The varieties in bloom had been selected with great care, the very best or most showy only being admitted into this tent. To hold so many the tent is necessarily large. Where the mound is, it is much wider and more lofty than the avenue. The following are such as struck me as being particularly good:—

Let the reader understand that the collection under shelter contained a goodly number of the best hardy *Azaleas* as well as *Rhododendrons*. The bright yellows of this tribe supplied a colour which the *Rhododendron* family does not contain.

*Album elegans*, fine white, suffused with flesh colour.  
*Atro-sanguineum*, very dark; free to bloom.  
*Blandyanum*, bright crimson; fine form, good truss.  
*Brayanum*, rosy crimson; excellent.  
*Cadmus*, dark and fine; a new variety.  
*Elegantissima*, lovely flesh colour, splendid trusses.  
*Fastuosum plenum*, a double variety, purplish-lilac; extra well bloomed.

*John Waterer*, brilliant carmine; fine form.

*Juba*, fine crimson, thickly marked with dark spots, fine compact truss, and excellent in form and substance. I consider this the finest dark variety in the collection.

Mrs. John Waterer, rosy crimson; very fine.

Pardoloton, purple shaded with crimson.

Seedling, a white variety, edged partially with light pink; very good.

Schillerii, purple, with dark chocolate spot; new, and very fine.

Van Dyck, dark crimson; very good, almost as good as Jubæ.

I might have swelled this list to a great extent, but the rest were either well-known sorts, or not in flower sufficiently to enable one to judge of their merits.

Leaving reluctantly this beautiful floral scene, I passed by several ranges of turf-pits covered with glass. These pits now are filled with Strawberries ripening fast their fruit. The plants had been grown in pots in the usual way. When the pits were emptied of their winter occupants they were filled with a slightly-fermenting material on which a sufficient thickness of soil was placed. Then the Strawberry plants were turned out of their pots, and planted in rows across the pit to flower and fruit. This practice is a successful one. The fruit, from being near the glass and on fine days fully exposed, swells up very large, and ripens well. There is always a danger when Strawberries are forced in vinerys or Peach-houses of their harbouring and feeding that enemy, the red spider; but by growing them in pits, as they are grown here, that pest is avoided.

I found Mr. Yates busy planting-out his large collection of Gladioli; they are grown in pots first in frames, and as soon as all danger from frost is over they are planted in a fresh loamy soil freely manured with hotbed dung. Mr. Yates is a great lover of these gay summer and autumn flowers, so much so that he plants them all out with his own hands. He declared to me that he valued them so highly that he would not trust any one but himself to plant them out.

From him I wended my way to the Orchid-houses, where I had a rich treat, so many Orchids were in flower. I noticed especially *Dendrobium Devonianum*, two plants grown in baskets with seventeen and fifteen long spikes of their delicately beautiful flowers, all expanded together; *Cattleya lobata*, a fine plant with thirty-five large flowers; *Burlingtonia venusta*, eleven spikes; *Calanthe veratrifolia*, seventeen spikes; *Odontoglossum citrosimum*, two fine spikes; *Dendrobium tridenum*, two pots, ten spikes; *Lælia cinnabarina*, four spikes, holding twenty flowers, very large and fine; *Dendrobium nobile*, two large plants 3 feet across, with innumerable blooms. The East Indian species are full of spikes, but not yet in bloom, excepting two species of *Saccolabium*—namely, *Saccolabium guttatum* and *S. retusum*, which were in fine bloom. I find Mr. Yates grows all the epiphytal Orchidæ in nothing but sphagnum moss well drained, and well they thrive in it.

I could not help noticing what large numbers here are grown of some species, especially *Coleogyne cristata*. There are thirty large pots filled with this plant alone. Of *Calanthe vestita*, upwards of a hundred pots, and many others in proportionate numbers. I was informed they were grown chiefly for bouquets in early spring.

In the stove I observed a remarkable specimen of *Caladium bicolor splendens*. I measured one leaf, it was 23 inches long and 15½ inches broad. There also was a nice specimen of *Coleus Verschaffeltii*, which, being grown in a full light and close to the glass, was the densest dark-coloured that I have ever seen. There was not a particle of green visible. If this plant proves hardy enough for the open air it will banish the *Perilla* from our ribbon-borders. I also noticed an old bulbous plant seldom seen now, named *Zephyranthes rosea*. The pot was full of bulbs, and had nearly a dozen large rosy-coloured flowers expanded.

From the houses I wandered into the Fern-valley. The denizens here have grown into large specimens. Many hardy exotics, such as *Osmunda spectabilis*, *O. cinnamomea*, *O. interrupta*, *Struthiopteris pensylvanica*, *Onoclea sensibilis*, and others, have been added to the collection, and are now thriving well. I saw, also, several plants of that singularly beautiful hardy Fern, the *Lastrea filix-mas multifida*, with fronds 2 feet and upwards long, every pinna being elegantly tasselled. In the Fern-house adjoining the inmates have made great progress; the plants seem quite at home.

I remember when I was here some two years ago, I noted a method of making specimens of evergreen Hollies by planting them out in rows as far small plants, a great distance from each other, giving each a quantity of good manure to encourage rapid growth. Or viewing them now I find they have made, as I prognosticated, great progress. They are now very handsome, shapely plants, from 2½ feet to 3 feet high, furnished with

branches down to the ground. I should think there is nearly half an acre of them. Such a method is worthy of imitation by any nurseryman that has space for them. T. APPELBY.

### "IT FOLLOWS THAT THE CAT MUST STAY AT HOME."—SHAKESPEARE.

I AM pleased that the Press has taken up the question as to the policy of destroying small birds. Since the severe winter of 1860, the numbers have considerably fallen off. Poison and schoolboys destroy many, but the birds have other enemies than poisoners and schoolboys.

I have watched the nests in my garden for these last three weeks, and have counted seven nests that the old birds have been taken off, or the young birds destroyed, by cats. In addition to the destruction of small birds, the mischief the cats do in the garden is immense.

I consider that with their nocturnal squallings, and the injury they do, the cats are the greatest pests in this country. Surely it is not unreasonable to require the owners of such vermin to keep them at home. A goodly increase in the revenue may be made by taxing cats.—A LOVER OF FLOWERS AND BIRDS.

### UTILITY OF SMALL BIRDS.

IN several of the public prints, especially in the *Times*, there have lately appeared very interesting letters on the destruction of small birds; and I would ask your numerous readers, country gentlemen, farmers, and others, to think this matter coolly over, and consider if there is not a great necessity for the preservation of these small birds, from the simple fact that where they have been exterminated, as in France, there has been such an inroad of caterpillars that they have been compelled to legislate for their preservation.

Let us look at the case of the House Sparrow, perhaps the most destructive to the cereal crops of all the feathered race. Now, Bewick in his "British Birds" says, "It has been observed that a single pair of Sparrows during the time they are feeding their young will destroy about 4000 caterpillars weekly; they likewise feed their young with butterflies and other winged insects, each of which, if not destroyed in this manner, would be productive of several hundreds of caterpillars."

In "White's Selbourne," in a note the Editor says, "A young Sparrow which I picked up in my garden, and placed in a cage for the purpose of ascertaining what food would be brought to it by its parents, was almost wholly fed on cockchafer."

Lastly, I will quote Dr. Stanley, the late Bishop of Norwich, who states that "Sparrows feed their young thirty-six times in an hour, which, calculating at the rate of fourteen hours a-day in the long days of spring and summer, gives 3500 times per week; a number corroborated on the authority of another writer, who calculated the number of caterpillars destroyed in a week to be about 3400."

I would add, supposing the Sparrow does much mischief in the harvest, which may be prevented by a few live scarers, does not this bird pay back a good percentage in the destruction of grubs and insects?—J. L. P., *Edgbaston*.

THE FAIRCHILD SERMON.—The old church at St. James's Aldgate, on Whit-Tuesday evening wore a charming aspect, which was certainly not due to its architectural pretensions, nor to its ornate condition, for it is terribly out of repair. The charm lay in the pleasant smiling faces of the girls and boys who filled the pews, and in the bouquets of flowers which they carried in their hands. They listened with fixed attention while the Rector (the Rev. W. Meynell Whittmore) discoursed, according to annual custom, on a topic allied to "flowers." His text was Isaiah lxi. 11, and his subject was "Beauty of Character, as illustrated by Floral References." The preacher duly admired a nosegay which some kind young friend had placed in the pulpit, and requested his audience to notice how beautiful are the flowers which God has so bountifully scattered over the earth; and then he bade them learn, (1.) that in every station of life it was quite possible for them to show beauty of character; but he was careful to state that mere external beauty must not be always regarded as an index of the state of the heart; for (2.) a pretty face often hides a disagreeable and injurious disposition.

Then he went on to describe (3.) how fragrant is the memory of a beautiful character, like crushed and dried Rose-leaves, which preserve their pleasant odour; and (4.) he assured his youthful hearers that, by Divine assistance, they would be able to produce spiritual beauty in other hearts, even under most unfavourable circumstances. A pennyworth of seed would insure many pretty flowers, and a penny tract might change a spiritual desert into a garden of the Lord. The assurance rests on promises such as the text. This delightful promise not only encourages our own efforts, but opens a glorious prospect of the whole world, filled and fragrant with the "beauty of holiness."—(*City Press*.)

### AIR-ROOTS ON VINES.

I QUITE coincide with Mr. Fish in considering that those roots are the effects of an over-moist and stagnant atmosphere. By this I do not mean to say that the vine in question has not been properly aired, but what I mean is, that there is an absence of air-circulation, which is necessary to prevent roots protruding from the stems of Vines growing in a high temperature and stagnant atmosphere. Every practical gardener knows that ventilation can only be properly effected by having the front sashes to open either by a crank or by sliding right and left as in the old-fashioned Vine-houses. In such houses aired on his principle I never have seen air-roots appear, and I have in my own experience commenced forcing at the new year. Nor did we then disapprove of moisture, for these houses were engined at least once a-day and occasionally twice, as was formerly the practice. Although I do not use so much water now, I do not at all disapprove of humidity if not accompanied by defective ventilation.

I have of late seen some of my neighbours' houses literally full of these roots, and as raneid inside as a dunghill. Now, this is entirely the result of bad ventilation. Opening ventilators at the top and front of the house is all that is wanted to prevent air-roots.—J. REID.

### A PLEA FOR SPERGULA SAGINOIDES.

NOTWITHSTANDING the up-hill work that the first suggestor of this valuable adjunct to our gardens had in bringing it before the public, it is fast gaining a reputation for itself; and, if I am not deceived, the day is gradually approaching when *Spergula* will be hailed for small places and geometric gardens as an indispensable article. With me, *S. saginoides* has far surpassed my most sanguine expectations, and, where the soil is suitable, I should recommend it in preference to *pilifera*, as it preserves its bright green hue through all vicissitudes of damp, frost, or drought; and, if I mistake not, its constitutional properties enable it better to withstand the vicissitudes of an English winter, for with me it has withstood the last two winters unhurt, whilst *pilifera* has died at the rate of 30 per cent. Soil and situation, of course, have much to do with this, and experience has taught me to pause ere I recommend either the one or the other for any particular soil; in fact, I believe no one from reading a description of any soil can unhesitatingly recommend either plant, and, if any one could, I should receive the testimony in such an ungracious manner that I might be taken for one of those who look upon the recommendation as an intrusion, though I value the introduction as a boon to English gardens.

What I recommend is, that those who intend to adopt *Spergula* turf should choose a small piece of ground—a fair sample of the whole. Upon this plant out a little of each sort; let it remain a summer and a winter, and then will they be able to judge from the results which is the more suitable to the soil.

Such a process, of course, would only be necessary where it is in contemplation to use *Spergula* extensively. Far better will it be to advance thus cautiously than to run the risk of a failure of any magnitude; one defeat of any extent will do more in giving the plant a bad name, than its advocates could remove in twelve months by writing.

It is not from any fear which I have that *Spergula* turf will not answer that I suggest this caution; but it arises from a desire to see it receiving from those who intend to use it a fair and impartial trial.

I confess that at first it was foreign to all my notions of utility, and it was not till I had tested its merits that I banished

those preconceived opinions for one more deserving and favourable.

A few seedlings of *saginoides* raised and planted out by me last May twelvemonth, have made a charming piece of turf; and some of them now measure 5 inches across, and present to the feet a soft, verdant turf. The more I beat it the better it seems to enjoy itself; in fact, no amount of wear will ever hurt it, and if it were possible I should have no hesitation in planting the whole of White Hawk Down with *S. saginoides*, and then permitting the whole of the rifle volunteers to exercise upon it next Easter Monday, for *S. saginoides* would benefit from such a thorough trampling.

To keep it assiduously weeded and continually rolled in the earlier stages of its growth is highly important, and a neglect of the latter is fatal to the natural habit of the plant.

The one grave and only objection that has at all times been raised against it I am very pleased to see is removed—I allude to the numerous small white flowers. The remarks which they drew from the writer who penned the notice of Messrs. Carter's nursery in these pages a week or two since, show that they are easily removed at pleasure. I have refrained from giving an opinion upon this point, but I never doubted the practicability of it; and I hail with pleasure this, to me, new piece of information, and I would advise those who still retain their old ideas upon *Spergula* turf to visit the above nursery, or some other spot where it is grown as it should be. An indifferently managed piece of turf, under the charge of individuals who, perhaps, still retain a spice of prejudice against it, is not the place to go and draw your conclusions.

It is not to be expected that *Spergula* will meet with a general reception in large places, because its adaptation for geometric purposes totally unfits it for the other, as it fails to harmonise with surrounding objects if used upon pleasure grounds of large extent; but for villa-garden verges, and where well-defined margins are required, or where grass will not do well, *Spergula* will, with careful management, effect the desired end.—J. C. CLARKE, *Wakehurst Place*.

### BEAUTY AND UTILITY COMBINED.

"A Vine-clad home—sun-light without,  
Smile-light within."

THREE years ago I asked you the same question as a "SUBSCRIBER." I built of stone a corridor 36 feet long, 6½ feet wide, 7 feet high in front, and 11 feet at back, due south aspect, forming a garden entrance, and means of communication between the drawing-room and inner hall. At your suggestion I planted in a narrow border at back *Camellias* alternating with choice climbers, the border being kept filled with plants flowering, in pots, from the greenhouse. In front were planted thirteen Vines for shade and beauty. The Vines which were left to Mr. Rivers for selection (the seven first have turned out A1), are—Black Hamburg, Black Prince, Trentham Black, Muscat St. Lawrence, Chasselas Vibert, Champion Hamburg, Prolific Sweetwater, White Malvasia, Royal Muscadine, and Madeira Muscat. They were planted in an outside border (partly under the gravel walk), in good turfy loam with a slight mixture of mortar rubbish. Nothing can exceed the health and luxuriance of the Vines, which having been for two years very slightly cropped, are this year allowed to bear as they will. The promise of fruit is very great, the bunches being both numerous and fine. They will be very much thinned, but I purpose to allow them all to stand.

This corridor is in every way beautiful, always a pleasant object from the drawing-room, one window of which looks down it, and is, summer and winter, a pleasant lounge. There is ample ventilation from the lights in front, which are glazed with large sheets of ordinary glass, the roof is formed of Hartley's rolled plate. Two inches against the wall are found ample to carry off the heated air. In winter a small moveable stove of Brown and Green's answers to keep out the frost, and is removed in the early spring. The flowers keep in bloom much longer than in the greenhouse, and remain longer on the plant. Altogether, your suggestion has proved a success, for which I am much obliged.

Whilst I am writing, may I offer a few remarks on economy of fuel? I have built at various times a greenhouse 33 feet by 12 feet (7 feet in front, 12 feet at back), opening into which at one end is a small stove, to correspond with a smoking-room at

the other. Also, a propagating-house, 25 feet by 11 feet, and a cool-house adjoining. The first three have furnaces (with but small fireplaces), built of firebrick with fireclay joints, surrounded by a mass of brickwork enclosed in a chamber within the house. In the greenhouse both the fire and the flue for the greater part of the distance are below the level of the floor, in a chamber with gratings. In the stove and propagating-house the fire and flues are aboveground. In all cases they are fired from potting-shed or enclosures outside. The fires in the severest weather can be left for twelve hours, on account of the great mass of heated brickwork, and the amount of air admitted round the flues can be very easily regulated. In general, the warmer the flues the greater the quantity of air admitted, except at night, when the object is more to warm than to ventilate. We find that a little small coal with the cinders from the house answers all our needs, and during the past mild winter we have lighted the greenhouse fire but twice, as by leaving the door of the stove open, and with the aid of the kitchen which runs up the back wall, we find heat enough to keep the frost out when not excessive.

The experience of many years has taught me that in small houses a flue with air-chamber is far better than hot water alone. In large houses both are of importance. I consider my little stove first-rate; the stand is built of stone slabs forming a large air-chamber, within which are the fireplace and flue. Narrow slits in the stone admit the air into the stove, previously admitted to the air-chamber, through holes round the fire; the stove is consequently charged with currents of fresh warmed air perfectly under control. The propagating-house and cool-house adjoining are partly underground; but the fireplace and flue in the former are above the floor and under the stands. The chimney-stack of this just keeps the frost at bay in the cool-house during the severest weather, so that things standing a few degrees of dry frost are safe enough.

The air-chamber round the fireplace prevents them ever getting very cold, or cold at all if a small fire is lighted once in twenty-four hours, so that the heat is quickly gained and easily kept up. I find that the free circulation of air caused by this plan aids very much in keeping the plants in health.

As a bit of garden news, I may say that we found last year many self-sown seedlings of bedding-plants—*Salvias*, *Calceolarias*, *Geraniums*, and *Verbenas* especially; some of which, in addition to robustness, seem to promise well, especially a scarlet *Salvia*, with petals, that if laid on the petals of *Sutton's Scarlet Geranium*, cannot be distinguished from it; and a seedling from *Calceolaria aurca floribunda*, seemingly more dwarf, with rather darker flowers (in great profusion), and a darker foliage. I think in exceptional years these self-sown seedlings might be kept with advantage.—L.

## THE INTERNATIONAL EXHIBITION.

(Continued from page 196.)

2011. TRUSS, T. S., C.E., 53, *Gracechurch Street, E.C.*—Patent Pipe Joints for Hot-water Apparatus, Gas, and Water Mains, &c. These are constructed so as to be water-tight without the usual tedious method of caulking, and are stated to be easily made in a few minutes, and capable of sustaining any required amount of pressure. They can be readily disconnected at any time to allow of alteration or removal, and remade without injury to any of the parts. The pipes are cast with a bead at each end upon which the ring of elastic packing (Indiarubber or, in the case of hot-water pipes, woollen felt), is placed when the ends of the pipes are brought near together. The iron band formed in three or more segments with two interior grooves corresponding with the beads on the pipes is then placed around the packing and drawn together by means of screw-bolts and nuts, thus making the joint upon the tops of the beads. According to the width of the band and the interior grooves the joint is more or less elastic, resembling in action a ball-and-socket joint, and is thus specially adapted to gas and water mains which are liable to deflection, for which purpose they are in use, varying from 2 inches to 4 feet in diameter.

2393. MOORE, J., 81, *Fleet Street*.—Patent ventilators. These are of very simple construction, consisting of glass louvres which can be opened more or less at will by pulling a cord or working a screw. The best proof of their efficiency is the fact of their adoption in nearly all public offices, and it would be well if they were found more frequently in dwelling-houses, especially those in which the top-sashes of windows are fixed. In such cases the

only outlet for the escape of the vitiated air is by the chimney, for even if the lower sash of a window is thrown up the heated air, by reason of its less specific gravity, cannot pass downwards, and it remains to mix with the purer air. Besides, in winter when the atmosphere of living-rooms is more liable to become impure than at any other time, windows cannot be opened without admitting much more air than is either desirable or pleasant. By the use of this simple ventilator, however, the bad air can be drawn off without danger of draughts and without involving any alteration in the construction of the window. The invention may also be applied to conservatories.

—COALBROOKDALE CO.—The chairs shown by this Company are of cast-iron bronzed, very handsome in design, and of solid construction. The bottom of each chair is of oak. They would suit extremely well for placing in entrance-halls and on raised terraces in gardens. A very good scraper is also exhibited; it is oblong in form and consists of strips of iron set on edge, whilst at each end there is a stiff brush for more effectually freeing the sides of the boots from mud. It would answer well for conservatories or villa entrances. Its cost is about a guinea.

2330. PERKINS, A. M., 6, *Francis Street, Regent's Square*.—Hot-water apparatus for warming buildings, drying, and laundry purposes. This is what is known as Perkins' high-pressure system, and consists of a coil of small pipes placed in a furnace and connected with other pipes for circulation. No space being left in the pipes for the water to expand into steam, it becomes heated far beyond the boiling-point of water, exercising an enormous pressure. However well the plan may answer for drying purposes, pipes heated to such an extent are not desirable for garden structures, nor altogether safe where constant attention cannot be given.

2411. RIDDELL, 155, *Cheapside*.—Slow combustion boiler. This essentially consists in two upright wrought-iron cylinders of different diameters inserted within each other, and welded together, the base resting on a bed of firebrick. The intermediate space is occupied by water, the centre of the inner cylinder by the fire; and the cavity between the water and the outer iron casing serves as a flue for conducting the smoke towards the chimney. Air is admitted to the fire by a regulating-door at the bottom of the outer case, and fuel is supplied from the top which can be closed nearly air-tight, so that the gases resulting from combustion may not escape otherwise than by the flue.

It is adapted for heating small conservatories, entrance-halls, &c., and is said to require very little attention. The smallest size, it is stated, will burn twelve hours, and heat 80 feet of 4-inch pipe, at an expense of 3*d.*; and that a larger boiler, on the same construction, will, during the same time, heat 350 feet for 8*d.*

2441. PULHAM, J., *Broxbourne*.—Terra cotta "Ferdelabrum." This has a neat appearance, and would be suitable for situations where small fountains or similar decorations could with propriety be introduced. The outline of the base is that of a square with semicircles turned on a portion of each of the sides; the stage above this is composed of intersecting circles, and then follow a number of basins diminishing in size to the top, which is surmounted by a boy and shell. Ferns or flowers may be planted in these basins, or the whole may be used as a fountain, the water dropping from basin to basin, as shown in another part of the building.

2370. BEAGLE & Co., 71, *Cannon St. West*.—Ventilators. The distinctive feature of these consists in the front of the ventilator, which is fixed, being closely perforated for a certain distance, then quite close for an equal distance, and so on alternately; over this a plate with corresponding openings is made to slide backwards and forwards. When it is desired to admit air, the openings of the two plates are made to coincide; if the contrary is desired, the perforations are completely covered by the close portions of the slider.

In our last week's report, it should have been stated that in Kistell's patent labels, exhibited by Nixey, the name is enamelled and hermetically embodied with the cast-iron.

ALOE ABOUT TO BLOOM.—In the conservatory of the Royal Horticultural Society may be seen the rare event of an Aloe coming into flower. As Fellows will remember, this is the plant which is said to flower only once in 100 years, and although this, like other exaggerations, is only half true, still the long period of its life which elapses before it flowers, and the very

rare occasions on which it has done so in this country, render the specimen in the conservatory, now about to flower, an exceedingly interesting object. It has been presented to the Society by Mr. Nash, of Bury House, Edmonton, who has had it in his family for nearly half a century, and until this year it has never flowered. Two years ago a companion plant, which had been in possession of his family for the same period, at last flowered. The present plant is sending up a splendid spike, which has been advancing at the rate of about 4 inches every day, and may be expected to burst its sheath in the course of this month.—(*Royal Horticultural Society's Proceedings.*)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

EVERY vacant piece of ground should now be well filled-up with Broccoli, Cabbages, Kales, and Winter Greens. *Asparagus*, this is a good time to apply salt to the beds, about one pound to a square yard is sufficient. If this stimulant is applied now, it will assist the roots to lay up a good store of organised matter for another season. The good effects of this kind of treatment will be perceived in the autumn by the plants retaining their green colour longer than others not so treated, and in the spring by increased size and productiveness, evidently showing that the longer the functions of the plants can be kept in action by the application of stimulants, the greater the amount of organised matter that will be stored up for the ensuing season. *Broad Beans*, continue to top them as they advance, and keep them well gathered as they become fit for table. *Celery*, the trenches for the main crops should now be prepared. For this purpose the spaces between the rows of Peas are very suitable; the shade from the Peas will be beneficial to the Celery in its earliest stages, and the Peas will be entirely removed by the time they are likely to be injurious. *Dwarf Kidney Beans*, another sowing may be got-in for succession, and the advancing crops, both of these and Scarlet Runners, well thinned-out; keep the soil about them well forked-up and pulverised. Experience goes far to prove that the fork is the best instrument that can be used amongst all wide open crops. *Tomatoes*, see that they are well thinned-out and nailed to the walls or fences.

### FLOWER GARDEN.

Examine all newly-planted things, and see that the soil is well closed around their stems. Use the hoe where requisite to break the surface crust. Attend to pegging and tying. Fill up all vacancies where there is a deficiency of stock. Annuals may be sown for that purpose. Roses may be budded, taking eyes from those trees which have been forced. The regulation, as far as is necessary, of wild creepers, such as Clematis, Honeysuckles, Hops, &c, about shrubberies should be at once attended to. The rambling and irregular growth of shrubs to be pruned, and evergreens may now be layered. Tie-up whatever may require it. Pipe and lay Pinks and Carnations. Stick Sweet Peas and Convolvulses. Thin hardy annuals. Pot Chrysanthemums as they require, and put in more cuttings. Propagate herbaceous plants that are difficult of increase by divisions of the roots. If little besidea Daisies are growing on the lawn, they should be mown in the middle of the day when the flowers are fully expanded.

### FRUIT GARDEN.

Lay-in the shoots of Apricot and other wall trees while the wood is pliable. We have seldom seen so fine a development of wood on espalier trees. Advantage may be taken of the circumstance to lay in an extra quantity, with a view to the ultimate removal of old unsightly wood. Stop and nail-in Vines. Thin Raspberry-suckers.

### STOVE.

We must here repeat the advice so frequently given—to keep up by all means a sufficient amount of atmospheric moisture, increasing it with the increase of heat and light, and accompanied with a gentle motion of the atmosphere. Springe freely twice or thrice a-day, and give morning air freely. Some of the Orchids will now require a little assistance in the way of topping-up, and a watchful eye must be kept for insects. The *Barkeria spectabilis*, the *Lycastes*, the *Odontoglossum grande*, *Epidendrum Skinneri*, &c., will enjoy the greenhouse temperature without fire.

### GREENHOUSE AND CONSERVATORY.

Many plants will now be growing vigorously, and should be shifted as soon as they require more pot-room. Attention to be

given daily to watering, syringing, stopping, shading, and turning them to the light, and to allowing each sufficient space to develop its increasing size and beauty. It is only by such attentions that they can be expected to do well and give satisfaction. The general stock of greenhouse plants may now be readily increased by cuttings. A lot of the best Scarlet Geraniums should be selected for blooming in the winter. These should be grown rapidly, and frequently stopped. Towards August they will become rather pot-bound; they must not, however, be shifted, but merely hardened in a very exposed situation until the end of September, in order to get them sturdy and very short-jointed. Where Orange trees are kept in-doors, give abundance of air night and day, wash them frequently with the engine, using clean water, and damp the paths and floor often. Such of the Heaths and New Holland plants as are making their growth should be duly encouraged by frequent syringings and waterings, and liberal airings. *Cinerarias* and herbaceous *Calceolarias* that are now going out of bloom, and are not required for seeding, should be planted out on some good light soil in a cool shady situation, where they may remain for a couple of months, to be parted and potted for next year's blooming. The plan is useful if it is desirable to retain the stock of any good sorts; but plants from seeds sown now will grow more freely and produce finer specimens under treatment common to both. The Balsams to be sprinkled overhead morning and evening in fine weather; when the last shift is given, they may be potted deeper as they emit roots from the stem. Although the Balsam is a thirsty subject, it requires a good drainage, as the least stagnation of water will rot the stem.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

WEATHER very uncertain, and work regulated accordingly. Rained pretty well on the 11th, and poured on the 12th without intermission, giving us abundance of moisture without any help from the water-pail. A poor look-out, though, for those who have commenced hay-making. Besides staking Peas, sowing Turnips, thinning plants, the work has been of a routine character, such as planting, weeding walks, making sticks, washing pots. In fact, we had been so busy outside, that we needed a day or two in the sheds, as a kind of change and rest, and to get things ready for the fine days. After this the pot-washing always comes in as a stop-gap, as one of my rules is, never to allow a plant to be put in an old pot before it has been well scrubbed and dried. Even such a thing as this needs looking after; for though strict orders are given to this effect, many men will give them a dry rub, and so use them, and that for no reason but because they will not give themselves the trouble to see if they are properly clean, or just have as much objection to wet their fingers as a cat has to wet her paws, if such wetting can be avoided.

### FRUIT GARDEN.

Put a net over a bed of Strawberries just coming in, to keep the birds from them, though there are yet plenty under glass. Went over the Gooseberries again with soot and lime, where a few caterpillars had appeared. Commenced a second time with caterpillar and black fly on Cherries out of doors, using the fingers for the former, and a little tobacco water for the latter, intending to syringe heavily with lime and laurel water when the weather changes, and then with clear water to take away all marks from the fruit. I forgot to say that we pretty well finished strawing and littering between the Strawberry-beds, as it is very annoying to have a particle of grit or mud on such fruit. The liming and sooting have pretty well driven off slugs and ants, the latter of which are very trying at times. The straw used, ehichly, had been employed to thatch the exposed sides of brick pits during winter, which is more secure, neat, and every way better than dung-linings, when much heat is not required. The rest consisted of long litter from the stables well shaken, and the rains it has received will so wash it, that it will be quite clean for the fruit to lie upon. We have used short grass for the purpose, but we like the litter best, as in heavy rains the grass is apt to cling to the fruit, and, generally, there is no end to the crop of Daisies that come on the ground. "What an old-fashioned foggy you must be! Why not use lines, or boards, or tiles?" Well, we have done so, and find, on the whole, nothing superior to the straw. In some weathers the tiles, for example, will suck the fruit until it is as dry and flavourless as a stick. No doubt they are an improvement on doing nothing. In

vineries regulated shoots, thinned Grapes, and attended to Melons, Figs, &c.; and in the orchard-house took off a great quantity of fruit, and still, we fear, left them thick enough. All the fruit taken off, as well as what shoots were too numerous, were bruised with a mallet, some laurel leaves added, and boiling water poured over them, to make laurel or weak prussic acid tea; this, well reduced, will be used to give a good syringing. The fruit, when small, Peaches especially, make fine tarts, but we never found anybody that cared much for Nectarines when so used. Several cooks have told me that though they look well and taste well, they never could get rid of a certain grittiness in them. Speaking of this reminds me that one of the most delightful tarts I ever tasted was made of the thinnings of Grapes, when less than the smallest Peas; in fact, not larger than small shot. Hardly any one could make them out. They are very nice themselves, and also when a few small Gooseberries are added to them. When of this size there is nothing uneconomical in their use. When the berries are as large as Peas and onwards, there is little of the economical in their use, for there is no end to the sugar they require, and still the cry would be "more."

#### FLOWER DEPARTMENT.

In these wet days a good many plants of Begonias, Camellias, Fuchsias, &c., have been examined and shifted. Balsams had a large shift into blooming-pots, and been placed under a frame with abundance of air and a mild bottom heat. Tender annuals have been potted. Scarlet Geraniums have also been potted for late summer and autumn blooming. Those intended for winter should have an open space, and be allowed to bear no flowers. Nipped the points from Chrysanthemums for the last time, or nearly so, intending to pot and train as soon as possible. It is a good plan to pot a few *Salvia fulgens*, &c., now, and also yellow *Calceolarias*, &c. Plant them out in rich soil, and raise and pot in September for winter and spring blooming. We have broken the back of our bedding now; but still there is a good deal of making-up and finishing, especially edgings of beds and baskets, when the weather will permit. We are longer in doing this work, not only because there is much to do, but from the necessity of securing all plants almost as soon as planted. Before now, I have had the pleasure to see one half of a bed all broken, and the other half nowhere, being all carried off by the wind. We use, for supporting, chiefly spruce and larch twigs and branches. The spruce requires to lie long enough to get rid of all its leaves. Some rough spruce sticks, or branchy twigs, we have had for at least five years, as the resin preserves them. These do not look pretty at all in the beds, though there is a degree of pleasure in seeing them nicely arranged; but there is little of the ugly about them when you know the purpose they serve. No straight whittled sticks could ever have the same effect. The shoots after the first tying generally look after themselves, as they get interlaced among the smaller branches and twigs; and, by the time the beds and borders are in their glory, there is nothing seen of the braces and stays that keep them in their place. I may also mention what I consider another improvement this season. Mats are dear, and rubbishy into the bargain; and, in tying, some pieces are sure to be blowing about. This season I have used balls of small cord. The ball is put into a small flower-pot, and is always beside the tyer; and, after a little practice so as not to waste by cutting off more ends than is necessary to form the knot, I am convinced that the twine will not cost half what the tying with matting did.—R. F.

#### TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

ONION CROP DESTROYED (*T. E. C.*).—The decay in the hulbs is caused by

the grub of the onion fly (*Anthomyia ceparum*). You will find a full description of it, and a drawing of the parent in "The Cottage Gardener's Dictionary." The female inserts her eggs within the leaf-sheaths of the Onion, close to the ground. She continues to lay her eggs from May to September, producing several broods during that period. The latest brood remains in the pupa state through the winter, so that all old-decaying store Onions should be burnt up as spring advances. The best preventive of this grub is to sprinkle gas-lime between the rows of seedling Onions, its fumes being offensive to the fly. It may be well, also, to try spreading powdered charcoal among them in a similar way, for the fly is said to deposit her eggs in this powder as readily as in the Onion plants.

INSECTS (*F. S., Muddersfield*).—The specimens you enclosed were of the snake millipede (*Julus terrestris*). We incline to the opinion that they are not the originators of the mischief. A wound is made by slugs or other cause, and then the millipede feeds on the decaying part. There is no application we know of that would destroy the millipede without including the destruction of the plants. If you resolve to extirpate the millipedes you must pare and burn the top 6 inches of the surface of your garden.

PEAR SHOOTS AND PEACH LEAVES BLIGHTED (*O. V. J.*).—They are both suffering from one, or both, of two causes—sudden severe cold and the roots being in a wet or ungenial soil. Peach trees on an open wall, even with the most favourable soil, are liable to that thickening of the young shoots and blistering of the leaves. Our climate is so very different from that of the Peach's native country, that except in warm spots the trees are liable to these attacks.

SEEDLING GLOXINIAS (*A. S.*).—Keep them in the hotbed the whole summer, and first transplant them in tens or twelves round the sides of No. 48-pots, and keep them growing in heat as long as they are green. Then dry them, and next February put them singly into 60-sized pots, and probably they will flower next summer; but you were two months too late in sowing them this spring, and that time can only be made up by good treatment. Of course you have them growing in a very sandy peat.

HARDY EXOTIC FERNS (*Fern-grower*).—We shall publish very soon a small volume on the cultivation of exotic Ferns, stove, greenhouse, and hardy.

DESTROYING HARD-HEADS (*W. Lewes*).—This weed, *Centaurea nigra*, is very tenacious of life, and one of the most troublesome that could have invaded your meadow. There is no way of extirpating it but by the Dock-iron to take it up by the roots, and the scythe to mow down the leaves as fast as they appear.

MOWING MACHINES (*P. B.*).—We believe that the silent movement answers. We cannot recommend one in preference to the others, for they all mow well if properly managed.

PEACH AND NECTARINE BLOSSOMS UNFERTILE (*A Subscriber, Z.*).—It is just possible your fruit blossom was defective, though it seemed to set; but as it did set, we think it very likely that after a period of dull weather, a bright day came, and the roots from being cut in autumn had not been sufficiently watered. A slight shade in such circumstances for a few hours would have been desirable.

VENTILATORS (*Dorset*).—We do not like your ventilating-boards fixed between the sashes, as they will obstruct the light. Why not make 15 inches or 18 inches of your hipped roof to open as a ventilator, and 1 foot at the posts in front the same way for front air? and you may then place the sashes close to each other and fix them. The only other thing desirable would be a few holes at the bottom of the back wall to insure most thorough ventilation. We have not a doubt then of the Aprieots doing well, more especially if you open the doors likewise, and the angle above them in extra hot days. There is no other peculiarity between them and Peaches except needing more air. We have no doubt the north border in your kitchen garden would do for Filberts, the bushes are not particular. We shall publish a paper before the autumn on their culture. Such a border would also be very useful for late small fruit, as Gooseberries, Currants, Raspberries, and Strawberries.

CORBEA SCANDENS SEEDLINGS (*R. J. B.*).—The *Corbea* is a beautiful thing, but just, because it is strong-growing and easy of cultivation, it is not met with so often as it ought to be. If you put your plants in good fibry loam and a little leaf mould, into 12-inch or 15-inch pots, and treat them plentifully with water when dry, they will run a long space during the summer, and reward you with their large bell-flowers from August and onwards. If these pots stand on the soil, the plants will need but little water in winter to keep them green; if they stand on a shelf or stage, they will need more. In spring the plants may be pruned pretty freely to the main shoots, leaving a few buds of those that will dangle this autumn, and the fresh shoots produced will bloom all the summer and autumn if the pots are top-dressed and manure water given. If planted out in a small border, the plant will pretty well take care of itself. The plant is either annual biennial, or perennial, just as you choose to treat it. Expose it to frost the first winter, and it will be an annual; do so or neglect it the second winter, and it will be biennial; treat it kindly, keep it from frost, and it is likely to live quite as long as yourself. One or more stout iron or wire rods are as good as anything for fastening it to.

INSECTS IN GREENHOUSE (*A Suffolk Subscriber*).—We found no insects on the leaves. The Begonia leaves were quite healthy. On small leaves were signs of where thrips had been, and on the Fuchsia leaves were marks as if made by thrips and red spider. We would advise you to smoke the house with shag tobacco, taking care that the smoke is presented cool, and syringe well with sulphur water or laurel water next day. You may place the plants in any small, close case to be smoked. Use the syringa afterwards freely, and if you could daub the walls with sulphur, and keep a moist atmosphere, we think your plants will soon be all right. We regret you are so soon depressed. There is no good gardening by chance work. It demands constant, unintermitting attention. Were there no difficulties, there would be no charms in success. If you dislike any of the above modes, sponge the leaves with weak glue or size water.

FUCHSIA SPECTABILIS CULTURE (*Subscriber since 1856*).—There is not the slightest difference required for the treatment of *Fuchsia spectabilis* from that of all the family. In 1838-9 and 1840 nine out of ten growers were in the same fix with *Fuchsia fulgens*, and it is on record that some of the best gardeners considered *Fuchsia fulgens* as perfectly beyond their art twenty-four years back. Since then *spectabilis* has been exactly in the same category, and even at this day some of the exhibitors believe it to be un-cultivable; but rest it as you would *fulgens*, and grow it the same way as any other *Fuchsia* and you will succeed.

**AMERICAN PLANT LEAVES CURLING AND DYING** (*R. R., Hammersmith*).—We have seen many thousands of all sorts of Rhododendrons, and all other American plants going to ruin exactly as yours are going, and if yours are going from the same cause the sooner you let them go and have done with them, the sooner you will get rid of one great trouble which you would never be able to overcome entirely. What we have seen was the effect of unmitigated chalk, and chalk will never allow a Rhododendron to do much good on it, not even if all the good gardeners had nothing more to do than to attend to them. But at Hammersmith and with Wimbledon peat you can hardly be exposed to much chalk, unless it be in the water, and you have, at the very least, given your Rhododendrons ten times too much water this season, and yet we should not be the least surprised to find, on proper examination, that the plants are having the young leaves scorched for want of water. At all even's, the decay of the young leaves is the effect of a perfect want of action in the roots. The roots may have been poisoned by chalk water or soot water, or half killed for want of water, or else the plants are exposed to some poisonous gas in the air from some sort of manufactory, shaft, or furnace. To ascertain how it is, take up three of the plants from the three widest-off points of the beds or borders, and see if the original peat you had with the roots is not as dry as Lundyfoot snuff. If those original balls became even half dry about the time of planting, all the water in the Thames would not save them as you served them. The only means of getting over the difficulty would be to lift every one of the plants, and to steep the balls for a whole night in the nearest pond or some other water; then to replant them; and give one good watering with a rosed watering-pot, then muleh the bed and only water once in three weeks. If the cause is from chalk, chalk water, or furnace work, you cannot cultivate the plants successfully unless you can remove the injurious agency.

**CUTTINGS OF VERBENAS, &c.** (*A Twelve Years' Subscriber*).—Were we in your case we would not keep one of those stock plants over the winter. Now, we would prepare a nice, rich, light border for them, and plant them out and treat them just as you would do those in a bed. They will be easier kept healthy and vigorous than if kept in any pots. About the beginning of August take off cuttings and insert them in pots in a hand-light kept shaded from the sun. We would prefer striking in soil in the hand-light. When struck pot them separately and pot again in a size larger in October—say in small 60's first, and 54's or small 48's afterwards. Use light sandy loam and a little peat. These will keep well over the winter with little trouble, and from these you may propagate freely in spring, as spring-struck plants generally flourish best. Those struck and potted in autumn would, however, cover a large space. For want of room we keep a dozen or a score in a 48-sized pot over the winter. The best compost for *Cinerarias* is rich sandy loam, such as loam from the roadside two parts, and the other part of sand, leaf mould, and rotten dung, with some little bits of Charcoal. *Calcæolaria* much the same. More depends on coolness and airiness in winter than compost.

**CLEAR LIQUID MANURE** (*Jonquil*).—It is best to be used clear for two reasons—first, because the muddy, or merely mechanically suspended portion, cakes over the surface of the soil and prevents the air penetrating; and secondly, such muddy portion renders the surface unsightly.

**NAMES OF PLANTS** (*A Subscriber of four years*).—Some *Brassia*, probably maculata, but the flowers were much damaged, and badly packed. *Cercis siliquastrum*. (*H. R. P.*).—The Hornbeam, *Carpinus betulus*. (*J. O., Salop*).—1, *Kerria japonica*; 2, *Symphoricarpos racemosa*; 3, *Polygonatum multiflorum*; 4, *Calycanthus floridus*. (*S. W., Upton*).—2, *Salisburia adiantifolia*. The other specimens are insufficient. (*John Stephenson, Cavendish*).—1, *Blechnum spicant*; 2, *Lastrea dilatata*; 3, *Thalictrum aquilegifolium*; 4, *Lastrea filix-mas*. (*J. B., Chorley*).—*Habenaria bifolia*. (*Filix-femina, Gloucester*).—Certainly not a *Blechnum* but a *Nephrolepis*, and apparently a vigorous growth of *N. tuberosa*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

JUNE 26th and 27th. SUFFOLK (Woodbridge). *Sec.*, Mr. J. Loder, jun. Entries close June 5th.  
 JULY 3rd. PRESCOT. *Sec.*, Mr. James Beesley. Entries close June 21st.  
 JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. *Secs.*, G. Newton and J. Wade. Entries close June 21st.  
 SEPTEMBER 9th. WOSLEY AND ARMLEY (near Leeds). *Sec.*, Mr. Robert Hoyle, Armley, near Leeds.  
 DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

### NORTH HANTS AGRICULTURAL SOCIETY'S POULTRY SHOW.—JUNE 12TH.

It is impossible to deny that the poultry question has to struggle with great difficulties in agricultural districts. Those that have adopted it find their account in doing so; but the shows do not increase as they have done where they have depended for support on towns. We, nevertheless, think the importance of the question is gradually forcing itself on the public, and properly-compiled statistics would astonish many who now despise it.

Poultry should be as much part of farm stock as cattle; but while no pains are spared to secure the best breeds of the latter, and to give them the food best adapted for growth or for fattening, the unhappy fowls must take their chance in all particulars, and when failure is the result of neglect or inattention, it is at once asserted that success is impossible. We suppose a certain time must elapse before a radical change takes place, and prejudice is overcome. We also suppose there are necessary fluctuations. Marketable poultry has been dearer and scarcer for

the last three years than for any similar period in the last quarter of a century. Those who breed in towns and the suburbs find no innumerable difficulties in rearing early chickens, yet they have often to encounter every disadvantage.

In speaking of these matters we refer only to that which we know to be true, and we should fail in our mission if we did not mention them. Hundreds of thousands of fowls within the last three months have realised from £3 to £4 per dozen. They are still doing so. We have often been told in answer to this, that people have sent up chickens to London on the strength of such statements, and have received but sorry returns. This is true, but it is because the chickens did not possess the necessary qualities to insure the best price. Early poultry like early fruit and vegetables, will command a great price; but it is on the condition it shall be as nearly perfect as may be. Peaches and Grapes in May would be unsaleable if unripe, although quotations and accounts might show that good specimens were realising large prices. They would not the less be what they were represented to be, but they would lack the elements of success. Just so, to insure the prices we have named, chickens must not only be young, but they must be perfect as to fatness and delicacy. It is almost impossible to rear very large numbers of chickens when space is limited, and for that reason every advantage would seem to be on the side of those who occupy large tracts of land, and can conveniently spread their stock.

These considerations always cause us to hail the addition of a poultry show to an agricultural meeting with great satisfaction. It seems a move in the right direction, and we congratulate this Committee on having made a beginning. Everything favoured it except the weather. Of that we can only say it alternated between hurricane, storm, and pelting rain all day; yet with this drawback the tent in which the poultry was exhibited was full the moment the Show opened to the public. We will now speak of the classes.

There were fifteen pens of good *Dorkings*. First and second went to Mr. Griggs, of Romford, but they were hard run by Mrs. Pettat and Mr. H. H. Allen. It was a most excellent class, and the birds were shown in very good condition.

*Cochins* were very good. This will be evident when we say the first prize went to Mrs. Henry Fookes, and the second to Major Hassard. Mrs. St. John and Mr. Peters well deserved their high commendations.

There were fourteen pens of *Game*, and, with one exception, all were shown strictly according to rule. Mr. Dupe's first-prize Duckwing Cock is a large and good bird. Miss Wyndham took second prize. There was here no fault in matching legs or hens, but some of the cocks could have spared a little more comb. Either they were dubbed too early, or were not cut closely enough.

It was a good show of *Polands*, but they are strong in Hampshire. Mrs. Pettat took the first, Mr. T. P. Edwards the second prize.

Fourteen pens of *Hamburghs* made a goodly show, and six of them figured in the prize list. Mr. Brown, of Chard, was first; and Mrs. Pettat second.

*Turkeys* were very good, Mr. H. Matthews and Mr. W. Manfield were first and second with first-rate birds. The Rev. T. Stevens, of St. Andrew's College, Bradford, showed a single cock of rare merit.

Two well-known names tried for the first prize for *Geese*, Mr. W. Manfield secured it with a pen of White. Mrs. H. Fookes well deserved the second awarded to her pen of Grey ones.

There was no class for *Spanish*; if there had been, the pen shown as extra stock by Mr. Thomas Lyne, of Reading, would have been very hard to beat.

The Show was held in a convenient, and, fortunately, a water-proof tent. The excellent pens of Mr. Cooke, of Colchester, were used.

If the present attempt was intended as a seeler, it was eminently successful in everything but the weather.

If the counties of Hampshire, Berkshire, and Wiltshire were combined to compete for an extended prize list, we think that they would not only succeed in making a large Show, but they would do good in bringing together those concerned in the pursuit. Wokingham is a considerable poultry market, and inquiry there would convince any one that the prices we have named are things of weekly occurrence at this season of the year. Salisbury sends many thousands of chickens to London, but they are capable of great improvement; and it is more than probable that without any increase of outlay, at least 20 per

cent. might be added to the value of its consignments. Much of the light soil of Hampshire is admirably adapted for poultry; its contiguity to London, and its railway accommodation should make it a competitor for some of the many thousands spent by the metropolis on the delicacy of which we have treated.

Mr. Downes was a most able, painstaking, and courteous Secretary.

**DORKING.**—First and Second, G. Griggs, Romford. Highly Commended, H. H. Allen, Evelyn House, Liphook; Mrs. St. John, Oakley Cottage, Basingstoke. Commended, Mrs. Pettat, Ashe Rectory.

**COCHIN-CHINA.**—First, Mrs. H. Cooke, Whitechurch, Blandford. Second, Major F. C. Hassard, Hulsea, Cosham, Portsmouth. Highly Commended, A. Peters, Priory, Fratton, Portsmouth; Mrs. St. John, Oakley Cottage.

**GAME.**—First, S. Dupe, Evercreech, Bath. Second, Miss C. L. Wyndham, Sutton Mandeville, Salisbury. Highly Commended, D. Tubb, Basingstoke; S. Dupe, Evercreech, Bath.

**POLAND.**—First, Mrs. Pettat, Ashe Rectory. Second, T. P. Edwards, Lyndhurst. Highly Commended, G. Ray, Ivy Cottage, Lyndhurst.

**HAMBURG.**—First, T. L. Brown, Chardley Green, Chard. Second, Mrs. Pettat, Ashe Rectory. Commended, Mrs. Pettat; W. Manfield, Jun., Dorchester; J. Cooke, Maitland Cottage, Colchester.

**TUNKEYS.**—First, H. Matthews, Sherborne St. John. Second, W. Manfield, Jun., Dorchester. Highly Commended, Rev. T. Stevens, St. Andrew's College, Bradford. Commended, Mrs. P. Warren, Worthing House.

**GESE.**—First, W. Manfield, Jun., Dorchester. Second, Mrs. H. Fookes, Whitehuch, Blandford.

Mr. Baily, of London, was the Judge.

## DO BEES VARY IN DIFFERENT PARTS OF GREAT BRITAIN?

ARE LIGURIANS LARGER THAN COMMON BEES?

MR. DARWIN'S query as to whether there is any sensible variation in the size of bees kept in different localities, would probably be answered in the affirmative by nine out of every ten of our rustic bee-keepers. During the many years that I have kept bees I have purchased a great number of swarms from cottagers, and have, in almost every instance, been assured that they were "a very fine sort," remarkable for being in some cases "larger," and in others "smaller" than usual, but invariably recommended as possessing every possible good quality. A somewhat similar opinion was expressed in my hearing last autumn by a clergyman who resides about a mile from me. He prided himself not a little upon possessing a stock of bees which he had brought from Cornwall, and which he considered infinitely superior to any in Devonshire. Upon my pointing out that the queens of his old stock and second swarm had been hybridised by my Ligurian drones, he really appeared somewhat chagrined at this stain in the purity of his Cornish breed.

The same idea is countenanced in the following quotation from Rees' "Encyclopædia," article "Bee," which I find in the appendix to the English translation of Huber's invaluable work:—"The cultivation of the common honey bee, in the warmer countries of Europe, being an object of the utmost consequence to the farmer, every means that ingenuity could devise to improve the breed and management of these profitable creatures has been adopted, and with success. They distinguish three kinds or varieties of the common bee (*Apis mellifica*). The first is large and of a deep brown colour; the second is smaller and blackish; those of the third sort, called the 'little Flemings,' or 'little Hollanders,' are much smaller than either, and of a fine glossy yellow colour. It is the latter that is very generally cultivated on the continent at this time." If it were not that "the little Flemings" are stated to be "much smaller" than the others, I should have deemed them identical with the newly-introduced Ligurian bee. This latter is, however, certainly not smaller than the black species; but, on the contrary, I believe them (in common with nearly every one who has observed them), to be slightly longer than the ordinary British bee.

Although the notion of there being different sorts of the common honey bee is so widely and generally diffused, it may, I think, be fairly classed among what are generally termed "vulgar errors." After many years' observation of bees in numberless apiaries in this and the adjoining counties, as well as in a midland district (Warwickshire), I have come to the conclusion that there is really no substantial difference in bees of the common species (*Apis mellifica*). There are, undoubtedly, accidental variations in size and colour, but these are often to be found in as marked a degree in different bees of the same hive, as in those of apiaries hundreds of miles distant from each other. The question of size might, it appears to me, be most readily determined by careful measurement of the cells of combs fabricated in distant localities, for if these are all the same size we may safely conclude that the bees themselves do not differ in

this respect. I have already satisfied myself that the cells made by *Apis Ligustica*, are identical in every way with those fabricated by *Apis mellifica*, and this seems to decide the point that the bees of both species must be of the same diameter. I have, however, long entertained the idea that the breeding-cells of the former may be slightly longer than those of the latter, and that therefore the sealed brood-combs may be thicker in order to afford room for the full development of the insect. If this should, indeed, be the case, it will confirm most indisputably the impression that the Italians are really longer than the ordinary species.—A DEVONSHIRE BEE-KEEPER.

P.S.—Since writing the above I have measured the thickness of sealed brood-combs (the combs in both cases being nearly new), of *Apis mellifica* and *Apis Ligustica*. The result is, as I anticipated, that the latter is very slightly thicker than the former, thus confirming my impression that the Ligurian bee is rather longer than the ordinary species.

Bees certainly vary in size, probably from two causes. First, There seems certainly to be found in various counties a species of hive bee less in size, and different in shape, and darker in colour, than the most common are. Secondly, Bees which have been bred in old stocks of seven or ten years standing, become smaller and more puny as the cells are lessened, in some degree, by a thickening in the interior, from being continued brood cells for too long a period.

As to the difference of the tempers of bees, I have found that proceed from being too roughly handled, and also from their being placed too far from the usual haunts of their owners, many of whom visit them less frequently than they ought, and thus the bees become wilder.

A gentleman who saw my bees last week informed me that his father had kept bees for a great many years in Suffolk, and that his bees were of a much smaller sort than those of some of his neighbours, and also that it was a well-known fact these alluded to were considered quite a novelty.

Respecting wild bees in certain forests in Nottinghamshire, mentioned by Mr. Darwin, being smaller than the hive bees, there are several species of small bees, nearly all solitary, which frequent Sherwood Forest, and most of these are smaller than hive bees. For an account of these I refer him to Mr. Frederick Smith's excellent work on "Hymenoptera," lately published, or to that learned book published nearly sixty years ago, by that venerable entomologist, the Rev. J. Kirby, entitled "Monographia Apium Angliæ," in which two publications Mr. Darwin will find nearly a hundred species of wild bees.

The common Boinatrices of a larger sort, are scarce in all the forests, because they are eaten when in a dormant state by the field, or rather forest, mice, which abound in all large woods. Many of the smaller species of wild bees are propagated by eggs (or larvæ), so that they are not noticed by the mice.

I should rather guess that the grey or light-coloured bees mentioned by Mr. Lowe in this Journal, may have a very newly-hatched swarm, which differ considerably, and are often of a leaden colour, but change afterwards.

There is one fact quite apparent, that hive bees differ in colour a good deal, and the smaller they are in general their colour is darker.—H. W. NEWMAN, *Hillside, Cheltenham*.

P.S.—When at Dieppe some years ago, I observed no difference in the size of the hive bees to those in England, and as to the Boinatrices, I found the same species, about seven or eight varieties, precisely the same as in England. Bees of all sorts are abundant all through Normandy. I never was far south in France.

## COMPARATIVE MERITS OF LIGURIAN BEES—SWARMING IN A STORM.

SOME time ago some remarks of mine were inserted in THE JOURNAL OF HORTICULTURE as to the inoffensiveness of the Ligurian breed, and while my experience for some time after the receipt of them, and especially after their journey from Devonshire (thanks to Mr. Woodbury's most expert packing), was the same as that of your correspondent Mr. Shearer, yet I am bound to say, on a more lengthened acquaintance, I must endorse the testimony of the American apiarians, and of your correspondent at Wolverhampton, "J. E. B.," that they are generally, and especially during the swarming season, much more prone to attack than the common black bee. When forming an artificial swarm,

about three weeks since, I found, as did "J. E. B.," that they made a "dead set" at my hands and fingers, and though my hands were defended by three thicknesses of leather gloves, I discovered how much I had calculated without my host as to what protection would be sufficient; for the gloves were found full of stings, and my flesh by no means scathless. I also find they will attack persons in the neighbourhood of the hives without any provocation whatever. I have since had two natural swarms from them, and being from home, they were obliged to be hived by whoever could be procured—different individuals, old cottage bee-keepers in both cases who have taken hundreds of swarms; both were well stung in doing it. One of them said, "If that's a sample of the foreigners we shan't stand no chance in case of an invasion." The other pronounced them "the most vicious animals he'd ever meddled with in the shape o' bees." Still, prolonged acquaintance only confirms my opinion as to their general superiority over the black race, especially their fecundity, which the fact of my having obtained one artificial and two natural swarms from one stock this season, all four doing well (and there is every prospect of as many more, from the state of the parent hive), abundantly proves. A little extra care will be more than a match for a trifling display of ferocity.

A rare thing occurred on Monday—a very wet, boisterous day here. A hive of common bees threw off a fine swarm in the very midst of a hailstorm, accompanied by a torrent of rain which had lasted half an hour when they began to swarm, and continued at least that time after. The hive had been quietly working a super without any symptom of swarming previously. G. F. B., *Colney Hatch*.

### BEES DESERTING THEIR HIVES.

THE case of your correspondent, Mr. Farebrother, is very singular, but nevertheless most disheartening, although from his statement it does appear an isolated instance. I have myself noticed the same decadency in this part, but no wholesale instance has been brought under my observation for some years past.

About ten years since I purchased a couple of strong stocks in the spring of the year, being desirous of tenanting a new bench made on an improved principle, and was in great expectation of eclipsing everybody in this part. Having another bench which I had contrived at the end of a coach-house to work through the wood, and which pointed full south, giving me an excellent opportunity of operating behind them; but I suppose I despised it because not grand enough. However, I was taught not to be deceived by appearances; for things went on charmingly for a few months in my new bench, but in the autumn I noticed both swarms and old stocks thereon gradually diminishing, whilst my other bees were proceeding vigorously. At first I condemned the construction of my idol, then I fastened on the ventilator, and threw open the doors behind and before. Presently I conjectured it was something about the wood with which the bench had been constructed; and after fruitlessly searching about for a cause, in complete vexation and utter despair of ever doing any good with this new domicile or its tenants, I ultimately found the bench literally swarmed with the wax moth.

Thought leads to investigation, and away I went to the old bench from whence I had translated the two stocks in the spring, and ascertained that the stocks there were infested with these plagues. At once I set to work with my own establishment; but ere the following spring arrived I found my enemy had made such ravages and gained such a footing that hardly a bee was there; not as in the case of damp, where lots of putrid bees are found on the floor-boards, but downright desertion. There was in each hive honey tolerably plentiful, and in one instance a queen remaining with a few forlorn bees. I, therefore, removed the hives altogether; and those which were worth it, cleaned out the combs, washed the interior and painted the exterior, and sent to the rightabout what I conceived to be the originator of all the mischief. But it occurred to me I had not vanquished my enemy—that he might be lurking in the bench waiting for an opportunity to commence again his work of devastation; and since I found my simple-constructed bench had far exceeded my expectation, and having an instinctive horror that a similar calamity might again befall me, I abandoned the idea of ever adapting it again for a bee-house, and I suspect that the moth has something to do with Mr. Farebrother's complaint.

Mr. Payne, in his "Bee-keeping for the Many," says that moths are by far the worst enemies bees have to contend with;

and with this opinion I quite coincide, because they proceed so stealthily to their work that, before the bee-master becomes aware of the danger, these little vagabonds have insinuated themselves into every part of the hive. Payne also says "Watch carefully for the moths." Huber, I think, speaks of the *Spbynx atropos* (death's-head moth), and says they will harass the bees without mercy till they leave their habitation. One writer, I believe Huish, says, in a hive infested with moths the floor-board is marked with small red particles of wax.

Mr. Farebrother's case exactly corresponds with my own; and as it is one of great importance to the bee-keeping community at large, perhaps we shall be favoured with the experience of those interested in the subject. Our friend from Mount Radford is the very person to unravel this mystery, I should like to have his notions on the subject.—BAR-HIVE.

### TOLLING OR TITHING BEES.

I SHOULD be glad if any of your correspondents would inform us whether this custom prevails anywhere in the present day. Nearly three centuries since it seems the profit of bees was watched pretty closely by the lords of manors, and I dare say more so by the clergy of the day, as the following extracts will show.

"*Warmingham, Manor Elton,\* Temp. 12th Elizabeth.*—William Stanway hath taken up to his own use 2 Swarms of Bees, and had the benefit of one Swarm for five or Six Years, not making them known to the Bailiff. Witness, William Bateman."

In and from the time of Queen Bess, and for many years subsequently, it appears to have been customary for lords of manors to receive advantages from the bees within their manors; but I cannot discover to what extent they were tolled, whether after the same ratio as the clergy levied their vicarage tiends.

Honey and wax were, it seems, titheable at common right (Toller, 124), the honey by measure or weight, and the wax by weight; but no tithes were payable for the tenth swarm of bees, because they were considered *fera natura* (Langford Case, 1 Rolles Abrid. 651, Pl. 15; Barfoot v. Norton; Croke in the time of Charles, 559; 1 Eagle and Younge's Tithes Cases, 399). A modus of a hen called a "loak hen," in lieu of tithes of honey, &c., was established (Burslem v. Spencer, 2 Eagle and Younge, 65). A modus of one penny for a swarm of bees (Smithson v. Dodson), of two pence for every hive of bees in lieu of tithes of honey and wax (Gould v. Pearce, 1 Eagle & Younge, 806), and of two pence in lieu of all tithes of bees, honey, and wax were established (Reynall v. Wells, 1 Eagle & Younge, 808).

I have seen in some of our parish churches terriers, which are large black boards with legibly written letters, placed generally in the church, giving a scale of titheable articles, and amongst other things "a tithe on bees." I am, therefore, desirous of ascertaining whether such a custom is now known to exist; and, if on record, whether the tithes were originally conceded by the monks to the lords or barons, or whether the lords or lords feudal surrendered their tiends to the monks. It was not very likely, from the rapacious character of the latter, they would without compulsion part with either their prerogative or their chattels, without being compelled (as I suspect they were), at the dissolution of the monasteries; and, perhaps, at this period their property in tithes was indiscriminately distributed to laymen as well as to ministers of the reformed religion.—E. W. JONES, *Nantwich, Cheshire*.

\* Six miles N.E. of Crewe. The principal proprietor the Right Hon. Lord Crewe.

### OUR LETTER BOX.

GAME COCKS FOR EXHIBITION (*A Notice*).—It is absolutely necessary for adult Game cocks to be dubbed before they are exhibited. Failing it, they are disqualified. Chickens may be shown undubbed, but it is a disadvantage.

CHARACTERISTICS OF PURE AYLESBURY DUCKS (*Old Deer*).—Large size, especially breadth. Large head and bill. The latter should be long and broad. The colour of it a very delicate French white. The plumage should be entirely white. Yellow bill or any mixture of plumage are positive disqualifications. Short narrow bills and small size arise either from a cross or from degeneracy.

SUPPORTING A SPANISH COCK'S COMB (*Ignoramus*).—In our opinion if the comb has not been disfigured by the means used to make it erect, it should not be considered a disadvantage. We do not, indeed, know how it is to be discovered. There was no process by which the old lop-comb of the Spanish cock could be made upright. The means that have been most successfully used are silver wires supporting it on each side, running through the top, and fastened to the thick base. These leave no marks.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 73.2° and 49.8° respectively. The greatest heat, 93°, occurred on the 27th, in 1826; and the lowest cold, 34°, on the 24th in 1859. During the period 147 days were fine, and on 98 rain fell.

“EYES AND NO EYES.”

WHEN a child I was much pleased with a tale I read in a book called “Evenings at Home,” the title of which was “Eyes and no Eyes.” As some of your readers may not have met with it, I may say it represented two lads having taken the same walk: one on returning declaring he had found it a dull part of the country, and had seen nothing to interest him, the other having been delighted with his

walk, and having collected a budget of facts and specimens.

Ever since that time I have tried to educate my naturally-inferior powers of observation, and have been inclined to envy those who appear to see everything without effort. Lately I have been impressed with the idea that many of these quick observers are not equally apt to draw correct deductions from what they see, and that a remark indicating a quick perception is often followed by one showing that no just inference has been drawn from the fact observed.

I think if we were anxious for mutual improvement—that is, as anxious to impart knowledge as to gain it, these two classes, the observers and the reasoners, might render more assistance to each other. Suppose each of your readers were to carry a small memorandum-book, and when they met with any fact new to them, or for which they did not know how to account, they were to make a note of it, and, when opportunity served, send such notes to you, how useful such a proceeding would prove.

A note in my own pocket-book, “Value of Geese,” has caused you to be troubled with this communication. Have not many of your readers heard the remark from many intelligent farmers, “Oh, I hate geese. Nasty things, they dirty the grass, and eat all the best of the herbage.” A very different estimate of their value has been forced upon me. Some years since a home field of rich pasture had turned into it for the first time a flock of geese. I soon after remarked that a space increasing in size around the stable-yard was divested of Buttercups; and from its rich green appearance presented a striking contrast to the rest of the field, it struck me immediately that a goose-common was always green. Watching the geese, I saw them pull up the Buttercups and eat the roots, leaving the stalks on the grass. Having mentioned this to many farmers, I have never met with one who knew it before, though some have said they always thought geese healthy things amongst stock. The destruction of so acrid a plant as Ranunculus acris must be desirable in a cow pasture, as it takes the room of good grasses, in addition to being itself injurious.

No. 65.—VOL. III., NEW SERIES.

So much for note No. 1. Here is a second. “Why do I so often find wood pigeons in an orchard quite close to a village?” They appear to be attracted by the Pilewort, *Ficaria ranunculoides*, growing under a hedge, as they have evidently been feeding on its roots. Perhaps this is known to every one, but as it is new to me I mention it, not caring that it exposes my previous ignorance.

Here is another note—a single word, “Toad.” This reminds me of an observation I made the other day. In a large house devoted to Cucumbers a number of toads had been placed to eat the woodlice. I saw one running past a toad which struck at it with its singular tongue. Though I have seen numbers taken, this was the first time I observed a toad fail to swallow one when it attempted to do so; my surprise was much increased on finding the insect dead. How was this? Was the stroke sufficient, or is there some power possessed by toads of killing instantaneously the insects on which they prey? Does this account for their feeding on wasps and bees without inconvenience to themselves?

Will some of your clever correspondents, able to impart information on this subject, help me with answers to these questions?—J. R. PEARSON, *Chilwell*.

EXAMPLES OF FLOWER-BEDS.—No. 1.

(WITH COLOURED PLAN.)

[MR. FISH in his description of Linton Park, published in Vol. XXIII. of our first series, gave particulars of the large central bed in its terrace garden. Of that with some slight alteration we now furnish a coloured plan, and at our request Mr. Robson has furnished the following notes:—]

“The design here given, the one that was adopted in 1859, is not put forth as the best that could be made. On the contrary, I think that both before that time, and also since, we have had prettier patterns; but it must not be understood by any means that much intricacy can be introduced into figures intersecting each other, and planted with bedding things that it is advisable not to meddle much with after planting time; but the space being large, more figuring may be given when judiciously planted than is shown in the present drawing, and still a clear outline be kept of every part, groundwork as well. This can only be accomplished by limiting the planting to such things as require little or no after-attention, and which, by keeping a uniform height, the same design started with is the same at the end of the season—even when looked at obliquely or almost horizontally. This, it is needless to say, is not the case when one class of plants overtops another, and consequently hides from view those behind it. These conditions disqualify many of the most popular ornaments of the parterre, and the plants that I have hitherto used in this way, both before and since the accompanying design was in existence, are only increased by the additions of Variegated Geraniums (white and yellow edged), *Perilla nankinensis*, and once or twice *Verbena pulchella* as a ground; but it is much less applicable that way than *Lobelia*, being so disposed to invade its neighbour's territory. I may, however, say that plants suited to a striped border are available here,

No. 717.—VOL. XXVIII., OLD SERIES.

provided always that they be all of equal height at all periods of the season; and I may here state that I have not found anything more really useful for single lines, edgings, or stringwork than *Alyssum variegatum*. A scroll of this plant formed a pretty feature on a part of the groundwork of last year's design. *Perilla* is also very well adapted for that purpose, and this season we have it worked into extensive use in this bed as well as in others.

"In reference to the planting of the bed in question, in 1859, it is only fair to the readers of the Journal to point out where improvements could be made, by mentioning the results as well as the reason which led to the adoption of the plants indicated.

"*Trentham Rose Geranium* in the ventre oval. This being a stronger grower than the surrounding plants became a little taller towards the end of the season. It was, however, adopted in consequence of not having a sufficient quantity of the kind intended.

"*Verbena Ariosto* in the two large scrolls, deep plum colour, throws the flower well up to the top, and is less rambling than most Verbenas, though more so than *V. Purple King*.

"*Lobelia speciosa*, blue; very good.

"*Trentham Rose Geranium* in the two three-striped beds was Tom Thumb Geranium in 1859.

"*Calceolaria*, yellow kinds, matching the Geranium in height.

"*Lobelia speciosa*, blue, in the two three-striped beds was *Verbena Purple King* in 1859.

"The groundwork was intended to have been entirely *Alyssum variegatum*; but lack of plants led to a white *Verbena* being partly substituted, the *Alyssum* being planted by the edges of everything, and the central space filled in with a white *Verbena*. But there is no comparison between the one and the other: the *Alyssum* being so much the whiter, besides commencing its duties as a white plant at once, and continuing so up to the time of the frost killing it; whereas the *Verbena* is only really showy when in flower, and even then it is less effective than the *Alyssum*.

"To the lovers of flower gardening who delight in a yearly change—and who is there that does not?—the style of which the accompanying sketch is an example affords an endless opportunity for change, as figures differing from each other may be introduced each year, and it is possible the number of plants suitable may also be increased; but with those we have an excellent result may be obtained. The only thing I have to caution the inexperienced in such matters against is not to attempt too much, and avoid all complicated figures. The double scroll of the present example is quite as intricate as can be made to distinctly show itself; only its great size enables that to be done. Generally speaking, simple circles look as well as any form; and it may, perhaps, afford the student in such matters some guide to say that the design we have adopted this season (1862), is entirely composed of circles and parts of circles. A large six-lobed figure of rather more than semicircles meeting, with a circle in the middle of all, forms the central compartment, which, taken as a whole, is larger than No. 1 of the accompanying plan. Surrounding this are twelve circles of three different sizes, the outer edge being composed of twenty half-circles or scollops with their convex sides inward. The easy simplicity of the design will, I believe, tell as advantageously as anything we have yet had. All the circles, scollops, and the bed itself are edged with *Perilla*, which in this season made to form the stringwork to the whole. *Calceolaria Aurea Floribunda*, *Verbenas Purple King* and *Pulehella*, and *Geraniums Tom Thumb*, *Christina*, *Golden Circle*, and a white-edged one called *Shottishan Pet*, are the plants used; *Lobelia* and *Alyssum* being in this bed dispensed with this time, simply because they have on former years been so extensively used that a change was necessary.

"Of the winter management of large beds like the one in question descriptions have at times been given in these pages, and at a future period a more explicit article on the subject and illustration may appear; but anything short of a coloured plan fails to convey a true idea of what may be done in this way. Those, however, of our readers who have seen the embroidery at the Horticultural Gardens, Kensington, with its coloured gravels, &c., may have a just conception of the effect; only in our case, the work being simply done to give effect in the dull winter months, it is not always so accurately executed. Lines of pebbles or broken stones of uniform size are adopted for the outline of the different figures, which in this case may be as elaborate as the taste of the designer may suggest; for in the

commanding position it is placed all its parts can be distinctly seen. Colouring matter an inch thick is then put on; and I believe we have on one occasion begun and finished the bed in one day, and this in November, so that the labour is not a serious affair. But as this may possibly be treated of in detail hereafter, it is needless saying more now."

## SUMMER PROPAGATION FOR THE FLOWER GARDEN.

No sooner one meal is over in the kitchen and out of it than they begin to prepare for the next. And it is the same in every human employment. In shows and seasons, seeding or sowing, such above all others is the case; and then it follows as the best thing one could do, or all of us could attempt, would be to begin to propagate or prepare for the next season, and prepare for it too in a different way, and with different materials if they can be had. But a man who does not do the best with what he has is not entitled to his share in the different ways or to different materials from what he already possesses; or, at all events, the man is not the man "for a' that" who does not try and make both ends meet if it took the twelve months to do it.

Before I finished my planting-out last week, I began putting in Rose-cuttings of *Géant des Batailles* and two or three more like it for bedding purposes, as they say. There seems to be almost a universal desire that Hybrid Perpetual Roses could be so bedded as to harmonise more than most Roses can be made to do with the bulk of the bedding stuff.

I recollect very well when Mr. Rivers "let out" the first *Géant*, he had an ordinary Frenchman to send out with it—Lafitte, or some such named Rose, after a banker of Paris—and both were to be bedders, but Lafitte I could not manage at all as such, while the *Géant* did better than any Rose I ever tried out of the *Chinas* and *Teas*; worked upon what stock so ever, it would not bed one-half so evenly and of such uniform bloom, and two-year-old plants of it were the best. But then the soil was very bad for Roses, being on the chalk and so impregnated with that as to ruin every Rose on the Dog Rose stock in three years.

Last year the most telling bedding new Rose was *Reynolds Hole*; it is quite a lady's colour for a bright bed of rose-coloured Roses; and this season Mr. William Paul's *Multiflora* bedder is just the gentleman's style of bedder—a bold, bouncing, high crimson in a rosy shade all over.

Now, although I am content to plod on with *Géant des Batailles*, I mean to be in real earnest in advising all men and most women not to buy one morsel of these splendid bedding Roses for bedding purposes except they be on their own roots. For any other purpose than the bedding, people may have them on *Manetti* and welcome for aught that I care, after having so carefully warned the unwary from paying through the nose for such Roses.

But about the way to strike them. Why, there is no end to the ways of striking Roses; but most things will easily root from now to the middle of August. Roses have two natures, as it were: they can be made to strike from cuttings as fast and as readily as Tom Thumbs in bottom heat partially confined in the height of summer, and they will remain in the open ground from October cuttings to the end of the following April, and then be not more rooted than you can now have them in one month from bottom heat. I have no bottom heat, however, for my Rose cuttings for bedding, nor do I think I would adopt it now if I could, for this reason—it would take up more of my time than would pay the cost of buying Roses on their own roots from a nursery; but gardeners, now that their beds are filled, have more time than a pilgrim like me—at least, I used to have plenty of time and to spare for cuttings when I was in harness.

The quickest way to strike a bargain, or a parcel of cuttings, is always the best way: and a mild moist bottom heat in a close cold pit that was lately, is the very best way to strike Rose cuttings in June, July, and August; but whether it is the best way earlier or later in the season depends on circumstances. What is the best way for one man to strike his cuttings from the end of August to the last of May might be the worst plan for another to attempt. But we are all on the same level in that respect from the 10th of June to the 20th of August most certainly: therefore, those of us who can spare the time to have a daily look after Rose cuttings in heat ought to have them in heat if they can afford to make a very slight hotbed inside some-

thing or somewhere which could be covered with sashes, or even with hand-glasses.

I have seen Roses struck under hand-lights, on and between the "hills" of ridged-out Cucumbers forty years ago, when there were no Perpetual or Hybrid Perpetual Roses to be had. The way that is best for me at present is a cold pit in which bedding plants were all the winter. I had the pots plunged all the winter in one-third very fine screened coal ashes, and two-thirds of the cocoa-nut refuse to lessen the need of much watering; and in this very stuff I find that all manner of cuttings will root easier than by any other means within my reach, and here I have put in the Rose cuttings. I daubed the inside of the lights with a wash of common whitewash with a whitewash-brush to lessen the need for shading; but in very sunny days I put on a mat in the middle of the day. There is no more over the cuttings than the common lights of the pit—three in that division; and a hundred kinds of softwooded shrubs, such as Honeysuckles, Weigelas, Deutzias, Philadelphias, Forsythias, Lantanas, Bouvardias, Veronicas, and all such plants, will now strike in this pit with one-tenth of the attendance and care of a dung hotbed in the spring, and all may be done just like the Roses. A slight watering at the first, and a little damping with a very fine rose of an evening are all they need.

Then in the open air I have begun with that lovely rose-coloured new Dianthus called *Hybridus multiflorus*: this is a lovely Hybrid Perpetual bloomer, and there is no end of it for cut flowers; but, like Roses, it is not a very fit plant for bedding, only for the mixed border. After it Captain Trevor Clarke's Indian Pinks, the single and the double, both of the very highest style of "Indian Pinks" as they are called. Last year I had these to cut more like barley harvest than flowers, to give away for rooms and nosegays. They all came with me from cuttings, free as willows, under a common garden-pot; the first ten days any pot will do, after that I have a set of pots with the bottoms of them broken out all but a slight rim, and over the bottom I put a loose square of glass, and that is all. No hand-glasses were ever more lucky in hitting-off cuttings.

But there are two plants in particular of which one can hardly get too many, and now is the best time of all the year round to put in and get up a stock of them. I allude to *Aubrietia purpurea*, and to the variegated *Arabis alpina*. The *Aubrietia* grows here about Kingston and Surbiton just like a weed, and is one mass of bloom with every one who has it from the middle of April to near the end of May, and the variegated *Arabis* is the very best edging plant after *Cerastium*, if it is not better than it. But there were many odds against it for the last two seasons about London. It was unfortunately propagated in the spring of the year, when it was natural for it to have been in flower; and the consequence was a hungry set of skeleton plants, which would neither grow kindly nor could be pushed. June and July, and hand-lights or pots upside down, are the right way for it, and for *Aubrietia* to make florid and flourishing growth; but the variegated *Arabis* does very well from November cuttings entirely in the open air. I did not lose one from a batch I put in about that time; but June and July cuttings of it, to be finally planted about the end of October, have made by far the finest plants with me.

Then there are the Pentstemons and the Phloxes, which do exactly alike in June, July, and August, from cuttings got from any parts of the plants, provided they are not of the flowering portions; and if you turn a pot over a batch of either on a light border as I do, you will have plants which never had any forcing or fuss, and which will bloom the next season finer than some plants can do, till you do them yourself afresh after losing two years expecting they would come round to the proper pitch. But just like the spring-struck *Arabis*, and like the foolish notion of taking any cuttings from the flowering branches of such kinds, you never can get a kindly plant of Phlox or Pentstemon if they come out of pent-up and stewing propagation; you only get the strain or the breed, and so much vexation for a huck-penny, if the propagation has not been as simple as I say, or, indeed, more simple still—say from bottom shoots next the soil where they are just beginning to root, and that is, perhaps, the best of all ways for a poor man, or a man that is not so.

Where is there a more drawing-room plant than *Centaurea candidissima*? with candle-light it is a silver ornament without being frosted in any room in the house, and there is not one plant in the catalogue that will do better for turning out in summer. If I were a duke I would have the third or the fourth

row of my best ribbon-border planted with it from one end to the other, even if the border followed the carriage drive from the London Lodge to the front door, if only to show them what a duke could do. In the third row would be my two-year-old plants; and if they were three years full I would have them in the fourth row, and after that cut them up in pieces for propagation, except a dozen or so, which I would keep for vases on the terraces wherever I could find a back of green to the view. These would soon be of the size of big Pine Apple plants, and I would have the centre twisted out as for Pine Apples, of all the first main heads, or divisions of each plant, till it assumed the appearance of a plant of "hen-and-chickens" fashion. Then four of such splendid form, and such silver-like things, I would winter in the front gallery, or even in the front hall, if I had no gallery for stately and stately plants like this. The rest of my *Candidissimas* I would winter with my Punches and Tom Thumbs, just as I did last winter without any notions of the duke about them at all. In the spring I sliced off some of the side shoots, or half-suckers, as a gardener might sever a smooth-leaved Cayenne Pine plant, stuck them in the everlasting cocoa stuff, and they rooted as fast as Yuccas or Pine Apples; but now in June is the time to hit them on the head and get them by the hundreds, twist out the heart of the centre of so many plants, and the side shoots soon come thickly. Slip these off Pink-ping fashion, put them in like Heath cuttings and treat them as such for the first fourteen days, then into bottom heat with them; and before the middle of next August just begin to think how you are to winter so many of them; but they will do with Tom Thumbs of the same age in the same soil, and with the same treatment from first to last. Last year the poor man's turn came first, and, of course, he is at it, or about setting to it already; and were it not for fear of tempting him beyond his means, I would explain the twisting-out of the heart-bud of a Pine Apple.

Have you seen the new shrubby *Mimulus*, after the way of *Diplacus californicus*, and the new *Calceolaria* I mentioned from the Exotic at the May show, which was the old but long-lost *plantaginea*, the very best of all the wild ones to cross with viscosissima and those in that section for a race of genuine bedders, as I can tell, having worked that plant just thirty years since come next August, and yet being lost for twenty-six years it is now the newest of the lot? D. BEATON.

#### TREATMENT OF HARDWOODED GREENHOUSE PLANTS IN SUMMER AND AUTUMN.

I SHOULD be glad if you would give, in one of your next Numbers, a few simple hints about the best way of managing some hardwooded plants out of doors during the summer and autumn that have flowered the previous spring in a greenhouse. I mean such plants as *Camellias*, *Azaleas*, *Acacia armata*, *Coronilla*, *Genista fragrans*, &c.

I am proposing to place mine under a north wall about 7 feet high, the pots plunged to the brim in sifted coal ashes, without any protection overhead. In such a situation, to what extent would they be likely to require watering in continued dry weather? Would they be likely to need a supply in such case as often as every other day?—COUNTRY CURATE.

[Repeatedly instructions have been given on the above subject; but every one thinks that, however special or general these instructions are, they cannot be quite suitable to his or her case; and, no doubt, in writing general directions we often recommend processes which many readers may not have the means of carrying out. In the present case, we shall suppose that the inquirer has little or no glass for such plants except his greenhouse; and besides having such plants in bloom in winter, early spring, and early summer, he wishes to get them out of doors in summer and autumn, in order to have some more temporary flowering plants to make the house gay in the summer and autumn months. We have little faith in the indiscriminate turning-out of plants, when finished flowering, to be plunged in ashes against a north wall, and kept there until taken into the house at the approach of winter, so far as free and early flowering is concerned. We have more confidence in such plants as *Camellias* doing well in a north aspect, if kept there all the year round, and the plants protected from severe frost and the flower-buds from wet. No protection overhead in summer forms a part, however, of our correspondent's case, and thus we must keep in mind; though an awning of glass, or even of

calico, or lace netting, or frigi domo would be useful alike for moderating the force of the sun's rays, and the lashing of heavy showers, with plenty of air, however, all round.

The first thing, then, necessary to high success, is the setting aside one end of the house, or a part of it, as a growing department, the other end being kept to flowering plants—that is, so that the plants at that part of the end may be kept closer and in a moister atmosphere than the general collection, and that to this part plants shall be brought as soon as they are cleared of their fading flowers, which process, too, will have the tendency to bring on the different plants in succession. Keeping this in mind, we will take the plants in the order mentioned.

1st, *Camellias*.—When done flowering remove all faded flowers, take the plant or plants to the place or end spoken of. Keep it closer by giving less air. Use the syringe freely to cause the shoots to elongate, giving no more water at the root than to keep them moderately moist. If the branches are open and thin, or the head too tall, you may now prune back pretty freely; but if much cutting is required, that ought to be general, as the old stems will not break regularly if some young shoots are left to carry on the running. Otherwise the stems will break as freely as a large Portugal or common Laurel when it is rather severely pruned-in. When such cutting-in is resorted to the stems must be kept more than ordinarily moist by dousing them often and lightly. When the young shoots are 3 inches or 4 inches long, either after such cutting or otherwise is the best time to examine the roots, drainage, &c., and to give a larger pot when necessary, though *Camellias* will flourish long in the same pot if of a fair size, and helped by a fresh top-dressing and manure waterings every year. Fresh sandy loam one part, and a third part of peat, sweet leaf mould, and sand, grow them well; but extra care must be bestowed on the drainage. When in this position the plants will be better if shaded from the brightest sun. As soon as the young shoots are formed more air and light should be admitted, and in a fortnight or so afterwards the plants may be moved to the north side of the wall you speak of, choosing a dull day for the operation, that no severe check be experienced. We will suppose this takes place in June and onwards. According as the plants are thus gradually forwarded will they form flower-buds, and come into bloom in succession in winter and spring. In such a position, as but little sun will ever play on the pots, we would prefer setting each pot on a slate to plunging them in ashes. There is more likelihood of the roots being saturated when so plunged than suffering from dryness by the pots being exposed. If for saving a little watering you prefer the ashes, we would recommend setting the pot on two bricks, leaving an open space between them to let the water pass freely.

Here they might want water once a week in dull weather, and perhaps every day when the atmosphere was dry and the sun powerful. A syringing in the evening after hot days will refresh them. Such plants should have the pots scrubbed, a dusting of fresh compost placed on the surface of the ball, and the plants be placed in the conservatory or greenhouse by the first week of October.

2nd, *Azaleas*.—These want a similar but still a rather more particular treatment. The routine of management will be much the same, only old plants do not bear cutting-in so freely. If when after being kept rather close and moist the young shoots come away freely, care should be taken to see that they are nearly of equal strength, as the extra strong will rob the rest, and will most likely not be ripened enough to form flower-buds at their points. If the point is nipped out when these are 3 inches or so in length, two or three will be produced instead of the one strong shoot; and thus the young growth on the plants will be equalised in strength, and there will be every likelihood of securing a good regular bloom. The tenderer kinds of *Azaleas*, with a longer continuance of the growing period as recommended for the *Camellia*, will do with out-door treatment in summer; but they would be more sure if kept under glass for most of the season. When by such means the young wood is regular, and some 2 inches or 3 inches in length, the syringing must be gradually discontinued, and the plants moved to where there will be more light and air, so that the growing process may be so far arrested and the ripening process encouraged; as before flower-buds in their incipency begin to form, which is known by the hardening of the points, the mere elongating process must be arrested. When thus treated for three weeks or so the *Azaleas* will be safe enough at first in front of the *Rhododendrons*, as they will not need so much shade as they; but a sprinkling

several times a-day with the syringe, if at all dry and hot, will do them good. The plunging in the ashes we would in this position thoroughly avoid, unless the pot stood on two bricks, with a space between them below the main hole in the bottom of the pot, as anything like stagnant moisture is ruinous to *Azaleas*. Large plants in large pots will need no repotting for years if the drainage is all right, and top-dressings of very old sweet cowdung, mixed with peat and sand, and weak cool manure-waterings when making fresh wood and swelling their flower-buds, are given to them. When shifting into larger pots is necessary, sandy heath mould is the best compost, and a little very sweet and old leaf mould may be added. For small houses the shifts from one pot to another should not be large. For some of the stronger kinds a little sandy loam may be added. As a general rule it will be safest to use sandy heath soil, and assist by surfacings or manure-waterings. If when placed in the closer shady end of the house there are thrips or fly on them, they had better be smoked, or taken out of doors and well syringed at one time with weak tobacco water, and at another time with very weak glue or size water. In neither case should the syringings be allowed to get into the soil. A piece of cloth of some kind should cover the soil to prevent it.

As said above, when the shoots are browning and hardening, from elongation being arrested, will be the time to place them in front of the *Camellias*, in the manner already stated. By the middle of August it would be desirable to give them more sun, by moving them still farther from the *Camellias*, or placing them in another situation where they could get a good portion of the morning and evening sun. In this case, provided such a preventive to seaking as the bricks is resorted to, the plunging the pots in ashes will be an advantage, as the roots will be kept healthy and cool, whilst the tops are exposed to a thoroughly ripening heat. The plants should be cleaned, washed, &c., and housed by the middle of October.

3rd, *Acacia armata*.—This plant, when young, thrives best in sandy peat and loam; when old and established, it does best in stiffish loam with a little rotten dung. It flowers one season on the wood made and ripened in the last. If this wood is made at all regular, and fairly exposed to sun and air, there can be little doubt of success following. The plant has one great enemy—a little white scale, and when once it gets ahead, so as to encrust the small leaves, cure and deliverance are hopeless. The only cure is to stump the plant in, leaving nothing but the main stem and some of the larger branches, or at least bits of them, and then to scrub the stems with a lather of soft soap and tobacco water, the latter not too strong, and leaving it on for twenty-four hours. Wash all off with a sponge and warm water; take the plant out of the pot; remove a portion of the surface soil; replace in a similar-sized pot, using fresh compost only for 2 inches or 3 inches at the top, so as to get rid of the insects and their eggs, and treat as the *Camellias* until fresh shoots are coming all over, when you can decide at once on the shape of the future plant. This will suit another inquirer, whose plant can only be cultivated pleasingly by first undergoing such a process. If a few of these insects are appearing on the plant of a "COUNTRY CURATE," he had better dip the plant in a weak solution of gum water, allow it to stand dry and in the shade for a couple of days and nights, and then shake it well; pull dry hands through the branches, and then syringe it freely all through and round with water at 100°. The plant may be kept in the house a few days after this; but, in general, it will be safe out of doors from June to the middle of October. The shady place will suit it best, but it will enjoy exposure to the full sun in September; and, if at all warm, a copious watering every day. Ashes, or a sod laid against the pot, will keep the roots next the pot exposed to the sun from being scorched-up; in fact, the shady place became essential for many plants from the greenhouse in summer—not so much because the sun was hurtful to their leaves and branches, quite the reverse, for the want of flowering was often owing to want of sunlight; but just because we clever gardeners chose to forget that the tenderest roots in their natural soil are never, or rarely exposed to the parching, burning heat of a red pot exposed to direct sunlight. So far then, when such plants as *Azaleas*, *Heaths*, and *Epacris* are placed in the sun, some modification of our correspondent's covering for the pots is of far more importance than the mere saving of watering; waterlogging, however, must be avoided.

4th, *Coronilla* and *Genista*.—I need say little of these. If it is necessary to prune them in much, treat the old plants much the same as pruned-in *Camellias*, until the young shoots are

4 inches or 5 inches long. If not pruned-in much the plants will make and ripen their wood sufficiently out of doors after June. The great thing is to cut away all decayed flowers, stop any too-rampant shoot; syringe them well several times with soap water and clean water alternately, using the former at night and the latter in the morning. A little sulphur water may go with the soap water, or you may have both in Gishurst Compound, using one ounce to two gallons. The object of this washing is to clear away and keep away every vestige and egg of the red spider, which dearly likes to nibble them, and especially the beautiful yellow *Cytisus*. For young plants a little heath soil may be used with the sandy loam, but as they get established they do best in sandy loam with a little leaf mould. The free use of the syringe in summer is a first necessity for securing fine plants in winter and spring. They do best when protected from the midday sun in summer, and when the pot is not exposed plunging is less needed. They should be housed before the end of October.

So much for a few minutes of success. I regret I cannot follow them up with simple directions as to how often such plants need watering. Were it possible, one charm in gardening would be dissolved—that which proceeds from the care and attention our favourites constantly require, inasmuch as we soon cease to appreciate a right the greatest blessings, if they involve no care or anxiety on our part. We can do no more than tell our correspondent, just to treat his plants in the liquid way, as wise people treat themselves—that is, give them water when they are thirsty, and at no other time.—R. FISU.]

#### HARDY RHODODENDRONS IN POTS— COCOA-NUT FIBRE REFUSE FOR PEAT.

IN answer to "H. B." we have to observe that the Rhododendrons would be better out of pots (in peat) all the summer, and to the very day in winter when you house or frame them for forcing or early flowering—the only reason we know of for potting them at all. About having them in the cocoa-nut fibre refuse, if any kind of Rhododendron, Heath, or Kalmia, or any other of those kinds of plants needing peat soil is once established in a pot, and the ball is full of roots, it will never do to thrust it suddenly, or by slow degrees, into a mass or bed of the refuse; for this is as loose as a heap of moss, and a heap or bed of it is always as damp as moss just taken out of water and squeezed. Then when a ball of peat needs watering, and is watered in a heap of the refuse, the water elips past the peat on all sides and runs into the refuse; in ten days the ball is as dry as tinder, and no more watering would wet it again, until it is taken up and put into something which will hold water till the ball is most thoroughly soaked. We were consulted about the Ferns and other plants which are now in the International Exhibition, growing in the cocoa-nut fibre refuse. They were bought of the Messrs. Jackson, of Kingston. The whole of the peat or other earth—or say the whole of the balls, having been shaken from the roots as much as could be done, they were set in the refuse and then placed in the Exhibition. All that was done in less than twenty hours, which was giving the plants no chance at all; yet they took to the refuse at once, and they had very little, or indeed no attendance for the first three weeks—perhaps none yet. The way to have done them is this—they should have been partially shaken out of the balls at the beginning of April, then well watered, and the case or box should have been under glass; they should have had good garden management to the end of the month, and then been sent to the Exhibition.

All the balls of all sorts of plants ought to be partially broken or loosened before putting them into the refuse, and peat balls much more so than compost balls. It has not yet been fully proved that American plants will do entirely in this stuff instead of peat; but we took an opportunity last May to visit the works and the great refuse heaps for the first time, and we found upwards of thirty thousand tons of it as black as bog peat, and naturally heated to 70° at the bottom of the mass, say such as was from eight to twelve years old. We have no doubt whatever but all American plants would do in it as well, if not a vast deal better, than in the best Wimbledon peat; the only care would be to see that the plants had not much peat about the roots at the time of planting, and that the stuff was pressed together as firm as man could make it. The refuse would come much cheaper than peat in some parts of the country, and we can

affirm from our own experience we could have it at seventy miles from London at one-half of the price we used to give for the loam and the peat we annually had from Epping Forest, because all the railroad Boards have agreed to carry it at the same rate as dung in truckloads. A truck carries 4 tons of it, and the Company send it off from Kingston Station at the rate of 30s. a-truck, so that it would be an excellent speculation to some nurserymen far down in the country to have so many truckfuls of it in a season, and then to sell it at the same price as the Company charge here for the small quantities in bags. Our friends, the florists, will find it the best stuff in the world to make composts with. Mr. Wood, our principal stonemason in Kingston, and the oldest and best Auricula grower and fancier thereabouts, told us this season it was "prime stuff" for Auriculae. But we would ask for the black old stuff for all florists' flowers, and use nothing with it but so much pure loam.—D. B.

#### VARIEGATION IN PELARGONIUMS.

Now, Mr. Beaton, what would you have me to say? Make the theory of variegation meet at both ends, eh? Why, both ends are already met, as sure as you met with the "White Lady" at the Crystal Palace Show the other day. Really, it is by far too bad of you to put it about that she "is against all the variegated doctors by hand entirely," when all the while she had neither lot nor part in the matter. Yes, Mr. Beaton, it is all very well for you to throw the burden off your own back; but, mind you, I have my own opinion still.

About these variegated seedlings from Messrs. Downie, Laird, and Laing, Did you say they were better than their parents, or was it that they were whiter? H'm! I thought so—exactly. Alike will always have a tendency to produce alike, and when any difference occurs it is sure to be either better or worse than the parents. I have proved this hundreds of times, and so have you I am sure. Did I understand you to mean, that you would take up this cross of Messrs. Downie, Laird, & Laing's, and follow its fortunes with a sure and certain hope that you will thereby gain a thorough knowledge of the original cause of variegation? Very well, I shall not follow you. The truth of the matter is, pardon me for what I am about to say, I verily believe you are labouring under a grand mistake, endeavouring to solve a primary problem by secondary causes. Indeed you are. I am not at all surprised you have been puzzled to make both ends meet. Why, you never had but one, and that was the wrong one. The seedlings you have mentioned are the very best proofs you possibly could have advanced to illustrate the transmission of the disease, which is a something; but as regards the origin of the disease, why they prove nothing at all. When you and I last had a confab on variegation, I told you I wanted to get Général Pelissier; now I have got it, and a beautifully-marked thing it is. I have also doctored one of my seedlings named after the place I live at, but too near Punch to keep. However, I have now obtained a variegated one from it. I have also got a variegated Ivy-leaf, the Scarlet variety, but I think it inferior to Mangles'; therefore, I will discard it. I believe the Ivy-leaf, from the wiry nature of its stem, is the most difficult to change of all the so-called Scarlet Pelargoniums.—AN OLD SHOWMAN.

#### NEW BOOK.

*The Fruit Manual: containing the Descriptions and Synonymes of the Fruits and Fruit Trees commonly met with in the Gardens and Orchards of Great Britain, with Selected Lists of those most worthy of Cultivation.* By ROBERT HOGG, LL.D., F.L.S. Second Edition. London: Journal of Horticulture and Cottage Gardener Office.

THE rapid sale of the first edition of this useful work has enabled the author to produce another, which is a considerable improvement on its predecessor, inasmuch as the greater part of it has been rewritten and an opportunity afforded of correcting several mistakes that had crept in, and of introducing a great number of varieties that were not recorded in the first edition. Great additions have been made to the number of the Apples, the Grapes, the Plums, and the Strawberries, and all the novelties that have been discovered in the other classes of fruits since the publication of the first edition have been introduced into this. Numerous synonymes have been added, while others have been corrected; and it may be said that this second edition embraces all the pomological information up to the present time.

### FLOWERING SOME SELECTED PLANTS AT A MORE ACCEPTABLE SEASON THAN USUAL.

I will presume that plants in flower are in greater request at or about Christmas than many other periods, more especially some of those beautiful varieties which flower as a rule between June and October, several of which, if flowering at the above festive season, would be vastly more appreciated than when blooming amid all the gaiety of English gardens in summer. I have this as my object, and I will not in these short notes state anything beyond what I have proved, and which cannot be most easily practised by others.

#### VALLOTA PURPUREA.

From June to September are the months in which this exceedingly useful plant flowers; but by the following treatment, than which nothing can be more simple, it has flowered from the first week in November, having two fine five-flowered spikes in perfection on Christmas-day; it is then excellent for standing in rooms, &c. In-doors it is as valuable a plant as any in cultivation, and its value is enhanced fortyfold when in flower as above. To attain this, pot in May, studiously avoid letting the plants get too dry; keep them in a shady place until you find the roots have rambed into the fresh soil a little, then place them out in the open air under a Laurel or other shade, where they are effectually screened from the sun, leaving them in this position until September, when in all probability they will be just showing flower; if not, put them in the full sunshine, slightly diminish their usual allowance of water, and as soon as the spikes are shown replace them in their shady position. Leave them there until you house your greenhouse plants, when they may also be taken in. When required to expand their flowers, give them a moderate temperature—such as the warm end of the greenhouse or the cool end of the stove.

#### THE ORANGE TREE.

It is rather unusual to have this plant in flower on Christmas-day, so I will explain the treatment by which I succeeded in flowering one most profusely at that time.

From the middle of December to the end of January, what better suited to an antique ebony basket on a British winter's day than this poetical plant, imparting the delicious perfume of its ivory-like blossoms through a whole suite of rooms? It should receive the entire treatment of a Camellia, with one exception. Place it in the warmest situation you can command during summer, in the warm corner beneath the south and east wall—in fact, imitate its native climate, accompanied with a suitable amount of air to keep the sun's rays from scorching it. During summer carefully take off all flowers and fruit, should there be such on it. The object chiefly in view should be to obtain a nice growth matured by the end of September to forward the embryo flowers upon the same as much as possible, avoiding everything likely to cause it to grow or move perceptibly until a month before you wish to have it in flower, when you should treat it as you would a white Azalea when forcing it. How exceedingly well our French neighbours do the Orange! I cannot see why they should be so far in advance of us when I consider the warmth obtainable under a south wall in summer. Our object should be to ripen the wood more rather than to make so fine a growth.

#### INTERMEDIATE STOCK.

The use of this, as also of Ten-week and other Stocks in the spring is well known. By a very simple process the Intermediate can be had in flower in perfection during the whole winter, with spikes as fine and plants as large as when out of doors at midsummer. Their usefulness is indisputable as cut flowers for bouquets and house-decoration. Even in the conservatory they are very acceptable in the middle of winter.

They should be sown in February or March, started into showing bloom, whether single or double, in April. The single having been discarded, when properly hardened plant them out in a medium good border about a foot apart, to be eventually properly staked if necessary. As the flower shows during the whole of summer, cut it off. The plant becomes more bushy if those flowering shoots are cut home. In October the plants should be taken up, carefully potted, and placed under a north wall, where they must remain until they recover from the check received, when they can be taken into the greenhouse. I find the Scarlet Intermediate does best.

#### GESNERA LONGIFOLIA.

This useful plant may be had in bloom during the whole of winter. Give it a shift in the spring to induce it to make a nice

growth. I prefer a young plant of two seasons' growth. The pot into which it is shifted should be so sized as to cause it to well fill the pots with roots. Being pot-bound will induce it to show profusely for flower in the autumn. Keep it in an even, moderate temperature until the first flowers open, then give it the smallest shift possible; this will induce the whole of the flowers formed to open well. By the time the last are opening the second pot will become full of roots, and cause a succession of short profusely-flowering joints, which will give you a show in continuation. This plant does best when in flower in the coolest end of the stove, with an occasional syringing. When treated this way, and tied round a hollow plant-trellis, it is a pretty object.

#### IMPATIENS JERDONIE.

This admirable variety of a very singular species can with very trifling trouble be had in flower at Christmas; the principal features of the necessary treatment being not to dry it too hurriedly when it has done flowering, and not to start it quite so early as is usual after rest. When showing for flower place it under a north wall; let it be carefully watered, and while in this position, protected from draughts and heavy rains. When the weather proves too cold, or you conjecture it will be so, return it first to the greenhouse for a week, to be eventually replaced in the stove.

#### POINSETTIA PULCHERRIMA.

This most useful plant flowers at a season too acceptable to require any remarks on that head, yet it may be of use to some readers of this Journal to know, that in preference to the original mode of growing large shapeless plants, it may be easily propagated from the young growth previously to the same showing any signs of flowering. By judicious topping a trio is formed from a single stem. Arising thus from the pot the singularly beautiful bracts upon a plant so grown, some 7 inches high and 12 inches in diameter, have a highly ornamental effect. Single cuttings so grown should be struck in 60-sized pots, and only once shifted into 48's, for flowering. If dwarf plants are required, keep them studiously near the glass as you would young Balsams when you wish to grow them well, and give them the usual amount of air allowed to plants requiring a medium temperature. We cut the last beautiful head of scarlet bracts to enliven a bouquet on the 14th of March. This in a measure is attainable by striking successive cuttings, the latest struck blooming last. I have known it to be in perfection in May.

#### LUCULLA GRATISSIMA.

One of the most elegant fragrant plants in cultivation. It requires no high temperature, indeed a temperate one is just that which suits it. Then why is it not more commonly grown? I am forced to admit that I believe it is absent because its little peculiarities are not better known. Who can remember how it was once shown when the old Chiswick was in its meridian of displays? Does not the veteran Mr. Beaton bear in mind this plant as once shown there? If so, no subject would interest us, the young beginners, more than a full description of the plant, accompanied with his experience in its treatment. Its usual time of flowering is about the same as that of the Vallota, if simply placed upon a pot turned bottom upwards under a north wall immediately after its flower-buds appear. Keep it there until the morning after the thermometer has registered 40° at night. Take it thence into a cool greenhouse; and when the first flower-bud begins to expand remove it into the cool end of the stove, and syringe freely. By this treatment it is possible to have it in flower in December. Among its many peculiarities is its antipathy to the least restraint; but I believe this is easily overcome if the plant is taken into training young. For soil, mixed with the best of maiden loam and sand, it has a great liking to charcoal in small pieces.—W. EARLEY, *Digswell*.

AWARDS TO LAWN-MOWING MACHINES.—Referring to the advertisement in your last publication of awards to Lawn-mowing Machines at the Royal Horticultural Society's Garden, we should wish your readers to know that there were no trials of the various machines exhibited. Our Shanks' Patent Lawn-mowing Machines were sent on the first day for exhibition only, and we intimated this to the Secretary of the Implement Committee. We also more than once distinctly refused on the first day of the Exhibition to allow our machines to be "tried" there on that occasion. We quite share in the very general opinion now entertained among those who have the best opportunities of judging, that these so-called public trials are, from their very nature, mere delusions,

misleading rather than safely directing the public. The practical experience of persons who have used the several machines, and know all about their respective merits or defects, is, as common sense must tell, by far the best and indeed the only safe guide.—J. B. BROWN & Co.

### RAIN, SUNSHINE, AND THE WATERING-POT.

THERE are comparatively few people but are more or less interested in the weather. True, every one is not alike in his wants, but that does not imply that he lacks an interest in it. A brickmaker wants but few rainy days, while such days are the harvest of the street shoeblacks and London cabmen, and in rural districts, millers, whose water power is inadequate to the demands on it, often enough wish for a wet day. But my purpose is not to descant on the requirements of any particular class, but to explain some of the anomalies we often hear of as to the effects of a very wet or a very dry season, on the crops of the same or different districts, and to point out what seems to be the cause of these apparent contradictions. Taking, therefore, one of the most common circumstances, that of grass land, let us see the effects of wet and drought upon it.

It cannot have escaped the notice of most people engaged in husbandry, that after a lengthened period of wet weather grass land very quickly feels the effects of dry weather when it sets in, if even for a limited time, and if it be continued it soon burns up, as the phrase is. Now, there is every reason to believe that this is not owing to any want of moisture below—on the contrary, there is a superabundance of that: hence the apparent puzzle, and examples are common enough. Last year, for instance, presented several cases of this kind. The early part of summer was certainly not deficient of rain. July was wetter than I ever remember that month to have been before, and yet when dry weather did set in, the grass and other herbage soon showed signs of suffering, and I never saw the grounds at the Crystal Palace look so bad before, neither am I aware of ever witnessing any grounds suffering so much since the memorable hot summer of 1826, and that was dry from April up to autumn, with the exception of some few thunder-showers. The cause, therefore, of grass and other herbage so quickly succumbing to drought after a lengthened period of wet, must be sought for from some other source than lack of moisture below; and as the reason most likely occasioning this has a strong analogy to effects produced by artificial watering, the case cannot be without interest to all classes of cultivators of the soil.

We all know that abundance of sunshine is incompatible with frequent and heavy rain: hence, the latter cools the ground below its proper temperature. This is more especially the case in the subsoil, which, being deprived of its heat, is less inviting to the roots of plants, which are at the same time under no necessity to travel so deep for moisture, and consequently confine themselves to the few inches at top. The continued saturation by rain also sours, or in some way renders the subsoil unfit for them. These causes united render the amount of surface mould occupied by the growing crop much smaller than usual, and, consequently, the same effects are produced when dry weather sets in as when a plant is compressed into a pot much too small for it. In common parlance, it burns quickly. This is the reason I give for it, and some other collateral ones might be added; but these are certainly the primary ones. Let us, therefore, compare them with the effects produced by artificial watering, and mark the result.

I remember when but a boy of hearing a disension between two cottagers about watering their Onion-beds. They were both painstaking, good managers, grew very large Gooseberries, and had Tulips, Pinks, and Auriculas that would pass muster very well at a show of the present day. One of these cottagers was watering his Onion-bed with a pail and hand-bowl with more liberality than discretion, and was urging the propriety of the other doing so also, when he was met by the answer, "That if once begun it must be continued, and the ultimate benefit was questionable." Here, then, was a direct elucidation of the problem. "Watering by hand once begun must be continued," and, in a great measure, the lapse of years has not affected this law. The roots of the cottager's Onions that were watered nightly kept near the surface, and were fed by the liquid he supplied them with, and any accidental diminution of their daily food of course distressed them. More recent practice has told us that in crops like the Onion, systematic watering, except in special cases or situations, is bad; and although

I forgot which of the two cottagers produced the better crop in the end, there is reason to believe that the one who did not water had the better. A good depth of sweet, well-pulverised soil will, in general, furnish better and more suitable food for most plants than the contents of the well or pump, and I have traced the roots of Onion to the depth of upwards of 20 inches, and the crop was all that could be wished for. The laws, therefore, to be deduced from this state of things are that mere surface wetting, is of much less consequence to vegetation than a healthy medium for the roots to ramble in, that it rarely happens that established plants suffer much from drought even in a dry season, where there is sufficient depth of healthy soil to support them in; and with this depth of material they are less dependant on the casual wettings the surface may get, and the result of a dry season will be more satisfactory than a wet one, even for such gross-feeding plants as require a great amount of liquid food.

Notwithstanding all the benefits which science has been enabled to confer upon artificial husbandry, there are natural effects which we have but little hopes of imitating. When Nature works on her own account, she is so accommodating as to enable plants grown in an ordinary way to endure double the amount of moisture at one time which she supplies them with in another. The elevated districts of Derbyshire, Westmoreland, and Wales, receive more than double the amount of rain that falls in Norfolk, and yet hay is made, and corn is ripened in both places; certainly not so well in the one as the other, but it is done. Natural outlets are made for the superabundant moisture, and the soil if not more porous, is so arranged as to let the water run off. Corn will ripen under a great amount of rain-fall, and the moralist may find a fit theme for a lengthened article. But the plain, dry facts of the matter that relate to gardening must be confined to less space; and retracing our steps, let us see whether a dry season or a wet one affects us most, and in what way.

I believe it will be generally acknowledged that the dry seasons we have—those, for instance, as only come once in a lifetime, affect but very little the most robust vegetation, such as trees. Now and then we hear of one or more growing under circumstances foreign to its habits succumbing to the continued drought; but these cases are rare, while in very many instances important benefits are derived from dry, hot seasons, the buds are well ripened, and an abundance of bloom of a kind likely to produce fruit the ensuing season is the result. Plants having a more ephemeral existence suffer more; their wants are confined to the current season, and absorbing moisture in greater abundance exhausts the supply sooner, and a more stunted growth follows. It is, therefore, only to such plants that watering by hand is applicable, and this should only be done when absolutely necessary; and such cases will be found much fewer than is generally supposed, and by timing the duty to the periods Nature points out as being the most suitable, a better result will be arrived at. Quarters of Lettuces, Peas, and other things which on dry soils certainly do benefit by copious watering in dry weather, ought to have it administered to them on dull days, or when it rains a little. A good watering at such a time will be more useful than at one of a contrary kind; but be sure to give as much at one time as will reach the bottom of the lowest root. Dribbles wetting the top only keep the roots there to be burnt up by every gleam of sunshine that acts on them; and as we have shown the grass field to burn up with a little dry weather after a wet period, in consequence of its roots deriving their nourishment from near the surface, in like manner vegetables and other things may be taught to do the same, and once their artificial feed is stopped, bad consequences are sure to follow.—J. ROBSON.

GARDENER'S ROYAL BENEVOLENT INSTITUTION.—The Annual Dinner in aid of the funds of this Society will take place on Thursday, the 26th inst., and we hope that the visitors now in the metropolis, in such unusual numbers, will increase the number of those who patronise this excellent Society. It is firmly established, and has received a small share of public support, but not in proportion to the calls made upon it. It is now affording relief to fifty-seven poor persons who would otherwise be lingering out their existence in the workhouse. The Committee announce that the demands for assistance become more numerous year by year, and we would urge those who do not already aid the Society to add their names at once to its subscription list.

## ECONOMY OF FUEL.

I AT once admit the force of your reasoning with respect to the iron jacket, and the advisability of making it of brickwork instead, on the joint score of expense, liability to burn the air, and the more equal combustion insured by the heated brick; but beyond this comes the passage—"No such air should be allowed to pass into the atmosphere of the house." Now, I submit that such an arrangement would constitute a Kiddean furnace, pure and simple. If my memory fails me not, Mr. Beaton, in describing the Kiddean system, likened the furnace to a small flower-pot inverted, with a large one over it, the intervening space constituting the air-chamber. Now, if my proposed plan would not be a literal carrying out of that idea I am mistaken altogether as to the principles of Mr. Kidd's system. Again, with respect to the proposal of Mr. Fish, I cannot see the force of it, as were the air confined, the outer casing must absorb heat from it, and that heat be lost which a current passing through the chamber would carry with it. The task you set me in the latter part of your remarks is indeed a puzzler, and could I accomplish it I should well deserve the title of "ingenious correspondent;" a little might, however, be accomplished in that way by carrying the chamber round the flue as far as the damper. It seems plain to me that a furnace constructed in this way would effect as great an economy as a thing possibly could do; for with a small extra amount of fuel the full advantages of a Kiddean and a hot-water apparatus would be gained from one fire, and that without loss.—M. G. CUNNINGHAM.

[With the exception of a slight error in the printing, we hold to the ideas expressed at page 194. Your prominent idea to save fuel was the iron jacket. We urged reasons why, economically and otherwise, it would not answer, merely from our general knowledge, of course, and not from any particular knowledge of the effects of an iron jacket. We know something of the effects of taking air from red-hot iron among plants, though well moistened by various means beforehand. The case is different when taken from bricks, because at the hottest the outside is never so hot as iron, and plenty of moisture before reaching the plants will neutralise to some extent its unkindly nature. We would not, therefore, exclude the heated air from such a chamber if suitably ameliorated before it entered among tender plants. Mr. Fish, to a limited extent, has recommended such chambers over and round boilers, especially when set in sheds outside of the houses, instead of allowing it to heat the shed or the external atmosphere. In such cases he so far acts on the Polmaise principle as to have one opening from the house into the bottom of the chamber, and an opening at the top of the chamber into the house, so that there is a constant rush of air through the chamber—the cool entering below and the heated coming out at the top. Even then, however, when a damper was freely used, the openings had to be shut at times to prevent unhealthy gases being thrust through the brickwork. When there was plenty of draught given and a more free use of fuel there was no danger in this direction. This plan, however, has nothing of the novel in it; it is merely appropriating so much of the Polmaise or Kiddean idea, though we rather think these plans were adopted before there was much discussion about either. If, however, you substitute the brick for the iron jacket, so as to carry out literally Mr. Kidd's system, where is there any originality? You have also clearly misapprehended the writer in the other idea of a close chamber round the boiler. He evidently acts on the principle that though close confined air is not a perfect non-conductor of caloric, it is one of the best non-conductors, so that where such chambers exist little heat is given out to the earth or brickwork round the boiler. By such means heat is accumulated about the boiler and furnace instead of being freely diffused or conducted to the surrounding medium, be it air, or earth, or brickwork. So far as heat is concerned there might be more economy in throwing it at once from an open secure chamber into the house; but, on the other hand, by concentrating it more round the boiler by a close chamber, there would not be very great difference in this respect, and then there would be the security that no heat would enter the house, except what was fitted for plants to breathe in, instead of an atmosphere kiln-dried and robbed of its oxygen. All these contrivances, however, do not meet the great robber of heat from any system of boiler-heating—that which goes up the chimney to the benefit of the general atmosphere.—R. F.]

## WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from Vol. II., page 68.)

## CRUSTACEA—(continued.)

THE COMMON SHORE CRAB (*Carcinus mænas*).—This is a very common species, and has a shell of somewhat greater breadth than length, covered with minute tubercles. It has four flat triangular teeth on each anterior side. The anterior feet are pretty nearly of equal size, strong and smooth; the claws both toothed. The remaining feet are compressed slightly, especially the last pair, and the terminating joints are, as in the last species, adapted for swimming. The ordinary colour of the common Shore Crab is a blackish green, and a dull red underneath. The colour, however, is by no means constant, the young, indeed, being sometimes entirely white, with a solitary black spot in the centre of the shell.

This creature, as its name implies, may be found on all our shores. It is, in fact, the commonest British species, scores and scores of them may be seen daily on every part of our coast. It is frequently left by the receding tide on sandy beaches, where if alarmed and failing to reach its natural place of refuge, it either hides itself, or endeavours to do so, under a commodious stone, or buries itself entirely in the soft wet sand. For one or two interesting details touching these Crustacea, I shall again avail myself of Professor Bell's able work. "Its food consists principally of the fry of fish, Shrimps, and other Crustacea; but it will also feed upon dead fish, and almost any other animal substance. Indeed, the most common method of taking these Crabs at Poole, where numbers are caught by the fishermen's children, is by tying a mass of the intestines of either a fowl or of any fish to a line, and hanging it over the quay. The Crabs seize upon this bait and are drawn up in considerable numbers. Mr. Hailstone states that they attack Mussels, and that he once saw one carrying about on its claw a Mussel which had closed its shell upon it. They run with considerable rapidity and with an awkward sidelong gait, and they lurk in pools of water left by the tide, partially concealed in the sand, but with the anterior part of the carapace including the eyes exposed, so as to watch for the approach of their small living prey, on which they spring with great activity. They are, however, very timid and wary, and will not move if they discover that they are watched. They simulate death, if disturbed, as completely as do many coleopterous insects."

THE VELVET SWIMMING CRAB (*Portunus puber*).—The shell of this species is about a fourth part broader than its length. The anterior portion is semicircular, and has five strong teeth on either side. The eyes are round and placed on short stalks. The anterior legs are very robust, the claws grooved longitudinally and furnished with strong teeth. The second, third, and fourth pairs of legs are alike, long, grooved, with a slender pointed terminal joint. Whereas the fifth pair has the two last joints considerably flattened. The whole of the legs as well as the shell are covered with a thick shaggy hair, except on the raised portions, which are naked.

The colours of the Velvet Swimming Crab during life are wonderfully bright and showy, but they speedily fade after death. It exhibits a multitude of tints, the prevailing ones being a reddish-brown and a bright blue. It is found in large quantities all along the south-western coast of England, generally lurking among the stones. It is very active and courageous, running away with great speed at the approach of an enemy; but if it finds escape impossible, it turns at bay and exhibits every inclination to decide the question by combat.

THE ARCHED-FRONTED SWIMMING CRAB (*Portunus arcuatus*). The shell of this specimen is four-fifths as long as it is broad, and has the surface grained. The front, as its name signifies, is arched, and the margin on either side of it has five teeth. The anterior feet very strong, with a sharp spine on the wrist. The claws are extremely powerful and furnished with a quantity of teeth. The rest of the feet are slight, the second pair shorter than the third and fourth, and the fifth pair is fringed with long hair. The colour of this Crab is a blackish-brown above; beneath, the hue is much fainter and has a tinge of red. The colour of the legs much paler than that of the body.

The Arched-fronted Swimming Crab may be found in most localities, more commonly, however, on the northern coast than any other. Professor Bell states that he has dredged it in Poole harbour, in the bays of Studland and Swanage, and plentifully at Bognor, all on the south coast. The general character of these animals may be summed up in the Professor's own words:

—“They are active, bold, swimming with agility, and seizing with great sharpness, and pinching severely with their acute claws. They are gregarious like most of their congeners, and I found them extremely abundant at Bognor, where they constantly infest the Prawn-pots, and, as the fishermen believe, keep the Prawns from the bait.”

**THE CLEANSER SWIMMING CRAB (*Portunus depurator*).**—The shell of this Crab is rather more broad than it is long, and the surface very uneven. It has three flat teeth on the front, of which the central one is the longest. On the side margins anteriorly are five triangular teeth. It has very large eyes fixed on short stalks. The first pair of legs, which are rather unequal, are beautifully carved; the wrist furnished on the inner side with a sharp spine; the claws are tuberculated. The second, third, and fourth pairs of legs are long and slender, the last terminating in a very sharp point. The fifth pair is flattened, the margins of the two first joints being ciliated, the terminal joint is flat, smooth, and oval. The young ones are flesh-coloured, but those which have reached maturity are of a light reddish-brown colour. “This, species,” says Professor Bell, “is not unfrequent on our coasts. During some weeks spent at Bangor, near the entrance of Belfast Bay, in the autumn of 1835, I found this to be the most common species of Crab thrown by the waves on the beach.” This latter statement is on the authority of Mr. Ball. Professor Bell himself has “dredged it in Studland Bay, in Dorsetshire,” but did not find it “on the coasts of Sussex and Kent.” He adds, however, on the authority of Mr. Hailstone, that “it is frequently caught at Hastings in the shrimping-net.” It derives its name of Cleanser from the duty it performs of removing impurities from the sea.

**THE MARBLED SWIMMING CRAB (*Portunus marmoratus*).**—The shell of this animal is slightly convex and granulated, smooth and naked. On the front it has three teeth, the central one the longest. On the margin on either side are five teeth, flat, sharp, and triangular. The front feet strong, the claws furnished with tubercles, the movable one being very much curved. The second, third, and fourth pairs of feet are slender and compressed, the last joint being curved and fringed on the under edge with hair. The fifth pair is fringed with hair on both edges, and the last joint is very smooth and oval.

“The colours of this species,” remarks Professor Bell, “are exceedingly varied and beautiful, particularly in the males. Buff, light brown, deeper brown, and brownish-red, are arranged over the carapace in varied, but not always exactly symmetrical patterns. The only way in which these beautiful markings can be preserved is by raising the carapace, taking out the soft parts, and drying the specimens in a shady place in a brisk current of air. If they are put into spirit, the whole of the beauty of the colour is lost. The younger specimens do not possess these markings. They are, as Dr. Leach has observed, of a plain brown colour, and much resemble the fry of *Portunus depurator*, from which they may be easily separated by their more considerable convexity.”

The Marbled Swimming Crab is said to be common enough on the sandy shores of the southern coast of Devon, where it is frequently met with entangled in the nets of the fishermen, or cast up on the shore after a storm, and Professor Bell mentions having procured a specimen at Hastings.—W.

(To be continued.)

## THE AQUATIC PLANT CASE, OR PARLOUR AQUARIUM.

SOME years since Mr. Warington communicated to the Chemical Society the following interesting paper:—

“This communication will consist of a detail of an experimental investigation which has been carried on for nearly the last twelve months, and which appears to illustrate, in a marked degree, that beautiful and wonderful provision which we see everywhere displayed throughout the animal and vegetable kingdoms, whereby their continued existence and stability are so admirably sustained, and by which they are mutually made to subsist, each for the other’s nutriment, and even for its indispensable wants and vital existence. The experiment has reference to the healthy life of fish preserved in a limited and confined portion of water. It was commenced in May, 1843, and the subjects chosen were two small gold fish. These were placed in a glass receiver of about twelve gallons capacity, having a cover of thin muslin stretched over a stout copper wire bent into a circle,

placed over its mouth, so as to exclude as much as possible the sooty dust of the London atmosphere, without, at the same time, impeding the free passage of the atmospheric air. This receiver was about half filled with ordinary spring water, and supplied at the bottom with sand and mud, together with loose stones of limestone tufa from Matlock, and of sandstone; these were arranged so that the fish could get below them if they wished so to do. At the same time that the fish were placed in this miniature pond, if I may so term it, a small plant of the *Vallisneria spiralis* was introduced, its roots being inserted in the mud and sand, and covered by one of the loose stones so as to retain the plant in its position. The *Vallisneria spiralis* is one of those delicate aquatic plants generally selected by the microscopist for the exhibition of the circulation of the sap in plants; it throws out an abundance of long strap-shaped leaves, of about a quarter of an inch in breadth, and from 1 foot to 3 feet in length. These leaves, when the sun shines on them, evolve a continued stream of oxygen gas, which rises in a current of minute bubbles, particularly from any part of the leaf which may have received an injury.

“The materials being thus arranged, all appeared to go on well for a short time, until circumstances occurred which indicated that another and very material agent was required to perfect the adjustment, and which, from my not having thought of it at the time of commencing the experiment, had not been provided against. The circumstances I allude to arose from the decay of the leaves of the *Vallisneria*, which became yellow from having lost their vitality, and began to decompose. This, by accumulation, rendered the water turbid, and caused a growth of mucous or green slimy matter on the surface of the water, and on the sides of the receiver. If this had been allowed to increase, I conceive that the health of the fish must have suffered, and probably their vital functions have been destroyed. The removal of these decaying leaves from the water, therefore, became a point of paramount importance; and, to effect this, I had recourse to a very useful little scavenger, whose beneficial functions have been too much overlooked in the economy of animal life; I mean the water snail, whose natural food is the very green slimy growth or mucus and decaying vegetable matter, which threatened to destroy the object which was wished to be obtained. Five or six of these creatures (the *Limnæa stagnalis*) were consequently introduced, and by their continued and rapid locomotion, and extraordinary voracity, they soon removed the cause of interference and restored the whole to a healthy state: thus perfecting the balance between the animal and vegetable inhabitants, and enabling both to perform their functions with health and energy.

“So luxuriant was the growth of the *Vallisneria* under these circumstances, that by the autumn the one solitary plant that had been originally introduced had thrown out very numerous offshoots and suckers, thus multiplying to the extent of upwards of thirty-five strong plants, and these threw up their long spiral flower-stems in all directions, so that, at one time, more than forty blossoms were counted lying on the surface of the water.

“The fish have been lively, bright in colour, and appear very healthy; and the snails also, judging from the enormous quantity of gelatinous masses of eggs which they have deposited on all parts of the receiver, as well as on the fragments of stone, appear to thrive wonderfully, and besides their functions in sustaining the perfect adjustment of the series, afford a large quantity of food to the fish in the form of the young snails, which are devoured as soon as they exhibit signs of vitality and locomotion, and before their shell has become hardened.

“Thus we have that admirable balance sustained between the animal and vegetable kingdoms, and that in a liquid element. The fish in its respiration consumes the oxygen held in solution by the water as atmospheric air, furnishes carbonic acid, feeds on the insects and young snails, and excretes material well adapted as a rich food to the plant, and well fitted for its luxuriant growth. The plant, by its respiration, consumes the carbonic acid produced by the fish, appropriating the carbon to the construction of its tissues and fibres, and liberates the oxygen in its gaseous state to sustain the healthy functions of the animal life, at the same time that it feeds on the rejected matter which has fulfilled its purposes in the nourishment of the fish and snail, and preserves the water constantly in a clean and healthy condition. While the slimy snail, finding its proper nutriment in the decomposing vegetable matter and minute confervoid growth, prevents their accumulation by removing them, and, by its vital powers, converts what would otherwise act as a

poison into a rich and fruitful nutriment, again to constitute a pabulum for the vegetable growth, while it also acts the important part of a purveyor to its finny neighbours."

In this way is the economy of the animal and vegetable kingdoms wisely and beneficently adjusted, so that the vital functions of each are permanently maintained.

The engraving represents an improvement on the original plan; for the opportunity of presenting it we are indebted to Mr. Warrington, who has also kindly furnished the following additional observations founded on his now more lengthened experience:—

"Since the reading of my paper before the Chemical Society, on March 4, 1850, respecting the miniature aquarium (*Quarterly Journal of the Chemical Society*, iii. 52), I have continued the investigations, introducing other water plants, and also three other varieties of water snail. But the principal alteration has

been the construction of a better form of vessel for holding the water, as I found that the globular form of the glass receiver produced a distortion in the vision of the fish, besides being very inconvenient for observation. I have therefore adopted the form of vessel, of which a sketch is appended, having flat surfaces of plate-glass at the back and front, the bottom and ends being formed of slate, and supplied with a loose plate of glass at the top to keep out dust and soot. To render the whole more ornamental, as it was to stand in a sitting-room, some pieces of tufa, or sandstone, were attached to the ends by means of Roman cement, so as to form ledges and slopes rising from the water line, on which Mosses and Ferns, such as luxuriate in an atmosphere loaded with moisture, could be grown. These materials are set in a stout, angular, zinc framework, and connected with a mixture of white-lead ground in oil, to which about an equal

MR. WARRINGTON'S AQUARIUM.

quantity of red-lead is added. This arrangement I have found to answer all my expectations, as it has been going on most flourishingly since January, 1851. The plants consist chiefly of *Hymenophyllum tunbridgense*, and *H. Wilsoni*, *Trichomanes speciosum*, *Blechnum boreale*, *Adiantum capillus-Veneris*, and several Mosses. The whole of the interior can be viewed with the greatest ease, so that the natural habits of its living inhabitants can be watched and accurately noted in every particular.

"The rapid increase in the growth of the *Vallisneria* is very extraordinary. As I have before mentioned, the plants of necessity get the whole of the rejected matter from the fish and snails for their nutriment, and in consequence of this great supply of food their propagation by runners is very rapid, so that I have found it necessary to weed out this vegetable member of the series, and thus prevent it from becoming too extended, as I conceived this would interfere with the health of the fish, inasmuch as there would consequently be more decaying vegetable matter than the snails present could remove. It is true that

this might be remedied by increasing the number of snails which would no doubt effect the object, but the increase in these two members of the arrangement must, in such a case, be continually going on, so that the removal of the plant is the least troublesome course. Thus in the spring of 1850, twenty-eight healthy plants were weeded out; and in the spring of 1851, thirty-five more were removed. The prolific growth of this plant may be further illustrated by the observation made during the last summer, on the rapid elongation of the silky, spiral, flower-stem, which was found by actual measurement to have increased in length 14 inches during twenty-four hours; the total extent was 5 feet, and as soon as the flower expanded itself the growth of the stem ceased altogether. At present I am attempting the same kind of arrangement with a confined portion of sea water, employing some of the green seaweeds as the vegetable members of the circle, and the common wrinkle or wulk to represent the water snails."—(*Gardeners' Magazine of Botany*)

HARDY CONIFERS.

**SAXE-GOTHEA CONSPICUA** (Conspicuous Saxe-Gothæa).—*Nat. Ord.*, Coniferae. *Linn.*, Monœcia Monadelphia.—This plant, which has been named in honour of his Royal Highness the Prince Consort, is a very beautiful, hardy, evergreen tree, growing 30 feet high, and in its foliage and habit of growth, resembling the common Yew tree. It is, in truth, intermediate between the Yew tribe and the coniferous plants, having, as Dr. Lindley has remarked, the male flowers of a Podocarp, the

female of a Dammar, the fruit of a Juniper, and the seed of a Dacrydium. It is described as a tree of beautiful growth, and will, no doubt, rank as one of our most highly-valued hardy evergreen trees affording also a useful timber. It inhabits the Andes of Patagonia, ascending from the summer snow-line to that of perpetual snow, and was introduced in 1819 by Messrs. Veitch, of Exeter and Chelsea.

**FITZ-ROYA PATAGONICA** (Patagonian Fitz-Roya).—*Nat. Ord.*

1. SAXE-GOTHEA CONSPICUA.

2. FITZ-ROYA PATAGONICA.

3. ARAUCARIA COOKII.

Coniferae. *Linn.*, Monœcia Polyandria.—This is a fine hardy evergreen sub-antarctic tree, forming, when young, a graceful evergreen shrub, but growing to a magnificent size (100 feet high, and 8 feet diameter) in its native regions. The leaves of young plants are spreading, linear acute, decussate, with two glaucous lines on the under side. When they become older, the leaves have the character of triangular sessile closely imbricated scales. It is from the Andes of Patagonia, and was introduced

in 1819 by Messrs. Veitch. Dr. Lindley remarks, that "Saxe-Gothæa conspicua, Fitz-Roya patagonica, Libocedrus tetragona, and Podocarpus nubicola, are, no doubt, the four most interesting conifers for this country after Araucaria imbricata, which South America produces." It is injured by severe winters.

**ARAUCARIA COOKII** (Captain Cook's Araucaria).—*Nat. Ord.*, Coniferae. *Linn.*, Diœcia Polyandria.—This is a fine evergreen greenhouse tree, with the general appearance of the well-known

*Araucaria excelsa*, but differing from that in having a more compact habit when old, and in being less rigid and graceful while young, in the scales of the cone having a longer and more reflexed mucro, and in their gibbous, not wedge-shaped form; the scales moreover do not terminate in a hard woody truncated extremity, as in *A. excelsa* and *A. Cunninghamii*, but are wholly surrounded by a thin wing. It is naturally a very tall-growing narrow-branched tree, and has been compared to a factory chimney. A native of New Caledonia, whence it was introduced in 1850 by Mr. C. Moore, Superintendent of the Sydney Botanic Garden, under the MS. name of *A. Simpsonii*.—(*Gardeners' Magazine of Botany*.)

### BOX-EDGING DESTROYED BY SALT.

YOU mistook my question about the Box-edging. It was not that it had been planted in November, but that the edging had been clipped in that month, and was nearly all dead. The gardener said it died from the salt put on the walks that it edged; I said from clipping it in November; as, where the Box had not been clipped, the salt had not affected it.—R. F. S.

[That alters the question, particularly in favour of our view—newly-clipped Box being much less liable to be hurt by salt; and it is on a par, as to sound doctrine, to clip Box, Yew, and Privet in November and December, as to clip Thorn-hedges all over the kingdom in June and July. We have done both ways to a great extent, and both ways answer perfectly, yet both are in direct opposition to scientific rules so-called.]

### THE INTERNATIONAL EXHIBITION.

(Continued from page 221.)

IN the classes devoted to architectural and building contrivances, pottery, and glass, we find an assemblage of articles, such as bricks of various shapes and materials, drain and paving tiles, cements, mouldings, corrugated iron and zinc roofing, and samples of different kinds of horticultural glass, &c.

Messrs. F. & G. Rosher have garden edging-tiles of various designs in terra-cotta and artificial stone, prepared with an indurating solution; the colour of one kind, a dull red, is scarcely to our taste, and in some the design appears too ornate for general purposes.

J. F. Howie, Hurlford Fireclay Works, has a garden vase suitable for small gardens, and remarkably cheap; also a poultry-feeding trough, which will be found useful in preventing waste.

Kilner Brothers have edging-tiles of green and purple glass of the forms seen in our advertising columns, with the addition of a flat-topped kind. The pattern No. 2 is still, in our estimation, the best which has been devised for garden purposes, assorting well with straight lines parallel to walls, and being simple and not overloaded with ornament, on which the eye is apt to dwell instead of on the plants, which should constitute the principal feature in a garden, unless, indeed, this be of a highly architectural character.

Messrs. Minton & Co., Stoke-upon-Trent, show majolica garden seats of a barrel form, malachite and gold, white and orange, crimson and blue, &c.; also costly flower-baskets of the same material.

From Mr. Blashfield, Stamford, comes a large collection of articles in terra-cotta, including busts, vases, and fountains, some of which are of extraordinary size, and, from the ease which has been taken in burning, remarkably fine specimens of this ware. We noticed here a very pretty flower-basket, a Mignonette-box emblematical of the four seasons, and terra-cotta paving-squares, which, as we were informed, being each subjected to a pressure of 25 tons, are nonabsorbent and very durable. Many thousands of these are laid down on Westminster Bridge.

—THE CENTRAL COTTAGE IMPROVEMENT SOCIETY, 37, Arundel Street, which has been instituted with the laudable object of providing better house-accommodation for the labouring classes and improving their existing dwellings, exhibit the models of a pair of cottages which have been erected outside the building, designed more particularly to meet the wants of artisans. They contain four rooms—a sitting-room 12 feet by 10 feet; kitchen 12 feet by 9 feet, fitted-up with oven and boiler-range; and two bedrooms—one 12 feet by 10 feet, the other 12 feet by 9 feet; in addition to which there are a store-closet under the stairs, and a washhouse 8½ feet by 7¼ feet, with copper, fireclay oven,

sink, and dresser. It will thus be seen that these cottages are very commodious and well calculated to meet the wants of the class they are intended for; and, costing about £220 the pair, they would pay a good percentage on the capital invested. The Society has also published designs for four-roomed cottages not quite so large nor provided with the same amount of conveniences, which have been built for from £160 to £180 the pair. A comfortable dwelling with a piece of garden attached is conducive to the morality, health, and industry of its inmates, thus rendering them more valuable members of the community. When a man comes home from his day's labour he requires rest, or at least change of employment, which is a kind of rest; but where the number of rooms is inadequate the family is crowded together in the living apartment, in which at the same time various household operations are being carried on; comfort is destroyed; he cannot profitably occupy either mind or body; he seeks recreation elsewhere, and becomes careless of home. On the other hand, where the labourer has a comfortable dwelling with a piece of ground, he can, after having recruited his strength, amuse himself in his garden, which becomes a savings-bank of labour, paying back good interest in the shape of various articles of necessity and luxury which would either have to be bought or done without.

2387. KEY, E. S., *Sharrington*.—Models of cottages. One of these is similar to that erected in Hyde Park in 1851; the others would, doubtless, answer well for agricultural labourers, costing from £120 to £180 the pair. Some of the bedrooms might be advantageously increased in size; those in No. 3, 9 feet 6 inches by 10 feet, are too small; but one of those in No. 4 is 13 feet by 10 feet, which is very good; but another is only 11 feet by 6 feet: much, however, would depend on the height of the ceiling.

In the iron and general hardware department there is but little of interest in a horticultural point of view. There are several exhibitions of galvanised and painted wire, forming archways for training Roses and other plants upon, seed-protectors, flower-stands, baskets, &c., exhibiting a variety of designs, some of which are very elaborate. Very good specimens of this description of work are shown by Reynolds, of New Compton Street; Geddes, of Manchester; Walker & Clark; Richards and Co., Oxford Street; and Harriet West, Euston Road. Spades and draining-tools, as used in different counties, are also shown in this class by Watkin & Co., Stourbridge.

Among the cutlery and edge-tools, F. Parkes & Co., Birmingham, show their steel forks, which are now largely employed in the London market gardens instead of the spade in preparing the ground for certain crops; also draining tools, spades, and bill-hooks. R. Thomas, of the same town, exhibits axes, hedge-shears, bill-hooks, &c.; M. Eaton, Driffield, hedge-pruning hooks of various forms, one of which has a V-shaped head, with which a branch can be cut by an upward thrust; and Waldrow & Sons, Bellbroughton, scythes as used in different parts of England, in Scotland, and the south of Ireland, only slight differences in the form and dimensions existing between the different kinds. From Gilpin & Co., Cannock, come hoes, Dutch and crane-necked, steel forks, hedge-bills, axes, and edging-irons; and lastly, from Saynor & Cooke, of Sheffield, hedge and edging-shears, parrot-bills, pruning-shears, and garden knives. Among the latter are knives for pruning, budding, and grafting in great variety, and, doubtless, of excellent quality; but what is singular, we did not notice among them a single pruning-knife with a fixed blade—a kind which is more useful and durable than any other where there is much pruning and where strong wood has to be cut out. This is the only exhibition of garden cutlery which we have been able to find in the British portion of the building, unless we dignify by that name two vegetable knives which are to be seen in one of the cases. The excellence of British cutlery for gardening purposes is well known, and it is a matter of regret that this branch of manufacture should not have been brought forward with that prominence which its importance entitles it to.

This subject reminds us of another great shortcoming—the deficiency there is in the display of horticultural tools and implements generally. The spade, for instance, is a tool in the making of which we are excelled by no other nation—it is hardly to be found. Then we have pickaxes and grubbingaxes, and rakes and hoes, the various modifications of the latter peculiarly well adapted for different crops, as well as barrows and baskets for market and other purposes; but these articles are either not shown at all, very partially so, or, like many other things in

this Exhibition, in such a way that no opinion of their merits can be formed. From the examination of such tools foreigners and our own colonists would have derived great advantage; for, having seen the superiority of our implements, they would not be slow in bringing them into use, benefiting themselves by the saving of labour and our manufacturers by an increased demand.

As the fact has not as yet been noticed by the daily Press, we will mention that there has been just added to the Exhibition a case of Japanese silk from Lord James Hay.

To this and the Ailanthus silk, exhibited by M. Guérin-Ménéville in the French department, we shall refer in future reports.  
(To be continued.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

AVOID getting on the ground while in a wet state, clear all the Brassica tribe from dead leaves, and where slugs are very numerous lime the whole of the garden during damp weather. *Cabbage*, sow a good breadth of some dwarf and compact sorts for early Coleworts. *Carrots*, sow a bed of the Horn. Loosen the earth between the main crops where it is battered down hard by the late heavy rains. *Celery*, the earth should be loosened about the plants where it appears crusted. *Endive*, make a full sowing. As soon as the plants are a few inches high mow the top of the leaves off, cutting about one-third of the leaves away. This will stiffen the plant and cause much heart to develop itself, and also enable them to bear transplanting better. *Mushrooms*, this is a good time to make spawn for winter and spring use. After the bricks are made and partially dried, they may be placed in layers in an open shed, with a thin layer of spawn from the old beds which have done bearing, between each course, the whole to be afterwards covered with dung sufficient to keep it moist and warm. *Small Salad*, keep up a succession by repeated sowings in the open ground in a shady spot. *Spinach*, it is necessary to sow once a fortnight, let the weather be what it may, as it so soon runs to seed. *Turnips*, this is a good time for a liberal sowing of the Dutch or Stone sort.

### FLOWER GARDEN.

Pay attention to the stirring of the soil amongst the plants in beds and borders, such attention to be continued until the plants have nearly covered the surface of the beds. Remove all suckers from Rose trees, and keep a sharp look-out after insects, use all means at hand to destroy them. As evergreens have now done shedding their leaves for a while, a general clearance should take place in dressed grounds. As Auriculas are often at this season of the year attacked by the green fly, it is advisable to remove them with a camel-hair brush, keep the plants in the shade, and water them occasionally. As the capsules of seed become of a brownish tint gather them with a stalk. Tie eight or nine together, and let them dry carefully, after which put the heads in small paper bags, and hang them up in a cool, airy place until they are wanted to be sown. The principal part of the blooms of Ranunculuses will now be past their best; as the grass withers the roots should be taken up, for none is more easily excited into growth, and should they emit fibres again the danger of losing them is imminent. Attend carefully to the Dahlias as they grow, and do not neglect tying-up the shoots to stakes, as they are easily broken by the wind, and the plants ruined for the season.

### FRUIT GARDEN.

Those who understand the importance of a thorough ripening of the wood of all wall and espalier trees, will, no doubt, pay attention to the early thinning and training of the branches. It is unreasonable to expect Peach and other wall trees to perfect this process when the young wood is left dangling from the wall until August. The practice to be recommended for Pears at this period is to cut out a few of the watery and luxuriant shoots as a slight thinning, to equalise the light, then to tie down on the old stems, or to nail down a regular supply of the brownest, shortest-jointed, and earliest-made wood, and finally to stop the points of all the remainder left as breastwood. The latter if totally disbudded now would cause the embryo fruit-buds for the next year to burst, whereas, if stopped they will cease to obstruct the light in an unnecessary degree, and will operate as safety-valves for a period. In the early part of August these foreright shoots to be cut back to about 5 inches or 6 inches in length. From that period all the sunlight possible will be wanted to perfect fruit-buds for the ensuing season.

### STOVE.

The prevailing dull weather will render the use of the syriug less frequently necessary. Atmospheric humidity may be sustained by frequently damping the house. Many of the showy specimens coming into bloom here may now be removed to the conservatory or greenhouse. *Clerodendrons*, *Erythrinas*, *Gardenias*, *Ixoras*, *Jasminums*, *Liliums*, *Pergularias*, *Plumbagos*, *Stephanotes*, &c., are of this class. By removing them they will allow more room to the young and remaining stock, and where their beauty will be longer preserved in the more moderate temperature of the conservatory or greenhouse. Many of the basket Orchids will soon be protruding their roots through the moss or soil, and a little additional fibrous peat or moss should be added in due time.

### GREENHOUSE AND CONSERVATORY.

Now is the time to encourage a rapid and sturdy growth in *Corræas*, *Chorozemas*, *Ericas*, *Leschenaultias*, *Pimeleas*, *Polygalas*, &c. A constant stopping of gross shoots will be necessary, in order to equalise the sap, and to encourage the lower parts of the plants liberal shifts to be given during their season of active growth, that the pots may be pretty well filled with roots before the approach of winter, by which stagnation in the soil is most likely to be avoided. The soil for general use to consist of three parts fibrous sandy heath soil in a lumpy state to one part of turfy loam, with a good sprinkling of charcoal. The crocks to be carefully placed to provide various outlets for the water, these to be covered with smaller sizes of pounded crocks, and, finally, the rough of the compost to place the ball on.

### PITS AND FRAMES.

As a guide to select for propagation, let cuttings of all soft-wooded and quick-growing plants be selected of a somewhat firm character, and those from hardwooded plants in rather a young state—that is, the newly-made wood with full-grown leaves and beginning to turn somewhat brown at the base.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

SOWED succession of Peas in hopes of a fine autumn; thinned *Turnips*, and sowed more: the only means for having crisp, sweet bulbs is to sow often, a little at a time, and to use them young. By July and August more breadths may be sown. The Strap-leaved and the American Red Top are the two best that have come in my way. It is no use specifying yellow-fleshed ones, cooks will not use them, and ladies dislike them at table; but amateurs who can dare to be singular have a treat before them in the little yellow Maltese, and some others. Gardeners, if they wish a quiet life, whatever they have besides, should keep a supply of what the artistes of the kitchen chiefly need and like. So far as my experience goes, they would do more with varieties and novelties, if ladies and gentlemen would permit them. A yellow Turnip at many a table, whatever the flavour, would be ranked as among the vandalisms and vulgarisms that were on no account to be approachable. Cleared *Celery*-trenehes of the remains of bedding plants, to get out strong and large plants of the white Incomparable *Celery*, the best and most economical I have met with, the flavour being so sweet; the plants are so compact and dwarf, that 12 inches, or even 10 inches, when late, will be far enough apart, plant from plant in beds holding three or four rows, and then if the plant should be 15 inches in height, you may send 12 inches of that length to table. Last season I do not think I had a single run or hollow head. In gardens of many acres it is all right enough to grow *Celery* some 24 inches to 36 inches in height; but for small gardens as those we chiefly write for, this little, white, crisp Incomparable is the best, as a few square yards will furnish a nice lot for the bread and cheese for supper. Have strong plants of *Tomatoes*, but find we must use the Kiddean system chiefly, and plant them on the ground, training them out like ridge Cucumbers, only keeping them more thin. Attended to herbs of various kinds; pricked out seedlings, and transplanted cuttings of *Sage*, *Tarragon*, &c.; staked Scarlet Runners as the weather would let us get at them without potching the soil.

### FRUIT GARDEN.

Finished strawing and littering *Strauberies*; turned out another lot of forced ones. The first forced are beginning to show bloom again, which will just come in after such late kinds as Elton and Eleanor are gone. Before strawing, put a little

soot and lime close to the rows to start slugs and ants; would have used a little guano for the latter if we had happened to have any, but all such manures cost direct outlay, whilst we obtain the others chiefly by looking after them at flue-and-chimney-sweeping times. Top-dressed Peas and other trees in pots with an inch of decaying horse-droppings; would give a couple of inches to the Vine-borders if we were able to do it, so that the rain should wash it in. There has yet been little occasion for manure-watering, as there has been more from the heavens than was quite agreeable. The earliest Vines have not yet had the whole covering of litter removed from the borders, and a little manual virtue would be washed into them. The late-house has several times, before a shower, had a sprinkling of superphosphate of lime, which I also could use more freely than I do, and which everything seems to like. *Figs* ripening and swelling fast have had a good soaking of farmyard manure, reduced when too strong; the wood thinned and stopped for second crop, and plenty of air given after such watering to prevent any of the Figs damping at the ends.

Fig bushes do capitally in pots if properly attended to, but they generally do best when the gardener allows no one to touch them but himself. If the soil gets waterlogged when the fruit is swelling, or gets suddenly dry for any time, every fruit runs the risk of dropping. I once saw a number of pots partly plunged, well set with fruit swelling kindly; but all at once they dropped, and without any apparent cause, for the leaves showed no distress, and the surface of the pot seemed damp for anything. But on lifting the pot and feeling its weight, ringing its sides, and sticking fingers and stick down into the soil, the cause was too apparent; the bulk of the soil about the roots was dry—the moist surface not only deceived the gardener, but prevented the dry roots raising moisture from the bed in which the pots were plunged. Two or three such visits, and the first crop of Figs will drop to a certainty. With ample drainage, and a little sun, it is hardly possible to injure by overwatering in such circumstances; though, of course, when not needed, extra watering would be labour thrown away.

Figs out of doors, showing well, have been regulated, and some strong shoots stopped. Whatever stopping in their case is needed, however, should be done earlier, as late stopping has a tendency to produce shoots when there is not time nor sun enough to ripen them, and next year such shoots will be destitute of fruit. Stopping much now, too, has a tendency in out-of-door Figs, if shoots are not thrown out, to cause young fruit to show themselves, which, unless in extraordinary seasons, will never come to anything, but will drop in winter. It is quite as well if no fruit shows on the young wood, as none, if protected, can hardly be saved for next season, if larger than Peas at the approach of winter. The great object is to have them not larger than pins' heads; if larger, they should be neatly cut off, and then there may be some young ones that will come from the same joint. I am speaking of north of London and common situations, and not of places in the south of England where the Fig has made itself a native, and bears profusely with little more attention than is necessary for a Currant bush.

Went over *Apricot trees*—a disheartening job, some of the wood poor, and little fruit; the continued wet weather having done more injury to the blossom than even the frost. Hope to get them under glass some day, and before that time have no hope of certainty in our cold place. Even when a crop was obtained in a fine season, it was a rarity to have them thoroughly ripened all through; as the one half would be melting and rich, and the other half greenish and hard. Glass at 2d. per foot, with plenty of ventilation, would give us something like certainty; and, in a few years, would be less cost than bothering with simpler modes of perfection.

The great advantages of glass are, that it secures all the light possible and dryness to the plants when in bloom, to say nothing of a still atmosphere in severe frost. Pretty well finished thinning the fruit of Peaches and Nectarines which, both under glass and exposed, set in many places like ropes of Onions; showing, in the latter case, how much more hardy they are than the Apricot. Those out of doors, however, had less rain when in bloom. Picked caterpillars from Pear trees so infested, and nipped the points of the summer shoots, leaving a number of points untouched to carry on the running, and prevent the starting of fruit-buds.

Removed extra wood from *Cherries*. Nipped the points of what was wanted for fruit next season, and dipped and brushed

with tobacco water where there was any appearance of black fly, and in a day afterwards engaged hard with sulphur and lime water. Netted also, as some of the *Cherries* were changing, and found that all the birds praised as caterpillar-killers were more inclined to take a half-ripened Cherry, or dig their bills into a dozen of the best Strawberries, than rip up leaves to get the gentlemen safely rolled up there. I am not insensible, however, to their merits as insect-destroyers. One of the greatest pests in the garden is the tomtit in the spring, and he looks so knowing and complacent-like at you, that it goes against the grain to knock him over. Let but a dozen of them have free scope in a garden when the buds are moving, and what desolations of bare wood they will leave in their track. But at this season there can be no mistake as to their good service, as the quantities of caterpillars and various kinds of aphids they carry to their young are amazing. Nipped the points of dwarf Pear and Apple trees with the thumb and finger. This is easily done when soft, throws the sap back from fruit-buds, and gives scarcely any check to the tree.

#### FLOWER DEPARTMENT.

Much the same as last week. For hardwooded plants out of doors, see page 229. Potted some old and chiefly young *Fuchsias* into rough loam lightened with road drift and enriched with old cowdung, horse-droppings, and old Mushroom dung, &c. Kept filling up the edgings of flower-borders and beds, and transplanting China Asters and Stocks, which, pricked out as previously advised, and lifted with balls will scarcely know the moving. Finished beds and lines of *Zinnias*, which I hope will do well. When thus pricked out and lifted of a good size they are generally worth looking at. Secured forward *Phloxes*, *Hollyhocks*, *Roses* against pillars, &c., and as we have not been able as yet to mow the whole lawn and get it in order, have got everything passable near the house, and kept a broad swathe by all the walks close cut. This I do not only for neatness, but for ultimate economy. Walks not well kept had better be sown down at once. Nothing gives a bad impression of a place sooner than rough, weedy, dirty walks. To keep them well, is just another word for keeping them economically. To do the latter, and lawn at the sides, no grass or *Daisies* ought to be allowed to seed near them, or picking, salting, or something of that kind must be interminable, and often salting will spoil the finest walks, making them as retentive of moisture as a sponge. When a lawn is so large that to attend to other things it cannot always be shot grass—say until the end of June, it will be found ultimately very economical to keep a good swathe at the sides of the walks mowed regularly.—R. F.

MISTLETOE ON THE MAPLE AND ACACIA.—Mistletoe is growing here on trees not mentioned in your Journal—viz., the *Acer campestre*, or common Maple; and a beautiful specimen is on the common *Acacia*, now looking most luxuriant, and measuring 2 feet in diameter. Locality, three miles from Worcester.—J. M. H.

#### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

GERANIUM AND PELARGONIUM (*Patelin*).—Many minor distinctions have been made, but are not sufficiently invariable to sustain the title of a distinction. The only one we know is that the *Geranium* has no nectary, and the *Pelargonium* has a nectary adherent to the peduncle. It is impossible to answer the query about the pump and hose without more particulars.

WOODLIE IN CUCUMBER-BEDS (*Cranford*).—There is no mode of destroying them without breaking up the beds. Gas lime sprinkled about their haunts will expel them, but it must be frequently renewed and care taken that it does not injure the plants. Two pieces of board or tiles kept about one-eighth of an inch apart form a good trap. Toads kept in the frame will destroy the woodlice.

**ZINC LARVIS (W. H. R.).**—The zinc will become white by oxidising—that is, combining with the oxygen of the air, but it ought not to render the writing illegible. To prevent the oxidising try putting varnish over the face of the label after you have written upon it and the letters have become black.

**HEATING BY GAS (A Lady Gardener).**—For a small greenhouse we have employed a common gas stove with two circles of jets, one circle 12 inches in diameter, and the other circle within it 9 inches in diameter. The pipe, 3 inches in diameter, from the top of the stove, passed along the entire length, gradually rising all the way.

**COCA-NUT FIBRE REFUSE FOR CUTTINGS (Idem).**—As cuttings may be struck even in wet moss, we have little doubt that they would do likewise in cocoa-nut fibre refuse; but we should employ had light loam and half refuse mixed thoroughly together, and passed through a sieve afterwards.

**ORCHIDS AND PLANT-CASES (C. B.).**—You must say what kind of Orchids you want—natives of England or of any particular country abroad; for some stove Orchids, intermediate stove Orchids, greenhouse Orchids, and hardy Orchids can be grown in any good plant-case.

**ZOOLOGICAL GARDENS (J. D. C.).**—We remember Hoel's "Ode to Mr. Vigors" perfectly well. It was not "a satire," but a good humoured jeu d'esprit. Here it is, extracted from "The Comic Annual:"—

"What is your gardening volume?—like old Mawe's?"

Containing rules for cultivating brutes

Like fruits,

Through April, May, or June;

As thus—now rake your lions' manes, and prune

Your tigers' claws;

About the middle of the month, if fair,

Give your chameleons air;

Choose shady walls for owls;

Water your fowls,

And plant your leopards in the sunniest spots;

Earth up your beavers; train your bears to climb;

Thin out your elephants at this time,

And set some early kangaroos in pots;

In some warm shelter'd place

Prepare a hotbed for the boar race,

Leaving them room to swell;

Prick out your porcupines, and blanch your ermine;

Stick out opossums; trim your monkeys well;

And 'destroy all vermin.'"

**SPERGULA PILIFERA**—USE OF OLD TURF (*Darby and Joan*).—As you are so satisfied with the Spergula on your terrace, you are quite right in your idea of flaying off the coarse grass of that piece of ground and laying it all down in Spergula after a good trenching and a winter's frost. But do not burn the rough sods; that is a most wasteful garden plan even if the surface were brick earth. Let the turf be cut rather thicker than for turving; then pile it all up in a heap out behind the shrubs; then let it rot and mellow; and no loam will be better after a while for potting with. The best loam we ever potted with was from a "bank" of surface clay, turf, and shingles, which was thrown up and stood so for eighteen years at Claygate—the exact place where the Claygate Pearmain Apple was found. The clay there is the stiffest in England, but it has mellow loam mellow as corn flour; and it takes just half and half of very rotten cocoa-nut refuse to make it "fine-Apple loam," and fit for most plants when rightly reduced; so you see the value of your rough turf. But if you burn it there will be no more goodness from it than from any burnt common stuff. Pray do not disgrace the 12 feet long and 5 feet wide of your beautiful Spergula by cutting it into little bits of beds with b. by beds in them. Such a piece of perfect Spergula will be of itself the gayest flower-bed you ever saw in the height of summer.

**MOLEWORM (G. P. Yorkshire).**—This is commonly known in England as the Mole. Your name is nearer the Anglo-Saxon name, derived in that language from *Mold*, earth, and *weorpan*, to throw up. The mole lives upon worms and underground insects which it finds near the roots of plants. The only way to destroy moles is by trapping them. You may buy mole-traps of iron at the ironmongers, but one of wood and wire is usually employed. We will give a drawing of this next week.

**FARMING INFORMATION (Intending Farmer).**—There is no such journal as you inquire about. No editor will undertake to teach you farming. Buy our "How to Farm Two Acres and Make the Most of Them" That with our "Poultry-Book for the Many," will give you all the general information you need. As for buying stock, the best guide you could have would be a farmer near where you settle. Make his acquaintance and ask his advice.

**ANTS IN MELON-BEDS (Flax).**—Placing a little guano round the sides of your Melon and Cucumber beds, or watering with weak guano water, an ounce to the gallon, will send all the ants off. We have found quicklime and fresh soot mixed together do much the same thing. Ants threaten to be most mischievous this year; they are seizing the Strawberry-quarters in some places. The tall sucker of the American Blackberry should have its point nipped out, and it will most likely bear plentifully next season.

**GRUB ON CELERY LEAVES (J. C.).**—They are the grubs of the Celery Fly (*Tephritis onopordinis*). Unless very numerous they will not perceptibly injure the plants. Pick off the leaves attacked and destroy them, or the grubs will give birth to flies and the mischief be increased.

**TAR FOR DESTROYING GOOSEBERRY CATERPILLARS (Rebecca).**—Neither Mr. Candlin, at page 194, nor the correspondent in Vol. XX., quoted by him, mentions whether they employed gas or archangel tar. We presume the latter.

**BEAUTY AND UTILITY COMBINED.**—"In your last issue you print a very interesting letter from a correspondent signing himself 'L.' As he appears to be a real lover of gardening, and has succeeded so well with his small stores with chambers surrounding them, perhaps he would not object to show a novice his mode of proceeding, as I cannot understand sufficient from his description to enable me to construct such a system of heating.—B. West, 69, Old Broad Street."

[Will "L." be so kind as to communicate with our correspondent, who adds, that he would not mind travelling thirty or more miles to see the plan adopted by "L."]

**VINES LUXURIANT BUT UNPROFITFUL (R. W. P.).**—We are afraid your surmises as to the roots are right, and, if so, lifting them would be the grand

remedy. This might not be approved of in the case of such fine-looking vines. We are also doubtful if your wood was so well ripened in such circumstances. The first palliative is by saucers, &c., to prevent the waterings soaking the border. The next is to open a drain 4 feet deep in front of it and fill up with rubble. This will secure dryness, and we would advise you next season, in your circumstances, to have short rods on your Vines—say of four to six or more joints on each shoot, instead of spurring back, and then when you have selected your fruit you may prune more and the Vines are in leaf. If we are right as to the causes, until the drains &c., take effect, you will be more sure by the rod-system than by spur-pruning.

**ROSE PRIZES (T. Parsons).**—We have no right to interfere. We never make any reference to the society you mention; but if we did, we should only say if an exhibitor felt aggrieved, he must complain to the committee.

**EARTHING-UP POTATOES (An Amateur).**—It is quite true that Mr. Keane in our Number of June 10th says, "Earth-up Potatoes immediately after rain;" and that in the "Garden Manual" the instructions given are, "Do not earth-up at all, as earthing-up diminishes the crop one-fourth." With the author of the latter we coincide in opinion. You can easily try the experiment; earth-up some of your crop, and I leave some unearthed. The results will show if the labor of earthing-up is not worse than thrown away.

**EPHYGIUM LEUCOGOTRYS (Subscriber, Z.).**—It is a native of the Duppla Hills, in north-eastern Bengal. It is a greenhouse evergreen shrub, flowering in summer, and ripening its clusters of white, wax-like berries in autumn. A soil of equal parts peat, sharp sand, and light loam will suit it.

**RED SPIDER IN VINERY (One in Distress).**—As the Grapes are ripening, you can do no better than keep the path well watered daily, paint the stems with clay and flowers of sulphur paint, sprinkle some of the sulphur on the surface of the borders, and dab some of the sulphur paint on the flue at the end farthest from the fire. If the air of the house is impregnated with the fumes of sulphur, without burning the sulphur, they are fatal to red spider.

**VARIETATED RUMEX (J. Shield).**—Your *Rumex obtusifolius*, a wild British Dock, would be as conspicuous in rockeries and the banks of the wilderness, as *Aloesia macrorrhiza* is in the stores and show-rooms, for it is marked very much on the same model, and we think we have seen the like of it once with Mr. Salter, who, if he has not got it now, would probably give you a collection of fine *Chrysanthemums* for it.

**DOUBLE PANSY (J. T.).**—This is a "Good Gracious" Pansy at last. The very finest Pansy we have ever set an eye upon. Pray communicate some information about how you got it for our register. It looks just as if the Magpie Pansy (the *Torenia*-island-like Pansy), was turned double, and to double the size at one turn. It is as double as the most double *Ranunculus*, and is so heavy that four blooms cost 6d. through the post. Let us know more about it, for it is a very strikingly beautiful flower.

**PRESERVING GRAPE (West House).**—The best of all modes of preserving Grapes as long as possible in an unshrivelled state is to leave the bunches on the Vine, keeping the vine dry and well ventilated. If they must be cut, hang them in a dark, dry, cold closet, suspending them by a string tied to the lowest end of the bunch, as the reversed position keeps the berries as much separated as possible. Mr. Thompson, of Dalkeith, a first authority, cuts off the spur with the bunch, and thrusts the cut end into a thick slice of Mungold Wurtzel; half a small Turnip might do as well. Which plan is adopted they should be looked at almost daily, and each berry cut off by the help of a pair of sharp-pointed scissors immediately any mould appears upon it.

**VINE AND FIO LEAVES BROWN-SPOTTED (A Subscriber, Gt. Staughton).**—If only a few of the leaves are blotched like those you enclose, the damage is occasioned by irregularities in the glass which, acting as lenses, concentrate the rays of the sun and scorch the leaves. The best remedy for this will be to paint over the inside of the glass with a thin mixture of size, whitening, and a little Prussian blue to give an agreeable tone to the colouring. If the blotching of the leaves is general, it is occasioned by the roots being defective; probably occasioned by the excessively rich compost you employed. The remedy in that case will be to remove the compost as much as possible from about the roots, to mix it with an equal proportion of bricklayers' limy rubbish, and refill the border with that mixture.

**NAMES OF PLANTS (G. R. B. Oringham).**—It is the Palmate-leaved Ivy, *Hedera digitata*. (*C. R. Leeds*).—*Franciscea calycina* in a stunted condition. It is a stove plant. (*H. G. B.*).—1, *Betula alba laciniata*; 2, *Andromeda speciosa*; 3, *Lonicera Ledebourii*. (*L. B.*).—1, *Spiraea arifolia*; 2, *Cornus sanguinea*; 3, the white *Thalictrum aquilegifolium* if not tuberous-rooted; 4, *Callistachys ovata*. (*A. X.*).—1 and 2, *Cystopteris fragilis*; 3, *Coleonema pulchrum*; 4, *Sarracenia purpurea*. (*Chesterfield*).—1, *Salisbtria adiantifolia*; 2, *Lelium bifolium*; 3, *Andromeda polifolia*; 4, *Astrantia major*; 5, *Spiraea levigata*. (*Verescens*).—The rock plant is *Nepeta micrantha*. The leaf seems to be that of a *Fic. Hogg's* "Vegetable Kingdom" will suit you. *Lapageria rosea* will do in your greenhouse. (*Dublin*).—Your basket plant is probably *Senecio mikanooides*, but it was much crushed. (*Crauefer*).—The leaf is from a *Crassula*, probably *C. arborescens*. (*L. W.*).—*Diosma cricoides*. (*Rev. B. Lincke*).—*Periploca græca*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

JUNE 26th and 27th. SUEZOLK (Woodbridge). *Secs.*, Mr. J. Loder, jun. Entries close June 5th.

JULY 3rd. PNESSCOT. *Secs.*, Mr. James Beesley. Entries close June 21st.

JULY 9th, 10th, and 11th. LEENS and WEST RIDING. *Secs.*, G. Newton and J. Wade. Entries close June 21st.

AUGUST 2nd, 4th, and 5th. SHEFFIELD. *Secs.*, Mr. George Westerholm, 49, Queen Street.

SEPT. 4th. WAKEFIELD and WEST RIDING. *Secs.*, Mr. J. Cresland, jun. Entries close August 23.

SEPTEMBER 9th. WORSLEY and ARMLEY (near Leeds). *Secs.*, Mr. Robert Hoyle, Armley, near Leeds.

DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Secs.*, John B. Lythall 14, Temple Street, Birmingham.

POULTRY AND ITS PRODUCE.

THERE was a time—and compared with the age of a nation and civilisation, not so very long since—when to enjoy the luxury of a salad or a cauliflower it was necessary for the wealthy and the titled, and even for the Sovereign herself, to send an express to the continent in order to obtain it. Doubtless, the farmers of that day thought it beneath the dignity of their cloth to devote any portion of their time, attention, or land to so insignificant and ignoble a species of produce. It might do very well for the poor people of France and the Low Countries to fiddle-faddle themselves about such trifling productions, but an English farmer had something more worthy of his attention to look after than pot-herbs and lettuces, with their accompaniments. But that day is gone by, and these things are cultivated in old England with as much success and to as great an extent as on the continent; and any farmer has now only to step out at his back door in the kitchen garden attached to every house in the country to supply himself with whatever of culinary or other vegetables he delights in.

There are, however, still articles of daily consumption, the production of which in England is far from being commensurate with the consumption or with the capabilities of the soil, and for a large supply of which we are indebted to our neighbours, the French and Belgians, to an extent that will appear apocryphal to those who are not initiated into the history and mystery of the Board of Trade returns. We refer to poultry and its produce, in the raising of which the British farmers are far behind their neighbours.

A stimulus, it is true, has been given to this branch of rural economy the last few years, but at present the "poultry mania," as it is justly termed, is chiefly confined to amateur breeders. In order to extend the "poultry mania" amongst the agricultural classes, or rather to induce them to pay greater attention to the business of rearing and fattening fowls for the market, we will place before them the returns of the Board of Trade of the quantity of eggs and poultry imported; the former for the last ten years, whilst the latter, since the reduction of the duty not being inserted in the returns, we can only give them for a limited period.

With regard to eggs, then, the following are the average numbers per annum imported since 1828, taking every five years:—

AVERAGE ANNUAL IMPORT OF EGGS FROM	
1828 to 1832 inclu five	61,431,062
1833 to 1837	68,493,516
1838 to 1842	91,393,732
1843 to 1847	72,690,051
1848 to 1852	103,120,221
1853 to 1857	147,342,219
1858 to 1861	163,581,140

There has, therefore, been a gradual increase in the supply ever since 1828, with the exception of the fourth average; but to show the enormous extent to which it has now reached, we may state that whereas in 1833 the quantity imported was 70,415,931, in 1861 it reached 203,313,360. And, if we reckon the cost price of these at 4*l.* per dozen, their value is £282,379 10*s.*—upwards of a quarter million sterling for a species of produce that could with the greatest ease be raised at home. With regard to the poultry imported, there is reason to believe that it has increased in an equal proportion. The returns have not noticed them since 1856, but for that and the two previous years the imports were in value as follows:—

1854	£38,874
1855	42,075
1856	48,230

So that the increase was about 25 per cent. on those three years, and has probably been quite in an equal proportion since, making up an aggregate amount for 1861 of fully £360,000 for poultry and eggs.

The number of eggs sent from France is not so surprising, when we take into account that every farmer has his *basse-cour*, or fowl-yard, the produce of which constitutes no inconsiderable item in the accounts of the year. M. de Lavergne, in comparing the produce of the United Kingdom with that of France, states, that while the poultry of the former amounts to only 20 million francs (£800,000), that of the latter country amounts to 200 million francs (or £8,000,000 sterling); there is, therefore, a large margin left from the home consumption to be exported.

That the farmers would find it to their interest to cultivate more sedulously this branch of rural economy there cannot be a doubt. In London there is always a demand. Like all other

provisions, there are different periods for different prices, and here it is that poultry shows do much good in offering premiums for early maturity. If those who have facilities for rearing chickens would do so in January, or even in December, and bring them to market in a fat state in April, May, and June, they cannot fail to receive a remunerating price. Three pounds per dozen is a common value for fowls four months old. At this season, less than two guineas would be ridiculously low.

There is a collateral advantage to the farmer in keeping a large stock of fowls. The inferior grain could then be profitably consumed on the farm at a remunerating price, instead of being subject to the fluctuations of the market. Nor is the dung that would be made an object of no account. It is certain that fowls' dung is exceedingly valuable, and where large numbers are kept a considerable quantity would be made in the year. For the present we leave the subject for the consideration of those whom it concerns, but may probably recur to it on some future occasion.—(Mark Lane Express.)

PIGEONS AT THE BATH AND WEST OF ENGLAND EXHIBITION.

THREE pens belonging to Mr. E. Smith, 18, Steelhouse Lane, Birmingham, never appeared at all in the printed catalogue of the Bath and West of England Society; and in the Judges' award-book are entered only by numbers in pencil: consequently, it is most probable, they were post-entries at the last moment. To the Judges it was never at all known to whom they belonged. The awards were as follow:—

OWLS.—Pen 263*a*, second prize.

TRUMPETERS.—Highly Commended, pen 267*a*.

NUNS.—First prize to pen 279*a*.

These were items waited for during twenty-four hours after the time specified for the entry of the birds, and left even then a confused jumble. This irregularity should be strictly guarded against. No pens should be admitted after the time for entering has passed. Prizes awarded to pens not in the catalogue create suspicion of undue favour.

PROPOSED POULTRY SHOW AT SHEFFIELD.—We see it is stated that the active Committee of a new Society is at work, with a good prospect of success. They have secured an eligible site, and propose to hold the Exhibition during the summer.

DO BEES VARY IN DIFFERENT PARTS OF GREAT BRITAIN?

I HAVE two hives at present in my garden on the same stand, 3 feet apart; one a frame-hive containing a strong swarm of fine yellow bees, lately lived in the neighbourhood of Ealing; the other a common straw hive, with a year-old swarm of small black bees, from the neighbourhood of Woking. Both swarms are English bees, work vigorously, and do not interfere with each other, but vary in form, colour, and temper; the smaller bees being thicker, darker, and quieter than their more taper, brilliant, and demonstrative neighbours.—SURREY HIGHLANDER.

My attention having been drawn to a communication in a recent Number of THE JOURNAL OF HORTICULTURE from Mr. Darwin, entitled "Do bees vary in different parts of Great Britain?" and, being solicited to give my views on the subject, I make the following remarks:—

In the communication I made in your Journal, published May 15, 1860, to which Mr. Darwin refers, I announced to the scientific world the curious and highly interesting fact that a peculiar variety of honey bee was then in my possession, so sensibly different in its appearance and colour from the ordinary bee as to be easily distinguished from it. I propagated this variety of bee both naturally and artificially, but owing to certain fatalities arising principally from the past two adverse seasons, the progeny from the original stock all died out but one, which is still in my possession; but which, unfortunately, is not in the most flourishing condition.

In the article referred to I gave a particular account of this bee, and of its peculiar characteristics. The colony was lodged in a Huber-hive, and therefore I had every facility of internal examination. The queen was large and most brilliantly tinged

with a deep golden colour underneath and around the abdomen, the segments of which were particularly distinct and well defined. The depth and brilliance of colour far surpassed that of any ordinary queen; while the pale thick downy hairs which covered and surrounded the thorax showed very conspicuously. It was at once evident that the peculiarities of the common bee owed their origin to the very marked and distinctive colouring of their queen. In the drone the difference was not so manifest. I may mention that this queen died a natural death in the autumn of 1860, having been for some time previous so languid and feeble as to be scarce able to hold by the combs; she was thus in my possession fully three years. How old she was when she came into my hands I cannot say, but I conjectured she had been bred during the preceding summer. I regret I did not attempt to keep this variety of bee separate from my other hives. Owing to this circumstance, and perhaps from other causes, the distinctive peculiarities became gradually less marked, so that in the stock now possessed, being the third generation, the difference, more especially of the working bee from the ordinary variety, is scarcely discernible. In the second generation even the peculiarities of appearance were sensibly altered, though any ordinary observer might at once distinguish the bee from the common species. Indeed, I have repeatedly tested this by collecting a number of bees from different hives on a honied leaf, along with the grey variety, and placing them at a distance from the apiary in one promiscuous crowd; and have amused my friends by asking them to pick out from amongst the hundreds thus collected together the grey bees, which they were at once enabled to do; and by holding them on the point of the finger would see them fly direct to their hive. The bees of my present stock, which is the third generation, are, as I have already stated, not much different from the ordinary bee; and the curious circumstance is, that some are less marked than others, so that I have a difficulty in distinguishing some of them at all. A great number, however, still retain the traces, though faint, of the original colony. More especially is this the case with regard to the queen; but the altered aspect of both bees and queen is such that very little now remains of their former distinctive characteristics.

I will not attempt here a solution as to the origin of this peculiar variety of bee. In the communication before made, I merely hinted at probabilities, and I am still unable to go beyond mere conjectures. Certainly it is the first and only instance I know of where a marked distinction was ever discovered in the bee cultivated in this country. This leads me, however, to Mr. Darwin's inquiry, "Do bees vary in different parts of Great Britain?" This question I have no hesitation in answering in the negative, notwithstanding the observant Nottinghamshire clergyman and learned French naturalist, referred to by Mr. Darwin, being of a contrary opinion. The black bee alluded to by the celebrated Huber is an instance of how far even renowned naturalists may be carried away and misled by merest trifles. We can scarcely excuse this celebrated observer, even on the score of want of sight; though it is a great palliative to have arrived at such absurd conclusions on this matter, seeing that, according to his own account, there was nothing apparently peculiar in the appearance of the queen which produced the alleged monstrosities. The black bees, however, which have been thus immortalised by the great Huber, were nothing more than superannuated bees whose downy hair had been rubbed off by hard labour and incessant toil—either in collecting from some particular plant, or else from the pressing and wrestling consequent on robbing and plundering some neighbouring hive. From both causes I have often seen the bees become perfectly black and glazed in appearance, and the downy hair almost entirely rubbed off. By coming in contact with any glutinous or resinous substance the bees are often thus altered in appearance, and such was the effect produced on my own bees during a particularly warm season, by their feeding upon the exudation of a resinous fluid from the larch, that great numbers became prematurely old-looking and glazed in appearance, with tattered wings and perfectly disabled.

That bees of certain stocks differ in size from bees of other stocks is a fact not to be disputed, and, also, that they occasionally differ in their tempers is likewise a fact which most apiarists have ample evidence of to their cost; but that these differences of size or temper are sufficient to stamp the bees exhibiting them as a distinct variety, is a proposition too absurd to be for one moment entertained. If such a rule were to be applied to animal life of a higher order, how preposterous the conclusions!

M. Godson, the learned French naturalist before referred to, and the Nottinghamshire clergyman, should have known better. They should know that queens differ greatly in size, that drones differ greatly in size, and that bees differ greatly in size, and that these differences are simply and solely owing to the different sized cells in which they are cradled and reared. I have seen queens and drones not much larger than common bees, and I have seen common bees not half their natural size. But, apart altogether from extremes, there are marked differences as to size among all the three varieties. I had once a queen which was reared in a small royal cell, and a prolific queen she was too, though scarcely larger than a common bee. I could see no difference, however, in the size of her progeny, and even if there should, that difference would, as in the case of bees reared in old comb, disappear with the removal of the cause, the death of the queen or the renewal of the combs; for it is not the common bees that perpetuate their peculiarities. To the queen alone belongs the function of propagating the species. So much for size. Then as to temper. I have heard much of the amiable dispositions of some bees. "They are so gentle, my bees," said an apiarist to me, "they scarcely ever sting;" but in an operation which I saw performed in the apiary of this same person we had ample testimony that these amiable bees could use their weapons like others of their race when occasion so required. The fact is, that the temper of the bees of any stock is entirely influenced by its circumstances and conditions for the time being, so that we shall often find the bees of the same hive at one time irascible and furious, and at another time docile and peaceful. *Ceteris paribus*, I can always deal with a hive with greater freedom and less risk during the early summer when the combs are full of brood, than with the same hive in the autumn, in the midst of heath, engaged principally in storing and amassing honey.

