which, therefore, yields the true and original Peruvian bark, is the Chahuar-guera variety of the *C. Condaminea*.† This kind contains a large percentage of chinchonidine, an alkaloid, the great importance of which is only now just beginning to be recognised, so that it is to chinchonidine, and not to quinine, that the Countess's cure is due.

"The Count of Chinchon returned to Spain in 1640, and his Countess, bringing with her a quantity of the healing bark, was thus the first person to introduce this invaluable medicine into Europe. Hence it was sometimes called Countess's bark, and Countess's powder. Her physician, Juan de Vega, sold it at Seville for one hundred reals the pound. In memory of this great service Linnaeus named the genus which yields it Chinchona, and afterwards the lady Ana's name was still further immortalised in the great family of Chinchonaceae, which, together with Chinchonæ, includes Ipecacuanhas and Coffees. By modern writers the first *h* has usually been dropped, and the word is now almost invariably, but most erroneously, spelt Cinchona.

"After the cure of the Countess of Chinchon, the Jesuits were the great promoters of the introduction of bark into Europe. In 1670, the Jesuit missionaries sent parcels of the powdered bark to Rome, whence it was distributed to members of the fraternity throughout Europe by the Cardinal de Lugo, and used for the cure of agues with great success. Hence the name of 'Jesuits' bark,' and 'Cardinal's bark;,' and it was a ludicrous result of its patronage by the Jesuits that its use should have been for a long time opposed by Protestants and favoured by Roman Catholics. In 1679, Louis XIV. bought the secret of preparing quinquina from Sir Robert Talbor, an English doctor, for two thousand louis-d'ors, a large pension, and a title. From

\* "The only valid argument against this change is, that it may cause confusion, but the alteration is too slight for this to be possible; and it is not uncommon, among botanists, to correct the usual spelling of genera or species of plants, when it is found to be erroneous. Among other examples of such changes may be enumerated those of Plumelia, now altered to Plumieria; Bufonia to Buffonia; and Genzeria to Gesoera."

† A large supply of seeds of this kind has been sent to India and Ceylon.

that time Peruvian bark seems to have been recognised as the most efficacious remedy for intermittent fevers.

"The first description of the Quinquina tree is due to that memorable French expedition to South America, to which all branches of science owe so much. The members of this expedition, MM. De la Condamine, Gedin, Bouguer, and the botanist Joseph de Jussieu, sailed from Rochelle on the 16th of May, 1735, to measure the arc of a degree near Quito, and thus determine the shape of the earth. After a residence at Quito, Jussieu set out for Loxa, to examine the Quinquina tree, in March, 1739; and in 1743, La Condamine visited Loxa, and stayed for some time at Malacotas, with a Spaniard whose chief source of income was the collection of bark. He obtained some young plants with the intention of taking them down the river Amazons to Cayenne, and thence transporting them to the Jardin des Plantes at Paris; but a wave washed over his little vessel near Para, at the mouth of the great river, and carried off the box in which he had preserved these plants for more than eight months. 'Thus,' he says, 'I lost them after all the care I had taken during a voyage of more than twelve hundred leagues.' This was the first attempt to transport Chinchona plants from their native forests.

"Condamine described the Quinquina tree of Loxa in the 'Mémoires de l'Académie;' he was the first man of science who examined and described this important plant, and in 1742 Linnæus established the genus Chinchona, in honour of the Countess Ana of Chinchon. He, however, only knew of two species, that of Loxa, which was named *C. officinalis*, and the *C. caribœa*, since degraded to the medicinally worthless genus of *Exostemmas*."

Let us follow Mr. Markham a little way on his journey after the trees:—

"In 1859, my services were accepted to superintend the collection of Chinchona plants and seeds in South America, and their introduction into India; and I was authorised by Lord Stanley, then Secretary of State for India, to make such arrangements as should best insure the complete success of an enterprise, the results of which were expected to add materially to the resources of our Indian Empire. The urgent necessity of this measure had become more apparent since Dr. Royle's time. Then the Government of India expended £7000 a-year upon quinine; but in 1857, the expenditure had risen to £12,000, and continued to increase during the following year."

We have not sufficient space at command to follow him through his various adventures, but one quotation will give a fair idea of his proceedings, and of the skill with which he narrates them:—

"I left Pancar-collo early next morning, and passed by several fields of quinoa (*Chenopodium quinos*), the harvest of which was just beginning. The stalks are cut and tied up in heaps, and then the grain is beaten out with sticks. It is used by the Indians in their universal dish, the chupe, and in various other ways; but it is an insipid and not very nutritious grain. Just beyond the village there is a stream called the Ilpa, which, in the dry season, scarcely wets the mules' hoofs; but at this time of year it was swollen into a broad river, and it was necessary to cross it on reed balsas, with the luggage, while the mules swam. A very large troop of mules, laden with aguardiente, was passing over at the same time—a long and tedious business."

Here our extracts, for the present, must terminate, and we will only add, that Mr. Markham continues his narrative until he arrived with the plants at the Neigherry hills, in India. It is not a dry detail, but is enlivened and rendered useful by descriptions of the people, the products of the countries, the soils and climates, with glances at the history of the localities and their customs. It is a volume such as is rarely met with, being a blending of amusement with science, and will be equally acceptable on the table of the naturalist's library and of the drawing-room.

### SMALL BIRDS.

Mr. ROBSON invites observation on the amiable propensities of these. I live in a neighbourhood where acres of Radishes are grown. From the time the seed is sown until the plant is in leaf, it is watched from daylight till dark, or there would be no crop. A rush sentry-box is erected as a shelter from the rain, and boys are heard for weeks keeping up an incessant din from morning till night, with tongue and clapper, scaring the birds.

Gooseberry and Currant trees are also extensively cultivated. After the leaves have fallen the tips of the shoots are stuck over

with egg-shells, and streamers of tow and coloured shreds to frighten away the small birds from the buds, and it answers to some extent. There can be no doubt as to the serious injury done to the crop of small fruit by these innocents, if means are not taken to protect the trees.

I saw some large Plum trees in the spring which ought to have been covered with bloom, with scarcely a vestige of life. These had been disbudbed by Bullfinches. In my younger days I have watched and killed numbers of these birds, busy cropping the opening buds of the Larch and Cherry, of which they seem particularly fond. Sparrows! We have them here when the corn is ripening in flights of hundreds, and it is scarcely to be credited what a breadth of Wheat or Oats will be white over by their eating-out the soft, unripe corn, if the crop is not watched. A gun is the thing, they do not like being shot at.

The Thrush class are more in the fruit line. I can endorse every word of your correspondent, "G. M.," as to their mode of treating Pears. My own have suffered in that way this season, and a crop of Grapes on a wall has been entirely taken by these birds.

There has been a good deal of twaddle in the papers about these small birds, and needless alarm. If materially lessened we should miss them greatly in many ways. I have no doubt, but as long as there is so great an extent of wood and other land from which trespassers are rigidly excluded by game-preservers and others, there is little chance of their failure. What I think most to be regretted is, that the rarer birds, when they make their appearance anywhere, are not spared, but specially marked for destruction.

One fact appears to have been quite overlooked in this discussion. The utility and sim of an All-wise Creator in the appointment of "small birds," has been rightly and truly contended for; but do the poor snails, and grubs, and insects, the scavengers of our gardens, form no useful part in His great design? If they were annihilated should we not miss them? My watch stopped, I examined the works, but could not make out why it would not go, and so took it to the maker; a little pin had disappeared.—K.

[Our correspondent views the subject through the untinted eye-glasses of common sense. Slugs and snails have their uses as well as small birds, and the object which a wise man aims at is, not to annihilate the race if they happen to intrude where he does not wish for them, but to keep them from intruding. Lime sprinkled on the surface and around a bed keeps the slugs away from it, yet they may pursue their scavenging elsewhere. Boys in sentry-boxes and guns with blank cartridges will keep birds away from places where they are not wished for, yet they are spared to seek for caterpillars, aphides, and other insects in other localities.—EDS.]

### BIRDS.

#### THE BLACKBIRD, THRUSH, STARLING, &c.

THE present chapter I shall devote to the above-named birds, and those of similar kinds that are met with in this country.

The Blackbird, known also as the Merle or Black Ouzel, is one of our common and melodious songsters. The bright black plumage of the male with his yellow beak, and the brownish-black of the female, and still browner colour of the young, are familiar to most persons. They are frequent in all parts of England, and very early and productive breeders. The immense number of their eggs taken by birdnesting boys is something extraordinary.

The Blackbird feeds on insects, their larvæ and various grubs, as well as berries and small fruits. In the destruction of slugs, grubs, wireworms, the larvæ of the gaddies and many other destructive beetles and insects, they render great service to the agriculturist and gardener; but as they are also fond of berries and small fruits, they are much persecuted by the latter, who too often entirely overlooks the good they perform and as often much exaggerates the depredations they commit. If persons would only reflect that the time when fruit is accessible to these birds is but short compared with that during which they feed on insects, they would be obliged to acknowledge that these black musicians really do much more good than ill. But the loss of the fruit is a great annoyance: it is a tangible fact, yet the good they do is not so visible, and, consequently to the superficial observer, it is all injury and no good: thus the birds have a very black repute.

It might be an interesting study for some to compute the number of insects destroyed by these and other birds; the probable produce of the pests if not destroyed; and what amount of corn, hay, and other crops they would devour, or, rather, prevent growing were they not kept in check by the birds; and whether this injury in raising the price of bread, meat, and other food would not be of more national importance than the failure of the fruit crop. Still I see no reason why the fruit cannot be preserved without destroying the birds. Mr. Loudon observes ("Encyclopedia of Gardening," page 426):—"It is a too common practice amongst gardeners to destroy without discrimination the birds that frequent their gardens. This, in my opinion, is a bad policy. Although I am aware some kinds of birds are great enemies to some crops, it certainly must be a trifling crop indeed that will not bear the expense of a person to watch it, or a net to protect it, until it is out of danger: thus the gardener preserves the birds to perform a double office—eating up the vermin from the trees, and the seeds of weeds and eggs of insects from the ground."

The Ring Ouzel is something like a large Blackbird, the male having a white ring or crescent on the breast. They are more of a mountain bird, and not very common: consequently, but little known to the gardener.

The Rose Ouzel and Golden Oriel are too rare to require a description here.

The Water Ouzel or Dipper is found about hilly streams and rivulets, and is accused of doing injury to the spawn of salmon and other fish. It is, however, a disputed point; and as they feed principally on aquatic insects, which are in a high degree destructive to the spawn of fish, it stands to reason that they save much more than they destroy.

Having discussed the Blackbird we will proceed to the Thrushes, the largest of which is the Missel Thrush, or Storm-cock, or, as it is called in this part, the Scheweecher. This bird is much more of a berry-feeder than the Blackbird; he is a shy, noisy fellow, but becomes bolder during the breeding season, and I strongly suspect him of robbing the nests of smaller and more useful birds; and from his berry-eating propensity I suspect that he is the real aggressor when damage is laid to the charge of the Thrush; for gardeners are not very discriminating, and as but few are ornithologists, all are Thrushes that come in grey plumage.

The Song Thrush, the musician of our woods and coppices, is a delightful performer, and is known by various names, as the Mavis, Throstle, or Greybird. He is as common as the Blackbird, and, like him, feeds on insects, grubs, larvæ, and snails. The latter he is very fond of, and has a peculiar instinct of extracting them from their shells. Seizing one by the rim of the shell he carries it to a stone, against which he raps it, swinging it over his head much as a woodman uses his axe, and thus breaks the shell. Many thus broken and empty shells may be met with lying near the stones in the paths during a country walk, telling plainly of the good service of these birds. As to fruit, it is not much to his taste. The injury laid to his charge I believe would be more justly attributed to the Missel Thrush; and even in cold frosty weather, or when the ground is covered with snow, the Song Thrush is the last of the tribe to resort to the berries to save himself from starvation.

The Redwing, or Redwinged Thrush, sometimes called the Swedish Nightingale and Wind Thrush, like the Fieldfares, which are sometimes designated Blacktails, are only winter visitants; and as they come when our small fruit is over, they do not trouble the gardener. They feed on insects, and resort to haws and other berries when frost or snow covers the ground. They are shot by the sportsman and considered good eating.