On the whole, therefore, I am decidedly of opinion that no difference of climate or locality in Great Britain has any influence or effect either upon the size, colour, or temper of the honey bee; and that if any differences do exist in the size or temper of the inmates of any particular stock, they must be ascribed to those incidental causes, which being only temporary in themselves, cannot be perpetuated beyond a single generation, and cannot, therefore, constitute a claim to have such a colony exhibiting them designated as a distinct variety of the *Apis mellifera*—J. LOWE, *Edinburgh*.

#### BEE SEASON IN NORTH LANCASHIRE.

SINCE my last communication to you the bee season in this district has been anything but favourable. The month of May was a very wet one; but June up to this date (13th), I think has been worse than the memorable one of 1860. There have only been two days that rain has not fallen: therefore the swarming season has been impeded. The earliest swarm in this district May 15th (last year on the 27th), and there have been a few since in different parts. I had my first swarm the same as last year (June 9th), and two swarms since. It is possible that I should have had one in May, but I made an artificial one on the 27th—my maiden effort at this game; but I succeeded in obtaining a small one, enough for my purpose, as I can strengthen it to any extent at pleasure.

On the 25th of May I received, per rail, the same little box as last year, and upon it "Living Bees, with Care," of which I knew nothing. As might be expected, the lid was soon removed, and to my surprise there was a number of Ligurians. Getting too late for a thorough inspection, matters rested as they were until the next morning, when, to my wondering eye, there issued forth a Ligurian queen bee. What can this mean? Perhaps when the postman arrives he may have something that will solve this mystery. And so it proved: a letter from your valuable correspondent, "A DEVONSHIRE BEE-KEEPER," informing me that he had sent me a present, for which I thank him.

As I have no great opinion of placing strange queens at the head of a stock where there is brood in all stages, I adopted the plan as above. How this was accomplished some, perhaps, may want to know. For such inquirers I state it.

I removed my earliest stock from its stand, and placed an empty hive with the box at the top, separated by perforated zinc. As the day was not a very good one I did not get enough, and they were not satisfied with their adopted mother, if they found her at all, as they made to the hive adjoining; so I

cleared the bees from this, and removed it also. But proceedings were no better; so, as a last resource, I brought the first stock to its old stand, and the bees soon made themselves at home. But this was but of short duration. As soon as they were settled I inverted an empty hive, and placed the stock upon it. Of course, this was not the way to drive them—that is, the most fashionable way at present, but to use the magic fungus, as my great object was not to get the queen. By this means I obtained a little swarm; and whilst in their stupor

I put her Italian majesty to them. I adopted the same plan with the hybridised one last year, and both, I have no doubt, with perfect success. As my little ones have been bearing pollen every favourable opportunity since her introduction, I think she must have commenced her duties immediately, as I had supplied the frames pretty liberally with comb; but I have no intention of disturbing them at present for an ocular demonstration, as comb-building is going on favourably.—A NORTH LANCASHIRE BEE-KEEPER.

### LA FLÈCHE FOWL.

**FIRM**, strongly constituted body, standing proudly on long and sinewy legs and feet, appearing less than it really is, because the feathers are close; all the muscular proportions well developed; black plumage.

Of all the French breeds the La Flèche cock is the tallest; in many respects he is like the Spanish, and, I believe, he is originally the result of a cross between the Spanish and Crève Cœur.\* Others think this breed comes from the Breda, and it must be admitted they have many points in common.

Their *Skin* is white, fine, transparent, and soft; meat short, juicy, delicate, and very easily fattened.

The *Topknot* is formed of a little bunch of feathers, sometimes short and straight, sometimes rather longer and drooping. It rises from the crown of the head behind the comb. The comb is transversal and double. It assumes the form of horns leaning to the front, joined at the base, divided at top, sometimes smooth and pointed, sometimes ramified on the inner sides. A very small comb, likewise double, springs from the top of the nostrils, and stands in front of them. Although not much larger than a pea, this *combling*, which surmounts a small rising formed by the nostrils, contributes much to the remarkable and unique aspect of the head.

\* We are disposed to think it is more likely to be the result of a cross between the Spanish and Malay.

The *Wattles* should be very long and pendent.

The *Ear-lobes* should be very large, and meet under the neck; they should be of a dead white, especially at the breeding season. Of all the breeds that possess the white ear, this has the largest except the Spanish. The tuft of small feathers that covers the ear itself should be black.

The *Nostrils* are very open and unique in their form; they form, at their insertion, the rise from which springs the combling. The beak should be very strong, slightly curved, of a dull grey colour, and yellowish at the end.

*Physiognomy of the Head.*—The La Flèche has a physiognomy peculiar to itself, and which is principally caused by the prominent monticule which forms his nostrils, and which is surmounted by the small comb. The prominence of the comb seems to increase the characteristic depression of the beak, and gives some likeness to a rhinoceros. The comb, divided into horns, suggests the Crève Cœur, and the large white deaf ear the Spanish.

*Colour of the Legs.*—Slate blue, lighter or darker according to age, turning to a deeper leaden grey as the birds get older.

*Weight of the Fowls.*—They may be eaten towards the age of five months; but, generally, they are not fattened till they are from seven to eight months old, when they are arrived at their full growth. The male is then called a virgin cock, and when

his treatment, which should last a month or six weeks, is finished he will weigh 8 lbs., sometimes rather more. A virgin cock not fattened will, at eight months, give from 6 lbs. to 7 lbs. The weight of the flesh naturally varies according to fatness. If in a normal state the bones form an eighth of the entire weight, they form a much smaller proportion when the bird is fattened.

**Plumage.**—Entirely black, excepting some small white feathers that are sometimes to be found in the crest that is on the head. The neck-feathers are long, fine, and ample, with green or violet lustre on them; so are the wing and the tail-coverts, all others are black except those of the body, which have a greyish tinge. Among the flight-feathers, which should be of a violet black green shaded, some white ones may often be found till after the first moult.

(To be continued.)

### BEES DESERTING THEIR HIVES.

I EMBRACE the first opportunity of replying to your kind inquiries respecting my bees, and I do so the more readily because I know very many people are interested therein. If I write too much you can abridge anything you please.

But first let me observe that I am rather an old bee-keeper, as my first stocks were kept on the old plan thirty years ago, near Woodstock, in Oxfordshire; but the disasters to which I have referred occurred during the last few years. Living in a large town as I do, I should attribute my failure to my situation, did I not know positively that the like has occurred to others in very different situations; for example, a philosopher living at Perry Hill, Sydenham, in a very paradise for bees. If pure air, and "sylvan scene, with hill and dale, and liquid lapse of murmuring streams" be advantages, indeed, he has everything but the "heather." He has, nevertheless, always lost his bees in the same way I have described, and, being unable to solve the problem of their exit, after again and again replenishing his apiary, has at last, with deep regret, given them up altogether. The same thing nearly has occurred to a gentleman living on Plumstead Common, not far from my house; and this very day I met a friend from Bexley, in Kent, and inquired after his bees; he informed me that he intended purchasing no more, that his number had dwindled down to one stock, and that was very weak indeed. All had left as I have described.

Now, as to your first inquiry, I have used both boxes and straw hives. My boxes are made exactly, and, in every respect, like those recommended by Mr. Taylor, and all have bars alike; the straw hives are the "common cottage," being those in which I have generally purchased my bees, and, as you know, they vary in shape and size in different parts of the country.

Second inquiry: I have them well protected in an excellent bee-house made of deal, not painted; a zinc roof, close in front, but opening the whole length behind with shutters. This house will hold about twenty stocks, allowing them to be worked on the depriving plan; but it stands in an elevated situation, yet it is protected from wind. It occurred to me that something here might be unfavourable, and I removed them into my little garden, and placed them separately, thus:—I laid three or four bricks upon the ground, then on those I placed strips of board, on which I placed the floor-board, allowing a free circulation of air, still preventing any damp being conducted; their top protection is pieces of old carpet covered with zinc; their entrances are lough, but sufficiently narrow to prevent a mouse from entering.

Thirdly, I think they have not suffered from internal moisture, for I have sometimes ventilated and sometimes not. I have, however, kept them without ventilation for these two or three years.

Fourthly, I am not annoyed with ill smells; but in Woolwich, as in other towns, we have smoke enough, but one would think not to blow down so as to effect the bees; nevertheless, in the Royal Arsenal, within a mile from my house, from the Government works volumes of smoke rise high from the tall chimneys.

I have seen bees not one-hundredth part so well cared for as here, yet do ten times better, so far as swarming is concerned. I may be wrong, but it appears to me that the queen does not breed or continue to breed from some cause or other, and up to the present spring I have almost always attributed it to age, but now I know that this cannot be the case in every instance, neither can I conceive what becomes of the bees, for there are none dead in or about the hives. I do hope our Devonshire

friend, as well as others, will afford us all the assistance they are able to give; and further, I am sure that by giving us space in your truly valuable Journal, you will confer a great and lasting benefit on a very great number of bee-keepers through the country.—EDWD. FAIRBROTHER.

[I have much pleasure in tendering to Mr. Fairbrother all the advice and assistance in my power, regretting at the same time that my experience does not enable me at once to suggest a certain remedy for the evils of which he complains.

In the first place, it appears to me that he is mistaken in supposing that his bees "desert" their hives. All his descriptions go rather to prove that the rate of increase during autumn and early spring does not keep pace with, much less overtake, the mortality, and that a gradual dwindling away of the population is the consequence.

I have myself met with isolated instances of the same kind, although never to the extent related by Mr. Fairbrother; but in every case the cause of the misfortune was either at the time or afterwards sufficiently apparent. Although none of these appear completely identical with that under consideration, I will briefly relate them, in order to show what different causes may produce the same evil effects.

Some ten or a dozen years ago, before I was aware of the injurious results of fumigation upon bees, I made several attempts to establish stocks in autumn by fumigating condemned colonies, putting the inhabitants of two or three hives together, and endeavouring to keep them alive through the winter by copious supplies of artificial food. The result was exactly similar to the experience of Mr. Fairbrother. The bees survived until spring, and then dwindled away. Since I have attained the art of driving bees with facility, I have repeatedly tried the same experiment with the most complete success.

About the same time I was asked to fumigate a weak stock in the autumn for a gentleman residing in an adjoining parish. Having cut out the combs and collected all the bees, I found they numbered less than 200. There was a miserable little abortion of a queen, and about a dozen specimens of worker-brood of all ages in as many different cells, but a fair quantity of honey. The hive in this case was a straw one with a flat top and large central aperture for supering. It had been worked on the depriving system; and the combs being very old my impression at the time was, that swarming had been too long prevented, the queen had become superannuated, and that a failure in her breeding powers was the result.

A third instance occurred in 1851 to one of my own stocks in a Taylor's amateur's bar-hive. Finding in the month of May that the bees diminished instead of increasing in number, I came to the conclusion that the queen had perished, and fumigated the remaining bees with the view of adding them to another colony. To my surprise I found a living queen and a small quantity of brood, but the hive itself was completely saturated by internal moisture, and altogether in a most unwholesome condition. At the present time such a state of affairs would be checked at the outset by shifting the combs and bees into a dry box, but in the then state of my bee knowledge (albeit I commenced the pursuit eleven years previously), although I used bar-hives, so simple a matter as changing bees from one box to another appeared quite out of the question, and I have often watched a dwindling colony in a bar-hive for months together totally unable to decide whether the queen was alive or not, and utterly ignorant of the power I possessed, if I had known how to exercise it, of determining the point in a few minutes by an examination of every comb.

The full development of the extraordinary breeding powers of the queen or mother bee is a point of the utmost importance in scientific bee-keeping; and yet it is one upon which few certain rules can be laid down. Feeding is usually one of the greatest stimulants which can be applied; but even this may be overdone, for a more than sufficient supply will cause the bees to fill those cells with food which should be devoted to breeding, and the queen is often for this reason unable to find a sufficient number of empty cells in which to deposit her eggs. From what Mr. Fairbrother states it appears just possible that he may have erred in this direction. On the other hand, the insertion of an empty comb between the full brood-combs often appears to stimulate the queen to fill it with eggs immediately; but the following instance shows that this, like most other things, may be overdone:—One of my best colonies this spring was in a box with only eight frames. As the season advanced I thought a change to a larger hive would be advantageous, and accordingly placed it in a box with ten frames, putting at the same time an empty

comb in what the Germans call the "brood-nest." Finding after some time that the hive remained stationary, I examined it and discovered that the change appeared to have paralysed (so to speak) the breeding powers of the queen. She had confined her ovipositing to the combs on one side of the empty one, and even there had not laid so freely as I should have expected. Even when the offending comb was removed she failed to make up for lost time; and as I tolerate no queens in my apiary that are not first-rate breeders, I ultimately did away with her, although apparently a fine handsome queen not quite twelve months old.

I have entered thus fully into my own experience of bees dwindling away in their hives from causes other than that of the loss of queens, not because I find myself able satisfactorily to account for Mr. Fairbrother's misfortunes, but because I think it may throw some light on the general principles upon which advice should be tendered. I have myself kept bees in the centre of the city of Exeter, and do not fancy the smoke, &c. of a large town a sufficient reason for so complete a failure.

I have never suffered any injury from the wax moth in inhabited hives, although sometimes this pest makes sad havoc in my store of empty combs. Were the wax-moth really the cause of all the mischief, as suggested by "BAR-HIVE," it could scarcely fail to have been detected on a *post-mortem* examination.

If Mr. Fairbrother be not thoroughly discouraged, I should advise him to start afresh in his old bee-house (to which I can see nothing objectionable), with either bar-hives or frame-hives, and endeavour to attain sufficient skill in their manipulation to enable him to ascertain for himself at any time if there be anything wrong in their internal economy. If his wooden bar-hives are as I imagine, 13½ inches square by 7 inches deep, with eight bars, have them remodelled to nine bars, seven-eighths of an inch wide by three-eighths of an inch thick, and deepen the box to 8 inches, leaving three-eighths of an inch space between the top of the bars and the crown-board. Let him be on his guard against the injurious effects of internal moisture, and when food is really required (and then only), administer it liberally, but not lavishly. I should recommend also a judicious combination of the swarming and depriving systems, never allowing a queen to degenerate by old age, or a strong stock to destroy itself by over-swarming. With these precautions, and by neglecting no hints which his own observations and experience may furnish, I should have every confidence in his ability to make head against, and ultimately entirely avoid, the mysterious failures which appear to have attended his apiarian proceedings.

Whilst regretting my inability to pronounce more decidedly as to the exact cause of his ill success, I may be permitted to hope that some among the many accomplished apiarian correspondents of the JOURNAL OF HORTICULTURE may yet be able to throw a clearer light upon the subject than is in the power of—A DEVONSHIRE BEE-KEEPER.]

**LYTHRUM AS A BEE PLANT.**—A correspondent inquires of the Editors what specific name is given to a species of Lythrum greedily sought after by the domestic bees. It is either, perhaps, *Lythrum superbum* or *salicaria*, as your inquirer is told that they never leave a single bloom as long as one is out.—W. T., *Wimborne, Dorset*.

**AUSTRALIAN WILD HONEY.**—The bush around Adelong has this summer been remarkably prolific in honey, the wild bee appearing to increase in a much faster ratio than his domesticated brother. The number of hives captured, and the weight of their valuable contents, is really surprising. It is said that one party of Americans, well acquainted with the habits of this little industrious insect, and able to track them like genuine Kentucky bee-hunters, who are regular clippers at the business, are gathering their honey by the quarter-cask, and from this source indulging to its full measure their national weakness for sweet morsels. There are but few homes on the Adelong to which the labours of the bee have not this season contributed a welcome addition to their supply of comforts.—(*Wynyard Times*.)

**AILANTHUS' SILKWORM.**—A note has been addressed to the Academy of Sciences by M. Guerin-Ménéville on the progress of the cultivation of the *Ailante* (*Ailanthus glandulosa*), and of the breeding of the silkworm, introduced by him into France. It appears from M. Ménéville's note that the tree and the silkworm

will flourish in any country in Europe as well as in Africa, America, or Australia. By means of this precious importation M. Ménéville asserts that France may obtain a textile matter superior to cotton. A hectare of land (2½ acres) of the worst quality to be found in France planted with *Ailante* will produce the fourth year £16 worth of cocoons—a produce equal to that of an equal breadth of land planted with Mulberries in the best part of the south of France.—(*Times*.)

**VENOMOUS CATERPILLARS.**—A most singular case, perhaps the only one on record, of death caused by caterpillars occurred a few days ago in the commune of Dardilly, near Lyons. A little boy, not more than eight years old, had gone into a neighbouring wood in quest of birds' nests. Perceiving one on the top of a tree, he climbed up, but in so doing shook down an immense number of caterpillars, many of which fell on his shirt, his only upper garment, and soon covered his breast, which was bare, and penetrated to his arms and shoulders. For a few minutes the child took no notice of this, but he soon felt such an itching sensation that he was compelled to get down again and run home for assistance. Upon examination his skin appeared covered with large red spots, which were soon followed by a general swelling, then by fever, somnolency, and delirium; and, notwithstanding all medical care, death ensued in the course of a few hours. The kind of caterpillar which caused this disaster was the *Bombyx processionea* of Réaumur, a very venomous species. Naturalists know that if a nest of these insects be touched, or only stirred up with a stick, the person so doing, and remaining for some time near the spot, within reach of the emanations arising therefrom, will be attacked with a papulous eruption of a more or less confluent nature, which will last several days, and be attended with violent itching. Dr. Calmeil, physician to the hospital of Charenton, had preserved a nest of these caterpillars in a large glass phial, which was not opened for upwards of ten years. At length, the phial being accidentally wanted, it was opened in the presence of several persons, who all caught the eruption. This strange property has even suggested to several members of the faculty the idea of using these caterpillars in cases in which it is required to subject the skin to a strong and permanent irritation. We may remark, in conclusion, that the number of caterpillars which infest the trees this year all over France is quite unprecedented—a circumstance which has called the attention of the authorities and of various learned societies to the question of protecting insectivorous birds, the only really efficacious enemies of the caterpillar.—(*Galignani's Messenger*.)

OUR LETTER BOX.

**TOXOMA ON SPANISH FOWL'S EYE (E. S. H.).**—Your fowl has not the ring, as Spanish are not subject to it. We shall be but poor comforters when we tell you they seldom recover from the disease you mention. If the swelling becomes hard they never do. Your remedy is to purge very freely with castor oil, a table-spoonful at a time, and to bathe the face frequently with hot water. She should have no whole corn, a little meal, and plenty of lettuce to eat. Baily, in Mount Street, publishes a work on "Pheasant-rearing," which is sent by post for thirteen stamps.

**SPANISH COCK'S COMB BLACK—PREVENTING SOFT EGGS (—).**—Judging from such symptoms, all your fowls are rather out of condition. The colour of the cock's comb may be the result of the changeable weather and of a chill. The soft eggs are unmistakable evidence of bad condition, unless their yard or run lacks the necessary ingredients for making egg-shells. Throw down a basketful of bricklayer's rubbish, mortar, old ceilings, &c., and they will find stuff for egg-shells. If they already have this, give them food sparingly, and let them have plenty of lettuce.

**FALCON HOOKS IN COCHIN-CHINAS (Cochin-breeder).**—We never knew the time when falcon or vulture hooks were considered a beauty or desirable. We can only speak our own opinion, and that is, if they are not a disqualification they ought to be. We would not be misunderstood when we speak of falcon hooks. We do not mean slightly projecting feathers, but such as used to be seen on the Ptarmigan fowls, and are still met with at times in the White Cochins. The original Cochins of all colours had no vulture hooks.

**BEE-HIVES AT THE INTERNATIONAL EXHIBITION (E. K.).**—They will be noticed before long.

LONDON MARKETS.—JUNE 23.

POULTRY.

Indications are not wanting that we approach the end of June. Small chickens are more plentiful, and were it not that the capacious crop of the International Exhibition is capable of receiving any number, we should have to chronicle a great falling-off. It acts now as Vauxhall used to do formerly.

METEOROLOGICAL OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 74.7° and 51.4° respectively. The greatest heat, 97°, occurred on the 5th, in 1852; and the lowest cold, 36°, on the 7th in 1860. During the period 146 days were fine, and on 99 rain fell.

ROYAL HORTICULTURAL SOCIETY'S NATIONAL ROSE SHOW.

JUNE 26TH.

SPLENDID day at last, the 26th of the month being the first really bit of summer we had, in June, about London this season. A splendid Rose Show, too, and the first splendid exhibition of ladies' summer dresses which I have seen this season. The dresses came out luxuriantly at the Crystal Palace, on the first day of the grand Handel Festival; but what with the fathers, uncles, brothers, and foreigners, there was at least one and a half of them to every flounce. But

here, as luck would have it, a thousand of the men went to the dog show that day, and a great many more of them went over to the cattle and farming show at Battersea Park, and so many were absorbed at the International, that the real pink of the fashion only gathered about the Roses, but could not get a glimpse at them, so they filled the garden, up and down, and all over, in flowing beauty. Altogether it was a grand sight; the garden was gloriously green and gay, the bedding plants in exceedingly good bloom for so early a period; the walks were all fresh done up, and the freshness of the waterworks, with the refreshing influence of their murmuring waters "louping o'er the lins," had a magical effect in the heart of new London.

After all, I prefer the cascade, in imitation of the "lin," or waterfall, to the spouting system of exhibiting water in motion; but, perhaps, that only comes of early associations, and those who cannot get to see grand waterfalls in nature, ought to enjoy it in the next grandest form in which it may be made to play a part in their enjoyments, for water seems now as essential for the enjoyments of a great or public garden as music itself, and there is enough of both to be enjoyed in the new garden of the Royal Horticultural Society, and visitors did enjoy them that afternoon, although they could not see the Show. The Roses, like the ladies, were never more blooming, nor more fresh to look at either, or better placed for effect and for being judged, but they were four times too close together, and so occupied only one-fourth, or one-sixth rather, of the space in which they could be comfortably seen by so large a concourse of eager visitants, for of all the shows about London the florists carry off the palm for riveting the public attention with their Roses. All ideas of dresses, faces, shapes, and sizes of Self & Co., are completely out of book, before the Rose-stands, and you see nought for the moment but purple and pink note-books, and all note-takers and non-note-takers engaged as keenly, and with more earnest looks than at the gathering-in of the harvest.

All the nursery collections, except those in pots, were set in one tent at the west end of the conservatory, and those of amateurs with the pot Roses were in a similar tent at the other end of the conservatory. Both tents spanned the walks in front of the arcades, and both were span-roofed, and with a high centre division down the middle of the flat stand on which the Roses stood, each side being sufficiently wide to hold two rows of boxes; and there was an avenue made of moveable plants, along the centre of the conservatory, to communicate between the two tents, and along both sides of that avenue were four duplicate stands for showing Roses on, and most of them were filled with boxes of one kind, as Jules Margottin, Paul Ricaut, with Madame this, and Madame that, and Madame Furtado fuller than both, or of one strain, as blush, buff and creamy Tea Roses, and of seedlings and new comers.

The nurserymen occupied 44 yards of length of double boxes twice told—that is, the two sides of the stage, or four times 44 yards for a single run of boxes. Now, had they been placed in single file along the arcades, a half a yard to be between box and box, I am quite satisfied there would not have been one inch too much room for all to get a thorough good sight of the Roses, as everybody there wanted to see them.

The stand for the Amateurs' Roses was 32 yards long, and they occupied one whole side of it and one-half of the other side with a double row of boxes; the other half of the 32 yards of that side was occupied with the collections of pot Roses, the best pot Roses that ever were shown in June, and they were in the kind and style of growth which all amateurs and lovers of pot Roses indoors ought to aim at, instead of the monster specimens which the giants of exhibitors bring out to prove their pluck—that is to say, these June Roses were in No. 24-pots, and had from three to seven or eight perfect blooms on, and a few more coming. They were set in two rows, and Mr. Turner adopted a perfect novel way of setting in twos, which I will show you, and which I assure you had a very marked effect on the eye, before the place got crowded. The first name of each pair was in the front row, thus—

- Général Jacqueminot and President
- Baronne Prevost and Paul Ricaut
- Général Jacqueminot and Duchess of Norfolk
- Then a summer Rose in the centre of the two lines
- Louise d'Antriche and Jules Margottin
- Général Jacqueminot in the centre
- Lady Franklin and Paul Ricaut
- Duchess of Orleans in the centre
- Comtesse de Chabrilant and Jules Margottin
- Pio Nono, and a very light Rose
- Général Jacqueminot and Jules Margottin
- Paul Ricaut in the centre
- Général Jacqueminot and La Reine
- Paul Ricaut
- Anna Alexieff and Madame Zoutan
- Paul Ricaut
- Baronne de Prevost and Sombreuil

all in first-rate style of domestic comfort, as were the rest, though less elaborately set out.

The Rose which made the greatest sensation amongst the leaders of the fancy, is one which was sent to the

Floral Committee late in the autumn two years since, from the neighbourhood of Ipswich, from Robert Ward, Esq., Foxall Road, Ipswich—a Suffolk seedling, which he named John Hopper, and there is not one Rose from France or far away that will excel it anywhere. It is a most splendid Rose, with a strong free habit, and a profuse manner of blooming, and in one Rose, or in a cluster of them, there are three as distinct colours as if on purpose. A rich crimson, or rosy crimson face to the flower, the edges of the petals in a richer shade of carmine, and the whole of the back of the petal a lilacy violet tinge, that is both rich and lovely. I think I never set my eye on a more telling Rose; the blending of the tints in that flower is a perfect charm for the eye.

By the side of it stood another charmer in a very different way, a fine dwarf seedling bedding *Calceolaria*, of the *Anrea floribunda* strain, from the Messrs. Downie, Laird, & Laing. As far as pot culture can tell a tale in this class of *Calceolarias*, this will be the best at present of that strain.

The following, in masses of one kind in a box, were particularly rich in looks:—Baronne Prevost, Jules Margottin, Général Jacqueminot, Charles Lawson, Anna de Diesbach, looking like a deep rose-coloured tree Pæony, or Moutan, Gloire de Vitry, two magnificent boxes of the grand dame, the Comtesse de Chabrilant, and one of the best of all the French Roses, *Senateur Vaisse*.

The collections from the Amateurs I grouped according to their colours, which, like the natural system of botany, is the best assistance to the memory and to a knowledge of any particular kind of Rose; as, if you only know but one Rose out of each group, it enables the mind's eye to perceive what the rest of them are most like. Beginning with the darkest, perhaps General Washington is one of the best. Cardinal Patrizzi and Empereur de Maroc, Ohl and Emperor Napoleon, are four of a class. Shakespere and Garibaldi the same, Triomphe des Beaux Arts and François Arago next, Triomphe de Lyon and Gustave Coraux next, Ardoisée de Lyon and Léon des Combats, Triomphe de Paris, and Arthur de Sansal, with Prince Noir, the very darkest, are about the best way I could bring them in. The next darkest group begins with Général Jacqueminot, Géant des Batailles, Lord Raglan, Eugène Appert, Paul Ricaut, Grandissima (a Gallic Rose), *Senateur Vaisse* (fine), Victor Trouillard, Gloire de Santenay, Ornement des Jardins, Duke of Cambridge, and ends with François Premier. Red and rose-coloured is the next group, and Jules Margottin takes the lead in red, then Gloire de Vitry, Baronne Hallez, Charles Lawson (a double X), Victor Verdier (Pæony fashion), Madame Furtado (a beauty), La Reine, La Fontaine, Pauline Lanzezeur (a double X), Pio Nono and Sir Joseph Paxton in contrast; Gloire de France and Baronne Prevost ditto; La Ville de St. Denis, Anna Alexieff, Chénédole, Evêque de Nîmes (a very peculiar Rose), Anna de Diesbach (an open double X), Général Castellane, Victor Verdier, Jacques Lafitte, Paul Perras, Letitia, Comtesse de Chabrilant (double X), Souvenir de Leveson Gower, Madame Knorr, William Grillich, Alphonse Karr, Comte de Beaufort, Alexandrine Bachmeteff (double X), and Madame Schmidt.

Light rose and blush kinds. Madame Angelina (a Bourbon), Madam Rivers, Virginal (a blush in all the collections), Félicité Rigeaux, Laura Raymond (a fine lilacy shade), Comtesse de Lacpede, Queen Victoria (all a blush), Juno, Madame Vidot, Général Pélassier (lilacy), Caroline de Sansal, Madame Duchere, Auguste Mié, Impératrice Eugénie, Joan of Arc, and Lælia, finer than the first day it appeared in St. James' Hall, a very beautiful Rose.

The pure whites were only in summer and Tea Roses. But, recollect, all these are only a selection from private growers; the trade will come in for a turn at the Crystal Palace, and by putting the two lists together with the interval of time we may get at the most lively of the season.

Some said Général Jacqueminot did not grow well on its own roots, but give it plenty of *cocoa-nut* refuse (not *cocoa-fibre* refuse), and no manure for two years, and, perhaps, like mine, it would beat all that was there, and have a point or two to spare, as mine certainly would on its own free roots in that stuff, with no other help.

There were lots of fine-foliaged plants, Ferns, and others from Mr. Bull; and *Serissa fœtida variegata*, as it should be, among the rest. Also three specimen plants of the pale yellow-leaved *Geraniums* Golden Fleeca and Cloth of Gold; and another from Mr. Chilvers, gardener to F. G. E. Jervoise, Esq., Herriard Park,

down in Hampshire, where that breed first originated; but I could not see Mr. Chilvers—a well-known gardener once in Surbiton—to learn about the way he got the disease into or out of such healthy-looking variegation.

The Good Gracious double Pansy was sent in the name of Messrs. Carter & Co., and had a first-class certificate from a flying quorum of the Floral Committee, for they all seemed to do the honours of the summer shows, there were the Chairman, J. J. Blandy, Esq.; the Rev. J. Dix, who takes the chair in turns; the Secretary, Mr. Moore, and a lot more of us, and we were unanimous on the award. Many ladies also seconded our resolve; and you may expect it next spring as cheap as it is good. But I have not yet had its genealogy farther than it is a Devonian.

D. BEATON.

THE 26th of June is early enough, too early indeed, for any season almost; and in a cold, dull, and dreary one, such as this has been, the wonder is, that although most of the exhibitors complained that their Roses were not in bloom, so many were collected together on this day. Many well-known names were altogether absent, and many exhibited in fewer numbers than ordinarily. In the Nurserymen's Stand of 48 there was but one exhibitor, and even his were adjudged only to be worthy of a second prize; but then the very coolness of the season had contributed to give a character to the blooms such as they could not have had in a hotter one. Some varieties were shown with a colour they never had before, and even that old and well-established favourite, Général Jacqueminot, eclipsed himself. Shall I not, then, best satisfy the wishes of such Rose-fanciers as were not present, if I first speak of what I regarded as the most noticeable things in the Exhibition, and then give the more ordinary details of the Roses in some of the winning-stands? What of the new Roses? will, I know, be the first question. Is there anything good? Will it be a *Senateur-Vaisse* year, or not? From what I saw to-day, although I think it to be next to impossible to judge of the quality of a Rose the first year it is received from France, cut and hacked about it, as it is for buds and grafts, I think one may safely say, that there is a vast amount of rubbish—some Roses that it is a disgrace to have sent out, others which promise well, and others decidedly good. But, and let it be well trumpeted forth, the best new Rose in the Exhibition came from our dear old country—a seedling raised by Mr. Ward, of the Rosery, Ipswich. It was the admiration of all who saw the box of it that the owner had there. Crowds of Rose-fanciers were around it all day, and heartily congratulated the raiser. It is called John Hopper, and is a cross between Madame Vidot and Jules Margottin, of a lovely crimson, with a lilac hue over it, something like Pauline Lanzezeur, but much brighter and fuller. It received a First-class Certificate from the Sub-Committee of the Floral Committee, and a first prize as a seedling, and it deserved it well. It is of very vigorous habit, and a most prolific bloomer.

New Roses were shown by Messrs. Cranston, Fraser, Cant, Paul & Son, and Keynes. Paul & Son were first. The really new Roses—that is, of 1862, in their collection, were their own seedling Lord Clyde, Wilhelm Pfizer, Mademoiselle Julie Daran, vermilion red, a pretty thing; Paul Ferval, rough and bad; and Louise Darzins, apparently a good white. Mr. Cant was second with Roses of the year before, none of those of 1862 being, I believe, amongst them. Mr. Cranston was third with Charles Lefevre, a bright purplish-red flower of large size, and apparently of good quality; Comtesse de Seguier, worth nothing; Eugène Dubois, if possible worse than Reine des Violettes; Maurice Bernardin, an extremely good Rose, dark crimson, something of a *Senateur-Vaisse* look about it; Duc de Rohan, very fine, a double Jacqueminot it seemed to me, and shaded like its parent; François Lacharme, purplish-carmine, dying badly I fear, but very double, and of fine form, foliage good; Gloire de Chatillon, very bad; Eugène Bourcier, dark shaded; Souvenir de Mons. Rousseau; I fear there could not have been much affection towards poor M. Rousseau by the raiser, for it is a rough, bad, coarse flower; La Brillante, a finely-shaped, transparent, carmine Rose, of good quality, blooming freely, and of vigorous growth. Messrs. Fraser were fourth. Vicomte Vigier, promises to be good; Triomphe de Caen may be a good dark of the Duc de Cazes style; Alexandre Dumas is a very dark plum and crimson Rose of peculiar hue, not shown very double, but it may improve on this (many of the most promising Roses have not yet been shown); Madam Charles Wood,

M. Boutin, Maréchal Vaillant, &c. Gloire de Bordeaux, one of "Lartey et fils'" new Teas, raised from Gloire de Dijon, promises well, and may be equal to the gasconading account given of it; the inside of the petals is white, and the outside bright rose, and it is very vigorous in habit.

In one of Mr. Cant's boxes there was a bloom of Comtesse Cecile de Chabillant, which was a perfect gem. It was regularly and beautifully striped with small narrow bands in each petal. It was the most exquisite thing that could be imagined. It was, of course, only a chance sport. By-the-by, I hunted after Mr. Cranston for an hour and a half, but could not find him, as I wanted him very much to "eat his leek" about Triomphe d'Amiens. There were some perfectly mottled blooms of it shown in Messrs. Pauls' collection of pot Roses, which fully bore out all that I said about it. These pot Roses of Mr. Paul's and Mr. Charles Turner's were to my poor ideas the very models of what pot Roses ought to be: I think (but it may be want of taste), they are as far to be preferred to those giants of pyramids shown in the earlier part of the season as were the Fuchsias the other day at the Botanic to the ordinary type of Fuchsia-showing.

They contained, too, some very good Roses. Messrs. Pauls', which obtained the prize, were Victor Verdier, Général Jacqueminot, Dr. Bretonneau, l'Elegante, Triomphe de l'Exposition, Anna de Diesbach, Baronne Prevost, François Premier, Viscountess de Cazes, Général Jacqueminot, Duchess of Sutherland, Mademoiselle Louise Carique, Buffon, Jules Margottin, Madame Boll, Baronne Prevost, Léon des Combats, Gloire de Santenay, Catherine Guillot, and Triomphe de Lyons. Mr. Turner had President (very fine), Général Jacqueminot, Paul Ricaut, Baronne Prevost, Duchess of Norfolk, Jules Margottin, Criseelle, Louise d'Antriche, Paul Ricaut, Lady Franklin, Duc d'Orleans, Comtesse Cecile de Chabillant, Pius IX., La Reine, Madame de Trottiere, Anna Alexieff, and Sombreuil.

In the Amateurs' Class Mr. Hedge, of Colchester, carried off every first prize, and certainly his flowers were models of growth.

In 48's, single truss, there was hardly an indifferent, and certainly not a bad Rose. Oderic Vital, Pius IX., Madame Rivers, Jules Margottin, Comte de Paris, Engène Appert (very fine), Louise Magnan, Prince Regent, Madame Bravy, Madame Boll, Juno, Sénateur Vaise (a splendid bloom), Coupe d'Hébé, Letitia, Devonienais, Général Jacqueminot, La Reine, La Fontaine, Caroline de Sansal, Bizarre Marbrée, Jaume of Smith, Dominic Daran, Madame Hector Jacquin, Charles Lawson, Clara Sylvain, Comtesse Cecile de Chabillant, Madame Vidot, Souvenir de la Reine de l'Angleterre, La Ville de St. Denis, Vignerol, Lord Raglan, Pauline Lanzezeur, Princesse Hélène, Mathurin Regnier, General Washington, Baronne Prevost, Anna de Diesbach, Madame Knorr, General Simpson, Reine Victoria (large Tea), Gloire de Dijon, Mr. Griffith, and Madame de Cambacères were all in fine condition. Mr. Wm. Corp was second; Mr. Worthington, third; and Mr. Hollingworth, fourth.

His 24's were, if possible, still finer, comprising Comtesse Cecile de Chabillant, Adam, Jules Margottin, Paul Ricaut, Lord Raglan, Mrs. Rivers, La Ville de St. Denis, Juno, Bizarre Marbrée, Alexandrine Baelmeteff, Aurora, Letitia, Madame Knorr, Souvenir de la Reine d'Angleterre, Coupe d'Hébé, Madame Hardy, La Fontaine, Queen Victoria, Général Jacqueminot, Gloire de Dijon, Baronne Prevost, Madame Vidot, and Reine Victoria.

In 18's and 12's, Mr. Hedge was again first. To give the names of his flowers is but to repeat over again the list of the above names, and the prize list will give the names of the other successful competitors.

Amongst Nurserymen there was a very sharp contest, and here one must say a word as to collections of 96 Roses, 3 trusses of each—i.e., 288 Roses in each collection. It is, I believe, utterly impossible that so large a number can be staged without some bad Roses being amongst them; and when, as in the present case, seven stands were entered, it was almost work enough for the Judges without anything else, for they had thus 2016 Roses to adjudicate upon. I hope some day that either trebles will be dispensed with, or that fewer varieties will be required. Mr. Francis, of Hertford, occupied the first place, and Mr. Mitchell, of Pilsdown, second. His Roses were Catherine Guillot, Princesse Mathilde (very good), Madame Hector Jacquin, Souvenir de Comte Cavour (dark and good), Louise Darzins (white), Madame de Lamoricière, Triomphe de Paris, François I., Comtesse Cecile de Chabillant, Adelaide Fontaine, Souvenir de la Malmaison, Madame Laffay, Duc de

Magenta (fine Tea), Madame Vignerol (coarse), Duchess of Norfolk, Pauline Lanzezeur, Oderic Vital, Vicomtesse de Cazes, Crested Moss, Homère, Duc de Cazes, Leonise Moire, Louise de Savoie, Madame Van Houtte, Baronne Prevost, Buffon, Clement Marot, Madame Knorr, Souvenir d'Elise Varden (fine Tea), Ornement des Jardins Gloire de Santenay, Comte de Nanteuil, Comte de Paris, Léon des Combats, Madame Domage, Sénateur Vaise, Baron Wassacner, Evêque de Nîmes, Madame Schmidt (coarse), Devonienais, Louis XIV., Norma, Amabilis, La Brillante (very bright), Charles Lefevre, Auguste Vacher, Agatode, Triomphe de Rennes (very fine), Archduke Charles, Madame Damazin, Prairie de Terre Noire, Jules Margottin, Triomphe des Beaux Arts, Narcisse, Dr. Bretonneau, Madam Rivers, Darzins, and Narcisse, Alexandrine Baelmeteff, Lord Raglan, Victor Verdier, La Ville de St. Denis, Elise Sauvage, and Gloire de Bordeaux. Mr. W. Paul was third, and Mr. Keynes fourth.

In the Class of 48 trebles there was but one stand, and that only deemed worthy of a second prize.

In the Class of 24 trebles Mr. Cant took first with the best stand to my mind in the Exhibition. His Roses were Victor Verdier, Engène Appert, Général Jacqueminot, William Griffiths, Prince Léon, Comtesse de Chabillant, Devonienais, Paul Ricaut, Col. de Rougemont, Pauline Lanzezeur, Louis XIV., Anna de Diesbach, Duke of Cambridge, Coupe d'Hébé, Madame Vidot, Triomphe de Paris, Clement Marot, Baronne Prevost, Victor Trouillard, Mathurin Regnier, Jules Margottin, Rubens, Souvenir d'un Ami, and Madame Boll. Some of the Roses in the stand were models of growth. Such Victor Trouillards I never saw before. Mr. Francis was second, and Mr. Keynes third.

In 24 singles Mr. Keynes, of Salisbury, was first with Anna de Diesbach, Victor Verdier, Pauline Lanzezeur, Wm. Griffith, La Reine, Duchesse d'Orleans, Comte de Nanteuil, Souvenir de la Malmaison, Paul Ricaut, Jules Margottin, Général Jacqueminot, Madame Knorr, Prince Léon, Charles Lawson, Gloire de Vitry, Madame Vignerol, Sénateur Vaise, Madame Boll, Caroline de Sansal, Comtesse Cecile de Chabillant, Louis Peronny, Madame Vidot, La Fontaine, and La Ville de St. Denis. Mr. Charles Turner, of Slough, was second with a fine box of Lord Raglan, Duchesse d'Orleans, Baronne Prevost, Souvenir de la Malmaison, Jules Margottin, Madame Masson, La Ville de St. Denis, Sénateur Vaise (a magnificent bloom), Queen Victoria, Comtesse de Chabillant, Anna Alexieff, Général Jacqueminot, Léon des Combats, Charles Lawson, &c.

There was not that competition for the classes for single blooms, boxes of blooms, &c., that I should have expected. For a box of 12 blooms of Sénateur Vaise Mr. Keynes obtained the first prize, and no one can doubt the extreme value of this noble flower; and although Gloire de Santenay has by some been preferred to it, I think it must hold the premier place.

In 12 blooms of any other kind Mr. Hedge was first with a fine box of Charles Lawson. Mr. Francis second with Madame Boll. Mr. Keynes third with Anna de Diesbach; and Mr. Fraser fourth with Comtesse de Chabillant.

In bouquets of 6 sorts Mr. Keynes was first, Mr. Francis second, and Mr. Cranston third.

Teas were pretty good, but by themselves are hardly attractive enough owing to want of colour. We must not omit to mention a very nice box of blooms of Reynolds Hole shown by Mr. Standish; although, owing to the earliness of the Show, it was not seen in as good condition as it will be. As I hope to see some other shows next week, I must wait until they are over to give my notions upon the subject in its general aspect, while I know Mr. Beaton will not fail to give us his views of the decorative aspect of the Exhibition. The day was fine, and a numerous and fashionable attendance filled the grounds.—*D., Deal.*

## NEW ROSES.

As the admirers of the "queen of flowers" are now busy with their note-books, and seeking reliable information about the new Roses now blooming for the first time under an open British sky, I presume the following notes (made from personal observation of the several varieties while blooming here), may not be unacceptable:—

H.P. SOUVENIR DE M. ROSSEAT D'ANGES (Fargeton).—Brilliant clouded crimson; colour rich and effective; flowers large, well formed, full, and of good quality; good foliage and moderately robust habit. A handsome and useful flower.

H.P. VULCAIN (Verdier et Fils).—Rich velvety plum or dark purplish-maroon; colour fine, distinct, and very striking; petals shell-shaped and of good substance; flowers finely formed and double, in the way of Général Jacqueminot, but apparently not quite full when expanded; habit moderate. A fine, distinct, and novel flower.

H.P. COMTESSE DE SÉGUIER (Samson).—Reddish-crimson, suffused with violet; flowers of good size, full, and well formed; rich foliage and free habit.

H.P. MONTE CHRISTO (Fontaine).—Rich dark reddish-crimson; colour fine; petals of good substance; flowers large, full, and well formed; habit moderate. An attractive Rose, somewhat after Madame Masson.

At present I am only in a position to speak of the above, but shall be happy to continue the list as far as I may be able.—W. W., Nurseries, King's Acre, near Hereford.

## CULTURE OF THE PEACH AND NECTARINE.

It may seem superfluous to write upon the culture of the Peach and Nectarine, because so many cultivators have already given their experience on the subject. Now I have been a grower of these fruits for nearly half a century, and during that long time I have studied the various causes of success, and, what is equally important, the causes of failure; and the result of my reflections leads me to the conclusion that there are several points of culture that the writers on this subject have either entirely overlooked or have not given sufficient importance. I have come to the determination, therefore, of writing a few notes on their culture; and in so doing, I shall endeavour to treat fully of everything necessary to be done in order to grow healthy long-lived trees that will produce annually a fair crop of fruit. I attempt this with all due deference to those who have gone before me, and shall not in order to set up myself as a critic dwell upon, or even mention, where I think they are mistaken or not explicit enough to be understood by the tyro in Peach-culture.

I know of late years it has been the fashion to decry the hardihood of these fruits in this country. Now that glass is cheap every unsuccessful grower says the Peach should be in all cases covered with glass to insure a crop. I would ask such, Are you prepared to prove that the climate of this country is more severe than it was thirty or forty years ago? Unless that can be proved, I opine that, with proper care and close attention to a proper course of culture from making the border to the ripening of the first crop of fruit, the trees bearing these delicious fruits can be grown as successfully now as our older gardeners grew them fifty years ago. It is true when unfavourable seasons occur unprotected trees will suffer; but in such seasons the skill, attention, and forethought of a good gardener will be brought into play to overcome the untoward weather; and success in such seasons shows the difference of skill. Any careless cultivator can have a crop of fruit in warm summers, provided the preceding one has been warm also to ripen the wood of his Peach trees. But that is not sufficient for the owner; he wants fruit every year, and if he has provided all things necessary he ought to have his want supplied.

The question now arises, What is required in order to succeed with moderate attention in cultivating the Peach in this country without the aid of glass? The first thing is a proper situation. Formerly a great notion was entertained by our gardeners, or planners of gardens, that a low sheltered situation was the very best for a garden. That mistaken idea is, I think, now entirely exploded. A low situation, instead of being the best, is the worst for a fruit garden. The most careless observer must have remarked that tender plants suffer earliest from frost, both in the spring and autumn, in low grounds; whilst on moderately high land the slight frost has no effect on them. Many an autumn eve we see heavy mists on low grounds, whilst higher land is quite clear of them. The reason of this is that cold air is heavier than warm air, and therefore it sinks down by its gravity and shows itself as mist, displacing the warmer; and when the cold is so intense as to reach the freezing-point, vegetation suffers. These patent facts lead to the conclusion that a fruit garden should be placed on a moderately-elevated platform. Even an elevation of 50 feet or 100 feet above the bottom of a valley would be desirable. I might give many instances of places where the gardens are placed in low situations, where such fruits as the Peach, Nectarine, and Apricot often fail in yielding fruit. Sufficient for my purpose it is to mention Chatsworth,

Worsley Hall, Trentham, and the old garden now removed at Welbeck. In such places where the gardens are still continued it has been found necessary to cover the Peach walls with glass, in order first to ripen the wood, and secondly to ripen the fruit: this covering of glass is not adopted for the purpose of forcing the fruit into early maturity, but is used merely as a protection against early and late frost. In a properly-elevated situation the glass as a protective agent may be dispensed with.

From the above remarks I think it will be seen, that in order to succeed in Peach-culture against walls without glass, it is desirable—nay, absolutely necessary, to place the garden, where possible, in a moderately-elevated situation. If there are higher grounds on the north, north-east, and north-west sides of the garden, and those hills are planted with forest trees to shelter the garden from the winds blowing from these quarters you have the best situation imaginable, not only for fruit-tree walls, but for every other production expected from a garden. Let every one, then, who has the forming of new gardens study over the above remarks, and, if possible, choose such a site for the fruit and kitchen garden.

*Soil.*—The next most important agent for the production of the fruits, Peaches and Nectarines, is the soil. This includes drainage, subsoil, and surface soil. In the course of my experience I have observed that all stone fruit, without any exception, thrive best and are most fruitful in calcareous soils. In the limestone districts of Yorkshire the Peach trees against walls, where properly attended to, are healthy and fruitful; and round the town of Sherborne where limestone abounds, that excellent preserving Plum, the Winesour, grows in the hedges and bears profusely, and also the Damsou Plum is still more common. Almost every cottage has its garden hedge formed of these excellent fruits. I mention these as a proof of my maxim that stone-fruits thrive best in the limestone districts, where the subsoil is formed entirely of that material. The garden at Womersley Hall, the seat of Lord Hawke, has a subsoil of limestone. There I served part of my apprenticeship to gardening, and there the Peach trees lived to a great age and bore fruit plentifully. Also near there is Byram Hall, the seat of Sir John Ramsden, and the garden is also similar to Womersley as to its soil. In that garden twenty years ago there was the finest Peach wall in the kingdom. I forget the length, but it was considerable, and eight trees completely covered it, not a sickly branch to be seen; they were trained in what was termed the Seymour method, which I shall describe presently.

Well, what does all this amount to? Why, that whoever has the opportunity should form his Peach-borders with soil containing calcareous matters.

Let me, however, begin at the beginning. Supposing it is determined to make a Peach-border, either in a new garden or an old one, begin first by excavating the soil; the necessary width for ordinary walls need not exceed 12 feet. In general, as a useful rule, let the border be the same width as the wall is high. Then as to depth, 18 inches to 20 inches will be amply sufficient. The width being set out, then cut a main drain deeper than the bottom of the border: this main drain should be built with bricks laid flat and covered with flags the exact size of the drain. It should be placed at the side of the border the farthest from the wall, then form transverse drains across the border. If the subsoil is wet these cross drains should only be 10 feet apart; if moderately dry, then 12 feet or even 15 feet apart would do. Lay earthen tiles at the bottom, connecting them with the main drain in front: of course these cross-drains should have a gentle fall to carry off the superfluous water; next fill up the drain above the tiles with open rubble or scoria that has had the smaller particles sifted out of it. Then, if it can possibly be procured, lay all over the border a layer of broken unburnt limestone. If this, however, cannot be obtained, then instead cover the bottom of the border with brickenda mixed with rough pieces of lime rubbish. This completes the drainage.—T. APPEBY.

(To be continued.)

CHLORIDE OF LIME AS AN INSECTICIDE.—Dingler's "Polytechnische Journal" says, that sprinkling beds of vegetables with even a weak solution of this salt effectually preserves them from caterpillars, butterflies, morderella, slugs, &c. It has the same effect when sprinkled on the foliage of fruit trees. A paste of one part of powdered chloride of lime, and one-half part of some fatty matter, placed in a narrow band round the trunk of

the tree, prevents insects from creeping up it. It has ever been noticed that rats and mice quit places in which a quantity of chloride of lime has been spread.—(*Prairie Farmer.*)

### PEACH AND NECTARINE TREES FAILING.

THE leaves of the Peach and Nectarine trees here are withered, and most of last year's wood is quite dead. The trees were planted about six years ago by my predecessor, who tied all the wood that grew on them each year. They did not bear much fruit since they were planted. The border is a strong stiff clay, and nearly level.—S. H. D.

P.S.—Some of the trees are 2 feet deep in the border.

[We suspect the trees were done for by the severe frost of 1860 and 1861, and have been languishing since. We like to see every gardener do the best he can, but we have no sympathy with any one dwelling on the deficiencies and shortcomings of his predecessor. We hope in this respect our brethren of the spade will become more noble-minded. There can be no question that such reflecting is a professional shortcoming which respectable men should guard against. If all the wood made was *tied-in*, we should form an idea of a faggot rather than of a bearing Peach tree. The winter, the stiff clay, and the deep planting are sufficient to account for the failure. You do not mean the stems of the trees being 2 feet deep in the border? if so, they cannot thrive. Even the roots would be rather deep in such soil. A fresh border made at times would be the thing, and good drainage. If last year's wood is dead, the trees must be far gone. If, however, wood is breaking pretty regularly, we would, by stopping extra strong shoots and regulating the others, get what wood we could in good position, if it was determined to keep the trees, and raise them and plant in light sandy soil, in mounds, in the beginning of October. A little shading in bright days will insure the perfecting and ripening of the wood. If the trees are too far gone, light loamy soil should be got in readiness; and if renewing the whole border would be too much, plant the young trees on raised stations, drain the border, and add a little fresh soil every year. If the front part of the border is well trenched and ridged after draining and limed, it will get lighter; but the roots should be kept well up.]

### CAUSING VARIEGATION.

IN answer to "AN OLD SHOWMAN'S" first question, page 231, What would I have him to say? I did not want him to say one syllable, but rather to show us how to make a plain-leaved Geranium into a variegated Geranium by some sleight-of-hand way, by which he said it could be done, and I think he said that he could do it. Messrs. Downie, Laird, & Laing's variegated seedlings are not to put an old man like me off the scent, nor will chaff avail a fox before my hounds; he shall be run to earth, or to the very roots of his brush if he does not double about too cunningly. But to make the thing more easy than talking about it, I shall assume that my own view of it is perfectly wrong, and of no avail; and I again invite "AN OLD SHOWMAN," and those others who have given free opinions on the point, to tell us how to do the thing in their way, to begin afresh, but, at the same time, each of them to give us one sample of their view of the question, which sample we may prove ourselves by direct experiment. Anything of that sort, that cannot be proved by experiment, and come out the same way three times running, is not worth one straw more than the prophesy of Thomas the Rhymer, if even one-half so good. In one word, tell me how to "doctor" one out of one hundred of my own seedlings so as to "disease" it; and if I can do it, and do it once and again, you shall have an Arabian pony this time.—D. BEATON.

MEAN TEMPERATURE OF THE AIR.—The Academy of Sciences has received a communication from M. Becquerel, showing that there exists a vast difference between the temperature of the atmosphere close to the ground, and that measured at an altitude of from 60 feet to 70 feet above it. The soil, its nature, colour, and the objects which cover it, all influence the temperature within the above limits. It had long been observed that vegetation varies according to height, and that certain plants which cannot be cultivated in the valleys will thrive very well on the tops of the adjoining hills. Often also frost will injure the

flower of the Vine, and respect that of the Almond tree close by, which grows at a greater altitude. M. Martins, Director of the Botanical Garden at Montpellier, has observed that Laurel, Fig, and Olive trees die away in the lower parts of his garden, but are spared a few metres higher up, though in both cases protected by the same contrivances. M. Becquerel states that the mean temperature of the air at the Garden of Plants during the year 1861 increased regularly from 1 metre to 33 metres above the soil, and this circumstance has prompted him to endeavour to fix the altitude of which the temperature represents the real average at a given spot. He has remarked the curious fact that at six o'clock A.M. all the year round the temperature is the same at any altitude not exceeding 21 metres; six o'clock A.M. is, therefore, a critical period of the day, the temperature of which must stand in a certain relation to that of the month or year, and this relation he expresses by certain co-efficients which vary according to the different seasons, and reach their maximum in summer and their minimum in winter. These co-efficients and the mean temperature at six A.M. will determine the temperature of the air at a given hour and altitude.

### A FEW DAYS IN IRELAND.—No. 24.

#### HAM WOOD.

THIS picturesque residence of Charles W. Hamilton, Esq., is about twelve miles west of Dublin, some four miles from the station of Clonsella, on the Midland and Great Western Railway, and a mile and a half from the village of Dunbeyne. On calling on an afternoon at the seed warehouse of the Messrs. Dickson, Hogg, & Robertson, we were much taken with fine specimens of the white Globe Pomeranian Turnip, which seemed individually to be more than a stone in weight; and Mr. Robertson, as the seedsman, somewhat exultingly inquired if we could show a better sample in England. These Turnips from the farm of Mr. Hamilton added an additional incentive to visit Ham Wood, though there were plenty of reasons beforehand—such as the report generally diffused, that Mr. Hamilton was the most extensive breeder and the most successful exhibitor of the Shropshire sheep in the country, that his own place was a little model of neatness, suitability, and compactness, combined with a stern regard to economy; the question, Will such improvements pay? never for a moment being lost sight of, to gratify any mere whim or hobby. And that thus from practice, as well as extended observation, he was well qualified for giving counsel to the noblemen and gentlemen for whom he acts as agent and friendly adviser, so that the improvements that are carried on so extensively shall not only be substantial but remunerative. Add to all these that Mr. Hamilton is an enthusiastic gardener, as these pages already testify, fond of new things, without forgetting or losing relish for flowers and fruits that are old; and that his enthusiasm is shared in by his excellent gardener, Mr. Langdon, between whom and his employer we can fancy many of these conversations about fresh arrangements and new combinations that leave such pleasant impressions behind them, and do so much to make toil a pleasure. The expectations cherished were fully realised; and at the risk of being somewhat egotistical, we may be allowed to mention that on entering the nice library the first thing that rivetted our attention, and holding a prominent post of honour, was the whole of THE COTTAGE GARDENER, from the first to the last finished volume neatly bound.

Gardening being chiefly our theme, to it we will first direct attention. As far as we recollect, the house well sheltered and seeming to stand in a level country, is somewhere about 300 feet above the level of the sea. The best rooms face the south, and the flower garden is placed on this front, a broad walk acting as a terrace, the west side being flanked with fine Hollies and other evergreens, and the east with similar plants extending to a pinetum. The offices and kitchen garden are to the north and west of the mansion, and little or nothing is seen of them from the ornamental front.

Mr. Hamilton, well knowing the effect thus produced, took us to the upper principal rooms that we might look down upon the well-filled flower garden, and perhaps with the exception that the centre was rather dull, and the beds there rather crowded, the uncommonness of the grouping of the clumps and roominess of the whole, with plenty of grass to give relief, produced a very pleasing effect. The wet season in Ireland was much against flower gardening, and had a tendency to render the blue Lobelias somewhat grassy in their appearance; but the

generality of the beds were as bright in the middle of September as if they had enjoyed the dry weather and the bright sun we were privileged with in Hertfordshire.

Mr. Hamilton, thanks no doubt to Mr. Robertson, thanks in part to THE COTTAGE GARDENER, treated us so much less as a visiting gardener than an old friend, that there was no end to the comparing of notes and the free interchange of ideas on all gardening matters; and especially on everything connected with flower gardening. We found that in one thing, the shading of colour, and the mixing of shades, closely allied to each other, Mr. Hamilton had more experience and a finer eye for effect than we could boast of. On the other hand, we imagined we had clearer perceptions of contrast, and the importance of relative heights in forming groups, a matter often much neglected.

The various plans that were decided upon as improvements, and all good, and yet laid aside for something more novel, if not really better, could not be detailed in a single article, and with illustrations not in a whole Number. We must content ourselves with a slight criticism of some of the prominent features in last year's planting, and also in that which has been decided on and planted for the present year.

In looking from the upper rooms of the house, the whole

was very pleasing; when looked at from the walk, there was rather too much levelness, and want of relief-points to the eye. In our first engraving, *fig. 1*, the centre of the group was the only lofty object, in the shape of a column of Ivy with a vase at its top; and the principal part of the circle was devoted to a rustic seat round the column. This gave a dull appearance to the centre, and the seat would have been better at the south side of the garden, shaded from the sun. The seat has now been changed into a raised bed round the Ivy column, and is to be filled with Tom Thumb Scarlet *Tropæolum*, which will come in well with the other planting, and serve to drape the upright circumference. The two other circles in a line, marked 17, were filled with the low Baron Hugel Geranium—a good companion and contrast to the base of the four shells that were filled with *Cerastium*. This season, these circles are to be appropriated to tall pyramidal *Fuchsias* with an edging, and we are sure they will give relief; and if 3, or some of the circles beyond had also been pyramidal, the effect would have been good from the walk or the grass, though not so striking from the higher windows. The figures marked 4, 4, with distinct and shaded colours of *Verbenas* were beautifully done, and so were the shaded Geraniums in Nos. 5, 5.

The four shells in the centre, marked 2, are the most prominent features in the garden, and have cost the greatest amount of consideration from the proprietor. In 1861, though finely bloomed, the shells did not seem to be quite satisfactory. First, there seemed a want of balance as to sides, and a balance as to size and height. The first would be deemed a desirable thing by those who hate uniformity and balancing, and who, for the sake of variety, would have every clump in a geometrical plan different. We think, however, this variety often leads to confusion and sameness. Any one can estimate the value of balancing, and see the uniformity in making 3 the central colour; then different colours, but either the same, or the same shade in 2 and 4, and then others complementary or contrasting to those in 1 and 5. If these five separate beds in the one shell are the same in height so much the better; if not, 3 should be the highest, 2 and 4 next, and 1 and 5 lowest. If great variety was the object, then there might be three lines of colour in No. 3, and so of all the others, the outer lines of each division shading or contrasting with each other. Thus there might easily be three or nine distinct colours in each shell, and a narrow band might go round the whole of a distinct colour as the setting of the jewel case—such, for instance, as Variegated Mint, *Cerastium*, *Cineraria maritima*, *Gnaphalium lanatum*, &c. The shells having been filled as follows, readers

will judge for themselves as to balancing and height:—The circular end *Cerastium*, too low, and not good enough for the position. No. 1, *Lobelia speciosa*; 2, yellow *Calceolaria*; 3, *Commander-in-Chief Geranium*; 4, *Countess of Warwick ditto*; 5, *Shrubland Rose Petunia*.

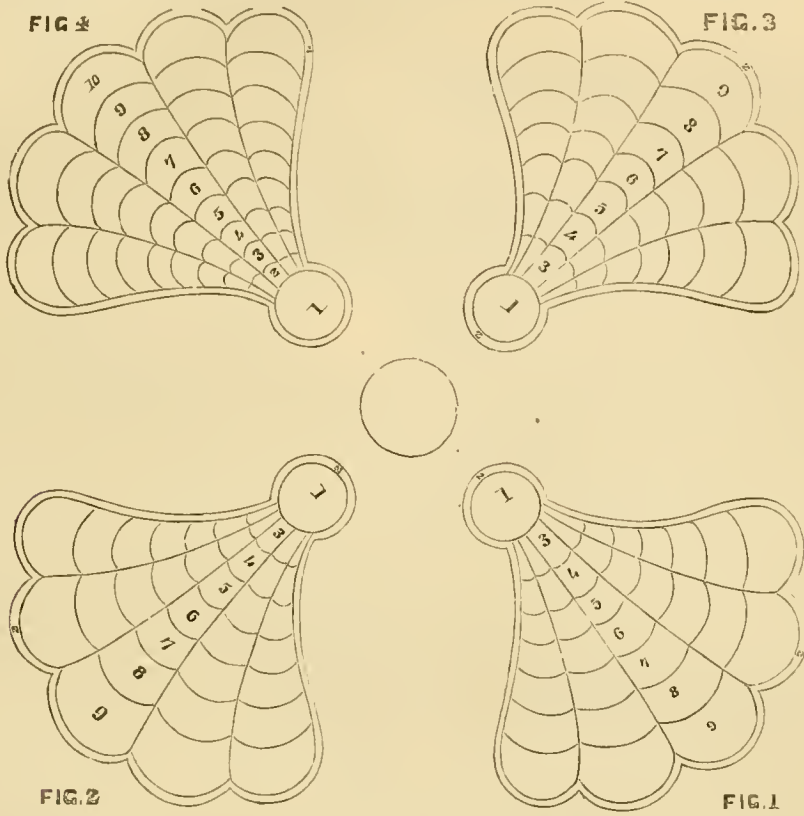

Then, again, the planting and management of these supposed shells were not so artistic as to carry out the leading idea. The shell was divided into five long beds, but there was no seen division between them; nor was there any, but four small irregular pathways were left at the wide end, alike to separate the colours there, and permit, we presume, of each bed being regulated. This latter was not indispensable, as Mr. Robson's huge beds can testify. However, if a marked division was to be seen, it should have been in straight lines of Box or other material. We should have preferred showing no divisions at all, filling up the whole shell, showing merely the volutes at the circumference or wide end, and depending entirely on marking the five divisions by the straight lines of contrasted colour touching each other, and yet kept quite distinct.

In carrying out such an idea, and the planting the shells separately or in pairs, either opposite each other or on the cross system, Mr. Hamilton thought of many modes which would have been very beautiful on the balancing system, whether each shell consisted of three or of nine colours. A happy thought,

however, struck him—that this season he would plant the shells in cross bands, these bands being curved to be in accordance with the volutes of the wide end of the shell. The beauty and interest of these curved lines will be seen just in proportion as the plants shall be trained to occupy the sharp angles in each curve. Without that a curved straight circular line would have the same effect. As shown, the figure is more artistic. In either case much of the interest will depend on the training, and that, again, in choosing plants that will fit into each other not only as respects colour, but height.

Many combinations were under review, some, we think, better than those decided on; but they had to be given up for want of the sufficient number of plants, &c. In all of them the circular end of the shell was made more telling, and of a more uniform height with the bed than last year, and in most cases a

low edging surrounded the whole shell. As good examples of arrangement of Mr. Hamilton's, not, however, carried out, we may instance the shells Nos. 1 and 2, in cut 2. In both the base of the shell was to be filled with crimson Geraniums of a dwarf character, such as Newllii, and a border round that, and all round the shell of Golden Chain Geranium, which would give a brightening, charming effect to the whole, and make the bands of Lobelia a brighter blue by being separated by the yellow leaves from the grass. The Ageratum nanum, and the Perilla, would be the only things that would need much training. The planting was to be as follows:—1, Imperial Crimson; 2, bordering Golden Chain; 3, band of Golden Chain; 4, Ageratum, dwarf; 5, Rose Queen Geranium; 6, Perilla; 7, Cerise unique Geranium; 8, Variegated Geranium; 9, Lobelia speciosa; 2, Golden Chain band.

In fig. 2—1, is Geranium Newllii, and the plants are repeated, except 5 was to be Geranium Christine, and 7, Commander-in-Chief.

No. 3 in the above represents one of a pair of shells as planted this season. No. 1 circle, Imperial Crimson Geranium; 2, band of blue Lobelia; 3, band of Crimson Imperial Geranium continued; 4, Golden Chain Geranium; 5, Ageratum nanum; 6, Christine Geranium; 7, Perilla; 8, Commander-in-Chief Geranium; 9, Countess of Warwick; 10, Blue Lobelia. The match bed has Newllii for Imperial Crimson, and Mangles' Variegated for Countess of Warwick.

No. 4 is one of the other pair of beds, or shells, and is thus planted—1, Hackness Geranium; 2, Senecio, new crimson; 3, Golden Chain; 4, Brilliant Geranium; 5, Perilla; 6, Ageratum nanum; 7, Trentham Rose Geranium; 8, Flower of the Day Geranium; 9, Lobelia speciosa; 10, border of Variegated Alyssum.

Mr. Hamilton has promised to tell us how he likes the planting ultimately decided on. For the present, though we sometimes place the blue Lobelia against grass, we are seldom satisfied with it, as it wants a bright season to make it bright enough. We prefer much the edging of No. 4, even though it gives some trouble, as we expect the Alyssum will in cutting, as it will grow stronger than the Lobelia, but it will stand any amount

of cutting or pegging. In another year we should expect the number of bands to be lessened.

We will now glance at the general planting shown opposite. The pair 3 are planted in three bands—centre Perilla, next Yellow Calceolarias, outside Lobelia speciosa; 4, 4, Verbenas, chiefly shaded, but the broad corners divided into distinct colours; 5, 5, shaded Scarlet Geraniums; 6, 6, Yellow Calceolaria, with broad band of Purple King Verbena; 7, Prince's Feather, and Love-lies-bleeding; 8, 8, crescents, raised beds, elevated by stakes of Larch of equal size, and thus forming by their elevation alone a fine feature in the background. These are planted with Scarlet Dahlia in the centre, a band of Verbena venosa, and an edging of Cerastium tomentosum all round at the top of the stakes intended to hang over and drape them. We are sure this will have a fine effect in winter, early spring when in bloom, and all the season through. The stakes meanwhile might be covered with Sedums or Ivy. For such elevated telling beds Punch Geranium might have been better than the Dahlia, though the latter, if early, will look well. 9, 9, Salvia patens for centre, and surrounded with Verbena venosa and Variegated Alyssum mixed, which we are sure will be charming; 10, 10, Gazania splendens; 11, Spitzfira Geranium; 12, Beaton's Stella, more appreciated in Ireland than even in England; 13, Lady Plymouth Geranium; 14, Beaton's Variegated Nosegay; 15, 15,

Mrs. Miller Geranium; 16, a nice finish for the place, when we saw it, radiant with Trentham Rose Geranium, this season it is supplied with little circles inside filled with Lobelia, and various colours of dwarfish Geraniums; whilst all the spaces between the circles, and round the outsides of them are to be carpeted with *Cerastium tomentosum*. Two years ago we did a good deal in this ground-colour-carpeting style, and we prophesy that this bed will not be the only one at Ham Wood. It is hardly necessary to mention any little differences on the other side of the garden. What pleased us greatly, was not only the general success, but the deep interest taken in the arrangement of each bed. We do hope that this will be truly an exhibition year at Ham Wood, and that the pleasure from success will repay the thought and labour involved.

R. FISH.

### PRUNING CLIMBING VERANDAH PLANTS.

SHOULD not a Honeysuckle and Jasmine, growing up a trellis under a verandah, be pruned at some time of the year, to prevent their running up and making a quantity of new wood above the trellis without blooming?—NOVICE.

[When a climber of any kind, indoors, or under a verandah, or in the open air, puts forth strong young wood above or beyond the trellis or limits of the space allowed for that plant, and this new wood does not bloom like the tops of your Honeysuckle and Jasmine, pruning does more harm than good, because pruning will only and in every one instance aggravate the evil—that is, pruning a "proud" plant under the conditions is the most sure and the most certain way of keeping it from blossoming. Your Honeysuckle and your Jasmine would load the air all round your house with their fragrance, if you could give each of them five or six times more room than they now have, and then train over that space all the medium-sized shoots, each of them made in a season; cutting clean out every puny little shoot as soon as it was from 4 inches to 6 inches long, and also stopping every gross shoot that was much bigger than the rest when it was 4 inches or 6 inches long, getting two ordinary shoots from the cut part instead of one extraordinary shoot without stopping; and any shoot that was large, or little, or middling, if it crowded that part of the plant, to be cut clean out from the branch as soon as one saw the crowding. But, as in this little island we have not room for one-tenth of the climbers with which we are charmed, and whereas we cannot afford sufficient space for the tithes of them, our people have invented a process which hinders most plants from growing away so fast; and unless you can afford more or rather much more room for your Honeysuckle and Jasmine, you must have recourse to that process which consists of baring the roots all round and 2 feet from the stem, and then severing every large root and one-half of the medium-sized roots just as the top shoots have been served above, only that the cutting-away of the large and larger roots is done 2 feet from the stem, and all the very little roots are left to provide for the tops till the cut roots make new ones to help them. But, like bleeding, it needs to be repeated occasionally, or as often as proud growths continue.]

### SUMMER PRUNING OF GRAPE VINES.

At a meeting of the Grape and Wine-Growers' Association of Northern Ohio, on the 24th ult., Charles Carpenter, of Kelley's Island, gave the following as his method of summer-pruning:—

"The many directions given for summer-pruning Grape Vines are enough to bewilder the novice, if not those of some experience, and I hope, in attempting to elucidate, I shall not further mystify the subject. As a general rule, prune as little in summer as you can, and not let the Vines get so thick as to cause any of the leaves in the thickest places to turn yellow, or deprive the fruit of plenty of light and air. The winter pruning should be more severe than is usually done. The vineyard culture, where 40 or 45 superficial feet of land are allowed to a Vine, from thirty to forty eyes to a Vine for bearing are plenty for most varieties. Never leave over one bud or joint per surface foot of land where the soil is favourable; and where it is unfavourable, the Vines should be planted further apart, and a less number of eyes for a given surface left.

"Now, if the winter pruning has been properly done, but little will be necessary in summer, and should commence early by removing water sprouts, superfluous buds; and whenever

from short-jointed canes, or too close training of them, there will evidently be too dense a mass when grown, thin out a part.

"As soon as the fruit is set, select the shoots for the next year's bearing, which should be grown on spurs on the lower part of the stock, and trained as much as practicable aside from the fruit and above it, and have the laterals picked out for 3 feet or 4 feet, so as to have a clean cane for next year, and keep the Vine open near the fruit. Beyond this remove no laterals, nor stop the ends of their canes.

"Some of the fruit-bearing shoots, particularly those near the ends of the canes, will incline to make too much growth; these may be stopped at from three to six leaves from the last cluster of fruit. Of the fruit-bearing shoots, except those near the ends of the cane, but few will need stopping, if there is a full crop of fruit, and proper attention is given to tying-up so as to keep the growth spread and open. Always endeavour to prevent growth by stopping ends and removing buds, rather than to cut away after the growth is made.

"In all summer pruning and tying-up, care should be taken that fruit grown in the shade should not be exposed to the direct rays of the sun. If the shade under which it has been growing is removed, it will surely be injured, if not spoiled.

"The best Grapes are always grown in the shade of the foliage. They require light and circulation of air. Those grown under the direct rays of the sun are smaller, harder pulped, and inferior to those grown where they have considerable protection."—*(Prairie Farmer.)*

### THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT BATTERSEA PARK.

It is impossible to speak in too high terms of this truly grand national display of what must ever prove the primary source of the riches of a nation—its agricultural products. In no other country have these been so fully developed as in Britain; in none has ingenuity of invention been combined with such an amount of mechanical skill in constructing means for reducing the soil to subjection; and in none, too, do the great mass of the people take so lively an interest in farming matters. Selecting a spot within sight of the Houses of Parliament and of the International Exhibition, this great and useful Society has succeeded in gathering together, from all parts of the country, a more extensive and varied collection of stock and implements than has ever before been seen; and what redounds scarcely less to the Society's credit, the whole is arranged and classified in such an admirable manner, that any article in the catalogue, however small, can at once be found. The Show has proved a complete success, both financially and as a means of giving a just idea of the present advanced state of British agriculture, both to foreigners and our own countrymen.

In the miscellaneous department Messrs. Lawson & Son exhibit a most extensive and interesting collection of cereals and grasses, including all the principal varieties both ornamental and useful, accompanied with samples of their seeds, as well as those of agricultural roots. Occupying the centre of the stand there are in pots upwards of 140 of the best and rarest species and varieties of Conifers, among which were several of the new Japanese kinds, such as *Sciadopitys*, *Retinospora obtusa*, *pisifera*, &c. They have also wax models of various kinds of Peas, Beans, and Kohl Rabi. Turnips would likewise have been shown in the same way could room have been spared for the large number of varieties which had been prepared. Some fine stalks of a new kind of Rhubarb, called the Scottish Champion, which is said to be greatly superior to the Victoria in every respect, were also shown; and numerous coloured plates from the "*Pinetum Britannicum*," and "*Jardin Fruitier du Muséum*" were hung in different parts of the stand.

Messrs. Gibbs & Co., of Half Moon Street, had likewise an extensive collection of seeds of various kinds, and dried specimens of cereals and grasses, together with roots of Red and Yellow Globe, Long Red, and Long Yellow Mangold, White Belgian Carrots, and Kohl Rabi in a remarkably good state of preservation for this advanced period of the season.

Messrs. Carter & Co. had also a good exhibition of seeds of grasses, roots, &c., with numerous specimens of the former and coloured representations of the latter, as well as growing samples in pots. But as striking a feature as any was a large box or tray of *Spergula pilifera* in beautiful verdure, which, when we visited Sydenham a few weeks ago, had been recently planted for the purpose of exhibition here.

Among the implements, lawn-mowers were present in great force and variety from the usual exhibitors, but differing nothing from those which have been already frequently noticed in our pages. In one machine the cogs, apparently for silent, easy working, were of brass; and Green, of Leeds, had a new kind of chain, the outside links of which were made to come down like a flange over the cog wheel, which they were intended to clasp so as to prevent slipping off. Garden rollers came from the same exhibitor, Amies & Barford, and several others. Garden chairs were also to be seen in great variety; a number of excellent ones being exhibited by Messrs. J. B. Brown & Co., from whom there were, in addition, several very ornamental cast-iron vases. Seats and chairs of good construction were also shown by Picklesy & Sims; Barnards, of Norwich; Dray and Co.; Mapplebeck & Lowe; Haywood, of Derby, and some others. Reynolds, of New Compton Street, has one of iron, the bottom wrought in imitation of cane; and a good assortment of wire baskets, trellises, flower-stands, &c., similar to those shown at the International and Royal Horticultural Society's exhibitions.

In hot-water apparatus, the only contribution worthy of note was from Wood & Tomlinson, of Altrincham, consisting of two tubular boilers—the one of a horizontal, the other of an upright description. The principal peculiarity of these is the form of the tubes, which are scooped out on four sides, and rounded at the corners, so as to expose a greater surface to the action of the fire. The firebars are hollow; in the horizontal boiler, cylindrical; and in the upright one, of the regular furnace-bar shape; and in both cases the return passes in at the bottom by a syphon bend. They are said to be very economical of fuel, and powerful in their action.

Messrs. Warner & Sons have a fine display of hydraulic apparatus of various kinds, including pumps, garden-engines, &c., which demand no particular description here. We also saw a water and liquid-manure distributor from Mr. Baker, of Compton, near Newbury, consisting of an iron barrel containing 180 gallons, mounted on wheels, and which is light, neat, well-fitted for the purpose for which it is intended, and very cheap. It would prove useful for watering approach-roads and extensive lawns.

From the Hurlford Fireclay Works were several garden vases of that material, combining an excellent appearance with a very trifling cost, and which would just meet the wants of the large class of persons having small villa gardens admitting of such decorations. There were also wall copings, paving tiles, and garden-bordering of various descriptions, some of the latter being of a very good design, but ugly colour, together with feeding-troughs for cattle and poultry and numerous other articles of an agricultural character.

The St. Pancras Ironwork Company have a specimen of Scott's glass walls, already noticed fully in a report of the International Exhibition. Sir Joseph Paxton's watering-pot is shown by Thomson, of Hounslow, and garden netting by Cullingford; besides which there are numerous exhibitions of wire-fencing, and various kinds of ironwork, which need no particular mention here.

## THE INTERNATIONAL EXHIBITION.

(Continued from page 239.)

Of meteorological instruments there is a goodly display, contributed by Negretti & Zambra, Adie, and other eminent makers; but it is unnecessary to enter into descriptions of such familiar instruments as barometers, thermometers, and hygrometers, the principles on which these are constructed, and their mode of action, being well known, whilst as to their comparative accuracy no opinion can be formed by mere inspection from the outside of a glass-case. To do more would require lengthened trial and careful comparison in a place much less subject to vibration than the galleries of the Exhibition building.

As a barometer adapted for scientific observation, or, in fact, any purpose, the standard instrument of Negretti & Zambra is certainly one of the best, and it is procurable at a cost little exceeding that of the imperfect wheel barometer, which, if not made with extraordinary care, is liable to derangement, and is useless except as a "weather-glass." In Negretti's instrument the scale terminates in an ivory point, which, when a reading has to be made, is brought down to the surface of the mercury in the cistern by working a tangent screw. As soon as the ivory point and its reflection just touch each other, the vernier is adjusted to the top of the mercury in the tube, and the height of a

column of mercury equivalent in weight to the pressure of the atmosphere is read off to a five-hundredth of an inch, subject to correction for the capillary action of the tube and the expansion of the mercury by heat. It will thus be seen that no correction has to be made for capacity of cistern as in instruments with fixed scales, which is an advantage, by saving calculation; but it is doubtful to us whether this advantage is not more than counterbalanced by the necessity of making two adjustments—that of the ivory point to the surface of the mercury in the cistern, and that of the vernier to the surface of the mercury in the tube. These two adjustments cannot take place simultaneously, and in the interval, however short, which may elapse between the two a change may take place in the pressure of the air; the ivory point and its shadow might be no longer in contact, and, consequently, the true height of the mercury in the tube at that particular moment of observation would not be read off.

The same exhibitors have also a standard maximum thermometer, which has been found to act very well. Instead of the extreme highest temperature being marked by an index pushed forward by the mercury, as on Rutherford's principle, a piece of glass or enamel is introduced into the bend of the tube next the bulb, and which acting as a valve permits the mercury to flow past it when the temperature increases, but does not allow it to return when it becomes colder. Thus the extremity of the mercury in the tube always marks the highest temperature. To readjust the instrument it is merely necessary to lower the bulb end. Without venturing any opinion on the merits of the instrument as compared with those on Rutherford's principle, which are also exhibited, we may state that they have been tried at Kew, Greenwich, and other places, and that they have given great satisfaction.

In connection with the subject of self-registering thermometers we may state our regret that so few reliable observations on maxima and minima temperatures have been kept; for such are far more useful both to the horticulturist and the meteorologist than the readings of the ordinary thermometer made at a particular time, and actually involve less trouble. To be told that the mean temperature of a place is—say 50°, will afford but little idea of the vicissitudes of temperature to which vegetation is there exposed; but if known that in winter the thermometer stands frequently at zero, in summer at 100°, that the day temperature of certain months is so much, that the night temperature is so much, a tolerable approximation may be made to the true character of the climate, and productions of that particular spot.

We also noticed in other cases what were termed agricultural barometers, shown "merely as weather-glasses," by which we presume no great accuracy was implied, and some of which would cost half as much at least as a really good instrument. Adie, of London, exhibits an ingenious self-registering barometer, the invention of Admiral Sir A. Milne, which by a clock and float working an arm to which is attached a pencil, traces on a diagram lines indicating the height of the barometer at particular hours; and from R. Adie, of Liverpool, we find a conservatory hygrometer, in which the warping of a slip of wood is made to indicate the moisture or dryness of the air on a scale beginning at very damp, and ending at scorching. The principle of this, however, is not novel.

Before quitting the British portion of the Exhibition, we must notice the large case exhibited by the Liverpool Committee of Imports. It contains samples of all the varied importations which are made through that great commercial centre, comprising cottons, wools, bread-stuffs, sugars, teas (from the commonest to the finest), coffee, rice, arrowroot, spices, drugs, gums, minerals, dye-stuffs, &c., together with specimens of 180 sorts of wood. Most of the articles exhibited are accompanied by a comparative statement of the quantities imported during the last ten years, and an account of the sources from which these supplies were drawn, and the uses to which they are put.

We have now briefly reviewed the Exhibition in the British department, but from the immense number of articles displayed, and the additions and changes of position which have from time to time taken place, several have no doubt escaped our notice. To any of such that merit particular notice we shall revert on a future occasion, and we shall now proceed to examine the colonial departments, which, though less rich in examples of manufacturing skill, are particularly interesting by the raw products which are there displayed in profusion.

(To be continued.)

### DESTRUCTION OF SMALL BIRDS—A PLEA FOR THE SPARROW-SHOOTERS.

A KENTISH farmer, in the *South Eastern Gazette*, says, "Having noticed in your paper some account of the ravages of caterpillars, &c., attributed to the destruction of small birds, I should like to state my opinion on the subject. I am now using a farm where, I am ashamed to say, there are thousands of Sparrows and other small birds. There are also as many caterpillars and different kinds of insects as in any part of Kent; and but for the constant use of soot and water I should have had my fruit trees entirely stripped both of leaves and fruit. I am informed by many large fruit-growers that small birds are their greatest pests, and they have to thread their Gooseberry trees to keep them off in January, as well as to employ a man to shoot them.

"As an agriculturist and fruit-grower myself, I believe the way of farming in this country is to grub up all the hedgerows, and thus do away in a great measure with birds, and also with rats and mice. As to moles, I should very much like any one who speaks in favour of them to have twenty in his garden, so that he might understand the nature of them. A farmer must not depend on moles to destroy the wireworm; that must be done by ploughing and good cultivation."

[The above, sent to us by a correspondent, we insert because both sides should be heard, and because the above is a fair example of what the alayers of small birds say. Perhaps more inconclusive reasoners could not be encountered. Admit that there are many small birds on the farm alluded to, and many caterpillars too, yet even "A Kentish Farmer" could not believe that there would not have been more caterpillars if there had been fewer small birds, in the face of the fact that small birds feed their young ones on caterpillars? Some caterpillars there are which birds will not touch; and others which they will not touch when grown large—but that does not refute the demonstrated truth that they collect such caterpillars as those which feed upon the Apple and Pear blossoms. There is but one course sanctioned by common sense—scare the birds from the ripening corn and fruit, and let them live to help the cultivator in destroying insects at other seasons of the year.—EDS. J. or H.]

### HARDY FLOWERING PLANTS.

#### BERBERIS AURAHUACENSIS (*Aurahuacan Barberry*).

*Nat. Ord.*, Berberidaceæ. *Linn.*, Hexandria Monogynia. A half-hardy, sub-evergreen shrub, with straight, erect branches, bearing leaves of two kinds—the lower ones cordate, with a long petiole; the upper ones obovate, elliptical, tapering to the base, coriaceous, wavy, with a few marginal spiny teeth near the end,

and very glaucous on the under surface. The flowers are a very deep yellow, drooping, and grow in compact racemes. From New Grenada, near the village of Aurahuaco-Taquina, in the

Sierra Nevada, 9000 feet above the sea, near the snow-line. Introduced to Belgium in 1847. Flowers in summer.

#### PENTSTEMON CORDIFOLIUS (*Heart-leaved Pentstemon*).

*Nat. Ord.*, Scrophulariaceæ. *Linn.*, Didymia Angiospermia. A pretty half-shrubby hardy plant of spreading habit, having downy stems. The leaves are small, green, shining, cordate-serrate. The flowers grow in large, leafy, one-sided panicles at

the end of the shoots; the calyx is covered with glandular hairs; the corolla nearly an inch and a half long, the tube almost cylindrical, the upper lip straight, the lower lip three-parted; colour, a "rich dull red." Suitable for rock, banks, or against a wall. From California, mountains of Santa Cruz. Introduced in 1848. Flowers from June to October.

### THE CONSTRUCTION AND HEATING OF GARDEN WALLS.

No horticultural erection is so generally met with as garden walls, and nothing so frequently shows the want of proper care. Walls may be built either of brick or stone, as is most convenient in the locality. Bricks are generally preferred, but their superiority in radiating heat is not so great as to be worth incurring extra expense, for stones make a wall fit for all purposes required, if care be taken by the masons to make proper joints, and they are not permitted to fill up with large seams of mortar, which fall out the first winter, leaving crevices capacious enough to shelter an army of insects, sufficient to eat all the fruit. The objects of a garden wall are specifically twofold: first, protection from radiation during the absence of the sun, by which excessive cold is avoided. Dr. Wells' experiment on dew illustrates this. A thermometer, protected by a handkerchief held horizontally, was found, by repeated experiments, to be from 4° to 6° higher than one openly exposed on a grass plot. This is the conservative power of the garden wall, and it is one of great importance; for the greatest radiation takes place during calm, clear nights, and may be so much in excess as to produce frost ten months in the year in our climate. The second object of the garden wall is accelerating vegetation, by increasing the temperature of the atmosphere in which the tree grows. When the wall is heated by the rays of the sun, it, in common with all heated bodies, radiates its caloric in ratio to the square of its distance: thus, if at 1 foot from the wall we have the power of 1°, at 1 inch we have a power of 144°. The reflection of all the unabsorbed rays of the sun, impinging on the surface of the

wall, increases the temperature of the atmosphere considerably. This power I will term forcing. That it may be as efficient as circumstances will admit of, the coping must only project 2 inches over the top of the wall, that it may not prevent the rays of the sun falling on the trees, but at the same time be sufficient to protect them from rectilinear radiation by night.

SECTION OF A HOT-AIR STOVE CHAMBER, AND FLUES FOR HEATING A GARDEN WALL.

- a, Furnace.
- b, First iron plate on which the fire acts.
- c, Second iron plate.
- d, Brick arch.
- e, Air-boles, opening into the hot-air chamber.
- f, Hot-air chamber.
- g, Flue, communicating between hot-air chamber and flue h, h, &c.
- h, Flues in the interior of the wall.
- i, Door to slide open when it is desirable to accelerate the circulation of the air.
- k, Soot-door and damper.
- l, Door for removing dust from the bottom of the hot-air chamber.

The heating apparatus, being placed below the ground level of the wall to be heated, is, as much as is practicable, situated at the lowest point of the ground level of the wall. The furnace is bricked (m, n) that a supply of the coal may be coked, thereby reducing the consumption of fuel, and lessening the attendance requisite. The air in contact with the plates b, c, being expanded by heat, will flow into the chamber f, coming into contact with colder air there, it will acquire a rotatory motion, retaining a tendency to ascend in ratio to its rarefaction, and in consonance with which tendency, it will flow along the flues h, as indicated by the arrows. When the heated air is found to circulate sluggishly, in consequence of its peculiar electric condition, sliding open the door i, will accelerate its circulation.

The conservative power is often aided by canvass, nets, straw, or Spruce Fir branches. Of these, canvass spread by night, and removed by day, is the best for increasing the forcing power, which is imperatively necessary; for Peaches and Nectarines, in cold, cloudy seasons, when they make late growth, are badly ripened—that is, they are unproductive next year, which often ends in the total destruction of the tree by canker. If the wall is flued, and fire heat is introduced by smoke, these flues are unfortunately found in practice too difficult to clean, and, consequently, draw badly when damp or foul, from their great length and necessarily tortuous course. Hot-water pipes have been used with better effect; but the expense in procuring and fixing them has prevented their use in a general way.

The method of heating that I recommend, with hot air, is one which may be effected at no more expense than flues; and, however doubtful may be the propriety of introducing air, deteriorated by passing over a highly heated surface, for the supply of animal and vegetable organisation, in this case it can be productive of no evil, being merely introduced into the interior of the wall. In height, the wall should not be under 8 feet, from the ground level to the coping; but 10 feet will be found the most useful height for general purposes. Where the area of the garden is flat, the appearance is much improved by raising the wall, on the north side, a foot or two higher, carrying the rise round the north-east

and north-west angles, and finishing with a cavetto or turret, in character with the architecture of the place. Not that I would recommend too much architectural display, to which fitness and propriety are frequently sacrificed by architects and builders; but the style of architecture adopted in the mansion, ought to pervade its appendages, or a bizarre and mean appearance will be the result. Thus, on the simplest plan, the garden doors should be supported by a couple of pilasters or pillars engaged. But where Gothic architecture is adopted, a buttress may be made to support each angle, adding both to the beauty and utility of the wall.

A coping is essential to the preservation of the wall from the effects of weather, at the same time it much improves its appearance. One of the most simple and efficient that I have seen is used by Mr. Walker, Preskilly Gardens, Pembrokeshire: this is made of slate flags, a couple of inches thick, bevelled off to three-quarters of an inch at the edges, and projecting 2 inches on each side. These projections, as before stated, greatly enhance the conservative power of the wall. Training is generally effected by nailing with shreds, but is attended with this evil—the wall, after a few years, becomes so full of holes, that destructive insects, such as earwigs and woodlice, find ample shelter therein. It has, therefore, been attempted to remedy the evil by fitting wires along the face of the wall, on which the trees are trained. Unfortunately, in this case, a space intervenes betwixt the trees and the wall, where the heated air escapes at the small angle of divergence, in consequence of the greater lightness, caused by the rarefaction of the air, while the constant flowing-in of the denser and colder air to supply the place of that escaped, produces a current which completely destroys the forcing power of the wall. I, therefore, come to the conclusion, that the only eligible mode of training trees, on an open wall, is by rails and shreds. For the purpose of destroying the larvæ of insects, I mix quicklime, as for whitewash, adding an equal quantity of soot, so as to make a thick wash. With this I wash over the walls and trees every winter, at the time when I unvail and train them. This, with attention to pointing the walls with good cement, when they require it, will keep them in good order.—P. WALKER.—(*Gardeners' Magazine of Botany.*)

A MOLE TRAP.

A PIECE of half-inch board, 6 inches long by 4 inches wide, through which four holes are bored near the four corners, and one in the middle. A piece of half-inch hoop-pole is split, the ends pointed a little, and so bent as to fit in and appear as the two pieces marked A, A. Another forked piece, of the same or smaller material, is cut, and one end round-pointed, so as to fit in the central hole of the main part of the trap, as B; C is a piece of stout twine, to which are attached pieces of very fine copper wire D, D. Each of these two sides of wire is double, and is, when the trap is set, opened out and led along inside the wooden loops A, A; E is a common wooden peg, of which four are necessary to set the trap; their use is simply to keep the board to the ground, against the upward force of the bent spring stake F. The trap is set level with the ground, in a "run" of the mole, taking care to disturb the run only enough to allow the loops A, A to enter it. A mole passing through the run, has to go through the loops, and in its passage has to scratch away the fork B, when the string C is allowed to be forced upwards by the spring E, drawing up, at the same time, the wires D, D, between which and the board the mole is caught.

Moles are far less suspicious of these wooden traps than they are of east-iron ones.

The chief art is in choosing the "runs" in which to set the traps. In soft ground, a mole would as soon make a new run

as use an old one; but as they usually return to banks and dry places to rest, a "run" through hard ground, between their resting-places and their "hunting-grounds," generally makes sure work of them.

### "I LOVE THE BIRDS, BUT I LOVE THE CHERRIES TOO."

As you are taking up the cause of the poor little birds, and as many would preserve all the cock and hen Sparrows in the country, I thought I would give your readers the benefit of nearly four years' experience—that is, if there be any benefit, on this truly interesting subject.

"Live and let live" is undoubtedly of Divine origin; but then, again, all creatures are given to man for his use, and if he will only employ sense and not temper he will seldom go far wrong. These were my ideas, and are now, when I first came here—one of the most beautiful spots in Surrey; and in order that the remarks which follow may be fully understood, I will in part describe the place—my house and grounds.

We are a mile from the village, no house nearer than 500 yards. On three sides of my grounds there is a high plantation and shrubbery, on which during the season you can always find from six to ten nests. I have never disturbed them, and unless the Jays, the Cuckoo, Night Hawk, or some such enemy pay them a visit, they always hatch out and fly. At different times I have taken a nest of young birds about four or five days old, have put it into a wire cage so that the old ones could feed their brood, and have seen with pleasure the immense quantity of wireworms, slugs, grubs, &c., brought in. I say "immense;" for on some days we have found at the bottom of the cage as much as a quart pot would hold, and these were the insects that the old birds could not put into the young ones' mouths. Now, if we take the average of one dropped for two swallowed, we see how much a single pair do.

On another occasion I sat and watched a Wren feed her nestlings. Every minute she came in with some insect. In a quarter of an hour that I watched she had first a spotted white moth, then a small butterfly, then a dark grub, then some kind of fly, then came a small worm or caterpillar. I could not tell which. Off she went again, and again some insect. How long I should have sat watching I cannot say, as I was called in to "my grub." So often have I seen birds catch insects that I thought they, the birds, were an unqualified good. Even the tale of the Swallow eating bees I did not believe, for I have seen a bee chase a Swallow, not one of the white-tailed fellows, but those that have two long feathers in the tail, as you may see at times a small bird chase a Hawk. Cock Sparrows became friends. Now so much for the good birds do.

I have now in my garden a great many Gooseberry and Currant trees stripped of their leaves by the caterpillar. I have also plenty of Sparrows' nests; but Sparrows must be like human beings—when they have plenty they care not for that for which, if only given in part, they would hop for joy. Never a caterpillar will they eat; but as soon as a Pea-pod swells, or one side of a Strawberry ripens, at that they go. The Blackbirds are as bad. I have driven out four at one time from a small bed of Strawberries, 17½ yards by 6 yards. All this year I never have had a ripe whole Strawberry; I get plenty of halves and bits. Now, the birds will not eat the caterpillar. Up to the present time I let the birds have the first crop of all they chose to take; but I have now such a stock of birds, that it will be all first crop and no second for me. I have not a Raspberry. They even eat the ripe side of the berry, and wait till the other side ripens, and then come again; and as these chaps come at two in the morning, even Mr. Fish, who could never have been "a six o'clock man," would not match them. Now, what are we to do? "Live and let live?" Do the birds follow this golden rule? Wasps, I believe, kill more caterpillars than birds. Can you, and the combined talent of 162, Fleet Street, help us? Will "D. B." give us his aid? "D., Deal," will say, "Birds are not florists' flowers;" and the "DEVONSHIRE BEE-KEEPER" cannot be expected to interfere. The only conclusion I can come to, is to have a machine that will fire a gun every hour, half-hour, or quarter-hour, or even every two hours, and to put it in the garden. Will this do? I have taken into my confidence a working clockmaker, and we got out a thing that would "shoot-off;" but as he has not time to work for me, and not knowing another mechanic, I will give you the plan as well as I can on paper, and

if any of your readers have a mind to try, I will aid. The cost will not be more than £1 or 30s. We first took eight pieces of stout iron gas-pipe, inch bore, and 3 inches long; fixed this on to a wheel, and there we stopped work, but not thought. However, this piping was to have had a gun-nipple screwed on to one end, which end was, of course, to be closed by a smith making it hot and welding it together; then we were to have a clock movement to turn the wheel round, and, at certain times, a spring was to let fly a hammer which would fire off a barrel. The movement would be similar to the striking movement; the whole to work with a cord and pulley; also a pendulum as a clock, and by raising or lowering the ball on the pendulum, the rate of movement would set going the machine in half-quarter or eighth time. In short, it was a "hybrid" between a revolver and a Dutch clock, or a cross between a Yankee and a Dutchman.

My practical friend said there was "no difficulty in making it, but that he had so much to do that he could not make the toy."

Well, if it was made would it scare the birds? They soon became familiar with all kinds of guys, and build in old coats, hats, &c. Tell me, you learned men of Fleet Street, can I have fruit, and Peas, and also birds?—X.

[Nothing more easy. One or two live old women or old men for scarers, during the Pea and small fruit season, will save the crops and the birds at the same time. Boys and girls cannot be trusted implicitly; and the best wax figure from Madame Tassaud's would soon be a rest instead of a terror to the winged marauders.—EDS. J. OF H.]

### ENTOMOLOGICAL SOCIETY'S MEETING.

The June Meeting of the Entomological Society was presided over by the President, who announced that it had been made a special one, in order to proceed with the election of a Member of the Council in the place of Dr. Knaggs, resigned, when Mr. Stainton was unanimously elected. Among the donations received since the last Meeting was the very excellent memoir on the late Professor Henslow, by the Rev. Leonard Jenyns, just published, a truly worthy record of a good man. A copy of the fine work, by Jacquelin du Val, on the "Genera of European Coleoptera" was also on the table purchased by the Society. A note was read by Mr. Barton, of Lymington, on the sudden appearance of a yellowish dust on the leaves of plants in his garden, which he thought might be the eggs or excrement of insects, but was pronounced by several botanists present to be the pollen of coniferous trees.

Professor Westwood exhibited a dry collodion plate, communicated by Mr. Ormerod, on the coating of which, composed of gelatine, collodion, nitrate of silver, and tannin, considerable devastation had been committed by *Blatta orientalis*, the common Cockroach, the action of the jaws being visible in several places. The Professor also mentioned other instances of insects attacking chemical preparations.

Mr. Waterhouse exhibited two small but rare British Beetles, *Scraptia nigricans* (Stephens), taken on rotten Oaks, and *Trichonyx sulcicollis* belonging to the family *Pselaphidae*, both taken in the neighbourhood of London.

Mr. Reading exhibited *Pentarthrum Huttoni* (Wollaston), taken at Plymouth in a cask made of birch staves with hazel hoops.

Mr. W. F. Kirby exhibited a very rare and beautiful Moth from India, *Brahmæa Hearseii*, white; and *Parnassius clarus* from Asiatic Russia. And he read a paper on the specific difference between *Colias Boothii* and *C. Hecla*; also, a description of *Cononympha Mandare*, a new species from Polish Ukraine.

The President exhibited specimens of a very remarkable species of Ant from Mexico, *Myrmecocystus mexicanus*, the abdomen of which is very large and inflated, and which secretes a kind of honey sold in the market of Mexico, and which makes an agreeable liquor. A somewhat similar kind of Ant had been sent from Borneo by Mr. Wallace, which the President had described under the name of *Cremalogaster infustus*. In this species, however, the honey-like secretion is discharged from the metathorax and not from the abdomen as in the Mexican species.

A paper by Mr. E. Newman was read, entitled "Varieties versus Hybrids," in opposition to Mr. Faraday's paper read at the May Meeting, and which Mr. Newman appears entirely to have misunderstood, supposing Mr. Faraday to have maintained

that remarkable varieties occasionally observed were hybrids between distinct species, instead of being the produce of two varieties of the one and the same species; Mr. Faraday contending that where both parents belonged to the same variety, or to the type of the species, the progeny would follow the parents. Experiment and direct observation of facts could alone prove or disprove this assertion.

Professor Westwood gave an account of the different collections of insects and insect produce contained in the International Exhibition, and which were of two kinds—those consisting of geographical collections of insects from different localities, and those containing illustrations of the habits or economic application of insects. In the former series were especially to be noticed the collections from Guiana (containing a new species of Paussus), Adelaide, and Natal; and in the latter the illustrations of silk-producing Moths formed by Mr. F. Moore (in the Indian department), and by M. Guérin-Ménéville (in the French department), the latter containing illustrations of the new Japan *Ailanthus Silk-worm*; and a remarkable collection of specimens illustrating the insects injurious to agriculture, horticulture, timber, &c., in the French department.

Mr. Waterhouse read a paper entitled, "Observations upon the Nomenclature adopted in the recently-published Catalogue of British Coleoptera, in opposition to the Remarks of Dr. Schaum contained in a paper entitled 'On the restoration of Obsolete Names in Entomology.'" This controversy is of general interest, as it involves the propriety of taking up the earliest-published name of a species which may have happened to have been overlooked by subsequent describers or monographers.

## THE BOTANICAL GARDEN OF MAURITIUS.

I HAVE never yet seen anything to compare with the floral glory of this island, either in the beauty and abundance of the flowers, or in their astonishing gorgeoussness. I have seen others as fragrant and delicate, but none so rich in tints and colours, and none of such magnificent proportions. It seems, indeed, that every form of vegetable life here is ambitious to be a flower, and is a flower, from the tiny plant, and Vine, and dwarf shrubs, up to the tall bushes and stately trees. The roadsides, even in the wildest and most rural districts, are bordered with beautiful forms of vegetable life; and when you leave the road you plunge into the wilderness of flowering plants, through which it is hard to make your way; and the mean bamboo huts of Coolie, Indian, and Malay labourers and apprentices, as they are called, who by words of misrepresentation and fraud are imported here to the number of twelve thousand a-year, and having worked for almost nothing, are in the end cheated out of even that, are fairly embowered in flowers, and perfumed with what is sweeter than incense.

I cannot give the names of the different flowers, wild and cultivated, which adorn the island, nor would the character of them be understood from the name if it were given, since a great part are indigenous to this island or others in this intertropical latitude. I will merely state in illustration, that no less than one hundred and fifty varieties of the Rose are cultivated in this little island.

I had visited the botanical garden at Cape Town on the Cape of Good Hope, and seen much to admire, though it covers only half a dozen acres, but which are covered with a forest of all the rare trees of Southern Africa, with its plants and flowers. From what I was told by gentlemen of Port Louis, I could not doubt of a higher gratification from a visit to the botanical garden of Mauritius, far more ample in its dimensions, and in which a great part of the vegetable and floral wonders of the tropics had been collected, while the Government had made more liberal outlays in preserving and adorning it, and the Superintendent, whose life had been devoted to it, was celebrated for his good taste as well as for his care and fidelity. It was, therefore, with pleasure that I received a polite invitation from a gentleman to accompany him in his own carriage in a drive to the garden, which is eight miles distant from Port Louis, and in the neighbourhood of the reputed graves of Paul and Virginia.

So bright and early we were on our way, resolved on making the most of the day. The road lay through a charming part of the island, being in a high state of cultivation, and crowded like a bee-hive with the different-coloured races who make the labourers. The island is just within the tropics, and therefore luxuriates and blossoms in an everlasting summer. Here fields

wave with the tallest and rankest corn, a young forest at least 15 feet or 18 feet high. Some fields are ripe for harvest, the long pendent ears glittering in the sun; others are densely crowded with juicy green stalks in the stages of adolescent life, while in other directions are seen young crops shooting up from the naked soil. Thus crop succeeds to crop in uninterrupted succession, the one almost taking hold of the other, and pushing it along to find room for itself. There are some immense fields of sugar cane, some estates or plantations embracing from three thousand to four thousand acres; thus a dense forest is annually created and annually destroyed, into which the eye cannot penetrate—one great jungle for wild beasts, did any live upon the island. Here and there heavy dark piles of buildings are seen rising in the centres of the plantations, with their chimneys shooting up above the rank vegetation and even the trees. These are the sugar mills of the estates, and are generally propelled by steam. Back from the road at a small distance, and always embowered among the trees and flowering shrubs, may be seen, in the luxuriance of the foliage, the fine houses of the planters, which are approached through high gateways and over smooth and wide carriage-ways, and fine pathways lined with shrubbery and flowers. Palms, Palmettoes, Bananas, Aloes, some of them 30 feet high, the Cocoa, the Shaddock, and other luxuriant trees, with tall, straight, and graceful shafts, border each side of the road wherever you go. Amidst this array of natural beauty, which no art or expenditure in our country can equal, are seen and encountered crowds of the degraded coloured races on the roads in a continual stream, going and returning in all directions, bareheaded, barefooted, barelegged, and often utterly bare, except the small domain covered by a rag about the loins. Mingling sights of natural beauty and human misery and degradation!

At length we approached a village called Pamplemousses, from a fruit-bearing tree growing in the vicinity in great abundance, and which is also known by the name of Shaddock. Here is a wilderness of the most luxuriant vegetation which the eye cannot pierce, and above which it can hardly rise. Three or four roads centre here in an open area, in the middle of which rises a large stone Catholic church. A short distance from the church is the Botanical Garden. Twice we called at the house of Mr. Duncan, the Superintendent, to obtain his assistance as our guide and *cicerone*, but without success, as he, too, had gone to his church to participate in the services of the occasion. Near to the house I observed a picturesque little lake, the work of art and taste, over which a flock of ducks were sailing and sporting, apparently sympathising with the spirit of the day. Not so, however, with their predecessors, if not their progenitors, as I afterwards learnt, and whose tragic history I must give your American readers. Mr. Duncan had stocked his tiny lake with a large number of beautiful ducks, and which, in addition to "personal beauty," had other attractions for Mr. Duncan, their owner and master. At length, to his deep regret and sore amazement, he observed a rapid diminution in their number; for as he and his children gazed upon their gambols upon the water, strangely to him one plunged beneath it, and, though it was not in *gurgile vasto*, it never rose again! Unable to account for so strange a disappearance of his pets, he at last resolved to drain his pond, when at once the mystery was solved, for at the bottom of the lake lay a monster eel, which might almost be taken for a veritable sea-serpent. There he lay, splashing, and twisting, and wriggling in the mud and water, and decidedly uncomfortable in his position and prospects. He was not less than 8 feet long, with a corresponding circumference, in whose capacious maw was found the last of the extinct flock of ducks. The monster was slaughtered, the waters turned back, and the ducks flourished again.

At length we found the botanical garden—a grand forest rather than a garden, and in territory a good sized farm, instead of a small plot of ground merely sufficient for a few vegetables and flowers; for the botanical garden of Mauritius covers not less than forty acres. I entered the gateway; I walked the magnificent avenue; and, stretching my eye along as far as it could reach, stood silent, amazed, and wondering, in the unknown, unimagined, and undescribed wilderness of vegetable and floral glory before me. To study it, to comprehend it, to describe it, was altogether out of the question, and I could only wander here and there as fancy and accident directed, and gaze, and enjoy, and, when weary, sit down upon some grassy mound, or by the side of the bank of a little lake, or under the shadow of some magnificent Palm. Wide gravelled roads run from one end to the other, crossed by others at right angles, while walks

are opened here and there bordered with flowers and overshadowed by trees, while bizarre pathways steal around the lakes and into the wilderness of trees and shrubbery, which it was almost perilous to follow. Small artificial lakes are constructed with admirable taste by letting in the water of a brook which runs through the grounds, and tiny islands again are constructed in the lakes, trees shooting up from bank and centre, and giving all the appearance of nature. The principal roads, or walks rather, for carriages and horses are not permitted to enter, are lined by tall and graceful Palms, planted at regular distances, which, as seen from end to end, resemble the rows of pillars in an ancient church or an old heathen temple. Nothing could be grander, while there was added all the freshness of life and the truth of nature. In some of the walks, whose width is most ample, the luxuriant branches, spreading out 40 feet or 50 feet high from the naked trunks, reached across the way, and intertwining twigs and foliage made a vast and beautiful arch, which no art can equal. The sun could not penetrate it, the heat in vain sought to pour itself upon the earth; it was midnight beneath at noon, and cool and moist within the burning tropics. Such flowers, so large and so fragrant, and of such tints and colours! I plucked some, and carefully preserved them, and yet they have faded and all their glory is gone. Such shrubbery, all covered and bending with flowers! Then "the Traveller's Tree" was pointed out, of which I had never read or else had forgotten, which a kind and wise Providence had provided for this burning climate, and which, with a small gash, gushes out with delicious water. And there is the Dragon Tree, which sends out blood by a light incision in the bark, and you feel guiltily as though you had killed a human being. —, *Port Louis, April, 1862.*—(*Boston Traveller.*)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE weather is now most favourable for planting-out good breadths of various sorts of vegetables for autumn, winter, and spring use. *Broad Beans*, a few *Mazagans* may yet be put in, which will produce late in the season if the weather prove favourable. *Broccoli*, *Cape* and *Grange's* may now be planted where the early *Peas* have been gathered, and also the *Waleheren Cauliflower*, which may be made to afford a supply from the end of October till January. *Cabbage*, sow a little more seed immediately if the sowing recommended last month has failed. *Chervil*, another sowing to be made for succession. *Dwarf Kidney Beans*, make the last principal sowing. Earth-up the advancing crops. *Endive*, continue to plant-out a few about once a fortnight to keep up a succession. Another sowing to be made. *Leeks*, transplant; they are the better for being earthed-up like *Celery* to the depth of 6 inches. *Parsley*, make a sowing now to insure strong plants before winter. *Peas*, earth-up and stick advancing crops. A few more may yet be sown, which will come into bearing if the autumn weather prove favourable. Top the tall varieties, as they are growing very rampant this season from the prevailing moisture. Continue to sow *Lettuces*, *Radishes*, and *Salads* of all sorts, according to the consumption. *Tomatoes*, keep them nailed to the walls or wooden fences; thin also or stop their shoots frequently, as they require all the sun possible to produce good crops of fruit in our climate. *Vegetable Marrows*, these plants will require a pretty liberal supply of water during the continuance of dry weather. Stop the main shoots to cause them to throw-out laterals. Hoe in dry weather between all crops in rows, if they are not mulched with short grass or litter, to kill weeds and to loosen the soil around the plants.

### FLOWER GARDEN.

Attend to the greenhouse plants now placed out of doors. See that the worms do not effect an entrance into the pots. Attend to the routine of tying, stopping, &c., as we may presume the principal planting-out for the season is now over. The usual routine of pegging-down plants intended to be kept dwarf, tying others up, and keeping the surface of the beds free from weeds until it is covered by the growing plants, will require frequent attention. The *Roses* to be well staked, the shoots disbudded and stopped, and the roots mulched or supplied with liquid manure according to the state of the weather. Budding to be commenced on all stocks from which the bark will rise freely; and such as are more sluggish in their circulation to be excited by a copious supply of liquid manure. *Carnations* and

*Picotees* to be layered: this is done by cutting through the second or third joint, bringing the knife about half an inch up the centre of the shoot, making a tongue; the small portion of stem beyond the joint is cut back to it, and when pegged-down in the soil, which should be fine and light, it will soon emit roots. These plants require a good supply of water during the time they are in bloom; but it is necessary to be cautious in not overdoing it, for if too much is given they will assume a sickly appearance. If any of the pods appear likely to burst on one side they must be eased by slitting each division of the cup with a thin piece of ivory sharpened at the point.

### FRUIT GARDEN.

Vines on the open walls still require rubbing off the useless shoots, nailing-in those that are useful, and thinning the *Grapes*. *Currants* and *Gooseberries* require all the watery useless shoots to be thinned-out.

### STOVE.

As many of the principal plants of this house will now be in the conservatory, advantage should be taken of their absence to encourage the plants for winter blooming—such as *Aphelandras*, *Begonias*, *Eranthemums*, *Euphorbias*, &c.; and a batch of *Achimenes picta* and *Gesnera zebrina* should be started for the same purpose.

### GREENHOUSE AND CONSERVATORY.

Should these structures require repairs or cleaning, the stock may be removed with greater safety at this than at any period; it is injudicious to leave the completion of such work until late in the season. Proceed with propagating such things as are required, and attend to *Violets* and *Pinks* for autumn potting. *Roses* and other plants in pots to have liquid manure occasionally, as also *Lily of the Valley*. All plants which have done blooming to be cut-in and vegetated preparatory to starting for new growth, and remove the decayed flowers and seed-pods before they exhaust the energies of the plant by perfecting their seed.

### PITS AND FRAMES.

Stock for autumn and winter blooming will now require some care to get it sufficiently forward to be useful at the proper time. *Chinese Primroses*, especially the double varieties, if at all backward, should now be placed in a cold frame, and shaded from the sun, when they will be found to make satisfactory progress. *Cinerarias* for early blooming should also be potted and started at once, choosing the strongest suckers for the purpose, and placing them in a close shady frame until they have been rooted. Examine young specimens that were potted early in the season, and shift at once such as require more pot-room. W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

AS soon as the weather cleared up have been busy hoeing-up weeds, and in other cases where thick, pointing them in. It saves much labour to cut them up and leave them on the ground, when they are not more than 1 inch or a little more in height. A sunny day then soon does for them. Threw a little salt among *Asparagus*. Earthed-up *Cauliflowers* to prevent the wind knocking them about. Staked *Peas* after forking-up the ground near the rows, alike to let in air and keep the moisture from too freely evaporating; will mulch with short grass if hot weather sets in, and give them a little manure water besides. I notice that a good many of the cut-up sets from *Sea-kale* that had been forced have rotted this season, showing that, in all cases, and especially in wet seasons, it is safest to stick the roots thickly in sandy soil, and plant only after they break, as already intimated. Those from unforced roots are more sure, and the smaller roots, between the size of a quill and the little finger, are the sweetest of all. On the whole, however, I like seedlings best, and where much is wanted a piece should now be selected for seed, and the other flower-heads cut away, otherwise the crowns will be inferior. Find plenty of pieces coming up in the ground from small roots left when the crop was taken up for forcing, which seems to show that roots much forced are not so much to be depended on. Sowed *Peas*, which, with the exception of a few of the earliest in July, will be the last for the season. Find that this season that good *Pea*, *Dickson's Favourite*, sown without any help has only been three days or so behind the *Early Frame*, and in quality and bearing there is no comparison. We shall not get a first-rate *Marrow* fit for table until July. Earthed-up some *Potatoes* on the sides of a raised bank, which were planted

shallow on account of the weather being damp, and the soil wet. I notice answers to correspondents, as to Mr. Keane advising to earth-up, and the not earthing-up being followed by a greater crop. I could not say there was the difference of a fourth there spoken of; but there was so much difference that in fine, dry, light soil we could plant from 6 inches to 8 inches deep, and not earth-up at all. But in stiff, wet soil we would plant more shallow, and earth-up, and for two reasons. First, if not earthed-up the Potatoes get so near the surface as to be greened, and thus are unfit for table, whatever their quantity; and, secondly, in such wet seasons as this, the rain instead of sinking into them, is taken past them, especially if there is any decline. I notice some planted on the tops of ridges, with trenches between them, as lately recommended by a correspondent; and though they show for a large crop, a slight earthing here and there will be required, in order to cover those that are cropping out to the surface. In wet seasons, too, those on the flat are more subject to the disease, so far as I have noticed. I say this much as confirmatory of the principle, that circumstances often show reasons for altering treatment. Both plans are right according to these circumstances. Gardeners must often do the best with what they have; it is no use being contented with saying that such and such treatment would make the land better, and be a saving of labour afterwards. All right to say so, and get it if possible; but not to get careless and inconsiderate when it is not done.\*

#### FRUIT GARDEN.

Proceeded with regulating fruit trees; protecting from birds; syringing in houses—as orchard-houses, night and morning—to keep off the red spider, and watered with manure water as needed. So far as our little experience goes, feel convinced that much may be done with fruit trees in pots in small places, and where a little labour is not grudged. Had some small Cherry trees in March sent from a nursery in a bundle without a particle of earth about the roots, and from two of these, the *Impératrice Eugénie* have had a dozen of nice dishes since the beginning of June. One out of the dozen is sickly, threatens to go, but will get hospital treatment. Some others have not given us any fruit, but most have ripened. Will ripen a few to tell us what they are, and if true to name. Of course they had a little more care than being merely jammed into a pot. I feel sanguine that next season they will produce heavily. They are under glass, with abundance of air night and day, the pots partly plunged in the earth, and I incline to keep them there. Would Mr. Rivers or others of more experience tell if it would be an advantage to place them out of doors in the autumn, and how and when? The leaves are large and fine on the stopped shoots, and I think fruit-buds are already forming.

#### MELONS.

So many try Melons after their bedding plants, that, to save room, I will here answer a number of inquiries as to treatment. In a fine season most of those generally grown will ripen well if strong plants are turned out in stiffish loam after the middle of June with the protection of glass only, as in hot days little air need be given if the heat is not above 90°. The seasons are so uncertain, however, that it is preferable to use a little bottom heat, such as from grass and litter if it can be got. In such a case there is little necessity for the material being sweet, if you cover all over with from 15 inches to 18 inches of soil, and that soil is 15 inches from the glass. Now, in the case of beginners, I would advise using two or three plants to a light instead of one, as the management is more simple, and you are likely to get the fruit set more equally. From six to eight fruit in a light 7 feet by 4 feet is a good crop. If the kind is a pocket Melon of course you can have quantity accordingly.

Now as to stopping and training. We have had a good deal of trouble from new comers not understanding our plan, and stopping and nipping the shoots as they would do a Cucumber: I will, therefore, try and make my simple plan as clear as possible. It is based on a series of facts or, rather, observations. First, that in general the Melon bears most freely on the third shoots that the plants make; secondly, that the fruit swells most freely when the plants are strong, before these show fruit; thirdly, that once a fruit sets and swells on a plant it is almost use-

\* We quite agree with Mr. Fish, that where the tubers are so near the surface as to be exposed to the light, it is desirable to draw over them a little earth, not more than an inch deep. Whether earthing-up is more needed on a heavy soil we do not know, as we never had to grow Potatoes on a soil so unsuited for them; but as Mr. Fish says it is so, our readers may safely accept so good an authority.—Eos.

less to try and get another fruit to set and swell before that first fruit is ripe. Now then for the simplicities if possible. There is a seedling Melon plant a few inches in height, and growing up, upright as a young Oak; that is the primary shoot; but as we neither eat the shoot, nor use it for timber, we pinch the top terminal bud out. This will cause a shoot to come from the base of every leaf left; these are the secondary shoots. To make matters simple, we shall only keep two of these; though if a plant was to fill a light we would prefer four or six. Well, we select two, and all the others, when an eighth of an inch long or so, we nip out clean from the axil of the leaf with the point of a penknife. The two little incipient shoots left, will soon begin to grow rapidly. The plant is turned out into the middle of the bed, and we train one of these secondary shoots to the back, and the other to the front, *no stopping of these shoots yet, mind*; but as they grow, nip out the bud in the axil of each leaf, but not hurting a leaf, to the length of 15 inches or 18 inches from the collar of the plant. This prevents the third, or tertiary shoots coming until the plants are strong. Then nip out the point of the secondary shoot, leaving about four joints, from the disbudded part and the stopped point. From each of these joints the tertiary shoots will come, and will generally show fruit at the first joint; stop at the joint immediately above, and treat in the usual way. By this mode little pruning is necessary; the plants are strong before they are allowed to show fruit; the fruit comes into bloom on the plant almost all at once; and, if too many set, it is easy to thin them out. I believe that those who try this mode will give up the everlasting stopping, and treating Melons much as they would do Cucumbers. If people were to be paid for novelty now-a-days I might expect some patent of reward, as I believe the plan was originally my own. Lately in some contemporaries I have noticed it advocated; but it is many years since I practised it and recommended it. If I can learn a better and more regular and simple mode, I shall be glad to hear of it.

#### ORNAMENTAL PLANTS.

Much the same as last week. Mowed lawn; switched part with daisy-knife, with which a man can do four times as much as he could do with a scythe, and with half or less than that of labour. Regulated and planted rough rockery ground. Hoed all the flower-beds we could get at, to break the crust and destroy the weeds, keeping all rakes locked up.—R. F.

#### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

CAMELLIA CULTURE (*J. M.*).—See page 229 of the current volume. If the wood is made, and the buds formed, give them more light in the greenhouse, abundance of water, and give them more light out of doors, if removed there. The drying-up will not do at all, it is apt to make buds drop, as well as elongate. Perhaps you do not comprehend the exact state of your plants.

MELONS FALLING OFF (*N. P. Hunts*).—We question if there is anything to correct. Nature is doing what you should have done in the thinning way. Twelve good, fair-sized fruit are enough for such a pit, 12 feet by 6 feet. We presume your heat is sun heat, if not, from 65° to 70° is hot enough at night. If more, leave a little air on to reduce it. In fact, a little air at all times will help you, especially in such heat.

DAPHNE LEAVES DECAYING (*A Cheshire Subscriber*).—Such leaves will always be found on Daphnes, on growing afresh, for like other evergreens they then shed a few of their older leaves. If there are many such, it shows the plants have been too dry and cold, or, what is more likely, have been waterlogged on swampy soil from deficient drainage. If so, examine the roots, and if the soil is bad and swampy, drain well, put in a smaller pot, using sandy heath soil and fibry loam, and set the plants where you can keep them close, shade from bright sun, and syringe the heads frequently. As they break and grow inure to more air and sun by degrees.

CELERY ROOTS (*B. W.*).—We never trim them, but move each plant with a trowel. The avoidance of any check to the growth of the plants is one necessity in growing fine, crisp Celery. The Dianthus you mention are both hardy.

**CHLORIDE OF LIME (J. S. S. W.).**—You will see an extract in our paper to-day relative to the strength of the solution for killing insects.

**WARINGTON'S AQUARIUM (L. L. S.).**—The glass is fixed into the zinc by the white and red lead mixture. Zinc has no injurious effect upon fish, nor has either white or red lead after it has become dry and hard. To make assurance doubly sure, you could varnish over the metal and the white or red lead before putting in any water.

**GARDENERS' HOURS (W. T. F.).**—We do not see anything in your communication but what Mr. Fish has said.

**MILDEWED ROSES (J. A. P.).**—We fear the mildew has progressed too far to be much subdued by flowers of sulphur. Mulch the surface of the soil about the roots and give liquid manure freely two or three times a-week, and not too strong. If you adopt this precaution earlier next year you will not be troubled with mildew, probably. The *Berberis japonica* is likely to do better now it is less shaded.

**VINE LEAVES ROUGH ON UNDER SURFACE (D. Moubray).**—It is not a disease, but a consequence of the excessive activity of the roots. These planted inside the house in a border soil of "2 feet deep of rich loam, cow-dung, and half-inch bones," supply sap to the leaves faster than the latter can expand, the parenchyma of the leaf consequently swells, and acquires the warty appearance so frequent in such cases. It will not injure the Vine, and as the organic refuse in the border will decrease annually, so will this appearance in the leaf. A little less water to the roots, and a little more moisture in the air of the house will also diminish it.

**ICE-HOUSE (A. Notice).**—There are about twenty communications on this subject in our last volume, giving directions for making ice-houses and ice-stacks. We have not a single new suggestion to make.

**ROSE "JOHN HOPPER" (R. Ward, the Rosery, Ipswich).**—We consider this to be a first-rate Rose, of magnificent habit, raised, as you say, between Madame Vidot and Jules Margottin, it bears traces of both parents, and somewhat resembles Pauline Lanzeteur. It is, however, much fuller, of a different shade of colour, and more cupped in shape. We consider you very fortunate in having produced so fine an English Rose. Let the Floral Committee see it.

**ANTS AND NETTLES IN GRASS (Ants and Nettles).**—The ants can be destroyed and driven away by perseveringly sprinkling gas lime over their haunts. The Nettles can only be destroyed by forking-out the roots, and mowing-off the tops as fast as they appear.

**POND OR CRESSPOOL MUD (Idem).**—Mixed with loam it may be employed without any fear for forming your terrace-border; in fact, it would be an enricher, and would well suit Roses.

**EXCRESCENCES ON WHITE THORN (W. Barlow).**—We have seen similar excrescences before, but have been unable to determine either their nature or cause. However, though they appear on the bushes one year, it is not certain that they will do so in the year following.

**INSECTS (B. C.).**—The caterpillars sent as infesting the Apple trees, were dead when they reached us. We can only, therefore, conjecture that they were the larvæ of the Winter Moth (*Cheimatobia brumata*), which had gnawed round the stem of the flowers. A solution of hellebore (1 lb. to 4 gallons of water) will kill them.—W.

**OUT-OF-DOORS FERNERY (M. D.).**—This idea, the design, and the execution of it are all in the right direction; but the principal part—the really practical part—is not touched upon, and whether Ferns will live there or not no one can tell, or even guess from the data given. If the roots of the plantation are not excluded entirely from running into the newly-loosed soil in the made banks, they will occupy every inch of it before this time next year, and no Fern less strong than *Osmunda regalis* will do the least good in it, and the fern cocoa stuff is put into and over the soil for the Ferns, the more greedily the roots of Elms, Oaks, Ashes, and other trees will run through and through it, and the less fit it will be to sustain a fernery. But suppose no tree roots can get into the banks of this fernery, no place could be more suitable for growing a choice collection of Ferns, and no stuff is one-half so good for mixing with the native soil for Ferns as the cocoa-nut-fibre refuse fresh from the mills. The mat-manufactories do not have it all. The older it is the better to mix with sandy soil, and the newer it is the better for heavy lands, and the age makes no difference for Ferns. The best arrangement would be to keep all the low-growing Ferns down near the bottom, and to have all the kinds in each genus kept together, the medium-sized next, and in the same way, and the commonest and tallest all along the top, and you will find all the kinds fully described by Mr. Appley in former Volumes.

**MISCAT GRAPES SPOTTED (T. D. H.).**—The roots are not sufficiently active to supply the sap required for your very vigorously growing and well-loaded Vines. Remove the soil from over the roots and substitute for it some light loam mixed with a little well-rotted dung, all warmed to about 90°, and water with weak liquid manure of the same temperature. If the roots are outside, cover with a tarpaulin at night and during cold or wet weather, but uncover during bright sunshine.

**IRON WINDOW CASEMENTS (Westmorland).**—So far from these and iron staircases rendering the buildings to which they are attached more liable to injury by lightning, we believe that they promote their safety. Injury from the electric fluid is occasioned by the bad conducting power of the body with which it comes in contact, and which body is, consequently, shivered into fragments. Lightning conductors, as the name intimates, allow the electric fluid to pass along rapidly. Galvanised iron is not a nonconductor.

**EYES AND NO EYES (T. Parsons).**—What you say may be true, and we shall be very ready to publish the results of your experiments so soon as concluded.

**NAMES OF PLANTS (Ignoramus).**—The leaves enclosed are those of the Variegated Alyssum, but rather more yellow than usual. (J. D., Dundee).—Your specimens were not fit to name. They are too young and too much bundled up. 2, *Epilobium montanum*; 4, *Lycopis arvensis*; 5, *Myosotis collina*. The others utterly undeterminable. (C. H., Upper Deal).—1, *Athyrium filix-femina incisum* (small); 2, *A. filix-femina laxum*; 3 and 4, other forms of the Lady Fern, *A. filix-femina*, but not having special names; 4, is something like *molle*, but may be only a young plant of some other form. (J. E., Ashwicken).—*Nepeta micrantha*. (R. B.).—1, *Agapanthus umbellatus*; 2, *Francoa appendiculata*; 5, *Gesnera zebrina*; 7, *Begonia Griffithii*; 8, *Cissis discolor*; 11, *Pteris aquilina*; 6 and 9, *Begonia*, but these are too numerous to name from withered leaves. *Asplenium marium* not

numbered. (An Old Subscriber, Sunderland).—Varieties, which are numerous, of *Erica ventricosa*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

JULY 3rd. PRESCOT. Sec., Mr. James Beesley. Entries close June 21st.  
 JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. Secs., G. Newton and J. Wade. Entries close June 21st.  
 AUGUST 2nd, 4th, and 5th. SHEFFIELD. Sec., Mr. George Westerholm, 49, Queen Street.  
 SEPT. 4th. WAKEFIELD AND WEST RIDING. Sec., Mr. J. Crosland, jun. Entries close August 23.  
 SEPTEMBER 9th. WORSLEY AND ARMLEY (NEAR LEEDS). Sec., Mr. Robert Hoyle, Armley, near Leeds.  
 DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.

### WOODBIDGE POULTRY SHOW.

JUNE 26TH AND 27TH.

THROUGH the endeavours of a few of the zealous supporters of poultry shows, inhabitants of the town of Woodbridge, the first Exhibition ever held there took place on the Thursday and Friday of last week; and whether we take into consideration the number of pens entered, the quality of the birds, or the support it met with in the way of visitors, it must be pronounced a decided success, and we heartily congratulate the Committee upon it, and can but attribute it to the zeal with which one and all of them entered into it, evidently determined not to leave a stone unturned that would in any way tend to promote the interest of exhibitors or visitors, or aid in establishing a permanent poultry society for the county of Suffolk.

The pens used were Mr. Cook's, of Colchester, which were judiciously arranged in a large and commodious tent on the bowling green adjoining the "Crown" Hotel. All birds of one class being on the same level. We must also call attention to the substitute for sawdust placed in the pens, which was a craig, or fine gravel, peculiar to the neighbourhood, and to this to a great extent may be attributed the healthy appearance of the birds.

The first class on the list was *Spanish*; but, if we except the prize pens, there was nothing worthy of note. Mr. Rodbard's pen was empty.

*Dorkings* were both numerous and good, and afford another triumph to Lady Julia Cornwallis for distancing any other competitors. We can also speak well of Mr. Frost's pens, with which he obtained the third prize, and two high commendations.

In *Cochins* Mrs. Fookes stood first, Mr. Fowler being a good second, and the whole class was good.

As usual *Game* fowls were the great attraction of the Show, and amongst them were to be found some of the best birds England can produce. We need only mention the names of Messrs. Fletcher, Matthew, and Dawson, to give a pretty correct idea of the competition. Notwithstanding this, Messrs. Goodwin and Watson figured in the prize list in the class for Reds. The first prize went to Mr. Fletcher's pen of Brown Reds, as well as the cup for the best pen of Game fowls in the Show. His Black Reds were particularly good, as well as his Duckwings; but many of the pens were very much out of condition. We had here another proof of the desirability of having but one hen and a cock in the Game fowl classes, as invariably there are pens with one of the hens taken out in consequence of her being beaten either by the cock or the other hen.

The *Hamburghs* had but two classes—one for Gold, the other for Silver-spangled. In the latter, Lady Cornwallis took first with a very excellent pen. The Rev. T. L. Fellowes' pen contained two very beautiful hens, but his cock had but bad ear-lobes.

In the "variety class," the first prize went to a good pen of Brahmas, the second to Silver-pencilled *Hamburghs*, the third to White-crested Black Polands.

The *Game Cock Sweepstakes* was carried off by Mr. Matthew with a beautiful Black Red, shown in very fine condition; he was, however, hard run by Mr. Camm. Many of the birds in this class lost all chance by want of condition, which may be accounted for by the moulting season being so near at hand.

Mr. Camm's pen of *Duckwing Game Bantams* well deserved the prize they won. They were one of the best pens we ever saw. The cock bird is a perfect little gem. The class for "other varieties" produced only two pens of inferior Black.

Mr. Fowler again carried off the Aylesbury *Duck* prizes; also, the second for Rouens, with a promising young pen.

**SPANISH.**—First, R. B. Postons. Second, J. K. Fowler. Third, Rev. G. F. Hodson.

**DORKINGS** (Coloured or White).—Silver Cup and Second, Lady Julia Cornwallis. Third, J. Frost.

**COCHIN-CHINA** (Coloured or White).—First, Mrs. H. Fookes. Second, J. K. Fowler. Third, J. Wright.

**GAME** (White and Piles, Blacks and Brassy-winged).—First, S. Matthew. Second, W. Dawson. Third, R. Goodwyn.

**GAME** (Black-breasted and other Reds).—Silver Cup and Second, J. Fletcher. Third, F. Watson.

**GAME** (Duckwings and other Greys and Blues).—First, J. Fletcher. Second, W. Dawson. Third, J. Goodwin.

**HAMBURGERS** (Golden-spangled).—First, Mrs. Pattison. Second, Rev. T. L. Fellowes.

**HAMBURGERS** (Silver-spangled).—First, Lady Julia Cornwallis. Second, Rev. T. L. Fellowes.

**ANY VARIETY.**—First, J. Wright. Second, Rev. T. L. Fellowes. Third, T. P. Edwards.

#### SWEEPSTAKES.

**GAME COCK.**—First, S. Matthew. Second, J. Camm. Third, R. Goodwyn. Fourth, W. N. Walker.

**DORKING COCK.**—Prize, Lady Julia Cornwallis.

**COCHIN-CHINA COCK.**—Prize, Mrs. H. Fookes.

**GAME BANTAMS.**—First, J. Camm. Second, R. E. Postons.

**BANTAMS** (any variety).—First, J. Wright. Second, Rev. H. Curry.

**DUCKS** (White Aylesbury).—First and Second, J. K. Fowler.

**DUCKS** (Rouen).—First, N. Barthropp. Second, J. K. Fowler.

**TRURYS.**—Prize, R. Garrett.

Judge: G. Saunders Sainsbury, Esq., Devizes.

### THORNE AGRICULTURAL ASSOCIATION'S POULTRY SHOW.

THIS was held at Thorne on the 18th instant, in the grounds of Makin Durham, Esq. There were more than 250 pens, and the birds exhibited were generally excellent.

The following were the awards:—

**SPANISH.**—First, E. Brown, Sheffield. Second, J. Dixon, Bradford. Commended, H. H. Downs, Doncaster.

**COCHIN-CHINA.**—First, W. Dawson, Hopton, Mirfield. Second, J. Dixon, Bradford. Commended, J. C. Trotter, Hull.

**DORKING.**—First, J. Sledmore, Epworth. Second, J. Dixon, Bradford. Commended, J. Sledmore.

**GAME** (White and Piles).—First withheld. Second, T. Walker, Swinfleet.

**GAME** (Black-breasted and other Reds).—First, H. Adams, Beverley. Second, H. M. Julian, Beverley. Highly Commended, C. Marsden, Thorne; Messrs. Bentley & Sales, Crowle; G. Helliwell, Walkley, Sheffield. Commended, J. Crossland, jun., Wakefield; C. W. Brierley, Rochdale.

**GAME** (Duckwings and other Greys and Blues).—First, G. Helliwell, Walkley, Sheffield. Second, J. P. Hepworth, Bearswood Green. Highly Commended, H. Adams, Beverley. Commended, J. Mowbray, Finningley.

**GAME** (any Breed).—Silver Cup, H. Adams, Beverley. Highly Commended, H. M. Julian, Beverley; H. Adams. Commended, Messrs. Bentley & Sales, Crowle; C. W. Brierley, Rochdale.

**POLAND** (any variety).—First and Second, J. Dixon, Bradford.

**HAMBURG** (Silver-spangled).—First, J. Richardson, Thorne. Second, J. Dixon, Bradford.

**HAMBURG** (Golden-spangled).—First, G. R. Tate, Driffield. Second, J. Dixon, Bradford. Commended, E. Brown, Sheffield.

**HAMBURG** (Silver-pencilled).—First, G. Helliwell, Walkley, Sheffield. Second, J. Dixon, Bradford. Commended, J. Dixon.

**HAMBURG** (Golden-pencilled).—First, E. Brown, Sheffield. Second, C. W. Brierley, Rochdale. Commended, J. Dixon, Bradford; W. F. Entwistle, Bradford.

**ANY FARMYARD CROSS.**—First, H. Adams, Beverley. Second, T. Downing, Thorne.

**BANTAMS** (Silver or Golden-laced).—First, F. Wragg, Walkley, Sheffield. Second, J. Dixon, Bradford.

**BANTAMS** (Black, White, or any Colour).—First, C. W. Brierley, Rochdale. Second, J. Dixon, Bradford. Highly Commended, G. R. Tate, Driffield; J. Staley, Newark; C. W. Brierley; H. Adams, Beverley. Commended, J. Crossland, jun., Wakefield; G. R. Tate; W. F. Entwistle, Bradford.

**COCK** (any Breed or Cross).—First, H. Adams, Beverley. Second, W. Boyes, Beverley. Highly Commended, Messrs. Bentley & Sales, Crowle; T. B. Perry, Hull; T. Candy, Rotherham; C. W. Brierley, Rochdale. Commended, G. R. Tate, Driffield; Miss E. Blackburn, Howden.

**HENS** (any Breed or Cross).—First, E. Brown, Sheffield. Second, Lady Hawke, Womersley Park. Highly Commended, G. R. Tate, Driffield; J. Dixon, Bradford; J. B. Perry, Hull; H. Adams, Beverley. Commended, Lady Hawke; J. Sledmore, Epworth; J. Richardson, Thorne; C. W. Brierley, Rochdale.

**ANY PURE BREED.**—First, J. Staley, Newark. Second, J. Sledmore, Epworth. Highly Commended, R. Williamson, Wheatley Toll Bar; J. Sledmore. Commended, R. Williamson; J. Sledmore.

**EXTRA STOCK.**—Commended, W. B. Key, Epworth (Golden-Pencilled) J. Cawkwell, Belton (Black Game).

**GUINEA FOWLS.**—First and Second, G. R. Tate, Driffield. Commended, H. Mirkin, Driffield.

**TURKEYS.**—First, J. Dixon, Bradford. Second, G. R. Tate, Driffield. Highly Commended, Lady Hawke, Womersley Park. Commended, Miss Smith, Hatfield.

**GEES.**—First, G. R. Tate, Driffield. Second, J. Dixon, Bradford. Highly Commended, Lady Hawke, Womersley Park; Mrs. Goldthorpe, Cantley.

**GINS** (Goslings).—First, Mrs. Langhorn, Thorne. Second, Lady Hawke, Womersley Park. Highly Commended, G. Moody, Thorne Mors; J. B. Hepworth, Bearswood Green. Commended, Mrs. Stanley, Thorne.

**DUCKS** (any Breed).—First, G. R. Tate, Driffield. Second, J. Dixon, Bradford. Commended, G. Helliwell, Walkley, Sheffield.

**DUCKS** (Aylesbury).—First, G. R. Tate, Driffield. Second, Mrs. Thompson Wormley Hill. Highly Commended, S. Robson, Brotherton.

**RABBITS.**—*Duck and Doe.*—First, J. T. Spencer, Doncaster. Second, Miss R. Richardson, Thorne (Chinehillas). *Duck.*—First, J. Cresser, Thorne. Second, R. Gravit, Thorne. Highly Commended, W. Dury, Thorne. Commended, G. Woodley, Thorne. *Doe.*—First, R. Gravit, Thorne. Second, J. T. Spencer, Doncaster. Highly Commended, J. B. Hepworth, Bearswood Green. Commended, W. Dury, Thorne. *Doe for weight.*—First, J. Cresser, Thorne. Second, J. Gregory, Hatfield.

**PIGEONS.**—*Carriers.*—First, S. Robson, Brotherton. Second, W. F. Entwistle, Bradford. Highly Commended, J. B. Hepworth, Bearswood Green. *Croppers.*—First, S. Robson, Brotherton. Second, W. F. Entwistle, Bradford. *Tumblers.*—First, W. F. Entwistle, Bradford. Second, J. W. Edge, Birmingham. Highly Commended, W. Catterson, Hull; J. C. Addy, Epworth. Commended, R. Gravit, Thorne. *Ja obins.*—First, W. Carlton, Howden. Second, Master C. Darley, Thorne. *Nuns.*—First, W. F. Key, Beverley. Second, W. Catterson, Hull. *Trumpeters.*—First, F. Key, Beverley. Second, E. Smith, Birmingham. Commended, E. Smith *Turbits.*—First, J. W. Edge, Birmingham. Second, E. Smith, Birmingham. *Fantails.*—First, F. Key, Beverley. Second, S. Robson, Brotherton. Commended, J. W. Edge, Birmingham; E. Smith, Birmingham. *Owls.*—First, F. Key, Beverley. Second, J. W. Edge, Birmingham. Commended, J. W. Edge. *Extra Stock.*—Highly Commended, T. Addy, Epworth (Tumblers). Commended, R. Gravit, Thorne (Tumblers).

The Judges were C. Bllance, Esq., of Taunton; and T. B. Stead, Esq., of Leeds.

### ARTIFICIAL COLONIES.

ARTIFICIAL colonies may be made as soon as sealed drone-brood can be seen in the more populous hives, because drones will then be sufficiently abundant when the young queen has matured and begin to make their hymeneal excursions. If a few of the stronger stocks, especially such as have much drone-comb, be selected and divided early by drumming-out a swarm from each, a large number of supernumerary queens may be procured in the course of from ten to fourteen days, and an excessive production of drones be prevented for that season in such colony. These young queens, or the royal cells containing them, may be used with great advantage in forming artificial colonies.

A fertile queen obtained during the interval of deficient supplies is highly valuable, as she is able to produce a large number of workers which mature in season to appropriate the nectar of the lindens and white clover. And in fact, the worth of a weak colony, preserved over winter with much care and difficulty, consists almost entirely in its fertile queen, qualified to furnish a numerous progeny early in the opening season. The advantage of possessing fertile young queens (more to be prized than the old ones of previous years) need hence scarcely be adverted to.

Not every young queen that is bred becomes fertile. Many are lost on their hymeneal excursions. Colonies to which such have been given should, therefore, be watched with peculiar care, till we have ocular proof that they contain worker-brood. If a queen be lost, measures should forthwith be taken to remedy the evil by introducing a reserve queen or a royal cell. But as these are not always at hand, it is advisable to insert a piece of worker-comb, containing eggs and larvae, in every colony respecting which doubt is entertained. Those who use movable comb hives can greatly aid their young stocks, and guard against this kind of calamity, by the insertion of combs with uncapped worker-larvæ at intervals of three or four days, until they are satisfied, by actual observation, that the colony contains a queen qualified to lay worker eggs. The bees will always thus have within reach the means of rearing a queen in case of accident; and at this season the uncapped larvæ is not likely to perish from want of heat or due attendance, unless the colony be very feeble.—(*American Bee Journal.*)

**DAMSON WINE.**—Let the damsons be ripe, but not damaged. Pick out carefully any leaves or other dirt that may be amongst

them. Put them into a boiled tub, and having a quantity of clear soft water, let it stand till cold, and pour it over the damsons in sufficient quantity to cover the whole, and 2 inches or 3 inches more; let them stand in a cool place for a fortnight, stirring them gently two or three times a-day, but by no means break them, as that imparts a muddiness to the liquor not easily got rid of. At the time mentioned pour off the water carefully, which by this time will have become strongly impregnated with the juices of the fruit, add  $3\frac{1}{2}$  lbs. of good "Foot-sugar" to each gallon, and boil it gently for about forty minutes; after which pour it into a cask, and if no signs of fermentation take place, bung it down in a day or two. A few raisins may be added if thought advisable; but the great secret is not to break up the fruit, and when once put into the barrel to let it alone for about two years or more, when an excellent wine will be produced differing not materially from what is called "Test wine." Some

makers who object to a sweet wine do not boil the liquor, but, after drawing it off the fruit, add the sugar, and let it stand in a tub a few days, where it will ferment; or they ferment it in the cask. This fermentation takes off part of the sweetness, and the wine is, perhaps, sooner ready for use; but the little sharpness arising from the fruit is more predominant than when it is allowed to soften down by more time being given to it. Good damson wine is, perhaps, the nearest approach to good port that we have in England. No currant wine can equal it—in fact, wines made from red or black currants are going fast out of fashion in fruit-growing districts, the sharp acids of these fruits predominating so much. A mixture of fruits is sometimes used, but these, perhaps, may be described hereafter. Suffice it to say that those who have had the good fortune to manage damson wine well may with much propriety call it English port; and it requires no spirit to impart strength to it.—J. R.

## LA FLÈCHE FOWL.

(Continued from page 245.)

### THE HEN.

RATHER smaller than the cock of the same breed. Firm and consequential carriage, eye lively and bold. Round upright body, supported by strong sinewy legs of moderate length; great muscular development; flesh abundant and fine; large head; ample belly-feathers but close, not fluffy; plumage black.

*Head.*—Long and large, having all the characteristics of the cock but of smaller proportions.

*Comb.*—With very small horns, but apparent from their projecting forwards.

*Deaf-ears.*—White and very apparent from the decided contrast of colour and their large size.

*Nostrils.*—Like the cock.

*Beak.*—Strong and long.

*Physiognomy of the Head.*—Very fine and intelligent, similar in many respects to that of the cock. The comb shaped like horns, causes it to be called in many parts of the country the horned hen.

Good and early layer, of remarkably large eggs.

Does not sit.

#### GENERAL CONSIDERATIONS ON THE BREED.

The thorough-bred La Flèche, or Horned Fowl, is peculiar to the country of Maine; its type has always remained pure there, especially round La Flèche, where the mode of feeding seems to agree with it.

M. Letrove, to whom I owe part of the information which has served for this article, thinks their origin is unknown.

"Their renown," says he, "may be said to date from the fifteenth century, according to the testimony of some old historians. I, nevertheless, think their origin still more ancient." It was at "Le Mans" that the beautiful and primitive Poulardes were made, then at Méséray, then at La Flèche. These products

were known at different places under different names. The trade has long ceased at Le Mans, it is falling off at Méséray, and has only maintained its vigour at La Flèche and the surrounding country.

These fowls, so fit for fattening, are very robust, and seldom ailing. They acclimatise easily and preserve their purity, provided promiscuity is avoided—that is to say, that fresh blood shall be now and then introduced. They will take to any kind of food after they are grown up; but when young care should be taken to feed with food analogous to that they have in their native place. When reared at liberty they do not wander if they have grass at hand.

This breed of La Flèche may be classed as one of the two or three best French breeds. Although its plumage is uniformly black, it is extremely rich on account of its brilliancy, and of its fine green and violet tints. The bright red comb and wattles and the large white deaf-ear form as good a contrast with the black plumage as in a Spanish fowl.

The fine grain, the delicacy, and the peculiar taste of the flesh are very perceptible when the fowls are lean, and still more developed by fattening, to which cocks and pullets are alike subjected at the age of seven or eight months.

The ordinary food of these birds consists, in their own country, of three meals per day of wheat in the husk. It is necessary to limit the quantity as they are voracious, and at certain times would become too fat. After the peculiar and necessary food of the first week or two, and during the six first months hens and chickens should be fed on paste made with bran and meal. The older they get the more the bran may be increased and the meal diminished.

### THE PRESENT SEASON FOR BEES.

IN the neighbourhood of Exeter, and I believe in Devon generally, the season for bees is about the worst, up to this period, ever known. Towards the close of May, we had a week or ten days of very good honey-gathering weather; but, since then, bees have been living on their stores. A hive, which on June 5th possessed a considerable quantity of sealed honey, I found on the 22nd in a starving condition—bees lying about in hundreds, attempting to kill their drones, but almost too weak to accomplish it. A bottle of food was supplied them, and taken up in a few hours, to their very evident improvement. The queen is a Ligurian, substituted for the lawful head of the colony—a miscrably small black queen, which was at least four years old. The new queen had filled a great portion of the combs with eggs, most of which had shrivelled up from the incapacity of the bees to hatch them out. I should say that the hive is a unicomb, with a large population and many sealed royal cells, which were commenced prior to the introduction of the new queen, and have been gradually matured since. The bees deserted the upper combs, where this quantity of abortive brood and eggs is situated, and congregated towards the lower part of the hive, even clustering outside. Kept in the country at some miles distance from my own home, I was unable to see what was going on; but those who noticed it attributed the cause to the probability of a swarm being about to be thrown off. It was not until I was able to see for myself that the true cause was suspected. A number of dead and dying bees on the ground; a small cluster of very weak ones outside; the upper combs nearly deserted; the queen travelling in a very apathetic manner over the lower ones; the royal cells but scantily guarded by the workers, and apparently unnoticed by the queen; all presented a picture lamentably different from that which I had seen on my last inspection of the hive.

The bees in the apiary, more immediately under my own eye, had been liberally fed some days before, with manifest advantage.

With respect to artificial queen-raising, the season is sadly against us, and herein I am sure "A DEVONSHIRE BEE-KEEPER" will fully agree with me. Some hives, in which I commenced raising artificial queens on May 16th, have as yet remained queenless; numbers of cells having proved abortive, or the queens being lost during their usual flights in search of drones.

The reports from Kingsbridge, further south, generally a fine honey district, have been even more lamentable, and it would appear as if the bees had had a hard struggle for bare existence. Swarms are few and far between, and working in a super—a thing unheard of. Here we had some rare work done in supers for a short time, though much of the honey has been since gradually removed, all work being suspended, so that we have not had so great cause to complain as our Kingsbridge friends.

Should the weather now become settled, we have a chance of picking up a little, and supers pretty well furnished with combs may be completed; but, on the whole, I fear it will prove one of the worst seasons we have known for ten years past.—S. BEVAN FOX, *Exeter*.

### SWARM NOT WORKING—WAX-MOTHS.

I HAVE a swarm which has now remained for a fortnight hanging on to the side of the hive, exactly in the position which they took the day they were hived (June 8th). During this time they do not appear to have moved. For the first week I left them to themselves, but this week I have fed them a little with honey and sugar in hopes of rousing them, and thinking also that they would become weak; and since doing so a few bees appear to go out for food, but I can see no signs of comb-making. Ought they to be fed or not? And in what way can you account for this sluggishness?

The next hive has nearly filled a large glass during the time that this swarm has been sleeping away the days, so that the weather will not account for it.

Can you also tell me what is the best plan for getting rid of moths in hives?—M. H.

[You cannot do better than continue feeding, as the recent unfavourable weather may have had something to do with such unusual idleness. Should this not set matters right, there is probably something wrong with the queen, and in this case adding a small swarm to the bees already in the hive will prove an effectual remedy.

With either bar or frame-hives the wax-moth is readily extir-

pated by examining every comb separately, and cutting-out any damaged portions, which the bees at this season will readily replace. In common hives no remedy can, we believe, be applied by the apiarian; but the probability is that the bees themselves, if strong and vigorous, will succeed in expelling the intruders.]

### DEATH OF A QUEEN—HYBRID BEES—AND BEES AS CHEMISTS.

I SEND a dead queen which I should like "A DEVONSHIRE BEE-KEEPER" to dissect, as I think from her appearance she is a virgin. As she led off my best swarm on the 13th of June, she should, of course, have been an old one; but may have been a similar case to that of your Devonshire correspondent on the 4th. I am anxious to know, as on the 15th at five o'clock the bees became very uneasy; so much so, that I was satisfied there was something wrong with the queen or queens. My first thought was that she had taken flight on the 15th and got destroyed, and then that it might be a similar case to the one above referred to—that two had issued with the swarm. Of course these were only thoughts, as time proved; for, on Monday morning (16th) at seven o'clock, they brought her majesty from the hive, dead, and then commenced the return of the bees to the parent stock, where they were well received. I kept a few to strengthen an artificial swarm, with which they united peaceably. Many say that bees will not return to the parent stock after leaving with a swarm, but this case proves the contrary. They bore pollen up to noon on the 15th; and, on examining the guide-combs which they had scoured and added to a little, I found five cells full, and every available cell full of honey and syrup. The result of the investigation will greatly oblige, as it may upset some of our preconceived notions.

I also enclose a few crystals from the hive mentioned in page 37, which I should be glad to have examined.

I have had three swarms; and, as the weather is likely to take up (we had the first summer day since the first of the month yesterday, and to-day, the 17th, splendid), I expect them every day for a fortnight to come. I am looking for Mr. R.'s Italians every day, and shall very much like to see "the cloth of gold" upon a bush myself, as it is very likely I shall do if at home. I saw them yesterday, and there are now some splendid young ones coming out.

The hybrids\* vary much. The first that made their appearance I could not see any difference in, and then a fortnight after came some very good marked ones, and so on at intervals since.—A NORTH LANCASHIRE BEE-KEEPER.

[The box had been opened before it reached me, and all the crystals had disappeared. Fortunately, the dead queen, which appeared to have been a fine one, remained behind. I dissected out and examined her spermatheca, and found that she had been impregnated, so that there can be no doubt of her being the old queen. The cause of her death can only be guessed at. It does not appear that any eggs were deposited in the cells, which would probably have been the case had she been uninjured, and I should therefore surmise her death to have arisen from some accidental injury received in hiving, but not immediately fatal. I shall be glad to receive some of the sugar crystals from the hive to which you allude. It will be more satisfactory if they are accompanied by a few crystals of the same syrup before it was supplied to the bees. Both of these shall then be subjected to examination and comparison under the microscope, and the result reported by—A DEVONSHIRE BEE-KEEPER.]

### DRONE INFLUENCE.

IN the Number of the Journal for October 8th, 1861, my friend Mr. Woodbury related a very remarkable instance, in which a young black queen was impregnated by one of his Ligurian drones, at the distance of two miles in a direct line from his apiary. He also stated that he had preserved her life and given her to me to place at the head of a colony, to see what would be the result. This I succeeded in effecting, and a rare breeder she has proved herself. Some time since I removed more than half of the brood-combs from the hive (a large ten-framed one); subsequently, every comb, save a newly-formed

\* These are the offspring of a black queen bee which I presented to the writer last autumn, and which had been impregnated in an apiary a mile distant by my Ligurian drones.—A DEVONSHIRE BEE-KEEPER.

one, was taken away, and all the bees, an immense number, shaken off to form a swarm to begin the world anew. A large proportion of the bees were very decidedly marked with the distinguishing Ligurian signa. Some few could not be told apart from those bred by a true Italian mother; while still many thousands were in no way different from common bees. Here is a proof of the same queen giving birth to bees of three different shades of colour, and it is remarkable that we can often perceive this tendency even with first-class Ligurian mothers.

While engaged in depriving the bees aforesaid of their combs, I was curious to see the queen. I found her no different in appearance from ordinary black queens, although a remarkably large one.

Her drones do not in any way differ from common drones, which may be accepted as a proof of the correctness of the theory of the doctrine of parthenogenesis by its advocates.—S. BEVAN FOX, *Exeter*.

### “WHO FIRST ASCERTAINED THE SEX OF THE QUEEN BEE?”—(QUERIST.)

IN reply to the above pithy letter we will give all the information we possess.

Aristotle says that the *Basileus* of the bees is the parent of its own kind and of the working bees, but that the working bees generate drones. It is right, he also observes, that the *Basileus* (which by some was called the mother), should remain within the hive without labouring, being made for the multiplication of the species (*Hist. Animalium*, l. v., c. 21; *De Generatione Animalium*, l. iii., c. 10.) This opinion has been entertained by some moderns, among whom were Riem of the Palatinate Apiarian Society, and Wilhelmi of the Lusatian Apiarian Society. But being a point not now under our consideration, we pass on to remark that it is evident that Aristotle considered the *Basileus* of the hive is a female; and though *Basileia* would more decidedly have been synonymous with our word queen, yet *Basileus* may be interpreted by our word monarch, and include one of the female sex.

Pliny, on the contrary, leans to the opinion that the sovereign bee, “usually called the king,” is the only male in the hive, all the other bees being females (*Nat. Hist.*, l. xi., c. 16). Varro, Palladius, and Columella speak of the sovereign bee merely as “the king;” and Virgil does the same, but adds that bees gather their young from leaves and sweet herbs!

Thomas Hyll, in his “Profitable Instruction of the Perfite Ordering of Bees,” published during 1579, only speaks of “the king” of the bees; but the work is a mere compilation from other writers, ranging from Aristotle down to Hieronimus Carduus.

Butler in his “Feminine Monarchie,” published in 1634, asserts that “Reason and sense agreeing do show that the honey bees are the females, by whom the bees of both sexes (first the females and then the males), are bred.” In the same work he speaks of the queen “bringing forth many princes,” so that it is evident that he thought her progeny were all royal.

In “The Ordering of Bees—by the late unparalleled experience of John Levett, Gent.,” edited in 1634 by Gervase Markham, it is said, “The master bees breed or spat in their houses (the royal cells), as the other bees do in their combs or cells.”

Richard Remnant inclined to the same opinion. Writing in 1637 “A Discourse or Historie of Bees,” he there says, “The lesser bees are the females. Whether the queens blow (lay the eggs producing) the queens I am not very certain, but I take it to be so.” In Cromwell’s time it was not politic to discourse even of insects having either a king or a queen, so a work was published in 1655 entitled “The Reformed Commonwealth of Bees!” Its contents are a strange medley, and the only allusion to the production of these insects is in a detail of some experiments by a Mr. Carew, to show that they can be bred out of a dead calf!

Samuel Purchas, in his “Theatre of Political Flying Insects,” published in 1657, concludes that the working bees are females, producing workers and drones, and the queen only queens.

Rusden published in 1670 his “Further Discovery of Bees,” in which he maintains that “The king bee is a male and the only male in every colony.”

John Gedde in his “New Discovery of an Excellent Method of Bee-houses,” published in 1675, does not allude to the

subject; and Worlidge in his “*Apiarium, or a Discourse of Bees*,” in 1686, avoids the question, leaving such topics, as he says, “to the judgement of the most experienced and ingenious Butler.”

It is curious that from the time of Aristotle down to the end of the 17th century at which we have now arrived in due chronological order—that is, during a period of 2000 years, no naturalist had examined practically this subject, and that Aristotle was nearer to the truth than any of his successors.

The time had now arrived when men of science ceased from surmising, and addressed themselves to examining.

M. Reaumur examined bees anatomically; and in 1742 announced as the result of his researches that “the sole office of a queen bee is to produce a numerous progeny.” But he had been anticipated in this discovery; for Swammerdam in his “*History of Insects*,” published in 1669, states, “From one female, which is the only one of that sex in the whole hive, are produced all the three kinds of bees in nearly the following proportion:—10 to 14 females (queens), some thousands of the labouring bees, and some hundred males.”

Schirach, however, was the naturalist who most especially devoted himself to the study of the bee, and in his “*Histoire Naturelle de la Reine des Abeilles*,” published in 1770, he observes, “The queen is of the feminine gender, and is the mother of the whole race of bees.” He describes the two-branched form of her ovary, and the many thousands of eggs it contains. He states decidedly that the eggs are fertile without access of the male to her, and he details how artificial swarms may be made.

Warder, from whom we should have expected better knowledge, for he was a physician, is the last writer on bees who clung to old opinions on this subject; for in his “*The True Amazons, or Monarchy of Bees*,” published in 1720, he states that all the working bees are females, and that the queen produces only a royal progeny.

Other practical bee-keepers assented to Swammerdam’s discovery. Thus Thorley says in his “*Melissologia, or the Female Monarchy*,” published in 1744, “Without the queen they cannot breed;” and he is, like Schirach, a decided advocate of parthenogenesis.

John Mills, F.R.S., &c., in his “*Essay on the Management of Bees*,” published in 1766, says, “A hive of bees cannot subsist without a queen, as she alone produces their numerous posterity;” and Thomas Wildman, in his “*Treatise on the Management of Bees*,” published in 1768, observes, “What is commonly called the king is really a female, and the mother of all the bees.”

In fact, we know of no writer since that has maintained a contrary doctrine; and as he is the discoverer of a truth who proves it to be true, Swammerdam, we think, was the discoverer of the sex of the queen bee and that she is the sole mother of bees.

### OUR LETTER BOX.

**EAR-LOBES OF GAME BANTAMS (F. C. H.).**—There is no objection to their ear-lobes being white. Some judges prefer it. For example, in almost all Black Reds with yellow legs, the ear-lobe is a mixture of white, red, and yellow, the latter colour forming a bright edge to the lobe.

**EGGS RETAINING POWER TO BE HATCHED (A Young Beginner in the Poultry Line).**—We have the information from one who has tried the experiment, that few eggs will hatch when six weeks old, and that none can be relied upon after the fourth week. The fresher the eggs the stronger the chickens. Much depends upon the mode of keeping the eggs; laid upon their sides on bran, with the small end pointing rather downwards is the best position. Mark each egg with the date of the day on which it was laid, and put eggs of nearly similar age under a hen for hatching. This renders the hatching more likely to be simultaneous; as the older the egg the longer before the chicken attains strength to break the shell.

**WRIGHT OF EGGS (D. F. G.).**—The average weight of the eggs of the breeds you mention is as follows:—Dorking (Coloured), 2½ ozs.; Ronen Ducks, 3¼ ozs.; Game, 2½ ozs.; Golden-spangled Hamburgs, 1½ oz.; Malay, 2½ ozs.; Spanish, 3¼ ozs.

**DAMSON WINE (Lex).**—You will find a recipe in our paper to-day.

### LONDON MARKETS.—JUNE 30.

#### POULTRY.

We have nothing fresh to remark on the state of the market.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 74.8° and 51.1° respectively. The greatest heat, 93.4°, occurred on the 14th, in 1817; and the lowest cold, 37°, on the 9th, in 1856. During the period 153 days were fine, and on 92 rain fell.

THE CAMELLIA AND ITS CULTURE.—No. 7.

PROPAGATION. — Propagation and engrafting may be considered twin sisters, although in the general acceptance of the terms in a gardening sense, the one signifies simple multiplication, the other compound addition. The former method is resorted to to perpetuate genera and species, to supply the demands made upon any given establishment, and to promote progressive variation; whereas the latter is com-

ound in its nature and auxiliary in its tendencies. It is practised not only because it is a stimulant for the time being to the well-favoured, tender scion of probably a long line of illustrious ancestors, but because the stock with whose lifeblood it is commingled is generally selected as one of the hardest of its congeners, and, consequently, imparts a constitution to its weaker associate scarcely inferior to its own.

Well, then, in the first place, all Camellias are propagated either by seed, cuttings, grafting or layers; and then, generally speaking, the better sorts and the seedlings, if they turn out to be any way meritorious, are grafted in a variety of ways on these stocks before they are sent out to the market. So that all our fine varieties from the old white upwards undergo a twofold process, which, paradoxical as it may appear at first sight, in this case fully warrants the terms of affinity above prescribed. There is first the striking of any given number of stocks from cuttings, and, next, the grafting the desired and desirable varieties thereon before they generally fall into the hands of the amateur and gardening public as marketable commodities. Had we not entered so fully into details concerning this interesting tribe of plants, it might have scarcely been advisable to go into the *modus operandi* of propagation and grafting, as it more concerns the nurserymen than the gardener or amateur. A few pounds at any time judiciously spent will furnish the buyer with probably a better style of plants, and very likely at much less cost in the aggregate than trusting to his own efforts at successful manipulation. Besides, in the great majority of cases, including even some of our large garden establishments, there are not the same facilities for successful propagation, in all its phases, as there are in places that lay themselves out expressly for the purpose. Do not let the reader mistake me, however. I am not attempting to mystify the art, for most things are simple enough when any one knows how to do it, and this forms no exception to the general rule, and sometimes cost is only a secondary object, especially to the amateur, who loves to while away a spare hour at any pet project; besides, the gratification I had almost said is bewitching, at knowing that this beautiful variety of Camellia was grafted or inarched with his own hands, under his own eye, and in

his own estate, however circumscribed the latter may be. That idea just recalls to my recollection an incident in the history of my own life, where a gentleman whom I served a short time, contiguous to one of the great commercial towns in the West Riding of Yorkshire, had such an idea of the produce of his own garden, that go wherever he might to dine out, he found no vegetables so sweet and nutritious as his own. Of course, I, as an interested party, reserved my opinion; but a great many people living under the influence of a pure atmosphere will doubt the correctness of his taste, when I tell them that I was never able to cut a single vegetable, or pull a single fruit, that was not more or less coated and "burked" with smoke.

I remember perusing an article some three or four years ago, translated from the French. By whom, or in what locality of the Continent the article emanated from, I cannot now positively say, but it was to the effect that the finer varieties of Camellias, including the old white, would not propagate from cuttings. This is decidedly a mistake. It was contrary to my experience at the time, and after-years have only fortified what was then my opinion. Albeit, there are some varieties that are not so easily propagated in this way as others, and the old white is one of them, which may account for the false theory, if it might be dignified as such, promulgated. I and others whom I know, and very possibly many others whom I do not know, have propagated the finer sorts, aye, even from four-year-old wood, although if any one wishes to be in the highest degree successful, he had better select the wood of the previous season, which is consolidated sufficiently to maintain the balancing power until the inserted extremity begins to callus, and thus pave the way for the emission of roots. Cuttings from 6 inches to 9 inches long cut smooth across below the latent eye at the base of the leaf, and the leaves in turn for—say 3 inches upwards stripped off, and inserted in well-drained pots with a little fibry matter over the potsberds, and filled afterwards with pure sand, will root freely, especially if they can be placed in an intermediate stove-house, with a little bottom heat. They will require to be covered with either bell-glass, hand-light, or frame, just to meet the requirements of the several interested parties. To keep them air-tight for a series of days or weeks, as is occasionally the case, is fraught with no good results. Every careful observer knows that the moisture accumulates to such a great degree in these shut-up laboratories, that even to the succulent leaves of these plants, which, by the way, from their constitution withstand the maximum degree, it may do no small injury. Ventilation is necessary, and must be regulated according as circumstances require. The day, the position of the cuttings, and the temperature of the house, should all be considered. In most cases between the hours of six and nine in the morning is the best time, for absorption goes on rapidly during night, evaporation during day; but the cutting cannot withstand the fatigue of the heat of the day, and is thus shut up to keep good the life blood it had when cut from its parent. But I have been reading the novice a very nice

lesson about the propagation of these fine varieties, and I am now going to tell him that unless in some special cases, it is of little use propagating them in this way at all. The same lesson, however, is equally applicable to stocks, although they will root with much less attention, and almost by the simplest means conceivable, so that the advice may be useful after all.

As was suggested above, to engender and promote a healthy and vigorous constitution, and at the same time accelerate the growth of choice varieties, they had better be grafted upon stocks, or if the stocks are large, and the possessor wishes to get up fine sorts as quickly as possible, then they must be inarched or grafted by approach. To dabble away with cuttings, unless it be of such sorts as *Chandlerii* elegans, or *Centifolia alba*, which are as vigorous as the best stocks that have come under my cognisance, is simply wasting a season or two, not to speak of the delicacy of their constitution as compared with the original stock.

Layering is not much resorted to in this country; but in France, Belgium, and Italy, we are told, where climate is favourable, the stocks are planted out into beds of peaty earth and sand, in some cases in the open air, but more frequently into pits or frames, cut down the one season, and the young shoots layered the next, they are generally sufficiently rooted in the autumn to be severed from the stools, parted, and the following year used for grafting. There is no doubt, however, in our estimation, that good cuttings properly managed would supersede, in point of economy, the above practice, as they come away very rapidly, and occupy much less space than is requisite for layering. The fact is, that we have inserted cuttings in the autumn, parted them off the following spring, and engrafted them with fine sorts, which in turn required about from six to eight weeks to form a perfect union, and they grew with a vigour and rampancy unknown to these hard, hidebound, ayered stocks.

We have practised several methods with more or less success, among which might be mentioned what is called crown-grafting—viz., cutting down an old plant and inserting two or three scions at equal distances round its circumference, which is, in point of economy, one of the very worst methods you could hit upon. Inarching is the proper and by far the best method to make the most of a plant from five years old and upwards. For plants younger than this age almost any method which fertility of resource can conceive, is sure to be successful, provided the wound upon the stock and the wound upon the scion fit each other's component parts, so that the outer rind of the one may embrace the outer rind of the other as nicely as possible. This being firmly secured with matting, all that is requisite to observe is to keep the plants as close, or air-tight, as possible, always recollecting to let off superfluous moisture at the proper time, until the cambium oozing out from both wounds becomes solidified and organised, which will be, sooner or later, according to the state of the stock and scion, temperature of the house, and skill brought to bear upon their needs.

Supposing any amateur may have half a dozen of good, healthy stocks to manipulate upon, we would advise that the whole of them be beheaded about 6 inches above the pot, putting the tops in as cuttings if he has a mind. The best time to conduct such an operation would be from February up to the time the plants are making fresh growths. There will very likely be half a dozen sorts in his collection that he has a particular regard for, and these, of course, will be the varieties from which the scions are taken. The stocks, in the first place, should be cut smooth horizontally, just above a leaf-bud. The scions should in like manner be cut off from their parents immediately below the leaf-bud, and the leaves in either case retained, so that when the two wounded surfaces are joined together there is less chance of failures, for the continuity of the sap goes on, so to speak, unchecked, being reciprocated by the solitary leaf at the extremity in either case; whereas if the manipulator made the incisions upon the smooth wood of both stock and scion, and bandaged them together, it is possible that no union might be effected. These incisions spoken of should be made in a sloping direction, about  $1\frac{1}{2}$  inch long, with a sharp knife, and any leaves but the lower one that are in the way of the bandaging should be cut off, and the *modus operandi* thereafter is the same as suggested in the preceding paragraph. It is a good plan to cover the bandaging with a little sphagnum, this being a capital hygrometer for the novice, and accelerating the union of stock and scion. There is no quicker, easier, or more successful method than this for getting up vigorous plants to begin with;

and a corresponding state of things only requires to be maintained to make any one in a high degree successful as a Camellia-cultivator.

Particular stress must be laid upon grafting by approach or inarching, for it is an operation which every Camellia-grower within the circle of my knowledge resorts to. There are always some varieties that do not altogether suit the taste of the possessor, and these are marked out for inarching other favourites thereon. The greatest novice in the art cannot fail to reduce this into successful practice if the admirable gift of patience can be added to his other virtues. The union must be thoroughly effected before one endeavours to cut the connection, else the labour of more than one season is given for nought. So long as the stock with its, probably, numerous branches remains not cut down, the loss is not so great, although the scion when severed from its parent withers away; but patience for six, or even twelve months if necessary, will insure a perfect union. In the case of small branches put upon stocks equally small, two months in a moderately warm house will be sufficient; but in the case of branches, probably, nearly an inch in diameter, inarched on strong leading stems, which is generally the case, a far greater amount of time is required. Much depends upon the neatness of the operation, the caution displayed when cutting down the stock (for often a hoggling knife will cause an accidental slip against the scion, and at once sever the connection), and the vigour of the plants. To say that this stock, or that variety, you wish to propagate should be raised in pots so high, or be sunk so low, would be trifling with the space of this admirably conducted Journal. Every one is fertile enough in expedients to suggest and carry into execution his or her own requirements. The nearer the pot, in general, that any one can effect a union with the stock the better, as it the more discourages the emission of suckers, which, of course, are not wanted.

By far the best method we have ever attempted for effecting union to a nicety, is by using a carpenter's gouge, which hollows out the alburnum of the stock without disturbing a greater surface of outer bark than is requisite. All that it is necessary to do to the variety intended to be propagated, is to cut out the outer and inner bark to fit the cavity, and then you have stock and scion, so to speak, dovetailed together, thus promoting the object desired in a far more scientific manner than any other method we have ever practised.

Propagation from seed is a work of years, and well repays the amount of attention required to bring it to a successful issue. It is by working away in this direction that horticulture is in the greatest degree advanced, and there is really little to complain of, or cavil at, as to what has been already effected. Such varieties as those we have, in a previous paper, alluded to, as well as Countess of Derby, *Lavinia Maggi*, *Bonomiana*, and some others are practical examples of what is doing, and speak well for what is likely to be done in the same direction. It is well, however, to keep the "ball rolling" to incite the sympathies, the energies, and the skill of other growers in this direction, as there is a wide field before every one of us and no favour. Plodding minds are ever on the *qui vive*, and resources are as astonishing as their methods are elaborate. Much can be done by skilful manipulation. A great deal is effected without it.

Donckelaari and *Corallina* are the only two varieties which we have obtained seeds from, sometimes without manipulation, and occasionally *vice versa*. Pods after formation require from six to ten months to perfect the seed, which is generally in pairs, sometimes solitary, but we never obtained more than two seeds from one pod. They are of irregular oval form, and are perfectly black when ripe. We have sown some almost as soon as coming from the pod. A little bottom heat induces quicker germination. Peat and sand in equal proportions does its duty well, the grower requiring not to overwater the seeds, else they will fail to germinate, as was the case in one or two instances with ourselves. A good, moist medium, and stove heat in February, will germinate the seeds in autumn.—J. ANDERSON, *Meadow Bank, Uddingstone*.

#### THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.—JULY 2ND.

A GOOD day for the haymakers about London, threatening in the morning to keep them to their staff, and in the afternoon a strong, rushing, gusting wind sufficient to drive the dews of June right out of their hayricks, and leave them sweet as Clover. And a mighty rush it did make, again, in the eastern arcades,

where the most luxuriantly gorgeous fine-foliaged plants that ever were staged were exposed, fierce as in June, to the elements "of all the arts the wind can blow."

The lowest 50 yards at that side, with only one stranger, were full of the most select plants with remarkable foliage or variegation, which puts the doctrine of disease in such rare and beautifully luxuriant markings right heels over head. The most luxuriant smooth-leaved Cayenne at Windsor, Trentham, or Dalkeith, is not more healthy in looks, or bigger in bulk of proportions, than the deeply variegated Pine Apple in fruit in that collection from the Exotic Nursery.

On towards the conservatory the next 44 yards were full of collections of stove and greenhouse plants, without a single stranger at all among them.

Then, what the amateurs had for their Roses the week before did for the fruit on this occasion, and the most remarkable "fruit" there was a dish of Love Apples. That was coming it too strong in botany for a dessert for decent folks, and was simply ridiculous. The *Nux vomica* is just as good a "fruit" as the Tomatoes; and unless it be the smell of Garlic, or of ripe Tomatoes, I can think of no other "fruit" that would be more likely to drive a party not only out of the dining-room, but right away from the mansion, as that Nut and those Apples. I wonder what the wedding party from Osborne thought of it.

Among all the plants on the east side of the conservatory there were only two with the names wrongly spelt—the two plants of the old *Heliclyraum proliferum*, and one *Dipladenia*. The former is now called *Phanecoma*, there it was *Phanecoma* and *Phanicoma*, and *Dipladena* for *Dipladenia*. The only wrong spelling I noticed on the west side was *Hedaroma macrostigia* for *macrostegia*—only another name for *crinoline*, a large covering.

The only stranger among the fine-foliaged plants was from Mr. Smith, gardener to the Duke of Northumberland. It was named *Duranta Baumgardi*, with little difference, however, if any, from the variegated form of *Duranta Plumieri*; and it struck me that *Baumgardi* was only a German name for that plant.

Among the greenhouse plants there was a fine specimen of *Mirbelia Meisneri*, which one seldom sees at an exhibition. All the rest of them were as familiar as "How do you do."

The Orchids occupied the one-half of the back part of the conservatory, and *Vanda Lowii* was the rarest of them. You know the tricolor, and teres, and the *Batenanii* run of *Vandas*: this was a fourth and a new form in the genus—long, hanging-down racemes from the top of a noble growth, exactly as the pack-of-hounds racemes come from the bottom of *Gongoras*. The flowers come along the whole length of the hanging chain, and there were twenty of them on this plant all open but one or two, and all fresh but the two top ones. They are exactly of the same colour as those of the richest *Gongoras*, and about four times the size. It was in the collection of the Messrs. Veitch, one of the richest collections of the family the firm ever staged, and the most few in generic numbers, which was a particular feature all over the Show; *Arides*, *Saccolabiums*, *Vandas*, and *Cattleyas*, comprising nine-tenths of all that were there. *Dendrobium*, only two sorts; *Lælia*, only *purpurea*; *Anguloa*, only *Clowesii*; *Cypripeds*, three sorts, of which *grandiflora* the rarest to the shows; *Phalenopsis*, the three sorts, but *Schilleri* not in bloom; *Oncida*, four sorts, three puny ones, and one *ampliatum* major in bloom, from the May show; while of *Cattleya* there were *Mossia*, *lobiata*, *superba*, *crispa*, *Leopoldi*, in almost all the best lots; then there were *Arides affine*, *odoratum*, and *roseum*; and major, *Blumei*, *Lobbi*, *cornutum*, *Lindleyi*, *nobile* (a fine creamy kind), *maculoseum*, *speciosa*, *Fieldingii* or *Fox-brush*, and *Larpentæ*; and of *Saccolabiums*, *Blumei*, and *Blumei major*, *guttatum*, and *Holfordiana*. *Vanda Lowii* was the only Orchid at which the wedding party from Osborne looked particularly, and of them only the Princesses took the least notice of the Orchids; but the Princess Charles of Hesse did not miss a plant out of all the popular kinds. The Princess Anna of Hesse did not seem quite so fond of plants, but Her Highness was the second European lady who first smelt the grandest new flower that was at the Show, which is a most magnificent new Lily from Japan, among the rarest novelties from the Exotic Nursery. The Princess Charles was the first lady in Europe who smelt that flower in public, and she seemed delighted with the fragrance, and with the size and beauty of the flower. You may depend upon it, the Princess Charles of Hesse is as fond of flowers as any lady in England, and she was the only one of the whole party who looked at them as a gardener would.

As luck would have it, the *Fuchsias* were never one-quarter so fine or so numerous at any of our shows as on that day, and the Princesses admired them as much as anything at the Show. I did not see how they seemed about our fruit-tent; but somehow or other the fruit does not look nearly so well at the new garden as we used to have it at Chiswick, and you will see by the prize lists the winners are not all in the usual run.

I never saw so many new things at one show—that is, newish, for most plants are old with us up here before you can make out what they are like down with you; and if you had been there, my word for it, you would see, even among the Japanese novelties, many plants of which no one ever yet gave you the least hint. There was a Fern-leaved Oak in each of the Japanese collections—that from the Exotic, and that from the Bagshot of Mr. Standish, also a Fern-leaved Maple, both from Yeddo.

The white *Lapageria rosea* is out at last. I told you of it, if you recollect, five or six years back as being up with Mr. Low at Clapton. It was here from the Exotic, however, and with two flowers open right over the sensation Lily, which was the flower of the day. In the first place, this Lily is more of a Tulip shape towards the bottom, and more like a flower-vase in the top than any Lily you ever saw; from the edge of the vase the segments curve back or reflex very much; the ground colour all over and under is light; there is a deep broad band of yellow up from the very bottom to near the top of each division or segment in the centre; and the whole face of the flower is as regularly studded with prominent pink processes as the drum of a musical box, and quite as far raised from the surface of the flower. The plant which produces all that is of very genteel and slender make at present, and there are more than forty kinds of new Lilies from Japan, and some of them are said to eclipse even this one.

But I shall take a lot of the novelties just as they stood. *Heleclium macrophyllum* from M. Verschafield would put you in mind of a young vigorous sucker of a *Paulownia imperialis*. Then the said Fern-leaved Oak and Maple from Yeddo, *Zebra-stemmed Caladium* and a most beautiful new *Zebra Dracæna*, all from the Exotic Nursery. *Phyllanthus rotundifolius* in bloom from the Messrs. Jackson, of Kingston. A cream-coloured *Dendrobium* from Moulmein, with a yellow eye, from the Messrs. Low. A large blush *Cattleya*, with yellow down the lip, from the same firm. Some new *Tydasæ* from Mr. Bull. *Anthurium Scherzerianum*, the queerest thing you ever saw—from the top of a slender flower-stalk hung down a crimson flap-like spathe, like a piece of Morocco leather, and above it, twisted up, an inch and a half of crimson pigtail, and that was all the flower; but where the botany of it was goodness knows, unless it was in the pigtail twist of the spur or spadix. It was from the gardener of the King of Hanover. Then the new *Rhodanthes* from Mr. Thompson, of Ipswich. The little pale purple sweet *Calceolaria* in the habit of *arachnoides* is now *C. auavis*; and *Chamæbatia foliolosa* is one of the prettiest of the fine-foliaged plants, and like some *Selaginella*. A curious *Vaccinium*, with inflated grey pendulous flowers; the Bornean *Plocostemma lisanthus* and *Genæra refulgens*, the darkest lot of the *G. zebra* race, all from Messrs. Veitch's Exotic Nursery. Three plants of *Retinospora retusa* from Mr. Bull. A large mass of *Anætochils* and Orchids from Mr. Williams. Then a most capital thing, a lot of window-sill flower-boxes in full bloom; and none was ever better done than the first-prize one from the Messrs. Veitch, which was in the true cottage style, thus:—Three rows, the back row of mixed *Calceolarias*, *Stocks*, and *Fuchsias*; then a row of Variegated *Geraniums* and a fringe of blue *Lobelia*. In another window-box the plants were just as far wrong, being *Ferns* and *folies* all over, even for the inside of a cottage window, but I shall not mention the exhibitor's name.

Then a fine lot of fine-leaved *Begonias*, without one of the *Rex* race among them; and next, the grand *Disa grandiflora*, with flower-stems stronger than for Japan Lilies, from J. C. Lesch, Esq., of Clapham Park. One little plant that has been fifteen months in water, and out in the open air since the middle of last April was in bloom, and throwing-up the first side-sucker over the rim of the pot. A shallow bed of the cocoa-nut refuse by the side of a pond, which would supply the roots with constant moisture from May to October, and protection being given from frost by some slight covering, would make this splendid plant grow and bloom like a *Disa magnifica* to a certainty.

Then, a large *Goodyera*, like the cross at the June show, was named *Veitchi*; then a lot of little plants of bedding *Geraniums* from Mr. McIntosh, of Hammersmith. But I

shall propose to the Floral Committee, at our very first meeting, that all new bedding plants whatever be exhibited in boxes, like the window-boxes aforesaid, and only in May, June, July, and August, or else not to call them bedding plants. Who will give a ten-pound note for the first start, in three prizes of £5, £3, and £2 for seedlings not more than twelve months out, or if never out at all to be all the better? The boxes to be not less than 18 inches long, 9 inches wide, and never more than 6 inches deep, but any length to a yard would do. There is no other certain way of judging of a new bedding plant; and ladies or their gardeners must help us at these shows, to decide the merits.

Then an Alberti-like new Heath, from the Clapton Nursery, with four very large double Petunias; and a host of single Petunias and fine-leaved plants from Mr. Bull, reached along that side of the long tent. The other side was filled with the two large collections of Japanese plants. That from Messrs. Veitch was edged with their new *Amaranth*.

There was a fresh new *Lonicera reticulata* in the Japan collection of Mr. Standish, the very best of the Japan plants to my eye. It has the leaf of our own larger Periwinkle, when veined or reticulated with golden network; and the *Euonymus radicans variegata* in the Messrs. Veitch's Japan collection is my next favourite, for an edging plant in-doors or out. Then a silvery white variegated *Hemerocallis* in the same collection next; and there was a silver variegated *Tradescantia*, with the habit of a *Torenia*, which will make one of the best hanging-basket plants. I am not sure if I should not be proud of a hedge of the golden variegated Privet from Japan as well; and it strikes me, moreover, that one by one I should be tempted to buy them all, if I could afford the "siller" and the room.

The top of this side was full of cut Roses, Verbenas, Pinks, Picotees, and Pansies, and with them I am quite satisfied.

The Fuchsias were the pride of this Show. If there was a bad one among them all, it was a great deal better than the best Fuchsia I ever saw staged. You never saw anything like it. It was that *Disa grandiflora* that must have opened the ball, for the first, the second, and the third prizes went straight on to Clapham Park, where the *Disa* found the first home in England. Madame Cornelissen and Rose of Castille were the two best whites in two distinct strains, Madame having on a crimson erinoline reflexed. By-the-by, they say it was from our reflexed Fuchsias the ladies took their notion of tucking-up to see the petticoat; and Madame Cornelissen is, therefore, strictly in the fashion, as well as in the first rank of reflexed Fuchsias. But have you seen Maria Cornelissen and Mrs. Scott, two Merrimaes for such as Madame Cornelissen is? I have them both, as well as Madame and the rest of the cream of the flock; but, after seeing the Fuchsias in this competition, I must hold my tongue to them. The plants in the first-prize collection were not more than one-half so tall as some of them. It was the natural style of growth in which they were trained which gained them the day, and here is how it was. Catherine Hayes, not over 5 feet high, but about as much through, and the tops of the bottom shoots flowering to within 4 inches of the ground, all round the pot, and not the slightest sign of training about them. Prince Alfred, Isa Craig, Madame Cornelissen, Rose of Castille, and Wiltshire Lass were the rest in the first collection. The second-prize collection was more fat, much taller, and bigger every way, but not a quarter so nature-like; and the third prize collection was of medium-sized Fuchsias. Madame Cornelissen and Rose of Castille were in almost all the collections. One of the latter, a magnificent plant from 10 feet to 12 feet high, in a collection from the Messrs. Lee was, without exception, the best bloom of Fuchsia I ever saw. The next best I had myself two or three times on Ricartoni, but then it was in a rich border, and growing against a conservatory wall. Stove and greenhouse plants in collections filled the rest in the west arcades, after the *Pelargoniums* and Fuchsias.

*Hoya bella* was the only stove plant not out in June. Lower down the western arcades were two collections of orchard-house plants from the Messrs. Lane & Son, one of them being different Plums, the other all to the sorts of pot fruits; and there was a large and a well-grown collection of fruit trees in pots, from the Society's garden, from Apples and Pears to the best Peach in the book; and down there was the battle for the Ferns. Mr. Ivory and the Messrs. Veitch were beaten out and out at last by a gardener—Mr. Lavey, gardener to E. A. De Grave, Esq., Fetcham, near Leatherhead. He had a span new Surrey Fern there which you must have, if you have only two others out of

all England. It is an extra form of our *Athyrium filix-femina*, the most sportive Fern nearest to Epaoon Downs, and called Fieldie, after Miss Field, who first found it in Ashurst Park, near Tunbridge Wells. Mr. Ivory had a whole edging of it from seeds, and he has a thousand of them without the least variation, and is selling them cheap as Verbenas, at least his foreman offered it to me at so much per dozen, as if I were a Fern man. Mr. Lavey had another new sport British Fern, from *Lastrea filix-mas*, found by Miss Bolland, of Fetcham Park, in their own woods. This is named after Miss Bolland. Mr. Lavey is a British botanist as well, for he had a very large collection of cut wild flowers there from all parts within his reach, and where he could not go he sent his wife or his first-born for a posy of some good thing, and he had a prize for the lot and likewise for *Lycopoda* in pots. I knew a gardener's daughter, twelve miles out of Perth, on the way to Dunkeld, who knew the names of all the plants in the British Flora, but this is the first time I ever heard of a gardener's wife going out botanising in the country. Mr. Appleby, the foreman to Messrs. Ivory, is my authority for that wife, and for the prize of Miss Field's Fern, and for my beautiful specimen of it, the very finest Fern, now in my herbarium, and the very first.

D. BEATON.

### FRUIT.

THE show of fruit was good, but not equal in quantity to that brought forward in some previous years, when we have seen a hundred Pine Apples staged. Many of the exhibitions, too, were deficient in flavour—a circumstance doubtless attributable to the cold sunless weather which has prevailed throughout the season. The gardener can produce any amount of heat requisite for growth in size, but he cannot create light, which is essential for the proper maturation of his fruit; and, consequently, when grown under disadvantageous conditions in this respect, it will prove more or less watery and insipid as well as deficient in colour.

The only two collections of Grapes came from Mr. Standish and Mr. Henderson, of Trentham. The former received the first prize, his exhibition comprising not only the best old varieties, such as the Black Hamburgh, Muscat of Alexandria, Chasselas Musqué, Royal Muscadine, Frontignans, Sweetwater, Charlesworth Tokay, &c.; but also Gros Bleu, Early Saumur Frontignan, General Marmora, Muscat Troveren, Ingram's Hardy Prolife Muscat, Due de Malakoff, Groa Colman, Long noir Durant, Sarbelle Frontignan, and several others, either entirely new or but rarely seen in this country, and making in all twenty-five varieties. Mr. Henderson, who was second, had excellent bunches of the Black, Golden, and Victoria Hamburgh, Trentham Black, and Chasselas Musqué.

In the next Class, collections of fruits, there were likewise only two competitors, Mr. Tillyard, gardener to J. Kelk, Esq., Stanmore Priory, and Mr. Henderson; the former receiving the first, the latter the second prize.

Mr. Tillyard had three Pines, two Queens, and a Providence, Black Hamburgh, and Muscat Grapes, two kinds of Melons, Elton and Black Tartarian Cherries, a very fine dish of Green Gage Plums, Violette Hâtive Peaches, and Nectarines; four sorts of Strawberries, and very good Fastolf Raspberries. Mr. Henderson showed Trentham Black, Golden Hamburgh and Black Hamburgh Grapes, Black Eagle, and Bigarreau Cherries, in both of which respects he had a superiority over Mr. Tillyard; whilst his Peaches, consisting of the Royal George, Violette Hâtive, and Magnum Bonum varieties, with Violette Hâtive and Murry Nectarines were equally good; but his Pines, being two Montserrat, were not considered so good. He also had Trentham Hybrid Melons, two sorts of Strawberries, and some very good Jefferson and Victoria Plums.

In Pines, the first prize for Queens was taken by Mr. Tillyard, with one weighing  $4\frac{1}{2}$  lbs.; the second by Mr. Bwey, gardener to R. Crawshay, Esq., Cyfarthfa Castle, which weighed 3 lbs. 7 ozs.; and the third from Mr. Young, gardener to C. Bailey, Esq., Aberdare, was 3 lbs. 13 ozs., but not so well grown and ripened as the preceding, and it had also a larger crown.

In the next Class, Mr. Allen, gardener to J. B. Glegg, Esq., Withington Hall, received the first prize for a Providence weighing  $7\frac{1}{2}$  lbs. Mr. Ruffett, gardener to Lord Palmerston, was second, with a good fruit of the same kind, weighing  $6\frac{1}{2}$  lbs.

Of Black Hamburghs there were several very fine bunches, the best being from Mr. Henderson; Mr. Petch, gardener to R. Barron, Esq., Chesterfield, and Mr. Jackson, Taxhall Hall, were second and third, with very good exhibitions of the same kind.

In other varieties, three large bunches of Black Prince weighing more than 7 lbs. were shown by Mr. Hill, of Keele Hall, and obtained a first prize; Trentiam Black, very fine, from Mr. Henderson, came next; and Mr. Brooks, gardener to J. Lee, Esq., Dillington, was third with three good bunches of Black Prince, but the bloom was rubbed.

Muscats were not sufficiently ripe; the best were from Mr. Beck, Tedworth; Mr. Horwood, gardener to G. Turnbull, Esq., Bromley; and Mr. Standish. The latter obtained the first prize in the next class for Chasselas Musqué, Mr. Allen being second.

Among Peaches and Nectarines many dishes were very fine, besides those which obtained prizes. Mr. Rawbone, gardener to C. Campbell, Esq., Stoke-upon-Trent, was first in three dishes with Royal George, Grosse Mignonne, and Violette Hâtive. Mr. Maclellan second.

Of single dishes there were seventeen in competition. Mr. Snow, of Wrest Park, was first, the variety shown being the Violette Hâtive. There were also several fine exhibitions of the Royal George, Grosse Mignonne, and Bellegarde; as well as of Nectarines, such as the Violette Hâtive, Elruge, and Pitmas-ton, the best coming from Mr. Rutland, Mr. Horwood, and Mr. Allen. Altogether 12 single dishes of this fruit were shown.

In the Class for three dishes Mr. Tegg was the only exhibitor.

Strawberries were in some instances very fine, notwithstanding the unfavourable nature of the season, which has rendered the crop of those out of doors almost a failure near London. Mr. Turner, of Slough, exhibited a collection of nearly forty sorts, and received the first prize for four dishes, and an equal first for collections. Mr. Widdowson, Chorley Wood House, had also a first prize for his collection; and Mr. Lydiard, of Bath-easton, obtained the third award in this class, and the second for four dishes.

There were some very good Melons, especially those of the Bromham Hall breed. Mr. Weir and Mr. Kaile had Scarlet Gem, taking the first and second prizes in that class; and in Green-fleshed, Oscar from Mr. Kaile and Golden Perfection from Mr. Maclellan were the best two.

There was also a hybrid from Mr. Meredith with very delicate flesh, but rather too far gone, which received an equal second; and a similar award was made to Mr. Tegg.

Vines in pots were shown by Mr. Smith at Syon, Mr. Standish, and Mr. McPherson: those from the former being very good examples of this mode of culture.

Some very good Figs were shown in the Miscellaneous Class by Mr. Ruffett and Mr. Cross; and large well-ripened Tomatoes forced in pots by Mr. G. Smith, Liscard Hall.

The only collections of fruit trees in pots were from Messrs. Lane, of Great Berkhamstead, and from the Society's garden at Chiswick, the latter being very well grown, but, of course, not for competition.

## THE CRYSTAL PALACE ROSE SHOW.

It is impossible to convey by words a just idea of the superb display of Roses which was brought together at the Crystal Palace on Saturday last. The Exhibition occupied one-half of the long nave, extending in a double row of stands along the centre, the interval between which was filled with Dracaenas, Ferns, &c., and, notwithstanding the length of the line thus formed, so great was the interest taken by the numerous visitors, and especially the ladies, that a near approach to the tables was almost impossible—in fact, the only period of freedom which we enjoyed was during M. Blondin's performances.

The stands came almost exclusively from southern growers, and comprised admirably-grown blooms of all the leading varieties, among which *Senateur Vaise*, *Lord Raglan*, *Souvenir de la Malmaison*, *Général Jacqueminot*, and *Jules Margottin* were everywhere conspicuous.

In the Nurserymen's Classes for 96 and 48 varieties the chief honours were, in both cases, carried off by Mr. Cant, of Colchester. In single trusses of 24 varieties Mr. Turner was first with a magnificent stand; that from Mr. Cant, which was also very fine, coming in second. The best 12 trusses came from Mr. Francis, of Hertford; and in the succeeding class for 24 varieties, 3 trusses each, he was equally successful, notwithstanding a close competition from Mr. Keynes and Mr. W. Paul, who had both admirable exhibitions.

In the Amateur's Classes were numerous stands of great excellence, only a few exhibitions falling below the standard of merit. Mr. J. T. Hedge was first in the three classes for 36,

24, and 18 varieties in single trusses; Mr. J. Hollingworth, Mr. Grant, and Mr. A. Moffat being respectively second. Mr. S. Dobree, of Wellington, and Mr. Corp, of Milford, Salisbury, gained the first and second prizes for 12 varieties; and in the same class there were several other very good stands.

The best collection of new Roses was shown by Mr. Cant, who had *Madame Furtado*, *Belle de Bourg-la-Reine*, *Admiral Nelson*, *America*, *John Waterer*, *Victor Verdier*, *Senateur Vaise*, *Madams Boll*, *Triomphe de Lyon*, *Madam Standish*, *General Zachargersky*, *Baron Gonella*, *Eugénie Lebrun*, and some others. Messrs. Paul, who were second, had also a fine display of new kinds; and from the same firm there came a good collection in pots.

Orchard-house trees in pots were shown by Messrs. Lane and Son; double Sweet Williams by Mr. Jarman; and several baskets of artificial Roses by Adcock & Co., of Princes Street, Cavendish Square, so life-like that they would almost deceive any one. Annexed is a list of the awards on the occasion.

### GROWERS, FOR SALE.

Class 1.—96 VARIETIES, ONE TRUSS OF EACH.—First, Mr. B. R. Cant, St. John's Street Nursery, Colchester. Second, Mr. J. Mitchell, Pitdown Nursery, Maresfield, Sussex. Third, Messrs. Paul & Son, Old Nurseries, Cheshunt. Fourth, Mr. W. Paul, Nurseries, Waltham Cross. Fifth, Mr. J. Cranston, King's Acre Nursery. Extra, Mr. J. Keynes, Salisbury.

Class 2.—48 VARIETIES, ONE TRUSS OF EACH.—First, Mr. B. R. Cant, St. John's Street Nursery, Colchester. Second, Mr. C. Turner, Royal Nurseries, Slough. Third, Mr. J. Keynes, Salisbury. Fourth, Mr. J. Cranston, King's Acre Nursery, near Hereford. Fifth, Mr. E. Eley, Bath.

Class 3.—24 VARIETIES, ONE TRUSS OF EACH.—First, Mr. C. Turner, Royal Nurseries, Slough. Second, Mr. B. R. Cant, St. John's Street Nursery, Colchester. Third, Mr. R. Laing, Twickenham. Fourth, Messrs. Paul and Son, Old Nurseries, Cheshunt. Fifth, Mr. E. P. Francis, Nurseries, Hertford. Extra, Mr. J. Keynes, Salisbury.

Class 4.—12 VARIETIES, ONE TRUSS OF EACH.—First, Mr. E. P. Francis, Nurseries, Hertford. Second, Mr. B. R. Cant, St. John's Street Nurseries, Colchester. Third, Mr. J. Keynes, Salisbury. Fourth, Mr. C. Turner, Slough. Fifth, Mr. G. Clarke, Nursery, Streatham Place, Brixton Hill.

Class 5.—24 VARIETIES, THREE TRUSSES OF EACH.—First, Mr. E. P. Francis, Nurseries, Hertford. Second, Mr. J. Keynes, Salisbury. Third, Mr. W. Paul, Nurseries, Waltham Cross. Fourth, Mr. B. R. Cant, St. John's Street Nurseries, Colchester. Fifth, Mr. G. Tiley, Nurseryman, Bath. Extra, Mr. R. Laing, Twickenham.

### AMATEURS.

Class 6.—36 VARIETIES, ONE TRUSS OF EACH.—First, Mr. J. T. Hedge, Reed Hall, Coleher. Second, Mr. J. Hollingworth, Maidstone. Third, Mr. A. Moffat, Easton Lodge, Dunmow, Essex. Fourth, Mr. H. Grant, Cleve House, Midford, Bath. Fifth, Mr. W. Corp, Milford, Salisbury. Extra, Mr. G. Wortley, gardener to Admiral the Hon. P. Cary, Norwood; Mr. T. Laxton, Stamford; Mr. Terry, Wades Mill, Youngsbury.

Class 7.—24 VARIETIES ONE TRUSS OF EACH.—First, Mr. J. T. Hedge, Reed Hall, Colchester. Second, Mr. H. Grant, Cleve House, Midford, Bath. Third, Mr. J. Hollingworth, Maidstone. Fourth, Mr. A. Moffat, Easton Lodge, Dunmow, Essex. Fifth, Mr. W. Corp, Milford, Salisbury. Extra, Mr. J. Dennis; Mr. J. Churchfield.

Class 8.—18 VARIETIES, ONE TRUSS OF EACH.—First, Mr. J. T. Hedge, Reed Hall, Colchester. Second, Mr. A. Moffat, Easton Lodge, Dunmow, Essex. Third, Mr. J. Bristow, gardener to G. Orme, Esq., South Farm Mansion, Broadwater, Sussex. Fourth, Mr. W. Corp, Milford, Salisbury. Fifth, Mr. J. Dennis, gardener to H. S. Hayward, Esq., Hurst Green, Sussex. Extra, Mr. J. Hollingworth, Maidstone.

Class 9.—12 VARIETIES, ONE TRUSS OF EACH.—First, Mr. S. Dobree, Wellington, Somerset. Second, Mr. W. Corp, Milford, Salisbury. Third, Mr. J. T. Hedge, Reed Hall, Colchester. Fourth, Mr. John Cranwell, gardener to R. Pelling, Esq., Penge. Fifth, Mr. J. Bristow, gardener to G. Orme, Esq., South Farm Mansion, Broadwater, Sussex. Extra, Mr. H. Hodson, gardener to — Hardcastle, Esq., Park Place, Lenton, Essex.

### OPEN TO ALL.

New Roses of 1860 and 1861.

Class 10.—FOR THE BEST COLLECTION, ONE TRUSS OF EACH VARIETY.—First, Mr. B. R. Cant, St. John's Street Nursery, Colchester. Second, Messrs. Paul & Son, Old Nurseries, Cheshunt. Third, Mr. J. Cranston, King's Acre Nursery, near Hereford. Extra, Mr. J. Mitchell, Pitdown Nurseries, Maresfield, Sussex.

Class 11.—30 TRUSSES OF ROSES, VARIOUS, EXHIBITED IN A VASE OR OTHER ORNAMENTAL STAND, SUITABLE FOR TABLE DECORATION.—First, Mr. C. Turner, Royal Nurseries, Slough. Second, Mr. E. P. Francis, Nurseries, Hertford. Third, Mr. T. Varney, Weston Villa, Upper Norwood.

### Roses in Pots.

Class 12.—10 ROSES, 10 VARIETIES, IN POTS NOT EXCEEDING 13 INCHES IN DIAMETER.—(No competition.)

Class 13.—FOR THE BEST COLLECTION OF ROSES, IN POTS OF ANY SIZE.—First, Messrs. Paul & Son, Old Nurseries, Cheshunt.

## MEETING OF WORKINGMEN-BOTANISTS.

In the manufacturing districts there is a goodly number of men who earn their bread amidst the whirl of wheels, the noise of the forging hammer, and in the midst of circumstances which in themselves are enough to distract man's mind from the beauties of nature; yet they find time to become, not only well versed in botany, but to have a good knowledge of entomology and of other natural sciences. They have their meetings periodically in their different localities, to which they bring their specimens for examination and for the information of others.

For the last five years those who study botany have made a

practice of meeting once a-year in some central place, so that the plants indigenous to a district some fifty or sixty miles in diameter are brought together. This year the meeting is at Ashton-under-Lyne, on Sunday, July 13th, and from two to three hundred working men are expected to be there from various parts of Lancashire, Yorkshire, Cheshire, and Derbyshire.

The custom of meeting on a Sunday was established when the hours of labour in our mills were very long, and Sunday was the chief time that the operatives had for mental improvement. The above meeting will be in the Odd Fellows' Hall, at two o'clock, P.M.—J. H.

[We willingly insert this announcement, and shall be glad if our correspondent will send us a report of the Meeting, with the names of the rarer plants exhibited. We shall be glad if he will send us his address, as we may wish to write to him. We think these most praiseworthy men will see the propriety of now changing their day of meeting.—EDS. J. OF H.]

### VINE FROM THE ELYSIAN FIELDS.

A Subscriber requests advice as to the cultivation of a Vine brought from the vineyard near Naples, which occupies the site of the old Elysian Fields of Virgil. It is the common Vine of the country, and the soil is dry there. On being brought to England in November, 1860, it was planted against a south wall in one of the midland counties, but soon gave no sign of life in any part of it. Yet, in May, 1862, a shoot from the root came up, which is now 9 inches high and appears to be the only part alive. How can it be encouraged to grow? Does it require the shelter of glass in this climate? Will it bear removal? Or can any particular treatment be advised to insure its flourishing?

[We think the top of your Vine was killed by the frost. Part underground had so far escaped as to be growing now. Though the soil was dry in its native climate, there is no saying where the roots went in search of moisture. We have little hopes of your plant succeeding well in a midland county unless the place is sheltered and warm; but there will be no doubt of its growing. The difficulty will be to get the wood ripened enough to be fruitful. For this purpose you must encourage moderate instead of strong rampant growth. It would, no doubt, be improved if under glass, with or without artificial heat. It may easily be moved and replanted in the autumn when the leaves are falling. If you refer to the page in which this answer is given, and tell us what you decide upon doing, then we will publish the details of how you should proceed.]

### COCOA-NUT FIBRE REFUSE GENERALLY USEFUL AS A MANURE.

FOR the last seven years I have been telling how good I found the cocoa-nut fibre refuse for all plants, and when I suggested it the other day as a good speculation for nurserymen to get truck-loads of it down into the provinces, I was certain it would be much better for all kinds of soil, and pay better than guano. That I am quite sure of; but I did not expect to be asked privately how to use it, as I am in a letter from "F. D." I said at least a hundred times the way I did use it, but the best way to use it is probably not yet discovered. Indeed, the best of us do not know yet one-fourth of its value; but I put it only higher in importance than guano. Although sixty years of age I expect to live to see it coming in shiploads from Ceylon and other places, after the farmers have exhausted the supply of it in Europe. There is not a kind of soil but it will improve. The very stiffest clay, if you drain the water from it, might be rendered as mellow by it as to do for potting Cinerarias in, or Ferns, or any plant; and the sand of the desert is not so dry but it will cool and moisten it, and keep it so if it is well covered with it. For all market-garden plants, and for Asparagus in particular, I have full testimonials that nothing can excel it. My own garden, which was a poor black sand, is now one of the most fertile in Surrey—by mixing two parts of the stuff to one part of the black sand to the depth of 18 inches; but I have it mixed twice that depth.

Use it like leaf mould, or in lieu of peat, mulch and mix with it all manner of soils; sift it and put half an inch of it over all your grass land, and it will give such a "bottom" as it never had before. The rankest clay in England could be made into potting loam by mixing twice its bulk of the refuse with it in two

seasons. When mixed spread out as thin as possible to get it well frosted and sunned, and when it is quite dry in July or August run a roller over it, and then give it another frosting and summering, and see if it does not do anything you require.—D. BEATON.

### SULPHUR VERSUS RED SPIDER.

In your answers to correspondents you say that the air of a house impregnated with fumes of sulphur, without burning the sulphur, is fatal to red spider. Have you proved this by experiment? I have repeatedly placed a pan of sulphur on a warm flue, strewed leaves covered with red spider on the surface, covered the whole with a bell-glass, and found that the insects were alive and lively after an exposure to the fumes for twenty-four hours, the leaves in the meantime being dried to chips.—E. T., *Solihull*.

[We have proved the matter often, but as stated in "Doings of the Week" lately, what will kill insects at one time will not do so at another; but, at any rate, this is one of the most effectual means we know. Are you sure the sulphur did give off its fumes? We have smoked a place with burning sulphur when we wished to kill everything alive in it; but though the vast majority of all living things were dead, we found some young thrips and red spiders hatched after the burning; and though some lizards and a prized toad or two were killed when we opened the place, we found a robin chirruping, though how he escaped we never knew. If fumes of sulphur and moisture will not destroy red spider, and if fairly got a-head, it will not do so without continued applications. Prevention is better than cure. Are you sure the insects were red spider?]

### THE BIRMINGHAM ROSE SHOW.

A ROSE Show in Birmingham? Anything so poetical in so matter-of-fact, practical, smoky a metropolis of iron as Birmingham? Yes, truly, and what is more, a Show which in point of beauty of arrangement, excellence of flowers, and general character, may vie with any that have been as yet held in honour of the queen of flowers. I have seen all the Rose shows, been deafened at the Hanover Square Rooms, squeezed at St. James's Hall, pushed about at Kensington, and enjoyed the Crystal Palace with all its charms; but I have not seen one which afforded me more real pleasure than the Birmingham one, projected, I believe, by the staff of the *Midland Counties Herald*, and adopted at once by the Rev. Reynolds Hole, who waived his own project of a Midland Show in order to give greater effect to this effort. And so, when from this centre of England went forth the proclamation, it was no wonder that from fifteen different counties should have come up a bevy of fair maidens and gallant knights to show their allegiance to her floral majesty.

"Well, but was it a good Show?" was the first question I was saluted with at Kensington the following day (where, according to the *admirable wisdom* that arranges the proceedings of the Royal Horticultural Society in the very height of the Rose season, not a single prize was offered for Roses, and this though the Society took £800 at the doors on the days of the Rose Show! They, of course, could not afford it, and made amends to the floral world by giving a prize for a fresh-water aquarium!) Yes, it was a capital Show, and the Roses were finer, especially those of the nurserymen, than at Kensington on the 11th.

Nor were the Roses the only things that were good. So beautiful a collection of electro-plated flower-stands, parian vases, and glass stands for flowers I never saw collected together. Garden implements, too, of all kinds were there, wire baskets and terra cotta stands, all catalogued and priced, so that any one could at once ascertain the important information what each article would cost; and when to this one has to add that courtesy and kindness (not snubbing and high-and-mightiness, as in more fashionable localities), marked all concerned, it is not to be wondered at that I felt the enjoyment of being there to be a great one; nor was it without some feelings of hearty thankfulness either. Two and thirty years had elapsed since I was in Birmingham before; and one could not look back on the many years during which one had "been led," without being grateful to Him to whose care and love all was due.

And who were the successful competitors? Amongst amateurs, our trusty and well-beloved brother the Rev. Reynolds Hole;

and amongst nurserymen, our excellent and clever friends, Mr. Cant, of Colchester, and Mr. Turner, of Slough, were the principal ones, and beautiful their flowers were.

The Birmingham folks have adopted some plans new in execution, if not in idea, and they are, we think, well worthy of imitation. They have abolished the (to my mind) absurdly large class of 96 trebles, and made it 96 singles. They offered, also, prizes for the best 6 blooms of any new Rose; and also (though this is more questionable), for 6 blooms of expanded, and the same of cupped Roses. There is the difficulty in the latter case of deciding which a Rose belongs to, some being cupped in a young state, and expanded when old. Then it was a good thought to offer a prize for *haud-bonquets* of Roses; and altogether their plan displayed great judgment and taste, and reflected great credit on all concerned. The taste of the Committee, Secretaries, and of Messrs. Hole and Perry, on whom a good deal of it devolved, being no light one; it will not be so heavy another year, when things are in better working order.

Mr. Cranston took the first prize for the best 6 blooms of a new Rose of 1859-60-61 with Madame Furtado, which were magnificent blooms; and Mr. Keynes second, with Senateur Vaisse. Three of these were very fine, the other three not quite open enough.

In stands of 24 varieties of new Roses of 1859-60-61 Messrs. Paul & Son, of the Old Nurseries, Cheshunt, were first, with James Dickson 1861, a forcing Rose; Madame Boll, too apt to show a green eye; Prairie de Terre Noire; Lord Canning, seedling, pink flower, likely to be good; General Washington; President; Victor Verdier; Mr. Pierson, will not do; Madame Pauline Villot, good; Mademoiselle Bonnaire; George Peabody; Alexandrine de Belfroy; Lord Clyde, scabby; Belle de Bourg-la-Reine; Madame Charles Crapelet, excellent; Catherine Guillot; Mademoiselle Julie Darzins, 1861, very good; Agatide; Senateur Vaisse; Louise Darzins, 1861, a pretty white; Mademoiselle Eugénie Verdier; William Pfitzer 1861, good; and Madame Furtado. Mr. Cant's were François Lacharme, 1861, large and excellent; Parmentier; Eugène Appert, very good; Marguerite Appert; L'Enfant Trouvé, very good Tea; Victor Verdier; Madame Furtado; Louisa XIV. good; Regulus; Triomphe des Bagatelles; Amiral Gravina; Modèle de Perfection, good Bourhon; Vainqueur de Solferino; Comte de Beaufort; Baron Gonella; Céline Forestier, good Noisette; Madame Boll; Rubens; Marquise de Foucault; and Princesse Mathilde.

In the Nurserymen's Class of 96, Mr. Cant held the first place with a beautiful collection of Roses. Some of the individual blooms I have never seen excelled, if indeed equalled. There was one bloom of Colonel de Rougement which was a perfect model: it was large without being faint, and most regularly formed. I mention this because I am afraid that the desire to have large blooms is leading to a deterioration in character and colour. His flowers were Senateur Vaisse, Bougère, Marquise de Foucault, Princesse Mathilde, Vicomtesse de Cazes, Madame Furtado, Eugène Verdier, Madame Boll (a very fine bloom), Triomphe de Paris, Gloire de Vitry, Madam Standish, Mathurin Regnier, Victor Verdier, Adelaide Fontaine, Céline Forestier, La Ville de St. Denis, Kean, Madame Tredeaux, Souvenir de le Leveson Gower, Lamartine, Comtesse Cécile de Chabillant, Anna Alexieff, Baron Gonella, Prince Léon, Regulus, Madame William, Vainqueur de Solferino, Col. de Rougement, Général Jacqueminot, Devoniensis, Pauline Lanzezeur, Anna de Diesbach, Géant des Batailles, Madame Vidot, Jules Margottin, Adam, Lord Raglan, Caroline de Sansal, Baronne Hallez, Maréchal Beaugard, Triomphe de Lyon, Madame Knorr, François Lacharme (one of the new Roses, and likely to be a good one), Pauline Leberté, General Forey, Niphotos, Baronne Prevost, Madame Bravy, General Simpson, Souvenir d'un Ami, Madame de Cambacères, Empereur de Maroc, La Fontaine, Triomphe de Rennes, Madame Pierson, William Griffiths, George Peabody, America, Model of Perfection, Victor Emmanuel, Julie Mansais, Etendard des Amateurs, Comtesse de Labothe, Victor Trouillard (a wonderfully fine bloom), Duke of Cambridge, Odeur Vital, Eugène Appert, Rubens, Belle de Bourg-la-Reine, Duc de Cazes, Solfaterre, Robert de Brio (very dull), Madame de St. Joseph, François Premier, Coupe d'Hébé, Louis XIV., Buffon, Comte de Nanteuil, Evêque de Nîmes, Bellonie, Comte de Beaufort, General Zachargersky, and Mrs. Bosanquet. The second was awarded to Messrs. Paul & Son, of the Old Nurseries, Cheshunt.

In the Class of 48's three trusses, there were some finely-bloomed specimens in the boxes of Mr. Francis, of Hertford, who was first, and Mr. Keynes, of Salisbury, who received the second prize.

In 24's, three trusses of each variety, Mr. Charles Turner, of Slough, was first, and Mr. Cant, of Colchester, second.

In 24 varieties, single truss, Mr. Turner was again first. His varieties were La Reine, Victor Verdier, Boule de Nanteuil, Duchesse d'Orléans, Senateur Vaisse, Souvenir de la Malmaison, Madame Charles Crapelet, Gloire de Dijon, Général Jacqueminot, Anna Alexieff, Jules Margottin, Madame Willermoz, William Griffith, Comtesse Cécile de Chabillant, Lord Raglan, La Ville de St. Denis, Paul Ricaut, Victor Trouillard, Lamartine, Louis XIV., Madame Boll, Madame Hector Jacquin, Narcisse, and Madame Furtado. Mr. Keynes was a worthy second.

In the Amateur's Class of 48's, the Rev. Reynolds Hole was first—no slight testimony to the zeal and skill of a connoisseur, who lost 1000 out of 1200 Roses in the winter of 1860-61. He had some fine blooms, especially his Cardinal Patrizzi, which was in finer condition than I ever saw it. He had besides La Ville de St. Denis, Madame Vidot, Devoniensis, Anna de Diesbach, Prince de la Moskowa, Joseph Vernet, Comtesse Cécile de Chabillant, Madame Hector Jacquin, Victor Verdier, Mathurin Regnier, Evêque de Nîmes, Dr. Bretonneau, Louise Perony, Paul Ricaut, Comte de Nanteuil, Jules Margottin, Souvenir d'un Ami, Duchesse de Cambacères, Grégoire Bourdillon (a fairish Rose, very like Géant), Odeur Vital, Baronne de Heckeren, Céline Forestier, Reynolds Hole (very bright lively pink), Chateaubriand, Madame Knorr, Madame Boll, Madame Bravy (Tea), Eugène Appert (very fine), Duc de Cambridge, André Desportes (a good purplish-rose), Caroline de Sansal, Noemi, François Arago, Charles Lawson, Géant des Batailles, Gloire de Dijon, Duc de Cazes, Coupe d'Hébé, Louis XIV. (very fine), Madame Furtado (a splendid bloom), Senateur Vaisse, Triomphe de Rennes, and Gloire de Vitry. Mr. Evan, gardener to C. N. Newdegate, Esq., M.P., Arbury, Nuneaton, was second; and Mr. Alfred Henderson, of Joywell House, Durdham Down, Bristol, received a third (extra).

In 24's Mr. Hole was again first with Triomphe de Rennes, Madame Boll, François Arago, Mrs. Rivers, Paul Desprez, Coupe d'Hébé, Général Jacqueminot, Charles Duval, Oriflamme de St. Louis, Madame Furtado, Caroline de Sansal, Vainqueur de Solferino, Souvenir de la Malmaison, Reynolds Hole, Senateur Vaisse, Madame Knorr, Paul Ricaut, Madame Hector Jacquin, Géant des Batailles, Charles Lawson, Cardinal Patrizzi, Mathurin Regnier, Lord Raglan, and La Ville de St. Denis. The Rev. P. M. Smythe, of Solihull, was second; Mr. E. Hunt, highly commended; and Mr. Brown, gardener to W. C. Abeton, Esq., Elmden Hall, commended.

In 18 varieties Mr. E. Sage, gardener to Earl Howe, Gopsal, Hall, was first with La Reine, Souvenir de la Reine de l'Angleterre, William Griffith, Madame Furtado, Céline Forestier, Coupe d'Hébé, Madame Willermoz, Alexandrine Bachmeteff, Léon des Combats, Anna de Diesbach, Gloire de Dijon, Lord Raglan, Caroline de Sansal, Madame de Cambacères. The Rev. S. Reynolds Hole was second; and Mr. Evans third.

In 12 varieties Mr. Hunt was first. His Roses were Charles Lawson, Comte de Nanteuil, La Ville de St. Denis, Lord Raglan, Jules Margottin, General Simpson, Général Jacqueminot, Madame de Cambacères, Madame Vidot, Madame Boll, and Souvenir de la Reine de l'Angleterre; Mr. Sage was second; and Mr. Hole third.

In 6 varieties Mr. Sandford was first with Triomphe de Paris, Madame de Cambacères, Paul Desprez, Souvenir de la Malmaison, Senateur Vaisse, and Lord Raglan; and Mr. C. J. Perry, of the Cedars, Castle Bromwich, was a good second.

It will thus be seen that whenever a Rose show is held, there are some kinds which are sure to hold a leading place; and that all over the country Général Jacqueminot, Eugène Appert, Madame Vidot, Jules Margottin, and other well-known names are certain of victory, or of a place in the victor's triumph.

There were so many things in the ornamental way for holding flowers that it is impossible to particularise. I cannot, however, forbear noticing a beautiful pair of ceramic parian ware vases, ornamented with tourquoise and gold, and painted with beautiful groups of flowers, which were made expressly by Messrs. Turner, Banby, & Hassall, of Stoke-upon-Trent, to do honour to this Exhibition. Some idea of their beauty may be obtained from the fact that they were 42 guineas the pair, about 15 inches high.

I hope that financially the Show was a success; for it would

be a great pity that so excellent, liberal, and well-managed an Exhibition should fall to the ground. Personally I have to thank all concerned for the attention I received, and have only to regret that I could not remain to drink (although a teetotaler) at their Rose-show dinner, "Success to the Birmingham Rose Show."—D., Deal.

## A FEW DAYS IN IRELAND.—No. 25.

HAM WOOD.

(Continued from page 254.)

THE kitchen garden is one of the useful old-fashioned kinds that it is now becoming a rarity and a pleasure to meet with, reminding us of times when gardeners prided themselves on having the best of flowers, fruit, and vegetables all within one enclosure, and when employers did not think there was so much of the incongruous between a first-rate Cauliflower and a splendid Tulip or Carnation. Looked at in this light, not the least striking things were arches of Roses, beds of Roses, and long, spacious borders of mixed herbaceous plants. Here nothing was more perceptible than that if it be possible to have a mania for the beauty of flowers, there is no necessity for that merging itself into a monomania. We use the word "mania" here, not in its more generally received acceptation, but as denoting a stronger passion of admiration than could be described by the word "enthusiasm." Listen to Mr. Hamilton descanting upon the shades and contrasts of colouring in massed grouped flower-beds, and you would be led to imagine that plants that could not be so used were of little value in his estimation. It is not seldom we form wrong estimates by merely looking at one side of things, or beholding the mere partial development of character. Who could imagine that these mixed borders of fine old herbaceous plants would, if anything, be still dearer to the heart of their possessor than his grouped beds? We should like to chronicle every instance in which these fine old favourites of our fathers were receiving again their full meed of deserved attention, and that, too, without any unnecessary undervaluing of the grouping system; though it may not be easy to combine and develop, as in the case of the proprietor of Ham Wood, such an earnest love for all forms of the beautiful.

These fine old perennials have, no doubt, for Mr. Hamilton an extra charm, as blended and associated with the times and the loved ones of the past. The Michaelmas Daisies (Asters), Aaron's Rods (Solidagos), Veratrums, Phloxes, &c., seem so much more beautiful as he tells you he inherited his love of gardening and of these flowers from his mother, who collected them with great care and diligence, and must have shown her enthusiasm for them to have wheeled a slip or a cutting from the worthy but crusty old man that presided over the Liverpool Botanic Garden half a century ago, or the equally worthy but eccentric predecessor of my friend Mr. Niven, at Glasnevin Gardens. And then, forgetting for the time his enthusiasm for the distribution of colours as seen at the Crystal Palace, Trentham, and Enville, you will be told of the great difference as to effect on individuals—between the love of mere gaudy colours and the love of the plants individually for their own sake—that the hundreds and thousands massed together for display may be good friends at a grand review, but hardly friends for a chit chat *tête-à-tête*. Then, again, the rearing of such numbers of plants merely to perish when winter comes, yields few of the pleasures arising from association in the culture of perennial herbaceous plants; as after you have carried a slip home and watched over its infantile growth, it will then pretty well look after itself, and every time you see it you think of the place and the friend from which it came. True, the finest herbaceous border will not be in a blaze at one time, and some things will need cutting down when others are in their glory; but there need be no great gaps but what might be supplied with annuals, Sunflowers, Dahlias, &c., and a few bedding plants as Calceolarias and Geraniums for variety.

Mr. Hamilton contends, and we fear with too much justice, that if the bedding system become the all-in-all, gardeners will not only pride themselves in numbers and gaudy display, to the neglect of the individually interesting, truly refined, and symmetrical; but so few plants—that is, in variety and species, being cultivated, the taste for geographical study as respects the locality and the distribution of plants would be endangered, and thus one of the greatest charms connected

with their cultivation would be apt to be lost. Finally, you may expect to be asked, If not neglecting the new friends—the bedding plants, would it not be wise policy not to lose sight of the old ones—the herbaceous perennials? Coming from such a keen bedder, we answer in the affirmative; and feel sure that a place will be set apart in many gardens for these loved plants of our fathers.

In addition to nice crops of vegetables and fruit trees, rather scanty of fruit this season as elsewhere, and a new wall of considerable length with nice, healthy, young trees growing against it, and the fresh-made border cropped with Strawberry plants, which we hope by this time have fulfilled the promise they made last September, the kitchen garden had several houses for Grapes and bedding plants, built chiefly on the plan of Mr. Rivers, and in them were some good Grapes, which had not been much assisted with artificial heat. In addition to these was a nice span-roofed orchard-house, constructed as Mr. Rivers advises, 64 feet long, 12 feet wide, and 8 feet high at the ridge, and being entirely of wood and glass, it cost £26. In this house the trees were planted out (Peaches and Nectarines chiefly) on raised borders on each side of the central path. They had borne a heavy crop in pots—too heavy the gardener and proprietor said, in 1860. They were planted out in February, 1861; and to the heavy crop of the preceding year, the lateness of the planting-out, and the sunless summer of 1861, they attributed the fact, that though there was plenty of bloom it did not set well, and the fruit was rather deficient; but we hope all this was rectified this year, as the shoots in September were getting well ripened, and clustered with fine, well-swelled, rounded buds. A flow and return hot-water pipe has also been introduced.

At the west end of the garden is a broad slip backed by a dense wood of Conifers and deciduous trees; and in front of these some of the finer of the Conifers and Cyresses, &c., are receiving a fair trial, and as the wall of the garden is here covered with the tenderer and more beautiful creepers and shrubs, the place will have an interest of its own. If Mr. Hamilton should catch the prevalent mania for rockwork and ferneries, here would be the suitable and appropriate position for them, feeling convinced that at no time will a visitor see a rough heap of stones in the centre of the pretty flower garden or lawn at Ham Wood.

Mr. Hamilton has entered somewhat largely on trying the best Pinuses and other so-called hardy plants, and it was gratifying to notice many plants that were destroyed north of London, in high health fourteen miles west from Dublin, 300 feet above the sea, and in a soil not naturally propitious. An account of these will be found at page 136, for May, 1861; and as belonging to the place, we will make the following extract, merely premising that the plants from growth were larger on our visit, but that the *Libocedrus chilensis*, which seemed in a dormant state in the severe frost, died about the middle of May. The following plants had been planted eleven years:—

Two fine specimens of *Pinus insignis*, one 26 feet in height, spread of branches 15 feet, girth at 2 feet from ground 4 feet. The other was 27 feet high, girth at 2 feet from ground 3 feet. *Pinus strobus*, 24 feet high, girth at 2 feet from ground 30 inches. *Pinus excelsa*, 18 feet. *Pinus monticola*, 12 feet. *Pinus Pallasiana*, 16½ feet. *Pinus rigida*, 15 feet. *Picea cephalonica*, 15 feet. *Picea nobilis*, 15 feet, growing freely and gracefully. *Cedrus deodara*, 21 feet, elegant specimens. *Taxodium sempervirens*, 20 feet, girth 2 feet from ground 3 feet; a compact specimen. *Cupressus thurifera*, 20 feet. *Araucaria imbricata*, 15 feet, with many smaller ones. Of plants grown from four to ten years, there were nice thriving plants of *Cupressus Lawsoniana* and *McNabiana*, *Thuja Lobbi*, *gigantea*, &c., *Thuja borealis*, *Cryptomeria Lobbi*, *Wellingtonia gigantea*, *Abies morinda*, *Picea Nordmanniana*, &c. Of shrubs, there were *Desfontainea spinosa*, but not healthy; *Myrtus apiculata*, injured; and the following in full health, *Weigela rosea* and *amabilis*, *Berberis Darwini*, *Philæa buxifolia*, *Eurybia alpina*, *Grisolinia littoralis*, *Escallonia macrantha*, *Hibiscus syriacus*, *Spiræa*, the newer and tenderer varieties, &c. The cold in the winter of 1860 and 1861 ranged from 12° to 20° Fahr.—a rather different thing from being below zero with us, and showing how many plants may succeed in Ireland that will not endure the general range of cold in our winters. All round this neighbourhood scarcely a *Pinus insignis* had escaped, while many were completely killed, and as fine as Mr. Hamilton's.

"There, now, what a rambling fellow you are! Commencing with arousing our attention about Turnips; and here you have been leading us a dance about flowers, and taste, and everything.

else except the one thing chiefly interesting to me as a small farmer." Well, we know more about such matters than Turnip-growing by the many acres. However, we may state that the large field of Turnips was a sight worth going to see: the crop was so regular and level throughout, as if no allowance could be given for a single miss or blank. There was a peculiarity also in the mode of cultivation which we observed here as well as at Lough Crew and Woodstock. The rows were much the same as to distance from each other—from 27 inches to 30 inches; but the bulbs were much closer to each other in the rows than generally prevails on this side of the water. These huge, clean, well-shaped globes almost touched each other; and when taken up to be pitted or given at once to the young sheep (the lambs of that spring looking at a distance like two-year-olds), the Turnips thoroughly covered the ground. That ground, whatever its texture naturally, was as fine and clean as an Onion-bed, and was to be sown directly. The largest of these white Pomeranian Turnips weighed 19 lbs. We have it in our note-book, that from weighing small portions of the crop the average weight was computed to be 60 tons per acre, and that the Swedes swelling fast would average 40 tons. Mr. Hamilton, however, has no faith in such averages, and the result of weighing every earload exactly was 35½ tons to the statute acre. An acre of Swedes, including two headlands and a narrow farm road in the measurement, gave 34 tons to the statute acre, every load being carefully weighed. There was not a weed to be seen in the field, and no harbour for such in the fences round it. We regret we did not inquire the minutiae of culture; but for the sake of many small and amateur farmers who feel a sort of patriarchal pleasure in attending to and making the most of their few acres of a farm, we hope that Mr. Hamilton will furnish such readers with a few practical hints on the subject.

One secret, no doubt, consists in the goodness of the manure used—not poor washed material, the good properties of which have been conveyed to the nearest ditch or rivulet. The farm and domestic offices close to the mansion are a nice combination of the suitable, the convenient, and the economical. The receptacles for keeping and preparing food are so placed as to economise time and labour. No steam power is used; as, more horses than are required for the farm being kept, occasion is taken, when not wanted otherwise, to use them for working the necessary machinery in grinding, threshing, bruising, and cutting. The stalls of the byres and stables are elevated sufficiently to permit of a shallow waterproof gutter behind, so that all the rich manurial liquid shall be conveyed at once to suitable tanks. There is nothing of the *ferme ornée* about such buildings, but there is the greatest cleanliness and attention to the health of the cattle combined with the economical. The whole of the manure from the buildings is taken to a yard, nicely mixed, and trodden; and if too dry to undergo a very slow decomposition, it is turned over in wet days, and the rich pure liquid manure added to it as necessary. Why do this in a wet day? Because the men will be in the dry, as the dungyard is all covered with a shed-roof, so that no rain shall deteriorate the manurial material. Contrast such a mode with that which too often obtains in England amid all our boasted improvements, where the rains that would naturally fall upon the dungyard and from all the sheds and buildings surrounding it, are allowed to soak and percolate through the manure, until, when thrown together, it is little better than mere decomposed litter, and fitted to act upon the land more as a mechanical than an enriching agency.

The waterproofed shedding-roofs are quite a feature at Ham Wood; and though in the places of rich gentlemen and noblemen we would like to see such sheds and buildings covered with slate, &c., we have no doubt that many will be indebted to Mr. Hamilton for the hint how to make such sheds, so as to be somewhat lasting and combine the great requisites of efficiency and economy. We saw all the corn under these sheds; and we understand, that since we were there Mr. Hamilton has resolved to do away with all thatching of ricks and substitute sheds, as being in a few years by far the more economical, besides being in every way more neat, serviceable, and convenient. Some sheds we saw had been standing from eight to ten years, and seemed as sound as the day they were put up. The shed in which the corn was placed was 60 feet long, 20 feet wide, and 20 feet high. The flooring of this, consisting of strong pieces of wood, was placed about 18 inches above the ground, supported in the middle chiefly by short posts of wood fixed in the ground, and standing up to that height, and having their tops covered with a piece of tin or iron projecting 2 inches or 3 inches

all round, so that neither mouse nor rat could get up into the corn.

These usually called "baulks," supported the rough flooring. The stout outside posts supporting the building had a piece of the same material nailed on, beat or bevelled, so as to project in the same way. Our neighbour, Mr. Ross, who superintends the splendid farm at Luton Park, has much more substantial buildings for a similar purpose, but for keeping out rats and mice similar pieces of zinc or plate-iron are fastened all round the posts for some 18 inches deep, without any projection, and he thinks they are quite as efficient in preventing the destruction of victuals. This by the way, only any such system does show something more of carefulness than building stacks on the ground, and letting rats and mice devour what ought to be carefully saved as human food.

The roofing, however, is the chief thing we have to specify. The ridge-board and rafters are managed in the usual way. On these rafters the boards are nailed, placing them close, edge to edge, the boards being about three-eighths of an inch in thickness; in other words, five boards are cut out of a batten or plank 2 inches thick. On this board roofing stout unbleached double-width calico is stretched, and tacked neatly, covered over with gas tar, which soaks through the wood, and when that coating is dry a second coating is given, and when wet a pretty liberal dusting of rough sand or dry road drift thrown over it. There seemed to be no comparison between neatness, lastingness, and efficiency between this mode and such plans as asphaltum at 1d. per foot. The whole cost for this shed, 60 feet long, 20 feet wide, and 20 feet in height, was £25. The rafters, roofing, &c., ready sawed, cost £22 16s., and the calico, gas tar, &c., about £2 4s.

Since then 10 feet have been added to the length, and other two sheds adjoining to it built, each 70 feet long; so that there is now a space enclosed by waterproofed roofs of 70 feet by 60 feet, and the whole will cost about £70. These latter have been erected in addition to the usual labour on the farm. Those who pay for thatching similar spaces every year, and put a value on the straw so used, will be able to judge how soon such sheds will pay the cost of thatching, whilst the damp, unseemly litter will be all got rid of, and the expense of canvass in wet weather avoided. We forget in how many years, we think six or eight, Mr. Hamilton deems it advisable to give a fresh coat of tar, but which at 1d. per gallon, or so, involves little expense but the labour of putting it on. All straw and hay will now be thus stored at Ham Wood.

The few pleasant hours we spent at Ham Wood not only tended to show the truth of the old adage that "short accounts insure long friendships," but demonstrated a principle of still greater importance—that a man of activity and perseverance may prove a thorough philanthropist, in elevating and improving the condition of his countrymen, and yet never be insensible to the charm of having a good balance on the right side of the ledger.

R. FISH.

## A PLAN OF A DUTCH GARDEN AND GREENHOUSE.

THE subjoined plan is a modification of the ground plan of the Dutch greenhouse and garden at Redleaf, and affords many facilities, not only for the production of effect, but also for a great diversity and choice of plants.

The chief interest, and indeed beauty, of these kinds of gardens is peculiarly intrinsic. They possess no features by which they can be moulded into a combination with natural scenery, and, therefore, are only appropriate as accompaniments to architectural embellishment, or to be placed in some warm secluded nook, where the boundary (to be presently remarked upon) may legitimately form a portion of the general scenery, without offending the taste by placing the extreme artificial in juxtaposition with the purely natural. The form of the boundary, marked in the plan No. 1, must be determined by circumstances. If only a square plot is to be operated upon, and the exterior is of no moment, it may be a border bounded by a conservative wall for choice climbing plants and Roses; or, if room will serve, it may be a low wall with iron palisading, and the border planted with evergreen and deciduous shrubs; but, if it is placed in any part where a formal boundary is inadmissible, I would have it formed of Azaleas, Andromedas, Rhododendrons, and other American plants in combination. The interior line being of course quite straight, the exterior may be varied in a

multitude of ways by indentations and projections, so as to appear part of a general design, and in keeping with surrounding scenery.

In order to assist the effect of this boundary, it would be as well to throw up a mound of earth suited to the growth of American plants, and by planting some large specimens on the top, some of which should be standards, and filling up the intermediate spaces down to the ground level with evergreens and deciduous shrubs intermixed, an appearance will be produced which it would take many years to arrive at, if the plants were all started from a level surface.

Near the interior line of the outside border I have placed crosses (+) at intervals where the taste of many persons might lead them to approve of a plan which would produce a unique and fine effect—viz., to plant at each + a strong-growing climbing Rose, to be trained up a pole 12 feet high, and when they

reach the top to be guided across by means of a strong wire, so as to meet each other; they would thus form a beautiful living festoon. Near this interior line also, the Chinese Pæonia Moutan, and varieties, should be liberally distributed; a sheltered situation of the kind suits them well. The beds, No. 2, may be filled with choice herbaceous plants, to be assisted during summer with plants from the greenhouses and pits. Double White Rockets are very conspicuous in such a situation in spring, so also are the herbaceous Phloxes in summer. Conspicuous showy plants of such kinds will require a certain degree of uniformity in the arrangement to be in keeping with the artificial character of the garden. No coarse or common plants should be admitted. The interior octagonal portion of the plan (No. 3) may be devoted to bedding plants in masses, in the summer and autumn.

No. 4, Beds of hardy Fuchsias. No. 5, Beds of Roses.

A PLAN OF A DUTCH GARDEN AND GREENHOUSE.

No. 6, Choice plants from stores, with some ornamental trellises covered with *Lophospermum*, *Maurandya*, *Tropæolum*, and other rapid-growing creepers during the summer, and *Hyacinths* in spring.

No. 7, Bright dwarf Scarlet Geraniums in summer, *Turban Ranunculus* in spring.

No. 8, The greenhouse. This, of course, as well as the whole plan, may be varied and modified so as to suit particular circumstances: as, for instance, instead of a greenhouse the garden might be formed in front of a cottage ornée. Taste will easily suggest a different arrangement, only the style must not be departed from, and neither circles nor curvilinear figures admitted.

No. 9 Affords an excellent situation for a small architectural temple, where seats may be arranged, or it may be formed of rustic woodwork, and covered with *Roses*, &c.

In a garden arranged according to the above routine, there will be, except in severe frost and snow, some objects of interest in flower all the year round; whilst, at certain times of the year the effect will be truly gorgeous.

Lastly, with regard to the formation of the walks and borders, I must observe that the walks here are formed of paving-bricks laid flat, and the edges with a smaller brick set up end-ways, and it affords a dry and comfortable walk all the year round, which is a great desideratum; but they may be formed with gravel and edged with Box or slate, or whatever the taste may fancy, except grass, which, in such a situation, would be as inappropriate as it would be difficult and troublesome to keep neat.—J. Cox, gardener to W. Wells, Esq., Redleaf.—(*Gardeners' Magazine of Botany.*)

ORNAMENTAL PLANTS.

**BEJARIA COARCTATA** (Close-headed Bejaria).—*Nat. ord.*, Ericaceæ. *Linn.*, Dodecandria Monogynia.—A beautiful half-hardy evergreen shrub, the branches of which are shaggy with spreading hairs. The leaves are oval-acute, on short stalks, closely imbricated, glaucous beneath. The flowers are in close

terminal corymba; the petals, seven or eight in number, erect, nearly parallel—that is, not spreading; the colour, deep crimson. From the Andes of New Grenada, and the mountains of Peru. Introduced about 1818, by Mr. Purdie. Flowers about May.

1. *Bejaria coarctata*.

2. *Bryanthus erectus*.

3. *Hypocyrrta gracilis*.

**BRYANTHUS ERECTUS** (Upright Bryanth).—*Nat. ord.*, Ericaceæ. *Linn.*, Octandria Monogynia.—A charming little hardy shrub, more impatient of heat and dry air than of cold. It forms a compact dwarf bush, with erect much-branched stems, bearing linear-obtuse, obscurely-serrated leaves, and flowers, eight or ten altogether in corymbs from the ends of the branchlets. The flowers are campanulate, resembling miniature *Kalmias*, of a delicate pink or flesh colour; very pretty indeed. It is said to be a hybrid between *Rhodothamnus* (*Rhododendron*) *Chamaecistus*, and *Phyllodoce taxifolia* (*Menziesia cœrulea*); and Dr. Lindley thinks it may be a cross between these plants, though he would rather refer its origin to the *P. empetrifomis* (*M. empetrifomis*). The north side of walls where the sun never shines, and low, but thoroughly-drained places, suit this and allied plants; better still, damp, cold, shaded pits in which the air

remains always damp. A garden hybrid, obtained by Mr. Cunningham, of Edinburgh. Flowers in spring.

**HYPOCYRTA GRACILIS** (Slender *Hypocyrrta*).—*Nat. ord.*, Gesneraceæ. *Linn.*, Didynamia Angiosperma.—A pretty creeping stove plant, with branched purplish-brown stems, rooting from below the insertion of the leaves. The leaves are opposite, an inch long, thick, fleshy, ovate, on short petioles; dark green above, paler and often blotched with red beneath. The flowers grow singly or in pairs, on short red peduncles, from the axils; the corolla is rather large, between funnel-shaped and bell-shaped, with a curved tube; creamy white, spotted with orange on the under side of the tube within; the limb consisting of five nearly equal, rounded segments. According to Dr. Lindley, this is, probably, an *Alloplectus*. From the Organ Mountains of Brazil. Introduced before 1850 by Messrs. Backhouse, of York. Flowers in spring.

DESTRUCTION OF RED SPIDER BY VAPOUR OF SPIRIT OF TURPENTINE.

HAVING read in the *Cottage Gardener's Dictionary* (an excellent and cheap publication, by the way, that I would recommend to every amateur in gardening), that "the vapour of spirit of turpentine is said to be as effectual as sulphur" in destroying red spider, and having destroyed some plants in applying it, I send you an account of the means I used, in the hope that you will publish my failure for the warning of novices like myself, and at the same time give some instructions how it should be applied if really a useful agent in the destruction of that gardeners' pest—the red spider.

The plants I operated upon were six plants of *Thunbergia*—two of them large plants in flower in 5-inch pots, the others

small plants in 4-inch pots, and one *Brugmansia* in a 10-inch pot, These I put at night in a box 32 inches long, 17 inches wide, and 11 inches deep, and with them three small pieces of cotton wool, each about the size of a pigeon's egg, saturated with about a dessert-spoonful of spirits of turpentine, and covering the whole over with waterproof oiled calico, thus making the box almost air-tight, left them until morning. On first uncovering them they seemed but little injured, except that the leaves of the *Brugmansia* drooped considerably. I syringed the whole to help to get rid of the red spider, and in the afternoon found the plants all dead, the leaves looking as if they had been dried with considerable heat. They had been carefully shaded, so that I

attribute the loss of the plants entirely to the effect of the spirits of turpentine. As I had applied the remedy once before with considerable effect in destroying red spider, and without the loss of my plants, with this difference—that in the other case the spirit of turpentine was in an open saucer, and not nearly so much was evaporated as from the cotton wool, I write you these particulars in the hope that you will point out what was the probable cause of my failure, and give some hints on the application of this remedy for red spider, as I have proved that it is efficacious in the destruction of this pest, and think my failure arose from my want of skillfulness or judgment in applying the remedy.—COUNTRY CURATE.

[We have no personal experience of the use of the fumes of spirit of turpentine as an insect-slayer; but it is very evident that the fumigation was too strong and too long continued. The evaporation from the saucer was quite rapid enough. Much must depend, however, upon the temperature. We shall be obliged by reports of experiments upon this subject.—Eds. J. of H.]

### GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE Annual Dinner in connection with this Institution was celebrated on Thursday, the 26th ult., at the London Tavern, under the able presidency of Sir Arthur Buller, M.P., who was supported by a considerable number of gentlemen, amongst whom were the Rev. J. M. Bellow, R. Wrench, Esq. (Treasurer), — Wodehouse, Esq., Morgan O'Connell, Esq., Messrs. Oram, W. S. Barton, C. A. North, W. N. de Matton, R. Marnock, G. Childs, F. Ledger.

After the usual loyal toasts, the Chairman proposed the toast of the evening—"Success and Prosperity to the Gardeners' Royal Benevolent Institution." To appreciate, he said, thoroughly the progress that had been made within the last few years, even in the science and practice of gardening in this country, were indeed a task of difficulty. For himself, he must say that, in endeavouring to do so, he could not but feel that it was a great advantage to him having been abroad for many years; because on his return he remembered well the astonishment he felt at the advancement he found in the practice of which he spoke. Wherever he went, whether to a county, a house, or to a cottage in some country village, there were palpable evidences of progress in the business of gardening. Gardens had sprung up, too, in busy cities, and even many lodging-house windows in dark, dismal, dingy streets, possessed floral decorations which were in other times considered but the fair products of the greenhouse. Fruits, too, which in his time had been deemed but small and insipid, had now become of enormous size and of the most delicious flavour. Indeed, it almost seemed as though Flora and Pomona had again come amongst them, and had again taken into their own hands the culture of the earth. These vast results, as they could bear witness, were the results of the untiring energy, industry, and ingenuity of those hard-working classes, the poorer and worn-out members of which it was the object of this very Institution to assist. Whilst those who sought to carry on this excellent work recognised and enjoyed the fruits of their success, they should ever bear in mind and endeavour to alleviate illness, which might often be the result of the means exercised towards the achievement of that success. In many cases the poor gardener had but little indeed to set aside out of his scant resources towards provision for the infirmities of age. And, in addition to this, they must not forget to what risks he was subject in going from heated atmospheres into cold—say, for instance, from theinery or the greenhouse, into, it might be, frost and snow, or rain. He (the Chairman) believed that King Rheumatism had more subjects amongst gardeners than amongst almost any other class of the community. In aid of such sufferers, then, he had on the present occasion to appeal. It was for such that this Institution was founded; and he was proud to add, and rejoiced indeed to say, that in cases where sympathy and help was needed it was administered both with integrity and discretion. Referring to the report which had been placed in his hands, and to which he would beg to call their attention as a very gratifying document, of which even Parliament might be proud on account of the clear and intelligible figures in its balance-sheet and of its unmistakeable surplus, he would add that, however agreeable it was, more money was yet wanted. It still appealed to the

benevolence of the public for support. As it was customary, therefore, on such occasions as this to embrace any opportunity of indulging in any exuberance of generosity which the circumstances which accompanied the occasion might inspire, lists had been provided, and which would be handed round, in which the names of any gentlemen who so wished it might be recorded. The process of subscribing they would find extremely simple. There was a column on the left for the name of the subscriber; columns next to that on the right for his address, &c.; and further still to the right, columns in which persons so disposed might put down certain figures representing money, for which the officer duly appointed to that business would call in due course. If any gentleman present felt so nervous that he had not the courage to do so at the present moment, he (the Chairman) might reasonably suggest that a glass or two more of wine, which was said to have an effect on the human eye, might perhaps render his the brighter, and he might thus see more clearly his way to do that which he had the pleasure to suggest. Seriously, however, he could not sit down without adverting to a paragraph in the Report to which he had referred, and which ran as follows:—

"Your Committee notice with pleasure that year by year they continue to receive the patronage of gentlemen interested in horticulture; but at the same time they regret that the class of persons for whose benefit the Society has been specially formed, should respond in such a lukewarm manner. Your Committee find that among the gardening world there are a great many whose names ought to be in the list, and to whom the amount of an annual subscription would scarcely be felt; and they are sure that many more gentlemen would become donors to the Society were they to see the names of their gardeners on the list of subscribers. The Committee earnestly appeal to gardeners holding good situations to support this Society; they would then be assisting their poorer brethren, and at the same time laying by for themselves a small provision in the hour of distress and need, if overtaken by misfortunes, to which all are alike exposed."

With these remarks he would leave the toast he had already named in their hands. The Chairman sat down amidst loud cheering, and the toast was duly honoured with "three times three."

The other toasts were the "Secretary," the "Treasurer," "Literature and Art," the "Seed and Nursery Trade," the "Stewards," and the "Ladies."

The sum subscribed during the evening amounted to £200.

### THE PLAGUE OF SLUGS, AND HOW TO REMEDY IT.

THE destruction of plants in fields and gardens by grubs, slugs, and insects of all kinds this season has considerably exceeded the average loss from this cause, and drawn the attention of agriculturists and gardeners to the subject. There have always been partial and local attacks both of grub and insects, but the complaint this year is general, and may even be called national. From all quarters the cry is still, "They come, they come;" and though the ravages which have been already chronicled are, of course, merely a tithe of the actual loss, yet they are sufficient to make us view the subject with all the seriousness which it deserves. Some seasons are prolific of insect and animal life, just as they are of vegetable life. This year the wet and moisture seem to have been favourable to the development of slugs and grub. There is little doubt that the open winter also fostered, if it did not stimulate, the propagation of insects of all kinds. A keen black frost, or even one with a sprinkling of snow, would have thinned the insect ranks materially. There was no frost, however, of any great severity, and the principal assistance in keeping the insect tribe within due bounds was to be expected from the feathered race. Unfortunately, however, birds of all kinds, from rooks and magpies down to sparrows, are scarce, and they seem destined to become scarcer. The country is almost as bereft of birds as the town. The fashion among boys for collecting eggs, and the wholesale destruction of rooks and other large as well as small birds, has reduced the feathered race to such a degree that the hedgerows and forest glades are all but deserted. Indeed, with the exception of the lark and the house-sparrow, there is scarcely any bird to be seen. Birds which used to be quite common twenty, and even ten years ago, are now seldom to be met with, and it is only too evident that they are dying out altogether. The balance of power between the feathered race and the insect tribe has suffered an infraction, and as Nature never allows her laws to be broken with impunity, we are now reaping the fruits of our own wanton acts. In these circumstances it is scarcely to be wondered at that the slugs and snails have it very much their own way.

With this rapidly decreasing list of the *feræ natura*, it has been found beneficial to supplement it with domestic fowls. This, of course, can only be done to a very limited extent, but, so far as gardens are concerned, the system is quite practicable. Indeed, our own experience this season, as well as that of a number of others, is quite conclusive on the subject, and goes far to prove that the ravages of insects are to be attributed more to the want of birds than to anything else. Last summer a kind friend presented us with a pair of chickens, a cock and a hen—beautiful spangled Hamburgs. Having an eye to the flower parterres in particular, and to the amenity of the grounds in general, we must confess that we looked somewhat askance upon the gift, and wished that our friend's generosity had taken another shape. However, there they were; and as our motto is, "Live and let live," they were permitted to go about, and soon became general favourites with every one except Punch, the terrier; whose jealous spirit would "brook no rivals near his throne." They grew in beauty side by side," and, as they were neither addicted to scraping or burrowing, they had the run of the garden for the whole season. Throughout the winter and spring they have been almost constantly in it, and, with the exception of walking over a flower-plot or an Onion-bed, they have done no damage. The result of the experiment is that there is scarcely a slug or snail to be seen in the garden; and all those who have adopted the same plan are rejoicing in an almost complete immunity from the plague which has eaten up their neighbours' plants. Broods of ducklings have also been introduced into several gardens for the same purpose. They do not scrape, are keen on the hunt for slugs, and very few escape them. Those who have not made the trial may be apt to suppose that the cure is worse than the disease, and may incline rather to "suffer the ills they have, than flee to others that they know not of." This, however, is not the case; and, if farther proof were required, it might be enough to state that in several instances there is only a garden wall between the healthy and luxuriant plants preserved by means of the chickens and those eaten and destroyed by the unchecked slug. The lesson to be learned from the whole matter is the preservation of our small birds, and it is to be hoped that it will not be lost upon

"The rude, unfeelin' gang  
Wha teir the nestlins e'er they flee,"

stirring up the eggs, or waging indiscriminate war upon the old birds.—*Scottish Farmer.*

### IMPROVEMENT OF COTTAGES.

*On the Establishment and Management of Cottage Improvement Societies.* By W. A. GREENHILL, M.D., Oxon. London: Longman & Co.

So entirely convinced are we that one of the most efficient agents in improving the condition of the labouring classes, both morally and physically, is by improving their dwellings, that we hail this and every other effort to promote that improvement with much heartiness. It is true that such societies as Dr. Greenhill teaches "the proper management" of, restrict their exertions chiefly to town cottages; but these cannot be improved without a lesson being taught to the owners and builders of country cottages: therefore, we are very willing to give our aid to the promotion of such societies, and recommend all who wish to establish one to read this pamphlet.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

TAKE advantage of dry weather to eradicate the weeds which may have sprung up during the late rains, and where the soil is not sufficiently dry for hoeing, hand-weeding should be adopted. Carrots, make a small sowing, if they are in request, for drawing early. Celery, the main crops to be got out without delay, the plants to be well supplied with soft water, and shaded for a few days if necessary. The early crops to be liberally supplied with liquid manure, and the soil about them to be frequently stirred with a fork, but the moulding of them up to be postponed until they have nearly attained their full growth. Onions, sow a few for drawing young; the Tripoli answers best for that purpose. Potatoes, the spaces between the rows of early sorts to be forked-up, and planted with crops of Brussels Sprouts, Kales, and Coleworts. Turnips, keep up good successional sowings, of which a large breadth may now be got in. Bear in mind that charred

refuse suits them well, and that dried wood ashes sprinkled on them when they are wet is a good preventive against the fly.

#### FLOWER GARDEN.

Fill up vacancies caused by the removal of hulba or early-flowering annuals, with German Asters, Stocks, Zinnias, or any other such plants in reserve. Decayed blooms to be removed from Perpetual Roses, and the young wood cleaned from insects. Continue to propagate Picotees, Pinks, and Pansies; clip Box-edgings in cloudy weather, bud Roses, roll and mow lawns, and follow up assiduously the extirpation of weeds. Proceed with pegging and otherwise training young plants as they advance. See that Dahlias, Hollyhocks, and the tall-growing herbaceous plants are properly secured to stakes as they grow.

#### FRUIT GARDEN.

The principal operations here will consist in keeping the young wood of wall-fruit trees constantly nailed-in, the laterals from the young wood of Peaches and Nectarines to be spurred down to the first joint, which spurs will often produce fruit, but do not trust to the laterals for filling up the walls, as they seldom get sufficiently ripened to produce good fruit. A considerable portion of the young wood of Gooseberries and Currants to be spurred-in at this season, which will both increase their productiveness and the size of the fruit.

#### GREENHOUSE AND CONSERVATORY.

Shading to be used sparingly except on bright days, as during dull, unsettled weather plants require all the light that conservatories (the roofs of which are generally shaded by twiners) afford. The plants in the greenhouse should now be carefully looked over for the purpose of affording such of them as may require it a final shift for the season; by shifting them now the plants will accumulate before winter a sufficient mass of roots to support them through that trying season. Allow conservatory border plants the full advantage of favourable weather, that a compact, hardy habit may be produced. Regulate the shoots of Passifloras and other climbers, repressing irregularities of growth, and giving, where necessary, support by judicious tying, and sufficient supplies of water to the roots. Continue Epacris under glass till their growth is complete, but more air and light should be allowed them, increasing them as the wood gets firmer. Towards the end of the month they may be placed out of doors in an open situation, but where they can be protected from heavy rains. The last batch of Achimenes may now be potted and placed in a cold frame for a last show of bloom. Balsams, Thunbergias, &c., for decorating the conservatory for the next two months, should be finally potted in light, rich soil. Keep down red spider by frequent applications of the syringe. Brugmansias, Neriums, and similar plants of vigorous habit should be frequently assisted with manure water. Introduce Liliun lancifolium, L. eximium, and a few of the more forward Gladioli, and other Cape bulbs, to supply the places of the Pelargoniums, &c., now on the decline. Lechenaultias should be carefully examined for green fly, and smoked at once, if at all infested, and the flowers to be picked off the young plants as they appear.

#### PITS AND FRAMES.

Chinese Primulas, especially the double varieties, if at all backward, should be placed in a close frame, shaded from the sun, where they will make rapid progress, especially if the pots stand upon a slight bottom heat. Cinerarias for early blooming should also be potted and started at once, choosing the strongest suckers and placing them in a close, shady frame till rooted. The general stock here will now be growing freely, and should be frequently examined to see that they do not suffer through any neglect in watering. Young specimens of hard-wooded plants should be carefully trained, keeping the shoots neatly tied-out or pegged-down in order to secure close, compact foundations, upon obtaining which future success will, in a great measure, depend.

W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

SOWED Lettuce seed and Endive, this being early enough for the latter, unless where Endive is preferred to Lettuces. Planted out Lettuces against the north slope of a bank, and others on the level ground, to succeed each other; watered those nearly fit for use to make them crisp, as though the weather has been dull and showery, there have been no rains to reach the roots to any extent. Watered young Canflowers, and planted out more,

and will prick out young ditto, that the plants may be some size before planting, and also to enable the ground to be cleared of other vegetables. As stated before, would always prefer sowing Lettuce thin, and allowing them to attain maturity where sown, but that would take more ground than I could well spare at a time. Hoed all Onions, Carrots, &c., once more, as shortly there will be no room for the hoe, and hand-weeding is a miserable affair. Planted out some beds of *Celery*, fine stout plants, mostly two or three rows in a bed. These would have been out before, but could not get the ground earlier. The plants though large from being pricked out some 3 inches apart, in loose earth and leaf mould, rise with large balls, and never feel the removal. As to curtailing leaves or roots as used to be done in the days of old, that is now out of the question, but the bottom of each plant should be carefully examined, and every vestige of a sucker-like appendage carefully removed. It is much easier doing it now than after the plants are growing freely in the beds, and if not done, instead of having one nice, solid plant of *Celery*, you will have a principal one in the centre, and ever so many smaller ones all round, disputing the pre-eminence with the central one, and of no use but to be cut away when the *Celery* plant is wanted for use. A little leaf mould, or very rotten hotbed dung are the best manures for *Celery* that you wish to be presented at table crisp and sweet. If size is the object, you may give dressings of guano or superphosphate of lime, and if the rotten dung is scarce, a little of the latter may be used to give extra strength; but, as a general rule, *Celery* thus rendered extra luxuriant is deficient in sweetness and crispness. Find to my sorrow that Potatoes lately so healthy showed signs of withering in some places, after a few sunny days, and though they had been planted shallow, found on examination that the stem below the ground was quite gone, the withered skin only remaining, and on looking carefully found numbers of *Julus complanatus*, one of the snake millepedes. It is doubted whether these do anything to a plant but feed upon its previously decayed parts. If they cause decay I feel a little doubtful what remedy to apply, believing that lime or ammoniacal liquid from the gas works, if it destroyed the insects, would also be liable to hurt the crop. It is quite a new mode here of interference with this crop, and I attribute it partly to the fact, that from close and constant cropping the ground had not received the exposure and aeration it ought to have done. With the exception of Carrot ground, &c., I can give a great portion of mine no such treat. I should feel disposed to ridge such ground in winter, and dress it with lime, and a little of the refuse lime from gas works. On pulling up a *Cucumber* plant, we found the heart nibbled with a harder gentleman of something of the same nature, but which had not hurt the plants much, and, therefore, could scarcely be the cause of a curl and brownish blotches in the leaves again making its appearance, after I flattered myself I had got rid of that, and also a gummy secretion which troubled me for two years, as, until just now, the Cucumbers have borne well, and looked healthy. A two-light box strong and healthy, which along with others I meant to succeed these older ones, is also showing yellow points at the end of the fruit, without any apparent cause. For many years we found it easier to get plenty of Cucumbers, with less trouble, than a good early supply of Turnips; but for three seasons there have been times in which I could scarcely get the necessary supply, and after a number of experiments, I am forced, in answer to many complaints on this subject, to say I know of no remedy but fresh air, fresh soil, sweet and rather light, and planting frequently, so as always to have younger plants to fall back upon. It is true, these plants have been grown in pits and lights, with light merely above them, and the season, as a whole, has been very deficient in light and sun, but in many places the plants grow as healthy as ever, whilst in other places they can scarcely be made to grow at all. To make more certain I procured seed from a distance, and of people who had plants from me, some have done well, and others not so well. In span-roofed *Cucumber*-houses I hardly know an instance of such diseases manifesting themselves.

#### FRUIT GARDEN.

Much the same as last week. Have had and still have a good supply of *British Queen Strawberry* in pots under glass, and in this dripping weather they are far superior in flavour to any we have had as yet out of doors. Few *Queens*, however, are yet ripe with us in the open air, and if the weather does not change, I do not hope they will at all equal those in pots which have

come in as change with *Keens'* for the last month. Hit upon two dry days to gather lots for preserving, and among these a good portion of *Cuthill's Black Prince*, which is much liked for that purpose, it is so firm and hard when not over-ripe.

#### ORNAMENTAL DEPARTMENT.

Proceeded with shifting *Fuchsias*, some hardwooded plants, chiefly, however, encouraging their growth. Potted *Geraniums* for autumn blooming, *Balsams*, *Browallias*, *Amaranths*, *Feather Cockscombs*, &c. Cut down large plants that bloomed early, as variegated *Geraniums*. Syringed such plants as *Cytisus*, *Genista*, &c. Watered everything as required, and in the flower garden chose a dull day to give all the plants, and especially *Calceolarias*, a good drop of water at their bottom, the skill of showers doing nothing but refresh the foliage. *Calceolarias* are a mass of bloom, but the ground is too cold to enable us to say the same of *Geraniums*, &c., though showing what they would do with a little more warmth. The small weeds have come so much that we were obliged to hoe again, using three-inch Dutch hoes, which permit of a good workman stirring the ground amongst the beds. A few sunny days would prevent much use of the hoe, as the ground would be so covered that the weeds could hardly get light to grow. Finished planting borders and out-of-the-way corners pretty well for the season, and filled a number of vases, set out of doors, that used to be placed in glass-covered verandahs. When so used these vases and verandahs, were as the very apple of my eye, and exhibited a very artistic and unique style of gardening. All the higher vases, some of them with their pedestals 6 feet and more in height, were filled with large, lofty, flowering plants, and creepers depending all round them. One part of this verandah connected with the library, was an elegant lofty structure, glass all in front, and a hipped-roof of *Hartley's* fluted patent, so that a leaf was never burned. The other part was merely glass in front, 10 feet in height, and a circular zinc roof, and acted as the approach to the other, altogether some 150 feet in length. These overlooking a sunk Italian garden, had (from their uncommonness, not a red pot being seen, and each vase being a little picture in itself), a very striking effect, and there was a pleasure in getting up fine showy plants to occupy them. But it is possible to have too much of a good thing, and my worthy employer giving full credit for their beauty, &c., came to the conclusion of having them all removed, as though the sight was very pleasing to a visitor, the scent and the damp, and the necessary attendance became too much when presented to a person every day, and every hour of the day. I mention this just to show that gardeners must not expect to have everything their own way. That I was vexed at such a style of gardening being abandoned is no doubt true, but I could also see there was much force in my employer's objections, the seeing plants at a time being very different from having them damp, and their scent thrust on you whenever you opened the door of the sitting-room, or hearing the rattling of blinds, or the squirting of a syringe, when reading some very interesting part of a book. The verandah for the present will be transferred into a sort of corridor, furnished with seats, and if plants are to be banished, might be made ornamental in an artistic point of view.—R. F.

#### TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PLANTS IN ROOMS (*J. R. Ridley*).—No plants, except Cactuses and other succulent-leaved species, can be kept long in vigour in a dining-room or drawing-room. The air is too dry for them; and the only reason why they decline sooner if the room is lighted with gas is because the gas gives out more heat than a lamp or candles, and consequently dries the air more and faster. This is taking for granted that the room is properly ventilated. The only way to keep plants vigorous for a protracted time is in a plant case. The air in that is kept moist by evaporation being checked.

**VARIOUS (A Go-a-head Doctor's Boy).**—Your plants potted now in 9 inch pots will bloom better if not potted again, and will look better too. Give them manure water, and get them to the greenhouse in a fortnight or three weeks. Take all the flowers off the Balsams, pot into 9-inch or 10-inch pots, in rich soil, give liberal watering, and pot again if you like. Keep the flowers off till August. You will do with the Scarlet Geraniums. Better stop and prevent flowering for two or three weeks. Any sort will do; and they will stand either out of doors or as much heat as you like, provided they have sun and air. Calceolarias will be of no use except shrubby ones. The best is all fancy, the growth will be the thior. Verbenas may still be potted and do first-rate. They have two months to do well in. The largest flowers are best for pots. Kidney Beans and Turnips would come in if sown now. It is too late for Peas to do any good that would be worth showing. Were we to enter fully into all your questions it would require a little volume, and then we could merely repeat former instructions.

**SUMMER-PRUNING ORANGE AND LEMON TREES (J. S.).**—Pinch back the strong shoots, so as to induce from them two or three weaker ones. If only a few and they are not wanted, cut them out altogether, and the strength will be taken by the other and weaker shoots.

**CHERRIES FALLING (A. R.).**—Cherries usually set multitudinously, and fortunately thin themselves—that is, they fall off because the tree does not supply sufficient sap for the growth of all. If they all remained, and by a supernatural exertion the tree sustained them to ripeness, it would probably never recover from the consequent exhaustion.

**PONO MEO (A Constant Subscriber, Mud).**—We answered a precisely similar question last week. You must not add lime to the mixture if the terrace is to be planted with Rhododendrons or other American shrubs. For other evergreens you may add a bushel of lime to each single horse-cartload.

**DISSOLVING BONES (Quiz).**—The mode with oil of vitriol (sulphuric acid), is as follows:—On a small scale, 6 lbs. bone-dust, 3 lbs. oil of vitriol, 1½ lb. water. Sprinkle the water on the bones first, and then add the vitriol. Be careful, for it is very corrosive. Use a cask large enough to hold twice the quantity. As such ashes or water may be mixed with the dissolved bones as will enable you to sprinkle it over the plot of ground regularly. The above quantity of oil of vitriol would be enough for 100 square yards. If you purchase the sulphuric acid in large quantities, you may obtain it for three-half-pence per pound. We advise you to try to reduce the bones to powder as the Americans do, by putting a layer of bones broken small, and a layer of potash alternately in a cask. Hensley's "Rudiments of Botany" is the best book for a beginner. The other author you name disgusts by his dry technicality.

**WORKS ON FERNS (Harry A.).**—A volume is now going to press, which, with Johnson's "British Ferns" will give you full information relative to the species and culture of both exotic and native Ferns.

**EARTH-NUTS, &c. (M., St. Ives).**—The gentleman you referred to obtained a supply at the time—thanks all the same. If you mix the old sawdust with lime, it is well decayed, the grubs, &c., will be destroyed. It will form a good manure for your Strawberries, and the Potatoes in a heavy soil. As the Wild Strawberry thrives in the peaty soil you mention, it may do as a dressing for your cultivated Strawberries; but we would try it on a row or two before using it generally. Peat is not considered a good soil for Strawberries. Hurts or Whorls is a common name for the Whortleberry.

**GRUBS IN COWDUNG (C. E. Lucas).**—Mix it thoroughly with freshly-slacked lime, one part by measure of lime to two parts of the dung. Before adding it to the other ingredients take care you do not over-ferd your greenhouse plants, for then you will have more foliage than flowers.

**GRAPES SPOTTED (W. G. B. Newark).**—The answer we gave at page 262, last week, relative to spotting in Muscat Grapes is applicable to your case. Inactivity in the roots is the usual cause of spotting.

**CAPE GOOSEBERRY CULTURE (Norwich Z.).**—There are several kinds of Physalis called Cape Gooseberry, but all requiring much the same treatment as Tomatoes. If we knew the kind you mean we would give you a full statement of its management. The treatment of the common kind was given fully four or five years back, when the fruit was exhibited before the Horticultural Society, both in Regent Street and Willis's Rooms.

**CARROTS AND PARSNIPS (F., Hitchin).**—We presume that "the grub" attacking your Carrots and Parsnips is the wireworm. It is the larvæ of the click beetle (Elatér). Gas lime mixed with the soil is said to protect the crop, and that growing white Mustard drives them away. We have no faith in those remedies unless they are obnoxious to the parent insects, and prevent them depositing their eggs in the soil.

**SHRUBBY CALCEOLARIAS (Andrew).**—Many varieties have been of late raised very much in the style of yours, and their value would entirely depend on their habit if they were dwarf—i.e., about 9 inches or a foot high, and stout in the stem and floriferous; they might be desirable, but they must have these qualities to be at all thought of now.

**ROSES NOT THRIVING (B. Z.).**—Your Roses from the market came out of a forcing-house, and the sudden change chilled them; but they will get over it though you put them in the wrong stuff—cocoa fibre refuse. It is the refuse from the crushing of the nut shells which is the real stuff, and in which our Roses luxuriate without any other assistance for the last two years. To make it more plain to you, we may observe that every Rose in the catalogue, if it is on its own roots, is just as easy to grow and to bloom in a greenhouse as any of the new Fuchsias; and the very same kind of soil, the same sized pots, the same quantity of water (weak and strong), and the same quantity of air and sunlight will do for all Fuchsias and for all Roses. The only difference is, that Roses are more liable to flies and smut than Fuchsias; but so they are out of doors, and there is no better remedy than dipping the tops into a basinful of very moderately strong tobacco tea.

**ASPARAGUS-BEDS (A Subscriber, Duxford).**—Sprinkle salt over them once a-month during all the growing months, from March to October, about a pound to 4 square yards. Draw a trench about 3 inches deep between each two rows of the plants, and fill it with strong liquid manure once a-week during the same period: this is our own mode of culture, and by this, and avoiding the old atrocious system of digging the pathways between the beds, we have grown the finest Asparagus possible. We put about 1 inch deep of thoroughly-decayed manure over the surface in autumn when the seed stems are cut down, but eschew the old mode of burying the crowns deeply with earth. We let the shoots rise fully 6 inches high before we cut them for table. Make the cut only just below the surface of the soil, and thus

have about 5 inches of eatable full-flavoured Asparagus, instead of a little tip of insipid stuff, such as is upon the drum-sticks usually brought to market.

**LEAVES OF MOSCAT OF ALEXANDRIA (W. R. J.).**—The Vine was, if anything, too luxuriant, and the roots more active than the leaves, &c. We do not think there is anything unwise with the Vine; but it is impossible to say from one leaf. The white Salvia patens, as you say, is one of the best whites we have, and the blue of the patens is also the best blue we have of that tint; but like Roses, they do not come in so tidily as others, and people get tired of tramping them.

**TODIA HYMENOIDES (L.).**—This, one of the filmy Ferns, a native of New Zealand, requires a cool close treatment under a bell-glass, exactly in the same way as Hymenophyllum and Trichomones. For these tiny Ferns the cocoa-nut refuse is particularly useful, and heat is particularly dangerous to this kind of Todia.

**COCOA-NUT-FIBRE REFUSE FOR CYCLAMENS (St. Mary Church, Torquay).**—The dry pericarp which envelopes the hard horny shell of the cocoa-nut is crushed into powder in order to get the fibre out of it, that fibre is then dressed like Flax, to make all manner of things with, from a brush to a cable, and the sawdust-like powder obtained when crushing the pericarp, is what is so good for all plants, and not the refuse fibre. One-half of that dust and one-half of very good loam is a first-rate compost for Cyclamens. We have hundreds of them in it now, and the last batch from our Sardinian correspondent are now resting on a whole mass of it, pure and simple, and macrophyllum is just putting out the first leaves. We put all our Cyclamens while at rest between two layers of the cocoa-nut refuse, the top layer only 1 inch thick, the bottom may be any depth. This keeps them not dry or wet, as all the Cyclamens ought to be kept, and at whatever time young leaves begin to come, we lift the roots and pot or box them in half-and-half, as above specified. We have been thus particular again, because of mistakes made and samples sent to us for identification.

**NAMES OF PLANTS (J. S.).**—1, an Ornithogalum, but the specimens sent are inaudible; 2, the common Lastrea filix-mas. (A Subscriber).—It is not Tartagon but the common Hyssop. (M. H., Timperley).—Aralia trifoliata. (J. C.).—Your Lycopods look as if the same species in different stages of growth. No. 2, which is the only perfect one, is one of the forms of Selaginella Martensii, of which there are several in cultivation. (C. Y.).—1, Orehis pyramidalis; 2, Bunium flexuosum; 3, Lastrea filix-mas; 4, probably Fipactis grandiflora, but not enough advanced to be certainly recognised.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

JULY 9th, 10th, and 11th. LEEDS AND WEST RIDING. Secs., G. Newton and J. Wade. Entries close June 21st.  
AUGUST 2nd, 4th, and 5th. SHEFFIELD. Sec., Mr. George Westerholm, 49, Queen Street.  
AUGUST 25th, 26th, 27th, and 28th. CRYSTAL PALACE. Sec., W. Houghton. Entries close July 26th.  
SEPT. 4th. WAKEFIELD AND WEST RIDING. Sec., Mr. J. Crosland, jun. Entries close August 23.  
SEPTEMBER 9th. WORSLEY AND ARMLEY (near Leeds). Sec., Mr. Robert Hoyle, Armley, near Leeds.  
DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.

### FATTENING YOUNG FOWLS.

THE process by which fowls are fattened is no secret in the district which produces the fowl so well known, and so much esteemed, called the "Poularde du Mans." This trade, singular from its surprising results, and justly appreciated by the most refined "gourmets," is confined to the following districts:—Mésery, which formerly was first but is now somewhat fallen, Arthezé, Courçelles, Bousse, and Vilaine; the last takes first rank for fine productions and numerous feeders. There is no falling-off at Crosniere or Veron, or the adjoining villages. All these places belong to the district of La Flèche. It is to the chief town all the feeders bring their productions on market-day, and they are offered for sale by hundreds. Seeing this trade is specially local, should not the fowls be called "Poularde de la Flèche," rather than "Du Mans"?

The origin of the trade is forgotten in the country, as well as the author of it. It must be left for some learned gastronomist to throw light on the subject.

The special work of fattening belongs principally to country dealers and small farmers, who are called "poultersers." They buy at the markets or of their neighbours the pullets that are called "gelines," and which appear the finest and the likeliest to fatten. When aged between seven and eight months they are considered old enough to fatten. Those which are called virgin cocks are as much esteemed as the gelines. They are birds of the year that have never been used as stock; they are put up in an entire state, and differ from the others only in requiring more time and food to fatten.

The finest poulardes sometimes attain the weight of 7 lbs., and virgin cocks 10 lbs. They have been seen heavier.

Feeders have from fifty to a hundred fowls under treatment at the same time. The season generally begins in October and ends

at the Carnival. A room or any other convenient place being chosen, small coops are placed all round. These may be made with laths or rods of the commonest wood, plainly sawn or even chopped out with an axe. Nothing is too common to make sides and open divisions. Some of the coops may be made fixtures and others moveable. They are generally rudely constructed by the poulterers themselves, and involve little more expenditure than the time employed and a few nails. There are no fixed dimensions: the largest, however, should be only large enough to contain six fowls, and afford only sufficient space for each bird to stand easily without being able to move about.

All light coming from without is intercepted, the doors and windows are papered in order that fresh air shall not penetrate freely.

In order to accustom fowls to the diet and the confinement to which they are about to be subjected, they are shut up during eight days in a darkish place, where, for only food they have a thickish paste made with the same flour that serves for making the crams, and mixed with sometimes a third, sometimes a half of bran. During this first trial they are allowed to eat and drink as much as they will.

The meal of which the crams are made is generally made as follows:—Half of buckwheat, a third of barley, and a sixth of oats. The bran is taken from it. This should be mixed every day with fresh or with sour milk, each time enough should be prepared for the feed at night and in the morning.

Some people add lard to the composition of this paste, especially towards the end of the fattening, and this paste, which should be neither too slack nor too stiff, should have the form and size of an ordinary olive. The poulterer, or feeder, at the feeding time, which should be very regular, takes three fowls at a time, ties them all three together by the legs, puts them on his knees, and by the light of a lamp he begins, but once only, by giving them a spoonful of water or of skimmed milk. Some give no drink at all. Then he puts a cram in the mouth of each of the fowls, and to facilitate the immediate introduction of this cram he exercises a slight pressure with the thumb and two first fingers, sliding them down from the mouth to the crop of the bird. This does away with all danger of the rejection of the cram. By treating three fowls at once they have sufficient time to swallow, and each is crammed in turn at short and equal intervals.

In the early stage of cramming the crop of the fowl should be only partially filled at each meal, the quantity should then be gradually increased. Thus at last the number of crams reaches twelve or even fifteen. Every cram should be dipped in water before it is given, it facilitates the operation.—(*Le Poullailier*, by C. Jacque.)

### COOKING OLD FOWLS.

I HAVE followed your receipt for old fowls, to cook them with bread, &c; but this way they must be served cold, to turn in a nice-looking shape out of the stew-pot. If you think the following worth insertion, it may be a saving to those, who, having old fowls, would rather eat them than take the low price offered for them. Take one or two old fowls, and, having roughly plucked them, skin and cut into pieces, put them in stew-pot with odd pieces of meat, bones, or gravy, onions, and whole pepper, cover with soft water, and let the stew-pot be placed in a slow oven; if not tender at night, leave in all night. When tender, put them in pie-dish, with or without hard-boiled eggs; cover with crust, and bake as for a common meat-pie.

I have cooked several dozen in this way, and find it much liked. The care must be to cook slowly—to stew, not to boil.—B. B.

CRYSTAL PALACE SUMMER POULTRY SHOW.—An announcement of this will be found elsewhere in our columns to-day, and its list of prizes we observe in the schedule are as liberal as heretofore, and with a few additions. Thus there is a class for Bantam cocks; and in Pigeons one for Agates, Kites, Duns, and Grizzles. The only fault we have to find with the classification is in the Rabbit classes. It is a palpable absurdity to offer distinct prizes for Rabbits, the sole difference of which is their colour. The classification ought to be—1, longest ears; 2, greatest weight; 3, combining all properties, any colour; 4, Chinchilla; 5, Angora, and so on for any distinct valuable variety.

### PRESCOT POULTRY EXHIBITION.

THE Exhibition of poultry just closed is the ninth annual meeting of this Society. It is gratifying to report that the Show just held was by far the best of any, whether regarded as to numerical amount of pens, or the universally excellent character of the specimens entered for competition. The reasons productive of success are twofold—the locality being in the first place that in which are resident a considerable number of our principal exhibitors, and, again, the well-deserved confidence reposed by those of more distant parts, has never, throughout the long period of nine years, been in anyway trespassed upon.

We think it right as strongly to express our approval of the Prescott arrangements, as it is unhappily compulsory on us in too many instances to speak reprehensively of committees who permit the prize money, nay, further the very sums paid for "claimed" pens, to remain unforwarded for months, and even years after the time of exhibition! We repeat, such defaulters may vastly improve public confidence to themselves by closely treading for the future in the footsteps of the Prescott Committee, for, certainly, such delays admit neither of palliation nor justification. With these passing remarks, we trust to hear that at least some of those committees, whose prizes, though won, have never been remitted to the successful exhibitors, will allow no longer so palpable a stain on their proceedings to remain as a subject for universal censure.

*Spanish* were appointed as Class I. The class was numerous; but, with the exception of the two prize pens, the birds were not unusually meritorious. Mr. Martin, of Claines, Worcester, and Mr. Rodbard, of Wrington, respectively proved the winners. There cannot be a doubt that the hens in the second-prize pen were the best exhibited, but the cock belonging to them appeared suffering from being over-shown.

So good were the *Grey Dorkings*, they are always first-rate at the Prescott Meeting, that every pen throughout the class is favourably noticed in the prize list.

The *Cochins* were a most praiseworthy class, and every variety of colour was well represented.

Both varieties of Spangled *Hamburghs* were shown together, and most excellent they proved themselves. We much regretted to notice in this class a pen of Golden-pencilled birds wrongly entered by the exhibitor's oversight, that had they been correctly sent in would have held a very different position in their proper competition. Entries can never be made too carefully. In the Golden and Silver-pencilled *Hamburghs* were many superior pens, and barring the one always fatal mistake (a wry tail in the cock), undoubtedly the best feathered pen was compulsorily passed over on account of this single failing. Another exhibitor in this class showed a most extraordinary male bird, the product of interbreeding the Spangled and Pencilled ones together.

In *Polands*, the Black White-crested ones were decidedly the most perfect of any shown.

Perhaps one of the highest features of the Show was the *Game* fowls, and, undoubtedly, we never saw a collection so universally excellent. We must again guard exhibitors against the so-constantly-repeated faults of jenned fowls of various coloured legs in the same pen. However good otherwise, this must disqualify them.

In the *Cochin-China* chicken class were exhibited (Pen 78) the two best pullets we have seen for years past, but the male bird is ruined for show purposes, by some untoward accident to the comb.

The *Spanish chickens* are deserving of the most favourable mention.

As every breed of *Bantam* was eligible in a single class, of course the competition was beyond precedent. Every pen appears noticed save one. Surely this may influence an increased amount of premiums to these general pets at future meetings.

The *Ducks*, though good, as might be expected, did not, on account of the time of year, weigh well. The plumage of most of the Rouens was, however, faultless.

In all our experience we never saw a more excellent competition with the same amount of entries as among the *Pigeons*. The exhibitors seem to have entered from nearly every part of the kingdom; and we must add, that those of our readers who did not visit the Prescott Meeting lost sight of a perfect treat, for class after class of those birds was unexceptionable.

As the Show is only held during one day, of course favourable weather is all-important. At daybreak the sun betokened a favourable change of the weather from that of the late week's, but about eight a severe fall of rain damped the ardour of all

parties. Long before the time of public admission, however, the sky became unclouded, and, consequently, the Show was ultimately well attended, and successful every way. The tent in which the fowls were exhibited is a peculiarly good one, and the view from it is extensive. We might suggest, that for Pigeons pens somewhat smaller than those used on this occasion would, undoubtedly, be the most effective arrangement, besides presenting less danger when the repacking rendered their recapture imperative. With this single change we really think the Prescott arrangements are not open to even a single quibble.

**SPANISH.**—First, J. Martin, Church Cottage, Claines, Worcester. Second, J. R. Rodbard, Aldwick Court, Wroughton, near Bristol. Highly Commended, J. Mangnall, Leigh; J. K. Fowler, Prebendal Farm, Aylesbury.

**DORRING.**—First, Capt. W. Hornby, R.N. Knowsley Cottage, Prescott. Second, J. Friar, St. Helens. Highly Commended, C. H. Wakefield, Malvern Wells; Master E. Sergenson, Huyton. Commended, Capt. W. Hornby, R.N.

**COCHIN-CHINA (any variety).**—First and Second, T. Stretch, Marsh Lane, Bootle. Highly Commended, Capt. W. Hornby, R.N., Prescott; R. E. Ashton, Limefield, Bury, Lancashire. Commended, Miss V. W. Musgrove, West Tower, Aughton, near Ormskirk; G. Green, Knowsley; H. Bates, Harbour Health Cottage, Edgbaston, Birmingham.

**HAMBURG (Gold and Silver-spangled).**—First, N. Marlor, Denton, near Manchester. Second, J. Dixon, Bradford. Highly Commended, G. R. Tate, Driffield; J. Dixon, Bradford; J. Kellett, Widnes Dock, near Warrington.

**HAMBURG (Gold and Silver-pencilled).**—First, J. Martin, Claines, near Worcester. Second, A. Nuttall, Newchureh, near Manchester.

**POLAND (any variety).**—First and Second, J. Dixon, Bradford. Commended, S. Farrington, Chat Moss, Astley.

**GAME (Black-beasted Reds).**—First, H. Adams, Beverley. Second, H. M. Julian, Beverley. Highly Commended, E. Archer, Malvern; H. Worrall, Spring Grove, West Derby. Commended, C. Chaloner, Steetley, near Worksoop.

**GAME (Brown Reds).**—First, C. Chaloner, Steetley, near Worksoop. Second, H. Adams, Beverley. Highly Commended, C. W. Brierley, Rochdale; H. M. Julian, Beverley.

**GAME (Duckwings).**—First, P. Howard, Knowsley. Second, H. Worrall, West Derby.

**GAME (White and Pile).**—Prize, T. West, Eccleston Place, near St. Helens.

**GAME CHICKENS (any variety).**—First, C. Chaloner, Steetley, near Worksoop. Second, G. Green, Knowsley.

**DORRING CHICKENS.**—First, C. H. Wakefield, Malvern Wells. Second, Capt. W. Hornby, R.N., Prescott. Highly Commended, S. Farrington, Chat Moss, Astley; G. Green, Knowsley; J. Rowlandson, Hawkshead, Windermere.

**COCHIN-CHINA CHICKENS (any variety).**—First, T. Stretch, Marsh Lane, Bootle. Second, J. B. Walthew, Aughton, Ormskirk.

**CHICKENS (any other variety).**—First, J. R. Rodbard, Wroughton, near Bristol. Second, A. Nuttall, Newchureh, near Manchester. Highly Commended, J. K. Fowler, Aylesbury.

**BANTAMS (any variety).**—First, G. C. Whitwell, Kendal. Second, T. H. D. Ray'ey, Ickwell House, near Biggleswade. Highly Commended, G. Green, Knowsley; C. Martin, Fairfield, near Liverpool; C. W. Brierley, Rochdale; N. Marlor, Denton, near Manchester; J. Holden, Westhoughton, near Leigh. Commended, P. Howard, Knowsley.

**DUCKS (Aylesbury).**—First, J. K. Fowler, Aylesbury. Second, G. Green, Knowsley. Commended, J. K. Fowler.

**DUCKS (Rouen).**—First, H. Worrall, West Derby. Second, G. Green, Knowsley. Highly Commended, H. Worrall; J. K. Fowler, Aylesbury; R. E. Ashton, Limefield, Lancashire. Commended, R. Tate, Driffield, Yorkshire.

**DUCKS (Buenos Ayres).**—First, F. W. Earle, Edenburs. Second, J. R. Jessop, Hull.

**SINGLE GAME COCK.**—First, E. Archer, Malvern. Second, W. Doyce, Beverley. Highly Commended, Capt. W. Hornby, R.N., Knowsley Cottage; E. Archer; J. S. Butler, Ponilton-le-Fyde; C. W. Brierley, Rochdale; B. W. Bretherton, Rainhill.

**GAME BANTAM COCK.**—First, T. H. D. Bayley, Ickwell House, near Biggleswade. Second, E. Holdsworth, Leeds. Highly Commended, H. Adams, Beverley; J. Holden, Westhoughton, near Leigh. Commended, W. O. Kenyon, Mossfield, Wavertree.

#### PIGEONS.

**CARRIERS.**—First, D. Thwaites, Rock Ferry, Cheshire. Second, G. Green, Knowsley. Highly Commended, A. L. Silvester, St. Paul's Square, Birmingham; H. Yardley, Market Hall, Birmingham; D. Thwaites. Commended, R. Dyson, Filch Lane, Knotty Ash.

**ALMOND TUMBLERS.**—First, A. L. Silvester, Birmingham. Second, T. D. Walker, Liverpool. Highly Commended, E. Holdsworth, Calls, Leeds. Commended, D. Thwaites, Rock Ferry.

**TUMBLERS (Rough Leg).**—First, H. Yardley, Birmingham. Second, J. Sephton, Prescott.

**TUMBLERS (any other variety).**—First, J. Sephton, Prescott. Second, E. Holdsworth, Calls, Leeds. Highly Commended, F. Else, Bayswater, London; Lady Emma Talbot, Knowsley.

**BARBS.**—First, E. Holdsworth, Calls, Leeds. Second, Lady Emma Talbot, Knowsley.

**TURBETS.**—First, J. Beesley, Prescott. Second, F. Else, Bayswater, London. Highly Commended, H. Yardley, Birmingham; J. W. Edge, Ashton New Town, Birmingham.

**OWLS.**—First, F. Else, Bayswater, London. Second, F. Kay, Beverley. Highly Commended, D. Thwaites, Rock Ferry; J. W. Edge, Ashton New Town, Birmingham. Commended, E. Holdsworth, Calls, Leeds; H. Yardley, Birmingham.

**FANTAILS.**—First, D. Thwaites, Rock Ferry. Second, G. Green, Knowsley.

**RUETS.**—First, F. Kay, Beverley. Second, E. Holdsworth, Calls, Leeds.

**POWERS OR CROPPERS.**—First, F. Else, Bayswater, London. Second, D. Thwaites, Rock Ferry. Commended, R. M. Brocklebank, Aigburth, near Liverpool; H. Yardley, Birmingham.

**TRUMPETERS.**—First, F. Else, Bayswater. Second, F. Kay, Beverley. Highly Commended, D. Thwaites, Rock Ferry. Commended, D. Thwaites.

**JACOBS.**—First, D. Walker, Liverpool. Second, D. Thwaites, Rock Ferry. Highly Commended, R. M. Brocklebank, Aigburth, Liverpool.

**ANY OTHER NEW OR DISTINCT VARIETY.**—First, A. S. Bretherton, Hamilton Square, Birkenhead. Second, J. W. Edge, Ashton New Town, Birmingham. Highly Commended, Miss M. Sergenson, Huyton (White Doves); T. D. Walker, Liverpool; Lady Emma Talbot, Knowsley (Brown Shields).

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, as on many previous years, officiated as poultry Judge.

#### MORTALITY AMONG CANARIES.

I was formerly very successful in rearing mules from the Goldfinch and Canary, and latterly have been anxious to get a breed from the Bullfinch hen and Goldfinch cock; but having for two successive seasons lost my Bullfinches, I venture to ask your opinion as to the cause, or the experience of any of your readers on the subject would be appreciated.

Last year in April, a young cock Canary paired with a hen Bullfinch; she laid two soft eggs and died on her nest. Some months later, another hen of the same species mated with a Goldfinch, when she suddenly sickened and died without laying. This spring I had a Goldfinch hen, two years old, which would have paired with a cock Canary, but he showed no wish to do so, and I then gave her a cock Goldfinch. They soon paired, and so beautiful were they that I had intended exhibiting them at a bird show; but the hen suddenly became bloated and short-breathed, and in a fortnight died. The cock was then put up with a Bullfinch hen, and in about three weeks she took to a ready-made nest, laid one egg, which the Goldfinch unfortunately destroyed, and then another (now under a Canary hen), but immediately after this, much to my mortification, she sickened, and the day after died. They had plenty of groundsel and watercress, but do you think the egg and bread-crums, which they ate of very freely, was the cause? I gave each of them two drops of sweet oil, but it did no good. As I sell my young birds for a local charity, this disappointment has much vexed me. With the Canary I have been very successful this year, though indeed among my disasters I must mention, as a warning to others, that a large slug destroyed four fine young Cinnamons of a few days old. They disappeared out of the nest all but one, which was left there without his head. On taking down the cage we found a huge slug as large as a finger.—E. C.

[The most probable, and perhaps the only cause that we can assign for your birds dying so suddenly, is that they were in too high condition, caused by being fed on too much fattening and oily food, such as hempseed, rape, and flaxseed. Finches, and especially Bullfinches, are very fond of hemp, which should be given sparingly, as, unless the birds have plenty of room to exercise, they soon get fat upon it, the result of which is apoplexy, or, in case of sudden fright, blood to the head. Apoplexy, if taken in time, may be relieved by cutting the toonail until it bleeds. Egg and bread alone would not kill the birds, although too much egg is not good for old birds.]

#### BIRDS AND BEES.

I AM happy to say we are smothered with small birds, for the more the merrier, as they are the best friends we have got here, and we adopt the modes I described in 1851 to protect our small fruit.

My bees are going on very well—that is, as well as the weather goes, not making honey very fast, though I have some fair-filled glasses of honeycomb; and I have made a great improvement for the bees to ascend thither, which I will take the first opportunity to acquaint you with.—UPWARDS AND ONWARDS, *Woodstock*.

**CAUTION.**—A person named W. G. Ridgway, writing from "Berwick Lodge" and "Berwick Brewery," near Manchester, lately obtained some valuable Rabbits from me, promising to remit the amount on receipt of the goods. Deceived by the printed headings of his letters I complied with his request, and now find that he is well known. I trust you will protect your advertisers by publishing this.—T. C.

[We have repeatedly warned our readers not to part with live stock to unknown applicants without prepayment.—EDS.]

## DO BEES CONVERT SUGAR INTO HONEY?

BEFORE complying with "A DEVONSHIRE BEE-KEEPER'S" request to test by the saccharometer the contents of the honey-bag of a bee, in No. 60 of THE JOURNAL OF HORTICULTURE, page 147, I waited, thinking others might suggest some other test. None having done so, I will now inform your readers of the result of the trial.

I first took some honey I had by me and prepared it, and put it into the saccharometer-tube, when it clearly indicated uncrystallisable sugar. I then made some loaf-sugar syrup, put it into another tube, and it gave just the reverse, showing it to be crystallisable sugar. I then poured a little of the same syrup on the landing-board of a hive in the morning as the bees were leaving the hive, and as soon as one filled itself and was about to return into the hive, it was killed, and the honey-bag taken out and broken into a little water, and applied to the saccharometer, when I am bound to confess, notwithstanding I imagined the change would have taken place, it had not done so, as it still indicated crystallisable sugar. I must own, however, that the instrument acted in the same manner with the broken honey-bag as it did when I tried the treacle, showing there was both crystallisable and uncrystallisable sugar present; and I am still of the opinion that when put into the bell the change has taken place. But how to prove that remains the difficulty. I might have kept the bees for a time after being filled, still I thought they would immediately go and empty their honey-bags at once, and, therefore, I did not try it in that way. I repeated the experiments on two different occasions, and both with the same results, along with a neighbour, who is a great apiarian, and who takes great interest in the matter, and who is likewise of opinion that when the syrup of sugar is laid in the comb it is changed into honey.

I shall be very willing to try any experiment your correspondents may suggest. I confess I do not see my way to how we are to succeed in getting, for certain, from the comb that same syrup they have just been fed with, so that there can be no cavil about it.

But I have hopes that your correspondent "A DEVONSHIRE BEE-KEEPER," will be able to suggest some plan wherein it may be tested; or if he and one of his opponents to the theory agree on any plan and send down the honey to me (three drops in a small phial of water are sufficient), I will put it to the test; and if they have any doubts as to the correctness of the instrument, or myself, if they send the same quantity of the sugar-syrup, of honey, and one phial of pure water, and mark the phials in numbers, or otherwise, that they may be distinguished, I will detect them when it is utterly impossible to do so by the taste.—ALEX. SHEARER, *Yester Gardens.*

## DO BEES VARY?

LIKE Colonel Newman, I have often been assured when purchasing swarms that the bees were of a better sort than ordinary. Generally, the recommendation urged in their favour has been that the bees are smaller and more active than the larger and more lazy "varmints" of their neighbours. To argue them out of their fond belief I have never attempted, knowing that my labour would have been vain; but that there is any difference in the ordinary English hive bee, further than may be seen in any apiary or single colony, I do not for a moment believe. I have been an ardent apiarian, and a tolerably close observer of the species, for nearly twenty years, four of which were spent in Ireland, and have never met with an instance in which there was any difference of colour or size, further than an accidental or a merely temporary one. Occasionally the bees of a hive would appear both of a lighter grey colour and of a smaller size than those of the other stocks; but in a very short period the peculiarity disappeared. To theorise, I should imagine that the stock had lost its queen, and between that time and the exit from their cells of the young bees bred by the young successor of the defunct queen (a period of nearly two months), a great proportion of the old bees had disappeared: consequently, the majority of the foragers were of a light colour compared with the rest of the apiary. That old combs are the cause of a difference in the size of bees I think can hardly be disputed. Many years since I had a singular proof of the influence the dimensions of cells exercise in this respect. The bees and some of the combs were transferred from a straw hive into a glass globe, of the peculiar form drawn by Wildman or Thorley, and which had

been used as a honey-glass sixty years ago. There was no aperture in the top of the bell and no cross-stick, or other support to the combs was supplied. The combs rested on the floor-board, and the bees built upwards to the top of the glass; but they were never able to reach it so as to make their work adhere. Want of ventilation, and consequent great heat, caused the combs to collapse and sink downwards as fast as they were carried upwards. To live at all, the poor bees were obliged to gnaw away the wax at the bottom, which at length bore the appearance of an almost solid mass, perforated with passages for communication with the upper portion of the hive. But the most singular result of all was, that in time a number of most diminutive bees made their appearance. I am sure I do not go too far in asserting them to have been no larger than a good-sized house fly; they appeared perfectly formed, and ran to and fro on the alighting-board. I do not now remember seeing any of them take wing, and in a few days they had all disappeared, probably being found incapacitated to perform the duties expected of properly-constituted bees.

We know how great an influence the capacity of the cell exercises with respect to the size of drones. Until my attention was more particularly drawn to the subject within the last year or two, I had no idea of the numbers of drones which are bred in worker-cells. Thanks to the introduction of the Italian (or as I still like to call them, the Ligurian bees), I have learnt within the last two years from actual experience respecting the artificial rearing of queens, and the scientific manipulations which arise therefrom, much more than in my whole previous career. Drones so small issue from the worker-cells as to appear quite pigmies in comparison with their more-fully-developed brethren. In transferring brood-combs from common bees into hives of Ligurians, where it is desired that no common black drones should exist in the apiary, it is requisite to keep a sharp eye on the cells whose projecting caps indicate the presence of embryo drones within, and destroy them all. Their position and size may easily cause the operator to overlook them.—S. BEVAN FOX, *Exeter.*

## A BEE-KEEPER'S PERPLEXITIES.

IN the spring of 1860 I bought a swarm of bees, which I kept through the severe winter of 1860-61 on a shelf in my coach-house, feeding in the spring by an inverted bottle, as taught in your Journal. My neighbours, old bee-keepers, lost nearly all their stocks that winter. I had a good swarm on the 11th of June, and a flight on the 19th; the former hived themselves in a very old skep in a neighbouring garden, the latter I hived in a box with three drawers as supers, patented by King, of Cambridge. In the autumn of 1861, my swarm in the old skep seemed so weak, and suffered so much from robbers, that I fancied it had no queen; I therefore fumigated with fungus, took the honey, and, as I could find no queen, added them to the parent stock. I had therefore two very good stocks to keep through the winter of 1861-62. I bought this spring one of Neighbour's cottage-hives, and a Woodbury comb-bar box. Now, here I come to a difficulty. Early in the spring I let the bees in King's box into two of the drawers (one filled with comb last autumn), hoping to prevent swarming; but no, that box sent out two strong swarms early in May, since which they have done nothing. They seem to have no life or energy. Now, did I go the right way to prevent a swarm? and, if so, why did it fail? Would you advise me to add a swarm which I expect daily to this King's box?

I ordered this spring some shallow, flat-topped straw hives and small straw supers, and requested the maker to get me a swarm in one. I got these home by the middle of May, the super already on the hive. The swarm seemed weak, the bees much smaller and rather more grey than my own. Last week I raised this super, and, instead of finding it still empty as I expected, it was quite full, so I took it off rejoicing in so rich a harvest; but to my surprise it was entirely full of brood in various stages, and I could see what I believe, from the drawing in Taylor's "Manual," to be a partially constructed royal cell. It was like an egg-shell cut across about three-parts down, and hanging from the side of a comb. I immediately replaced the super, and now the whole hive is so full of bees that for several days they have been hanging out in a great bunch, even remaining there during rain, so that one day a few were drowned. Why did these bees breed in the super instead of storing in it? Is it

because it was put on too soon? Shall I leave them to their own devices, or try to drive? I would have done this before, but did not know how to fix the super safely to the hive when I turned them over.

Yet again, I observe in your Journal of June 24, in replying to Edwd. Fairbrother, "A DEVONSHIRE BEE-KEEPER" talks of the injurious effects of fumigating, and of the facility with which he drives and shifts bees without it. Will he in pity explain the manipulation to a beginner? Last week I particularly wanted some honey. A super was full of brood only, and, as my bar-box (a second swarm of this year from King's box), seemed quite full, I determined to try and extract the two outside bars. Enveloped in a bee-dress and buckskin gloves, and armed with a fumigator, I boldly removed the lid of the box and got the honey; but I made an awful mess of it, my knife was too large to cut the end-combs clean away, and when I began to lift the bar the comb separated in the middle. I then had to remove a second comb and put my hand down and lifted out the broken comb as well as I could, getting my gloves stuck full of stings, three or four of which went through and made my hands twice too big, besides drowning several bees in the honey that escaped, and making that hive so savage that I cannot go anywhere near them without getting stung, though before I could walk among them as I liked. I do not much mind the pain, which I feel I deserve for my awkwardness; but it is a nuisance to have one eye or other periodically closed, and, worst of all, my workmen, who began to think some of the new dodges really might be better than their old plan of burning every autumn, will soon turn to their evil ways unless I can triumph over my present difficulties. One question more: I cannot get the bees to work in bell-glasses. I have tried, awkwardly enough, to put in guide-combs, and one glass I have smeared with melted beeswax to give them a hold; but they do not seem to like it.—A. W. B.

[We are not acquainted with the construction of King's hives, but you appear to have gone the right way to prevent swarming by giving additional room. *Why* you failed is a far more difficult question, and one which we believe no apianarian can answer with certainty. The fact is there is very often, especially in seasons like the present, so strong a disposition in bees to swarm, that no amount of care in affording room and ventilating will suffice to prevent it. All you can now do is to accept circumstances, which you cannot control, until you attain sufficient skill in your turn to play the tyrant, as pointed out in the reply to "A DISAPPOINTED BEE-KEEPER" in another column.

If the queen be dead in your King's hive, by all means add a swarm; if not, your doing so may produce a fatal quarrel. But how, you will probably ask, am I to ascertain this important point beforehand? This is just what we cannot tell you. If the hive has either bars or frames there will, of course, be no difficulty in deciding; but, if not, you must form your own opinion from external appearances, and act upon it whether right or wrong.

The small super was put on too soon, and the bees, therefore, commenced by building combs in it, which the queen at once filled with eggs. Had the honey season been a good one, you might probably by this time remove the super full of honey, and the combs be not very much the worse for having had brood in them. Perhaps in two or three weeks you may yet be able to do this, but the probability would be much increased by feeding regularly in the meantime. We should be inclined to adopt this plan (giving the room which appears to be required by placing an eke under the hive), in preference to driving.

We have submitted your letter to "A DEVONSHIRE BEE-KEEPER," who says, "'A. W. B.' does not appear to have done so much amies for a first attempt. He obtained what he wanted, which is a great point, but he appears to have mortally offended his bees. Had the matter been managed more adroitly they would have manifested a much more forgiving spirit. Premising first that in speaking of the injurious effects of fumigation, I meant only when it is pushed so far as to produce insensibility. I will briefly describe how he should amend his proceedings in future. Let him by all means envelope himself with a bee-dress and arm himself with his lighted fumigator, but in mercy to himself and his bees, exchange his buckskin for Indianrubber gloves, such as are worn by photographers, and take with him a sop for Cerberus in the shape of some sweetened water. Commence proceedings by slightly raising the crown-board at the back and blowing under it two or three good whiffs of smoke. Then close

it down and wait a minute or two whilst the bees are filling themselves with honey. Next lift it boldly off and stand it safely on one side so as not to crush any bees which may adhere to it, and liberally sprinkle the interstices between the exposed bars with sweetened water. Should the bees take this in good part without commencing an attack the operation may be at once proceeded with; but if their pugnacity be not quite subdued, a second subsidy of sweets should be accorded them, and the crown-board replaced for a few minutes to give time for their acceptance of the proffered bribe. All these manipulations are based upon the fact, that when bees are alarmed they immediately fill themselves with honey or such other sweets as may be at hand, and that if we can once induce them to do this they become as inoffensive as house flies. No provocation short of absolute crushing will induce them to sting. Your correspondent will do well to provide himself with a bent knife adapted for severing the side-attachments of the combs; but much better if he adopts frame-hives in which there are no side-attachments to sever."

With regard to bell-glasses, we can only recommend you to insert decoy-combs in such manner as you find most convenient. If filled with honey they—*i.e.*, the combs, may prove more attractive; but, after all bees will seldom work with freedom in bell-glasses. Why not try glazed bar-supers such as were described by Mr. Woodbury in page 74?

In conclusion, we would warn you and bee-keepers generally against over-deprivation in so bad a season as the present.]

### EXCESSIVE SWARMING.

Will you inform me if any remedy can be applied to make bees collect honey, instead of incessantly swarming. I have been a bee-keeper three years, and have never tasted or gathered any honey yet. I have tried Taylor's amateur's bar-hive, Neighbour's cottage and Stewarton hives, but all with the same result. All goes on well for three or four weeks after a swarm is hived, then just as the hive is overflowing, and room necessary, caps put on, and beautiful comb made, all is spoiled by swarming. One hive swarmed on the 30th of April, and four or five swarms have since left it. It is now a perfect wreck, with not a particle of honey remaining. A swarm of this season (double, as two swarms issued together from two hives on the 29th of May), have filled a box and a 10-inch glass with comb and honey; and just before the combs are sealed all work is suspended, the honey taken by the bees about to swarm, and the business of the season ruined.

I have tried shading the hives, giving additional room, &c., and I am rapidly coming to the conclusion that all the books tell us of caps, supers, and bell-glasses is "bosh," and that the old straw hive and burning the bees is the only way to secure having any honey. I am quite sure that I speak the experience of all or most amateurs.

As to cutting the queen out after fumigating with the pipe and tube, there is such a certainty of injuring the bees by the smoke and small particles of the puff-ball which are blown into the hive that I do not think it desirable to try this plan.—A DISAPPOINTED BEE-KEEPER.

[Your stocks appear to have been ruined by over-prosperity, their hives also being probably too small for the locality, which seems to be a first-rate one. We are perfectly aware that when bees are disposed to swarm no increase in the size of their domicile will at all times prevent it; but much may be done by the good management which is best attained by practice and experience. It is too late in the day to doubt that large harvests of first-rate honey may often be obtained in supers, whether of wood or glass,\* although bees will sometimes thwart the intentions of the apianarian by perversely swarming in the most provoking manner. We know of but one way of avoiding these occasional disappointments, and that is by adopting frame-hives and bar-supers, as recommended by Mr. Woodbury in page 73, endeavouring at the same time to attain sufficient skill in their manipulation to enable you to gain a thorough insight into their internal economy. When this facility has once been attained, the rest is comparatively easy. Drone-breeding may be curtailed by diminishing the combs in which it can be effected; and during the filling of a super the disposition to swarm may be nipped in the bud by the excision of queen-cells, without having

\* Messrs. Neighbour & Sons show some very handsome supers in their stall at the great International Exhibition. They are from the apiary of our correspondent, "A DEVONSHIRE BEE-KEEPER," and are the first worked in England by Ligurian bees.

recourse to fumigation. Even if an unlooked-for swarm should make its appearance, either the young queen or the old one may be removed at your option, and the swarm returned to its hive after cutting out all the royal cells which it contains. If none of these have been overlooked, no second issue will probably take place; or if it does, sufficient time will have elapsed to admit of the completion of the super. The same means are equally effectual in preventing a strong stock from destroying itself by over-swarming.]

#### A CHAPTER OF WELL-SETTLED FACTS.

1. All stocks of bees should be kept strong in numbers.—A well garrisoned city may defy assault.

2. A moderate increase of swarms will keep them strong, and secure the largest yield of honey.—As the calves are raised at the cost of butter and cheese, so bees are multiplied at the expense of honey.

3. Bees filled with honey are not inclined to sting.—As the robber's knife is stayed by your purse, so bees are bribed with profured sweets.

4. In natural swarming bees fill themselves with honey.—Emigrants to a new country carry their treasures along as capital to begin with.

5. Bees alarmed with smoke or otherwise, instinctively seize upon their stores.—The householder at the cry of fire secures what he can.

6. There should be no communication between occupied hives, allowing the bees of one to pass directly into the other.—“No house is large enough for two families.”

7. A swarm of bees destitute of a queen fast dwindles away; and, unless supplied with one, soon perishes either by robbers or moths.—A country without a government, a farm without an owner.

8. Swarms having combs insufficiently protected by bees, furnish a retreat for “millers” \* and food for worms.—Un-guarded treasures invite thieves.

9. An excess of drones should be avoided by discouraging the construction of the cells that produce them.—Drones are the “dead heads” of the hive—the useless males in the farmer's herds.

10. The building of drone-comb may, to a great extent, be prevented—first, by securing the construction of new combs in hives containing young queens; and, second, by placing frames to be filled, in other hives, near the centre.—“An ounce of prevention is better than a pound of cure.”

11. Queens are most economically reared in small swarms.—Who would employ ten men to do what one could do better?

12. Small swarms, if united in the fall, winter more safely and consume less honey.—“In union there is strength.”

13. Bees of colonies containing fertile and unfertile queens, should not be put together without first “breaking them up”—i.e., inducing them to fill with honey, and destroying the unfertile queen.

14. Natural swarming, always uncertain and perplexing, exposes the bee-keeper to much loss of time and money; while artificial swarming, securing at all times the presence of a worker-laying queen, doing away with all watching and loss by flight to the woods, is both sure and economical.—*Metcalf's (American) Key to Bee-keeping.*

**A NOBLE AUSTRALIAN DOG.**—The dingo, or wild dog of Australia, although he has none of the nobleness of eye and gesture of the beautiful cooley terrier, nor attains generally to his size, is yet a dog far from being unlike him in general outline and feature. But the dingo in his wild state, and the domesticated cooley, are as unlike as Nero and Howard. I well remember a beautiful cooley at Bong Bong; he was the property of an aged couple, and his old mistress, who was sadly addicted to intemperance, fell a victim to this awfully besetting sin. She was bedridden; and smoke being observed to issue from her dwelling, parties ran, and discovered that, in crawling to the fire to light her pipe, some articles of apparel had become ignited. She never rallied; and a day or two afterwards a few neighbours assembled to follow her remains to the pretty little graveyard of Bong Bong. One followed in the train who wore no mourning

\* *Anglicæ*, wax-moths,

garb; his coat, which I have often patted, as it hung so beautifully around him bore no funereal hue—it was a bright fawn—but who shall say there was no real mourning in the heart of that dog when he reads this canine reminiscence to a close? The remains of his old mistress being deposited in her grave, the earth was turned in, and all but one of the mourners departed to their homes; they returned to their varied avocations; he found one on the spot; it was the cooley dog, who stretched himself upon the grave, the guardian of the manes of his mistress. There kept he his post, in sunshine and in storm, by night and by day; and, gentle as he was, it perhaps would not have been well unguardedly to have invaded the privacy of that spot. He just visited his home and ate the food given him, and was away to his post again on the grave of the poor old woman, who had won his heart by long acquaintance, and a crust of bread. Months had elapsed since her death, but when last I heard of the noble cooley, he was yet the guardian of the grave of his mistress. That dog drew many an emotion from my heart. So fast a friend for so few favours, and I so failing a servant of “the Friend who sticketh closer than a brother,” whose mercies have indeed been far and infinitely more to me, in any moment of time, than the whole burden of those dispensed by that erring woman to her dog.—(*Rev. R. W. Vanderkiste.*)

#### OUR LETTER BOX.

**DORKING FOWLS** (*A Subscriber, Eslington*).—You have hatched very good chicken, measurement and weight are both good. When you get these two last qualities you need not be so particular about colour. From the feathers sent, the match pullets appear perfect in that respect. Had we to choose or describe, we should like the cock darker on the breast; but it is necessary to say no painstaking will insure the colour of chickens, and it is also notorious the largest and best birds are not, generally, perfect in colour. This fact has caused the institution of Silver Grey classes, where colour is the chief point. Your birds will not do to exhibit in these, but they bid fair to stand well for open competition.

**FOWLS LOSING THEIR FEATHERS** (*P. W. T.*).—It is possible, but not probable, as you suggest, that they may be moulting, but we rather incline to think that the loss of feathers arises from a fevered state occasioned by overstimulating food. Cease altogether from feeding with maize, and give them very little barley, but as much of the barleymeal and boiled potatoes as they will eat without wasting any. We would also give each of them a table-spoonful of castor oil. You say they have plenty of green food, but if it is in the form of Cabbage leaves do not let them have any more; for uncooked Cabbage leaves are acid and stimulating. Let the fowls have as much of Lettuce leaves and grass as they choose to eat.

**TRAVELLING-BASKETS FOR FOWLS** (*A Debtor*).—We have always been advocates for round baskets closed round, and made of wickerwork; they should be 35 inches high, 18 inches in diameter for a single cock, 24 inches for a pen of three birds. If any alteration, rather larger in the latter case. The top to be covered with stout canvass.

**VULTURE HOCKS IN COCHIN-CHINA FOWLS** (*Idem*).—Vulture hocks do not disqualify, but they are not desirable, and experience will tell most breeders that it is easier to perpetuate defects than merits in a strain. We advise all amateurs to avoid them as much as possible.

**CAROLINA DUCKS—SPANISH PULLETS' COMES** (*A. H., Calne*).—We do not know where you can buy the eggs of the Carolina Duck. They are not very difficult to rear, but they require a good deal of attention. It is not necessary to feed Spanish pullets on meat to induce growth of comb. It will always be developed when they first begin to lay, and it is possible to have too much of it. No amount of food of any kind will make an upright comb fall over. It is a defect, and the bird should be got rid of.

**KEEPING POULTRY AND PIGS** (*Columbus*).—They may be advantageously kept at the same time. The same land would do for them. Cows are not very liable to lose their hoofs unless kept many together and closely confined. Of course you can buy corr. &c., of farmers near where you settle. The advertisement would be 2s. 6d., or 3s. 6d., or more, according to length. Judging from your questions, you must know more about the subject than you seem to do now before you will be able to keep your family upon the produce of pigs, poultry, and a cow, though it is all simple enough.

**ROCK-WORK MAP OF THE WORLD.**—*J. McD.* intends copying a map of the world in rockwork, size 3 feet by 2 feet, having a sheet of glass for a foundation, and to represent the ocean he will first paste a map of the world on the glass, and then edge round the land part of it with a knife, rubbing away that part which represents water. His chief difficulty is this—he wishes to represent the different vegetation of different parts of the earth. We can get a chemical substance to represent snow. Moss would do to represent palms. How is he to represent grain, tea, and different other plants which would require to be represented? Sand will represent deserts. *J. McD.* has got a phythographical map of the distribution of plants. He could do it by having numbers with a reference, but he does not want numbers.

**KILLING MOTHS AND BUTTERFLIES** (*J. S.*).—For an entomological collection no mode of killing them is so immediate and non-damaging as putting them into a glass pickle-jar, tightly closed, in which jar some laurel leaves, previously bruised with a hammer, have been put, and covered over with a thin layer of cotton. The fumes of prussic acid emitted by the leaves are rapidly fatal, and all the quicker if the glass jar is put into a dark place. It is desirable to have a glass jar, because the effects may be readily ascertained. If it is kept closed, the laurel leaves do not require renewing very frequently. Put in enough to emit a strong fume.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 74.5° and 51.1° respectively. The greatest heat, 91°, occurred on the 18th, in 1859; and the lowest cold, 39°, on the 18th, in 1851. During the period 127 days were fine, and on 118 rain fell.

THE FRUIT-ROOM.

AMONGST the various appendages to a garden an efficient fruit-room is certainly not the least important, yet such a room we seldom see. Generally some back shed is fitted up with shelves in a very rough manner, and on these the winter Apples and Pears are laid, more or less thick as the crop may have been. In too many instances they are obliged to be laid too thick for their keeping well; as they are likely to be all wanted, there is no alternative but to place them so,

if the space be too limited for their being kept more thinly. Although we all know that good-keeping fruit will remain sound a considerable time, even when subjected to this treatment, there is no doubt but it would keep much longer if allowed more room from the first, and those instances in which fruits have been kept for long periods will be found to be where plenty of space was accorded them; some other conditions seem necessary for the well-keeping of fruit, and it will be advisable to point out a few of these individually.

Whatever may be the reputation of a certain variety of fruit for keeping purposes, there is no question but its merits that way are influenced by the situation in which it is grown, as well as the period at which it is gathered, and the condition of the atmosphere at the time. By way of exemplifying these three conditions it will be as well to take a very common case to point them out, and though there may be some difference of opinion on the habits and qualification of the variety given as an example, there is certainly none that has a wider reputation. I, therefore, by way of pointing out the conditions necessary to enable a fruit to keep as long a period as possible in a sound condition, will take the Ribston Pippin Apple as an example, not on account of its long-keeping capabilities—on the contrary, it is only an indifferent one in that respect; but by it we may learn the laws that govern other fruits as well.

In very many districts the Ribston Pippin Apple has ceased to be cultivated as a profitable fruit; the trees thriving indifferently for a very few years, either die off or linger on a wretched existence, the dead branches almost equalling the live ones in number. Though there is generally a fair proportion of blossom each season, what fruit there is can seldom be classed higher than second, or, perhaps, third-rate. Now, these fruits have, in many of them, the germs of decay before they are gathered from the tree; black specks near the eye, or, in some cases, near the other end, turn into a mass of decay of a peculiarly bitter quality, differing widely from the ordinary "rot," by which most other fruits are carried off more quickly, but not less surely, than by this black bitter spot of the Ribston.

Whatever may be the different opinions regarding this, it seems pretty generally admitted that it is mostly due to the diseased condition of the tree on which it grows, or, perhaps, the worn-out constitution of the variety. Whether this be so or not (and there seems every reason to believe it is so), certain it is that a very large proportion of the Ribston Pippin Apples that are grown, fall a victim to this black spot, which, by being of an intense bitter, disqualifies this Apple from mixing with others for making cider, which the decay in other fruits does not necessarily do, as they are not so bitter. Now, this bitter principle is, doubtless, imparted to the fruit by the decaying process it goes through differing from the same conditions by which other fruits become decayed and rotten; and whether the chemical change which takes place in the Ribston Pippin has its origin in the imperfect condition of the fruit at the time it is gathered, and the latent seeds of this disease be engendered then or afterwards, certain it is that a very great proportion of the fruit of this variety falls a victim to this disease. Though some situations favouring the better development of the fruit may render them less liable to it than in others, still it is reasonable to suppose that those places now in a great measure exempt will eventually become diseased like the rest, and the Ribston Pippin Apple will become a matter of history. The purpose is not now to prognosticate this, but to point out what conditions are necessary to preserve what healthy fruit there may be as long as it is possible to do so.

No one who has visited a fruit-room in the warm days of September, when there was a quantity of fruit all ripening into that mellow condition which betokens perfection, but must have been struck by the odour which is emitted from them. This odour, it is needless to say, must be as hurtful to the well-keeping of fruits as anything can be—say, for instance, a quantity of Williams' Bon Chrétien Pear all ripening at once into the condition fit for table, and in a day or two all will be in a stage beyond this, and become a mass of juice which it is difficult to handle without bursting them. Now, I always look on a mass of this kind as the most dangerous to a fruit-room; and as all early fruits ripen in warmer weather than other kinds do, they ought to be furnished with a degree of ventilation almost amounting to complete exposure, in order that the odour emitted by ripening fruit, which very quickly takes a decaying turn, may not contaminate the rest. Fruit at that time ought also to be kept thin. But to return to the Ribston Pippin. It often happens that these have to be gathered when the fruit-room is more or less occupied by fruits in the condition spoken of; and if the weather be warm at the time, as the whole of October was the past season, the fruit is impelled onward to a condition fit for table much earlier than they otherwise would be if kept cooler; and what is, perhaps, as bad, the infectious character of the atmosphere they are in hastens on decay some time before ripeness or mellowness has done its part: hence fruits that ought to be in perfection in January are ready by the end of November, not Ribston Pippin Apples only, but

all other kinds of fruits as well. This is one of the reasons why fruits in certain seasons keep longer and better than they do in others—the simple fact they are not ready to gather until cold weather insures their keeping, as more fruit generally perishes in November than in December and January, and no amount of mere cleanliness and care of removing diseased fruit can compensate for the crowded condition of the fruit-room in the early autumn months, when the weather at the same time is of a kind that favours “foreing,” which it certainly does when it is warm at the periods spoken of.

Now, as the Ribston Pippin cannot be preserved under circumstances as described, let us suppose an opposite case—a backward unkindly season like that of 1860, when there was no lack of fruits generally; the fine autumn of the year before securing sufficient bloom, but the multitude of fruits only resulted in each being very small, and the unfavourable season did not mature them with that degree of perfection so requisite in good fruit: hence we had a quantity of half-perfected fruits, presenting little but a thick tough skin, and a core quite as large as usual. Some of these fruits possibly might keep longer than was ever known before; as they contained so little saccharine matter, there was scarcely anything within them to engender decay: hence a sort of withering or shrivelling-up instead of the usual spot and rot which consume the better class of fruits.

From the above it will be seen that warmth favours decay by forwarding the fruits and thereby hastening on the period of their existence; so in like manner cold encourages preservation by retarding the natural ripening of the fruit, and when it has approached that condition it tends to keep it from advancing further. But this unnatural state of things has its disadvantages. Fruits so treated are never good. Pears may be kept in an ice-house to a period much beyond that of their usual keeping time; but the flavour is gone. The same may be said of summer fruits, as Strawberries, Peaches, and the like, which have been so tried frequently. We may therefore learn from this that Nature cannot be so far outraged as is here shown with impunity. There exists a proper time for such fruits to be had in perfection, and to retard them much beyond it only produces an article much diminished in its most important qualities. From this we therefore learn that an ice-house is not a suitable place to preserve fruit intended for table, although it may become a very good medium to preserve some that it may be desirable to keep from motives of curiosity for as lengthened a period as possible. Some other conditions are also necessary to the well keeping of fruit, as will be shown.

Whenever a quantity of fruit is piled up in a heap, it begins what in common language is called “to sweat.” This sweating brings out an oily substance to the outside. Sweating will also occur without the fruit being so closely piled up as spoken of, but it is more slow; and if it be thinly on a shelf it is in its most legitimate way. This sweating coats the skin with a sort of varnish, which resists the action of the atmosphere, and certainly promotes the keeping qualities of the fruit. This varnish ought not to be removed by any means, handling being one of the certain ways to do so. Let the fruit, therefore, be placed at first singly on the shelves, and little else will be wanted but looking over them and picking out decayed ones; and the place being kept cool and well ventilated, there is a tolerable certainty of their keeping well, other things also being favourable.

As every one is agreed that perfect cleanliness and sweetness are indispensable requisites in a fruit-room, the situation ought to be so chosen as to insure these as far as external circumstances will do so, but a full southern exposure is not good. The best fruit-room I ever remember to have seen was at Knowsley, the princely seat of the Earl of Derby, the internal fittings being so good; broad shelves surrounded the building, and in the centre a tier of shelves with drawers in the bottom compartment, the whole affording ample space to get round, and the shelves not too crowded. I forget the means of ventilation, but believe it was ample. Some other useful fruit-rooms that I have seen are lean-to against the north wall of a garden, the great defect in these being the want of ventilation which, in part at least, ought to be at top, and is rarely thought of in a lean-to shed. The sides being low, the exhalation from fruit cannot well be all carried off them; it is better, therefore, to leave an opening at top to allow it to escape, otherwise the fact of being behind a wall is an advantage rather than otherwise, and more so if it be isolated, and not form part of a series of buildings, as by that means end ventilation could be more

easily accomplished. I have also seen a very useful fruit-room half underground; but this is only advisable on a dry, gravelly, or sandy soil. I have also seen one under the shade of a tree, not in a dense wood (which is bad), and it answered very well. The main thing to stipulate for is plenty of space and ventilation, and to use the latter on all occasions, except, perhaps, in damp, warm weather, and the probability is that fruit will keep as long as it is required to do. A Kentish farmer stores his Apples away in the oak kiln, than which nothing can be more airy; and although the large quantity they often have compels them to lay them thicker than they otherwise would, they often contrive to keep Nonpareil and Golden Knob Apples in a good condition till March, and French Crabs still longer. But enough has already been said on this subject.

J. ROBSON.

### CRYSTAL PALACE ROSE SHOW.

ANOTHER grand opportunity for proving that there is no place like home, all shows being more at home at the Crystal Palace than anywhere else. All judges and reporters say the same, and all the mothers of England with all their grown-up families ditto. And such Roses! but they were too high set by 10 inches or 12 inches for me and most like me in height. Whether it be that the authorities are getting higher in the world themselves, or of higher notions, I do not know; but this I do know, that I got a crack in my neck and a cold for having had to strain on a stretch of full four hours so far back off the centre of gravity as threw me off the balance for the next week, and, therefore, had more time at home to prepare the most useful report I ever made of Roses. But what ladies want, and, indeed, the great body of the people want, is a man like Mr. William Paul, the raiser of the Beauty of Waltham Rose, to take a season's selection, and class them as I have been endeavouring to do from merely seeing so many of them in one day, and to make two classes of my third class—that is, to bring in all the best rose-coloured Roses, as the Cabbage Rose, into one of them, and the red or reddish-crimson into the other. Then, if one had to plant ever so many kinds of Roses in long rows, or in beds of any shape, he could put the kinds in after what you might call their natural affinity—that is, shade the colours from pure white to the Black Prince himself, without one break in the affinity of tints, if they have such a property. Then you would get the effect in full of all the Rose can give.

Effect is the last thing thought of at a Rose show, because they muddle all the colours together in mixtures—“for the sake of variety,” as they say; but I never could see the variety yet in a florist-setting. The greatest truth about Roses on that occasion was that nine-tenths of all new Roses now are dark, or very dark; and as England is on the eve of breeding her own Roses, and some for exportation as well, it is high time to give up breeding from any darker than Général Jacqueminot. We have too many first-class dark Roses already, and too few of the Madame Furtado style and colour and of Baronne Prevost, the two nearest to the two oldest of our dear old Roses—the crimson Moss and the Cabbage Rose. Madame Furtado, with the accent on the u, or first syllable, is the very best of all the Roses in that old tint of colour; and if you could get it to seed here, and mind both sides of the line in the crossing—that is, the best light and white Roses to cross it with, and the best of the reds as well, you would soon have what the Frenchmen will never strive to furnish you with—all the shades of our summer Roses reproduced in Perpetuals, and of improved forms and textures to the bargain. To that it must come at last, or else we shall get into one circle of dark Roses from which it will not be easy by-and-by to extricate the breeder—a repetition, in fact, of the failure of fifty years back in running the gold, the silver, and the brass out of the wild breed of Geraniums, for then they were all Geraniums, compelling the breeder to run his course in a ring of bronze from which he cannot now help himself out. Just look at the number of my first and second groups of dark Roses from one show, and then say if all the shows were in one, and all the dark Roses in it, what a bulk they would make, and who could buy them; or if they did buy them, of what use could so many kinds be to most people. One could tell the best Rose of all those, or the best six, or best dozen, and one could divide them into three distinct shades also; but all that would be of no practical use, as I could only do it from what was before me, and not from practice in growing them. Madame Furtado, shaped like Baronne Prevost, and a much deeper red,

is a first-class Rose in this group; so is Charles Lawson, Madame Craplet, Jules Margottin, Pauline Lanzezeur, and many more of them. A lot of them on their own roots in half clay and half cocoa-nut refuse, with 2 inches of old cowdung put over the border in April, and then covered like one of Sir Joseph Paxton's Vines-borders with an inch or 2 inches of fresh cocoa-nut refuse, would give a fair representation of a bed of tree Peonies—say Baronne de Heckeren, Prince Imperial, La Fontaine, Madame Charles Craplet, Victor Verdier, Anna de Diesbach, Louise Peronny, Duchesse d'Orleans, and Gloire de Vitry, all of which were more or less rising into open centres just like Moutans in one or other of the collections. Another bed might be planted to represent Sally Brass in Roses; I mean such as Evêque de Nîmes, with hard rigid hearts and bare puckered faces, firm as brass itself—say Evêque de Nîmes, Agatoide, François Premier, General Simpson, Victor Trouillard, Madame Boll, and l'Etendard des Amateurs. Whether a liberal or shortcommons-fare would make these assume the same kind of face as Evêque de Nîmes I do not know; but they assume more or less of a family cast of countenance.

One of Triomphe d'Amiens, (in Mr. Keynes' collection of 96, was as striped and as mottled as a Picotee; one in Mr. Cant's collection was more minutely picotee; and Mr. Laing, of Twickenham, had a Général Jacqueminot striped and mottled differently from Triomphe d'Amiens. Mr. Cant must have made a good harvest of the Tea Rose, which was long lost, and for which we of the Floral Committee could not supply the proper name, so he named it himself, 'The Foundling, "l'Enfant Trouvé," and his lucky neighbour, J. T. Hedge, Esq., who swept the rosy race all round the course, did good justice to the darling restored. He had a large bunch of it with full-open, half-open, and not-open flowers, in his 36-kinds collection, and just opening in the 24-kind collection, and I would push the harvest home to all the mothers in England, alongside of the tea-caddy, for it is just as sweet, and it has the cream in itself. What more could they want, except, perhaps, to know that Mr. Cant has fish to his Tea Roses, and feeds the rest of his Rosés on sprats? One of the Judges told me so, and told me, also, that he, the said Judge, feeds his own Roses on star fish, and it is a hundred to one if Mr. Hedge does not give sprats, star fish, and sturgeon to his Roses, and that may be how he gets off with all the prizes; and if you had seen his Baronne Prevost, his Adam, his magnificent Lælin, his La Fontaine, his Charles Lawson, his Gloire de Dijon, and his Louise Darzins, the newest and the whitest of all the Perpetuals, the chances are that you, too, would put fish for Roses, and so would I—but I would mix them with four times their bulk of this cocoa stuff, fresh from the mill, and put in mulebing, to bring up the roots into a natural hotbed, moist as Melons, quite near to the surface. But never would I give a morsel of fish to a Rose stock, Dog or Manetti.

In front of that mass of Roses I would plant the following:—Madame Vidot and Mrs. Rivers, to see if they be different; also Mlle. Bonnaire and Mlle. Therese Appert, with William Griffith, and Queen of Denmark, and outside them none but pure whites, which I would select from the Noisettes and Teas for a change, and because the new whitest Perpetual, Louise Darzins, is too strong a grower for an outside row. That arrangement would throw the best, or, at least, my own selection of the very light Roses at that Show, into a bed or group by themselves, and, of course, it would include Madams Vidot, Mrs. Rivers, W. Griffith, Queen of Denmark, and Therese Appert. I object altogether to catalogue the word Mademoiselle at all in England, for two reasons—it is too long, and the nymph may have been given in marriage ere the Rose is ripe to show in England: therefore, I would say Therese Appert till I could call her Madame something.

Alphabetical list of the darkest Roses, or Class I. :—

- |                              |                                     |
|------------------------------|-------------------------------------|
| 1, Abd-el-Kader              | 18, Mrs. Dombrain (1862)            |
| 2, Arthur de Sansal          | 19, Oriflamme de St. Louis          |
| 3, Cardinal Patrizzi         | 20, Prairie de Terre Noire          |
| 4, Dr. Bretonneau            | 21, Prince de Noire                 |
| 5, Duc de Cazes              | 22, Prince de Moskowa               |
| 6, Empereur de Maroc         | 23, Princesse Mathilde              |
| 7, François Arago            | 24, Rebecca                         |
| 8, François Lonvat (1862)    | 25, Rosine Parron                   |
| 9, François Premier          | 26, Souvenir de Lady Cardley (1862) |
| 10, George Peabody (Bourbon) | 27, Triomphe des Beaux Arts         |
| 11, Gloire de Santenay       | 28, Triomphe de Lyon                |
| 12, Jean Bart                | 29, Triomphe de Paris               |
| 13, Leonie Moise             | 30, Victor Emmanuel                 |
| 14, Louis XIV.               | 31, Victor Trouillard               |
| 15, Lord Clyde (1862)        | 32, Victor Verdier                  |
| 16, Lord Raglan              | 33, Wilhelm Pfützer                 |
| 17, Marie Portemer           |                                     |

Oriflamme de St. Louis is the connecting link between the darkest and next dark Roses, being a shade deeper than Général Jacqueminot; but, after all that had been expected of it, the Général is much the better of the two. The four Roses of 1862 in this class are the best four of this season in that shade, looking at them like a gardener, and this is how they stood alphabetically:—François Lonvat, Mr. Garnston, which is one of the very best of all his novelties; Lord Clyde, Paul & Son, their own seedling, the best of the very dark Roses yet raised in England; Mrs. Dombrain, from Mr. Standish, a fine, foreign, dark-ahed purple Rose; and Souvenir de Lady Cardley, from Mr. Mitchell, which is seemingly a very good dark Rose, with a shade of purple in it as in Mrs. Dombrain. Wilhelm Pfützer is in the way of the Gallic Rose Oh! No. 2. Prairie de Terre Noire was the darkest of all this lot; and Rosine Parron, Abd-el-Kader, and Oriflamme de St. Louis were the lightest of them, and some of them were quite different from the catalogue description. When the same name appears in two lists it shows how the tint varies with age.

The next darkest Roses begin with Général Jacqueminot, Senateur Vaisse, Gloire de Santenay, and Beauty of Waltham, all of them first-rate, but for reference they are placed in alphabetical order :—

- |                             |                                     |
|-----------------------------|-------------------------------------|
| 1, Abd-el-Kader             | 12, Madame Boutin (1862), very good |
| 2, Baronne Hallez           | 13, Madame Masson                   |
| 3, Beauty of Waltham (1862) | 14, Madame Pierson (fine)           |
| 4, Dr. Berthet (Bourbon)    | 15, Maréchal Vaillant (1862), fine  |
| 5, Eugène Appert            | 16, Ornement des Jardica            |
| 6, François Arago           | 17, Paul Ricaut                     |
| 7, Francis I.               | 18, Rosine Parron                   |
| 8, Général Jacqueminot      | 19, Senateur Vaisse                 |
| 9, Gloire de France         | 20, Souvenir de Leveson Gower       |
| 10, Gloire de Santenay      | 21, Triomphe de l'Exposition        |
| 11, Louis XIV.              |                                     |

The championship of these lies between Senateur Vaisse and Gloire de Santenay, two of the very best Roses we have.

The third class consists of 40 of the best of the light crimson, red, and rose coloured, running into various shades, but all of them, or any number of them, might be planted in front of any of the dark Roses as above.

- |   |   |
|---|---|
| 1, Agatoide, fine                           | 21, La Fontaine   |
| 2, Alexandrine Bachmeteff                   | 22, La Reine  |
| 3, Alphonse Karr                            | 23, La Ville de St. Denis                                   |
| 4, Anna Alexieff                            | 24, Lælia   |
| 5, Anna de Diesbach                         | 25, L'Etendard des Amateurs, like a crimson Evêque de Nîmes |
| 6, Armide                                   | 26, Lord Nelson   |
| 7, Baronne de Heckeren, red Peony-like      | 27, Madame Boll, very large                                 |
| 8, Baronne Gonella                          | 28, Madame Craplet, fine                                    |
| 9, Belle de Bourg-la-Reine                  | 29, Madame Domage   |
| 10, Charles Lawson                          | 30, Madame Furiado  |
| 11, Colonel de Rougemont                    | 31, Madame Hector Jacquin                                   |
| 12, Duc d'Osuna, a deep red Baronne Prevost | 32, Madame l'Aniline Villot                                 |
| 13, Duchess of Sutherland                   | 33, Mathurin Regnier  |
| 14, Duke of Cambridge                       | 34, Pauline Lanzezeur                                       |
| 15, Evêque de Nîmes                         | 35, Prince Imperial, like a Cabbage Rose and a rosy Peony   |
| 16, François Premier                        | 36, Prince Léon   |
| 17, General Brea                            | 37, Reine de la C <sup>te</sup> , fine                      |
| 18, General Castellane                      | 38, Reine des Fleurs  |
| 19, General Simpson                         | 39, Triomphe d'Alençon                                      |
| 20, Jules Margottin                         | 40, Victor Trouillard                                       |

Very light and blush Roses.

- |                                    |                                  |
|------------------------------------|----------------------------------|
| Auguste Miç                        | Mesdames Boll, Vidot, and Rivers |
| Armide                             | Madame Vigneron                  |
| Caroline de Sansal                 | Mathurin Regnier and Malmaison   |
| Comtesse de Chabrillat             | Rose                             |
| Duchess of Orleans                 | Queen Victoria                   |
| Eugénie Verdier (Mdlle.)           | Therese Appert                   |
| Général Pôissier                   | Virginal                         |
| Gloire de Vitry, was lavender tint | William Griffith                 |

Here will be seen how changeable some Roses are, as Madame Boll, Armide, and two or three more in these lists. Among the light Tea Roses the best were Madame Halphin, Madame Damaizin, Madam Williams, Barbot, Gloire de Bordeaux, and d'un Ami. There was but one example of Cloth of Gold, but Gloire de Dijon was all over the place, and there were several Céline Forestiers. Madame Falcot was of the Elise Sauvage tint of yellow, and both were very fine there; also, Nareissa, a fine yellow; Souvenir d'Elise Varden, a very large beautiful blush Tea; Archimede, fine salmon tint; Gloire de Bordeaux will turn out a very fine deep blush Tea; Niphotos and Sombreuil were the two whitest Teas; Lamarque and Madam Hardy being still the best white Roses at shows; and Triomphe de Rennes seems, after all, to be the most certain yellow among Noisettes, and the favorite after Gloire de Dijon from among the Teas.

Were it not that nine hundred and ninety-nine ladies out of

every thousand of them would place and plan, shade and plant, all Roses on this model, we should have a rebellion among the florists, who are the best hands under the sun at producing the least colour-effect by the arrangement of the flowers they take in hand, for thus assorting them in order to be of some use to those who do not use catalogues, or those, in fact, who know very little about Roses. Lists of any kinds of plants without the colours are of no more use, to most men, than a list of the parishioners farthest off from their own.

D. BEATON.

THIS, the third and last great Rose Show of the season, was held under very favourable auspices on Saturday the 5th inst.; when the very liberal schedule of prizes was sufficient to bring together not only the great growers for sale, but also a large number of the most distinguished amateurs. The Roses, generally speaking, display themselves in excellent character, giving to an eager crowd of admirers an excellent opportunity of making notes, selecting new varieties, and seeing whether their own cultivation needed not some improvement. Eleven or twelve counties were represented, distant Hereford and Somerset competing successfully with Hertford and Middlesex; and assuredly Hertford must look to its laurels. It has so long been the home of the Rose, so long considered the only place where the queen of flowers could be done in perfection, that it had almost come to be a universally admitted fact that no other soil in any other county could compete with it. But the past few years have dispelled the illusion.

Amongst Amateurs the most successful exhibitor has unquestionably been Mr. Hedge, of Reed Hall, Colchester. Both here and at the Royal Horticultural Society's at Kensington he has taken almost every first prize in the classes in which he exhibited; while the same may be almost said of Mr. B. R. Cant in the Nurserymen's Class. Nor is this the mere effort of one season—at all times both of these growers hold a distinguished place. The Sussex growers are coming out in force, too. Let our Hertfordshire friends remember this, and see if they cannot do something for the honour of the old flag. We never like to see the glory of a house departing, nor sit with the complacency which some profess while others step in to take the place of old occupied by others. Besides, it will stimulate emulation, and where this is the case all benefit. But of these things I hope to speak more at length when I do (as I hope to), give a review of the Rose season. My present object is the Crystal Palace Rose Show. In all that pertains to the decorative portion of the subject, there will doubtless be abundance of useful and entertaining information from Mr. Beaton, while I speak more of the florists' view of the subject.

New Roses were not to my mind so good as either at Kensington or Birmingham, and were contributed by Messrs. Cant, Paul & Son, Cranston, and Mitchell; while Mr. Standish sent a few not for competition. The fact of his new Roses having remained five weeks in some railway office in Paris will sufficiently account for his not being in the way of doing anything amongst them this season.

Mr. Cant had Madame Boll, Belle de Bourg-la-Reine, both good Roses; Vainqueur de Solferino, confused; Montebello; Marquise de Foucault, a pretty Tea; Triomphe de Lyon; Rubens; Victor Verdier; Sénateur Vaisse; Princesse Mathilde; Madame Pierson, pretty; La Boule d'Or, good yellow; Reine des Violettes, I said when this first came out that it was rubbish, and I am not inclined to alter the word, strong though it be; John Waterer; America; Admiral Nelson; Louis XIV., a well-built flower; Madame Furtado, a first-rate Rose; Duc de Cazes, somewhat dull; Madame Charles Crapelet, very bright and good—I have before me a sweet bloom from my own garden; Robert de Brie, one of the Reine des Violettes stamp, and equally undesirable; Catherine Guillot, an exquisite beauty; Clement Marot, good; Comtesse de Kergolay; Jean Bart, showy; General Zachersgersky; Abd-el-Kader, bright and good; Madam Standish, too thin; Olympe Freanay; Adelside Fontaine; Triomphe d'Amiens, beautifully splashed, as indeed it was in several stands.

In Messrs. Paul & Son's were Robert de Brie, Madam Charles Wood (a good and large flower), Madame Boll, Jean Bart, Clement Marot, Burke, Eugène Appert, President, Gloire de Santenay (very fine), Madame Charles Crapelet, Amiral Gravina, Parmentier, l'Elegante (rather disappointed in this this season, but I would try it another year before discarding it), Catherine Guillot, Lord Clyde (a promising Rose), Agatoïde (bright), Souvenir de Comte Cavour (dark, and I think will be good),

Buffon, Comtesse de Kergolay, Alexandrine de Belfroy, Victoire de Magenta, Prairie de Terre Noire, Madame Furtado, Mademoiselle Bonnaire, Mademoiselle Julie Daran (midding), Belle de Bourg-la-Reine, Louise Darzins (a pretty white), Sénateur Vaisse, Leonie Moise, Madame Charles Crapelet, Mademoiselle Eugénie Verdier, Louis XIV., Le Royal Epoux, and Mademoiselle Pauline Villot.

Mr. Standish had Vulcain, very dark, but dull to our English taste. Verdier told me it was a seedling from Général Jacqueminot, but it lacks the brightness of its parents; Comte de Falloux, bright and good; Souvenir de Comte Cavour; Mrs. Dombraïn—what can I say but that

"She's all my fancy painted her,  
She's lovely, she's divine?"

but, seriously, a pretty-looking, well-shaped flower; J. F. Lombard, a very large, stiff-petalled, crimson rose; John Standish, dark purple; Gregoire Bourdillon, like Géant des Batailles; Reynolds Hole, bright and lively pink; André Leroy, a very fine-looking, deep crimson, shaded rose; Marguerite Appert, light flesh colour; André Desportes, a well-shaped full flower. I have an exquisite bloom before me now, a bright purplish-crimson; and La Boule d'Or.

Mr. Cranston had a goodly number of the Roses of 1861. Robert Fortune, promises well; François Lacharme, (Verdier's), very good; Richesse des Couleurs (Touvais), cannot say much for its richness at present; Notre Dame des Fourvrières, will not do for our taste; Olivier Delhomme, very good; Souvenir de Monsieur Rousseau; Maurice Bernardin (Granger), a fine rose; Vicomte Vigier (Verdier), violet purple; Monsieur Joigneux; Buffon; La Brillante (Verdier), bright and clear; John Waterer; Souvenir de Lady Cardley; Duc de Rohan; François Louvat (Touvais); Maréchal Vaillant, good; Louise Darzins; Leonie Moise; Triomphe d'Amiens; Modèle de Perfection; Charles Lefevre; Duc d'Alençon; Madame Furtado; and Madame Melanie.

In the Class of 96 trusses, singles, a great improvement on the huddled-up trebles, Mr. Cant held an undoubted first with Evêque de Nîmes, Madame Knorr, Pauline Lanzeur, Odeur Vital, Louis XIV., La Ville de St. Denis, General Simpson, Duchess of Sutherland, Victor Trouillard, Mademoiselle Bonnaire, Parmentier, Rubens, Triomphe de Paris, Madame Masson, Madame Halphin, Lord Raglan, Anna Alexieff, Princesse Mathilde, l'Etendard des Amateurs, Adam, William Griffiths, Madame Boll, Baronne Hallez, Clement Marot, Baron Gonella, Cloth of Gold, Gloire de Vitry, Victor Verdier, Madame Damazin, George Peabody, Souvenir de la Malmaison, François Lacharme, Mrs. Rivers, Eugène Appert, Général Castellane, La Reine, Seedling Admiral Nelson, Madame Furtado, Sénateur Vaisse, Comtesse Cécile de Chabillant, Empereur de Maroc, Madame Hector Jacquin, Comte de Paris, Julia Margottin, Madame Willermoz, Souvenir de Leveson Gower, Madame Vidot, Général Jacqueminot, Prince Léon, Vainqueur de Solferino, General Forey, Mathurin Regnier, Duchess of Norfolk, Elise Sauvage, Anna de Diesbach, Triomphe des Bagatelles, Mademoiselle Eugénie Verdier, Colonel de Rougemont, Charles Lawson, Duke of Cambridge, Madame Falcot, Victor Emmanuel, Buffon, Comtesse de la Bathe, Louise Peronny, Prince Regent, Lælia, Darzins, Comtesse de Kergolay, Comte de Nanteuil, Bougère, Belle de Bourg-la-Reine, Goubault, Madame Pierson, Mademoiselle Pauline Villot, Céline Forestier, Madame de Cambacères, Madame Standish, Paul Ricaut, Vicomtesse de Cazes, and Amelia Lemaire (Gallica).

In 48's Mr. Cant was also first. His stand contained Comtesse Cécile de Chabillant, Eugène Appert, Triomphe d'Amiens, Madame Knorr, Louis XIV., Admiral Nelson, Mathurin Regnier, Rubens, Sénateur Vaisse, Devoniensis, Victor Verdier, Gloire de Dijon, Etendard des Amateurs, Madame Furtado, Madame Boll, Comtesse de la Bathe, Lord Raglan, Pauline Lanzeur, Victor Trouillard, Madame Tredeaux, Auguste Mié, Empereur de Maroc, Caroline de Saneal, Souvenir d'un Ami, Anna de Diesbach, Vicomtesse de Cazes, Baron Gonella, Madame Willermoz, Souvenir de Leveson Gower, Madam Rivers, Duke of Cambridge, Louise Peronny, Général Jacqueminot, Regent, Triomphe de Paris, Madame Vidot, Evêque de Nîmes, and General Castellane.

In the Class of 24 singles, Mr. Charles Turner, of the Royal Nurseries, Slough, exhibited an admirable box, containing Comtesse Cécile de Chabillant, Mrs. Rivers, Louis XIV., Duc d'Orléans, Niphotos, Louise Peronny, Sénateur Vaisse, Madame de Cambacères, François Arago, Victor Verdier, Baronne Prevost,

Madame Hector Jacquin, Lord Raglan, Madame Charles Craplet, La Reine, Madame Boll, Général Jacqueminot, Jules Margottin, Boule de Nanteuil, Souvenir de la Malmaison, Gloire de Dijon, Anna Alexieff, and Madame Furtado.

And here my note-taking came to an untimely end. The barriers were removed at twelve o'clock, and an eager crowd of Rose admirers and growers rushed in. For a while I stood my ground; but it was not a pleasant thing to hear, "Well, it certainly adds to the effect very much to have two or three people standing between you and the flowers, don't you think so?" "Oh, I suppose he is one of the bigwigs, who is not restrained by any rules of politeness." I therefore bent a timely retreat; and as I had to leave before M. Blondin's performances commenced, when the stages were comparatively clear, could not obtain any of the names in the Amateurs' Class; but I have little doubt they were very much the same flowers that the growers for sale exhibited, Mr. Hedge holding the first place.

As there was a large attendance I hope the liberality of the managers was rewarded. Of the excellent character of the arrangements it is impossible to speak too highly; and when I add that Mr. Houghton's usual kindness, activity, and politeness were put in requisition to make all concerned comfortable, it would be needless to add that everything went off smoothly, and that the character of this annual gathering was fully maintained.—D., Deal.

## CULTURE OF THE PEACH AND NECTARINE.

(Continued from page 250.)

*Soil (continued).*—These trees require, in order to produce healthy, fruitful, and long-lived specimens, a strong pure loamy soil of an adhesive character, such as an upland good pasture would furnish. Take it off in turves about 3 inches thick, and cart it home near to the garden. Lay it in a long heap, and when sufficient is procured commence at one end to chop it into small pieces, and whilst that is going on mix it thoroughly with some old lime rubbish, unless you are so fortunately situated as to obtain the turf from a pasture on a limestone basis, then the lime rubbish will not be needed. Whilst the chopping and mixing process is going on procure some thinner turves, and with them cover the drainage grass side downwards. This will prevent the finer particles of the soil from falling into and choking up the drainage. When that is done lay some boards or planks, and wheel in the soil to one end, forming the border with a very gentle slope to rather more than the full height to allow for settling. From 18 inches to 2 feet will be ample depth. If the garden is situated on a level country, I would advise the border to be raised a foot higher than the general level; but if the garden is on a gentle eminence, as recommended in my last paper, then it may be nearly level with the rest of the garden.

It will be observed that I make no mention of dung as a component part of the soil. It is a great mistake to put any manure of any kind in a Peach-border. It is injurious to the trees in many ways, the worst being in inducing young trees to make what gardeners call water-shoots, or, as the French term them, gourmands or gluttons. Such shoots not only rob the rest of their due nutriment, but, also, they seldom in our climate get duly ripened, and then become diseased, ulcerated, and gummy. If, however, in process of time the border become exhausted, then it will be proper in the autumn to lay on the surface a mulching of rotten dung. The autumn and winter rains will wash down the soluble enriching qualities of the dung sufficiently, so as to give fresh food to the trees.

As to the time of making the border, I would advise the end of July and through August. The weather then is generally dry, and the soil is, of course, dry also. By doing it thus early the grass plants will perish all but those on the surface, and they may be killed also by digging the border over two or three times before the winter sets in.

*Varieties of Soil.*—The only successful adaptation of a different kind of soil to the above that ever came under my notice occurred in the gardens at Wheatley Hall, near Doncaster, the seat of Sir W. B. Cooke, Bart., where I spent part of my apprenticeship. The natural soil there is of a light sandy nature, which, though excellent with plenty of manure for vegetable crops, was found not to be favourable for Peach culture. The river Don runs through the estate and deposits a close, compact sediment. This is called "warp soil." A sufficient quantity of this warp was collected, laid in heaps, and when in a proper mellow

condition the Peach-borders were made of it without any other ingredient. The then gardener was a Mr. B. Mann. He had been chief there for a quarter of a century, and used this warp soil with the best effect. The trees grew well in it, producing just the right kind of healthy wood, and bore excellent fruit annually. It is true the walls were flued, and we used canvass screens to protect the blossom from late spring frosts, and in wet summers the fires were lighted to heat the walls and ripen the wood; but these protective measures had been adopted before when the natural soil formed the borders and were not found effectual to keep the trees in health. Whoever, then, has such a soil conveniently placed near to his garden, may make his borders of it without any fear of failure.

*Choice of Plants.*—This is an important part of the business. When time of coming into bearing is not thought of much account, then maiden plants—that is, trees a year old might be preferred, the cultivator then has the mode of training from the beginning under his own care; but I certainly would prefer trees that have been trained in the nursery three years. I should, however, take the precaution of visiting the nursery early in the autumn and choosing the best-trained and most healthy trees, then and there putting a mark upon them. This plan is the best and most satisfactory both to the buyer and seller. Then as soon as the leaves fall the trees should be carefully taken up, the roots packed in moist moss, and the trees so packed as to travel safely to their destination. Thus packed both at the root and the top, they would in these railroad days come to hand in good condition. Directly they arrive, let them be carefully unpacked and planted as soon as possible. If the roots should have become dry, I would dip them in water thickened with fine soil. The question now arises, At what distance should they be planted from each other against the wall? Some writers say 15 feet, and some as much as 24 feet. These are, however, extremes, the first being too close and the other too wide apart. The medium is the best. Eighteen feet is the distance I recommend. The best trees I know in existence now are at that distance. If, however, the walls are low—that is, only 9 feet or less high, then the trees may be planted nearer to each other, as the angles of the shoots will bring them soon to the top of such a wall; but if 12 feet high, then my 18 feet will be a fair equable distance. As it will take several years before the trees will meet, standard-trained trees might be planted between those that are finally to cover the wall; but the cultivator must have the nerve to remove those riders, as they are termed, the very year the permanent trees require the space.

*Planting.*—In doing this let the roots be spread out equally every way, and not covered too deep—2 inches or 3 inches are enough. By spreading them out horizontally the roots will continue to, at least, have a tendency in that direction—a point to be desired, for then the roots are within the reach of the heat of the sun just at the time the shoots need all the help the roots can give them. In most Peach-borders, for the convenience of attending to the trees, there is a narrow path formed some 2 feet from the wall. That path should be made of a trellis of wood, so that the soil may not be too much compressed. If the path is soil only, the constant treading upon it must be injurious to the roots. Let every cultivator, then, set his face against such a path unless it is trellised.

The planting being finished, the shoots should be securely fastened to the wall to prevent them being blown about with the wind, which otherwise would in heavy gales rub the branches against the bricks and bruise the bark, which might bring on in such places wounds that would canker and exude gum, a casualty always to be avoided. After that is completed, then lay a mulching of littersy dung, extending a foot or so beyond the extremity of the roots. This will protect the roots from the frost and will keep them in action all through the winter. It is remarkable what a large number of rootlets will strike out immediately after the trees are planted. It would seem as if Nature was putting forth every effort to recover lost time in root-action in consequence of the removal, and the more these efforts are protected and encouraged, the greater chance there is of the trees pushing vigorously in the following spring: hence the utility of protecting these young fresh roots, by mulching, from the winter's frost.