The last bird of this group I shall here allude to is the Stare, or Starling; more, however, allied to the Crows than the Thrushes. They are among our most useful birds, and perform great benefit for the agriculturist and grazier. They feed entirely on insect food, never eating any corn or other vegetables. They are beautiful-plumaged birds; the feathers are black, with iridescent gloss, the body-feathers tipped with white, and the wing-feathers edged with brown; the young in their nest-plumage are, however, of a dull greyish-brown, and lighter underneath. They have a peculiar song, containing many pleasing as well as harsh notes. In confinement they are amusing, and may be taught to whistle a tune, and even to speak words or short sentences. They breed in holes in trees or walls, and under the eaves of houses and such like places, and find their food in the fields, where they destroy many insects; grubs, beetles, cater-

pillars, and the wireworms and many other larvæ make up their bill of fare. When the broods leave the nest they collect in small flocks, and towards autumn into large flights or shoals, often feeding with the Rooks, and in hard weather collecting in the marshes and fens, where they are said to do some damage by settling on the reeds in such numbers as to break them down, which is the only injury that can be laid to their charge. Notwithstanding their innocence and very great usefulness, that ought to cause them to be everywhere protected and encouraged, there are those who make unfounded charges against them. They have been accused of sucking the eggs and killing the young of Pigeons; but this is incorrect, and they are innocent of the charge. Mice sometimes suck the eggs of Pigeons, and young Pigeons often die from cold, owing to the old ones leaving them at night before they are sufficiently feathered, and when dead they are gnawed by mice, the eyes being the favourite part, and the poor Starlings are accused of that in which they did not participate.—B. P. BRENT.

## CITY GARDENS.

WHY should we not have gilt upon our gingerbread? Why should not our squares and closes and waste places be made to blossom like the Rose, and emit something of the smell of country? Nobody will do it except the honourable Societies of the Temple; and for centuries the City has been mocked by a company of lawyers, supposed to be hopelessly committed to parchment and red tape, but who all the while have made a better display of geniality and warmth of sentiment than any other section of the community. In the annals of the City we hear of a Company of Gardeners. It has a name still, and that is all. There is a Company of Fruiterers, too, and they have more than a name, for they, once a year, make the Lord Mayor a present of some choice Apples. If these Companies are worth the gelatine that may be boiled out of their deeds and charters, they must take shame to themselves once a year on hearing the approving murmurs of people who have visited the Temple Gardens. If they have a single flickering spark of their old life left, the flower shows of the city got up, sustained, admired without their help or countenance, ought to kindle that spark afresh, and beget for us some warmth from its generous flame. But, unfortunately, the general public are as cold as the Companies: it is one thing to see a sight that costs us nothing, and another to lend a hand in adopting it as the idea of a local institution, and the foundation for some improvements in our domestic life. We may not be able to stir the depths of the general apathy, and it is not our business to insinuate public gardens. All we can hope to do is to "mention the matter" as circumstances afford excuse, and go on hoping that some day or other the means will be found to bless the city with a sprinkling of flowers.—(City Press.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE occurrence of sharp frosts, severe for the season, will urge more effectually than arguments here the necessity of the speedy adoption of precautions for the protection of vegetables liable to be injured by the severity of the weather. *Artichokes*, *Globe*, clear away all decaying matter from them, and protect them with a covering of leaves. *Artichokes*, *Jerusalem*, a bushel of them may now be got up, and placed among some mould in any convenient corner for use when frost renders it difficult to take them up out of the open ground; *Horseradish* may be treated in a similar manner. *Celery*, it is necessary to take advantage of every favourable opportunity to earth-up all that requires it; rather let it remain as it is than attempt to do so while wet, as it will afterwards rot in a very short time. *Cauliflowers*, those already headed should be carefully taken up, and stacked in a dry pit, or within the protection of a wall where a thatched shutter may be employed in unfavourable weather to ward off the wet. *Cabbage*, keep the young plants, and also the young plants of *Lettuce*, dusted with lime and soot. *Peas*, sow, and also *Broad Beans*, in rich soil on a warm border. *Parsley*, shelters thatched with reed or straw should be prepared for its protection, and also for the protection of *Endive*, &c., in snowy weather. *Sea-kale*, a little leaf mould, tan, or cinder ashes should be laid over the crowns of the plants, pots may then be set over a portion of the plantation, and be covered with leaves as they are collected, or if required for use

in a short time, stable-dung should be used. *Spinacli*, in gathering the leaves the beds should be trodden upon as little as possible, as its growth is injured by having the soil so consolidated about the roots. Clear away decaying leaves from Winter Greens, and raise the earth about the stems. All sorts of refuse matter, of which leaves should form a large proportion, from the garden should be collected, and added to the dung-heap. Let proper channels be kept to carry off quickly water from suddenly melting snows or heavy rains.

#### FLOWER GARDEN.

If the flower-beds are now empty, and to be left so during the winter, let them be well turned-up to the bottom, and if much exhausted by continued cropping, the application of a good dressing of leaf mould will be found the most suitable restorative for this department. The introduction here of strong manures has frequently a tendency to do more harm than good, by causing an overluxuriance rather unfavourable to the free production of bloom.

#### FRUIT GARDEN.

Continue to prepare for fruit-tree planting by draining, trenching, and pulverising the soil, and after planting stake, tie, and mulch them securely in good time. Clear away all dead leaves from the wall trees; remove the green fruit from the Fig trees. The established strong fruit trees that are tardy of producing fruit should be root-pruned. This must be performed according to circumstances. If the trees are planted too deeply, or the soil has been raised above or about them since planting, by all means fork the roots out carefully, and plant again with care on the surface, spreading out the roots carefully, and then mulch them. If trees to be operated upon are planted high and dry, fork about them at a reasonable distance, and prune back the main or strongest roots as you discover them. Raspberry plantations may be cleared of the dead canes and superfluous wood; the suckers to be taken off, and, where required, the strongest to be at once planted for succession.

#### GREENHOUSE AND CONSERVATORY.

While the principal collection of Chrysanthemum is in bloom a selection should be made of the best and most useful sorts. They are very impatient of a close, rather warm atmosphere, and if the house contains plants requiring this treatment, the Chrysanthemums should, as far as is practicable, be placed in the coolest part, where air can be given freely on every favourable opportunity. See that they are kept well watered at the root. Use fire only when absolutely necessary, either to prevent the temperature from falling too low, or to dry the atmosphere. Regularly remove all dead leaves, and prevent the spread of moss in any situation. Creepers should be closely tied, that they may interfere as little as possible with the fall of light on the house. Place Mignonette, Primulas, and tree Violets in a light warm situation. The present is the best period for the general potting or transplanting of Liliams, the flower-stems are now sufficiently withered to allow of their safe removal without injury to the bulbs. Any small bulbs of scarce sorts that may have formed on the flower-stems should be saved, and either potted separately in small pots, or planted out in a pit or frame in suitable soil, where in a year or two they will make strong-flowering bulbs. The soil found most suitable for the cultivation of Liliams is a rich fibrous heath soil in a rough state, with a small portion of silver sand.

#### FORCING-PIT.

It will now be necessary to introduce into this structure a supply of those plants usually employed in early forcing, such as the first-potted Dutch bulbs, hardy Azaleas, Kalmias, Rhododendrons, of which the hybrids from *R. caucasicum* will be found the most suitable, being generally early and abundant bloomers, and of every shade of colour from white to scarlet.

#### PITS AND FRAMES.

This is trying weather for the plants in these structures. All that can be done for them is to give as much light and air as their safety from frost will allow, and to pick off every decayed leaf when a favourable opportunity as regards the state of the weather permits.

W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

FROST, having succeeded the heavy rains, has imposed on us the necessity of getting most things under protection that would

be apt otherwise to suffer. Artichokes (Globe) have had some litter placed tightly round them, so as to prevent the frost getting to the roots, and a little earth from between the rows was thrown over the litter, alike to prevent its being blown about, and to make it go as far as possible. Collected a quantity of leaves from the pleasure grounds, which, with a little of the last mowings off the lawn, and the clearings of Verbena and Petunia-beds, when all thrown together, will produce heat enough for the first Asparagus-bed and the first Radish-bed under a frame, which has just been sown. We had nothing else with which to make a moderate hotbed for Asparagus, and we have no doubt it will answer well enough. A row of Parsley being sown in a cold house in June, and now strong, we will not require to pot or box any of that herb. Mint, Sorrel, Tarragon, &c., will be placed in a corner of the Asparagus-bed. Celery earthed-up has, as yet, needed no protection. Cauliflowers under hand-lights have had a little litter placed near, in readiness to throw over them if the ground get crusted inside. Those in the ground and protected there, being fit for use, have been put into a shed to be secure. Lettuces and Endive have also been partly moved under old lights and straw covers, and a portion of the most forward Endive was covered over with dry leaves and straw hurdles, to blanch where it stood. Some Rhubarb roots and Sea-kale roots have been placed in the Mushroom-house; the latter, seven or eight roots in a large pot, which enables us to give less or more of bottom heat, and even to move the pots, if the Kale come faster than we want it. Beat down the last bed in the Mushroom-house for the present, and will earth it in a day or two. This is the fourth succession there. The first is in full bearing, the second just beginning to show, and as soon as we can we will put up a bit more for the fifth succession. Got in all the Beetroot, &c., before the frost injured it, and will earth-up Coleworts, and lay down and cover the stems of Broccoli as soon as we can get at them.

#### FRUIT GARDEN.

Looked over Grapes to remove a casual bad berry. Kept a little fire on to secure ventilation, but gave very little front air. Find that as the Figs out of doors are now done for with the frost, those in the Fig-house are still rich in flavour though small. The leaves are now beginning to change, however, and to look ripe, and we must be content with a few more fruit as they are, instead of swelling them out larger with moisture, as we would prefer instead having the wood firm for next year, and keeping the plants rather dry all the winter. In a few weeks, therefore, we will clear away all the fruit and leaves, for soon the flavour will be very fat; and though we have sometimes made the Fig, with heat and moisture, an evergreen and a continuous bearer, we do not think there is any advantage gained from not making it a deciduous tree and giving it a rest in winter. Melons all cleared to make room for other things, are still ripening their fruit on a shelf near the fireplace in the vinery. Strawberries, in pots, have been put under cover, so as to keep them from severe frost, and heavy drenchings of rain and sleet. In frosty mornings, a ridge of rotten dung and tree leaves has been placed between the rows of Strawberry plants out of doors. A number of trees of Peaches in a cool lean-to house, with trees against the back wall, were smoked with sulphur as previously described; and these we will wash and clean, remove surface soil and top-dress, and cover pots with litter to-morrow or next day. There has been no frost to hurt the roots yet; but many plants are ruined from being exposed to frost in pots, that would have suffered little if the pots had been protected or plunged in the ground. The Strawberry plants, such as Black Prince and Keens', which we will start first, are now being kept dry. As the pots will absorb enough of moisture from the ground, the soil must not be allowed to get dust dry, or the buds will most likely perish, and there will be nothing but handsome leaves to gather.

#### GREENHOUSE AND CONSERVATORY.

These have been well cleaned for the winter, and will require more care in giving air than hitherto, and that not by doors or in large openings, but well regulated over the building, confining the air chiefly to the apex of the roof in cold weather, and shutting-up pretty early in the afternoon. All watering now should be done immediately after breakfast, and as little spilled as possible, and no plants watered that do not require it, for some things that would need it every day in summer may not require it for a fortnight or three weeks at this season. The tenderer kinds of hardwooded plants, as Gompholobiums,

*Ericas*, *Epaerises*, &c., would be better in double pots for the winter, as, the roots are less liable to sudden variations; and other things, as *Beronia serrulata* and *Pleroma elegans*, should be kept by themselves at the warmest end of the house. When a general collection is grown the hardwooded things should be at one end, and the softwooded things, as *Geraniums* and *Cinerarias*, at another end. Examine bulbs that were potted, and see if ready for forcing from having the pots filled with roots. Tuberosus *Tropæolums* will want training, and others will want potting. These always do best on the one-shift system. The roots dislike being interfered with. Gave manure water to *Chrysanthemums* and *Salvias*, &c., and took care that *Camellias* and *Azaleas* were not getting too dry; the forwardest of the latter might be placed in forcing-pit. Regulated climbers so as to give light to the house.

## PLANT-STOVE.

Made as much room here as possible, allowed *Orchids* to rest, curtailed climbers, watered *Ferns* and *Mosses*, and put lots of large fine-leaved *Begonias* under the *Figs* to dry pretty well off, as they make a fine show in greenhouses in summer when a little shaded.

## PITS.

Took most of the bedding and other things out of earth pits, and placed them in houses getting empty, in *Vine-pits*, &c., where a little fire heat can be given if necessary, to avoid so much covering-up. This changing plants that were standing so very thickly furnishes a good opportunity for clearing the cutting-pots and boxes, and removing all signs of damping. Some kinds of *Geraniums* that were scarcely rooted got a little bottom heat from fermenting tree leaves below them, with a cover of rough ashes and lime in case there should be some slugs. Even a very hot fermentation will not kill these gentry, but they do not like lime nor rough ashes; and their trail, at any rate, can be followed without the instinctive wisdom of a red Indian. The *Verbenas* that were hardened-off in earth pit, dipped as reported for thrips, and syringed several times afterwards, and the worst put into a close box with a lot of *Laurel* leaves bruised, seem at present clean, and now stand thickly in a brick pit, where a little fire heat can be given on an emergency, and where they will have air night and day except in frosty weather. As the thrips did show itself after all our care in washing the cuttings, I will be afraid to place them in any *vinery* or *Peach-house* this season. We have not yet got all our *Geraniums* from the beds that we took up faggotted in pots, but they are safe enough under a lot of stubble in a shed. One wet day would finish all the lot; and they would have been done, only the clean pots were all used-up, and the dirty ones outside were crying out not to blame them if, after so much rain, a good percentage of them came in for crocks and drainage after a sharp frost. Before the frost got severe took off roughly some thousands of shrubby *Calceolaria* cuttings, as we did not make ourselves sure of having quite enough in the brick pit, the filling of which with cuttings was previously described. In the brick pit I have not seen the signs of one going yet, and I am just as well pleased if there is little rooting as yet. Not being able to get a pit ready for these cuttings, we have daubed them in about  $\frac{1}{4}$  inch apart in shallow wooden boxes, and placed them under glass in frames. These will even stand more frost than those earlier planted in the pit, and if they do not begin to root much before March they will be quite forward enough. The reason they will stand the frost better is just because they will be more limp and have less sap in them, for as soon as roots are freely protruded the stems will get stored with juices and growth will go on. Now the less growth before spring the less likelihood is there of losing one per cent. or one per thousand of these cuttings.