*Pruning, the First Season.*—It is a common practice to cut back almost close to the stock, not only maiden trees but even such as have been trained at the nurseries, for one, two, or three years. This, it is alleged, is done in order to get the centre of the tree well filled with leading shoots to form the future tree. This is an undoubted mistake. There is no necessity for it unless

the trees are very weak indeed. Maiden plants must of necessity be cut down to four or five buds to obtain as many branches to form a tree for a wall, and nurserymen, perhaps, are compelled for want of a wall to cut back older trees; but when a three-year-old tree is planted against a wall as a permanent tree, it is a barbarism to cut it down so severely the first year after planting. As, however, the pruning has necessarily a connection with the future training of the tree, and that part of my subject is too important to be thrust in at the tail-end of a paper, I must defer it to another opportunity.

T. APPEBY.

(To be continued.)

### ORCHARD-HOUSE FOR VINES IN POTS.

I ASK your advice relative to erecting an orchard-house-like structure (span-roof), with the chief purpose of fruiting Vines in pots. As I have an orchard-house besides, which gets rather filled up, I wish to combine both Vine and orchard culture in the intended house, and have in mind the following arrangement.

A wooden span-roof house (no stove-forcing is intended)—say 18 feet wide, 10 feet to 12 feet high, sides 5 feet, the shutters to be glass instead of wood; one centre bed of about 5½ feet for Peaches, late Pears, &c., a footpath round it about 3 feet, and border all round—say 3 feet. On the latter the Vines are to be put, trained up the glass at about 3 feet to 4 feet distance, the remaining place to be occupied by Strawberries in pots; the length of the house to be about 30 feet; in that way eight to ten Vines to be on each side.

The principal questions now are:—Must the position of the house be N.E. to S.W. as generally for orchard-houses? So my first house is situated, but having grown one summer some climbers on the rafters, I found the house losing too much sun and warmth. This might be made up for, perhaps, by giving the roof more elevation—say 45°, instead of the usual 35° for orchard-houses. Now, in case this alteration may be advisable, will not the fruit trees in the centre bed then be too far off the glass, and have too little light and sun, and what is of chief importance, will they do well in the somewhat higher and less ventilated temperature which is required for Vines?

Our summer (at Hamburgh) is very like the English summer; we enjoy, perhaps, a little more sun, but the contrast of temperature, cold and warm, is greater.

As a German, I may be excused for not having expressed myself perhaps altogether in good English.—AMATEUR OF FRUIT-CULTURE.

[With the arrangement of the house as to form we have no fault to find. It matters but little the mere height of the ridge, so as to present a wider plane to the light. We have tried the matter often, and we think the old dogmas about placing the plants near the glass is, to a great extent, a fallacy, in all these nearly-all-glass orchard-houses. What we consider of far more importance is, that nothing shall interpose between the plants and the glass. We might make an exception in the case of such low plants as early Strawberries in pots. We should like them to be as near the glass, and under such a roof that the sun would strike them in as direct lines as possible, about the time when coming into bloom, and when in bloom. Farther on in the season, in a fine open house, with nothing to obstruct the full blaze of light, we have found them do remarkably well when set or planted on the floor, with the glass 6 feet or more from them; in fact, they did just as well as those in a frame or pit, with the glass a foot from them.]

I should have expected no such result if the roof had been covered with creepers or Vines, allowing a peephole just here or there. Strawberries, swelled and ripened in such circumstances, after they have been set in a more suitable open place, can seldom lay much claim to flavour or compactness, and those who eat them often complain, though they will do nothing to avert or mitigate the cause. I have known many instances of gardeners having their Vines so much thinner on the roof, because though they were wanted and more than could be got, the under-crops of Beans and Strawberries were wanted as well, and a sacrifice must be made somewhere to get the greatest amount of desirables out of one place.

We have before us a proposition from a gentleman about building a house the same size as our correspondent's, with a similar pit in the centre, only he proposes planting Vines on each side, 3 feet apart, to go over the roof; and so sanguine is

he that, besides these Vines, he seems to feast already on luscious Figs, Cherries, Peaches, Apricots, and Pears grown in that central pit. I know I shall go against the grain in stating it cannot be *continuously* done, if the plants are intended to ripen their wood as well as their fruit in such a pit. I use the word *continuously* advisedly. I know he saw a similar house, with vigorous Vines, Figs, and Peaches, &c., in the pit and bearing well; but, in that case, the Peaches and Figs had previously well-ripened wood. The Peaches were in bloom, and set before there was much shade from the Vines, and they swelled well, though we would have considered them to be deficient in flavour.

Advice was pretended to be asked, and it was to move the plants of Peaches, &c., to get more light in the autumn. But the highest authorities were cited that Figs, &c., did admirably in a little shade, and the first success was so tempting that the plants in pots were turned out into the beds, with the result of a few fruit the second season whilst the Vines were young, and the result since—plenty of nice wood on Peaches and Figs, but no fruit; for though there are flower-buds on the Peaches they all drop, and, if closely examined, there is not an embryo fruit in one of them. The proprietor has not yet come the length of saying, "You are right;" but in the few times I have seen the houses he has directed my eyes to the rafters, and kept me so engaged that I could only get a peep in passing at the plants in the beds, with plenty of nice wood on them, only, unfortunately, we cannot eat the wood. Had these Vines, which did well, been 6 feet apart and spurred, there would have been a chance for the crop in the pit. About 3 feet apart and established, there was no chance whatever, farther than setting the bloom securely, if the buds were right, or swelling the fruit after being set; the shade prevented, and will prevent the wood for the following year being finished, or ripened. Consulted as we are, as these pages testify, by many amateurs, who imagine that every foot under glass wherever it may be ought to be remunerative, we would just simply say that, when you expect the best fruit and good crops of it, you must have unobstructed sunlight. If at certain seasons such plants as Cherries, when in bloom, need a little shade under glass, they must have little or none to insure fruitful buds.

Our correspondent from Hamburgh does not contemplate, we believe, any such extra shading. Nevertheless, there is an incipency of the same evil. The sun there is brighter and less cloudy than with us, but still shade is shade. We make little account of the extra cold in winter. That is of less consequence if the wood is consolidated by a more powerful sun in summer. Many of our greenhouse plants in their native homes in Australia are exposed to frost that would kill them in our conservatories, because from our humid and cloudy climate the wood is left more spongy and juicy than in their native country. Our correspondent with his Vines 3 feet apart, and using no artificial heat, will succeed just in proportion to the short space these Vines are allowed to mount the roof. Many things, also, are to be considered as to what the plants require when in bloom, &c. On the whole, then, what we have said will be a certain sort of guide to our correspondent, from whom we should be glad to hear again.

In the first place we should like to know how he proposes to have a succession of these Vines in pots without artificial heat, because if he bears them heavily one year, the plants will be of little use the next. And, in the second place, some of the plants he mentions for the beds will not stand the same high temperature as would suit the Vines. We have only had a quarter of an hour to read and re-read and think over his letter; but the result of that is the conviction that he would act wisely if in his thirty-foot house he would have a division in it, and appropriate one part wholly to Vines, bed as well as sides, and the other part to his Cherries, Plums, Peaches, Pears, &c. A little changing of the plants would then be of importance, as to the ripening of the fruit, the giving of it flavour, and the ripening of the wood.

A correspondent to-day speaks of trying Vines on the vineyard style. At Hamburgh, with Vines planted out at the two fronts, Vines being also planted out in the middle bed, and treated on the short-cane or the bush system, we believe that our correspondent would obtain a greater amount of Grapes year after year, and with less trouble than by any other mode except making his house into a regular vinery, by covering the roof in the usual way, and using under-growths merely as an accession, not much to be depended on. We should be glad at least to hear the exceptions to such a plan.—R. FISH.]

ARRANGEMENT OF VINES.

I INTEND erecting houses, about 63 feet run of small span-roof, after Mr. Rivers' plan, having, however, plenty of ventilation, divided by divisions into three of about 21 feet each, running nearly north and south, trifle north-east and south-west; how would you divide the Vines, of which I enclose the list, to furnish these? Would the following do?

For early, say ripe in May:—First, Black Hamburgh, 9; Bowood Muscat, 3.

For July and August:—Second, Muscat of Alexandria, 4 or 5; Trebbiano, 2; Black Hamburgh, 1; Tokay, 1; Bowood Muscat, 2; Muscat Hamburgh, 1; or more Alexandria and omit some others altogether.

For the third or late, without much heat:—Lady Downe's, 4; West's St. Peter's, 4; Black Hamburgh.

I am willing to omit any sort or increase or decrease the numbers of any. Would growing the Vines up one side of the span and down the other side, thus giving 16 feet of rod, be a good plan? Will the down-growing top do as well.—A YOUNG HAND.

[We approve of your arrangement for first and second houses; but what do you call Tokay in the latter? For the third, along with Lady Downe's and West's St. Peter's, we would substitute Muscat of Alexandria for Black Hamburgh, and place the Muscats at the hottest end. They will generally hang much longer than Hamburghs, and if kept back so as to be in bloom when the sun is high, will set well without much heat.

The training down the opposite rafter is a mere matter of choice, and there is no doubt of its answering; but, either you must plant all that thinner, or if the Vines are opposite each other, you must keep the stem on one side clear, to be covered by the bearing part of the Vine opposite. If you resolve to confine the Vines to 8 feet run each, the roots had better be under control, as to depth and width. There is no doubt that the cane, or rod, or bush-form vineyard-fashion would answer equally well, but it would cost more trouble and care, and you would not see the bunches hanging overhead.]

REPORT ON THE VARIETIES OF KALE, OR BORECOLE,

GROWN IN THE GARDEN AT CHISWICK DURING THE SEASON OF 1861-62. By ROBERT HOGG, LL.D., F.L.S., Secretary to the Fruit Committee.

ASPARAGOUS KALE.

It does not appear to be clearly understood to what kind of Winter Green the name of Asparagus Kale properly belongs. The name is evidently derived from the spring shoots of some of the sorts being cut into lengths and cooked like Asparagus, to which they bear some resemblance when treated in that way. The two sorts to which this name has been applied are the Braganza Cabbage (*Couve tronchuda*) and the Egyptian Kale. Both of these throw out in the spring a great quantity of long thick succulent shoots, which, when cooked like Asparagus, are no mean substitute for that vegetable. To which of these the name of Asparagus Kale belongs is quite a matter of opinion, and no disappointment need be experienced should the one at any time be substituted for the other. One advantage, however, which the Egyptian Kale has over the Braganza Cabbage is, its greater hardness, which is so great as to withstand the frost of our ordinary severe winters; whereas the Braganza Cabbage always more or less suffers unless the winters are mild.

BUDA KALE . . . . . COOPER & BOLTON.

The plant produces a stout stem, 18 inches to 2 feet high, clothed with leaves, and in the spring it throws out a leading shoot, and numerous side shoots from the ground upwards, which are not more than 6 inches long. The leaves are almost plain, and bluntly toothed. The plant is very hardy, and though somewhat similar in the general appearance of the foliage to Egyptian Kale, it is much taller and not nearly so productive.

CESAREAN KALE . . . . . COOPER & BOLTON.

*Chou Cavalier* . . . . . VILMORIN & Co.

This is the Cow Cabbage, or Tree Cabbage, as it is sometimes called. The plant is 4 feet high, clothed with long, broad, glaucous green leaves, having long footstalks. In spring it throws out a great many long slender shoots of a very coarse description. It is very hardy, but quite unfit for use as a garden vegetable, being more adapted for cattle.

CHOU BRANCHU DE POITOU . . . . . VILMORIN & Co.

There does not appear to be a great difference between this

and the Cow Cabbage. It may not be quite so tall, and not so robust in its growth, but in every other respect there is no difference.

CHOU CAULET DE FLANDRES . . . . . VILMORIN & Co.

The habit of growth and general appearance of the variety is exactly the same as in the *Cesarean*, or Cow, Cabbage, except that the whole plant has a purple tinge. It is, in fact, a purple form of the Cow Cabbage. The stalks, midribs, and veins of the leaves are tinged with purple; and in the spring it throws out long purple shoots, 1½ foot in length; but the produce is small, and the sort, though hardy, is not worth growing, being a tall, ngly, coarse-growing plant.

CHOU FAUCHER . . . . . VILMORIN & Co.

This very closely resembles the Buda Kale, and is of a paler green and dwarfier. It has a very short thick stem, about 6 inches high, and throws out long shoots from its whole surface close to the ground. The shoots are more slender than those of Egyptian and Buda Kales. It is very hardy.

CHOU FRISÉ DE NAPLES . . . . . VILMORIN & Co.

The distinguishing character of this variety is its swollen stalk, which resembles that of Kohl Rabi; the leaves are curled, but not like the leaves of Curled Kale. They resemble more those of the Curled Mallow, the disk being flat, and the edges plaited and serrated.

CHOU LANNILIS . . . . . VILMORIN & Co.

This does not differ materially from *Chou Moellier*. It grows to the same height, produces the same foliage, and differs merely in not having so weak and fleshy a stem.

CHOU MOELLIER . . . . . VILMORIN & Co.

This is a form of the Cow Cabbage, which produces a thickly swollen stem, thick in the middle and small at both ends. It grows 4 feet to 4½ feet high, and the stem in the thickest part is about a foot in circumference in the largest specimens. The inside of this thick stem is filled with succulent pith, which is supposed to be the part fit for use. When cooked, however, it was discovered to be strong and coarsely flavoured.

CHOU VERT GLACÉ D'AMERIQUE . . . . . VILMORIN & Co.

This appears to be intermediate between a Cabbage and a Borecole. It has a stem from 9 inches to a foot high, terminated by a very loose flat head, which very soon runs to seed. The whole plant is of a pale, sickly, yellowish-green colour, and entirely without any glaucescence or "bloom" upon the foliage. It is very tender, and quite worthless as a winter green.

CHOU VIVACE DE DAUBENTON . . . . . VILMORIN & Co.

This is merely a dwarfier form of *Chou branchu de Poitou*, from which it may also be distinguished by its spreading lower shoots, which incline towards the ground, where they sometimes take root. It is a coarse and inferior sort, and not fit for garden culture.

COTTAGER'S KALE . . . . . TURNER.

*Selected Cottager's Kale* . . . . . SCOTT.

The stem is about 2 feet high; the plants are partly green, and partly purple, some with plain leaves and some with curled, while others formed buds on the stem, like a spurious stock of Brussels Sprouts. In spring, the plants throw out a great mass of shoots, and yield a large crop of greens.

(To be continued.)

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

RHODODENDRON DALHOUSIE HYBRIDUM (*Lady Dalhousie's Hybrid Rhododendron*).—*Nat. ord.*, Ericacæe. *Linna.*, Decandria Monogynia.—A cross-bred between *R. formosum* and *R. Dalhousie*, raised by J. Anderson Henry, Esq., Hay Lodge, Edinburgh. The flowers are of a noble size, white, with a very slight tinge of pink.—(*Botanical Magazine*, t. 5322.)

CÆLOGYNE PARISHII (*Mr. Parish's Cœlogyne*).—*Nat. ord.*, Orchidacæe. *Linna.*, Gynandria Monandria.—Sent by the Rev. C. S. P. Parish, of Moulmein, to Messrs. Low, of the Clapton Nursery. Flowers green and yellowish-green, lip pencilled with dark purple.—(*Ibid.*, t. 5323.)

IACHARUM PYRAMI (*Calla-leaved Ischarum*).—*Nat. ord.*, Aroidæe. *Linna.*, Monœcia Polyandria.—Tubers brought from the Lake of Tiberias, by Dr. Hooker, and flowers produced in a warm greenhouse in January. Spadix and interior of spathe dark rich purple.—(*Ibid.*, t. 5324.)

**CLUSIA BRONGNIARTIANA** (Brongniart's Clusia).—*Nat. ord., Guttiferae. Linn., Polyandria Monogynia.*—It has also been called *Tovomitia oblongifolia*. Native of Cayenne, flowered in the Kew store in January. That specimen is a male plant, and is a woody shrub. Flowers creamy white, with a crimson centre of anthers.—(*Ibid., t. 5325*).

**SACCOLABIUM MINIATUM** (Orange-red Saccolabium).—*Nat. ord., Orchidaceae. Linn., Gynandria Monandria.*—Native of Java. Introduced by Messrs. Veitch. Blooms in May.—(*Ibid., t. 5326*).

**AZALEA MARS.**—Raised by Mr. Kinghorn, Sheen Nursery, Richmond. "Brightest of all those with red flowers approaching to scarlet. It is, indeed, a remarkably brilliant and attractive flower."—(*Florist and Pomologist, 97*).

**SUMMER DOYENNÉ PEAR** (Doyenné d'été).—"This is the earliest Pear known." Ripe some years in the third week of July. "Very juicy and melting, with flavour not unlike that of the Jargonelle." It is an excellent bearer. Raised by Dr. Van Mons, and first appeared in his catalogue for 1823.—(*Ibid., 104*)

**CAMELLIA CONTESSA LAVINIA MAOGL.**—Blush white, regularly marked with bright carmine stripes; form very good; plant vigorous. It has received a first-class certificate from the Floral Committee of the Royal Horticultural Society.—(*Floral Mag., t. 105*.)

**MAUVE-COLOURED SWAINSONIA** (*Swainsonia violacea*).—From central Australia. Probably hardy. Raised from seed by Messrs. E. G. Henderson & Son, Wellington Road, Nursery.—(*Ibid., t. 106*.)

**METEOR FUCHSIA.**—Received from the Continent by Messrs. Carter, of Holborn. It obtained a certificate of merit as a pretty-foliaged plant from the Royal Botanic Society. Leaves "rich golden yellow variegated with bronze."—(*Ibid., t. 107*.)

**AURICULAS GEORGE LIGHTBODY AND SOUTHERN STAR.**—The first-named raised by Mr. Headley, Stapleford, near Cambridge, received the premier prize at the National Show. Green edged spotted with white and with white margin. The second, raised by Mr. Holland, gardener to S. W. Peake, Esq., Spring Grove, Isleworth. It is a purplish-crimson flower. It had a label of commendation from the Floral Committee of the Royal Horticultural Society.—(*Ibid., t. 108*.)

## WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 235.)

**THE DWARF SWIMMING CRAB** (*Portunus pusillus*).—This little creature is common on the coasts of Devonshire and Cornwall, although it may not be very frequently met with by the tourist, as it is an inhabitant of deep water. The shell is of greater breadth than length, the surface being rough and grained. It has five teeth on each anterior lateral margin. The first pair of legs are large and strong, the wrist of each being furnished with a very strong spine. The second, third, and fourth pairs are slightly compressed and grooved. The fifth pair terminates in an oval joint; that and the joint next to it being ciliated. The colour of the Dwarf Swimming Crab is a reddish-brown, the back being frequently marked with red spots. The legs are usually surrounded with rings of the same colour.

**HENSLOW'S SWIMMING CRAB** (*Polybius Henslowii*).—So called from its being first discovered by Professor Henslow on the north coast of Devon. This animal, in Professor Bell's words, "exhibits the natatory structure to the greatest extent of any of the British examples of this family." The shell is extremely flat and minutely grained; the first pair of legs are large and strong; the wrist armed with two sharp teeth. The claws are long, slightly compressed and curved. The other pairs of legs are much compressed, particularly the last two joints, which in the fifth pair are very broad and flat. All the legs are ciliated on one margin, the fifth pair on both. In colour it is of a rich red brown, which fades to a pale salmon colour in drying. The under parts are pale. The following interesting remarks on this curious Crab are extracted from Couch's "Cornish Fauna":—"This is, more than any others, a Swimming Crab, for whilst the other British species of this family are only able to shoot themselves from one low prominence to another, the Nipper Crab, as our fishermen term it, mounts to the surface over the deepest water in pursuit of its prey: among which are numbered the most active fishes, as the Mackerel and the running Pollock; the skin of which it pierces with its sharp pincers, keeping its hold until its terrified victim becomes exhausted. We are witnesses of this curious method

of obtaining food in the summer only, at which time the fishermen's nets intercept them and their prey together; and it is probable that in colder weather they keep at the bottom in deep water, from which, however, I have never seen them brought in the stomachs of fishes. So far as my observation extends, it is chiefly or only the male that pursues this actively predacious existence; but for a time they also remain quiet, as appears from the fact, that while for the most part the smooth and flattened carapace is clean, I have seen it covered with small corallines."

Henslow's Swimming Crab has been also found on the western coast of Devon, and on the Dorsetshire coast. Professor Bell states that he has obtained it at Hastings, and received specimens from Cornwall and from Worthing.

**THE COMMON PEA CRAB** (*Primotheres Pisum*).—On many parts of our coast if you pick up a common Mussel (*Mytilus edulis*), and break it open you will stand a very good chance of finding a little soft-bodied Crab within it. This is the Pea Crab, it is not unfrequently found in the shell of the Cockle (*Cardium edule*), and sometimes though rarely in that of the Oyster. Individuals of this family differ so much, according to sex, that it becomes necessary to give a separate description of the male and female. The shell of the male is very nearly round, slightly narrowed towards the front. The eyes are small and round, filling the orbits. The first pair of feet are strong, the hands ovate, the claws much curved, the moveable one armed with a single tooth. The remaining legs are fringed with hair on both margins, and terminate in a hooked claw. In the female, the shell is also nearly round, and of greater breadth than length. The hands are weak and oblong, having underneath a single line of hairs. The remaining legs are slender, the thighs being furnished on the upper side with a line of hairs. Professor Bell says—"The colour of the male varies. It is usually of a pale yellowish-grey with rather darker symmetrical markings. The female is ordinarily slightly transparent, brown above, a yellow spot over the front, and an irregular one on each branchial region. The abdomen yellow with a central large triangular brown spot, extending from the base nearly to the extremity."

**THE ANGULAR CRAB** (*Gonoplax angulata*).—This is rather a rare species: indeed, as Professor Bell states, "It was not until it was obtained by Montagu, in the estuary of Kingsbridge, Devon, that it was ascertained to be British. Since that period it has been repeatedly taken on the southern parts of the coast. I have received it through the kindness of Mr. Couch, from Cornwall, and from the coast of Wales, where it was procured by Mr. Eytton, but I am not aware of its having been found on the eastern coast, nor have I heard of its being taken in Scotland." The shell of this creature is as broad again as it is long, and broader in the front than in the hinder portion. The eyes are placed on long stalks. The front legs of the male are amazingly long, four times the length of the shell: they are shorter in the young ones and in the females. The arm is slightly curved and cylindrical, furnished about midway with a sharp spine. The hand gradually increases in size towards the extremity. It is rounded and slightly compressed at the sides. The claws are furnished with five teeth, and a few tubercles. The rest of the feet are long and slender, the margins of the two last joints fringed with hair. The colour is a dull yellowish-red, a peculiarity of the male being that the moveable claw is black." To conclude this account with a short extract from Professor Bell. "It is found in moderately deep water, and Leach records, on the authority of Cranch, that 'they live in excavations formed in the hardened mud, and that their habitations, at the extremities of which they live, are open at both ends.' They appear to constitute a favourite food of the cod and other fish, as in addition to the observation of Mr. Ball—viz., that he found this species in the stomachs of cod fish purchased in the markets of Youghal and Dublin, Mr. Couch states that 'it is often taken in their stomachs.'"

**PENNANT'S EBALIA** (*Ebalia Pennantii*).—This is a somewhat rare species, and found most frequently on the coast of Devon. The shell is four-sided, a little broader than it is long, and has a raised cross upon it, formed by two ridges, running, the one longitudinally, the other transversely. The first pair of legs are longer than the rest and grained. The others are slender, with rounded joints, the last one being slightly curved. The colour is a reddish-brown, paler beneath, the abdomen being frequently marked with red spots. Professor Bell states, that he has one in his possession "which is all over of a lovely bright rose colour."

**THE CIRCULAR CRAB** (*Atelecyclus heterodon*).—The shell of

this species is nearly circular, and entirely surrounded with hair. It has three teeth on the front, the centre one being the largest, and on the margin on either side are placed nine teeth, alternately larger and smaller. The front pair of legs are very large and powerful, flattened, and when at rest pressed closely against the under portion of the body. The claws are compressed, curved, slightly toothed, and meet only at the points. The other pairs of legs are of moderate length, and fringed with long hair. The colour, according to Professor Bell, "is reddish-white with red spots, the anterior feet red, the fingers black, the hair light brown."

The Circular Crab is found on the Devonshire coast, on the Welsh coast, and at Scarborough. It has also been taken on the Scotch coast, in the Frith of Forth, and occasionally on the coast of Ireland. Although it chiefly inhabits deep water, small ones have been taken in rock pools accessible at low water.—W.

(To be continued.)

### THE INTERNATIONAL EXHIBITION.

(Continued from page 255.)

If there is any part of this Exhibition better arranged than the others, it is that devoted to our colonial possessions. Their raw products are peculiarly interesting, and are accompanied in most instances with every necessary explanation, an important point which has been very generally neglected in the British department.

#### SOUTH AUSTRALIA.

The Province of South Australia comprises a vast area lying between 129° and 141° E. longitude, and extending from the sea on the south to the twenty-fifth parallel of south latitude, which constitutes its northern boundary. The coast line stretches downwards from 31½° to about 38° S.; the capital, Adelaide, being situated 34° 56' S., and six miles from the sea.

The climate is one of the finest in the world; even in the coldest parts of the country the temperature rarely falls below 36°, and the long-continued periods of drought which are so destructive in other parts of Australia are here unknown, although in the plains the grass is usually parched-up in summer. Peaches, Olives, Vines, Oranges, Melons, and Pumpkins, are successfully cultivated in the plains; but Apples, Pears, Cherries, Strawberries, Gooseberries, and Raspberries can only be brought to full perfection in the cooler climate of the hills.

On entering the South Australian Court we meet with a tree bearing on its branches stuffed specimens of the aboriginal birds whose gay colouring would almost lead one to believe they were painted. At the base of the tree there are several lizards and amphibious-looking animals of by no means prepossessing appearance, while a native dog is peering very sharply through the long grass. The natural history of the colony is further illustrated by cases of admirably stuffed birds; and its mineral riches by ores from the famous Burra Burra, Kapunda, and other mines, including a beautiful malachite table-top from the former.

In 1851, South Australia took the prize for the finest Wheat shown, and thousands of acres are now annually sown with this grain. Some beautiful even samples are exhibited, several of which are of remarkable weight. They are:—From Allan Bell, 1862, weight per imperial bushel, 68 lbs. 1 oz.; James Hay, 1861, 67 lbs. 7 ozs.; Hackett Brothers, 1861, 67 lbs. 5 ozs.; John Dunn, 1861, 66 lbs. 12 ozs.; J. Waddell, 1861, 66 lbs. 10 ozs.; J. B. Buttfield, 1861, 66 lbs. 8 ozs.; W. Wedd, 1861, 66 lbs. 5 ozs.; Allan Bell, 1861, 66 lbs. 4 ozs.; J. Stevens, 1861, 65 lbs. 10 ozs.; J. McDougall, 1861, 65 lbs. 8 ozs.; Griffin Cant, 1861, 65 lbs. 8 ozs.; E. Wehl, 1861, 64 lbs. 10 ozs.

The capabilities of Australia as a wine-producing country are now beginning to be developed, and we gather from the well-written and very interesting official account of the colony of South Australia, prepared by Mr. Sinnett, the following information as to the progress of this branch of industry:—"A patch of Vines is now a very general feature in South Australian homesteads, and a garden and orchard have long been so; but wine-growing is now rapidly becoming a separate pursuit, and before many years, probably, we shall not be sending away wine in sample quantities, but by cargoes at a time.

"The production of wine here is, however, still in its infancy, and for the most part our wine-growers are comparatively inexperienced; or if they have gained knowledge in the vineyards of Europe, they have not yet adapted it to the widely different circumstances in which they are now placed. One consequence

of this has been that in numerous cases vineyards were planted a few years ago with Vines unsuited to the particular soil and position selected, or different varieties have been planted, ripening at intervals from February to April, and thus rendering it almost impossible to conduct the operations of the vintage with any degree of success. Another serious drawback is, that but few of our Vine-growers have either sufficient cellar-room or sufficient capital to hold their wines until they mature. In many cases publicans, who have to suit the palates of their colonial wine customers with a strong luscious wine and their pockets with low prices, buy up the produce of certain vineyards when the wines are about six months old, and, of course, before the fermentation is completed. These wines are drawn off from the wood perhaps a fortnight after leaving the cellar of the maker, and thereupon a large section of the public found their estimate of the 'colonial wines.' But such liquors bear no resemblance to what our wines become with proper treatment. If the most critical connoisseur of wines were set down in the cellars of some of our best wine-growers, he might taste samples which he would be compelled to pronounce equal to any wines of their class to be found in any part of the world. We may particularly instance a pure Riesling wine, made by Mr. Joseph Gilbert, at Pewsey Vale, and a red wine resembling Burgundy, the produce of the same vineyard, of which he has, we believe, samples from every vintage since 1852; also, a pure Riesling wine and an Epauroir, made by Mr. Henry Evans, at Evandale; a Shiraz and Donzelino, a superior claret and an excellent Verdelho, made by Mr. Patrick Auld, at the Auldana Vineyard; and a particularly delicate, fragrant, and grateful wine, something between Hock and Sauterne, made by Mr. Peske, at Clarendon Vineyard. Mr. Waterhouse, at Highercombe, on an elevated site among the hills near the sources of the Torrens, makes a red wine resembling Burgundy, which has a high reputation here. Dr. Kelly, the author of a well-known treatise on wine-growing in Australia, has selected Morphett Vale for the site of his vineyard. Thus the suitability of a large part of the colony for wine-growing has already been fairly tested, and every year a largely-increased acreage is planted with Vines. Samples of most of the above-named wines, as well as many others, have been sent to the International Exhibition.

"One thing which is wanted in the colony to give our wines a fair chance in our own and foreign markets, is a class of traders to step in as 'middlemen' between the producer and consumer; men purchasing wines from the growers—say after the first fermentation is over—and maturing them under their personal superintendence.

"Referring to the introductory chapter of Dr. Kelly's work, entitled, 'The Vine in Australia,' we find that, as the eldest colony, New South Wales took the lead in wine-growing, and produced samples which have been brought into comparison with first-class wines in Europe, and have stood the test of that ordeal. Adelaide following in the wake of the elder colony, has imported thence the varieties of Grapes there found suited to the Australian climates, as well as the best kinds grown in Spain. The greatest obstacle which our Vine-growers have had to contend with in extending their vineyards has been the abstraction of nearly all the available labour in the colony by the gold diggings in Victoria and New South Wales; and even at the present time vineyard extension is in numerous instances retarded, not merely by the actual scarcity of labour and its consequently high price, but by the uncertainty whether, after a vineyard has been planted, sufficient labour will be obtained to cultivate the Vines. I am told there are many acres of good soil, in capital situations, ready ploughed and trenched, and intended for Vines, but still lying fallow, solely in consequence of the state of the labour market. Still extension is rapidly taking place. Thus, one gentleman planted one hundred acres last season; another, in 1863, will have eighty acres in bearing; and there are many others whose acreages range from fifty to twenty. The latest official returns give—

Years .....	1856.	1857.	1858.	1859-60.	1860-61.
Acres under Vines .....	753½	1,055½	1,626	2,201½	3,180

"From the report of the Superintendent of the Census, respecting the Agricultural Statistics for the year March 31, 1861, we extract the following:—"The apparent decrease in gardens, and increase in acreage under Vines, is chiefly attributable to greater care having been taken in distinguishing between them. The increase of 979 acres under Vines is not, therefore, altogether to be considered as land newly devoted to Vine-culture. The

planting of Vines progresses with vigour—the number not in bearing being 1,948,510, against 1,577,881 returned in the previous year; whilst 420,280 came into bearing; making a total of 1,874,576 actually under crop. The total number of gallons of wine made was 182,087, or only 1,763 gallons more than returned in the previous season.

The weight of Grapes returned, as sold or otherwise disposed of—*i.e.*, not converted into wine, was 23,398 cwts. Seventy-five wine-presses are noted against sixty-one last year.

It is remarked that the Vines planted during the past two or three years have been more carefully selected with regard to adaptability to soil and aspect, and their value as wine-producing varieties.

“A wine-producing association has been already formed, composed chiefly of large capitalists and experienced vignerons, who are prepared to operate upon a large scale, and to make it an especial feature of their business to reserve their wines from the market until they are in some measure matured.”

In addition to samples from different growers of the wines above referred to, there are exhibitions of good Muscatel raisins; and judging from their external appearance, some very fine soft-shelled Almonds, from G. Brandis, Esq., Enfield, S.A.; also, a plank of gum-wood used for fellocke of wheels and other cart and carriage work, and carriage wheels made of different kinds of gum-wood, stringy-bark, iron-bark (species of Eucalyptus), shea-oak, &c.

(To be continued.)

### RED SPIDER ON STOVE PLANTS.

I FIND red spider numerous on some of the climbers in my stove, and the pest is extending to other plants. What can I do to get rid of it? Pastils will not touch them. Syringing with Gishurst does not reach the whole of the leaves; and, moreover, I am afraid of it, for Orchids and Ferns which are under. I cannot get to the plants so as to dip every leaf. The books recommend a paste of sulphur and lime on the pipes. I wish to try this, but I can find no exact directions. What proportions of flowers of sulphur and lime? How thick must it be put on? To what extent of surface? How long must it remain? How soon be renewed?

I should add that the plants have been drenched with the syringe twice a-day for months. Temp. 63° to 70°, night; 74° to 80°, day (without sun).—P. H. G., *Torquay*.

[Your excessively high temperature, 74° to 80°, without sun, has brought you the infliction. We should be inclined to move the Orchids, &c. Paint the pipes with sulphur, or sulphur and lime, every three or four days, it will get off of itself. Keep a fire on, especially when dull. Give air to keep down the temperature, and syringe with sulphur lime water made thus—Put a pound of flowers of sulphur and a pound of fresh lime in a gallon of water. Stir and mix well, and boil for twenty minutes. Allow the liquor to cool and clear itself, and then put one drachm-glass full (half a gill in Scotland), half a quartern, into three gallons and a half of clear water. You must persevere. The fact is, the painting of the pipes and the syringing may kill many of the insects, but day after day fresh eggs will be hatched, and they, too, must be destroyed: hence the importance of attacking the pest early.]

### TWO GREENHOUSE STYLIDIUMS.

*STYLIDIUM MUCRONIFOLIUM* (Bristle-leaved Stylidium). *Nat. ord.*, Stylidiaceæ. *Lin.*, Gynandria Diandria.—A very pretty greenhouse herbaceous perennial, with wiry roots, and tufted stems 2 inches or 3 inches long, copiously furnished with glabrous, spreading, linear, subulate leaves, which are each tipped with setaceous mucro. The scapes are terminal, 6 inches or 8 inches high, bearing a compact oval panicle of numerous bright yellow flowers, the segments of which are marked with a conspicuous zigzag line around the mouth; these segments are of nearly equal size, and of a somewhat ovate figure. From Australia: Swan River colony. Introduced in 1848. Flowers in the latter part of summer. Messrs. Lucombe, Pince, & Co., of Exeter.

*STYLIDIUM SAXIFRAGOIDES* (Saxifrage-like Stylidium).—*Syn.*, *S. assimile*.—A pretty greenhouse, perennial, herbaceous plant, bearing rosulate tufts of densely imbricated, spreading, linear leaves, which are somewhat incurved, acute, ending in a long hair or bristle, and fringed on the margin with short scabrous

hairs; the colour yellow green tinged with reddish-purple. The flower-scapes grow from the centre of the tufts, 10 inches or a foot high, bearing a simple raceme of eight or ten blossoms,

1. *Stylidium saxifragoides*.

2. *Stylidium mucronifolium*.

which are, comparatively, large, creamy yellow, the column knee-jointed and red; the flowers consist, apparently, of four spreading segments, two of which are larger than the others; the upper part of the scape, pedicels, ovary, calyx, and the outside of the corolla are clothed with short glandular hairs. From Australia: Swan River. Introduced about 1848. Flowering in summer. Messrs. Veitch, of Exeter and Chelsea.

REMARKABLE SPECIMENS OF *CYCAS REVOLUTA*.

It must be considered a remarkable circumstance, that infinitely more female than male plants of *Cycas revoluta* are known to exist, not only in the gardens of Europe, but also in their native habitat—China and Japan, where Thunberg and Siebold found the Sago Palm in its wild state; but rarely met with male plants. In European collections, too, but one solitary male specimen has been recognised; it flowered in the Botanic Garden of St. Petersburg.\* Again, Mr. Regel observes, that he himself never encountered a single male plant of *Cycas revoluta* in Surinam; and, with the exception of one plant, which has not yet flowered, all the specimens that gentleman sent home from Paramaribo, had previously flowered, and proved females.

Perhaps no specimens of the Sago Palm, remarkable for their great height, and extraordinary branching habitude, existing in their native elimes—certainly not in Europe—can at all compare with those here portrayed, which were brought to the Ghent Nurseries from near Paramaribo, the capital of Surinam.

In Surinam there were seen some plants in full bloom at 4 feet high from the ground; but the tallest specimen forwarded to Belgium was 9 feet 3 inches high from the ground to the top of the trunk, or base of the fronds (fig. 1). The largest branching specimen exhibited in the engraving is 8 feet 6 inches high from the ground to the apex of the head divisions (fig. 2); the other branching specimen shown in the drawing is 8 feet in height (fig. 3). Mr. Regel is himself of opinion, from what he observed in Surinam, that the Sago Palm has never attained greater dimensions than those just stated, either in that or any other country—not even excepting the native habitats of the plant, China and Japan. Moreover, respecting the presumed age of these fine Cycads, supposing that full forty years must have elapsed previous to the formation of the “annual rings of the stem” at present observable, and reckoning the number of the latter as amounting to about sixty, they have, in that gentleman’s estimation, passed through all the wondrous phases of vegetable development for a good round century, or even a longer period.

It is worthy of remark that in China and Japan the Sago Palm produces its plume-like crest of leaves but once a-year; but in Surinam, impelled by circumstances relating to its climatology, they frequently make two distinct growths during the same period. That this is mainly, if not solely, attributable to the

\* A male plant of the *Cycas revoluta* is recorded as having bloomed in the collection of Miss Neilson, of York, about 1835 (“Flor. Mag.”). This, which was an aged plant, is stated to have been presented by the Earl of Derby to Mrs. Beaumont, of Bretton Hall; it afterwards came into the possession of Miss Neilson, and subsequently passed to the Sheffield Botanic Garden, where it flowered again in 1839. This was stated to have been the first and only male plant that had bloomed in England.

presence of a greater amount of humidity in certain localities compared with others in that country will be evident, when it is stated that plants of the Sago Palm, which grew in situations becoming inundated during the “rainy season,” were observed to have made two growths; whereas, others growing in more elevated, and consequently much drier places, accomplished but one seasonal development of their frond-like foliage. Reasoning analogically, does not the knowledge of this fact supply us at once with a feasible explanation of the reason why Cycadaceæ coming from Surinam are not as readily and as rapidly induced to vegetate as members of the same family imported from climes less hot and moist?

The magnificent Cycads which form the subject of these remarks grew upon the site of what had once been a cemetery, adjacent to the town of Paramaribo. My Surinam informant enters somewhat further into a description of the situation in

question. He describes it as “a deserted, sunny spot, near to a marsh,” which regularly becomes so much swollen during the primary half of the “rainy season” as to overflow to some distance the subjacent territory; but partly in consequence of the great heat inducing a rapid evaporation, and partly owing to the porosity and thirstiness of the soil occasioned by the plentiful presence of sand, the inundation quickly subsides or rather disappears. *Polypodium aureum* grew luxuriantly, but gracefully, upon the trunks of the Sago Palms; luxuriant grasses, and Cyperaceæ clothed the spongy ground around them; close at hand were various *Malpighias* and *Melastomaceæ*; also several *Polygonaceæ*, as *Coccoloba guayanaensis*, &c., the *tout ensemble* composing a pretty

exotic wilderness of shrubs and herbaceous plants, festooned with white, rose-coloured, and golden *Ipomæas*, and a diversity of *Convolvulacæ*. Far away in the background uprose the slender stems of the royal *Oreodoxa*, whose long fronds contrasted remarkably with the simple fans of *Mauritia flexuosa* standing isolated here and there. In this direction a primeval forest surrounded the entire scene. “Turning myself,” says Mr. Regel, “to the opposite side, before me lay the marsh diversified with *Limnocharis Humboldtii*, grasses of different kinds and dimensions, and numberless *Alisma echinocarpum*. Farther on were herbaceous *Melastomada*, with rosy flowers, and the beautiful *Cassia alata*, profusely adorned with glorious flower-spikes of yellow. Beyond was the capital of Surinam, above which were visible the crests of many Palms, and immense trees of the white-flowered *Magnolia-like Mammca americana*.” What a delightful recollection!—G. TAYLOR, *Chatsworth*. (*Gardeners’ Magazine of Botany*.)

### TOO-HASTY CONCLUSIONS.

I FULLY concur in the remarks made by Mr. Pearson in your Number for June 24th, page 227, where he speaks of the incorrect conclusions of too quick observations. How frequently is it the case with many, who as soon as they see any insect on an unhealthy tree, that they conclude this is the cause of the evil. And again, when some parasitic fungus is found under the same circumstances, the same conclusions are arrived at for want of more accurate observations; whilst, at the same time, these may not be the cause of the mischief, but only accompany it. But, in most cases, it may be found that hasty conclusions are mostly like a blaze of straw; as, for instance, funguses may be doing more good than harm by inhaling the gas escaping from decomposing matter, and exhaling pure gas for those to breathe who so detest them.

And this reminds me of a disease which has appeared in the Spinach this year, and which makes its appearance on the leaf. It is similar to that which affected the Celery last year, with the exception of the insect, instead of which there is what appears to me to be a fungus. Have you had any previous complaints?—J. DIVERS.

### THE SMALL BIRD QUESTION.

I QUITE agree with THE JOURNAL OF HORTICULTURE, and the Press generally, in emphatically condemning the indiscriminate slaughter of small birds. But, as there are generally two sides to a question, I am not sorry to see that THE JOURNAL OF HORTICULTURE is quite willing to give its readers the benefit of seeing both sides in the present instance.

Certainly no policy can be more suicidal than for the gardener and farmer to indiscriminately destroy small birds, when many of them from their exclusively insect-devouring habits are, undoubtedly, his very best friends. Amongst these may be mentioned the Swallow, the beautiful tribes of Wagtails, the Hedge Sparrow, a sweet songster; the Robin, the Tite, the Wryneck or Snake Bird, the Starling, the Wren, the Redstart, the White Throat, and the Black Cap. As regards the two last-named, judging from the unceremonious manner in which they help themselves to ripe Raspberries, Currants, &c., which leads to the supposition that their notions respecting "mine and thine" are not quite correct, still the quantity of small caterpillars which they devour, and their sweet song may well be received as their payment and apology, and as they are never very numerous, indulgence may well be accorded to them.

Good-natured fears have been expressed that from the working of sparrow-clubs, &c., our races of small birds will ultimately become extinct.

I am inclined to think that a ramble in the country some miles from any town will have the effect of dispelling those fears. It so happens that the feathered tribes most injurious to the farmer and gardener, have the power of increasing themselves very rapidly. The common House Sparrow, the Chaffinch, the Greenfinch, the Blackbird, and the Thrush, will all rear three broods of young in one season, each brood consisting of five or six individuals, and the natural term of their existence is not less than ten or twelve years.

The Blackbird and Thrush are both delightful songsters, and, no doubt, do much good by devouring insects, &c., but as far as they are concerned the insects have all a holiday during the fruit season, as they certainly bestow upon the fruit their undivided attention; and gardeners in the country find that it is quite impossible to obtain ripe Strawberries, Raspberries, Currants, or Cherries when they are allowed to abound. So I can quite sympathise with your correspondent "X," and as to the advice which you so kindly give him—viz., to employ a live old man or old woman to protect them, I can only say that I fear "X" will be much puzzled to find either sufficiently lively for this purpose about two or three o'clock in the morning, the time when their protection will be most required.

In speaking of birds injurious to the farmer and gardener, I have not mentioned the Bullfinch, and I am truly sorry to say that I have nothing to say in his favour further than that he is very beautiful; but if even a pair or two of them be tolerated in a garden during the spring months, the gardener will have very little trouble in gathering his wall-fruit or Gooseberries that season.

On the other hand let me say a word in favour of the Goldfinch, without exception the most beautiful of British birds, a

sweet songster and perfectly harmless. He is seldom seen in the garden, and when seen, either on the farm or in the garden, some instances of bad farming or gardening are at hand. Allow the Thistle and the Chickweed, &c., to run to seed and the beautiful Goldfinch will appear upon the scene; but harm he does none.

I must now claim for the farmer or gardener, &c., who reluctantly destroys a portion of the birds which he sees in the act, as it were, of destroying the crops on which himself and his family are depending, an excuse which ought not to be extended to the cockney sportsman, who sallies forth for the purpose of killing, merely for the sake of killing, everything that has the misfortune to come within his reach, from a barn-yard fowl or tom cat to a Wren or field mouse.

But, in conclusion, let me say that I am afraid that Game-preservers have something to answer for in this matter, inasmuch as they have disturbed the natural balance of creation by almost exterminating the beautiful tribes of Hawks, Owls, &c., which naturally preyed upon the very tribes which prove so injurious to the crops of both farm and garden, rendering it quite necessary for man to directly interfere; only let him do so with discrimination and with mercy.—G.

[It must be remembered that what the gardener and farmer require is, their enclosures to be frequented by insect-devouring birds during the times that those insects are in the state proper for such devouring, but to make the said birds abscond whilst certain fruits are ripe and to be preserved for the growers' consumption and use. Now, both these ends cannot be attained if you kill the birds, but it can be attained by merely scaring them. We assure our correspondent that old men and women can be had lively from 4 A.M. to 6 P.M., and we know places where even during the recent wet weather they pursued their scaring, and the scaring, perhaps, was intensified by the Sarah-Gampish umbrellas under which they moved about.—Eds.]

### SPARROWS ARE OUR FRIENDS.

"X" TELLS us "Never a caterpillar will the Sparrows eat; but as soon as a Pea-pod swells, or one side of a Strawberry ripens, at that they go." "X," perhaps, forgets that my friends, the wantonly-persecuted Sparrows, have young ones when the Pea-pod swells and Strawberries ripen. May I not ask if they feed their young at one time upon insects, and at another upon fruit and vegetables? At the time I am writing, no less than twenty nests with young Sparrows in them are fed by their respective parents, without touching our Peas, Strawberries, Raspberries, or Cherries, though they have free access to them. Certainly owing to our living so near a smoky town, where no less than two hundred long chimneys emit their suffocating fumes unrestrained by smoke-consuming apparatuses, we have not so many vegetables or fruit for the Sparrows to eat; but we have enough to afford a tempting bait. If Sparrows are so partial to Peas and fruit, would they not help themselves to a few as well, and quite as soon, as they are said to do to a larger quantity?

Sparrows eat various cereals and leguminous seeds in a raw state, even the young growths do not escape, and almost anything in a cooked condition; but fruit they do not eat, neither boiled nor raw, nor seasoned with sugar. Sparrows are blamed for many mischiefs they never commit, and so are convicted upon suspicion, and sentenced to death without the slightest commiseration. I have heard some people say Sparrows eat Cherries, but not a Sparrow did I see touch those very same Cherries; but the Blackbird takes a slice out of the ripest side, and is off in an instant. The Sparrow, young and not possessed of the cunning of his parent, stays behind, picking the caterpillar out of curled leaves, and only thinks proper to move when his foe—man, is close upon him. Man says the Cherries are eaten, and as Sparrows were last seen there they were the eaters. I have seen all that, and I have noticed when some clear-sighted but quick persons have said that Sparrows eat Currants, that the hens have pulled them off the trees from no delight they take in eating them, for the ground was covered with the berries. Surely Sparrows do not play with an empty stomach; but fed fowls do play with the currants, and even with their usual food.

I have seen Sparrows in flocks of a thousand strong, and have brought them down by the score with the contents of a gun, just as they rose from the little plot of barley it was my duty to mind, and have lived close by where Cherries grew, and those Sparrows were reared, and not a fruit of any kind did they

eat but caterpillars for themselves and young. I have received as much as 4s. worth at a time, which at the rate of one egg or young Sparrow for a farthing is equal to 192 birds destroyed. Now, then, from observations I have taken since then I compute that I wilfully caused 1,843,200 caterpillars to be left to prey upon our fields and gardens. A nest of Sparrows is fed forty times in an hour by both parents on an average, the average of more than 40 observations taken at distant and short intervals; and presuming that one bird is fed or one caterpillar only is taken at one time, we shall have, for sixteen hours per working day, a grand total of 640; but as Sparrows take four and five caterpillars at a time, that estimate is considerably below the approximate amount. However, we will be content with the smaller number, and when we multiply the daily consumption by the period that transpires between hatching and leaving the nest (fifteen days, and from that to twenty), we have 9600, the amount of caterpillars destroyed by a pair of Sparrows.

In connection with those observations I undertook another, which informed me that 500, or thereabouts, of caterpillars unharmed a Gooseberry bush, 5 feet through and 3 feet high, in fourteen days, or reduced the tree to such a miserable-looking and weakened condition that its fruit withered, leaves were skeletons, and existence terminated at once after a few droughty days. Thus it seems a single brood of Sparrows is capable of destroying the caterpillars that infest seventy trees; but we wish it to be borne in mind that Sparrows are just as fond of the larvæ of the daddy-longlegs: therefore we will allow half, if you please, which is equivalent to thirty-five trees being cleared of their enemies.

Sparrows have not taken wireworms, nor any other grub with so tough a covering to their young, as far as my experience has tested: consequently, I do not reckon wireworms as Sparrow food, but they are the food proper for the Rook, the Starling, and Jackdaw. Neither have I seen Sparrows take the aphid nor any of the beetle species; but caterpillars of all the moths they consume without partiality, and the eggs, too, of moths they devour, as you may soon notice if you will watch them in plantations of winter greens in the autumn, Cabbage-grounds in July, or Turnip-fields in August and September onwards. You may then see them fly from the Turnip-field in flocks of a thousand strong at the approach of the sportsman, after the stubbles are cleared, and the grain housed, and when it is growing, ripe, or in sheaf.

Just another word (a long one please, Editors). We have had a plague of caterpillars this season, and our neighbours have been even worse off, as their trees tell too plainly. For nine days the caterpillars were in the ascendant, and more than one gardener laughed at my notions of the Sparrows eating them, and recommended me to use lime and hellebore, for which I was much obliged; but my faith in Sparrows remained unshaken, particularly as I saw the Sparrows at work and the number of the caterpillars decrease. However, some lime was ordered, and to my delight there was no necessity to use it, for the caterpillars had disappeared, and certainly not in the shape of a butterfly. And the Sparrows took the trouble of being in the Gooseberry bushes every time I passed that way, and, moreover, they (the Sparrows) pulled the soil away from the roots of the Peas, and cantered off with the larvæ of the daddy-longlegs.

Our neighbours are using poisoned wheat, and destroying all the young Sparrows they can lay their hands upon to save a few grains of corn; but they are paying the penalty, for they have little verdure on their Gooseberry bushes but quantities of small withering fruit. One party boasts of having destroyed 600 young Sparrows, and as many at a time as 170; but even yet there is hope, for we have sent out a thousand young Sparrows on their errand of general utility: thus, as they kill, I rear and protect.

"X" can save his fruit for a few shillings by using nets; but if he wants a scarer nothing will avail him so well as a young Sparrow Hawk, with a wing pinioned and raw meat to eat, for the Sparrow Hawk is the natural enemy of the Sparrow.—*GEORGE ABBEY, Gardener to E. Haulstone, Esq., Horton Hall, Bradford.*

**WOLFF & SON'S SOLID INK PENCILS IN CEDAR, FOR GARDEN TALLIES.**—We can say from experience that these pencils are an excellent substitute for paint or liquid ink, as they possess indelibility, and have the advantages of great cheapness and of being cut and used like the ordinary lead pencil. They are well adapted to writing upon wood, zinc, parchment, &c., being perfectly unacted upon by water.

## CAUTION.

I BEG to caution your numerous readers in the trade and the poultry fancy against the orders of "J. Becke, Esq., 6, Trafford Street, Hulme, Manchester;" also of "64, Major Street, Manchester;" also "124, Oldfield Road, Salford." A few weeks back I received a small order for flower seeds from the first-mentioned address, which were duly forwarded. Instead of a remittance by next post a further order came for vegetable seeds to the amount of £10 or £12. This looking rather suspicious, I immediately wrote for a remittance or reference to some London house, but no answer was returned. I then requested a friend in Manchester to make inquiries; the result communicated was, that my customer rented an empty room in each of the before-mentioned addresses, and that he called at each about twice a-day near post time.

I enclose you a paragraph cut from the *Manchester Examiner*, of July 7, you will there perceive *J. Becke, Esq.'s* name prominently mentioned.—*B. J. EDWARDS, 222, Strand, London.*

"A STORY ABOUT THE 'LONG FIRM.'—On going into the detective office a day or two ago, our reporter saw two men, both of whom were drunk. They were discussing in a rather angry tone with Mr. Maybury, because he insisted on keeping 5s., belonging to the one, and 4s. to the other, until the following morning. On the counter were 'odd and ends,' which had been taken from their pockets, consisting of tobacco pipes, bits of black lead pencils, scraps of paper, and many letters. They were not well off, notwithstanding that some scores of ill-gotten pounds must have passed through their sinful hands within a few weeks. All the money one possessed was 6s., while the other had 4s. and some copper. Yet these were two of the most successful members of the 'Long Firm;' one was known as 'J. G. Harrison, Esq.,' and the other as 'John Munn, Esq.' The gullibility of tradesmen is shown to a remarkable degree in the history of these men. Again and again have their swindling tricks been exposed in trade circulars and in newspapers. Their letters to firms in every part of the United Kingdom have been repeatedly published, and the success with which they have obtained goods of every description has been constantly exposed. Very recently, we believe, they made Derby their head-quarters, and, in a few days, articles of every description arrived, and were immediately sold at about a fifth of their value. They are now again in Manchester, issuing orders on a neat sheet of paper surmounted with the royal arms, and with the heading, 'Hulme Hall Lane, Newton Heath, near Manchester.' They were brought to the detective office to have an interview with a superintendent of police from the county of Hereford, who had been sent over by Lord Bateman. His lordship had received a polite letter, signed 'J. G. Harrison,' and asking for one dozen of his best breed of young turkeys to be sent to the address. His lordship has been robbed of a number of fowls lately, and, believing that the writer of the letter had had something to do with the robbery, sent over the superintendent to make inquiries. The two men were accordingly captured, and there is little doubt but that the action taken by his lordship will be the means of saving many tradesmen from being victimised out of large sums of money. At the time the men were caught, a messenger was sent to the railway stations to inquire if any goods awaited delivery to the firm in question, and the result was the reception at the Town Hall of a splendid Enfield rifle, from a firm at Plymouth; a packet of Lord's loading chambers; and a box of flies for salmon fishing. The letters found on them nearly all bore dates of July 2nd and 3rd. One letter showed that they had ordered brushes to the amount of £12 14s. 8d. from Cork; but, fortunately, the goods had not been sent. They had also ordered some kind of a machine from a London maker, and a tallow press, valued at £7 10s., had been forwarded to their address from Luttermouth. What has become of the 'tallow press' and the other machine we have not been able to learn. The persons residing in the neighbourhood, the address of which was given by the 'firm,' received a hint from the police to communicate the character of the men to the drivers of the railway vans and luries, whenever they came with goods for them. The people good-humouredly took the hint, and sundry packages were reconveyed to the railway stations from whence they came. It is hoped that the 'tallow press' and the machine are now at one of the stations, or the makers and owners will have to register them amongst their bad debts. Other letters show that the firm had ordered a refrigerator, value £5 5s., from Mr. G. Acton, York, and that it had been sent to them, and that a bottle-washing machine had been put upon the railway for them by a Liverpool house. One letter, dated July 2nd, 1862, is stamped from Leadenhall Market, London, and is signed by E. Howard, dealer in poultry; in it are particulars as to the prices of all sorts of choice fowl; and, in conclusion, Mr. Howard expresses the hope that he may be entrusted with orders. From Messrs. Kirke & Company, of Sunderland, they appear to have obtained timber, during the last month, to the value of £60 13s. 2d. Some time ago the firm ordered an omnibus and a pulpit and obtained both. Their success in those instances partook of the ludicrous, and though the 'goods' were peculiar, yet both were quickly disposed of; and a letter dated the 3rd of the present month, shows that they had unsuccessfully endeavoured to obtain a cow from a person at Southgate. They were prompted to give this order by their success in another instance, when they actually obtained a horse, worth 40 guineas, from a magistrate in Ireland, and on its arrival in Levenshulme they sold it for £11. Upon another occasion they got rabbits to the worth of £6 10s., ate some and sold the rest. A country parson sent to order a quantity of fancy fowl, but these were fortunately intercepted by the police and restored to 'his reverence.' Last week they wrote for and obtained £40 worth of pork pies from a firm in London. All the scattered members and friends of the firm were brought together, and they feasted for several days upon the pork pies. Then two members of the 'pork-pie' firm—a London one—arrived, and, after making due inquiries, returned sadder and wiser men. Another order of a singular character was a set of coal-field plans from Newcastle-upon-Tyne. The plans were ordered by *James Becke, Esq., of 124, Oldfield Road, Salford*, as he gave the address, but what became of them or him was never known. The original cost of the order was £16 16s., but to the 'Long Firm' one would have thought they were only worth the price of waste paper. A more singular order still was one they sent to Scotland

for an eagle. The monarch of the hills arrived in Manchester in due course, but was captured by the police, died at the detective office, and its stuffed skin is now in Belle Vue Gardens. The men were not detained in custody because there was really no criminal charge against them; but the practices of such men almost incline us to regret that defrauded creditors have not the power to try them before Judge Lynch."

[We are weary of this "old, old tale." We have other letters to the same effect as the preceding, and all tending to the same conclusion—namely, *never part with your property to unknown purchasers without prepayment*. If any doubt upon the point arose, it should be effectually removed upon observing that the application came from Manchester or any place near it.—EDS.]

## THEORY OF COLOUR, AND THE INFLUENCE OF LIGHT ON VEGETABLES.

(Concluded from page 197.)

THE varied and gorgeous tints which leaves assume on the approach of autumn are due to the absorption of oxygen gas, those leaves which remain longest green absorbing least oxygen. Some species of the Maple, the Poplar, and the Beech, are remarkable for the rapidity with which their leaves change colour: these, it has been demonstrated, will absorb eight or nine times their bulk of oxygen in the same time that the Portugal Laurel or the common Holly will absorb the smallest fractional amount. If several green leaves of the Poplar, the Beech, the Holly, and the Portugal Laurel are placed under the receiver of an air-pump and dried thoroughly, keeping them from the action of light, when dried let them be taken out and moistened with water, and immediately placed under a glass globe filled with oxygen gas; it will be found that the several leaves change colour in exact proportion to their powers of absorbing oxygen, the best absorbers changing colour most rapidly. The result of this absorption is the formation of an acid, and this acid changes the chlorophyllite, or green principle, from green to yellow, and then to a reddish hue. A similar change is effected in the colour of the leaves of plants by merely treating them with an acid; and if a red leaf is macerated in an alkali (potash for example), it becomes green. We thus have another proof that chlorophyllite owes its formation to the absorption and decomposition of carbonic acid by the plant under the influence of light; for if this agent be withdrawn no absorption takes place: on the contrary, a continual disengagement of carbonic acid gas from the tissues of the plant is the result.

The result of the experiments instituted by Professor Draper on this subject fully proves that the capabilities of a plant for absorbing carbonic acid gas from the atmosphere are in exact proportion to the illuminating powers of the rays of light. The varied and delicate colours of flowers are produced by a somewhat different process from the other colours of the plant, inasmuch as the flowers do not appear until the plant has attained a certain degree of maturity. On this subject Liebig has the following remarks:—"The leaves of the plant being fully developed, they take in more nourishment than what is necessary for the existence of the plant. This extra nourishment takes a new direction; a peculiar transformation takes place, new compounds are formed, which furnish constituents of the blossom, fruit, and seed."

It is very probable that all the colours of flowers depend upon only a few approximate elements formed in the vegetable, and that their various hues are the consequence of the presence of acids affecting more or less this colouring substance. The following ascertained facts tend to support this theory:—The expressed juice of most red flowers is blue: hence it is probable that the colouring matter in the flower is reddened by an acid, which makes it escape when the juice is exposed to the air. The Violet is well known to be coloured by a blue matter, which acids change to red, and alkalis and their carbonates first to green and then to yellow. The colouring matter of the Violet exists in the petals of red Clover, the red tips of the common Daisy, of the blue Hyacinth, the Hollyhock, Lavender, and in the inner leaves of the Artichoke. The same substance made red by an acid colours the skin of several Plums, probably also gives the red colour to the petals of the Scarlet Geranium. It is remarkable that these on being merely bruised become blue, and give a blue infusion with water. It is also probable that the reddening acid in these cases is the carbonic, which, on the rupture of the vessel which encloses it, being a gas, escapes into the atmosphere. If the petals of the red Rose be triturated with

a little water and chalk a blue liquid is obtained. Alkalis render this blue liquid green, and acids restore its red colour.

The absolute necessity there is for studying the arrangement of colours in the carrying-out flower-gardening operations, or, indeed, in any work of art so as to produce a harmonious whole, is so evident that any remarks on the subject would be superfluous. But in concluding our remarks on the theory of colour, we feel we cannot do better than quote the words of Mr. Craee, as spoken by him at the Society of Arts, concerning the colours employed in the International Exhibition, and which are applicable to every other decorative purpose:—"Avoid blazing contrasts of colour, such as bright red next bright green, or bright blue next bright yellow. Such contrasts are not harmonious. Let one of the two colours always be subservient to the other. It is not so much what colour a material is, but how that colour is made to appear. It is necessary to bear in mind that all colours have their complementaries, which add to or detract from the beauties of the adjoining colours, according to what they may be. Thus the complementary of red is green, of blue is orange, of yellow is violet. If you cut out pieces of grey paper in an ornamental form, and stick a piece on each of the three colours I have named, you will find in a shaded light the grey will be fully tinted by the complementaries of these colours; but you cannot lay down precise rules. An experienced artist can bring any two colours together by properly modulating them. Nothing is so charming and so refreshing to the eye as a harmonious arrangement of colours. They are 'like a sweet chord of music to the sense.' The hand of Nature never errs. Whether it brings together scarlet and crimson, as in the Cactus; scarlet and purple, as in the Fuchsia; yellow and orange, as in the Calceolaria; or the colours in the varied plumage of exotic birds—the harmony is always beautiful, ever perfect. I will suggest a few contrasts:—Black and warm brown, violet and pale green, violet and light rose colour, deep blue and golden brown, chocolate and bright blue, deep red and grey, maroon and warm green, deep blue and pink, chocolate and pea green, maroon and deep blue, claret and buff, black and warm green."

The influence of light upon the flowers, the leaves, and branches of growing plants is so manifest that it can scarcely have failed to attract the attention of the most superficial observer. The familiar instance of plants standing in the window of a dwelling-house being attracted towards the light, and, unless frequently turned round so as to expose every part of the plant to its influence, becoming one-sided and unsightly, is well known to almost everybody. Many flowers are peculiarly sensible to the effects of light. The annual Sunflower, *Helianthus annuus*, may be cited as an example. Its stem is somewhat compressed, apparently to facilitate the movements of the flower, which, after following the sun all day, returns after sunset to the east to meet his beams in the morning. It was the opinion of Hales that the heat of the sun contracted the stem on one side, and thus occasioned the flower to incline that way; but if this were true, how should the flower return so completely at night? But this property of flowers following the course of the sun is not confined to flowers only; many leaves are influenced in the same way. A Clover field is a familiar instance of this kind. Composite flowers, or those with radiate florets, are most sensible to the influence of light, as the Daisy, the Sunflower (already mentioned), the Marigold, and numerous others belonging to different families, as *Nymphaea alba*, which opens and closes at pretty regular periods of the day; also the *Anagallis arvensis*, or Poor-man's Weather-glass, which latter, however, loses its sensibility in continued wet weather. On the other hand, the leaves of leguminous plants, especially those with pinnated leaves, are more sensible to the influence of light than those of any other tribe of plants. Indeed, in a vast number of cases it would appear to be the sole cause of their expansion; for in the absence of light the leaves droop, and actually fold over each other.

The extreme sensibility of the leaves of *Mimosa sensitiva* and *putida*, not only to light, but to the slightest touch of any extraneous body, is a good example of the exquisite sensibility of leaves. In dull sunless weather the leaves never fully expand; whilst at night the leaflets fold up close together. But the most remarkable instance of the kind is, perhaps, to be found in the spontaneous motion of the leaves of that very singular plant the *Hedysarum gyrans*. Its motions are independent even of the agency of light, or of any other stimulus whatever, only requiring the warm temperature of the stove, with a perfectly still atmosphere, to be performed in perfection. The leaves of this most singular plant are ternate, and the small lateral leaflets

are in almost continual motion, generally moving by sudden jerks; the movements of each separate leaflet seemingly independent of the other—at least, there is not in general any uniformity in their motions.

At one period only in the life of a plant is the agency of light injurious—viz., in the first process of the germination of the seed. A short time after a seed has been committed to the ground it begins to absorb moisture, and gives out a quantity of carbonic acid gas, even though no oxygen be present. In this case the process stops; but if oxygen gas be present it is gradually absorbed in the same proportion; at the same time the farina of the cotyledons becomes sweet, being converted into sugar. "Hence it is evident" says Dr. Thomson, in his "System of Chemistry," "that the farina is changed into sugar by diminishing its carbon, and, of course, by augmenting the proportion of its hydrogen and oxygen. During the process of germination a considerable amount of heat is evolved, which always happens when oxygen gas is absorbed. The whole process so far seems to be the work of chemistry alone. The reason, then, why the agency of light is injurious in the germination of the seed is because it tends to fix in the tissues of the embryo plant the carbon which ought to be thrown off."—J. DUNN.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

CONTINUE to ply the hoe freely among all growing crops, both for the destruction of weeds and for loosening the surface of the soil. *Cauliflowers*, let as large a piece of ground as can be spared have a thorough trenching, and a heavy dressing with manure to receive the latest crop, which should be planted without delay. This crop will prove the most useful of the season, and, with care in taking up the heads when ready and hanging them in a dry shed, it may be made to afford a supply from the end of October to January. The Walcheren is the best for this purpose. It grows more compact than other sorts; its foliage affords better protection to the head, being of a cup-like habit, and it does not open and wither so soon when hung up. *Pot-herbs*, care must be taken in gathering and drying the various sorts in request by the family. Choose a dry day, cut them just as the bloom begins to expand, and spread them thinly in a dry shed, which is preferable to drying them in the sun; when dry, they can be tied in convenient bundles and hung in their winter quarters. *Shallots*, to be pulled as soon as the tops begin to decay; if left in the ground after they are ripe they are apt to mildew and rot in wet weather. To be spread out in any airy place to dry before storing them away. *Tomatoes*, to be regularly attended to, keeping the shoots thin, and stopping them above a cluster of fruit; for if the plants are allowed to ramble and grow too freely, there will be but a poor chance of seeing a ripe crop.

### FLOWER GARDEN.

Trimming, staking, and pegging-down must be followed up at this period where neatness and order are essential. See that sufficiently strong stakes are applied to plants with heavy foliage and gross habits, such as Dahlias, Hollyhocks, Larkspurs, Phloxes, and tall-growing Asters. Keep Roses as much as possible free from insects, and, if time can be spared, dead blooms should be removed. Let Carnations and Picotees be layered; they make useful border flowers. See, therefore, that plenty of them are secured for next season.

### FRUIT GARDEN.

Look over all trained fruit trees frequently, for the purpose of stopping and shortening any gross shoots, and keeping their growth properly regulated; also get the young shoots of wall trees laid-in where not already done. Those who depend upon young plantations of Strawberries for fruit, should get them planted while the ground is moist and the weather favourable. If planted at once and properly attended to until the plants get established, a fine crop of fruit may be expected next season. Espalier Apples and Pears should have the leaders tied in, the superfluous shoots spurred; and attend also to choice Apples and Pears planted in the open quarters, but not trained. Remove superfluous shoots, and try the effect of tying downwards the points of some of the strongest shoots; it has been practised with very good results on trees inclined to grow too luxuriantly. Attend to the stopping and nailing of wall trees in general, and to the thinning of Grapes on the open walls.

### STOVE.

See that the young growing stock is not allowed to suffer for want of pot-room, and attend carefully to watering, giving manure water occasionally to all plants in free growth that enjoy it. Gardenias, &c., which have been removed to the conservatory while in bloom, should be replaced in heat as soon as their beauty is over, to allow them sufficient time to ripen their wood before the approach of winter. The Orchids to be allowed as much light as they will bear without injury, and using a very slight screen when shading is absolutely necessary.

### GREENHOUSE AND CONSERVATORY.

Some of the stove plants that have recently been brought into the conservatory will require attention to prevent them from being injured by damp, and it will, probably, be necessary to use slight fires occasionally, for the purpose of expelling the damp that may be produced in the house during such cloudy weather as we have had lately. In small, well-ventilated houses, damp will hardly be troublesome, but in lofty houses with but little ventilation, and the roofs overgrown with twiners, it may be very injurious. As there is nothing to fear from cold at this season, air should be freely admitted on every favourable opportunity to keep the atmosphere of the house as dry as possible. Recently-repotted plants will require to be watered with great care, as they will require but little, and will be speedily injured by a careless supply in dull weather. A quantity of stocky plants of the Scarlet and Variegated Geraniums, Heliotropes, late-struck Fuchsias, and Perpetual-flowering Roses, &c., should be duly encouraged for late autumn-blooming. The growth of specimen Fuchsias should also be encouraged, also the Cockscombs, Balsams, Globe Amaranths, Thunbergias, Gloxinias, Achimenes, Japan Lilies, Erythrina crista-galli, Chimney Campanulas, &c. Guernsey Lilies should be ordered in due time, they are pretty and useful autumn-flowering plants.

W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

SOWED Onions, &c., for salads, covering them with a wattled hurdle until fairly up. Planted out young Cucumber plants. Pegged down Vegetable Marrows. Potted in rich soil Capsicums and Chillies, and placed the pots into a cold pit, where by means of little air the plants can have something like hot-house treatment, as it requires a very fine season to get them ripe here out of doors, and if not ripe, though suitable for pickling, they are no use for making Cayenne pepper—a thing much run upon when home made, and free from red lead and other adulterations. Planted out some strong plants of *Tomatoes* out of doors against walls, but mostly in a row in a cold earth-pit, with branches behind them to form a sloping bank to run upon. In general seasons they do well thus treated. Planted out also in a similar pit as soon as emptied and cleaned of bedding plants, with good plants of tobacco, it being, on the whole, for destroying insects, just inferior to shag tobacco, and superior to much of what is sold under the name of tobacco paper. Thinned Turnips, sowed more. Planted out Savoys, Greens, and Brussels Sprouts. Gathered the first dish of Jeye's Conqueror Pea, otherwise No Plus Ultra—the finest Pea for colour and flavour, though not so large as Veitch's Perfection. After this until the month of October we will get little store set by any of the commoner Peas. I have repeatedly advised amateurs in or near towns to purchase their early Peas, and if they can grow only a few rows, to have these of the best Marrows, when they will obtain such a treat as they that get their Peas at market never can know. Sowed successions of *Spinach*, generally following with one crop as soon as the preceding one is an inch in height. Pegged-down older *Spinach* running to stalk. If between Peas, frequently cut it over and lay it along the rows of Peas, which thus acts as a mulching. Pricked out Leeks, young Cauliflowers, Broccoli, which may thus stand and grow until we find more space for them, and watered Cauliflowers, &c., swelling their heads, with danglehill water.

### FRUIT GARDEN.

Much the same as preceding weeks, nipping the summer growth of fruit trees, watering trees in pots, soaking the soil in orchard-houses with manure water, but doing it gradually a little at a time; syringing to keep down or keep off red spider. Watered Melons that were set, and those ripening freely and very dry on the surface watered through tubes at the bottom of

the roots, leaving the surface dry; just dewed the foliage gently after hot days. Protected Strawberries and Raspberries, &c., out of doors, and commenced layering *Strawberries* in pots for forcing. We use many plans for this purpose, such as taking up the runners as soon as formed, and even before they root, and fastening them by a piece of the stem into rich, light soil, above a slight hotbed. Here shaded and syringed, they soon root, and then can be lifted with balls and potted. The layering system is still, however, a good one, and some layer in the pot in which they mean to fruit. I prefer layering in what are called small 60-pots, taking these to the bed, placing one crock in the bottom, filling them with rich, light loam, placing the layer firmly on the surface, using the earth as a firming agent, or placing a pebble or a crock over the runner to prevent its being blown out by the wind. These frequently sprinkled will be filled with roots in a fortnight or three weeks, and will then be firmly potted in their fruiting-pots. We are waiting to get ground cleared for those grown in pots. Our small plants of Queens have done extra well this season.

#### MUSHROOMS.

I have forgotten to mention that we have had still a few in the house, and abundance in the thatched-roofed open shed. The weather being rather cold we have placed hurdles along the sides to keep the place warmer. We only do a little bit at a time. We are just preparing the third piece, and are not at all particular as to the bulk of the bed, if we get a few inches of rather fresh droppings for the surface. One great secret is firm treading. This and next month are generally the best for making spawn with least trouble. See previous directions.

#### ORNAMENTAL GARDENING.

The week has been a busy one, potting all sorts of plants, putting in cuttings of Pinks, Carnations, &c., double Rockets, Campanulas, &c., Roses, &c., budding Roses, tying-up Dahlias, Hollyhocks, &c., securing flower-beds, mowing lawns, rolling walks, and top-dressing Verbena and Calceolaria-beds, &c.—R. F.

#### TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**HOLLYHOCKS (W. H.).**—Mulching round them will keep the soil moist, prolonging and invigorating their blooming. Your gardener was quite right. The large leaves ought not to have been removed: their removal diminished the vigour of the plants, whether they show symptoms of such weakening or not.

**STORING POTATOES (H. A. D.).**—We never pit Potatoes, but put them under a dry shed in layers alternating with coal ashes. Over the outside a layer of straw may be put to exclude frost. In no mode can they be preserved better. Dry sand might be substituted for the ashes, perhaps, without deducting from the preservation of the Potatoes. The object is to check evaporation, to exclude air and light, and to keep cool.

**STORING APPLES (Idem).**—An attic is never a good place for storing fruit—at times it is too hot, at other times too cold, and always too dry. If it was thatched thickly with straw inside, and the roof painted white on the outside, the evil incidents might partly be diminished. Ventilation would be desirable, but moister air and darkness also. See what Mr. Robson says to-day about fruit-rooms.

**VINE LEAVES BROWN (A. B. Cole).**—The leaves have every appearance of being thoroughly ripened. If the wood is getting brown and hard they are just as they ought to be. If only a few are thus getting brown and yellow, and the rest and the wood are yet green, the plant must have had a check, such as a Geranium being left quite dry, when the lower leaves wither as a matter of course.

**SWEET-SCENTED VINE (A. A. Smith).**—Now you have sent a specimen we can determine the name. It is the *Vitis riparia* or River-side Vine, sometimes called *V. odoratissima*, or Sweetest-scented Vine. It is a native of gravelly river-banks in Pennsylvania and other parts of North America, but female plants of it are rarely found north of the Potomac river. Yours is a male plant, and consequently unfruitful. As you only require it for its leaves and fragrance you may train it like any other hardy climber, and autumn-prune it as you do your common Vines.

**CARROTS ON CLAY SOIL (M. G. C.).**—If you improve the staple of the soil by the admixture of the pond sand, &c., as you propose, and if you turn in a little of the manure with the bottom spit when digging preparatory to sowing, we think you will succeed. We should like you to try improving the staple with the cocoa-nut fibre dust.

**PELARGONIUMS OVER-TALL (Majestic).**—They have too little light, too much heat, and the soil is too rich. Turfy loam without any leaf mould would be better than your mixture. Cut the plants down when finished blooming, re-pot with the turfy loam, keep them cooler, and expose them to more light.

**PEAR TREE UNFRUITFUL (G. K. Sevenoaks).**—The Pear tree about six years old and 10 feet high we would prefer lifting and replanting again about the end of September. Nip the points of the shoots now. After thus lifting, the tree would need to be shaded or syringed in sunny days. If you dislike that trouble, cut a trench round the tree 3 feet from the stem; undermine it so as to get at the tap roots, which cut clean away and fill up with fresh poor soil. In doing this, the roots beyond the three feet had better be saved and planted near the surface. Syringe a little during hot days if the leaves flag. This we would do in the end of August, as there is no fruit, and that will give time for fruit-buds to ripen for next year.

**PEAR-TREE LEAVES DISEASED (A Subscriber).**—Excessive moisture at the roots and too little sun on the leaves probably is the cause of their warded appearance. If the trees are fruitful a good drain would remedy the evil. If not fruitful, the roots had better be raised and fresh poorer soil put about them.

**YOUNG WELLINGTONIAS DYING (T. O. G.).**—We have noticed nothing of the sort on older plants. It would be wise to shade the young plants a little, and to have the foliage dry before the sun shines strongly on them. Baldry's Scarlet Delianee Rhubarb is grown extensively about Enfield, and is very productive. All Rhubarb to be crisp likes plenty of nourishment, and sucks in manure water greedily.

**GOOD GRACIOUS PANSY (Madeline).**—Double Pansies never seed at all, and the only way, and the time to get a "slip" of it is to apply for it to Messrs. Carter & Co. next April. It will grow well in your part of Lancashire if any other Pansy grows in that smoky atmosphere. We have reason to believe that this Pansy is not a novelty.

**BASKET PLANTS (Idem).**—*Convolvulus mauritanicus*, when we first saw it at the end of March, was the prettiest basket plant we had ever seen. *Nierembergia gracilis* is very good for all the summer and autumn; and so are all the new *Tropaeolums*, and all the new fancy *Petunias*, and the fine variegated *Vines* are good for out doors as well. So are several little *lilac Campanulas* and *Labellias*; but for the dead of winter none are better than the German Ivy plant, which, of course is not a real Ivy, and Ivy-leaved *Geraniums*.

**ECREMOCARPUS SCABER (M. A.).**—There is not the least fear of your *Ecremocarpus* against a south wall doing badly. There is nothing at all the matter with it; on the contrary, it is prospering, and all you will have to do will be to cut off the lower leaves when they turn yellow. It is the nature of the plant to let go the leaves at the bottom as fast as the parts ripen properly; and there is not a worse sign in an *Ecremocarpus* than to see the bottom leaves green any day from the end of May to the time of the frost. We have seen it with a stem 17 feet long, and bare and pliable as a cable, on a gentleman's cottage on the south west side of the Hereford-hire Beacon, at the end of the Malvern Hills, where it stood out ten or a dozen years. It used to be pruned close in November, and the bare pliable wood was folded up in straw and matted for the winter, and the roots were protected as you do. That was previous to 1840.

**RETARDING ROSES (Young Amateur).**—There is no method for keeping back Roses when showing bloom, or of hurrying them on at that period, unless they were in pots, when they could be removed out of the sun into the coolest place about the garden to keep them back, or to be put under glass for getting them on a little faster. *Verbenas* do as badly as yours this cold season in all the public gardens round London; to refresh them with a rose-pot of an evening is by far the best way to keep the dust off them, and make them look as if they were at home, which very few of them have done as yet this season. You ought to have the *Cottage Gardener's Dictionary*, it is just written for such as yourself, and by men who knew the value of sound instruction.

**NATIVE PLANTS (H. A. D.).**—They were duly received and forwarded to Miss Gower. All are obliged. The *Orchises* were *apifera*, *comopsea*, and *pyramidalis*. Two of the other plants were not sufficiently open to be identified.

**STAMPED COPIES (Patelin).**—A stamped copy of this Journal can be sent to you, and from you to a friend, and back to you, all by post within the week, without any other stamp than that impressed on the sheet by the Stamp Office.

**STRIPED PETUNIA (O. Barton, the Gardens, Oxton, Notts).**—One of the best striped single *Petunias* we have seen, and if a constant flower in the same degree as Mrs. Ferguson, for instance, a decided acquisition. The flowers set (four in number) have uniformly a broad bar of bright magenta rose running up to the sinuses of the segments, the segments having in addition a lozenge-shaped tip of the same colour, the tip sometimes joining with the bar, sometimes not. The rest of the flower white. Described in other words, we might say the segments have each a broad V-shaped white mark, the rest being magenta rose.

**VINES VERY VIGOROUS (Three-years Subscriber).**—The swelling of the young shoot to so large a size is a very common affair, and shows the vigorous action of the roots. Why not place a small rod, to which tie the old stem and the new carefully instead of letting the latter throw itself off, or drop off by its own weight. This would seem as simple a matter as securing a common plant from the wind. The stem will partake of the strength of the young shoot if you wait long enough. We can offer no explanation about the shoot dying down, unless the plant was allowed to be extra dry; the mere syringing would never have any such effect. Of course, boiling water, or water very hot, would soon do the job; but, then, what wretches to do such a thing if done willingly. We find out the reasons of such disasters, sometimes years afterwards, where the perpetrators can make a joke rather of their ignorance than their intended ill-doing.

**BULB FLOWER (C. C.).**—You did not manage the flower right for examination. It ought to have been sent in a fold of the finest oilskin, and a piece of one of the leaves should come with it. Your flower was crushed and glued to your letter, and then dried into a mere film.

**DOUBLE PANSIES (A. W. F.).**—Many thanks, but you mistake the meaning. There have been many double Pansies within the last twenty years; there are four now in England, and one in Ireland, and it is not over ten years since Messrs. Downie & Laird had lots in Edinburgh, and in their catalogues. But, like the "foundling" Tea Rose with Mr. Cant, and the very old and "foundling" *Calceolaria plantaginea* with the Messrs. Veitch, any good double Pansy of thirty or forty years back will sell now, and give as much satisfaction as a new sport or seedling.

**OLD VINES UNFRUITFUL (One in a Fir).**—If the wood on the old Vines is so strong, but unfruitful, we should think it proceeds from the wood not being ripened so as to be thoroughly exposed to the sun in summer, and not getting fire heat to harden it, more especially as the roots are most likely deep. The easiest remedy if the roots are deep would be to make a deep drain in front, remove a good portion of surface soil so as to get near the main roots, and top-dress with lime rubbish and sandy loam, with a little horse-dung, burying it shallowly, and giving a yearly top-dressing of an inch or two of the same kind of compost as the roots rise into it. It would require much care to raise the roots of such Vines nicely. There can be no question of the Vines doing well in the pit if that too is drained and has a loose bottom, and there would be the great advantage of having the roots completely under control as to moisture and warmth.

**PROPAGATING CRASSULA COCCINEA (W. W.).**—Make cuttings of the tops of the offsets of this *Crassula*, and let them be about 4 inches or 5 inches long, not more. They will root fast in half sand and half leaf mould, or any light soil, without bottom heat or being under a hand-glass or frame. They would now root in the open air. When you pot them, give them the same soil as for *Geraniums* with twice the quantity of sand, and keep them rather dry in water upon a shelf near the glass in the greenhouse.

**ROSES IN POTS (Idem).**—After they ripen the wood in October, you should prune them and plunge the pots in the open air till the beginning of January unless it come hard frost, when the China and Tea ones would be better in a cold frame. Put them all in the cold frame early in January, after seeing that the drainage is right and that the roots are not too much cramped, and give them a little fresh surfacing of very rich compost. Let them remain there till they come into leaf, and then you may force them gently or merely bring them into the greenhouse and grow them as you did before. See that no water lodges where they are at rest and planted.

**MILDEW ON GRAPES (J. S.—, Fulham).**—Dust leaves and berries—in fact the whole Vine—with flowers of sulphur. Do not syringe, but keep the air moist by watering the path of the greenhouse, and ventilate freely.

**MELONS AND CUCUMBERS WITH IMPERFECT FRUIT (W. H. G. McKnight).**—You have four times too many shoots on your Melons, or the leaves are too large and shade each other with that rampant growth; and the tale would imply that the side shoots are not stopped a joint or two before the fruit, when it appears with the blossom. It is dangerous for amateurs to cut back Melon plants as gardeners do occasionally. Thin them, give them less water, and where you find many flowers, at once, set them with pollen, and stop the shoots two joints above the fruit. The secret is to get a crop set at once, even if it must be thinned.

**STEPHANOTIS FLORIBUNDA NOT BLOOMING (Idem).**—As it is growing so fast and flourishing, the best way is not to prune it at all. Pruning is the ruin of all strong climbers in-doors or outside. Give them headway the whole summer. In winter thin out instead of pruning back, and the *Stephanotis* will bloom from end to end of the longest shoot in the house. No plant blooms more freely under that system.

**NAMES OF PLANTS (J. O. Attingham).**—1, *Spiraea salicifolia*; 2, *Saxifraga hypnoides* var.; 3, *Clematis erecta*; 4, *Dentizia scabra*. There is no better book for your purpose than Bentley's "Rudiments of Botany." (W. T.).—1, *Lathyrus pratensis*; 2, *Vicia cracca*; 3, *Myosotis silvatica*; 4, no leaves, some labiate; 5, *Prunella vulgaris*. (*Nemo*).—A form of *Polystichum aculeatum*, rather narrower than the type. (*J. G.*).—1, *Lotus corniculatus*; 2, *Gallium palustre*; 3, *Viola tricolor*; 4, *Eriophorum angustifolium*; 5, *Holcus adunatus*; 6, *Verbena officinalis*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

JULY 29. NEWMILLERDAM. Secs., Mr. J. Turner, Walton; Mr. W. Pashley, Newmillerdam.  
 AUGUST 2nd, 4th, and 5th. SHEFFIELD. Sec., Mr. George Westerholm, 49, Queen Street.  
 AUGUST 25th, 26th, 27th, and 28th. CRYSTAL PALACE. Sec., W. Houghton. Entries close July 26th.  
 SEPT. 4th. WAKEFIELD AND WEST RIDING. Sec., Mr. J. Crosland, jun. Entries close August 23.  
 SEPTEMBER 9th. WORSLEY AND ARMLEY (near Leeds). Sec., Mr. Robert Hoyle, Armley, near Leeds.  
 DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.

### CRYSTAL PALACE POULTRY SHOW.

"They say," said one provincial to another at the International Exhibition, "there were fifty-eight thousand people here yesterday. Now just look here: Pedlington is a biggish place, is it not? Well, that has only four thousand inhabitants. Just fancy fourteen times the population of Pedlington in this building, which, large as it is, is small compared to our town." It struck us, as we heard this, there was force in the way in which the question was put, and with the homœopathic dose of conceit and self-satisfaction which a Londoner has a right to indulge in, we chuckled and said, "Send all the world to London, and we have room for all." When we got into the streets we were elbowed and shored (excuse the expression, it is the correct one), in all directions. The streets were too small. We longed for

space to move, and space to breathe. We could understand the villager who, returned from London, became the oracle of his village (it was before railways), and having described all he had seen and heard, said "only one thing was wanted as an improvement, and that was, instead of being built in town London should have been built in the country." We know nothing so refreshing as the contrast—the rush from a crowd, lack of room, and suffocation, to space, fresh air, and an open landscape.

We started with the intention of reminding our readers that the entries for the Crystal Palace close on the 26th of this present month. So many temptations to giddiness surround people, there are such multitudes about, and there is such a whirl, the amount of what is called pleasure so nearly approaches to business, that we feel bound to use our flappers to recall people to the world as it was last year, and probably will be next year, and to remind them of the important fact mentioned above.

We expect we shall see many of our foreign friends who turn from science to animated nature; men like the author of the book we have lately been quoting from. We hope there will be hundreds such, and that our best yards will send specimens that will worthily represent us.

The general management needs no encomium from us. We have many times stated we consider this Show one of our holidays, and at this season of the year when the gardens (like the silver rims of the spectacles Moses bought), are worth twice the money. The addition of the Poultry Show makes us long for the time.

### FOOD FOR POULTRY.

Is barleymeal equally nutritious and wholesome for fowls as oatmeal? The fowls prefer the latter, but it is so high in price here, 23s. or 21s. per cwt., that it is too expensive for general use; the barleymeal is only 9s. per cwt. Are wheat cleanings, or "screenings" as they are here called, as good food for fowls as pure barley? The "screenings" of the wheat contain besides the smaller grains of wheat seeds of other kinds, and the fowls prefer it to barley, and it is less expensive, 6s. per cwt.

What description of food is best for Carolina and other Ducks of that class? Should they be fed on grain or soft food?—AMATEUR DE VOLAILLE.

[Oatmeal is certainly the best poultry food there is; but it is not exactly oatmeal as used for human beings—it is the oat ground entirely without taking away any part whatever of it. A peculiar process is necessary to prepare the stoves for this operation, and that being accomplished there is no difficulty. It is used exclusively in Sussex, and goes there by the name of "ground oats" and not oatmeal. Barleymeal hardens and heats poultry. Wheat screenings or cleanings amuse fowls, but do not feed them. All such things as these are "fond inventions" if they are intended to be substitutes for food. Our experience is that nothing is so cheap as the best corn or meal.

All Ducks like food that floats on the surface of the water. For this reason bread and meal are favourite food with them, although corn is their dependance.]

### REVIVAL OF PRESTON POULTRY SHOW.

WILL you allow me through your columns to point out to the parties interested the most excellent opportunity afforded by the celebration of the Preston Guild, in September next, to re-establish and carry out the Poultry Exhibition, which was for many years held in that town and attained a very high character? The Guild is held once in twenty years, and on this occasion there will be balls, concerts, processions, reviews, agricultural and other exhibitions, and many other entertainments, extending from the 1st to the 8th of September.

To this I would propose that a magnificent Show be added for two or three days of all kinds of poultry, Pigeons, Rabbits, song birds, and, if possible, dogs. Under good management, and on an extensive scale, such an exhibition would answer well financially, and would afford a fine chance to many a cue of being—AN EXHIBITOR.

### RESTLESSNESS OF AN ARTIFICIAL SWARM.

I MADE an artificial swarm on the 19th of May from a Ligurian stock obtained from "A DEVONSHIRE BEE-KEEPER" last year, which swarm has done very well under the old queen,

On the 4th of June, as several queens had arrived at maturity, I drove part of the bees out of the old stock to form a second swarm; and after a great number of bees had ascended into the upper hive, and I had heard a queen pipe inside, I removed it and put the bees into a bar-and-frame hive, which I placed in the situation of the old stock. The stock-hive was then placed on a separate stand; and having heard a queen piping inside, I congratulated myself on the success of my experiment.

Two supernumerary queens were cast out of each hive, and for some time they worked well and seemed all right. About ten days ago the bees of the second swarm appeared very restless, running about the entrance and front of the hive, so that I concluded they had lost their queen. I examined the hive on the 25th of June, and finding neither brood nor queen, I took two frames full of brood of all ages out of the swarm of May 19, and put them into the swarm of June 4.

Yesterday (July 3), I examined them, expecting to find royal cells, but found they had made no preparations for raising a queen, although they have been quiet and worked well since they received the brood. The old stock became very irascible, and, as they carried in little or no pollen, I concluded all was not right; so yesterday I examined their hive, and found it contained no brood, and having captured the queen found one of her wings imperfect, and suppose she is still a virgin. I put her in a bell-glass, with a few workers and some honey, over the top of the hive with perforated zinc between, intending to see if she could fly, but found her nearly dead this morning (July 4). I send her herewith by post to "A DEVONSHIRE BEE-KEEPER" for examination, and shall feel obliged by his informing me whether she is a virgin or not, if the point can be ascertained after death.

I found a little brood in one of the combs of the second swarm yesterday, which I expect will turn out to be drones laid by workers; they are in worker-cells, and not yet sealed over.

A hive of black bees treated in the same manner has been much more fortunate. The second swarm obtained in the same way was placed in a unicomb-hive; and although one of the queen's wings is imperfect, she has been duly impregnated. Are artificial queens more liable to defects in their wings than natural ones, or not?—J. E. B.

[If you had opened and examined the hive at the time the bees were so restless that you concluded they had lost their queen, you would probably have been convinced of your mistake by discovering her majesty a close prisoner amidst a dense cluster of her subjects. The only author who, as far as I can remember, notices this remarkable phenomenon is Mr. Langstroth, who says, "Bees are sometimes so excessively agitated when their queen leaves for impregnation, that they exhibit all the appearance of swarming. They seem to have an instinctive perception of the dangers which await her, and I have known them to gather around her and confine her as though they could not bear to have her leave." Mr. Langstroth is, however, most probably wrong in his conclusions, since it can scarcely be affection which prompts a confinement of such severity as frequently to result in the permanent mutilation of the unfortunate captive. "J. E. B." remarks that the wings of both his young sovereigns were defective, and asks if this is to be attributed to their being what is usually termed artificial queens. To this I should reply, Certainly not. The defect in the wing of the one he sent to me was but trifling, and was evidently not congenital, having doubtless resulted from ill-usage by the workers, either before or after her wedding flight.

My own experience this season of the maltreatment of queens by their subjects is so extraordinary that I will briefly relate it. I need only advert to the death of the last of my foreign queens, as that story was told at length in page 110, and pass on to subsequent events. On the 3rd June I found a queen, which was hatched on the 12th of May, closely imprisoned by her subjects. Although released the next day, one of her hind legs was permanently crippled; and after keeping her till she was a month old, without any appearance either of impregnation or of egg-laying, I ultimately made away with her, although I now fancy I was somewhat hasty in so doing. The next case occurred on the 16th of the same month (June) with a queen hatched on the 30th May. She had evidently just returned from her wedding trip, as she possessed the undoubted sign of impregnation noticed by Huber. No evil consequences followed in this instance, and eggs were laid three days afterwards. Another queen hatched on the 29th May was twice closely imprisoned—viz., on the 19th and 25th of June. The bees at both times

appeared greatly excited and rushed about the entrance and front of the hive, apparently in search of her. On the 29th of June, being then thirty-one days old, she was none the worse for the ill-usage she had received, but commenced laying worker-eggs in spite of Huber's dictum that queens whose impregnation is retarded beyond the 21st day lay only drone-eggs. Again, on the 23rd of June, a queen hatched on the 31st May was confined and so maltreated, that, although she has turned out remarkably prolific, she has entirely lost the use of one of her second pair of legs. The last and most singular case is, however, that of a queen, one year old, which I found a captive on the 3rd instant, and which two days afterwards I discovered to have lost a part of one of her hind legs, the foot having (so to speak) been amputated at the ankle joint. Notwithstanding this mutilation her fecundity is not the least impaired, and she is still capable of performing every royal function.

All these proceedings (especially the last, in which a fertile queen was imprisoned and actually maimed by her subjects), are so extraordinary, and are so opposed to what we have all heard of the unswerving fidelity and devoted loyalty of bees to their sovereign, that I acknowledge them to be quite beyond my comprehension, and, therefore, entirely refrain from theorising; merely surmising that the inclemency of the season (our English summer having set in this year with more than its usual severity), and consequent scarcity of honey may have something to do with them. Whilst honestly confessing my own sagacity to be entirely at fault, I am not without hope that other apiarists may be able to assist in elucidating the mystery, and shall be obliged to any one who may endeavour to do so through the pages of THE JOURNAL OF HORTICULTURE.

The queen sent was undoubtedly impregnated. A microscopic examination of her spermatheca revealed countless thousands of spermatozoa which still retained sufficient vitality to exhibit their peculiar rotating movements; whilst the ovaries were well developed and filled with eggs, which the microscope demonstrated to be connected together by their ends like so many strings of sausages.

I have no doubt that the swarm of the 4th June possesses an impregnated queen, although she eluded your observation. The occurrence of fertile workers is so rare a contingency that it may be altogether left out of the calculation.—A DEVONSHIRE BEE-KEEPER.]

#### THE SEASON—HYBRID LIGURIAN QUEENS— LATE BEE FLOWERS.

I PERFECTLY agree with Mr. B. Fox, that the present season has been one of the worst we have had for years. I have been feeding all my hives for more than a month, as I found they were not doing well, and on examining some of them found that it was from starvation by cold and want of food. I have had about a dozen swarms, and should have had more, but the weather was so bad that some came off, but the queen went immediately back and destroyed the young queens, and had I not fed the swarms I do not think that one would have existed. If the Ligurian queen throws both Ligurian and black bees, how do you know when she herself is pure bred? as I observe one of my queens from M. Hermann breeds very fine Ligurian bees, and the other are darker and not so much yellow, but many of the drones are better marked, whereas some of the drones from the queen that throws the best bees come very dark, and some well marked. Would the "DEVONSHIRE BEE-KEEPER" give us his experience on this subject? as no one in England understands them so well, and there is no doubt they are superior in every respect to the black bees; and I do not find them when swarming more inclined to attack you than the black bees, but I have always found that the weather has a great influence on them, and especially when swarming.

Can Mr. Fox, or any of your bee-keepers say, should the weather change, what flowers they will be able to get honey from? as I observe mine are able to get plenty of pollen, but very little honey, and I do not observe anything now left but the white clover, and, as "AN OLD BEE-KEEPER" remarked the other day, if we should have a bad ling (heather) season, it will be all up with the bees.—A. W.

[M. Hermann's queens were certainly not always to be depended upon. I should say that the one which breeds the yellowest workers is probably pure, the other impregnated by a black drone. The variation in the colour of bees bred by the best

Ligurian queens is often very remarkable; but with regard to the drones it must be remembered that the first cross does not affect them, so that a hybridised yellow queen may possibly breed even better drones than one which has had a true Italian impregnation. I believe what is left of the white clover and heather when within reach, is nearly all the pasturage that now remains for our bees.—A DEVONSHIRE BEE-KEEPER.]

### BEEES IN JAMAICA INCREASE THE SIZE AND SUBSTANCE OF THEIR CELLS.

I AM very much obliged to your several correspondents for their information in regard to the supposed differences in the bees of Britain. Possibly some few of your readers may be interested in the following case:—The hive bee was introduced many years ago into Jamaica. Having seen it stated that the cells were larger, I procured (through the kindness of Mr. R. Hill, of Spanish Town), some bees and comb. The bees have been carefully examined by Mr. F. Smith, of the British Museum, and pronounced to be the common species. I also secured the hind and front legs, the antennæ and jaws of worker bees from Jamaica and my own stock, and could detect no trace of difference in size or other character. But here comes the remarkable point—the diameter of the cells is conspicuously greater in about the proportion of 60 to 51 or 52 than in our English combs. The wax seems tougher, and the walls, I think, are thicker. The cells in parts of the comb were much elongated, and the whole hive contained a great quantity of honey. It certainly appears as if the instinct of the bee had become modified in relation to its new, hot, and rich home. But it seems to me an astonishing fact that the cells should have been made larger without a corresponding increase in the size of the body of the architect.—CHARLES DARWIN, *Down, Bromley, Kent.*

[The extra thickness and toughness of the wax employed by the bees in the torrid climate of Jamaica render the combs better capable of resisting the heat. The increased size of the brood-cells would better protect the larvæ from the same excessive heat by interposing a wider air-filled space between them and the walls of the cells; for air is one of the worst conductors of heat. If such be the true explanations of the changes adopted by the bees, they are additional instances of instinct approaching closely to the confines of reason.—EDS.]

### BEEES AS CHEMISTS.

I AM very much obliged to Mr. Shesrer for his kind attempt to prove what we both believe—viz., that simple syrup is changed by bees before it is stored in their combs, although I am by no means surprised at the result.

I really see no better test of the truth of our opinions than that which I have offered more than once, and which I now beg to repeat. I have some simple syrup in comb, made and stored by bees so late last autumn that all honey-gathering was over at the time, and this I am willing to submit to the Editors of THE JOURNAL OF HORTICULTURE, or such other tribunal as they may point out. If this is not satisfactory to our opponents, I submit that the burden of proof lies with them. Supposing them to be right, and that bees always store their food unchanged, what can be easier than to produce a bit of sealed comb in which simple syrup may be found unaltered? But this has not yet been done, although I offered a good stock of Ligurian bees to any one who could effect it, and I am well assured that it cannot be done. A few weeks ago "A NORTH LANCASHIRE BEE-KEEPER" sent me a bit of comb in which were what he considered to be crystals; but these turned out to be only esudied particles such as are constantly to be found in true honey, and from which they did not differ in any respect when examined under the microscope.

The plain fact that no one can produce simple syrup which has been stored by bees in the same state in which it was given to them, appears to me quite sufficient evidence of the correctness of the opinions expressed upon this subject by—A DEVONSHIRE BEE-KEEPER.

[We think our friend is rather unreasonable. The proof is required from those who maintain the affirmative; and the only conclusive proof, we think, would be to have, in a hive already combed, a swarm—an artificial one for example—and to

confine the swarm in a light room or greenhouse entirely without plants, but with a full supply of sugar syrup, and nothing else. If the bees converted that syrup into honey, the problem would be solved. Mr. Shearer's experiment merely shows that the bee, by the act of swallowing the syrup, does not convert the sugar into honey. It would have been more conclusive if he had allowed the bee to fly about in an empty room for an hour before he emptied its honey-bag.—EDS. J. OF H.]

### NON-IRASCIBILITY OF LIGURIAN BEES—FUMIGATION—BEEES LEAVING THEIR HIVE.

I THINK the Americans are wrong when they say the Ligurian are more irascible than the black bees. I suppose they judge the bees by themselves, as I believe the two mixed are very irascible, as I nearly always find the bees that come at me are the black ones. I consider the Ligurians are superior to the black; they are prettier, more prolific, and are quicker in finding out honey pastures. I have a queen I got from M. Hermann that swarmed four times in five days. The swarms are very fair and doing well, although we have had bad weather in this part (South Durham); and I observe the bees have not been able to make much honey, and very many swarms have gone back to their parent hives from starvation. Two of last year's swarms (black bees) I took the bees from the other day did not appear to have a quarter of a pound of honey each. I have, therefore, been feeding my hives.

FUMIGATION.—Not being so expert with bees as "A DEVONSHIRE BEE-KEEPER," I have generally adopted it as the only way to get the queen from a hive or a swarm, and if not overdone, do not see that it injures the bees, and certainly seems to be the only plan of joining without fighting. I have a hive of Ligurians to which the black bees were added now nearly two years since by fumigation. I observe many black bees among them, and, therefore, am of opinion that bees live much longer than six months; and those bees do not appear to have suffered from the fumigation.

BEEES DESERTING HIVES I think may arise from many causes. I had two last-year's swarms that appeared doing well early this spring; but as the weather got warmer I did not see so many about, and when I looked found only three or four bees in one, and in the other not more than a dozen or so, but did not see a queen in either. The bees from one I am almost certain joined the next hive; but what became of the bees from the other I do not know. I also had a hive that had swarmed twice last year, and had when brought from the moors 36 lbs. of honey, and was well off for bees in the beginning of the season; but I observed some of the Ligurians found it out, and robbed it; consequently nearly all the bees went with the robbers. About a month since I fumigated it, to see if there was a queen, when I found only about a handful of bees, and after taking out some of the comb observed the queen at the very top of the hive (straw), I therefore returned the bees, and at ten A.M. removed the next hive on another board, and placed this one on its board, since which it seems to be doing well. I have found a great deal of honey candied in three or four hives this last winter; what can be the cause of this? I do not find the Ligurians attack more at swarming than the black ones; but should the weather be windy and wet I think both will do so.—A. W.

[You are mistaken with regard to the longevity of bees. The existing black ones have either strayed from other hives, or are bred by the Ligurian queen. Honey candies by exposure to cold.]

### LIGURIAN BEEES IN AMERICA.

It will be perceived from the following advertisement which we copy from the *Prairie Farmer*, that Ligurian queen bees fetch high prices on the other side of the Atlantic:—"ITALIAN QUEEN BEEES.—We guarantee the purity of all queens, bred by us, and their safe arrival at any express office. Price for a queen of a beautiful colour in a small box with a few workers 10.00dols.\* or 5.00 dols. when not warranted to be impregnated by an Italian drone. Ministers of the Gospel are entitled to use 'Langstroth's Moveable Comb Hive' without charge, and can have warranted queens for 5.00 dols.—L. L. LANGSTROTH & SON, *Oxford, Butler County, Ohio.*"

\* £2 1s. 8d. sterling

## THE CROW AND THE FARMER—A FABLE.

"FROM a forthcoming volume of Fables of Æsop and others, done into modern verse, and with copious illustrations drawn from the life by able artists, and the speeches of the several animals, birds, and reptiles, rendered from the ancient shorthand of one who was familiar with their several tongues."

The Crow is walking all over the field  
As if he were counting how much it will yield;  
He's as clear at his ease as if it were known  
That that very big field and the grain were his own!  
And there isn't a blade, and there isn't a shoot  
That he doesn't inspect from the tip to the root.  
And when he finds one that he thinks locking ill,  
He goes at it and digs it right up with his bill.  
And wherever he turns up a little green shoot,  
He gobblea up something he finds at the root;  
And he marches along with a satisfied look,  
As much as to say "I'm a very good rook!"

The Farmer is strolling all over his land,  
With his dog at his heels and his stick in his hand,  
All at once he pulls up and he comes to a stand,  
Then he walks very fast, and he looks in a rage,  
And he'll do for the crow, that he will, he'll engage!

He is all in a pet,  
In a fume and a fret,  
At the corn he sees pull'd;  
And he spreads out a net,  
And it happens just so  
That he catches the Crow,  
And he holds him quite tight,  
And he won't let him go!

And he calls him "a thief, and declares that a peck  
He has pulled of his oats, and he'll twist off his neck!"  
And that instant he's going his fury to wreck,  
The Crow can do nothing the murder to check.

"He declares and protests,  
Not the oats but the peets,  
He has pick'd from the roots  
Where they lay in their nests!

And it's never the grain that he preys on at all,  
But the worms and the grubs be they ever so small.

And he knows by the way  
The blades droop and decay,  
Where these ruinous swarms,  
Gnaw the roots in the lay!

What he looks for and kills, eats, hunts up, and stabs—  
But he can't get believ'd—are the worms and the grubs.

And but for the Crow  
So fast they would grow,  
They'd be millions of millions,  
And no grain to mow!

And yet for his labour, and watching, and use,  
Why the best that he meets with are blows and abuse!  
He can't think how the Farmer can he so obtuse."

The Crow is hanging the corn among  
He argued in vain, and his neck it was wrung;  
And the Farmer he's getting a poor little yield,  
Of very small oats from his very large field!  
He looks at the reapers, he looks at the sheaves,  
He pulls up the stubble, and sees and believes;  
For he finds that the worms have been at it again,  
And have cut at the roots ere he cut at the grain,  
And he feels very bad, and he doesn't quite know  
How it is, but he can't bear to look at the Crow.

## MORAL.

Watching the crops from day to day,  
The birds on preying insects prey!  
Grubs, worms, that else in endless swarm,  
Would strip the Farmer and the Farm,  
They slay and keep the crops from harm.  
The bird may pick some random grains,  
But earns them fairly for its pains,  
And bushels full the farmer gains!  
The French their birds have shot and eat,  
And find in wonderment complete  
They've neither fruit, nor oats, nor wheat!  
Do nothing on suspicion merely,  
Investigate each matter clearly,  
Or, blundering, you'll repent it dearly.

—(Western Times.)

ROWAN WOLF.

**EPSOM RACES.**—The course at Epsom is in the midst of downs, intersected by three hills in parallel lines: in the vales between these hills the champions entered the list. Several of the spectators came in coaches, which, without the least bustle or dispute about precedence, were arranged in three or four lines, on the first of those hills; and, on the top of all, was a scaffolding for the judges who were to decree the prize. The scaffolding was the goal which bounded the race, and the starting-post was at the head of the outer vale of the second hill: four horses starting from thence ran in this vale about the length of a mile, turned round by the next hill, to the height of the starting-post, and at length reached the hill, on which stands the scaffolding, where he that came in first was declared the victor. The prize is not adjudged till after three heats; and to him only

who has won two out of three. If he be so successful as to win the two first, the third is dispensed with, which was what happened at the race where I was a spectator.

There are neither lists nor barriers at these races: the horses run in the midst of the crowd, who leave only a space sufficient for them to pass through; at the same time encouraging them by gestures and loud shouts. The victor, when he has arrived at the goal, finds it a difficult matter to disengage himself from the crowd, who congratulate, caress, and embrace him, with an effusion of heart which it is not easy to form an idea of without having seen it.

The deference to the victors is not confined to these transient homages. All the houses of country gentlemen, all the inns, are lined with pictures of horses, painted or engraved, in various attitudes of strength or agility, with an account of the victories they have won, their names, those of the jockeys by whom they were trained—in fine, those of the noblemen to whom they belong, and from whom they met with all the care and tender treatment that favourite children can expect from a parent.

So great was the crowd, which covered the place where the horses ran, that I could not see them, except upon the ridge of the second hill. They kept upon the full stretch, without rising or darting forward, and appeared to me to resemble wooden horses that had been fixed in full stretch upon the rim of a great horizontal circle, moving round upon its axis, with the utmost rapidity imaginable.

In order to cut the air, the groom, who is almost totally inclined upon the neck of the horse, holds the handle of the whip fixed before him, or shakes it before his mouth.

Before the race begins, the jockey, the saddle, and whole furniture of the horse, are weighed in the presence of the judges; and care is taken that all the horses admitted to run be equally loaded.—(Notes on England by a Frenchman a Century ago.)

## OUR LETTER BOX.

**PLUMAGE OF SILVER GREY DORINGS (T. R.).**—The cock of the Silver Grey Dorking should have perfectly black breast and tail light, almost white hackle and saddle. The slightest deviation from the former is fatal to success. The hen should have grey feathers with white shafts, save on the breast, which should be robin or salmon, and the hackle which should be distinctly striped with black and white. We dare not say that any spreading of the red breast to the outer part of the wing should be a disqualification, but it is a disadvantage.

**NOISE IN THROATS OF CHICKENS (B.).**—The guttural noise in breathing, and the endeavour to remove something from their throats, indicates that there is something in their windpipes; and that something, probably, is the parasitic annats which constitute gapes. If the birds yawn much, there is no doubt about it. Inhaling the vapour of spirit of turpentine, and taking tonics, such as sulphate of iron in the water, are the best appliances.

**EGGS OF LA FLÈCHE FOWL (A Cottager).**—There are none of the eggs or fowls for sale at present in England. There will be some advertised in our columns in the autumn.

**HIVES (Mrs. Bent).**—If you write to Messrs. Neighbour, High Holborn, they will send you a list of prices. You had better leave the bees in the old-fashioned hive, and put their swarms next year into the hives you prefer.

**PARROTS (E. D. S.).**—We know of no book devoted to treating of the management of Parrots. All that is necessary to be said would not fill two pages.

**DESTRUCTIVE CAT (A. A. A.).**—As its owner knows its propensity to steal Pigeons, &c., and drives it out of his own house, you need have no compunction in destroying it, though you have no legal right to do so. We should kill it and bury it without any hesitation. If you can prove the cat killed your birds, you could recover their value from the owner of the cat by suing him in the county court. Of course you would have to prove the ownership.

**RENDERING HAY UNEATABLE.**—At this time, straw in this neighbourhood is worth full as much as hay; and having to find bedding for six horses regularly, being in stable at nights, but not having to find food for them, I find it very expensive to purchase straw. Having a quantity of a rough kind of hay which I wanted to use for bedding, but which I am prevented from doing because the horses eat a considerable quantity of it when put under them, what could be done to the hay to make it so that the horses would not eat it?—WM. WATKINS.

[Why not sell the hay and buy straw with the money obtained for it? We know of no harmless, cheap mode of rendering the hay uneatable. Eds.]

## LONDON MARKET.—JULY 14.

## POULTRY.

The supply gradually increases, and at last is equal to the demand. There is a trifling diminution in price, and as the former must increase while the latter diminishes, we shall soon note a greater change.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 74° and 51.8° respectively. The greatest heat, 92°, occurred on the 25th, in 1841; and the lowest cold, 31°, on the 25th, in 1860. During the period 133 days were fine, and on 107 rain fell.

THE KENSINGTON GARDEN OF THE ROYAL HORTICULTURAL SOCIETY.

HORTICULTURE is losing nothing in popular estimation in our own day. In whatever quarter of our seagirt home we survey, there seems no lack of spirit to promote its growth—no power at work, if such there may be, that at all can influence or propagate a retrogressive tendency.

Happily its progress keeps pace with the age we live in; and although it is absolutely and only a study of Nature and the best

methods by which Nature can be aided, we have as much reason for gratulation, at all events, as those that are pursuing kindred arts. Even since the dawn of the present century, or the most palmy days of Mawe, Abereromby, and Speechley, to say nothing of the genius and practical skill of Knight, for he was a man far in advance of his day, much has been effected, which is due in a high degree to the enterprise, not of botanists altogether, else we would pay homage to that illustrious Swede who organised a system out of chaotic confusion, as well as to Jussieu and Decandolle, who each wrought hard to found the system which takes precedence in our own day, and which Lindley and Arnott, living authors, have so ably sustained. But it is due to those men who were sent out, in a commercial point of view, to ransack the earth, to wander over paths where the foot of civilisation had in many cases never trod, for the numerous novelties which grace the conservatories and parterres of the affluent both in this and other European countries, and which time after time have justly excited the admiration of foreigners in particular, for the skill brought to bear upon their successful cultivation as exhibited here.

What a wonderful and interesting addition has recently been made by the indomitable perseverance of Mr. Fortune, who has hitherto figured so largely in adding to the European herbarium, as well as by the youthful but enterprising Mr. Veitch, who was only two years absent from this country, and sent home so valuable a collection from China and Japan of plants likely to stand the test of our northern climate.

Nor has there been any lack of skill at home. Hybridisers have set judiciously to work, and have met with their reward. The florist has had certain forms turned out with compasses as the summit of perfection for him to imitate, and has laboured hard until he has almost attained what by some was considered an impossibility. Skilful crossing and reproduction from seed have wrought out a wonderful reformation. The rarest plants are sent abroad brought from afar to be cultivated and bloomed here, scarcely inferior to the excellence they attain in their

native wilds. The taste for flower gardening is immensely on the increase, and thousands of plants are bedded out in the parterres of the noble and the wealthy for every ten treated in the same way a quarter of a century ago. Fruit-houses, instead of covering square yards, are now covering acres in proportion, and still the extension is on the increase. Such are the advantages surrounding the path of all devoted to gardening.

Now, the Royal Horticultural Society was inaugurated under the highest and most distinguished patronage, and can still boast of an illustrious roll of names, from our sovereign Queen, and a long list of noble peers and wealthy squires, down to numbers of those who make horticulture their study and their profession. It is to be expected, then, that, availing itself of the advantages we have specified, all the operations of that Society are to be conducted on a superior scale; that the gardens are to be worthy of the high patronage which they bear; that flower gardening and the present fashionable style of floral decoration, which is so captivating the public mind at the present time, should be aptly represented; that the landscape should be so planned as to offer to the practical gardener in charge the best and most suitable groundwork to display skill and taste in arrangement, in order to produce striking effect, and, what is sure to follow, a pleasing sensation on the part of the visitors who pay their mite, many of them all the while believing that they are promenading the best style of gardens that it is possible for the horticultural mind to conceive; that, in short, it should convey to the minds of the numerous body of gardeners who go up from all parts of the country to see it, a largeness of design and a method of execution which they would be eager to copy.

But what is the fact? What is the opinion of the best-informed of those who have seen the Garden for the first time while visiting the great world's fair? "I am very much disappointed with the Kensington Garden," says one, "there is really nothing in it worthy the high name it bears." "The Kensington Garden" say more than one, "is admirably adapted for being one of the great 'tea gardens' of England." "Nesfield's plan is a sham and delusion on terra firma; it only looks well on paper," says another very respectable authority. "The flower-beds are so small on the sunk panels of grass; besides, they are completely lost amongst so much grass and water, that they have only a partial effect."

Indeed, we did not hear a single complimentary remark, barring that it was "kept in good order."

We were very much pleased with the fountains, especially those spouting out cascade fashion, which was novel and refreshing to the promenader, tempering the sun heat reflected from the noble conservatory and those immense domes and other glass coverings of the International building; but we also were very much disappointed with the plan as a whole, as completely unsuited to the great requirements of an immense sight-seeing population.

Nobody expects to see a botanical collection. It is avowedly not a botanical garden. Everybody expects to

see a great floral display. As at present laid out that is simply impossible. A great proportion of grass is well enough; a good proportion of water in the shape of fountains is indispensable; but a great display of bedding-out plants arranged on a scientific plan, and of some magnitude, so far as length and breadth are concerned, is quite as indispensable. Nothing pleases the sight-seeing public better. You deprive them of walking upon the grass as a matter of necessity, but you certainly ought to give them something that the naked eye can rest upon in the shape of flowers, without having recourse to their eye-glasses. Justice compels us to say that the beds were well filled, and while we write will be full of bloom. The fault is not in the carrying-out of the plan, but in the plan itself.

Very few gardeners will dispute that a chain-border on either side the walk from the main entrance up to the conservatory well filled would have a far more gorgeous effect than all these detached plans in the sunk panels, or those elaborate devices in boxes filled with "broken bottles," sands of various colours, &c., which have called forth hostile criticism already. In fact, a simple border 12 feet wide on either side running the whole length, or the whole breadth, or both, planted in straight lines with telling colours, would have a very grand effect.

If we be correct in our notions, we aver that flower gardening proper is not so much a nibbling out of geometrical figures before planting as it is the proper disposition of plants in circles, squares, and parallelograms in an artistic point of view in the act of planting. Anybody can see that you will gain by this method, for you can alter your plan every year.

Some may suggest that this would be all very well for summer decoration; but what of winter and spring? We say that such gardens as that of the Royal Horticultural Society can have furnishing for both winter and spring, and can be arranged to have quite as artistic a finish.

Look, again, at those miserable lines of Portugal Laurels, and those forlorn groups of Limes which are pining away a wretched existence. Decidars and some others of the Coniferae are doing little better. It is clear that the Laurels will not thrive. Rhododendrons would do very much better. These stunted-looking Limes for decency's sake should be thrown out, and if the Council are determined to perpetuate the group, why not get young vigorous trees? Wellingtonia, Cupressus Lawsoni, Thuja borealis, Thuja gigantea, and some of these hardy and ornamental "denizens" are likely to do well if introduced; so also are Irish Yews. Why not introduce some of these, however small, which are likely to maintain the character of being healthy? Far better to do this than to be laughed at, not only by those who know what horticulture is, but by those whose knowledge of it is somewhat circumscribed. — JAS. ANDERSON, *Meadow Bank, Uddingstone.*

### BEDDING-OUT AT THE CRYSTAL PALACE IN 1862.

THESE notes were taken at intervals during the rehearsal and the three days of the glorious Handel festival.

The great range of beds, along the centre of the grand terrace walk between the two chain-patterns in the sunk panels, is in two divisions, the main centre walk from the Palace cutting it into halves. Each half begins and ends with a circular bed 6 feet through, and there are ten of them in each half of the range, and also ten oblong beds 6 feet wide and 18 feet long, alternating with the circles—that is to say, there are forty beds in all; and all the circles have standard plants in the centre, as Rhododendrons, and the Umbrella Acacia, plant for plant, and two Cedars in each division.

All the circles are planted alike with Purple King Verbena, edged with variegated Alyssum; the oblong beds are also all alike in the ridge-and-furrow, or double style of ribbon stripes—that is, a centre of three rows of the Crystal Palace Scarlet Geranium, then two rows of Christine on each side of the centre, and two rows of Tropaeolum elegans on the outsides; or say a broad stripe of deep scarlet along the whole centre, with a less broad band of rose on each side, and the edges in equal breadth of orange, with a contrast circle of dark purple intervening at every 20 or 22 feet of the distance, or thereabouts, by allowing for the space of grass between the beds. The Rhododendrons in the four corner beds, in the sunk panels at either end of the grand terrace, have been removed; the beds being now, as at the beginning, filled with bedding plants (and

the filling is the same in all of them), will be more gay than they have yet been. These beds are true angle-beds; they fit the angle of two walks, and both ends of the beds are in this form.

They are edged all round with Flower of the Day, then yellow Calceolaria. The circular ends have Christine Geranium after the Calceolaria, and in the middle of Christine comes the Crystal Palace Scarlet Geranium; but in the rest of the centre, between the circular ends, the Cottage Maid Scarlet Geranium is planted with Cerise Unique between it and the Calceolarias. The shape of the beds is unique, and the planting not less so; and it only wants an oval-shaped group of Christine in the centre, as represented in the dotted oval, to correspond with the two ends, to make these corner beds not only wholly unique in the planting but perfect of their kind. Even as they are, and not yet in full bloom for telling the pattern, I could see thousands standing over them, and others looking at them out from the gallery above the colonnade more earnestly than even I saw on the grand terrace arrangement.

The chain pattern this season, is edged all round with variegated Alyssum, and the yard links between the beds are also all in Alyssum—the most aristocratic touch in all England very probably. I must get the number of the hundreds of yards in those edgings, and the number of the thousands of plants it took to fill them and the links. The rest of the chain is in scarlet and yellow as usual.

From the corners of the chain-pattern panels, next the centre of the terrace, there is a run of neutral beds to each end. The oblongs have been all along in Rhododendrons edged with the best of all the dwarf China Roses, Cramoisis Superieur, and the circles in bedders. Here is where you may always look for the newest things and all the titbits of the establishment, because there is no law that can be violated or made good in whatever kind or manner such isolated beds are planted. Let us, then, have them one by one from the very west end of the terrace. No. 1 is Unique Geranium in the centre; two rows of St. Clare, a pale flower of a variegated Geranium; one row of Baron Hugel, and the outer edge of Lobelia speciosa—a very pretty bed indeed in any part of the three kingdoms; and when the Italian Ricasoli comes next year in the place of the Austrian Baron Hugel, it strikes me you could hardly better it in most places. No. 2, Nosegay Fothergilli or Purple Nosegay for centre; Richmond Gem all round it; and then an edging of the variegated Prince of Orange, which first originated in a "sport" on an old plant that had been some years planted in a border, and trained against the back wall of a greenhouse, a mile or more out of Ipswich, when I was at Shrubland Park. No. 3 you have probably never seen. It is of the Carmine Nosegay, for the first time there; and is rounded by a band of Blush Minimum, which must be a wonderful favourite, for they have it in all ways, and that is the only garden in England where it is grown, for it is not a poor man's plant. These are edged with a double row of the Golden Chain, the plants being very young, and not over 3 inches high. No. 4 is of the old Ignescens major, now called Scarlet Unique; one row of Shottesham Pet variegated Geranium round it, with an edging of Lobelia speciosa. No. 5, Miss Jago Nosegay, Blush Minimum round it, and two rows of Golden Chain outside. These finish the west side of the grand terrace arrangement; and the five corresponding beds on the east side are a little different—thus: No. 1, Carmine Nosegay, Blush Minimum, and Golden Chain. No. 2, Shakspeare Scarlet Geranium, with Nosegay footstalks to the trusses; Princess Alice Geranium round it; and the pink Lateripes (Ivy-leaf) mixed with the Lobelia speciosa for edging. No. 3, Spitfire, a Horseshoe Scarlet; Blush Minimum; two rows Golden Chain, mixed with the original scarlet Verbena Melindres. No. 4, a seedling Horseshoe raised at the Crystal Palace; one row of Blush Minimum; two rows of Crimson Minimum, the best of that race; and one row or edging of very young plants of Alma variegated Geranium.

Here you see Crimson Minimum, which is twice the size of Blush Minimum, is yet planted in front of it; also Alma, which is as big as the two Minimums put together, is yet an edging to them. That is how people who are not burdened with "sillar" ought to manage. It is quite manageable to have a bed of double Daisies edged with Punch, raise the bed well to the centre, and make Punch in little bits of cuttings in April.

The half circle or sweep of the *Araucarias* in the very centre of the great terrace, reads differently from any of the other arrangements, a fact which has puzzled some good gardeners. That half circle is cut in two by the main centre walk, and each side of the half circle, right and left of the centre walk, is as it should be, a duplicate of the other, on both sides of the circular walk: therefore, the beds do not read in duplicates across the circular walk, but right and left of the centre walk; and we take the outside or the upper part of the sweep first from the lower corner. There are seven oblong beds in each half of the sweep, with pedestals and statues between, and one set of the seven beds will give the contents of the corresponding number. No. 1, Shrubland Rose *Petunia* all over, and an edging all round of a new *Lobelia*. No. 2, Golden Chain and Alma variegated *Geranium*, plant for plant, and all mixed with *Impératrice Eugénie*, a low-spreading striped *Verbena*, which heightens the effect wonderfully. No. 3, *Commelina cælestis* all over, and the edging as before. No. 4 is the centre or key bed, having three beds on each side of it. This is full all over with *Petunia Inimitable* (double), the very gayest of all the double kinds indoors, and now we shall see what it will turn out in beds. No. 5, *Verbena Lord Raglan*. No. 6, *Calceolaria amplexicaulis*; and No. 7, a very good new cross seedling *Tropæolum*, raised at the Crystal Palace, between *elegans* and *Triomphe de Hÿris*—only one good seedling out of a large batch. Now, both sides and the two ends of all these seven beds are edged with the same new *Lobelias*, and the seven corresponding beds on the other side of the centre are edged like them; and the *Lobelia* seedlings, with which the whole are edged, are the most telling and at the same time the most lovely edging plants on the face of this earth. You never saw them unless you have been there; but happen what will, you must have them next year if you be within a thousand miles of our shores. I have ordered my own share of them already. Sir Joseph Paxton who has seen as many good plants as most people, says he never saw a *Lobelia* more lovely to look at than one of them, or a more beautiful combination of colours; and certainly I never did, nor did I expect to see such a combination of colours in the family.

One is a *Nemophila insignis* transfigured into a *Lobelia speciosa*, but with the flowers twice as big as those of *speciosa*, the habit about the same, or, perhaps, the new one is a little more free, which makes it all the better. If it were an *Orchid*, I would say the upper sepals were of *Nemophila* tint, and the labellum or flat front part of the flower is white as the driven snow, and is edged all round with the tint in the sepals, the peculiar blue blending imperceptibly into the unusual expansion of white on the lip of a *Lobelia*.\* The *Araucaria*-side of the sweep is thus planted. All the *Araucaria* beds of raised mounds are as last year, *Cerastium* top and bottom of the slope, and *Lobelia speciosa* covering the slope.

The pedestal-beds, seven on each side of the centre walk, have all *Flower of the Day* for edging on the inner side, and on the outside; and between the two rows of this variegated favourite in the first bed is *Trentham Rose Geranium*; No. 2, *Cottage Maid*, a *Horseshoe Scarlet*; No. 3, *Crystal Palace Scarlet Geranium*, and so on alternately to the other end of the sweep or half circle. The centre walk down through this half circle has two pedestal beds on each side; two of them are with the old purple *Nosegay*, and two with *Cottage Maid*. Then we have only the eardrop-like beds pending on the bank at each end of this terrace. These drop-beds hang from the points of reversed festoons of variegated *Holly*. In the bow of the festoons is first, next the *Holly*, yellow *Calceolaria*, then a row of *Crystal Palace Scarlet*, and an edging of *Mangles'*, which comes down round each of the drop-beds, which beds are planted as the bounds of the festoons on each side of them, with the addition of a fat edging of the spring blue *Gentiana acaulis*, which does remarkably well on this strong soil.

From this upper terrace is the best place to read the arrangement on both sides of the main centre walk down from it to the basin between you and the water-temple, and here it is. Seven circular beds and seven oblong beds on either side. All the oblong beds are alike, and all the circles the same, but different from the planting of the long ones. Down the centre of all the oblongs are three rows of the *Crystal Palace Scarlet Geranium*, then two rows of yellow *Calceolaria* on each side of the centre, then two rows of double white *Pyrethrum*, and two rows of *Purple King Verbena* for edging. All the seven circles have *Purple Nosegay* in the centre, *Cerise Unique* round it, and the new

\* This variety is to be called *Paxtoniana*, and one with a pure white rent *Gordoniana*.

seedling *Tropæolum* next, then an edging of the variegated *Alyssum*. All the beds round the centre basin are much in the same way; but the dwarf *Rhododendron Wilsoni* has been removed from the two large circles west of the centre of the basin, and all the bedding *Dahlias* are to be set there in place of the *Rhododendron*. This, and the end panel-beds of the upper terrace, may be taken as putting the best foot foremost in honour of the International Exhibition, which is fast gathering girth to the Palace mill. On the sides of the secondary walks down from the terrace the borders were gay with common *Pinks*, *Cloves* and *Picotées*, *Delphiniums*, and all manner of old-fashioned flowers coming on to succeed each other to the end of the season.

The *Perilla* and the *Orach* have got out of favour at the *Crystal Palace*, but they are going to try their luck in the race with *Verschaffelt's Coleus*. I saw a large batch of *Perilla* in the propagating department, to be ready to run to if needs be, for a second start. The *Rose Mount* ought to have a chapter for itself this season, were it not that we have irons enough in the fire already. There is where the new style of planting in festoons is after the patent for tucking up ladies' dresses in bad weather. The six divisions round the top part of the *Mount*, above the *Roses*, are planted in that style, each division being a duplicate of the last all round; and in each of the six divisions there are ten festoons, and five kinds of plants to make them, besides a regular edging all round the bottom and ends. At the top of the slope are three rows of *Crystal Palace Scarlet Geranium* in ten festoons—thus ————, then two rows of the double white *Pyrethrum* to follow suit, two rows of *Christine* next, two rows of *Purple King* follow, then two rows of *Tropæolum elegans*, and the edging all of *Mangles'*. The triangles, which the form of the festoons leaves below the last run of them, are filled up with *Lobelia speciosa*.

The effect of this elaborate work will be surprisingly good, but I refrain from prejudging effect till the autumn. They tell me that scores may be seen every season with this *Journal* in hand going round and round the garden reading off all the beds and particulars as soon as they appear, which must be a good way for gathering notions to many.

All we want is a few acres of ground laid out and planted in the composition style, which no one can see in any of our public gardens round London, except the few leaflets of it in our new garden at South Kensington. On the *Rose Mount* and on the north-east side of it you will see another new edging—the *Gnaphalium lanatum* as they call it, but it will come in first-rate style at any call. It is quite as good but not a whit better than *Antennaria margaritacea*, the finest silvery plant I ever saw in a flower-bed; but being the poor man's plant, the rich may like this *Gnaphalium* better; for it will require about the same expense as *Verbenas*, comes quite as free from cuttings, and is more easily kept in winter, and less liable to insects. There are many yards of it as an edging to one of the largest *V*-beds, or corner beds, round the *Mount* on the north-east side; but it will do in rows and lines, and to be allowed to grow to a foot or more in height. The proper name of a very old plant, like the age of a horse, cannot be known without looking at the flower as you would at the mouth of the horse; and the bother of the botany of this plant is, that one cannot catch at a flower with all this propagation. I expect the name is older than I am, and to be different, that it is one of *Masson's* plants sent to *Kew* from the Cape of Good Hope, unless you can show it up in another light. I have it at home, and can tell to a shade that it will soon be as much used as *Cerastium*; also that there is no flaw or failure in the expectations about *Cerastium Biebersteinii*.

We begin the beds round and round the great circle girding the *Rose Mount* from the railway entrance at the bottom of the colonnade, and the right-hand walk from there up the *Rose Mount* will be our No. 1 walk, there being six of them leading up in gentle curves from the circumference walk. The nature or natural run of these up-walks, as one might say, allows of but one corner bed to each walk, which is of a long *V*-shape; the rest are all circles in pairs up the hill, and along, singly, by the upper side of the main walk all round. We begin with the *V*-bed of walk No. 1. It was planted all over in the spring with *Delphinium formosum*, and at bedding time with the *Cottage Maid Geranium*, edged with *Flower of the Day*; opposite is a circle bed of *Petunia magnifica*, edged with white *Verbenas*; then a pair of circles, one on each side the walk; and one is with *Lobelia speciosa* mixed with *Dandy Geranium*, with an edging of the same *Lobelia*. The opposite or lowest side bed is

of Purple King Verbena mixed with variegated Alyssum, with a Purple King edging. The top pair is in Tropæolums—the one with elegans, the fellow to it with Triomphe de Hyris, edged, the former with Alyssum, and the other with Mangles'. From this, the first walk, we go towards the Crystal Palace, and the first side bed is a Nosegay Lord Palmerston, edged with Blush Minimum; the second is Unique Geranium, edged with Alma; and the third is with Sidonia Geranium, edged with the golden-leaf Ivy-leaf Geranium.

The next is the corner bed to the second walk, with Crystal Palace Scarlet Geranium in the centre, two rows of Christine next, and then two rows of Purple King. Opposite is a circle of Nosegay Geranium, edged with two rows of a good new greenhouse perpetual Geranium, after the look and fashion of Lady Flora Hastings, but much stiffer, and seemingly a very good light bedder. The next is a pair up the walk, the pet pair of the Mount, the one Lady Plymouth Geranium mixed with the striped Verbena Empress Eugénie, and edged with Golden Chain; the other with Verbena Melindres in place of Impératrice.

The top bed to this walk is Crimson Minimum Geranium, edged with Baron Hugel this year, and next year with Baron Ricasoli. Then comes a corner bed on the way to the upper terrace; and then turn round to the east for the third walk up to the Mount. That corner bed is like No. 1—Delphinium, and Punch in place of Cottage Maid.

The next is the corner bed for the third walk, a very long corner it is. This is of the Fothergilli Nosegay, surrounded with brown and yellow Calceolaria, within the edging.

There are two circles opposite this long corner bed. One, Tropæolum elegans, edged with variegated Alyssum, and one with Verbena venosa mixed with Lantanas. The next up the third walk is a pair, one with Sidonia, edged with Black Prince Geranium, which is of the Citriodorum race, the other with Rubens Geranium, edged with Harkaway. The top is a pair also; one, Defiance Verbena, the other with Purple King ditto, and both edged with a white Verbena.

From the third to the fourth walk are three beds, the first of them Gaines' yellow Calceolaria, and two rows of Brilliant Geranium. This they reckon the best yellow Calceolaria for the whole garden. The second bed is Ignescens Superb, edged with Cuphea strigillosa that was; and the third is of Gazania splendens. Then the fourth walk; and the corner bed to it is also a very large one, and is entirely of two of the oldest plants in the garden, and two of the newest bedders there. We shall say 60 feet of edging of the Gnaphalium lanatum aforesaid, and the whole bed of Commelina caulescens, prepared particularly for bedding. The bed opposite is of three dwarf Verbenas mixed—thus, Melindres, Impératrice, and Hendersoni, an old crimson, and it is edged with Melindres. The next pair up the walk is one with Trentham Rose Geranium, edged with Baron Hugel; the other with Miss Vernon Nosegay, edged with Shrubland Pet. The upper pair are—one, Shottesham Pet variegated Geranium, edged with Impératrice Verbena; the other Alma, edged with Verbena pulchella. Then between this and the fifth walk on the very south side of the Mount are five beds along the walk: 1, is of Triomphe de Hyris Tropæolum, edged with Mangles'; 2, with Heliotrope, edged with Nierembergia gracilis; 3, China Rose; 4, a scarlet seedling Geranium of their own, and two rows of Fairy Nymph variegated Geranium for edging; and the fifth, a purple-streaked Petunia, edged with Verbena venosa.

We now come to the fifth walk. The corner bed of it is of Trentham Rose, and two rows of Aurea Floribunda Calceolaria, edged with Purple King Verbena. The bed opposite is rose-scented Geranium mixed with Defiance Verbena, and edged with Melindres. The next a pair, one of which is of Gazania splendens, edged with Gnaphalium lanatum; the other is of Tom Thumb Tropæolum, edged with Gnaphalium lanatum again; and the top pair are thus—one, Crimson Minimum Nosegay Geranium, edged with the crimson Ivy-leaf ditto; the other, Brilliant Geranium, edged with the lilac Ivy-leaf. From the fifth to the sixth and last walk, are four beds—thus, 1, Verbena Great Eastern, edged with Verbena Hendersoni; 2, Attraction Geranium, edged with a seedling Verbena; 3, Camden Hero, a dark Calceolaria, mixed with Verbena Seymouriana; and 4, Gazania splendens.

The corner bed of the sixth walk is of Calceolaria amplexicaulis, edged with two rows of Brilliant Geranium; the opposite is of the old crimson variegated Geranium, edged with the golden Ivy-leaf Geranium. The next up this walk is a single bed of Fuchsia Queen of Hanover, edged with Fuchsia Globosa, mixed

with Verbena Melindres. The next is a pair: one of which is mixed Nosegays, Blush Minimums, and a row of Fair Helen Geranium; the other, Princess Alice Geranium, edged with lilac Ivy-leaf Geranium; and the top pair are—one, Julia, a variegated Geranium, edged with lilac Impératrice Eugénie Verbena; the other, Alma variegated Geranium, edged with the true Verbena pulchella, the one so called above being Sabina.

Three more beds from this to the first walk finish the circle. The first is Gaines' Yellow Calceolaria, they say the best sort of the integrifolia race, edged with Sidonia Geranium; the second, Crimson Ivy-leaf Geranium, edged with the dwarf Pink Ivy-leaf Lateripes; the last, Tropæolum elegans, edged with Tom Thumb Tropæolum.

The broad bank above the Roses is planted all round the Mount on the same plan, which is all the rows or kinds of plants in festoons instead of straight lines as formerly; and there are ten festoons in each line of every division—that is to say, sixty festoons in the top row of plants all round, and the rest of the rows the same number. The plants are thus:—three rows of the Crystal Palace Scarlet Geranium at the top; then two rows of the double white Pyrethrum; after that two rows of Christine Geranium, two rows of Purple King Verbena, two rows of Tropæolum elegans, and an edging of Mangles'. The triangles left below the last row of festoons are filled with Lobelia speciosa.

The top of the Mount is edged all round within the arcades with a narrow border of Musk Mimulus and Mignonetta. The six sunk beds are in three match pairs—thus, one opposite pair with the centre of Calceolaria amplexicaulis, two rows of Crystal Palace Scarlet, and two rows of Geranium for edging; the second pair has Cottage Maid for centre, Cerise Unique Geranium next, then Gaines' Yellow Calceolaria, edged with Mangles'; the last pair, of Fothergilli or Purple Nosegay Geranium, Ignescens Superb ditto, and Alyssum for the edging. The four circles for the four guy-ropes holding the flagstaff are of Cottage Maid in the centre, Trentham Rose round it, Ignescens Superb next, then Alma and Flower of the Day, and edged with Lobelia speciosa.

The China Rose which does so well at the Crystal Palace in beds, and in edgings to Rhododendron-beds, is remarkably good for that purpose, and it ought to be brought out again by some one on the authority of these gardens as the best of all the Chinas, being even superior to Fabrier. I believe it to be the old Cramoisié Superieur which is sold in every Rose nursery; but you see it nowhere about London, except at the Crystal Palace.

They are getting up a host of Tritoma uvaria to bloom in the water-basins, and the Orange trees have been saved from entire destruction by gas at last. In May, 1861, you would not buy a score of those which stood out of doors in the back ground for firewood—they were a perfect wreck; but now, having got an Orange-house for themselves, a very good manager to look after them, and one-third of cocoa-nut refuse in their fresh compost, they are looking far better than I expected to find them—in fact, they are just renewing their age, as it were, and by-and-by they will be the pride of the place entirely. D. BEATON.

## CULTURE OF THE PEACH AND NECTARINE.

(Continued from page 292.)

*Training.*—There are only two methods of training the Peach tree that are worthy of notice. The first is the one generally followed, and is named the fan method, from the main branches spreading out in a similar manner to the ribs of a fan; the second is a modification of it, and was invented by Mr. M. Seymour, gardener at Carlton Hall, near Snaith, in Yorkshire. Good fruit has been produced by both of these modes of training. In the course of my gardening life I have practised both methods, and must confess that I give the preference to Seymour's plan.

The first may be described as having the young shoots on both sides of the main shoots; and the other—that is, Seymour's, has the young shoots only on the upper side. It is necessary to mention that the Peach and Nectarine bear their fruits on the shoots made the previous year: hence it is needful to train in annually young shoots to bear fruit the following year. This being understood, the cultivator will have to determine, at the time of planting, which of the above methods he will follow. Trained Peach trees from a nursery have generally five shoots.

Now, if either method be adopted, the trees should be pruned in the latter end of February or beginning of March, and trained with one shoot for a leader and the others horizontally, two on each side, then every bud or nearly so will break; and the trees may then, by disbudding the useless or superfluous shoots, and training the remainder in, be furnished with well-placed leading branches and bearing shoots. The cultivator should study the figure the trees are to assume when the wall is covered with them, and lay-in branches accordingly to effect that purpose.

In the second year, if all has gone on well, the trees will be again pruned at the same season, and the year's shoots trained in fan-form; and so the management in regard to pruning and training must be followed up till the trees cover the walls.

If, however, the cultivator should choose to adopt my favourite mode of training, then he will proceed from the first to prune and train-in the shoots only which are produced upon the upper side of each branch. He will find this the most asymmetrical, and, at the same time, the most simple and most easily understood of any mode of training.

The summer pruning and training commences almost as soon as the buds break. The grand object is to obtain shoots for bearing the year following. In any mode of training, the young shoots should be retained that are placed near to the base of the shoot that is bearing fruit; all others should be rubbed off at once—they only, if left on any time, rob the really useful ones of nutriment, and crowd them unnecessarily: therefore I say, Off with them at once. If the leading shoot of the bearing branch is too vigorous, nip off the end, leaving a sufficient number of leaves to draw up the sap. Well-managed trees should never present a crowded appearance of shoots in summer, and no part of the tree should have any shoots stronger than the rest; should any such appear, their vigour should be arrested by stopping, though I always consider that a misfortune. I like to see every young shoot of equal strength. A young shoot in the right place may appear in early summer weak and unpromising; but, if all the rest that are useless are removed, the shoots in the right place will quickly gain strength. Let the cultivator never run away with the idea that, by retaining a greater number of young shoots, he is thereby multiplying the chances of having fruitful branches. It is often a fatal and always a mistaken notion. Adhere to the rule that a few shoots well ripened are far more sure to produce good fruit than when a larger number are crowded in between the main branches. Should any of the trees grow too strong, and make long, watery shoots, the best way to check such is to lift them up early in the autumn and replant them; that will be sure to moderate their growth, and cause them to produce more kindly wood. In performing this operation, great care must be taken not to injure or mutilate the roots. Open a trench at the very extremity of the roots and undermine them carefully, picking out the soil from amongst them with a three-pronged fork; replant the tree immediately exactly the same depth it was before, unless by some means or other too much soil had accumulated above the roots; then plant them shallower—that is, cover the roots with a less thickness of soil.

**Nailing.**—Where that mode of fastening the branches to the wall is followed, the operator must be exceedingly careful not to wound them with the hammer-head. Sometimes the hammer will slip off the nail-head and hit the branch instead, abrasing the bark at least, and thereby often bringing on a gummy state. To prevent such a misfortune, he should always place his fingers round the nail, and hit them instead of the shoot. However, in many good gardens, they have had the walls wired 6 inches or 8 inches apart, and the shoots are tied to these wires. This, in some respects is a better plan, because the ties do not harbour insects like the common cloth shreds, and there is no danger of bruising the shoots with the hammer. But there is another danger, and that is, if the shoots are tied-in tight at first, the shoots swell and increase in thickness and become strangled at that part: hence, at pruning time they are apt to break at that part, and thus disappoint the hope of fruit from such branches. Let the grower then be aware of this evil, and watch over the ties; and when they are approaching to being too tight cut them loose, and re-tie them more loosely.

As soon in summer as the young shoots have grown long enough, let them be secured to the wall to prevent them being blown off by the wind. This is of consequence, as after the superfluous shoots are rubbed off, the loss of any branch required

is difficult to be repaired: therefore, secure such shoots as soon as they can be handled, place them in the most open space, so that every leaf may have its full share of light, yet not shade the fruit-bearing shoots. I consider here and there a part of the wall even should be unshaded, to gather heat from the rays of the sun; that heat helps to ripen the fruit and the wood also.

T. APPELEY.

(To be continued.)

## LILIUM AURATUM AT THE ROYAL EXOTIC NURSERY.

THIS, the grandest of all Lilies, may now be seen in full perfection at the above establishment, and all who wish to form a just idea of this magnificent flower should see it.

The flower is borne upon a purple stem about 2 feet high, and the thickness of a goose-quill; and in shape it forms a wide-mouthed shallow bell 10 inches in diameter, the six divisions of which the perianth is composed being about 2½ inches across at the widest, curled back at the point, towards which their outline is undulating.

The colour is snow white, thinly but regularly strewn with oblong purple dots and markings; and a broad band of golden yellow runs down the centre of each division nearly to the base, where the purple markings become elevated above the surface into short bristles.

The stamens have reddish-brown anthers which tremble with the breath, and projecting beyond these is the dull purple stigma; the whole forming a conspicuous and elegant centre.

In addition to its beauty, the flower possesses a powerful but delightful fragrance, partaking of that of the Orange blossom and the Honeysuckle.

The leaves are narrow-lanceolate, acute-pointed, and of a very dark green.

We were informed by Mr. J. G. Veitch that he found the plant growing wild on the hills in the midland provinces of Japan, and in places where from 11° to 16° of frost occur in winter: there is, therefore, every probability of its standing out of doors with us. To the same gentleman we are also indebted for the following information:—"The flowering season is July and August, at which time it is common in situations exposed to the sun. It grows 1½ foot to 2 feet high, and is remarkable for the size and fragrance of the flowers. The roots are boiled by the Japanese and eaten like Potatoes, and in flavour they resemble the Chestnut."

On another plant there is a bud 6½ inches long, which will shortly open, and there are indications of others forming in the axils of the leaves, so that it is probable that the flowering may not be merely terminal.

We may mention that there are also in flower just now the beautiful white Lapageria, a lovely companion to the well-known rosea; and the curious Anthurium Scherzerianum, with its bright scarlet shield, not unlike a Roman standard surmounted by a crook.

The collection of curiosities, woods, cones, &c., to which we alluded in a former report, is now arranged in a large room, and is open to public inspection.

## RAISING FUCHSIAS FROM CUTTINGS— DATURA ARBOREA CULTURE.

OUR answer to an inquiry from "M. F.," must depend on your taste and the natural habit of the Fuchsia. Fine large plants for this season are best obtained from cuttings struck last year, and grown on slowly all the winter. Some kinds of Fuchsia are naturally bushy, and look best when trained to one shoot, which as it grows throws out side shoots thick enough. With such a habit there is no necessity for stopping. If instead of a single stem you would prefer several stems in the bush form, then stopping when a few inches high should be resorted to. Most growers frequently stop the side shoots several times in order to produce density of sprigs. In such case early blooming is less thought of than a dense mass of flowers at one time.

Again. Whatever style of growth be approved of, whether single central stem or the bush form, some Fuchsias are naturally so long-jointed and lanky in their growth as to require stopping frequently to make them massive, and, therefore, the circumstances of the plant must regulate the operations instead

of any unvaried rule. In general, plants trained to a single stem, and all the others radiating from it in the form of a cone, widest at bottom, will look best and be most artistic.

As to *Datura arborea*, the shoots 7 inches to 8 inches long at the top of a four-foot stem ought to bloom freely, and will do so if the wood from which they came was well hardened in the sun last autumn. The picking-out of the points of these shoots will not prevent them flowering if there are flower-buds formed on them; but, provided flower-buds are formed, it will lessen the amount of flowering, as the fresh shoots thrown out will not blow this season, and the flower-buds that formed as the original shoot lengthened, would, of course, be lost. We are presuming that these seven-inch shoots are of that season's growth. If so, and these shoots are well hardened this summer and autumn, every bud you leave on these shoots will throw out flowering-shoots next season. You may thus without stopping now have half a dozen or a dozen of shoots next year, and flowering too if you treat them well.

### GRAPE VINES ON TRELLISES.

THE first season a trellis is not absolutely required beyond a temporary support to keep the Vine off the ground; still, it is not objectionable, in most instances, to have it erected at once, and it should always be done before the roots extend too much, so as not to interfere in setting the stakes or posts for general support, as no good can come in displacing or bruising them in the operation. It will be required early in the second season's growth, and a few months gained never come amiss. We shall not speak at any length, or describe the practice with some, of using stake supports. We have never seen it giving good satisfaction in this climate, and it usually has been abandoned, so far as my observation goes. A trellis 6 feet high is sufficient, usually constructed by setting posts at either end of the row of Vines, with one between each of the Vines planted; upon this nail strips of board 1½ inch wide, and 15 inches apart from the bottom upwards. This makes a cheap trellis, both in first cost and durability. It is better to set posts as above, omitting every alternate one except at the ends, taking pains to select such timber as will prove most durable. Work them down to a neat and tasty size (4 inches to 6 inches), facing one side, except for the end ones, which may be round. A man's habits in taste are easily read about the grape, and nothing contributes more to the well-being and appearance of a garden than a light, airy, and durable trellis. Number eight wire, drawn horizontally the same distance apart as though of wood, and attached to the posts by passing through them at the ends, and fastened to the others by staples formed from pieces of the same wire, but not so tight but that the wire can play horizontally, will be found much

more durable; and where the extended trellis is wished, upon which to train long, horizontal arms of the Vine, as good, if not the best mode of construction. In short seasons, changeable climate and frosty locations, something more is often desirable than the immovable support upon which, the Vine once attached, it must remain till fall, or with much difficulty be removed. It is not unfrequently the case that a frosty night, late in spring, cuts off the tops of the Vine; and again in early fall, just as we are ready to gather the luscious fruit, nearly covered with bloom, unlucky Jack Frost makes our acquaintance, and gathers to his fireside that which was our own choosing. Under such a state of things, and having been robbed of one of Pomona's best gifts, we constructed a trellis which met the emergency, and saved a crop from the frost in 1859. The figure will illustrate it.

It consists of two posts 3 feet long, set in the ground upon

either side of the Vine, and 6 feet apart equal distances therefrom, with 6 inches above the ground, and pin-holes near the tops for attaching the frame, which is made of two-by-four scantling, 6 feet long, with corresponding pin-holes; or what is preferable, use strap hinges for attachments, and then, when the frame is erected, it will rest upon the posts, and not on the pins. Upon the scantling fasten cross-bars half an inch thick by 2 inches wide, embattened their thickness in the frame. The whole tapers to 3 feet at the top, which is supported by a moveable lever or part to any height required, and may be as readily changed from a horizontal position for covering-up to an upright position for sunning, as the blade of a knife may be opened and shut upon its handle. The bars being placed upon alternate sides, the Vines can be passed between them, thus needing no other support by twines or otherwise. In this arrangement the Vines require no removal for winter; simply lower the frame, or upon an occasion, if frosty at night, lower in the same manner, covering with blankets, &c. The heat passing from the earth's surface at this season of the year will be retained in the covering, and thus a crop or feast of good things is saved for the stomach's sake.—O. S. WILLEY, *Madison, Wisconsin*.—(*Prairie Farmer*.)

### SEEDLING ORANGE TREE NOT FRUITFUL.

I HAVE an Orange tree which has been raised from a pip planted about sixteen years ago, when I was a child. It has grown to be a large tree, but has never had any fruit on it. We have now a greenhouse, and as I am very anxious for it to thrive, can you tell me whether it will require grafting, and what kind of soil to put to it?—A NEW BEGINNER.

[You certainly have had great patience. It is seldom such Orange trees are good for anything, except as stocks for grafting choice kinds upon. We would advise trying it another year in the greenhouse, where the wood will get well ripened, as it may probably bloom next season. If it did not do so, then it might be either cut down and two or more grafts placed on the stem in April or May, or the whole head might be grafted with different approved kinds. It will be advisable to keep the place hotter, moister, warmer, and more shady than usual until the grafts are growing freely. Sandy loam, a little heath mould, and a little leaf mould or rotten dung, will grow the plant well.]

### STAMFORD FLORAL AND HORTICULTURAL FETE.

THE Exhibition was arranged in six spacious marquees, provided by Mr. Aitken, of Peterborough, the snow white sides of which stood out in happy relief to the rich verdant carpet underfoot. The tents were erected at the east end of the show-yard, and the ground surrounding them was ornamented with specimens of terra cotta. Flags of various colours were flying in almost every direction, and a more animated scene we have seldom witnessed. The show-yard was fitted up by Mr. J. T. Jeffs, of Stamford.

Mr. Wilson, silversmith, of Stamford, exhibited in a tent contiguous to the above a splendid assortment of cups, goblets, silver, and trays (the total value of which was about £300), from which the winners of the plate prizes, in both agriculture and horticulture, made their selection. The cups were richly chased, and those intended for the agricultural prizes contained appropriate devices. The silver and bronze medals distributed by the Horticultural Society were very handsome. In the centre of the obverse are the borough arms, encircled by Laurel and other leaves, around which is the inscription "Stamford Horticultural Society;" on the reverse is a wreath of fruit and flowers exquisitely designed.

The attendance was very large, and included the *élite* of the town and neighbourhood. The weather altogether was favourable, and when old Sol began his accustomed diurnal round he smiled upon as lovely creation as has been seen since the days of Adam. It was hot enough, we think, for reasonable beings; and, as for brightness, had we not abundance of it in the broad daylight, the masses of gay flowers, and the equally varied and dazzling costumes of the ladies? We have reserved, of course, for special mention, the smiling faces which beamed from beneath the most miscellaneous assortment of bonnets ever brought together.

The great attraction of the Show was the tent for Roses; the collection was really magnificent, and the delicious fragrance which was emitted on entering was surpassingly exquisite. It would be tedious, and perhaps invidious, to embark in a detailed criticism of the merits of this collection of flowers, where by far the great majority deserved commendation.

The next attraction to the Roses were the stove and greenhouse plants, and the foliage plants. In the latter, John Torkington, Esq., exhibited some splendid specimens which included the *Cyanophyllum magnificum*, *Caladium Bellemeyi*, *C. Chantini*, *Alocasia metallica*, *Pandanus javanicus variegatus*, *Cissus porphyrophyllus*. Mr. Brown, jun., of Stamford, also exhibited a very handsome specimen of the *Alocasia metallica*. The *Fuchsias*, *Begonias*, and *Achimenes* were deserving of favourable notice, and the specimens exhibited by the Marquisness of Exeter were really magnificent. The Cockscombs were not inferior in merit. We noticed a very beautiful show of exotic *Orchids*, which, from their admirable arrangement and the beautiful variety of their foliage, were the "lions" of the tent they occupied. The show of *Verbenas* was fair, but we observed nothing particularly striking in their general character. There was a very excellent show of Ferns, amongst which we noticed one with a silver leaf, belonging to John Torkington, Esq., which was very beautiful, and a very handsome one exhibited by S. Sharp, Esq., of Dallington Hall, Northampton.

Great credit is due to Mr. James Holah, gardener to Mr. Torkington, for producing such a fine show of foliage plants.

There was not a large display of fruit, owing probably to the backwardness of the season. The specimens shown by the Marquis of Exeter were particularly good, and deservedly attracted a great deal of attention.

The contest for the cottagers' prizes, which is to us one of the most interesting departments of a horticultural show, was very spirited.

#### AWARD OF PRIZES.—(OPEN TO ALL.)

- Class 1.—Twelve Stove and Greenhouse Plants in Bloom.—First, a Silver Cup, A. Turner, Esq., Leicester. Second, Wood & Ingram, Huntingdon.
- Class 2.—Six Stove and Greenhouse Plants.—First, T. Almey, Oakham. Second, — Walters, Oakham.
- Class 3.—Twelve Fine Foliage and Variegated Plants.—First, J. Torkington, Esq. Second R. L. Bevan, Esq., Brixworth, Northampton. Third, A. Turner, Esq., Leicester.
- Class 4.—Six Fine Foliage and Variegated Plants.—First, R. Brown, Wothorpe. Second, T. Almey, Oakham. Third, — Walters, Oakham.
- Class 5.—Twelve Exotic Ferns.—First, R. L. Bevan, Esq., Brixworth. Second, S. Sharp, Esq., Dallington Hall, Northampton. Third, T. Almey, Oakham.
- Class 6.—Six Exotic Ferns.—First, — Walters, Oakham. Second, R. Brown, Wothorpe.
- Class 7.—Six Exotic Orchids.—None exhibited.
- Class 8.—Twelve Pelargoniums (including French or Spotted).—First, — Walters, Oakham. Second, Messrs. Wood & Ingram, Huntingdon.
- Class 9.—Six Pelargoniums (Fancy).—First, — Walters, Oakham. Second, Messrs. Wood & Ingram, Huntingdon.
- Class 10.—Six *Fuchsias*.—First, Lady Exeter. Second, — Walters, Oakham. Third, T. Almey, Oakham.
- Class 11.—Six *Caladiums*.—First, Messrs. Wood & Ingram, Huntingdon. Second, R. Brown, Wothorpe.
- Class 12.—Six *Begonias*.—First, Lady Exeter. Second, T. Almey, Oakham. Third, Messrs. Wood & Ingram.
- Class 13.—Six Roses in Pots.—First, — Walters, Oakham.
- Class 14.—Six *Achimenes*.—First, Lady Exeter.
- Class 15.—Six *Gloxinias*.—No award.
- Class 16.—Six *Calceolarias*.—No award.
- Class 17.—Six *Verbenas*.—First, Richd. Brown, Wothorpe.
- Class 18.—Six *Petunias*.—First, Richd. Brown, Wothorpe.
- Class 19.—Six Balsams.—First, W. F. Taylor, Esq., Wellaston House, Wellingborough.
- Class 20.—Six new Annuals in Pots.—Messrs. Wood & Ingram, disqualified.
- Class 21.—Six British Ferns.—First, A. Turner, Esq., Leicester. Second, S. Sharp, Esq., Dallington Hall.
- Class 22.—Newly-introduced Plant.—First, A. Turner, Esq., Leicester. Second, Messrs. Wood & Ingram.
- Class 23.—Three Fruit Trees in Pots, Miscellaneous, excluding Vines and Peaches.—No award.
- Class 24.—Three Peaches in Pots.—No competition.
- Class 25.—Two Vines in Pots.—First, Lord Exeter. No Second or Third.
- Class 26.—Collection of Fruit.—First, Silver Cup, Lord Exeter. Second, Jas. Landon, Wood Newton.
- Class 27.—Pine Apple.—First, T. Pagett, Esq., Leicester. Second, Lord Exeter.
- Class 28.—Black Grapes, two bunches.—First, Lord Exeter. Second, J. Harrison, Esq., Leicester.
- Class 29.—White Grapes, two bunches.—First, J. Hardy, Esq., Grant-ham. Second, L. W. Watson, Esq., Rockingham Castle.
- Class 30.—Scarlet-flesh Melon.—First, Wood & Ingram.
- Class 31.—Green-flesh Melon.—First, J. Hardy, Esq. Second, L. W. Watson, Esq.
- Class 32.—Six Peaches.—First, Lord Exeter. Second, T. Pagett, Esq.
- Class 33.—Six Nectarines.—First, Lord Exeter. Second, T. Pagett, Esq.
- Class 34.—No competition.
- Class 35.—Collection of Strawberries.—First, the Earl of Gainsborough. Second, Lord Exeter.

Class 36.—Brace of Cucumbers.—First, T. Paget, Esq. Second, Messrs. Wood & Ingram.

Class 37.—Six Varieties of Potatoes.—First, H. Thorneycroft, Weedon. Second, Jas. Warrell, Dallington. Third, Thos. Kilburn, Daventry.

Class 38.—No competition.

Class 39.—Twelve *Verbenas*.—First, Wm. Green, Rugby. Second, Wm. Draycott, Leicester. Third, Messrs. Wood & Ingram.

Class 40.—No competition.

Class 41.—Twelve *Carnations*.—First, Messrs. Wood & Ingram.

Class 42.—Twelve *Picotees*.—First, Messrs. Wood & Ingram.

Class 43.—Twelve Hollyhocks, Single Blooms.—First, Messrs. Wood & Ingram.

Class 44.—Stove and Greenhouse Cut Flowers.—First, Messrs. Wood & Ingram. Second, T. Almey. Third, Messrs. Walters.

Class 45.—Hardy Cut Flowers.—First, Messrs. Walters. Second, Messrs. Wood & Ingram. Third, — Lawrence, Chatteris.

Class 46.—Twelve German Stocks.—First, Messrs. Walters.

Class 47.—Device or Design in Cut Flowers.—First, Jas. Major, Oundle. Second, Messrs. Walters. Third, J. Almey. Highly Commended, John Fryer, Chatteris.

Class 48.—Wardian Case, arranged for the Drawing-room.—No competition.

#### OPEN TO GARDENERS AND AMATEURS.

Class 49.—Nine Stove and Greenhouse Plants in Bloom.—First, a Silver Cup, R. Bevan, Esq., Brixworth. Second, John Torkington, Esq.

Class 50.—Six Fine Foliage or Variegated Plants.—First, Earl of Gainsborough, Exton Park.

Class 51.—Six Exotic Ferns.—First, John Torkington, Esq. Benjamin Johnson, Dallington, G. L. Watson, Esq., Rockingham, were equal for second.

Class 52.—Six *Fuchsias*.—First, Richard Thompson, Esq., Stamford.

Class 53.—Six *Gloxinias*.—First, Richard Thompson, Esq. Second, Joseph Phillips, Esq., Stamford.

Class 54.—Six *Verbenas*.—First, Richard Thompson, Esq., Stamford.

Class 55.—Six *Achimenes*.—No award.

Class 56.—Six *Petunias*.—First, Richard Thompson, Esq., Stamford.

Class 57.—Six Cockscombs.—First, Sir Montague Cholmley, Bart., Second, T. H. Jackson, Esq., Stamford. Third, Joseph Phillips, Esq., Stamford.

Class 58.—Six *Calceolarias*.—No competition.

Class 59.—Six Balsams.—First, R. Thompson, Esq., Stamford.

Class 60.—Strawberries.—First, H. Thorneycroft.

Class 61.—Cherries.—First, J. Phillips, Esq., Stamford. Second, Lord Exeter.

Class 62.—Raspberries.—First, H. Thorneycroft. Second, H. Johansen.

Class 63.—Gooseberries (weight).—First, R. R. Crosby, Stamford. Second, G. Abbott.

Class 64.—Gooseberries (flavour).—First, R. Thompson, Esq. Second, T. H. Jackson, Esq.

Class 65.—Currants, Red.—First, G. Abbott. Second, H. Thorneycroft.

Class 66.—Currants, White.—First, H. Johnson. Second, T. Kilburn.

Class 67.—Currants, Black.—Second, Lord Exeter. No first prize.

Class 68.—Brace of Cucumbers.—First, T. Kilburn. Second, W. Corp.

Milford, Salisbury.

Class 69.—Collection of Vegetables, including Salad.—First, T. H. Jackson, Esq.

Class 70.—Celery.—First, T. H. Jackson, Esq. Second, G. Abbott.

Class 71.—Twenty Potatoes (Kidney).—First, G. Abbott. Second, T. H. Jackson, Esq.

Class 72.—Twenty Potatoes (not Kidney).—First, J. Islip. Second, G. Abbott.

Class 73.—Twelve *Verbenas*.—First, T. Pagett, Esq. Second, R. Thompson, Esq.

Class 74.—Bouquet for the Hand.—First, R. P. Voules, Esq., Uffington.

Class 75.—Glass of Honey in the Comb, free from Brood.—First, Rev. E. Holmes, Wakerley.

#### OPEN TO AMATEURS ONLY.

Class 76.—Four Stove and Greenhouse Plants.—First, W. L. Hopkinson, Esq., M.D., Stamford.

Class 77.—Four *Fuchsias*.—First, W. L. Hopkinson, Esq., M.D. Second, J. Swan, Stamford.

Class 78.—Four *Verbenas*.—First, J. Islip, Stamford. Second, J. Swan.

Class 79.—Four *Petunias*.—First, J. Islip.

Class 80.—Four Balsams.—First, J. Islip.

Class 81.—Six Cut *Verbenas*.—First, J. Swan. Second, W. Sells, Uffington.

Class 82.—Six Cut German Stocks.—First, J. Islip. Second, J. Swan.

Class 83.—Collection of Cut Flowers.—First, J. Swan. Second, J. Islip.

Class 84.—Basket of Fruit.—First, J. Islip.

Class 85.—Basket of Vegetables.—First, G. Abbott. Second, J. Islip.

Class 86.—Basket of Salad.—First, J. Islip.

Class 87.—Brace of Cucumbers.—First, Mr. Caltherpe.

Class 88.—Melon for Flavour.—First, J. Swan.

Class 89.—Bouquet for the Hand.—First, T. G. West, Dallington. Second, W. Sells.

#### CUT ROSES.

Class 90.—Forty-eight Varieties (Open).—First, A Silver Cup, Paul and Son, Cheshunt Nurseries. Second, E. Francis, Hertford. Third, B. R. Cant, Colchester.

Class 91.—Twenty-four Varieties (Dealers only).—First, W. Draycott. Second, S. Walters. Third, G. Battley, Rugby.

Class 92.—Twenty-four Varieties (Gardeners and Amateurs only).—First, a Silver Cup, Rev. S. R. Hole. Second, H. Thorneycroft. Third, A. Moffatt, Dunmow, Essex. Highly Commended, W. Corp: J. Watt.

Class 93.—Twelve Varieties (Gardeners only).—First, Rev. S. R. Hole. Second, C. C. Round, Esq., Colchester. Third, H. Thorneycroft, Esq.

Class 94.—Twelve Varieties (Amateurs only).—First, a Silver Cup, W. Corp. Second, J. Hepworth, Leicester. Third, J. Swan. Commended, E. Hunt, Leicester.

Class 95.—Six Varieties (Amateurs only).—First, W. Corp. Second, J. Hepworth. Third, T. H. Burroughes, Esq., Ketton Hall. Extra prize, J. Fryer, Esq. Commended, J. Swan.

Class 96.—Twelve Varieties Tea-scented Roses (Open).—First, Paul and Son. Second, B. R. Cant.

Class 97.—Twelve Trusses of Cloth of Gold (Open).—First, B. R. Cant.

Class 98.—Twelve Trusses of *Senateur Vaisse* (Open).—First, E. P. Francis. Second, B. R. Cant.

Class 99.—Twelve Trusses of any other kind (Open).—First, B. R. Cant. Second, S. Walters, Trowbridge. Recommended for Prize, T. Draycott.

Class 100.—Best Collection of New Roses (Open).—First, S. Walters. Second, B. R. Cant.—(*Lincolnshire Express*.)

## ORCHIDACEOUS PLANTS.

*Select Orchidaceous Plants.* By ROBERT WARNER, F.R.H.S. *The Notes on Culture by B. S. WILLIAMS, Author of the "Orchid-grower's Manual," and "Hints on the Cultivation of Ferns."* Assisted by some of the best growers. London: Lovell Reeve & Co.

This work promises to be excellent in every respect. The portraits of the Orchids in the first Number just published are of life-size, and truthfully drawn and coloured. They are four in number—*Phalenopsis Schilleriana*, *Cattleya amethystoglossa*, *Vanda insignis*, and *Cattleya Warscewiczii delicata*. The work will embrace only those Orchids which are most beautiful and recently acquired, whether they be species or varieties, and thus will include "real gems of the Orchid-house, which are rather ignored by those who look at the subject from a purely scientific point of view." Yet there is enough of scientific description given in language intelligible to every reader sufficient to confirm him in his identifying the plant, which he may do, however, by the portraits, without any such aid. The directions for cultivating the Orchids portrayed are also full and good. In fact the work, judging from the specimen, will be such as might be expected from the authors, they being one of the largest amateur proprietors, and one of the best practical cultivators of Orchids in our times.

We will extract a portion of what is stated relative to

### PHALENOPSIS SCHILLERIANA.

"This magnificent addition to our collections of Orchidaceous Plants has been introduced to this country by ourselves during the past year from Manila, and has proved to be one of the finest of the whole race. Several plants have blossomed during the spring of the present year, and divers of them have shown considerable difference in the colour as well as in the size and shape of their flowers, though all have been fine and ornamental in character. The plant has indeed already sufficiently shown its free-growing and free-blooming habit, three vigorous specimens having been flowered by J. Day, Esq., of Tottenham, and others by E. M. Morland, Esq., of Haverstock Hill, by J. A. Turner, Esq., of Manchester, by ourselves, and by other growers: all these having been imported since April, 1861. It has, in fact, every good quality which can be desired in such a plant, and we have no hesitation in asserting that it will prove to be one of the most charming Orchids in cultivation. Not only are the leaves handsomely variegated, but the flowers are large, showy, and fragrant, as well as distinct from all others, and they continue in beauty for a long period. It is, moreover, a capital exhibition plant, as is proved by its having travelled without injury to Belgium, as well as to one of the spring meetings of the Royal Horticultural Society at South Kensington, at which latter place we exhibited in bloom the first example which flowered in England. This specimen, though imported so recently, bore sixteen perfect blossoms on the scape at one time, and they all continued in good condition more than eight weeks, a peculiarity which will make it a more useful plant for exhibiting than even the older species.

"This *Phalenopsis* is of compact growth, and attaches itself by means of flat roots, which have a white frosted appearance. It bears remarkably handsome variegated foliage, which, as shown by the imported specimens, sometimes reaches from 12 to 15 inches in length, and 3 to 4 inches in breadth. These leaves are similar in form and size to those of *Phalenopsis grandiflora*, of a dark green colour, and marked with irregular transverse bands and blotches of white. The flower-spikes are produced from the axils of the leaves, and in their native country are over 3 feet long, and more branched than in the other kinds. Mr. Williams has a dried specimen which has borne more than a hundred blossoms. In the plant now before us, the flowers are 3 inches across, and arranged in two rows along the spike; the sepals and petals of a beautiful light pinkish-mauve, passing almost to white at the edge, and the lip of the same colour, with darker purple spots, yellow towards the base, and there spotted with reddish brown.

"The accompanying illustration was taken from a plant which bloomed with Mr. Williams, at the Paradise Nursery, Holloway.

"The plants require the heat of the "East-India house," with a good supply of moisture during the growing season. In Manila they are found growing on the branches of trees, in moist shady places, where the temperature is high; and to grow them to anything like perfection, the climate in which they grow naturally ought to be imitated as nearly as possible. They are of easy culture, and if properly attended to seldom get out of health. Unlike many of the Orchids, the plants of this genus have no thick fleshy pseudobulbs to support them, and they consequently require a larger supply of nourishment to cause them to grow to perfection. This must be afforded by supplying them freely with moisture at the root during their growing season; in fact, they should never be allowed to get dry, for if so they are apt to shrivel, and then often become disfigured by losing their lower leaves. The beauty of the plant consists as much in having perfect healthy foliage, as in producing good flowers.

"The growing season extends from March to the end of October, during which time the temperature by day should range from 65° to 75°, or it may be allowed to rise to 80° or more by sun heat, provided the house is shaded from the sun's rays. The night temperature should range from 65° to 70° during March and April; afterwards it may be allowed to rise a few degrees higher. During the resting season, from the end of October to February, the temperature should range from 60° to 65° by night, and about 65° or a

little more by day. When these data are exceeded, it is desirable to admit a little fresh air, and this should be admitted close to the hot-water pipes, so that it may be warmed as it enters the house. A little water should be thrown about on fine days, but this should always be done in the morning, so that the house may be dry again by evening.

"These plants are grown in different ways, some persons placing them on blocks, some in pots, and some in baskets. We find them to succeed well under each of these modes of treatment; but they require more moisture to be applied to the roots when fixed on blocks, and if they are grown in pots, they must have more drainage than when put in baskets. The best plan of draining is to turn a smaller pot upside down in the bottom of that intended for the plant, and then to fill in around this to within about 2 inches of the rim, with posherds, broken into pieces of about 2 inches square. Above this the pot is to be filled up with sphagnum moss, mixed with a few small posherds, the plant being so placed as to be elevated 3 inches above the rim; it must also be kept well above the moss. The successful culture of these plants, as well as of all other Orchids, depends upon good drainage. When grown on blocks, they should be placed on a good-sized one, so that there may be surface enough for the roots to cling to. In fixing them, first put a little live sphagnum moss against the block, and then tie the plant to it with copper wire. The blocks should be hung up to the roof of the house, but should not be placed too near the glass, in order that they may not be affected by the cold; this should be guarded against, especially during the winter, at which season Orchids frequently sustain injury in this way.

"If the plants should get into an unhealthy condition, the best course is to turn them out of the pots or baskets in which they are growing, to shake the material off the roots, to wash them with clean water, cutting away all the decayed parts, and then to place them on blocks of wood, with a little sphagnum moss. They must have a good supply of moisture at the roots, and should be placed at the warmest end of the house, and where they will not receive too much light. With this treatment they will soon begin to root and improve in appearance. They must be kept perfectly clean from insects, especially the thrips, which soon disfigures the foliage if it is allowed to increase. This troublesome pest is best kept under by frequently washing the leaves with a sponge and clean tepid water, or by fumigating the house with tobacco smoke, which should be applied with great care.

"The species of *Phalenopsis* are difficult to propagate. Sometimes they will produce young plants on the old flower-stems; such plants should be left on till they are well rooted, and should then be placed each on a small block. All the kinds occasionally produce plants in that way. Sometimes they throw out side-growths, which can be taken off when well rooted; and when the plants get large they may be cut in two, so that roots are attached to each portion. They are best cut when just beginning to grow, and the divided plant should not be allowed to flower until it is well established."

## REPORT ON THE VARIETIES OF KALE, OR BORECOLE,

GROWN IN THE GARDEN AT CHISWICK DURING THE SEASON OF 1861-62. By ROBERT HOGG, LL.D., F.L.S., Secretary to the Fruit Committee.

(Continued from page 293.)

CURLED KALE, TALL . . . COOPER & BOLTON.

This is what is known by the names of Tall Green Borecole, German Greens, Tall Scotch Kale, and by the French *Chou frisé vert Grand du Nord*. The plant grows 2½ feet high, and produces a great quantity of dark green curled leaves. In the spring it throws out a large supply of shoots, which are much esteemed as a culinary vegetable.

CURLED KALE, DWARF . . . COOPER & BOLTON.

*Chou frisé vert à pied court* . . . VILMORIN & Co.

*Dwarf green Curled Kale* . . . LEE.

The Dwarf Curled Kale is in every respect similar to the Tall Curled, with the only exception that it is of a dwarfer growth, and not more than 18 inches in height.

EGYPTIAN KALE . . . COOPER & BOLTON.

This is very distinct from either Buda or Jerusalem Kale. The stem is very short, being not more than 6 inches long, and in spring it throws out numerous long, stout, succulent shoots, from a foot to 15 inches long. The leaves are sinuated, coarsely serrated, and plaited on the margin. It is very hardy and very productive, perhaps the best of all the sprouting Kales.

HEADING KALE . . . CARTER & Co.

*German cabbage Greens* . . . LEE.

*Heading Kale* . . . COOPER & Co.

This is a variety of Curled Kale, which forms a close head on the summit of the stalk. The leaves are exactly the same as those of Curled Kale, and the plant grows from a foot to 18 inches high. It is a very valuable winter green.

JERUSALEM KALE . . . COOPER & BOLTON.

The habit of growth is exactly similar to Egyptian Kale. It has the same short stock, which is only about 6 inches long, or even less in some instances, and it throws out in spring a profusion of long, stout, succulent shoots. But it is readily distinguished from Egyptian by its more deeply sinuated leaves, which are crisped or curled on the margin somewhat in the same way as in Scotch Kale. The very young and partially developed leaves are tinged with purple on the margin, and clothed on both surfaces with stiff bristly pubescence—very hardy, and very productive.

MELVILLE'S VARIEGATED KALE . . . COOPER & BOLTON.  
*Melville's new triple curled varie-* } DICKSON and  
*gated Kale* . . . . . } SONS, Chester.

The varieties raised by Mr. Melville are a decided improvement on the old variegated German Kales, and are more curled and ornamental. They consist of almost every imaginary colour and shade of colour, and are more or less variegated. In some the disk of the leaves is white, and the margins fringed with green, red, or purple. In others the disk is green, red, or purple, and the margins white; while others are variously blotched or veined. As ornamental plants for autumn or winter decoration they are very desirable; and for garnishing they are very valuable. When cooked carefully, some of them preserve their natural colours, and are equally as ornamental and useful on the table as they are in the garden.

MILLER'S KALE . . . . . COOPER & BOLTON.

In the habit of growth and general appearance this is the same as Buda, but it is so very tender only a few plants of it stood the winter.

PALM KALE } . . . . . VILMORIN & Co.  
*Chou Palmier* }

The stem is from 2 feet to 2½ feet high, clothed with large oblong-obovate winged leaves, of a dark green colour, which curve gracefully upwards and outwards much in the way of feathers in the Prince of Wales' crest, and the whole plant in this state has the appearance of a miniature Palm. In the spring it throws out a great mass of long slender shoots, which speedily run into bloom, and render the plant of little value as a winter green. In this state it entirely loses its ornamental character, but in autumn and during the winter it is an object of great beauty, and might be advantageously introduced as a prominent feature in a winter garden, or as a plant for a vase in architectural gardens. As a winter green it is quite worthless.

RAGGED JACK . . . . . COOPER & BOLTON.

The growth of this is similar to that of Egyptian, having the short stock and long succulent shoots, but it differs from both that variety and Jerusalem in having the leaves very deeply lacinated, and the segments either trifid or multifid. The young leaves are not hairy, as is the case in Jerusalem Kale. This is remarkably hardy and very productive.

RED KALE . . . . . COOPER & BOLTON.  
*Chou frisé rouge grand* . . . . . VILMORIN & Co.

Stem 2 feet to 2½ feet high, sending out in spring a great profusion of shoots from the bottom to the top, of a dark purple colour. The leaves are like those of Scotch Kale, but purple. This is a first-rate and very productive Kale, and exceedingly hardy.

PROTECT YOUR FRUIT AND SPARE THE BIRDS.

If an ornithologist and gardener, though only an amateur, but an admirer both of fruit and flowers as well as a sincere friend to the feathered race, might be allowed to trespass on the good nature of the Editors, and the patience of the readers of THE JOURNAL OF HORTICULTURE, in making a few remarks on the present engrossing topic, "Birds versus Fruit," he would gladly avail himself of their kindness.

Having for many years advocated the protection of our birds among neighbouring farmers and gardeners, though I fear with but indifferent success, it has been with no small interest that I have from time to time read the various articles on the subject in your columns, and none with more than the very able and explicit remarks made both by "G." and Mr. George Abbey, in No. 68. The latter especially, as the opinions of a practical gardener.

As I sit writing, this 16th day of July, a pair of Sparrows are feeding their young in the window-sill above my head. Not near a smoky town however, "with two hundred chimnies emitting their suffocating fumes unrestrained by smoke-consuming apparatus, where there are not so many vegetables and fruit for the Sparrows to eat;" but in a lovely country with a pure exhilarating air, in the midst of sunshine and plenty, a kitchen garden close at hand, with Currants, Raspberries, Strawberries, and Peas now in abundance. Well! and what then?

Here comes the cock bird to answer for himself. There he is sitting on the window-rail with his peculiar self-satisfied chirp, and a fine, large, green caterpillar curled over his bill. I have

not long to wait. Here comes his mate with a large yellowish grub, they give a note of recognition, first one dives through a chink in the wall, and then the other. A number of small voices are heard proceeding from the said chink, a couple of dark objects suddenly dart past the window. There, they are off again on another caterpillar hunt, and so it goes on from morning to night. All our small birds are equally busy. The amount of good they do to man is beyond calculation.

Some will say, This is an oft-repeated story. So it is, and, therefore, I will not dwell on it. But there is one in the black books that I feel bound to say a good word for, especially as "G." says he has nothing to say in its favour, and that is that most lovely of British birds, the Bullfinch.

It was in the spring of 1857, I was living in a part of the country where Bullfinches abounded, and where I had continually to be on the watch to scare them from the garden (for, mind, I never destroy birds). When on a certain Monday morning on looking over some of my dwarf standard Apple trees, to my consternation I found the ground strewn with their buds, the Bullies having taken advantage of the previous Sunday when all was quiet to commit their work of havoc. One tree in particular was so divested of its buds that I considered it ruined for the season. Bullfinches were, consequently, in disgrace. Yet, truth is stranger than fiction! Business called me away for some time, and I did not return till the autumn of the same year, when on examining my little trees, to my amazement I discovered that those which had been attacked by the Bullfinches were loaded with fruit, especially the one which was apparently stripped of all its buds, so much so that the branches had to be propped, and nearly three dozen fine fruit were gathered off it, which, by-the-by, was too much for it to bear. But still more marvellous, the trees which I had been congratulating myself on as having their buds safe, had hardly a single fruit. This was too much; I said nothing, but made a note of it.

Three years afterwards I happened to be on a visit at a friend's in another part of the country, a Number of THE COTTAGE GARDENER was on the table.\* I took it up to wile away an idle moment; it opened at an article on British Finches, headed "The Bullfinch." Being interested in birds, I glanced it over, when my eye fell on the following:—"In 1847 I was living at Salehurst, Sussex, and in the spring the Bullfinches came in great numbers to the fruit trees. Being desirous of catching some, I requested they might not be shot or driven away, and I set traps for them; but without success. In a few days after, the gentleman with whom I resided showed me the trees and bushes stripped of their buds, the snow beneath the trees being scattered over with the bud-cases. He remarked that, in consequence of sparing the Bullfinches, they would lose all the fruit that year. I examined a Green Gage tree in particular, and I could not find a bud on it anywhere, and I regretted to think I had been the unthinking cause of such destruction. But, after all, the trees blossomed well, the fruit set, and they had abundance of fruit that summer on those very trees which had been so stripped of buds." He then goes on to say—"I have often since been laughed at for trying to persuade others not to kill the Bullfinches, but to let them eat the buds. By noticing the effect, and pointing it out to my neighbours, some of them have also been convinced—one in particular, who showed me his Gooseberry bushes stripped of buds, was very angry with me because I would not believe but that he would have fruit there. He said it was impossible. 'Wait and see,' said I; and those very bushes were loaded."

I could not help being much struck with the coincidence. Mr. B. P. Brent, the writer of the above, should he ever read this, will have the satisfaction of knowing that from that moment he was the innocent cause of adding one to the list of the subscribers to THE COTTAGE GARDENER, and one who has never had cause to regret it.

One word more for Bully. The vast amount of seeds of Dandelion and other noxious weeds which he destroys more than compensates any mischief he may do in assisting the gardener to disbud his trees. Let every one protect his fruit and spare his birds.—ORNITHOLOGIST.

P.S.—Would Mr. Edward Hewitt kindly mention which Flycatcher he alludes to as "the common Flycatcher," in No. 63, page 200? as I have always considered the spotted Flycatcher (*Muscicapa grisola*) to be the common one, and not the pied (*Muscicapa atricapilla*).

## THE PICTURESQUE IN HOTHOUSES.

THE usual internal arrangements of a hothouse—or stove, as such a structure is more commonly called—are such as to render a visit to its botanical treasures anything but a luxury; on the contrary, in an artistic point of view, it is too often utterly unworthy of notice. The most rare and beautiful plants are usually put away as closely as they can be packed, with only room sufficient, as it were, to pass round them for the vulgar purpose of counting or numbering them like so much common merchandise: this is surely not treating a collection of the most exquisite creations of nature with due respect. The expense of erecting a structure of sufficient size to exhibit a large selection from the flora of the tropics, so as to give adequate space for the full display of the habit and character of each individual plant, is not an argument against the position just assumed, inasmuch as it would surely be more consistent with the highest principles of taste that the collection should be small, but spaciouly, elegantly, and conveniently exhibited, rather than that it should be large, and stowed away like merchandise in a warehouse. Where the plants are cultivated for sale, it is of course necessary that they should be grown in as small space as possible; even where a collection is made for the purposes of scientific study only, it may be equally necessary to abandon all idea of picturesque arrangement, in deference to convenience of reference, or

the introduction of a greater number of genera. But where a structure for their growth is considered in the light of an elegant, luxurious, and instructive appendage to a private residence, all reasons for rendering its arrangement inconvenient and repulsive disappear, and leave the ground clear for attempting some improvement which shall render the hothouse a more picturesque and attractive object than, in ordinary cases, it has hitherto been.

There are many modes in which such a structure might be rendered both picturesque and interesting. The present paper embodies a theory that has long been a very favourite one with me. A principal feature is to relieve the spectator from the impression that he is walking under glass, thus destroying the illusion of a tropical scene which the plants around him would otherwise convey. I propose to effect this by making the framework or skeleton for receiving the glass of irregular forms, resembling interlacing branches of trees, which would greatly tend to encourage the illusion that the openings between the branches were actual openings and not glazed. This effect may again be considerably heightened by training climbing plants over some of the framing branchwork, as though climbing the trunks of natural trees, while others of the simulated branches should be left bare. Bananas and Palms, by occasionally reaching near to the branchwork roof, would still farther aid in con-

SKETCH OF A CONSERVATORY FOR TROPICAL PLANTS.

cealing its artificial character. In an experiment on a small scale I would only have a path through the centre, so that the sides should also be concealed by plants rising above each other on an irregularly formed bank.

Through the centre of the house a stream of tepid water should flow, in which, amid fragments of rock and large boulders, aquatic plants of the tropics should be seen displaying their wildest habits, and assuming all the varieties of character which they exhibit in their natural localities. This stream might also be enlivened, not only by gold fish, but by other species of curious freshwater fish of the tropics, and its borders might be enriched by shells suitable to the natural climate. The stream could be made to assume the appearance of a partially-dry forest torrent, such as would during the hot season leave a sandy or pebbly beach on either side of its diminished waters; these again might form two pathways through the midst of this miniature forest, imitative of an Indian or Brazilian climate.

Some of the very finest *Ipomæas* and *Passifloras* might form the matted foliage above, interspersed with the heads of a few trees and fine Palms of large foliage, without strictly confining the selection of trees to such as would be proper in forest scenery. The undergrowth should be intermingled with gigantic Ferns

and other green plants, to form a rich background for highly-coloured flowers, which should be such as would flower best with only a moderate degree of light. A selection of very splendid plants might easily be made, which would actually flourish best under these circumstances, and the wild and forest-like effect of such a scene might be greatly heightened by the addition of a few of the more brilliant and sweet-scented Orchids suspended from the roof.

Another addition to the scene—one which I have alluded to in another work—is the introduction of exotic butterflies, which, in such a situation, fluttering from flower to flower, opening and closing their gorgeous wings, and exhibiting their rich metallic hues in various lights, would impart a tropical life to the composition hardly to be obtained in any other way. This experiment might very easily be tried, as the capture and sale of tropical insects has become quite a trade in districts where they are remarkable for their beauty. The men employed in this pursuit might easily be instructed to procure chrysalids instead of the perfect insect; and in the chrysalis state they are easily packed for carriage without the slightest risk of injury. Chrysalids so imported might be placed in secure positions in a hothouse of this description, and when the time arrived for the

perfect butterfly to come forth, they would find a temperature suitable to their constitution and structure; and if they did not become the parents of future broods, they yet would exist during their own natural term of life, and a fresh importation could be made in the next season. In some cases the eggs might be imported, as those of the silkworm are, care being taken to provide the peculiar plants on which they feed, and this would probably prove the most effectual mode of naturalising a family of exotic butterflies in an English hothouse.

The structure I have been describing would not exhibit attractive features on the exterior, which should therefore be concealed by shrubberies placed at sufficient distance, however, not to impede the light; and the small open space between the building and the shrubbery might be made use of for raising cuttings or other unsightly operations where concealment is desirable. I propose that the approach to the "tropical forest" should be through a valley of rocks well clothed with Yuccas and other plants of exotic appearance that yet bear our climate well. In this piece of rockwork, a tunnel or passage might be constructed containing a door—the actual door of the hothouse,

but which will not be seen from the interior of that structure, being concealed in the rocky passage. On emerging from the comparative darkness of this passage, the height, light, and general dimensions of the building will expand upon the eye in a very striking manner, while the illusion will not be destroyed by the act of unlatching a glass door to effect an entrance—the door and all its appendages being concealed in the tunnel. When within the structure the spectator will only perceive, on looking back, a group of rocks with a cave-like opening, the exit at the other end being managed in a similar manner.

The stream of water should enter at one end among the trees, and wind to the centre, as it appears in the accompanying design; at the other extremity it should, in a similar manner, turn among the trees and find its exit at a concealed point, leaving the centre of each end free for the rockwork entrance and exit. The water could be warmed to the necessary temperature by pipes passing over the general heating apparatus previous to entering the building.

The object of the following design is to show how, in quite another style to the one above described, a conservatory may be made highly decorative, so as to produce a more gârdenesque

SKETCH OF A JARDIN D'HIVER, OR ENGLISH CONSERVATORY.

effect than is usual. In the first place, the walks are intended to be of fine gravel instead of the chilly and ungentle tile floor generally used. Secondly, the centre part of the building, instead of being choked up with tall shrubs and trees, is to be kept spaciouly open, low-growing plants only being placed in the ground as in a flower-bed, in the central compartments. These plants are to be brought from a reserve-house when in perfection, and removed in succession as they get past their best, their places being filled with fresh ones. The side walks, which cannot be shown in the drawing, are to have a bank next the glass filled with plants in flower like those of the central beds, and these walks are likewise to be of fine garden gravel. The plants in the vases, &c., are intended likewise to be removed continually, the only permanent ones being the Palms and larger shrubs planted in the ground in the central and most lofty compartment of the building, and the climbing plants attached to the supports and the roof.\* Large seats of bold design, either

of stone or of wood painted stone-colour, should be placed at certain distances apart, and a well-designed circular seat is meant to extend all round the group of Aloes and other plants in the centre.

A spacious and pleasant promenade might thus be arranged, which, in wet weather, would be no contemptible substitute for the garden itself, while, during four or five months of the year, it would form a true jardin d'hiver, to which a covered passage might be constructed from some conveniently situated room which can be visited from the house without passing into the open air.

As a place where pleasant exercise might be taken daily among beautiful trees and flowers, there can be no comparison between the house just described, and one in which the whole building is so choked up with plants and flower-pots that there is no room to move; where the air is so overlaid with close earthy smells, that any sensation of pleasant or healthy exercise within its heavy atmosphere, must at once evaporate, as inconsistent with the place.—H. N. HUMPHREY, Esq.—(*Gardener's Magazine of Botany.*)

\* The roof of this building is not intended as a model for execution, being merely a rough sketch introduced to exhibit the interior arrangement.

## FIFTH ANNUAL MEETING OF WORKINGMEN BOTANISTS.

[This report is written by one of the "Workingmen-Botanists" who attended the Meeting, and we are well pleased at being able to publish it. Those artisan searchers after good knowledge stand out a noble example for the working men of other parts of our native country. May they prosper and add to their numbers a thousandfold.—Eds. J. of H.]

At the Meeting on July 13th, of the Botanists of Lancashire, Cheshire, Derbyshire, and Yorkshire, were brought together about five hundred specimens of plants, both native and exotic, in the Odd Fellows' Hall, at Ashton-under-Lyne; and amongst that number of plants the most rarely seen in these districts are the following:—*Isatis tinctoria*, *Samolus Valerandi*, *Thlaspi arvensis*, *Hippuris vulgaris*, *Poa aquatica*, *P. glauca*, *Rubus chamaemorus* or Cloudberry (in fruit). Amongst the Mosses were *Hypnum falcatum*, *H. exanulatum*, *H. giganteum*, and *H. stramineum*. Among Ferns the scarcest was *Woodsia ilvensis*. The Mosses were in good fruit.

The scarcest exotic plants were *Dictamnus fraxinella*, *D. albus*, *Gentiana lutea*, *Mimulus glutinosus*, *Pea elatior*, *Eucomis punctata*, *Sedum perfoliatum*, *Antirrhinum molle*, *Verbascum ferrugineum*, *Uvularia perfoliata*, *Cimicifuga serpentina*, *Andromeda speciosa*, and *Rhus glabra*.

Messrs. Edwin Clough (a cotton warp dresser), John Whitehead (a self-acting minder of spinning-jennies), Henry Newton (a plumber and glazier), and James Percival (a mechanic), from Prestwich, near Manchester, were called upon to name the plants, and Mr. John Hague was called to the chair.

Mr. Robert Lees, of Manchester, brought the following specimens of the *Carex* family—viz., *muricata*, *teretiusecula*, *remota*, *aurita*, *ovalia*, *vulgaris*, *palleseens*, *panicea*, *strigosa*, *pilulifera*, *glauca*, *Cederi*, *lævigata*, *sylvatica*, *pseudo-cyperus*, *hirta*, *ampullacea*, and *paludosa*.

The Chairman in opening the Meeting, said he felt highly flattered in having been called upon to preside over a meeting of this description, and he should endeavour to do his duty to the best of his ability; for if there was one thing he loved more than another it was to be amongst plants and students of the vegetable kingdom. And whether mythical or true that our first parents were placed in the midst of plants in a garden, it was a beautiful conception, and most of the histories and traditions of olden time noticed the wisest and greatest men as having some connection with plants. Diocletian, one of the Roman Emperors, could not be brought back from his plants, after he had abdicated his throne that he might devote more time to the cultivation of his garden. To the man who would excel in any of the fine arts, whether as a painter, a calico-printer, or any other ornamental pursuit, a knowledge of plants was indispensable; for a person having a knowledge of them, had an acquaintance with the thousands of beautiful forms and arrangements of colours in the vegetable kingdom; and one reason why English artisans were so far behind the artisans of some of our continental neighbours in their arrangements of colour, was because continental artisans were taught to study flowers for their designs.

The study of botany was of immense importance to the denizen of a city or a town, for it invited him out to converse with Nature, and some of the conventionalities of a town life were lost thereby. It induced him to visit the country more often than he would do if he had no knowledge of natural objects, and he derived a thousand more pleasures when visiting the country if he were able to converse, as it were, with every humble-looking weed he might meet with.

By a knowledge of botany the seasons were more comprehensive. Each as it came round on the wings of time brought old acquaintances to view; and the genuine lover of flowers was as glad to see the first Primrose in spring as if it were some old friend, and would gladly shake its hands if it were gifted with those members.

Botany is a means of preserving health, for to acquire a practical knowledge of it the student had to go into the pure air of the country; and the pursuit of it leads men into the regions of the grand and beautiful, where the mind could find exercise or rest without the contaminating influences that often accompany a town's pleasures.

The study of botany had this advantage over other sciences—it could be pursued everywhere; and to attain a knowledge of it did not require costly apparatus. All the sciences were

nevertheless connected, and those who had leisure and means could not spend life better than in investigating the tens of thousands of wonders in both the terrestrial and celestial worlds.

The plants in the world would not cease to grow if there were not some system of botany; but it is very doubtful whether they would be so extensively known as at present, for order was quite as much required in the vegetable kingdom as in the ordinary affairs of life. The large mills we have around us in Lancashire could not be so successfully carried on if there were not separate departments for each kind of work to be done; and the systems of botany, whether of Linnæus or Jussieu, which are arrangements of plants into classes, orders, families, and members of those families, were based upon no fanciful ideas, but upon the structure of the plants themselves. He, the Chairman, felt confident that many who were present who were strangers to botany would think it a science of break-tooth names, but he could assure them that the names were quite essential to a thorough knowledge of botany; but he disapproved of always giving a Latin or Greek name to plants to persons who do not understand those languages. With these few remarks he begged to thank them for their patient attention, and he felt confident that all would be not only gratified but instructed by their attendance.

The Meeting was attended by over three hundred persons, and the naming of the plants required more than two hours.

Persons attending these Meetings must not expect to find men with the polished manners of a courtier; but, on the contrary, men who speak in the dialects of the districts they come from.

The Meeting passed off very successfully, for the day was remarkably fine, which enabled many to come long distances.

## BALANCE THE GOOD AND THE EVIL.

### BIRDS OF PREY.

I HAVE been much interested in the various opinions lately expressed in THE JOURNAL OF HORTICULTURE in reference to the good or evil conferred by birds in the destruction of insects; and I have no doubt but that such discussion will call forth attention to this important question. It is not whether the birds do any harm, but if the good they perform exceeds the injury they inflict, and whether the injury from insects would not be a thousandfold greater than it is if the birds did not keep them in check. I am certainly of the opinion that the birds generally are our great benefactors, and that they are not properly appreciated, and that to destroy them is only "jumping out of the frying-pan into the fire;" still I have no doubt that there are those who could not be persuaded of their good services until they had suffered the grievance of their loss.

As I fear but little is known of the habits of birds generally, I beg to say a few words on the different kinds of birds as bearing on this subject, though I know they will be but very imperfect.

I propose in this letter confining myself to the birds of prey. The first, then, on our list will be the Eagle; and as the question is the good or harm they do, I shall have but little to say of him. His majestic flight, circling, soaring, and stooping over mountain or moor adds grandeur to the scenery, and there are those landed proprietors who would protect them on that account. On the other hand, as they prey on rabbits, hares, lambs, kids, fawns, and once or twice have been known to carry off a child, I do not think they can be considered a national benefit, nor will they become general favourites.

A step lower and we come to the Falcons, among which the Peregrine Falcon attracts notice. This bird, too, is admired for its aerial flights and enhancing the picturesque. It is also the great favourite of the falconer, who delights in the ancient and once noble sport of hawking, in which he may find amusement and health as well as giving some employment to others. As the Peregrine Falcon strikes or catches its prey on the wing, it is not thought to be very destructive to game; and consequently many sportsmen, if they do not actually protect them, at least do not destroy them. At liberty their favourite quarry seems to be Ducks, then Pigeons and Rooks: they are, therefore, injurious to wild-fowl decoys, although the birds are tolerably secure while they keep the water. To the Pigeon-fanciers they are his most dreaded enemy, whether he is a fancier of Homing birds or a flyer of Tumblers. Nor can any good arise from his

considered he will stand rather below the mark in utility.

There is one Hawk—the Kestrel or Windhover, which, though according to naturalists is a true Falcon, yet, despised by falconers, is a truly useful bird. His diet consists of mice, varied with an occasional cockchafer or other large insect, and on this account is of great use to the farmer and agriculturist. He is not addicted to poaching, nor need the farmer's wife suspect him of taking her chickens: therefore he should always be protected and regarded as a national benefactor.

Of the other Hawks, as the Sparrowhawk, the Merlin, and the Henharrier or Blue Hawk, I can say nothing in their favour, as they destroy alike game, poultry, and useful small birds. On this account they are destructive pests, but the farmer and gamekeeper will do well not to confuse the harmless and useful Kestrel with these destroyers.

Before closing this letter I must give a few words for the Barn Owl. This quaint fellow, which shuns the glare of day, sallies forth at evening and hunts through the night for mice. Mice are his principal food, of which he destroys immense numbers; and if he varies his food, it may be a large insect or young rat. Of game or poultry he is innocent, and has been known to live in the dove-cote without injury to the Pigeons old or young. He is, therefore, a great public benefactor. Every farmer and gardener should encourage and protect them. Gentlemen should forbid their gamekeepers and servants to destroy or interrupt them. Their great usefulness should cause them to be held in high esteem, whereas ignorance and superstition too often consign them to an ignominious death.

The Brown or Wood Owl is also useful in destroying vermin; but of its other habits I am unable to speak with certainty.—  
B. P. BRENT.

## THE INTERNATIONAL EXHIBITION.

(Continued from page 296.)

### WESTERN AUSTRALIA.

The colony of Western Australia comprehends the whole of that continent lying to the west of 129° E. long., extending in its greatest length 1280 miles from north to south, 800 in breadth, and having a coast-line 2000 miles long.

The climate is not so dry as that of Eastern Australia, and is generally considered very salubrious. All our English vegetables succeed well; and the Apple, Pear, Peach, Apricot, Orange, Melon, Banana, Olive, Fig, and Vine grow luxuriantly. To the cultivation of the latter particular attention is now directed with a view to the production of wine, of which 20,833 gallons were made in 1859.

Several samples of wines from different vintages are shown. Those from W. P. Clifton, Esq., Leschenault, are labelled Pedro Ximenes, White Frontignan, and Black St. Peter's; and we learn from the "Descriptive Catalogue" published by the colony that they were produced on strong sandy land capable of growing Wheat, the subsoil, at from 2 feet to 4 feet deep, being sand. The ground was trenched 2½ feet to 3 feet deep, and the Vines planted 6 feet by 4 feet apart; the produce of Pedro Ximenes is stated at 400 gallons per acre; that of another kind, the Fontainebleau, at 1200 gallons. Mr. Little exhibits wine from the Black Frontignan Grape grown on a soil of decomposed granite; Mr. McGuire, probably, the same kind of wine; and Mr. Barlee six bottles of a wine said to resemble a light claret, obtained from a small Black Cluster Grape grown on a loose dry sandy soil near Perth.

Dried fruit, and particularly figs and raisins, is another object to which the colonists have turned their attention, and is now rising into considerable importance, 18,952 lbs. having been dried in 1859. Mr. Hardy, of Peninsula Farm, is, however, the only exhibitor of dried fruit in the shape of a box of raisins made March, 1861, and accompanied with some finely-grown almonds.

Some fine Wheat is also shown here—that from S. Parker, Esq., weighing 64 lbs. 12 ozs. to the bushel; from A. Muir and Sons, 65 lbs. 6 ozs.; whilst Mr. D. Clifton has a sample stated to be of the extraordinary weight of 70 lbs. per bushel; from the same gentleman there likewise comes a gallon of apparently very good olive oil.

Mr. G. Clifton, Fremantle, exhibits 50 ozs. of "Eucheuma speciosum," or jelly seaweed, a quantity which is stated to be sufficient to produce 100 quarts of jelly or blanc mange. To

prepare it for use the following instructions are given:—First soak it in cold water for twenty-four hours, when it will become perfectly white, and swell considerably; then boil it in a quart of water or milk till it is perfectly dissolved; sweeten, and flavour to taste, and put into a mould. Let it stand until cold, when it will become a firm delicious jelly, remaining so in the hottest weather.

If on trial here this substance is found to bear out the account given of it, it would no doubt become an article of considerable import.

We now come to by far the most important part of the Western Australian exhibition—the timber, of which several kinds are shown.

The most valuable, apparently, is the Jarrah wood, a species of Eucalyptus, commonly called mahogany in the colony from its resemblance to that wood. It is remarkable for its immunity from decay, resisting the influences of the atmosphere and water, the white ant, and the sea worm, by which every other kind of timber is soon destroyed. As a proof of its enduring qualities a pile which had been twenty-nine years in the sea at Fremantle is exhibited. The lower portion was under water, and exposed to the attacks of the sea worm, the middle was between wind and water, and the upper part was exposed to the summer sun and winter rains. On examination we found it had scarcely suffered from decay, and that only on its outer surface. The resistance of the Jarrah to the attacks of the white ant is also shown by a beam which had formed a doorstep to a house, and which had been constantly subjected to the influence of wet sand from the oozing of a spring. It is still quite sound all but the surface, which had decayed to a very trifling depth.

From the Royal Engineer department at Fremantle there come two posts of the same kind of timber which had formed part of a bridge, and had been seventeen years in the water. The tenons were left in an almost perfect state, and one of the posts was polished on one side to show the small amount of deterioration which it had undergone. Captain Wray, R.E., says of this wood, "I have myself used upwards of 3000 loads of it in building jetties and bridges, and I have examined timbers which have been exposed to the action of the white ant and sea worm in situations where it would have been destroyed if liable to destruction from either of these causes, and I never saw any penetration deeper than the sapwood, though deal or other timber close by was completely eaten away. This immunity from destruction is generally attributed to its containing large quantities of gum resin. The strength and elasticity are about equal to Rigs Fir.

"I know of no objection to it except that it is somewhat slow to season, and if exposed before seasoned will fly and cast, perhaps, rather more than other timbers. The plan lately adopted in Western Australia to season it was to leave the logs in the sea for a few weeks, and then draw them up on the beach, and cover them with a few inches of seaweed, taking care to prevent the sun getting at their ends. My experience led me to the conclusion that logs might lie in this way without injury for almost any length of time."

It thus appears that the Jarrah is invaluable wherever timber is to be exposed for a lengthened period to the action of water or of the atmosphere. Accordingly, if found in other respects suitable, it might be very advantageously employed in ship-building, whilst its value for piling and railway sleepers is unquestionable. For the latter purpose large quantities are now exported to Eastern Australia and India.

The Tooart and Blue Gum, of which there are vast forests in the southern part of the colony, are said to be equally valuable with the Jarrah, and that the close hard-grained wood of these will endure a great amount of heat without splitting, and to be extremely durable; they are, consequently, recommended for engine-rooms and other ship-building purposes.

Of other species of Eucalyptus, that called Raspberry-Jam Wattle is a very handsome wood, susceptible of a high polish, and scented somewhat like the fruit from which it takes its name.

The White Gum which grows in the limestone district, is stated to be a most valuable wood for millwrights, shipwrights, and wheelwrights, as it is almost impossible to split it even when closely morticed. From its not being liable to splinter, it is suggested as likely to be useful for war ships.

There are also, accompanied with specimens of shoots, leaves, and seeds, planks of Morrel, a hard wood used for shafts; Tutala, not unlike Oak when polished; Mallet, a nice light wood; Wandow and Kirdang, together with Shea-oak, a kind of Casuarina,

used by wheelwrights, and to make shingles which are cheap and very durable for roofing; a log of the Sandal Wood of Western Australia, which is largely exported; and, lastly, several excrescences from Jarrah trees, cut through and polished, one of them being of immense size and very beautiful.

A pretty cabinet made of the various woods of the colony is exhibited by the Royal Engineer Department, under whose direction it was carried out by the convicts. It well displays the capabilities of the different woods for cabinet work.

Samples of barks used in tanning are exhibited, together with leather tanned by their agency, which has given such satisfaction that we believe orders have been taken for many thousands of skins since the opening of the Exhibition. Silver Wattle bark from a species of *Acacia*, and a fibrous Rush found plentifully on the banks of the Swan River, are shown as likely to prove good materials for cordage; also, the bark of a *Melaleuca* which being easily reduced to a pulp, might be useful for paper-making, though it appears scarcely fibrous enough.

A resinous gum which is found useful by the colonists for illumination, and from which it is believed that a new and valuable pigment can be obtained, is likewise exhibited. It is produced by the *Xanthorrhoea arborea*, called *Bulga* by the natives, and *Grass-tree* or *Black-boy* by the colonists. This is a useful plant to the natives. The frame of their huts is constructed from the tall-flowering stems; the leaves serve for thatch and for a bed; the resinous trunk makes a cheerful fire; and the flowering-escape yields a gum for food. The trunk affords a resin used for fixing the glass on their spears and other weapons. Fire is readily kindled by rubbing together the dry flower-stems, and the withered leaves furnish a torch. Cattle feed upon the leaves; sheep pull up the centre leaves when they can reach them, and eat the lower blanched ends; and settlers have even dressed the crown, which tastes like an Artichoke, for food; and also used the young stem when boiled and carefully scraped, but some persons are said to have suffered from doing so. Finally, there is a *hortus-siccus* of the Swan River, consisting of 140 specimens, exhibited by the Rev. A. Du Cane, and some of the poison plant, *Gastrolobium calycinum*, which is so fatal to sheep and cattle eating it. Several other plants of the same genus have the same effect.

(To be continued.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

PLX the fork frequently amongst the growing crops of Cauliflowers, Broccoli, and Winter Greens, and continue to manure and trench-up every piece of ground as it becomes vacant, for planting with any of the Brassicas for late crops. *Asparagus*, keep the weeds down in the beds, for which purpose an occasional sprinkling of salt is a great help, besides being of benefit to the plants. They also require to be properly supported, as the crowns may be much injured by the stems being blown down. If any are required extra fine they should not be allowed to perfect seed, but to have plenty of liquid manure, bearing in mind that if the drainage is not perfect such applications will be more injurious than beneficial. *Cabbage*, plant out some of last-month's-sown plants for use in the autumn. In Coleworts, make a sowing about the middle of the week for the first main spring crop. *Carrots*, thin the late-sown crops, and loosen the earth between them where they have been sown in drills. *Dwarf Kidney Beans*, a last sowing should now be made in a sheltered situation, the drills to be watered if the ground is very dry. *Endive*, transplant a few more and make another sowing. A few days' difference in transplanting at this season sometimes proves of great advantage. *Sorrel*, to be cut down if required for use in the autumn. At the time of planting Celery, *Endive*, or any other culinary vegetable, they should by no means be deprived of any portion of their leaves, the ill effects of such a practice may be easily proved by experiments. When planting great care to be taken to press the soil close to the roots.

### FLOWER GARDEN.

Evergreens which require pruning should now be attended to without delay. Clip Box-edgings and evergreen edges. By such attention at this season a higher degree of neatness and uniformity will be better attained. Advantage should be taken of moist weather to plant out the principal sowings of biennials—such as Wallflowers, Sweet Williams, Canterbury Bells, &c., into nursery-beds; allow plenty of room between plant and

plant if it is intended to allow them to remain in the beds till spring. Propagate *Antirrhinums*, *Pentstemons*, *Phloxes*, and other showy herbaceous plants by cuttings. They take root readily under the shade of a north wall covered with hand-glasses. The budding of *Roses* should now be proceeded with and vigorously followed up till finished. Cuttings of *Roses* may now be taken and planted in a cold frame with a northern aspect. In about a month they will show indications of rooting, when they may be taken up, carefully potted, and plunged in a slight bottom heat. Treated thus they make nice plants in a short time, and if kept under slight protection during winter, will fill their pots with roots, and be ready for planting out next May. Pink pipings put in early will now be ready for transplanting; and if so, this should be done at once, as they will require time to establish themselves before winter. If the situation ultimately intended for them is vacant, they may be planted there at once, but if occupied at present by something else, let the young Pinks be planted about 4 inches apart in nursery-beds in an open situation.

### FRUIT GARDEN.

Prepare the borders intended for new plantations of Strawberries by very deep trenching, and afterwards lay on a dressing of half-decomposed manure, and fork it in. Old worn-out beds to be trenched-up, and the crop changed. Keep the runners well removed from the permanent beds. Applications of liquid manure will be beneficial at this season. Thin-out the shoots of Figs, and keep them well nailed. Vines on walls will want frequent attention: see that late-growing spray do not shade the principal leaves; these should enjoy full exposure to the light. The Currant bushes to have some of the extremities of their watery and late growths cut away, cutting a handful or two also from the interior of the bush, when gross, to give them the benefit of sun and a free circulation of air.

### STOVE.

When a fire is necessary here it should be lighted about one o'clock, and allowed to burn briskly for a couple of hours, and permitted to go out of itself by four o'clock. The house to be shut close at five o'clock, and water to be used liberally to produce a moist atmosphere.

### GREENHOUSE AND CONSERVATORY.

Some of the early-blooming *Pelargoniums* will now be out of bloom, when they may be placed out of doors for a fortnight in a sunny situation to ripen their wood; then to be cut to the second or third eye on each shoot, and returned to the house or close pit, to be supplied very moderately with water until they break. When they have made fresh shoots an inch long, to be turned out of their pots, the soil shaken away, the roots trimmed, and the plants fresh potted in light loamy soil in pots a size or two smaller, according to the state of the roots, than they had been in before. *Cinerarias*, whether seedlings or suckers, should have regular attention, and those intended for autumn work to be potted forward without delay. Where Grapes are grown in the greenhouse they should be forwarded as much as possible, so as to have them fully ripe before any of the plants will require protection.

W. KEANE.

## DOINGS OF THE LAST WEEK.

"JUST one of that ilk—another of the same," might serve for all our jottings now; the work of one week so closely resembling the one that has passed, that a general routine characterises the proceedings.

### KITCHEN GARDEN.

We did what we have not had to do much this season—watered Celery, Cauliflower, Greens of kinds, so as to keep them growing freely, using clear water for the Celery, and manure water for the Cauliflower. Moved shading from vegetable seeds as soon as they were up, to prevent them being drawn. Filled every spare bit with Cauliflower, Winter Greens, &c. Pricked out a lot of Cauliflowers to come in after the Potatoes are raised, so that they can be lifted with balls. In finally planting such we generally take out a slight trench with the spade, and the plants scarcely feel the moving, which plants merely dibbled, however well done, constantly do. Run strings of soft twine along the rows of strong-growing Peas, as, owing to the moisture and the dulness, though not mounting higher than usual, the sticks are of little use in keeping them in their place sideways, and a storm of wind and of hail as we had here on the 16th, would be apt to break them down, and once by any means bruise or break

the haulm or stems, and farewell to fine-swelled, well-flavoured Peas. My sticker of Peas has rather helped the evil of the stems falling through the sticks by his very nattiness in staking. Before I noticed he had done the principal Peas, bringing the stakes together at the top, which no doubt

looks neatest, instead of standing apart basin-shaped, which gives more justice to the Peas. In the one case, the stems, if strong, will pass through the stakes; in the other case, room for them, and the stakes will keep them

up much better. Where the haulm is knocked about by imperfect staking, it would often be better to leave the plants on the ground, as in a field, in a state of nature. I think I mentioned last year that some great judges spoke so magniloquently about the flavour of the shelled Peas in Covent Garden, and more especially when they went to the expense of getting these passed through a sieve, so as only to have those that were very young. Well, I tasted lots of these shelled Peas in Covent Garden last week, and will only say, that those who can praise them would be satisfied with almost anything in the country. A first-rate Pea can only be obtained in Covent Garden when the Peas are taken there in shallow baskets, and are shelled at home, instead of in the market. No Peas carried for hours in bags or large hampers can have the rich flavour of a nice young Pea gathered only a short time before it is cooked. When I saw the women so busy shelling, and the huge heaps sweltering in the sun, I could not but think that some very wise people might do better than go down to the country, and so praise the Covent Garden Peas, as by implication to cast reflections on those they were eating at their friends' tables. I state it broadly as a fact, on which I would be willing to stake my professional reputation, that every amateur, eye and every cottager, that has a garden in the country, may have Peas on his table, that for flavour and richness far transcend those obtained in Covent Garden, if they are taken there in the usual way, in large bags and hampers, and are shelled in the usual way before they are purchased. Be it recorded, we find no fault with the system, which in many respects is suitable to and pleases our London friends; but that is no reason why we should permit a few would-be arbiters of taste to be croaking continually upon the thorough superiority of Covent Garden Peas. We say simply, that if equally young and of good quality, such Peas cannot be so rich as those fresh gathered in a garden. Of course, we make allowance for different tastes. Some people may prefer Peas that have gone through a heating, fermenting process. We find no fault with those who praise this and that kind of sour vinegar-like wine, though we are vulgar enough to prefer instead a glass of good London porter. I wish the humble cottager fully to know, that in cutting a nice Cabbage in his own garden, and cooking it properly, he may have a delicacy which a peer in London cannot obtain at his club, if the Cabbage of which he partakes formed one of hundreds of Cabbages in a waggon at market.

#### FRUIT GARDEN.

Besides routine of nipping, fastening, gathering fruit for preserving, which we were fortunate to do after several days' dry weather, and before the dreadful hail of the 16th, we have gone on with layering Strawberries for forcing, planting-out Melons, which we prefer doing to cutting back the old plants, as, if a heavy crop is taken, and the plants are kept rather dry to secure flavour, the plants rarely will do so well afterwards. In case there should be any insects or their eggs, we generally remove 2 inches or 3 inches of the surface soil, dig up and add more fresh before planting, and whitewash the walls or boards, if a frame, with lime and sulphur. If in a frame or in a whole pit we would use the precaution of burning a little sulphur a couple of days before planting; but this cannot be done when only a part of a frame or a box is to be planted, as the burnt sulphur will kill every green thing it has access to. The squares of glass, 15-oz., 20 inches by 12 inches, stood the hail well, though it fell with such force as to rebound frequently 2 feet from the glass. In a moment the spouts were filled, and the hail hanging over them as in a snowstorm at Christmas. Many stones were as large as good-sized marbles, and I noticed the glass bent and bounded considerably. What is the experience of friends and readers as to thicker glass in similar circumstances? I sometimes think that where there is no bending, there is more danger of cracking.

#### ORNAMENTAL GARDENING.

When we cannot do what we wish, the next best thing is to do the best we can. Go into such nurseries as Mr. Veitch's, &c.,

and you will find Azaleas making their new wood in a more close, moist, tropical heat than they give even to their Indian Orchids. This presupposes, at least for the time, a house for the purpose; and growth being made, the hardening-off process will be equally well and systematically attended to. Of course, with one house an approach can only be made to such a system by keeping the plants needing fresh growth together, giving more of the syringe and less air than would be suitable for flowering plants. We learn little even from the largest and best-managed establishments, if we do not carry along with us this accommodating-to-circumstances principle. All hard-wooded plants would, less or more, require similar treatment when making their wood. The thing which young beginners most commonly err in is acting at least on the principle that a plant when placed in a certain position, be it a Heath, an Azalea, or a Chrysanthemum, is to remain there. The man of intelligence and action, who thinks as well as works, tries according to his means to give each plant what it wants at every season of the year, and is not more careful that growth should be made under stimulating circumstances, than that growth should be duly matured under certain other circumstances of sun and air; and for this purpose the character of the house is changed, or a part of it changed, or the plants are moved out to another more suitable place. In most gardens of limited extent this moving, at the right time, will make all the difference between the very successful and the very indifferent. It is always pleasing in large princely establishments to find things used and valued according to their simplicities. The house in which the Azaleas were made to grow was a large span-house with no staging. Much fewer plants of large size would have been accommodated on the floor, and the syringe could not have played so well beneath and all through them. Each plant was therefore raised on a pedestal, which brought it nearer to the glass, enabled more plants to be placed, and gave every facility for getting thoroughly about them. But what about the pedestals? Aye, there was the simplicity. Four boards some 10 inches wide, and in height—say each four from 2 feet to 1½ feet, were fastened together at the corners so as to make a hollow square tube. One end of this was fixed in the floor of the house, and the huge pot on the other end kept it steady enough; and when done with the boards could easily be removed and packed in a heap until they were wanted.

Proceeded with potting stove and greenhouse plants, and the hardier Geraniums, Fuchsias, Balsams, feathered and other Cockscombs, Amaranths, &c., for late blooming; and began taking a few cuttings of some scarce bedding Geraniums. Out of doors, as the ground is now getting warm, began mulching the Calceolarias to keep them cool. Pegged down with cracked sticks Verbenas, &c., the crack making them just as useful as wire hair-pins. Tied-up Hollyhocks: those sown in autumn will bloom very late. Tied-up Dahlias; bush-staked the dwarf ones. Kept the hoe going, as small weeds were never more troublesome, and may top-dress Scarlet Geranium-beds when the ground gets warmer; at present it is rather cold to have them in full perfection, and the slightest mulching would keep the heat out. When the ground is hot enough, then we must try and keep heat and moisture in.—R. F.

#### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

ASPARAGUS-BEDS (*B. W.*).—For the present be content to give the salt and liquid manure as we before directed. When the stems of the Asparagus are cut down in the autumn, remove "the gravelly poor stuff," and replace it by a mixture of light loam and decayed stable dung, or fowl's dung, in equal proportions. Do not cover the crowns more than 2 inches deep.

**SEEDLING GERANIUM** (*W. Hutchison*).—The trusses of bloom which you enclosed are very fine, and the pink of the petals bright. We can say no more, not having seen the plant. In what does it differ from *Christie*?

**INSECTS** (*T. T.*).—Your Mangold Wurtzel leaves are infested by the larvæ of a two-winged fly (*Anomyia beta*), very closely resembling the common house fly, the larvæ of which burrow within the leaves. As there are several generations in the year, we advise you to pluck off and burn every infested leaf. (*P.*)—The thin fleshy maggots which are destroying your Carrots are evidently the young of a pretty two-winged fly (*Psila rosea*), which lays its eggs on the young Carrot roots, and causes the disease called rust. We advise you to water your plant with gas-tar water or strong lime and soap-suds.—*W.*

**TOMATOES AT A FRUIT SHOW** (*G. S., Birkenhead*).—Mr. Beaton thought they were out of place, and you differ from him in that conclusion; but that is no reason why you should be discourteous. You are both entitled to abide by your opinions; and we shall not charge you with "evident ignorance" when we add that we differ from you. Cucumbers strictly are not entitled to a place at a fruit show, and can only be tolerated in a miscellaneous class. The same observation is applicable to Tomatoes, which, like Cucumbers, are only fruit in a botanical sense.

**ERYSIMUM PEROFFSKIANUM** (*H. P. D.*).—We have often had it vary, but we never thought of the convertibility of the two species. The seed we always took for *Erysimum diffusum*, and it is difficult to clear a sample of it if once it is gathered with *Peroffskianum*.

**DELPHINIUM FORMOSUM SPORT** (*Idem*).—Your seedling sport from *Delphinium formosum* is quite new to us, and quite as valuable as ever *formosum* had been. The *Salvia patens* blue in *formosum* is, in this new form of it, converted into a deep violet purple, making a very rich *Delphinium*.

**LILIUM GIGANTEUM** (*Idem*).—This great Indian Lily requires exactly the same kind of treatment after it has gone out of bloom, down to the period the leaves cease to be green, as it had in the fore part of the season. We have seen it go to rest early in October, and not till November, December, and the turn of the new year. The seeds being of little or no value to most amateurs, if the plant were ours we would cut the flower-stem off just below the seed-pods, and plunge the pot in the hottest and most sheltered border in the kitchen garden, there to take care of itself for the rest of the season; but we would stand the pot on two pieces of brick to secure perfect drainage, as, if the autumn should turn out after the manner of long wet, long dry, it may need some heavy waterings, and heavy watering is dangerous to some plants when thus plunged, for fear of bad drainage.

**GLOXINIAS** (*R. P., Shrewsbury*).—Your two flowers were destroyed by the post-office punch; but if they had not been it is rarely possible to give the name of a flower where the varieties are legionary, from the mere inspection of a single flower. We cannot say whether a box from you was received—we have none the contents of which are waiting for naming.

**CAMELLIA CULTURE** (*A Beginner, Chesham*).—Water the seedlings carefully, and as soon as handleable prick them off in sandy loam and peat, four round the sides of a four inch pot. When growing freely, and filling the sides of the pots with roots, break the ball carefully so as to pot each separately in a small pot in similar material. Keep the plants in as close and humid an atmosphere as they will bear without damping. When these pots are filled with roots, you can grow on, or bud, inarch, or graft the seedlings.

**LEAVES OF STOVE PLANTS INJURED** (*H. H.*).—The leaves have every appearance of being scalded. Use less deluging with water; give more air, especially early in the day; shade in bright sunshine, especially when it comes after a few dull days; in dull weather, use less heat, and little or no water on the floors.

**PRUNING ERICA CAVENDISHII** (*Idem*).—When cleared of its dead flowers, it will require little more trimming with a sharp knife than merely to stop free-growing shoots, and to induce fresh growth regularly all over the plant. If at all symmetrical, little pruning beyond this will be required. It is not like a very strong grower, which you may round-off with a pair of scissors.

**REPORTS** (*G. B.*).—We are greatly obliged by your letter, and assure you that suggestions made in the same courteous tone are always desired and welcomed. If we saw that our not reporting the Society you name was an occasion of any loss to our readers, we should take care that reports should appear in our columns; but after carefully watching the subject we find that almost every novelty of the season is exhibited at the Shows of the Royal Horticultural Society and Crystal Palace, and any novelty which appears elsewhere we take care to have noticed in another form. There is no need, therefore, to occupy with repetitions the space which we can fill with fresh information.

**GEOMETRICAL DRAWING** (*J. C.*).—We shall be obliged by having your address that we may compare notes.

**NAMES OF PLANTS** (*H. B.*).—1, *Phillyrea media*; 2, *Magnolia glauca*; 3, *Acanthus spinosus*; 4, *Alstromeria aurantiaca*; 5, *Sisyrinchium striatum*; 6, *Silene armeria*. (*W. H. K.*)—*Cerastium tomentosum*, *Alyssum maritimum variegatum*. (*J. O., Salop*).—1, *Viburnum lentago*; 2, *Hypericum calycinum*. (*S. K. B.*)—1, appears to be *Myrsine africana*; 2, a small state of *Polystichum aculeatum lobatum*; 3, *Festuca ovina vivipara*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

**JULY 29.** NEWMILLERDAM. *Secs.*, Mr. J. Turner, Walton; Mr. W. Pashley, Newmillerdam.  
**AUGUST 2nd, 4th, and 5th.** SHEFFIELD. *Sec.*, Mr. George Westerholm, 49, Queen Street.  
**AUGUST 25th, 26th, 27th, and 28th.** CRYSTAL PALACE. *Sec.*, W. Houghton. Entries close July 26th.  
**AUGUST 27th.** COTTINGHAM. *Sec.*, Mr. J. Brittain. Entries close Aug. 20th.  
**SEPTEMBER 2nd.** PÖCKLINGTON, Yorkshire. *Sec.*, Mr. T. Grant. Entries close August 20th.  
**SEPT. 4th.** WAKEFIELD AND WEST RIDING. *Sec.*, Mr. J. Crosland, jun., Entries close August 23rd.  
**SEPTEMBER 9th.** WORSLEY AND ARMLEY (near Leeds). *Sec.*, Mr. Robert Hoyle, Armley, near Leeds.  
**DECEMBER 1st, 2nd, 3rd, and 4th.** BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

### GRAVEL IN EXHIBITION PENS.

We are asked to use our influence with committees and managers of poultry shows to induce them to cover the bottom of the cages or pens with gravel. Where they can do so, it is beyond doubt the best thing there is for the purpose; but in some districts it cannot be had. We were lately paying a visit to some model poultry-houses, and finding the floors of asphaltum covered with a sticky sand, we urged the use of gravel, both for the hard and the loose floor. We were told there was not a cartload of gravel within twenty miles of the place. Much mischief has been done by the use of sawdust, which swells in the gizzard, and renders the grinding and consequent digestion of food impossible.

### THROAT DISEASE IN POULTRY AND PHEASANTS.

I HAVE a pullet nearly four months old suffering from some affection of the throat; she has been ill for several weeks, is very thin and weak, gasps for breath, and makes a loud noise clearing her throat. She is not of much value, but I should like to know what remedy to use, as I may have the same complaint with valuable poultry. The disease does not appear like the gapes in younger chickens, which I have often seen.—

[The disease you mention has many points in common with that which has nonplussed fowl and Pheasant breeders in many cases this year; and if, when handled, the bird is found to have a hard lump in the throat, it is a bad case. We do not know its origin. The only treatment we have found effectual is to give decoction of wormwood in their water, and to feed freely on bread and ale. This has been successful only in the early stages. If there is no improvement, we advise you to kill.]

### LEEDS AND WEST RIDING POULTRY AND PIGEON SHOW.

AN attractive and pleasing Exhibition was held in the Music Hall, Leeds, on the 9th, 10th, and 11th inst., in connection with the Leeds and West Riding Horticultural, Floral, Poultry, and Fancy Pigeon Society. This is the first show held under the auspices of the Society, which has been lately established, and of which the Right Hon. the Earl Fitzwilliam, K.G., Lord-Lieutenant of the Riding, is the President.

The result of the efforts of the Society are, for the first year, highly gratifying, and augur well for its future prosperity. Not only was the Exhibition a success; but it may be safely said that it was, as far as regards the poultry and Pigeons, which formed its chief attraction, superior to any that has been held in the West Riding.

The following is a list of the awards:—

**SPANISH.**—First and Silver Medal, R. Teebay, Fulwood, near Preston-Second, J. R. Rodbard, Writington, near Bristol. Highly Commended, S. Corner, Fulwell, near Sunderland; T. Greenwood, Dewsbury; F. Crook, London; E. Brown, Sheffield.

**DORKINGS** (any Variety).—First, Silver Medal, and Second, T. W. Hill, Heywood. Highly Commended, H. W. B. Berwick, Helmsley.

**GAME** (Black-breasted and other Reds).—First, H. Beldon, Bradford. Second, C. W. Brierley, Rochdale. Highly Commended, J. Fletcher, Stonecough.

**GAME** (Duckwings and other Greys and Blues).—First and Silver Medal, G. Hellewell, Sheffield. Second, J. Riley, Dewsbury.

**GAME** (any other Variety).—First, J. Fletcher, Stonecough. Second, W. Wood, Sheffield. Highly Commended, T. Hartley, Gomersal; H. C. Mason, Drighlington.

**COCHIN-CHINA** (Cinnamon and Buff).—First and Silver Medal, H. and G. Newton, Garforth. Second, R. White, Sheffield. Highly Commended, E. Smith, Middleton.

**COCHIN-CHINA** (any other Variety).—First, R. White, Sheffield. Second, W. Dawson, Mirfield. Highly Commended, E. Smith, Middleton; A. Cattle, York.

**HAMBURGS** (Gold-pencilled).—First, F. Hardy, Laister Dyke. Second, C. W. Brierley, Rochdale. Highly Commended, Carter & Vaillant, Poulton-le-Fylde; R. Hemingway, Halifax.

**HAMBURGS** (Silver-pencilled).—First, G. Hellewell, Sheffield. Second, H. Beldon, Bradford. Highly Commended, W. Wood, Sheffield.

**HAMBURGS** (Gold-spangled).—First and Silver Medal, N. Marlor, Manchester. Second, R. Tate, Driffield. Highly Commended, W. Lawson, jun., Otley; J. Ellis, Leeds.

**HAMBURGS** (Silver-spangled).—First, H. Beldon, Bradford. Second, S. Campling, Collingham.

**POLANDS.**—First, H. Beldon, Bradford. Second, F. Hardy, Laister Dyke. Highly Commended, F. Hardy.

**ANY BREED NOT PREVIOUSLY CLASSED.**—First, R. Teebay, Fulwood. Second, H. & G. Newton, Garforth. Highly Commended, — Robinson, Mansfield; R. Tate, Driffield; J. Harrison, Blackpool.

**CHICKENS of 1862 (any Variety).**—First and Silver Medal, T. Greenwood, Dewsbury. Second, A. Nuttall, Newchurch. Third, H. Mantle, Collingham. Highly Commended, S. Dupe, Everecreech; W. Bentley, Low Moor; R. G. Gilbert, Claxton.

**GAME BANTAMS (any Variety).**—First, and Society's Silver Medal, C. W. Brierley, Rochdale. Second, G. H. Crosland, jun., Wakefield. Highly Commended, R. Tate, Driffield; G. H. Crosland, Wakefield.

**GAME BANTAMS (Black or White).**—First, E. Holdsworth, Leeds. Second, G. H. Crosland, jun., Wakefield.

**GAME BANTAMS (Gold or Silver).**—First, E. Hayton, Pudsey. Second, G. H. Crosland, Wakefield.

**GUINEA FOWL.**—First, H. & G. Newton, Garforth. Second, R. Tate, Driffield.

**Ducks (White Aylesbury).**—First, R. Tate, Driffield.

**Ducks (any other Variety).**—First, and Society's Silver Medal, R. Tate Second, H. & G. Newton, Garforth.

**TURKEYS.**—Prize, Lady Hawke, Womersley Park.

**GESE.**—Prize, Lady Hawke, Womersley Park.

#### SWEEPSTAKES.

**GAME COCKS (any Colour).**—First, C. Brierley, Rochdale. Second, M. H. Walker, Clowae. Highly Commended, J. Robshaw, Whixley.

**SPANISH COCKS.**—Prize, R. Teehay, Preston.

**DORING COCKS (any Colour).**—Prize, H. W. B. Berwick, Helmsley.

**COCHIN-CHINA COCKS (any Colour).**—First, W. Dawson, Hopton. Second, R. White, Sheffield. Highly Commended, W. Cople, Prescott; H. W. E. Berwick, Helmsley; C. E. Kildale, Halifax; W. Wood, Sheffield.

**HAMBURGH COCKS (any Colour).**—Prize, T. Carr, Lancaster.

**GAME BANTAM COCKS.**—Prize, E. Holdsworth, Leeds.

**BANTAM COCKS (any other Variety).**—Prize, E. Holdsworth.

#### PIGEONS.

**Carriers.**—First, A. L. Sylvester, Birmingham. Second, S. Robson, Brotherton. Highly Commended, Miss H. Hughes, Leeds. *Almond*

**Tumblers.**—First and Silver Medal, E. Holdsworth. Second, A. L. Sylvester, Birmingham. Highly Commended, A. Evans, Salford. *Tumblers*

(any other Variety).—First, E. Holdsworth. Second, J. W. Edge, Birmingham. Highly Commended, J. Percival, Birmingham; Miss H. Hughes.

**Croppers.**—First, S. Robson. Second, Miss H. Hughes. Highly Commended, S. Robson. *Jacobins.*—First, G. H. Crosland, jun., Wakefield. Second, A. L. Sylvester. Highly Commended, H. Yardley, Birmingham; Miss H. Hughes.

**Owls.**—First, H. Smith, Skipton. Second, F. Key, Beverley. Highly Commended, E. Holdsworth; H. Yardley. *Nuns.*—First, F. Elze, Bayswater. Second, H. Yardley. *Turbits.*—First, E. Holdsworth. Second, A. L. Sylvester. Highly Commended, F. Elze; J. W. Edge, Birmingham.

**Fantails.**—First, F. Elze. Second, F. Key. Highly Commended, A. Evans.

**Bars.**—First, E. Holdsworth. Second, A. Evans. *Trumpeters.*—First, F. Elze. Second, F. Key. Highly Commended, Miss H. Hughes. *Antwerps.*

—First, E. Holdsworth. Second, Miss H. Hughes. *Any other Variety.*—First, E. Holdsworth. Second, G. H. Crosland, jun. Highly Commended, J. W. Edge.

**RABBITS.**—Second, G. Bentley, Kirkstall.

The Judges were Mr. George S. Sainsbury, of Devizes, and Mr. S. Bird, of Shipley.

### RAISING TURKEYS.

I GENERALLY raise more Turkeys than I know what to do with, and I have Turkeys now left over from last season that will be eaten as we want them. Last winter we fairly revelled in roast Turkey—gave quite a number away, sold others, have some, beside the breeders, still left.

My plan of raising is simple, and I will give it in as few words as possible. First, I never allow a Turkey to sit until about the middle of May. They will commence to lay early in April, but I take their eggs away as fast as laid, and keep them until they lay their second batch, which will be finished about the second or third week in May. I then give the hen some eighteen or twenty of the eggs, and let her sit. About the middle of June she will be off. I then take her, put her with her young on an old barn floor, or other outbuilding that is dry, and feed on curd and cracked corn. Curd is the best for a continual feed when the farmer has plenty; but cracked corn or coarse meal, mixed with lobbered milk, will answer about equally as well. After they have been in-doors for two or three days, or long enough to get fairly on their legs (for the Turkey is the weakest of all fowl when young), I let them out, providing the weather is fine, and there is no dew on the grass. The great reason why people cannot or do not raise Turkeys is because they turn them out as soon as hatched, and about the first wetting they get they keel over and die. To succeed in raising Turkeys, therefore, you must keep them dry until at least ten weeks, when they will stand as much water as other fowls—Geese and Ducks excepted. Of course, they must be driven in every night, and on all occasions when a storm is threatening.—(*Dollar Newspaper, American.*)

**ROYAL AGRICULTURAL MEETING, 1863.**—We are informed by Mr. John Holland, the Secretary of the Committee of the Worcester Poultry Show, that an Exhibition will be held in July, 1863, during the Agricultural Society's Meeting, for which a liberal prize list will be issued. At the same time a Dog Show will be held, particulars of which will appear shortly. Many well-known local sportsmen are its supporters.

### INFLAMMATION OF THE LUNGS OF PIGEONS.

I HAVE a flock of from twenty-five to thirty pairs of birds, Carriers and Tumblers. The first bird which was attacked was a cock three years old. I first discovered it by his breathing, and shortly he appeared as if he had inflammation on the chest. He laboured hard to breathe, just as one does who has a bad cold in the head, or having the sniffles. I took him in and gave him several things, but he died in a week. Since that time one after another of my birds have been attacked. The crop at first seems distended and puffed out with wind, the wattle becomes unusually red, and the wheezing and breathing very difficult. The birds lose flesh, get very thin and mopish, but I have not had one die since, and some of them are better. The breath is very offensive, and there is a coating of mucous-like matter on the inside of the mouth, which I can wash off. There is no running of the nostrils. It is singular that none of the Tumblers have been attacked, while one after another of the Carriers have and are getting it.

My houses are open and airy, from 30 feet to 50 feet long, and 8 feet high, and they can have free access to open cages of 10 feet by 8 feet, wired over.

On its first appearance I had all the flooring taken up, hot lime laid over the whole of it and well gravelled, and the walls well washed with strong lime.

I feed my birds with a mixture of tares, peas, Indian wheat, and buckwheat, with barley mixed altogether, and they are never without food. They have also a mixture of sand, mould, and coarse salt, which they seem to use freely. The only thing I have given either of them since the first, when I discovered them to be ill, is an aperient pill and a lump of beef or mutton suet, which I fancy has benefited them. As I said before, I have not had one die since. I am not aware if such a disorder is prevalent among Pigeons, if so, perhaps some one has discovered a remedy which may be serviceable to the fancier generally, and will be thankfully received by me in particular.—W. VICKERS, 3, Coburg Place, St. Sidwells, Exeter.

P.S.—I should state that ever since my keeping Pigeons, my houses and floors have invariably been raked and scraped twice or thrice a-week; indeed, I have been told that my success in rearing has been marred by too frequently cleaning my houses.

[Your birds are evidently suffering from inflammation of the lungs, most probably of a contagious character. We should advise the immediate removal of those affected from the remainder. The disease is of a very intractable character; but we have found more benefit result from the administration, in the first instance, of one-twelfth of a grain of tartar emetic, and one grain of calomel, than from any other remedy whatever. After the inflammatory symptoms have subsided, a capsule of copaiba balsam has great effect in enabling the bird to throw off the diseased secretion.]

### BEE-CELLS IN JAMAICA NOT LARGER THAN IN ENGLAND.

I AM sorry that you did not append the closing sentence to my communication about the Jamaica bees, as it would have shown your readers that I was doubtful on the subject. I have now to confess that I have made a gross blunder. The cells which I measured were drone-cells, as I am informed by the "DEVONSHIRE BEE-KEEPER." I could offer some explanation and apology to your readers for making so great a mistake; but it is a personal matter and would not interest them. How the statement in French works arose that the cells in West Indian combs are larger than those in European combs, I cannot conceive.—C. DARWIN.

[We certainly did not understand, nor do we think our readers understood, that Mr. Darwin stated the increased size of bee-cells in Jamaica as an established fact, and we made our comment hypothetically. We have seen combs from Jamaica since then, and the drone and worker cells are of the same sizes as in England. When Mr. Darwin wrote, he, probably, had not seen the cells of the workers.—EDS.]

### UNITING SWARMS.

I WISH to transfer the bees of a second swarm to the hive of a first swarm, having an old queen, and intend to fumigate the bees of the first swarm, and then drive the bees of the second

swarm into their hive; and when the greater portion of the bees have ascended place it where the hive of the driven bees stood, and put the hive from which they have been driven on the top of the other, and draw out one of the slides so that I may preserve the late brood of both hives. My reason for doing this is that the hive is to be removed to a distance in September, and the second swarm, in consequence of the very unfavourable weather, has not half filled the hive with comb, so that it could not be carried so safely as a hive quite filled and firmly fastened at the sides.

Will the fumigation either with fungus or chloroform destroy the brood which may not be sealed over? and will the queen of the driven bees be sure to ascend with the first rush into the hive placed over her own reversed one where she will find honey and brood? I have some puff-balls gathered last summer, but do not know how they should be prepared for fumigating.

[Stupefaction by chloroform is very destructive to adult bees; of its effects upon unsealed brood we have had no experience upon which to base an opinion, nor have we any authority to quote upon the point. With regard to fumigation, a German writer, whose name we do not now remember, declares it to be fatal to unsealed brood; but how far he may be correct we are not prepared to say.]

The ascent of the queen with the first rush of driven bees is probable, but by no means certain unless the *spirit* moves her. She is often not to be driven up by any amount of rapping. Are you sure that the queen is an old one, and that she has not recently been changed, as is very often the case? Would it not be better to let well alone, and unite by driving in September as recommended in pages 45 and 46 of "Bee-keeping for the Many?" Bees in a half-filled hive are, however, very difficult to drive, but when once subdued by drumming, the combs may be cut out one by one, and the bees swept off with a feather into an empty hive without the slightest difficulty. Puff-balls should be dried in the sun, or in a cool oven. If those you have will hold fire and smoulder slowly they will probably answer.]

#### "B. & W.'s" ITALIAN ALP BEES.—1862.

On settling accounts last year with my esteemed apiarian friend, who is so favourably known to the bee-keeping readers of THE JOURNAL OF HORTICULTURE under the signature of "B. & W.," I found I owed him a Ligurian queen, which debt I was not able to discharge until the 4th inst. The following interesting particulars by way of acknowledgment have been kindly furnished by him to—A DEVONSHIRE BEE-KEEPER.

"My dear Sir,—Your letter of the 4th announcing the intended arrival of another Italian queen, described as 'a beauty, of the best blood, and amazingly prolific,' was a most welcome communication; and still more welcome, of course, was the arrival of the precious little box itself on Saturday afternoon. I had a good view of the queen the same day, and was glad to observe her to be lively and vigorous; and a 'beauty,' too, she is, being of good size and decidedly marked. At the same time I do not think she is yellower or larger than a splendid hybrid which I raised artificially this year, in May, out of worker-brood, which was the offspring of one of my hybrids of last autumn. Her mother was hardly, if at all, distinguishable from a common English queen.

"The box arrived too late on Saturday for anything to be done that day, so it was put carefully by till Monday, the 7th, the bees being only supplied with food. The condition of my apiary did not allow me to adopt your plan, excellent as it is,\* so having succeeded in a plan of my own, which I adopted last year (see page 509, Vol. I., JOURNAL OF HORTICULTURE), I had recourse to it again, and, I am happy to report, with the most complete success. I varied my plan of operation so far as to drive all the bees out of one of the stocks in my bee-house, at the same time catching and killing their queen. The stock itself full of brood was removed elsewhere, and an empty bar-box with some comb of their own making put in its place. Of course, the bees returned to their old haunt as soon as they missed their queen, when I immediately set your Italians over a hole at the top of the box, a piece of perforated zinc intervening. When I say 'your Italians,' I should state that I find it convenient to

\* I know of but one way of placing a queen at the head of a stock without any risk, and that is to drive all the bees out of a hive, and having made an artificial swarm of them give their hive full of brood to the strangers."

retain only a very few common bees (half a dozen at most), as a guard to the queen during the process of uniting the queen to a stock. So out of the sixty or more bees which you sent, I only retained four, which I put with the queen into a small bee-glass, which had some bits of comb adhering to its sides. A large number of bees increases the difficulty of effecting the union, as a proportion of them are sure to be irascible, and it is as well to provoke as little fighting as possible. Now, if you will imagine the bee-glass containing these five bees (including the queen) placed upon a piece of perforated zinc over the top hole of the box, you can easily follow my movements. About an hour after the old queen was dead, the bees being very much agitated, I let in one bee from below, by pushing the zinc very gently a little on one side. As this bee was well received and behaved well, I proceeded to admit one more. This one, too, appearing to be well received, I next let in two. One of these instantly rushed up to the queen, seized her by one of her wings, and pulled her about for some little time. You can imagine how anxiously I watched these proceedings, being ready to interfere at a moment's notice. However, no real injury was inflicted upon the queen, but a fight among the common bees immediately occurred, and three of the lately-admitted ones perished. Warned by this mishap I waited an hour and tried again. This time no fighting occurred, so every quarter of an hour I introduced a few more, increasing the number admitted till I thought it safe to admit the bees en masse, who rushed up from below in streams in the most joyous manner. Thus you will perceive that only three lives were sacrificed, and the junction effected most satisfactorily. The whole operation was a lengthy one, however, and took me from morning till night, owing to the extreme care which I took to avoid mishap. I may mention that I did not restore the brood-box out of which I had driven the bees till the following morning, when the bees had passed a whole night with their new queen. The hive is now just as it was before the Italians arrived.

"I was amazed to find from the condition of this stock how poverty-stricken the bees are this year. It was an artificial swarm of May 16th, but though full of comb I could not see a single cell with sealed honey, and, in fact, no honey at all was visible. I can say the same of two other of my stocks, both swarms of this year (one of April 30th), which I fear are in a miserable condition. The only swarm of this season which has sealed honey-comb is that which I made out of my old Italian stock on the 29th of April. Am I to consider this a proof of the superiority of the Italian? Breeding has gone on amazingly in all hives, but very little honey has been stored. I have made in all this summer four swarms out of seven hives, after the plan recommended by Langstroth; and three of the queens have been reared artificially. One only have I seen as yet, the one to which I have alluded in the earlier part of this paper. Those hives which have had to rear queens are the best provided with honey of any in my apiary, having had little else to do but to collect honey during the month of May, when there was no breeding going on. But a worse season for honey I never knew.—B. & W."

#### SAVING THE DRONES—MAKING ARTIFICIAL SWARMS.

My Ligurian box is brim full of bees, but owing to the bad weather they are turning out their drones. Will "A DEVONSHIRE BEE-KEEPER" kindly inform me if it be advisable to take the queen away and make an artificial swarm? I trust bees are doing better in Devon than they are here (Wiltshire). I can see but little honey in any of my hives, although they are all crammed with bees. I am quite delighted with the Woodbury-bars, the bees have attached their combs to them very regularly indeed.—H. C.

[Regular and liberal feeding until honey-gathering recommences is the most probable mode of saving your drones.]

The safest and best mode of making an artificial swarm is the following:—Set an empty box close to one side of your Ligurian stock, and shift the combs one by one into it, looking each carefully over until you see the queen. When she is discovered, put her with the comb she is on\* into the middle of an empty hive, and fill up on either side with bars and as many clean worker-combs as you can spare. This box must take the place

\* This comb should be carefully examined in order to ascertain that no royal cells are attached to it. If any be found, the queen must be transferred to another comb, and the royal embryos returned to the hive.

of the old stock, and all the bees on the remaining combs should be brushed off with a feather on the top of the exposed bars; the combs being carried one by one into a warm room out of the reach of the bees until all are cleared, when the crown-board should be screwed down. The combs that have been abstracted must be put into a hive, which should take the place of a strong black stock which must be removed to a new position. The returning bees will raise a Ligurian queen from the brood in their new domicile. All this must, of course, be done in the middle of a fine day when the bees are in full work. Unless the weather alter very much for the better, the swarm will require liberal feeding to enable it to proceed with comb-building.

I do not think the season can be worse anywhere than it is at present in the locality of—A DEVONSHIRE BEE-KEEPER.]

### COMMENCING BEE-KEEPING.

WISHING to commence the keeping of bees, both for the study of their habits and for the profit said to result from their careful management, I find a difficulty at the outset from the multitude of counsellors and the various, not to say contradictory, advice they give. May I be allowed to ask the following questions? Is it better to begin with black bees or Ligurians? If the latter, how must they be obtained? I fear almost to ask, What is the most useful hive for general purposes? What are the best books on the management of bees?

Whilst reading some of the papers in your Journal on the winter ventilation of hives, and the evils resulting from damp, it has occurred to me that advantage might probably result from placing a piece of unslaked lime within the hive; of course properly secured from the bees. Its position would be determined by the construction of the hive; but skilful apiarians would require no hints on this point. It would, of course, need renewal from time to time; but its well-known property of absorbing moisture could not fail to be useful to some extent—at least, in maintaining the wished-for dryness of the atmosphere within the hive. This may or may not have been tried, but I trust you will pardon its suggestion by so complete a novice.

How can I obtain Mr. Woodbury's "Essay on Bee-keeping?"—M. D.

[If you have no black bees within a mile or so, you might commence at once with Ligurians. If otherwise, perhaps you had better wait until you attain sufficient practical knowledge to aid you in keeping the breed pure. Mr. Woodbury, of Mount Radford, Exeter, would supply you with an Italian stock.

If by "general purposes" you mean keeping bees in the common way, we think nothing answers better than straw hives with flattened crowns, and apertures at top for feeding and occasional supering.

Taylor's "Bee-keeper's Manual" and "Bee-keeping for the Many" are good practical books.

One of our bee-keeping friends, who is also an excellent chemist, suggests caustic potash, and we believe intends trying it, as well as lime and other substances of like properties, with the view of maintaining a dry atmosphere within his hives during winter. We may, however, hint that even this may be overdone, since much has been said in Germany of the danger of bees that have upward ventilation perishing in winter from want of water.

Mr. Woodbury's "Essay on Bee-keeping" appeared in the last "Journal of the Bath and West of England Agricultural Society," published by Ridgway, Piccadilly, and obtainable through any bookseller.]

### SYDSERFF ON BEES.

It is many years since I first met with this book, and I must confess that it never impressed me with any particularly high idea of the author's "being in advance of his age." But as this seems to be the opinion of the Editors of THE JOURNAL OF HORTICULTURE, I have been induced to reperuse the book with increased care; and without wishing to controvert the judgment passed upon it, a few matters have presented which seem worthy of observation, some of which may perhaps rather modify the somewhat high encomium passed on the book and its author.

From his own assertion in the commencement, he allows himself to have been indebted to M. Réaumur in some degree, and

it is evident to me that he was even much more indebted to him than he allows.

That he was a practical and fearless operator, and that he was in advance of most bee-keepers of his condition, is evident from the succeeding pages; but that he had certain curious crotchets of his own, and that all his views were not quite correct, it will be my purpose to demonstrate by a few extracts.

He believed that a multiplicity of stings in or near the same place counteracted the effects of the poison, and devotes several pages to the promulgation of this theory. He strongly recommends that a person when stung by one bee should make others sting him in the same place. Strong-minded Mr. S., how many would wittingly follow your advice? To illustrate this he mentions an accident which befell his little brother, "then a child in coats," who, pushing off part of a cluster of bees which hung out of their hive, was furiously attacked by them, and stung from head to foot—many stings being extracted from the tongue, and no less than thirteen from one ear. By the advice of the apothecary the child was anointed with sweet oil from head to foot; but he says, "I believe it did the child neither good nor harm." The only ill effects were that he looked pale and appeared sick, but there was no sign of any swelling. After some hours' sleep "he opened his eyes and appeared to be perfectly recovered." Now, in this case, the soothing qualities of the sweet oil and the child's favourable constitutional temperament are perfectly ignored. If I get a sting or two, the swelling and subsequent irritation are in general, but not always, very great; but my friend, Mr. Woodbury, I have often seen quietly picking off stings on nose, face, and hands, with perfect nonchalance, and with little or no subsequent inconvenience.

But this puts me in remembrance of your late correspondent's assertion as to the comparatively harmless effects of the sting of the Ligurian bee. Now is the thing easily accounted for. It was not because of their nationality that their "bark was worse than their bite," but because he was stung by thirteen in or near one place. But I also can relate a fact, which, to the credulous, may appear certain proof that Mr. Sydserrf's theory is correct. Some years since, while cutting out the combs of a hive that had been fumigated, I received five stings on the middle finger of the right hand; at the same time one sting was planted in the fourth finger of the left hand. I remember thinking at the time that it was a grand opportunity for testing the truth of the author's theory; and, singularly enough, there was little or no pain or swelling in the hand which received the five stings, while in the other I suffered considerably. Nevertheless, I was sceptical on the point, as I noticed that the finger which was most stung was thickly covered with honey, which I have frequently noticed modifies the effects of the poison, while the other finger was quite dry. But it is also very certain that a sting or stings will take much greater effect at one time than at another, probably from the state of the blood; and also that some stings will be vastly more painful than others, attended with more or less swelling according to the spot in which they are planted, no doubt from the vicinity to certain nerves or blood-vessels which facilitates the spread of the poison.

Mr. Sydserrf carries his view on this point so far as to assert that if "stung once, I have no objection against being stung twice; and after I have been stung twice or three times, I do not mind if I am stung fifty or a hundred times;" and further on he says, "I formed a resolution never more to be stung by one bee alone unless another cannot be had."

He is common with many old authors asserts the drones to be the nurses of the brood. While we cannot coincide in this opinion, may not drones be of more service in the hives than many are disposed to believe? During the height of the honey-gathering season drones are most plentiful. May they not serve to keep up the temperature of the interior when so large a number of the working bees are abroad?

We may notice that if cold and wet weather sets in during the summer, the drones are attacked and slaughtered by the bees; but with a change for the better, not only are the lives of those in existence spared, but the queen renews her deposit of drone eggs.

Mr. Sydserrf asserts, that in uniting bees of different hives there will be no fighting if there is only one queen. Now, we know that this is not always the case, I have had as much fighting under such circumstances as any other. Warder also, as well as Sydserrf, states that fighting will continue until one of the rival queens is destroyed, but that it immediately ceases so soon as this occurs. This is by no means correct. I have frequently

united bees where the deposed queen was the only sacrifice, except a few crushed or accidentally injured bees. It is not likely that she was killed the very instant that the union was effected; as in the case of knocking out on a cloth and placing the hive to be reinforced over them, hundreds and thousands of the workers most probably ascended among the others before the queen attempted to do so.

Sydserriff evidently believes that bees invariably exhibit loyalty to a strange queen—that is, if they have lost their own. This is certainly not correct, as I have found to my cost in attempting to place Ligurian and other queens at the head of stocks from which the rightful monarch has been deposed, the failures have far exceeded the successful issues of this experiment. In an instant after liberation has the queen been violently assailed by several bees, her wings gnawed to pieces, and the fatal sting applied to her defenceless body.

Another of Sydserriff's fond fancies is that the queen is always attended by certain guards; and more than this, that these guards are easily distinguished from the rest "by the crest, tuft, or tassel which they wear on their heads. They are different in colour, and in some greater and some less, perhaps according to their dignities. These may be seen to walk in and out of good hives, several in an hour in the swarming months; at other times they are not so visible. Many of them may be seen in a swarm; and in hives pestered with robbers they will be seen about the door, walking to and fro among the bees, as if directing their fighting. When I want to look for a queen in the midst of a swarm, I look for these attendants."

In the case of your being surrounded by angry bees, our author directs you to spit on them. As I never tried it, I cannot speak as to its effectiveness.

In driving he seems, like Warder, to have been an adept, and to have understood the value of this mode of possessing himself of a hive's contents, and of forcing an artificial swarm much better than many a more modern author.

At pages 63 and 64 he states, that when cells are being gradually filled with honey, a crust or cream is formed on the surface of the honey in every cell; that every bee that deposits honey in the cell pierces this crust, and, having discharged its contribution to the hoard, at once closes up this crust again. I believe there is no crust, cream, or covering of any description until the wax-cover itself is formed and closed.

The last of his crotchets which I shall allude to is that of the medicinal property of dead bees dried to a powder. This given to either man or beast will give immediate ease in the most excruciating pain, and many lives have been prolonged by its use. He therefore, for many years, desired persons when they killed their bees to preserve as many as possible in clean paper. "I have often been applied to for dead bees, and in some particular cases, in order to save life, I have gone and put my hand into my hive and took out as many live bees as necessary, and killed them." I should like to know in what their marvellous medicinal property may lie.

This book was published in 1792, so that it is not so very ancient a treatise. The Rev. Mr. Thorley's work was published about the year 1761 by his son; but the experience therein detailed relates to a period including the year 1713. With some exceptions I consider Thorley's book superior to Sydserriff's. Warder published in the reign of George I. a fine old treatise. This may well be styled in advance of the age.

Keys, a cotemporary of Sydserriff (whose first treatise was published in 1780, but the edition which I have in 1814), is the author of a work very far superior to Sydserriff in practical value, and in views generally equally if not further advanced.

Wildman's work, also of a considerably anterior date, is practically infinitely more useful, and altogether superior. There is much to be learned in the perusal of all these old authors; but it appears to me that Sydserriff's treatise must take rank among the lowest of those mentioned.—S. BEVAN FOX, Exeter.

[We were quite aware of Sydserriff's shortcomings and erroneous opinions, and intended to assert no more than Mr. Fox admits—namely, that Sydserriff "was a practical and fearless operator, and that he was in advance of most bee-keepers in his condition," and this we think is especially so in relation to driving bees. We quite agree in thinking the works of Thorley, Keys, Warder, and Wildman are superior to that by Sydserriff; but they were men in a higher station, and yet they are not free from crotchets and errors demonstrated by later apirians.—Eds. J. or H.]

DOG MUZZLES.

THE muzzles generally used for the purpose of preventing dogs from biting are those made of leather, having a strap surrounding the nose and under jaw in such a manner that the mouth cannot be opened. This contrivance is most cruel in its effects. It prevents the animal from breathing and perspiring freely when the respiration becomes accelerated from exertion and the perspiratory action increased from heat—whether that acquired through the medium of the surrounding air, or generated within the system from violent exercise. It should not be forgotten that the dog perspires from the mouth instead of the skin; also that, from the formation of the air-passages of the head and nostrils, a sufficiency of air cannot pass through them to the lungs for the accomplishment of quick breathing: therefore, unlike the horse, whose even quickest breathing is carried on entirely through the nostrils, the dog is obliged, when his respiration becomes at all hurried from increased circulation, to breathe through his mouth, which he opens for that purpose as well as to allow the increased salivary secretion to freely flow from it. Who has not observed the copious flow of saliva from the widely-opened mouth and tremblingly protruded tongue of the panting dog in warm weather after exertion? The ordinary leather muzzle, by keeping the jaws together and the mouth consequently closed, though it has the advantage of preventing the animal from biting, has also the disadvantages of inflicting on him the cruel tortures of partial suffocation from want of sufficient air to the lungs, as well as from the accumulation of saliva within the mouth having a tendency to embarrass the throat; also those of thirst—for the dog, excepting from the mamæ of his maternal parent, drinks not like the horse and human being by suction, but by the process of lapping with his tongue, to accomplish which the mouth must have perfect liberty of opening.

The wire-basket or cage-muzzle, when made sufficiently large to admit of the jaws being opened apart for drinking and tongue-panting, is a humane and efficacious invention. It effectually prevents the animal from doing mischief with his teeth, while it allows sufficient freedom to the mouth and tongue for his comfort. The mere screen muzzle of wire projecting forwards from the upper part of the nose, leaving the under jaw and mouth uncovered, is often found ineffectual as a preventive of biting, particularly when dogs quarrel with each other, as in the scuffling and wrestling, a limb or some other part of the animal attacked may present itself under the wire projection at the top of the nose, and enter the very jaws of the assailant.

All persons muzzling dogs, particularly in warm weather, with the ordinary leather muzzle that prevents the opening of the mouth, should be punished for cruelty to animals.—PROFESSOR FEROUSON, *Veterinary Surgeon to Her Majesty in Ireland.*—(Dublin Agricultural Review.)

OUR LETTER BOX.

COMBS OF COCHIN PULLETS (*Cochin Breeder*).—The twist in the combs of your Cochin pullets is a disqualification. They could only be successful where there were no perfect pens, and then only on the principle that "where all are blind, a one-eyed man is king." Nevertheless, these twists are very common among chickens, and as many are in the same vicinity, we advise you to show those that approach nearest to perfection. Faultless pens are very rare, and you may, therefore, have a good chance of a prize.

DOVE WITH DARKENED PLUMAGE (*A Regular Subscriber*).—It is not likely that the p usage of your Dove will revert to its original hue until after the next moult. We have never found medicine of much avail with these delicate birds, but when sick have endeavoured to re-toen them by a change of diet and enlarged space for exercise. To do well Doves require pulse, grain, a little green food as tufts of grass in seed, lime rubbish, water to wash in, and above all a place sufficiently large to admit of their exercising themselves by flight.

LONDON MARKETS.—JULY 21.

POULTRY.

The trade becomes less, and supply greater. Diminution of price is the natural consequence, and it will, doubtless, continue till we reach the usual average of the dull time in London.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 75.3° and 51.4° respectively. The greatest heat, 92°, occurred on the 1st, in 1846, and 2nd in 1856; and the lowest cold, 33°, on the 29th, in 1858. During the period 134 days were fine, and on 111 rain fell.

THE KENSINGTON GARDEN OF THE ROYAL HORTICULTURAL SOCIETY.

SIR JOSEPH PAXTON'S GARDEN.

Did not I have many irons in the fire just now, and were I not behind time in my annual reviews of the state and progress of my calling around London, I should be much tempted to review the last Number of THE JOURNAL OF HORTICULTURE, if only to get a say about

eagles, hawks, and falcons, with Mr. B. P. Brent, our great authority for all that is on the wing, and what is in the wind about them. Having begun life, as it were, in the very eyrie of the eagle, the raven, the roe, the "glade," and the ptarmigan, my own favourite bird out of the British fauna, I could tell and say things about them worthy of Audubon himself, for I was with him in the spirit when he first saw that grand eagle, the "Bird of Washington." But, of course, I would begin at the beginning, shake hands with my friend, "Jas. Anderson, Meadow Bank, Uddingstone;" tell him "as how" I once mistook Uddingstone, in the west country, for Duddingstone, in the heart of Midlothian, and the Anderson of Meadow Bank, for the great hybridiser who sits in the 'ha' where the laird of Cockpen found the solace of his best days after all, or thereabouts; then tackle him for having been led away by the rattling of the "broken bottles." For although I never pretended to any very great things in the line myself, yet I have not disguised from the first that, having had the ear of the gardening public for so many years, I was made the acknowledged mouthpiece of a large section of the class to whom the subject is as familiar as their own gloves; and they tell me, and I tell it to you with the greatest pleasure imaginable, that all the criticisms that have yet appeared upon this garden have their basis just as substantial in fact, as the basis on which Chevreul built up his ideas on the way by which flowers ought to be set for effect, and you all know by this time what that effect ended in.

Now, I shall just tell you a secret. I told of the fact that I was deterred from reading Chevreul's book for three years after it appeared, from merely reading the nonsense for which Dr. Lindley and the Times had given leaders to explain. But the utter nonsense of the matter was pointed out to me, and I was told that I was not then firm enough in the faith to enable me to resist the fascination of the strange doctrine in that book about flowers; and when I did read it I said I would as soon read the Koran on flower-gardening as the French dyer. And only last week I received full powers to say, that

with a few accidental errors in the details, by Mr. Nesfield, the rest is as true in artistic design as anything that is on record since art left the cradle, without having any material thing new in the composition. Ten or twenty artists might produce as many different designs for the same piece of ground, and every one of them might be as true to art, and to the history of art so exemplified, as this one is, and yet scope enough be left for the fancy in criticism without foundation. As long as an artist does not violate a principle, he is safe from criticism; for all that the critic can bring against him is based on fashion only, and fashion is as the wind for constancy, while principle remains firm as the tide of time.

Mr. Nesfield made an egregious blunder, and broke a principle in natural science itself, in the very centre of each of the four glaces, by making the English Rose with six petals—a mere matter of detail, which Mr. Eyles could put right for the value of one man's time for two days. There is another great error of detail in not making the highly artistic fans in the centre of the garden neither duplicate nor balancing each on its own axis. Both fans, therefore, are as a pig with one ear, as artists have it, when a thing of the sort is seen; and there is a third error in detail, in the planting of the rows of trees the whole length of the middle terrace on both sides.

There are two rows of trees on either side of the garden, and the "ramps," or the beautiful and easy incline of grass from level to level in place of steps, come in between the two rows, but not in the very centre between the two rows: therefore they, the rows of trees, are "out of joint," as they say, or else the ramps from north to south are a pig with one ear.

Correct these three manifest errors, and the rest that you can bring against our most beautiful and most artistic town garden is a mere matter of taste or fashion. Then one fashion or one taste is just as good or just as bad as another, and all you say for or against it goes to the four winds of heaven without detracting a hair's breadth of merit from the design.

After discussing all that, with variations about Repton and London, with my esteemed west-countryman, I would hold him by the button-hole while I would discuss with him about the value and about the weight of the value of the opinions "of the best-informed" of our ain kinsfolk, "who have seen the garden for the first time;" and I would tell him from my own experience of my corner of the column for correspondents, that better folks than the "best-informed" among the Scottish clans do fall into as much and much greater errors from preconceived notions about things they learn, or endeavour to comprehend, from seeing it in black and white.

Nothing is more common than to hear, "I was, or we were, quite disappointed." I myself was as thoroughly disappointed as any man ever was about anything on this earth, when I first saw the King's London house; also London west, as compared with the new town of Edinburgh, was a sham and a delusion in my eyes, just like those who thought Mr. Nesfield's plan of our garden

looked so fine on paper, and so much different from the looks when they looked at the reality.

Now, I shall just tell you a truth, with which I would illustrate this part of the question, while I held him still by the button-hole. I once knew a great man; he was very rich, and he had very good taste, and was a good critic, and yet he had not a good eye. He would need to see a model of a thing before he could tell you how it would look; but a journeyman in the art by which the model was made, could see and point out any fault or any superiority in the model quite as well as the great man, or any other person or critic whatever. I knew another who was, by a gift of Nature, exceedingly clever, in addition to good taste, and a thorough good eye, and that other would readily detect the smallest error in the largest design or plan after a few glances. There is nothing of the fancy in this, I know the parties well. Now, the application I make of my knowledge of the facts just stated is this: When a man tells me he was very much disappointed with a book or a plan after reading and seeing so much of it on paper—say in plans, or in reviews, I put him down as a man who would need a model to understand a thing of that sort; and as models cannot be made of anything, or seen by all such men, there must always be certain men who must necessarily pass through this life in disappointments of one sort or another: and therefore I weigh the value of the weight of their adverse or fair criticism before I would be influenced by them one way or the other; and if others would take a leaf out of that part of my book, they would soon find out the weight and value of it when they had a need of putting it in practice. The great natural defect in the great mass of mankind is their liability to put their fancy in place of a model, before the mind's eye, and so misjudge or be led by misjudgment.

After saying all that, with what his remarks might suggest in addition, I would attempt a paraphrase of part of the dialogue between Louth and Cecas, Burn's two dogs; and to break off in better mood than you might think of, I would say the most funny thing that I could think of, in comparison between the Irishman and his horse, and the "miserable lines of Portugal Laurels and those forlorn groups of Limes," from Lord Holland's place to our garden. You recollect Paddy sold his horse free from all faults; and when it had been discovered that the beast was blind of one eye, and half blind of the other, he declared that was no fault at all at all, but a misfortune. Neither is it a fault of us or ours, that our trees and shrubs have not yet recovered sufficiently, in eighteen months, from the effects of their removal to a more smoky climate, to be of much interest to people who have been familiar with what Sir Henry Stewart had done at Allanton Park.

But what I was going to write about to-day was altogether different. I was going to bring up all my arrears in a lump, now that the summer shows are over; rehearse all the new bed and edging plants of this season; say what I had seen afresh and what I had been doing at home—and, as charity begins there, so will I.

I cut out-of-door Grapes in July this year for two reasons: the first to get before Capt. Hopkins, of Surbiton Hill, who had done me in Grapes; the second reason was, because the weather, be it ever so fine, would not ripen one of them, except it might be for Covent Garden. I went then and told the Captain I had the start of him, and I was startled myself at his flower-gardening, his ribbon-borders, his new edgings, his Farfugiums, his Harry Moore's system of growing specimen Geraniums up to seventeen years of age, his propagation, and his waterworks; and, above all, after discussing some of the reminiscences of our garden exploits with his father, the best specimen we have in Surbiton of the old English gentleman, now over eighty years of age, I thought the least I could say about my Grapes the sooner I could get the Captain in the humour to allow me to report him as he is.

Sir Joseph Paxton's bedding plants are much the earliest I have seen this season anywhere. I thought Mr. Eyles was more forward with Geraniums and Calceolarias at our new garden than any one else till I got to the heights of Sydenham, and when I could hardly believe my own eyes there they told me the whole secret. Sir Joseph's Geraniums are on Harry Moore's system, very old, very strong, and one mass of bloom all over and down the sides, in the same pots goodness knows how long, and the pots planted with them and taken up and housed with them, wintered and set out again and again till at last they gain in their turn one whole month in advance of bloom in the London season. But it requires good gardening to do such

masses of plants as they should be under that system, and no gardener out of five thousand has the command of house-room to keep a whole host of specimen plants in pots, and in a way that some Australian plants for exhibition do not receive. But depend upon it, ere many years are passed over our heads, all the chief bedders for the London season will be done on this plan and principle.

It has now been proved practicable by the first garden authority of the age, and no doubt at all about it, and others who are able to afford the expense and the luxury will follow suit; and like the fashion of the dresses where there are not many years between the drawing-room and the back-kitchen, the fashion of the early flowers of the London season will reach the back premises of suburban gentility; and if you want to see a fashion carried out with the pride and spirit of our race, that is just the very place to look for it. Every kind and sort of bedding plant will then, and must, therefore, have a compartment or so much room for its own necessities till the plants are too big to move about.

Well, at the first day of the Handel Festival, and again at the Rose Show at the Crystal Palace, the very Lobelias in Sir Joseph Paxton's garden were 9 inches and a foot respectively in diameter; they must have been big enough last Christmas for planting-out as we have been accustomed, and they must have been in bloom by the 1st of May to make such a start as I have seen at those periods. There is a chain pattern on grass in front of a long verandah, where the new lovely Lobelia Paxtoniana runs all round, and in and out through the pateras—the most beautiful thing I ever saw; but the blaze of yellow and scarlet, of white and blue from the bank beyond, must have lent aid to the brilliancy, and the sun was just getting low enough behind one to make the whole thing an Eyebright.

In the different orchard-houses there is not a fruit tree in a pot—all are planted-out, trained in various ways, and closely stopped, the crops very large and promising. In one house, in which Strawberries had been ripened early, there was a full crop of early Potatoes just as in an open border; the large house for the supply of early Kidney Beans. Melons were again the same as last year—no bottom heat, or bed of any sort; a hole in the border under the centre of each light, and a barrowful of compost mixed with the natural soil, and the "hill" raised 2 inches above the level of the border, the surface of the whole of the borders covered with coal ashes for standing the pots of Beans on, were all the preparations which were visible, the plants and the crop looking splendid.

Of all the writers about Melons Mr. Fish comes the nearest to Sir Joseph's practice. The practice of both and the result appear to me to be just as close as any two methods not exactly alike can possibly be; the only difference is, that there they do not disbud the main leaders as he does, but they keep the Vines or stems as far apart as he recommends—indeed, no two leaves are allowed to touch, and yet you do not see an inch of bare stem in the house. The fruit is elevated a little on some nonconductor of moisture as soon as it is set, or just when setting.

D. BEATON.

## GRAPES SHANKING.

I TOOK charge of a vinery the latter end of January last, the Vines in which, all Black Hamburgs, I pruned at once, and commenced forcing about the middle of February. They have made some good, strong, healthy wood, and shown plenty of middle-sized bunches of Grapes, which looked well until the swelling-off and colouring process, then they began to shank off very badly. I suppose my predecessor had the same Vines under his care nearly fourteen years, and he was known to produce some very good crops of Grapes, but rather wanting in colour and flavour. I doubt this cold wet season is telling on their roots. The two original Vines are planted outside, one at each end of the house. Since the Vines were first planted they have been layered in the inner border at the back of the house, and two stems allowed to run down each rafter. The two original Vines are planted outside under a gravel-walk that leads from the kitchen garden, &c., where neither protection nor nutriment can be given satisfactorily. I understand the stems that are layered at the back of the house were lifted about seven years ago, and replanted in fresh compost, into which they were expected to root and run across the inner border under the flue and front wall into a new border made at the same time in front of the house, 4 feet deep by 18 feet wide. I am afraid their roots are too deep. I have examined the roots in the inner border, and find that they are

not within a foot of the surface; and if that is the case (so near home), how deep will their roots be after they have gone under the front wall, &c., into the outside border, which is 2 feet above the inner border and ground level, making the roots between 3 feet and 4 feet deep in the outside border?

Will you give me some information respecting their further treatment, &c.? Do you think it would be advisable to purchase half a dozen strong, healthy Vines, and plant them in the outside border, and cut one of the old stems away to make room for the young Vines, retaining the other old stem for further crop, until the young Vines come into bearing?

I forgot to say that two or three old dead horses were cut into pieces and buried in the outside border. For my own part I am no great advocate for such carrion borders. I propose to turn the border the latter end of January next, and at the same time to mix a few cartloads of turf, to lighten and make the soil more porous, to cause the wood to grow short-jointed, and to give the fruit higher flavour. If you should approve of planting young Vines, will you kindly inform me whether the annexed list of Vines would answer in this cold part, in the north, near Newcastle? I had almost forgotten to say that the house in future will be used as a greenhouse in autumn, winter, and early spring for bedding-out plants, &c.

Black Hamburgh, Dutch Sweetwater, Black Hamburgh, and Golden Hamburgh, at the warmest end. Black Hamburgh, Royal Muscadine, and Black Prince, at the coldest end.—A SUBSCRIBER, *Newcastle*.

[Your case is a singular one in many respects, and Vine-borders having formed a prominent feature in the last and present volumes, we will just shortly offer a few ideas on your case.

Firstly, We do not think that the wet season would have much to do with the shanking and want of colouring, because so great a proportion of the roots would be inside the house, where rains, &c., would not reach them, and we should not imagine that many of the roots had got into the outside border. If many had got there, and at such a depth, that would no doubt account for it; and so would having a high temperature and a moist atmosphere in such dull weather, with a languid root-action owing to the coldness of the soil, and the depth of the roots in it.

Secondly, All layering of Vines, however vigorous the growth afterwards, has a tendency to produce bad colouring and shanking, inasmuch as the roots are placed in different circumstances, and one set may be excited whilst the others are comparatively dormant. Plants layered so that each layer shall have its one set of roots, and the layer then be separated from the parent plant, will then be much in the same condition as a plant raised from a cutting, with its roots radiating from one point. If left to continue as a layer, the plants will not have fair play, as one part of the roots, as in the present case, will be in very different circumstances from the other. We know some houses where there has been such twisting and layering, that it would be difficult to know which was the original plant, and which the layer; but we have never seen the Grapes free of shanking and shrivelling, and that chiefly because while one set of roots might be 3 feet down, others might be no more than 3 inches. The discord among the roots left the tops in the lurch whenever a stress came.

Thirdly, In most cases where forcing is to be given to Vines, we prefer them being planted inside, as then there is no trouble in securing their stems from frost; but, then, we have equally insisted on one of two things—either that the roots shall also be confined inside, or if allowed to go out, the outside border shall not only slope, but be lower than the inside one, so that the roots shall not be buried. In your case, after layering the Vines at the back wall of a lean-to house, and giving them some 12 feet or 15 feet, or more, inside the house, another border is made outside not only 18 feet wide, but 2 feet higher outside the house than the floor inside. Were no other remedies applied, and this outside border was made, we would remove the 2 feet outside, and as much more as would render the inside border the highest. We should then expect the Vines you have to do better.

Fourthly, But the border being made there seems no reason why it should not be occupied with young Vines, and the old ones retained until the young ones were in full bearing. The first thing against doing this at once is the depth of the border—4 feet, which will have a tendency to give strong, luxuriant, instead of well-ripened wood, a tendency increased by the carrion of which you disapprove. That, however, having lain so long,

will be somewhat mollified now, and if there is good drainage, one of two modes might be adopted now. 1st, Supposing that after drainage the soil is pretty good for the purpose, get good young plants, and plant at once; they will grow a good bit, and ripen their base buds this season well, so as to start strong in the next. But in this case in such a border the plants would require to be raised, and planted again in two years near the surface, and surfacings and mulchings would require to be afterwards used to keep the roots near the surface—in other words, entice them to the surface, instead of letting them go down as they otherwise would. This would involve, on the whole, less trouble, but would not be so satisfactory.

As to your second plan. The border seems to have just the right slope now. Well, then, see the drainage in front is all right, take out 3 feet of the soil, beat the bottom, concrete it, lay drains across to the front drain, place over that 9 inches of rubble, and an inch of finer lime rubbish, then replace with 2½ feet of soil, using the best of the old and a little new, and lime rubbish, and plant as soon as finished. You may expect this to settle from 3 inches to 6 inches, but then the border will be as high as it is now. Such a border should produce Vines more fruitful than extra luxuriant, and luxuriance can be supplied by top-dressings. This plan would be the best; but if the deep border was otherwise good, the first plan would involve less labour, and if Vines are raised the second year after planting, there is not the same disposition in the roots to descend afterwards, if the soil is kept moist and mulched at the surface. For the extra trouble, however, it would be well to make all sure. The Vines are all right, only we would place Dutch Sweetwater at the warm end.—R. F.]

#### BLUE VITRIOL AS A CURE FOR ROSE MILDEW.

In reply to your correspondent, I beg to state that the vitriol which I use for white mildew in Roses is blue vitriol (sulphate of copper). Sulphur out of doors is not a sure cure. I have used vitriol with complete success on strong Rose plants. For pot plants when their leaves are tender, probably 1 oz. to a stable-bucket of cold water would be safer than 2 ozs., which is the quantity I have used for older plants with hardened leaves.

I may observe by the wayside that hot and close situations are sure to produce white mildew in pot plants. The novelties of 1862 planted in the open garden have been quite free from it, while those planted in front of my house have been attacked. The fingers are the best cure for aphides and white mildew.—W. F. RADCLIFFE, *Rushton Rectory*.

#### COUNTRY HORTICULTURAL SOCIETIES AND THE RAILWAY COMPANIES.

We think that the railway companies are not only illiberal but penny-wise and pound-foolish in their conduct towards local horticultural societies. For example: neither the North-western nor the Great Northern would convey free of carriage the unsold plants from the Stamford Horticultural Fête: consequently we are told of first-rate specimens which were not sent. Surely the companies in question might have afforded this encouragement to the Exhibition, since we are informed that they had to run ten or twelve special trains for the conveyance to it of passengers. We are willing to lend our aid to promote these great local shows, and wished to send a special reporter, but the Great Northern Railway declined to give him a free pass. Now, they act more liberally in the conveyance of live stock and reporters to and from agricultural shows, and we are unable to penetrate the subtleties of the railway mind so far as to discern why they make a distinction where there is no difference.

At the Stamford Horticultural Fête were from 10,000 to 12,000 visitors, and surely if the Marquis of Exeter will incur the intrusion of such numbers on his grounds at Burghey; if the Committee and the Secretary of the Society will undergo the labour and bestow the time required for such a Show; and if the Press are willing to help and increase such gatherings—surely the railways ought to be more liberal, for they are the only parties who are peculiarly benefited by them.

We will take this opportunity to add a few notes with which we have been favoured on the Roses exhibited at Stamford.

There were over a hundred entries for Roses, which formed an extensive feature in the Exhibition. These were contained

in a tent 120 feet long, in double rows down the centre after the plan of arrangement at the South Kensington Exhibition.

The first prize in the Open Class of three trusses of 48's was awarded to Messrs. Paul & Son; but the stands of Messrs. Francis, Cant, and Harrison, of Darlington, contained some very fine blooms. We noticed particularly the unequalled trusses of *Senateur Vaisse* and *Anna de Diesbach*, two gems in the stands of Mr. Francis.

Mr. Wm. Draycott, of Leicester, was first in the 24's; Mr. Walters, of Trowbridge, was second; Mr. Batley, of Rugby, third.

The Rev. S. R. Hole carried off his due—the cup for 24 varieties in the class for Gardeners and Amateurs; and Mr. Wm. Corp, of Milford, that for the 12 varieties.

The Rev. S. R. Hole was again first in the Class of 12's for Gardeners only; and Mr. Corp first for the 6 varieties.

In Tea-scented *Roses* Messrs. Paul were first with *Triomphe de Rennes*, and Mr. Cant second with *Céline Forestier*. Mr. Cant exhibited a stand of Cloth of Gold in fair condition—a novelty indeed for this season.

The first for 12 blooms of *Senateur Vaisse* was awarded to Mr. Francis, whose blooms were dazzling and well coloured.

Louis XIV. was well shown by Mr. Walters, of Trowbridge, who was first in *New Roses*; and Mr. Cant second.

As a *Rose show*, the Exhibition has barely been equalled. A heavy thunderstorm on the previous Wednesday marred the hopes of some intending exhibitors; but, considering the season, the *Roses* were decidedly good. From the success which has attended this Exhibition we trust it may not be the last. The fine old town of Stamford, with its magnificent mediæval churches and remains, combined with its convenient and delightful situation, render it a most suitable centre for a joint meeting of northern, midland, and southern growers.

## ROYAL HORTICULTURAL SOCIETY.

JULY 22ND.

**FLORAL COMMITTEE.**—There were two grand novelties before the Committee at this Meeting—the great gold-gilt Lily of Japan, *Lilium auratum*, referred to at page 311, from Messrs. Veitch and Son, the Exotic Nursery, and a new crimson and gold *Disa*, a superb variety of *Disa grandiflora*, from J. C. Leach, Esq., Clapham Park. The Committee were unanimous in their awards to these splendid flowers, giving a Special Certificate for the Lily, in addition to the first-class honours which were bestowed on it at the July Exhibition of the Society.

Mr. Leach sent a noble specimen of *Disa grandiflora*, that the Committee might compare it with the much superior variety shown now for the first time. They named it *Disa grandiflora superba*, and gave it the highest award at their disposal, a First-class Certificate. The difference between it and the species consists in the superior colouring of all the parts of the flower. There were three noble spikes of bloom on it, and three flowers open on each spike.

The variegated Day Lily from Japan (*Hemerocallis*), which was particularly referred to in our report of the Exhibition in July, was also awarded a First-class Certificate at this Meeting.

The first *Dahlia* of the season was there, but no one proposed honours for it. A pale-flowering *Fuchsia* was exhibited from Buckingham Palace, to show the ancient tendency in the family to bloom at the extreme points of the shoots in close cymes or trusses of bloom, standing upright, as in *Fuchsia arborescens*. In this instance the flowers were not in "heads," like those of *F. arborescens*, or say like *Laurustinus* flowers, but they were most numerous towards the points of the shoots, and standing upright. Some of the members were familiar with this kind of deviation from the usual habit of the family.

There was a good collection of superior *Verbenas* exhibited by Mr. Smith, of the Hornsey Road Nursery, for which a Special Certificate was given. Also, a collection of white *Fuchsias*, of which *Prince Alfred* and *Bridesmaid* were our choice. But *Fuchsias* must be something very superior in these days, and so must *Pinks* and *Carnations*.

Mr. Turner, of Slough, sent three boards of *Carnations* and *Picotées*, every one of which was quite good enough to present to the Pacha of Egypt, and sweet enough to vie with the most spicy odours of Arabia; and yet the florists, to whom all such are specially referred, selected one kind only for the highest honours to the race. That one is called after *Lady Elcho*, and is

ivory white, and of ivory substance, with a fairy ring of puce purple all along the edges—that is to say, Mr. Turner has changed this flower at last from being a *Picotée* to be a plain flower, and is rewarded for cancelling the very best flower that his grandsires had in their borders.

A pyramidal device was exhibited, wide as a bushel measure across the bottom, and high as a heaped measure on the rise. This was planted with the finest of our tiny flora, the *Sundew*, *Drosera rotundifolia*; but the sun was not up enough to give the reflection from the pearl-like dew or natural secretion of the plant standing on all parts of the surface of the plant.

**FRUIT COMMITTEE.**—A Meeting of the Fruit Committee was held on Tuesday, the 22nd inst. Mr. Edmunds in the chair. Prizes were offered for the following subjects. Class A.—For best dish of Peaches. In this class the only exhibitor was Mr. Charles Turner, of Slough, who produced *Grosse Mignonne* in fine condition. The fruit being well grown and highly flavoured, the First Prize was awarded to Mr. Turner. The same gentleman also exhibited a very fine dish of *Noblesse*. In Class B, for the best dish of Nectarines, Mr. Turner was again the only exhibitor. The variety shown was *Hunt's Tawny*, and to this the First Prize was awarded. In Class C, for the best dish of Plums, Messrs. Lane, of Berkhamstead, exhibited handsome fruit of *Kirke's Plum*, which were unripe; and Mr. Tillyard, gardener to J. Kelk, Esq., of Stanmore Priory, exhibited *Green Gage*, *Jefferson*, and *Victoria*. All three were remarkably fine productions, particularly the *Green Gage* and *Victoria*. The First Prize was awarded to *Green Gage*, and as *Jefferson* was not quite ripe, the Second was awarded to *Victoria*, which was not only of large size but of excellent flavour for that variety. In Class D, for the best collection of the newer sorts of Strawberries, Mr. Ingram, of Frogmore, exhibited *Cockscob*, *Rifleman*, *Frogmore Late Pine*, *Elton Improved*, and *Fairy Queen*. This being the only competition and the examples being very good, the First Prize was awarded. In Class D, for the best collection of any varieties of Strawberries, Mr. Turner, of Slough, exhibited *British Queen*, *Carolina Superba*, *Rifleman*, *Frogmore Late Pine*, *Rivers' Eliza*, *Wizard of the North*, *Ingram's Prince of Wales*, *Ingram's Prince Arthur*, *Elton Pine*, *Filbert Pine*, *Empress Eugénie*, *Sir Charles Napier*, *Crimson Queen*, *Oscar*, *Trollope's Victoria*, and *Eleanor*. This was a fine collection, and received a First Prize. In Class F, for the best collection of Currants, Mr. Turner showed fine dishes of *Cherry*, *Red Grape*, *Willmot's Red*, *Black Naples*, *White Dutch*, and *Champagne*. The bunches and berries in every case were large. Mr. Lakeman, gardener to J. Campbell, Esq., Grove House, Hendon, sent *Houghton Castle* or *Goliath*, *Red Dutch*, and *Knight's Red* (which were the same), *Black Naples* and common *Black* (also the same), *White Dutch*, *Pearl White*, and common *White* (all three the same), and the *Green-fruited Black*. Mr. Turner's collection being the best, he was awarded the first prize, and the second was given to Mr. Lakeman.

A seedling Strawberry was received from Capt. Goldney, of Slough, called *Etonia*; but the flavour was very inferior and acid. It evidently wants a better season to perfect it. Robert Wrench, Esq., of London Bridge, sent a dish of the now very rare *Myatt's Pine Apple Strawberry*, a very richly flavoured variety, having the true *Pice* flavour.

Mr. William Thomson, gardener to his Grace the Duke of Buccleuch, Dalkeith Park, sent fruit of the same seedling Grape which he exhibited last year. On this occasion the bunch was a foot long, and weighed 1 lb. 2 ozs. It was well set, and the berries were larger than they were last year. The flavour is as fine as that of the *Chasselas Musqué*, but it is a totally distinct Grape from that variety. It was not quite ripe, but it was sufficiently so to enable the Committee to form a high estimate of its value. Mr. Thomson intimated that he would submit this Grape again to the Meeting on the 12th of August. Mr. Thomson sent three other seedlings, which, however, were in too early a stage to enable the Committee to form an opinion upon them.

A very nice collection of Grapes was received from the garden, grown on Vines in pots.

A seedling Melon was sent by Messrs. Carter & Co., of Holborn, which, however, was found not to possess any remarkable merit.

**CRYSTAL PALACE.**—The gardens and grounds of the Palace are now in their prime, flowers and foliage at their best. The beds on the terraces and the rosery have been kept back by the unseasonable weather, but the sun of the last few days is now

bringing them out in astonishing beauty. The view of the surrounding country from the terraces, and from the superb dining-rooms in the south wing, are most charming; while to those who do not mind a little fatigue, the panorama spread out before them when at the top of the lofty water-towers is without its equal. The whole of London spread out as a map, the windings of the river, the extensive views into Middlesex, Essex, Kent, Surrey, Sussex, and Berkshire, show a beauty of home scenery which cannot be surpassed. Attendants with telescopes are provided in the tower galleries to point out surrounding objects of interest.

### THE SEASON.

We have had, and are having, a weary season; rain, wind and cold, more like October or November than July. Such have been the afternoon and night of yesterday.

We thought 1860 and 1861 were wet seasons, but this year it is worse, and you cannot imagine the wretched appearance of the flower-beds. Zinnias, Asters, Verbenas, &c., never seem to have grown since put out of doors. The Roses are dashed to pieces ere their beauties have been half developed.

I never saw a greater show of Apple and Plum bloom, but there is very little fruit. Half the Apples have dropped off grub-eaten.

Snails are as plentiful as locusts in the east. Caterpillars are innumerable, and I have only been able to save the Gooseberries by having the trees "hand-picked;" this is the way to make sure of the vermin. I tried soot, suds, and tobacco water in vain. The ashes of burnt bark have been strongly recommended, and are, I believe, a good help; but the only cure is "catching and killing."

Many fruit trees are blighted; my Black Currants are only half-size, as they have been left without sufficient leaves.

This is a great Potato district, and, so far, the earlies are a good crop and free from disease.

You may judge of the sort of haytime here when I inform you there have only been four days without rain since June 7, and until within a week the temperature has been very low.

With all this rain my bees have done well. From two common straw hives I have had four good swarms, and a fifth has either "gone" or the exceeding wet of the last few weeks has stopped them.

These few lines are simply to afford a little information about this wet and out-of-the-way county.—CHESHIRE.

P.S.—I do not allow any birds to be shot on my grounds.

### WINTERING PLANTS IN A FRAME.

Will you oblige a cottager with your opinion as regards wintering common plants in a cold frame? By "common plants" I mean such as are generally termed bedding plants. I used to succeed pretty well in the county of Oxford; but I am now in Lancashire, and I fear I shall not succeed so well. I intend placing my frame on the south side of my cottage, and am obliged to have the back of it close to the building, else it would be in the way. It is only a two-light frame, so that I think the disadvantage of getting to the back of it will not be great. I am thinking of making a floor of bricks, as they will make a drier bottom than anything else I know. Where I intend placing my frame is an iron air-grating, the size of a brick, which admits air under the floor of my cottage, and another on the west side, measuring, I suppose, under the floor, 4 yards or 5 yards. I should like to know if it would be an advantage in helping to remove the damp stagnant air when the frame is closed so long in frosty weather if I cut a piece out of the back of the frame so as to admit air into the frame where it fits against the iron grating? I also think it would be an advantage to make another opening through the frame near the top, and also another opening through the wall with another grating put in the wall opposite the piece cut out from near the top of the frame. The top opening through the wall would be inside my cottage just above the floor. I am thinking of mixing some soot, lime, and ashes together to cover the earth before I lay the bricks.—A LOVER OF NATURE.

P.S.—You might say a small greenhouse would be far the best; but a greenhouse, however small, would be far more expensive than cottagers generally could afford. I know many cottagers that have their little cot full of plants, and would have

a pretty show about their cottage in summer could they secure more plants through the winter.

[We do not think you will find much difference in the management of your frame in Lancashire, from what you practised at Oxford. Your idea of the air-gratings is a good one, only you must be sure that the air that thus comes below your floor is heated enough to be free of frost in severe weather. This you can remedy by partially or wholly shutting at times the external air-brick. The having an additional one entering the cottage from the frame is also a good idea; and if the position of the frame would admit of it, if that air-opening was a foot or 15 inches higher up, it would be all the better. Then we would improve on the lower grating a little. Even then your two openings would be at the back, and in dull weather there would not be much circulation at the front; but carry a drain from the lower grating to the front, and raise an upright pipe there, and the circulation would be complete.

In cold, frosty weather there would be little harm in shutting the external air-opening, for if the air in the frame gets down to 35°, or so, there will be little danger from damp, especially with the gratings inside open. With plenty of covering, frost may be easily kept out. Be sure that any opening between the frame and the wall is thoroughly packed with sawdust, or some other non-conducting medium, as dry moss, &c. Damp, as you seem to be aware, will be your great enemy; avoid having moist litter against the sides of the frame in winter. The cheapest protection in the end would be a double frame, with 3 inches between, and that packed with sawdust dry, and a board on the top to keep out damp—that is, covering the space securely between both boxes. That will keep out more cold than a 14-inch brick wall, solid. The next best would be to use straw 3 inches thick, tied neatly to the sides and front of the frame. So far for the outside. Your proposed flooring of brick will be neat and cleanly, but it will not prevent damp rising, and, withal, will be rather expensive. If you do it now, a more secure bottom would be formed of the ashes you speak of and gss tar some 3 inches thick. No damp would rise through this, and none will go through it. For this purpose the site of your frame should be raised—say 9 inches or a foot above the surrounding ground, the site being larger in length and width than the frame by 18 inches, and the ground to slope down to the level beyond that. On this put a stiff mixture of the ashes and the gas tar, and press it smooth, and if you then like lay your bricks on the top of it; but we would prefer some road-drift sand when the mixture was getting a little tough. This will be all sweet enough before you want to use it in the autumn, and you would be sure of dryness. In summer a few holes should be left to allow the water to run out that escapes from pot-watering. In winter no pot should be watered except on a fine day, and then it should be watered outside, allowed to drain, and then be replaced in the frame. If you could lay your bricks thus elevated on dry chalk, and cement them together, it would be pretty well; but whenever the bottom side of the bricks gets damp, you will soon have the upper side damp likewise. Much, however, may be done by dusting the bottom with dry sand, as you move and shift the plants in a fine day. In such a frame we would hardly water a plant from October to March, but when a plant got dry we would take it out, water it, allow it to drain thoroughly, and then replace it.

We have been thus particular as to minutiae to oblige many like our correspondent who desire to make their cottage gardens brilliant with bedding plants in the season. If they have no frame, however, they need not despair of doing this, as a few windows rightly used, and the plants moved to the centre of the room on cold nights, will enable them to have as many plants as they could well keep in a two-light box. The box may, however, be used for so many purposes that we should be anxious to see one in every cottager's garden; and a handy man might soon put a rough one together for himself.]

### SOME OF OUR RARE WILD FLOWERS.

Of the rare *Lobelia urens*, which grows only on Helmington Common, near Axminster, and of the Cheddar Pink (*Dianthus cæsius*), which is confined to the Cheddar rocks, I can obtain specimens; and I now enclose a drawing and also a dried specimen of the equally rare little *Trichonema bulbocodium*, which has only one habitat in the kingdom—namely, the Dawlish Warren, which is in this immediate neighbourhood. It is a most

interesting little plant, abundant in Guernsey, whence it is supposed to have been brought to this country in ballast, and thrown out on the Warren, where it has become naturalised. It was, I believe, first observed there about the year 1833, and recorded by botanists in several subsequent seasons, but after a time it disappeared, and was supposed to be lost. We, however, were fortunate enough to rediscover it some ten years ago, whilst in company with the late Dr. Landsborough, and since that time I have observed it nearly every season; but it is exceedingly shy of blooming, and very difficult to detect by those who are not well acquainted with its habitat, as the flower is minute, and grows in the turf close to the ground.

In cold, wet springs it rarely opens its blossoms; but in the warm sunshiny days of a genial April it is seen in great profusion, its delicate flowers of blue lilac covering the sward in large patches like exquisite little gems.

To show how difficult it is of detection, I may mention that a gentleman, a friend of mine, to whom I had described its locality on the Warren, told me he had marked out a large patch of ground on which he thought he was certain to find it, and being determined to succeed, he subdivided the space thus marked out into small squares, and went over the whole patch most carefully, but failed in his object. You may, therefore, imagine his delight when I accompanied him to the Warren, and showed him the plant, which was then in full beauty.

The *Tussilago fragrans* grows quite wild in our lanes, and about Torquay there are many rarities.—A. C. G.

### THE GRAPE VINE.

*A Practical Treatise on the Cultivation of the Grape Vine.* By W. THOMSON, Gardener to the Duke of Buccleugh, Dalkeith Park. W. Blackwood & Sons, Edinburgh and London.

MR. THOMSON has long been known as one of the most successful cultivators of the Vine. He is also well known as one who can clearly and well express his thoughts, and narrate facts either in conversation or by the aid of his pen. A book upon Vine culture from him, therefore, must be expected to be excellent, and that before us will not disappoint that expectation.

Mr. Thomson omits the out-door culture of the Grape altogether, because, as he states, "in these days of cheap glass it is a most unsatisfactory investment of both time and skill to attempt its culture except under glass."

Our author then details the construction of a vinery, gives directions for heating the atmosphere and soil, dwells upon ventilation, drainage, covering the surface of the borders, preparing the soil, planting, choice of plants; proceeds to detail the treatment of the Vines during their first, second, and fruiting year; describes the pruning and propagating of Vines; shows a new mode of growing Vines in pots for table decoration; descants on the diseases of Vines and their cure; concluding with notes on packing Grapes, keeping them after they are ripe, an amateur's vinery calendar, and some experiments with Vines. In all these sections the practical directions are clear, simple, and excellent, and may be consulted advantageously by the amateur and tyro Grape-grower. We will extract as an example the section on

#### KEEPING GRAPES AFTER THEY ARE RIPE.

"This is a matter where care and attention can do much. I have this season kept Lady Downe's Seedling Grapes hanging on the Vine till May, in a house where we began cutting Black Hamburgs in August. This house is 110 feet long, 11 feet high, and 11 feet wide, and has been referred to already as having been planted in 1858. It is a common lean-to house, built to serve the double purpose of growing Figs on the back wall, a Vine up each rafter, and one half-way up the centre of each sash, the sashes being 5 feet wide. The ventilation is by an opening sash to the north on the top of the wall, and the front sashes open outwards in the usual way by lever and rod. The cost of this house, including boiler and two rows of four-inch pipe along the front, was under £200, and at Christmas last we had four hundred bunches of Lady Downe's and West's St. Peter's Grapes hanging in it, representing a commercial value little short of its original cost.

"In order that Grapes may keep well, it is necessary that they should be well ripened by the end of September, and not grown in a wet berry; nor should the internal atmosphere of the house be kept loaded with moisture. What is required in Grapes to keep well is a firm fleshy berry, not one full of water. The bunches should have the berries well thinned out, more so than in the case of Grapes that are to be used shortly after they are ripe. Long tapering bunches keep better than broad-shouldered ones, as the berries in the centres of the latter are apt to damp off and destroy the bunch before it is observed. As soon as the Grapes are thoroughly ripe, the night temperature should at once be lowered to 50°, till the leaves fall off or ripen, when they should be removed carefully by hand from the Vines. After this date the fire heat should never exceed 45°, nor fall below 35° at night; and in damp foggy weather, I keep the house carefully shut up for nights and days at a time. To give air during a damp foggy day is to fill the house with the very evil you wish to avoid—damp air. The surface of the internal border is

allowed to get perfectly dry, and to remain so all winter, care being taken that as little sweeping or raking take place as possible, for by this means dust is raised which settles on the bunches. Half the roots are in the outside border, and had no covering at all.

"Towards the close of February I cut about fifty bunches of Lady Downe's, detaching the branch on which the bunch grew as when pruning the Vine. I then sharpened the ends of the branches, and run some four or five of them with a bunch on each into the side of a Mangold Wurtzel laid on the shelf of the fruit-room, allowing the bunches to hang over the side of the shelf. In this way the Grapes kept perfectly fresh till April. I left some fifteen bunches on one Vine for experimenting upon, two of which are still hanging at this date, May 2. About the 15th of April the sap began to rise in the Vines, and some of the berries that were a little shrivelled suddenly got plump, while others that had shown no signs of shrivelling burst their skins, and the sap of the Vine that had forced itself into them began to drip from them. It was tinged with colouring matter out of the berry, and had the taste of the berry. To stop this bursting of the berries, I made an incision in the lateral on which the bunch hung, betwixt it and the parent stem of the Vine, in two places, half through, at opposite sides of the lateral. This drew off the sap, and no more berries burst. The Vines have now young growths on them 9 inches long, and are appropriating all the sap, and the bleeding has ceased from the incisions. In February I had all the eyes picked out of the laterals, except the one at the base of each. These are showing fruit like others that were pruned in the usual way, except the three I bled: they are much weaker than the others. From this experiment it may be reasonably inferred that it is not judicious to keep Grapes hanging on the Vines after the sap begins to rise. It, however, proves that it is possible to cut old Grapes in May, and, considering that new can be cut in January, gives an overlap of four months in the supply of Grapes."

### CROSS-BREEDING CAMELLIAS.

BEING myself a great admirer of the Camellia, you may imagine with what joy I discovered last April that I had succeeded in impregnating seven blossoms on one of my trees. I have lost two, but I have five very healthy pods, and the seeds are bursting through the crown, which is now as large as a good-sized Walnut. Having a profusion of semidouble blossoms on my "Old Red" plant, and perceiving the stigma protruding through the opening flower of a very double Carnation-like bloom on another plant, I introduced the anthers of the former to the pistil of the latter without much hope of success, but the result has been as before mentioned. As this is a feat which those professionals who have not seen my plant are unwilling to believe can have been produced from a very double flower, several of Messrs. A. Henderson & Co.'s men being amongst the number, I have troubled you with this communication, which may equally surprise some others of your numerous readers. The Hon. and Rev. W. Herbert considered it necessary to keep the Camellia in great heat, and not to allow a breath of air to blow upon it, to produce fruitfulness. Mine had no additional heat but the sun, and it stood close to a window which was open all day. No! the virtue, in my humble opinion, all rested with the beautiful golden farina upon the anthers of the Old Red; and any one possessing a plant of the same may soon have a young crop of Camellias not two alike. I am sorry I have lost the name of the mother plant. It was a noble bloom, Poppy-like, very double, and rather light colour. Next year, if I live, I will send a blossom of it to your office. The plant came from Belgium.—DAVIS.

[Those who have doubted the result of your highly interesting experiments with these Camellias are not less learned in the ways of crossing than all of us had been at one time or another. The next greatest pleasure after such enjoyments as you experienced is that of learning others, such as some of Messrs. Henderson's men, how to come to a knowledge of the truth; and you have taken the best means for that end. You have mistaken Dr. Herbert's meaning, however. It was not to "produce fruitfulness" that he confined the mother of his Camellia seedlings, but in order, as he then erroneously supposed, that the particular treatment "of the mother plant while in flower and seeding" should produce "an unusual result"—that is to say, to produce double flowers instead of single ones. He did not mean "to induce fertility." The person who first reviewed that work was a practical crosser himself, and that was the only thing about crossing of all that Dr. Herbert advanced on the subject with which he would not assent. That led to an interview between the author and his reviewer, and ultimately to a close intimacy on a fellow-feeling pursuit: it also resulted in the conversion of Dr. Herbert after many experiments, every one of which went against the doctrine of the possibility of influencing crossed seedlings, as far as the flowers are concerned, by any mode of treating the parent plant while it is in seed, or after fertilisation is once effected.

The influence of any mode of cultivation during the interesting period affects the growth and health of the seedlings only, not

the colour, or size, or substance of their flowers, or their singleness or doubleness. That is the only thing about crossing of which we are quite certain, and in four years after Dr. Herbert published his theory of the question he was convinced of its untenable foundation; and a few years later, in his *résumé* of the whole subject of crossing in two long and elaborate articles in the "Journal of the Horticultural Society," this question is not once mooted. Still, the idea of one being able to bear a hand in this, one of the greatest mysteries in nature, is prevalent at the present day; and what is more strange is now before us—men engaged in a first-class London nursery not being aware of the fact that if you detect one anther only in a thousand double flowers, the pollen in it is as effectual as the pollen from a single flower. But that there may not be room for doubt or uncertainty, even in so large a place as London, we give the matter in Dr. Herbert's own words (the work appeared in 1837). He said, "I have had greater success than any other person in raising from seed double Camellias of various tints and appearance; and some of the best have been produced either from single flowers, or plants raised from single ones, impregnated by the pollen of double flowers preferring, where it could be got, *the pollen that is borne on a petal.*" The italics are our own. Pollen is occasionally found on the edges of ragged petals in the centre of many double flowers, as those here referred to, and more often in the family of *Dianthus*. So that with the stamen converted into its element, the petal, it may yet bear the anther and the pollen; and if so, and you fall in with it, no other arrangement of the parts is more sure for turning out double flowers.]

### THE WEATHER AT ASHTON-UNDER-LYNE— THE LANCASHIRE COTTON-SPINNERS.

THIS part of Lancashire seems not only to have dark, dark days, owing to the want of cotton, but owing to the want of good weather too.

On the north side of Ashton there are some hundreds of cottage gardens, owned mostly by operatives. These gardens extend for more than a mile and a half, and are mostly on the edge of "Ashton Moss." Many fine vegetables are grown in them in good seasons; but this year seems as if it would not only prevent them from earning an honest respectable living in the mills, but also would stop them from enjoying a few choice flowers and vegetables of their own growing.

My worthy employer has laid out considerable sums of money in purchasing choice things to cultivate for a floral and horticultural show, which they intend to have the first Saturday in September; but the weather damps their spirits, though they have had but little of the cotton famine.

For my own part I never had such a season for outside plants, for what with the weather and the hotts (the grub of the daddy longlegs), it has been an up-hill fight all the season. I have caught as many as three pints of botts in a day, and on one occasion I swept up on a walk in front of the house nearly four quarts of the dirty-looking vermin. I began to think they were as numerous as London reports them to have been once in Ireland. Some wags who had noticed the large quantity we had on the carriage-road, changed the name of our place from "Grobby Lodge," to "Grubby Lodge."

Of Kidney Beans I scarcely entertain a hope of having any outside. Peas are rather better than in the year 1860. Celery is very late, and other things also. Gooseberries and Currants have been plentiful. I have plenty of Wallflowers and other things in bloom that should have been over long since. I bedded out four hundred Geraniums, but I do not see that one of them has made a new leaf, and other bedding stuff looks miserable, save some beds of German Stocks and Saponarias, which are a little sheltered.

There has been a cold west or north-west wind blowing nearly all the summer, and it has been so cold that I have had to use fire heat all through June and July to keep a late house of Black Hamburgh Grapes swelling.

Some of the poor operatives who were accustomed to spend five or six shillings on Verbenas and other bedding stuff, were rather down in the "dumps," as we call it in Lancashire, this spring; but I and other gentlemen's gardeners gave some that we knew a few plants, for which they were very grateful, and I fear many of the poor fellows will be too poor to buy seeds for next year; but if all be well with me I intend to beg from the

gardeners of the country both seeds and plants for them. But let us hope things will be better, for they are bad enough here at present.

To give your readers an idea of how matters are here, I may state that I have had men offering to work for me for their food alone, men who have been accustomed to get from £1 to 36s. per week—so anxious are large numbers to be rid of the task of having nothing to do.

My worthy employer has not only kept most of his work-people in full employ, but he has given them a prize of £5 value for their horticultural show mentioned above.

In conclusion, I hope your readers will not be frightened at my threat to "hand the hat round" next spring, for I can assure them it will be the last extreme for a Lancashire man to do such a thing, for we are thoroughly versed in every man "doing his own" here.—J. II.

[We ask of our readers to bear these statements upon their minds, and we tender our aid to our correspondent in carrying out his good purpose. We know the Lancashire operatives well, and bear an unreserved testimony to their clear heads, large hearts, and ready hands. It is no degradation to receive aid under present circumstances, any more than it is for a patriot in a tyrant's prison to receive aid from his friends who are at liberty. He is cut off from his own private resources without any fault of his own, and only requires aid until he is once more permitted to provide for himself. So is it with the cotton-spinners.—EDS. J. OF H.]

### REPORT ON THE BROCCOLIS

GROWN IN THE GARDEN AT CHISWICK IN THE AUTUMN OF 1861 AND THE SPRING OF 1862. By ROBERT HOGG, LL.D., F.L.S., Secretary to the Fruit Committee.

THIS is the second season during which an attempt has been made to try the different varieties of Broccoli. The first was made in the previous season of 1860-61, but the frost of that winter was so severe as to result in the total destruction of the crop. Neither has this second attempt been so successful as could have been desired. The seed was sown early in March, and the plants made satisfactory progress till the period when they were planted out, after which many of them made so rapid and luxuriant a growth in the autumn that they had not sufficient vigour left to develop good-sized heads during winter and in the spring; added to which, it is the opinion of all practical gardeners that the soil of Chiswick Garden is not adapted for the successful cultivation of Broccoli.

Under these circumstances it was not possible to make a complete report of all the 103 varieties that were planted; but of such as did come to maturity and withstood the winter, the following observations have been made.

It is quite evident that the varieties of Broccoli as now grown are in a state of great confusion, the old varieties, such as Grange's and the Old Early White, having entirely disappeared or lost their original character; for instead of coming into use from Michaelmas till Christmas, as they were wont to do, the former did not, in one instance, come in till February 7, and in another till March 7, while what is called Early White was not fit for use till April 18. The distinctive names of Early White and Late White seem now to be possessed of no value, as in some cases the one is used for the other, and *vice versa*.

As there are distinct races among Broccoli, it would be very desirable if some definite nomenclature were adopted, which would at once convey some idea of the character of the varieties. These races may be distinguished as follows:—

#### I. WHITE BROCCOLI.

- |                  |                        |
|------------------|------------------------|
| A. Autumn White. | C. Early Spring White. |
| B. Winter White. | D. Late Spring White.  |

#### II. PURPLE BROCCOLI.

- |                   |                   |
|-------------------|-------------------|
| A. Autumn Purple. | B. Winter Purple. |
| C. Spring Purple. |                   |

#### I. WHITE BROCCOLI.

##### A. Autumn White Broccoli.

The earliest of the autumnal varieties are the Dwarf Erfurt, Le Normand, and Walcheren. Properly speaking, these are not Broccoli, but Cauliflowers, and ought not to form any part of this report; but as they have now for some years been known among seedsmen and gardeners as Broccoli, and as they were received as such in the collection, they are introduced as the earliest of the autumn sorts.

DWARF ERFURT . . . . . BENARY.

The plant is dwarf, not above a foot high, and produces a large, clove, and compact head, 6 inches to 9 inches across, which is of a creamy colour. The leaves are short, winged, tapering abruptly to the base, spreading and exposing the head. In use August 1st.

LE NORMAND . . . . . VILMORIN & Co.

Plant about 15 inches high, with winged leaves, which are broad, and taper abruptly towards the base; they are toothed and waved on the margin, exposing a head which is about 9 inches in diameter, and of a creamy colour. This is earlier than Walchereo, and is readily distinguished from it by the waved and toothed margin of the foliage. In use August 8th.

WALCHEREN . . . . . VEITCH & SON.

- Covent Garden White . . . CHARLWOOD & CUMMINS.
- Selected Early Erfurt . . . SCOTT.
- Stadtholder . . . . . NUTTING & SON.
- Hammond's White . . . . . TURNER.
- Late White Cape . . . . . TURNER.

The plant is from 18 inches to 2 feet high; leaves winged, tapering abruptly towards the base; the inner ones turning with a spiral twist over the flower-heads, and protecting them from the sun, enable them to preserve a clearer whiteness than either of the former, which, from the spreading habit of the leaves exposing the heads to the direct influence of the sun, are always of a cream colour.

The true Autumn White Broccolis ought to be Grange's and Early White; but in the whole collection there was not an approach to either of these, and out of the whole 103 varieties there were not any to supply the long gap between the flush of Walcheren in the end of August and the time when Snow's Superb came in on the 8th of December.

B. Winter White Broccoli.

SNOW'S SUPERB . . . . . VEITCH & SON.

- Gill's Yarmouth White . . . FLANAGAN & SON.

This variety came into use on December 8th, and was a large and handsome head, perfectly white. It continued in use during the winter, and by the end of January was entirely over. This is the only one in the whole collection that could be called a Winter White Broccoli.

C. Early Spring White Broccoli.

Of these there are a vast number, all differing very slightly from each other in their general characteristics, and distinguished more by the care that has been bestowed on the selection of the stock than upon any permanent features they possess.

SNOW'S SPRING WHITE . . . HURST & McMULLEN.

- Snow's Winter . . . . . NUTTING & SONS.
- Imperial Early White . . . BUTLER & McCULLOCH.
- Grange's Cauliflower . . . VEITCH & SON.
- Early White . . . . . CHARLWOOD & CUMMINS.
- Adams' Early White . . . BUTLER & McCULLOCH.
- Covent Garden Market . . . BUTLER & McCULLOCH.

The plant grows about 2 feet high, and is very hardy. It produces large white flower-heads, which are well protected by the incurved leaves. It comes into use about the 7th of February, and continues during the whole of that month.

NEW EARLY INVISIBLE . . . NUTTING & SON.

- Incomparable or } . . . . . TURNER
- Melville's Large White }

This comes into use about the 7th of March, and is rather open-headed. It was found to be so very tender that good specimens could not be obtained from which to form a judgment of its merits.

(To be continued.)

CULTURE OF A FEW HARDY ORNAMENTAL PLANTS.

WE print the following to meet the requirements of *Virgil, Derby*, and another correspondent:—

**WATSONIA FULGIDA.**—Grow it in sandy loam and leaf mould. When started, give a top-dressing of old cowdung. When showing for bloom give weak manure-waterings; give less water after the flower-stems decay, and withhold it altogether after the leaves get yellow in the autumn. The tubers may be kept in the pot or in sand. They are as hardy as the general run of *Gladiolus*. With protection they might be left in the ground

all the winter. We know, however, of some fine beds of *Gladiolus, Watsonia, &c.*, that stood well for years, but they all rotted in 1860 and 1861. If taken up they would have been safe, and flowered just as well if planted early. The *Watsonia* named generally blooms early in summer, and should be potted or planted as soon as growth appears.

**TRITONIA AUREA.**—These, like the *Watsonia*, are hardy enough to stand out, with protection from frost and wet in winter. According to kinds they will bloom from early spring to autumn, and should be treated accordingly. It will be best, in the first place, to keep them in pots until you obtain a stock. Early kinds will now be going to rest, and should have no water, but may remain in the pots until they show signs of growth in the autumn. Those flowering and growing now should be watered until the leaves begin to get yellow, when it should be discontinued. The roots may then be kept dry in the pots, or, better still, be taken out, and placed in a saucer covered over with dry sand. As they begin to move when kept in a dry, cool place, pot them—say four or five roots in a five-inch pot, placing them so as to be slightly covered. The pots should be well drained; and the best soil is sandy loam one part and heath soil two parts, and the smallest roots should have a little sand about them, if silver sand all the better. Do not water much until the roots are taking hold of the soil; but the soil should be moist—not wet nor dry. Setting in a cold frame and keeping the floor damp will give moisture enough until the roots are progressing freely, when more water will be required. After they are several inches in height, an airy window or the front shelf of a greenhouse will be the place for them.

**DEUTZIA GRACILIS.**—This is a beautiful little shrub, and, we believe, quite as hardy as *scabra*, which stands out as a shrub or against a wall north of London, and it seemed to suffer little by the frost of 1860-61. It is easily grown in sandy loam and a little leaf mould. It looks best when it has a great many little twigs—say a foot or 18 inches long, covered with its small snow-coloured flowers. Whether, therefore, grown for ornamenting the greenhouse, or to be forced in winter, the treatment it requires is much the same. As soon as it has done flowering, prune off the flowering shoots, and encourage it by active growth to make fresh wood, and then get these young shoots full in the sun in the summer and autumn months that the wood may be ripened before winter. If in pots, the plants may be plunged in a sunny place during the summer.

**DATURA WRIGHTII.**—We are not sure by the leaf whether you have got the right variety or not, as the leaf was too withered to detect its woolliness or scent. You should also have told us whether your plant was a seedling or a last-year's plant. To get it vigorous it requires a warm place in the conservatory or greenhouse at first to encourage active growth. When growing it likes a rich soil, such as sandy loam and rotten dung, lightened with silver sand, and plenty of water, with good drainage. The large, rather sweet, double flowers are worthy the little extra trouble. Towards autumn water should be curtailed, and if the plant is merely kept from frost in winter the leaves may be allowed to drop. This will insure the ripening of the wood, and the fresh shoots next season will generally be well stored with flowers. Damp and a low temperature in winter will be sure to make an annual of it. In the summer of 1861 it bloomed pretty well with us out of doors; but we were too long in looking after it, and the frost settled it.—R. F.

WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 295.)

CRUSTACEA (continued).

**THE MASKED CRAB (*Corystes cassivelaunus*).**—The reason of this singular species having been thus named by Professor Bell may be given in his own words. "The carapace in this species is longer than it is broad, in the proportion of three to two; convex, with the regions somewhat distinctly marked, having a groove surrounding the cardiac and genital regions, and another short transverse depression over the intestinal region, forming altogether in many specimens a remarkable similitude to the features of the human face, from which circumstance I have given it the English name of "the Masked Crab."

The formation differs according to the sex of the animal. For instance, in the male the fore legs are twice as long as the body, whereas in the female they are only of the same length

There are also other distinctions; but this one is so marked and so easily recognised that it would be impossible to mistake the male for the female. The remaining legs in both sexes are slightly flattened and fringed with hair on both margins.

The colour is a palish-red fading into a yellowish-white, the legs being of a much deeper red. The colour of the male is much brighter than that of the female. "It is generally," says Professor Bell, "rather a deep-sea species, and is occasionally thrown on shore after storms or gales of wind that have been tending towards shore." He also mentions having taken it at Sandgate and Hastings, and proceeds to give an extract from Mr. Couch's "Cornish Fauna," which is interesting enough to warrant my doing so likewise. Mr. Couch says of the Masked Crab, "It is scarcely common, which may be accounted for from its habit of burrowing in the sand, leaving the extremities of its antennæ alone projecting above the surface. These organs are of some use beyond their common office of feelers. Perhaps, as in some other Crustaceans, they assist in the process of excavation; and when soiled by labour, I have seen the Crab effect their cleaning by alternately bending the joints of their stalks, which stand conveniently angular for this purpose. Each of the long antennæ is thus drawn along the brush that fringes the internal face of the other, until both are cleared of every particle that adhered to them."

The Masked Crab is rare in Scotland, but is frequently met with off the coast of Ireland.

**THE NORTHERN STONE CRAB (*Lithodes Maia*).**—This strange species is by no means common to our shores; but it will be worth while to devote a small space to a description of it in case any of my readers should chance to fall in with a specimen. The shell is heart-shaped, covered with tubercles and spines. The entire margin also of the shell is furnished with long powerful spines. The fore pair of legs are unequal, sometimes one, sometimes the other being the larger. The other legs are much longer and equally armed with spines with the exception of the fifth pair, which are very diminutive and destitute of spines.

The colour is a yellowish-red, the under surface being paler, and the spines much darker. With regard to the localities where it has been obtained, we may borrow the words of Professor Bell. "It is," says he, "strictly speaking, a northern species, not having yet been found farther south than the Isle of Man, with the exception of a specimen in the Museum of Trinity College, Dublin, recorded to have been taken on the coast of the county Wexford. I possess, through the kindness of my friend, Mr. McAndrew, several specimens of various sizes, taken by him in dredging in Loch Fyne. They have also been dredged between the Isle of Man and the Mull of Galloway. The Frith of Forth (Goodwin), the coast of Ayrshire (Thompson), of Aberdeen, and of Yorkshire (Leach), are localities where this Crab has at different times been obtained, and I have a specimen which was taken from the stomach of a Cod on the coast of Orkney."

**THE COMMON HERMIT CRAB (*Pagurus Bernardus*).**—This very singular animal belongs to a family of the Decapods, called Anomura, from two Greek words (*anomos*, unlawful; and *ayra*, a tail), and so called from the unusual conformation of that appendage. Instead of being encased in a hard coat of mail as in the Macroura, the hinder part of the body is soft and coriaceous, possessing only a few detached calcareous plates—analogueous, it is true, to those found in the Lobster, but strangely altered in structure. This animal is called the Hermit Crab, or the Soldier Crab, indifferently. The anterior feet are very unequal, that on the right side being ordinarily the larger; both, however, are thick and strong, and covered with spinous tubercles. The second and third pairs of feet are armed on the upper side with spines. The last joint is very long, flattened, and slightly curved. The two hind pairs of legs are simply rudimentary, and terminate in a short compressed pincer. These two latter pairs are fringed with hair. The usual colour is red, fading into yellow, the abdomen being brown, and it measures when full grown about 5 inches. The Hermit Crab is an extremely common species, abounding on all parts of our coasts, and is highly interesting from its habit of fixing its residence in some empty shell or other, to which refuge it is driven in consequence of the unprotected condition of its hinder parts. Nature has provided no defence for it. It is compelled, therefore, to have recourse to art, and to secure a protection without which it would in its helpless state fall a prey to the many voracious members of its own fraternity. The Hermit is frequently found in a shell which is apparently too large for it. He has his reason for choosing it however, as it admits of an increase in his growth. When the

lodging becomes too confined for the tenant he quits it and casts about for a fresh one. I shall take advantage of the interesting remarks with which Professor Bell concludes his notice of this singular creature:—"It is a question of some interest whether the Hermit Crab always chooses for its habitation a shell already empty, or whether it actually kills and devours the inhabitant of one that suits its size, and then takes possession of its violated home. The latter I believe to be true, in many if not in most cases; certainly, however, not in all, as we often find the Hermit occupying an old and long-abandoned shell. But so much more generally is it found in fresh shells that it can scarcely be doubted, even on this ground alone, that it often obtains its habitation by violence. The fishermen on the coast are fully persuaded of this, and an intelligent person of this class at Bognor assured me that the fact had often been observed by himself and others. He stated that the aggressor seizes its victim, the Whelk for instance, immediately behind the head, and thus kills or disables it, then eats it, and finally creeps into and appropriates its vacant shell. It holds on with great force and tenacity by means of the terminal appendages, and if taken hold of when running about, which it does with great rapidity with its usurped shell attached, it draws itself in with a sudden snap, and then resists every attempt to pull it out, closing the aperture with its stout strong legs and pincers, and thus also protecting the soft membranous abdomen. The Hermit Crabs are much employed by the fishermen (who call them 'wigs,' or possibly 'whigs'), as bait for Cod, for which purpose they answer very well for immediate use, although the original possessors and builders of the house, the Whelks, are much preferred for night lines, as remaining more firmly on the hook. They are taken in great numbers in Prawn-pots for this purpose. The species is very widely distributed, and exists in every part of our coasts in great numbers, being continually taken in the dredge, the keel-drag, and the Prawn and Lobster-pots."—W.

(To be continued.)

## LIGHT IN PLANTS.

THIS light may be classified into two kinds—first, continuous, mostly phosphorescent; second, in the form of lightning.

Decaying wood belongs to the first. A fungus (*Byssus phosphoreus*, L.) has till lately had the credit for it; but Retzius, Von Humboldt, and Bishop Agardh (another Swede) agree in ascribing to the wood itself the faculty of shining.

Any kind of wood, if we believe Dessaignes, can get phosphorescent under certain conditions—viz., a proper degree of decay, thermometer 46° to 53°; sufficient dampness and atmospheric air. We find it, however, mostly with Alder, Beech, White Pine, and Willow wood. They shine before actual decay, but moisture rules the intensity of the light—the less moisture the less light; no moisture no light. Where the shining has ceased, it can be restored by a little cold water thrown on the wood, and by enveloping it with paper or canvass.

Temperature, we believe, is of no account, so the thermometer does not exceed either the boiling or the freezing point, as in either case the water would disappear.

But not decaying wood alone has this phosphorescence; other parts of plants have it when decaying. Thus Meyer tells us that, wandering by night through a forest, he found decaying Mushrooms in a phosphorescent state, and that he took up the shining matter with his stick and rubbed against trunks of trees.

Tulasne has given us a very interesting treatise about the shining of dead Oak leaves. Moisture is in every instance a necessary condition. Of all things, however, it is the Diptam which is best known for its remarkable and beautiful light circling round the whole upper part of the plant, when, after warm and calm days, a match is brought near it. It is the ætherial oil evaporated by the plant which burns, and makes it appear as if the atmosphere round the plant was in a mild blaze. The beauty of this phenomenon is worth trying it, and enduring the failures which an unfit condition of the atmosphere will often bring.

Less strong than the Diptam, but stronger than decaying wood, shines the milky sap of *Euphorbia phosphorea*. Martius, during his travels in Brazil, found it to shine mostly when a storm was coming on. He also relates that he was told by the natives of a *Euphorbia* growing in impenetrable thickets of several thousand square feet, which often spontaneously ignite, emit a column of smoke for a while, and ultimately blaze in a clear flame.

But not dead matter alone has this phosphorescent quality. We find it in living plants—for instance, *Rhizomorpha subterranea*, a fungus found on decaying trunks or on timber used in moist mines, emitting light from the tops of its branches so strong that, according to De Candolle, you can read by it; or, *Agaricus olearius*, a fungus growing on the Olive tree, which shines best when vegetation goes most forward, and which fact Tulasne therefore calls “une manifestation de l'activité de sa végétation.”

The cause or causes of the phosphorescence of these plants have not been found. A very long range of experiments under all temperatures and at the various stages of vegetation would be required. This explains also why the statements of botanists differ so much—why one has never found that such and such plant emitted light; why the other asserts that only the lamellæ of different fungi had it, &c. We must, however, here mention a no less interesting phenomenon than either of those already stated. It is offered to us by *Schistostegia osmundacea*, a moss growing in caverns and grottoes, which in daytime is in a state of lucidity similar to the *Smaragd*. In this instance, the structure of the plant, as the rays of the sun refracted on it, seems to be the cause, though we would not like to vouch for it.

We would rather speak now of the second class of light in plants—namely, where that light appears in the shape of lightning. And the first observation it appears has been made by Linnæus's own daughter, Elizabeth Christine, who found that one evening in the year 1762, the orange flowers of *Tropæolum majus* produced a kind of lightning—that is, the flowers seemed by fits and starts to dash light. She ran to her father, not believing her own eyes; but the phenomenon had disappeared when the father came, and what he had never seen nor heard of he would not believe in till he had seen it himself. On subsequent evenings, however, he himself witnessed the fact, whereupon he asked his daughter to make a report of it to the Royal Academy of Sciences. This report has been accepted, and exists on the record. We are sorry that we have to add that neither the great Linnæus, nor his daughter, nor Linnæus's son, nor any one of a great many chemists and botanists who undertook to study the matter, could to this day succeed in telling us anything better than suppositions, which were hardly uttered before upset by themselves, and amounted to nothing. If the stirring-up of observations, the reiteration of facts, the discussion of probabilities, not to say possibilities, can ultimately lead the investigating mind to the true cause, then there is hope for our enlightenment. But as we doubt that, and will not weary our readers, we will, before we conclude this article, tell them that electricity seems not to have anything to do with these phenomena; that orange colour of high intensity and fire seem to have a good deal to do with it; that weak eyesight does not cause it, as Linnæus naively says, and that besides Linnæus's daughter, Lector Haggren (also a Swede), noticed it in the year 1788 on *Calendula officinalis*, *Lilium bulbiferum*, and *Tagetes patula* and erecta, also, but very slightly, on the orange variety of the Sunflower, *Helianthus annuus*. Lastly comes Mr. Fries, and tells us that he was induced to write his essay on Light in plants, by one night walking about in the botanical garden (in Upsala) and seeing lightning shooting up from an isolated growing plant of *Papaver orientale*, strangely enough after having passed a large group of them without seeing anything; that he then led other persons past who did not know of it, and they were equally struck by the sight; and that he then began to study the light in plants. May he be able to enrich science with the knowledge of its true causes.—(*American Gardener's Monthly*.)

### NEW TOBACCO FUMIGATOR.

It must be truly gratifying to the lovers of the science of gardening to witness the long list of practical gardeners who have taken up the pen to contribute to your excellent Journal, and who had never written before in any publication. The great utility of your work and the improvement it is effecting among those for whom it is intended is obvious to us all. It calls forth latent abilities, and promotes a generous emulation amongst gardeners. A spirit of improvement, passion for experiments, and a liberal curiosity prompt them to quit the old beaten paths to explore untried ways, and to seek to acquire wisdom by experience.

I have been a subscriber to your Journal for a length of time,

and in return for the many useful hints which I have received from it I am desirous of contributing one.

STEPHENS' TOBACCO FUMIGATOR.

- A. The fumigator, 7 inches by 6 inches.  
 B. A pan for cold water, 9 inches by 9 inches.  
 C. Pipe, 2 inches diameter, that conducts the smoke through the cold water.  
 D. A joint to separate the one from the other.  
 E. The lid of the fumigator.

In your Journal (March 18th, 1862, page 504), there is something said about injury from tobacco fumigation. Mr. James Stephens, the gardener at the Oaks, has kindly permitted me to send you the sketch of his fumigator, which he invented several years ago. It has been found infinitely superior to all fumigators in common use, and its advantages are much prized, as all injury from hot smoke is prevented, because it has to pass through a vessel of cold water. Mr. Stephens gives to the public his fumigator unfettered by patent.—JAMES BARR, Foreman, The Oaks Gardens, Barlowmoor, Didsbury.

### BEDDING-OUT AT CLIVEDEN.

(WITH A COLOURED PLATE.)

THE piece of flower garden shown in the coloured engraving contains 3 acres 2 roods 10 poles. The beds have each a low, dwarf hedge round, 1 foot broad and 9 inches high, of common Spruce and evergreen Privet. The centre beds are Ghent Azalea and Rhododendron, of the better sorts, alternately, having space between for Gladiol, Foxgloves, and Hollyhocks in summer. The grass in the beds is raised, which gives more effect to the flowers. The circles are cut in the grass: the outside being all Roses, dwarf and half standard; the inside for flowers in spring, *Honesty* in the centres, then circles of Stocks, Wallflowers, blue *Myosotis*, and *Cerastium*.

With this general outline we will take the beds from the top as they come, and give the plants they were filled with this spring.

1st. Top inside beds. Mixed Anemone and Jonquil; the centre chsin, *Silene pendula* and yellow Tulips.

2nd. Top beds outside. Blue *Myosotis*; chsin, white *Myosotis* and Arabis.

3rd. Outside beds. White *Silene*; chsin, pink *Silene* and Tournesol Tulip.

4th. Inside bed. All blue *Myosotis* and white *Is Candeur* Tulip.

5th. Inside bed. All pink *Silene* and *Rex Rubrorum* Tulip.

6th. Outside bed. *Limnanthes Douglasii*; chsin, blue and white *Myosotis* and mixed Tulip.

7th. Outside. Mixed Anemone; chsin, pink *Silene*.

8th. Inside. Blue *Myosotis* and yellow Rose Tulips; chsin, white *Myosotis*.

It will be seen from the above, the variety of plants is very limited, but great effect can only be got by having such as will come in simultaneously, and being common are easily got in plenty, except the Tulips, which I should not recommend.

The beds are planted in the autumn as the summer bedding is taken out and labour will permit, and all through the winter months, taking care to plant those first that experience has proved requires it. Each bed takes 2000 plants and 800 Tulips. If the spring is favourable we have two months' good bloom, and are little behind the usual time for summer bedding.

I add our summer practice for the benefit of any party interested.

In May we sow the Anemone in pans, and prick them out

when ready; also outside, Stocks, Wallflowers, Honeysuckle, Foxgloves, and Sweet Williams. In the last week of June or first of July we sow *Myosotis* (white and blue), put in cuttings of Pansies ("Cliveden blue," yellow, and dark), for ribbonwork, on a north border, under hand-lights, or any temporary old lights; also, yellow *Alysaum*, white *Candytuft*, *Cheiranthus Marshalli*, &c. This goes on as other labour will permit. In the last week of August we make a first sowing of *Silene* (white and pink), *Limnanthes Douglasii*, *Pansy*, and *Saponaria*. In lifting such plants when done blooming as *Daisies*, double *Cardamine*, *Saxifraga granulata*, and other things similar in the small beds, we lay them in on a north border, dividing and planting out as we can, and according to the quantity required for another season.—J. FLEMING, *Cliveden*.

#### HOW GARDEN-POTS ARE TO BE MEASURED.

WHICH is the proper way of measuring a garden-pot? Should the measure be taken across the top, or should an allowance be made of say half an inch or an inch down the pot, and then the measure be taken inside? My *Geraniums* have been disqualified in consequence of one of the six pots in which they were exhibited measuring  $8\frac{1}{2}$  inches across the top, whereas the limit was 8 inches. Do you consider the judgment just?—P. S. H.

[The measurement of the diameter of a pot is usually taken just within the top. If, as you state, only one out of six of the pots was in excess of the measurement, when so taken, and that excess was only half an inch, then, we are of opinion that you were treated with undue severity. It is a good maxim that the extreme application of a rule renders it unjust.—EDS. J. or H.]

#### ORNAMENTAL PLANTS.

##### PENTARHAPHIA CUBENSIS (*Cuban Pentarhaphia*.)

*Nat. Ord.*, Gesneraceæ. *Linn.*, *Didymia Angiospermia*. A neat and pretty, dwarf, shrubby plant, of compact habit, with obovate, dark-coloured evergreen leaves, crenated near the point. The flowers grow in the axils of the leaves, and are attached by

slender stalks an inch long; corolla about an inch long, tubular, curved, and of a rich scarlet; calyx of five, straight, narrow lobes, "not unlike five brown needles." It requires a cool stove, and remains a considerable time in bloom. From Cuba; introduced in 1848 by Messrs. Henderson, Pine Apple Place, Edgeware Road. Flowers in summer.

##### OPHELIA CORYMBOSA (*Corymbose Ophelia*.)

*Nat. Ord.*, Gentianaceæ. *Linn.*, *Pentandria Digynia*. *Syn.*, *Swertia corymbosa*. A greenhouse or half-hardy annual, growing a foot high, with four-angled stems, corymbosely branched in

the upper part. The leaves are opposite, obovate-spathulate. The flowers in terminal corymbs, pale purple, with a white eye; the corolla rotate, deeply cut into four spreading, obovate-veined segments. From the Neilgherry Mountains. Introduced in 1848, by Dr. Schmidt. Flowers in summer.

##### ANTHURIUM SCHERZERIANUM.

THIS plant was mentioned in your report of the Royal Horticultural Society's Exhibition a short time back by Mr. Beaton, since which no one seems to have taken any notice of it. It was exhibited by Mr. Wendland, gardener to the King of Hanover, and was brought by him from Costa Rica, where he says it was one of the loveliest things he saw. And as I, like all the world, have been up to London this summer to see the sights and scamper through the gardens round it, I stumbled upon it among many and many a grand thing when going round the Botanic Gardens at Kew, where I had a better opportunity of looking at and examining it than I had at Kensington; a brief description, therefore, may not be uninteresting.

It belongs to the natural order of Arads, a class of plants which have given us some of our finest ornamental foliage, but the flowers of which, as a rule, are the most insignificant; but this plant will, I think, become a favourite with every one, and be welcomed by every one that has a stove, be its dimensions ever so small; for, being naturally a diminutive grower, it is not likely to get too large for any. The leaves rise upon a slender petiole, are lanceolate in shape, of a sombre green colour and leathery texture, with a light-coloured midrib, above which stand the flowers, composed of spathe and spadix of a most brilliant scarlet colour. The spathe is about  $1\frac{1}{2}$  inch long, of an oval form; the spadix stands straight up above it, and is about 2 inches long, and of the same beautiful colour.

Mr. Wendland says it is a very free bloomer, and continues in flower some four or five months. I shall be among the first to add it to my collection so soon as it is to be purchased.—JUVENIS.

## THE INTERNATIONAL EXHIBITION.

(Continued from page 320.)

## NEW SOUTH WALES.

THE boundaries of this colony having within the last ten years been greatly changed by the separation of Victoria and Queensland, it will be useful to state what its limits now are. On the west New South Wales is divided from South Australia by 141° E. long.; on the east it is bounded by the sea, the coast line extending upwards of 700 miles from 28° 8' S., to 38° 31'; and on the north by a chain of hills, and by rivers till 29° S. is reached, which parallel then becomes the boundary line till it meets that of South Australia. From Victoria on the south it is divided principally by the Murray river.

Within the above limits is included an area of 207,000,000 acres, or three times that of Great Britain, and of this extent only 260,798 acres are under cultivation. The climate over such a wide tract of country must of course present great diversities; and from observations it appears that the mean annual temperature varies in different parts of the colony from 40° to 75°—the maximum summer heat being in some inland districts 120°, while on the high table lands severe frost occurs for several weeks in succession. Round Sydney the mean annual temperature is from 63° to 65°, or somewhat higher than that of Naples, and the winter months are 4° to 5° warmer than in that beautiful climate; but sudden changes in temperature to the extent of 20° or 30° are of common occurrence.

The fall of rain also varies greatly. In 1860 the least amount was 18 inches in the interior, and the greatest, 82 inches at Sydney—the mean, for the whole colony, being 43 inches.

We learn from the catalogue published by the colony on account of the International Exhibition, and which may be regarded as entirely reliable, that in 1861, of the land under cultivation, not quite one-half was under Wheat, about one-fifth under Maize, another fifth was sown with Barley, Oats, and artificial Grasses, and the remainder was occupied by Potatoes, orchards, and vineyards.

The average production of Wheat is only fifteen bushels per acre; but that this low rate of production is due to imperfect agriculture rather than to the soil and climate is tolerably evident from the samples exhibited. Thus, Messrs. J. & W. Macarthur, Camden Park, show some weighing 64 lbs., 66 lbs., and 68 lbs. per bushel, and there are several other samples of excellent quality, but the weight of which is not stated.

The average produce of Maize, for which the climate is peculiarly well adapted, is stated to be about thirty bushels, and on rich land seventy bushels have frequently been grown. All the cobs exhibited are particularly fine. In the collection of six varieties, from Messrs. J. & W. Macarthur, the large yellow sort weighed 65 lbs. to the bushel, the smaller yellow 66 lbs., and the large white is stated to have yielded, over an extent of 23 acres, at the rate of eighty-eight bushels of 57 lbs. each per acre. Another kind, from Mr. Oaks, is said to yield as much as a hundred bushels to the acre; and the yellow sort, from Mr. Peck, Hunter River, produced seventy bushels per acre, and arrived at perfection within a hundred days from planting.

Remarkable, however, as these cereal productions are, of far more importance both to this country and to New South Wales is the question of cotton-supply—a subject of such absorbing interest in our manufacturing districts at present. But the International Exhibition has demonstrated that cotton of the finest quality can be grown in several of our colonies, equal to any the Southern States could produce; and that if our manufacturers will give the necessary impetus to its cultivation in quantity, and the colonists will promptly bestir themselves, we need no longer be dependant on North America for our supply.

The New South Wales cotton in particular is, in some instances, not surpassed by the finest Sea Island. The beautiful sample from Mr. Nowlan, of Hunter Hills, near Maitland, is valued at *four shillings* a pound, and there are exhibitions of great excellence from Mr. Hickey, Osterley, Hunter River; Mr. Ireland, Williams River, and some others. Rich as the gold-fields of Victoria have proved, if the extensive cultivation of cotton be carried out in New South Wales, a still richer and more constant source of wealth will be opened up which will bring her into closer communication with European nations, and give a more rapid development to her otherwise great natural resources, not the least of which are coal and iron.

Of vegetable fibres several kinds are shown, the principal

being Nettle-tree bark, Brown Kurrajong bark, Tea-tree bark, and Wattle bark.

The Large-leaved Nettle tree attains a height of 60 feet, with a diameter of as much as 5 feet or 6 feet at the base, and the wood is soft and worthless, even for firewood. The bark varies from a quarter of an inch to an inch in thickness, and consists of a large proportion of fibre, which, when freed from the abundant watery juice filling up the intervals, is used by the natives for making nets and limes. It might be obtained at from 3d. to 4d. per lb., and would apparently answer for making ropes, and coarse paper for wrapping, &c.

The brown Kurrajong has a hard bark filled with a quantity of mucilaginous matter which can only be removed by severe crushing; and the fibre, though strong when moist, becomes more brittle when dry, so that it is doubtful whether it will prove of sufficient commercial value to become an article of import.

The Tea-tree bark is apparently the same as that shown in the Western Australian department, as belonging to some species of *Melaleuca*, and as being likely to be useful for paper-making. Several kinds of gum, including that of the Grass tree, are also exhibited.

The subject of wines has also attracted the attention of the colonists of New South Wales, and there are now 1583 acres under Vines, the produce of which was last year 99,791 gallons of wine, and 709 of brandy. Bottles of red and white wine, and what are called Burgundy, Claret, Shiraz, Verdelho, Riesling, Tokay, &c., are exhibited by Messrs. Macarthur, Sargar, Aspinall, Capt. Smith, Sir D. Cooper, and others, and it will be interesting to know, when the reports of the juries are completed, what standing these and other colonial wines take as compared with those of European manufacture.

Of other vegetable products two excellent samples of tobacco are sent by Mr. Church and Mr. Cormack, of West Maitland; Carob Beans by Messrs. Macarthur; and some fine Walnuts by Mrs. J. Macarthur. Lastly, we have the following note accompanying a Sugar Cane from Mr. Scott, Brisbane Water. "This is the sixteenth ratoon crop—*i.e.*, the sixteenth crop from the one planting of twelve months' growth, and it has not yet attained to that perfection which a longer growth would give it. I have frequently made sugar from the same plot, equal in quality to the finest samples of West India, and of a greater return per acre than we obtain there; the molasses from which were totally unlike any I had ever before seen, being like clarified syrup. To me, as a West India planter, these results were astounding; but they are readily explained and clearly accounted for by the following—*viz.*, in the tropics our canes attain to perfection in twelve months; they then cast an arrow, cease to grow, and afterwards they deteriorate in quality and yield; here they do not cast that arrow, but continue to grow for more than two years, during which time the saccharine matter most materially improves in richness to the extent of from 8 to 10 or more per cent. above the tropical juice. Two other great advantages in the culture of cane in this colony are—that here the lands will give from six to eight or more crops from one planting; in the West Indies barely two, and in New Orleans (subject to heavy frosts) only two. Here, crops could be taken off all the year round; in the tropics during four months only; and at New Orleans sometimes only five weeks, as the frosts at that time visit and often destroy the cane."

It thus appears that in the northern and warmer parts of the country the cultivation of sugar can be prosecuted with great success; and if, as we presume, the samples of refined sugar from the Australian Sugar Company are the growth of the colony, the quality leaves nothing to be desired; but whether they are so or not is not stated.

Among animal products we remarked some excellent silk accompanied by the worms, moths, and eggs, from Mr. J. Kellick, Mr. Whiting, Woolloomooloo, and Mr. Lee, of Paramatta; but the great staple of New South Wales is wool, and of this her contributions are remarkable for their fine quality, and the number of awards with which they have been distinguished.

The credit of having established this branch of production is due to Capt. John Macarthur, of Camden, who in 1797, obtained from the Cape of Good Hope, three rams and five ewes of pure Spanish merino blood with which he crossed all his coarse-woolled sheep; and the result has been, that while in 1807 the total export of wool was 245 lbs., in 1861 the quantity exported from all the Australian colonies and New Zealand was 68,313,903 lbs.

In 1796 the whole live stock of the colony, exclusive of pigs and goats, consisted of 57 horses, 227 cattle, and 1531 sheep; and in 1860, from this stock had sprung the numbers beneath.—

Colony.	Sheep.	Cattle.	Horses.
New South Wales .....	6,119,163	2,108,586	251,497
Victoria .....	3,794,127	683,534	69,288
Queensland .....	3,449,350	432,890	23,564
South Australia .....	2,824,811	278,265	49,899
Tasmania .....	1,790,950	83,366	21,034
Total.....	19,888,381	3,886,641	414,722

The introduction of the alpaca into this colony by Mr. Ledger is another step that cannot fail to be attended with great results. It is found that these animals, the long clean fleece of which is so valuable to the manufacturer, accommodate themselves perfectly to the climate and natural herbage of the country, and, according to Mr. Ledger, come to maturity earlier than in South America, are larger, and have a finer and heavier fleece. By crossing with the llama he hopes to obtain a larger, heavier, and more hardy animal, with a finer and more glossy fleece than in the case of the pure alpaca, and in confirmation of these views a case of seven stuffed animals, together with samples of the fleece, are exhibited to show the advance which has been already made in this direction.

The flock of alpacas now numbers 358, and it is computed that in fifty years they will have increased to more than 9,000,000.

Besides the above features which render the New South Wales department peculiarly interesting, there is a magnificent collection of the various woods found in the northern and southern districts, though brought together in spite of great difficulties, and shipped before many of the specimens had time to get seasoned.

The following are some of the woods that appear the most useful:—

Of species of *Eucalyptus*:—

The White or pale Iron Bark of Illawarra.—This is regarded as the most valuable of the Iron Barks from the hardness and toughness of the wood. The tree grows 80 feet to 120 feet high, and 3 feet to 4 feet in diameter.

Iron Bark from Illawarra.—Very hard and tough, and reported to be strong and very durable. Tree from 80 feet to 130 feet high, and 3 feet to 5 feet in diameter.

Broad-leaved Rough Iron Bark, said to be one of the strongest and most durable of timbers; takes a good polish. Tree 80 feet to 120 feet high, and 2 feet to 4 feet in diameter.

Red Iron Bark from Camden.—Of a reddish colour, softer, and apparently not so liable to crack as the others. Said to be highly valued for timber. Tree 50 feet to 90 feet high, and 2 feet to 4 feet in diameter.

Box of Illawarra.—Very hard, tough, and durable, somewhat cracked at the heart; very strong, and said to be exceedingly durable. Tree 120 feet to 180 feet high, and 4 feet to 6 feet in diameter.

Flooded Gum.—Wood reddish, very solid, and without cracks; said to be excellent for ship-building.

Blue Gum of coast.—A red and rather close wood, but somewhat cracked; said to be excellent for ship-building. Tree 100 feet to 160 feet high, and 3 feet to 6 feet in diameter.

Blue Gum of Camden or Yarrab.—A beautiful close-grained hard wood, the only drawback to which are some perforations by grubs; extremely durable, and useful for maves and feloes of wheels, and for work underground. Tree 70 feet to 100 feet high, and 3 feet to 4 feet in diameter.

Blue Gum of Appin.—Likewise a timber of good quality. Tree 80 feet to 100 feet high, and 3 feet to 4 feet in diameter.

Grey Gum.—This appears to be a good timber. Tree 60 feet to 100 feet high, and 2 feet to 4 feet in diameter.

Woolly Butt of Illawarra.—A fine wood, said to be much prized by wheelwrights on account of its strength and toughness. Tree 100 feet to 150 feet high, and 3 feet to 6 feet in diameter.

Black Butt Gum.—An excellent, very strong timber; said to be very durable. Tree 100 feet to 130 feet high, and 3 feet to 6 feet in diameter; but one has been measured which was 41 feet in circumference, and presented no symptoms of decay.

Swamp Mahogany.—Of this there is a beautiful slab, the outer portion of which seems best. It appears soft, and is stated to be neither strong nor very durable, but is found extremely useful for inside work. Tree 60 feet to 100 feet high, and 3 feet to 5 feet in diameter.

Mahogany.—Quite as pretty when polished as its namesake, and said to be very strong and durable. Tree 60 feet to 130 feet high, and 3 feet to 5 feet in diameter.

Stringy Bark of coast.—Hard and solid, considered excellent for horsework. Tree 80 feet to 120 feet high, 3 feet to 5 feet in diameter.

Stringy Bark of Camden.—Not so hard as the preceding, but looks well and takes a good polish. It would do well for inside work in buildings. Tree 50 feet to 100 feet high, and 2 feet to 4½ feet in diameter.

*Banksia serrata*.—Handsome for cabinetwork. Tree 20 feet to 40 feet high, and 1 foot to 3 feet in diameter.

*Acacia*.—Of this there are several species with very handsome close-grained wood which takes a high polish, and which might be turned to account.

*Cryptocarya* sp.? Flindosa.—A soft light-coloured wood, used for decking small vessels.

*Cargilea* sp., Grey Plum.—Wood yellow, strong and tough, and apparently not apt to crack. Tree 30 feet to 40 feet high, and 1 foot to 2 feet in diameter.

*Pittosporum undulatum*.—Wood white, hard, and very close-grained; excellent for turning. Likely to be a useful substitute for Box in many kinds of engraving. To show its adaptation to this purpose, blocks prepared by Professor De la Motte, of King's College, are exhibited, and have received a medal. Sound sections of more than 10 inches to 16 inches, it is stated, would be rare. Tree 50 feet to 80 feet high, and 1½ feet to 2½ feet in diameter.

Of the northern woods, one of the most valuable is that of *Araucaria Cunninghamii*, or Moreton Bay Pine, which grows from 100 feet to 150 feet high, with a clear stem of 80 feet or more in length, and 4 feet or 5 feet in diameter, some trees yielding as much as 10,000 cubic feet of useful timber. It is stated of this that spars for ships may be obtained in any quantity and from 80 feet to 100 feet in length.

*Catanospermum australe*, or Moreton Bay Chestnut.—This is a pretty dark wood, the heart being somewhat like Walnut. Tree sometimes 130 feet high and 5 feet or 6 feet in diameter.

Black Myrtle.—Wood rather soft, but takes a good polish; very tough. Tree 100 feet high, and 2 feet or 3 feet in diameter.

Rosewood.—The heartwood red, rather soft, said to be useful for cabinetwork and ship-building. Tree 70 feet to 100 feet high, and 4 feet to 5 feet in diameter.

Bastard Myall.—A pretty dark wood, suitable for cabinet-work.

The above are only a few of the kinds that struck us as likely to be most useful out of the great collection of woods brought together through the exertions of Sir W. Macarthur and Mr. Moore, of the Sydney Botanic Gardens; and it is to be regretted that the whole of the woods collected could not, owing to want of space, be shown, whilst others had to be crammed into an inaccessible corner.

In closing our account of the exceedingly useful and interesting exhibition which New South Wales has furnished, we must acknowledge our obligations to the Catalogue published by the Commissioners for the colony—a work which is replete with reliable information on the resources and products of the country—as well as to the courtesy of their Secretary, Sedgwick S. Cowper, Esq., who kindly undertook to point out the most remarkable features in this department.

(To be continued.)

### THE CAUSES OF THE DECAY OF TIMBER.

In addition to the causes of decay arising from the effects of the vital disorganisation of the trees by the wounds superinduced by the disruption of branches, blows, sun-strokes, frost, lightning, or from the attacks of the countless insect plagues to which trees are exposed during their period of growth, timber is exposed, after having been felled, to another class of destructive actions arising from the decomposition of its elements, under the ordinary laws of organic chemistry, and occasionally to the attacks of other insects than those above mentioned, when used in certain positions. The marine boring worms are the most dangerous of these insects, and they will be more especially noticed in the following remarks.

The first description of decay, arising from organic decomposition in wood, is produced by the changes which take place in the sap retained in the wood at the period of felling; for the albuminous portions of that sap commence a putrefactive process directly they meet with the conditions of warmth and heat necessary for its development. All timber must, then, whether

it be the sapwood or the heartwood, be placed in situations which would allow the sap to exude, or to evaporate, and this process is the one technically known by the term "seasoning." Evidently, the period of the year when the tree is felled must have an important influence on the mode of seasoning; for, in the winter the circulation is torpid, and there is then far less sap in the pores than there is when the vital functions of the tree are in full play. Nevertheless, timber felled in winter requires a certain amount of seasoning; and equally with wood more highly charged with sap, it will decay if that fluid should not be allowed to escape. The sad tale of the decay of the gun-boats may be referred to as an illustration of the danger of shutting up unseasoned timber; and unquestionably the dockyard authorities who neglected to provide means of establishing a current of air through the framework of the vessels, awkwardly built of unseasoned timber, should be held partially responsible for their decay. Wood, such as Lord C. Paget stated these vessels to have been built of, must of necessity have decayed by what is called wet rot, under the circumstances these boats were placed in. It may be as well to state that the term "wet rot" is applied to the decomposition which takes place in timber containing sap and exposed to moisture. If the sapwood or the alburnum be cut off from a tree, and the heartwood be exposed to an energetic dry current of air, there will be no danger of its perishing by this particular process; and it therefore follows, that if the sap or the sapwood cannot be effectually removed, it is necessary to prevent the destructive decomposition of the sap by treating it with some fluids which should be able to form at once with it indestructible compounds.