## FLOWER GARDEN.

What a wreck now! Beds not cleared, leaves not all down, even more mowing needed after the frost is gone. *Dahlias* that had some earth thrown against the stems, and were left in the ground to ripen a little, have now been taken up. We have always kept them successfully on the floor of a shed that forms a stokehole for the conservatory. Some dry earth has been there for years, and the tubers are placed on it, and then covered all over with it. A rough stage is put up above these beds, and these are now crammed with *Fuchsias* and old *Scarlet Geraniums*. The shed has two skylights, and had I had my way it would have been at least half glass and cost no more; but in this, and many things besides, we must put up with and make the most of what we have. *Dahlia* stems are for little use but

the rot-heap. Most other things in beds, as *Calceolarias*, *Agaricums*, &c., after the sticks are pulled out and tied in bundles, are cut two or three times over with an old scythe, and then they mix with leaves and litter in making a large fermenting heap of good hot stuff, so useful for helping-on many things. Were such things some 18 inches or 2 feet in height so used without cutting them at least twice over, they would not mix so nicely with other materials; and turning the whole over with a fork might lead the workman to say, "they were put there just to annoy he." *Hollyhocks* have bloomed until the frost came—nothing in their favour, however, making them more liable to feel the frost. The strong stems cut with a bill may be mixed with the fermenting-heap, but we generally make them a portion of the charring-heap. As soon as possible we will place a cone of dry earth or of ashes, and lime round each plant to keep frost and extra damp from the roots.—R. F.

## TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

**COLD VINERY (C. S.).**—We could have answered your questions better if you had stated the case more clearly. We presume that in your large cold vinery, 14 feet wide, there are only 18 inches of that space inside devoted to the roots of the *Vines*, and as these *Vines* have been planted this autumn, they will interfere but little with early crops on the rest of the ground. We see no objections, therefore, to early *Potatoes*, nor yet dwarf *Beans*, as you propose, though, in such circumstances, we do not see any advantage that will be gained in having them in pots. If you had room after that, we should also fruit a portion of your six hundred pots of *Strawberries* in the same place, but we would keep them in pots, though wholly or partially plunged. We are told that the back wall is 9 feet in height, and we now perceive that two questions are made in different places respecting it. The first is, "How many shelves, and how wide ought I to have them?" That just depends upon what you want them for; we presume for *Strawberries*. Well, for them you could scarcely have more than two, one as near the top as will permit of watering, &c., and the other about 15 inches below it, and the upper one at least not more than 8 inches wide. These you could manage by placing the plants in bloom on the upper shelf, and, as soon as set, moving them to the lower shelf, where they will do well until your *Vines* shade them. For other purposes, and having nothing against the back wall, you might have shelves from top to bottom. But that seems settled by another question, "Could the back wall be brought into bearing more quickly by planting maidens en cordon oblique?" Now we do not know what your maidens are to be, but we presume *Vines*, though we are by no means sure; and we would only say that, though this mode of training is much practised in Guernsey, and gives much facility for filling up vacancies, we do not think you would gain anything in point of early cropping, and that must be the chief thing, for when once you allow the *Vines* to monopolise the roof, you will not do much with the back wall. See pages 632 and 633.

**YUCCA (H. N. E.).**—We do not know *Yucca Parmentieri*, and never heard the name before. If any of our readers know it, can they say if it is hardy?

**CRACKED PEARS (L. T. P.).**—We once had some *Grafioli Pears* that ripened well, though slightly cracked. Keep your *Chamontels* and *Beurré d'Arenbergs* in the dark and cool to give them a chance. Your soil is too dry, or those *Pears* are worked on a quince stock. In either case mulching over the roots and watering in summer will be a preventive of the fruit cracking.

**REMOVING TREES AND GREENHOUSE (Subscriber).**—The moment trees and bushes of any kind are planted they are attached to the freehold, belong to the landlord, and cannot be removed without his permission. A greenhouse on posts probably could be removed, but we could not say without seeing it; the glass sashes certainly could be removed.

**IPPOGES (A Norwich Subscriber).**—An article on hedges of various kinds will appear in our next Number from one of our correspondents to whom we had referred your inquiries, in which full information will be given on all points.

**CUTTING DOWN NEWLY-PLANTED FRUIT TREES (A Subscriber).**—It is better not to cut-in newly-planted young trees until they have been established a year, by which time the roots will have taken possession of the ground. As the cutting-in of young fruit trees at planting time renders them liable to send up a quantity of suckers to the injury, and, not infrequently, the death of the grafted tree, wait one year, and then cut-in as you like. With old trees that have a greater abundance of top than root the case is different, the top then might be reduced, but not entirely cut away.

**MUSCAT GRAPE (C. T. H. Dorset).**—You will find either the *White* or the *Black Frontignan* do well in a greenhouse, and both are *Muscats*.

**MOVING A PASSION-FLOWER (E. S.).**—The young *Passion-Flower*, which has only been planted two or three years, may be removed any time now in mild weather; but the beginning of April is the best time to transplant *Passion-Flowers*, and the middle to the end of May is the best time to plant a *Passion-Flower* out of a pot. In your case, make a flat level bed for the roots 6 inches below the surface, no matter how long they are. When they are all spread out, put nearly 2 inches deep of rough leaf mould over them, and then put on the soil. After that add a thicket of something to throw off the wet, and to keep the frost out of the ground. See the stem all the way up from the roots 4 inches or 5 inches from the wall, to allow for a thick stem without chafing itself against the wall for want of room to swell properly.

**VIOLA PYROLÆFOLIA (A. R.).**—According to specimens which have been exhibited ten years since, there did not seem to be any difficulty in cultivating this yellow Violet in any light compost; but where it, or any of the yellow kinds may be had we do not know. The list of Violets you sent us from an "eminent nurseryman" is entirely wrong, except one species, Nuttall, and that is wrong as to colour. Any one making such a list could know little about wild Violets. It strikes us both the lists you sent are out of Oxalis and Violets in mixture; several of the names belong to Oxalis, and were never given to Violets. There are no such names now acknowledged as *Viola maculata*, *microphylla*, and *pensylvanica*, nor does Don give either of them as synonyms of *pyrolæfolia* in his last arrangement on De Candolle's method, neither do any recent writers that we are aware of. We have grown Nuttall, which is a pale blue not a yellow. We understand the best collection of rare hardy species in England is in the Hill Botanic garden.

**LILIES OF THE VALLEY IN POTS (Elizabeth).**—We cannot say that you could not grow Lilies of the Valley from year to year in pots, and flower them in a greenhouse, but we are quite certain the pot Lilies referred to will not bloom so as to please so good a judge of these "nice old flowers;" therefore, we would have them turned out of the pots at once, the most of the soil shaken from their roots, and then planted in bunches in a row, and next summer water them once a week in hot weather, and by this time next year they would be fit, in your hands, for another start.

**THE GERANIUM SPOT (Idem).**—A dreadful malady, of which no man knows the cause and hardly the cure. It is an infectious as the scarlet fever and quite as fatal, and not one single plant has ever yet been cured of it, after all that has been said to the contrary on each of these heads. The only way to get rid of it is to destroy every vestige of the plants, to white-wash the house or pit, and not to introduce another Geranium there for three months. The best preventive where, from the situation, there is a liability to the disease, is to make cuttings early in July in the open air, from the top of the shoots of old plants turned out at the end of May, to lift and pot the cuttings about the middle of September, and never confine them much, or place them in damp places in winter.—D. E.

**MEALY BUG ON VINES (A New Subscriber).**—We hope that the bug has not got to the roots of the Vines, for then there will be great difficulty; but if confined to the tops you may manage thus:—make sure of all the leaves and prunings and burn them; then wash the whole wood, wash with soap and soda water as hot as it can be used. Wash all the Vine stems after taking off the rough bark with the same at about 160°; scrape off a couple of inches of the earth inside the house, water that, too, with water about 160°, and fresh surface with new soil; then paint the Vines with a mixture of clay, sulphur, and tobacco water put on cool, and fresh paint all the walls, or colour them with fresh lime and sulphur. The difficulty will be with eggs and insects in the soil.

**WALL TREES PLANTED TOO CLOSE IN A PEACH-HOUSE (A Constant Reader).**—If you wish to retain the whole of the trees the most vigorous must be root-pruned, and that will lessen growth and keep them fruitful. You do not say where you live, but there are few places where Peaches or Nectarines will do you good as standards out of doors. If you should resolve to take the standards out, you must in that case just thank them for past services. What like is your house? We have seen standards taken up and bent down to cover a low trellis in front, so as not to shade the wall.

**SELECT HARDY RHODODENDRONS (B. H.).**—Blandyanum, rosy crimson; Brilliant, scarlet crimson; Lucifer, bright scarlet; Mars, rosy scarlet; John Waterer, crimson; Rifleman. These are the six highest coloured. The best three whites are, Mrs. Standish, Minnie, and Maid of Honour. These splendid kinds are dearer than the rosy crimson sorts.

**NEW GREENHOUSE (N.).**—We shall be glad to have an account of your houses and how they answer. At present we can only say that, in placing in one part one bed above another, that the upper beds will do for all you wish; the lower beds will do in winter, if you use little heat, for Fuchsias, Dahlias, Scarlet Geraniums, bulbs, tender roots, &c., and when you use heat to force on the beds above you could not have a better place for Mushrooms, Rhubarb, Sea-kale, Chicory, &c.

**PROPAGATING HARDWOODED PLANTS (A Constant Reader).**—There is no work devoted to this subject. See what is said in "Greenhouses for the Many," which you can have free by post from our office for seven postage stamps.

**NAMES OF PLANTS (H. C.).**—1, *Athyrium Filix-foemina*; 2 and 6, *Polygonum aculeatum*, c. lobatum; 3, *Blechnum spicatum*; 4, *Scopolendrium vulgare*; 5, *Lactuca dilitata*; 7, *Lastrea Filix-mas*. (H. M. K.).—*Drynaria Wildenowii*. The production of sessile Oak-like fronds is characteristic of the true *Drynaria*—e.g., *D. quercifolia*. (A Two-years' Subscriber).—1, *Blechnum occidentale*, and apparently the variety minor, but it is a poor sample; 2, *Phlebotium aureum*, both stove Ferns. The *Bouvardias* require intermediate treatment—that is, to be started in a warm pit, and finished in a greenhouse. (Eliza).—It is the leaf of some leguminous plant, and probably of *Swissonia Greyana*; but we cannot be certain. All you can do is, by keeping the soil dryish, to try and prevent its damping-off during the winter months.

## POULTRY, BEE, AND HOUSEHOLD CHRONICLE.

### JUDGES AT THE NEXT BIRMINGHAM POULTRY SHOW.

It is with great regret I hear that Mr. Hewitt has declined to act as one of the Judges at the coming Birmingham Poultry Show. I have inquired but cannot learn his reasons for so doing. His objections may be substantial; if not, it is unfortunate that exhibitors should be deprived of his valuable services. The arrangements in selecting the Judges I know are most unsatisfactory, and Mr. Hewitt may have some good reasons for declining.

I always considered Mr. Hewitt's services of great importance at Birmingham, for exhibitors in him gain the advantages of

that great experience and truly straightforward honourable decisions that have gained for him the esteem of all exhibitors; and I certainly think the Birmingham Committee, in not availing themselves of his services, do that important Show a very serious injury, and the interest of exhibitors I think ought to be studied, or they will lose ground. I trust Mr. Hewitt will explain, through your columns, his reasons for declining.—AN OLD EXHIBITOR.

[In consequence of several letters such as the above, and of others which contain personal allusions too strong to justify us in publishing them, we wrote to Mr. Hewitt, and requested from him some information on the subject. The following is his reply:—

"As I find that even already a report is put into active circulation quite at variance with facts, permit me to state for the information of the poultry world—and to its members alone is this subject of interest—that I have again declined the office of arbitrator at our fast-approaching Birmingham Exhibition, for precisely the same reasons as last year. I coupled my refusal of yesterday, however, with the courteous expression, to the gentleman who alone orders the appointment of the Birmingham Judges, of my still perfect willingness to fulfil the office as hitherto appointed during so many years past, and, as on all occasions heretofore, by my own request, gratuitously rendered. This offer of mine was declined. Again: I volunteered that if the classes of poultry were fairly divided among the arbitrators individually, so that the public might at a glance ascertain the responsibility applicable to each one of us severally, I would, without a single murmur, at once accept the least creditable remnant of the poultry classes which might be left unappropriated after each of the other Judges had made their own selections. This too was refused.