It frequently happens, however, that during the growth of trees the druxy knots before alluded to have established the germs of a putrefactive process in the wood, which cannot be stopped by any method of seasoning; and I myself suspect they can only be arrested by the injection of creosote. There are occasionally, no doubt, difficulties attached to this mode of preserving timber, on account of the impermeability of the wood, and there are practical objections to its application for building purposes. But whenever knots of the description referred to may be suspected to exist in timber, especial precautions should be taken to prevent its being used in situations where it is likely to be covered, or where its decay might compromise the stability of the structure into which it enters; and as the mere lapse of time required for seasoning would allow the decomposition of very bad druxy knots to display itself, there seems to be the more reason for attaching importance to the use of seasoned timber in the framework of ships.

But seasoned or unseasoned timber alike is exposed to the cause of decay specifically known by the name of the dry rot, which is considered to arise from the development of several species of fungoid growth in the wood; or, according to Dr. Birkbeck, of the *Boletus*, *Agaricus*, *Lycoperdon*, *Mucor*, &c. It would seem as though some of the organic tissues of the wood—not the sap, observe—decomposed under certain conditions of the surrounding atmosphere (as in close, damp, confined air), and that they thus furnished, as it were, a soil for the growth of the fungi, which, in their turn, disintegrated the remaining portions of the tissues by their mere mechanical expansion in growing. The wood becomes, in fact, reduced to a mere powder, and may then be rubbed away by the finger, sometimes with a rapidity which is quite alarming. There is also this particular danger about the dry rot—viz., that the germs of the fungi producing it are carried easily, and in all directions, in a building wherein it once displays itself, without necessity for actual contact between the affected and the sound wood; whereas the communication of the disease resulting from the putrefactive fermentation, or the wet rot, only takes place by actual contact. It may possibly be the case that woods grown in certain soils are more exposed to dry rot than others are, and that the germs of the fungoids are taken up by the spongioles of the roots; for timber grown in situations where large fungi abound are said to be more exposed to this disease (the dry rot), than those which are grown on dry, well-drained soils. At any rate, wood kept for any length of time in situations where it is exposed to become covered with fungi is very likely "to take on" the dry rot at an early period; and I feel it, therefore, to be my duty to state publicly that much of the timber arriving from the north of Europe leaves the ship in a state which seems to me to contain the germs of decay; and that the method of stacking the timber and deals in some of our docks is often very dangerous. From whatsoever source the fungoid growth producing dry rot may

proceed, if once it should be recognised to exist in a building, the affected parts, and all the woodwork around them, should at once be removed; if the various processes for preserving timber should not then be applicable, great precautions should be observed to cut off the access of moisture, and to insure a free circulation of air around the newly-fixed wood.

The insects which prey upon growing timber very rarely attack the qualities of wood used for constructive purposes, because in almost all cases the soft alburnum of the trees used for such purposes is cut away, and the bark and bast are entirely removed, so that the few larvæ which may have been left in the rest of the tree perish for want of nourishment, as a general rule. There are, however, as was before observed, some insects which prey on what may be called dead timber, such as the *Lymexylon navalis*, the *Sirex gigas*, the *Callodium bajulum*, and the various tribes of ants. At times their ravages are very serious, especially in the case of Oak timber stacked in large quantities, which in the north of Europe is exposed to the attacks of the *Lymexylon*, and of all descriptions of wood in warmer climates which are exposed to the attacks of the destructive termites, or the white ants. In sea water there are two species of insects which commit great ravages—viz., the *Teredo navalis* and the *Limnoria terebrans*; and they devour instinctively the alburnum or the heartwood with such rapidity that in a very few years large sticks of timber—whole piers, in fact, are destroyed by them. It is said that the *Teredo* was imported into the seas of northern Europe by the Dutch, from their colonial possessions, about the middle of the 17th century; but I suspect that there is little reason for this opinion, and that the *Teredo* has been a constant inhabitant of our coasts at least from the time of the deposit of the London clay. About 1660, however, the safety of Holland was seriously compromised by these animals, and since that period the attention of engineers and naturalists has been earnestly and anxiously directed to the study of the best method of combating this apparently insignificant enemy. The habits of the *Teredo* have thus been carefully studied; but those of the *Limnoria* are not so well known.

Of these causes of decay it is singular that the most general and the most fatal—viz., the wet rot, has attracted less attention than the more startling but less common evils—the dry rot, or the destruction by insects. The methods of prevention and cure for either of the rots are, however, fortunately nearly the same, and they may be described by saying that if some of the more recently discovered processes for the preservation of timber cannot, for economical reasons, be resorted to, no unsound timber, nor timber containing sap or sapwood, should be employed in positions where it would be covered in such a manner as to prevent its examination and repair. Great precaution should be taken to insure a perfect circulation of air and a freedom from moisture to all unprepared timber, let it be ever so sound, free from sap, druxy knots, star, cup, or ground shakes. If for constructive purposes it be necessary, however, to use timber in the above dangerous positions, some one or other of the processes for resisting the chemical changes in the tissues of the wood must be resorted to.

These processes are all founded on the principle that it is essential to inject some material which should at once precipitate the coagulable portion of the albumen retained in the tissues of the wood in a permanent insoluble form, which should not hereafter be susceptible of putrefactive decomposition. For this purpose many substances, many solutions, have been employed with variable success, of which the most important and the best known are—1. Kyan's patent, or the injection of a solution of the chloride of mercury. 2. Margary's process, or the injection of a solution of the sulphate of copper. 3. Sir William Burnett's process, or the injection of the chloride of zinc. 4. Payne's process, or the production of a double decomposition in the pores of the wood, by firstly injecting a metallic solution, such as the sulphate of iron, and then injecting a second solution, such as the carbonate of soda, which would form an oxide of iron in the cellular tissues. 5. Bethell's process of creosoting, or the injecting of the heavy oil of tar; and Boucherie's process, which is perhaps rather a modification of the manner of injecting the sulphate of copper than the application of a new solution, although he occasionally uses the chloride of calcium and the pyrolignite of iron. The experience furnished by the railway system, and the various hydraulic works of our own and foreign countries, appears to me to have shown that the efficacy of those various processes may be described as follows:—The creosoting one is the most generally successful; the application of the

sulphate of copper is successful in many cases; the other processes, although no doubt of occasional value, have practically been abandoned. It will, therefore, only be necessary to revert to the creosoting process, and the use of the sulphate of copper.

Now, the application of any of the aqueous solutions of mineral salts, as a preservative process, seems to me to be of limited benefit in cases where the wood is exposed to the action of frequently-renewed water; for it has been proved, practically, that the combination between the salt and the albumen is not sufficiently permanent to resist the long-continued solvent action of such water. For piers, bridge foundations, or dock work, or even for railway sleepers, I myself should hesitate to use any of the mineral salts; but for house-building purposes, I think that there cannot be any reasonable doubt of the beneficial effects of the application of the sulphate of copper for the prevention of rot in its various forms, and I should decidedly recommend its use for the timber of ships not immediately exposed to the action of the water, whether the timber be or be not seasoned. It is also to be observed that the solution of the sulphate of copper does not communicate any disagreeable smell to the wood, an objection which applies forcibly to creosote; and the former process may, under such circumstances, be adopted for domestic purposes. The proportion of the sulphate of copper in the solution should be 1 lb. of the salt to 4 gallons of water.

In addition to the objection to the sulphate of copper and the other metallic salts, on the score of their solubility in running water, there is this peculiar objection to them in the case of timber used in sea water—viz., that the action of the albumen in the wood renders them perfectly innocuous to animal life, however poisonous they might originally be. Woods thus treated are not, then, in any way protected against the timber-destroying insects, whereas it is certain that the injection of creosote is a most effectual protection against some of those creatures; for you may observe that, in the section of a pile exhibited, the Terebo has gone out of his path to avoid the portions of the wood impregnated with that substance. In India it seems also that the white ants have a dislike to creosote, and they avoid wood which has been prepared by its injection; so that inasmuch as the experience of nearly twenty years has shown that the ordinary causes of decay are arrested by this process, and that it affords an effectual protection against many timber-destroying insects, it seems to me that wherever the peculiar odour of the creosote does not constitute an objection to its use, it should be applied. I beg, however, distinctly to call attention to the fact that I do not assert that creosote will protect wood against all descriptions of boring worms, for samples of wood said to have been creosoted have been occasionally shown which exhibit traces of the ravages of the *Limnoria* terebrans. I think that much reason for doubt exists on this matter, because in far too many cases the creosote used has been of inferior quality, and in many others the pyrolignite of iron has been substituted for it. I have not been able yet to analyse the samples of the prepared and attacked woods I have seen; but I am very strongly inclined to question whether any authenticated cases of the failure of creosote really exist. The asserted fact of the attacks of the *Limnoria* is, however, a very remarkable phenomenon under any circumstances, and it merits very serious inquiry by our scientific and technical bodies. If the pieces of wood in question were really creosoted, it would seem to prove that the material which is distasteful to one animal may be attractive to others, and, therefore, that the green heart-timber, which is said on very doubtful authority to be protected from the Terebo by the essential oil it contains, may be exposed to destruction from the *Limnoria*, or from the land insects I have myself noticed in it. If the piece of wood just referred to were prepared by the injection of pyrolignite of iron, it would equally seem that that ingredient is no more able to protect wood against insects than it is admitted to be able to protect wood against rot or decay. There are several very obscure points connected with the habits of the marine-boring worms which I am at present studying, and I hope, on some future occasion, to be able to dwell more at length on the subject. My present impressions are, that these dreadful pests have peculiar habits—that is to say, that they respectively select the localities for their residence on account of some peculiarities in the chemical composition of the materials of the seashore, and that they have peculiar and distinct tastes, so that the immunity from the attacks of one of these classes of insects does not necessarily imply immunity from the attacks of others. But as the Terebo is the most destructive

of the marine, and the white ant the most destructive of the land-devouring insects, it seems to me that the process of creosoting (which is now generally admitted to be an effectual protection against both of these enemies) should be adopted in all cases where wood is likely to be exposed to their attacks. That creosote is able to protect wood against ordinary decay is proved by the state of the sleepers of some of our railways, laid down as far back as 1811; but, of course, this process, like all practical chemical ones, requires to be applied skilfully and conscientiously.

Much prejudice against the use of creosote seems, for instance, to have been created by the decay of timber treated by the pyrolignite of iron, and still more by the shameful manner in which the creosote itself has been used; for in the section of the pile on the table no more of that oil is to be found in the wood than the latter would be able to take up by a very temporary immersion. In the best creosoting works, such as those of Mr. Bethell, or the still more extensive ones of Messrs. Burt & Co., the oil is injected at a temperature of 120°, and under a pressure of 150 lbs. on the square inch, so that ordinary Fir timber absorbs on the average from 8 lbs. to 10 lbs. weight of the creosote to the cubic foot. For all building or hydraulic engineering purposes, Fir timber thus treated is far more durable than the best Oak, Teak, or other hard woods; and as the cost of the operation is very small, it certainly should be resorted to on all occasions where the smell of the creosote is not likely to be objectionable. When this is the case, I certainly think that some modification of Margary's process should be adopted, and that house or ship timbers exposed to damp, warm, and confined air should be treated with the sulphate of copper.—G. R. BURNELL, ESQ., in *Journal of Society of Arts*.

#### NOTES ON ENGLAND BY A FRENCHMAN A CENTURY AGO.

PRICES IN 1772.—To enable the reader to form a judgment of the dearness at London, I shall here give a list of their prices during the time of my residence in that city:—bread was 2½d. or 3d. a-pound; coarse meat 4½d.; roasting beef 8d.—9d.; bacon 10d.; butter 11d.; candles 7½d.; the price of a milch cow was 12 or 14 guineas: an acre of land, in the neighbourhood of London, was let for four or five pounds; and a cartful of dung, taken at London, was valued at twelve shillings.

BREAD.—The English bread is very good, and very fine, though it has a great deal of crumb. It was the English that first thought of using yeast or the flower of beer for leaven to make bread—a custom, which, with great difficulty, began to obtain at Paris about the middle of the last century. The first edition of the History of the Police of Paris presents us with extraordinary papers relative to the contests which it occasioned. The Parliament of Paris, taking cognizance of this affair consulted the most eminent citizens, together with the gentlemen of the faculty, and were almost for consulting the Sorbonne; their contradictory opinions increasing the difficulty, instead of diminishing it, the little loaves continued in possession of the yeast or flower of beer. The case will, no doubt, be the same with regard to inoculation, for which likewise all Europe is indebted to England. Those who are interested on either side of the question, cannot read the pieces relative to this affair, collected by the commissioner la Marre, without the highest satisfaction, especially the opinion of the famous bookseller Vitré: that piece could not discover more humour if Moliere himself had drawn it up.

The butter and tea, which the Londoners live upon from morning till three or four o'clock in the afternoon, occasion the chief consumption of bread, which is cut in slices, and so thin, that it does as much honour to the address of the person that cuts it as to the sharpness of the knife. Two or three of these slices furnish out a breakfast. They are no less sparing in their other meals: what would be scarce enough for a Frenchman of an ordinary appetite, would suffice three hungry Englishmen. They seem to eat bread merely through fear of being thought to eat none at their meals: as this is the national taste, their physicians look upon bread as the heaviest of all aliments, and the hardest of digestion.

VEGETABLES.—The price of garden-stuff is in London proportionably dear with other commodities,\* and they are not much better than the rest. All that grow in the country about

\* A Leek was sold for one penny.

London, Cabbage, Radishes, and Spinach, being impregnated with the smoke of sea-coal, which fills the atmosphere of that town, have a very disagreeable taste, which they communicate to the meat wherewith they have been boiled. I ate nothing good of this sort in London, but some Asparagus, which doubtless grew at a good distance from that capital. It is to be further remarked, that the constant mildness of the climate of England supercedes most of those precautions which the French gardeners are obliged to observe. They sow almost everything in unprepared ground, more or less covered with rich mould. I saw no hotbeds, except at the country-seats of gentlemen, whose gardens are kept in the most elegant manner.

**CLEANLINESS.**—The humid and dark air which enwraps London, requires the greatest cleanliness imaginable; and in this respect, the inhabitants of that city seem to vie with the Hollanders. The plate, hearth-stones, moveables, apartments, doors, stairs, the very street-doors, their locks, and the large brass knockers, are every day washed, scoured, or rubbed. Even in lodgings-houses, the middle of the stairs is often covered with carpeting, to prevent them from being soiled. All the apartments in the house have mats or carpets; and the use of them has been adopted some years since by the French.

But what is an article of necessity in England, is mere extravagance in France. The houses in London are all wainscoted with deal; the stairs and the floors are composed of the same materials, and cannot bear the continual rubbing of feet without being cracked and worn. This renders carpets or coverings necessary. Add to this, that these floors, which are of excellent deal, and are washed and rubbed almost daily, have a whitish appearance, and an air of freshness and cleanliness, which the finest inlaid floor has not always.

**PUBLIC WALKS.**—Besides St. James's Park, the Green Park, and Hyde Park, the two last of which are continuations of the first, and which, like the Tuilleries at Paris, lie at the extremity of the metropolis, London has several public walks, which are so much the more agreeable to the English, as they are less frequented and more solitary than the Park. Such are the gardens contained within the compass of the Temple, of Gray's Inn, and Lincoln's Inn. They consist of grass plats, which are kept in excellent order, and planted with trees, either cut regularly, or with high stocks: some of them have a part laid out for culinary uses. The grass plats of the gardens at Lincoln's Inn are adorned with statues, which, taken all together, form a scene very pleasing to the eye.

St. James's Park and its appurtenances are not kept in such good order as these gardens which belong to particular buildings. In that part nearest to Westminster, nature appears in all its rustic simplicity; it is a meadow, regularly intersected and watered by canals, and with Willows and Poplars, without any regard to order. On this side, as well as on that towards St. James's Palace, the grass plats are covered with cows and deer, where they graze, or chew the cud, some standing, others lying down upon the grass: this gives the walks a lively air, which banishes solitude from them when there is but little company: when they are full they unite in one prospect, the crowd, the grandeur, and the magnificence of a city, as wealthy as populous, in the most striking contrast with rural simplicity.

Agreeably to this rural simplicity, most of these cows are driven about noon and evening to the gate, which leads from the Park to the quarter of Whitehall. Tied in a file to posts at the extremity of the grass plat, they swallow passengers with their milk, which, being drawn from their udders upon the spot, is served, with all the cleanliness peculiar to the English, in little mugs, at the rate of a penny a-mug.—(*Grossley's Tour in London.*)

**VEGETABLE PEARLS.**—A correspondent says, "It may not be known to many readers of the 'Monthly' that pearls are also found in the vegetable kingdom. Three kinds of fruit have been found, though in extremely rare instances, to contain pearls. They are Ficus Benjamina, Datura alba, and the Cocoa-nut. The natives of Macassar, when they find such a cocoa-nut pearl, cherish it highly, wear it in the form of an amulet, and ascribe wonderful powers to it. Two hundred years ago the German botanist, Rumph, presented the Grand Duke of Tuscany with a ring of cocoa-nut pearls, so he says in his 'Herbarium,' without, however, mentioning the dual return, if ever any were made. These pearls are sometimes round, sometimes conical, sometimes

spheroidal." [We have often seen these hard pearly processes in acorns, but not in any other fruit that we remember.—*Ed. of American Gardener's Monthly.*]

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

GAVE manure-waterings to some of the best Marrowfat Peas to prolong the yielding process. Such kinds as Jeyes' Conqueror, Knight's Tall Marrow, Mammoth Dwarf, &c., if close-quick and well manured, will hardly ever stop bearing if the roots are in good deep soil. Thinned Turnips and sowed succession, also Lettuces, Spinach, &c. Will get ground ready for winter Spinach ere long. Made also a sowing of Dwarf Kidney Beans, to which we can give protection late in autumn. These often come in very useful in the end of autumn, and even the beginning of winter. Broke down some of the stems of spring-planted Onions to cause them to bulb larger and sooner, otherwise they are apt, in such a season, to grow considerably to neck. Took up Shallots that were ripe. Sowed Onions thickly for salad. Weeded Asparagus-beds, some large plants of Wheat getting up among them, and scattered a little salt over the surface. Have left more eed on Sea-kale than is desirable in order to get a good lot of fresh seed for next season, as I still prefer seedlings to cut roots, and plenty of this vegetable tends to make the winter pass more cheerfully. Sowed a few Cabbage seed for early produce in spring, if they stand. What we sowed in the middle of August last year gave us a number of run heads. In a common winter not one should we have expected to run. As it was there was enough; but it is always best to have a reserve, and therefore a later sowing should also be made. Planted out Coleworts, which will give a good autumn supply of young greens, and winter, too, if mild. Planted out succession Cucumbers. Pegged-down and regulated Gherkin Cucumbers, Vegetable Marrows, &c. Watered Tomatoes, Tobacco, and kept Chillies and Capsicums growing freely, giving them plenty of the syringe after hot days, to keep fly and spider away from them. Find that our transplanted Celery has some of it a yellowish tinge, which we attribute to a soil too cold, not rich enough, and a full sun when it did shine. I allude chiefly to that in beds that had previously been used for bedding plants, and where, consequently, I could grow nothing tall on the ridges. When such trenches were dug out early in spring, and Peas sown on the bank, their shade always prevented any of this yellow appearance, even when turned out into soil not so rich as it ought to be. Celery naturally loves a damp shady place. When nearly grown in the autumn it will stand any amount of sun.

### FRUIT GARDEN.

Kept layering and watering layers of Strawberries, and dunging, trenching, and preparing ground for a fresh plantation. In the present case Strawberries will have to follow the second lot of Cauliflowers, as these again followed late Celery. We like to enrich and deep-dig such ground if we can, as we never let Strawberry plants see a spade again until they are dug down, to furnish some aliment for other crops. I begin to find that our ground constantly cropped without a chance of fallow, eries out for a little fallow, or dressing with lime, and more sweet manure. Protected small fruit from the ravages of birds—sweet songsters though they be, for they know nothing of conscience or what is their right share when once they begin. There is nothing effectual but the net. Stopped and regulated the shoots of fruit trees indoors and out, in order to swell the buds, and give more air and light to the fruit. Will soon liberally remove laterals from growing Vines—that is, taking them away at three or four different times, some days, say a week between each, in order that no check be given, and looking on a fair amount of laterals hitherto as so many root-encouragers. In future we shall want the strength of the plants to be devoted less to growth than to the ripening of the fruit and the ripening of the wood. Watered the soil beneath Melons now showing signs of ripening, leaving the surface soil dry.

### ORNAMENTAL DEPARTMENT.

Removed a good number of Pelargoniums from conservatory, as they were getting to be hardly worth picking the flowers, and so many fell from them on stage and path. Will replace with Scarlets, a few Ferns, fine-leaved Begonias, Fuchsias, Feathered Cockcombs, &c. Potted more Geraniums, &c., for succession, and put in a few cuttings of Geraniums, Carnations, Roses, &c.

Carnations and Picotees strike very well if first inserted in a mild heat, and then a brisker one, and kept shaded during sunshine, air being given at night. Phloxes, Antirrhinums, &c., may now be struck in a shady place under a hand-light; but the first Phloxes strike best in spring when the shoots are some 3 inches in length. Watered Cineraris-stools turned out for suckers into a border with nice rich loam round the plants. Sowed and pricked-off *Primula sinensis*, *P. cortusoides*, Auriculas, &c. Watered according to weather and circumstances.

Out of doors in the flower garden attended to tying, regulating, and training, and then loosened the soil of the beds by means of small 3½-inch Dutch hoes, or small forks, cutting up the small weeds at the same time; the soil with rains and hail getting almost as hard as a pathway, though the surface was stirred not long ago. The ground, too, from constant cropping and little or no manure, is apt to become harder than it otherwise would be. This hardness, however, enabled the sun in two or three nice days to exert considerable influence in heating the soil, and so telling on the Scarlet Geraniums; and alike to keep heat and moisture in, to keep the surface rough and open, and yet finished and neat to the eye, as well as to help the plants a little to a rigour which would be combined with abundance of bloom, a slight top-dressing has been given to a portion of the beds, after which, except in long-continued hot dry weather, they pretty well look after themselves. I am convinced that this top-dressing suits all these purposes better than if I gave the beds the same material at planting time, and, besides, I could not have given it to them then, because I had not got it to give. The top-dressing, then, is chiefly half-rotten leaves, used for temporary beds and Mushroom-beds, in full bearing at planting time. These, as can be got, are wheeled out into a heap, passed through a one-inch sieve, the Mushroom-dung predominating three to one, and then about a fourth of the whole is added of burnt rubbish, burnt earth, clay, &c. We give Calceolarias about 1½ inch of this; other things get less than an inch, because we cannot spare more. The ground is generally wholly covered before the loose surface is again consolidated by the rains. I need not add, that this weather has given plenty of work to scythes, mowing machines, and clipping-scissors.—R. F.

### TO CORRESPONDENTS.

“\* We request that no one will write privately to the departmental writers of the “Journal of Horticulture, Cottage Gardener, and Country Gentleman.” By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the “Journal of Horticulture, &c.”* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**VINE LEAVES SPOTTED (G. W. H.).**—There was a little appearance on the leaves as if attacked by mildew, but the leaf was too dry to enable us to say so with certainty. If so, and whether or not, a little sulphur on the heating medium, and plenty of air to counteract the heat applied, will be the best remedy. The red spots will often appear as the Vines approach maturity; but if your wood is still green, and the Vines growing vigorously, this cannot be the case. We incline, therefore, to think that if the Vines are still green, that the plants growing vigorously have had too much heat in dull weather, that the moisture in the house has been condensed on the leaves, and these have been struck by a powerful sun before the ventilation had dried the foliage. We have seen like effects produced by such causes, but we by no means say, that such was the cause in your case. The oldest leaves would soonest be affected, and we just think that something of this kind may have taken place, from the fact that the Vines in pots are not affected. They would not be so vigorous, and, perhaps, farther from the glass.

**VERBENA LORD LEIGH (P.).**—There cannot be two opinions about this seedling raised by Messrs. Perkins, of Coventry. The trusses are large, the pips bold and stout, and the colour the richest scarlet. If it stands exposure to the rain and sunshine, it will be a most desirable bedder. It has been awarded a first-class certificate by the Royal Horticultural and Botanic Societies.

**MELONS NOT SETTING (Constant Subscriber).**—We expect the soil and the air are too damp. Allow the former to get drier, and that will check the luxuriance, and more air will cause the fruit to set. In such a house the plants would have done best trained against the roof—say 16 inches from the glass. We do not think the smell of the air will influence the setting, if it does not hurt the plants. You have no reason to despair yet. You would see mode of treating Melons in “*Doings of the Week*,” lately.

**GERANIUM BLOOM FALLING QUICKLY (A Humble Learner).**—It is little use giving manure water to Geraniums when in full bloom. It is most useful when the buds appear, causing them to open strong. The extra stimulus will cause the flowers to be thrown off sooner than otherwise; but such plants will shed their blooms do what you will to prevent it. We suspect that the Fancy Geraniums have had too much water, and too little air, and that you have poured your water on close to the stem of the plant. In watering avoid this, or the tenderest will get a certainty. Everybody cannot have the very best; strive to excel, but do not get in the dumps because somebody may excel you. You will find that to be the case in something all through life. In general, it is best merely to nip the point of the shoot in budding, so as to give no great check.

**VINES BEARING ONLY AT THE TOP (A Constant Subscriber).**—Most Vines trained up the glass like yours are apt to produce the best bunches at the top of the house—that is, farthest from the roots. That they should be productive there only, must be owing to encouraging growth chiefly there. If the top part has a tendency to rob the lower so much, then there should be more pruning and pinching at the top, to encourage more growth nearer the base, and then it all the wood is ripened equally, there will be something like a general crop.

**DISEASED GRAPES (J. M.).**—The berries are very severely spotted. See what we said at page 262, relative to “Muscat Grapes Spotted,” the same remedial measures we recommend you to adopt, whatever variety of Grape yours may be. Lose no time.

**ANTS IN CUCUMBER-FRAME (E. L., Bristlington).**—They are not the cause of the young fruit dying off. That, probably, arises from the roots being out of order. To drive ants from the frame sprinkle a little guano over their haunt, and repeat the sprinkling until they have emigrated.

**ONCIDIUM INSELEATI—ODONTOGLOSSUM INSELEATI (Inquirer).**—They are distinct species, though the Oncidium was at first considered identical with Odonoglossum grande. The specific name in each is in honour of Mr. Tooleay, gardener to Mr. Barker, the well-known Orchid-grower at Manchester.

**THE FLYCATCHER.**—Permit me to thank your correspondent “ORNITHOLOGIST,” for his correction. When speaking of “the common Flycatcher,” I certainly alluded to the Grey Flycatcher, which in this neighbourhood (Birmingham) is comparatively general, when compared with the far more rare visitant *Muscicapa atricapilla*, or Pied Flycatcher.—EDWARD HEWITT.

**FORMATION OF WOOD (Ignorance).**—It is formed from the descending sap. If you will read “The Science and Practice of Gardening,” which you can have from our office free by post for forty penny postage stamps, you will find this and all the other phenomena of vegetation and cultivation explained. At page 203, it is there stated—“In order to ascertain whether the new layer of wood is formed from the former layer of wood, or of bark, M. Du Hamel made a graft *par Ceusson* (*Phys. des Arb.*, liv. iv., chap. 4); which is done by means of detaching a portion of bark from the trunk of a tree, and supplying its place exactly by means of a portion of bark detached from the trunk of another tree that shall contain a bud. In this way he grafted the Peach on a Plum tree, because the appearance of the wood which they respectively form is so very different, that it could easily be ascertained whether the new layer was produced from the stock or from the graft. Accordingly, at the end of four or five months after the time of grafting, the tree was cut down; and as the season of the flowing of the sap was past, a portion of the trunk, including the graft, was now boiled to make it part more easily with its bark; in the stripping off of which there was found to be formed under the graft a thin plate of the wood of the Peach, united to the Plum by its sides, but not by its inner surface, although it had been applied to the stock as closely as possible. Hence Du Hamel concluded that the new layer of wood is formed from the bark, and not from the wood of the preceding year. The same experiment was repeated with the same result upon the Willow and Poplar; when it was also found that if a portion of wood is left on the graft it dies, and the new wood formed by the bark is exterior to it.”

**NEVER DESPAIR (An Afflicted Gardener).**—You have indeed been visited by a series of heavy trials—failure of crops, sickness and death among those dear to you, yet we can say from experience that you will acknowledge after a time that all has been ordered wisely. Send us your address, and in the meantime, as you ask “What shall I do?” we reply, Go and see Lessing’s admirable picture exhibiting at the Egyptian Hall, Piccadilly, “The Martyrdom of John Huss,” and learn a lesson from him. We recommend all who have the opportunity, to see that picture; it is a picture never to be forgotten when once seen, and no one but feels he is the better for having seen it.

**STRAWBERRY CULTURE IN POTS (A. Z.).**—You may pot your Strawberries as soon as you like, one or two according to taste in a six-inch pot. Use stiffish, rich loam. Keep the collar of the plant well up, and thump the soil as firm as you can about the roots. This is point first. Then place the pots on a hard surface full in the sun, shade at first, water freely in dry weather, allow no runners to come, and protect from frost and wet in winter; then, if you have no fire heat in your leaf-bed, take your Strawberry-pots to the greenhouse in March, and, if you have plants to spare, place them in mild heat in your bed at the end of March. There have been full details given lately of the culture of such plants in pots, according to season. For instance, you might prick the plants in a border, and raise them in the end of March for the bed. Is it mildew you have on the Vine? If much spotted and only on one Vine, we would sacrifice the fruit rather than let it spread. If not much affected, dust with flowers of sulphur, and give more air in the house.

**MOVING KITCHEN-GARDEN STOCK IN OCTOBER (A. R. R. P.).**—The propriety of this, including trees we presume, will depend much on the winter. If trees, the shoots should be well stumped or nibbed-in previously, that the main stems may be full of sap; if sunny, you will be obliged to water, shade, and syringe. We should think that in general the work might be proceeded with after the middle of October—in fact, if syringing and shading could be given, we would begin on the 1st of the month, as there will then be much heat in the ground to encourage rooting.

**PRODUCT OF STRAWBERRIES (W. Grove).**—We have had forty or fifty berries on plants in six-inch pots, but we often had more weight when we limited the number to six or eight. It would be useless telling you what price they would then bring in April—in the London market, probably from 6d. to 1s. per ounce; but they might be hardly saleable at all, as the price depends so much on the bright or dull weather, and on the number of or the absence of parties. Our aristocracy even rarely purchase such things for

their own use, and therefore the price greatly depends on the number or the scarcity of fashionable parties.

**CULTURE OF EPIMEDIUMS** (*Victor Verdier*).—Sandy peat and the edges of Rhododendron-beds are the very best places for all the Epimediums, and once planted they should not be disturbed nor the soil about them save to keep down weeds. *Macranthum*, or *grandiflorum*, is the best of them all; *pinnatum* or *colchicum* the next best, and then *violaceum*. *Diphylum* and our own *alpinum* are the only two more of them known to us; the spikes of yellow flowers of *pinnatum* come very early in the spring, and the leaves of this species are the next best after those of *Asarum europaeum* of all that we have tried to gather for mixing with cut flowers in water-glasses indoors, and a bed of each of them in a shady, sheltered corner out of sight would be a treasure to those who use much decoration with cut flowers. These, with any favourite-scented leaves, and a few *Lycopods*, would be our dwarfia, and for "tail-feather" leaves, some kinds of narrow-leaved Iris, and some after the way of young Pampas Grass would be all our suite.

**HOUSE-SEWAGE WELL** (*Westmorlander*).—As nothing which you can devise will render its contents as fragrant as the gales from "spicy Araby," the further you have it from the house, and on that side from which the wind blows most seldom, the better. It emits no strong smell except when being pumped-up, and applied to the ground. So soon as it has soaked into the soil the smell ceases. The well represented at page 5 of our "Muck for the Many" is about 50 yards from the house, but the outlet where the smell alone is perceptible is about 100 yards away. Slate, with concrete or puddling behind, would be as effectual as bricks for lining the well. The sediment in a sewage-well we have does not require emptying more than once in two or three years. How soon the well fills depends entirely upon the inmates in the house. Of course the well requires to be pumped-up in time to prevent overflowing. Common sense is always a safe guide on these minor points.

**PEAR TREE ATTACKED BY CATERILLARS** (*M. E.*).—Those which eat into the trunk are the larvæ, probably, of the Goat Moth (*Cossus ligniperda*). We know of no better mode of destroying them than finding the holes in which they are, and thrusting in a stout wire. Look out for the parent moths; they are grey, and difficult to see. They rest during the day, with folded wings, against the trunks of trees.

**NAMES OF PLANTS** (*J. D.*).—1, *Roseda luteola*; 2, *Silene infista*; 3, *Fumaria officinalis*; 4, *Stellaria glauca*. (*H. R., Bromley*).—*Morina longifolia*. (*J. B. S.*).—*Philadelphus latifolius*. The other looks like *Trymalium odoratissimum*, but that is a greenhouse shrub.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

JULY 29. **NEWMILLERDAM**. *Secs.*, Mr. J. Turner, Walton; Mr. W. Pashley, Newmillerdam.  
 AUGUST 2nd, 4th, and 5th. **SHEFFIELD**. *Sec.*, Mr. George Westerholm, 49, Queen Street.  
 AUGUST 25th, 26th, 27th, and 28th. **CRYSTAL PALACE**. *Sec.*, W. Houghton. Entries close July 26th.  
 AUGUST 27th. **COTTINGHAM**. *Sec.*, Mr. J. Brittain. Entries close Aug. 20th.  
 SEPTEMBER 2nd. **POCKLINGTON**, Yorkshire. *Sec.*, Mr. T. Grant. Entries close August 26th.  
 SEPTEMBER 4th. **WAREFIELD AND WEST RIDING**. *Sec.*, Mr. J. Crosland, jun., Entries close August 23rd.  
 SEPTEMBER 9th. **WORSLEY AND ARMLEY** (near Leeds). *Sec.*, Mr. Robert Hoyle, Armley, near Leeds.  
 SEPTEMBER 9th and 10th. **CALNE**. *Secs.*, A. Heath and F. Baily. Entries close August 28th.  
 DECEMBER 1st, 2nd, 3rd, and 4th. **BIRMINGHAM**. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

### NORTHAMPTONSHIRE POULTRY SHOW.

JULY 17TH.

GENERALLY this Show has its gathering in the month of September, but in this Exhibition year of 1862 it seems agreed to crowd all our enjoyments into one period, and therefore it was held in July.

This is one of the Shows that move about like the Royal Agricultural Society of England, the Bath and West of England, &c., and every year it appears at a different place till the list is exhausted. We are great advocates for this plan, as turn by turn it identifies every town with the Show. The growth of this Exhibition is continuous. It is no bringing together of a few beasts, and two or three ploughs, and a horse or two, but it is really a large exhibition. It is beyond our duty to say anything of it in detail; but we may be permitted to speak of the pleasure we feel in noting the increasing success of every meeting. They are truly county gatherings for every class. Cattle, horses, sheep, pigs, wheat, and butter, fruits and flowers, have their separate classes, while the band of the Foot Guards is an attraction for the fair sex. A Sybarite might be content listening to such music while seated in a tent presenting a mass of roses to the eye. The Show has gone on increasing till it is not always an easy task to find a convenient spot for it. This year was an exception. The Marquis of Exeter very kindly allowed it to be held in Burchley Park—a truly magnificent spot for it. When we add that the day was a fine, the attendance larger than was ever before known, and that all things went off well, we shall have nothing to do but to note the classes in their order.

*Dorkings* were first on the list, and the prize for the best pen

was a silver cup given by Lord Burchley. It was gained by Mr. John Shaw. There were fourteen pens of good adult birds shown. Those belonging to Mr. Rowland Wood deserve especial mention, also those of Messrs. Brown and Burnaby. The utility and progress of these Societies may be shown by the class of Dorking chickens entered here: twelve good pens were shown, and the competition was severe for all but the first prize. That was never in doubt, and went to the Rev. F. Thursby, of Abington Rectory. Messrs. Swinger and Hanbury showed capital birds. The classes for the silver cup and for adult birds seem to have exhausted the lists of cocks at this trying season. The class for single birds was very weak. Mr. Brown's was meritorious.

The *Spanish* class improves yearly at this Show, and it produced excellent birds. There were ten entries. The Rev. F. Thursby and Mr. Smith deservedly headed the class. We were sorry to see a trimmed pen. We hoped that practice had disappeared for ever. The only effect of it is to cause birds that would otherwise, perhaps, be at the head of the list to occupy an inferior position. A good bird does not need it, and a bad one cannot be improved by it. Spanish chickens showed the season had not been propitious for rearing. There were but three entries, and there was only one good pen. It belonged to Mr. Smith. The other two pens had no chance against it, and were so deficient, the second and third prizes were withheld. It is only kind to exhibitors in this class to tell them that faulty-combed cocks cannot take prizes.

The *Game* classes were large and excellent; every prize in all of them was taken by Mr. H. Shield, of Northampton.

Messrs. Biggar and Brown were deservedly successful with *Cochin-Chinas*.

Northamptonshire is not a *Hamburgh* county, and the show of them was weak.

The entries for "Distinct Breeds" were good, but the birds were not sent.

The next prizes were four offered by the Marchioness of Exeter and Lady Burchley for "the exhibitor of the best pen of three barndoor fowls, one cock and two hens, of any kind, to be owned by labourers, cottagers, and small farmers of not more than twenty acres of land within fifteen miles of Stamford." Will it be believed—there was one entry? We know those cottagers only who live in the neighbourhood of commons can keep poultry; we know that in many instances masters will not allow their labourers to keep fowls; but surely in the country for fifteen miles round Stamford, there are persons coming within the limits of the class who could make a fair competition for these prizes.

*Aylesbury Ducks* were very good; and the "Various Class" showed unusually good White Calls, Buenos Ayrean, and Rouens. The *Turkeys* were very good.

Mr. Baily, Mount Street, Grosvenor Square, was the Judge.

**DOAKING** (A Silver Cup, given by Lord Burchley, M.P.).—Cup, J. Shaw, Hunsbury Hill. Highly Commended, Rev. F. Thursby, Abington Rectory.

**DORKING** (by the Society).—First, R. Wood, Clapton, Thrapston. Second, W. Brown, Kingsthorpe. Third, T. Burnaby, Upper Lodge, Pipewell. Highly Commended, Marchioness of Exeter, Burchley House. *Chickens*.—First, Rev. F. Thursby, Abington Rectory. Second, T. Swinger, Langham, Oakham. Third, J. B. Hanbury, Clipston House. Commended, J. B. Hanbury, Clipston House; J. Shaw, Hunsbury Hill. *Cock*.—First, W. Brown, Kingsthorpe. Second, J. Sheffield, Geddington Grange.

**SPANISH** (by the Society).—First, Rev. F. Thursby, Abington Rectory. Second, J. W. Smith, Oundle. Third, J. Biggar, Northampton. Commended, J. W. Smith. *Chickens*.—Prize, J. W. Smith.

**GAME** (by the Society).—First, Second, and Third, H. Shield, Northampton (Duckwing, Brown-breasted Red, and Black-breasted Red). Commended, —Everard, Bardou Hill House (Black-breasted Red).

**GAME COCK** (by the Society).—First and Second, H. Shield, Northampton (Brown-breasted Red and Black-breasted Red). Highly Commended, —Everard, Bardou Hill House. Commended, S. Deacon, Herne Lodge, Oundle.

**COCHIN-CHINA** (by the Society).—First, J. Biggar, Northampton. Second, W. Brown, Kingsthorpe.

**HAMBURGH** (any variety, by the Society).—First, S. L. Mason, Essendine (Golden-spangled). Second, J. Phillips, Stamford.

ANY OTHER DISTINCT BREED.—Prize, J. Beasley, Brampton (Silky).

**BARNDOR FOWLS**.—To the exhibitor of the best pen of three Barndoor Fowls, one cock and two hens, of any kind, to be owned by labourers, cottagers, and small farmers of not more than twenty acres of land, within fifteen miles of Stamford (by the Marchioness of Exeter and Lady Burchley).—Prize, E. Speed, Exton, Rutland.

**DUCKS** (Aylesbury, by the Society).—First, J. Shaw, Hunsbury Hill. Second, —Everard, Bardou Hill House. Third, C. Watts, Kislingbury.

**DUCKS** (any other breed, by the Society).—First, Miss Boyle, Weedon (White Decoy). Second, Rev. F. Thursby, Abington Rectory (East India). Third, J. Beasley, Brampton.

**TURKEYS** (any age or colour, by the Society).—First and Second, J. Beasley, Brampton.

## LEEDS AND WEST RIDING POULTRY EXHIBITION.

[The following from our reporter reached us too late for insertion last week.]

For some years past there has been an annual horticultural show held in the town of Leeds, and this year some of the local poultry exhibitors bethought themselves that notwithstanding the fact of there being an annual exhibition of poultry in connection with the Leeds Smithfield Show, it would be a good opportunity to establish a summer show in connection with the Horticultural Society's Meeting; and upon this basis one or two of the most zealous in the cause started what promises to be a first-class annual summer exhibition, as the support the Committee met with from exhibitors both far and near was certainly most encouraging, many of our best yards being represented; and we do not think any will have cause to regret having exhibited, as the greatest care was taken of all specimens, and the arrangements in every respect well deserved the approbation they met with on all sides. The pens used were Mr. Turner's of Sheffield.

As usual, *Spanish* headed the list, and proved themselves worthy of the honour, as they were decidedly the best class in the Show. Mr. Teebay carrying off the silver medal with one of his well-known good pens. Mr. Rodbsrd having to be content with a second prize. There were several excellent pens amongst those who had to be content with high commendations.

The *Dorkings*, if we except the prize pens, were nothing particular, many of them being wretchedly out of condition.

In *Black-breasted Red Game*, Mr. Beldon was fortunate enough to stand first. We say fortunate advisedly, for we certainly could not see wherein the merits of his pen consisted, to place him before Mr. Fletcher and other well-known breeders; but if we are rightly informed there was some difference of opinion between the Judges in this class, and as they could not agree, a referee was called in, who, in spite of the fact of Mr. Beldon's being a small, loose-feathered cock bird, with two ordinary hens, placed him first, his only claim to distinction being a good head and a good colour; but as a *Game* cock requires to be a good bird in hand as well as to look at in the pen, though giving the arbitrator credit for all good intention, we can but *in toto* disagree with him—and one of the Judges ignored the award altogether, and declined having anything whatever to do with it; and being totally contrary to his opinion as to the best pen, the silver medal was awarded to a pen of *Duckwings*, and the first prize, "any variety class," going to a good pen of *Blacks*.

*Cochin-Chinas* were numerous and good, the medal going to an excellent pen of *Buffs*.

In *Hamburghs*, Golden-spangled formed decidedly the best class, the medal being awarded to a beautiful pen of Mr. Marlor's. The other varieties were also well represented.

*Polands* mustered three pens only.

In the class for "any variety not mentioned," the first prize went to a remarkably fine pen of *Brahmas* of Mr. Teebay's; second to a good pen of *Black Hamburghs*. There were also good *Malays*, and *Crève Cœurs* in this class.

*Chickens* of all varieties were shown together, and formed an excellent collection. The prizes going to *Spanish*, *Golden-pencilled Hamburghs*, and *Black Red Game*, in the order mentioned.

For the best *Game Bantam* prizes there was a hard run between Mr. Brierly and Mr. Crosland, the former gentleman eventually taking first as well as the silver medal for the best pen of *Bantams*. There were also some good *Whites*.

In *Guinea Fowls*, Messrs. H. & G. Newton stood first with a pretty pen of *Whites* shown in beautiful condition.

*Ducks* were not well represented, there being three pens only, and those of very ordinary merit.

*Turkeys* and *Geese* numbered one pen of each, exhibited by Lady Hawke; but they well deserved the prizes awarded to them.

In *Game cocks*, Mr. Brierley obtained first prize with a good *Black Red*. In *Cochins* every bird exhibited appeared in the prize list, so this is sufficient to speak for their quality. Mr. Holdsworth was first in *Game Bantam cocks*.

*Pigeons* formed a capital show of every variety. The medal for the best pair went to Mr. Holdsworth's *Almond Tumblers*. The *Carriers* and *Powers* were also excellent, and we must not omit to mention a beautiful pair of white *Jacobins* exhibited by Mr. Crosland, which deservedly stood first in their class, and the

well-known names which obtained prizes in the other classes, will speak for themselves.

We have omitted to mention that the Show was held in the *Albion Music Hall*, admirably suited for the purpose, as two spacious rooms afforded accommodation, one for poultry and *Pigeons*, the other for horticultural productions.

The Judges for Poultry and Pigeons were Mr. G. S. Sainsbury, Devizes, and Mr. S. Bird, Shipley.

## BULLFINCHES' EGGS DISAPPEARING.

As you are friends of the small birds, I venture to ask you if there is any bird that preys upon the eggs of *Bullfinches*. In this part they are not very common, and are therefore much prized; but in four or five instances the eggs have marvellously disappeared, and it was the same last year, although every one seems desirous to preserve them. We do not think the boys are the robbers, as the place is private and none are ever seen about. We are, therefore, quite at a loss to know what becomes of them, and any suggestion that would be likely to throw light upon the subject would be thankfully received. We are five miles from a town, and there are no bird-dealers in it, and we can hardly think that they can disappear in that way. Other birds' nests are not molested, as they generally bring out their young ones, for which we are thankful, as we are sensible of the great good they do in destroying insects and caterpillars. The *Blackbird* and *Thru-h* are the only ones we think we might have too many of; the *Blackbird* especially is a great rogue, and does not care much about grubs if he can get *Cherries* or *Strawberries*.—CUMBERLAND.

## CONSEQUENCES OF LOSING A QUEEN.

I HAVE had some rather amusing incidents in connection with my swarms of this season. My first swarm came on the 24th of June, was hived in the usual way and left. In the evening I went to cover them up, but lo! they were gone! On examining the parent stock I found them crowded on the outside. Of course, the swarm had returned, but from what cause I could not ascertain. Probably the queen was either lost, or, as I have sometimes proved, incapable of flying, and, therefore, lost after leaving the landing-board. However, in two or three days I found a couple of young queens, and concluded at once there would be no more swarms; but on Sunday, July 6th, although we had heavy rain in the morning, a swarm issued and settled, and before I could collect them my other stock sent forth a very large swarm; but the rain coming on again it also returned, and was outside the parent hive during the whole of the day. I naturally supposed it would come again the following day, as I have known them do so frequently. But no such thing; a swarm did come, but not till the following Sunday, and of which I was aware, having heard the calling of the queens. Both swarms are now working hard, and, if the present seasonable weather continues, have no doubt they will do well; because, if our own neighbourhood fails to supply them with a winter store, I can remove them to the heather only a few miles distant, where they mostly find a sufficient supply.—J. C.

[There is little doubt that the original queens were lost in both cases, and that when the swarms issued for the second time they were headed by young queens.]

## MISFORTUNES OF THE SEASON.

IN No. 41, New Series, I wrote you a short article on "Ventilating Hives during Winter." Possibly you may find room for a short history of the doings of my bees since that time, though it will only add to the unfortunate list, which we are all sorry to hear is in the ascendant this season.

Shortly after writing the above article, the weather proving unusually mild, I placed my hives (six in number) on their stands, and removed the zinc from the top apertures, placing squares of glass in their places, so as to increase the temperature of the hives—my object being to promote early breeding. Of course this had the desired effect; but in a day or two after the severe frost set in, which easily penetrated the glass, and before I was aware had done its work with half my stocks by freezing them into solid masses between the combs, thereby affording me a very painful proof of what I had stated.

Being left with only three hives, and also being anxious to

place my bees in bar-and-frame hives, I adopted Mr. S. B. Fox's plan, drove them and placed the combs in frames to my own satisfaction, and all went on well. I have since made three artificial swarms—one with the bees alone, leaving the queen with her subjects; two others I made as recommended in *THE COTTAGE GARDENER*—namely, by taking out two brood-combs from the stock and placing them in another hive on the stand of the stock, removing the stock to a distance. Both these went on satisfactorily, each constructing queen's cells, though only one cell in each hive contained a royal nymph. One of these duly made her appearance, but has since been lost, probably not finding her way home after her wedding excursion. The other swarm, after duly sealing up the nymph, waited till her appearance was due, and then, as she was not forthcoming, they tore open the cell to discover that their expectations as well as mine were disappointed. The queen had died before spinning her cocoon.

But my tale of misfortune is not yet finished. On Saturday, the 12th inst., I found the queen of the swarm which was formed by the driven bees alone lying on the ground in front of the hive. On taking her up I found her abdomen perfectly empty, yet she was alive and could creep about.

To this hive I have added my second artificial swarm which had lost the artificial queen before-mentioned, expecting a queen from a neighbour who thought he was about to put two second swarms together. In this, however, I am disappointed, as the swarms have not made their appearance, so that I have now two queenless hives.

In order to make the best out of a bad job, I think this would not be a bad opportunity to place a Ligurian at the head of one of these stocks. Should there be one among your many apian readers who has a supernumerary fertile Ligurian queen I shall be most happy to hear from him.—W. JOHNSON, *Essington, Wolverhampton*.

### BEE SEASON IN MIDDLESEX—UNSUSPECTED ENEMY OF BEES.

I SEE that several of your correspondents are giving you reports of the season as it affects bee-keeping this year, and it may not be uninteresting if I add a statement as to this in so central a place as Middlesex. I fear, however, I can but add a groan to the general wailing, for at present this has proved incomparably the very worst season in my experience—very far worse than the notoriously wet summer of 1860. We are here getting neither swarms nor honey. Out of eleven stocks I do not detect sealed honey-cells in more than one, and the working of supers, which commenced vigorously in May, is almost totally abandoned.

During my temporary absence in June, a swarm of Ligurians was lost from sheer starvation; and, therefore, I would advise all bee-keepers wishing to preserve their this-year's swarms not to be chary of a bottleful of food now and then—it may save several bottles in the winter, by keeping the bees strong enough to gather what little is to be found.

In such a season as this the superior merits of the Ligurians are very manifest, my solitary stock of last year having given an artificial and two natural swarms, and is still full, almost to overflowing; while six stocks of black bees have given me one swarm amongst them. We have, however, some little hope left. There is an abundant appearance of white clover, from which I usually find they collect much honey, and up to a late period of the season. [There is also the blossom of the limes.—EDS.]

I should like to caution apianians against a not-generally-suspected enemy to their bees. I find that cats are very fond of eating them. I possess a cat that will, if permitted, sit for hours under a pedestal, snapping them up with evident gusto as they go out. I am, too, unfortunate enough to have neighbours of strong philofeline propensities, and it is not uncommon for me to find a cat above the hive pouncing upon them returning, and one below securing the exits.—G. F. B., *Colney Hatch*.

### APIARIAN NOTES.

**THE BEE SEASON.**—Up to the present time (18th of July) the season has been most unpropitious for bees; the want of sun has been felt by them very much. For several of the last days of June the bees have been chilled in great numbers near their hives; and as to honey, about the 20th of June three swarms

which were weighed a month after being hived were no heavier than on the day of swarming. A very few days of honey-gathering now remain; and as the weather improves, it may be presumed that in some good localities enough of store may be saved by our pets to keep them through the winter. Our county is an overstocked one, and there is little late white clover; being near the town, the honey season pretty nearly closes about the third week in July. We hope some of the writers will furnish an account to *THE JOURNAL OF HORTICULTURE*. The writer of this communication has been obliged to feed young swarms in June! a very rare occurrence, and accounts have arrived from Exeter to the same effect.

**SWARMING PREVENTED.**—In answer to a correspondent in *THE JOURNAL OF HORTICULTURE*, let him try the moving the old stock immediately after swarming; he will find that an infallible plan to prevent a second swarm. The new swarm should be placed in the exact spot where the old parent hive was taken from. I have never found it to fail.—H. W. N.

### THIS HONEY SEASON.

YOUR correspondent "A DISAPPOINTED BEE-KEEPER," in No. 67, 8th July, must indeed live in a land overflowing with honey, and cannot have read the bee-books with much advantage; for if he refers to "COUNTRY CURATE," he will then see he states, a person commencing bee-keeping must not be disappointed if he gets no honey after keeping bees for some years; for if the weather and country are bad for honey they cannot gather it, and this season is the third bad one, two out of the three the poor bees have hardly been able to live, and must, as many have done, if they had not been fed, have died out, and very many this season have gone; and if he will read the bee-books a little more carefully, he will observe they say when there is not much honey to gather there are more swarms, as the queen has more room for breeding.

Bees will fill glasses when there is no honey to gather if properly managed, but it is useless trying them in bad and cold seasons, as they can scarcely keep their hive warm enough for breeding, and, therefore, find a glass too cold. You may often observe in the daytime when it is warm they commence in a glass, and at night are compelled from cold to leave it; and at all times if a glass is not kept warm, bees will not work in it, and there must also be something to gather, which has not been the case this season—for, only yesterday, I took a swarm of the 7th June out of a hive, and did not observe an ounce of honey but a good deal of brood, and, therefore, put the hive on the top of another one to be hatched out.—A. W.

P.S.—I have had two or three swarms this season without drones, and they did not make their appearance in the old hive till some days after.

### OUR LETTER BOX.

**SPANISH HENS DYING SODDENLY (H').**—How can we tell the cause in the total absence of any information as to their diet, place of keep, or previous symptoms? They "drop dead from the perch," probably, from being over-fed with too-nutritious food, which induces apoplexy. But you might as well have told us that "Tom Nokes is dead," and then have added, "What caused his death?" Editors are *not* clairvoyant.

**GRAVEL IN POULTRY PENS.**—I see you have mooted the gravel question. Gravel being nearly as important to birds as food, I cannot see why its scarcity in the vicinity should ever be an excuse for its absence; a sack or two could always be had by train at a slight cost, and I know many people who refrain from entering valuable birds because of its not being supplied.—W. II. B.

**VARIOUS APIARIAN QUERIES (S. A., Braintree).**—A Woodbury frame-hive weighs about 19 lbs. when empty, and your stock must be fed up at least to 15 lbs. beyond this weight before winter. The crown-board should be removed before a super is put on, and a thin adapter substituted as represented in page 74. There would be no difficulty in driving your second Ligurian stock, and introducing it into a hive filled with brood and combs taken from condemned bees. The supers shown at the International Exhibition were filled last year.

### LONDON MARKETS.—JULY 28.

#### POULTRY.

The increased supply and the falling-off in trade indicate the close of the spring season. London will soon be out of town.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 74.4° and 51.1° respectively. The greatest heat, 93°, occurred on the 19th, in 1842; and the lowest cold, 36°, on the 6th, in 1833. During the period 140 days were fine, and on 105 rain fell.

DEVICES FOR DINNER-TABLE DECORATION.

If there is one thing more than another that the British public delight in possessing, it is the freedom they have in criticising the works of all who compete for public prizes. The privilege of passing an opinion on private works is often enough indulged in, but ordinary courtesy forbids that any severe censure

should be passed in cases of this kind. There is less reserve where the aspirant aims at public distinction. In the latter case the public claim as a right the privilege of giving an unfettered opinion on the merits of the competing article, whether that be political or social, a work of art or skill, or a service performed; and whatever be John Bull's failings, he is, perhaps, after all, the best of all men for acknowledging real merit. But, as he has so many things before him daily, it is not to be wondered at if his judgment now and then should take a backward turn, either from inattention, or it may be a little wayward capriciousness, which in light matters he is not unlikely to fall into. By-and-by, however, his sound common sense discovers the error he has committed, and the opinion previously given is reversed.

There is, however, one subject in which John Bull's judgment is said by foreigners to have been at all times guided by caprice, rather than by just and acknowledged laws, and that is the Fine Arts, for if we are to regard the opinion of our neighbours across the channel, we have little to congratulate ourselves upon on the score of taste. Whether this be so or not need not be argued here; suffice it to say, that the laws which govern good taste in such an article as that of dress must be of a very comprehensive kind, or surely the term "good taste" could not alike be applied to the belle of the present day, with that of her prototype thirty years back. Neither are the vagaries of the rougher sex less conflicting to reconcile to the doctrine of good taste, if that be brought to bear upon them; so that I fear I must court a more humble idea in support of my views on a matter which has attracted no small attention on the part of the floral world, and the assistant I mean to call to aid my views is plain "Utility," whose existence even is too often ignored by those who soar to the position of shaking hands with Good Taste; but with Utility, I, for one, would be the last to quarrel,

Nevertheless, I cannot see any reason why a more close union between Utility and Beauty should not often be made. The homely usefulness of the one, certainly ought not to be so much despised by the other; and though the more attractive one may, and often does, receive the first attentions, second thoughts often accord the other as distinguished, and, eventually, a more

lasting place. Let us see how a union between these two can be made so as to bear on floral table decoration.

The visitors at the South Kensington Gardens Horticultural Show in June last, cannot have forgotten the most attractive feature there, if they had the good fortune to see it, despite the throng which surrounded it. I allude to the dinner-table decorations, for which liberal prizes were given and numerously competed for. The readers of THE JOURNAL OF HORTICULTURE who had not the opportunity of seeing the prize decorations, will have read a description of them sufficiently clear to give them a tolerably good knowledge of what they really were; and as these were selected from amongst a number of others, and selected, too, by those whose judgment it is next to treason to dispute, I confess it is not without considerable diffidence that I address myself to the task of calling that decision in question, though not in a factious manner, but, perhaps, with a view to serve the interests of my presiding genus, Utility, and, in some respects to urge her claim on the consideration of those who legislate on higher matters. I am the more emboldened in this by the many revolutions I have seen in what is called taste, while the dictates of Utility remain as stationary as a rock.

It will be universally admitted that a dinner-table is a place of social enjoyment, the assembled guests being expected to derive as much pleasure in each other's company as they do in partaking of the good things provided for them by their host. Now, taking the treat to be as much a mental as a physical one, and in many respects it ought to be regarded as still more so, might we not ask, Why is there any obstruction in the way of mutual greetings or interchange of ideas or courtesies? Assuredly Good Taste with her all-but-boundless empire ought not to invade this domain; and yet she does, and that in the very dinner-table decoration to which prizes have been awarded.

Taking it for granted that a dinner party is met for social enjoyment, mental as well as bodily, I would certainly not allow any obstruction to the full enjoyment of the first of them, and however loaded the table may be with objects of luxury or beauty, I would preserve the line of vision from one person's countenance to another clear of every obstruction whatever, either of floral design, or cumbrous lights, or any other intervening object. Assuredly there is plenty of space in a dining-room for the display of either wealth or ornament without obtruding it in the way of two people engaged in conversation. To be practical, I would say, that the space of about a foot in the line of vision ought to be clear of all obstruction, and measuring from the table-cloth, if we stipulate for the space above the fourteenth inch and under the twenty-sixth, to be thus clear I do not care how much the space below and above this area is loaded with ornament; and I cannot see any reason why the advocates for display should not be satisfied with the ample scope still left for them.

Certainly they have no more excuse for sticking a

bunch of flowers or a piece of valuable metal between two people's faces, than an Eastern beauty has for wearing a thick veil in company. A tyrannical fashion, fostered by jealousy and centuries of usage, may prolong the latter custom; but I shall be much mistaken if high services of fruit and flowers receive the countenance of the thinking part of the public long, however tastefully these groups may be arranged.

I do not mean to detract from the praise awarded the prize design at the Show in question, but I certainly should have liked it better if it had conformed to the rules above laid down; for whether we regard a dinner-table as a meeting for a few private friends, or as a public gathering for some especial purpose connected with business, I cannot but think the first of all duties on the part of those who prepare it, is to enable the assembled guests to see each other without the unpleasant necessity of peeping round, or under, some floral device perhaps not much smaller than a handbox. However thinly the spikes of flowers may rise upwards, or however wide they may be in a pendent position, they all but entirely conceal everything beyond them.

Much stress has been laid by some on the propriety of having the stem and bowl of such stands made of transparent glass, but it will be found that at the distance of a yard they can be no more seen through than if they were of metal; and if any one be dubious of this matter, and think that a slightly dressed-up stand obstructs but little of the light, let them take one so prepared into a dark room, and placing a single light in the line of vision, they may trace on the opposite side the amount of shade caused thereby. I shall be much mistaken if it does not amount to full two-thirds or three-fourths of the whole space. Assuming such a stand to occupy the centre of a table when twenty guests are seated, the one near the bottom will be unable to see three or four that are at the top on the opposite side to him; and if the table be a long one, and there are several such stands, they would effectually screen one-half of the company from the other half.

While condemning such objects for the dinner-table, I by no means exclude them from the dining-room, but would suggest their being placed on the sideboard, in which case care must be taken in dressing them so as to form a suitable contrast with the background, whether that be of furniture or the walls of the room.

A supper-table when the company stand to partake of it is also a suitable place for such stands, and I am not aware of any objection to their being introduced into the drawing-room.—  
J. ROBSON.

## CROSSING FLOWERS—CYCLAMENS AND VARIEGATED GERANIUMS.

THE weather in the months of June and July this season was so unsuitable for crossing, that the more experienced hands at it, as far as I can hear, have done very little indeed. But now we seem to be in for six weeks of the finest weather for the purpose. But before doing more than opening the subject, I wish to make a proposition about some Cyclamens for crossing.

I have now, through the kindness of a good Cyclamen authority, two more bulbs of the true Cyclamen vernum and another kind of some "hybrid origin," and, probably, in near relationship to vernum itself, and if my vernum from my Sardinian correspondent be the true one, I shall be pretty well up in vernums. Now comes the question, What is vernum, and where is it a native of? or has any one ever found it growing wild? I cannot answer that, and I know of no one of whom to ask: therefore, I ask all whom it may concern.

I said long since that I suspected vernum to be a cross between eoum and some late-flowering autumnal kind, and it seems as if Fortune would favour the bold in assertion, as well as the brave in deeds of arms.

My original vernum now has been six or seven years in my hands. At first it bloomed with me at the beginning of March, and was considerably lighter in tint and longer in petal than eoum; but the blooms were from a spur down the middle of the bulb, the top of the bulb being crested and blind of eyes, and it is so to this day. After planting it in a corner of a cold pit it took to flowering at the end of October and all through November to near Christmas. Then the tint of the flower was altogether different—very pale indeed, and it was from the change in the time of blooming, and in this circumstance about the change of colour, that I have been led to believe the plant to be

a cross from a pale autumnal kind; and the time of blooming being a compromise between the September-blooming parent on the one side, and the February-blooming parent on the other side, and if you balance these considerations, you will I am sure allow that I had some fair foundation for supposing the vernum to be a cross-bred plant.

Now, however, I have a new leaf to turn over for your special consideration. My ancient vernum has taken a right good hold of this cocoa-nut refuse, which is, of all materials ever tried, the best for growing all the kinds of Cyclamens in; and from the impulse of the "pulp," as poor old Mr. Barsham used to call the refuse, the old root has put out another spur on the other side of the bulb, and lower down. Both the spurs are just within the cocoa-nut fibre refuse, but the crown of the bulb is up above it, and always has been with me. The second spur put up the first leaf early in June last, and by the first week in July, a fine handsome flower came up from the same part. This is the twenty-ninth day that flower has been open, and there are only some signs yet of its fading. The colour of the flower is now more intense than in eoum, but not of the same tint at all, being a dark purple, while that of eoum is between carmine and magenta colour, and seldom varies. When the flower was eighteen days old it would pass for the very blooms from which the original drawing was made for Sweet's plate of vernum; after that it became much deeper in colour, but is now beginning to be lighter—a sign of fading. The second flower opened last week, and I can count five or six more blooms coming, so that I shall, probably, have it in one or two blooms till October.

Now, my proposition is this: I know the pollen of my plant is good, for I have had one pod of seed ripened by it this season, and if the pollen is able to fertilise another kind of Cyclamen, any such Cyclamen in any part or corner of Europe could be fertilised by my plant just as readily as if it were in Surbiton and in my own garden. But there may be sixty of our readers who would like to try that experiment, and as there are no more than six flowers in expectation, what am I to do? Shall I raffle for the pollen of a plant, as they do for the crumbs in the Royal Horticultural Society, or what? They call it balloting, but what is the difference? I think the best that I can do will be to offer one flower to each of six persons only—that is my proposition, and the next question is, Who are the most likely six among our readers to have the knack of crossing Cyclamens? A man may be a good general crosser, and yet be not an adept at particular instances of it. After a close consultation, on the subject of crossing Cyclamens, between your humble servant and the best practical crosser near him, Mr. Holland, from Twickenham, who possesses the perpetual bloomer of europeum, we decided that all Cyclamen flowers ought to be turned upside down while they were being dusted with pollen. Cyclamens have the pistil as fine and as sharp-pointed as a cambric needle, and, therefore, are very liable to miss the dust if these sharp points be left in their natural position. I heard since that Mr. Holland has succeeded in fertilising his perpetual europeum Cyclamen, but whether by its own dust or that of some other kind I am not sure. However, he would be likely to do the vernum with some autumnal kind—Neapolitanum, for instance, and I offer him a bloom when his plants are ready to cross. The other correspondents who took a part in the Cyclamens, may each also have one, as far as they go, for none of my own autumnals are likely to bloom this season, so that I am not likely to be able to test the crossing myself; but the opportunity is certainly too good to be lost, and it may not happen again in our lifetime.

It always struck me as desirable to pass the late-spring Cyclamens into the summer, and get them to cross with the earliest of the autumnal kinds. Also, if the latest of the autumnals could be made to flower later, and so bring them on to the time of the very early winter ones, which, like the Camellia, though they are strictly spring bloomers, could be so managed as to bloom as early as November. That once accomplished we should not only possess Hybrid Perpetuals, but a more hardy race.

If it were a matter that would well pay for the care and trouble, it could be done in another way more easily, and this brings me to a question in crossing for which I had been expecting all this summer to be called over the coals. I repeated an old saying of mine last spring, about the possibility of gathering Rhododendron pollen on the Alps of Thibet, if they be there, or so far north in that part of the world, and taking it home to cross with

here the following season, and some one said that it could not be done; at least, I have been told so. Well, perhaps it cannot be done, but who knows it cannot? It is on record that dry pollen from an herbarium had been put to the test of moisture after fifty years from the time the specimen was dried, and that the pollen grains or particles had first swollen, and then burst, the discharge looking in nowise different from that of the pollen of a recently-gathered flower. Absolute exemption from the access of moisture seems to be the essential to the preservation of pollen. At all events, I am certain that the pollen of a *Cactus* twelve months old, in my own keeping, fertilised a flower upwards of a quarter of a century back, and since then I have often used dried pollen some months old; but unless there was a natural secretion of moisture on the stigma, I do not remember that I ever induced dried pollen to act on an artificially-moistened stigma, as some have said. There are thousands of plants the stigmas of which appear always quite dry to the naked eye. The *Cyclamen* is one of them. I have tried pollen after a shower, when the stigmas were damp from the rain, and never could succeed in forcing any of them to seed; and it seems to me that any moisture, save the secretion of the plant, is fatal to the power of the pollen in every instance.

To ascertain the best way to transmit pollen from place to place would be a very great point gained. When I cut the anthers a day or two before they would open naturally, taking some length of stamen with each, and then place them apart in a fold or two of silver paper, and lay them in a tin-box, that pollen is safe enough for three months, but it must be applied with something like the old notion of camel-hair brush; shake the dust or pollen about in the silver paper, get it in a corner, and then it will stick to the point of a pen, or pin, or needle, or any sharp-pointed thing, but not a real brush, for that would be the height of extravagance on the one hand, and the extreme of folly on the other. The smallest brush would take up very much more pollen than would be necessary, and that brush would be of no more use for other pollen till after it had been wetted or washed and dried, for fear of not otherwise getting rid of the first kind of pollen before trying another.

There is but very little risk in sending pollen by post from any part of the three kingdoms to any other part, and if I had an ivory white strain of *Lady Elcho's* style of *Picotée*, I would as soon go to Japan for *Mistletoe*, as send blooms of that strain by post to a rival cross-breeder at Inverness, or any other Inver round the coast, for he would be sure to look out for the anthers, and to make use of that pollen in order to get hold of my superior strain without paying the piper.

It was only the other day that a bunch of the tops of a new seedling *Lobelia* came up from "A. O.;" the flowers were all withered, but I arranged the shoots as for long-legged cuttings, trimmed them, and put them in water and moss in a glazed saucer, and I would take in hand now to be in the market with seedlings of that *Lobelia*, which I shall thus ripen almost as soon as "A. O.;" but "A. O." took the temptation out of the way by sending three little plants of this seedling which are now in my keeping, and which must bloom before we can know anything of the *Lobelia* in question, for it does not seem likely that any of the shoots will make another flower.

They say it is a temptation and a danger to send money through the post, and I say it is equally so to send some flowers to some quarters, by the same or any other conveyance, and I wish particularly to impress this upon youngsters, and I shall wind up to-day by giving out a fair idea for a fortune. I suppose you have got the *Golden Fleece* and the *Cloth of Gold Geraniums* by this time, and also that you have not forgotten how Mr. Smith, of York, got *Mangles'* to seed last year by using the back pollen of the *Golden Chain*. Well, then, you get all the yellow, or golden-leaved sorts of *Geraniums*, and use the pollen in the two bottom anthers on the points of the *Fleece*, and of the *Cloth of Gold*; and if there is luck anywhere this season, you will soon find it in the seedlings; and if not, there is nothing lost, and you need not follow the seedlings beyond the third or fourth leaf, for, then, if they also are not gilded with this kind of gold you can destroy them. D. BEATON.

THE BOTANICAL GARDEN AT ADELAIDE.—It contains about forty acres of undulating ground, very prettily laid out for purposes both of ornament and classification. It is at the north-east corner of the town, and commands a fine view of the hills. It was commenced in 1855—the previous botanical

garden having been a very small place on the banks of the *Torrens*. The new gardens are laid out in various departments for a scientific arrangement of plants, pleasure grounds, an arboretum, &c. There are a good house for the Director, three propagating and green houses, and a handsome domed conservatory. Since water has been brought into the town, the beauty of the place has been greatly increased by the introduction of fountains and ponds, now well stocked with various kinds of water-fowl. There are also several aviaries and cages, and enclosures for animals—the gardens being zoological as well as botanical, at present. The collection, except of native animals, is as yet small, but receives occasional accessions. There are more than three thousand species of plants represented in the Botanical Garden, and this number is continually increasing. The garden is already rich in succulents, Ferns, florists' flowers, and bulbs. The garden is supported by an annual grant, and the public are admitted every day during daylight, except on Saturdays and Sundays, when the hours are more restricted.

### ALLOWING GARDENERS TO EXHIBIT PLANTS.

Is it justice or injustice not to allow a gardener to exhibit? My gardener is very much put out because I refuse to allow him to exhibit at the different flower shows held in this neighbourhood (Corentry). I take very little interest in the shows myself, and I think it takes the gardener's thoughts too much off from other work; though I admit that my gardener has no other holiday except on those show days, and he works many hours, even more than "R. W." thinks a gardener ought to work. He says he considers it not only a privilege but the duty of a master to allow it.—RIFLEMAN.

[We do not think that your inquiries involve anything at all of the principles of "justice or injustice." But the question is one among many others which has been pressed upon our attention relating to the position of gardeners, their rights and responsibilities, the practices and usages which generally exist, some of which may be too easily considered in the light of a law of use and wont, and therefore sometimes leading to the most unpleasant circumstances; because an employer, very likely from not being consulted, may choose to say that he never gave his consent, but, on the other hand, wholly disapproved of such proceedings. Such matters will lose little by being held somewhat in abeyance for a short time, because just as in the matter of hours and holidays, neither the professional writers in this Journal nor the Conductors could hope to establish a general rule of action in these cases; nor would it be altogether desirable if they could, as then the pleasant reciprocal obligations between employer and employed would lose much of their force and binding character.

Write as we have done or may, advocate certain principles of action as we may, tending, as we believe, to the general advantage of all parties concerned, the stubborn fact must remain, and it is well it should be so—that all such matters must be settled by a clear understanding between the master and the servant. The former has a perfect right to decide how he will be served, what he prefers to have grown, and what shall be done with every part and particle of the produce; the gardener has just as perfect a right to decide whether he will cheerfully give his services on these conditions.

There is seldom a real grievance or hardship in such cases. True, we have known instances and heard of others in which employers, ignoring such conditions, have wantonly committed reckless injustice; but, if even beyond the reach of legal redress, they were made to feel that they were not beyond the still more scathing condemnation of public opinion; and much as the gardening market is overstocked, there is still a growing demand for men who combine intelligence in their profession with strict moral rectitude, and nothing will prevent such men from ultimately succeeding. Still, it is always best to serve an employer in his own way, and when that is disagreeable or contrary to our cherished wishes, to terminate such a service in an honourable manner.

I am more particular on this point, because I believe that urging exhibiting on an employer as a privilege and a duty, is just much of a piece with representing the not exhibiting as an act of injustice. If "RIFLEMAN" gives an accurate version of the story as between him and his gardener, then, it is evident that the gardener has indulged in the too general but

perilous course, not only of deciding what would be best and most pleasing to himself, but also of deciding what should be the duty of an employer, and telling him what that duty and privilege is. Much would depend on the way in which that was done; yet, under any circumstances, the pointing out to an employer, by a servant, what his "duty" dictates in certain circumstances, is rather reversing the social order of things. Employers may be led, but few will bear to be driven. Had we been in the gardener's place, we would have urged exhibiting, if we wished to do so, on the grounds of its being a pleasure and a privilege to a gardener, and sound policy as respects the community; as most of the improvements of the day, from which employers and the public are receiving the benefit, may be traced to the stimulus and excitements of exhibitions. These might inculpate a sense of duty and privilege, which is very different from telling an employer what was his "duty," and what he must do to escape a charge of injustice.

The whole question, in fact, resolves itself into one of agreeable policy, and not one of justice or injustice. There is an old proverb, that "Every man would be a Pope if he could." Some men are more exposed to this egotism than others, and I fear we must class gardeners in retired places high up in this love for dictating. We all dearly like to have our own way. An exhibition often has the influence of shaking the conceit and egotism out of us, and comparing notes and opinions lets us often see our deficiencies. Even the best things, however, may be perverted; and there is no doubt that exhibitions have sometimes spoiled the best of gardeners, just because exhibitions became the all-in-all with them. "RIFLEMAN," therefore, has not only the right to decide whether his gardener shall exhibit or not; he might, from examples, adduce evidence that it would not be to his particular advantage that his gardener should exhibit. This should make exhibitors very careful that the general supply should suffer no diminution from their exhibiting. We have known many cases in which gentlemen have forbidden exhibiting because their tables were not supplied as they used to be.

On the other hand, we have known the most successful exhibiting associated with the strictest attention to general details; so much so, indeed, that the exhibitions were fully entered into by the employers as well as the gardeners.

Leaving, then, "RIFLEMAN" to come to the conclusions that may be prompted by his own feelings of publicity or retiredness, or merely from having an eye to his own private advantage, and waiving all about privilege and duty, there are two arguments that common policy will throw in his way. The first is, if such exhibitions improve the gardening of the neighbourhood, would he not like to have some hand in effecting that improvement; or will he take some other means to show his sense of these improvements in which, directly or indirectly, he must have a personal advantage?

Secondly, according to the account given of the gardener, if he is a little blunt, and not thoroughly conversant with social economy, he seems a thoroughly honest and more than ordinarily industrious man, working very long hours cheerfully, and seeking no holidays except going to an exhibition. Now, granting that his favourite hobby reaches the verge of enthusiasm—that the bee in his bonnet, if you will, is a very wild, loud, humming bee, would it not be sound policy, even consulting your own individual advantage, to give him a little of his own way, and let him exhibit as he wishes?

We know how men will toil in order that they may make a creditable appearance at an exhibition-table, and have the pleasure of dining and comparing notes with their brother competitors afterwards. We know, also, that when such stimuli are withdrawn there is less of an inducement to labour; and a man comes to feel that he has a right to stand out for something like regular hours. Even these hours insensibly may not be worked with the same spirit and earnestness. As stated previously, long hours can only be continued when there is a suitable stimulus presented: hence we have known cases when gentlemen interdicted their gardeners from competing, there was not in their conduct a thing they could pick out as a fault; but insensibly, and by degrees, the superfine productions melted away, and the employers came to the conclusion they had gained little by the change.

In conclusion, then, believing that "RIFLEMAN" may have good reasons for not exhibiting, for causes which he alleges or otherwise; yet we are so sure that a gardener will not continue the industry and the long hours of which he speaks without

some encouragement, that we would earnestly present the above advice, and if that is not suitable, then send him up to the International Exhibition, paying all expenses; and allow by other modes, if you disapprove of exhibitions, that you can thoroughly appreciate industry, activity, and attention to your interests.

One word more as to justice and injustice about exhibitions. First, let there be no mistake about the matter, but have everything clearly understood. I knew a case of one of the richest men in England encouraging his gardener to exhibit at a horticultural show; and in this, by downright hard work and industry, he managed to receive a good number of prizes. When settling-day came, he was asked to see his employer in his study, who read-off all the tickets of prizes, and then coolly pocketed the money without as much as "I thank you" to the gardener, who won them by extra toil and labour! Need I say the rich man pocketed no more money from that source?

A greater injustice than even this is perpetrated when an employer becomes a member of a country society, and tells his gardener to prepare things for exhibition, and yet gives no other encouragement; and would, after all, object to having the best plants removed, because they would disarrange the appearance at home for a day or two. In such a case, justice requires there should be no exhibiting.

Again, there are employers that are fond enough of taking prizes, but will do nothing to assist in getting prizes; nay, grumble because their gardener does not stand in the front rank, when they have given no help to enable him to do so—gave him nothing at all to work upon, except a grumbled mere labour power. I once heard a great lady rate her gardener in an exhibition-room because he did not hold the first place, telling him that they spent enough and as much as anybody, and ought to be first. If, instead of a prudent man who there pocketed the affront, the lady might there and then have been told that, whilst the successful competitors had spent hundreds and hundreds of pounds on new and desirable things, she had taken care not to spend ten pounds for such a purpose in the ten years he had been in her service. In one sense, such a statement would have been supererogatory, as few of any note there did not know that the maxim with this lady was to get all she could, and spend as little as possible. Now, in all such cases, the gardener is only unjust to himself if he takes his plants to exhibitions. Without being encouraged by the purchase of the best new things, common prudence would say, Let exhibiting mostly alone. Few exhibitors can continue to exhibit satisfactorily unless their employers not only permit it, but give it unmistakably their active encouragement, or enter into such arrangements as will present a purpose in and a stimulus to exhibiting.—R. FISH.]

## PARIS, JULY, 1862.

MONS. MARGOTTIN, BOURG-LA-REINE.

I HAD partly prepared a few remarks in connection with the great Rose shows of the past season and the novelties that have been brought before us; but the time for paying a projected visit to Paris arrived, and in the bustle and hurry of preparing to depart and of leaving all one's parochial matters in their due train, the paper was thrown aside, I consoling myself with the idea that I might perhaps finish it during my short sojourn there. But, alas! Sight-seeing in the month of July, even although it was not so warm as Paris is generally during this month, was by no means conducive to mental application, however slight; and as disappointed people always look for that "fool's paradise" to-morrow, I had e'en to think that day by day I should be able to do something. When all hope of this vanished I had got a best bower-anchor left, and to that I must certainly trust—viz., that I was obtaining newer information on the subject of Roses especially, and that in this respect I should be beforehand any of my fellow mariners in England. It was with no ordinary pleasure that I revisited my former acquaintances in the horticultural world; and the intelligence and kindness of all with whom I came in contact naturally enhanced the pleasure of my visit: and while all were ever ready to impart any information, I cannot but say that the impression that was made on my mind last October was fully confirmed now—that of all Rose-growers in France Mons. Margottin, of Bourg-la-Reine (or, as we should call it, Queensborough), is the most thoroughly practical. His son, too, is a most intelligent young

man; and the whole establishment evidences the thorough manner in which the Rose has been cultivated. An expression which dropped from him when we were strolling round his garden clearly showed the man. We were speaking of some curious points in common with his *spécialité*, when he exclaimed, "Ah! Monsieur, c'est une étude!" A man who has devoted a lifetime to its cultivation, with the feeling on his mind that it is a veritable study, is as likely to know as much about it as the celebrated Bonnet did of that caterpillar (*Cossus ligniperda*), to whose anatomy he devoted twenty years of scientific research. He is not a man who talks largely of what he has done, or who makes use of the brains of other men as if they were his own (a by-no-means-uncommon thing), but one who watches over his pets as a judicious parent over his children—studying their idiosyncracies, humouring their prejudices, and applying to each the peculiar treatment they require. The immense demand for Roses in England during the past season and the failure of the seed of 1860 (that fearfully wet year), have combined to make a material difference in the appearance of his garden—and Oats now occupy the place devoted last year in some parts of his garden to Roses. The first bloom, too, was nearly over. A few flowers were, however, still left—smaller, of course, than the earlier ones, but just sufficient to show the character of the flowers.

In speaking of the exhibitions here this year, I happened to mention the blooms of Comtesse Cécile de Chabillant shown by Mr. Cant, which were so beautifully mottled. He said, "Come and I will show you something of the same kind." And truly there was a bloom very similar to, although not, perhaps, so beautifully and regularly marked as the one I allude to. "And now," he added, "I will show you a curious thing." It appears last year he had a somewhat similar bloom, and that, believing it could be perpetuated, he budded it. In one sense his conjecture came true—the *panachée* character of it remained, each bloom being regularly mottled, but in other respects the Rose had lost its character; the exquisite shape and the delicate turn of the petals were gone, and the flower was a loose and open one with about half the number of petals. His idea is that it is disease—a disease which (as all Frenchmen delight in philosophising), he ascribes to sudden changes of temperature, comparing it to the affections in the human body which oftentimes ensue when a cold air or water is supplemented on a highly heated state of body. The poverty of the flower when propagated would seem to bear out this idea, and may perhaps add an atom to the controversy now carried on as to the cause of variegation in general. There were other items of this subject which were new to me. He says that every "panachée" Rose has been a sport—that is, one has never been raised from seed. This rather confirms the notion which one entertained—that *Triomphe d'Amiens* was a sport from *Général Jacqueminot*. This he stated positively was the case; and hence when some complain that it is no other than *Jacqueminot* they may be speaking of some which have reverted to the original type.

Mr. Cranston complained of Mr. Andrews' figure in the *Floral Magazine* of this flower that it was too highly coloured, and that he had a hundred blooms of it, but none like the figure. Another fact which Margottin mentioned throws some light on this. He confirmed what we have always thought—that *Madame Campbell d'Isly* is merely a sport from *La Reine*; but while showing me a whole row in which every bloom was beautifully mottled, he said at Paris it never came otherwise than as *La Reine*. What the climate of Paris, then, does for it hereford may for *Triomphe d'Amiens*. When these caprices are shown in the Rose it only shows how careful we must be in generalising upon individual facts or places, and how important to gather as many data as we can from various localities.

Again, I learned for the first time that *Panachée d'Orleans* and *Madame Desiré Gerand* were both sports from *Baronne Prevost* and came in the same year, the one at Orleans, the other at Valenciennes, and that in each case a change had taken place in the constitution of the plant—that *Panachée d'Orleans* was entirely without thorns and *Madame Gerand* was largely covered with very minute ones of quite a different character to those of *Baronne Prevost*. I do not know whether Mr. Cant has attempted to propagate from the branch of *Cécile de Chabillant* from which his blooms were cut; but if he has, I should be curious to know the result.

I saw a large number of blooms of *Souvenir de Comte Cavour*, and am quite persuaded this Rose has not been seen to advantage in England yet, nor were the blooms that I saw of it at

M. Margottin's at all fair one to judge by; but I feel certain that it will be, from its brilliancy of colour and regularity of petal, a great favourite. The same thing is said in France as we find here—viz., that plants are so hacked and hewn about that it is impossible to tell for the first season what they will be. *Alexandro Dumas*, too, was much brighter and richer than I had before seen it; the dark appearance indicating more age. "The only Rose which seems," says Margottin, "to grow brighter as it grows older is 'Lord Palmerston.'" Curious, I thought; is not this the character of the man himself, whose brilliant career certainly seems to acquire greater brilliancy as he has reached that term of life when most other men consider that life's business and cares are not for them, but who is "as ready to give as good as he gets" as any youngster of twenty-five? And what shall I say of *Boule d'Or*? Why, that I saw one blossom of it, beside which *Cloth of Gold* (or *Chromatella*, as it is called in France) was even dull; but although this was cut from the open air, I fear that, in our less favoured climate, we must consider it as a greenhouse plant.

Of *New Roses*, *Mons. Margottin* has but two to send out this autumn; one of these, *Louise Margottin*, will be a decided acquisition. It is a seedling of *Louise Odier*, of the same shape and character, the colour a very light blush pink, and the habit vigorous—in fact, I should, perhaps, well give an idea of it when I say that it is a *Modèle de Perfection* in the Hybrid *Perpetuals*, fuller and more vigorous in growth than that pretty *Bourbon*. I very much mistake if this will not be a very favourite flower. It is a somewhat curious thing, that although *Louise Odier* was raised by *Mons. Margottin* fifteen years ago, and has always seeded freely; and although he has had *Roses* from it of all shades of colour, from pure white up to dark crimson, that they have all proved worthless in their habit, and have departed in the first or second year of their brief existence, here, at last, he has obtained one vigorous in habit, and good in other respects. The other Rose, also a Hybrid *Perpetual*, was not in bloom, and is not yet named; I conclude, therefore, that *Louise Margottin* is the better of the two.

We had much more interesting talk on the *Roses* of the past season. *M. Margottin*, who is no bad judge, considers *François Lacharme*, *Duc de Rohan*, and *Chrétien Pulteny* as excellent *Roses*; while, as with us, two of his favourites are *Senateur Vaisse* and *Cécile de Chabillant*. He deprecates the flooding of the market with new *Roses*—a matter which must find its level; and he was delighted with the figure I showed him of "John Hopper"—a Rose, I believe, not likely to be surpassed by any arrivals from the Continent this season.

I have again to record the extreme kindness with which I was received; and, after a pleasant and profitable forenoon, found my way back to Paris, of which more another time.—*D. Deal.*

## SOWING AND PLANTING THE CABBAGE.

DURING the hot and sultry month of August it is not always an easy matter to induce seeds to grow, of which the natural period of vegetating is at another season, but it is not always hot and dry, and when it is so some artificial means must be taken to insure the conditions necessary for success; and however simple these may be, it is of the greatest importance to the crop now under consideration that attention be paid them; and though August may possibly be a dull and showery month like the two last that preceded it, yet, assuming it to be dry, bright, and sunny, with only an occasional thunder-shower, some little care will be wanted to secure a good breadth of young plants for next year's supply. As there are few other crops in which an omission in the sowing and rearing of a batch of plants is attended with such bad consequences, it cannot be too strongly impressed on the kitchen-gardener to endeavour by all the means he can command to secure a good brood of healthy young Cabbage plants fit for planting out at the proper time, and also be sure that the variety he has is one not likely to run to seed in early spring, and is in other respects a suitable one for the purpose wanted.

I believe it will be generally admitted that the Cabbage, taken as a useful early vegetable, has improved as much in the last twenty years as most products of a like kind. The liability to run to seed in March has to a certain extent been got over, and plants of a larger size and greater age are made to stand the winter and form nice useful heads in early spring than was the case in years gone by.

It is well known that the parent plant of the cultivated Cabbage flowers in spring, ripening its seed and shedding it on ground as hard as the beaten path of a public highway. On this it vegetates in due time and propagates its species; but in the cultivated varieties something else is required than merely the reproduction of plants, and a few hints on the conditions necessary to insure success in the several operations of sowing, planting, selecting varieties, &c., will, perhaps, be the best way of elucidating this.

*Time of Sowing and the Mode of Doing It.*—By the time this Number reaches the readers of THE JOURNAL OF HORTICULTURE, it will be quite time to sow the principal batch; in fact it would have been as well if a few for early use had been sown late in July, as it is important that a few for very early use should be tried. We have sown some as early as the 24th of July, and succeeded pretty well. Generally, however, it is not safe to trust too much to these early sowings, as they are apt to run to seed in March; but a few might be tried each year, and if sown at two or three intervals between the 22nd of July and the 15th of August, the last may in all cases be depended on if the former fails. In a general way, however, it is better to hasten on a few of those sown the first week in August, by giving them some good ground to grow in, and whatever encouragement they can have in order to encourage their growth in the autumn and mild winter months; but, as before stated, a few of the earlier ones ought also to be trusted, but by no means for the main crop. However, if a crop has been sown take the necessary care to save them, and let everything be done to insure their growing; and in sowing fresh batches of seeds, if the weather be dry and the ground has been dug some little time—say a month or so before, let it be trod evenly over and the seed sown; then rake and finally beat over with the back of a spade, afterwards cover it with a few old pea boughs, and over this a little pea haulm, and if the weather still keep very dry, water the bed pretty well in three or four days after, letting the covering still remain, and the probabilities are, that in a week or so an excellent bed of seedlings will reward the care; but attention to them must not cease when the young brood is up, for the fly is very apt to play havoc with them if not retarded. When, therefore, this appears likely, dust the plants over carefully with soot, or soot and lime, or wood ashes, or all three mixed, and if the evil still appears unchecked water gently with a weak decoction of tobacco. This last is rather an expensive item where it has to be extended over a large space; but for a small quantity which it is important to save, it may be done with advantage. It is proper to observe, that the shading mentioned above must be removed when the plants are fairly up, taking advantage of a dull damp day for the purpose, or if it still continue bright and sunny remove it by degrees.

*Varieties Suitable for Sowing Now.*—It is a difficult task to name the kinds that might be expected to do best everywhere, as local circumstances exercise so much influence on them; but I may say that some of the early kinds, of which the old Early Dwarf York was the type, will be found to answer for the earliest crop. The distinguishing features are a plain rather deep green leaf, and dwarf and somewhat small habit, for this reason they may be planted closer. Shilling's Queen and Matchless are somewhat in this way; while the larger sorts, more truly "Sugar Loaf," and with leaves more or less glaucous and wrinkled, are represented in the Imperial, East Ham, Enfield Market, and many others. This class is, however, hardly so hardy as the former, but they are equally good in resisting the temptation to run to seed. It is, however, better not to depend on one kind only, and it not unfrequently happens that a local variety unhonoured by any name possesses all the qualities wanted in a Cabbage. When such can be obtained do not let the high-sounding title of one paraded forth in print prevent you using it, and it is very likely it will do better service than the more assuming one. It is, therefore, best to sow three or four kinds, and to plant a few of each, and if they be all good so much the better, and if one fail it is better so than if they were all bad.

*Subsequent Planting-out.*—The early sorts to come into use in early spring ought to be planted on a south border which had previously been well manured. These may also be planted somewhat closer than the main crop—the rows say 2 feet apart, and the plants 18 inches in the row. The main crop may be 6 inches more each way, and may consist of the larger kinds mentioned above. This plantation may be somewhat later than the other, and in the open quarters of the kitchen garden. Besides these

two permanent plantations, it is prudent in many cases to plant out a large batch on some prepared bed, as a nursery-bed, to stand the winter, for planting-out in spring, or to fill up gaps in the main crops. The plants also by being planted-out thus do not become so elongated as when left in the seed-bed, and are, consequently, in a better condition to plant afterwards when wanted.—J. ROBSON.

#### STEMS OF MELON PLANTS SPLITTING.

THE plants died away very suddenly by splitting up the stem just above the surface of the earth; likewise several of the strong roots, near the stem, of some of the plants cracked or split up. It occurred when the fruit on the plants was nearly half-swelled, and in a few days after a heavy watering had been given them, the first watering after the setting, the border having become very dry at the time. The plants were remarkably strong, clean, and healthy.—T. T.

[Rich soil, too much bottom heat, dull weather, and too much water at once, are the chief causes of the misfortune. Melons, like men, must have changes presented to them gradually. If a man were next to famished, what would be the result of giving him as much fat beef as he could eat? We hope, however, you will make no uncharitable use of this, for you say the loss occurred to a neighbour. We prefer people stating their *own* case, and our help is given to assist if we can—never to gratify mere curiosity, or to encourage fault-finding.]

#### GLOUCESTER FLOWER SHOW.

WEDNESDAY last was a high day in the ancient city of Gloucester. On entering the town on the morning of that day the stranger was forcibly informed that some great event was being celebrated, by the profusion of banners that floated in festoons across the streets, or hung in lazy grandeur from the windows of the houses. On that day the Mayor and Corporation were to present the inhabitants with a new park, and the occasion was to be celebrated by a grand meeting of the Gloucestershire Agricultural Society, with which a great Flower Show was to be associated. The Exhibition took place in the ground which has been set apart for the new park; that devoted to flowers was held in a paddock adjoining the pump-room, where two large tents were erected for the reception of the exhibitions. The larger tent was arranged with a wide stage down the centre and one on either side. On the centre stage were some very excellent examples of fine-foliaged plants, and these formed the main attraction of this part of the Show: indeed, had it not been for the nurserymen who exhibited in this class, the whole would have presented a very meagre appearance. We regret to say, that from what we saw on this occasion we were not induced to form a very high estimate of the horticultural taste of the gentry of Gloucestershire; for with the exception of the meritorious exhibition of fine-foliaged plants from Mr. John Hunt, gardener to Lord Fitzhardinge at Berkeley Castle, there was nothing from any private grower that contributed a prominent feature to the Exhibition.

As the agricultural portion of the Show does not come within our province, the observations we have to offer will be confined to the flowers and fruits.

The prizes offered for flowers and fruits were on the most liberal scale, and it is to be regretted that in Class A, for 15 Stove and Greenhouse Plants, £28 should have been offered and called forth so poor a response. This was, perhaps, the weakest part of the Show, considering the inducement held out, and consisted of only one competition to which the first prize of £15 was awarded, the fortunate winner being Mr. James Cypher, of Cheltenham. There was nothing remarkable in any of the specimens, for they were just such as might be brought from the houses of any well-conducted nursery. They consisted of *Allamanda cathartica*, *Rondeletia speciosa*, *Erica inflata alba*, *Kalosanthes phœnix*, *Achimenes Ambrose Verschaellé*, *Statice Holfordi*, *Erica vestita rosea* (scarcely in bloom), *Ixorajavanica*, *Russelia juncea*, *Allamanda Schottii* (badly flowered), *Erica tricolor elegans*, *Achimenes Sir Treherne Thomas*, and *Erica Jacksoni*. We think it was rather an oversight on the part of the Committee to offer £15 for Stove Plants at this season of the year when they are past their best, and to restrict the Class of Fine-foliaged Plants, which, in fact, contributed the best part of the Exhibition, to £5.

In Class B, for 10 Stove and Greenhouse Plants, there were only two competitors, and their exhibitions were such as to induce the Judges to withhold the first prize. The second prize was awarded to Mr. Pilgrim; and the third to Mr. Hooper, both of Cheltenham.

In Class C, 6 Stove and Greenhouse Plants, the first prize was awarded to Mr. Hamlett, of Cheltenham. This exhibition contained a good specimen of *Hoya carnea* variegata, and a pretty good specimen of *Statice Hoffordii*, but with these exceptions there was nothing worthy of special mention. The second prize was awarded to Mr. Dingle, gardener to T. B. L. Baker, Esq., of Hardwicke Court; and the third to J. J. Marling, Esq., Stanley Park.

In Class D, 6 Ornamental-foliaged Plants, the first prize was awarded to Mr. John Nelson, nurseryman, St. Michael's Hill, Bristol. These were handsome, well-grown specimens, and consisted of *Latania borbonica* (Palm), *Thamnopteris australasica* (Fern), *Maranta zebra*, *Cyanophyllum magnificum*, *Sphaerostemma marmorata* (a very excellent specimen), and *Alocasia metallica*. An equal first prize was given to Mr. Heath, nurseryman, of Cheltenham, for *Pandanus utilis*, *Cyanophyllum magnificum*, *Pandanus javanicus* variegatus, *Alocasia metallica*, and *Croton pictum*. The second prize was awarded to Mr. John Hunt, gardener to Lord Fitzhardinge, for *Cyanophyllum magnificum*, *Caladium Chautini*, *Maranta Warzewiczii*, *Croton elegans*, *Dracæna variabilis*, and *Colens Verschaffelti*. All honour to Mr. Hunt, who was the only gardener in the county who came forward and so nobly upheld the credit of his craft.

In Class E, Collection of not more than 30 Plants grouped for effect, the first prize was awarded to Mr. Heath, of Cheltenham. This was altogether a very creditable exhibition as regards the plants themselves, but we should like to have seen more taste displayed in the grouping. With such materials much more could have been made of them. On one side of the stage a magnificent specimen of *Asplenium nidus* occupied the centre, the longest fronds of which measured  $\frac{1}{2}$  feet long. To the left of this, as you look at it, the group was perfect, and consisted of very fine plants of *Coleus Verschaffelti*, *Pandanus javanicus* variegatus, *Dicksonia antarctica*, and *Yucca aloifolia* variegata. Between the *Asplenium* and the *Coleus*, and standing a little forward, was a nice plant of the true *Cordyline indivisa*. To the right of the centre plant the grouping was decidedly weak in effect, and came far short of the other side, both in regard of colour, form, and harmony. On the right of the *Asplenium* was a small specimen of *Maranta truncata*, contrasting, but certainly not matching, with the *Cordyline* on the left. Then followed a tall leggy *Croton pictum*, which harmonised ill with the fine round bushy *Coleus* on the other side, *Pandanus utilis*, *Aspidistra variegata*, and *Cycas revoluta*. The ridge of the collection consisted of *Cordyline smaragdina*, *Phoenix dactylifera*, *Aralia leptophylla*, *A. pulehra* (an elegant plant), *A. reticulata*, *Caladium atro-purpureum*, *Angiopteris longifolia*, and *Grevillea robusta*. The other side of the group did not seem to have a centre, and was composed of *Platycerium stemmaria*, *Croton longifolium*, *Cyperus alternifolius* albo-*vittatus*, *Alsophila australis*, *Latania rubra*, *Pyrostrea polymorpha*, *Rhopala Skinneri*, *Caladium pictum*, *Calathea zebra*, and *Dracæna ferrea*. The second prize was awarded to Mr. Nelson, St. Michael's Hill, Bristol, who exhibited a very nice collection of well-grown, young, healthy, and vigorous plants; they were not so large nor so tall as those of Mr. Heath. It contained some very good specimens, particularly one of *Cyanophyllum magnificum*, the leaves of which were 27 inches long. Among the most noteworthy we observed *Curcuma Roscoeana*, *Curcuma rubricaulis*, *Pteris argyræa*, *Philodendron pertusum*, *Pandanus javanicus* variegatus, *Pteris cretica* albo-*lineata*, *Costus elegans*, a fine specimen of *Gymnogramma chryseophylla*, *Campylobotrys repulgens*, &c.

In Class F, for Ornamental Baskets of Flowers, there was a very meritorious exhibition by Mr. C. E. Brydges, of Cheltenham, which obtained the first prize. It consisted of a rustic stand with three circular tiers; the outsides of the tiers were covered with green moss, and the interiors were filled with *Hydrangeas*, *Scarlet Geraniums*, *Fuchsias*, *Petunias*, *Phloxes*, *yellow Calceolarias*, &c., relieved with fronds of *Lastrea dilatata* and *silix-mas*, the whole adorned with a neat plant of *Dracæna variabilis*. Here and there was introduced the graceful pendent foliage of *Gynerium argenteum*. The base of the stand was also covered with green moss and planted with small plants of *Coleus Verschaffelti*, relieved with pieces of *Hydrangea varie-*

*gata*, and short fronds of *Lastrea dilatata*. The other two exhibitions in this class were stiff and formal, partaking too much of the village-festival style of decoration to be either artistic or pleasing.

In Class G, Mr. C. E. Brydges, of Cheltenham, exhibited, and received the first prize for 12 well-bloomed *Fuchsias*.

In Class H, Mr. A. Maisey, of Cheltenham, exhibited 6 very handsome and well-bloomed plants of *Fuchsias*, which obtained the first prize; the second was awarded to Mr. C. E. Brydges.

In Class I, Mr. Hooper, of Cheltenham, took a first prize for 6 *Roses* in pots, in praise of which we cannot say a great deal.

In Class J, for Cut *Roses*, Mr. Morse, nurseryman, Dursley, was first; and Mr. Walters, gardener to James Akers, Esq., Prinknash Park, was second. Neither exhibition was anything to boast of. But why did the Committee offer £1 10s. for twelve cut blooms, and only £1 for six plants in pots? Surely they do not suppose there is more merit in cutting twelve good blooms from out of doers than there is in blooming six good plants in pots, apart altogether from the expense of production and transmission.

Among Miscellaneous Plants, Mr. Hodges, nurseryman, Cheltenham, exhibited a nice stand of *Carnations* and *Picotees*; and Mr. Dingle received an extra prize for a collection of plants which contained some good specimens of *Begonias*; among which were *Regina*, *Rex*, *Rollisoni*, and *Marshalli*.

The show of Fruit was not remarkable nor so good as we had expected from a district so rich as is that of Gloucester and the adjoining counties.

In Class O, the only exhibitor of *Pines* was Mr. Hunt, of Berkeley Castle, who took a first prize with two small *Queens*.

In Class P, for two dishes of Black and two of White Grapes, Mr. John Hunt, of Berkeley Castle, was first for both Black and White. The former were Black Prince and Frankenthal (shown as Black Hamburg), and the latter Golden Hamburg and Bowood Muscat. William Metcalfe, Esq., of Clifton Gate, was second for Black, with Frankenthal (shown as Black Hamburg), and *Barbarossa*; and Mr. Cramb, gardener to the Earl Ducie, Tortworth Park, was second for White, with Muscat of Alexandria and Golden Hamburg. This exhibition was good, but the Muscats looked green and not quite ripe. The Golden Hamburg was very good for that variety which requires so much management in its cultivation.

The first prize for Melons was awarded to Mr. A. V. Temple, gardener at Colesbourne, and the second to Mr. Cramb, of Tortworth Park.

In Peaches, J. W. Halliwell, Esq., of Stroud, was first with four large *Bellegardes*; and G. S. Wintle, Esq., of Gloucester, was second with a capital dish of Barrington's. Mr. Halliwell, was also first in Nectarines with Pitnaston Orange.

In Class T, for Collections of six dishes of Fruit, Mr. Cramb took the first prize. This collection was tastefully arranged and altogether meritorious, it consisted of Hybrid Green-flesh Melon, Frankenthal, and White Muscat Grapes, Bigarreau d'Esperen Cherry, very fine; Florence Cherry, also very fine; and Brown Turkey Fig. Mr. Halliwell was second. This collection consisted of a dish of Nectarines, two indifferent *Pines*, two bunches of Frankenthal Grapes, six indifferent over-ripe Peaches, Muscat Grapes, and a dish of Plums. In the Collection of four dishes of Fruit, Mr. Hunt was first with a Queen Pine, a Bromham Park Melon, Muscat of Alexandria, and Frankenthal Grapes. S. Marling, Esq., of Stanley Park, was second with Frankenthal Grapes, White Dutch Currants, Late Duke Cherries, and a Melon.

In Class V, for Vines in Pots, Mr. Hunt, of Berkeley Castle, had two first-rate plants of Black Hamburg laden with fine large bunches of fruit, but which were so awfully rubbed, that they shone like glass balls, some of the spectators remarking, "Oh! they are only tied on." Mr. Holder, of Cheltenham, was a bad second.

As is proper after such an occasion the time-honoured ceremony of a dinner was celebrated in a large marquee, and at which Edward Holland, Esq., M.P., of Dumbleton, acted as Chairman. The finest feature on this occasion was the presence of ladies, who seemed to enjoy the effect of these social meetings equally as much as the sterner portion of the community. The substantial portion of the entertainment was well served; but of the wines—what shall we say? Hock in Gloucester signifies something resembling the risings of a cask of very bad cider. Where were the stewards?

## AN ACT FOR THE PROTECTION OF CERTAIN GARDEN OR ORNAMENTAL GROUNDS

IN CITIES AND BOROUGHS.

THE following are the chief clauses in a Bill now before Parliament, and which, if passed, will bear the above title :—

"Whereas it is expedient to make provision for the better protection and charge of enclosed garden or ornamental grounds which have been set apart for the use of the inhabitants of any square, crescent, circus, street, or place surrounding or adjoining such gardens or grounds in any city or borough: Be it enacted—

"1. Where in any city or borough any enclosed garden or ornamental ground has been set apart in any square, crescent, circus, street, or place, for the use or enjoyment of the inhabitants thereof, and where the trustees, commissioners, or other body appointed for the care of the same have neglected to keep it in proper order, or where such garden or ground has not been vested in or placed under the management of any trustees, commissioners, or other body for the care of the same, and from the want of such care, or from any other cause, has been neglected, the Metropolis Board of Works, where the same is in any place under their jurisdiction, except the City of London (where the provisions of this act shall be carried into effect by the Corporation of the same City), and the Corporate Authorities in any other city or borough, shall take charge of the same, putting up a notice or notices to that effect in such garden or ornamental ground, and if after due inquiry the person entitled to any estate of freehold in the same cannot be found, or if it shall be vested in any person by whom it is held, subject to any condition or reservation for keeping the same as and for a garden or pleasure ground, or that the same shall not be built upon, but not otherwise, shall cause any buildings or other encroachment made therein within the period of twenty years before the passing of this Act to be removed, and (if requested by a majority of two-thirds of the owners and of the occupiers of the houses surrounding the same) shall vest such garden or ornamental ground in a committee consisting of not more than nine nor fewer than three of the rated inhabitants of such houses to be chosen annually by such inhabitants; and the Vestry or Board of any and every parish or district within which the same or any part thereof is situate shall from time to time cause to be raised the sums required by such Committee for defraying the expenses of the maintenance and management of such enclosed garden or ornamental ground, or of such part thereof as is situate within their parish or district, by an addition to the general rate to be assessed on the occupiers of such houses; or if the said owners and occupiers shall not agree as aforesaid to undertake the charge of such garden or ornamental ground, the Metropolis Board of Works or Corporate Authority aforesaid shall, within six months after the notice hereinbefore mentioned shall have been put up within the same, or within such further time as the said Board or authority may think it expedient to allow for such agreement to be come to, vest the same in such Vestries or Boards, who shall thenceforth take charge of and maintain the same as an open place or street in such manner as shall appear to them most advantageous to the public, subject to the approval of the Metropolis Board of Works or Corporate Authority, as the case may require; saving and always reserving to every person or persons, his and their heirs, executors, administrators, and assigns, all such estate, right, title, and interest as he, she, or they would or ought to have had and enjoyed of, in, to, from, or out of the gardens and grounds aforesaid in case this Act had not passed.

"2. And whereas the public are greatly interested in the maintenance of such gardens and grounds as open spaces, and it is expedient that the same should be carefully protected from undue encroachment, where any right to require that any garden or ornamental ground as aforesaid be kept and maintained as such, or that the same shall not be built upon, shall belong to any person in right of any house or other property, and he shall by notice in writing signed by him addressed to the Metropolis Board of Works where the same is in any place under their jurisdiction, except the City of London, where the same shall be addressed to the Corporation of the said City, or in any other city or borough to the Corporate Authorities thereof, requesting the said Metropolitan Board of Works or Corporate Authority to protect the right before-mentioned, the said Metropolis Board of Works or Corporate Authority, after due inquiry, may, if they shall think fit, accede to such request, and then and thereupon the right of such person to require that such garden or ornamental ground to be maintained as such, or that the same shall not be built upon, shall thenceforth be vested in such Metropolis Board of Works or Corporate Authority, who shall be fully empowered, for and in their own name, to exercise all the rights, powers, and privileges in relation thereto, and take such legal proceedings for asserting, defending, and protecting the same as the said person might have exercised or taken.

"Any charge incurred by the Metropolitan Board of Works in the execution of this Act shall be deemed to be expenses of the said Board for payment whereof provision is made by the Act for the better local management of the metropolis; and the expenses incurred by any Corporate Authority shall be deemed to be expenses necessarily incurred by them in carrying into execution within and for their city or borough the Act intitled 'An Act to provide for the Regulation of Municipal Corporations in England and Wales,' and any other Act amending the same.

"3. Where any such garden or ground is managed by any committee of the inhabitants of any square, crescent, circus, street, or place, such committee may make, and from time to time revoke and alter, byelaws for the management of the same, and for the preservation of the trees, shrubs, plants, flowers, rails, fences, seats, summer-houses, and other things therein, which byelaws shall be entered in a book kept for that purpose by the committee, signed by the chairman of the meeting at which the same shall be passed, and which book shall and may be produced and read, and taken as evidence of such byelaws, in all courts whatever, and any inhabitant, or servant, or other person admitted to such garden by any inhabitant, offending against the same, after they shall have been duly allowed, as hereinafter provided, upon proof thereof before a Magistrate acting for the district in which such garden is situate, shall be liable for each offence to a penalty not exceeding five pounds: Provided always, that such byelaws shall not come into operation until the same shall have been allowed by some Judge of one of the Superior Courts, or by the Justices in Quarter Sessions; and it shall be incumbent on such Judge or Justices, on the request of such committee, to inquire into any byelaws tendered to them for that purpose, and to allow or disallow the same as they think meet.

"4. Any police constable who shall see any person throwing any rubbish

into any such garden, or trespassing therein, or getting over the railings or fence, or stealing or damaging the flowers or plants, or committing any nuisance therein, may apprehend such person, under the authority hereby given to him; and any person convicted before any Magistrate acting for the district shall be liable for each and every offence aforesaid to a penalty not exceeding forty shillings, or to imprisonment for any period not exceeding fourteen days."

## THE ROSES AT REED HALL, COLCHESTER.

IN No. 68 of THE JOURNAL OF HORTICULTURE, Mr. Beaton makes the following statement—"That a hundred to one if Mr. Hedge does not give sprats, starfish, &c., to his Roses, and that is how he gets off with all the prizes." Fearing this assertion might mislead the Rose-growing portion of the public, and excite the ire of another class—the cod-loving portion, by anticipating a dearth amongst that (to them) interesting body of marine residents, these considerations have induced me to offer a few facts, to such of your readers, of what I saw and heard at Reed Hall. My intention is to be brief, as I have no time for perambulating the fields of Walker or Webster; so I will begin at the beginning and take you to the end of my ditty, as soon as the subject will permit.

One portion of the grounds is laid out in geometrical beds and filled with standards, each bed being planted with one *recherché* kind. Another portion is laid out in beds of about 6 feet wide, running the length of the quarter, with walks between, filled in a miscellaneous manner. Mr. Hedge is also an enthusiastic cultivator of other florists' flowers. From the appearance of his Dahlia-ground, I think he intends contesting the championship in this "fancy." I may also state that our hero is a systematic man, which is even carried out in his tool-house, which I fancy would satisfy Mr. Fish; not only the tools, but every label lies in due order. On show days there is no bustling about writing labels—here they are all ready for use, placed in separate compartments, with the initials outside. He is no six-o'clock man, but expects things to be done when circumstances require it, and his kindness insures their due performance. And now for his system of culture—it is very simple. The natural formation of the soil appears very favourable for the growth of the Rose, being a good, moderately-adhesive loam, resting upon a stratum of gravel, which insures good drainage. But, in order to assist Nature and insure success, he practises deep trenching, careful planting, sharp-pruning root and branch, biennial or triennial removal according to kinds, great care in cleanliness of plants and flowers. He has all stems well washed with a hard brush every winter, in a similar manner to fruit trees; the buds he keeps clear from aphid by drawing each tender branch between two soft brushes, which effectually clears them from this pest; and last, but not least, he makes a particular selection of blooms as to colour and age, so as to arrive at perfection on the exhibition-table.

Now about the "little fishes." On our expressing surprise at the luxuriance of his plants, he assured us that he had done nothing to his Rose trees this season in the shape of manure or disbudbing, except what they had when planted, which was a liberal supply of good farmyard manure (this gentleman has a home farm, which I daresay contributes in no small degree to his success). Notwithstanding his great success this season, he claims no merit to himself, but says that a moist season has done it, and that Nature frequently beats art. One other very significant assertion, and it was this—"When a prize is gained and the gardener forgotten, he seldom strives for more."

The following are the "gems" above referred to, which the champion says may always be relied upon for exhibition :—

HYBRID PERPETUALS.—Anna de Diesbach, Auguste Mîé, Baronne Prevost, Caroline de Sansal, Comtesse de Chabillant, Eugène Appert, Général Jacqueminot, General Simpson, Gloire de Vitry, Gloire de Santenay, Jean Bart, Joan d'Arc, Jules Margottin, La Ville de St. Denis, La Fontaine, Lælia, Lord Raglan, Louis XIV., Madame Boll, Madame de Cambacères, Madame Furtado, Madame Masson, Madame Vidot, Mdlle. Eugénie Verdier, M. de Martigny, Mathurin Regnier, Pauline Lauzeur, Prince Léon, Queen Victoria, Sénateur Vaise, Victor Verdier, Virginal, William Griffith, Madam Rivers, Comtesse de Kergolay.

BOURBONS.—Acidalia, Souvenir de la Malmaison, Baronne de Noirmont.

TEA-SCENTED.—Comte de Paris, Duc de Magenta, Devoniensis, Gloire de Dijon, Niphotos, Souvenir d'un Ami, Reine Victoria, Josephine Melton, Enfant de Lyon, Adam, Madame Sartot,

Rubens, Madame Damaizin, Madame Bravy, L'Enfant Trouvé Souvenir d'Elise Varden.

NOISETTE.—Triomphe de Rennes, Lamarque.

SUMMER ROSES.—Boule de Nanteuil, Coupe d'Hébé, Charles Lawson, Prince Regent, Shakespere, Bizarro Marbrée, Madam Hardy, Paul Ricaut, La Ville de Bruxelles, Ohl, Leo X., Juno.—S. AMEY, *Saling Grove Gardens*.

## PEACH CULTURE ON WALLS.

(Continued from page 311.)

**SUMMER TREATMENT.**—This season commences when the trees are coming into bloom, and ends when the leaves are fallen from the trees. The attention they require consists in, first, protecting the bloom; next, disbudding; third, thinning the fruit; fourth, watering; and lastly, destruction of insects and mildew.

**Protection.**—The shelters used for this purpose are various. Some use spruce fir branches tied to the main shoots, others use branches of beech with the dry leaves on; but these shelters are of but little use, and sometimes injurious. What is needed is a shelter from frost only; and, therefore, a contrivance whereby the trees may be covered at night, and exposed during the day, is far superior to a fixed one like the branches of trees. The best kind I ever used was made as follows:—A long board projecting from the top of the wall over the trees was fixed first, then to it a sufficient number of pulleys, through each of which a rope was threaded; one end was fastened to a pole on which was nailed a length of canvass or netting wide enough to cover the wall when let down. Another pole was fixed on posts near to the ground about 2 feet from the wall. To this pole the other edge of the canvass or netting was fixed. To keep the covering from the wall some rough larch poles were reared up at 6 feet or 8 feet apart. During the day, in mild weather this shelter was let down, resting upon the lower pole by means of a rope, and early in the afternoon it was drawn up, thus covering the trees completely. By this contrivance we sheltered the blossoms from frost by night, and exposed them to the warm sun during the day. In another place we used frames of wood, the height of the wall, made about 3 feet wide. These had thin canvass nailed to them, and when in use rested under a piece of wood nailed to the top of the wall, and on another laid on the ground. The frames were light, and easily moved. A young man in half an hour could remove them from a long wall in the morning, and lay them down in the walk on two pieces of wood to keep them from the damp, and replace them in the afternoon in the same time. This mode is rather troublesome, and, perhaps, expensive at first; but with care the frames last many years, and the protection they afforded was most effective. The late Mr. Errington always advocated the putting on of these shelters early, for the purpose of retarding the blossoms from expanding too early whenever a warm February or March occurred. Of course, when put up for that purpose, the sun is the object to be sheltered from; hence the protectors should be kept on during the day. No doubt other modes of shelter might be devised; but the object should be kept in view of not retaining them on in mild weather during the day, nor too late in the season.

**Disbudding.**—I have already incidentally mentioned this part of the summer treatment under the head "Training," I need only repeat here that disbudding can hardly be done too soon. If the superfluous shoots are left on too long they absorb that nutriment which should be given to the needful shoots, and also the scars that are made in removing them are injurious to the branches. The leading shoots must be left on to draw up the sap to feed the fruit; but they should have the end nipped off when about 8 inches to a foot in length. The shoots for bearing the fruit the following season should be retained their full length, and as soon as they are long enough should be nailed in. Give them as much space as possible, so that every leaf will have its due share of light. In this place let me warn the young grower against laying in too many summer shoots. Those growers that do so are under the erroneous idea that thereby they multiply the chances of a crop of fruit, whilst, in fact, the effect is the reverse. Crowded shoots injure each other; the leaves cannot perform their functions; the buds are all, or nearly all, wood-buds; and for want of light and air the wood in the autumn is crude and unripe;—all these fatal evils may be avoided by keeping the trees thin of wood during the summer, and also keeping the preserved shoots regularly nailed or tied close to the wall. Be careful, however, not to enclose the shoots too tight with the shreds or string.

**Thinning the Fruit.**—The Peach tree when healthy and its annual shoots properly ripened is very fruitful, and will set, as it is called, more fruit than will expand to full size and perfection; hence the advantage of thinning. The number of fruit that it may be advisable to leave on to ripen depends in some measure on the vigour of the tree. If very strong and healthy, the final thinning may leave a fruit to every square 6 inches the tree may cover of the wall; if moderately strong, extend the space for each fruit to 9 inches square; and if weak, thin them to a foot square. These distances may not be kept mathematically correct, for the fruit may be rather thicker in one part of the tree than another; but the number of fruit that is left should be such as would, if regularly and exactly placed, amount to the same quantity. At the first thinning, which should take place as soon as they are the size of a boy's marble, take away all that are of a bad form or are badly placed. At the second thinning remove such as are near the base of the bearing-shoot or near the top of it; and after the fruit has stoned thin them according to the above-mentioned distance, for then it may be considered certain that no more will drop off naturally.

**Watering.**—In dry seasons a good soaking of soft rain or river water will be necessary in order to swell off the fruit to the highest perfection. Some years gone by I visited a place in North Wales where there was a Peach-wall of considerable length. A new gardener whom I knew well had been engaged there. The owner told him that the Peaches and Nectarines were fruitful enough, but were always small and deficient in juice and flavour. His new gardener told him he could remedy that, providing the trees were left to his judgment to do what he thought proper to them. To this reasonable proposition the gentleman (who, by-the-by, was an amateur gardener himself, and perhaps had previously interfered too much), consented. The gardener then at the thinning time took away what he thought necessary; and when those that he left had stoned he opened hollows in front of each tree, and filled these hollows with water to the depth of 2 inches or 3 inches. The hollows or basins were filled up after the water had sunk into the soil. This was done three times during the time the fruit was swelling, and the effect was very remarkable—the fruit was above the ordinary size, and was well coloured and well flavoured. The water was withheld as soon as the fruit began to show signs of ripening, and was no more applied that season. The young wood was stronger, was well set with blossom-buds, and, as I was informed, the trees did equally well the following year. This example is, I think, worthy of imitation in all cases where the trees are rather weak, the border well drained, and where fine fruit is desired.

**Insects.**—The insects that prey upon the Peach during the growing period are the red spider and the green fly; woodlice and wasps also often feed upon the fruit when ripening. The red spider may be got rid of by frequent severe syringings. If very numerous, mix some sulphur among the water, which is also a remedy for mildew wherever it occurs. This remedy should be applied early in the season, but when the fruit is ripening it should be withheld, or it would disfigure the fruit; or if either the red spider or the mildew prevail after the fruit is gathered, then repeat the remedy till both are extirpated. The green fly is easily got rid of by syringing the trees once or twice with tobacco water. Woodlice harbour in old walls, and the only remedy is pointing-up the nail or other holes at the time the trees are loosened from the walls for pruning in the autumn. Considerable numbers may, however, be trapped during summer in hollow bean-stalks stuck behind the branches and emptied every day by blowing down them into a vessel containing hot water. When wasps are very abundant set traps for them. Wide-mouthed bottles half-filled with some sweet liquor are excellent traps, as are also doubled hand-glasses, the under one set on four half-bricks, one at each corner, with a hole or two made at the top, and then place the other hand-glass on the top of the first; put a plate containing sweet liquor on the ground under the hand-glasses. This will attract the wasps, and when satiated they will fly upwards, and make their way into the upper glass, where they will soon exhaust themselves, and finally perish. If the wall is a great length, and wasps prevail very much then these traps should be placed in a row in front of the wall at 20 feet or 30 feet apart. Of course the traps will catch not only the wasps that prey upon the Peaches, but also those that would otherwise attack any other kind of fruit in the garden.

T. APPLEBY.

(To be continued.)

## STYLE OF TERRACES OF DIFFERENT PERIODS.

BY H. NOEL HUMPHREYS, ESQ.

THE consideration of the style and character of the terrace, at distinct and distant epochs, is not without interest; and by the study of this—the historical part of the question—garden architects may frequently avoid absurdities and incongruities which are but too often found, and which, to the eye of the student of the subject, are at once glaringly and disagreeably apparent.

Few of our readers are unacquainted with the magnificent simplicity of the great terrace at Windsor Castle, which has been too often engraved to render its repetition here necessary; but a few remarks relative to the principles which should govern the construction of terraces of that description will not be out of place. In the first place, I hold that in imitations of any style of architecture belonging to a former period, the selection of site must be as carefully attended to as the architectural detail of the building; and, therefore, in buildings of a castellated character, an elevated position is, in most cases, absolutely necessary. Modern Gothic residences in the valley will be most successful in their effect, if the peculiarities of the monastic style are adopted; while those in elevated situations will derive a greater degree of appropriate feeling by the development of the castellated character. The two styles had many distinct lines of separation: first and most to our purpose is their respective treatment of that portion of ground prepared as a daily promenade—in the monastery, built generally in the valleys, where no extent or sublimity of prospect tempted the eye, an internal cloister was the promenade; in the castle, built on the commanded promontory, the rampart, from which the extended view of the plain below might be surveyed, became the favourite walk, which, in later periods, was widened into the rampart terrace—such is the one at Windsor. In this situation, the

terrace does not require blending into the landscape by any additional feature—the battlemented wall forms a sufficient modulation from the castellated features of the residence—and the park scenery beyond approaches, with natural and excellent effect, to the very base of the rampart wall; and this severity of treatment is absolutely necessary to terraces of this description, on which all attempts at the introduction of statuary, Roses, &c., would be utter failures, the only suitable ornament being a simple line of flower-border next the building, within a broad edge of turf. The more gardenesque features of the castle must develop themselves

in a less conspicuous situation in the rear of the building; and where wood or walls will shield them, and prevent them from weakening the severity of the main composition. It will be instructive to step back to the period of castellated strongholds, and see how their builders and indwellers managed these matters in their own day. A magnificent pictorial border, from the calendar of the Prayer-book of Anne of Brittany, one of the finest illuminated MSS. in existence, will furnish us with an example; it represents a rosery, enclosed by a battlemented wall partially screened by trees, much below the elevation of the castle. The Chatelaine is represented visiting her castle garden in one of the sunny days of April, where in some parts of France Roses are already in bloom, and she is in the act of receiving from her attendant chaplets and garlands of flowers, which are no doubt destined to decorate chalices and vases of cunning goldsmiths' work in her Gothic boudoir. This cotemporary garden picture, executed about the year 1499, contains many suggestions for garden features in similar situations, though not perhaps for too servile imitation. In the illumination, the palisades enclosing the Rose tree are gilt.

Let us now consider the castle terrace in its later form, when the severe character of the defensive stronghold had been modified by additional buildings of a later period engrafted upon them—the decorative mansion, like the change in a "dissolving view," emerging from among

GARDEN SCENE FROM THE ILLUMINATED PRAYER-BOOK OF ANNE OF BRITANNY

the towers of the defensive castle. Of this transition period, the terrace at Heidelberg, which, with the castle, forms one of the finest ruins in Europe, is a beautiful example. The embattled parapet of the ancient rampart has given place to an open balustrade; and the stone seats suggest, that, in the palmy days of this grand-ducal residence of the House of Baden, Orange trees and other plants, in ornamental vases, mingled with statuary, to give this noble terrace its finishing touch of palatial grandeur—forming a rich foreground to the magnificent view of the course of the Necker, which is the grand feature of the prospect from the terrace at Heidelberg. The introduction of any more trivial features, or of decorative features beyond the terrace, would destroy the proper character of a terrace of this description, which must still preserve a portion of the severity belonging to the castellated period.

Of decorative gardens of a strictly palatial character, where no remains of the castellated style are visible, those of Italy are the finest models, and among the finest specimens of these, taking into consideration the position, are those occupying sites among the beautiful rocky slopes of the Apennines, in the vicinity of Tivoli and Frascati, the noble and regular terraces of which, tier above tier, in contrast with the rugged yet lovely scenery which surrounds them, form the finest combination of outline imaginable.

From the days of Horace, and his description of his "Sabine farm," those beautiful hills have been the favourite retreat of the Romans; and the style of decorative gardening which surrounds the palaces of the nobles of modern Rome is, doubtless, very similar to that cultivated by the ancients. This is, in fact, proved by the representations of suburban villas in fragments of antique fresco and mosaic, while the description which Pliny gives of his garden might serve for that of one of the modern villas at Tivoli. The finest of these villas were erected during the fifteenth and sixteenth centuries, and as the feeling of Italian art spread rapidly northward during this period, the terraces, statues, and fountains of these noble residences became the

models on which the decorative gardens of the north of Europe were formed; those of Boboli and D'Este being the ideals from which Le Brun and others produced the magnificent wonders of Versailles.

The villa D'Este beneath Tivoli, [though its terraces are crumbling to ruin, and its fountains are dry, is yet one of the most wonderful of these great creations of art. It was among its mazes of marble and matted foliage that Tasso once mused away the soft and sudden twilight of the evenings of an Italian summer, and from the fairy picture with which he was surrounded painted, in immortal poetry, the fairy gardens of the palace of Armida; and, in all the freshness of their beauty, ere Time had touched "with his defacing finger" the spotless marble, or dried the sources of the countless fountains, or thinned the parquets of their exotic flowers, he might in vain have sought a more fitting model when he was composing the lines which may be thus freely translated:—

With aspect sweet, the smiling garden spreads  
Where water softly sleeps, or gush in crystal fountains;  
Flowers and sweet herbs form rich enamelled beds;  
Vales of deep shade there are and sunny mounts,  
And round the lawns a wood its freshness sheds;  
And that which yet increased each charm revealed  
Was, that the art that wrought it lay concealed.

Which is to say, that true art must not be obtrusive; the effects produced must not suggest the idea of painful and laborious operation; it is the perception of the beautiful that must be the first impression, and not that of the art by which it has been produced. This will depend much upon whether the beauty attempted to be created be of a temporary or a permanent nature—whether, as Sir Uvedale Price observes—whether it be merely adapted to the ac-

cidental prejudices prevalent in the artist's own day, or whether its principles be so founded upon the uniform constitution of the human mind as must command the approbation of any age. This great principle of all high art applies, continues Sir Uvedale Price, to nothing more strongly than decorative gardening. —(*Gardeners' Magazine of Botany*).

THE TERRACE AT HEIDELBERG.

GOLDEN HAMBURGH GRAPES SHRIVELLING.

In my earliest viney there are two Golden Hamburg Grape Vines; they were planted in the spring of 1860, and made very fine canes. This season I started them on a little early, so that the other Grapes in the same house are ripe. The sorts are the Pope Hamburg and Black Hamburg: these ripened and coloured like Sloes, but the Golden Hamburgs, just as

they commenced ripening, one-half of their berries shrivelled. They seemed to go in the fruitstalks first, while of the other Grapes there is not a bad berry in the whole house.

In the Muscat Grape-house, all Muscats of Alexandria cut back to one-third the length of the rafters, and bearing a crop of five moderate-sized bunches, are doing well; but the leaves

on the leading shoot drop down with the least sun, turn yellow, and drop off. That is on about 4 feet of the new growth, while the laterals on the same are perfectly healthy, as also the remaining part to the top of the house. I shaded the part of the house, but to no purpose.—E. W., *Cavan*.

[We are afraid that you have taken far too many bunches from your Golden Hamburg. It will scarcely stand the same amount of sun as some other kinds. A few inches further from the glass will help this Grape. We do not see through the cause of the leaves of the Muscats falling, but it is a consolation that the foliage on the laterals is all right. We have had several bunches scorched the last few days, owing to the great and sudden change in the weather.]

### RAVAGES OF THE (CURRANT) SAWFLY.

In the "Zoologist" for July, 1862, p. 8079, an interesting account is given of the Sawfly, *Nematus ventricosus* (Klug), translated from the Dutch of M. Snellen van Vollenhaven, by J. W. May, Esq. This insect will be familiarly known to your readers by the name of the "Gooseberry grub," whose ravages this year extending all over the kingdom have deprived us of many tons of fruit. By studying the natural history of this and other insects, we shall, doubtless, find a clue to the prevention of their ravages, and I wish now to lay before your readers some hints which may prove useful to that effect. After giving a description of the larvæ, &c., our author goes on to state:—"They feed both day and night, and beginning in company on a leaf they eat on until there is nothing left but the stalk and some of the thickest veins. Before quitting the bush they moult, once more assuming a pale yellowish-green colour, the first and terminal segments being orange; but they are now without the black spots and hairs which they had in their earlier state. After this they drop from the tree and construct a cocoon at the foot; this cocoon is made at no great depth in the ground, and is externally covered with little grains of earth. They assume the pupa state in the summer in the space of three weeks, in the winter only after an interval of eight months. The pupæ are yellowish-white and display all the parts of the imago. They very soon change their colour, and in eight or ten days, having moulted for the last time, the perfect insect gnaws open the cocoon and escapes." Our author then gives a description of the perfect insect, and further adds—"There was an incredible number of these larvæ in 1860. From observations made at Utrecht and at Leyden, there seems no doubt that the first brood in May attacked exclusively the leaves of the Gooseberry, some of the bushes being quite stripped, and that the second generation appearing in July, principally confined itself to the Currant, but small numbers having been seen on the Gooseberry. I observed this myself in a garden where the two plants were growing intermixed, both larvæ and imagos were decidedly of but one species." The truth of this latter observation, that the larvæ attack both Gooseberry and Currant trees (the former at an earlier period of the year), is quite borne out by my own observations this summer, and, I doubt not, by many of your readers. The second brood having now just made their appearance, I will detail a mode by which their ravages may be greatly lessened.

The eggs, white, elliptical, are laid on the under surface, along the ribs of the leaf, to the number sometimes of 120 on a single leaf; the larvæ, when hatched during the first twenty-four hours, make each one a little round hole. The leaf then presents the appearance of having been riddled by No. 7 shot. The second day the holes are larger, less regular, and soon coalescing, the larger veins only at the tip of the leaf remain undemolished. This is the critical time to destroy the brood. By gathering these leaves daily as the caterpillars are hatched (for they keep coming out during a fortnight or three weeks, according to the period at which the eggs were laid), the whole of the brood will be easily destroyed. The peculiar appearance of the leaf (specimens of which I enclose), renders the gathering of the brood remarkably easy; while the fact that at this early period they are altogether on one leaf, and that a week later they will be more scattered over the tree, as also that their destruction of the foliage is then at the minimum, peculiarly points out this period as the one most suitable to their destruction. I should say that on the 19th ult., from about ten trees in my own garden I picked off fifty to seventy leaves, each containing from five to seventy eggs and young larvæ just hatched. Since then I have

daily picked off about ten leaves similarly attacked. If each possessor of a garden would thus destroy the young brood, we should have no more sawflies next year to trouble us. Other methods are advantageously used at a later period for their destruction; such are hand-picking, shaking the stems—when the larvæ drop down and can be killed; syringing the under surface of the leaves with alum and water, or watering the larvæ when shaken down with the same mixture; but all these methods are put in force when the damage is half done, and when the larvæ are widely distributed over the trees, and are insignificant when compared with that which I now advocate for nipping the evil in the bud. Let your readers now look to their Currant trees, and next spring to their Gooseberry trees, and we shall get rid of the enemy.—ALEXANDER WALLACE, M.D., *East Hill, Colchester*.—(*Essex Gazette*.)

### THE INTERNATIONAL EXHIBITION.

(Continued from page 339.)

#### TASMANIA.

THIS island, formerly known as Van Diemen's Land, occupies a position to the south of the continent of Australia between 40° 45' and 43° 45' S. lat., and 144° 45' and 148° 30' E. long., comprising an area of about 25,000 square miles, or 16,000,000 of acres. The central portion of the island is an elevated plain, in which are several extensive lakes from which three considerable rivers take their origin, and by these, as well as the numerous streams which flow from the hilly districts, the country is well watered.

The surface is generally undulating, and several bold mountain ranges occur, rising at some points to 5000 feet above the sea level, their sides being generally densely clothed with trees, whilst in the cultivated regions the valleys are remarkable for their fertility.

The climate as regards temperature is nearly the same as that of the neighbourhood of London, the daily range, however, being much greater. The mean annual temperature at Hobart Town, as deduced from eight years' hourly observation, was 53.32°; that of Chiswick, on an average of thirty-six years, being 49.31°, or 4° less. The coldest month (July) has a mean of 45.82°, or 8.91° warmer than our January; whilst the mean of this month at Hobart Town is 63°.57, or only 0°.61 warmer than our July. The highest temperature that has been recorded in the shade is 105°, ours being 97°; but according to Dr. Hall, in the account of the "Products and Resources of Tasmania," published by the Commissioners, the thermometer has only risen forty-four times above 90° in the last twenty-one years. The sun's rays, however, are much more powerful than they usually are in England, or even on the continent of Australia, the haze which usually accompanies intense heat there being unusual in Tasmania. The greatest solar heat recorded is 143°, the next degree of intensity being 133°; but it must be remembered that 120° in the sun is not an uncommon temperature in hot summers in England.

Frost of greater severity than 2° or 3° below the freezing-point is unknown at Hobart Town, and snow is equally rare, except on the mountains.

The annual fall of rain is, on an average of twenty-one years, about 2 inches less than the neighbourhood of London, and it is distributed throughout the different months in very nearly the same manner; but whilst more than 4 inches of rain is an unusual quantity in one month near London, some exceptional instances have occurred of 7, 8, and 10 inches having fallen during a like period in Tasmania. The greatest amount of rain in any one year since the observations were commenced was 33.51 inches, a quantity about equal to the mean annual fall on the western part of England, and far below what is of frequent occurrence there.

Dr. Hall, with great justice, lays stress on the beneficial effect of the frequent moderate airs in purifying the atmosphere; he also states that ozone is very abundant in the air of the island, and to this circumstance he ascribes the comparative immunity from infectious diseases which the inhabitants enjoy.

That the climate is one of the healthiest in the world the statistics which he adduces in his essay leave no room for doubt, the rate of mortality being even less than that of the healthiest districts of England.

Having thus glanced at the climate of Tasmania, we shall next

proceed to state what are its productions. According to the useful pamphlet to which we have already referred, we find that in 1860 there were 218,315 acres of land under cultivation, of which 66,450 acres were in Wheat, 30,303 acres in Oats, 6238 acres in Barley, 7621 in Potatoes, and the remainder was variously occupied by pasturage, root crops, and garden ground.

To give an idea of the quality of the produce several fine samples of cereals are exhibited, amongst which some Wheat, weighing 6½ lbs. to the bushel from Mr. Marshall, and Oats stated to be 56 lbs. 10 ozs. to the bushel shown by Mr. L. Smith, are particularly worthy of note.

In Tasmania, as in the other Australian colonies, the growth of wool is extensively carried on, the number of sheep being 1,700,930 in 1860, or 18½ to each person, and the produce is of the finest quality, nearly every sample exhibited having been distinguished by a medal or honourable mention.

As regards horticulture, we extract the following information:—"Experienced horticulturists who come out from England are astonished to see six years gained in the maturity of Pear trees three years in Apple trees and other fruit trees; whilst the Raspberry, Strawberry, Currant, and Gooseberry flourish like indigenous plants. It is no uncommon occurrence to see young Apple trees in the Huon district the grafts of which have grown 6 feet in the year of grafting. The Apple and Pear far surpass those of Great Britain in size and colour, and are very little inferior in flavour.

"There are from 100 to 120 varieties of known Apples now in Tasmania, including most of the best sorts cultivated in England, America, France, Germany, and Italy. A few significant facts will convey to English horticulturists an idea of Tasmania's capabilities in fruit-growing. All the sorts described in English catalogues as below medium size have grown far above medium, and those described as medium here attain the catalogue designation of 'very large.'"

The Esopus Spitzenberg and the delicate Italian Apple, Mela Carla, will grow and ripen their fruit here without the protection of a wall. The Golden Pippin seems to have taken a new lease of life; the Scarlet Nonpareil is greatly improved.

"In 1860 Tasmania exported 118,810 bushels of Apples, at prices ranging from 5s. to 15s. per bushel. Some of the Golden Harvey, Pearson's Plate, and Scarlet Nonpareil have sold at Mauritius at from 2s. 6d. to 4s. per pound.

"About sixty good sorts of Pears are cultivated; and many of the tenderest kinds, such as the Beurré Bretonneau, ripen their fruit in perfection, without shelter, and have the most delicious flavour. Tasmanian Beurré Diel Pears have sold at Sydney at 2s. 6d. each.

The Pear tree grows here to a large size, one in the garden of Government Cottage, Launceston, is described as about forty years old, 120 feet in circumference, 86 feet in height, and 8 feet in girth 1½ foot from the ground. It is a handsome, shapely tree, and has produced over 50 bushels of fruit in a season. A Bon Chrétien Pear tree belonging to Mrs. Luckman, of Hobart Town, has also produced 50 bushels of fruit in a season. Of Pears 22,049 bushels were exported in 1860 at prices varying from 5s. to 15s. per bushel.

"All the choicest sorts of Plums which require shelter in England ripen freely as standards. Cherry trees grow from stones as freely as Oaks from acorns in the Weald of Kent; all such are called Kentish Cherries, and were sold last season at Franklin, Huon, at 1s. per pailful. About twelve of the best-known varieties of the Cherry are cultivated; the best Strawberries attain an enormous size; Raspberries bid fair to become wild fruit; the Fig bears well without shelter; the Mulberry is hardy and prolific; and about forty varieties of Lancashire Gooseberries are in cultivation, and produce most abundantly.

"The Walnut gains eight or ten years in bearing maturity; the Filbert grows and produces well; Peaches, Grapes, Apricots, Nectarines, Almonds, &c., although not equal to those of Australia, thrive and fruit largely, particularly on the northern side of the island. The total value of fresh fruit and preserves exported in 1860, was £56,203. The Fuchsia and Geranium become large shrubs."

To give a correct idea of the characters of the best Apples and Pears grown in Tasmania, three cases of well-executed wax models are exhibited, and which, being taken from plaster casts of the fruit, are exact representations of their size and shape. In their number are included many of the finest varieties grown in this country, and of a size to which even under the most favourable circumstances, they do not usually attain here, while the

colour is in general much higher. There are specimens of Uvedale's St. Germain Pears, weighing 2 lbs. 6 ozs., 2 lbs. 11 ozs., and one is stated to have reached the extraordinary weight of 3 lbs. 5 ozs. The heaviest which we have seen produced in this country weighed 3 lbs. 4 ozs.

The extraordinary growths made by fruit trees have been noticed above, and by way of proof shoots are exhibited which are not merely remarkable for their length but for thickness also. Thus, there is an Apple shoot 5 feet long; one of a Plum from a two-year-old sucker, 6 feet 2 inches; a Banksian Rose shoot, 10½ feet long; one of Cloth of Gold, 10 feet; and Aimée Vibert, 8½ feet, all of which are stout in proportion to their length.

(To be continued.)

## WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 335.)

**PRIDEAUX'S HERMIT CRAB (*Pagurus Prideauxii*).**—This species is found in very considerable quantities in Plymouth Sound. It is not uncommon, however, on other parts of the coast. It bears a great resemblance to the specimen last mentioned (the *Pagurus Bernardus*), differing at the same time in several marked characteristics, which plainly prove it to be a distinct species. The claws, for instance, are destitute of tubercles, being merely grained. The ambulatory legs are almost smooth, the end joint having longitudinal grooves on either side, and not being twisted. It is also a much smaller species than the *Pagurus Bernardus*, rarely measuring more than from two to two inches and a half from the front to the extremity of the abdomen. The eye-stalks are extremely thick and short, the end where the eye itself is inserted being globular. The colour is a pale reddish-brown.

Professor Bell quoting from Mr. Thomson, adduces a very remarkable fact—namely, that this creature is found "in every instance inhabiting the shell invested by the *Adamsia maculata* (*Actinia maculata*, Adams), and that among the numerous specimens in his (Mr. Thomson's) collection from all quarters of the Irish coast, and found inhabiting shells of various species, not a *Pagurus Prideauxii* occurs except in connection with the *Actinia* already named."

**THE SMOOTH HERMIT CRAB (*Pagurus lavis*).**—This is a very pretty little creature, found principally at Falmouth and off the coast of Cornwall. The shell is smooth and polished, and somewhat heart-shaped. The eye-stalks are short and thick. The front claws are very unequal, the right one being considerably larger than the left. In colour it is yellowish, a distinct red mark running the whole length of the claws.

**THE ROUGH-CLAWED HERMIT CRAB (*Pagurus Forbesii*).**—"This curious species," says Professor Bell, "differs obviously from every other inhabiting our coasts." The shell is quite smooth, the eye-stalks club-shaped and of greater length than those of the species just mentioned. The front feet are unequal, the right, as is usually the case, being the larger; both, however, are rough and strongly toothed on the inner side. The second and third pairs of legs are slightly flattened. The upper edge of the fourth joint is armed with spines, and all the legs are covered with small reddish-brown spots.

The *Rough-clawed Hermit Crab* is found most commonly off the coast of Falmouth.

**THE HAIRY PORCELAIN CRAB (*Porcellana Platycheles*).**—The shell of this curious species is of a little greater length than breadth, having a polished surface in young ones. This surface is covered with short hair, which increases in length towards the margins where it permanently grows. The fore legs are very large and furnished on the outer side with long close hair. The second, third, and fourth pairs of legs are flattened at the sides, rounded beneath, and fringed with hair on both margins. The colour is a reddish-brown, inclining underneath to a paler yellowish tint. The hairs are brown.

"The distribution of this species," says Professor Bell, "is extensive and in some localities it is also very numerous. I have received specimens from various parts of our coast, from the Orkneys to the Land's End. It is found also on several parts of the Irish coast, and it is plentiful on the coast of France, and in the Mediterranean. Some of the largest and finest that have come under my observation, were sent me by Dr. Duguid, from Kirkwall, in Orkney. It is a littoral species, being generally found under stones at low water. It bites

severely, as Dr. Duguid remarks, and if seized by its claws has the power of throwing them off instantly to facilitate its escape."

**THE MINUTE PORCELAIN CRAB** (*Porcellana longicornis*).—This is a pretty little species, and a very common one, being found beneath stones at some little distance beyond low-water mark. It is frequently, too, brought up in large numbers with the Oyster-dredge. It is very minute, the ordinary length of the shell being no more than two or three lines. The front legs are very unequal, one being as long and broad again as the other. The shell is almost round, convex, and nearly smooth. The colour of the shell varies. "It is generally," says Professor Bell, "pale red, frequently with irregular markings of dark reddish-brown; in other specimens of bright red."

**THE SCALY GALATHEA** (*Galathea squamifera*).—This is by no means an uncommon species. The carapace is of greater length than breadth, and armed at the sides with strong sharp spines. From the front projects a very powerful spine, supported on either side by four others. The front feet are broad and compressed, strongly spined on the inner edge, and having the surface covered with small scale-like tubercles. The second, third, and fourth pairs of legs are furnished with rows of spines on the anterior margin. The colour is mostly a greenish-brown, some specimens being occasionally tinged with red. The length is about three inches. "It is," remarks Professor Bell, "a common species all along the southern and western coast. I have specimens from Cornwall, Devonshire, Dorsetshire, and Sussex. The largest I have seen were procured by myself at Bognor, where they are often taken in considerable numbers in Prawn and Lobster-pots. It is recorded as the most common Irish species by Mr. Thomson, who observes that it is found on all the coasts of Ireland. It appears to be pretty much a littoral species, occurring, according to both Dr. Leach and Mr. Couch, under stones at low tide."—W.

(To be continued.)

## ENTOMOLOGICAL SOCIETY'S MEETING.

THE July meeting of the Entomological Society was well attended, several foreign entomologists, attracted by the great International Exhibition, being amongst the visitors, including Herr Fraenfeld from Vienna, and Dr. Stal from Stockholm. Amongst the donations were the publications of the Royal Societies of Sciences of Munich and Madrid, the Entomological Societies of the Netherlands, Vienna, and St. Petersburg (the latter recently established), &c.

The President, F. Smith, Esq., of the British Museum, exhibited a box containing a number of galls of different species recently received by that establishment from Germany, including specimens of the round oak gall (similar in size to the ink gall), which has during the last few years threatened to cause much injury to our Oak trees, having spread with extraordinary rapidity from Devonshire (where it was first observed), over the south of England. At the present time, however, thanks to the attacks of the Tomtits, not a single gall is to be found in places where two years ago it was very abundant; these birds having discovered that the interior of the gall contained a fat fleshy grub, have bored into the galls and eaten the inhabitants, thus affording another very convincing proof of the impolicy of the wholesale destruction of the small birds, against which the Editors of THE JOURNAL OF HORTICULTURE have so energetically raised their voice.

Mr. Walker corroborated the remarks of the President, and stated that in the neighbourhood of Highgate and Southgate where it abounded he had not been able to find a single specimen this season.

Professor Westwood exhibited a continuation of the series of illustrations of the habits and economy of various species of insects presented to the Oxford Museum by S. Stone, Esq., of Brixhampton near Witley, beautifully prepared, and including specimens of the preparatory states of several species of Dragon Flies, also of *Trichiosoma lucorum* (a large Sawfly) and its parasites, several other species of Tenthredinidæ and Sphegidiæ which bore into the pith of Brambles, various species of Gall-flies and leaf-mining insects, including a species of the Beetle-genus *Orchestes*, also the preparatory states of species of *Raphidia* and *Hemerobius*. Mr. Stone had also sent an extensive series of the leaves of different plants mined by various insects; and Professor Westwood also stated that he had received from Mr. Varsey a large collection of the leaves of different species

of garden plants which had been attacked by the Leafcutter Bee, and had portions of the leaves carried away by that insect for the manufacture of its nests. He also exhibited a drawing of *Acarus domesticus*, De G. (A. Siro, Linn.), found by Dr. Maddox, of Woolston near Southampton, in a nitrate-of-silver bath prepared for photographic purposes; and suggested that Mr. Andrew Crosse's wonderful creation of *Acari* might probably be explained on the principle that in that instance, as in this and some others to which he alluded, the insects had been attracted by some of the chemical substances employed, or the chemical action had caused the development of the insect from eggs. He also exhibited a great number of photographic representations of different species of British insects of the natural size, forwarded to him by J. C. Dale, Esq., some of which were remarkable for the marvellous manner in which the most minute species of Chalcididæ, &c., were brought out.

Mr. Stainton exhibited two species of the very remarkable genus of minute Moths *Micropteryx*, which had been reared by Mr. Wilkinson, of Scarborough, from mixed Birch and Oak leaves.

Mr. Pascoe read a note on two exotic genera of Longicorn Beetles—*Stenidea* and *Blabiotus*.

A paper was also read by Mr. F. Walker, containing descriptions of various new exotic species of Chalcididæ.

Another paper by Mr. Tremen was also read, containing descriptions of new species of Butterflies taken in British Caffraria by W. S. M. d'Urban, Esq., during 1860 and 1861. Eleven new species were described, including a new genus belonging to the family *Lycenidæ*.

On the following day the members of the Society enjoyed a delightful field-day on the range of hills between Reigate and Dorking at the invitation of one of their Vice-Presidents, W. Wilson Saunders, Esq., F.R.S., who is also Treasurer of the Linnean and Horticultural Societies. On arriving at Blechworth the party ascended the hills and commenced collecting in good earnest; and several important captures were made during the day, including a specimen of the extremely rare *Zyras Haworthii*. At the Deepdene, the grounds of which were thrown open to the Society by Mr. Hope, a picnic was held under the shade of the trees; and the party returned to dine at Reigate in the Town Hall, where they were joined by a further detachment of naturalists and by a number of the neighbouring clergy and gentry, invited by Mr. Saunders, whose kindness in again affording so pleasant an annual treat was duly acknowledged. We noticed amongst the visitors Mr. Wallace, returned from the Eastern Archipelago, Mr. Smith the President, and the other officers of the Society, General Sir J. B. Hearsey, Dr. Gray of the British Museum, Messrs. Bowerbank, Miers, Hewitson, Westwood, Walker, Stainton, Lovell Reeve, Dr. Stal, of Stockholm, &c.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE old saying, that "one year's seeding makes seven years' weeding" is generally very apparent at this season, when, after a warm shower and a few days' sunshine, weeds appear in myriads. Their destruction is then best effected by surface-stirring; but where, from want of available labour, they have stood so long as to perfect their seed, they should never be dug or trenched-in, but be taken quite away to the char-heap, or else burned on the ground. *Broccoli*, any that are now planted-out should have their roots dipped in a puddle of soot, earth, and water, and immediately after planting should be again watered. The Cape and Grange's, intended for use in the autumn, should also be watered; but the spring roots when they have got hold will not require it. *Cabbage*, there should now be no delay in getting in the main sowings: the Vanack, East Ham, and London Market are good sorts. *Carrots*, a few of the Horn may now be sown to stand the winter. *Celery*, an abundance of water to be given to that newly planted, and also to the earliest crop, which, if wanted early, should be earthed-up. Continue to plant-out, taking up the plants with as much soil about their roots as possible. *Lettuce*, make a sowing of Cos and Cabbage for late use. *Onions*, sow a few to draw young for winter use, or to stand the winter for transplanting in the spring. *Turnips*, as the ground becomes vacant another sowing may be made. If the weather continue dry, water the ground after the seed is

sown, and cover with mats. After the first shower of rain earth-up Brussels Sprouts, Savoy, Broccoli, and whatever crop requires it. Vacant ground, or that which can be cleared of early crops, may still be planted with Winter Greens, first giving it a good dressing of manure, and a trenching or good deep digging.

#### FLOWER GARDEN.

The late-planted flower-beds should now be looked over, and the plants therein pegged-down or staked, as their habits may require. Those that are planted against basket-edgings or against framework which is used to intersect beds should have their shoots neatly arranged or tied-in; and all decayed leaves and flower-stems removed; the flower-borders to be thoroughly cleaned; all plants which have done blooming to be cut down; and annuals that have ceased to be gay should be pulled up, to make room for those that are to succeed them. Proceed with the layering of Clove and other Carnations. Mule and Anna Beley Pink treated in the same manner will make strong healthy plants before winter.

#### FRUIT GARDEN.

Nailing, syringing, and paying attention to fruit as it ripens, and making new beds of Strawberries, form the principal routine here.

#### STOVE.

Orchids suspended in baskets or on blocks require a liberal supply of water at this period, and frequent but slight syringings, with sufficient fire heat to admit of a gentle circulation of air. Those *Isoras* which have done blooming to be cut down and started gently to make new growth. Attend carefully to the winter-blooming plants, and adopt the same system as advised below in the greenhouse department to mature growth that requires to be ripe in order to produce bloom.

#### GREENHOUSE AND CONSERVATORY.

The plants that have matured their season's growth should now be more sparingly supplied with water at the root, in order to promote the ripening of the wood. The twiners to be gone over frequently, that the shoots may be kept nicely regulated, cutting out where necessary to prevent their being too thick, and shortening any that hang down so loosely as to interfere with other things. Any of the plants which require more pot-room should be shifted without delay, taking care to have the balls moist, and keep them rather close and the atmosphere more moist than usual for ten days or a fortnight after potting. Cut down Pelargoniums as soon as the wood is properly ripened, and supply them very sparingly with water at the root until they start into growth, but sprinkle frequently overhead, which will cause them to break more freely. Camellias will now in general have formed their bloom-buds, and should be watered occasionally with liquid manure. It is also a suitable period for shifting them if the blossom-buds are quite perceptible. The pot Roses to have their decayed blossoms entirely removed, and those for winter blooming to be examined as to whether they want shifting. When shifting, the old balls to be loosened, and the heads to be slightly reduced. Remove the faded blooms of *Aphelxis* and *Helichrysums*, cutting the flower-stems close to the old wood and set in a cool shady place; when they begin to grow, such as require it to be repotted. When the flowers of the *Kalosanthes* are getting shabby cut them well in. Repot, stop, and strike *Chrysanthemums*. The *Cinerarias* for early blooming will now require attention; shift when necessary, for if they are to form large specimens for blooming in winter they must not be permitted to sustain any check.

#### PITS AND FRAMES.

The propagation of stock for next season to be commenced and carried on with expedition, so as to insure strong, well-established plants before winter, and without the necessity of keeping them so close and warm as to induce weak and tender growth. To be able to winter bedding stock safely with ordinary care the cuttings should be put in sufficiently early to allow of having them well established and fit to be exposed to the open air in September, previous to housing them for the winter.

W. KEANE

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

FORKED and hoed amongst general crops, alike to break the hard pan after the rains and hail, and to cut up any weeds that might be showing themselves, and they have not been few this

season. Planted a good breadth of Cauliflower after Potatoes, manuring chiefly with short grass that had been thrown into a heap for a few days, and digging such highly nitrogenised matter deep enough to prevent the roots touching it for some time, and then it will have lost its rankness, and the soil be all the better for absorbing it. The hoe and the fork have also been necessary by the sides of rows of late Peas, to prevent the ground cracking. This forking-up is often better than watering, more especially if a slight mulching is thrown over to keep the moisture in, and the extra heat out. Planted lots of Coleworts, Broccoli, &c., as room could be made for them, and will soon find more by digging-down Strawberries that have borne two or three years. Watered Celery, Lettuces, &c., and to give a start to young plants of the latter, just planted out, placed some common hurdles thinly wattled with branches over them, to screen them from the sun. Planted-out a lot, too, on the north side of banks, fences, &c., that they might stand longer and be more succulent. I plant thus because I am short of room. Where ground is plentiful, the best plan is to sow often and thin, and let the plants come to maturity where sown.

#### FRUIT GARDEN.

Have been obliged from the heat of last week to fork over the surface soil of fruit trees transplanted last season. Watered them, and placed a little half-rotten leaves over the surface to keep the ground from cracking. Proceeded with Strawberries; disbudbing and stopping fruit trees as last week. Have been obliged to net everything pretty well that was worth keeping. We heartily wish that all bird-fanciers had a share of our extra stock. I would not be extra hard upon the songsters, but I must make an effort to lessen the nests in the neighbouring covers next year. Whenever such dry, hot weather sets in, we have them in legions. On netting some Gooseberries a boy caught something about a score of thrushes and blackbirds below the net the first afternoon, and then they made such a yelling as if they had more than a right to be there. I am told that when young and fat they make a splendid pie, little, if anything, inferior to partridges. It is worth noting how a yellow-billed blackbird will cautiously go all round a net, and squeeze himself in underneath it. Were he not hurried when an enemy approached he might get out by a similar way, and escape free. Watered Melons, chiefly below the surface, unless when young, not giving too much at a time, which if it did nothing worse would be apt to crack the fruit. Watered Figs and all sorts of fruit trees in pots, giving weak manure water. The Figs since the change in the weather have been much better flavoured. Extra syringing in orchard-houses to keep them clean, and in a very bright day just dusted the glass with water outside, merely whitened so as to break the extra force of the sun's rays.

#### MUSHROOMS.

I should have had this in the kitchen garden, but say a word here in answer to "A LOVER OF MUSHROOMS." First, I can add nothing material as to the directions given some time ago for making and keeping Mushroom spawn. It may be done quite as well by other modes, but had I given a number of modes the reader would only have been perplexed. Now is a good time to set about making it. Second, An underground cellar is the best place to grow them in summer. I seldom bother with them elsewhere than in a common Mushroom-house, above the ground, they are so apt to come thin and maggoty. Third, I have had a good supply since June from shallow beds in a shed, open to the west with a thatched roof, and large Chestnut trees a little west of the beds, which shade them, and allow of a current of air through the beds. We are just earthing down our third and last piece to-day. The second piece is just beginning to show, and this third we shall expect to show in the beginning of September, and before then we shall have a piece made in the Mushroom-house. We are just now getting the last beds out and having the material sifted for top-dressing flower-beds. I am well aware that large, thick beds will bear a long time, if well managed; but then I could rarely get enough of material for such large beds, and a constant supply being desirable I prefer the continuous system of a number of small shallow beds. I do not see how "A LOVER OF MUSHROOMS" can be greatly interested in knowing whether I intend making spawn this autumn or not, unless he wants to see it done. That is a matter which will be decided on when I have an opportunity of examining the spawn-heap; for if there be more than enough to last me over this time next year, it is most likely I shall make none, for if the spawn is good, and kept dry, I like it as well three years old, as if it were fresh made. I may

also notice that the beds in the shed have a little dry hay sprinkled over them to keep the surface soil moist and more regular in its temperature, and in very dry, hot weather we prefer slightly syringing this dry hay to watering the bed much.

#### ORNAMENTAL GARDENING.

The conservatory was wholly retrenched, almost all Pelargoniums being removed, and a number of Balsams, Begonias, and other fine-leaved plants introduced. Amongst the latter few are more beautiful than *Amaranthus tricolor*, which is now seldom seen because it used to be rather common. The Pelargoniums are placed in an open yard to harden, the Fancy ones being kept by themselves, as they will not stand the same amount of drying. Potting and propagating as last week. Much of the time, however, was taken up in getting the lawn and flower-beds in full-dress order. The Calceolaria-beds in the latter still taking the lead of all others, and pretty well vying with the sweet human flowers, that with their long dresses swept every walk in such a regular manner, as no broom in the hands of a gardener could have done. My employer took a fancy to a couple of Mr. Green's 16-inch mowers, as used at the Gardens at Kensington, and having just tried them feel certain they will answer well. I do not know if I rightly understand all about them, but there is just one thing against them. They make no noise to speak of in cutting, and they work easily; but in pulling the machine back to make a fresh cut, which you must frequently do in small spaces among clumps, the clattering of the cogs is deafening. Mr. Green kindly referred to my notice last year about the inferior iron chains. Would he oblige me and others who dislike such clattering, by telling how such noise is to be obviated? There is no regulator as in the larger machines for bringing the cogs into play as desirable.—R. F.

#### TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**CLEANING A FALLOW KITCHEN GARDEN (J. E.).**—You do not state the most important fact—the nature of the soil. If it be at all heavy pare off and burn the top 6 inches. The ashes will be the best manures for such a soil, and the burning will destroy the seeds of weeds, and all the predatory insects.

**RED SPIDER ON VINES (J. H. S.).**—When leaves are sent on which it is supposed there are small insects, as red spider, they should be shut up carefully in oil paper, and then if shaken off the leaf we may detect them inside the paper. We failed to perceive an insect of any kind on your leaf packed loosely with a piece of a nurseryman's bill round it. We think, however, that a few spiders had been nibbling at it, and, therefore, a little sulphur will be an advantage. For your small house a pound of lime, two gallons of water, and half an ounce of sulphur, would be enough at a time; but we seldom advise using this remedy, as there is such a difference in the strength of lime, and if after shaking it with water it should be hot enough to ignite, or nearly ignite the sulphur, there will be other mischief to apprehend worse even than the spider. The remedy is a good one with practised hands, but requires being used with caution. We know a case where the sulphur was added too soon, and it flared and made its presence too well known. We think it would be safer as you propose heating the house, to put a wash of lime and sulphur on the flues or pipes at night, taking care, however, that the heating medium where the sulphur is, is not above 150° or 160°. That will throw off sulphur fumes that will not hurt vegetation, much higher will make the fumes too strong.

**PRUNING PEACH TREES IN POTS (Idem).**—You will err much in cutting back your Peach shoots to three buds now. It would cause most of the buds to start. Mr. Rivers recommends for pyramids, &c., not cutting back, but stopping after three or four leaves are developed, and continuing that stopping until the end of July—a very different thing indeed. When you follow any peculiar system, you must take it as a whole, and not in detached parts. The best you can do now, is to allow the shoots to grow and ripen, or merely nip out the terminal-bud, to swell the buds behind it.

**GLOXINIAS SHOWING BLOOM-BUDS (P. H. G.).**—Allow the Gloxinias to bloom, and encourage them with a moist heat and plenty of water. Discontinue the latter when the leaves begin to fade, and give none at all when fairly browned, but keep the pots standing on soil or stone, so that a little moisture may be absorbed from the bottom of the pot.

**SOFTENING PUTTY (J. B.).**—Putty may be softened by rubbing over it an iron heated until a dull red, or by applying flannel rags dipped in caustic potash, allowing the rags to remain on during several hours.

**HEATING GREENHOUSE FROM KITCHEN RANGE (A. B.).**—At such a distance as 70 yards we do not think it would be advisable to heat a small greenhouse, unless you could otherwise use the heat of the 140 yards of piping, which would be needed merely to connect your kitchen range and the house. Would it not be better to have a small boiler or a small flue for such a detached house? There is no objection to Vines being planted inside a vinery, but quite the reverse, though if the roof be already covered they will not do much good there.

**SEASIDE PEBBLES FOR WALKS (C. T. Hall).**—They will make a very good asphalt mixed with gas tar; but we do not think they would keep the walks more damp and soft than would other pebbles. We do not know whether *Gishurst Compound* will kill fleas in dogs, nor whether it would injure the dogs, nor, if it is a flea-destroyer, how much should be put to a gallon of water. Mr. Wilson, perhaps, will furnish some relative information.

**VENTILATORS (Thorn).**—Your openings in the back wall of your greenhouse should have been 18 inches by 6 inches. Then you would do for winter, and in summer you can leave the door open.

**SOIL FOR POTTING (Idem).**—Your loam with a little leaf mould and a little sand, will grow all common greenhouse plants. If small-rooted, as Heaths, you must use heath soil and sand nearly alone. As you have so many materials, we would recommend as a general compost, to have three-parts loam, one of heath soil, one of leaf mould, or dung very rotten, and one of silver sand. Some plants may want a little more loam, others a little more heath soil or sand, and the heaps being handy these are easily added. It is of no importance whether mixed long before or not. We prefer doing it as wanted. The soil from the sides of highways, and a little sand, will grow all common plants.

**GRASS SEEDS FOR LAWN (E. W.).**—For your grass plot, the subsoil of which is *caly*, or finely-divided greenstone, liable to be parched in hot, dry weather, we recommend you to sow at the rate per acre of Crested Dogstail (*Cynosurus cristatus*), 6 lbs.; Hardish Fescue (*Festuca durincola*), 4 lbs.; Fine-leaved Fescue (*Festuca tenuifolia*), 3 lbs.; Rough-stalked Meadow Grass (*Poa trivialis*), 2 lbs.; White Clover (*Trifolium repens*), 8 lbs.; Small Yellow Clover (*Trifolium minus*), 4 lbs. You can calculate the quantities by ascertaining what fraction of an acre your plot is. You had better dig the ground and sow the grass seeds at the end of March.

**OSIER-BEDS (A. Anderson).**—"A stiff, black, peaty moss" is not so good as a mellow sand for this crop. Generally speaking, the margins of rivers (not tidal ones) where the ground is occasionally flooded after heavy rains, are the best places for this plant, or some level tract but slightly elevated above the water mark, and where the uncertainties of flooding render cropping by other things precarious, is often planted with Osiers; but there is no question but that they will do well in any moist, deep soil, and if it were trenched so much the better. But on the margins of rivers liable to flooding this is imprudent, as a considerable part of the loose soil might be washed away, and it not unfrequently happens that Willows are planted by the edges to prevent this, and no planting is better for that purpose. The small Packthread Willow is much used for fine work; but we think the more robust Bedford Willow (*Salix Rosselliana*) will suit the stiff ground you speak of best; but there are a great diversity of sorts.

**INSECTS (W. G.).**—The insects which have spoiled the ends of the young shoots of your Fuchsias, are field bugs (*Phytocoris* sp.). They must be treated just as aphides. Tobacco smoke properly applied will destroy them.—W.

**SEEDLING ROSE (Thomas Laxton, Stamford).**—We are glad to receive another proof that English Rose-lancers are determined not to allow the French to have it all to themselves. You describe your Rose as the result of hybridisation between Général Jacqueminot and a Damask; but it bears so little appearance of having Damask blood in it, that we think the bees must have been beforehand with you, and fertilised it with some other pollen. The shape, colour, and perfume are all good; it being cupped, a bright carmine, and very sweet. It has the fault of its parent in not being sufficiently double, but this may improve. By all means propagate it, and exhibit it next season.

**STRAWBERRY-FORCING (Anna).**—There has been much just to meet your case in late Numbers in "Doings of the Last Week," &c. As your layers are in thumb-pots, as soon as rooted transfer them to 54's, using loam and a little leaf mould. As soon as rooted again, transfer to 32-pots, using stiffish loam and a little rotten dung or leaf mould, keeping the bud about level with the rim of the pot, potting very firm, and leaving about half an inch for water. Set them on a hard bottom full in the sun, water until rains in autumn, protect in winter, and force when you like.

**FUCHSIAS SHEDDING THEIR FLOWER-BUDS (H. W., Mile-end).**—Over-dryness or over-moisture will cause the blooms of Fuchsias to drop. They are more liable this season than usual to drop quickly, owing to the rapid changes in the weather from cold and dull to warm and sunshine. To keep them as long as possible, flies and bees should be kept out of the house by gauze. If the plants are very full of bloom a little top-dressing of rich compost would do them good. In our "Garden Manual," price 1s. 6d., you will find full directions for cultivating Roses.

**COIX LACHRYMA (A. B. W.).**—Your plant (*Job's Tears*), belongs to the Grasses, requires rich soil and tropical heat to bring it to perfection. We would keep it indoors unless the weather was very warm. The flowers hang rather gracefully; but the seeds are the great attraction for their pearl-like appearance, from which they have been designated "*Job's Tears*."

**NOVELTIES (A Very Old Subscriber).**—We cannot foretell whether "there is anything really new and good coming out this season in flowers or vegetables." All that we can manage is to notice them after they have come out.

**SEDUM (T. C.).**—It is an English Sedum, next of kin to *acre*, but with white flowers having a faint pink line in the centre of each petal. A very pretty and scarce sort; the name is *Sedum album*. Many thanks for the Cyclamens.

**NAME OF PLANT—ROSES (E. H.).**—It is the yellow *Datura arborea* of the gardeners, but the right name is *Brugmansia sanguinea*, one of the oldest names in the Flora Peruviana. Cloth of Gold Rose is a most luxuriant climbing Rose, and will do good in a pot. Mrs. Bosanquet is a very nice dwarf light or nearly white flowering China Rose, and one of the very best of that class of Roses to grow in a pot.

**OAKS** (*A. Countryman*).—There is no such distinction as a male Oak and a female Oak. The tree is monoecious—that is, although there are male flowers and female flowers, they are borne by one and the same tree.

**NEW IOBELIA** (*A. O.*).—We have sent the plants and the specimens to Mr. Beaton, and you will see in another page that he has not yet seen the flowers.

**PINE APPLES BLACK IN THE CENTRE** (*M. A. Devon*).—We had a similar inquiry last season; and though having thought much of the matter since, are unable to assign any probable cause, except too vigorous growth, too much moisture at the roots and in the atmosphere, with perhaps scarcely enough of air. We know that such swelling-out processes will produce such a result at times, but we could not say that such were the causes in your case.

**BRUGMANSIA LEAVES YELLOW** (*A. Cheshire Subscriber*).—We perceive the marks of red spider—that is, where they had been. The yellow appearance, however, we should consider to be the result of the roots getting too dry. If the weather was sunny and the pot rather small, such a plant would need watering twice a-day. In dull weather once a-week might do. Frequent syringing would also be an advantage. Most likely a larger pot and rich soil would help you.

**NEGLECTED VINES** (*H. B.—Northampton*).—You treated them quite right, and they will bear a good crop probably next year. If they are not very luxuriant apply a little rotten stable manure to the border, and keep it mulched during the dry, hot weather. If you cannot pick off the caterpillars from Geraniums, Calceolarias, &c. (we never saw such plants attacked), dust them with fresh white hellebore powder. Please to send your address, we have received thirteen postage stamps but no direction. You must send six more stamps.

**GRAPES COLOURING** (*J. W.*).—In answer to your query, "When Grapes are colouring should the house be kept wet or dry?" We can only reply, Let the air contain rather less moisture than during the swelling period. Mr. Thomson is rather emphatic upon the point; he says in his work lately published—"The moment the first berry in the house begins to colour the supply of air should be more liberal both by night and day, and the moisture less, if high flavour be aimed at."

**WHITE DAMSON** (*T. C.*).—Yes, there is such a fruit, you will find it described in Dr. Hogg's "Fruit Manual."

**NAMES OF PLANTS** (*C. Porter*).—1, *Sparanium ramosum*; 2, *Lythrum salicaria*; 3, *Lysimachia ciliata*; 4, *Epilobium angustifolium*; 5, *Poterium sanguisorba* (*A. R.*).—*Lysimachia verticillata*. Holt the *Veronicae* are garden forms, and nameless. One of yours seems to be *arguta*. We cannot tell the *Delphiniums*. *Saxifraga corymbosa*, and, perhaps, *S. adscendens*. We cannot, however, name such imperfect specimens satisfactorily. The London Pride is *Saxifraga umbrosa*. (*Nemo ad B. L.*).—*Euphorbia exigua*, *Asperula cynanchica*, *Polygala vulgaris*, *Gentiana amarella*. (*J. S.*).—1, *Veronica longifolia*, var.; 2, *Pyrethrum parthenium* fl. pleno; 3, *Polemonium ceruleum*; 4, *Lilium martagon*. (*W. B.*).—They are both variegated *Alyssum*, No. 1 being the variegated form of *Kouiga maritima*, the common Sweet Alyssum; and No. 2 the variegated form of *Alyssum saxatile* (*A. Robertson*).—The *Caladium undeveloped*, so we cannot name it. The other plant is *Chaenostoma polyanthum*.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**POULTRY SHOWS.**

- AUGUST 25th, 26th, 27th, and 28th. CRYSTAL PALACE. *Sec.*, W. Houghton. Entries close July 26th.
- AUGUST 27th. COTTINGHAM. *Sec.*, Mr. J. Brittain. Entries close Aug. 20th.
- SEPTEMBER 2d. POCKLINGTON, Yorkshire. *Sec.*, Mr. T. Grant. Entries close August 26th.

**FATTENING YOUNG FOWLS.**

(Continued from page 282.)

THE exact time a fowl should take to fatten is not fixed, it must be ruled by the greater or less predisposition and strength of the animal. Some poulardes cannot be thoroughly fattened without constant risk of failure; the experienced feeder knows exactly when he must cease his efforts. He knows he must suffer losses: spite of all skill and attention some years are more favourable than others without any apparent reason. A man full of the experience of many years following his business at two places will succeed at one, and experience serious losses at the other from utter inability to finish fattening his poulardes.

Some are fat at the end of six weeks, others at two months. When a poularde seems disposed to continue to do well, and to thrive, the feeding is persisted in, and marvellous weights are thereby attained.

It is estimated some fowls consume 20 quarts of meal, others as much as 30 quarts.

These birds equally imprisoned in constant obscurity never have any litter of any kind, and are never cleansed during their treatment.

If the emanations in consequence, and which are abundant, are necessary to assist in fattening, they are, nevertheless, very

hurtful to the health of the feeders, who suffer in proportion to the number of fowls under treatment. Where there are eighty or a hundred fowls, feeders pass almost the whole day and part of the night attending to them in a centre of infection. When the first meal begins at four A.M., it is hardly over at twelve, and the second begun about three o'clock, is only over at eleven.

When the fattening is over the poulter has to kill and pick them, and before they are cold he places them on their backs on a slab or narrow table, and gives them the form so well known by means of shapes of wood or stone, which compel them to stiffen in the desired position. Then, on every projecting part of the body, a thin wetted cloth is spread, and this gives a fine grain to the fat.—(*Poulailler, Jaquie.*)

We must reserve the continuation of this subject, which will now go into calculation for another paper. The practice in England is so different from that quoted from Mr. Letrove, many respects, that we cannot help remarking on it.

In England the process of cramming is not continued for five or six weeks. It may be that some old-fashioned poultry Rip Van Winkle, who still adheres to the idea there must be Capons at Christmas, persists in feeding the wretched animals; but as a rule our best fowls are only crammed during a fortnight or at most three weeks. The houses in which the fowls are fed are as clean and sweet as ordinary sitting-rooms; they are generally out-houses or other farm-buildings, square and lofty. The fattening-pens are ranged around; and so far from the birds being kept in filth, they are scrupulously clean. The bottoms of the fattening-coops are made of bars only; anything, therefore, like an accumulation of dirt is impossible, all falls through to the ground, and is carefully removed every morning. In this country the theory that anything is gained by dirt, or that it favours fattening, is exploded. For the same cause those who follow this calling are perfectly healthy. There is nothing to prevent it. They also cram fowls far more expeditiously than our neighbours. Judging from what we read, if Mr. Letrove is describing the present day, we are in Surrey and Sussex far a-head of La Flèche.

**GAPES IN POULTRY.**

So frequently have we been asked for minute particulars relative to the parasitical vermin causing this disease, that we readily copy the following from that excellent work now publishing in monthly parts, "Chambers' Cyclopædia"—

"It is a disease of gallinaceous birds, owing to the presence of a trematode worm (*Fasciola trachealis*) in the windpipe. This entozoon, allied to the fluke, is, however, a creature of very

different general form, being a red, wavy, cylindrical worm, tapering at the tail, and forking near the upper extremity, the branch which is sent off terminating in a sucker for adhesion, whilst the mouth terminates the principal trunk. The whole length of the worm seldom exceeds an inch. Twenty of these worms of various sizes have been found in the windpipe of a single chicken. Pheasants, Partridges, &c., are also liable to be infected by them. They produce inflammation, and sometimes suffocation and death. A common remedy is to introduce into the bird's throat the end of a feather, well oiled, and to turn it round, so as to dislodge the worms, which are then either brought out by the feather, or coughed out by the bird. Another cure is to give a little Epsom salts mixed with the food. Urine is often used in the same way, and with similar efficacy."

A The whole worm.  
B The upper end, magnified.  
a The sucker at the end of its branch.  
b The head, with mouth.