"I certainly never yet have, and most decidedly I never shall, accept the office of arbitrator at the meeting of any society in which my awards are to be previously made the subject of private dictation.

"In conclusion, I combine my best thanks to the many exhibitors who have favoured me with their unsought expressions of unabated confidence, with the heartfelt hope our Birmingham Show of poultry may still continue to maintain its now high position and prosperity.—EDWARD HEWITT, *Eden Cottage, Sparkbrook, near Birmingham.*"

SINCE the foregoing was in type we have received more letters upon the subject, all from well-known exhibitors, and from among them we select this, as fully expressing their opinions.

"I am sorry to intrude on your columns; but, as one of the oldest and most extensive exhibitors of poultry, I trust you will allow me to express my regret at the non-appointment of Mr. Hewitt among the Judges of poultry at the great Birmingham Show, to be held in December next. I will not enter into the merits or causes of his absence, although, if report speaks truly, Mr. Hewitt has good reasons for the position he has taken, but confine myself entirely to the serious injury that must arise both to the Society itself and the exhibitors generally, from his thus not officiating.

"From the most reliable sources, I hear Mr. Hewitt has never objected for a moment to carry out the duties he has always before fulfilled; but refused the new position forced upon him by the gentleman who, of his sole dictum, appoints the Birmingham Judges, amounting, in this case, to really a sort of 'Hobson's choice—that or none.'

"Hence, alone, Mr. Hewitt's disappearance from the list of Judges. This quite alters the views of exhibitors, and I emphatically ask, What unknown transgression have the owners of Dorkings, Spanish, Cochins, Hamburgs, and so forth committed, that we should be the sufferers because Mr. Hewitt refuses to be handed over to the Game fowls? There can be no good reason for this intrusion on our rights; for it is bad logic to assert that now the entries are, in these general classes, five times greater than a few years back, and besides the quality of the birds so evenly balanced as to need the closest discrimination, fewer and less practical Judges are requisite than when the disparity of merit was to be seen at almost first sight, as it was some time back. No! Instead of this we now want the very best and most practical men attainable to award these prizes, and such as are able and willing to do their duty faithfully, diligently, and well. Certainly we exhibitors have reasons to ask, Why are we summarily deprived of advantages that have already been most valued?"

"I am told Mr. Hewitt invariably gave his services as a free gift to his own town's Show, and that the other Judges were, as they ought to be, paid for theirs. This blocks out then, entirely, the item of expense being the reason.

"It appears to myself and other exhibitors, that the Judges ought always to be appointed by a vote of the whole Council as a body, and not by any one person. All things prove this to be the safest course; but if the Committee of Management for Birmingham feel themselves diffident or uncertain in the appointment, by all means let us, the now really-wronged exhibitors, have each his vote according to the entries his case affords, and the election be dependant exclusively on this issue. Either of these two plans will give us popular and efficient Judges, and do for ever away with these unaccountable divisions, and the owners of valuable and costly poultry will never be placed in the unenviable position of want of confidence in the awards.—AN EXHIBITOR FROM THE YEAR 1848."

### PIED OR PILE BANTAMS.

THE Bantams described by Mr. Clark in your publication of October 28th, are the Pile Game Bantams, a variety I have bred the last three years; and have exhibited a single cock and also a pen at the last Birmingham Show, both of which were successful. A pen of my breeding were also exhibited at Plymouth by Mr. Rodhard, and were successful in taking the silver plate for the best pen of Game Bantams in the Show. I have now a great quantity of them, and shall be very happy to give any fancier information as to how they were bred, and any other particulars.—R. HAWKESLEY, JUN., *Southwell Notts.*

### ARE FOWLS PROFITABLE TO THE FARMER?

THIS is a question often asked, and I now have in my possession three letters from correspondents upon this question, and my positive answer is—Yes. Fowls will pay a large profit when properly fed and cared for; a comparatively few in number will give a better return than a large flock; although they may receive extra care and attention, it seems impossible to keep a large number, even in a spacious enclosure, without disease. Twenty good fowls will lay more eggs, and be in better health, when enclosed in a coop, than a hundred in the same enclosure for two years. A hundred fowls may succeed well in a large coop for a short time.

Another mistake we are very liable to make is in keeping many breeds of fowls together. Have but one breed, keep them well, and ventilate their coops. A good hardy breed of fowls do not require such warm and close houses as they are generally kept in, although they require a dry coop, free from draughts. Ventilate freely, on the top if possible, feed through the winter upon corn and barley, and occasionally with raw fresh meat; beef preferred.

I still have a great preference for the Brahma fowls for our climate (America). They are hardy, and lay through the winter season as well as the summer, when eggs are worth double the price that they are in summer. They may be kept in the coldest coop, if properly fed; and in regard to profit, no fowls I ever saw, if kept by themselves, pay in every respect so large a profit as this breed. A neighbour of mine, a shrewd and very successful farmer, has kept no other breed of fowls for many years; he winters about twenty-five pullets in his barn cellar, and has eggs from them through the entire winter. In March he sits his hens, and hatches from one to two hundred chicks, and keeps them in his barnyard, allowing them to enter the barn at night; by the 4th of July he disposes of all except his winter stock, alive, at an average price of 50c. each, to the butcher. He has now laying pullets, which commenced laying by the last of July, hatched in March. I know of no other breed of fowls that will do this. My flock, when hatched in May, was 110. I have now 101, having lost but nine chickens this season; they are very hardy, which in our climate is a great recommendation to any breed of fowls. Fowls may be unprofitable when kept as many farmers are in the habit of keeping them—allowing them to wander about the farm, laying where they please, and feeding themselves upon melons, tomatoes, corn, and other valuable articles of food. I find, from practical observation, that fowls are like all other animals—they will be very unprofitable if not properly cared for, and very profitable if kept as they should be.—(JOHN S. IVES, in *N.E., Farmer.*)

### HYBRID LIGURIANS.

HAVING bought from a gentleman in the south of Scotland two hives of Ligurian bees, not having seen any of them before, I am anxious to know whether they are pure or not. I have, therefore, enclosed a few of them, and shall feel greatly obliged by your informing me in the pages of your Journal, whether they are the true Ligurian. Also, whether the same queen will produce bees differently marked as the enclosed are, or whether some of them may be without any yellow band on the back. Your answer will oblige.—B. G.

[Of the five bees which accompanied your letter, one was well marked, one but indifferently so, and the others appeared identical with the ordinary. If, as we suppose, all are the offspring of one queen, she must have been hybridised by being impregnated by a drone of the other species. Either Ligurian or black queens in this state breed some workers of both species, and some intermediate ones partaking, to a certain extent, of the characteristics of each.]

### "B. & W.'s" APIARY IN 1862.

(Continued.)

ACCORDING to my usual practice, I resume, from page 129 of THE JOURNAL OF HORTICULTURE, the record of facts in my experience as an apiarian. The story, unfortunately, is soon told this year. I began the year with every promise and hope of success. By the end of May the two swarms of April 29th and 30th respectively, artificially formed on Langstroth's admirable principles—i.e., making one swarm out of two hives, thus insuring absolute success without risk to the parent stocks, and putting the bees as to swarming entirely under control—were quite full of comb and brood, with supers also partially filled over each. The early part of May was perfection. Much honey was collected; and all stocks and swarms, including several others made also on Langstroth's principle, were doing well when I left home for a three-weeks visit to London on the 19th. That date, however, seems to have been the turning-point of the year as to honey at least, for on my return I found everything exactly as I had left it. Not one particle of honey apparently had been added to their store, nor has any been added since, although in every hive the population had increased and was increasing so rapidly, that I was obliged to give them all plenty of room to prevent their hanging-out. The only swarm which had collected sufficient honey (and it is the only stock at present out of all my eleven which needs no feeding), is the one of April 29th, which contains my old Italians, thus corroborating strongly what has been said in favour of this species, whether pure or hybrids. The contrast to the other swarm of the 30th of the same month was remarkable, as both appeared equally strong, and certainly the two queens bore comparison in point of breeding powers. The latter, however, did not contain 2 ozs. of honey when I examined early in August. This discovery led me to begin feeding at that time, and I have continued it from time to time ever since with nine out of eleven stocks.

Matters remained in *statu quo* till the arrival of the Italian queen, which the "DEVONSHIRE BEE-KEEPER" sent me on the 5th of July. The mode in which she was received by the stock to which I gave her will be found detailed at page 324, JOURNAL OF HORTICULTURE. The offspring of this queen, a few of which I saw on or about the 30th July, being very distinctly marked Italians, I determined to repeat the operation of last autumn, detailed in these columns, and to attempt to Italianise my whole stock *en masse*. By the help of Langstroth's nuclei and other artificial modes, I compelled five stocks to rear queens from brood supplied to them exclusively out of the new Italian stock. Their own queens, of course, were killed first, these being the queens raised last year in the same manner out of brood taken from my old Italian stock. Not one of them differed in the smallest perceptible degree from common English queens, although a good many yellow-banded bees were found in their hives. From this it was evident that the queen with which Mr. Woodbury supplied me last year was not a pure Italian.\* I had suspected as much before, but my imperfect acquaintance with the Italian race and its distinctive peculiarities prevented me from verifying the fact. One of the young queens

\* She had, doubtless, been hybridised by one of my neighbours' black drones, a contingency which cannot always be avoided, although I need hardly say that I was not aware of it at the time.—A DEVONSHIRE BEE-KEEPER.

raised this autumn was nearly as well marked as her mother (of whose excellence as a breeder and as a mother of a beautiful offspring I have had abundant proof), but I am still doubtful whether this young queen or any of her sisters have been duly impregnated, as I was only aware of the existence of about two dozen drones in the whole apiary at the time I commenced operations. During the last fortnight, it is true, I have been partially re-assured in my hopes by seeing a quantity of pollen carried into most of these hives, but I can know nothing for certain till I see whether drones or workers issue from the cells. No drones, however, have been seen by me since the middle of August, which I take to be a good sign.

Feeding is now, of course, in full operation. It is astonishing how little my bees have lived on since July. I know that seven or eight of them must have died but for my assistance, and yet I have only boiled about 55 lbs. of brown sugar as yet; and I hope with this supply, or little more, to carry them through the month of February—i.e., ten stocks in all. Whatever the expense, however, they must be kept alive and in vigour. A little outlay now will be well repaid next summer, if only we have a moderately fine season, as there is no danger of any part of England being overstocked with bees for many years to come. A profitable time is at hand for all careful and diligent bee-keepers. This is as "a word to the wise;" it remains for me only to arrange my hives in their present order, after the various shiftings of the season.

THE HONEY HARVEST IN GERMANY.

It will be perceived by the following article from the pen of Herr Dzierzon, and translated from a recent Number of the German *Bee Journal*, that the honey harvest in that country has been quite as bad as in England. With regard to the early cessation of breeding among Ligurian bees, I may remark that my experience is very different from that of my distinguished cotemporary, since I have found that the Italian species breed much later in the season than common bees. I would also warn bee-keepers against removing the queens from old stocks without some very cogent reason. It is true that young queens lay eggs in great profusion when once they begin; but setting aside the risk of their loss during their wedding flights, and other casualties of by no means unfrequent occurrence, I have generally found their superior breeding powers a very inadequate compensation for the loss of their predecessors' services during the interregnum which must intervene between the deposition of one sovereign and the qualification of her successor.—A DEVONSHIRE BEE-KEEPER.

“THE BEE YEAR 1862, AND THE ITALIAN BEES.

“The year 1862 will long be held in sad remembrance as most disastrous for bees. It is just the opposite of the preceding, which although at first very unfavourable, afterwards became so good that neither myself nor my cotemporaries could desire a better. This, also, on account of the excellent wintering and early spring gave rise to the best hopes, but the unusually cold, wet, and stormy summer disappointed us entirely. Whilst in other only middling seasons, I have often scarcely known where to put the honeycombs which I was obliged to take out of the hives in summer, partly to make room, and partly to admit of repeated operations; this year I have frequently not known where to find a small honeycomb when I wanted it. All my honey-casks have been emptied, because during many weeks when the bees should have gathered the most, they could not

supply their daily wants, whilst it was necessary constantly to feed the young stocks lest they should die of starvation, or leave their hives as hunger-swarms.