**CRAMP IN GOSLINGS.**—A lady, writing in the *Irish Farmer's Gazette*, says that she finds that this painful disorder is cured by, for about three hours, keeping on the legs of the birds so attacked strong mustard plasters. We should think the same remedy would be as effectual for the cramp in chickens, and the spraws in ducklings.

## DRIFFIELD & EAST RIDING AGRICULTURAL SOCIETY'S POULTRY SHOW.—JULY 25TH.

**DORKINGS.**—First and Second, H. Berwick, Helmsley. *Chickens.*—Prize, H. Key, Beverley. *Cock.*—Prize, M. Kirkby, Driffield.

**SPANISH.**—First, R. Tate, Driffield. Second, T. C. Trotter, Sutton. *Chickens.*—Prize, R. Tate. *Cock.*—Prize, A. Hudson, Onsecliff.

**GAME** (Black-breasted and other Reds).—First, H. Adams, Beverley. Second, W. Boyes, Beverley. *Chickens.*—Prize, H. Adams. *Cock.*—Prize, H. Adams.

**GAME** (Duckwing and other Greys).—First and Second, H. Adams, Beverley. *Chickens.*—Prize, H. Adams. *Cock.*—Prize, H. Adams.

**GAME** (Any other Variety).—First, H. Adams, Beverley. Second, W. Charter, Driffield. *Chickens.*—Prize, M. Merkin, Driffield. *Cock.*—Prize, W. Horner, Driffield.

**COCHIN-CHINA.**—First, W. Witty, Cottingham. Second, H. & G. Newton, Leeds. *Chickens.*—Prize, W. Witty. *Cock.*—T. C. Trotter, Hull.

**POLANDS.**—First and Second, H. Beldon, Bradford. *Cock.*—Prize, H. Beldon.

**HAMBURGS** (Golden-spangled).—First, R. Tate, Driffield. Second, H. Berwick, York. *Chickens.*—Prize, R. Tate. *Cock.*—Prize, A. Hudson, York.

**HAMBURGS** (Silver-spangled).—First, H. Beldon, Bradford. Second, S. Campling, Cottingham. *Chickens.*—Prize, H. Beldon. *Cock.*—Prize, H. Beldon.

**HAMBURGS** (Golden-pencilled).—First, H. Beldon, Bradford. Second, W. Charter, Driffield. *Chickens.*—Prize, R. Voakes, Driffield. *Cock.*—Prize, Mrs. Boynton.

**HAMBURGS** (Silver-pencilled).—First and Second, H. Beldon, Bradford. *Chickens.*—Prize, H. Beldon. *Cock.*—Prize, H. Beldon.

**ANY OTHER VARIETY.**—First, H. Adams, Beverley. Second, R. Tate, Driffield. *Chickens.*—Prize, H. Beldon, Bradford. *Cock.*—Prize, W. Witty, Cottingham.

**FABYAND CROSS.**—First, — Robinson, Frodingham. Second, — Bilton, Cottingham. *Cock.*—Prize, — Loft, Woodmansey.

**BANTAMS** (Black and White).—First, H. Layburn, Beverley. Second, R. Tate, Driffield. *Cock.*—Prize, — Holdsworth, Leeds.

**BANTAMS** (Any other Variety).—First, R. Voakes, Driffield. Second, R. Tate, Driffield. *Cock.*—Prize, K. Perrin, Hull.

**GEES.**—First and Second, R. Tate, Driffield. *Goslings.*—Prize, — Robinson, Swarthorpe.

**TURKEYS.**—First, R. Tate, Driffield. Second, Mrs. Dawson, Driffield. *Poult.*—Prize, Mrs. Conyers, Emswall.

**GUINEA FOWL.**—Prize, R. Tate, Driffield.

**DUCKS** (Aylesbury).—First, R. Tate, Driffield. Second, O. A. Young, Driffield. *Ducklings.*—Prize, G. Simpson, Burton.

**DUCKS** (Rouco).—First, R. Tate, Driffield. Second, O. A. Young, Driffield. *Ducklings.*—Prize, Mrs. Jordan, Driffield.

**DUCKS** (Any other Variety).—First, J. R. Jessop, Hull. Second, — Laybourn, Nafferton. *Ducklings.*—Prize, — Robinson, Frodingham.

**PIGEONS.**—*Croppers.*—Prize, W. Witty, Cottingham. *Carriers.*—Prize, E. Holdsworth, Leeds. *Trumpeters.*—Prize, F. Key, Beverley. *Jacobins.*—Prize, W. Charlton, Howden. *Fantails.*—Prize, J. R. Jessop, Hull.

**TUMBLERS.**—Prize, T. Rippon, Beverley. *Barbs.*—Prize, W. Witty, Cottingham. *Nuns.*—Prize, F. Key, Beverley. *Any other Variety.*—Prize, F. Key, Beverley.

**RABBITS.**—*Any Breed.*—First, J. Leason, Driffield. Second, W. Charter, Driffield.

**EXTRA PRIZES.**—*Game* (Black-breasted).—Prize, H. Adams, Beverley. *Cock.*—Prize, H. M. Julian, Beverley. *Game Cock.*—Prize, H. Adams, Beverley. *White Dorking Chickens.*—Prize, J. Harrison, Kilnwick. *Peacock and Hen.*—Prize, Mrs. Nicholson, Little Driffield. *Geese.*—Equal Prize, J. Hodgson, Belford; Mrs. Nicholson; F. C. Matthews, Driffield. *Extra Pigeons.*—Equal Prize, F. Key, Beverley; E. Holdsworth, Leeds.

**JUDGES.**—Matthew Hunter, Esq., Green Hammerton Hall, York; Samuel Bird, Esq., Shipley, Bradford.

## SHEFFIELD POULTRY SHOW.

This Show commenced on the 2nd inst., and will be continued till to-day (Tuesday). We shall give our report next week.

The following were the awards of the Judges:—

**SPANISH.**—First, R. Teebay. Second, J. Martin. Third, E. Brown. Commended, J. K. Fowler. **CHICKENS.**—First and Third, J. R. Rodbard. Second, T. Greenwood. **COCK.**—First, R. Teebay. Second, J. R. Rodbard. Highly Commended, R. Teebay; T. P. Wood, jun.

**DORKING** (any colour).—First and Second, Lady Julia Cornwallis. Third, T. W. Hill. Commended, Mrs. Gay. **CHICKENS.**—First, F. Key. Second, J. F. Newton. Third, T. Hadfield. **COCK.**—First, Lady Julia Cornwallis. Second, H. W. B. Berwick. Highly Commended, E. Tudman.

**GAME** (White and Piles).—First, H. Adams. Second, W. Wood. Third, G. Haigh. **CHICKENS.**—First, J. Wildens, jun. Second, J. Camm.

**GAME** (Black-breasted and other Reds).—First, W. Robson. Second, J. Fletcher. Third, H. Adams. Commended, S. Marsh; G. Hellewell; H. M. Julian. **CHICKENS.**—First, W. Bentley. Second, W. Robson. Third, J. Sunderland, jun. Highly Commended, T. Colley; T. Moss. Commended, T. Fiddler.

**GAME** (Black and Brassy-winged, except Greys).—First and Third, G. Hellewell. Second, W. Dawson. **CHICKENS.**—First, W. Dawson. Second, H. Hellewell.

**GAME** (Duckwings and other Greys and Blues).—First, S. Matthews. Second, W. Fell. Third, J. Fletcher. Commended, T. Greenwood. **CHICKENS.**—First, W. Fell. Second, W. Bentley.

**GAME COCK** (any colour).—First, J. Camm. Second, W. Robson. Third, S. Matthews. Extra Third, W. Boyes. Highly Commended, T. Colley; H. M. Julian. Commended, J. Fletcher.

**COCHIN-CHINA** (Cinnamon and Buff).—First, J. K. Fowler. Second and Third, T. Stretch. Commended, H. Bates. **CHICKENS.**—First, H. Bates. Second, T. Stretch. Highly Commended, W. Watkin.

**COCHIN-CHINA** (Brown and Partridge-feathered).—First, T. Stretch. Second, P. Cartwright. Third, H. Yardley. Highly Commended, E. Tudman. Commended, R. White. **CHICKENS.**—First, E. Tudman. Second, J. K. Fowler.

**COCHIN CHINA** (White or Black).—First, R. Chase. Second, W. Dawson. Third, no competition. **CHICKENS.**—First, W. Dawson. Second, R. Chase. **COCK** (any colour).—First, E. Tudman. Second, H. Yardley. Third, J. Martin. Commended, W. Wood; R. White.

**BRAMA POOTRA** (Light or dark).—First and Second, R. Teebay. **CHICKENS.**—First, J. K. Fowler. Second, R. Teebay. Commended, J. Fares. **COCK.**—First, R. Teebay. Second, J. K. Fowler.

**HAMBURGH** (Golden-pencilled).—First, J. Pritchatt. Second, A. Nuttall. Third, J. Munn. Highly Commended, R. Hemingway. **CHICKENS.**—First and Second, A. Nuttall. Highly Commended, J. Munn. Commended, T. Parkinson; Hon. W. T. W. Fitzwilliam; F. Hardy.

**HAMBURGH** (Golden-spangled).—First, G. R. Tate. Second, G. Brook. Third, J. Burton. Highly Commended, T. Wilcock; W. K. Lane. **CHICKENS.**—First, G. Brook. Second, J. Ashcroft. Third, G. Haigh.

**HAMBURGH COCK** (Gold or Silver-spangled).—First, Lady J. Cornwallis. Second, H. A. Hudson.

**HAMBURGH** (Silver-pencilled).—First and Third, J. Martin. Second, W. H. Kerr. **CHICKENS.**—First, J. Dixon. Second, Mrs. Harrop. Third, A. Nicholson. Highly Commended, T. Barber.

**HAMBURGH** (Silver-spangled).—First, H. Carter. Second, J. Ashcroft. Third, R. Teebay. **CHICKENS.**—First, C. W. Brierley. Second, W. M. Mellon. Third, J. Ashcroft. Highly Commended, H. Bancroft. Commended, J. Sunderland; H. Carter.

**HAMBURGH SINGLE COCK** (Gold or Silver-pencilled).—First, Mrs. Froggatt. Second, J. Munn.

**POLAND** (Black, with White Crests).—First, J. Dixon. Second, H. Carter.

**POLAND** (any other variety).—First, J. Dixon. Second, F. Hardy.

**COCHIN CHINA** (any colour).—First, H. Yardley.

**GAME BANTAM HENS** (any colour).—First, J. Camm.

**Judges:** Mr. Tegetmeier, of London, and Mr. Edwd. Hewitt, of Birmingham.

## LIGURIAN BEES IN SCOTLAND.

CIVIL WAR—COMBS BUILT IN A TREE—ACCIDENT TO A QUEEN—UNITING BEES.

MY stock of Ligurians which I received from "A DEVONSHIRE BEE-KEEPER" last April have done remarkably well, considering that they were decimated at the beginning by some mysterious internal broils,\* and the season has been all through uncommonly bad.

They threw a fine swarm in the beginning of June, another small one after the usual interval, and another still. Also, a smaller one has been given off since, but I do not know the time, as they were only discovered last week in a neighbouring orchard, established on the branch of a tree, and on which they had constructed two considerable combs, both containing honey and pollen, but no brood. I got them hived with some difficulty, and left the hive at the foot of the tree. They are very weak, and will not now have time to increase this season. I have been thinking whether I could strengthen with some common bees; and the other day an accident occurred to one of my hives, which has pointed my attention to it more particularly, and which seems to afford peculiar facilities for making my small Ligurian colony a strong one; but I would be particularly obliged by the advice of "A DEVONSHIRE BEE-KEEPER" in the matter before doing anything.

The hive to which the accident occurred is a year or two old. It is a common straw skep with a fixed wooden top, and is very strong, as it has not swarmed this season. It has two supers to give room—first, a large strong one, and above a glass. It has

\* A most inexplicable internecine war broke out amongst these Ligurians immediately after their arrival in "the land of cakes," which raged with such fury that for some time it threatened the same fatal result as attended the celebrated feud between two Kilkenny cats.—A DEVONSHIRE BEE-KEEPER.

been killing drones for a week past, and they are thickly strewn about. The other day I proceeded to take off the glass super by inserting a thin plate of zinc cautiously between it and the one underneath. The glass and zinc plate were then carried away; and some time after when the glass was lifted I found a queen at the side of the plate surrounded by a few bees so much injured that she died soon after. I must have done this while inserting the zinc, and the consequence is, that a strong hive is left without a sovereign, and at a time when I suspect it is too late to raise another. I may mention the mishap caused no particular disturbance, either among the bees in the hive, or those in the super I had taken off.

My idea is to drive them into an empty hive, put them back on their stool till night, then carry them to where the small Ligurian hive is, turn up the hive in which they are, sprinkle with syrup, set the Ligurian hive over it, and early the next morning when they may be expected to have all gone up together, carry the joined hive away a mile or two, as there being a few hundred yards between the places where they now are, the driven bees might come back from the spot where the Ligurian now is to their old place. I would expect to find a good deal of brood in the old hive if done now, and would either give it to the united hive to hatch out, or place it at once when driven on the top of some other hive.

If driven during the day would the bees without a queen remain quietly in an empty hive on their old stand (from which egress could be got) till the evening? In my little experience I have never been in the same position before.—J. B.

[The only improvement I can suggest upon the course you propose, is to scent the syrup by adding to it a little peppermint water, and baptise both parties liberally before their union, which I should effect by removing the crown-board, if the Ligurians are in a bar-hive, and knocking the cluster of common bees out on the top of the exposed bars. Should the Ligurians be in an ordinary straw hive or box, the cluster of black bees must be knocked out on a cloth spread on the ground, and the Ligurian hive at once placed over them supported on a couple of sticks at least an inch thick, laid on the cloth rather more than a foot apart. You may insure the queenless bees remaining quiet during the day by cutting out a royal cell with a piece of comb attached to it, and fastening it to the top of the hive in which you wish them to remain, by means of a flat-headed nail driven through the comb.—A DEVONSHIRE BEE-KEEPER.]

#### DELAY IN HATCHING A QUEEN.

I MADE an artificial hive twenty-five days since, and when I looked this morning I found one queen's cell not opened-up, but the cell seems long and too much pointed, so that I am afraid there is something wrong, seeing that it is now twenty-five days and all the other brood are out and the queen not. I may state that they began making eight queen-cells, and when we next looked they had only two with brood in them, and now only the one as I have stated. I always understood that a queen took a shorter time to raise than a worker bee or drone, and I shall be glad to know if I am mistaken, and that we may have hope of this one?—A. SHEARER, *Yester Garden*.

[I have had an instance this season in which royal cells did not hatch until the twenty-second day after the removal of the old queen, which is a sufficient proof that the limit of sixteen days fixed by Huber, Bevan, and others, is sometimes considerably exceeded. The queen was a very fine yellow Ligurian, and turned out (as all queens of this species appear to do), amazingly fertile. There is nothing wrong in the shape of the cell according to your description. A long-pointed cell generally produces a very fine queen. I should certainly recommend you at all events to furnish the colony with another brood-comb, which will be of great service to it, whether the royal cell has produced a queen or not.—A DEVONSHIRE BEE-KEEPER.]

#### QUEENS KILLED OR MUTILATED BY THEIR OWN WORKERS.

TO WHAT AGE DOES A YOUNG QUEEN REMAIN CAPABLE OF PERFECT IMPREGNATION?

THE present season may indeed be said to be adverse to bees and honey-gathering, and no locality appears to have been favoured; Devonshire and Somersetshire being announced as bad, and I can add, Middlesex is wretched, and Northumberland

still worse. What I would now call the particular attention of bee-keepers to is the note of warning sounded by "A DEVONSHIRE BEE-KEEPER," that the season has been peculiarly disastrous to the young queens, and it is well to look to the hives which ought to possess them while there is yet a chance of some favourable weather sufficiently warm to secure their due maternal character.

The singular treatment which several queens have been discovered to undergo from their subjects, detected by the vigilance of your correspondent, is a subject of much difficulty, and to which I confess to have been looking forward with interest, as likely to fall under his observation had he prosecuted experiments to test the effect of retarded impregnation by mutilation or otherwise. I have suspected for several years that in certain conditions of the queen and hive, rebellion, regicide, and civil war were not unknown in this unusually loyal community. The latter I have witnessed unmistakably, following, I suspect, on the two former. The question naturally occurs, Why should the bees destroy a queen which they find will not become fertile, when there is no brood in the hive, and no chance of improving their condition? Or does a queen become debilitated after a series of fruitless excursions or confinement to the hive from the unfavourable state of the weather?

Two out of three hives which swarmed early in June were found five weeks afterwards to be queenless. In one of these instances no particular observation was made. In the other, when the queen was near a month old, and it was expected had begun to lay, there was evident restlessness on the outside, and the next day the queen was seen to leave the hive. She was again seen three days afterwards, and the next day there was again excitement, and then she was found dead on the ground. I have since heard that a hive in an adjoining apiary which swarmed about the same time is also queenless.

The above corresponds with results which followed experiments I made some years ago in slightly mutilating the wings of young queens. It did not prevent their flying, as I frequently saw them go off; but two were brought out of their hives dead, one of them on the evening of a day on which I had seen her take flight, the bees rushing out as if going to swarm at eight P.M.

It is not less singular that the bees should be found to hold the queen a prisoner in her hive. That they may throw themselves round her, and enclose her in a dense cluster when threatened by danger, I have witnessed; still it is probable they may be impelled by other feelings than those of love\* in the forcible detention which has been observed. I once saw a queen most roughly received on her return from her last excursion; but I have no doubt it was in the excess of their joy that the bees seemed ready to tear her to pieces with their violent caresses, while the poor queen sought repose and rest. As they were in the unicomb-hive, I had a full view of the interesting scene, and was not without apprehension that the queen would be found minus a leg or wing.

It is satisfactory to find the excursions may not be limited to the fatal twenty-first day of Huber; now the apiarian readers of THE JOURNAL OF HORTICULTURE will hope to learn to what term this period may be extended before the queen becomes deteriorated so irreparably as to produce drone eggs only. Probably the temperature will have an important power in regulating this phase of queen-life.—INVESTIGATOR.

[I wish all apiarians who have sufficient leisure would follow the excellent example of "INVESTIGATOR," whom I beg to thank for his experiments, and for making their results public. At the same time I regret that I am not myself able to practise extensively what I so earnestly recommend to others. The cares attending the multiplication and dissemination of the Ligurian species of honey bee are such as almost to preclude me from entering the lists as an experimentalist, and confine me to observations only; the results of which, however, I am always happy to communicate to the apiarian readers of THE JOURNAL OF HORTICULTURE.

On the 29th July, I had a remarkable instance of the facility with which bees will sometimes rebel against their own sovereign. Having attempted to strengthen a weak Ligurian stock by standing it in the place of a strong half-bred one, I found the queen closely imprisoned (probably by the strangers), and on releasing her had the mortification of discovering that she had been stung, and was struggling in the last agonies of dissolution.†

\* I believe the reverse of love is always manifested by these demonstrations.—A DEVONSHIRE BEE-KEEPER.

† This case and several others which I have witnessed, prove Huber to have been mistaken in declaring that workers never sting a queen.

Not setting any great value on the hybridised queen-mother of the regicides, I thought I would try how she would be received, and accordingly took her from her own hive and transferred her to one of the brood-combs of the other. She was instantly attacked, but I got her away with some difficulty, killing a bee which had pinioned her close to the root of one wing, and whose head, even when detached from its body, still hung by the mandibles, and could not readily be disengaged. Disregarding this incumbrance, I introduced her at the top of her own hive, but was amazed to see her hostilely received after an absence of so few minutes, and was still more astonished to find her the next morning cast out of her hive quite dead.

In page 304, I related an instance in which a fertile and prolific queen only a year old was mutilated by the loss of the last joint of one of her hind legs. Since that article appeared, she has again been maltreated. On the 25th of July I repeated my examination, and found only the stump of the unfortunate limb remaining, another joint having been dismembered in the interim.\* At the same time I discovered and destroyed two sealed royal cells. This latter fact would seem to argue a chronic state of discontent, and a settled determination on the part of the workers to transfer their allegiance to a new sovereign, since the population is by no means sufficient to warrant the sending forth of a swarm.

With regard to the extension of time for the wedding flight beyond the supposed fatal twenty-first day, I can add nothing more from my own experience, but I find the matter has not escaped the close observers of Germany. In reference to this point Herr Neidholdt, writing on the 25th November last, says—"It was formerly thought that the impregnation of the queen had to take place in a certain period, and that it was afterwards no longer possible. This theory has recently lost its credibility since the Rev. Mr. Dzierzon says the time within which a young queen can take her wedding flights cannot be fixed. That this is indeed the case, the year 1860 has very clearly proved, owing to the alternations of warm and cold weather. In my apiary many a young queen took her wedding flights after four and even after six weeks, partly with success and partly without: many did not return. Herr Henmann confirms this, by declaring that one of his queens was not impregnated until the forty-sixth day. Nay, I assert that a queen continues her wedding flights, supposing the weather to be favourable, until she attains her end or perishes. I even go a step further, and say that a queen still flies out and retains the instinct of impregnation after she has begun to lay drone eggs." In this latter opinion, however, Herr Neidholdt differs from Herr Dzierzon who says:—"The queen certainly no more flies out after she (of course drone eggs), once has begun to lay." Two instances are given by Neidholdt in which young queens first laid drone eggs, remaining, as he declares, evidently in a virgin state, and afterwards becoming impregnated proceeded to lay worker eggs in the usual way. I have myself had a case this season in which a young queen commenced by laying a large patch of drone-brood in worker-cells, although ultimately she turned out perfectly fertile, and laid worker eggs with astonishing rapidity. In this case the miniature drone-brood was nursed to maturity, when the unfortunate liliputian males were expelled without mercy.—A DEVONSHIRE BEE-KEEPER.]

### DESTRUCTION OF A YOUNG QUEEN.

A FRIEND brought me a swarm this morning (23rd July), from a hive which had thrown a swarm on the 1st of June, and a second on the 14th. The queen had been thrown out during the night. The bees in this hive had always seemed unsozial. He examined them on the 10th of July and found no brood; again on the 20th, and found brood. We examined the queen with a microscope and could find no eggs as described by "A DEVONSHIRE BEE-KEEPER," only yellow matter. Does "A DEVONSHIRE BEE-KEEPER" know any case in which a queen has laid so few eggs and been thrown out?—A. SHEARER, *Iester Gardens*.

[I have known many queens expelled from their hives, but remember none so young being expatriated in this manner after they had laid eggs. It is by no means easy to distinguish eggs

in the ovaries of a queen bee under the microscope, especially when the ovaries themselves are not well developed, which was very probably the case with the one you experimented upon.—A DEVONSHIRE BEE-KEEPER.]

### OUR LETTER BOX.

**GOLDEN-SPANGLED HAMEDEGES AT LEEDS (W. Lawson).**—We are not surprised at any oversight which may have occurred to the Judges at that Show, for they had to commence their task at 9.30, and the public were admitted at 12. However, the bird you mention, we are informed, won the first prize at Prescott, and if so other judges were similarly deceived; and so good a bird was he considered, that one exhibitor expressed a wish to purchase him for five guineas. We state this to show that we have made inquiries. And now let us add what we consider was the duty of the two members of the Committee, who, with you, detected that the bird's earlobes were painted. They should have forthwith directed the Secretary not to pay the prize to the owner, for if the Judges had been informed of the fact they would have rescinded their award. It was a fraudulent proceeding, and we believe that the money could be recovered from the owner of the bird.

**HENS DYING OF APOPLEXY (A Subscriber, Midland Railway).**—Do not let them have the same nutritious food that you give to their chickens, but feed them chiefly on boiled potatoes, with a very little ground barley, or ground oats, mixed with them. Let the hens have a grass run, and lettuce leaves, but no cabbage leaves unboiled.

**GOOD POINTS IN COCHIN-CHINAS (Partridge Cochin).**—We cannot perhaps recapitulate all the points some of our judges look at, but we can give the principal ones, and the claws are not among them. Small sharp head, perfectly upright small comb, with numerous serrations; tightly clipped wing, large fluff, a gradual rise from between the two wings to the extremity of the tail, which should be small. Add to these, well-feathered legs, and even colour, and we should be satisfied. We forgot the wattle should be double, peadant, and red.

**CROOKED COMBS (Idem).**—We know to our cost crooked combs never become straight; it is like a stooping gait in a young man, it becomes worse as age grows on. All such go into puddings with us; and as they are excellent in that compound, we not only forgive, but look for them. The well-fasted chicken is killed; the next day, or two days after, it is cut into small joints, slightly, very slightly seasoned with pepper and salt. A good light but not very thin crust is made and put into a basin, the members of the chicken are mixed with small thin slices of bacon—if at hand, two or three kidneys are added to it, and it is boiled gently as long as you please, being tied in a cloth. In hot weather, when beef and mutton are hard, this will give a good dinner. It is hardly possible to overboil it.

**PINIONING YOUNG WILD DUCKS (Amateur).**—Your Ducks must be pinioned immediately. We need hardly say you will pinion but one wing. Take either the right or left wing, tell off the first five feathers, this will bring you to a joint. Some will tell you this is the flight, and you need cut no more. We assure you they fly nearly as well without as with these five feathers. Try the wing down with the thumb and finger till you come to the second joint: this is about midway between the spur and the tip. Keep on till you come to the spur, which is a very sharp projecting bone, take a sharp and strong-backed knife, put it under the spur dividing the ligament that connects it to the wing; and when you have brought the edge to bear on the bone, above the joint, which forms the third from the tip or extremity let some one strike the knife sharply with a stick or hammer—the bone is divided, the wing cut off, and the bird ready to feed. They do not suffer in any way from the operation. The spur must be left, as it protects the wound, and the joint should not be injured.

**RABBIT WITH FACE-SWELLING (S. H.).**—From your statement we conclude that a tumour is forming, and if so the only remedy is to open it by means of a pair of sharp-pointed scissors as soon as it has come to a head. No application will be needed. You had better write to Mr. Houghton, Secretary of Poultry Show, Crystal Palace, Sydenham, for we do not know what the railway arrangements are for the conveyance of poultry thither.

**EXAMINING A HIVE (R. C.).**—If you wish to obtain an interview with her Ligurian majesty without inconvenience to yourself and with safety to your bees, you cannot do better than commence proceedings in the manner described by Mr. Woodbury, in page 285. Having administered "a sop to Cerberus," and removed the crown-board, select the side-comb on which the smallest number of bees are congregated; look it carefully over on both sides to make sure that the queen is not present (which is, however, very seldom the case, her place being usually more near the centre of the hive); and having satisfied yourself on this point, place it in an empty box, or stand it carefully on one side where it cannot be blown down. Then steadily raise the next comb, holding it carefully over the hive, so that there may be no risk of the queen or any other bee falling on the ground; and, having completed your inspection of both sides, put it in the place originally occupied by the side comb. Proceed in this way by examining and shifting comb after comb into the place occupied by its predecessor until the examination is complete, when if the desired interview has been obtained, and nothing more remains to be done, the operation may be finished by inserting the first-removed side-comb in the vacant space left on the opposite side to that from which it was taken, and replacing the crown-board. If a repetition of the process be necessary, the combs should be again examined and placed one by one in their original positions. Whenever a side-comb is removed to the opposite side to that from which it was taken, the fact should be noted in order that during the next inspection things may be restored to their normal position.

**HEN CANARY (Bookworm).**—For such a bird as you need we can recommend Mr. Hawkins, of 6, Bear Street, Leicester Square. He is a very respectable dealer in birds, of whom the best and choicest varieties of Canaries can be procured. We believe that the price of Norwich Canaries per pair is from 10s. 6d. to £1.

**CUTTING A LINNET'S CLAWS (E. H.).**—A Linnet's claws which are such a length as to lap over each other, should be cut. Enough should be removed to reduce them to the ordinary length, and taking care not to cut down to the flesh.

\* At this point I dropped my pen and once more examined the hive (July 30). I found things in *status quo*, worker-brood in all stages, and plenty of it, with the poor mutilated queen hobbling over the combs in the due fulfilment of her royal functions.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 73.8° and 58.9° respectively. The greatest heat, 92°, occurred on the 15th, in 1842; and the lowest cold, 32°, on the 13th, in 1839. During the period 141 days were fine, and on 104 rain fell.

NEW BEDDING EDGING PLANTS, CAPE BULBS, AND NOSEGAYS.

**CERASTIUM** Biebersteinii is, indeed, a most charming plant, worthy of all the honours in the schedules of awards. I shall give you a comparison by which you may know it, and that without seeing it. It is exactly, to a shade, the best pattern of the most snowy white satin as compared with common ash-grey-coloured silk. Nor silk nor satin, Greek nor Latin, can be more different than the two Cerastiums in all other respects. More white, more woolly, more prostrate, more manageable, and more of an edging-like plant than even tomentosum, of which you might make a small bed about 4 feet across, and make the edging of Biebersteinii, to see the con-

trast, and to prove what "NICKERBOB" said about it. That bed would also prove another thing, if I am not much mistaken:—it would prove to a person half blind of vision that equal quantities of the Alyssum variegatum with Flower of the Day Geranium, is like salting vinegar, while the two Cerastiums would combine, and form one of the softest tints that you could find between any two plants in the catalogue. I shall never forget the disagreeable twinge of my eyelids when I first looked on that variegated Geranium along with the Alyssum as a mixed bed at the Crystal Palace, and now I am glad to have the opportunity for giving you a sample to enable you and your friends to decide for yourselves. Make two beds instead of one, both to be of one size, and not far apart; then any time between ten in the morning and three or four in the afternoon, just come upon these two beds with the sun directly to the back of the head, and to any one to whom the two are much alike, I do hereby engage to tell a secret. Another thing which I recollect had given a most painful sensation to one's vision, was the use of various-coloured sands round beds edged with various sorts of variegated plants. I think that was the most unpleasant to the eye of all the combinations of colours I ever set my eye on; and I am almost persuaded that no variegated plant ought to be used in beds which are surrounded with very white gravel, or sands, or broken doctor's bottles, if you like it that way, or, at all events when such plants are the edgings; and I prophesy that the new edging Lobelia Paxtoniana will not do well next to light-coloured sand or gravel, nor against white brick walls, or walls of light stone colour anywhere, because I never could fancy a variegated or light-foliaged plant against the Suffolk white brick walls when I had to "furnish" against them with flower-boxes and such contrivances.

But there is one thing here (Surbiton), that would prove the point, and it is worth going ten miles to see it, even if one had to walk half the distance instead of about 150 yards from our railway station. It is a new light-coloured-brick house in the Adelaide Road, behind the church; there is a large, or rather three large windows in one bow to a front drawing-room. The window-sill is as if the late Sir Charles Barry had been the architect, and quite different to the "snibs" of sills you mostly see to the windows of villas round London. This bow sill is boxed for flowers all round; the run of boxes may be about 12 feet or so. The three boxes are "rusticated," as they say—that is, small hazel-rods are peeled and split in two, and the flat side put next the box and nailed on in patterns. The whole is then painted and varnished—a very nice way indeed almost anywhere. But now about the colour of the boxes: there is where the grand secret is for giving a good or a bad effect to the thing itself. The colour which is best to put against a light-coloured wall, or house, is not the desirable colour for placing against a red-brick house. The case is like the white or whitish plants in beds on different-coloured gravels, as above; and without waiting to enumerate the best, the second, and the third best colour for this or that coloured wall. I will state that the boxes here alluded to are painted dark brown—say one shade darker than the colour of a ripe Horse-chestnut, and it seems a soft, agreeable contrast to the light walls.

I recollect three or four years since of hearing a smart, intellectual discussion at the Crystal Palace between some artists there about the best kind of colour for the screen behind plants at the Exhibition there, when the green cloth at the Palace and the green baise at other Shows were both put down as of third-rate merit, and dark brown as the best; but the second best was not mentioned. The chief reason against the use of any sort of green being used with plants was, that you could never get the varied green of vegetation to harmonise or combine with the green of the dyers, neither could they be made of shades to contrast; and when two colours, or two or more shades of one colour, will neither combine to make one whole, or full, or rich colour, or contrast, they should never be placed side by side. Well, then, dark brown carries the day at Surbiton against light-coloured walls; but the colours and the contrast of the flowers in the boxes are the equivalent value of the journey to these parts. The boxes are in one continuous line round the three windows in the bow, and are filled with one kind of Geranium, much in the style and colour of Christine, but not exactly that sort of Geranium; and the outside of the boxes is fringed all round, to the depth of a foot or so, with the *Oenothera prostrata* falling over the edges of the boxes, and hanging down that far on a dark brown ground colour. The whole has, altogether, the prettiest effect I ever saw produced with flowers; but it only shows what can be done with simple means when people know the value of effect, know what to choose, and what to reject, according to the situation. And it is just the same all through, from the milliner's show-room to the

dressing-room, and from the dressing-room to the farthest-off end of the garden—indeed, to all inside or out, upstairs or down. So much for new edgings, combinations, and contrasts in flower-gardening.

I have the most extraordinary edging plant this season almost without knowing it. I had twelve little plants of it sent me in a small 48-pot, last May, among a lot of experimental plants from Mr. Scott, of the Merriott Nurseries, Crewkerne, without a word as to what it or any of them was or were to be. I gave them all a run in cocoa-nut refuse; and whether it was the "pulp," or the nature of this plant, or both put together, I know not, but this one turns out the very next best edging plant after Bieberstein's *Cerastium*. It is some *Arctotis* from the Cape of Good Hope. The name I had with it is *Arctotis melanocyclus*; but in the free soil out in the garden, the habit is altogether different from the published description I have of that kind of *Arctotis*. It is a silvery, prostrate plant, and will not rise an inch off the surface of the bed or border, but will creep along slowly in all directions, and when a shoot gets out of the line, all it needs is a little peg stuck in the ground on the one side of it to direct it in the way it should go, and go it will, and look as pretty and as manageable an edging plant as any one of those now in use, and the *frosted-silver Arctotis* will be the best garden name for it; the look of it being more after the manner of a slender Ice Plant in silver, than any thing else to which I can liken it. Very likely it is as an outcast in many of our large nurseries, or has been time out of mind; but all you will have to bear in mind is, that it has been fixed to stand between the two *Cerastiums*, and, therefore, you can do as you please about it.

Then that other white, woolly, softwooded plant that has been brought out this season at the Crystal Palace, where it edges a long-pointed corner hed on the north-east side of the Rose Mount, and where it is called *Cnaphalium lanatum*, has proved itself to be one of the most useful of all the greenhouse or cold-pit plants for ribbon-rows up to 18 inches high, or not higher than 4 inches as a trailing edge plant. There is no mistake about this plant. There is not one now in use out of pots that will get near it in filling up the spaces allotted to it. Without a rambling habit, it yet runs and fills up as fast or faster in my own garden than any of the *Verbenas*. One man could manage to keep a row of it half a mile long by spending one hour on it for the whole month of June, two hours in July, and perhaps half an hour twice in August. Then take up so many of the plants at the end of September, keep from the frost, and force for cuttings early in the spring, when it will root as fast as *Verbenas* and not require one-quarter of the trouble in looking after.

I had twelve kinds or species of *Crocus* sent me lately without the list of names, and No. 8 is not among them; and if the worthy clergyman who sent them from the north sees this page, will he add to his gift the favour of naming them? also to remind another and a third party who have promised to look out *Crocus speciosus*, *Sibthorpianus*, and several others of the autumnal and winter-flowering species for me, that August is the best time of the whole year to pot such kinds of *Crocuses*, if not the very best time to pot all the garden kinds as well? But with the latter I have nothing to do in this attempt at gathering, once more, as many wild *Crocuses* as all the friends of this *Journal* can muster in the long vacation. If I get a bushel measure full of them, not one of the number shall ever be put under the hushel—at all events as long as I live; and who knows if many of them will not cross and seed as freely as *Poppies*? I know one reason why no *Crocus* could be crossed by Dr. Herbert, the only person who ever tried them in earnest, and I think I know how to avoid the cause of that reason. But without crossing at all, I am persuaded that one could get them to run into endless varieties from self seeds. My idea of them is this: not to have any of the late autumnal kinds out in the open ground, but all in pots; and, while in flower, to be in all places from the drawing-room down to the window-sill of the old woman who keeps the London lodge; to have more kinds of them so, on Christmas-eve, than could be got for Easter Sunday, and those to be far more varied in looks and stripes than the garden breeds from *vernus*, *versicolor*, and *lagenæflorus*.

To another class of our people I should point out how well they would do with the *Cyclamens* on raised beds 2 feet 6 inches above the level of the ground, on a west sheltered aspect, with glass over them, more to keep them dry than for fear of frost;

but to have frostproof mulching for the glass night at hand. Then the Royal Horticultural Society, having now a collector at the Cape of Good Hope, we shall run a chance of getting all the Cape bulbs over again, and we must not roast them a second time as our friends and fathers did those sent home by Masson, and almost all subsequent travellers and explorers of the Cape territory, and ten to one if we lose one out of a thousand of them. The same run of raised pits, and in many instances the very same pits as for *Crocuses* and *Cyclamens* will do, and will be the best of all means to grow the Cape bulbs as they have never yet been done. Then, instead of sandy peat, and starvation staring us in the face every time we go round the garden, we shall have 1 foot deep of rubble at the bottom of the raised beds, and 18 inches of two thirds of the cocoa-nut refuse, and the other third of half turfy peat and half best loam, and 2 inches of clean cocoa stuff for a top; and not one particle of sand at all in the compost. In those raised beds, and in that compost, all the finer *Crocuses* from Cintra to Mount Taurus, and all the *Cyclamens* from Persia to the Pyrenees will do equally well with all the bulbs that can be got within the range of our Cape colonies; and such as the *Vallota*, several *Hæmanthi*, and *Tritonias* with *Tritonias* from the lower grounds, where they run near the marshes; and such as the grand and superb *Disas* from the top of Table Mountain will, and must have, flat-bottomed beds to hold water, something after the way of Sir Joseph Paxton's beds for Water Cresses. Then the marshy ground, or bed, or compost for all these thirsty bulbs must be made of the cocoa stuff and loam instead of peat, the bulb part being wholly in the cocoa stuff, as in sand, to keep them clean and free from all crawling worms and grubs; and yet with full exposure to the outer air, notwithstanding the soft slimy nature of the bottom part of such marshy beds.

The first raffle for the Cape bulbs is just announced by the Royal Horticultural Society; and the next turn will be that the lucky winners will come, the one after the other, to our office to ask about the names and about how to grow them. It will be easy enough to tell the names of all the old bulbs at the Cape, when a whole flower-spike of the smaller kinds is sent, or two fresh flowers of the larger kinds, and one-half (the upper half) of one of the leaves, all as fresh as oilskin silk can keep them. Under no other conditions shall any one in our office, or any of us out of it, undertake to name any of the raffled-for bulbs of the Royal Horticultural Society. The Society intended to advise the Fellows to retain the number or numbers attached to their bulbs, in order to be able to name them more easily at some future time, because there will be dried specimens of many of them kept for reference, and the same numbers do for both the bulbs and the dried specimens of them. But somehow or other this part was overlooked; and as one of the Society who knows the great bother, and the loss of time in hunting after a hare which ought to have been in the cook's hands all the time, I gladly fill up that blank; and, for the future, it would be a good thing for all us to mind and keep the numbers we might get with any plant from a regular collector, or from an occasional contributor, as the gentleman who sent me twelve numbers with eleven *Crocuses*, the bulbs for No. 8 being wanting. If I should never get the names I shall not part with any of the numbers as long I hold the bulbs to which the number refers; and I advise the same care being taken, at least, of all the numbers referring to all the plants that will be raffled for from the Royal Horticultural Society, in order that the naming may be got over more easily by some one or other; but the outer world has no idea, comparatively speaking, of the value of time to men who can make out the names of plants, if they do not happen to know them by sight, by comparing the botany of their formation with the ancient descriptions of them given by authors before we were born.

To come still nearer home, I have good news for Mr. Robson at last; but I thought at the time he had a leaf out of my book when he wished for a *Nosegay Geranium* as big in the flowers as the *Nosegay Fothergillii* or *Purple Nosegay* of the gardens. Well, I have lots of that description now, and of all shades of the colour peculiar to the family of *Geraniums*, except the blue or purplish-blue of *sylvaticum* and *sibiricum*, with as broad and broader petals than those of *Fothergillii*, and with all habits, from that of *Mangles*' to those of *Punch*, *Cottage Maid*, *Tom Thumb*, and all the rest of them. And I have still hopes of obtaining a *Yellow Nosegay* clear as a *Buttercup*; but that will not be just yet; but I have the deep orange for a foundation.

I want a few kinds yet, with the right sizes of plants, before I can make the shaded arrangement, as with the Berlin wool, from the lightest to the darkest tints—a thing for which I have been urged on for the last twenty years nearly, by a band of hope who amuse themselves with such arrangements. It has been an up-hill work, however, but I have stuck to it. Mr. Eyles has been a right-hand help to me since I lost the Experimental. He has promised to do some of my Nosegays, as the ladies like them, at our new garden; and I am in expectation of an arrangement with the authorities at the Crystal Palace for having a display of some of the more delicate tints, next season, in the vases round the crystal fountains inside the Palace, and I have the fullest confidence that all of them will be as safe in both gardens as if they were in my own garden. D. BEATON.

### AMARANTHUS MELANCHOLICUS RUBER AND COLEUS VERSCHAFFELTI FOR BEDDING.

To the enterprising flower gardener there is nothing more interesting than the introduction of new plants suited to his wants, or, it may be, the restoration of old ones; for, however much he may wish to curtail the lists of plants available for general display and symmetry, he is, nevertheless, at all times anxious if these can be in any way improved or substituted by others of still superior merit. This spirit of enterprising industry has led to innumerable varieties of most of the favourite bedding plants of the day, some of them being decided improvements and some about equal to those previously in use, whilst a few have no higher claim to distinction than that of the high-sounding name they were ushered into the world with. Be this as it may, there are some new things which receive almost, if not quite, the entire approbation of every one in any way interested in the matter—plants with distinct coloured or singularly formed foliage being as much sought after as floral beauties. In fact, the rage for foliage of widely distinct colours and features has equalled that for flowering plants, and in some instances forms the more important part of the display; any addition, therefore, to the latter class is eagerly sought after. White-leaved plants, or those having broad margins of white or yellow on their leaves, form a very important item in the sum total of the flower-garden lists, and each year something fresh is added to the catalogue, the respective merits of which will doubtless be as difficult to settle as that of many other matters of a like nature where individual tastes are concerned. I may, however, be induced to give an opinion of these hereafter. Suffice it to say that for light-coloured edging plants I have not seen anything yet to excel *Cerastium tomentosum* for a low edging, unless it be the variegated *Arabis*. *Cineraria maritima* is as good, but not so easily kept in order. A white Grass I have looks as well as either, but gets higher than *Cerastium*. I am told *Centaurea candidissima* makes the best of all.

But my purpose is not to dilate on the respective merits of these, but to mention a crimson-leaved plant lately introduced from Japan by Mr. Veitch, and which, I think, cannot fail to become a favourite in the flower garden. This new plant is dignified by a name more grave than poetic, and I cannot but think inappropriate. This, however, has nothing to do with its merits, and I expect the season of 1863 will see the *Amaranthus melancholicus ruber* figuring in most flower gardens, as I expect that, like the Prince's Feather and other members of the family, it will be found to seed freely, perhaps abundantly. So far as I can judge by its habit and growth it will take the place of *Perilla* in many cases, and very likely may be still hardier than that popular plant, as some plants here seem to stand the cold winds very well, though only recently planted. But it is mostly in the colour of the foliage that its merits especially lie, and this is not easy to explain; but those who have seen the crimson tints of the Virginian Creeper when at its best will have a good idea of the rich hue this plant presents. The brightness of its colouring I expect will continue during the entire summer, as the oldest leaves have not that sombre hue the *Perilla* has very late in the season. It is, however, too early to prognosticate what its appearance so late in the season may be, but at the present it seems all that can be wished for; and to those who have not yet made its acquaintance I would strongly advise them to do so, and to judge for themselves.

I would also wish those who have grown *Coleus Verschaffelti* as a bedding plant to report their experience with it. If it has

prospered under the chilling winds and dull sunless sky of June and July up to the 21st, its hardihood may be regarded as fairly established; but if, like many other plants, it has succumbed to the unfavourableness of the season, it will require further trial to confirm its position in the front rank of useful flower-garden plants.

It is very likely, from the enterprising spirit now abroad, that something still more imposing than anything we have yet got will be forthcoming by-and-by in the *coloured-foliage-plant* way. In the meantime, however, I strongly advise those who have not seen the new *Amaranth* Mr. Veitch, jun., has introduced from the far east (we might almost say the land of fable) to make it a point to do so, and I flatter myself they will feel pleased with it, as I confess being unexpectedly so, and towards the end of the season a further report on its merits or shortcomings from those who have grown it will be very acceptable. Not having experienced its services throughout the whole season, the opinion above afforded is of course limited to the season at which it is given (July), and its aftergrowth may possibly be less satisfactory. This, however, I do not expect: nevertheless, experience teaches all things.—J. ROBSON.

### PEACH AND NECTARINE TREE CULTURE ON THE OPEN WALLS.

(Concluded from page 355.)

**WINTER TREATMENT.**—This season commences as soon as the leaves are fallen off. If the wood has been properly ripened the leaves will naturally fall off with the first frost. Collect them as soon as they fall and convey them to the rubbish-heap at once. Then loose the trees from the wall, take off all the shreds, burn such as are decayed, and let such as are fit to use again be put into boiling water to destroy the insects and their eggs. The nails should be carefully drawn out of the wall, and in order to do so without drawing away the mortar give each nail a gentle tap with the hammer. To cleanse them from dirt and rust throw them into a vessel containing hot oil, and let them steep for a few hours. Then take them out and put a few at a time in a rough, coarse bag, and shake them well backwards and forwards. This operation will cleanse and keep them from rusting, and will destroy insect life thoroughly.

The trees should be drawn from the wall, and the wall itself should be thoroughly cleansed, and repaired if necessary. If the red spider has prevailed during the summer it will be advisable to make up a mixture of sulphur and soap water, and paint the walls with it, rubbing it well into the crevices and nail-holes. The trees also should be painted over with this mixture, moistening every part of the tree, especially on the side of the branches next the wall. When all these are completed, then fasten the trees to the wall by a few of the main branches only. This is to secure them from being blown about by the wind till the pruning time. I prefer the end of February or the first week in March for that operation. Where the walls are extensive the pruning may be done sooner, in order to get through the work. The fruit-bearing branches may be shortened-in, but care must be taken that a wood-bud is next the cut. Those that bore fruit the preceding year must be cut out entirely, excepting the leading shoot at the end of a main branch. As soon as a tree is pruned it should be trained and nailed to the wall, or if the wall is wired it should be tied to the wires. Then, when all the trees are gone through, the winter work on the Peach and Nectarine trees is completed.

I do not think it necessary to enter upon the subject of propagating the Peach. It is seldom that a gardener has the time and means for that work. Indeed, the price of maiden and trained trees is so reasonable, that it is not worth the trouble, skill, and room requisite for that purpose.

**DISEASES.**—The only disease that I know of is that named *gumming*. It is a kind of gangrene, which first appears like a swelling, then bursts and exudes out the gum. If the border is made properly and the wood well ripened this disease will not appear; hence, if ever symptoms of the gum disease show themselves, the only remedy is to examine the border. If it is wet at the bottom, let it be thoroughly drained; if it is too full of manurial matter, remove that soil entirely and replace it with fresh maiden earth. Then, again, take great care that the branches are not wounded by the hammer or any other instrument.

*Mildew* is, I think, caused by insects (or perhaps fungus), and therefore is not a disease. The remedy for it I have already described. Sometimes the leaves are blistered. Perhaps the cause may be traced to sudden gleams of hot sunshine when the leaves are wet, as young tender leaves only are affected. When they are fully grown and become mature no blistering ever takes place. It all amounts to this: Make a right border well drained, water in dry weather, and get the wood well ripened, and then you need not fear but your trees will be clear of disease, and consequently healthy and fruitful.

I shall, therefore, conclude these few practical remarks on this part of gardening operations, by giving a select list of the best and hardest kinds of Peaches and Nectarines for out-door culture.

SELECT LIST OF NECTARINES, arranged according to their time of ripening:—

*Hunt's Tawny*.—Melting, flesh yellow. Earlier than most kinds.  
*Elruge*.—Medium size, melting. Rich and sugary.  
*Newington Early*.—Very large clingstone. Rich flavour.  
*Violette Hâtive*.—Medium size. Rich in flavour, melting.  
*Balgowan*.—Large, melting, and excellent.  
*Downton*.—Large, melting, rich, and very good. Raised by Mr. Knight between Elruge and Violette Hâtive.  
*Murrey*.—Medium size, melting. Rich and good.  
*Hardwick Seedling*.—Large, melting, rich and excellent.  
*Roman*.—A clingstone. Rich when thoroughly ripe.  
*Victoria*.—Melting, rich, and good. Mr. Rivers' seedling between Violette Hâtive and the Stanwick.

For a small garden I would recommend Early Newington, Violette Hâtive, and Victoria.

SELECT LIST OF PEACHES, arranged according to their time of ripening:—

*Early York*.—Medium size, melting, rich, and excellent. Very hardy.  
*Alice*.—Large, melting, and excellent.  
*Acton Seed*.—Medium size, melting, and excellent.  
*Early Grosse Mignonne*.—Medium size, melting, rich and excellent.  
*Early Savoy*.—Large, deep red next the sun. A fine, melting, early Peach.  
*Croxford's Early*.—Early, yellow flesh, melting, rich aroma, and very good.  
*Galande*.—Large, melting, and excellent.  
*Royal George*.—Large, melting, and excellent.  
*Noblesse*.—Large, melting, and excellent.  
*Bellegarde*.—Large, melting, juicy, and excellent. Leaves dark green. Fruit dark, almost black.  
*Chancellor*.—Large, melting, and very good.  
*Leopold I*.—Very large, melting, and rich.  
*Late Admirable*.—Large, pale yellow, flesh melting, rich and good.  
*Walburton Admirable*.—Large, melting and excellent. Hardier than the Late Admirable.  
*Gregory's Late Peach*.—Medium size, melting and excellent, and very hardy. Ripens in October.

For a small garden I would recommend Early York, Galande, and Late Admirable. T. APPLEBY.

## CHARCOAL AS A MANURE.

In the July Number of "Blackwood's Magazine," there is an interesting anecdote respecting the beneficial effects of charcoal-dressing on Vines, flower gardens, &c. Can you give any instructions or direct to any publication where such instructions may be found for the best and most successful mode in applying charcoal to Vines, flowers, or any fruit or flowering tree or vegetable? It appears to be an excellent thing to use, and it is very desirable that the best mode of application, and to what particular plants it is likely to be useful, should be made known.—N. X. T.

[The anecdote related by the author of "The Caxton Family," in "Blackwood's Magazine," is as follows:—

"A certain nobleman, very proud of the extent and beauty of his pleasure grounds, chancing one day to call on a small squire, whose garden might cover about half an acre, was greatly struck with the brilliant colours of his neighbour's flowers. 'Ay, my Lord, the flowers are well enough,' said the squire, 'but permit me to show you my Grapes.' Conducted into an old-fashioned little greenhouse, which served as a vinery, my Lord gazed, with mortification and envy, on Grapes twice as fine as his own. 'My dear friend,' said my Lord, 'you have a jewel of a gardener; let me see him!' The gardener was called—the single gardener—a simple-looking young man under thirty. 'Accept my compliments on your flower-beds and your Grapes,' said my Lord, 'and tell me, if you can, why your flowers are so much brighter than mine, and your Grapes so much finer. You must have studied horticulture profoundly.' 'Please your Lordship,' said the man, 'I have not had the advantage of much education; I

ben't no scholar; but as to the flowers and the Vines, the secret as to treating them just came to me, you see, by chance.'

"By chance? explain."

"Well, my Lord, three years ago, master sent me to Lannon on business of his'n; and it came on to rain, and I took shelter in a mews, you see."

"Yes; you took shelter in a mews; what then?"

"And there were two gentlemen taking shelter too; and they were talking to each other about charcoal."

"About charcoal?—go on."

"And one said that it had done a deal o' good in many cases of sickness, and specially in the first stage of the cholera, and I took a note on my mind of that, becase we'd had the cholera in our village the year afore. And I guessed the two gentlemen were doctors, and knew what they were talking about."

"I dare say they did; but flowers and Vines don't have the cholera, do they?"

"No, my Lord; but they have complaints of their own; and one of the gentlemen went on to say that charcoal had a special good effect upon all vegetable life, and told a story of a vinedresser, in Germany, I think, who had made a very sickly poor vineyard one of the best in all these parts, simply by charcoal-dressings. So I naturally pricked up my ears at that, for our Vines were in so bad a way that master thought of doing away with them altogether. "Ay," said the other gentleman, "and see how a little sprinkling of charcoal will brighten up a flower-bed."

"The rain was now over, and the gentlemen left the mews; and I thought, "Well, but before I try the charcoal upon my plants, I'd best make some inquiry of them as aren't doctors, but gardeners;" so I went to our nurseryman, who has a deal of book-learning, and I asked him if he'd ever heard of charcoal-dressing being good for Vines, and he said he'd read in a book that it was so, but had never tried it. He kindly lent me the book, which was translated from some forren one. And, after I had picked out of it all I could, I tried the charcoal in the way the book told me to try it; and that's how the Grapes and the flower-beds came to please you, my Lord. It was a lucky chance that ever I heard those gentlemen talking in the mews, please your Lordship."

"Chance happens to all," answered the peer, sententially; "but to turn chance to account is the gift of few."

"His Lordship, returning home, gazed gloomily on the hues of his vast parterres; he visited his vinerie, and scowled at the clusters; he summoned his head gardener—a gentleman of the highest repute for science, and who never spoke of a Cowslip except by its name in Latin. To this learned personage my Lord communicated what he had heard and seen of the benignant effects of charcoal, and produced in proof a magnificent bunch of Grapes, which he had brought from the squire's."

"My Lord," said the gardener, scarcely glancing at the Grapes, 'Squire ——'s gardener must be a poor ignorant creature to fancy he had discovered a secret in what is so very well known to every professed horticulturist. Professor Liebig, my Lord, has treated of the good effect of charcoal-dressing, to Vines especially; and it is to be explained on these chemical principles'—therewith the wise man entered into a profound disputation, of which his Lordship did not understand a word.

"Well, then," said the peer, cutting short the harangue, 'since you know so well that charcoal-dressing is good for Vines and flowers, have you ever tried it on mine?'

"I can't say I have, my Lord; it did not chance to come into my head."

"Nay," replied the peer, 'chance put it into your head, but thought never took it out of your head.'

"My Lord, who, if he did not know much about horticulture, was a good judge of mankind, dismissed the man of learning; and, with many apologies for seeking to rob his neighbour of such a treasure, asked the squire to transfer to his service the man of genius. The squire, who thought that now the charcoal had been once discovered, any new gardener could apply it as well as the old one, was too happy to oblige my Lord, and advance the fortunes of an honest fellow born in his village. His Lordship knew very well that a man who makes good use of the ideas received through chance, will make a still better use of ideas received through study. He took some kind, but not altogether unselfish, pains with the training and education of the man of genius whom he had gained to his service. The man is now my Lord's head forester and bailiff. The woods thrive under him, the farm pays largely. He and my Lord are

both the richer for the connection between them. He is not the less practically painstaking, though he no longer says 'ben't' and 'his'n'; nor the less felicitously theoretical, though he no longer ascribes a successful experiment to chance."

How much of substantial truth may be in this well-narrated anecdote we cannot take upon ourselves to say, but we can undertake to affirm that something more than charcoal was needed to produce super-excellence in the Grapes and flowers, and that the nobleman must have had some other ground of complaint, or he would have been very unjust to discharge his gardener because he was scientific and had never used charcoal as a manure. If these were just grounds of offence, we fear there would be a large number of vacancies immediately. We shall be glad to receive any notes on the employment of charcoal as a manure, and will only add at present the following from Mr. Johnson's "Science and Practice of Gardening," recently published:—

"It is to its power of gradually forming carbonic acid gas that charcoal partly owes its value as a manure. The chemical operation of charcoal, when employed for this purpose, is by no means so well understood as that of most other fertilising additions to the land. That the carbon of the charcoal operates so beneficially upon plants, amongst other modes by a gradual combination with oxygen, hardly admits of a doubt. Liebig gives the results of a series of experiments by Lukas on the use of charcoal as a manure, which seem to corroborate his opinion. From the facts which these chemists, however, adduce, it is evident that the beneficial action of charcoal, as a fertiliser, depends upon the presence of other substances besides carbon. Liebig notes (*Organic Chem.*, p. 62), that 'plants thrive in powdered charcoal, and may be brought to blossom, and bear fruit, if exposed to the influence of the rain and the atmosphere. Plants do not, however, attain maturity under ordinary circumstances in charcoal powder when they are moistened with pure distilled water instead of rain or river water. Rain water must, therefore, contain within it one of the essentials of vegetable life; and it has been shown that this is the presence of a compound containing nitrogen: the exclusion of which entirely deprives humus and charcoal of their influence on vegetation.' It is ammonia, to whose presence in rain water Professor Liebig thus refers, in whose valuable work (p. 207) the experiments of Lukas will be found. From these we learn that in a division of a low hothouse, in the Botanic Garden at Munich, a bed was set apart for young tropical plants; but instead of being filled with tan, as is usually the case, it was filled with powdered charcoal, the large pieces of charcoal having been previously separated by means of a sieve. The heat was conducted by means of a tube of white iron into a hollow space in this bed, and distributed a gentle warmth, sufficient to have caused tan to enter into a state of fermentation. The plants placed in this bed of charcoal quickly vegetated and acquired a healthy appearance. As always is the case in such beds, the roots of many of the plants penetrated through the holes in the bottom of the pots, and then spread themselves out; but these plants evidently surpassed in vigour and general luxuriance plants grown in the common way; for example, in tan.

"M. Lukas then gives a list of several of the exotic plants upon which charcoal appears to have produced the most beneficial effects. It appeared also to promote the rapid germination of seeds. He then proceeded to try the effects of charcoal when mixed with vegetable mould, all of which answered very well. 'The charcoal,' continues M. Lukas, 'used in these experiments was the dust-like powder of charcoal from Firs and Pines. It was found to have most effect when allowed to lie during the winter exposed to the action of the air. In order to ascertain the effects of different kinds of charcoal, experiments were also made upon that obtained from the hard woods and peat, and also upon animal charcoal; although I foresaw the probability that none of them could answer so well as that of Pine wood, both on account of its porosity and the ease with which it is decomposed. The action of charcoal consists primarily in its preserving the parts of plants with which it is in contact, whether they be roots, branches, leaves, &c., unchanged in their vital power for a long space of time, so that the plant obtains time to develop the organs for its further support and propagation. There can scarcely be a doubt, also, that the charcoal undergoes decomposition; for, after being used five or six years, it becomes a coaly earth. It exercises likewise a favourable influence by absorbing and decomposing the matters excreted by the roots of plants, so as to keep the soil free from the putrefying substances

which are often the cause of the death of the spongioses. Every experiment,' concludes M. Lukas, 'was crowned with success, although plants belonging to a great many different families were subjected to trial.'—(*Ibid.*, p. 211.)

"Professor J. F. Johnston (*Elem. of Ac. Chem.*, p. 142) recognises the good properties of charcoal as 'a valuable mixture with liquid manure, night-soil, farmyard manure, ammoniacal liquor, or other rich applications to the soil.' And, as he observes in another place, when speaking of the fertilising portions of farmyard drainage (*Trans. High. Soc.*, 1846, p. 190), 'The only substance at present known, by which the separation of all the valuable ingredients from liquid manure can be fully effected, is animal charcoal. A sufficient supply of this substance, when intimately mixed with the liquid manure, will take up nearly the whole of the saline and colouring matters it holds in solution, will carry down the substances it holds in suspension, and will leave the water nearly pure and colourless. The refuse of the prussiate of potash manufactories will have this effect, and what remains when ivory-black is digested in spirit of salt (muristic acid), will do still better; but this kind of charcoal is neither cheap nor abundant, and, therefore, cannot be recommended for general use. The refuse animal charcoal of our manufactories is now sold for manure at the price of several pounds a-ton: either those who sell it, or those who use it, might render it still more valuable by causing fermenting liquid manure to filter through it before it is applied to the land.

"But other kinds of charcoal possess this property to a certain extent: wood charcoal, reduced to powder, charred sawdust, and charred peat, are all capable of being used with advantage in extracting the ammoniacal and other salts, which give its value to the liquid of our farmyards. Experiment has shown that when filtered through a bed of such charcoal, the liquid escapes without colour, and almost without taste, while the charred peat or sawdust is converted into fertilising manure. A great portion of the loss now incurred may be prevented by the use of such kinds of charcoal; and the fertilising substance may, through their means, be applied to our crops at seasons of the year for which, in their liquid form, they are not suited. It is even capable itself of yielding slow supplies of nourishment to plants; and it is said in many cases, even when unmixed, to be used with advantage as a top-dressing. In moist charcoal the seeds of the gardener are found to sprout with remarkable quickness and certainty, but after they have sprouted they do not continue to grow well in charcoal alone.'—(*C. W. Johnson's Modern Agricultural Improvements.*)]

## THE TESTIMONIAL TO MR. MARNOCK.

MANY of our readers are no doubt aware that a subscription was set on foot to present the above-named gentleman with some token, in recognition of the unvarying courtesy with which he has for so many years discharged the arduous duties of curator at the gardens of the Royal Botanic Society. Probably there is nothing calculated to try the patience and temper of a man more than the conduct of horticultural exhibitions—there rival candidates meet to fight their battles for honours, there many exhibitors must necessarily be unsuccessful, and there too are jealousies to reconcile, and nice points to adjust, requiring the utmost discretion, tact, and good feeling to be exercised in order to give satisfaction.

Many men have under such ordeals given way, but Mr. Marnock has ever risen superior to them; and for the long series of years during which he has been connected with the gardening world, we have ever heard him spoken of in the highest terms by all with whom he has been brought in contact.

On Thursday last, the 7th inst., the presentation of a very handsome tea service took place at the London Tavern. H. G. Bohn, Esq., occupied the chair, the vice-chair being taken by Mr. Cutler.

The usual loyal toasts having been given, Mr. Bohn, in an appropriate speech, adverted to Mr. Marnock's services during the last twenty-one years, and that throughout that period he had won the good will of all, whether judges, exhibitors, or visitors, by his constant urbanity and kindness of disposition; and concluded by presenting the service in the name of the 153 subscribers.

Mr. Marnock, in returning thanks expressed the great difficulty under which he laboured in expressing himself in suitable terms. He stated that in his official capacity duty had ever gone

before friendship, but he had never found the two much at variance, and he had always met with persons who had afforded him every assistance.

The healths of the Chairman, Mrs. Marnock, and some other toasts having been given, the company separated, after spending a most agreeable evening.

### THE ROYAL HORTICULTURAL SOCIETY'S GARDEN AT CHISWICK.

ALTHOUGH the Society's Chiswick garden is no longer maintained as regards the ornamental portion in its former high condition it still presents a respectable appearance, whilst on the score of utility it has lost none of its ancient prestige. Whatever may have been the faults of the garden as originally laid out, it is certainly well adapted for carrying on those experiments which have been and are proving so useful to horticulturists. The collections of fruits and vegetables of different kinds here are such as probably no private individual could gather together; and even could he do so, the results and conclusions at which he might arrive would not inspire the same amount of confidence on the part of the public as the disinterested decisions of the Fruit and Floral Committees, who have the opportunity of ascertaining at Chiswick the comparative merits of the productions which belong to their respective departments.

In the ornamental portion of the grounds the arboretum, from the grass being tolerably short at present, is looking very well; and the ribbon-border on each side of the walk leading from the entrance past the council-room is exceedingly gay, although only made up of odds and ends. It is about 90 yards in length, and is planted as follows:—The first row next the walk is *Cerastium tomentosum*, the second is *Crystal Palace Nasturtium*, the third *Purple Verbenas* and *Heliotropes*, the fourth *Scarlet Geraniums*, and the fifth *Calceolaria Aurea floribunda*. The *Cerastium*, being in its second year, has gone off in places, and is elsewhere too bushy, and has lost much of that fine frosted appearance which constitutes its charm. The *Nasturtium*, on the contrary, is very even and covered with flowers. The *Verbenas* are very poor; and dark *Heliotropes*, such as *Voltaireanum*, *La Petite Nègresse*, *Beauty of the Boudoir*, &c., have been substituted for them throughout a great portion of the line.

By the side of the walk running from the conservatory to the old American garden are ribbons of annuals. The ribbon nearest the front of the border consists of *Silene pendula*, purple *Candy-tuft*, and mixed *Larkspurs*, and, being well covered with flowers, is free from that weedy appearance which annuals are so apt to assume. The second ribbon, which also looks well, especially the front row, consists of *Clarkia integripetala* backed with the double-flowering variety of *Clarkia pulchella*. At some distance from this there is a broad band of *Coreopsis hybrida* not yet out; and the back lines are composed of *Clarkias*, *Malope grandiflora* and *Coreopsis*, with a row of tall *Purple Orach* to divide it from the trees on the kitchen-garden side. We had almost omitted to say that just within the edging in front of this border is a long line of new *Petunias*, among which were several fine sorts in bloom, as *Coquette*, *Spitfire*, *Rubens*, *John Lothar Faber*, *Monarch*, and *Ruby*.

Among the bedding *Geraniums*, of which there is a collection of about two hundred varieties, *Victor Emmanuel* was conspicuous for its large truss and free-blooming habit; *Vivid*, another bright *Scarlet*, was also very fine; *Eclipse* is a strong-growing bright *Scarlet*, suitable for pillars in conservatories. *Madame Vaucher* is evidently one of the best *Whites*; and of the *Nosegay* sorts *Stella* was noticeable for its large scarlet truss and compact habit. In the *Variegated* class *Sunset*, *Mrs. Pollock*, and *Gold Pheasant* appeared the most striking. Of *Phloxes* and *Pentstemons* there are likewise very large collections containing several fine varieties.

The glass wall, which never was of any use for the culture of fruit trees, has been taken advantage of to construct a long house for proving about two hundred reputed sorts of Vines, the merits and distinctions between which have not been as yet satisfactorily determined. When completed this house will be about 200 feet in length; and as it is likely to be a very useful and economical structure, it may be of interest to state its construction. It is in the form of a narrow flat span-roof placed against a wall, which forms its back; and this being only about 8 feet high is heightened by the addition of 18 inches of glass, bringing

the total height at back up to 10 feet. The front is formed of the glass wall before alluded to, and the width is 10 feet. Heating is effected by two four-inch flow-pipes in front, and one return of similar capacity at the back, an arrangement by which Mr. Eyles obtains a more rapid circulation of water through the return. Ventilation is effected by moveable sashes in the roof, and every alternate light in front can be drawn behind the others which are fixed. All the moveable sashes in front are connected together by a rod resting on rollers; and this rod, and consequently the lights, can be drawn backwards or forwards with ease, by means of a large screw connected by a simple arrangement of bevelled wheels with a handle by which the whole is worked. A large number of Vines are already in this house, and there are also some young Peach trees in course of training *en cordon oblique* in the front of the house, as well as some Gourds of the bottle, club, and other forms. Besides these there were several handsome umbrella-trained Peaches and Nectarines in No. 4-pots, and others trained in the pyramidal form.

In the curvilinear vinery a number of varieties of Muscat Grapes have been planted in the border inside for the purpose of trial, and are now making vigorous growth, and will, probably, bear a few bunches next season, thus affording the means of judging of their comparative merit. There are also a number of other Vines in pots which will be eventually turned out in the new house, and a large number of pots of the different kinds of Capsicums, some of which are very pretty.

In the lean-to vinery is a collection of Figs in 24-sized pots, also for trial. These are grown as dwarf standards—a mode which seems the best suited to the Fig when subjected to pot culture.

Adjoining these vineries, in the quarter outside there is a collection of about ninety sorts of handsome pyramid Pears of the newest kinds, which were presented by Dr. Hogg about two years ago. They are all now in fine condition, many of them being 12 feet high and bearing well. In the spring they were covered with blossom; but, in consequence of frost, a great portion of it was killed; still the crop on some of them is quite heavy enough.

In the span-roofed Peach-house, formerly the *Geranium*-house, we found a number of fine umbrella-trained Peaches and Nectarines planted-out inside. They are all well covered with fruit, and have a very pretty appearance. There were also some in pots, but the fruit of those planted-out was the larger.

The Vine-pit is a beautiful sight, the roof being covered with bunches of black, white, and yellow Grapes. Here there are about eighty varieties for trial, which were struck from eyes planted about eighteen months ago. They are mostly growing in ten-inch pots, but some are in eight-inch ones; and on an average they are bearing six or seven bunches each.

Adjoining are two long pits, containing about 150 so-called varieties of Melons, grown in fifteen-inch pots, for the purpose of trial and comparison; but the results, it is to be regretted, will not be so conclusive as was expected, in consequence of the plants having been attacked with a disease somewhat like burning, but which was certainly caused by some kind of mildew. It first appeared on the old leaves, and then gradually spread over the whole plant, giving it a blotched, burned appearance. In consequence of this some plants are now leafless; but what is singular, others standing next to those severely attacked are untouched and extremely vigorous. Besides the Melons, there are several serpent and other ornamental Gourds.

We now come to the orchard-house, which is a fine example of this mode of culture successfully carried out, and which reflects the greatest credit on Mr. Eyles' skilful management. It is a sight which alone will well repay a visit to Chiswick, the trees with only a few exceptions being loaded with fruit, and all of them are models of judicious training. The Plums, of which there are *Victoria*, *Jefferson*, *Green Gage*, *British Standard*, *Golden Drop*, *Reine Claude de Bavay*, and some others, both in pots and planted out, are covered with fruit; and the Peaches and Nectarines in eight-inch pots are also particularly fine, as well as being perfect examples of pyramid training.

The Apricots, especially one grown as a standard, are likewise very productive, and the fruit on the standard is very large, being even of greater size than when grown on walls. We have only to add that the whole of the trees are perfectly healthy and vigorous and the foliage very clean.

Outside there are a number of Apple and Pear trees in pots, which were put out after having set their fruit in the orchard-

house in order to make room for the Peaches, &c. The Apples in particular are in a fine healthy condition and bearing an abundance of rosy-checked fruit; whilst the Pears, though not looking so well, are bearing in the greatest profusion.

The large conservatory is another beautiful sight, the Vines being this season covered with bunches up to the very top, produce a most imposing effect. The Barbarossa is bearing here as freely as the Black Hamburgh, and some of the bunches are enormous. The Frankenthal, Black Hamburgh, Black Prince, and Raisin de Calabre are likewise very fine.

Of Apples there is an excellent crop on standards, but the dwarf trees have not fruited so well.

There is likewise a very good crop of Pears on walls, the trees having been as usual protected with tiffany, otherwise the fruit would have been all cut off. The Peach-wall is now much improved in appearance, and the trees which were at one time getting bare at bottom and over-vigorous at top, have had the balance of vigour restored, and are now offering an excellent show of fruit.

In the border in front of this wall, and in other parts of the garden, there are about 150 varieties of Gourds, which, though the season has been hitherto unfavourable to their growth are doing very well, and some are attaining a large size. One a Potiron jaune growing on a dung-bed with very little soil, must have been about 2 feet across at the widest.

In the kitchen garden we observed a collection of about seventy distinct sorts of Peas grown for comparison, and about forty kinds of Potatoes, which here as elsewhere are but little affected by the disease. It would seem that the disease is wearing out, and the plant is regaining its former vigour, and the quality of the produce this season approaches nearer to that of the Potato of long-ago, than it has done for several years.

## NOTES FROM PARIS, JULY, 1862.

### VERDIER'S AND LEVEQUE'S.

THE same cause which has cramped the nurseries in our own metropolis—viz., the dearness of land, has to a much larger extent influenced those of Paris. The continued improvements that the Emperor is making quickly bring upon the inhabitants an edict of the Prefect of the Seine, and houses and lands under his transforming hand vanish out of sight, and boulevards and open streets make their appearance; and hence it must happen that nurserymen will either content themselves with small parcels of land, or else remove beyond the fortifications. Thus Marest, the raiser of Prince Léon and Cécile de Chabillant, has left the Rue d'Enfer for a place outside the barrière in the Route d'Enfer. Touvais has gone to Angers, and the Rose-growers I have named above are compelled to grow their Roses some leagues from Paris, and have only a small portion of them at their "homesteads." To see Roses in Paris thus becomes almost an impossibility—quite as difficult, at any rate, as to see them in London; and as flower shows are by no means so abundant there as with us, one has not that opportunity which they afford Rose-growers in England: hence, in receiving the accounts of new Roses from time to time, we must, as I ventured to say last autumn, depend more on the character of the persons who distribute them than on that given to the Roses. Applying this test to the list I gave last autumn, I find my judgment singularly borne out—the most telling Roses, as far as we have yet been able to judge, are those which come from Margottin, Verdier (the elder), and Levêque; for Souvenir de Comte Cavour, Alexandre Dumas, Frauçois Lacharme, La Brillante, Duc de Rohan, and Maurice Bernhardt may fairly be assumed to be among the best of those we have received; while of the twelve sent out by the younger Verdier only one or two—Madam Charles Wood and Wilhelm Pfizer—promise anything. Of Touvais' ten not one is likely to survive another season, and the same may be said of Pradel's nine. Of Lartey's five, one promises well—Gloire de Bordeaux; and owing to Trouillard's having been detained on their way to Mr. Standish for six or seven weeks, he has found it quite impossible to exhibit them, so that we cannot tell what they may be yet. There is one satisfactory item of news connected with this season—viz., that we are not likely to be inundated with such a host of new Roses as last autumn produced. Touvais has none; it is questionable whether Eugène Verdier will have any either. Jamin, the raiser of Madame Boutin, is *hors de combat*. Margottin, as we have seen, has but two. Marest none. But whether the south will make

up the deficiency I know not. The truth is, that the severe winter of 1860 effected a clearance here as elsewhere, and other circumstances have conspired: thus the depredations of the "ver blanc," as the grub of the cockchafer is called, has made such depredations on Marest's new grounds that he is unable to come into the market at all; and the difficulty of saving seed in the very wet summer preceding it has also greatly diminished the prospects of new Roses. I saw at Margottin's rods of ground in which he had sown seed, and which he always had filled with seedling plants, and not one had come up of that season's sowing—though the seed, he said, looked plump and good. The same has been experienced in other things beside Roses, and in other places than Paris.

I was fortunate enough to find both Mons. Verdier himself, and his son Mons. Charles Verdier at home, and to have an agreeable chat with them, and Madame C. Verdier, on our mutual pet. By-the-by, the good wives of these French nurserymen take far more interest in the "establishment" than those of our English ones do. You may be generally sure that if the head of the firm is out, his wife can give you quite as much information. It is she, too, who keeps the accounts, and knows how matters stand. We were all agreed on the impolicy of sending out such a multitude of seedlings, and as to the certainty of its defeating its object. Perhaps nurserymen in France may see this; but if not, I know of nothing so likely to open their eyes than to see that we can raise such Roses as John Hopper, Lord Clyde, and Beauty of Waltham, in England, and that they are sent out at 5s. each instead of £1, and 16s. 8d., as most of the new French Roses are.

Of new Roses, the Messieurs Verdier have three this autumn. One of them, *Madame William Paul*, I had the good fortune to see, for Mons. Charles Verdier very kindly went to a piece of Rose-ground that they have a little distance off, and brought me in some blooms; and although it was late, and the weather was very warm, yet sufficient was seen to enable me to pronounce it to be a desirable Rose. It bears a strong resemblance to Margottin's Souvenir de Comte Cavour, being of the same bright crimson, but a little more "velouté," or shaded with dark than that variety. It is not, perhaps, quite so full as it is, and in smoothness it would be difficult to beat that very smooth flower. The habit seemed good: it is evidently another of the Général's numerous progeny, and like all the children, and the parent, too, the footstalks are somewhat long and slender. His other Hybrid Perpetual I did not see, nor is it yet named. He has also a Tea, which he pronounces to be of excellent quality.

I may as well mention here what will, I fear, not be very acceptable news, that Gladioluses have done as badly at Paris as with us. The fault is laid, and I believe with justice, to the wet and cold of the months of May and June. They evidently, as natives of the Cape, prefer a more genial time than this year has afforded them, and the great coldness of the ground has prevented their starting, in some instances at all, and in others, has made them very yellow and sickly-looking. This is a matter to be deplored, for as they are making such progress as public favourites, that it is a great disappointment to many who had commenced their growth for the first time.

MM. Levêque et fils, of the Boulevard de l'Hôpital, grow very few Roses in their Paris establishment, and I could only gain from them the information that they have six Roses to let out this autumn. These are—Duc d'Anjou, Gustave Rousseau, President Lincoln, Madame Petit, Duchesse de Polignac, and Comte de Beuges. Of the first two, raised we believe at Angers, they speak very highly, and assured me that they would be found really valuable Roses. As they have proved themselves good judges, we may hope that in this respect also they are correct. We must make some allowance for the difference of taste in the two countries. Those dull-looking Roses, which to us seem so worthless, are not so with them. May it not be that the difference of climate has to do with this, their bright and glaring sun may lead them to admire the more sombre colours, as toning down the excessive glare, while with our sombre and leaden skies and our large quantity of verdure we, perhaps, look rather for brighter colours, as helping to give life to the garden? For the same reason I hardly fancy that our style of bedding-out would suit them; there is too much colour, too much red and yellow to please their eye, which would rather rest on masses of green foliage. But more of this anon. I mention it here, because Levêque seemed to think it odd that we did not like such flowers as Comtesse de Segeurier, which he let out last autumn.

I have thus given all the information I have been able to glean on the subject of Roses across the water, and hope that those numerous friends who asked me to give them what information I could obtain as to the new kinds will receive this in lieu of private communications. They are all, I believe, readers of THE JOURNAL OF HORTICULTURE, and some of them are aware of the many calls on my time that I have, and so will, I am sure, have compassion on me. I wish the information had been fuller, but the area in which I had to obtain it was circumscribed.

I hope to say a few words on the public gardens of Paris as compared with our own, and on the state of horticulture generally in France.—D., Deal.

GRAPES FOR A COOL VINERY.

I AM preparing to make a place to grow a few Grape Vines in, and to train them after the form shown by Sanders, in plate 7, and page 23, third edition, for the outside wall.

My wall is the end of the dwelling-house, having a south aspect, and 25 feet in length. I purpose covering the whole length of this wall with perpendicular sashes, 6 feet high, with 1 foot of a wood shutter below, and 3 feet from the wall, making them, or most of them, to open like so many glazed doors, so as to get at the plants when necessary. When the place is made it will look like a narrow lean-to house, 25 feet by 3 feet, and 7 feet to 8 feet in height (roof glazed, of course). Do you consider such a place suitable for Vines, and which of the best kinds will succeed? There will be no fire heat, except at the place where the kitchen fire is. The situation is six miles south-west of Manchester, and one of the warmest near Manchester.—NOTICE.

[For such a place we would prefer Black Hamburg and Royal Muscadine. We have no doubt that your plan will answer if well attended to; but if the place is your own, for convenience and economy combined, we would have a fixed roof, ventilation at top and bottom, and enclose 6 feet or 7 feet instead of 3 feet. This is merely our idea, and may not at all interfere with the success of yours; though sashes made to open as doors are not done economically unless pivot-hung.]

REPORT ON THE BROCCOLIS

GROWN IN THE GARDEN AT CHISWICK IN THE AUTUMN OF 1861 AND THE SPRING OF 1862. BY ROBERT HOGG, LL.D., F.L.S., Secretary to the Fruit Committee.

(Continued from page 334.)

LEE'S SPROUTING . . . . . J. & C. LEE.

This is a variety of Spring White Broccoli, which in its best state forms a good-sized terminal head about 8 inches across, and produces from the axils of the leaves smaller heads, about the size of Walnuts. It is very rarely, however, that this character is met with, the great bulk of the crop having the appearance of a spritious stock of Spring White Broccoli.

VEITCH'S SPROUTING . . . . . VEITCH & SON.

From the appearance that this and the preceding variety of White Sprouting Broccoli presented, it was the opinion of the Committee that neither of these was a variety desirable for cultivation.

MITCHINSON'S PENZANCE . . . . . TURNER.

Early White Cornish . . . . . TURNER.

Mitchinson's Early White . . . . . CARTER.

One of the best of the Spring Whites. The leaves are very much wavy on the margin, and enclose very large and fine heads, which are almost of a pure white colour. This is a very hardy sort, and comes into use about the 20th of March.

AMBLER'S EARLY WHITE . . . . . MINIER & CO.

Also one of the best Spring Whites. It is remarkably hardy, and produces a very large creamy white head, and very uniform in size. It may easily be distinguished from the preceding by its winged leaf, that of Mitchinson's being interrupted. It comes into use about the 22nd of March.

KIDDERMINSTER . . . . . BUTLER & McCULLOCH.

The head is large and handsome, of pure whiteness, and very much exposed. It is evidently a form of *Wilcove*, and has no doubt emanated from that variety; but it is a little earlier, having come into use on the 20th of March.

CHAPPELL'S CREAM . . . . . VEITCH & SON.

A very hardy and very fine Broccoli, coming into use about the same time as Ambler's. It produces large creamy heads.

D. Late Spring White Broccoli.

WILCOVE . . . . . VEITCH & SON.

The true *Wilcove* is a perfectly distinct variety from every other of its season. The heads it produces are very large, firm, even, and fine, and of a pure whiteness. They are fully exposed, and not protected by the leaves as most other Broccolias are. On this account it is more exposed to the influence of the weather than any of the other late sorts, and, therefore, in severe winters must be regarded as a tender variety. It is, nevertheless, one of the finest Spring Broccolias. It came into use on the 1st of April.

SHEARER'S LATE WHITE . . . . . LAWSON & SON.

This is a very fine Late White Broccoli, producing large heads; and is remarkably hardy. It comes into use in the beginning of April.

TAMWORTH . . . . . BUTLER & McCULLOCH.

The same as Portsmouth or Brimstone Broccoli, of which it is a very fine stock.

VEITCH'S EARLY WHITE . . . . . VEITCH.

A distinct sort, with a stem about a foot high, producing very large heads, of uniform size, and of a clear creamy white; very excellent and hardy. In use April 1st.

KNIGHT'S PROTECTING . . . . . MINIER & Co.

Invisible . . . . . BUTLER & McCULLOCH.

Frogmore Protecting . . . . . VEITCH.

Early Gem . . . . . NUTTING.

The Gem . . . . . SUTTON & SON.

Lake's Gem . . . . . TURNER.

Waterloo Late White . . . . . BUTLER.

Dillistone's Late White . . . . . HURST & McMULLEN.

Almost all the Late Spring Broccolias are more or less modified forms of Knight's Protecting, or, as it is sometimes called, Invisible Late White, and indeed all the truest stocks of these late sorts are the genuine Knight's Protecting. The true kind is of a dwarf habit of growth, close to the ground, and with long pointed and winged leaves, which have a spiral twist round the head, and turn in closely over it, so as effectually to protect it from the effect of frost, and preserve it of a fine white colour. The head is of good size, and comes into use in the beginning of April.

KENT'S LATE WHITE . . . . . BATT, RUTLEY, & SILVERLOCK.

A dwarf-growing variety, with very dark green foliage, and remarkably hardy. It comes into use about the second week in April, and produces a good-sized well-protected white head.

WARD'S SUPERB . . . . . SUTTON & SON.

This is a form of the Knight's Protecting, and considerably later than that variety, so much so, as to come in from a fortnight to three weeks later. In the trial from which these observations were made, while Knight's Protecting was ready from the 1st to the 6th of April, Ward's Superb did not come in till the 24th. It is of a dwarf habit of growth, closely protected by the spirally compressed leaves; and the head is of good size, and pure white. One of the best Late White Broccolias in the collection.

SHAW & CROSSLAND'S DWARF . . . . . TURNER.

This was the latest sort grown in the garden, as it did not come in till quite the end of April. The heads were small and very white, and deeply enveloped in the leaves.

II. PURPLE BROCCOLI.

PURPLE CAPE . . . . . BATT, RUTLEY, & SILVERLOCK.

Early Purple Cape . . . . . VEITCH & SON.

Howden's Superb Purple . . . . . BUTLER & McCULLOCH.

This is the earliest of the Purple Broccolias, and comes into use about the second week of August, at the same time as Walcheren. It produces a medium-sized head, which is greenish-yellow, with a purple tinge. The leaves are open and spreading, and expose the head during the whole period of its growth.

EARLY PURPLE . . . . . TURNER.

Early Purple Sprouting . . . . . CARTER.

At first this produces exposed medium-sized heads of a greenish-yellow colour, tinged with purple, which come into use in the beginning of November. It then throws out numerous

sprouts of flower-heads from the axils of the leaves which continue in use during the winter and spring.

DANCER'S LATE PINK CAPE . . . . . TURNER.

This is a very fine late Broccoli, in use in March. It produces very large heads, which are uniform in size, and with a fine even surface.

WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 360.)

CRUSTACEA—(continued).

**THE SPINOUS GALATHEA (*Galathea strigosa*).**—This specimen bears a very considerable resemblance to the foregoing one; still on examination it differs from it in several material points. There is the same sharp strong spine projecting from the front; but there are only three others on either side of it, whereas in the Sealy Galathea there were four. It is a little larger also, measuring about four inches, and the colour instead of being a greenish-brown is reddish, marked with blue lines and spots. The front legs are equal, long, flattened, and furnished plentifully with spines on all sides, excepting the outer margin of the arm. The second, third, and fourth pairs of legs are likewise armed with a quantity of strong acute spines. Professor Bell gives a very interesting account of this species, furnished him by Mr. R. Q. Couch, of Penzance, a part of which I make no apology for transcribing. "This is a common species throughout the whole of the south coast of Cornwall, and I have also found it on our northern shores. It frequents pools between tide-marks where there are loose stones and sand. It is, generally speaking, very slow in its motions, though it will frequently move with very great activity, especially when alarmed. From the great length of its first pair of legs, its motions are always retrograde. In walking its pace is tardy, but in swimming it darts from spot to spot with the rapidity of an arrow. It is never seen in any exposed part of the pool, but always seeks the shelter of stones or some hole in the rock, so that it can retire on the least alarm. It is very remarkable to witness the accuracy with which it will dart backward for several feet, into a hole very little larger than itself. This I have often seen, and it is always done with precision. The Galathea are very tender and require great care in confinement. They soon die, and hence it is not easy to rear the young. I have on many occasions hatched a very numerous family, but like those now before me, they soon die."

**EMBLETON'S GALATHEA (*Galathea nexa*).**—This is a much smaller species than either of the two just before mentioned, not measuring more than an inch in length; and from being a deep sea species not so commonly met with, the hands are hairy and destitute of spines, one being somewhat smaller than the other. Its colour is brownish. Professor Bell says:—"Mr. Thompson's specimens, which I have before me, were obtained 'from the stomachs of Cod fish brought from the coast of Down and Antrim to the Belfast Market, and in Dr. Drummond's collection are specimens which were similarly procured.' I have several specimens which were taken by Mr. McAndrew in dredging in Loch Fyne, at a depth of from twenty to seventy fathoms, and by that gentleman and Professor Edward Forbes, at Zetland."

**LONG-ARMED MUNIDA (*Munida Rondeletii*).**—This remarkable species derives its name from the great length of its anterior legs or arms, which are double the length of the body, measuring about six inches, whereas the animal itself from rostrum to tail measures only three. On the rostrum are three spines, the centre one being extremely long. The anterior legs are furnished with a series of spines, both on the upper and under surface. The remaining legs are long, slender, and cylindrical, the whole covered with close short hair. The abdomen is convex, the second segment having six small acute spines arranged on it. The third has four similar ones. In colour it is of a dull reddish-yellow, streaked with brighter red. "This remarkable species," says Professor Bell, "appears to be far from common on our coasts, although it is, probably, more numerous than has been supposed, from its frequenting deep water. It was found in Plymouth Sound by Mr. Prideaux. I have received it from Falmouth through the kindness of Mr. Cocks, but it is not included in the 'Cornish Fauna,' by Mr. Couch. Mr. Thompson in recording its repeated occurrence on the coast of Ireland, establishes its habitat in deep water, by stating several instances

of its being found in the stomach of the Cod, and, still more remarkable, by the fact of its having been 'dredged alive in water from one hundred and ten to one hundred and forty fathoms in depth, off the Mull of Galloway.' These were all of them very small specimens. It is, in fact, an inhabitant of deeper water than any other of the family, not excluding *Galathea nexa*."

**CALLIANASSA SUBTERRANEA (*Underground Callianassa*).**—

This strange species is by no means uncommon, particularly on the coast of Devon, where it resides in subterranean passages. It is about two inches in length, and when alive of a bright red colour, which colour, however, disappears shortly after death. The carapace is flattened at the sides, and the eyes very small. The anterior feet are remarkably unequal; the larger one, which in some specimens is the right, in others the left, is extremely large, flat, and polished, and fringed with hair on the margins. The smaller foot is very slender, the hand being small and smooth. The second pair of feet are two-toed, and the pincers strong. The third pair have the penultimate joint oval and hairy; and the fourth and fifth pairs are simple and nearly filiform. "Its claim to be considered as an Irish species," says Professor Bell, "is thus stated by Mr. Thompson," March 25th, 1839.—"On examining the contents of the stomach of several individuals of the *Platessa Pala*, which were taken off Newcastle (County Down), two of the larger arms of this species, so peculiar in form and still retaining their beautiful pink colour were detected."

**GEBIA STELLATA (*Starred Gebia*).**—This little creature is a burrowing species like the Callianassa. It is about an inch and a half in length. It has a pair of antennae about the same length as the body. The legs get gradually slenderer towards the fifth pair, and are all fringed with long hair. Leach states that "it has been taken on some of the shores of Plymouth Sound, under the mud of which it makes long, winding, horizontal passages, often of a hundred feet or more in length." This habit of burrowing is peculiarly strange. The following are Professor Bell's remarks on this head:—"The burrowing of these fossorial species is a subject which deserves more attention than has hitherto been paid to it. The means by which it is effected are at present absolutely unknown, nor is it yet certain whether they ever avail themselves of the labours of other animals, or whether the excavations in which they are found are wholly the work of their own hands. The account given above from Dr. Leach of the extent of these passages appears at first scarcely credible, and may well challenge a thorough examination of these points in the economy of these curious animals."

**AXIUS STIRYNCHUS.**—This is also one of the fossorial or burrowing species, about three inches in length, and of a pale reddish-brown colour. The first pair of legs are stout and slightly unequal; the second pair two-toed, rather small and compressed; the whole, especially the arm, being furnished with long hair on the inner margin. The remaining feet are all simple; the third pair being the thickest, and the fifth the most slender.

"This species," says Mr. Couch, "like those of the genus Callianassa, has the habit of burrowing in the sand, from which it rarely emerges; and then it seeks shelter in a crevice covered with weeds, for it is sluggish in its motions, and, if distant from a soft bottom in which to sink, incapable of escaping from an enemy. A female that I obtained, loaded with spawn, was dug out of the sand in the middle of summer." "This species," says Professor Forbes, "the largest of the family indigenous to this country, was first discovered by Dr. Leach at Sidmouth, where it was taken amongst Prawns on the shore; although," as the Professor adds, "this occurrence of Dr. Leach's specimen among Prawns must have been purely accidental, as it is essentially a fossorial species."

**CALOCARIS MACANDREÆ.**—This is also a fossorial species, and, as Professor Bell remarks, "constitutes one of the most singular

and interesting additions which have for a long time past been made to our list of British Crustacea." The shell is thin and flexible; the carapace large, narrowed towards the front, where it terminates in a sharp triangular rostrum. There is a small raised line running the whole length of the carapace. The fore feet are about two-thirds of the length of the body. The claws are very long, compressed, grooved, and furnished with some small tubercles. The second pair of feet are two-toed, and resemble the first pair in their general form, although considerably smaller. The other pairs are slender and one-toed. All of them, as well as most of the limbs and other appendages, are hairy. The usual colour is a pink or pale rose, varying in intensity in different parts; but the colour fades out if the

creature be placed in spirits, leaving it a simple white. The length is about two inches. The eyes have a strange peculiarity. Professor Bell states, "The absence of all colouring pigment, as well as of the cornea in the eyes, is a very remarkable, and, as I believe, a unique instance in the whole of the higher forms of Crustacea. But it is admirably in keeping with its habits; for," as the Professor goes on afterwards to say, "it occasionally inhabits a depth of no less than 180 fathoms, in which situation it is fossorial in sandy mud. Now it is clear that at such a depth, and of fossorial habits too, distinct vision would be useless and unavailing, and this at once accounts for the rudimentary character of the eyes, which are entirely white."—W.

(To be continued.)

### SOME HINTS ON BUDDING ROSES.

"WHAT is the best weather for budding? I am told damp cloudy weather is." How often would such a question, asked by an amateur, obtain such an answer? How startling, therefore, to him to be informed to the contrary! Why, he has seen it recommended in books! Yes, nothing more generally recommended than damp cloudy weather for budding! To say bright, warm, sunny weather is best, provided the stocks are in proper condition, will sound like heresy; extensive experience, however, tells me such is the case. I may be asked why? And I would answer, that in warm weather the sap is more gelatinous; and the bud, on being extracted and inserted in the stock quickly, properly tied, &c., soon takes. On the contrary, in wet cloudy weather the sap is more thin and watery, and the bud will not unite so freely. To this we add that a fall of rain (likely in such weather) after the buds are inserted, will fill up the incisions, and thereby rot and perish the buds before they have time to unite with the stocks. Not only is clear warm weather best for the experienced budder, but likewise for the amateur and tyro, and August is a good month for the operation.

Another question is common—Is it necessary to extract the wood from the bud? I answer, Yes; whilst American writers say, No. The Americans, indeed, work nearly all their fruit trees, ornamental trees, Rosez, &c., with the wood left in the bud as cut from the shoot. This may best suit their hot dry climate; but after giving it repeated and extensive trials, I must give the preference to our old system of extracting the wood from the bud, not only for Roses, but ornamental trees, forest trees, &c.; for in our comparatively cool moist climate it answers better. In all cases where they have been tried, the failures have been much more considerable under the American system than under the old, the circumstances being equal. Sometimes there may be an advantage in putting in the wood—namely, where the shoot is become firm, and the wood and bark will not freely separate; then, if inserted in a free-growing stock, it will in all probability take.

In budding, the top bud on the shoot should be commenced with, cutting from about an eighth of an inch below the bud or eye to from half an inch to an inch above it, in order that there may be a sufficiency of bark to hold with the fingers without rubbing the portion which is to be inserted (shown in *fig. 2*); take out the wood as already recommended. Next make an incision in the shoot of the stock close into the main stem, and about half an inch long: this is long enough. Cut across at top, raise the bark with the end of the budding-knife without

bruising it, and insert the bud, which will then have the appearance of *fig. 4*. It is now to be tied with a little worsted or cotton, as shown in *fig. 6*; one tie below the eye and two above will be ample, as its entire length will not be more than half an inch, and a quarter of that below the eye. The most inexperienced amateur need not give more than two rounds below the eye and three above, but the practical workman will find the number I have mentioned sufficient.

The superiority of this system of budding over the old must be apparent. *Fig. 1* shows a bud extracted on the old method, the whole more than an inch in length. *Fig. 3* shows the same inserted, and *fig. 5* the same tied-in with innumerable rounds of matting. *Fig. 7* shows it the following season, the buds having grown. *Fig. 8* represents the growth which the buds take on the new system; they grow out nearly from the axil of the branch, and look neat and workmanlike; and after a season or two, when the shoots are headed back and healed over, which they freely do, they have the appearance of growing out of the main stem, forming neat heads without scars, wounds, or knots, very different to the appearance of those worked like *fig. 7*, which have an unsightly and unworkmanlike appearance, and liable to be blown out by the wind, having scars and dead snags in abundance, and never forming such neat, compact, and clean healthy heads. Those who are acquainted with budding will easily understand this from the figures. I have purposely shown the one-year shoots in *figs. 7* and *8*, as if they had not been stopped the first season, to explain the system. When strong, however, they had always better be stopped the first season when they attain from 1½ inch to 2 inches in length, repeating it as the growth proceeds. In this way, by the end of the first season from the bud the heads will be fine and bushy, which will not be

Budding: Old plan, *figs. 1, 3, 5, 7*; New plan, *figs. 2, 4, 6, 8*.

the case if they are allowed to run up with single shoots.

I should have said that the shoots selected for budding must be pretty firm—young watery shoots and buds are useless; from the former the buds always take more freely, provided they only separate readily from the wood. For tying, worsted or cotton is in every way incomparably better than matting. Cotton I consider best of all; it is much cheaper, more expeditious in use, does not cut the bark as much as matting, and requires nothing more than cutting into lengths of from 4 inches to 6 inches to be ready for use; the former length will be sufficient for the experienced, whilst the tyro may require it of the latter length. Lamp-wick answers for this purpose, but it

requires splitting as it is generally too thick; about the substance of strong yarn is sufficient. Suitable yarn may be obtained of any dealer in cotton, or at a very cheap rate from any cotton manufactory where they sell retail. All things in these nurseries which are budded are now tied with cotton—Roses, ornamental trees, shrubs, fruit trees, &c.; it is found much

cheaper than matting at the first cost, and matting requires much more labour in cutting, splitting, wetting, &c., before it is used. Cotton, on the contrary, requires only cutting in lengths, when it is ready for use; it can be employed more expeditiously, and is more efficient.—J. SAUL, *Durdham Down Nursery, Bristol.*—(*Gardener's Magazine of Botany.*)

### ORNAMENTAL PLANTS.

*MOUSSONIA ELEGANS* (Elegant Moussonia). *Nat. ord.*, Gesneraceae. *Lin.*, Didynamia Angiospermia.—A rather handsome sub-shrubby herb, requiring a temperate stove. It has soft hairy stems and leaves, more or less tinged with red. The leaves are opposite, ovate-oblong, acuminate, crenate-dentate, and shortly petiolate. The flowers grow in three or four-flowered umbels, on

pedicels springing from the axils of the leaves; the corolla is an inch and a half long, somewhat curved and swollen about the middle of the tube, scarlet; the limb of five spreading, nearly equal crenate-lobes, yellowish inside, with lines of purple spots; the throat is yellow. From Guatemala: mountainous regions. Flowers during winter.

1. *Moussonia elegans.*

2. *Cuphea cinnabarina.*

*CUPHEA CINNABARINA* (Cinnabar-coloured Cuphea). *Nat. ord.*, Lythraceae. *Lin.*, Dodecandria Monogynia.—A very pretty sub-shrubby greenhouse or half-hardy plant, with strigulose branches, bearing opposite lanceolate leaves, acute and narrowed towards the point, and racemose panicles of showy blossoms; the viscid, hairy, calyx-tube is about three-quarters of an

inch long, pale red, with green ribs and tips; the two enlarged upper petals are minute and of the same colour. A variety called *atro-sanguinea* has the petals deep blood red. From Guatemala. Introduced to the Belgian gardens by M. Van Houtte in 1818. Flowers during summer.

### PORTRAITS OF PLANTS AND FRUITS.

**NOLANA LANCEOLATA** (Lance-leaved Nolana). *Nat. ord.*, Solanaceæ. *Linn.*, Pentandria Monogynia.—It has also been called *Sorema lanceolata*. Native of Chili. Introduced by Messrs. Veitch & Sons, of the Exeter and Chelsea Nurseries. Flowers brilliant blue, with white centre. "A charming, compact-growing annual, promising to be a great acquisition to our parterres."—(*Botanical Magazine*, t. 5327.)

**GRAMMITIS CAUDIFORMIS** (Taper-pointed Grammitis). *Nat. ord.*, Cryptogamia-Filices.—It has been called also *Selliguea plantaginea* and *Polypodium caudiforme*. A handsome Fern from the Malay Archipelago.—(*Ibid.*, t. 5328.)

**BOLBOPHYLLUM PAVIMENTATUM** (Clustered Bolbophyllum). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of the banks of the Nun, in Tropical Western Africa. Flowers purple, blooming in February.—(*Ibid.*, t. 5329.)

**IPOMEA ALATIPES** (Winged-stalked Ipomœa). *Nat. ord.*, Convolvulaceæ. *Linn.*, Pentandria Monogynia.—It has also been named *I. pterodes*. Native of Veraguas and Venezuela. Flowers rich salmon colour, blooming in the stove during June.—(*Ibid.*, t. 5330.)

**ANOMOCHELOA MARANTOIDEA** (Maranta-like Anomochloa). *Nat. ord.*, Gramineæ. *Linn.*, Tetrandria Monogynia.—A curious grass. Native of Bahia, Brazil.—(*Ibid.*, t. 5331.)

**NEPHALOPHYLLUM PULCHRUM** (Beautiful Cloudy-leaf). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Mount Salak, Java. Introduced by Messrs. Low, Clapton Nursery, where it flowered in May. Flowers green and white.—(*Ibid.*, t. 5332.)

**SINGLE PETUNIAS**.—Raised by Mr. Holland, and sent out by Mr. Williams, Paradise Nursery, Holloway. **ROSA BELLE-FORME** is "a flower of very fine shape and good substance, larger and stouter than any of its class; the colour a bright magenta, with a very clear white throat." **FLOWER OF THE DAY** is somewhat in the style of Madame Ferguson, "but the bands, which are bright rosy crimson, are much broader and brighter than in that variety."—(*Floral Magazine*, Pl. 109.)

**ROSE JOHN HOPPER**.—Raised by Mr. Ward, of the Rosery, Ipswich, from Jules Margottin fertilised with the pollen of Madame Vidot. A large Rose "somewhat in the style of Pauline Lanzeteur, but fuller, the colour a bright crimson suffused with violet, and is of a very vigorous habit."—(*Ibid.*, Pl. 110.)

**CINERARIAS**.—Three varieties from Mr. Turner, of Slough. **JAMES ANDREWS**, dark purple, of good shape. **THE ARTIST**, bright magenta with a small white circle round the disk. **THE WINNER**, a bright magenta self.—(*Ibid.*, Pl. 111.)

**SARMIENTA REPENS** (Trailing Sarmienta).—*Nat. ord.*, Gesneriaceæ. *Linn.*, Diandria Monogynia. Native of the Chilian Audes. Flowers tubular, swollen in the centre, light crimson scarlet.—(*Ibid.*, Pl. 112.)

**DOUBLE CHINESE PRIMROSES** (*Primula prænitens flore pleno*).—Two full-double fringed varieties from Messrs. F. & A. Smith, of Dulwich. **DELICATA**, nearly 2 inches across, white changing to a delicate blush. **RUBRA GRANDIFLORA** large, magenta, and the variety like the preceding, has the property of reproducing itself from seed.—(*Florist and Pomologist* i, 113.)

**APPLE, IRISH PEACH** (*Syn.*, Early Crofton).—Fruit middle-sized, roundish, deep crimson next the sun, streaked with deeper crimson, and strewed with yellow dots. Ripe in August, and lasts all through the month. "A most beautiful and certainly one of the most excellent summer Apples, possessing all the rich flavour of some of the winter varieties, with the abundant and refreshing juice of the summer fruits."—(*Ibid.*, p. 120.)

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE August meeting of the Entomological Society was but sparingly attended as usual at this season. Amongst the donations were the publications of the Royal Society, the Society of Arts, and various periodicals. Also, a fine new work on the Diptera of Mexico, by Luigi Bellarde.

On the motion of the Rev. Hamlet Clarke, a vote of thanks was unanimously passed to W. W. Saunders, Esq., F.R.S., Treasurer of the Linnean and Royal Horticultural Societies, &c., for his handsome entertainment of the members of the Society, at Reigate, recorded in our last report.

Mr. S. Stevens exhibited a very beautiful collection of Coleopterous insects captured in the interior of Cochinchina by the

late M. Moulhot, whose untimely decease was a great loss to natural science. Amongst these insects was a magnificent new genus of Scaritidæ of very large size, and a great number of new and splendid Longicorn Beetles.

Mr. Stainton exhibited a number of curious varieties of *Gracillaria semifascea*, which he had reared from small conical galls on the leaves of Maple trees growing in Headley Lane, near Croydon.

Mr. Wallace exhibited some very effective photographic representations of insects, both of the natural size and magnified. These were arranged on sheets of an octavo size, and were thus for publication in books without mounting. The smaller specimens had been mounted on gelatine, and thus the blurred appearance of photographic representations of insects gummed on cardboard was avoided.

The President, Mr. F. Smith, exhibited two rare Staphylinidæ—*Myrmecodia Haworthii* and *Heliobates propinqua*, taken by his son during the Reigate excursion. Also, a very remarkable specimen of Honey Bee, possessing characters of each of the three kinds of individuals in the hive, the head being that of a drone, the legs partly drone and partly worker, and the sting like that of the queen.

Professor Westwood gave an account of a specimen of the Honey Bee, which he had recently captured. The head of which was adorned with a large tuft of the pollen-masses of an Orchis, most probably *O. maculata*, as that species was in blossom in the Professor's garden. The specimen was captured on the alighting-board of one of his hives, another bee being in the act of dragging it out of the hive, where it was evidently obnoxious from its novel appendages.

The President read a memoir containing a revision of the tribe Cryptocerides (belonging to the family of the Ants), a group of great interest, and of which Mr. Smith has more than doubled the number of species within a few years, chiefly from the collections of Mr. Wallace in the Islands of the Eastern Archipelago.

Dr. Wallace made some observations on the destructive habits of the Gooseberry grub, *Nematus ventricosus*, and on the most effectual means for preventing its ravages. From the memoir of M. Vollenhoven it appears that the eggs are laid in considerable numbers on the under side of the leaves along the midribs, and that the young larvæ as soon as hatched commence feeding on the leaves, which they riddle with small holes like gun shot. As soon as this is observed the leaves should be gathered and destroyed; but if unattended to for two or three days the insects have eaten the whole of the leaf which formed their cradle and dispersed themselves over other leaves, where they are more difficult to be attacked. There are several broods in a year; and although the first brood confines its attacks to Gooseberry leaves, the second is said to attack the Currant with equally injurious effects. We have not been able to verify this observation, as we found the first brood indifferently on the Currant and Gooseberry.

### THE INTERNATIONAL EXHIBITION.

(Continued from page 359.)

#### TASMANIA.

AMONG the vegetable products of Tasmania, that which will probably hold the first rank in the estimation of the people of this country is its timber, which from its great size, strength, and durability, seems eminently suitable for ship-building, as well as for a variety of useful purposes of minor importance. The numerous specimens of the ornamental and useful woods of the colony are formed into a trophy, the flagstaff on the summit of which reaches the roof of the Exhibition building.

The tall central column consists of eight spars of Stringy Bark, Blue and White Gum, Silver Wattle, Blackwood, and Sassafras, arranged as an octagon, and the eight sides at the base are composed of planks of Blue Gum and Stringy Bark, the heart being sawn off; that part in most Tasmanian as well as Australian timber, being almost always more or less shaly.

"Samples of other ship timber form the base of the trophy—which is thus constructed:—Five planks (20 feet long) of Blue Gum, Stringy Bark, Blackwood, and Myrtle, the two former being fitted for ship-building, and the two latter for cabinet-work, are first laid down. Placed across these are ship's-keel pieces (10 feet long, squared) of Blue Gum, and Stringy Bark. Immediately on these lie, transversely, joists of Stringy Bark,

covered with ordinary flooring-boards of the same wood. The framework of the pedestal placed on this floor is composed of Blue Gum, White Gum, and Stringy Bark. The joists, quartering, and flooring-boards of the pedestal platform are also of Stringy Bark. The centre piece of the spiral staircase is formed of a spar of plain Huon Pine, the stairs being made of this free-working and almost imperishable wood. These samples will show what Tasmania can supply of plain timbers. Of large ship's knees an unlimited supply can be obtained from Tasmania, where the stumps of the large trees which might supply them are left to rot after the tree has been cut up. They are also shown in the angles of the pedestal frame, of various conditions as to seasoning. A large Blue Gum knee, and also a Blue Gum crook have been exposed to the open air nearly ten years, in the shipyard of Mr. McGregor. In other angles of the frame are three very fine ship's knees from Tasman's Peninsula, exhibited by Mr. Boyd. There are also three smaller knees, a Blackwood crook for curved banister work, and a fine Huon Pine knee, in the other angles. In the interior are some railway sleepers of Blue Gum and Stringy Bark, and pieces of White Gum, or Gun-topped Stringy Bark, 12 inches by 6 inches, 12 feet in length, contributed by Dr. Crowther, and by Mr. Boyd, together with some sleepers of Blue Gum and Peppermint wood. The split palings and roofing shingles here displayed are also fine specimens, varying in length from 5 feet to 15 feet, and in breadth from 6 inches to 24 inches. These are specimens of the ordinary splitting qualities of Swamp Gum."

There is also in the garden of the Royal Horticultural Society a spar of the last-named wood, from Mr. Boyd, of the extraordinary length of 230 feet, and which would have been brought in one piece to England could a ship have been found capable of taking it. In the absence of such it had to be divided into 20 feet lengths, and bolted together on its arrival in this country.

Besides these there are a plank of Blue Gum 90 feet long, 20 inches wide, and 6 inches deep; and one of Stringy Bark 80 feet long, 24 inches wide, and 6 inches deep.

Blue Gum, Stringy Bark, and Peppermint will, it is believed, from their great durability, prove of great value for railway sleepers, of which, according to Mr. Stephenson, 2,800,000 are required every year in Great Britain, and to supply this quantity it is estimated that the wood of 7000 acres of land is annually required. An ordinary sleeper lasts about twelve years, whilst these woods it is imagined would remain sound for fifteen or twenty at least, and, probably, much longer. To show their resistance to the action of the atmosphere and water, old piles and planks from the wharves at Hobart Town are exhibited, which have been exposed for twenty-one years to the alternate influences of sea-water, air, sunshine, and rain, without undergoing material deterioration. There is timber that was used in the construction of the old Court House, and the old Gaol at Hobart Town, as sound as when first used; and, finally, there is the fencing of the early settlers in an almost unimpaired condition after forty years' exposure.

In an appendix to the account of the colony are some useful notes on its vegetable products, by Mr. Archer, from which the following is extracted with some alterations and abridgments:—

**BLUE GUM, *Eucalyptus globulus*.**—The common name is derived from the bluish-grey colour of the young plants. Diameter, 5 feet to 30 feet; average of those felled for use, 6 feet. Height, 150 feet to 350 feet. Sp. grav. about .945 to 1.055. Abundant in the southern and south-western parts of the island. Cut for house-building it sells at 8s. to 10s. per 100 superficial feet—for ship-building at 12s. to 14s.

(Used for the same purposes as Oak, and, according to some experiments which were made, much stronger than either that wood or teak, its breaking weight being 1031 lbs., while that of English Oak was 637 lbs., and of teak 938 lbs.)

**STRINGY BARK, *Eucalyptus gigantea*.**—Common name taken from the coarse fibrous bark. Diameter, 4 feet to 24 feet; average of those sawn about 5½ feet. Height, 150 feet to 300 feet. Sp. grav. about .905. Abundant everywhere upon hilly ground. Price, the same as that of Blue Gum.

(Used for ship-planking, boat-keels, house carpentry, and found to be extremely durable for out-door work. Breaking weight 867 lbs., that of English Oak being 637 lbs.)

**SWAMP GUM.—WHITE GUM, *Eucalyptus viminalis*.**—Common name from its growing to perfection in humid situations—and from its gigantic white trunk. Diameter, 4 feet to 18 feet; average about 5½ feet. Height, 150 feet to 300 feet. Sp. grav. about .885. Growing in forests with other kinds of *Eucalyptus*, in rather humid localities. Price, for general purposes the same as that of Blue Gum; fire-wood palings, 6s. to 8s. per 100.

(Breaking weight, 784 lbs., against English Oak, 637 lbs.)

**GUM-TOPPED STRINGY BARK, sometimes called WHITE GUM, *Eucalyptus gigantea*, var.**—A tree resembling the Blue Gum in foliage, with rough bark similar to Stringy Bark towards the stem. It has been found recently that this wood possesses nearly all the properties of strength, solidity, and

durability of the Blue Gum—whilst being straight-grained, it is much easier to work. Price, about the same as Blue Gum.

**PEPPERMINT TREE, *Eucalyptus amygdalina*.**—Common name from the odour of the leaves. Diameter, 3 feet to 8 feet; average about 4 feet. Height, 100 feet to 150 feet. Sp. grav. about .895. The Peppermint tree abounds throughout the island on gravelly and other poor soil. Price, about the same as that of Swamp Gum.

(Some specimens of this timber have a fine wavy marking, which renders it suitable for cabinet work.)

**HUON PINE, *Dacrydium Franklinii*.**—So called because it was first discovered on the banks of the Huon River. Diameter, 3 feet to 8 feet; average about 4½ feet. Height, 50 feet to 120 feet. Sp. grav. about .650. Abundant in portions of the south-western part of the island. Price, about 16s. per 100 superficial feet, in the log.

(Excellent for ship building and for every purpose for which the Pine is employed, much heavier and harder than that wood, and taking a fine polish as well as being fragrant, it is excellent for cabinet work. To show its adaptation for this purpose, a wardrobe is exhibited which has been constructed of this wood and polished. The ship's knee is a beautiful example of this kind of timber without the slightest crack or unsoundness. It is of this wood also that the two whaling boats suspended from the trophy are constructed.)

**BLACKWOOD, *Acacia melanoxylon*.**—So called from the dark brown colour of the mature wood, which becomes black when washed with lime water. In moist shaded localities the tree grows more rapidly, and the wood is of a much lighter colour. Hence this variety is called "Lightwood," in Hobart Town, to distinguish it from the other. Diameter, 1½ foot to 4 feet; average about 2½ feet. Height, 60 feet to 130 feet. Sp. grav. about .885. Found throughout the island, but not abundantly in any one locality. Price, about 12s. to 14s. per 100 feet super., in the log.

(A beautiful wood for furniture, and excellent for the staves of casks. Lightwood is excellent for veneering. The bark is used for tanning. A large oval table is shown.)

**NATIVE MYRTLE, *Fagus Cunninghamii*.**—Common name from the fancied resemblance of its dark green leaves to those of the Myrtle. Diameter, 3 feet to 12 feet; average about 3½ feet. Height, 100 feet to 180. Sp. grav. about .795. The native Myrtle exists in great abundance throughout the western half of the island, growing in forests to a great size, in humid situations. Price, about 16s. per 100 feet super., in the log.

(Admirably fitted for furniture and for the purposes of the cabinet-maker. The timber possesses a lively reddish colour. There are splendid planks of the plain wood exhibited 20 feet and 30 feet in length, which are used for seats along the gallery. The figured wood, of which there are some fine polished slabs and panels shown, display deeper tints, with markings and venation of the richest and most varied character. A handsome bureau is shown made of this wood.)

**CELERY-TOPPED PINE, *Phyllocladus rhomboidalis*.**—So called from the fancied similarity in form of the upper part of the branchlets to Celery. Diameter, 1½ foot to 2 feet; average, about 1½ foot. Height, 60 feet to 150 feet. Sp. grav. about .655. Rather common in damp forests in the southern parts of the island, and in some sub-alpine localities.

(This tree yields timber remarkable for its close and clear white grain, and for its great strength and toughness. Where it abounds it is used for house-fittings and for agricultural implements, &c. Its strength and elasticity adapt the young spars for masts and yards of vessels.)

**MUSK-WOOD, *Eurybia argophylla*.**—Named from the musky odour of the leaves. Diameter 6 inches to 15 inches, the butt enlarging towards the ground to 1½ and even 2½ feet. Height, 15 feet to 30 feet. Sp. grav. about .685. Abundant throughout the island in damp localities.

(A most beautiful solid wood for cabinet work. The Davenport and round table exhibited are fine examples of this wood when polished and worked.)

**SHOE-OAK, *Casuarina quadrivalvis*.**—A portion of the common name is evidently derived from the resemblance of the markings to those of Oak. Diameter, 1 foot to 1½ foot. Height, 20 feet to 30 feet. Sp. grav. about .845. Very common on dry stony hills, excepting in the north-western districts.

(Hard, and takes a good polish.)

**SILVER WATTLE, *Acacia dealbata*.**—So called from the whiteness of the trunk, and the silvery green of the foliage. Used for cask-staves and treenails. Diameter, 1½ foot to 2½ feet. Height, 60 feet to 120 feet. Sp. grav. about .955. Very common.

(This timber makes good staves; and the young wood when split thin makes excellent hoops for dry casks. Bark considered in Tasmania the most valuable of any for tanning. It also yields a gum which is likely to prove useful.)

**IRON WOOD (Tasmanian), *Notela lignustrina*.**—An exceedingly hard close-grained wood, used for mallets, sheaves of blocks, turnery, &c. Diameter, 9 inches to 18 inches. Height, 20 feet to 35 feet. Sp. grav. about .965.

(Very hard and heavy, takes a good polish.)

Of the other woods, the native Box, *Bursaria spinosa*; White-wood, *Pittosporum bicolor*; Pink-wood, and the native Pear, are used for turnery; the native Cherry for tool-handles and gun-stocks; while the Dogwood, *Bedfordia salicina*; and Honey-suckle, *Banksia australis*, are very suitable for cabinet work.

Several kinds of fibres are exhibited, such as the Kurrajong, Lyonsia, Blue Gum, Stringy Bark, and a kind of Stipa, some of which may be turned to useful account, and though scarcely within our scope, the opossum furs are particularly worthy of attention on account of their good appearance, warmth, and agreeableness to the touch.

It will thus be seen that though Tasmania has brought forward but few examples of manufacturing skill, she has yet produced an exhibition of natural products of eminent utility to the rest of the world. The collection of timber in particular coming at a time when the growing scarcity of ship-building materials is beginning to be felt, cannot fail to attract the attention of those connected with our mercantile and war marine; the various woods and their adaptations will become the subjects of careful experiment, and their good qualities being once established, that which is now an encumbrance to the soil will become a source of wealth. The exhibition in the Tasmanian department will likewise serve another end of not less importance, for it furnishes the intending emigrant with incontestable proofs in its agricultural and horticultural productions of the great capabilities of the climate and soil of the rising colony which it represents.

The weight of the best sample of Oats in this department is 51 lbs. 10 ozs., not 56 lbs. 10 ozs. as printed last week.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE practice of keeping the surface of the ground loose and open about growing crops is most advantageous, especially to stiff, loamy garden lands. From inattention to this apparently simple matter, it is evident that both the absorption and evaporation of moisture must be impeded, and thus the advantage of atmospheric influences considerably diminished. *Broccoli*, the decline of some of the earlier quarters of Peas, Beans, Cauliflowers, and Spinach, will afford the opportunity of making further additions to the stock, or of planting a crop of Coleworts. Where there have been any planted between Peas, the latter should be removed as soon as they are done with, the ground to be dug, and the intermediate spaces filled up. *Cauliflowers*, the plants which are now coming in should be duly supplied with water, which is the means best adapted to produce close, compact heads. *Chervil*, make a sowing for autumn use. *Endive*, continue to transplant as circumstances require. Another sowing may also be made. *Lettuce*, keep a succession sown and planted, they will now require a good supply of water to make them crisp. *Onions*, bend them down by hand in order to accelerate their ripening to get the ground clear for winter greens.

### FLOWER GARDEN.

This is a good time for removing dead wood from shrubs, and controlling their luxuriant growth by careful pruning. Attend to the tying-up of Hollyhocks, Dahlias, &c., and go over the masses of Verbenas, &c., frequently, for the purpose of regulating their growth so as to keep them orderly and neat. Sow Ten-week or Intermediate Stocks for spring-flowering; transplant Brompton and Queen Stocks, and if the situations in which they are to flower are not at liberty, prick them out in nursery-beds, allowing them plenty of room to prevent weak growth. Pink-pipings to be planted out as soon as they are fairly rooted, the beds to be made of well-decomposed dung, loam, and leaf mould in equal portions. A second crop of pipings may be put in if an increase of stock is required. Attend to the layering of Carnations and Picotees as speedily as possible. Should the weather be dry attention to be paid to regular watering. Take off the rooted offsets of Auriculas, place them round the sides of the pots, and then in a shady place. Prick-out seedling Polyanthuses on a north border or any other shady situation.

### FRUIT GARDEN.

Keep the shoots of all fruit trees closely tacked to the walls, and afford the fruit as fair an opportunity of exposure as possible. Trap carwigs and ants about the trees. See to the speedy formation of Strawberry-beds. Examine the figatures of stocks budded in July. Budding may still be performed. No superfluous shoots ought to be kept on Peaches, Nectarines, and other fruit trees on walls and espaliers after this month, so that the wood for the ensuing year may be well ripened.

### STOVE.

Much moisture and free ventilation are to be provided here during hot weather. Indeed too much atmospheric moisture

can scarcely be supplied if free ventilation is given. Let all faded blossoms be constantly removed, straggling growth pinched back, and exhausted stock cut-in previous to making a new growth. Bear in mind that the autumn is fast approaching, and that the sooner new growths are encouraged, in order to become somewhat hardened, the better. See that the Orchids growing on blocks and in baskets are properly supplied with moisture at the roots, and to prevent any mistake handle every plant at least once a-week, and immerse those found to be dry in tepid water until the material about their roots is well soaked. Syringe slightly morning and evening, and sprinkle the floors, &c., frequently so as to keep the atmosphere thoroughly moist.

### GREENHOUSE AND CONSERVATORY.

The conservatory-borders to be liberally watered, and care to be taken to insure a sufficient supply of water to any plants which have recently been turned out of pots. Let the growing plants having occasional stoppings, as recommended in the stove department. New Holland plants and Heaths that have for some time been standing out of doors, should receive particular attention if wet or windy weather prevails, to ascertain that they are in a proper state as respects moisture, and that the mildew does not prevail. Some of the best and most tender varieties should be secured by placing them in cold pits. Keep the creepers neatly trained and occasionally washed with the engine or syringe. Cinerarias for early blooming should now be growing freely, and should be shifted when necessary, for if they are to form large specimens for flowering in the winter they must not be permitted to sustain any check. See that a sufficient quantity of the various kinds of Scarlet Geraniums, Heliotropes, and Chrysanthemums, Asters, and other autumn-flowering plants are duly encouraged.

### PITS AND FRAMES.

If a good stock of Scarlet and other Geranium cuttings has not already been put in, let no time be lost. Proceed afterwards with the general bedding stock. Endeavour annually to get some new plants, and to vary your arrangement in the flower garden that the scene may not be monotonous. W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

SOWED Atkin's Matchless Cabbage, London Market, &c., for the main spring crop. The glass has been low for some time owing to brisk drying winds, and though rain has threatened little or none has come. The ground has, therefore, been very dry—a matter of importance to us where we have little water to depend upon, except what we collect from the heavens. In sowing the above, and also Lettuces and Endive, the ground was dug, then raked moderately fine, sown, the soil patted down, well watered, and the seed covered with dry soil, refuse from the potting-bench. If the weather should be at all dull this will suffice. If the weather should continue bright, a few branches or mats, or a little litter will be put on before the seeds are up. For the last week, though the sun heat was seldom up to 70° in the shade, the sun and the wind together were very parching, and had a tendency to crack all the ground exposed to it. The light fork and the hoe were used to loosen the surface to keep the moisture in and the heat out, which latter but for the moisture we would not have minded, as the soil is not by any means up to the summer warmth as yet. Forked all along by the sides of the rows of Peas to prevent this cracking; gave them waterings in addition. Would have used manure water, but the tank is empty; or at least a little soot along the rows, but our soot-heap also is exhausted. So shall be glad to see the chimney-sweep coming to look after the chimnies again. Have asked him to bring a bag or two of his pure and undefiled net time he comes. There is no more valuable help than soot when obtained unmixed with earth, sawdust, &c. Our tradesman prides himself on selling it pure, and he says it pays him best to do so, as farmers depend on the article and cheerfully pay him accordingly. No soot goes away from our premises, that is one of the things I manage to get hold of. For all such accessories gardeners must keep their eyes open and never mind being accused for having an eye to everything, provided they fairly and honestly can get hold of it. The disagreeable affair is to obtain a character for coveting much that you may see without any satisfying of the desire; but then even we must make the most of what little we may manage to obtain. If the weather con-

time so dry, will be forced to mulch Peas, Beans, Cauliflowers, &c. At present, after stirring and then watering, threw a little dry soil over the sides of the rows after watering, to keep the moisture in. It will go off fast enough through the leaves and stems of the plants, without full permission to rise from the ground again by evaporation. Threw a dusting of soil over watered Celery-beds, as unless for the earliest it is too soon to earth-up. As fully explained some time ago, the bit-by-bit earthing-up of Celery an inch or two at a time, as most gardening books tell you, is the most fruitful source for causing early Celery to bolt up into flower-stems. Encourage such to grow, tie up the heads if you will, but do little as to earthing-up until a month before you want the plants for use. This practice is founded on the natural character of the plant, and when followed there will scarcely be ever such a thing as a run head. Proceeded with digging-down Strawberry ground for winter greens, Lettuces, &c. Just to show how taste changes, I may mention that for a long time it was a matter of no importance with me whether I had cabbage Lettuces or not, but now this season all the go seems to be for such Lettuces as the Victoria and the Marselles, not only for steaming, but for salad. Well, in all such matters the demand is the best remembrancer as to the supply to be provided. Sowed the first bit of Spinach for early winter use, using the Prickly or the Flanders variety for this purpose. We generally sow in rows from 15 inches to 18 inches apart. This crop likes a fair amount of organised material, but I could give it nothing but rotten short grass and a little rubbish-heap material, keeping it well down. Used in moderation, all such succulent vegetables like such rough manure. In last week's Number, page 361, in the paragraph on Mushroom-rooms, there is a period, which as printed is worse than nonsense. It begins, "I seldom bother with them elsewhere," &c. It should read, "I seldom bother with them in summer in a common Mushroom-house, above the ground; they are so apt to come thin and maggotty." In such a season as we have had there would have been no difficulty in getting crops in a common Mushroom-house. In such a hot season as the last in this part of the country, there would have been difficulty, and hence the propriety of recommending cellars and sheds out of doors in summer, or a shady place under trees. The mistake above has led to some inquiries being made direct to me instead of through the Editors, which is against rules; but the above correction will make all smooth sailing. The very interest such matter excites shows that Mushrooms, especially in the small button state, are fast becoming a necessary ingredient in the best dishes and the most famed cookery. Where such things are wanted all the year over, I only state my approval of the open shed or the shady place in preference to the common Mushroom-house, because it has saved me much bother and the unpleasantness of not having a thing fit for use when wanted.

#### FRUIT GARDEN.

Planted-out Strawberries; watered those laid in pots. Put a fire in Peach-house from which the fruit was all gathered, and smeared the pipes with sulphur, so as to give a start to any red spider that might be left; shutting-up the house, and giving but little air and heavy syringings next day, and since less air than usual, in order to keep up a moist sulphury atmosphere, and, the roots not being over-moist, to help to harden the wood thoroughly. Some fly appearing on Melons and Cucumbers, syringed early with soot and lime water holding a little sheeping in solution; and when the leaves were dry placed a shallow box of bruised laurel leaves—say a peck for a two-light box, inside the frame, and shut it up. A syringing next morning and a second application of the laurel leaves bruised seemed to settle every insect that was then alive. I believe that such a remedy would pretty well kill everything; but then, if too much were used it would kill the plants too. As stated some time ago, great care must be used in all such remedies, noticing the age and the state of the plants, &c. This spring I put two Peach trees in pots much infested with the black fly into a fumigating-box, used a Neal's pastil, allowed the trees to remain for three or four days, and then syringed them well: not a fly appeared afterwards, not a leaf was injured, and the fruit swelled nicely. A few days afterwards much less of the pastils were used for some nice Geraniums that had some fly; and if the fly was not destroyed we could not say the same as respected the fine foliage, most of which was much injured. Other things were tried—some with full success, others quite the reverse; and I could not form any correct idea as to the cause of success in one case

and failure in another. Two good gardeners were here the other day and asked me what I thought of the pastils. It would appear that both, and also a neighbour, relying on the recommendation of an authority in such matters, had tried the same specific, and irreparably injured some of their best plants. I mention this, not disparaging the pastils, but merely showing that just as in the case of the best remedy—tobacco, which sometimes kills plants as well as insects, that much depends on the state of the plants at the time. Taking such things into consideration, the simplest remedy is often the best. If we catch and kill, in other words squeeze and syringe, there will often be less time lost than by any other mode, and there can be no question as to the security.

Proceeded, as time would permit, in nipping young wood on fruit trees, shortening-in breastwood, and watering heavily trees in orchard-house, doing it at several times to prevent the fruit being thrown off. Find that in such weather the soil in such houses dries so quick, that I would have mulched if there had been any nice thing to use. Find also the importance of tanks for such houses, as all the rain that fell on the glass during the season will be transferred to the pots and trees inside if we happen to have five days more of such bright windy weather.

#### ORNAMENTAL GARDENING.

Proceeded with potting hardwooded and softwooded plants, giving them a shady position at first; layering Carnations, striking Pinks, Cloves; budding and propagating Roses; tying-up Dahlias and Hollyhocks, Pentstemons, Phloxes; regulating flower-beds; and not only bushing Calceolaria-beds, but running a string round them to prevent the wind breaking them and sweeping them away. A gentleman visitor expressed his surprise to the workmen at what he called the uselessness of this bushing of beds (which, however, he could not have seen without looking for it somewhat narrowly), as being done nowhere else, a waste of time, &c. Without it, it would be a waste of effort to make flower-beds at all here. Before now we have found half beds, tops and roots, careering over the park. Thus circumstances alter cases, though many wise people never can be made to understand such a simple thing. We have commenced getting a little sandy loam from the sides of the highway, preparatory to commencing bedding-propagating before long. Our chief work, however, for the last eight days has been securing and watering where most essential flower-beds, and especially those in which the centre was considerably raised. The water being scarce shortly after it was applied, the hoe was employed to level the light material used as top-dressing, and to loosen all the outsides to prevent cracking. By thus keeping the surface loose and moved little water is needed, and what is given is made to do its best in keeping the soil at the roots moist, whilst the surface is loose and dry. In extreme cases short grass might be used for mulching, but it is very littersy-looking, and moss would be little better unless it were fastened down and kept moist. Then an outside border next the grass would look very nice. There would be little use anywhere else now, as the beds are getting choke full.—R. F.

#### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the department writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**COCOA-NUT FIBRE REFUSE (A Working Man).**—Do not make a mistake—it is the snuff-like powder, not the fibre, which is useful. We should apply it for Potatoes when digging the ground for planting. It would improve the stiff soil with which you intend to make a Peach and Vine border.

**PERILLA (J. C.).**—Perilla nankinensis requires the same treatment as Barley, with the help of a hot bed or place—that is, to be sown every spring and reared like the little blue Lobelias, and then to be planted out. It comes easy enough from cuttings, but the plants will not stand over the winter to pay.

ATRIplex HORTENSIS (*Idem*).—This also must be from seeds annually, to be sown out of doors in the middle of April, or any day from September to April; but the April-sown seeds will give plants just as early as if the seeds were sown in October. All of ours come from self-sown seeds in the autumn; *Gazania splendens* from cuttings in September and kept like blue *Lobelias*.

STRIKING CARNATIONS (*J. C.*).—This is the time to put them in under a hand-glass in a shaded place, and the afternoon, about five to six o'clock is the best time of the day to water them; but they do not want much water, only that the soil should be moist and no more. But the "names." What have you been thinking of? Why their name is legion; we have known over five hundred names in our day.

PLANTATION OF LARGE TREES (*Patelin*).—Large trees to grow fast to screen a place, and to require little "looking after," near Bickley, are, of all other things, the easiest to find and the soonest told. But you are on the wrong scent altogether, it is simply a waste of time and money to plant "as large trees as can be put in." First of all, see that the whole space is most thoroughly trenched, and the soil is well mixed, not thrown over in layers as some do. Then take moderate-sized plants, not large or small, but well-rooted, also about equal quantities of evergreens and deciduous. The evergreens to be Firs, Spruce, and Pine, a few *Lomboc* Oaks, *Tunkey* and *Scarlet American Oaks*; *Cobbett's Loest*, or *Robinia pseudacacia*, common Birch, *Mountain Ash*, *Laburnum*, *Acer pseudo-platanus* or "Park Plane," *Horse-chestnuts*, and some worked *Thorns* to be near the outsides with the *Laburnums* and *Mountain Ash*. All these will soon take care of themselves; but you ought to keep the ground clear about them for the first three years.

DAHLIAS (*J. L.*).—All your Dahlias will soon be right enough. The first blossoms often come badly in such a season as this. This is the eleventh hour to talk about selections of Dahlias; wait a while, and you will see all the best kinds of the last few years in our autumnal reports of them.

PINK RINGS ON LEAVES (*W. H., Teignmouth*).—They are Oak spangles, which many persons have mistaken for fungi, and they are formed by the larvae of a minute Cynips, called by French naturalists *Diplolepis lenticularis*. The antennae of the perfect insect are blackish, a little longer than the thorax; the whole of the body is black and shining, and the legs yellow. They are sometimes so abundant in the south of France that in autumn when the Oak trees are shaken they fall like rain. They detach themselves from the trees in October, and remain buried in the earth till spring, when the perfect insect appears. These spangles are certainly very pretty objects for examination under the microscope. We know of no mode of destroying them.

DATERA ARBOREA (*M. F., Limerick*).—Give no extra heat to your plant now. If the weather should be cold give maure water at a temperature of from 80° to 90°. Continue this for a month, and the plant will be sure to bloom, if it has blooming blood in it. This is all you ought to do this season. As you have picked out the terminal buds give little water, and as much sun as possible after that; prefer, in fact, that the plant should show a little distress in October than otherwise, and this will ripen the buds well, and you will be almost sure to have a mass of flowers next season. When ready to bloom it is hardly possible to feed the plant over-much. This should be discontinued when it is desirable to have the plant ripened in its wood. When once a plant blooms freely, and it gets plenty of sun in summer, it generally gives little trouble afterwards, except storing free from frost, pruning back, fresh soil when fresh growth has commenced, and plenty of nourishment to give strength to the young shoots loaded with blossoms.

WHITE LILIES (*Idem*).—We presume you mean *candidum*. We have known it growing many years in the same place and to do well, with a top-dressing every year of leaf mould. Perhaps your soil has become exhausted. At any rate, a fortnight or so after the leaves and stems are fallen it would be advisable to take up the roots and replant in deep, rich, sandy loam, using very rotten leaf mould as the enriching medium, and sharp sand in moderate quantity as the lightening medium, if the ground is very stiff. The soil should be well firmed about them, and a mulching of very rotten dung and quicklime put over the surface. This Lily will not stand moving after growth has commenced to any extent. Such moving will injure its strength and beauty for years. It would be much the same as sending home bulbs from the Cape when the growth was appearing; then hardly any care or trouble will ever restore them to vigour.

GREEN MOSS OR SCUM ON GLASS (*Idem*).—For this which collects on the under side of the glass in a greenhouse, we know of no remedy so effectual as soap and water, and a fair portion of that most valuable recipe for removing all kinds of filthy encrustations—elbow grease. Such a house should generally be thoroughly washed, woodwork and glass, twice a-year. Mr. Thomson in his work on the Vine, lays great stress on the thorough cleansing of the house after the fruit is cut, and the Vines pruned, and not without reason. Without cleanliness there can be little satisfactory gardening. In fact, this cleanliness in minutiae often forms a good test for deciding whether a man is anxious and persevering, or a mere six o'clock man, passing through a number of hours in dull, plodding fashion, and then letting things succeed if they will, or die if they will, and influenced little by either. These encrustations are just as natural as fly-marks and cobwebs on a window never cleaned, and both tell their own tale. On once entering greenhouses under the care of one of the brightest geniuses in gardening, it was vexing to see the laps thoroughly festooned with filth. A morbid melancholy took possession of the manager, and the garden soon became a counterpart of the state of his own mind. The employers with great kindness never noticed the change, and chiefly owing to their concealed efforts, the usual buoyancy and activity of mind were restored, and the sight of the houses told us all that, even before we had the pleasure of encountering the sparkling eye of our friend. Take the plants all out, syringe the house all over, and wash with water holding a little soap in solution; but if there are creepers in the house at all thick, it will be best to use water alone. It is well not to use much soap, or it may take off some paint as well as filth. Be assured that all such appearances speak of slovenliness in gardening.

PALOX CUTTINGS (*Idem*).—We presume your seedling is a variety of *Drummondii*. You had better save the seed, if particularly fine. If you can get a few shoots on the plant not showing flower, and from 2½ inches to 3 inches long, slip them off and plant them in sandy soil under a bell-glass or hand-light. If not, wait until the seed is ripe, cut the plant over, and take the shoots that come.

GREENHOUSES FOR THE MANY (*G. S.*).—The new edition is ready, and may be had by application at our office, and enclosing seven postage stamps.

SPERGELAS (*Cramand, N. B.*).—None of them will do any good under trees where grass cannot get a hold.

SHRUB FROM THE CRYSTAL PALACE (*A Subscriber*).—It is *Spiraea arifolia*, a fine thing to stand out on the glass for a specimen.

LOBELIA PAXTONIANA (*Idem*).—This fine new edging *Lobelia* will, probably, not come true from seeds; but some one in the trade will surely take to it, and furnish the country with it next spring in the usual way.

SITUATION TO HARDEN-OFF AZALFAS (*An Old Subscriber*).—Pots answered last week. When Azaleas have finished their growth the terminal buds will become prominent, and the wood will begin to assume a brownish hue. After that Azaleas may be kept in the greenhouse, may be placed in cold pits, with lights over them, but plenty of air back and front; or they may be set in a sheltered place out of doors, keeping in mind that though the plants will stand sunshine the pots should be protected from it.

SUCCULENTS FOR GREENHOUSE (*H. B.*).—You will find much information in various volumes, "Window Gardening for the Many," &c.; but we are so convinced of the suitability of succulents for those who have an eye to beauty and to the grotesque in form, and but little time at their command, that ere long we will devote some more attention to a suitable list and culture. In the meantime you may be on the out-look for *Cereus*, *Euphyllium*, *Mesembryanthemum*, *Haworthias*, *Crassulas*, &c. Few of these plants will require much water in winter, and will not feel much if neglected for a day or two in summer.

VINES (*A Young Gardener*).—Your Vines have just done of their own accord what Mr. Thomson, of Dalkeith, has been doing by art for some seasons past. They have gone to rest in the summer. Now, if you seize the opportunity and start them in August, you will be able to do what that great gardener has done—viz., place new Grapes on your master's table on New-year's Day. You should read Mr. Thomson's papers on the subject in the "Florist and Pomologist," where you will learn all about it.

NAMES OF PLANTS (*Gay Street, Bath*).—It is one of the *Hepaticæ*, or *Liverworts*, *Marchantia polymorpha*, commonly called *Liver-green*. Not at all uncommon. (*Norfolk Subscriber*)—*Berberis aquifolium*. Sow as soon as ripe. (*Guisbro'*).—1, *Platanus orientalis cuneata*; 2, *Alnus glutinosa laciniata*. (*J. Straghan*).—A *Mesembryanthemum*, perhaps *lepidum*; but the specimen is insufficient. (*Ignoramus*).—*Pteris hastata macrophylla*, a hardy greenhouse Fern. The leaf is that of the variegated variety of *Arabis albidula*. (*A. B. W.*).—It seems to be nothing more than *Reseda fruticulosa*. It is not a *Mignonette* in the correct sense, as that name is only given to *R. odorata* and its varieties. (*J. D.*).—1, *Trifolium arvense*; 2, *Galium verum*; 3, *Lepidium campestre*; 4, *Verbascum thapsus*.

### POULTRY, BEE, and HOUSEHOLD CHRONICLE.

#### POULTRY SHOWS.

- AUGUST 25th, 26th, 27th, and 28th. CRYSTAL PALACE. Sec., W. Houghton. Entries close July 26th.
- AUGUST 27th. COTTINGHAM. Sec., Mr. J. Brittain. Entries close Aug. 20th.
- AUGUST 30th. HALIFAX and CALDEN VALE. Sec., Mr. W. Irvine, Holmsfield. Entries close August 16th.
- SEPTEMBER 2nd. POCKLINGTON, Yorkshire. Sec., Mr. T. Grant. Entries close August 26th.
- SEPTEMBER 4th. WARFIELD and WEST RINGING. Sec., Mr. J. Croxland, jun., Entries close August 23rd.
- SEPTEMBER 9th. WORSLEY and ARNLEY (near Leeds). Sec., Mr. Robert Hoyle, Ainley, near Leeds.
- SEPTEMBER 9th and 10th. CALNE. Secs., A. Heath and F. Baily. Entries close August 28th.
- SEPTEMBER 10th and 11th. MANCHESTER and LIVERPOOL. Sec., Mr. T. B. Ryder, Church Street, Liverpool. Entries close August 11th.
- SEPTEMBER 25th. STAFFORDSHIRE. Sec., Mr. W. Tomkinson, Newcastle. Entries close August 25th.
- DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John P. Lythall, 14, Temple Street, Birmingham.

#### FATTENING YOUNG FOWLS.

(Continued from page 363.)

THE method of practising fattening poulardes reduces itself to these principal conditions:—

- 1st. Among all the young cocks and pullets of the year to choose the best, and those that possess the qualities we have named.
- 2nd. Not to have recourse to mutilation, such as is practised on capons and even on hens in some places where they are fattened.
- 3rd. To prepare a dark place where little fresh air is possible, and where the birds are lodged in narrow coops without being too uncomfortable.
- 4th. Not to clean out the birds, or to remove the dung while the birds are fattening!!!
- 5th. To prepare the fowls for forced feeding during eight or ten days before they are submitted to cramming.
- 6th. To cram them quickly and cleverly.
- 7th. To give them two meals in twenty-four hours at regular intervals.
- 8th. Not to make it essential that the birds shall all swallow an equal number of crams; to be guided in that respect by the size of the crop, which during the first few days should be moderately filled. Later, it should be quite filled but without excess.
- 9th. To confine oneself to the food named without making

the least change, except altering the quantities of the same ingredients if it is thought advisable.

10th. To learn to discern the different stages of maturity in fattening, and to watch the subjects of it, that where it is necessary some may be withdrawn, although not quite fat, lest they go amiss or die.

Having duly observed all these rules, good results will follow.

In order to come to a calculation of the expenses of fattening, it is necessary to establish an average of a number of fowls. Then, suppose that each poularde during forty days of treatment causes a consumption of thirty quarts of meal thus composed:—

	Fr. Ct.
Three double decalitres of buckwheat, at 3 <i>fr.</i> .....	9 0
Two double decalitres of barley, at 3 <i>fr.</i> .....	6 0
One double decalitre of oats, at 1 <i>fr.</i> 50c. ....	1 50
Total .....	16 50

	Fr. Ct.
This disbursement of 16 <i>fr.</i> 50c. for 120 quarts of this meal or grinding, will suffice to feed four fowls. This allows for one, 4 <i>fr.</i> 12-50, which sum being multiplied by fifty fowls, will give a total of ...	206 25
Assume that 1200 crams—that is, twenty-four per head for two meals are necessary. Fifty centimes worth of skimmed or watered milk to mix them for forty days, will amount to .....	20 0
Forty days work at 3 <i>fr.</i> each, quarter of a day for a woman at 80c., to make up crams—say for forty days .....	128 0
Two kilos, five of hard for the last ten days, twenty-five decagrammes in cakes, at 1 <i>fr.</i> 60 the kilogramme .....	4 0
The purchase of each fowl in a lean state being taken at 1 <i>fr.</i> 50, fifty will cost .....	75 0
As the place that serves for a feeding-house, and the construction of the feeding-coops are almost nominal, as well as the expense of grinding, this fictitious cost may be advantageously counterbalanced by the produce of the feathers, and the coarse bran taken from the meal. Let it stand then .....	6 0
	433 25

This sum forms the necessary outlay to feed and attend to fifty poulardes. If this be divided by 50, it will be seen the expense per head is 8 <i>fr.</i> 26c., and as it must be admitted, large as the sum may seem, that there will still be one-sixteenth loss, each poularde will cost about 9 <i>fr.</i> It will then be necessary to add to the expenses of the fifty poulardes, 25 <i>fr.</i> , and this will make the amount .....	458 25
Now, if an average of 6 lbs. weight can be attained for each poularde, the result will be 300 lbs. As it always reckoned they will realize 3 <i>fr.</i> 60c. per kilo. (taken as 2 lbs.), the produce will be .....	540 0
Deduct disbursements .....	458 25

The profit will be..... 81 75

—(Translation from "Le Poulailleur," by Mons. Jacques)

[We give the translation and figures as they occur. At a future time we will remark on them.]

(To be continued.)

### SHEFFIELD POULTRY SHOW.

The Exhibition of poultry at Sheffield was this year held under an entirely different management to those of preceding years, and took place at the newly-opened Cremorne Gardens, within a comfortable walking distance of the town. The weather being so favourable, the attendance was most satisfactory, embracing members of almost every family of distinction in the neighbourhood, and the grounds even on the first day of opening were, therefore, well filled. We are informed, too, that on the ensuing days, when the price of admission was lowered, the accession of numbers was so great as to even exceed the anticipations of the most sanguine among its projectors. It must be borne in mind, however, that poultry was not the only object of attraction presented to the public; for combined with it was held one of the largest and best shows of dogs that has ever yet been got together. Horses, also, were exhibited for prizes, the competition being restricted to hunters only, the result being as goodly a muster of first-rate nags as any rotary of the fox-hunt could desire.

A great variety of manufactured articles were on the ground, and perhaps nothing connected with the Meeting caused so great an amount of general interest as an armour plate of 4½ inches thickness that had been subjected to the test of both Armstrong guns and likewise shells that had been, previously to firing, filled with molten iron. In these warlike days, when public attention is more than usually directed to matters of this nature, it is almost needless to say this portion of the Exhibition was thronged to excess, and many were the expressions of astonishment that were involuntarily uttered when viewing for the first time the frightful effects these missiles had produced. A plate newly manufactured, of the same strength, exhibited alongside of the one above re-

ferred to, added by contrast much to the information of visitors. The scene was certainly strange, and one that inspired the minds of the reflective with thankfulness to see on all sides so far as the eye could reach—and the view a most extended one—our own happy land glowing beneath a sunny sky, with corn fast ripening to the husbandman; nor were there wanting hopes again and again audibly expressed among the company that ere long our Atlantic brethren might again enjoy the blessings ever attendant upon peace.

But to return to the poultry. We did not anticipate first-rate condition among the adults; it was not to be expected, as the moulting this year is unusually premature; but we were certainly surprised at the general excellence of the classes, for decidedly we never visited a Show where the competition was so good and universal. The *Spanish* classes, whether old or young, were excellent throughout; Mr. Tebbay, of Preston, taking the lead in adults, and Mr. Rodbard showing pens of most enviable chickens.

The *Grey Dorkings* were equally good, Lady Julia Cornwallis and Mr. Key exhibiting specimens that not only secured for their owners present high positions, but which, we doubt not, will be heard of equally favourably at ensuing Shows. Only a few years back the attainment of such perfection would have been pronounced impracticable.

All amateurs admit nothing interferes so materially with an exhibition of Game fowls as moulting time. At Sheffield the *Game*, with few exceptions, were in really indifferent feather; indeed, it will generally take a month from the present date to insure plumage fully matured: consequently this portion of the Show, though by no means lacking the best of specimens, was not nearly so attractive as usual.

In *Cochins* the Show was perfection, the Partridge-coloured being, perhaps, the best represented.

In the *Hamburgh* classes the Golden-spangled were decidedly the best variety shown.

Nor were the *Red Caps* (a breed almost confined to the locality) less commendable than in former years.

The *White-crested* were the best of the *Poland* class, and the *Schbricht Bantams* were especially good.

Although the entries were not numerous, the *Geese* and *Turkeys* shown were very superior; nor were the *Aylesbury Ducks* and the *Rouens* less worthy of mention.

The *Game Bantam* classes were better than we remember ever seeing at a Sheffield Show; but moulting was almost universal among them.

We cannot close our remarks without expressing our satisfaction that the present Meeting has proved so successful—a "first effort" of a new Committee rarely exhibits so little to complain of; and we do not doubt, with the experience now gained, future exhibitions of this Society will be regarded with even increased popularity.

### PIGEONS.

The show of Pigeons was fully as numerous as that of previous years, and included many very first-rate specimens. In *Carriers* Sheffield is always powerful, one of the best breeders and most successful exhibitors of that variety living in the town. The first prize was awarded to a magnificent young black cock of very good carriage and colour. The blue taking the second was an older bird, one of the best of that colour we have ever seen. The third went to a dun. The first-prize *Carrier* hen was a very superior bird, though somewhat out of condition. In *Pouters* the best bird in the class in limb and feather was Mr. Taylor's young mealy cock. Mr. Smith's highly commended red was also very good. The prize for *Short-faced Tumblers* went to a good pair of Almonds. The *Fantails* were very good, whites winning the prizes. In *Owls* the pretty little white African variety took first. In the "distinct variety" class there were numerous entries. The first prize was awarded to a pen of feather-legged, silver-chequered, turn-crowned, rock-headed birds that have lately been shown as *Icelanders*; they were pretty, and good specimens of the variety. The second prize went to a good pair of black Swallows. We had omitted to mention the *Barbs*; they were broad-skulled, large-eyed birds; the second prize, yellows, being apparently a pair of cocks. But, considering the very short time allowed to the Judges, we are only surprised that there was so little to complain of in the awards.

*Carrier* (cock).—First, J. Wadsworth. Second and Third, T. Colley. Highly Commended, J. Percival; T. Colley; H. Merris. *Carrier* (hen).—First, W. Cannon. Second and Third, J. Wadsworth. Highly Commended, J. Dotchon. Commended, A. L. Sylvester. *Pouter* (cock).—First, H. Yardley,

\* It will be well to say we will take the frame at 25 to £1 sterling.

Second, W. Taylor. Third, H. Beldon. Highly Commended, J. Smith. *Powder* (hen).—First, H. Yardley. Second, W. Taylor. Third, H. Brown. Highly Commended, S. Robinson. *Short-faced Tumblers*.—First, Miss Brown. Second, W. Cannan. Highly Commended, A. L. Sylvester. Commended, T. D. Walker. *Fantails*.—First, Mrs. Taylor. Second, F. Key. Highly Commended, J. R. Jessop. Commended, H. Morris. *Jacobins*.—First, W. Cannan. Second, T. D. Walker. Highly Commended, H. Morris. *Trumpeters*.—First, H. Morris. Second, F. Else. Commended, H. Yardley. *Barbs*.—First, A. L. Sylvester. Second, T. D. Walker. *Turbits*.—First, A. L. Sylvester. Second, F. Else. Highly Commended, H. Yardley. Commended, T. D. Walker. *Owls*.—First, H. Morris. Second, F. Else. Highly Commended, W. Cannan; F. Key. *Any other New or Distinct Variety*.—First, H. Yardley. Second, H. Morris. Highly Commended, S. W. Turner. Commended, S. W. Turner; T. D. Walker; J. R. Ward; and H. Yardley.

**RABBITS**.—*For length of Ears*.—First, W. Howell. Second, G. Jones. *For Colour*.—First, G. Jones. Second, W. Hudson. Highly Commended, G. Gale. Commended, B. Gale. *For Weight*.—First, W. Rollison. Second, W. Howell.

## NEWMILLERDAM POULTRY SHOW.

THE tenth annual Exhibition of the Newmillerdam Agricultural, Horticultural, and Poultry Society took place on Tuesday, the 29th ult., in a field adjoining Chevet Park, the residence of Sir Lionel M. Pilkington, Bart., at Newmillerdam, near Wakefield. The poultry entries were not numerous, but many good birds were exhibited—Mr. S. Pickard and Master Crosland carrying off most of the prizes. Dorkings, Cochins, Game chickens, Golden-spangled Hamburgs, Geese, and Bantams, were the most meritorious.

We subjoin the prize list:—

**GAME** (Black-breasted or other Reds).—First, Master G. H. Crosland, Wakefield. Second, C. W. Brearley, Rochdale. Highly Commended, J. Riley, Chickenley, Dewesbury; Master Crosland; W. Cope.

**GAME** (any other variety).—First, J. Riley, Dewesbury (Duckwings). Second, Master G. H. Crosland, Wakefield. *Chickens*.—First and Second, Master Crosland, (Black Reds and Duckwings). Highly Commended, J. Craven (Blacks); J. Riley.

**COCHINS** (Cinnamon and Buff).—First, Messrs. H. & G. Newton, Leeds. Second, S. Pickard, Dittcar, near Wakefield.

**COCHINS** (any other variety).—First, S. Pickard, Dittcar, near Wakefield. Second, J. Hazelgrave, Chapelthorpe. *Chickens*.—First and Second, S. Pickard.

**DORKINGS**.—First, S. Pickard, Dittcar, near Wakefield. Second, H. Hims-worth, Lupset Hall, near Wakefield. *Chickens*.—First and Second, S. Pickard. Highly Commended, J. Hazelgrave, Chapelthorpe.

**SPANISH**.—First, W. Cope. Second, J. Ellis.

**HAMBURGHS** (Golden-spangled).—First, Master G. H. Crosland, Wakefield. Second, J. Ellis. *Chickens*.—Prize, Master G. H. Crosland.

**HAMBURGHS** (Silver-spangled).—First, Master G. H. Crosland, Wakefield. Second, G. R. Tate, Driffield. *Chickens*.—Prize, Master Crosland.

**ANY OTHER DISTINCT VARIETY**.—First, Lady Hawke, Womersley Park, Fontefract (Brahmas). Second, Master Crosland, Wakefield (Golden-pencilled Hamburgs).

**BANTAMS** (White or Black).—First, Master Crosland, Wakefield. Second, G. R. Tate, Driffield.

**BANTAMS** (any other variety).—First, Master Crosland, jun., Wakefield. Second, C. W. Brearley, Rochdale.

**GEESE**.—First, Lady Hawke, Womersley Park. Second, J. Fawcett, Wakefield.

**DUCKS** (Aylesbury).—First, J. Walsham. Second, Lady Hawke, Womersley Park.

**DUCKS** (Rouen).—First, J. Hazelgrave, Chapelthorpe. Second, J. Hirst.

**SWEETSTAKES FOR GAME COCKS**.—Prize, C. W. Brearley, Rochdale.

The Judge was Mr. T. J. Charlton, Bradford.

## YORKSHIRE AGRICULTURAL SOCIETY.

THE twenty-fifth annual Meeting of this Society was held last week, for the fifth time in the city of York. The show of cattle, horses, pigs, sheep, and implements was very extensive; while the poultry although not numerously represented, were of equal merit, many first-class birds being shown. Black *Span'sh* formed the first classes, Mr. Cannan securing both first honours with fair birds. *Dorkings* and *Cochins* were good. In *Game*, adults, Mr. H. Adams gained first prize with Brown Reds. The *Game* chickens, with the exception of Mr. Smith's prize *Duckwings*, were an inferior lot. Mr. Cannan showed good *Hamburgs*, more particularly Golden-spangled and Silver-pencilled. Mr. Dixon also exhibited several good pens, taking prizes. As usual, the same gentleman stood pre-eminent in *Polands*, old birds. In *Poland* chickens, Mr. Newsome's White-crested Black prize pen was much admired. Mr. Dawson added another to his many honours, in "any other variety," with his noted *Sultans*. In *Black or White Bantams*, the former variety took both prizes. *Silver-laced* and *Gold-laced* respectively were successful in "Bantams, any other variety." The *Geese* and *Ducks* were excellent.

**SPANISH**.—First, W. Cannan, Bradford, Yorkshire. Second, J. Dixon, North Park. Highly Commended, J. Katcliffe, Osbaldwick, York. *Chickens*.—Prize, W. Cannan.

**DORKINGS**.—First, H. W. B. Berwick, Helmsley. Second, E. Smith, Middleton, Manchester. *Chickens*.—Prize, Rev. J. F. Newton, Kirby-in-Cleveland, Stokesley. Highly Commended, T. W. Hill, Heywood, Manchester.

**COCHIN-CHINA** (Black or White).—First, J. Dixon, North Park, Bradford. Second, W. Dawson, Hopton Mirfield. Highly Commended, A. Cattley, Tower Street, York.

**COCHIN-CHINA** (any other colour).—First, Messrs. H. & G. Newton, East Street, Leeds. Second, E. Smith, Middleton, Manchester. Highly Commended, G. Jackson, Penley Grove Street, York.

**COCHIN-CHINA CHICKENS** (any colour).—Prize, W. Dawson, Hopton Mirfield. Commended, R. Gatenby, Shipton, Market Weighton. Messrs. H. & G. Newton, East Street, Leeds.

**GAME**.—First, H. Adams, Beverley. Second, H. Beldon, Park Cottage, Bradford. *Chickens*.—Prize, J. H. Smith, Skelton Grange, York.

**HAMBURGHS** (Golden-spangled).—First, W. Cannan, Bradford, Yorkshire. Second, G. R. Tate, Driffield. *Chickens*.—Prize, W. Lawson, East Chiven.

**HAMBURGHS** (Golden-pencilled).—First, W. Cannan, Bradford. Second, S. Cliffe, Grantham. *Chickens*.—First, J. Dixon, North Park, Bradford. Highly Commended, W. Cannan, Bradford, Yorkshire.

**HAMBURGH** (Silver-spangled).—First, S. Campling, Cottingham, Hull. Second, J. Dixon, North Park, Bradford. Highly Commended, G. R. Tate, Driffield. *Chickens*.—Prize, W. Cannan, Bradford.

**HAMBURGH** (Silver-pencilled).—Prize, W. Cannan, Bradford, Yorkshire. *Chickens*.—Prize, W. Cannan, Bradford, Yorkshire.

**POLAND** (any variety).—First and Second, J. Dixon, North Park, Bradford. *Chickens*.—Prize, W. Newsome, Bingley, Leeds.

**ANY OTHER VARIETY**.—Prize, W. Dawson, Hopton Mirfield. Commended, G. R. Tate, Driffield. *Chickens*.—Prize, J. Dixon, North Park, Bradford.

**BANTAMS** (Black or White).—First, J. Dixon, North Park, Bradford. Second, E. Holdsworth, 90, Calls, Leeds. Commended, G. R. Tate, Driffield; E. Holdsworth, Leeds.

**BANTAMS** (any other colour).—First, H. Beldon, Park Cottage, Bradford. Second, W. Hodgson, Grimston, Tadcaster. Highly Commended, E. Year-ley, Wood Lane, Sheffield.

**SPANISH COCK**.—Prize, J. Dixon, North Park, Bradford.

**DORKING COCK**.—Prize, H. Beldon, Park Cottage, Bradford. Highly Commended E. Smith, Middleton, Manchester.

**COCHIN-CHINA COCK**.—Prize, J. Bell, Thirsk.

**GAME COCK**.—Prize, H. M. Julian, Beverley.

**HAMBURGH COCK** (Golden-spangled).—Prize, J. Dixon, Bradford.

**HAMBURGH COCK** (Golden-pencilled).—Prize, S. Smith, Northwram.

**HAMBURGH** (Silver-spangled).—Prize, J. Dixon, North Park, Bradford.

**HAMBURGH** (Silver-pencilled).—Prize, H. Beldon, Park Cottage, Bradford.

**GEESE**.—First, G. R. Tate, Driffield. Second, J. Dixon, Bradford.

**DUCKS** (Aylesbury).—First, O. A. Young, Driffield. Second, G. R. Tate, Driffield.

**DUCKS** (Rouen, or any other breed, not Aylesbury).—First, G. R. Tate, Driffield. Second, Mrs. Jordan, Eastburn House, Driffield.

**TURKEYS**.—First, T. Ward, Bannial Hat, Whitby. Second, J. Dixon, North Park, Bradford.

The Judges were Mr. J. O. Jolly, Acomb, near York; and Mr. T. J. Charlton, Bradford.

## GOLDEN-SPANGLED HAMBURGHS AT LEEDS.

In your Letter Box of last week's Journal you gave an answer to Mr. William Lawson, who apparently complains that the earlobes of the first-prize Golden-spangled Hamburg cock were painted. On the second day of the Show Mr. Lawson did try to convince another member of the Committee and myself that the earlobes of the first-prize bird had been painted, but failed to do so. However, we promised him that the matter should be fully looked into, and, if necessary, the bird disqualified.

Several experienced breeders were asked to examine him, and their unanimous opinion was that the earlobes were in a perfectly natural state, and such confidence had the Committee in their judgment, that they did not think it necessary to trouble the Judges with the matter. What more have I to add except that the maligned bird has (under another ownership) taken a first prize at the late York Show, with exactly the same competition as at Leeds—the only difference being that other gentlemen officiated as judges? Is not this sufficient?

Allow me, in conclusion, to say a few words about the time the Judges were allowed for performing their labours at the Leeds Show. Twelve o'clock certainly was the hour at which the Show, by the rules, was to have been opened, but no time was set for the commencement of the judging. The birds were ready for inspection at six A.M.; and it the Judges did not commence before half-past nine it was not the fault of the Committee.—ONE OF THE COMMITTEE.

I AM very much surprised to find such remarks. I can assure every one that the earlobes were perfect and free from any paint; in fact, I got the bird out of the pen and handed him to Mr. Beldon, and in the presence of Mr. G. S. Sainsbury, one of the Judges, I took out my handkerchief and rubbed the earlobes to see if they were right. As I had heard here a remark passed that they were painted, I made the remark, "If the cock can be bought for £5, he will be mine." I was as good as my word. I wrote

to the owner to advise me the price of the cock, also the price of the pen. I got the reply by return of post that I could have the pen for £5. I was so dead on the birds that I took train to Dinton, in Lancashire, and got them. Since I got the birds I have had several parties in want of them. As I had bought them for my own use, I did not feel disposed to part with them. One of our well-known fanciers, Mr. Beldon, brought a gentleman to look at them, and we bargained that I should have £10 and show them at Newmillerdam, at which place the cock again took first prize, and if I be a judge the pen will take many firsts this season, without the assistance of paint. If Mr. Lawson attends the great Yorkshire Show he will find the pen there, and if the earlobes are yet painted, I will give Mr. N. Marlor the £10 for the receipt of his patent. I think the above remarks are a sufficient proof the birds were good.—JOHN CROSLAND, JUN., Wakefield.

HAVING noticed the remarks respecting the prize pen of Golden-spangled Hamburgs at Leeds, I assure you my birds were not trimmed either in earlobes or feather. I am very sorry such remarks should have been made. I sold the pen to one of our noted exhibitors, and he examined the same at my house and told me such remarks had been made at Leeds, but he was quite satisfied the earlobes were perfect. I am sure the above party is considered a good judge of poultry, and I have known him for years as a fancier and breeder of Hamburgs, and I trust he will give his opinion on the matter.—NATHAN MARLOR.

### FECUNDITY OF HENS.

The ordinary productiveness of a single hen is astonishing. Instances are recorded of hens laying over 200 eggs annually, while, probably, 120 would be a fair average. Undoubtedly much depends on circumstances as to the productiveness of hens. Climate has great influence on this subject, and the lodging, food, and attention which are bestowed upon these animals have more or less effect in promoting their fecundity. It is asserted by Buffon that a hen, well fed and attended, will produce upwards of 150 eggs in a year, besides two broods of chickens. We find statements recorded in our agricultural journals of several instances of extraordinary products of hens, which will enable us to form some judgment on the subject. The editor of the *Massachusetts Ploughman* says, from 83 hens 7200 eggs were obtained, which would give to each hen 84 eggs for the year. A remarkable instance of fecundity in the hen is related by a correspondent:—Three pullets of the Poland breed, hatched in June, commenced laying in December following, and, from that to the next December, laid 554 eggs, averaging 155 to each hen. It seems ever to be an object of great importance in an economical point of view to secure the laying of hens during those periods of the year when, if left to themselves, they are indisposed to deposit their eggs. Old hens cannot be depended on for eggs in winter, the very time we want them most. As pullets do not moult the first year, they commence laying at an earlier period than the old hens; and it is possible so to arrange as to have eggs throughout the winter as well as spring and summer. Some hens are ascertained to lay at longer intervals than others; some will lay one egg in three days; some every other day; others every day; and we have heard of one that laid two eggs in one day. The act of laying is not voluntary on the part of the hen, but is dependant upon her age, constitution, and diet. If she be young, healthy, and well fed, lay she must; if she is old and half fed, lay she cannot. All that is left to her choice is where she should deposit her egg.—(*Californian Farmer*.)

### GISHURST COMPOUND APPLIED TO DOGS.

IN answer to the query in last Number as to the use of Gishurst Compound to clear fleas from dogs. I have never tried it for this purpose myself; but a friend, knowing in dogs, having some time back told me that he regularly used it with entire success, I showed him your correspondent's question, and asked his *modus operandi*. He breaks up Gishurst into small pieces; then, having the dog wetted, rubs with his hand till the whole coat is in a lather. This, he said, effectually cleared off all fleas, but not the burrowing ticks. Some time ago I had a dog with mange, and thinking that Gishurst, from containing sulphur, must be beneficial, it was applied, and with obviously good

results. In this case Gishurst was dissolved forty-eight hours before—half a pound to a gallon of soft water, and, if I remember, was applied by means of a large painter's brush.—GEORGE WILSON.

**BULLFINCHES' EGGS DISAPPEARING.**—In reply to "CUMBERLAND'S" inquiry in THE JOURNAL OF HORTICULTURE, I am not aware of any bird that particularly destroys the eggs of Bullfinches; but Crows, Magpies, Jays, Squirrels, Rats, and Mice will destroy the eggs and young of any birds they meet with, and it is most likely to some of them that the disappearance of the eggs may be attributed.—B. P. BRENT.

### LIGURIAN BEES.

I THINK there can be no doubt about the Ligurians being more prolific than the blacks, as I have a last-year's swarm that swarmed four times in five days in June, and is now hanging out, and I believe would swarm again if the weather had been more favourable; but having killed the drones, and there being little honey to get, I suppose there will be no chance of its doing so. I observe my bees have been able to gather a little honey the last three or four days.—A. W.

### HINTS FOR PRACTICAL BEE-KEEPERS.

[THE following address was delivered on the 4th September, in last year, to the Potsdam Central Bee-keeper's Society, by Herr Viebig, of Klein-Glienicke, near Potsdam. The speaker is evidently one of the old school of apiarians, and deprecates some of the modern innovations with earnestness and no small ability.—A DEVONSHIRE BEE-KEEPER.]

"Prove all things, hold fast that which is good."—1 THESS. v., 21.

DURING the last fifteen years the science of bee-keeping has advanced and improved far more than during the thousands which have preceded them. The author of this progress is, as every one of you knows, Pastor Dzierzon, of Carlsmarkt; wherefore also he is termed by all rational apiarians, the master of modern bee-keeping. All of you, gentlemen, have, some by way of trial, but the greater number entirely, practised bee-keeping according to the new system. Unfortunately, however, success has not always equalled expectations. The last two years have been years of probation for bee-keepers, during which many of you have not unfrequently sighed and complained that things were going so badly with your bees. Of late years I have had many opportunities of becoming acquainted with other apiaries, and have frequently heard complaints sung to the same tune. Generally, however, I found that the fault was not so much in the season, but was often the consequence of wrong treatment. We all make the great mistake of refining too much, and in seeking after new discoveries, make too great sacrifices from which we expect as great success, forgetting that success is not always proportioned to the means employed and the sacrifices made, and not considering that the making of these experiments is the business of those who pursue other objects than our own. We aim at honey-gathering; they multiply the Italian species, and endeavour to enrich science. We practise bee-keeping from economical considerations; they from passion. We are practical men; they apply their minds to the development of theory. Not, therefore, that we should restrict ourselves to the narrow circle of our merely empirical endeavours, and reject the good which theory has produced, and which may be of practical utility. On the contrary, in this we will imitate the bees themselves which gather honey from all flowers, by making the blossoms of theory practically useful, whilst we shun prolix experiments, which are attended with trouble and expense, and the results of which, however good they may appear, are very often the reverse. In short, we will take the word of our greatest poet—

"Wilt thou still farther rove?  
Look, the good is near."

It need scarcely be said that by this revolution really useful ideas are by no means to be excluded, but only that blind zeal and rage for imitation, which, neglecting that which is old and well proved, looks always for that which is new, unproved, and very often far-fetched. This false passion for novelty shall be condemned by us, for that is mostly imitated which is praised as being clever by bee-keepers whose names carry weight with

the press without considering that different localities require different maxims. By this means, also, that which really practical and experienced bee-keepers advise and recommend is but seldom followed, although the ever-true words, "Prove all things, hold fast that which is good," are especially applicable to bee-keeping. We must not entirely cast aside the experience gathered during thousands of years, but rather seek to unite it to the present system of rational bee-keeping, if not in absolute contradiction to it.

As for me, I do not join in the complaints which are everywhere made. The want of honey was complained of in the year 1860. I speak the truth in asserting that I never gathered so much as in that ill-famed year. The last year, as I heard both privately and at public meetings, entirely ruined many apiaries, whilst others were reduced to a modest minimum. I kept last autumn and through the winter eighteen hives—namely, fifteen boxes, and three straw hives. The boxes were closely examined and the deficient food supplied; the straw hives were weighed, and, by means of food given to them, made able to stand the winter. I never put my stocks during winter into a cellar or other room—I should only do it if I feared their being stolen. In their wild state bees must winter in the open air, and there they are stronger and more diligent than our domesticated bees, although the former are less sheltered from the cold than the latter. The bees will, therefore, during winter breathe the pure atmosphere and not the damp cellar air. The only reason why bees are generally brought into cellars is to protect them from cold; but this can be done at least as well in the bee-house. I have never doomed my bees to the air of the cellar, and yet they were quite as warm on their stand as others in the cellar. To keep them in the latter has also other very disadvantageous consequences. With the greatest care and attention the appearance of light at some point or other cannot be entirely avoided; by this the bees are allured to fly out, and by this I have known them in certain cases killed in great numbers. What bees also have generally the dysentery in the spring? In most cases those which stood in the cellar. The damp air and unavoidable noises in the rooms above frequently cause an agitation among the bees, which very much promote both water-dearth and dysentery. How different is it on their stand! They are outwardly sheltered against the cold by means of wrappers (the best are pine-needles), are never disturbed, breathe the pure air, and are sheltered against cold storms by a curtain over the entrance. When there is a warm hour in January or February the curtain is removed, and the bees can employ themselves in cleaning. If they stand in the cellar this must certainly be left undone, as the transport is generally troublesome and the bees are put by it into such a commotion that a flight for cleaning would be hurtful. My stocks which were outwardly protected from cold by wrappers in the above manner have all, in spite of the cold winter, come excellently through it. They were very lively in spring, no sign of dysentery was observed, and no stock was without a queen. The loss of a queen during winter arises only from their being disturbed, for it is known that she does not grow old in this time. In their agitation the bees begin to hum, they disperse, and the queen gets benumbed or is even killed by the enraged bees.

A second plan which is frequently recommended is the removal of an old queen that a new one may be bred. I believe one makes oneself here sorrows without any necessity, as bees feel very readily the insufficiency of an old queen and kill her themselves (of course only in summer), in order to breed a new one. Although I have myself not yet seen this act of the bees, I think I have cause to infer it pretty surely from the following:—One of my Dzierzon-boxes must, according to my account, have a queen more than five years old. She would, therefore, if still alive, be no longer very fruitful; and yet is this stock particularly active. It bred many workers and but few drones. Certainly, therefore, the bees must already, during the summer, have killed their old queen and reared a young one. Also, I have boxes with queens four years old, but in none does there appear any decrease in fertility. The removing of old queens I deem, therefore, quite useless, and even a risk, although it is recommended by many authorities. Most bee-keepers would also be incapable of performing it, as it requires dexterity, boldness, and quietness, which are not often met with. In order, therefore, not to aggravate the difficulties, or create a distaste for bee-keeping, one may leave this experiment alone.

I turn now to artificial swarms. The fatalities attending our artificial swarms are, perhaps sufficiently well known; they have

either perished entirely, or become very weak stocks, whilst the boxes from which they proceeded have suffered endless evils. The best and most natural mode of increase is by natural swarms. If one keeps a few straw hives, and causes the bees therein to breed early by means of feeding, one receives swarms in favourable years in the middle of May. It can scarcely be expected that artificial swarms can be made earlier, as drones must previously exist for impregnation. It is altogether a mistake to believe that early swarms are more prosperous than later ones.

I got this year my first swarm on the 5th of June, and another on the 17th. On the 27th of June the latter had a perceptible advantage over the former. The principal thing is that swarms should issue during a fall pasture: therefore May swarms are less prosperous than those of June. But how stands a natural compared with an artificial swarm? The first has a strong people with the instinct to found immediately a separate family—it has a queen—it accepts any place which is offered to it, and flies from there immediately out for food. The artificial swarm has a weak people—it must generally be conveyed to another apiary—the instinct to form a new colony does not awaken till after some unquiet days—viz, when queen-cells have been begun. After several days the weak people (which, even with the assistance of the inserted brood, does not arrive at the condition of a weak second swarm for eight to twelve days), begin sparingly to fly out and to work. A first swarm is therefore farther advanced in one day than an artificial swarm in a fortnight. The boxes from which artificial swarms are taken are in reality only intended to give honey. If the bees, during their diligence, are suddenly disturbed—if their strength is weakened by the removal of brood-combs—they can seldom fulfil their proper purpose by giving much honey. He that would pursue bee-keeping with success should never increase his stocks by artificial but always by natural swarms.

(To be continued.)

### THIS HONEY SEASON,

I HAD two swarms about the 26th of June, and hived them into straw hives with comb and a little honey. A few days after I had another swarm, from which I took the queen by fumigation, and divided the bees between the two former swarms; but that night I heard both queens piping, and the next morning picked up a queen thrown out by one of the hives, since which I find they both have thrown out many drones; and yesterday the drones were flying out from one of the hives quite strong. Can you inform me how I can tell if they both have queens or not?—A. W.

[If pollen is carried freely into both hives, the probability is that both have queens; but there is no means of positively ascertaining the point unless they have either bars or frames, in which case an examination might be made, during which an interview with royalty could be obtained without difficulty.]

### OUR LETTER BOX.

BLINDNESS IN FOWLS (*Joghehah*).—Many persons, ourselves among the number, have had to complain of diseases this year that were previously unknown. Proof: In one yard we rear Spanish, Cochins, and Brahmans. We have not had a case of sickness among the latter. All the Spanish chickens die of a hard swelling in the face, generally between the eye and nostril. We hope this is no comfort to you. You may keep fifty fowls in such a place as you describe, if the run is unlimited, and if the doors and windows are open all day. The blindness may be cured by bathing the eye with vinegar and cold water. We do not believe there is much suffering, and we think castor oil, wormwood, and ale persevered in would cure any early cases.

BREED OF FOWLS (*Subscriber, Cork*).—It is impossible to say what breed claims the bird you have described; but as the eggs all came from Silver-spangled, it is more than probable they were laid by birds of that breed. The bird in question may be a "lusus nature," or the result of a "faux pas" or "né-salliance." Your description would portray an indifferent specimen, but not of necessity an impure one. Were it not for the Lark-crest, this animal may be a result of an experiment a long time ago.