“Bad years are, however, the best years for instruction. They afford opportunities for making many observations which are generally hidden from our sight when there is an abundance of honey. A remarkable circumstance, confirmed by many bee-friends who have visited me, is the far greater richness in honey of Italian stocks, no matter whether true or hybrid. When even the strongest stocks of the common species were nearly destitute of honey at the beginning of August, the Italians had always some stores, although generally a much more scanty population, because they are not only more diligent and intrusive, and, therefore, lose more bees, but because they leave off breeding earlier, and expel their drones sooner. They are, therefore, particularly suited to countries where the honey harvest is short. But even in countries where the pasturage is long continued, and where the harvest is good, the yellow bees will not be inferior to the black ones. I expected that the Italian stocks would be overtaken and surpassed by the, on-an-average, more populous native ones; but I do not find this to be the case at present, because they make up by diligence what is wanting in population, and they will hardly allow themselves to be surpassed, even if the weather permit a longer use of the buckwheat blossom. Another remarkable observation which I make at this time is, that all stocks from which the old queen has been removed in the course of the summer, either with or without a swarm, are more populous, and work stronger than those which have not been disturbed. Some even begin to lengthen their combs, which stocks with old queens no longer think of doing. This is owing to the great deposit of eggs, which, on the other hand has slackened long ago, if it has not entirely ceased in stocks which have remained undisturbed. Those, therefore, are mistaken who believe that stocks in order to remain strong must be left undisturbed. A stock from which a driven swarm has been taken at the right time, may yet in the same year eclipse in point of population a stock which remains undivided; for owing to the brevity of the bees' lives the strength of a stock is always dependant on the quantity of brood. During the gathering time the strongest stock soon becomes weak, when little or no brood exists, whilst the middling stock becomes strong, when by a rapid development of brood the increase of bees is greater than the daily loss. In a stock from which the queen has been removed, egg-laying is certainly interrupted for some time; it is, however, taken up again, and continued more rapidly than before after the impregnation of the young queen. By inserting a royal cell also, the interruption may be restricted to so short a time as to be imperceptible. Before all the brood of the old queen is sealed over, the young queen may have commenced egg-laying. Of course, the bee-keeper must endeavour so to manage that the largest number of young bees may leave their cells at a time when they can be most profitably employed, and return with interest the food which has been expended in rearing them.—DZIERZON, August 28th, 1862.”

OUR LETTER BOX.

POULTRY-HOUSE (*J. Styles*).—We are sorry we cannot furnish you with a plan. You can have “The Poultry Book for the Many” from our office free by post for seven postage stamps, and in that you will find drawings which you may adapt to your own views and situation.

CRAMP IN FOWLS (*T. G.*).—Your fowls die suffering from cramp. Symptoms—unable to walk, and contracted feet. It is generally fatal. The cause is mostly to be found in the flooring of the house; brick, wood, stone, or asphaltum will cause it. The only successful treatment is by stimulants, and the best stimulant we know of is strong beer. Nothing is of any use while a bad floor is permitted. If such exist, and it cannot be conveniently done away with, let it be covered with dry gravel 4 inches or 5 inches deep. Place all the sickly or lame birds in a perfectly dry warm place, and give them stale bread steeped in very strong ale.

PIED BANTAMS (*W. Clark*).—After looking at the feathers you enclosed, we are of opinion that although the parents were white, there is a stain in them from Piles; and this has shown itself in the chickens from which you took the feathers. The mixture of White and Black-red makes a Pile. For advertisements we charge 2s. 6d. for six lines, and 6d. per line for every line extra.

SMALL DRONE (*J. S., Dunce*).—We have very carefully compared the drone you enclosed with an ordinary drone, and cannot detect the slightest difference except in point of size. Yours was probably bred in a worker or intermediate cell.

DOGS (*H. Smith*).—It is quite impossible to give an opinion about the breed of a dog without seeing it. But upon dogs we must decline giving opinions at all. Buy Meyrick's little book, “House Dogs and Sporting Dogs;” it gives much information about them.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 47.2° and 34.5° respectively. The greatest heat, 62°, occurred on the 1st, in 1857; and the lowest cold, 14° on the 30th, in 1856. During the period 121 days were fine, and on 124 rain fell.

THE HOLLYHOCK.

VERY one who sees the magnificent spikes of Hollyhock exhibited at our autumnal shows must be struck with the wonderful advance they have made of late years, and the noble appearance that they

present even when cut, while their appearance in their growing state is so noble and stately that they ought to be more grown and appreciated than they are. Wanting, it is true, the brilliancy of tint of the Dahlia, they yet can claim a superiority in their habit of growth; and when good people have got over a little of the mania for bedding-out which has now seized upon us all—when we want to introduce something like variety into the surface as well as the colouring of our gardens—when we get dissatisfied with this dining-table and polychromic style which has run away with us—then I doubt not the old English favourite, the Hollyhock, (for it has been such), will come again into favour. I question, however, when it does so whether the highly-bred varieties which we see exhibited will be found quite as useful as the unbloomed or bloomed seedlings, as the case may be; for, if I may judge by my own experience, one pays for blood in this as in other cases. If the highly-bred hunter or racehorse requires more careful attention than their more plebeian associates, and if diseases are the adjuncts of a civilised life which are unknown to those living in a more natural state, so I may say that the highly-bred Hollyhock suffers from its very excellence. During the past summer, a most unfavourable one for this flower, after heavy rain I found my best varieties with their blooms all in a state of pulp, while those of a less perfect character did not look much the worse. It is, however, of the Hollyhock as a florist's flower that I want to write, and, it may be, to give them a lift in popular favour; and having last season had an opportunity, through the kindness of Mr. Chater and Mr. Laing, of Forest Hill, of growing some fine varieties, I am somewhat more interested in them.

I think we may fairly call Saffron Walden the home of the Hollyhock. Just as we look to Slough for Pelargoniums, to Bagshot for Gladiolus, and to Hammersmith for Chrysanthemums, so we look to Saffron Walden for the Hollyhock. There are other growers of Pelargoniums than Mr. Turner, of Gladiolus than Mr. Standish, and of Chrysanthemums than Mr. Salter, but they are nevertheless the monarchs of those classes of flowers; and so

there are other growers of Hollyhocks than Mr. Chater, but he reigns supreme, I think, as the first grower and raiser of them in the kingdom. He generally takes the first prizes at the exhibitions, though Messrs. Downie, Laird, & Laing run him very close sometimes; and the large number of certificates gained by him shows the excellence of the new varieties that he from time to time brings before the public. Indeed, the first step toward a real improvement of the flower was made at Saffron Walden, for it was there that Mr. Baron, a shoemaker, many years ago conceived the idea of improving it. Knowing little but the practical part of the craft, he, with the energy and perseverance so characteristic of our nation, year after year worked at it. Others afterwards entered the lists; and the names of Bircham, Paul, Roake, Downie & Laird, Turner, and especially Chater, are well known to all lovers of the flower; but Mr. Baron was the first to lead off the improvement.

THE SOIL in which the Hollyhock thrives best is a rich garden loam. Although it will not refuse any ordinary good soil, it is, as its large and fleshy roots indicate, a gross feeder, delighting in manure and in plenty of moisture, but, at the same time, in winter somewhat impatient of damp. Light soils do not suit it, and indeed it is almost impossible to get it to do anything in such situations.

THE SITUATION it ought to occupy in the garden should by all means be sheltered, but not under the shade of trees. The height to which some of the sorts attain, together with the great weight of the flowers, renders them peculiarly susceptible of "windy" influences: and hence in my own neighbourhood, where one would almost think Eolus holds his court, it is somewhat difficult to find a place to suit it. In my own little flower garden it would not have the remotest chance of being allowed to bloom—I should expect to see it carried away bodily; and am therefore obliged to grow them in my piece of vegetable garden, where there does happen to be a sheltered corner into which the south-westers (our worst winds), do not penetrate. At the same time other places should, if possible, have a fair proportion of sun, but this I hold to be secondary to the shelter. When one tells you to put them in an airy place, perhaps he is sheltered on all sides by trees and does not appreciate the violence of winds. If I were to put mine in an airy place I should have to get some of our school children to sit by them when our gales blow here, or else anchor them with chain cables.

THE TIME FOR PLANTING is an important matter, but it seems to me that spring-planting is preferable to autumn. It involves, however, the necessity of a cold frame or pit in which the plants should be housed; for although hardy, they are, of course, more liable to be affected by frost when in pots than in the open air. When the plants are received from the nurseryman in the autumn, the most desirable plan is to repot them at once, using moderate-sized pots and a light open soil. Ordinary attention should be paid them during the winter months, guarding against fogging, and not allowing them

to flag for want of water. In the beginning of April they may be planted out, the ground which they are to occupy having been trenched and laid up in ridges during the winter. It is desirable to plant when the ground is in good heart—not too “stodgy,” as the labourers call it here. Holes should be made about 3 feet apart, and a good basketful of manure, about half a bushel, may be placed in each. They should be planted firmly, but not too deep; and as late frosts occur in May, it is always well to have some large pots at hand to place over them if the temperature threatens to be very low. A stout stake may be placed alongside of each, so that when the plant grows it may be ready without injuring the roots. They will now require but little attention, if the weather be at all favourable, for some weeks.

THE AFTER-MANAGEMENT depends entirely on the wishes of the grower. If he be desirous simply of ornamentation, he may leave three or four spikes on each strong plant; but if he aspires to being an exhibitor, one only must be allowed. He must also take care to thin-out the bloom-buds, so as to obviate too much crowding together, which prevents the complete development of the flowers, on which so much depends. It is a good plan, too, to shorten the spike, so as to throw more vigour into the flowers left, and they are never exhibited with the full length of the spike shown. Those who are anxious for clean blooms will take care to protect them from the influence of the weather, and this can be done only by making calico shades to place over the individual spikes that are required.

VARIETIES.—With regard to choice of sorts, there is here the same difficulty as in most florists' flowers, owing to the immense variety; but I have not seen any catalogue of any plants, in which so admirable an arrangement is adopted as in Mr. Chater's, and all who wish to know what the best varieties are would do well to obtain it. It is arranged, not only in colours but in shades of colours: thus we have in rose colours nine different sections—rose pink, bright shining rose, deep rose, satin rose, amethyst, general rose, pink carmine tinted, rose carmine, and brilliant deep rose. From my own slight experience I can speak highly of the following varieties:—

- Madingley Perfection (Chater), deep rose, dark base.
- David Foulis (Downie & Co.), fine bright rose.
- Rowley (Chater), very bold rosy carmine.
- Lady C. Neville (Chater), deep peach.
- Countess Russell (Chater), a beautiful rosy peach.
- Candidissima (Chater), beautiful clear flower, white.
- Empress Eugénie (Downie & Co.), large white, with rose base.
- Bianca (Chater), fine bright cerise.
- John Keith (Downie & Co.), a very fine crimson, of excellent shape.
- Lady King (Chater), an extra fine ruby crimson flower.
- Illuminator (Chater), splendid scarlet.
- Joshua Clarke (Chater), a most beautifully-formed flower, one of the best, if not the best Hollyhock grown.
- Black Knight (Bland), fine black.
- Ochroleuca (Chater), a very fine atraw colour.
- Stanstead Rival (Downie & Co.), a splendid rosy salmon, of first-rate quality.
- Lady Dacres (Downie & Co.), a fine flower of great substance, flesh-coloured salmon.
- Premier (Chater), very fine buff salmon.
- Invincible (Chater), a noble flower of orange salmon colour, with a grand spike.
- Beatrice (Chater), a very delicate and beautiful buff.
- Miss Lizzie King (Chater), a very fine bright yellow.
- Mrs. Fyson (Chater), beautiful pale lilac.
- Agenora (Chater), fine deep lilac, excellent flower.
- General Wyndham (Chater), reddish-purple.
- Advancer (Chater), rose and white, a very fine and novel-looking flower.—D., Deal.

## GLOBE ARTICHOKE AND EUROPEAN CYCLAMENS—ARE THEY HARDY?

### CROSSING CYCLAMENS.

WITH the exception of Scarlet Runner Beans in a row on one side of my boundary, I grow no other vegetable whatever. The whole space is devoted to flowers and fancies. But I read every word of the weekly calendar by Mr. Keane, and of the “Doings of the Last Week,” by Mr. Fish, with greater relish than when I had to look out for the best ways to make both ends meet. And when I learn thence a better turn for doing anything than

the old way, I enjoy it as a triumph as much as if I were in the midst of it; and to say the ruling passion shall ever pass away to the end of the chapter is the very opposite of my personal experience.

But, at the end of forty years, there are some simple things yet in the calendar which I do not quite understand, and whenever I think of one of these things it vexes me without knowing the reason why. Take last week as an instance of what I mean.

In the first going-off Mr. Keane gives the usual annual notice to protect Artichokes from frost, and on the next page Mr. Fish says the “Artichokes (Globe) have had some litter placed tightly round them, so as to prevent the frost getting at the roots.” Well, it was thirty-nine years ago next Saturday or Friday, I am not quite certain which, when three men and a lad were wheeling-in littered dung from the framing ground into a large kitchen garden, to be placed tightly round Artichokes, the same as last week. The lad was your humble servant (a black sheep at the time).

About three in the afternoon of that day, a tall young-looking gentleman, straight as a ramrod, and wearing a white vest and blue coat and trowsers, stood above us, and as I can see him now, in my mind's eye, the handsomest young man I had ever seen up to that day; but none of us wheeling the litter knew who he was. He was some visitor to Mr. Strachan, the manager at Beaufort Castle, twelve miles above Inverness; had just come out of Mr. Strachan's house, now the gardener's house, stood on the bank over us, and viewing all around, and over and into the garden, as if he were planning something or other. He soon left, and so we did the Artichokes safe and sound. Next Tuesday, the extra lad, who was accused of having all the light jobs and the more pleasant terms given to him by Mr. Strachan, was sent over to Belladrum, the next large place to Beaufort Castle, with a letter to the head gardener there, and I knew him the instant I saw him as the gentleman stranger who was at “our place” the week before. I thought him very young to be trusted with a place of more responsibility than “ours,” there being three glass houses, and lots of pits and framing on the place, while “we” had lights for Melons and Cucumbers only. I thought I was as old as he was, and yet I really did not know when to give air to the frames, or how much air to give, or, indeed, anything at all about them; and as to the hothouses, the first range I had ever seen, I was awe-struck at the idea of a man of my own age being able to manage them, and to teach four young apprentices how to do the whole of the glass in two or three years. But, the pride of life came within me, and the new gardener at Belladrum, nor his young men after him, knew aught of what was passing in my mind. I could talk, even then, from reading books, so that they might think there was no lack of knowledge at Beaufort Castle at all events; but one question which the young gentleman gardener asked me was a stunner I could not answer, and I had depth enough to know that confession of ignorance was much more safe than to pretend.

“What were you wheeling-in that dung for last week?” was the question I could not respond to, and after forty-two years of it I cannot tell it now why it is done. He must have seen they were putting the dung on the Artichokes, and the purport of the question was to know from me what they did it for; so I told him that I was not allowed to know such mysteries, that I was only an extra hand for a time, looking for the better times coming.

“But you seem to me to know a good deal about gardening.” I never felt “vanity-daft” so strongly as at that moment. I believe to this day that short sentence was the turning-point of my career. “But you seem to me to know a good deal about gardening,” stuck to me for the next ten years, so as I could not get rid of the idea of being taken for a great man indeed, and I must do something to make the idea more than a shadow.

Then, to be told so by a man infinitely above me in that knowledge, and to be spoken to as kindly as if I had been his own equal, astounded me. He took me all round the garden, and through the houses, and to the framing-ground, and told his foreman to let me see everything whenever I chose to call; and I could now repeat word for word of all that was said on either side that day, at the distance of thirty-nine years this week.

The gentleman-gardener was no other than Mr. N. Niven, now of Drumcondra, near Dublin. He told me then that he was not quite sure if frost really hurt Artichokes; but he knew very well the question was a disputed one—his own belief in his own words was, that “the practice was the dictate of custom, and not the result of necessity,” as far as he could make out.

A change of gardeners at Beaufort Castle changed the system there of covering Artichokes, and none of them were protected there for three years before I left; but I forgot about the frost, and it was the winter of 1829 and 1830 before I could prove it under my own eye. A dire frost set in after the new year in 1830, but my Artichoke-beds suffered not the least harm, and for the next seven years the plan was the same, with the same result; but as there was no tremendous frost from January, 1830, to the end of 1837, and not till the following winter, I cannot say even now if Artichokes are hurt by our severest frosts; but during our ordinary winters for seven years, I did not lose a sucker or a stool of Artichokes, and they were all un-protected.

In the very severe winter of 1840 and 1841, my first winter at Shrubland Park, the Artichokes were not covered there, and they escaped one of the hardest winters of my day; but then the ground was deeply covered with snow, and after that the annual dressing of dung was given to the Artichokes before the winter set in, as part of the routine more than as means of protection. So that to the present day I am not quite sure if the Artichoke does, or does not, actually require protection.

I am quite sure, however, of what took place under the circumstances which I have instanced, and I think we might do worse now than canvass this question, as some gardeners did in the last generation.

But I have another string to my bow. I want to know if *Cyclamen neapolitanum* needs protection from frost. It is a native of England, of central and southern Italy, of Sicily, and of Algiers, and is as different in the leaf, in the different localities, as any plant in cultivation, if not more so. I have eight or nine different forms and differently marked leaves of it in my own collection. But all my stock is from central Italy, from "my Sardinian correspondent," and I do not know how far it may need protection or not.

The large-leaved *Cyclamens* of the London trade, which go under the names *macrophyllum* and *africanum*, are nothing more than genuine *neapolitanum* with different leaves, as far as my stock has yet bloomed; and I have one of them in bloom now, and have had the same for the last three months with no appreciable difference in the flowers.

*Hederæfolium* is the name by which *neapolitanum* is best known to English gardeners. Has any one ever known that kind to be cut off by frost? I believe not, yet my want is not supplied in the belief; and I am afraid the larger-leaved kinds of it from the far south, like our Globe Artichoke, will need some slight protection in most places, although I am not yet quite sure of the point for either the one or the other.

My *neapolitanum* has been too recently disturbed to be a fit subject for experiment this winter. Plants of the different-sized leaves of it ought to be two years established on the spot before experiments on them about enduring or not enduring frost, could be of much practical value. This, if I live long enough, I shall be able to put to the test. Meantime I want to know how far you, the readers of this JOURNAL, have traced the question. Have you planted out *Cyclamen africanum*, or *Cyclamen macrophyllum* in the open ground, and left them out without protection any time within the last ten years, or before that period, and how did it fare with them if you did?

I shall have *comum* and *vernum* in bloom this winter along with the true old English *neapolitanum*, otherwise called *hederæfolium*. The reason of that is this: My whole collection was frosted when in full leaf this time last year, or, at least, some of all my sorts which were planted out of pots for experiment on their hardiness, had their leaves frosted into jelly through an oversight on the part of the manager to put the covering over them for three or four days and nights, when we had the first hard frost last winter, and when I could not see to them myself. All that frost did not seem to hurt the bulbs or tubers, even of any of the finer races of *persicum*, for I had some of all of them in the wreck; but the *comum* and *Atkinsi* in variety, all had their leaves destroyed, but they were pitted and brought on three or four months before their time for the experiment which so ended.

The effect of that scourging frost was to throw them all out of their course of leafing and flowering; and, as in the case of young Norway, what I had long wished for chance brought to my door, though to my sorrow at the time.

You recollect how uppermost it stood with me not long since to have the autumn-blooming *Cyclamens*—that is, *europæum* and *neapolitanum* retarded; and the early spring bloomers,

beginning with *comum*, forced into late autumnal bloom, in order, if possible, to enable the two races to cross, and so obtain a race like *vernum* to bloom naturally from November on through the winter.

That very effect desired is now in my hands, and I can see how the same may be done every year, or every other season at all events, by just following my sad accident with part of one's stock. Order some London nurseryman who may have "a Sardinian correspondent," to obtain so many *europæum* bulbs, so many bulbs of *neapolitanum*, of *africanum*, and of *macrophyllum* from the wilds of Sardinia, and to lift them early in August before the kinds come into bloom. Then the lifting, the half-drying in the packing and during the journey to London, will put them off their blooming season, and you may keep them back from flowering a month or more after their arrival; and if they will begin to bloom early in October, none of them will finish blooming before this time or later, for they seem to take twice the time to get through their blooming by being thus kept so long out of their natural course.

Or, if we take such an instance at home as the case of Mr. Weaver, our *Cyclamen* correspondent at Winchester, who has large plants of the *neapolitanum* in the open borders, and probably of *europæum* also. Suppose he had a mind for this trial, or any one having the same opportunity, all he would have to do would be to lift a "root" with a large ball to it, as soon as he could see the buds for the bloom—say at the end of July, or early in August; he could partially dry it, but not let it become quite dry in the ball, and so keep it back fully two months, perhaps much longer. Would it not seem one of the easiest things in the world to have a *Neapolitanum Cyclamen* in bloom in November? then *vernum* would be naturally in bloom, and there would be no difficulty in preparing *comum* to bloom in November. I have a score of *comum* now in strong bud for blooming, which a few degrees of more heat would throw up and expand in a week or ten days. My recently-received *vernums*, and three roots of *ibericum*, are also in bloom-bud; and I have no doubt but if *Clusius's* true *hederæfolium*—that is, the late spring-flowering Ivy-leaf *Cyclamen*, had been in my wreck this time last year, it would now be in this interesting condition along with the rest of them.

Then, if the European *Cyclamens* will ever cross among themselves, this would seem to be the best chance for them. I cannot yet get rid of the idea that they have done so by some accident or design before I was born; for I can see nothing in *Goldie's ibericum* to distinguish it as a true species, or mark it in any way as different from sorts of *Atkinsi* that I have seen. Of course I may be wrong, but the proof is wanting. As to *vernum*, it is exactly what I should predict if a northern variety of *neapolitanum* were crossed with *comum*. After seeing the way *comum* subdued *persicum* with Mr. Atkins, and the way the *Atkinsi* breed has already branched out into dissimilar varieties at the Wellington Road Nursery, it would appear as if *ibericum* were nothing else than a dwarf seedling from *vernum* itself.

You may call that an odd way to account for the origin of species. Be it so; but I have seen the origin of too many species of that stamp and style in my day, to allow me to entertain a different opinion until that is controverted by proof positive, which proof can be made good again and again without a flaw in the procedure.

The next process is to bring the spring *Cyclamens* to bloom in November, without frosting them like mine, so as to meet the retarded autumnals for the purpose of crossing. I am quite certain now, from sad experience, that it is also quite as easily to be effected as the retarding of *europæum* and *neapolitanum*, *alias hederæfolium* of old English gardens.

Take any, or all, of the *persicum* breed and of *comum*, for there are two distinct varieties of *comum* in cultivation, the one having the flower much larger than the other, and that is the one which so many growers keep under the name of *vernum*. But take them both, with *ibericum* and with the true *hederæfolium*, if you can find it, and when any well-established plant of any of the varieties of the three races is throwing-up for bloom, be it in February, March, or April, cut off every one of the leaves, and all the flower-stalks and flower-buds you can perceive, and shake the plant out of the soil immediately, to prevent another effort of growth for the time being. Dry the bulb in that state—a far better state than that in which two hundred of my poor frosted bulbs were obliged to be dried-off last January, and early in the year. If the drying began in February or March, the bulbs should be potted again early in May, and the April-

dried ones in June, and be left to nature to get into leaf again, and to throw-off some blooms, probably, which you could not see to disbud in the spring. All this I have seen acted under my own eye this very season, only that the stoppage in the midst of their growth was by the frost; and now, if I had known it sooner, I might have had a score of spring bloomers full up to the crossing-point on the first day of November—that is, by giving them a lift in-doors of from 5° to 10° more heat all through October. Something about from 50° to 56° would probably do, but the degree they would soon settle themselves, and I could as soon see it. It strikes me, too, that the stimulus of about five more degrees than greenhouse temperature, would cause the persicums to cross the more readily—say from 40° to 45° or 47° of dry heat in November, would cause all Cyclamens to cross more readily than at their usual time of flowering.

D. BEATON.

### HEDGES—USEFUL AND ORNAMENTAL.

A CORRESPONDENT from one of the eastern counties, whose case no doubt resembles that of many others, asks advice on the management of hedges of various kinds, as enumerated below; and, as the subject may be of some interest to the general reader, the Editors have desired me to give such a reply as will meet the requirements of those similarly situated, and a few notes on hedges not mentioned in his list will also be given.

Taking the various cases in which the term "hedge" is used, we find it implies a fence, screen, shelter, or ornamental partition. Long and well-established practice has decided beyond the possibility of a doubt which plant is the best for all general purposes of a cattle fence; but others are at times used. For shelter or ornament there is, however, great diversity of plants, and very often accident is the cause of some of these being employed. Thus they may have happened to have been growing at the place where shelter was wanted, and were, consequently, made available to that purpose; and in a like manner many of our mixed hedges, crooked, and consisting of half a dozen or more different plants, have been simply appropriated to the formation of a fence, from having been found growing at the place that such fence was wanted. Hazel, Maple, Elm, Elder, Willow, Alder, and similar things, are often worked-in, not in consequence of having ever been planted by hand, but by being accidentally found there, and taken advantage of. The crooked, non-descript character of some old hedges may unquestionably be traced to this cause; but they are disappearing more or less speedily as the agriculture of the district advances. Boundaries of property and other causes will no doubt be the means of retaining many of them; and in some neighbourhoods the long time it takes to rear a good Quickset hedge renders a tenant unwilling to destroy one, which, however crooked and unsightly, answers for a fence. Though the generality of hedges for farming and other purposes of a like kind are of White Thorn, the culture and management of which belong more particularly to another class, yet for the guidance of those who may have such fences to plant and attend to, a few notices on these will be appended, as well as on the other kinds of hedge regarded as more ornamental. I will take them in the following order:—

- |                             |                              |
|-----------------------------|------------------------------|
| 1. White Thorn or Quickset. | 7. Box.                      |
| 2. Hornbeam and Beech.      | 8. Ivy.                      |
| 3. Holly.                   | 9. Arbor Vitæ.               |
| 4. Privet.                  | 10. Laurustinus.             |
| 5. Laurel.                  | 11. Other evergreen shrubs.  |
| 6. Yew.                     | 12. High hedges for shelter. |

**QUICKSET HEDGE.**—Nothing can very well exceed a good Quickset hedge when neatly trimmed and attended to; and I am told that some small fields, not more than a couple of miles from where I write, are surrounded with hedges of this kind so closely grown and compact, that if a hare were turned into one of them she would not be able to get out anywhere but at the gate; and yet these hedges are not more than a foot thick at the most, and often much less, and being planted on the level have no advantage from an additional depth of soil. The great secret is, that the soil suits them, and they are duly taken care of both at the beginning, and ever afterwards. A sort of slight digging with the fork is given once or twice a-year to the ground, about 18 inches or so on each side of the collar, and if the field is in tillage the cultivation reaches this margin; if in grass, the line of demarcation is like that of a walk cut in a turf lawn. Sheep are always kept from the hedges in summer by hurdles or

something of that kind; in winter they do not so much harm. The clipping or trimming of such hedges is generally done twice in the year, the first time often about the end of June, and the other in autumn or early winter, when the leaf has fallen. This is the treatment of an adult hedge. That of a young one is much the same; but it will be better to mention the planting first, as that sometimes determines the character of the future plant, and what is here stated is applicable to all situations.

Although this Quickset will grow and make a good fence on all kinds of soil where other ordinary crops will flourish, yet it does best on a soil of a dry and stony character. Wet soddened clays or marshes are unsuitable; neither is a very bleak situation, or one exposed to the sea spray, suited to it. The condition of neighbouring specimens will, however, give the best explanation of this; but if it be determined to plant one on the cold undrained clay of some districts, it would be best to plant on the top or side of an embankment, so that the roots being on a ridge will be drier than in the adjoining ground. This is the usual custom in districts less favourable to the growth of the Quickset than the one I write from; but it is certainly recommendable. On such ungenial soils it is also advisable to plant more liberally—say a double row of plants about 9 inches apart, and about 6 inches in the row. On drier and better soils a single row will do, and that on the level, giving the ground, however, the advantage of a good trenching; and if particular success be wanted, manure may be added, either at the time of planting or afterwards. One peculiar feature adopted here in planting is worthy of imitation everywhere, and is the same as we adopt in planting fruit trees of all kinds. The young plant is not cut down at the time of planting, but allowed to remain for one year, when it is cut down. The cutting-away of top and bottom at the same time is an ordeal some plants will not endure, but die under; and although the Quickset might not, perhaps, succumb to it, some solitary plants would do so, and leave the line gappy and bad. Some planters take the pains to bend the tops of the newly-planted Quicksets in such a way that the tips are buried in the ground at the collar of the second plant from them, forming at once a dwarf line of basketwork, and sometimes the shoots formed that season are not cut down the following one as stated above. This bending-down, however, cannot well be managed unless the plants are something like 2 feet high, and we would prefer smaller plants than this. Good fibrous roots are of more consequence than a strong coarser top, and being planted in good time in the autumn, in soil suitable, &c., a good result may be looked for.

The trimming of the young plant for the first two or three years must always be done in the autumn or winter, as cutting a deciduous tree of any kind in summer is an operation hurtful to it; and as the hedge wants encouragement rather than crippling, allow all but some very gross shoots to ripen their wood before cutting them in. The cutting-in may be more or less severe, as may be deemed necessary. Generally, however, if the hedge is thriving and robust, a foot each year will be ample addition to its former height until it reach the allotted height—say 4½ feet; but it is often advisable to cut-in to within 6 inches or 8 inches of the former year's cutting. It is erroneous to think that extreme cutting-in strengthens the hedge; such is not the case. The collar of a plant left entirely alone would be thicker than with any cutting at all; but a certain amount of shortening is necessary to secure a close compact body of shoots. The cutting sideways may, however, be more close, as narrowness is considered a qualification, if the mass that is left be close and compact. In dressing Quickset hedges, the hook in the hands of one well skilled in its use is a much quicker tool than the shears. The latter, however, must be used for the first few years until an established shape and form be given to the hedge.

**HORNBEAM AND BEECH.**—These are more generally planted for shelter than as a fence against cattle, and are, consequently, allowed to get much higher than ordinary fences. It is also considered an advantage to retain the old leaves on them all the winter, and it is, therefore, advisable to treat them accordingly. The Beech and Hornbeam being forest trees of large size, the dwarfing they undergo to keep them in the condition of hedge plants causes more or less unhealthiness in their growth, and this is one of the causes of their retaining their leaves during winter; but as another inducement for their doing so, it is advisable to cut and dress them once or twice during the season, taking care that the last time is not so late as to leave them no chance of making fresh shoots, for it is those late-unripened shoots that retain their leaves which give the shelter and

warm appearance these hedges present in winter. The Beech and Hornbeam thrive best on a dry chalky soil, and they quickly attain the condition of a full-grown hedge plant; and on bleak, high situations hedges of these plants will be found useful and more deserving of attention than they often receive.

**HOLLY.**—This is of much slower growth than the last; but, when once established, the hedge is second to none either in point of utility or appearance. Its deep glossy green leaves, matted thickly on stems robust and strong, seem to bid defiance to either man or beast. In fact, there is only one drawback to a Holly hedge—it does not grow so fast as one of Quick, and on some soils does not thrive at all. It has, however, the merit of doing well on rather damp soils—not those saturated with stagnant water, but damp hill sides more or less stony. In such places I have seen Hollies attain to fair-sized timber. Growth is more slow than most hedge plants, excepting Yew and Box; but when once arrived at that condition it will remain a long time without deterioration either in appearance or utility.

Hollies are said to be best planted in September, and it must be confessed they are not the best things to move. Small plants that have been frequently removed are best for a hedge, and with a little patience an excellent fence will be forthcoming in time. What cutting is requisite had better be done with the knife in early autumn, and, if necessary, with the shears in March; but to use the latter in September occasions the plants to look badly all winter, so many leaves being cut in two. Good soil will encourage the growth of the Holly as well as that of other things; and it is not bad practice to plant an occasional Holly in a Quickset hedge, the green patches looking well at all seasons.

**PRIVET.**—Where a hedge is wanted in a very short time this is one of the best plants for the purpose, as it grows rapidly and bears cutting well; but it is not by any means a substantial fence, being devoid of thorns, and, there being no thick wood in it, cattle are not easily turned by it; mixed with Quickset it is better. Its general hardihood and adaptability to all situations are features not to be disregarded. It will also grow under trees better than most plants, and when a hedge is wanted quickly, Privet is the plant; neither is its appearance bad, and it may be cut at any season.

**LAUREL.**—The common Laurel makes an excellent bank or hedge; but in general it yearly increases in size, the spurs growing out a little each year; still it makes a beautiful hedge, bank, or slope, and bears cutting-in to mathematical precision, and when once well established snow has no impression on it, which it certainly has on Privet and some other plants of a like kind.

A dry stony soil suits the common Laurel best, and on such soils it grows very freely, and also bears cutting well. We find the best way is to cut Laurel hedges over with the hedge-shears, about the second week in July, exactly to the shape wanted, and the after-growths of 6 inches or less we leave on all the winter, merely looking over them in autumn, and cutting out with the knife any long ones that protrude farther than the rest. At Linton these second shoots always ripen, and, consequently, stand the winter without turning yellow, which is not the case in places where the shoots do not ripen; in fact, in some cases it is no unusual thing to see the tips of such shoots all dead, and where the soil is not so well adapted to the Laurel, the plant often enough dies entirely, or now and then one succumbs to the unfavourable ordeal it has to go through. With us, however, this does not occur, although the number of years some of our slopes and banks of Laurel have been subject to close cutting would have sickened if not killed many other plants. Cutting with hedge-shears is a plan not to be recommended everywhere, for many of the leaves are necessarily cut through, and they look brown afterwards; but we do it for expedition, and established practice has enabled us to make sure of the speedy second growth which covers with verdure the brown disfigured leaves that were cut. A better way, and one I would recommend to all who have not gained their experience by practice, is to cut the Laurel hedge or bank with the knife, and if particular nicety is wanted let the cuts slant in such a way as not to face the eye of the observer. Generally in cutting between the finger and thumb the knife is so held as to make a slanting cut that looks one exactly in the face. This is wrong. All shoots below the eye ought to be cut from the under and not from the upper side, and a little practice will enable any one to do this as well as the other way. The same remark holds good with other hedges of evergreen that are cut with the knife.

**YEW.**—Of all hedges for ornament, this is perhaps, the most

ancient, and likewise ranks the highest in point of excellence. We are told of some hedges that have outlived two or three dwellings, and some are said to have been planted four or five centuries ago. An old Yew hedge is so venerable an object, that modern innovators generally pause before they condemn one. Being a native plant found wild on dry, chalky hills, as well as in other places, both on the exposed mountain-crest and in the shade, or enjoying the shelter of other trees, the Yew is very accommodating. Hedges of Yew are of slow growth, but the plant is not the worst to transplant, and it often happens that plants of 3 feet high and upwards may be made into a hedge at once. If the growth is only moderate it is best to cut the Yew in March; but if more robust it may be cut in dull, damp weather in July, when a trifling after-growth will give it a more cheerful appearance for the winter.

**BOX.**—Like the last this is of slow growth, even more so than Yew. It is also of a paler colour, but in many respects resembles the Yew in habit. It will grow on a stiffer soil than the Yew, and bears clipping well. When cut at the end of June or beginning of July it has time to grow a little afterwards, and recover the brownness that follows clipping. If possible, the cutting should be done in damp weather, and the disfigurement caused thereby to the foliage is the more quickly remedied. Box hedges seem to be long-lived, and they also attain a fair size when allowed to grow on. They are, however, no protection against cattle.

**IVY.**—It would be wrong to call the Ivy a hedge; the term "screen" is more proper. If a framework of timber or iron is fixed, Ivy planted against it will quickly occupy it and present an effectual screen in a shorter time than anything we know of, especially if the plants be good and in pots, and the soil they are planted in suitable. A little tying to the proper places as a sort of guide will enable the plants to ascend in the place most wanted, and it will be found that very little tying is wanted. The Irish and Heart-leaved Ivies are the best, and they quickly cover a wall, trellis, or bank. The cutting of Ivy is best done in this neighbourhood in August—say the middle of it, when we closely crop many houses and other places covered with it, leaving scarce a leaf, yet it regains its foliage before winter, and looks well after the first three weeks or a month after cutting. The Ivy is not particular as to soil, but the better it is the quicker the growth. I may, however, caution some inexperienced in such matters, that it will in time kill forest trees to which it clings, and of this we have had several instances in this neighbourhood.

**ARBOR VITÆ.**—This has risen into repute the last few years as a hedge plant, and, certainly, it seems suitable in many respects; but as I have had very little experience with it, I can only speak from impressions formed of what I have seen. One good quality it has—it moves well and grows quickly, and, I believe, bears cutting, but I would think it is better adapted for a high hedge than a low one. Good garden soil not too damp nor yet too shallow suits it best, and being pretty hardy it will endure any aspect. I am, however, not certain how it withstands the sea breeze and spray, but I expect not very well. It is, however, more of an ornamental plant than one adapted to hardships, and deserves to be treated as such.

**LAURUSTINUS.**—This makes an excellent hedge or bank; but it ought never to be cut with the shears, but large pieces cut out as wanted, so as to keep the mass in some degree within bounds, and in this way it looks as well as the most skilfully-cut hedge, and there is the additional pleasure of seeing it flower all the winter. A dry stony soil suits it best; but it will thrive and do well on one of a reverse description. Plant in September, and prefer good rooted specimens rather than large ones, and you will be rewarded in due time.

**OTHER EVERGREEN SHRUBS OR TREES OCCASIONALLY USED.**—There are many plants which the taste of individual growers have brought into use for hedges. Portugal Laurel will live, and some here (Linton), have borne cutting for twenty years or more; but, generally speaking, this plant is impatient of the knife, and it will not bear cutting below the leaves as well as the common Laurel. Phillyrea is better and looks well. Alaternus is not so good, the leaves looking rusty. I have not had much experience in Sweet Bay, but in soils that suit it I have no doubt but that it will do admirably. Some single specimens in our grounds are upwards of 30 feet high, and as vigorous as the Scotch Fir. Rhododendrons rarely make a regular line, and cannot well be made to do so without sacrificing their most important feature—the flowers. Whin or Gorse, single or double, looks well while in flower; but if very severe weather follows

after cutting in autumn, the brown, dead, and prickly mass looks badly. The same may be said of Broom; while Spruce and Scotch Firs are better adapted for high shelter than for the purposes of a hedge.

There are many other plants which may be worked into use in an ornamental way with advantage. I should think that *Grise-linia littoralis* might do very well: its glossy green leaves of a pale colour are inviting, and in favoured places there is no doubt but it will succeed well. There is also a plant which has been extensively used as a hedge plant by Mr. Ridgeway, of Fairlawn, in this county, and recommended by that gentleman as adapted even for cattle fences in situations where it will stand the winter. It is Osage Orange (*Maclura aurantiaca*), a prickly half-evergreen shrub, of far from a disagreeable appearance, the foliage being bright, shining, and abundant; the only drawback is, its points rarely ripen, and I do not know the effects of a very hard winter upon it. To this list many others might be added; but enough has already been said on hedges of an ornamental character.

**HIGH HEDGES FOR SHELTER.**—These are of various descriptions, and I think I have seen a Holly hedge, faced on one side, that was little short of 30 feet high; and some Quickset hedges are higher than that. There are hedges of mixed trees—Elm, Maple, White Thorn, and others, trimmed-up on both sides as shelter to the Hop plant, which are upwards of 40 feet high, and by their appearance seem likely to last a century yet; but I have never seen a high hedge of evergreen Fir trees at all satisfactory—they invariably lose their lower branches, besides which, as a single row, they never look well. The cold and high winds have so much effect on them, that a weather-beaten unhealthy appearance is the result even when not pruned, and very little cutting destroys all the life there is in the lower branches. The hardier deciduous trees had better be used if only one line of some 8 feet or 10 feet in thickness be wanted, and that something like 30 feet high. Some trees by their growth are not suitable. I am not by any means fond of Elder nor Willow. Some of the Poplars also quickly overcome their more useful neighbours; but Oak, Beech, Elm, Maple, and similar trees along with Thorns do very well, and if these be not thick enough, the wild Honey-suckle may be allowed to run up amongst them. I do not think it is advisable to encourage Ivy, it is apt to kill the other trees. But so many things tend to determine the trees that are most advisable, that it is not necessary to follow the subject further.

Before concluding I may say, I have omitted many plants occasionally used as hedgerow-plants, because in the most cases in which they were so employed, it was more in consequence of their accidentally being present than through the wishes of the cultivator. Black Thorn makes a formidable fence against cattle or anything else, but the live shoots are all at the top, and it is far below the White Thorn for general utility; and Willow Sallow, Dogwood, Hazel, Bird Cherry, &c., are only tolerated because others will not grow. But the ornamental list may, doubtless, be much extended, those given being only what I have had experience of.

J. ROBSON.

### CROSS-BREDS OF STRAWBERRIES.

Will any of your correspondents who have attended to the history of the Strawberry, kindly inform me whether any of the kinds now, or formerly, cultivated have been raised from a cross between any of the Woods or Alpines with the Scarlets, Pines, and Chilis? Also, whether any one has succeeded in getting any good from a cross between the Hautbois and any other kind? I am aware that Mr. Williams, of Pitmaston, succeeded in getting some sterile hybrids from the Hautbois and Wooda; but whether these were ever at all largely propagated, I cannot find out. I am, also, aware that Mr. Knight and Mr. Williams raised many seedlings by crossing Scarlets, Pines, and Chilis; but what I want to know is, whether any one has crossed these three latter kinds with the Wood or Alpine. I should feel greatly indebted to any one who would take the trouble to inform me on this head.—C. DARWIN, *Down, Bromley, Kent.*

[We shall be obliged by answers being sent to us in reply to this inquiry.—EDS.]

**CONSEILLER DE LA COUR PEAR.**—We have received a communication from Mr. George Lee, of Clevedon, near Bristol, to say that he is a market-gardener and not a nurseryman as we

stated in our notice of this fruit, and that he received his trees from Mr. Rivers, of Sawbridgeworth. This announcement is necessary, as Mr. Lee informs us that, in consequence of our notice of the fruit and of his name in conjunction with it, he has been besieged with applications for trees of that Pear.

### WATERING POTTED PLANTS IN A SUNK FRAME.

I HAVE always found some difficulty in watering crowded pots in a sunk frame without spilling much water among them, or, in the case of using manure water, without letting it touch the foliage. To avoid this difficulty, which I believe is of considerable consequence, I thought of a contrivance this year so simple that I should never have thought it worth your notice had it not been for the following remark of an eminent gardener to whom I mentioned it. He says, "I like your invention so much that I think it is worthy of more prominent notice. Send it to THE JOURNAL OF HORTICULTURE with a drawing." I can only add that if so simple a contrivance be of any use to your correspondents, I am glad to have the opportunity of making some small return for the full and courteous replies I have received to any questions (chiefly on bee-keeping) I may have had occasion to put through your columns.—A. W. B., *The Vicarage.*

A small tin tube about 3 feet long and half an inch diameter, with a funnel at top; to be held in the left hand while the water is poured into it from a jug or small can in the right. Mica is made to fit on to a small watering-pot at A, the rose of which will also fit on at B if required.

### BOTTOM HEAT FOR POTTED VINES.

Will you let me know the best way of managing my pot Vines, of which I have about three dozen two years old? I have no bottom heat, but a flue all round the house. Must I put the bottoms of the pots on the bare flue, or must I put a trellis under them? I wish to start them soon.—SAM SLICK.

[A couple of bricks set on the flue would do well for the pots standing on, leaving a space between the bricks. A large saucer on the top of the bricks would be advisable if water was not allowed to stand in it. Such vessels on the flue would also be useful in giving moisture before the Vines were broken.]

### GRAFTING ROSES BY THE FIRESIDE.

At page 171, Vol. XXIII., Old Series, of your Journal, Mr. Beaton states that Mr. Ruddock grafted Roses at his own fireside in March. Am I to understand that the Manetti stocks were really grafted while the roots were out of the ground, and do you consider such a safe practice? If so, is March a better season than any time during the late autumn or winter months—say at the present time?—B. W.

[Mr. Beaton repeated the tale from Mr. Ruddock's own account of the experiment. They were Manetti stocks, a lot he bought cheap at a sale. He grafted them by the fireside, and then planted them, and hardly lost one out of a hundred. You may give credit to its being a safe practice. March and April, in our latitude and climate, are the natural season for grafting all deciduous plants; and the autumn, and on to the new year, the most unnatural. That is thus accounted for: In the spring the sap is fast rising, and no time is left for the cuts to dry, but to unite by their edges. In the autumn and winter there is no perceptible rise of sap, or of growth "acting in" for months, and to graft when no means of healing or uniting is provided is just like grafting the wrong end of the stock. But gardeners often turn the autumn into spring, and graft and work accordingly. They cause their Vines to bud and blossom in the dullest months, and the Rose they bud and graft every week the whole year round—that is, they force the plants; and when once the Rose is under that natural impulse, the effort to grow and extend itself, it may be grafted or inarched, layered or budded,

no matter what the time of the season may be; but it will not do to graft Roses now, unless they are in a climate of from 50° to 60°, and kept so till the grafts have taken.]

### VINES IN A PLANT-STOVE.

A Reader having a stove 24 feet by 12 feet, well filled with good plants, will be glad to be informed whether ten Vines just purchased should be planted in a border outside the stove, taken through a brick wall 3 feet high, and trained on the spur system between the sashes? or should they be planted in pots, some of them trained between the sashes, and some on stakes in the pots? As a hot-water pipe (one of four) goes very near the brick wall, would the Vines suffer if exposed on the outside of the wall till near the coping? Would the heat required for the stove plants be hurtful to the Vines when resting in winter?

[Ten Vines would so crowd the roof of such a house in summer when once established, that you could hope to do nothing below them then with plants. There is in No. 84 a sketch of a double glass front for a house where the Vines could rest in winter, and be perfectly safe. Supposing you planted the half of your Vines outside, or say six out of the ten, and brought them in not through the brick wall but over the sill, you could place a small box with three sides and a top over the stems of the Vines, and could protect the stems there in winter. If part of that covering were glass, so much the better; and if there were some openings in the front wall, so as to shut and open at pleasure, the Vines might be gently excited before taking them into the house. Common frame-lights not used for the winter would do laid lengthwise. If you have any doubt about these modes, there need be none about growing the Vines in pots inside. The pots can be put in when desirable; and if a moderate crop is taken, the pots, when the wood is ripened, may be plunged in a shed before they are wanted.]

### REV. MR. BUSHBY'S VINERY.

As an encouragement to amateurs, we have much pleasure in chronicling Mr. Bushby's success in a vinery of very simple pretensions, but so managed as to give profitable returns to that gentleman and his family for a portion of the year.

This gentleman is at the head of the Episcopalian Church at Dalkeith; and mainly at Mr. Thomson's suggestion built a span-roofed vinery, about 25 feet long by 16 feet wide, which has produced, ever since it came into bearing condition, an excellent crop of Grapes, more especially the last two seasons. When we visited it some fortnight ago, there were some very good samples of Muscata yet remaining uncut; indeed, from that very house were cut the Muscat Grapes that took the prize in the open class at the Dalkeith Exhibition. The one side of the span is devoted to Black Hamburghs and the other to Muscata; and there were evidences enough remaining to show that such a house, so managed, is no more a luxury in the general acceptation of the term than the simplest fruit trees in the garden. Such a house as his could be built for £50; and if he was sending the produce of it to the market, it would pay very good interest for his money.—J. A.

### GREENHOUSE FERNS.

IN answer to "RUSTICUS," we believe that many of the tenderer Ferns are harder than is generally supposed; but many that would stand uninjured a good amount of cold will not endure a dry parched air, nor yet dryness, nor a soaked soil at their roots. Of the list you give, *Adiantum cuneatum* and *pubescens*, *Asplenium bulbiferum*, *Doodia cusdata*, and *Pteris rotundifolia*, will stand in a cool greenhouse, though the fronds may be a little injured; but the fresh ones will come up vigorously enough. We do not think you will succeed so well with *Asplenium lucidum*, *bulbiferum*, and *lanceolatum*, *Gymnogramma ochracea*, *Polypodium pectinatum*, *Pteris longifolia*, and *hastata*, if they just get the common treatment of the house. The last two are pretty hardy, and, perhaps, the *Gymnogramma* is the tenderest. To make sure of these, we would keep them together at the warmest end of the house, and, if convenient, place a hand-light over them, or make a small wood case or box, and cover either with moveable squares of glass, or even a piece of glazed calico,

that could be put off in fine, mild, dull weather, and put on when cold at night or extra bright during the day. The pots should also be plunged in moss that had previously been soaked in hot lime water to set all slugs, &c., adrift. With such a contrivance we believe you will succeed, if the average temperature of the house at night ranges from 40° to 45°. In watering, use water about 60° to 70°; but it will be safest to keep the moss rather moist.

Attention to these minutiae will explain why the *Trichomanes radicans*, &c., that grow at Killarney, under the canopy of heaven, requires to be protected by a bell-glass, when kindly treated indoors. This is always found in moist places, and often on rocks, considerably shaded, and where there is a constant trickling and vapour from water. To cultivate it successfully, the roots, slightly covered, must not only be moist, but the air in which the fronds grow must also be moist, and the air well changed. In "A Few Days in Ireland" sketches, which, in answer to many inquirers, we may say will presently be resumed, you would notice what fine specimens were grown by Mr. Bain, at Trinity College Gardens, by attending to these conditions, and also how well these plants thrive at Mr. Bewley's, under Mr. O'Brien's care, in houses for the purpose, and in glass cases—such as a beautiful one in a parlour window. The glass or the box enables us to give the conditions in a small space. All the tenderer hardy kinds will do best in a cool greenhouse. A list of the hardier exotic kinds will ere long be given. We shall publish a volume on Fern culture next spring.

### SMALL FURNACE FOR GARDEN STRUCTURES.

ABOUT eighteen months ago I wished to heat some small frames with flues instead of manure, and, preferring to do all I can by my own head and hands, I set to work to build a small furnace. Having neither fire-door nor ash-grate by me, I determined to devise something that should answer the same purpose. I accordingly built up the furnace of bricks and cement, leaving a square hole at the top to feed through, and over which, as a cover, I placed an old piece of sheet-iron about a quarter of an inch thick. As to the ash-grate, I secured the two portions of a broken iron bracket in the brickwork, and on them laid a moveable piece of strong iron wirework. Judge of my surprise at seeing in my this-week's Number an almost exact representation of my handiwork! The sole differences were that, as my cover was only about 7 inches by 5 inches, I had to build my furnace to correspond, that the ash-place fronts the flue, and that I have not indulged in the luxury of an attached iron handle; a trowel point doing duty for the same. I have only to add that it heated perfectly 18 feet of two-inch metal pipe (I have now brick flues), will keep alight for ten or twelve hours without any attention, and costs very little to make. It will, I think, burn anything: cinders, and occasionally small coke, being my fuel. A common brick placed before the ash-pit abates the draught, and makes the fire steadier.

The singular coincidence may, perhaps, excuse my troubling you with this letter.

The furnace is outside the frames. I almost think it would suit "H." and others.—L.B.

### GREENHOUSE FOR WINTERING PLANTS.

As I am strictly an amateur, and do not get home before half-past five, my cold frames often suffer. To-day (Nov. 12th), the frost was severe at nine A.M. when I left, and now, at noon, the sun has great power.