### LONDON MARKETS.—August 11.

#### POULTRY.

The market goes on without much fluctuation. There is an unusual trade which carries away all that is left by the ordinary buyers, and prevents the collapse which usually takes place when the house closes. Grouse-shooting comes in, and London goes out of town.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 71.9° and 50.4° respectively. The greatest heat, 89°, occurred on the 25th, in 1859; and the lowest cold, 32°, on the 21st, in 1850. During the period 138 days were fine, and on 107 rain fell.

THE PLANTING-OUT AT THE ROYAL HORTICULTURAL SOCIETY'S GARDEN AT SOUTH KENSINGTON IN 1862.

**M**OST alterations, additions, subtractions, and improvements have been made on the hot haste of the finishing, planting, and arrangements of 1861. And notwithstanding all the twaddle about "broken bottles" —referring, of course, to the spar glacis, and to the ground colour given to the fans and friezes of the corridors or arcades—our town garden is, most undoubtedly, the very best example in the three kingdoms of the old school of Italian design for a town garden, or for a suburban one either. Away, then, with the criticism on the design itself, and any slips of the pen or pencil which may have been made in the hurry of execution. Meantime let us note the process of planting-out, and the progress of the garden in general for the last twelve months. But first of all let me say that they have taken a leaf out of Sir Joseph Paxton's way of gaining one whole month on the London season in flowers by planting their pot-established Crystal Palace Scarlet Geraniums almost all over the garden. Let me be just also, and I must say that plan of planting out well-grown plants in the pots they were in all the spring entails just three times the usual expense of keeping up a flower garden very early in the season and very late in the autumn. Then it follows that if your flower garden cost you only £100 in keeping from May to October, and you should turn over this new leaf, be it known to you and yours and to all whom it may concern, that £300 will not more than keep one out of the fix of certain failure.

Beginning on the middle terrace next the council-room there are three pairs of oblong beds across the terrace, and along the walk which crosses the bottom of that terrace. The first pair is planted with Cottage Maid Geranium, the centre pair with two kinds of Nosegay Geraniums, and the third with the Geranium Attraction, and the whole is edged with Mint and Alyssum mixed. The soil in these wants renewing. Then up along the east side come Rhododendron-beds, Hollyhock-beds, and beds of bedding Dahlias. The Rhododendron-beds have, first, an edging of Andromeda floribunda, both doing exceedingly well; and outside three rings of flowers—Scarlet Geranium, Heliotrope, and an edging of Mint. The best

edgings of the variegated all over the garden are from cuttings put in at planting-out time just where they stand—say two rows of cuttings at 3 inches apart to make one row of edging, or, as Mr. Thomson of Archerfield taught us, how he made his edgings of Cerastium tomentosum. The best bedding Dahlias in these beds are four kinds out of six or seven kinds that are there. The best of the four is a very good dwarf yellow one called Titian; the next best is Royal Purple, which is of the same size and habit as Zelinda, which is planted next to it for comparison. The next kind is named Pigeon, one of the dwarf fancies, white and lilac; and the best white is named White Unique, but it does not seem to be so free in blooming as the rest, and there is a dingy-coloured one which ought never to have been even suggested for a flower-garden. There are abominations of colours in the Dahlias and in the Hollyhocks which no real lady can look on with approval. But the two friezes are the gems of this side of the terrace, or say they and the corresponding pair on the west side, are the pride of the arcade accompaniments; and the four are in four different patterns this year, all very beautiful, and, as far as the patterns would allow, remarkably well planted this season. In some instances there, and elsewhere in the garden, the Council of the Society and the artist who designed the plan both erred in principle by adopting too much of a good thing. I mean by attempting to make spar-coloured beds parts and parcels of groups of flower-beds, instead of ground colour only: that is a radical mistake, and an index to the value of the weight of these authorities on matters of flower-gardening.

The next question is, Would you alter them—that is, change the spar-beds to flower-beds? I would do nothing of the kind just yet. It is much better as it is, for we can afford to bear it and the blame of it: therefore, it will be a sample of a kind of work which is yet too new in this country to be generally understood and for avoiding certain errors which are very likely to creep in until the people get better accustomed to this style of decoration. A fresh hand at such designing or a young beginner might easily fall into the error as readily as Mr. Nesfield and the Council who adopted his ideas; but by seeing this example he will know how not to repeat the same error; and, therefore, the thing as it is is much more likely to teach the natives what to do, and what to avoid than the most perfect design.

The south-east frieze, or the lower one on the east side of the terrace, may be said to be a long oval not much short of 100 feet and of a proportionate width, and the planting to be done in three lines of beds, one set of beds along the centre of the oval all laid down in or on a light-coloured ground or gravel, and different-formed beds in duplicates along each side of the great oval in another kind of ground colour in gravel, all most exquisite both in the design and in the planting; but then comes the error in principle of having parts or centres of parts of beds in spar instead of flowers. Neither the Romans nor their successors in Italy did attempt to colour parts of a pattern with flowers, and other parts of

No. 725.—VOL. XXVIII., OLD SERIES.

the same pattern with coloured spar, gravel, or sand, as is here exemplified. When they used flowers, as far as I have seen in ancient authors, they made them as frames to a picture—the frames or borders in plants with or without flowers, and the patterns or pictures inside the frames—just like the glaciers, fancy figures in fancy-coloured gravels. But in the two fans even the frames of the pictures are, as it were, an allegory—so much of clay, so much of brass, gold, silver, and so on, as I shall show when we come to them.

The run of centre beds in this frieze are five groups or lobed beds, and lobes of Box in the angles, or as a four-petalled flower, and the Box to be the calyx; then the centre, where the seed-pod should come, is a diamond of coloured gravel, as low as the ground-colour gravel, and as stupid as anything any mortal ever put on paper, board, or bank. There is no meaning in it—no sort of contrast either; and as to harmony, you might just as well put a carp in a flower-pot out of the basin beyond, and set it up by a bright Scarlet Geranium. No one will ever copy such geologic polychromes, and, therefore, they had better remain as they are, like the hand-sign on Hungerford Bridge, to tell the way to the right or to the left, but never to the thing as it is.

Well, the four-lobed groups are five in number, up the centre of the big oval, planted with *Tropæolum elegans*, and in the same run are four circles of yellow *Calceolarias*. Then on each side of the oval, and opposite the *Calceolarias*, come half-circles of Scarlet Geraniums, with gravel for ground colour between the beds; but without a plan of the beds the mode can hardly be sufficiently explained. The upper frieze on this side is very differently planted. There is a bed at each end of the oval, which is three parts of a circle, enclosing a space of gravel. These are in Scarlet Geraniums and Purple King in the very highest perfection, then seven circles of yellow *Calceolarias*, and six diamond-beds alternating, in Scarlet Geraniums; and the beds on each side of the oval are in half-circles, in scarlet also and Purple King, or what you might call a blaze of scarlet, yellow, and purple; then the top with three beds only across, along the top walk, two of them being with Rose Queen Geranium, and one of *Tropæolum elegans*. Rose Queen is edged with Flower of the Day, and *Tropæolum elegans* with the Golden Chain.

Then the upper terrace on each side of the conservatory, where on the east side a big tree which had escaped the revolution puts the symmetry of the beds on either side out of joint—on the west side especially—the beds, indeed, are most perfect specimens of the highest style of our art, save the edge next the grass; and all over the garden, owing to the backward season, the edging plants do not yet fill up the space to the very edge of the grass, as all good and true edgings ought to do always and in all places and patterns whatever. And whether it be grass, Box, or the line of an architectural edging, no more room is allowed between the edging plant and the line it follows than just enough to make the two lines visible—the line of grass or Box, and the line of plants.

Next the conservatory, on either side, comes an oblong bed of the best variegated Geranium of the season; then, also, a pair of Lady Middleton Geranium, which is preferred to Tenthram Rose for its more close and more dwarf habit, as Rose Queen is preferred here to Christine for the opposite qualities—bigger and stronger in all respects. Here is a circular-bed of Lady Plymouth Geranium and variegated Alyssum, with *Coleus Verschaffelti*, all mixed, and all looking as comfortable as if they were inside the grand conservatory.

Another circle is of *Agathæa coleatis variegata*. Not so far amiss after all; but that plant was certainly not worth a first or a second class certificate, as we of the Floral Committee had given it. My ownself, as Sam would say, was hand and glove with the majority in giving the first-class prize. But "Once bit twice shy" is the saying; and I can never bring myself to believe the truth from a man who once told me a deliberate falsehood—for a man did tell me a direct falsehood with respect to that plant being a good or thoroughly good variegated plant, when I myself could not know anything of it but from seeing six little plants of it before us.

The next bed is another oblong of the new scarlet *Tropæolum* called *Eclipsæ*, which was raised last year by Mr. Headley, of Cambridge, one of the then Floral Committee. From him it passed into the hands of Mr. Turner, of Slough, who provided that bed to prove the fact: and the plant does indeed prove it to the very letter—proves *Eclipse* to be the highest-coloured of the race of *Lobbianum*, and equal to *elegans* in habit and flushness of bloom. It is a splendid bed; and indeed all about the con-

servatory are so, inside and out—vases, borders, beds, and music, and thousands of visitors from out of the International to hear and see it all, and enjoy it most thoroughly. But to be in the fashion the Society, too, must show off "an exotic bed" of fine-foliaged plants; and there it is—west side of the conservatory. The centre with *Wigandia caracasana*; Indian corn; Castor-oil plants; a row of *Selinum decipiens*, an *Aralia*-looking, softwooded, palmiferous-like plant (if there is such a word), which, in fact, is one of the great foreign umbel-plants—that is, related to our own *Angelicas* and *Archangelicas*—a very pretty plant, however, for this kind of work. The outer row is of *Perilla* and of *Coleus Verschaffelti* plant for plant; then extra beds and beds of *Dahlias* and *Hollyhocks* to the two grand friezes of the western terrace. The top frieze has six-feet-wide circles of white spar down the centre of the oval; and there are six beds of flowers embracing the circles in the form of the schoolboy's pothooks, with the points of the hooks cut off short—very pretty beds, and all exquisitely planted and flourishing, thus:—two rows of Flower of the Day in the centre of the pothook-fashion bed; two rows of Purple King *Verbena* on each side of the variegated Geranium; and two rows of *Tropæolum elegans* on the two outsides. The gravel under the pothooks, as it were, is of cream colour, and that of the centre circles is white—one of the most telling combinations in the whole garden. The last or lowest frieze is in this wise:—six beds across the oval diagonally, and six spar divisions between them; and two end beds in the lobed shape, and filled with another fine new seedling *Tropæolum* of their own raising, after the look of *Triomphe de Hyris*, and very good indeed.

The six diagonal beds are planted with the Nosegay Lord Palmerston—an immense trusser, of good habit, but, like some others of the delicate tints over the garden, the flowers get sunburnt this cold summer. This was one of my seedlings, which I sent to be proved, and they put it in the place of honour instead of in a large bed for trial. And with it I sent one plant of Nosegay *Cybister*, or the Tumbler—perhaps the very best bedder of all the race and a new style of truss. The back of the truss comes up first, and the first flowers open downwards; the truss then rolls round to put the flowers upright, or is tumbled round, from which the classic name is derived. As for the Tumbler bulb, *Sprekelia cybister*, Mr. Eyles and all the judges who have seen the Tumbler believe it to be the best bedding sort, and I hope it is; but a whole mass of it must be tried there another year, and if any other breeder can tumble in a rival to it that would please us all.

The three pairs of oblong beds below the frieze are thus:—Two pairs with *Attraction Geranium*, and the centre pair with *Punch*, all edged with *Mint* and all very good. Then the two grand pairs in the centre of the garden are bordered all round with oblong beds 6 feet wide and 22 feet in length, and circular beds between them—all quite grand. The oblong beds are thus:—three rows of the *Crystal Palace Scarlet* in the centre, and on each side a deep band of Purple King *Verbena* edged with *Mangles*. The circles are in pairs and in variegated Geraniums of sorts; and a top circle is of the new Lady Mary Scott *Verbena* from Dalkeith Palace—a fine dark crimson sort. The patterns inside these frames are very intricate, but the planting is much better than last year. The finest masses are of *Brilliant*, and they are brilliant. Mrs. Vernon Nosegay, *Aurea floribunda Calceolaria*, *Tropæolum elegans*, and the old crimson Nosegay, with smaller beds of *Mimulus cuprens*, a new and more scarlet *Orach*, the *Amaranthus melancholicus*, which promises fair, and several others, complete the patterns of the fans without an axis.

Then the two side grass ovals with pedestals and vases bordered round with four oblong beds, and as many circles. A pair of the oblongs are planted with Rose Queen instead of Christine, and a pair of *Scarlets* to match the circles in *Calceolarias*, all gayer than last year. Then the grandest composition in this or any country is the great middle circle, divided into eight circles in scrollwork, and all planted to the very letter of the law in opposite match pairs, with different accompaniments of scrollwork-beds to each pair, and a centre raised vase-bed on a platform of grass—a magnificent arrangement in the most artistic forms imaginable. The centre raised bed has a *Pampas Grass* plant in the centre, then a mass of the *Cottage Maid Geranium* edged with three kinds of Ivy-leaf Geraniums—the Golden-leaved sort, the lilac, and the old white; all too light, however, for resting against the white curve of the vase-like frame for the bed. The eight main scroll circles around are thus in opposite pairs:—one pair of *Crystal Palace Scarlet*; one of

Purple King Verbena; one of yellow Calceolaria; and one of *Tropæolum elegans*. And in the outer circle and between these come eight batwing-shaped beds, and all of them are in variegated Geraniums, edged with deep bands of *Lobelia speciosa*. Then eight pairs of small scroll-beds, as grace-notes to the larger circles; one in Golden Chain, Lady Plymouth, Burning Bush, and other variegated Geraniums, all nestling in blue Lobelias, and all in the most perfect order of high feeding, high training, and lowest training. They are all watered three times a-week, and occasionally with liquid manure, so that every plant in the vast polychrome is just done as if for a competition at a flower show; and nothing of the kind has ever been attempted which could excel all this in one single instance, as far as I have seen or heard.

D. BEATON.

### WINDOW GARDENING, BALCONIES, &c.

MR. FISH, in all his proposed arrangements for window gardening, presupposes more room than people in towns have generally, and his little book is much more for inside gardening than for balconies. I have six boxes outside my windows, 9 inches deep, 11 inches broad, and 4 feet long. Four have a south aspect, two a north; there is besides a large balcony with Ivy and Virginian Creeper in ornamental pots. My boxes are filled with shrubby Calceolarias, Scarlet Geraniums, *Tropæolums*, &c.; all the plants were from Messrs. A. Henderson & Co., Pine Apple Nursery, and planted not in pots but in the boxes. What am I to do with the plants in the winter? I have no garden, no open rear to my house. Of course, I shall have my boxes filled for spring with Crocus, Tulips, &c., and for next summer must I buy fresh plants? Mr. Fish says, "Put your pots, &c.," but my plants must be first potted, and repotting would not tend to keep plants quiet. I believe the Geraniums would do without pots. All these books take it for granted that there is previous knowledge. A few papers for beginners, I mean genuine beginners and townspeople, would be of use. Mr. Fish gives plants in his list as fit for town, which will only produce disappointment if tried—*Ericas*, for instance.—A CONSTANT READER.

[There has been so much commendation of the little manual on "Window Gardening," that it is almost refreshing to meet with something like grumbling criticism. Things go on all the better for a little grumbling, only the grumbling must be to the point, and no over-statement made. It would be thoroughly impossible in a pamphlet of a few pages to meet the case of every person. The aim of the book was not only to give the simplest details, the necessary culture, and short lists of suitable plants, but to get the cultivator to think and generalise for himself, so as to become something more than a mere routine gardener. The first objection is, that the plants are too numerous, and room could not be found for them in the generality of cases. Well, all that we can urge is, that not a plant has been mentioned that has not been seen successfully treated in windows. If our friend fancies Geraniums and Calceolarias only, if he gets not only general but specific directions about them, why grumble because his next-door neighbour likes a totally different tribe of plants? Such grumbling is much of a piece with the conduct of a man who bought a cookery book to find out the best mode of managing pork, and then pitched it aside, because it also spoke of beef and mutton, about which he felt no interest.

The second objection is, that the manual treats more of inside gardening in windows than gardening on balconies. The very title would just presuppose this, and, therefore, furnishes no ground of complaint. Besides, the person who could manage the plants named inside of a window in winter and spring would surely find little difficulty in growing the same things out of doors on the window-sill, or in balconies in summer. A paragraph or more is given on the arrangements, &c., on balconies, and specific directions not only as to sowing one of the plants mentioned, but also how to treat the two others, Geraniums and Calceolarias. Instead of finding it impossible to supply balconies from windows, what would our correspondent think of not only balconies but a few free beds in a flower garden being filled every year, and filled in first-rate style, too, from plants kept in three windows, with the assistance of an old store-room that has a small window?

Again, no instructions in a book, however ample, will ever make up for want of thought—want of generalising in the reader. Our correspondent has no garden, no open rear to his house;

but all the operations described, even to the minutiae of sowing and potting, may as well be done in a room as out of doors. Plants will even propagate as well under a bell-glass, or a cracked tumbler inside of a room, when the suitable conditions as to coolness, warmth, shade, &c., are secured, as they would do in a frame or a hand-light out of doors. The man who thinks about what he is doing, will soon find a means to suit his purpose.

Lastly, we are told the lists given in "Window Gardening" will, if tried in towns, only produce disappointment—*Ericas* for instance. Well, it was not intended that the work should be confined to towns. *Ericas* are never alluded to in the cultural notes. The word is only mentioned once among the shrubby plants that might be sown in spring by those who had plenty of room. We know that the raising of plants from seed imparts a pleasure that tending a purchased plant never can give. We have known hardy Heaths raised under a square of glass in a window, and the plants used for planting all round a stand of bee-hives. Thousands and thousands of the hardier Cape Heaths, as *Wilmoreana*, *hyemalis*, &c., are sold every year for windows and balconies in London, and generally are well tended so long as they remain in bloom. We have seen them kept in houses in the country, and tolerably healthy where there was no greenhouse—in fact, in a spare room, where little fire was used in winter, and air could be given pretty freely, there would be little difficulty in keeping such kinds healthy. The word *Erica*, however, is only once mentioned in a list of seeds that might be sown, and they occupy no place in the cultural directions because we were aware that beginners might find a difficulty with them—in fact, though extended lists are given to suit those with many windows, or who might make a sort of greenhouse of a room it is also broadly stated that where there is only a window or two, "I would confine the selection chiefly to *Pelargoniums*, *Fuchsias*, shrubby *Calceolarias*, and *Balsams*." That is no reason, however, why other people that liked other forms of beauty should not have an *Acacia*, a *Camellia*, a *Cytisus*, or a *Daphne*. One of the noblest plants of *Daphne odora* we ever saw was in the parlour of a lady in April in full bloom. When its beauty was gone it was placed outside of a window in a north-west aspect during summer, and into a sort of storehouse-room in winter, close to the glass, and in which room there was never above a degree or two of frost. The same lady had some Heaths and Camellias. The Heaths stood in winter in a room little used, near the window, and had plenty of air in mild weather; and instead of using fire heat, the shutters were kept shut in severe weather. When our correspondent has seen more of window gardening, he will not only limit his ideas of the impossible and the disappointing, but he may come the length of owning, as I here most unreservedly and gratefully do, that some of the most valuable ideas that have come in my way have been derived from enthusiastic window-gardeners, who, beside their window-sills inside and out, had no ground they could call their own.

Convinced that in "Window Gardening" there are many over-sights, and, perhaps, some errors, and cheerfully granting that if rewritten there might be many omissions and additions, I must still say that few will be led much astray that get imbued with the spirit in which it is written. When people, however, complain of want of succinctness, we expect them surely to avoid a similar error. Now, with the exception of our correspondent's six boxes and their size, and their being filled with *Tropæolums*, shrubby *Calceolarias*, and *Scarlet Geraniums*, we have no information whatever. Are these boxes mixed, or are they filled with one thing separately? Filled either way, there would be little difficulty as to their summer treatment; but the winter treatment would be very different if the proprietor chose to keep the plants for another season. Even in summer the treatment should be different. Coolness and moisture for *Calceolarias*; heat and not too much moisture for *Scarlet Geraniums*. When *Tropæolums* are established they need little moisture to cause them to bloom freely. If the proprietor chooses to purchase a fresh lot for a summer display, the best thing he can do is to let them all die with the frost, and plant with Tulips, &c., for spring. If he wants to save his plants he must proceed according to circumstances. If the *Calceolarias* and the *Geraniums* are mixed, it would be best to separate them either by potting each plant separately, or putting each kind separately into a larger pot or a box, so that each can get the requisite treatment. For instance: in the case of *Calceolarias* we would cut the plants pretty freely back—say in October, lift them a

week afterwards with all their roots and a good portion of soil, pack them close together, water them, place them near the glass in a cool room in winter, keep them as much from fire heat as possible, keep the soil rather moist all winter, and give more room to the plants by turning them out in boxes in April.

Now for Geraniums thus mixed. We would also take them up, and either pot or pack closely in a box, water to settle the earth about the roots, and about the end of October we would strip off the whole of the leaves and the very soft points of the shoots, allow the soil to become dryish, but not dust dry in winter, and we would keep such plants in a dryish place—say a dry cellar or a garret, being not at all particular as to much light before the old succulent stems began to break, which they would most likely do in March and April. In fact we like such old plants best, when they do not show a leaf larger than a sixpence before April. They will require more water and room after that, but they will bloom in balconies as no young plants will do, and require only a tithe of the trouble of young plants in winter.

If you ask if that is the best way of arranging them, we say, "No." We would keep the Calceolarias chiefly to one set of boxes, and the Geraniums to another, with appropriate and mere temporary edgings to each. Then we would have two sets of boxes for the balconies—one for bulbs, &c., in spring, and one for blooming plants in summer and autumn. With the last we have now to do. Well, about the middle of October we would prune back the Calceolarias pretty freely, so that we should have fresh shoots near the surface of the soil before winter. We would fresh surface the plants, and remove the boxes to a room where they could have a good portion of light, be kept moderately moist, and not exposed to more than a degree or two of frost during the winter. By April the boxes could go on the balcony during the day, with a little protection at night. These, with surface-dressings and manure waterings, would bloom early and well. If all this attention presupposes too much labour, that we cannot help; it is the only way under the circumstances by which the present plants can be made available.

If you ask me if that is the mode I would adopt, I would reply most likely in the negative, because I prefer young Calceolarias to old ones, and because the room that would be required for an old plant would hold something like a score or a dozen of cuttings up to March, and require no more trouble. A six-inch pot will hold about a score of cuttings about 2½ inches long, inserted from the middle of September to the middle of October, and these placed either inside or outside of the window will be sure to strike in a month or six weeks, if a bell-glass is placed over them, and a piece of paper to shade from bright sun, and a little air be given at night to prevent damping. If there are no bell-glasses, fill the six-inch pot half full with propagating, light, sandy soil, and place a square of glass over the top of the pot, shading and giving air as above. An improvement on the latter plan would be to use a 3½-inch pot, and set it when filled at the bottom of a six-inch one. When struck these young plants, so close together, would require little attention except watering and air-giving until March, when they would require more room before being finally planted out.

The advantages of such young plants are, that they require little room in winter, and generally bloom longer the following season, and are less liable to go off. Amongst the thousands I use, I never now plant out an old plant. The advantage of the old plants in your circumstances is, that there is less nicety required, but then more room is demanded in winter, and the plants are more apt to be exhausted early in summer. Again, we may say it is no fault of ours, if instead of this attention our friends prefer going to the nurserymen every spring. Without it, they must make up their minds to do so, and we do not expect that they will succeed thoroughly to their satisfaction at the first trial. Just as an instance as to young Calceolarias, we may mention we put out many thousand cuttings in a rather open cold pit last October, with less attention to minutiae than could be given in a pot with a bell-glass or a square of glass laid over the rim, and we did not lose a cutting in a thousand. They stood about 1½ inch apart, and stood there until thinned in the middle of March, and no plants could have done better.

Then as to the Scarlet Geraniums in boxes by themselves. Give little water after September, remove larger leaves gradually until the middle of October, clear all the leaves away by the end of it. The soil will be quite wet enough all the winter, if not dust dry. The stems will be like a succulent plant, and will hold quite enough of moisture to keep them pretty well, if the plants are not exposed to any drying heat. The best place for

them is a store-room or garret, and much light is no great object provided they are kept cool enough not to grow, and airy enough not to damp, and frost kept out by the covering of a cloth, or a little hay used to prevent the stems freezing. When such plants, about March, begin to break and show leaves the size of half a sixpence, the boxes should be brought near a window, and in a sunny day the stems should be dusted or sponged with water. Ere long a little water about 70° should be given the soil, not all over at first, but poured into holes made with skewers a few inches apart. In a few days repeat the process if the weather is at all bright. When the leaves get between the size of a sixpence and a new halfpenny, all risk is over. Scrape away then a portion of the surface soil—say from half an inch to an inch deep, without injuring the roots, and fill up with rich compost, of which soil may form one part and rotten dung another, and then water as needed. These boxes may be expected to bloom most splendidly during the summer, and to go on from year to year far exceeding in brilliancy, and with a tithe of the trouble involved in keeping young plants over the winter. Every year, for some time past, we have four fine plants of Tom Thumb Geranium in the flower garden. They are in largish pots, plunged. About the end of October the pots are generally raised, and plants and pots together go into a shed until we get time to pick the most of the leaves off. The plants then generally stand in a shed secure from frost all the winter. In spring a few withered points will want removing, and the plants are placed first in a cool house, just as inside the window of a room. When growth commences they get a little water and then are fresh surfaced, and so rich is the mass of flowers in general that but for the trouble and expense I would keep Scarlet Geraniums in pots, and plunge them in beds and boxes instead of planting them out.

One thing more our correspondent has omitted—namely, the kind of Tropæolums used, and we have omitted stating how to secure a fresh supply. If of the Elegans or Triomphe de Hyrie kinds we would place little dependance on the old plants. If taken up if the boxes must be changed, or if left alone in boxes of Calceolarias or Geraniums;—in the first case, they would have too much moisture in winter, and in the other case they would be too dry even for such succulent plants. The best way with them is to keep a supply of young plants from cuttings, and let the rest die. In the case of the common Tropæolums, and even the Tom Thumb scarlets and yellows, which are very beautiful, the best plan is to sow seeds at the sides of the boxes in April, or, what is better, sow in a pot inside the window at the end of March. Pot-off into small three-inch pots as soon as the plants are 2 inches high, and then in May turn out the nice-established plants in the sides of the boxes on the balcony.

We fear that even now we have not been minute enough to please our Dublin friend; but if he would tell us where the deficiency lay, we would be glad to remedy it, or get some one better qualified to attend to it. Meanwhile we can have no hope to meet every case until that is clearly stated, and to these in general short replies can only be given. There is no doubt much truth in what a nurseryman told us years ago. "Until 'Window Gardening' appeared I furnished many windows and balconies every year. At first I thought my trade would suffer, there was such a demand for pots in the autumn; but these, too, helped to bring grist to the mill. Many found that there was more difficulty in keeping the plants than they thought there would be from your representations, and of course there have been numerous failures, though also many successes. In both cases my orders have largely increased, so that to these people, in addition to what they carefully save, I regularly sell from three to five times the amount I used to do." Our own experience testifies to the same fact, and hence we wish to see people trying to keep their window and balcony plants over the winter.—R. FISH.]

#### NOTES WHILST RESTING.

BRAINS will not go on for ever without resting any more than legs will; so, having become brain-weary, I resolved in this present month of August to be turned out for a summer's run like our old coach horses. Now, if you need rest, take my word for it that there is nothing like resting earnestly and totally; it is of no use doing it as the Bristol merchants are said to sleep, with one eye open and at work. Don't go to Brighton, or to the Isle of Wight, or to the Highlands—for in every one of those places railways now bring against you some of the Browns,

Joneses, and Robinsons, or the Johnsons or the Smiths of your acquaintance, and rest is at an end when you look upon those Lombard-Street faces, and hear those Camden-Town voices. Avoid those *rencontres* as you value your rest; get to some place where their shadows fall not, and which is as free from the possibility of some ogre of a partner or client being able to write, "You can come up by the 9.30 to-morrow morning."

Resolved to be secure from all those rest-annihilators, I east about for a place of refuge, and some cunning cousins suggested Guernsey; conviction followed close on the heels of the suggestion—for do not sea commotions deter those Joneses and all the rest from seeking that island of fair girls, Parsnips, and milch cows?

But where to go to in that isle of quiet was the next query for solution, and again those cunning consins were my good geniuses. There is, quoth they, in a precipitate gorge of the rocks leading down to a little sunny bay called Moulin Huet—the very name is soothing—a certain widow resident; her cottage clean in the superlative, the scenery grand, and no neighbours but fishermen, who afford an unailing supply of crustaceae for breakfast. No more need be said. I supplicated successfully for the hospitality of the widow Falaise, and the 5th of this present August at midnight I was on the velvet cushions of the "Southampton," as she steamed out on her voyage; intent for St. Peter's Port.

Records of the voyage shall not be made public by me; let no more be my revelations than that there were a head wind and tumbling sea—disturbers, as usual, of the human system, and destructives of all regard for personal appearances. One face must long remain in my remembrance, so piteous and so reproachful that a smile *could* be permitted by me, whilst basins were being placed by that stoical steward preparatory for events foreshadowed on so many misery-stamped faces.

The harbour of St. Peter's Port is reached; that strange conglomeration of wood, the landing-place, is passed up, the luggage is stowed in one of the carts without ends, two miles are passed over, and I am under the thatched roof of La Fosse, the very unique residence of the widow Falaise.

That no unwarrantable suggestions may cross the imagination, even of the most uncharitable, let me premise that the said widow, having lived and thrived for some fifty years, is not now so well entitled as she may once have been to compete with Venus as to personal attractions, but that she is far superior to that goddess in honesty—honesty in its largest and most comprehensive acceptation.

But that there may be still less imaginable ground for alander against this vigorous and worthy widow, be it known, O reader, that I retain three dormitories, not for the eccentric purpose of sleeping with my head in one room, my body in a second, and my legs in a third, but because it has been wisely and benignantly ordained that I am united to a fruitful vine, and that the said vine and the fruits thereof are not discovered from me.

Let no one expect a continuance of this my chronicle, for I have no purpose to be historiographer of small events: henceforth my paragraphs must be beads without a connecting string—beads picked up, worth keeping, but unsorted.

I know the sea-coasts of England and Scotland, have searched them sedulously for their fossils, their plants, and their picturesque features, yet not one of those coasts has a rock-valley more wildly beautiful than La Fosse—no little rock-enclosed bay superior to that of Moulin. The valley is a chasm between gneiss rocks, with a narrow steep roadway descending one side, with recesses of varied extent, in which are established fishermen's cottages with their little gardens and orchards, whilst below a little stream steals along, but every now and then is seen sparkling and leaping along as if glad to be getting back to its ocean-parent.

And what an ocean is that! Nowhere on the British coast is sea-water intensely blue like this to be looked upon. I have seen such before between the tropics, and in some other latitudes far away from any land, and the bright blue of which was held as evidence of a depth almost unfathomable. It is not so here; for the peaked and spired masses of rocks, upheaved and confused mid the waters, and even fringed with white surf, or lashed by breakers which they dash into still whiter clouds of foam, tell and warn mariners of shallows and dangers not to be approached. What is the cause of this exceptional blueness? I would gladly have my ignorance enlightened on this.

The roadside gardens surprise the unaccustomed visitor by

the size and kind of some of their plants. The *Fuchsias*, all of the commoner red sorts, such as *Biccartoni*, are standard shrubs, reaching to 6 feet or 8 feet high, and those against a wall to more than 11 feet, profuse of flower, and evidencing that the winters do not damage even one of their annual shoots. *Veronica Andersoni* is entitled to a similar report. It is quite a common garden shrub, and 4 feet or 5 feet high, and now blooming abundantly. In one cottage garden, filling a corner formed by a wall at right angles with the cottage side, is a *Hydrangea*, full 6 feet high, and about the same in diameter, and it must now be bearing two hundred of its globular heads of bloom, clothing it from the very uppermost point down to the bed's surface—bloom of bright light blue, so unlike the sickly flowers partly pale pink and greenish-white we are accustomed to see on this plant in England.

The steepness of the rock-sides, against which the roads and gardens are established, rendered some ingenuity needful in adapting to them the carriages and implements in use. The soil being light, formed for the most part of disintegrated gneiss and other siliceous rocks, rendered it necessary to have the tines of the forks used in digging flattened, so as to prevent the soil passing between them. They are also small, for the labour would be great if the digger had to lift a forkful of earth such as is contained on the four and five-pronged implements used in England. The accompanying sketch is of one now using in the garden before my window. "We have them bigger," says the workman, "but they be't so handy." It has a handle 27 inches long; the tines are 8 inches long, and 2 inches broad at the spoon-shaped end; the entire width of the head of the three prongs is 7 inches. The soil is so light that the fork is thrust into it without using the foot.

The wheelbarrows we have in England are too large for use here; the labour of impelling them when loaded would be too great up the universal inclines; so the back, or body, of the barrow is very small, the arms long, and the diameter of the wheel large—all adaptations conducive to diminishing the force required in using these carriages. The wheel of a very small barrow used in Mrs. Falaise's garden is 2 feet in diameter.—*QUIS.*  
(To be continued.)

## CULTURE OF THE RASPBERRY.

THIS hardy fruit is a native of Britain, found in moist woods. In its wild state the fruit is red and very small; yet it is pleasantly sweet, and where it abounds is gathered by cottagers' children. It produces shoots one year, which bear fruit the year following and then die; but as the roots do not die, they send up annually other young shoots to supply fruit every year in succession. When removed to and grown in gardens the fruit is greatly improved both in size, juiciness, flavour, and quantity.

I have, however, observed in many gardens, both public and private, that the best mode of culture is either not understood or neglected. The difference between well-managed and ill-managed plantations is so great, that it has been a matter of great surprise to me that all cultivators do not pay more attention to and adopt the best mode of culture. I am certain that even the growers for the market would find the large crops they would obtain of superior fruit would abundantly repay them by bestowing proper attention to this fruit, which is always in demand.

Another mode of improving the fruit is to raise new varieties from seed. To some extent this has been done, and our list of sorts really improved is now increased considerably. From these improved kinds seeds should be saved, and still better sorts would no doubt be the result. From the success already achieved we are led to anticipate that the next generation will have fruits of this shrub as large as those of a kindred fruit—namely, the Gooseberry. To effect this equal pains must be bestowed as our Lancashire growers have bestowed upon that favourite fruit. They not only raise new kinds, but cultivate them so as to bring them to the highest degree of perfection.

As some of our readers may intend forming new plantations of the Raspberry, or may be desirous of improving their old ones, I purpose drawing up a code of instructions for their benefit; and as there is nothing like order in giving directions, I shall divide the subject into the following sections:—Situation, Soil,

Planting, Pruning, Training, Summer Treatment, Winter Treatment, Propagating, and lastly a selected list of the best varieties now in culture.

*Situation.*—The position of a plantation of Raspberries should be one fully exposed to the sun, but at the same time sheltered from high winds. This exposure is necessary both to ripen the wood and the fruit. If grown under the shade of tall fruit trees the fruit will be not so high in colour nor so fine in flavour, neither will the yearling shoots become ripened at the extremities: therefore plant your Raspberries in such a situation that the sun may shine upon them all the day.

*Soil.*—The best soil for them is a deep sound loam on a clay subsoil; but if the soil is a good loam and from a foot to 18 inches in depth, the kind of subsoil is not so very important. A good dressing of rotten dung should be added.

*Planting.*—The best season for this operation is November, as soon as the leaves are fallen. Choose the strongest young suckers you can get, and also from a healthy stock. In taking them up, keep as much soil to each plant as possible, and plant them immediately. Should the weather and soil happen to be dry, give them a good watering when the planting is completed. Plant three or four together to form what gardeners call "a hill." Place them in rows 6 feet apart, and 5 feet from hill to hill in the rows. Let the hills stand exactly opposite to each other for a reason that I shall give under the head "Training." Then tie the canes together loosely to prevent them from rubbing against each other with the wind. Fasten the soil well to the roots by treading with the foot; and then place a mulching of short dung around every hill or stool. That completes the planting.

*Pruning.*—It is not advisable to prune immediately after planting. Supposing the planting is completed in December, let them remain as they are till the end of January. If the weather has been moderately mild the root action will by that time have commenced; then the pruning may be done with safety. All that will be needed the first year is to cut off the ends of the shoots about 4 inches or 5 inches. The after-pruning will be described under "Summer and Winter Treatment."

*Training.*—The common method is to twine the canes round each other and tie them to a stake. The objection to this is that the lower buds do not break; and even the top buds of each cane that do break are so crowded together that there is a great waste of fruit for want of a due share of light and air, especially in wet seasons. There is a plan of putting in three or more stakes, and having a wide rim at the top to spread them open. This is a better method. But there is another objection to both ways—and that is, that the young shoots that spring up from the bottom must necessarily crowd the bearing-shoots, thus robbing each other of light and air. To avoid this, I recommend the training of them on the arching system, which is by far the best method. I have seen it in work, and finer Raspberries and a better crop I never witnessed anywhere. The stools being planted opposite to each other, and 5 feet apart, the shoots ready for bearing are, in the autumn after being pruned, bent down and tied together just at the points of the shoots. Thus the shoots form arches right across the plot occupied with the Raspberries. During summer the sun-beams are admitted, not only to the fruit, but also to the ground, in at least two directions; and the space between the arches is left open for the young shoots made during the current year to grow up in. There they will have their due share of light, and will not shade the fruit-bearing shoots. The buds on these last-named shoots break nearly down to the ground, and each lateral rises upright, bearing its blossoms and fruit separate, and clear from its neighbours. So managed and trained the plantation is even highly ornamental; and, besides that, the fruit is very easily gathered, as every one, when ripe, is exposed to the eye of the gatherer. Let any one try this method, and I feel confident he will be pleased with the result.—T. APPLEBY.

especially in wet seasons. There is a plan of putting in three or more stakes, and having a wide rim at the top to spread them open. This is a better method. But there is another objection to both ways—and that is, that the young shoots that spring up from the bottom must necessarily crowd the bearing-shoots, thus robbing each other of light and air. To avoid this, I recommend the training of them on the arching system, which is by far the best method. I have seen it in work, and finer Raspberries and a better crop I never witnessed anywhere. The buds on these last-named shoots break nearly down to the ground, and each lateral rises upright, bearing its blossoms and fruit separate, and clear from its neighbours. So managed and trained the plantation is even highly ornamental; and, besides that, the fruit is very easily gathered, as every one, when ripe, is exposed to the eye of the gatherer. Let any one try this method, and I feel confident he will be pleased with the result.—T. APPLEBY.

[The accompanying engravings represent a modification of the above system, which is also found to answer well. The Raspberries are planted as above, 5 feet apart; and during summer

only four new canes are allowed to be developed by each plant, choice being made of the most vigorous, and those which are placed nearest to the original stock; the others are removed when they are about a foot high. In the spring following the old canes are removed, and the four new ones are shortened, so as to leave them 2½ feet in length. They are then tied-down to two stakes, as represented in fig. 1, A A.

During summer the canes A A A, fig. 2, which were pruned and tied-down in the spring, bear fruit, and four new canes, B B, are produced from each stock. At the winter pruning following the canes A, fig. 2, which have borne fruit, are cut

away, and the new canes produced from B B are shortened back to 2½ feet, and tied-down to the place occupied by the fruit-bearing canes the year previously.]

(To be continued.)

Raspberries after the winter pruning.

Raspberries during their growth.

### LARGE FLOWER-BED AT EAST SUTTON PLACE.

FLOWER-BEDS are about their best at this time, and there are few greater attractions than a well-arranged flower garden. From the great number of such to which the general public have easy access, people are becoming daily more and more fastidious, and that which gave universal satisfaction a dozen years ago, or less, fails to do so now. The inquiry to be met with at every corner is, Have you anything fresh? anything new in the bedding line? This laudable desire to introduce fresh features, or new, or but little understood plants, has certainly very much altered the character of flower-gardening, and new and novel designs are as largely sought after as rare or valuable plants.

Flower-gardening has also its fashions, although the reigning one may not always be so implicitly followed by all, as in the equally variable article of dress; for we now and then meet with an elderly florist admiring and fondling his Ranunculuses, Auriculas, Tulips, and similar plants, that were fashionable before Roses, Dahlias, or even Pinks. This class is, however, fast wearing out, but now and then there is a revival of old customs, and these plants will, doubtless, have their turn again, though in a different form to what they held before.

It is unnecessary to give any opinion on the respective merits of the geometric or the picturesque arrangement of flower-beds,

as both styles have their admirers, and to a certain extent either may be right, as the other features of the place usually determine these matters. But there is another mode of giving a great mass of floral beauty to a flower garden, which I have on more than one occasion urged on the readers of THE JOURNAL OF HORTICULTURE as deserving of notice, and which hitherto has not, so far as I know, received any specific name yet. Perhaps, however, some one will give it a high-sounding title. Be this as it may, the term "massed panel system" will convey as much information to the general reader as most names usually do. In further explanation of this term, I may say that it is intended to imply a large plot of ground entirely planted with flowers in such a way as to present a coloured pattern or design. This method of giving a display to the flower garden we have adopted at Linton for several years, and on more than one occasion it has been explained in this Journal. I now give an example from another place where it has been successfully adopted; and it would be difficult to conceive anything more beautiful than the large bed presents, when seen from the eminence by which it is commanded on one side, every plant having performed its allotted duty to a nicety, and the whole being well-flowered.

East Sutton Place, the seat of Sir Edmund Filmer, Bart., M.P., in whose grounds the flower-bed to be described forms a feature, is delightfully situated on the southern side of a ridge of hills which overlook the extensive plain known as the Weald of Kent.

The mansion is a good example of what is called the Tudor style, and what additions have been made since the original (which is very ancient) was erected, have been in strict conformity with the features of the primitive building, and it presents a large and imposing aspect. The park also bears the same stamp of antiquity, being well, if not profusely timbered, many of the trees having attained an unusually large and healthy growth, while the age of others may be counted by centuries. Some very steep declivities, water, and other features of interest give it the true character of a park; and extending up to the front door of the mansion, the visitor sees before him the true features of a residence of the period it represents.

The dressed ground being on the opposite side, and enclosing the mansion on its west, north, and east sides, presents several objects of interest, in addition to the massed panel here represented, which is a circle of 45 feet in diameter, planted as detailed below.

- 1. Central circle, yellow *Calceolaria*.
- 2. Ring of *Perilla nankinensis*.
- 3. *Verbena Purple King*, in eight panels, each edged with *Alyssum variegatum*.

- 4. Ground of *Geraonium Tom Thumb*.
- 5. Ring of *Perilla nankioensis*.
- 6. Bank about 2½ feet wide, *Geraonium Mangles' Variegated*.
- 7. Outer edge of *Lobelia speciosa*.

The bed is surrounded by turf, which on two sides rises by suitable slopes to a position high enough to command the whole bed, which, as already stated, looks remarkably well. The easy simplicity of the figuring is clearly defined, and the plants used

are such as require but little after-care to keep them right, and their uniformity will continue to the last.

The same bed looked equally well last year, many of the same kinds of plants being used, but the pattern was different. In

fact, this style of flower-gardening gives scope for continual change, and those who have seen it never fail to admire it as a style, although its execution gives rise to many criticisms; but in the case described above, I confess that I am unable to suggest a single alteration.

This large circular bed is not the only example of the style of gardening it represents at East Sutton. A border facing the east side of the mansion is planted very effectively in what is usually called the "chain pattern" style, *Cerastium tomentosum*, *Lobelia speciosa*, and another plant, the name of which I have forgotten, being the plants used for that purpose, and it looked remarkably well. Some other large beds were also planted in two or three colours; but this was more in the usual way, and none of them looked so attractive as the one of which the figure is given. The other flower gardens, of which there were more than one, were remarkably well filled and judiciously arranged as to colour, being in beds of a full medium size arranged in a geometric figure, and surrounded by turf. The whole, being in excellent keeping, reflected the greatest credit on Mr. Skinner, the gardener, who, to the other attractions of the grounds, has recently added a fernery, of which I will possibly speak hereafter.

In winter Mr. Skinner marks out the large bed in the embroidered style, colouring it with two or three substances of widely different hues, and in a highly elaborate pattern, which at the time I saw it looked as well as the same style of ornament when done in a more permanent way as at the Royal Horticultural Garden and other places. The ensuing autumn, I have no doubt, will witness it transformed into something of the kind again, but of a different pattern, as the devices for such things are endless, both for winter and summer, so that there is no necessity to copy what has previously been done. The winter is quite as important a period as the summer at many country places, and unless something of the kind be adopted large breadths of naked ground, which look badly, must be left in the dressed ground; but with the above mode of winter-trimming the appearance is scarcely less attractive in the dull winter days than when the flowers are out in August.

At such places as East Sutton, where choice shrubs and Conifers meet you at every corner, and a noble belt of high Walnut and other trees forms the background, shelter and clothing are already provided for. The figured-embroidery-like picture of a large space when neatly done in a pretty design adds materially to the charm of the place, and especially if, as at East Sutton, both the summer and winter management are equally well executed.

J. ROBSON.

## ROYAL HORTICULTURAL SOCIETY.

AUGUST 12TH.

**FLORAL COMMITTEE.**—The subjects brought forward at this Meeting began with an interesting collection of seedling hybrid Lilies from Buckingham Palace. They were between the white *Lilium lancifolium* and the scarlet *Martagon* (*L. chalcedonicum*), and were decided crosses; but like *Gladiolus blandus* in the first crosses, the scarlet had not much effect on such a body of white as there is in *lancifolium*; and this will be another instance of how crossing, or breeding in-and-in, as against hybridising, or breeding by species, will effect the improvement of a new race of subjects. The next was a *Fuchsia*, the only one we have seen which took after *Riccartoni*, on which it is only an improvement.

A collection of striped *Petunias*, not so good as Mrs. Ferguson, were the next lot. Then a collection of fine *Hollyhocks* from Mr. Chater, of Saffron Walden. Of these, one called *Gem of Yellows*, and another splendid crimson kind named *Glory of Walden*, had First-class Certificates awarded by the unanimous assent of the Committee. Another called *Imperator*, a clouded salmon colour, had a First-class Certificate by one vote of majority; and one called *Hesperis*, a true "cottage *Hollyhock*" pattern, and the best of that race known to any of the members, had also a First-class Certificate by the casting vote of the Chairman—the one-half of the Committee considering that the associations of the cottage race of dark grey *Hollyhocks* and this improvement in that strain deserved such award; therefore, *Hesperis* must be taken to be only a first-class flower in the cottage *Hollyhock* strain. *Gloxinias*, *Tropæolums*, and *Lobelias* followed in succession, with some *Verbenas*, none of which were considered superior to predecessors.

Mr. Pope was so good as to send a bloom of his Lord Derby *Dahlia*, for which he had a first-class award already, to gratify those of us who delight in splendid colours; Lord Derby being in our eye the most splendid crimson scarlet yet obtained in *Dahlia*s. Then came Mr. Holland's strain of richly marked *Petunias*, which are neither striped nor blotched in the usual way; but the front is one rich purple blotch with a white edging, and the back part of the flowers one-half white and one-half purple in distinct markings. These *Petunias* are very handsome. *Butterfly* had a Second-class Certificate. Mr. Holland also sent his evergreen *Cyclamen europæum* in flower and in seed.

A weeping tree-like *Lycopod* from the Messrs. Veitch had a unanimous vote for a First-class Certificate. You train it up like a weeping *Ash*, then let the shoots take their way, and they grow down perpendicularly; and from the end of each a tassel of the spore-cases or cones hangs down in a cluster—one of the most interesting examples we have seen of the form of fructification in this the order of *Club Mosses*. The powdery matter in the fruiting cones of *Lycopods* is highly inflammable; if dusted against a candle it gives an instant flash of lightning. That of *clavatum* and *Selago* is gathered in Switzerland, and is used in pharmacy and in the manufacture of fireworks under the name of *Lycopod*; but whether this powder is pollen or spores is yet a question in botany. The name of this plant from the Exotic Nursery is *Lycopodium phlegmarium*. From the same firm was an *Oxalis*, very like a well-grown *Oxalis Bowlesna* but higher coloured. It was brought from Japan by Mr. J. G. Veitch; yet it was about in England and in Jersey for the last five years according to information from some of the members, and it was requested to be sent to be seen again, probably for comparison. A white *Lily* with a greenish inside and a long tube from Messrs. Veitch, and called *Nillgherii*, was considered a nice botanical *Lily*. The great *Lilium auratum* from Japan was there also and still in bloom.

There were several *Dahlia*s, but none of first-class merit, save one called *Caractacus* from Mr. Turner, of Slough. It is a rich creamy buff, deeply tipped and elegantly edged in the same tint—a lady's flower, and it had a First-class Certificate. There was a bunch of *Spiræa callosa* with variegated leaves from Mr. Tillery, and some nice plants from the Society's garden, sent by Mr. Weir, their collector in Brazil; of which the best and the best-known was *Hippeastrum reticulatum striatifolium*, in excellent condition, and much paler than the species.

**FRUIT COMMITTEE.**—Thomas Rivers, Esq., in the chair. In Classes A and B, for Peaches and Nectarines respectively, there were no competitors. In Class C, for the three best dishes of Apricots, distinct kinds, Mr. Cunningham, gardener to the Bishop of London, Fulham Palace, was the only exhibitor. He showed *Hemskerck*, *Moorpark*, and *Breda*; the two former were very similar in appearance, but the *Hemskerck* was very much riper and better flavoured than the others. To these a First-class Prize was awarded. In Classes D and E, for Pums and Cherries, there were no entries. In Class F, for the best three dishes of Apples, Richard Webb, Esq., of Calcot, Reading, exhibited very fine specimens of *White Astrachan*, *Red Astrachan*, and *Early Julian*; they were quite ripe, and beautifully coloured. To these a First Prize was awarded. The only other exhibitor in this class was Mr. D. Cunningham, of the Palace Gardens, Fulham, who sent four sorts, of which *Margaret* was the only one ripe. In Classes G and H, Pears and Raspberries, there were no entries.

Mr. Rivers, of Sawbridgeworth, exhibited fruit of his *Peach Early Victoria*, of which the Committee retains the high opinion formed of it last year as an early *Peach*. *Beaugé Apricot* was pretty well flavoured, but being hardly ripe its merit could not fairly be tested. *Beurré Giffard Pear* was quite ripe, very fine, and delicious in flavour.

Mr. Thomson, gardener to his Grace the Duke of Buccleuch, Dalkeith, again sent a bunch of his seedling *Grape*. It was now quite ripe, and was possessed of the richest and most delicious flavour, combining all the properties of its parents—*Muscad of Alexandria* and *Chasselas Musqué*. It was remarked by the Committee that the juice had a peculiarly honied character, and a flavour that remained long on the palate. Unfortunately the bunch had suffered considerably in the carriage from ill usage on the way, and many of the berries had been shaken off, while others were so loosened as to have become discoloured round the stalk. In consequence of this misfortune the Committee did not make any award; but, at the same time, stated that in their opinion the *Grape* was one of great merit and of first-rate excellence.

Mr. Melville, of Dalmeny Park Gardens, Edinburgh, sent

two bunches of his Champion Hamburgh Muscat. This also was exhibited last year, when the colour was of a grizzly appearance. As now shown the skin is almost as dark as that of a Black Hamburgh, and there is no doubt but that when the fruit is better grown and more pains have been bestowed on the cultivation of the Vine than Mr. Melville has been able to give it, the colour will be quite black. The flavour was excellent, of a decided Hamburgh character, and with a marked Muscat aroma. As Mr. Melville intimated that he would send a better bunch to the September Meeting, the Committee suspended final judgment till then; but meanwhile expressed the opinion that this is a first-rate Grape even as exhibited.

A collection of Melons was received from the garden at Chiswick, none of which had much flavour except Fleming's Hybrid and Turner's Scarlet Flesh. There were also Apricot Angoumois du Bar, a sort of Moorpark, and Standard of England Plum, both grown in the orchard-house in good condition.

Mr. Webb, of Calcut, Reading, exhibited splendid specimens of his Imperial Kidney Potato, which when cooked were found to be very fine.

Mr. Jennings, of Shipston-on-Stour, sent stalks of a Seedling Rhubarb, which has the flavour of green Gooseberries. This is a decided improvement on the old Gooseberry Rhubarb, being much larger. When cooked it was found to possess the flavour of green Gooseberries, and to have a fine piquancy.

### SCROPHULARIA NODOSA VARIEGATA.

"WELL," said a friend of mine the other day, "have you got this new *Scrophularia*—*nodosa variegata* they call it?" Now, in case I should have more friends in the world than one labouring under this belief, allow me to state that I have not yet seen *Scrophularia nodosa variegata*; still I can fancy it might be something good. When I heard of Mr. B. Williams having it, I ordered six plants of it through my nurseryman, which I received; I need not say they were small, everybody knows what to expect when they order a new plant. However, I was not long before I could see an old curiosity, *S. aquatica variegata*, a plant which I have with some difficulty managed to keep for a considerable time. I could not say how long; but if the late Dr. Neill, who lived at Canonmills, near Edinburgh, had been alive, I believe he could have thrown a little light on the subject. Be that as it may, I think it too bad to send out for new an old plant with a new name. There is a wide difference between *S. nodosa* and *S. aquatica*; one does not require much practical botany to decide between the two species. If well rooted, especially in pots, the granulated roots of *S. nodosa* settle all disputes at once.—AN OLD SHOWMAN.

### NOTES FROM PARIS, JULY, 1862.

In a comic album by Cham (the John Leech of Paris), entitled "The London Exhibition," we are treated to the adventures of a Frenchman who visits our great metropolis. He sees the Exhibition, makes all sorts of wonderful mistakes, and has a good laugh at some of our eccentricities, and at last returns to the land of his nativity, and is met with open arms by his "*cara sposa*." Joy at his arrival is also mixed with curiosity to know what bijou he has purchased for her. She eagerly inquires, "What have you brought me back?" "Le spleen," is the only reply that the knight of the rueful countenance makes. One could almost fancy that a recent writer in the *Revue Horticole* had been the hero of it, and that the very moment of his return he had sat down to pen the article in question, a translation of which appeared in a contemporary two or three weeks ago. In it he abuses the gardening of his countrymen in good, round, set terms; their flowers are worse than they were; Roses! poor in comparison with old times; their fruits bad; Carnations completely vanished. But the chief vials of his wrath are poured out on the public gardens—they are unmeaning and ugly, and display a deteriorated taste. The alterations in the Champs Elysées he especially deplores, and altogether the tone of his remarks is of the most deprecatory character. As I made a few notes on the same subject, and am, I hope, neither inclined to adopt everything French as good, nor abuse it as bad, the observations I now make may be erroneous, but I trust, at any rate, they are unprejudiced.

There is a great deal of difference between being fond of flowers and being a lover of gardening. The fair maiden, whose

delicate fingers so exquisitely arrange the vase for the drawing-room or boudoir, would, perhaps, think it a horrible nuisance to have to take any pains about growing them. Now, it seems to me that the French are very fond of flowers but not very fond of gardening. All round Paris one looks in vain for the villas which so surround London, with their elegant and often costly gardens. Nothing seems to strike a Frenchman more than this, and frequent are the exclamations one may hear this year on every side at the appearance of these proofs of real love of flowers. The little regard that a Frenchman, especially a Parisian, has for home, the constant out-of-door life that he leads, must unquestionably tend to diminish any interest that he might have in gardening; but, at the same time, there is not a people who are more enamoured with flowers for decorative purposes. The flower markets of Paris, held as they are every day in some portion of the city, are generally cleared of their contents, and hundreds of small nurserymen are engaged in producing plants for these markets. But then they are, for the most part, very common and cheap. Heliotropes, Mignonette, Roses, Verbenas, Fuchsias, and such like form the staple of their supply, and are purchased for the decoration of their houses; and the consequence is, that plants of rarity and high price are but little sought after. As one of the French nurserymen said to me, "Ah! sir, it is *rarity* you want, we require *cheapness*." "I have," he said, "all the newer varieties of *Rhododendrons*, but what I am most asked for are plants at half a franc or a franc each." This must seriously interfere with the advancement of horticulture; and I rather opine that "perfidious Albion" is the best customer for novelties that the French have.

There is another matter which I hinted at in my last paper which has to be taken into consideration—viz., the lack of verdure in and about Paris. This combined with the constant glare renders, I rather fancy, their taste in the matter of gardening somewhat different from ours, or rather from the prevailing one at present. The impossibility of keeping their grass fresh has led to the change in the style of the Champs Elysées, of which the writer I have alluded to complains, and to the filling of the beds with large masses of *Cannas*, *Caladiums*, and other fine-foliated plants. And I believe that the large masses of yellows, reds, blues, &c., which now form the staple of a well-arranged parterre would be offensive to them. And if any one will just call to mind what the Crystal Palace Garden was during some of the hot days of last summer when the grass was as brown well nigh as the walks, they will at once see that there is some probability that this does affect their taste, and that hence to their eye the duller colours on the bright verdure are more grateful. I can quite understand it by my own experience, living as I do on the seacoast, with the "white cliffs of old England" constantly in view, combined with the bright glare of the sea: nothing is more refreshing than to get a day's run into the country, and amidst the foliage of the woods have nothing but green to rest the eye upon.

We, as they, have two classes of public gardens—those which are completely so, open gratuitously, such as our parks, Kensington Gardens, &c., and those to which admission is to be had on payment, such as the Royal Horticultural Society's at Kensington, and the Crystal Palace. In both of these I do not hesitate to say we are immeasurably in advance. Compare with the first series the Bois de Boulogne, Jardin des Tuileries, the Champs Elysées, and the Parc de Montceaux, and I think even Frenchmen will acknowledge our superiority; while it would be simply absurd to place the Jardin d'Acclimatation, the only one in the same category, with either Kensington or Sydenham. The greatest advance that has been made in public gardens in Paris is in the Parc de Montceaux; and of this I would say a few words, as it seemed to me to be under careful management, and to be regulated with great taste.

The Parc de Montceaux was a private appanage of the Orleans family, and on the confiscation of their estates was made over to the use of the public by the present Emperor; it is on a line with the Champs Elysées, and from the Arc de Triomphe a handsome boulevard leads to it. Owing to there being a number of trees of some considerable age, there is much more shade than usual in the public gardens of Paris; and this will probably account for the greater freshness of the plants and flowers. And as the climate of Paris enables them to bed-out plants that must inevitably fail with us, the effect is very different and striking: *Caladiums*, especially *esculentum*, *Cannas*, *Wigandias*, different varieties of the Castor-oil Plant (*Ricinus*), *Ferdinandia*, *Begonias*, and *Bignonias* are largely used; while still more exotic-looking

things, such as the Indiarubber Plant, Banana, Palms, &c., were plunged in pots in various places on the turf; while in the grotto some fine specimens of tree Ferns were used in the same manner. There were also some beds of Erythrina; but floribunda had been used, and this was a mistake, as though flowering in a very small state it is apt not to flower at all. One large clump was planted with various species of Ricinus, African Marigolds, and some considerable number of Acer negundo variegata, which made a very pleasing contrast. Then, again, there were several ribbon-borders, although I do not think there was much to learn. Standard Fuchsias and Bignonias were oftentimes used in a background, and Cupheas, Ageratums, and Anthemis were

much more used than with us. A pretty effect was produced in one instance by a broad, flat border of Box kept in a dwarf state, and great care was evidenced in keeping every part well watered and clean. Altogether it struck me as by far the best of all the public gardens. The Jardin du Roi at Versailles I thought poor, very poor; and, indeed, altogether I was not a little comforted by the manifestly leading position we hold as horticulturists. It is said that the Emperor is about to erect an immense Crystal Palace at Passy, and perhaps then a further attempt at inducing a taste for our style of gardening may be made, although I question very much if it will take in France generally.—D., Deal.

### HORTICULTURAL EXHIBITIONS—THEIR INFLUENCE UPON CULTIVATION AND TASTE.

If the question was put to us—what, within the last several years has contributed the most to the promotion of first-class cultivation among gardeners?—we could have no hesitation in answering the public exhibitions of plants; for, though there may be many who may profess not to have been so influenced, there can be no question that the first great cause of improvements has been the noble examples of skill periodically brought together under the auspices of various societies; which examples, being to a very great extent particularly described, and sometimes pictorially represented by means of engravings, have through the medium of the horticultural press been sent through the length and breadth of the land—thus penetrating and eradicating prejudices in the craniums of some of our would-be-wise countrymen, which could not have been eradicated by any other means. Again, the employers of gardeners have witnessed what could be accomplished by proper management; and hence, where the means were allowed, the gardener had nothing but his own want of skill to blame, if he did not accomplish that which others had done before him. Apart, however, from the influence of these *fêtes* upon cultivation, there can be no doubt they have effected much good in guiding the artist, and in improving and correcting the taste of the

middle and higher classes of society, and of this we need no stronger proof than the fact that manufacturers look to nature and not to art for patterns to beautify the varied productions of the silk loom, &c.; whilst artists in wax and in artificial flowers imitate nature so very closely, as to render it difficult, in some specimens which we have recently seen, to tell whether they were real or not.

Our object, however, in this paper, is not so much to point out the benefits accruing from these exhibitions, as to call the attention of the managers of the exhibitions themselves to the necessity of infusing a little more artistic effect into the arrangements of the exhibition-tents, for we feel convinced there is yet much room for improvement. The best exemplification of artistic arrangement was seen at the exhibitions of American Plants in the Regent's Park Garden, where, by diversifying the surface of the ground, and grouping the plants with considerable taste, a very effective *tout ensemble* was produced.

Seeing, then, that improvements are to be made, and with the fact before us that the artistic arrangement of the plants in plant-houses, is a matter of considerable interest among persons of taste at the present time, we venture to recommend two stands for the exhibition of Orchids, from the designs of H. Noel Humphreys, Esq.; and

of considerable interest among persons of taste at the present time, we venture to recommend two stands for the exhibition of Orchids, from the designs of H. Noel Humphreys, Esq.; and

we venture further to assert that if these stands were as tastefully filled as the designs are appropriate, a very pleasing and highly gratifying result would be achieved. The large stand is supposed to be executed in rustic work, stands 4 feet in height, to the first tier of plants, and is proportionately large in circumference. The second stand is nearly of the same dimensions, but to render it more artistic, and at the same time durable, it is executed in "terra cotta." These stands tastefully filled and introduced into an Orchid-tent—say the rustic stand in the centre, between the tables, and a terra cotta stand at each end of the tent, thus forming a group with a centre and two sides—we are quite sure would be much admired, and would impart an entirely new feature to our exhibitions. Grouped artistically with mixed plants, some remarkable for their flowers, others for their noble foliage, and a third section as the Ferns, for their graceful habit, a very striking effect might be produced; and, introduced upon the same principle into a conservatory or ball-room, we cannot see that they would be out of place. To keep up the interest of an exhibition-tent, it is necessary that the plants should not all be seen on first entering the tent, for though the first effect may be very pleasing, the eye gets restless,

and seeks a change long before one can be met with; but if plants of an opposite and striking character were introduced in these or similar stands, we are quite sure the appearance of the tents would be greatly improved, and visitors would not fail to appreciate the improvement. — (*Gardeners' Magazine of Botany.*)

[We introduce these elegant designs not merely on account of the beautiful and graceful arrangement which they display as adapted for relieving the monotony of long lines of plants in horticultural exhibitions, for the decoration of architectural conservatories, or even when filled with hardier plants for placing in the centre of circles where several walks meet; but more particularly as being likely to suggest ideas for the tasteful grouping of dinner-table decorations.

For this purpose the vases if executed on a smaller scale, either in terra cotta or other more costly material, would be peculiarly suitable.

The prizes which have been offered at the exhibitions of the Royal Horticultural Society, have excited such an amount of interest in this subject on the part of the public, and so much emulation on that of the competi-

tors, that examples of correct taste and beautiful arrangement cannot fail to become more frequent than they have hitherto been.]

### A SELECTION OF GOOD OLD HERBACEOUS PLANTS.

IN the brief sketch given below of a few old favourites of the herbaceous border, I wish to bring what I consider a small selection of beautiful or singular plants (which, if better known would be far more frequently grown), under the notice of your readers fond of this class of plants.

*Lychnis fulgens.*—From its exceeding brightness this is undoubtedly the most gorgeous of an exceedingly pretty class. The flowers are in colour a beautiful crimson scarlet, from 1 inch to 2 inches in diameter. It is not well cultivated without a little special care in winter. Its habit is tolerably compact, and its usual time of flowering is June and July. Introduced originally from Siberia. This plant when kept in a cool pit during winter, cuttings being struck in early spring and grown in a nice warm atmosphere, I have seen flower when 3 inches high, looking very pretty when four or five cuttings were in a 32-pot.

*Rudbeckia pinnata.*—One of the most singular species of this genus, having but eight long broad florets in the ray, separated from each other, and falling back reflexed to the upright stem. The elongated or conc-like disk stands high and prominent, and is of a dark velvety colour, contrasting admirably with the long

yellow florets of the ray. It is quite hardy, being very fond of a dry garden soil. Flowers from June to October. Native of Carolina.

*Leptostelma maximo.*—Another most singular, and one of those not gny but very striking plants so admired for their singular flowers and stately forms. The leaf at first sight would cause one to pronounce it a Thistle; as such it is a magnificent object when full grown, its average height being about 7 feet, and covered with large masses of flowers. It has one drawback, which good gardeners seldom find fault with—requiring a little care, with slight protection in winter. A native of Mexico. Flowering from September to November.

*Scabiosa caucasica.*—A very distinct species, having broad, semi-silvery leaves, and a tall upright stem, its flower being composed of beautiful blue florets in the ray. Native of Mount Caucasus. Time of flowering, July and August.

*Potentilla atrosanguinea.*—A splendid flower of very dark rich crimson, enhanced manifold by its freedom of growth and flowering in almost any situation. Upon rockeries, old blocks, stony soil, in peat as an edging to Rhododendrons, Azaleas, &c., or wherever fancy can direct its being placed, it invariably

does well. It is of a decumbent habit. Introduced from Nepal. Flowering in profusion from early in July.

*Lathyrus magellanicus*.—It is strange that this Pea with its beautifully tinted blue flowers, and abundant green foliage, is not more sought after and more extensively grown for being hardy, more especially when trained against a wall. It is well suited to fill a vacant space upon a wall in summer, as it has the merit of retaining the beautiful green of its evergreen-like foliage to the base. Being a native of the Straits of Magellan, it has a great liking to an occasional watering with salt water, average strength of 2 ozs. to the gallon.

*Melianthus major*.—This attractive plant, even when not flowering, is a very stately object with its glaucous leaves. The flowers are also exceedingly handsome, though, unlike many, the calyx, which is coloured, is the beautiful part. If healthy, the flowers when shaken give out a sweet liquid, which the natives of the Cape, where it is found, highly prize as an enjoyable drink, supposed to have a very fine aroma. To flower this plant it should be planted on the sunny side of a wall, taking care, by protection from frost, to retain the young topmost shoots of last summer through winter, as if they are lost so is also the flower for the succeeding spring, for it always flowers upon the late mid-summer's shoots. Strong, rich soil induces it to grow to strong shoots. As a rule, to withstand the winter, I would recommend poor soil when it is planted out.

*Agrostemma coronaria*.—As regards merit, this, I am forced to confess, is behind each of the others yet enumerated; but as a free bloomer, singular foliage plant, &c., I give it a place. The following is one of my earliest notes taken of the same—"Rather a pretty plant, with upright habit, having very woolly leaves covered with an apparent mass of white hairs, distinct in winter from its greener companions; a profuse flowerer, with flowers an inch in diameter." Found among other places upon the mountains of Switzerland. Flowers from June to August.

*Silene compacta*.—This beautiful plant is strictly a biennial. It is a very showy plant, growing some 2 feet high, when well manured, &c.; and when starved upon rockwork or so, it is a dwarf, compact, free-blooming plant, and a very useful one, being perfectly hardy. It is propagated by seeds sown in the beginning of April, to be eventually transplanted where to flower in August. Native of Mount Caucasus.

*Argemone grandiflora*.—This is one of those exceedingly showy plants, easily grown, and is deserving of a place in the back row. Generally flowering in July. It has rather singular foliage, and is a native of Mexico.

*Aquilegia glandulosa*.—When properly grown I do not hesitate to express a belief that this is one of the most showy plants a garden can be possessed of. The flowers are large, of a deep blue, and what gardeners would call in their vernacular, "a self." It likes a dry situation, with sandy loam and leaf mould. Flowers between May and July.

*Dianthus libanotis*.—Though not a new Pink, yet I think it will vie in beauty and singularity with many of the more recently-introduced Chinese kinds. It grows some 3 feet or 4 feet high; likes a warm, dryish locality, and moderately good garden soil. Flowers in August and September very beautifully.

*Hesperis grandiflora*.—A showy plant, growing some 2½ feet high. To grow it properly it requires more care than many of its class, as it requires to be transplanted by means of dividing the young shoots from the old flowering-stem, placing in a cold frame during winter, to be turned out in the spring to a good place in the border.

*Corydalis nobilis*.—This is one of those beautiful objects which push through the earth in spring as do our Crocuses, Snowdrops, &c., of which we are quite unconscious until we behold them. From its sweet scent I have supposed this to be Primrose-scented. It is not exceedingly pretty or curious, but as suited to the front row, rockwork, or so, I give it a place. The green of its foliage is of a very pleasing tint; flowers, golden with dark velvety spots. Flowers in May and June.

*Anemone narcissiflora*.—A pretty, free-flowering variety, cream-coloured, fond of chalky soil. Flowers about May. Introduced from Canada.

*Leontice altaica*.—A very useful plant for front row or rockwork. Producing yellow flowers in spikes, from a tuberous root like the two above. It is a tolerably free bloomer. From the Altai Mountains.

*Epimedium macranthum*.—I believe this is called large-flowered, though possessed of very small ones. Very singular, and exceedingly pretty, taking the plant as a whole; about a foot

high, having leaves, in form triternate, of a lively green. The flowers upon the points of the young shoots giving it a very light, artistic appearance. Native of Japan. Flowers in May and June.—W. EARLEY, *Digswell*.

## SCHOOL OF AGRICULTURE.

WILL some of our readers be good enough to furnish the following information?

"Can you recommend or name any school where the study of natural science is alternated with practical gardening or farming? I wish to place my son, fourteen years of age, where his strong inclination for a rural life may be fitly directed, and industrious habits acquired; but I am altogether ignorant of the whereabouts of any such institution.—DOCTOR."

## GAS-WATER DESTRUCTIVE TO GARDEN INSECTS.

THE almost universal complaint of the ravages made by slugs and caterpillars in gardens this season is a sufficient apology for taking notice of any remedy, however simple, which promises in the slightest degree to alleviate the evil. Among other remedies which have been applied with beneficial results this year is gas-water—that is, water from a gas-tank. It has been applied in various ways, and to different kinds of insects, and, if not a panacea for all the ills that gardens are heir to, its effects have been such as are worth chronicling. A gentleman has favoured us with his experiments on an Apricot tree which had been seized by the vermin. Being anxious to secure the fruit, he had the tree protected by a covering of pretty close gauze-work. On removing the covering one day to inspect the progress of the fruit, he found that the caterpillar had got about halfway up the tree, and was devouring every leaf in its progress. He applied the gas-water by means of a common watering-pan, and after a pretty liberal application of the fluid at intervals during a space of four days, he found that he had completely destroyed the caterpillar, and saved his crop of Apricots. The same plan was followed with Currant bushes, and the same beneficial results followed. It was also applied to vegetables which were attacked by the worm at the root. Where the plants exhibited signs of being attacked, a hole was made in a slanting direction, so as to command access to the root, into which the water was poured. This plan, we are assured, seldom failed in destroying the insect, without endangering the plant. Those in the neighbourhood of towns will have little difficulty in obtaining a quantity sufficient for a few applications; and, as but few applications are necessary, the remedy can be easily tested.—(*Scottish Farmer*.)

## GREEN'S MOWING MACHINES.

I NOTE a paragraph in your Journal (dated August 5th), headed "Ornamental Gardening," in which "R. F." expresses his confidence in my machines, having two in use, but complains that they make a great noise when drawn backwards. If "R. F." will just lift up the machines so that the large drums will clear the ground, he will find that he can easily run the machines about on the front rollers, and avoid all the unpleasant noise he complains of. This is only necessary with my light single-handed machines, 10 inches, 12 inches, 14 inches, and 16 inches. All above that size being heavier, have a lever for withdrawing the catches.—THOS. GREEN.

ASPARAGUS TOPS.—Asparagus stems cut now half-way down and dried in the sun make a light shade for fruit blossom in the early spring. Cut now it is not so brittle as later, keeps the Asparagus erect, does not weaken the stools, and allows the beds to be cleared of surface weeds which are otherwise hidden. This may not be new, but it is very useful.—J. R. A. DOUGLAS.

STEPHENS' TOBACCO FUMIGATOR.—Having received many inquiries from your readers requesting information as to where they can purchase my new Tobacco Fumigator, I beg to state in an answer to them all that it is made by Messrs. Shillito and Shorland, 95, Stratford Road, Manchester.—JAMES STEPHENS, *Barlowmoor, Didsbury, Manchester*.

## OSIERS.

SEEING an answer in the last Number of your periodical about Osier-beds, it occurred to me that you would be able to furnish me with information as to the mode of preparing the land, the variety of Osier, the distance from plant to plant, whether cuttings or rooted plants are used, and where obtained?—P. B.

[The varieties are numerous, and in a very confused state, innumerable intermediate forms existing among the species. The selection of any particular variety for cultivation will be dependent, in a great measure, on the soil of the locality, and the purpose for which the rods are required.

The best variety of the common Osier, *Salix viminalis*, is the Speckled or Blotched, known also by several other names, which is good for basket-making. Most of the other varieties are coarse, brittle, and worthless. Of the Long-leaved Willow, *Salix triandra*, there are likewise several varieties, the best being the Black-budded Spaniard, which is much used for the handles, bottoms, and rims of baskets. The Basket Osier, *Salix Forbyana*, and Hollander, are very strong, and much esteemed for the finer kinds of basket-work. The French, or real French, and the Stone Osier, are excellent for fine work. The Green-leaved Osier or Ornard, *Salix rubra*, is very tough, and is preferred for carboy baskets; and the Bitter Ornard, *Salix purpurea*, and Golden Osier, *Salix vitellina*, being slender and tough are very useful for the finer kinds of baskets, as well as for tying and binding. The Silver Osier, the Bastard French, the Blunt-leaved Ornard, and some others, are used for coarse work, hampers, &c.

Some kinds will do very well in light soil, where there is an abundant supply of moisture; but rich, loamy ground, with a retentive subsoil is that in which the Osier attains the greatest perfection. The growth is always most luxuriant in the alluvial grounds by the banks of rivers, which are frequently flooded, and where the surface consequently receives a rich top-dressing of mud.

Prepare the ground by trenching 15 inches deep, and plant any time after the fall of the leaf; but best in the end of February or early in March. Take cuttings 15 inches in length from the lower ends of the well-ripened shoots, and insert them at least half their length in the ground. In rich soil where the Osier grows luxuriantly the rows may be 2 feet to 3 feet apart, according to the kind, and the sets 18 inches from each other in the row; but in light land 18 inches by 16 inches will be sufficient. We can give you no idea where the sets can be obtained. The basket-makers are the most likely persons to know.]

## WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 376.)

## CRUSTACEA—(concluded).

**NIKA EDULIS.**—This little creature is, according to Professor Bell, one of the rarest of our British species. It is found, however, occasionally on the southern coast of Devon. Its length is from two inches to two inches and a half; the colour a flesh red, more or less spotted with yellow and white, and marked along the back with spots of these colours. One particular singularity of the *Nika edulis* is, that the body is stated to be so transparent that the viscera may be seen through the integument. The whole of the shell is smooth; the upper portion, or carapace, slightly rounded, and terminating in a short, pointed rostrum. The external antennæ are remarkably long. The first pair of feet are different, one being two-toed, the other one-toed. Another inequality is observable in the second pair of feet, the right being considerably longer than the left. The fourth pair again are longer than the third or fifth, the fifth being the shortest.

**ATHANAS NITESCENS.**—This minute Crustacean, which measures but little more than half an inch, is not very common, although it is stated by Dr. Leach to be "occasionally found in pools left by the tide among the rocks on the coasts of Devon and Cornwall." The carapace is quite smooth, and narrowed towards the point, where it terminates in a pointed rostrum, about half the length of the carapace itself. The anterior legs are stout and strong, compared to the size of the animal; the second pair are very slender; the remaining pairs simple and slender. There would seem to be a doubt as to its colour, but light buff is that suggested by Professor Bell.

**THE VARYING HIPPOLYTE (*Hippolyte varians*).**—This is a

beautiful little species, measuring about three-quarters of an inch in length. Its ordinary colour is a bright, clear green, although Dr. Leach states that "it is very variable in colour, occurring with every shade of green, and of every tint between reddish and liver brown." The carapace is smooth, terminating anteriorly in a long, straight rostrum, which has a tooth near the base on the upper side, and another very much smaller near the apex. The first pair of feet are short and thick, the second pair are shorter than the third.

"This," says Professor Bell, "is the most abundant of all our species of Hippolyte, though probably not the most extensively distributed." "It is found," says Dr. Leach, "in profusion in pools amongst the rocks on the south-western coast of Devon and Cornwall. It is common all along that coast, and as far as Poole Harbour in Dorsetshire. It has been found extensively round the Irish coast." Mr. W. Thompson says, "It has been taken commonly by Mr. Hyndman and myself in the rock pools accessible at low water throughout the Down coast, and has been dredged by us in deep water on the north-east coast, and in Killery Bay, Connemara. Mr. R. Ball has specimens from the shores about Dublin. It is a beautiful and elegant species, but loses its lovely green colour soon after death."

**PAUDALUS ANNULICORNIS.**—"At first sight," says Professor Bell, "this species may be readily mistaken for a common Prawn; but a closer examination will show that its structural relations are much nearer to *Hippolyte* than to *Palaemon*." The carapace is smooth, terminating in a rostrum as long as itself. This rostrum is turned upwards towards its extremity, and for about half its length from the base furnished with teeth; it also has five teeth beneath. The eyes are remarkably large; the external antennæ are extremely long, and are marked with rings alternately dark and light throughout their entire length. The fore feet are simple, and slightly curved; the second pair very unequal both in size and length, one being very long and slender, the other short and thick; both, however, are two-toed. The rest of the feet are simple, and nearly of equal length, the end joint having on the under surface a row of spines. The ordinary length is from two inches to two inches and a half. The colour is a reddish-grey, curiously marked, and spotted with deeper red. "It is used," says Dr. Leach, "at Yarmouth as an article of food, and is at that place so much esteemed for the table as to afford constant employment during the summer season to several fishermen, who take it in abundance at a considerable distance from the shore, and name it from that circumstance the Sea Shrimp." It is found commonly on the southern coasts of England, and Professor Bell adds, "I have occasionally known it brought to the London markets, where, however, it is usually seen of small size."

**MYTIS CHAMELEON.**—The carapace of this small but very common species is slender, terminating in a very short rostrum. The eyes are large, and placed on a short, thick peduncle or stalk. The antennæ are also placed on stalks. Its length is about an inch and a quarter. With regard to its colour, which, as its name implies, varies, we will make use of some remarks of Mr. Vaughan Thompson. "Nothing," this gentleman remarks, "can show the fallacy of colour in distinguishing the species more clearly than the variety of tints which *Mytis Chamaleon* assumes as it occurs here in the river Lee and the Harbour of Cove, and which have suggested its trivial name. In the upper part of the river, below the city of Cork, it occurs of different shades of grey, inclining at times to black, having invariably the greater part of the anterior scales, inner branch of the inferior antennæ and joints of the outer laminae of the tail, black, and the fringe of the scales tinged with pink; lower down amongst the littoral fucæ it takes various tints of brown, and those obtained from sites abounding in *Zostera* and *Ulva* present us with green colours of greater or less intensity." "This is perhaps," says Professor Bell, "the most common and the most widely distributed of our native species. I have received it from various parts of the coast, both of England and Ireland, but from no place in such numbers as from Weymouth, where it sometimes swarms."

**SQUILLA DESMARESTII.**—This is a strange and beautiful species. The carapace is narrowed anteriorly, slightly marked and grooved. The claws are long and stout; the prehensile finger armed with five sharp teeth. The length is about three inches.

The *Squilla Desmarestii* is taken off Cornwall, and "I am informed," says Professor Bell, "by Mr. A. G. More, of Bem-

bridge, Isle of Wight, and of Trinity College, Cambridge, that it has also been taken repeatedly off Bembridge, by the fishermen of that place, on a muddy bottom grown over with 'grass' (*Zostera*); and from a sketch with which that gentleman has favoured me, and the testimony of the fishermen, it would appear that it has there attained nearly the size of those taken in the Mediterranean, whilst those found on the coast of Cornwall have not exceeded two inches and a quarter." "It abounds, Professor Bell proceeds to state, "amongst the rocks near the coast, in company with various Palemonidæ; and Roux informs us that it is commonly eaten fried with such smaller *Macroura*. Its habits are wholly nocturnal, as it hides itself always during the day. The colours of this species are described as very pleasing; the general tint is a yellowish-brown, the pincers white with a slight hue of rose. The scales of the antennæ and those of the tail are fringed with long, rose-coloured cilia. Two remarkable varieties are mentioned—one of a delicate rose colour, and the other a deep yellow, slightly varied with brown."

With this creature we conclude our notice of the Crustacea; some few species have been omitted, but such only whose rarity renders it improbable that they would come under the notice of the ordinary tourist. We shall now proceed to the next and last division of our subject—the *Mollusca*.—W.

(To be continued.)

## EXTRACTS FROM A TOO-MUCH NEGLECTED BOOK.

**PUMPKINS.**—*Saturday, September 16.*—Pleasant soft weather. The farmers are ploughing and sowing grain, and have been doing so for some days; they are earlier than they used to be with their autumn seed-time. The Buckwheat fields are turning red, and will soon be cut. The Maize-stalks are drying and withering as the ears ripen; on some farms they are harvesting both crops—red Buckwheat-sheaves, and withered corn-stalks, are standing about the fields. All through the summer months the Maize fields are beautiful with their long glossy leaves; but when ripe, dry, and colourless, they will not compare with the waving lawns of other grains. The golden ears, however, after the husk has been taken off, are perhaps the noblest heads of grain in the world; the rich piles now lying about the fields are a sight to rejoice the farmer's heart.

The great Pumpkins, always grown with Maize, are also lying ripening in the sun; as we have had no frost yet, the vines are still green. When they are harvested and gathered in heaps the Pumpkins rival the yellow corn in richness; and a farm-wagon carrying a load of husked corn and Pumpkins, bears as handsome a load of produce as the country yields. It is a precious one, too, for the farmer and his flocks.

Cattle are very fond of Pumpkins; it is pleasant to see what a feast the honest creatures make of them in the barnyard; they evidently consider them a great dainty, far superior to common provender. But in this part of the world, not only the cattle, but men, women, and children—we all eat Pumpkins. Yesterday, the first pumpkin-pie of the season made its appearance on table. It seems rather strange, at a first glance, that in a country where Apples, and Plums, and Peaches, and Cranberries abound, the Pumpkin should be held in high favour for pies. But this is a taste which may probably be traced back to the early colonists; the first housewives of New England found no Apples or Quinces in the wilderness; but Pumpkins may have been raised the first summer after they landed at Plymouth. At any rate, we know that they were soon turned to account in this way.

The old Hollander, Van der Donck, in his account of the New Netherlands, published in 1656, mentions the Pumpkin as being held in high favour in New Amsterdam, and adds, that the English colonists—meaning those of New England—"use it also for pastry." This is probably the first printed allusion to the pumpkin-pie in our annals. Even at the present day, in new Western settlements where the supply of fruit is necessarily small at first, Pumpkins were made into preserves, and as such pains are taken in preparing them as though they were the finest Peaches from the markets of Philadelphia and Baltimore.

When it is once proved that pumpkin-pies were provided for the children of the first colonists by their worthy mothers, the fact that a partiality for them continued long after other good things were provided, is not at all surprising, since the grown man will very generally be found to cherish an exalted opinion

of the pies of his childhood. What bread-and-milk, what rice-puddings, can possibly equal the bread-and-milk, the rice-puddings of the schoolboy?

The noble sex, especially, are much given to these tender memories of youthful dainties, and it generally happens, too, that the pie or pudding so affectionately remembered, was home-made; you will not often find the confectioner's tart, bought with sixpence of pocket-money, so indelibly stamped in recollections of the past.

There is at all times a peculiar sort of interest about a simple home-made meal, not felt where a *cordon-bleu* presides; there is a touch of anxiety in the breast of the housekeeper as to the fate of the boiled and roast, the bread and paste, preserves and other eates, which now changes to the depression of a failure, now to the triumph of brilliant success, emotions which are of course shared, in a greater or less degree, by all who partake of the viands, according to the state of the different appetites and sensibilities.

But this ghost of the schoolboy pie, this spectral plum-pudding, sitting in judgment upon the present generation of pies and puddings, when it takes possession of husband, brother, or father, has often proved the despair of a housekeeper. In such a case, no painstaking labours, no nice mixing of ingredients, no careful injunctions to cook or baker, are of any use whatever; that the pie of to-day can equal the pie of five-and-twenty years since, is a pure impossibility.

The pudding is tolerable, perhaps—it does pretty well—they are much obliged to you for the pains you have taken—yea, they will take a little more—another spoonful, if you please—still, if they must speak with perfect frankness, the rice-pudding, the plum-tart, the apple-pie they are now eating, will no more compare with the puddings, and tarts, and pies eaten every day in past times at their good mother's table, than—language fails to express the breadth of the comparison!

Such being man's nature, *apropos* of pies and puddings, it follows, of course, that the pumpkin-pies eaten by the first tribe of little Yankee boys were never equalled by those made of Peaches and Plums in later years, and the pumpkin-pie was accordingly promoted from that period to the first place in pastry, among all good Yankees. Probably the first of the kind were simple enough; eggs, cream, brandy, rose-water, nutmegs, ginger, and cinnamon, are all used now to flavour them, but some of these ingredients must have been very precious to the early colonists, too valuable to be thrown into pies.

Probably, there was also another reason why the pumpkin-pie was so much in favour in New England; it had never made part of Christmas cheer; it was not in the least like the mince-pie, that abomination of their stern old fathers. We hardly know whether to laugh or to cry when we remember the fierce attacks made upon the roasted boar's head, the mince-pies, and other good things of that kind, by the early Puritans; but when we recollect the reason of this enmity, we mourn over the evils that prejudice brings about in this world.

Strange, indeed, that men endowed with many Christian virtues should have ever thought it a duty to oppose so bitterly the celebration of a festival in honour of the nativity of Christ! Happily, Time, the great ally of Truth has worked a change in this respect; Christmas is kept throughout the country, and mince-pies are eaten with a quiet conscience and very good appetite by everybody. And what is vastly to the credit of the community, while all have returned to the mince-pie, all are quite capable of doing justice to a good pumpkin-pie also, and by a very happy state of things, the rival pastries are found on the same tables from Thanksgiving to Ash-Wednesday.

Mince-pies are even more in favour in this country than in England; some people eat them all the year round; I have been offered a slice on the eve of the 4th of July. Those made by the farmer's wives about the country are, however, very coarse imitations of the real thing; their paste is made with lard, and always heavy; coarsely-hashed meat, and apples, and suet, with a little spice, are the chief ingredients, and a dish more favourable to dyspepsia could not easily be put together.—(*Miss Cooper's Journal of a Naturalist in the United States.*)

**A LARGE ONION-GROWER.**—Mr. Circuit, a farmer at East Ham, Essex, employs upwards of six hundred people (men, boys, and women) in pulling, carting, and peeling Onions for pickling, and they are thus engaged for two months. He pays wages to the amount of £200 weekly, and the cost of each acre of Onions

averages £100. This includes preparing the ground, seed, weeding, gathering, and peeling. He has sowed nearly a ton of Onion seed. The Onions are pulled by women, by the rod, and skinned by the gallow.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

It may be useful to repeat that the destruction of weeds should always be considered an obligation due to the crops as well as to the soil, and that its efficient performance is weakened by delay. As the wet weather which has prevailed lately will probably cause a very general activity amongst annual weeds, corresponding exertions should be made for their extirpation. Within a day or two of the 21st of the month make the main sowings of Cauliflower, Bath Cos, Cabbage Lettuces, and Red Cabbage, to stand through the winter. As luxuriant growth is not desirable, the soil should not be too rich. Sow thin, and prick-out in time before they become leggy. *Cabbage*, another sowing may be made to stand in the seed-bed through the winter. A late sowing sometimes comes in very useful. *Dwarf Kidney Beans*, keep the crop closely gathered; if they are allowed to remain until they are too old for use they discontinue to bear as they otherwise would. *Endive*, a late sowing may be made. Keep up successional plantings from former sowings. *Onions*, the main crops to be pulled up, and the roots exposed to the sun: this is the more necessary, because as soon as the bulbs have attained their full growth, they will in a very short time begin either to decay at the root, or else strike root again into the earth, which is detrimental to their keeping. *Radishes*, make another sowing of Black and White Spanish, and also of the Turnip-rooted sorts. *Turnips*, it is not yet too late to sow for winter and spring use, for which purpose the ground where Potatoes have been lifted is very suitable. *Tomatoes* to be kept thinned, the shoots fastened to the wall or fence, and the fruit to be well exposed. *Vegetable Marrows*, see that they do not want for water.

### FLOWER GARDEN.

Continue to prick-out biennial and perennial plants in succession into nursery-beds. Give waterings in dry weather until they get good hold of the soil. Encourage those already pricked-out by frequent surface-stirring between the rows. Continue to plant-out the Pinks as soon as they are struck. The propagation of herbaceous plants, if the stock is deficient in any respect, should be attended to; the division of the old plants, in many instances, will be the preferable mode. Those who can find time may pick off the seed-pods from Rhododendrons and Azaleas: this will add much to the strength of the blossoms next year.

### FRUIT GARDEN.

As solar light is diminishing, particular attention should now be given to fruit trees. All the tender sorts of trained fruit trees will now be benefited by a constant stopping of the growing shoots. In looking over Peach and Nectarine trees it will be found that many of the shoots which were considered necessary and nailed-in for succeeding crops, will begin to overlap each other; a number of these should be stopped at this time. Any superfluous shoots of Pears that may have been retained, with the idea of preventing the blossom-buds of next year from "breaking," should now be well shortened-back to admit light and air to the shoots: thus cut back to form "spurs," and each carrying three or four leaves, they will assist in producing elaborated matter, both to nourish the fruit and to invigorate the embryo blossom-buds now actively engaged in depositing food for a healthy development in the ensuing spring. Keep the lateral growth of Vines removed, and the shoots spread out as openly as possible. Figs to have their principal shoots nailed-in, and the remainder taken off. Suckers of the same to be constantly removed. The sooner the new beds of Strawberries are finished the better. Raspberry canes to be stopped, and all small and spurious shoots cleared away.

### GREENHOUSE AND CONSERVATORY.

Attention should be directed to the stock of Chrysanthemums, Veronicas, late Fuchsias, Achimenes, Scarlet and other Pelargoniums, Verbenas, and Ageratum. Salvias, although not rare, will withstand the gloom of autumn, and greatly assist in keeping up a gay appearance to a late period. The continuance of unfavourable weather will render a further introduction of tender plants advisable. Those allowed to remain outside in the open air should

be carefully examined, and the assurance obtained that they are receiving no injury from defects of drainage or the presence of worms. Pelargoniums which have been cut down as advised, and have commenced to grow, to be shaken out of their pots and repotted into others of smaller size. Sow Mignonette for blooming late in the season. Keep climbers free from decayed leaves and faded blooms; remove any straggling shoots. Plants in pots that have not been placed out of doors should now be shifted if they are likely to require it before the spring, so as to make fresh roots before cold and damp weather sets in.

### PITS AND FRAMES.

Make all necessary preparations here for propagating plants for next year's decoration of the flower garden. See that all the structures are in good repair; all lights that require it to be glazed and painted, and the interior of the pots smartened-up by applying the whitewash-brush. Turf-pits, too, if damaged to be repaired. W. KEANE.

## DOINGS OF THE LAST WEEK.

VERY little difference from last week. The rain that we desired so much came, and gave us a good supply of water in our tanks, and made everything grow just as we wished it to do, though the weather has been cloudy and cold since. Of the "everything," however, I must except Prince's Feather in the flower garden—a great favourite with me, and a gorgeous affair in a hot season, without which it will rise to no height. I sowed the seed carefully from a beautiful bushy variety that was from 3½ feet to 4 feet in height last season, and this season it has not got to 18 inches yet—just a foot too low at least for what I wanted. Love-lies-bleeding, another grand old plant, has done better, showing that it does not require so high a temperature. These plants were carefully pricked-out, and then planted out. Those sown in the open air are not above half the height. I have long noticed that the plants grow little until the warm nights come in, and as yet we have known little of the heats of summer.

### KITCHEN GARDEN.

Weeding, surface-stirring, Pea-staking, and walk-rolling after the rains, have been the principal operations; looking after seed ling. Turnips and Radishes to keep the birds and slugs from them; throwing a little soot, lime, and burnt ashes over them when damp in a morning.

### FRUIT GARDEN.

Proceeded with regulating fruit trees, planting Strawberries, potting Strawberries for forcing that were laid in small 60-pots, and taking some up and potting in 60's at once. This is late enough, but we could not help ourselves, having so much just now to attend to in the flower garden, &c. These potted into 60's will have a little help from a slight hotbed of grass and rotten leaves, just to fill the pots with roots, when they will be potted as the layered ones. A good lot will also be pricked-out on a rich border some 6 inches apart, and these we can raise and force if needed after March. I have no faith in forcing plants before that time that were not potted and had well filled the pots with roots, as well as had the buds well ripened the previous autumn. The sorts we are now potting are chiefly Keens' and Queens, and mostly one in a six or seven-inch pot. The small plants in the 60-pots are brought to the temporary potting-bench, shaken out of the pot, and placed well up in the larger pot, the main bud being only a little below the rim. The soil is pressed firm in the bottom of the larger pot to prevent much sinking, the roots gently disentangled, and rich loam placed as firmly as possible round the balls, and then the pots placed in an open position full in the sun, and on a hard bottom. Water is given; but if the sun should be powerful a slight shading may be given, or, what is better, frequent dewings from a syringe, so that a leaf shall never be seen to flag. Many people treat their Strawberry plants as they do cuttings of various plants—allow the leaves to hang down and flag that they may have the pleasure of seeing how water will revive them. We think it is better never to allow a leaf to flag in either case. We know that plants as well as animals may survive much bad treatment—that they may have too much one day, and death may come as the remedy; and at any rate, it is such an unpleasant thing to see plant or animal endure suffering which a little attention would avoid.

In fruit-houses much the same as last week.

### HOUSES AND PLEASURE GROUNDS.

Much the same as last week, having had much to do to get all

the lawn and flower-beds up to the mark in tidiness for one day. A friend tells me I should try moss in the beds to keep them moist. Well, here, as I stated last week, if I did not fasten the moss down it would soon be over all the place by the winds and birds, and in a dry season I should never get water to keep it green, and brown moss has little of the attractive about it. It is used largely in the flower-beds at Woodstock, in Ireland, but then there is more of a dripping climate there, I believe. In general the plants conceal the earth pretty well, but I think that many beds that this season show a rim of earth between the foliage and the grass, would have been better if carpeted with some low plant that would make a nice border as well. I know some artists prefer to see a rim of earth between the plants and the grass or gravel, though I would prefer seeing no earth at all. I certainly should prefer the moss to the earth if it could be kept at all green and firm in its place. Commenced with preparations for cuttings. Will take a few Verbenas first, and as a precaution draw the cuttings, except their base, through weak tobacco water. This is sure to leave thrips, &c., behind if there should be such things, and in this as well as in most similar matters, prevention is better than cure. As a whole, Verbenas here have not been up to the mark this season.—R. F.

### TRADE CATALOGUES RECEIVED.

*A Catalogue of Stove, Greenhouse, and Hardy Plants, Hyacinths, and other Bulbous Roots, by Robert Parker, Exotic Nursery, Tooting, Surrey, S.*

*Wm. Cutbush & Son's Descriptive Catalogue of Bulbs for 1863. Highgate, London, N.*

*B. S. Williams' Descriptive Catalogue of Hyacinths and other Bulbous Roots. 1862. Holloway, London, N.*

*Catalogue of Dutch Flower-Roots, &c., by Edward Taylor, Malton, Yorkshire. 1862.*

*Richard Smith's List of Evergreen and Deciduous Shrubs, Rhododendrons, &c. Worcester, 1862.*

### TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We cannot reply privately to any communication unless under very special circumstances.

**CERASTIUMS (M. H.).**—You are just in time to remind Mr. Beaton, that with all his sayings about Cerastiums to-day, that he has not said one word on their cultivation. But the truth is, any garden or soil that will grow a Snowdrop or a Crocus, will grow both the Cerastiums to perfection. All that they require to be done to them is merely to plant them, in any way you choose, any day in the year; and they will take care of themselves for years and years to come, if you take care they do not overrun their bounds, and smother things near them. And in April, if you will it, they will do to be planted by cuttings where they are to remain, and all the cuttings want is to be put in right and straight in rows, or round about in circles and bends—in short, the only difficulty about these two Cerastiums is, that they require no care, no forethought, no nothing, but room to grow in, and to be let alone without any bother about gardening and all that sort of thing; but, of course, people must see they do not grow much out of bounds.

**LETTUCE (Idem).**—Our Lettuce never runs to seed, because we never plant any, and yet we have a full supply the whole season. We sow them every third Monday from February to May, and every other Monday from May to August. We sow very thin indeed, and thin when we see two within 10 inches of each other. We learned the plan in 1826 from Mr. N. Niven, of Drumcondra, and in 1846 we proved the superiority of it over all other methods; for then Lettuces round about us did little else but seed, while ours did better than in colder seasons.

**FRUIT GARDEN (M. B.).**—You cannot safely move Raspberry and Currant bushes before the beginning or middle of October, and then it is too late to sow grass seeds. You had better take time and do it well. You will be just as forward with the grass if sown in the spring.

**PLUM TREE PRUNING (J. H.).**—Frost is doubtless the cause of your Plums not bearing, particularly if the blossom was strong. You should cover with tiffany in spring, and keep it on till after the fruit has well set. Do not cut back the spurs of last year. You did quite right in shortening last year's wood.

**VEGETABLES AND EVERGREENS (W. D. Paine).**—Dress your Asparagus with a quarter of a pound of salt to the square yard in winter, and again in summer. At the latter period let it be done in showery weather, and in both cases rake it in. You may cut out the old wood from evergreens at any time; but undoubtedly the best time to do so is in spring if the parts to be removed are large, because the wounds made will be more speedily covered by the new growth that then begins.

**VINES IN POTS (W. R. J.).**—Shift the Vines into larger pots when they have gone to rest. Drain the pots thoroughly; there is no fear of the roots, as they will be sure to find their way into the border.

**ROSES AND AZALEAS (H. W. Down).**—Repeat and cut down your Roses in autumn after the leaves have fallen. If you want them to flower in February you must begin forcing in January; if in March, in February. Pot Azaleas whenever they have made their growth.

**FLOWER GARDEN ARRANGEMENTS (Tyro).**—Your three ribbon-borders are particularly well planted, and your promenade-beds are even better done. Thus, No. 1 ribbon, Lady Middleton Geranium next the shrubs, *Calceolaria amplexicaulis* to be trained down in front of it, then Christina, then Purple King, and then Variegated Mint. No. 2, in front of a wall, Rose of England Geranium at the back, Purple King next, and then the Golden Chain and Box edging. No. 3, also in front of a wall 70 feet long, Christina next the wall, *Coleus Verschaffeltii* next, and Lady Plymouth in front. All very good. As Lady Plymouth is the best, if not the only variegated Geranium with which *Alyssum variegatum* will agree perfectly, we should be tempted to put every third plant in the Lady's row of that *Alyssum*, if only to deepen the perfect contrast between the front and second rows, and we could not just now name three rows more telling for contrast. Your promenade-beds, a circle and an oblong bed alternately—not "panel bed" which is quite a different arrangement. The circles are 9 feet across, the oblongs the same, and 25 feet in length—that is, 2 feet short of three times the width, which is about the rule to go by. The centre of the circles in Scarlet Geranium, then a band of Purple King Verbena, then another band of *Triomphe de l'Élyris*, and the edge of *Cerastium tomentosum*; but of course you will get *Biebersteini* for next year. The oblong beds are on the ridge-and-furrow or span-roof system. The double white "Everfew" in the centre (not *Ageratum*), *Calceolaria anrea floribunda* on each side, Christina on the same plan, *Lobelia speciosa* ditto, and *Cerastium tomentosum* all round the whole. Of all our labours nothing gives us more real pleasure than to see how well and how soon the right principles of planting flowers take root.

**VINERY (Notice, Manchester).**—There is not the slightest objection to the form of vinery you refer to in your communication. Our reply was given upon the belief that you had not made any beginning in its construction.

**STRATHMORE HERO TEA (J. Divers).**—This is the same as Tall Green Mammoth, and several other names. It is a first-rate sort. The wet season has no doubt affected it.

**FLOWER GARDEN (Claude Rouget).**—Your three arrangements are without a fault. No. 1 is the best; No. 3 the next best; and if you adopt No. 2, all the alteration needed is to put Royal Dwarf Geranium where you have Tom Thumb now, and put up Tom in the centre of the circle No. 5. If you adopt No. 1, you must replace Kingsbury Pet in 5 and 6 by Christina, for it will not stand the sun there; or if it did, your successful attempt at shading the three Geraniums would be lost. Thus, Cottage Maid, Trentham Rose, Cerise Unique, and Christina give the soft tint in front, and Cottage Maid the hard tint on the off side of the shaded pinks. The Pet would muddle your shading. All the rest most capitally done.

**CLETHRA ARBOREA (W. R. S.).**—Your five-year-old *Clethra arborea* will be a young plant, comparatively, when it is fifteen years of age, at thirty-five it will be getting into manhood, and at forty-five it will be at its prime. Do not throw it away if it do not flower for two or three years yet; it will certainly not flower this autumn. It is one of the very best pot or tub plants in England, or in all Europe, only the people of this improved generation, or most of them, are not yet aware of that fact. Out of a hundred thousand people who thronged the new garden of the Royal Horticultural Society on the occasion of the distribution of the prizes for the grand International Exhibition, twenty thousand were knowing garden people, and every one of the number confessed and acknowledged that Mr. Eyles' *Clethra arborea*, then in full bloom in the great conservatory, was the best flowered pot-evergreen they had ever seen; and well they might. But Mr. Eyles gives a touch of the Chatsworth school to such plants as he thinks are worthy of it, and *Clethra arborea*, being what we have just said, has been done on that model, and the result is now before you; nevertheless, as your plant will not bloom this year, if you must part with it, pray send it to Mr. Eyles.

**FUCHSIAS (M. F.).**—You may put in Fuchsia cuttings now, but spring is the best time. Plant slips of Lemon Thyme in spring.

**CROSSING PELARGONIUMS (C. P.).**—We believe that Sweet's *Pelargonium grandiflorum* (*Geraniaceae* 29) from the Cape, is the original parent of all the white that is now in the plants of the florists, all the other white kinds having been discarded by the early breeders; that *Cucullatum* rules the leaf of the best of the race to this day; that the dark blotches are due to *Cucullatum*'s purple having been eradicated, or confined to a speck, as in *Ignescens minor*, by the superior power of the scarlet of *Fulgidum*. Then if any practical result is sought by "C. D.'s" crossing, there are three distinct species represented by *Alba multiflora* and Queen of the Scarlet according to this genealogy. About 1820 there were nine or ten original white *Pelargoniums*, and doubt that number of pale purple, pink, and streaky ones in Sir Richard Hoare's collections near Bath, and in Lady Cumming Gordon's collection at Aitrye, near Forres, in Scotland. About that time the breeders discarded the whole except *Grandiflorum* for white, *Cucullatum* for purple, leaf, and stature, and the strain from *Fulgidum* was then barren, after reducing the purple of *Cucullatum* to a brown speck—the origin of the present blotch.

**CROCUS BULBS (T. C.).**—Mr. Beaton requests us to thank you for him, and say the rare Crocuses and other bulbs came safe to hand, and were put into damp cocoa refuse stuff to sprout roots before potting. Also to remind our readers that this is the most safe way with all far-travelled bulbs, for tender ones, and for all those from foreign countries out of Europe. Pot none of them till the roots have sprouted. They will keep quite safe for months or years in the cocoa-nut stuff, even if they did not push a root, and the stuff is preferable to sand to put round bulbs at planting or potting time.

**SCARLET GERANIUM (R. R., Berks).**—As far as we can judge from a cut flower, your seedling must be a good bedder. The horse-shoe mark is very large, but not nearly so deep and distinct as that in Baron Ricassoli.

**FASTOLF RASPBERRIES (M. F.).**—They want to be renewed. Make a new plantation on another piece of ground, and, when it comes into bearing, destroy your present one. You might in the meantime try a good manuring.

**MINIATURE POTS (A Notice).**—Some of the seedlings will answer well for this purpose—such as some *Mammillarias*, *Cereus*, *Euphorbias*, *Sedums*, *Crasulads*, or any plants, in fact, that do not require much pot-room.

**HARDY EXOTIC FERNS** (*Angus*).—The work you refer to will not be ready before next spring. There has been no edition of *London's Hortus Britannicus* since the large supplement was added in 1850, and there has not been any other work similar to it published since that we are aware of.

**FLOWER-GARDEN PLAN** (*W. E., Herbs*).—We are very much obliged to you for your offer of the plans, but we do not intend to publish any more at present. If we should determine to do so we shall communicate with you.

**RHUBARB** (*B. K.*).—By your question we presume that you refer to the stalks of the leaves of Rhubarb. If so, they are no more entitled to be called fruit than the stalks of Sea Kale, or the shoots of Asparagus.

**FUCHSIAS AND GERANIUMS** (*Anna Craigie*).—You will find full information on the culture of both in our "Florists' Flowers," which you may obtain post free from our office for 5d.

**MYRTLE TREE** (*H. R. B.*).—Your Myrtle is infested with scale, which if not checked will ultimately completely cover and destroy the plant. Wash it well with a strong solution of soap and water, scrubbing it with an old plate-brush or some such instrument, then syringe well with water at the temperature of 100°, or apply a dressing of Gishurst Compound, eight ounces dissolved in a gallon of water.

**APRICOT TREES** (*Dorset*).—Shaw's Tiffany is by far the best thing for the purpose, as it neither abstracts the light nor the air.

**MELONS** (*A. L. M.*).—Turner's Scarlet Gem is a first-rate Melon, and has frequently been the first at the exhibitions this and last season. Bromham Hall is also first-rate.

**LOBELIA SPECIOSA AT THE CRYSTAL PALACE** (*A. L. M.*).—The gardeners there save their own seeds, as do those of the Royal Horticultural Society, and in both places they avoid gathering seeds from any of the plants which show the least tendency to vary from the type. But many do not follow that rule, and the consequence is, speciosa is fast degenerating. Get two or three good tufts and evenly-growing plants early this autumn, propagate your stock from them in the spring, and save your own seeds in future from the very best sample of your plants.

**EMIGRATION** (*J. G.*).—Apply at the office of the Government Emigration Commissioners, 3, Park Street, Westminster. We cannot recommend one colony in preference to another, but should imagine that Victoria would afford the greatest encouragement to a gardener.

**NAME OF FRUIT** (*Handsworth*).—The Grape you sent is Trentham Black.

**NAMES OF PLANTS** (*R. P., Shrewsbury*).—1, *Potentilla fruticosa*; 2, *Veratrum nigrum*. (*C. J.*).—This is the Purple Orach, which is now so much used in flower-garden decoration. (*D. C.*).—1, *Vinca major* fol. reticulata; 2, *Taxodium distichum*. (*A. Subscriber, Waterhampton*).—*Sphenogyne speciosa*, a well-known handsome garden annual. (*Wm. Legg*).—*Sedum papilionifolium*. (*A. B.*).—*Spiraea japonica*. (*J. G.*).—1, *Medicago lupulina*; 2, *Trifolium agrarium*, usually called *T. procumbens*. (*Old Subscriber, Dublin*).—*Juniperus virginiana* penula, or Weeping Red Cedar. Very different from *Juniperus Sabina*, certainly. (*Scipio*).—The plant is *Lycopodium denticulatum*, and it has not any flower. *Lobellias*, *Tropaeolums*, *Verbenas*, scarlet *Pelargoniums*, and such-like plants, will do for hanging-baskets. (*J. Todd*).—*Campanula Vidalii*. (*J. L.*).—*Filix-mas* certainly, but whether accidentally deperanated or a fixed variety there is, no evidence to show.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

AUGUST 25th, 26th, 27th, and 28th. CRYSTAL PALACE. *Secs.*, W. Houghton. Entries close July 26th.  
 AUGUST 27th. COTTINGHAM. *Sec.*, Mr. J. Brittain. Entries close Aug. 20th.  
 AUGUST 30th. HALIFAX and CALDER VALE. *Sec.*, Mr. W. Irvine, Holmsfield. Entries close August 16th.  
 SEPTEMBER 2nd. POCKLINGTON, Yorkshire. *Sec.*, Mr. T. Grant. Entries close August 25th.  
 SEPTEMBER 4th. WAKEFIELD AND WEST RIDING. *Sec.*, Mr. J. Crosland, jun., Entries close August 23rd.  
 SEPTEMBER 9th. WORSLEY and ARMLEY (near Leeds). *Sec.*, Mr. Robert Hoyle, Armley, near Leeds.  
 SEPTEMBER 9th and 10th. CALNE. *Secs.*, A. Heath and F. Baily. Entries close August 28th.  
 SEPTEMBER 10th and 11th. MANCHESTER and LIVERPOOL. *Sec.*, Mr. T. B. Ryder, Church Street, Liverpool. Entries close August 11th.  
 SEPTEMBER 25th. STAFFORDSHIRE. *Sec.*, Mr. W. Tomkinson, Newcastle. Entries close August 25th.  
 DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 14, Temple Street, Birmingham.

### FATTENING YOUNG FOWLS.

(Continued from page 383.)

"THIS sum of 81*l.* 7*s.* would be but a poor remuneration for the feeder, if we did not take into consideration the difference which exists between the wages allowed to him in this table of expenses and the value of his time if employed on ordinary work in the country, at which in the winter time he would earn but 1*s.* per day. It becomes then necessary in order to make out a reasonable account, to deduct two-thirds of the labour, which is put at 3*s.* per day, and to add them to the profit of feeding. Then for forty days we shall have 80*l.* to add to the 81*l.* 7*s.* result of the previous account, which will in reality give us 161*l.* 7*s.* profit on fattening fifty poulardes.

"It must, nevertheless, be admitted, this would not be very encouraging if the labour were confined to that number of fowls; but during the five months that these labours last, an active poulterer can not only fatten a larger number of birds at a time,

but he can keep replacing constantly those he has taken out or sold by fresh birds.

"All who follow this trade are well off, and some have made small fortunes. As the foregoing is the result of careful and patient investigation made by consulting and listening to many different breeders and feeders, who all agreed exactly in the answers they gave to my various questions, I do not think I have been deceived in any particular as to the method of fattening, which, after all, as I have already said, is no secret for any one in the country."

We will add to the information supplied by M. Letrove, that the La Flèche fowls, like all others, may be fattened by means of the funnel. It is probable that by this process the growth and weight may not be so great as those made by cramming. We think, however, the flesh must be more delicate and have a higher flavour.

### "FATTENING BY MEANS OF A FUNNEL. (From the Same Author.)"

"There are three sorts of fattening. The first, natural, consists in the food given to animals that are at liberty, in the voluntary absorption of food calculated to produce the result, as cooked Indian corn, rice, buckwheat, &c. The animal should be in perfect health and fit for the process, both by nature and age, for with young poultry nearly all the food turns to bone and muscle. The exceptions from this rule will be adult birds, and breeds like the Crève Cœur, Dorking, Houdan, &c. To fatten even these certain food must be given, and there must be no limit.

"We have described the second method, that of cramming, in our article La Flèche.

"The third sort is funnelling—forced introduction, by means of a funnel, of farinaceous food in a liquid state. Sooner or later this method must prevail everywhere, because it is simple, easy, and quick.

"It is practised in the following manner:—Get some oat flour, not ground oats, for there must be no bran in it—on the contrary, it should be carefully sifted at the mill. Mix a quantity of it with milk and water in equal parts. It should be as liquid as broth or clear soup, and, I must repeat, the milk and water should be in equal parts. Experience has proved that where there was more than half milk, fattening has stopped at the end of a few days, and the fowl has wasted and died."

(To be continued.)

### POULTRY FARM IN CONNECTION WITH A TEN-ROOMED HOUSE.

I SHALL feel obliged if you will inform me through the columns of your useful Journal, what kind and size of a farm, or quantity of land attached to a ten-roomed house, would be sufficient to yield profit enough to pay the rent of the same? Would poultry alone, with grass land as a run for them, yield enough? having business connections sufficient to supply with almost any quantity of eggs or chickens, Pigeons, Ducks, or anything of the kind. Although anxious upon the poultry subject, I am doubtful that they are not all profit by a very long way. Having kept them in London (rather confined), some time, and having been very successful with them for home uses, I am in doubt about their return in a business view upon an extended plan.—A NOVICE AT FARMING.

[It would be difficult to say what sized farm would yield sufficient profit to pay the rent of a ten-roomed house, so much depends on the locality, description of land, and its produce. Good land in the suburbs of large towns not unfrequently lets for £10 an acre, and in certain cases much more than that; but this is too much for ordinary farming, and it would be better to consult some one well versed in the farming of the locality whom you could depend on not giving a prejudiced opinion. But as a rough guess we may say, that if you hired as much land at the fair rental of the district as would pay £100 a-year, you ought to receive as much profit out of it as would pay for the house, assuming at the same time that the land is farmed judiciously, and a fair per-centage on all outgoings is charged for; but unless you have some knowledge of the matter you must depend in a great measure on the man who manages it for you, and if he does his duty it ought to pay. It is needless here entering into the character of the crops, as the local demand or other circumstances determine them; but in regard to the keeping of poultry on a large scale, it is best done when there is a great

breadth of grass land. In that case poultry-houses may be erected at distances of half a mile or less from each other, and quantities kept at each place with the run over the whole. Poultry are sad enemies to tillage, and confining them is an expensive and unsatisfactory way, for they are more liable to disease than when they have a good extensive run, and they often pick up so much on grass land as to care very little about hand-feeding. The sides of a wood or any rough ground is an excellent place for them, and as we are promised an article on poultry management in this way from a known correspondent, you will learn what more is to be gained on this matter.]

### TO MAKE FOWLS PROLIFIC.

A GREAT amount of the Californian farmer's success in obtaining the large number of eggs, as stated at page 385 of last week's *JOURNAL OF HORTICULTURE*, must be attributed to climate, with which good feeding is easily understood; but the long, cold winters of this country in a great measure, even with March pullets, stop the supply—so much so, that for weeks in the depth of winter, with so many hens, we have scarcely got one egg. Acting upon some hints I had from a Canadian gentleman, three years ago, when the cold weather commences, the quantity of barley we feed with each time is put in a tin on purpose, and put in the oven, or on the fire, and half roasted, with a small quantity of dripping, or fat, boiled down. It is then given to the fowls in as hot a state as it can well be handled; when given too hot it causes the yolk of the egg when cooked to have a black, unwholesome appearance. I have no doubt any party taking the trouble to have this done each time, will be as successful as we have been in getting a good supply all through the winter.—J. F., *Cliveden*.

### BIRDS—THE CROW FAMILY.

THE birds to which I would direct attention in this article are of considerable importance. The first or head of the family is that ominous bird the Raven, now, however, comparatively scarce. He is a carrion feeder, picking the bones of any poor animal whose body remains unburied; but as dead animals are mostly buried for manure and not allowed to rot above ground, as formerly was too often the case, his avocation is nearly gone. He has been accused of pecking out the eyes of sick sheep, and no doubt he appropriates any wounded or helpless bird or small animal which may come within his reach, be it game or not; nor would he go hungry to bed were reptiles or insects to be had. As, however, his chief good is as a scavenger, he is now but little required.

Next comes the Saddle-backed Crow, mostly found on the mountain, heath, or moor. He is a sad thief, and exceedingly audacious. Eggs and young birds, and animals, insect, or, in winter, shell fish, make up his bill of fare. He is the great enemy of the grouse-shooter, and indeed of all sportsmen, as he commits sad havoc with the eggs and young of game.

The Black or Carrion Crow is a rather solitary bird, usually living in woods and shrubberies. Cunning as he is knavish, he leaves no corner unsearched for eggs, of which he destroys immense quantities as well as young game and poultry. He may, when eggs run short and other game has grown wary, do a little good by eating grubs; still the injury he does is so very great that he is much persecuted, and, consequently, is becoming scarce.

The Rook, that sable fellow, who, in a business-like manner, visits the fields in excursion parties, bent on picking up a living, will not refuse an egg or callow bird should he meet with it on his march; but such things are merely stray fish; his occupation and employment is to search out and destroy the grubs and larvæ of numerous insects that prey on the crops. Sooner than starve he would swallow a few grains of corn or pulse; but these, to him indigestible fare, are not to his liking; though, when the ground is bound hard with frost and snow, or baked dry by a hot sun, he would be thankful for anything to fill his craw. But take him all in all, he is an honest fellow; and the immense numbers of the grubs or larvæ of insects he devours—such as the black grubs, the wireworms, the larvæ of the cockchafer, dorbeetle, gaddies, caterpillars, and many others, as well as the full-grown insects, is of exceedingly great benefit to the farmer and grazier, and through them to the country at large. It can not be reckoned what in a few years would be the produce of this army of insect pests yearly devoured by the plodding in-

dustrious Rooks—each insect laying many hundred eggs, and the larvæ burrowing in the ground, feeding on the roots of corn, grass, and other crops they would, in a few generations, reduce our smiling fields to a barren waste. On this account the Rook should be venerated and protected. There is no fear of his becoming too numerous while insects breed so fast; but should he succeed in reducing their numbers one year, he will himself have to starve his young for want of food the next, so that nature will hold the balance.

The Jackdaw, though rather more mischievous than the Rook, yet, like him, is a very useful bird, and generally accompanies him on his picnic parties, when he assists in the destruction of the ever-devouring multitude.

The Magpie is a very mischievous fellow—bold, daring, sly, and thievish. He is very amusing in confinement, and will learn to talk, whistle, or call the cat; but it she comes too close he will peck her nose, and he will brain any luckless chick that comes within his reach. In a wild state he is the country gentleman's pest. Eggs and young birds are his favourite food, then fruit; and, when these are scarce, he will look for the insects, which would have been much sooner destroyed by those he had either robbed of their eggs or young. I read in the papers that some one had let out some Magpies in Tasmania. I fear, a very foolish act, as they will do far more harm in destroying game, poultry, and useful small birds, than can be compensated by their very small destruction of insects.

The Jay, though less courageous than the Magpie, is equally destructive to eggs and small birds, and even more so to fruit.

Of the Red-legged Crow, or Cornish Chough, I can say nothing, not being acquainted with its habits.

The Hooded or Saddle-backed Crow, and the Carrion Crow, the Magpie, and the Jay, constitute among birds the regular banditti or guerilla bands, marauding, plundering, and destroying, with scarcely a good trait. Where they are numerous, game is scarce, small birds gradually disappear, and crops fail; but the Rook is a useful industrious member of the community, with even fewer faults than the others have good qualities.—B. P. BRENT.

### CAN THE WORKING BEE MAKE A QUEEN FROM A WORKING BEE'S EGG?

THE following communication from Mr. A. Shearer, Yester Gardens, is copied from *The Haddingtonshire Courier*:—

"Notwithstanding the many apiarists who have investigated and answered the heading to this communication in the affirmative, there are still, I believe, many old bee-keepers who would answer it in the negative, and, though asked for the proof of their doubts, give but very unsatisfactory ones. Having read a good deal myself on the subject, and the means which had been taken to prove that the working bee can make a queen from a worker's egg, I never had any doubt on the matter; but I have now put it to the test, and will, with your permission, give the details of the process, which may not be uninteresting to some of your readers.

"Having learned that the Ligurian or Italian Alp bees were superior as breeders and honey-gatherers, I was determined to give them a trial, and procured one from Mr. Woodbury, of Exeter, the original introducer of them into this country. They arrived here on the 7th May in a Woodbury bar-frame-hive. This hive is a 14½-inch square box, and 9 inches deep, having ten frames suspended for the bees to work the combs on. These frames are 13 inches long, by 7 inches wide, having a space of half an inch between them and the box. The combs, being wrought in these frames, can be taken out and examined at pleasure, and the combs are not liable to be broken in any way. This being perhaps the worst season for bees which the oldest bee-keeper has experienced, the Ligurians had not a good chance; still they did better than the common bee, and I determined to try artificial swarming. On the 4th July I took out from the Ligurians nine frames full of comb and honey, and brood in all stages, leaving only one frame with the old queen and all her bees, with nine empty bars for her to fill and breed in, and putting the nine frames into another box the same size in all respects. I put this box on a stand where I had just lifted a good strong stall of the common bee. Carrying the latter away 10 yards from its stand, I turned it upside down and shook almost all the bees out of it on a white sheet, that we might see that the queen did not go back. We got hold of her

majesty, and of course kept her until we had as many bees out as would bring out the young brood in the box-hive, and rear a new queen. The common bees naturally went back to their old stand, and though finding a change in a square wooden box from their own straw hive, they went into the box and began their work of queen-rearing. The hive of common bees was then placed about 30 yards from its old stand. But now comes the most interesting part, which we looked anxiously for. On the 11th July, seven days after the operation described, we examined every frame in what we shall now call the new hive, and found on one of the combs no less than eight queen-cells in process of forming, and one or two with the young brood of a good size. Again, on the 14th July, we looked, and found only two queen-cells with brood in them; the other cells had disappeared. We looked again on the 20th, and found one of the cells still sealed up; and it was twenty-five days since the combs had been put in. This we did not expect, as the bees should have been out. Still, the bees were working well, and they manifested no signs of being in want of a queen, but the reverse, and we thought we would give her a few days more. On the 1st of August we looked, and found the queen-cell in the same state. We broke it up and found her dead, and all our expectations blasted; but, to our great surprise, in the same frame we found a number of new-laid eggs, sometimes four in a cell. Here, then, was proof that a queen had been reared, had been impregnated, and had laid eggs of the same size as she had been herself exactly twenty-nine days previous. We examined all the other frames, and found brood laid in almost every empty cell, and also found the cell where she had been reared, and which had escaped us before, as we looked always at the one described as being prominent.

"Such, then, is a plain account of our doings in artificial swarming. The result has been complete success, and has proved that the working bee can produce a queen bee from a worker egg, if that egg is not too old.

"I must now state how the old Ligurian-hive has succeeded after being deprived of all her comb except one piece. We examined her on the 14th July, eleven days after, and found she had again filled all the bars with comb and brood, or made in all 5 square feet of comb in eleven days, and all full of brood and honey. On the 26th July we again took eight frames out of it and placed them in another box, and in the same manner as the first one, and on the 1st August we examined it and found two queen-cells sealed up, and all progressing as favourably as we could wish; and now we have two artificial hives from the Ligurians in good order, and the old one still better than any of the common ones. I have no doubt they bear out their character of being great breeders, and of course honey-gatherers. They work earlier and later than the common bee, and are more active.

"I may state that the two stalls of the common bees, from which I took the bees to rear a Ligurian queen and bring out the brood, have swarmed well also. The first one is again full of bees and brood, so that now I would never wait on bees swarming themselves, but do it artificially whenever I saw them ready."

### FUMIGATING BEES.

BEFORE I received your answer to my communication respecting the effects of fumigation on unsealed brood, the top swarm (whose hive I wished to give to the bees of the second swarm) threw off a swarm; and as soon as the bees were settled in a hive, I removed the stock from its stand and put the new swarm in its place. I then fumigated the bees that could not be persuaded to leave their hive, placed them in the sun on the top of the hive containing the swarm, and put the hive containing the combs and brood under the hive of the second swarm. The queen soon descended, for on the third day the royal cells, four in number, were torn open.

Now, I believe fumigating the bees to insensibility did not in the least injure the unsealed brood, as no grubs were brought out, only some drone nymphs. I used puff-ball.

Is it usual for bees, when prevented by the weather from swarming, and after the royal cells have been destroyed, to raise more young queens when the weather improves, and swarm after all, which was the case with this hive? I had been watching the progress of five royal cells through the windows, the bees trying to swarm when the sun shone (which indeed was very seldom). Three queens were sealed over, and two progressing; when one morning I found the royal cells torn open, and con-

cluded that all intention of swarming was given up. To my surprise, two days after the death of the princesses I discovered that two other royal cells were tenanted; and in a few days after two more. The day after the first was sealed over the swarm came off.—J. L.

[Your bees acted very much as we should have expected them to do under the circumstances, but we have had little practical experience on this particular point. Perhaps some of our correspondents may be able to reply more fully to your inquiry.]

### HINTS FOR PRACTICAL BEE-KEEPERS.

(Concluded from page 386.)

ARTIFICIAL swarm-making is only valuable to those who multiply Italian queens. For this purpose they want a large number of weak hives, which are united again to larger stocks in autumn. He who strengthens a second swarm by inserting brood-combs will make of it a strong populous stock in the first year. Such swarms prosper, of course, very much, and do not want a second apitory.

Further: It is in most cases disadvantageous to give to a stock which has done swarming either supers or nadirs. I do not myself practise it unless the second swarm has issued whilst the acacia is in bloom, and not even then unless the stock is heavy, and the bees hang out at the entrance. After swarming the number of bees in a straw hive is much diminished, whilst its store of honey is decreased and sometimes exhausted by the departing swarms. As it is known that the old queen leads off the first swarm, and the young queen does not usually become impregnated till eighteen or twenty days afterwards, it is nearly three weeks before breeding commences. The combs which become empty by degrees as the brood of the old queen hatches, must first be provided with a store of honey for feeding the brood, and for sustenance during winter; but this is neglected if supers and nadirs are used. When supers are put on, one obtains honey to be sure, but this is done to the injury of the stock, which can seldom keep its footing. When nadirs are used the bees make combs in them, which become filled with brood, by which all honey that is collected is consumed. In both cases such stocks will die of starvation, if not in winter certainly the following spring.

With regard to the swarming of bees which are kept in boxes, I have this to say—I think it a very great fault. Boxes are designed for obtaining honey. If I aim at swarms I do not want boxes which are known to be expensive. Straw hives, which are much cheaper, are used by me for swarming. The great superiority of the Dzierzon-boxes is that by their means one doubles the profit of the honey harvest. A stock in a box which gives two good swarms would without swarming give at least thirty, or even fifty pounds of honey. If I reckon one pound to be worth eight siber groschen (9½d.), this would be a profit of eight to thirteen thalers (£1 3s. to £1 18s.), leaving me a very populous stock, the value of which has much increased. On the other hand, two swarms, if they do not issue too late are worth, perhaps, five thalers (nearly 15s.), and the parent hive is destitute of honey, and weak in population. Whilst, therefore, it is foolish to spur a box-hive to swarm, it is a sign, if not of a bad, certainly of an inattentive bee-keeper, if he be not able to prevent swarming. In my apiary a Dzierzon-box has never swarmed. You will ask, "How is this to be effected?" Nothing easier. When the store of honey increases in May is the time to give the bees ample room. My box colonies fill the brood-room (which is enlarged, perhaps, by eight or ten new guide-combs) during the time when the trees are in blossom. The honey-rooms of a good populous stock will generally be filled before this kind of bee-pasture is at an end. Now, delay not to empty it immediately, and fill it up with new guide-combs. These perpetual operations and changes will certainly do away with all inclination for swarming, and the bees will apply themselves with increased diligence to honey-gathering. Many bee-keepers will, doubtless, reply, "I, too, have opened the honey-rooms, and my bees swarmed before they were filled." Certainly in this case they have been opened too late; the bees had already made preparations for swarming, and had begun queen-cells. When this has taken place the opening is, of course, useless, the inclination for swarming has been awakened, and can no longer be suppressed.

A few words now on the placing of stocks. I must declare myself beforehand decidedly against putting bee-boxes in the

open air. Not only are they continually exposed to the sun and rain, whilst the great heat induces them to swarm; but it is also very unpleasant to the bee-keeper to be compelled to encounter a burning sun whenever he examines his bees through the windows, and still more disagreeable if he has to perform operations upon them. When emptying the honey-rooms, as there are generally flight-holes on every side, the bees become wilder and more inclined to sting. How pleasant, on the other hand, to be able to observe bees in a bee-house sheltered against both sun and rain. If it is very difficult to bring boxes through the winter in the open air so much, I think it quite unsuitable for them to be altogether kept from the warmth of the sun. In a bee-house they are sheltered from the cold by leaves of trees, or better still, by pine-needles outside the hives. The objection that they mistake their hives when placed too near each other does not hold good. If the entrances are 18 inches to 20 inches apart a bee will seldom mistake her hive; and if it does happen, a weak colony is soon strengthened by some brood-combs. The rational apiarian will, therefore, put his hives in a bee-house as the most suitable place.

What aspect, then, is it best to choose for the prosperity of the bees? North, south, and west are decidedly prejudicial. North, because the bees have too little sun; south, because they are then annoyed by the intense heat; and lastly, west, because from thence comes the most rain. The morning sun is advantageous so long as it does not become oppressive—say till about nine o'clock. The best and most suitable aspect would, therefore, be north-east. I have two apiaries, one faces north-east, the other south-east. The straw hives in the former swarmed first, and the boxes have given the most honey. It cannot, therefore, be recommended that bees fly out from the pavilions in three or four directions. Cold, heat, and rain are all very injurious to bees. It may be replied to this, that from the north-east come cold winds and showers; but this happens mostly in winter when they are sheltered against them.

It has been recommended by many, and, if I mistake not, even by our teachers, to feed with lumps of sugar-candy. I have examined it closely, and find this mode of feeding extremely unpractical. That this way of feeding is a piece of cruelty to animals every one will admit who has observed what trouble and exertion it costs the little creatures to obtain a scanty meal.

From the continual fatiguing exertion, and from the quantity of water which it takes to dissolve the candy, the bees become so feeble that they get dysentery, and are not strong enough in spring to defend themselves against robbers. So that this innovation is a new means of promoting dysentery, which has been so prevalent of late years.

Besides honey, I feed my bees only with dissolved sugar-candy, and find them always very healthy, and strong and diligent in the spring. The feeding with solid candy is generally practised during winter, but the apiarian who examines his bees carefully in autumn, and supplies what is wanting, will never be compelled to resort to this most irrational plan of winter-feeding. Among all artificial compounds for feeding bees, whether in the autumn or in spring, this dissolved sugar-candy is the cleanest, cheapest, and most suitable.

In conclusion, I may refer to the interior arrangement of the Dzierzon-hives. As you all know, bee-keepers are not yet agreed whether ledges or rabbets are the best to carry the comb-bars. I have tried both, and experience has taught me to give a decided preference to ledges. How difficult it is to get out a comb, especially in the front.\* Comb-tonga are, however, said to do good service, yet I know that with them many a beautiful honey-comb has been mutilated. But why have such an expensive tool, which with ledges is quite superfluous? The skilful and steady hand may be relied upon with much greater certainty. When boxes are made, the rabbets give much additional trouble, which must, of course, be paid for; added to which if they are not worked with accuracy it is very difficult to put empty combs into them. Ledges require only to be nailed on, whilst comb-bars can on them be easily pushed in, and when it is desired to take them out, can be raised with the comb-knife. When a guide-comb in a hive with a new swarm becomes detached from the bar by the weight of the bees, which not unfrequently happens, it is not necessary for me to remove all the combs, but I take it out of the midst and make it up immediately

\* Combs are, I believe, extracted either from the back or front of Dzierzon-hives, and not by removing the top, as is customary in England, but this would be impracticable where one colony is located over another, as is the case in Dzierzon twin stocks, vierbeutera and achtbeutera.—A DEVONSHIRE BEE-KEEPER.

with another comb. I am also able to put the covering-boards immediately on the comb-bars, by which means the most inconvenient second rabbit to push in the covering-boards is omitted.

These, gentlemen, are the results of my experience, which I express fearlessly, as they rest on many years' practice. I have already said that I will not steal the crown from the merit of the modern go-a-head theory; but this, I think, we should keep fast—that as theory exists only for practice, we only act according to that theory which is approved by practice, and for the rest leave theory to stand or fall by its own merits. For apart from this that theory sprung from practice as the former reduced to order the experience derived from the latter. Thus we see that as practice existed before theory, the latter must be made practical (since theory is nothing without practice), for which certain conditions must necessarily be presumed. To speak specially of bee-keeping, to be a good bee-keeper three qualifications are requisite, and these are—courage, skill, and patience; courage, to become master of his bees; skill, to do without many useless instruments; and patience, not to lose heart in bad times. If we follow these hints, which are the results of many years' experience, the sad misfortunes which have been so frequent will seldom happen, and our harvest will become a rich one.—VIEBEG, *Secretary of the Potsdam Central Society of Bee-keepers.*

At page 355, second paragraph, read "resolution" for "revolution;" and at page 356, last paragraph, read "swarms should issue during a fall pasture" instead of "a fall pasture."

### GESTATION OF GUINEA PIGS.

IN fulfilment of my promise to send you the result of my second experiment to determine the period of gestation in Guinea Pigs, and whether warmth had any influence in shortening the time, I have to inform you that the sow mentioned as the first in my last year's account, and which was kept out of doors exposed to a north aspect, after a gestation of ten weeks and a few hours produced four young ones.

This year she went to the boar on the afternoon of Friday, May 2nd; I placed her in a hutch, and kept her by the side of the kitchen fire. Saturday morning, July 12th, I found she had two young ones, being exactly the same time as last year when exposed to the inclemency of a north aspect.

The other sow has not bred this year; but I consider this and last year's experiment to prove conclusively that their period of gestation is ten weeks, and also to disprove the assertion that warmth would hasten parturition.

Having bred only once a-year does not speak much for their rapid increase. Probably if the boar had run with the sows they might have bred oftener, but that would not have suited my experiments, as I required exact data. The numbers of the young have been on two occasions two, once four, and twice five.—B. P. BRENT, *Dalvington, near Robertsbridge, Sussex.*

### OUR LETTER BOX.

POULTRY MIS-SENT.—The following communication has been forwarded to us:—"I have received a pen of poultry which has been sent me with my address. I have written to many of my friends, and cannot ascertain from whom they have come. They may have been sent in mistake from some show or other. I shall be glad to return them to their proper owner, if properly described to me. I have had them nearly a fortnight, and have not yet had any application. The cock bird is not so healthy, but I shall attend to them as if they were my own."—FRED. HARDY, *Quarry Gate, Bradford, Yorkshire.*

COLOUR OF SPANISH COCKS (*Amateur*).—Spanish cocks are often white-faced when chickens. They should always be so when from six to eight months old. We should have little hope of a cock chicken, if at three months he showed no sign of white face. Pullets are much later, but they should show partial white at three months. You deserve your success, and you have made choice of a hardy breed well adapted for the neighbourhood of towns and confined spots; but we fear from your description they are not first-class birds. Bally's is the best book.

BREED OF FOWLS (*Francesca*).—We have no doubt you have received some of the offshoots from the Hanburgh, of which there are many in the low countries, just as the Hamburgs were called in this country Bolton Bays and Greys, Everlasting Layers, Crecls, &c., so the crosses from them have been termed Siberian, Egyptian, &c. They cannot be Bredas, as they have only an apology for a comb, and their colours are black, white, and cuckoo. The white-neck, pencilled body, and accented feathering prove their origin. They are generally very useful table birds, but more approved as layers than table birds. Their blue legs are an objection for the latter purpose.

RABBITS (*W. D. Paine*).—The Patagonian is a very different variety from the Hare Rabbit. If there is no special class for the latter variety at a show they may be shown in Miscellaneous. But in our opinion the schedules for Rabbits want great revision, as they are often positively absurd.

PARROTS (*M. F.*).—Give him plenty of well-sopped bread, and occasionally nuts, fruit, or, in fact, anything but salt. A little bit of meat occasionally will not hurt him; but, above all, a bath and as much water as he likes to drink.

WEEKLY CALENDAR.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 71.7° and 48.7° respectively. The greatest heat, 85°, occurred on the 1st, in 1843; and the lowest cold, 32°, on the 29th, in 1850. During the period 152 days were fine, and on 93 rain fell.

SCROPHULARIA AQUATICA VARIEGATA—  
GOLDEN CHAIN GERANIUM.

On page 395, last week, "AN OLD SHOWMAN" confirmed the statement I made last May about there being two plants in cultivation under the name of *Scrophularia nodosa variegata*. I think I said that Mr. Williams exhibited both of them at the May Exhibition, and that I had seen one of them in this neighbourhood with Mr. Donald, the gardener at Hampton Court. I also said that Mr. Donald was the best practical British botanist of all our craft as far as I knew, and he told me last

September that he had this *nodosa variegata*, and that he could hardly get it to go ahead like the plant from Ireland, which is a very free-growing plant: therefore, I expect, or almost suspect, that some one had cut the draft of *Gazania splendens*, and sent the wrong plant to "AN OLD SHOWMAN" for the Irish one; and if that is so it cannot be an isolated fact. Others must have been caught in the same net; and thus, without knowing it, people may come to the point of discarding a valuable plant.

Mr. Williams offered to send me trial plants of his *nodosa variegata*; but since I lost the Experimental I cannot undertake such work. "AN OLD SHOWMAN" says "there is a wide difference between *S. nodosa* and *S. aquatica*;" and that may be so to show people and to botanists, but I confess that plain people like myself can see little difference at all between the two, only their different habits, the one being a dry customer, the other a thirsty soul, delighting in marshy beds. They are both nodose certainly—that is, knobby-rooted, and from their knobbed roots the name Figwort has been given to the order to which they belong. Medical and botanical doctors are just as far wrong in saying these Figwort roots are dangerous to eat, while stern necessity proved just the contrary; for it is on record that at the siege of Rochelle by Cardinal Richelieu, in 1628, "the garrison was reduced to the necessity of supporting life upon the roots of *Scrophularia aquatica*," and the French call it *Herbe du Siège* to this day on that foundation.

There are certainly two kinds of variegated plants called *nodosa variegata*, and one of them is just as certain to be more free of growth than the other, the one from Ireland being a very free grower, and its too-much-freedom of growth is the only thing I would object to. All that I have seen with my own eyes. But there is another turn to the like of these tales. Our correspondent says he "thinks it too bad to send out for new an old plant with a new name." Well, if I thought any one had done such a thing for the purpose of deceiving, I, too, would be wroth about it. But this plant was never "out" before, and all those who have had a hand in bringing it "out,"

myself among the rest, are above suspicion; we do not and never did play at black legs. I knew every plant, and pot, and pane of glass which Dr. Neill possessed at Canon Mills, and to my personal knowledge he had many plants which you could not then find in the botanic gardens of Edinburgh, London, or Liverpool; for within three years—that is to say, between 1829 and 1831, I watered plants for Dr. Neill, or rather for his gardener, Mr. A. Scott, now nurseryman at Chichester, lately of Leigh Park, Hants, and who was at Kew, and at the Liverpool, Manchester, and Birmingham Botanic Gardens. At that period plants might have been in all these public gardens, and also in Dr. Neill's garden, and never have been "out" before or since, according to our common commercial sense of the term. Therefore, with so much glass about us it is not at all safe to cast stones about in this fashion.

But I will give you another illustration—my own silver-frosted, ice-like, edging plant, *Aretotis* something to begin with. I told how it had been sent to me by Mr. Scott, of the Merriott Nurseries, under the name of *Aretotis melanoeycla*, and have since learned that it has been about London for the last five years or more under the same name, and has been catalogued in that name; but the character of my plant would not agree at all with the character I had of *A. melanoeycla*. I also said it might have been an old east-out plant from some of our great plant-stores; but I did not say that any one attempted to put off an old plant for a new one in this instance, yet the thing was done unknowingly. A seed-grower in Germany, probably at Erfurt, got hold of an old botanical plant from the Cape from some ancient botanic collection under a wrong name. He found that the plant seeded as freely as a Poppy, and he brought it into his seed trade, and sent it to all his customers as a new article of trade, but not as a new plant, for *A. melanoeycla* was older than this generation. I detected the name to be wrong without attempting it, and I have since traced it to its origin, and have a figure of it now on the table taken from the second volume of *Jacquin's Plantarum Rariorum Horti Cesarei Schönbrunnensis*. It is *Aretotis reptans*, and is the very best edging pot plant I know. It creeps on the ground, and roots as it goes, and is, in garden language, a silver ice plant; and if you saw it with the morning dew on it as I have it now every morning you would allow the truth of my story.

But I have a lark by the two wings for you in relation to this very plant. A gentleman, a friend of ours in the London nursery and seed trade, ordered seeds of this *Aretotis reptans* as soon as he saw it in the foreign seed list; sowed some in March, and planted some plants out on trial five or six years since, and seeing that it was of running growth like a Strawberry, instead of an upright *Gazania*-looking character, he ordered every one of them to be dug down, and he had no more to do with it till he saw specimens of it in my own hands. He recommends the seeds to be sown exactly as you would a selected sample of the seed of *Lobelia speciosa*, in every respect. Thus an old and forgotten plant will be restored just at the right time, for every one is now looking out

for such things. Surely people engaged in active business are not supposed to be musty bookworms, and know the names of all that was in books, nor be accused of underhand work for merely catering, like the rest of us, to the requirements of their customers. In fact, to bring out an old or never-known plant of the oldest school, except to the students thereof, is of just as much merit as to raise a first-class seedling.

Then there is that other most useful novelty of this season, the plant called *Gnaphalium lanatum*. I am almost certain that is not the right name, but no one out of a strait jacket would ever think of accusing people of strange things for heralding it before a willing public. We shall not know if this be a right or a wrong named plant till we can get one of it to bloom, probably next May. But we are not to hold back from the use of it, or from the use of any plant whatever, for want of the proper name just at the time; neither shall we submit to be bamboozled by old bagmen or "OLD SHOWMEN," because the name is not just on the tip of the tongue for the moment.

#### GOLDEN CHAIN GERANIUM.

But in the midst of it all there is comfort for the thankless as well as for the most grateful. Look here: The back pollen of the Golden Chain has been only announced to do wonders, and up come a host of letters from eye-witnesses to the fact. Now listen to the tale, and you may change your plain silver into gold, and your frosted silver into huge fleeces of the purest gold refined. "I have got a Golden-Chain-leaved *Christine*, of which more anon. Golden Chain pollen will produce Golden Chain seedlings! If this is your correspondent's secret, why hasn't he the pluck to come out with it?—R. T. C." This secret was mine, by the way; and I was to tell it to any one who could not see the difference between two certain flowerbeds, and I shall out with it the moment I hear of such a person. But to proceed. Another gentleman far down in the country writes, "I was very much pleased with your article on cross *Cyclamens* and *Geraniums*, and you were quite right in what you said about Golden Fleece; I find it the best parent to breed from I have ever tried. I have some very beautiful seedlings, which I shall most likely exhibit in the autumn, from seeds saved last year. One has just come into flower. It is a beautiful Golden *Trentham Rose*: the flower and leaf are really splendid. Then I have *Golden Boule de Neige*, *Golden Christine*, *Golden Little David*, *Golden Lucia Rosea*, *Golden Madame Vaucher* [hear, hear], *Golden Paul l'Abbé*, *Golden Kingsbury Pet*, and many others, including the new ones, *Woodwardianum* and *Magenta*, in gold leaf. And I have also the *Golden Fleece* crossed with some Cape species doing well. In the autumn I expect, *Suffolk-like*, to bring out a good scarlet bedding *Lobelia* in the style and habit of *Lobelia speciosa*." But I am out of breath already, and this is but a tithe of my crop for this harvest. All that I mean to add is this, that I was aware of the influence of the Golden Chain and Fleece only about this time last year, and that I do not intend to do anything in that line myself beyond stimulating the crosses of the English, the Irish, and the Scotch, up to the highest pitch of breeding in-and-in all the improved races of which we are cognisant, and, if I can, to suggest subjects for the derivation of new races to be so improved. To show you what I mean by that, I have only to point to the quotation which you have just read.

All the improvement in *Geraniums* and in *Pelargoniums* for the last forty or fifty years, indeed since 1810, has been effected by breeding in-and-in as the breeders term the process of cross-breeding; but in the instance under quotation this is changed to hybridising, which means breeding by species and not by acquired seedlings. Cape species of wild *Geraniums* have been put to hybridise with a peculiarly marked seedling of *Quinans*, and thus new blood will be infused into the seedlings if they come; but the question is not yet without an "if." There seem to be two opposite ways in which breeding in-and-in affects families of plants. The *Geranium* is a good one to show one of these ways, and the *Rhododendron* is about the best to exhibit the opposite tendency. You may go on, as it were, in a circle for ever improving the *Geranium* race without fresh blood, if you only retain such seedlings as exhibit the strain you indulge in. All this time there are two laws or principles affecting your operations in opposite directions. The one is the law under which the *Geraniums* sport by seedlings to an unlimited extent; the other, the law by which the pollen of one seedling affects the seedlings from a kindred plant: and the influence of the first law is as a thousand to one against the

influence of the second law—that is writing within the mark. But in the *Rhododendron* family, or at least in the true *Rhododendrons*, you cannot thus go on long in a circle, or in breeding in-and-in, without fresh blood. Mr. Lindsay, whom I succeeded as gardener at *Shrubland Park* in 1840, went there from *Highclere*, where he had the first and the then finest races of the *Rhododendron* family in the world. He left me a legacy of four thousand seedling *Rhododendrons*, which he intended for the woods, and about sixty plants of kinds, which he assured me he had carefully crossed with his own hands at *Highclere*, every one of which he was confident would be worth its weight in gold. But the whole sixty were not worth two farthings. The plants would neither die nor grow kindly; and when they bloomed, not one of the blooms would stand the sun or the least puff of wind.

Some years subsequently, Mr. Standish, of *Bagshot*, wrote just such another account of crossing *Rhododendrons* to extremity, in the *Journal of the Horticultural Society*, and only this current month Mr. Standish told me the tale was always the same ever since, if he attempted to cross them beyond a certain limit. Then, there are two well-established facts in the way of crossing without hybridising, and both are now well known to cross-breeders. The *Hyacinth* has gone on, in a circle, improving by breeding in-and-in, and by self-seeding, without a drop of fresh blood, for nobody knows how long; and the *Gladiolus* has been in the same mill since 1808, with only one new species to recruit the power of the ring in 1831, when *Natalensis* was got over.

As a practised breeder, I do not see the slightest improvement in *Pelargoniums* for the last twenty years, nothing more than a reproduction of former facts. What they call improvement, and what is a wonderful improvement, looking at it in that light, is entirely due to the high cultivation of the plants. The *Gladiolus* was in the same position for twenty-four years to my own knowledge, going round and round as if in a ring, reproducing the same tints in varied ways, but always the same tints, as in the *Pelargonium*.

Now, if we could obtain some Cape species to do for the *Geraniums* and *Pelargoniums* what the *Natal Gladiolus* did to that family, we should soon see as marked an improvement on the face of them as we do now on that of *Gladiolus*. But how soon? That is the question. If you got a hybrid seedling between *Pelargonium Fulgidum*, and *Pelargonium Sunset*, or from any of the strain freest from the black spots, a florist would tell you there was no improvement; on the contrary, that the seedling was not worth growing. But your seedling, if it was a true hybrid, would be a greater improvement in *Pelargoniums* than any seedling that was got for the last forty years. All you would have to do would be to follow up your success, as the florists did before you, breed in-and-in with your "not-worth-keeping" seedling, till you had a new race with flowers as big as the old one, and of as bright a scarlet as those of the *Crystal Palace Scarlet Geranium*. But such a seedling has been got, and I saw one; and if it had been mine I would send it and half a dozen of plants of *Fulgidum* to my *Sardinian* correspondent, with full particulars about how he was to carry on the crossing; and with his climate I imagine that he would get up the new race in one-half of the time it would be done in England; besides, the greater chances of avoiding the seedlings turning out barren, as a vast number of hybrid *Geraniums* have done formerly with us.

Now, I have been writing all this time in a circle myself, and I have just got right round to the point I was anxious to arrive at, and if you have conceived the point of my story, you will now see the aim of it to the bargain. We had a fine lot of plants of hybrid *Lilies* the other day, before the *Floral Committee*, from the gardener at *Buckingham Palace*. They were from *Lancifolium album*, the plain white *Japan Lily*, by the scarlet *Martagon Lily*, or *Lilium chalcidonicum*; but from the use, or misuse, which some have made of the labours of the *Floral Committee*, we were all in dread of giving a prize to those hybrids, and yet they ought to receive the highest award in the power of the *Royal Horticultural Society*, but not as trade plants, only as the beginning of a new race—and I pledge all my crossing, that that race will one day excel in colour and in brilliancy of tint all that is now seen in *Gladiolus*, and more to the purpose; but I shall not live to see it. All the materials for my anticipation are now in our own hands, and by a skilful working of the parts another reading might be given to the array of the *Lilies*, not of the field, but of the garden. By that time the *Lilies* of the low

countries will vie with the Rhododendrons of the hills and valleys, in all the colours, and in all the shades of colour in the chromatic scale.

D. BEATON.

## CULTURE OF THE RASPBERRY.

(Concluded from page 392.)

### SUMMER TREATMENT.

**Mulching.**—If fine well-swelled fruit is desired, the best way to obtain it is to cover the ground between the rows with short littery manure. In rainy weather the enriching salts will be washed down to the roots; and in dry weather the manure keeps the ground moist, and consequently prevents its cracking. This point is of importance; so much so that I have, when dung was scarce or wanted for other crops, used old tanner's bark, the refuse from the pineries—a substance which, though not enriching, answered the purpose of keeping the ground in a moist condition.

**Thinning the Young Shoots.**—As these spring up they should be reduced to four, or at most five in number; and to prevent them being broken with strong winds or injured by the gatherers of the fruit, it is a good plan to draw them up together, but not tightly; and if stakes can be had cheap, let the shoots be drawn towards a stake. The best way of doing this so as not to crowd them together is first to tie a piece of matting to a shoot, then bring the two ends together, and twine each round the other for about 14 inches or 18 inches; after that bring the two ends round the stake, and tie them fast together on the other side. When the first shoot is tied take the next in hand, and tie it similarly, and so proceed till the whole are secured. When the shoots have grown a foot or so higher, then place another circle of ties to each shoot. This second tying will be sufficient. By tying these shoots up more air and light will be given to the fruit-bearing spurs, and a neat tidy appearance given to the rows of plants. During the summer, as a matter of course, the ground should be kept clear of weeds.

**Cutting-down.**—As soon as the fruit is all gathered the last year's shoots are of no more use. They should, therefore, be all cut away close to the ground; and, unless increase of plants is wanted, all the suckers between the rows should be pulled up. The shoots that are to bear fruit the following year will thus have more air and light, and will, in consequence, ripen their wood perfectly to the very tops of the shoots. Towards the end of August the very tips of these shoots may be nipped off. That nipping will strengthen much, and will fill the buds with substance, so that they will break quite strong in the spring following. This completes the summer culture.

### WINTER TREATMENT.

This work commences as soon as the leaves have fallen. Rake them up, and carry them away to the rubbish-heap. Examine the shoots, and loose them from the stakes. Then cut them to the proper length to reach across the row, to meet the shoots from the opposite stool, as already described; tie them together, and then remove the prunings out of the way. The ground is then ready for a winter's dressing. Wheel on as much good rotten dung as will cover the ground 2 inches thick. Fork the ground slightly over, and leave it in that state through the winter to receive the benefit of the winter's frost. In the spring it will be in fine order, mellow and rich, and full of young vigorous roots, which will draw up largely nourishment for the plants during the following year. Then when warm weather sets in, commence as before with the summer treatment. Any cultivator bestowing the above pains with his Raspberries will be richly rewarded for his troubles. A plantation of Raspberries should be renewed every seventh year if the stools show signs of weakness.

**Propagation.—By Suckers.**—This is the most common method. When a new plantation is required a sufficient number of suckers should be allowed to grow near the old stool. Prepare a plot of ground for their reception, so as to be ready for planting early in October, and plant them in the way I have already described. Some plant the suckers out in nursery-rows for a year previous to planting them in their final position. When this plan is followed, cut down the shoots close to the ground early in spring; they will produce their strong canes with buds at their base to form shoots the next season. When trouble is not regarded this is a preferable method.

**By Seed.**—Those who have time and space may raise Rasp-

berries from seed, and may probably succeed in obtaining improved varieties. Choose the finest and ripest fruit; gather it, and crush the berries into a pulp; then wash away the pulp from the seeds, dry them in the sun, and, when thoroughly dry put the seed up in paper, and keep it in a dry room till spring. Make up a gentle hotbed, and when it is sweet sow the seed in shallow pans. It comes up quickly, and the plants when large enough should be pricked out singly in other boxes. By the time that the seedlings in these latter boxes have got some strength, warm weather will have set in. Then give plenty of air, and moderate supplies of water. Gradually inure them to bear full exposure. By the end of May the seedlings may be planted out in wide nursery-rows, and mulched there in the same way as established plants. There they may remain until they fruit, and then mark such as are improved, and throw the rest away.

On this subject of raising new sorts from seeds I have had some correspondence with Mr. Rivers of Sawbridgeworth. He has, I believe, the best assortment of Raspberries in the kingdom. In an interesting letter now lying before me he says, "The autumn Black Raspberry is quite a curiosity. Its great, great granddam was said to be a cross with the common Dewberry [Blackberry], and only bore fruit in summer. I have, by several generations, got it settled down to a sort that only bears in October a very fine black or purple fruit. But the most curious part of the experiment has been the following: In 1859 I had a row of selected seedlings, all alike in their shoots and habit, which bore a fine crop of fruit in October—large, fine, black-coloured berries. There was no other kind of autumnal Raspberry growing near them; and so I saved the seed and raised a crop of many hundreds, thinking I had fixed the sort. Last year they all bore fruit; and although the majority grew black berries like the parent stock with the same autumnal habit of bearing, there were some sorts among them that bore yellow and white berries, the plants being easily distinguished by the colour of the canes; and two or three bore the largest and finest orange-coloured Raspberries I ever saw—sorts that would make a little fortune were they not so obstinate, for they will not put out a single sucker. Layering is slow, and cuttings I have not tried. I can, however, tell you that my bed of seedling black Raspberries is a study for Darwin. I intend to keep on raising seedlings, and have seed of the large orange sort sown. I must tell you a fact of interest to you: the autumnal Raspberries will not do in the north—they want more heat. The heaviest crop I ever saw was in the garden of a friend at Guildford, last October, of both red and yellow autumn Raspberries. They bore the canes down with the fruit, and pecks were gathered from the two rows." The experience of my friend, Mr. Rivers, is quite encouraging to all who like Raspberries, and I am sure all our readers will heartily wish him success; but I and gardeners who live in the north would be very much gratified and thankful if Mr. Rivers would operate on summer-bearing Raspberries, and improve them equally as much as the autumnal sorts. Perhaps, if some of us northerners were to try our skill in our climate we might succeed in raising sorts, even autumnal ones, that would ripen in our colder climate.

In regard to propagating sorts that are shy from suckers, I see no reason why they might not be raised from eyes in the same way as we raise Vines—that is, by cutting a stem into lengths containing one eye each, and slightly covering the eyes in soil in pots plunged in a gentle hotbed. I trust Mr. Rivers will try that way with his golden Raspberry, and be successful.

### SELECT LIST OF SUMMER RASPBERRIES.

- Antwerp, Red.*—Large, flavour excellent.  
*Antwerp, Yellow.*—Large, yellow, sweet. Excellent for dessert.  
*Black (Rivers').*—Purple, acid. Useful to correct the dull sweetness of jam made from other sorts.  
*Brinckle's Orange.*—A new American golden Raspberry, rather acid.  
*Fillbasket.*—Large, abundant bearer; good.  
*Filly or Fastloff.*—Red, large, and excellent.  
*Knevett's Giant.*—Very good.  
*Prince of Wales (Cutbush's).*—Red, large, firm; very fine.  
*Prolific (Carter's).*—Red, large, and excellent.  
*Victoria (Cornwell's).*—Large and good.  
*Sweet Yellow Antwerp.*—Particularly sweet. Shoot very slender.

### AUTUMN RASPBERRIES.

- Autumn Black (Rivers').*—Large, dark purple. Juicy and good.

*Belle d'Orleans*.—Dwarf habit; fruit large and good.  
*October Red*, or *Merveille de Quatre Saisons*.—Large, bright red. A most abundant bearer.  
*October Yellow*, or *Merveille de Quatre Saisons à Fruits Jaunes*.—Yellow; fruit large. Prolific bearer.  
*Victoria* (Rogers').—Large, dark red, dwarf habit. Bears abundantly, and is excellent.

T. APPELBY.

## FLOWER SHOWS OF WINDOW PLANTS FOR THE WORKING CLASSES OF LONDON.

UNDER this title the Rev. S. Hadden Parkes, B.A., Curate of St. George's, Bloomsbury, has published a pamphlet on the advantages, both in a moral and physical point of view, with which shows of the above description are attended. As yet they have only been adopted as an experiment in a few of our densely populated metropolitan parishes, but the results have been most encouraging; and we hope to see them in course of time not only permanently established, but also more widely diffused. That they are calculated to effect a considerable amount of benefit we think no one will deny; the tending which the plants require affords an innocent recreation during hours which might otherwise be spent in a more questionable manner; habits of observation and foresight are induced, and a desire for information is awakened.

In passing through some of the most miserable quarters in London,—and they are miserable indeed—when we have seen pet plants in the windows growing in no matter what utensil, we could not help thinking that amidst all the surrounding poverty and crime there was still a green spot left that might tend to better things.

The mute voice of the flower and the warblings of the imprisoned songster speak in language more intelligible and more moving than the cold voice of reason, which may neither be listened to nor understood—they speak to the affections and tell there is something to love.

The credit of having first started flower shows in Bloomsbury is due to the author of the little pamphlet before us, the experiment having been first made in 1860; and in consequence of the success which it met with, a second show, which was noticed in our Number for April 20th, 1861, was held in the following year.

"The first experiment was made in one of the poorest localities of the metropolis, among alleys and courts in which live some of the most degraded of the London poor. Little Coram Street, the spot first selected, is a narrow street, with a number of courts stretching right and left, containing about 1700 persons. The inhabitants of these courts are persons who generally obtain their living by selling Water Cresses, fruits, and small toys in the streets, with a larger number who obtain their living no one knows how.

"Last year the exhibitors were divided into several classes, according to the district in which they lived, so that the inhabitants of the smaller courts and darker dens might not have to compete with those whose airier neighbourhood and better means gave them an overwhelming advantage in the contest. The district of Little Coram Street showed the good effect of the training of the first year; for though in point of airiness it is infinitely inferior to the other parts of Bloomsbury, yet, with the stock of experience it had gained, it was able to compete successfully with the more favoured localities."

Thus in a single year these humble cultivators had made a marked progress in skill; and though, according to Mr. Parkes' experience, such shows have been found nearly self-supporting, we trust that from their elevating influence they will not for want of encouragement be allowed to go down.

**PECULIARITY IN ORANGE TREES.**—Many of the trees in one garden were a hundred years old, still bearing plentifully a highly-prized, thin-skinned Orange, full of juice, and free from pips. The thinness of the rind of a St. Michael's Orange, and its freedom from pips, depend on the age of the tree. The young trees, when in full vigour, bear fruit with a thick pulpy rind, and an abundance of seeds; but, as the vigour of the plant declines, the peel becomes thinner and the seeds gradually diminish in number, until they disappear altogether. Thus the Oranges that we esteem the most are the produce of aged trees, and those which we consider least palatable come from trees in full vigour.—(*A Winter in the Azores*.)

## ON FUMIGATING.

ON looking over No. 70 of your valuable Journal, I happened to stumble on an article upon fumigating, with a remedy for burning the leaves of the tender plants. I for one am always glad to see improvements, especially in gardening, and am much gratified at the very liberal diffusion that these improvements meet with through your pages from week to week. As to the apparatus there sketched, I do not for one moment doubt its efficacy; but you must remember the very large number of amateurs who look up to you for instruction, and who cannot conveniently get such an apparatus as your correspondent describes, and still they wish to combine both efficacy and cheapness. I am induced to think that this is done equally well, if not better, by the old system of moss than by your correspondent's plan. It has stood the test of years, and will, undoubtedly, do so for many to come. I have used it myself for more than half a dozen years, and can boast that I never burnt a single leaf in all that time. As your correspondent seems to have lost sight of it altogether, I would invite him to give it a candid trial, and report progress for the sake of those, if there are any, who do not know the plan I speak of, which is simply to place about half an inch or three-quarters of an inch thick of well-damped moss upon the common fumigator, of whatever construction, and the smoke passing through that will be perfectly cool and harmless; and there is no expense incurred.—THOS. H—, *The Priory Gardens, Guisborough*.

## THE ROYAL HORTICULTURAL SOCIETY.

THE Council of the Royal Horticultural Society have issued a circular to the Fellows, informing them that in consequence of the very general desire expressed that one of the French fountains, which now forms so conspicuous an ornament in the garden, should be retained, they have opened a subscription for the purpose of providing a fund with which to purchase them or some of the minor bronzes, &c., exhibited in the garden. So much remains to be done to complete the garden otherwise, that the Council do not feel justified in expending any portion of the means of the Society on this object, and therefore have had recourse to a special subscription for the purpose. We heartily concur in the desire to see one at least of these beautiful fountains preserved for the garden, and trust the Council will be successful in their application. Among such a numerous body as the Fellows of the Royal Horticultural Society, there must be many who would be willing to subscribe largely for the acquisition of one or other of these fountains.

It will require large subscriptions to do so, for the smallest of the fountains is priced at no less than £1000, and the larger at £5000. Perhaps were the subscription to reach within a few hundred pounds of the sum required, the Council might feel justified in supplying the difference from the funds of the Society. But even supposing they were to do so, it could only be a comparatively small sum which they could so contribute. It is clear that upwards of £3000 must be subscribed. The number of Fellows is understood to be now about 3500, so that £1 from each would accomplish the matter.

In the original plan of the garden a fountain is laid down at the spot now occupied by Marochetti's statue. It would, therefore, probably be here that the fountain, if purchased, would be placed.

Wishing all success to the movement, we shall keep our readers acquainted with its progress and success.

## THE PROPAGATION OF CONIFERÆ.

DURING the last few years, Coniferæ have become somewhat popular among gardeners and amateurs, and it will, doubtless, be interesting to give a short description of the mode of propagating some of the more ornamental kinds, especially those which are often grown in pots or tubs, as ornamental objects for the conservatory or the terrace garden.

The modes of propagation here described, are those practised by an experienced gardener who has been for a long time exclusively occupied in the culture of this beautiful tribe of plants. It is well known among practical men, especially by propagators, that Coniferæ are not readily reared from cuttings, and that other means, such as the different processes of grafting, are much more successfully employed. It is not the less true

that different species of Coniferæ require to be grafted by different methods. Many species cannot be propagated by cuttings at all, owing, no doubt, to their resinous nature. Those who cultivate Coniferæ, and desire to propagate them extensively, should keep at hand a number of the stocks best suited to the different species. The following stocks are recommended for this purpose:—*Arsucaria imbricata*; the different species of *Pinus*; *Thuja orientalis*, and *occidentalis*; *Juniperus virginiana*; *Podocarpus elongatus*; *Taxus*; *Cupressus*; *Taxodium distichum*; and *Dacrydium spicatum*, or *Podocarpus spicatus*.

What is called side-grafting, is the mode most successfully adopted with many kinds that are required to be quickly grown into strong and vigorous plants. The best time for performing the operation is in the months of March and August. The stocks used ought not to be stronger than a common quill. Worsted or woollen thread is found to be the best tying material that can be used. As soon as the plants are grafted, they must be placed near the glass of a propagating-house, in an inclined position, so as to impede the circulation of the sap to the top of the stock, and to facilitate the adhesion of the graft. The management must be the same as that given to grafted plants in general; but care should be taken not to allow them to become too moist. They must also be frequently cleaned, and the stock must not be cut down before the graft has grown somewhat strong and vigorous.

The best time for taking cuttings is towards the latter part of the summer, and it is necessary to select them from the young shoots that have grown the same year: they should be cut close to the old wood. The cuttings should be planted in pots of silver sand, and kept in a warm greenhouse or propagating-house, and covered with a bell-glass or a hand-light. Those persons who have not the convenience of a house in which to place cuttings, may avail themselves of the mode of propagating called layering. For this purpose, when the young shoots have become sufficiently strong, it will be necessary to erect an artificial stage around the plant which it is desired to propagate. On this stage, pots of suitable soil must be fastened, by being tied to the boards, and in the position best adapted for the operation. The branches must then be gently bent over the pot, and properly secured in their place; the young shoots inserted in the soil of the pot, and secured with a small peg. This is the most successful mode of propagating such kinds as *Pinus longifolius*, *P. palustris*, and *P. Hartwegii*, which have a spongy bark.

Grafting upon roots has been found very successful with the different species of *Thuja* and *Juniperus*. This mode is performed as follows:—In February or March, the small roots of *Juniperus virginiana*, and *Thuja orientalis* or *occidentalis*, are taken off: they must not be stronger than the scion or shoot, which should be selected from last year's wood, near the summit of the plant. When the grafts are made, the roots must be potted in small pots and placed on a shelf in the greenhouse, being kept close, and shaded until established.

As regards the most suitable stocks for Coniferæ, it may be observed that they are most successfully raised from seed. It is not advisable to take young plants from a collection for this purpose; because they do not accommodate themselves to pot-culture so well as plants obtained from seeds. Good healthy seeds of the species named at the beginning of this article, should be procured for the purpose of raising plants to be kept as stocks. Such plants will be found most suitable for those engaged in the propagation of Coniferæ. The seeds should be sown in February, in wooden boxes of convenient size, and 3 inches or 4 inches in depth. The soil most suitable for sowing them in is sandy peat, mixed with a fourth part of loam. The boxes should be well drained, and, after the seeds are sown, placed in a temperate greenhouse. As soon as the seedlings appear, the boxes must be removed near the glass, in order to give the plants plenty of light. Before the first leaves appear, the young plants should be taken out and potted in two-inch pots, using a sandy peat soil, but no loam. This treatment is preferable to allowing the young plants to grow large in the box, and then shifting them into pots; as, when they are taken out of the box very young, with only one or two roots, they are less liable to be injured, and they soon adapt themselves to their new situation. When the seedlings have been potted, they should be removed to a cool frame, and placed on a bed of ashes or gravel, but quite near the grass. They will require to be shaded during bright, sunny weather, and care must be taken never to allow them to become either too dry or wet. The frame may be kept rather close till the end of May, or the beginning

of June, according to the state of the weather, when the lights may be taken off. As soon as very rainy and frosty weather sets in, the lights must be put on again, to remain on all the winter. Very little shelter will be necessary, except during severe frosts. Air must be admitted to the plants on all favourable occasions. In spring, they will require to be shifted into four-inch pots, and, if properly attended to, they will be ready to graft upon by the autumn.

Seeds of *Taxus*, *Thuja*, and *Juniperus virginiana* may be sown in the open ground, and pricked into pots three or four months before they are wanted to work on. They may be removed to a shelf in a temperate, moist stove, to remain for some time, the better to establish them in the pots.—M. COURTIN, Bordeaux.

## NOTES WHILST RESTING.

(Continued from page 391.)

STRONG winds from the south-west have brought ashore large quantities of Seaweed—*Vraic*, as it is here called. The precipitous roads and pathways down to the shore of some of the bays will not allow of carts to proceed thither, so the *Vraic* is imported in panniers on donkeys. It is the chief maure of the island, and mine hostess, when showing me some noble round Potatoes, said the soil on which they were grown had been vraised. They averaged three to the pound, and had not a speck upon them. I shall learn more about vraising.

In answer to my question whether there was much disease among the Potatoes this year, my landlady replied, "None among the Early," and as yet I have only heard of severe disease among Flukes. A market-woman was selling these as fast as they were taken up "because they would not keep."

The abundance of Borage in almost every cottage garden is forced upon the attention by its bright blue flowers, and the "why" was not answered until informed that it is a favourite flavour of the soup which is the prominent dish of every Guernsey cottager's daily bill of fare. Heaps of it are to be seen now drying by each cottage's wall, preparatory to storing it for winter's use.

This might be called most appropriately the "Island of Ferns," for not only do most of our native species grow here, but they attain a luxuriance and size very unusual. *Scolopendrium vulgare*, or common Hart's Tongue, may be called the Fern of the island, for you find it everywhere, and, which is most remarkable, among the thousands of plants and tens of thousands of fronds I have examined, not one varied from the normal form. Does not this show that the many varieties met with in England are caused by ungenial soil or climate, and that they are mere deformities? Sir W. Hooker speaks as of a rare occurrence, that in the moat of Kenilworth Castle he gathered fronds of this Fern more than 2 feet long. In England that is a rarity, but here I could gather hundreds of the fronds of that length, and have some now between blotting-paper for my herbarium.

There is but one locality in the island where the somewhat rare *Asplenium marinum*, or Sea Spleenwort, has been found, and I have just returned from it with some of the best specimens I ever saw, most luxuriant, and loaded with ripe spores. At the south-eastern corner of the island is Bay d'Icart, and one little cove of this, guarded by a Martello tower on the rocks above it, is Petit Bot. Near the bottom of this little cove, and on its western side, is a chasm in the rocks, which are here about 300 feet in perpendicular height; and down the sides of this chasm is a constant dripping of water. No direct sun's rays, except at its rising, penetrate here, so that the shelter, moisture, and shade, render it a very home for the *Asplenium*, and there, far above our heads, I and my companion saw it growing. The tufts are many and very luxuriant. He mounted upon some projections on the face of the rock, and by the aid of a stout walking-stick was able to uproot one fine eight-fronded plant.

There is a peculiar fragrance emitted from the pasturage as it is bruised by the hooves and teeth of the cows, but from what plants it is emitted I cannot discern. The mildness of the climate and siliceous nature of the soil are promotive of fragrance in plants, and the flowers here are very strongly odiferous. I have no doubt that flowers for the manufacture of perfumes might be cultivated here profitably, and the perfumes attain a celebrity for their power. At present the chief locality for such manufactories is Cannes and its vicinity, especially a

little town called Graese. One manufacturer there, M. Herman, uses in making perfumes 140,000 lbs. of Rose petals, and the same weight of Orange flowers, 32,000 lbs. of Jasmine flowers, 20,000 lbs. of the Violet, and 8000 lbs. of the Tuberose, with less quantities of other sweetly-scented blossoms. About fifty women are employed by him in separating the petals from the calices and other parts not required for distillation. Orange flowers, however, do not have their perfume extracted by distillation, but are mixed with oily matters, pressed, and gently heated. The Rose grown for perfumery purposes is the *Rosa centifolia*; and I may observe, in passing, that its name of the Provence Rose is corrupted from that of the place of its birth, Provins in Champagne; the department of Provence has no relationship to the name.

Every cottage on this south side of the island has an Apple orchard around it, among the tenants of which one immediately remarked the Quarronden and Hawthornden; but I have had no leisure for attempting to identify the many other kinds grown, nor will it be easy to do so until the fruit, which is abundant, approaches nearer to maturity. Much cider is made on the island, but the samples I have tasted are thin and flavourless, but with more than a satisfactory proportion of acidity.

The orchard-culture is not characterised by skilfulness. The trees are crowded and very mossy. Some of them must have outlived nearly a century. Round the stem of some young trees Seaweed is bound, and I am told that it promotes their health, and prevents moss and caterpillars. A reason for such effects may be discerned, and certainly the trees so cared-for are more healthy than their older and unseaweeded companions.

The Potato crop is abundant, but they are dilatory in taking advantage of this fine weather for digging them up and storing or exporting them. To take Potatoes up in the dry hard state they are now in is one of the best securities for their keeping well. I am told that about 120,000 bushels are annually exported to England; but from Lorraine, in France, comes our chief importation of these tubers. The French reporter of the *Times* says, that at Luneville, and in the Vosges, last year the purchases for the English market were estimated to amount to £240,000, and the farmers in that country expect that this year the sale of Potatoes will be still larger. They are stored here in dry sheds, and covered with dried Fern.

A very peculiar country saddle I have come in contact with, but am told that at every farm-house one or more of such saddles are kept. They are made of that rare relative of the Grasses, *Cyperus longus*, English Galingale. In its wild state it is not of very frequent occurrence here, but it does grow abundantly in some low situations, and is cultivated for economical purposes. The saddle is all flap, about 6 feet from tip to tip,

and when spread out, which it can be quite flat, it looks like a large, misshapen, rush doormat, with an appendage to fasten to a nail, for such the crupper looks, and, like the bit of a pommel, is made of the Cyperus plaited. How the stirrups are attached, and how the saddle is fixed upon the back of the steed I have not yet ascertained, but I should think by a girth passed over the saddle like that used in racing. This *Cyperus* is called *Han* by the Guernseyers, and its use is not confined to saddle-making; collars for horses, mats, footstools, and ropes are made of it. The rope is of considerable strength, and, I am told, is employed by fishermen, being less injured by salt water than rope made of hemp.

I must thrust in a little bit of botany here, just, as was once said, to show the shape of my wrinkles, but also because it is interesting to point out that this said *Cyperus* is one of the genera which very markedly show how plants withdraw by degrees from temperatures distasteful to them. Within the tropics there are nearly 240 known species, but they gradually

diminish in number in the more temperate zones of the earth until they are reduced to two species in England (*longus* and *fuscus*), and these shrink from proceeding north of St. David's.

The fruits now to be had in the market at St. Peter's Port are purple Figs, Peaches, Apricots, various Plums and Pears, Apples and Raspberries. Now, be it known to you, O reader, that these Raspberries are only 4*d.* a-pound, small-seeded and luscious, and be it also known to you as a lesson learned during pilgrimages in many lands that it is pleasant to taste of the peculiar coquinary compounds of those lands, so I committed my Raspberries to the discretion of the widow Falaise—and was I not rewarded thereby? For did she not place before us a *Gosh*? She did not know how to spell it, nor do I; but the merits of the composition are the same, however mistaken may be the orthography; and it is so phonetic, that when, O reader, you come to La Fosse and succeed in having before you one of the ample Goshes of the said widow Falaise, you will feel that your good genius has led you to pleasant pottage in a pleasant place.—QUITs.

(To be continued.)

### THE LAWTON BLACKBERRY.

You will oblige me if you can inform me on the two questions, How to train the Lawton Blackberry? Mine is two years old, throws up long, upright shoots and suckers, and bears an abundance of fruit from old branches about the ground. Should the uprights be stopped or only cut down close to the ground? In fact, I want to know how to work the bush, and whether it is worth the trouble. I have plenty of room.

I have a Hoya *carnea*, an old one. It bears long, slender pods 4 inches or 5 inches long. Shall I get any variety from the seed, or anything at all?—FLAX.

[The Lawton Blackberry bears its fruit on shoots of the preceding year, which, after bearing, in most soils die down to the ground. The young shoots of this season's growth should each be tied to a stake, so as to have sun and air, and be well ripened. When they have made a growth of 6 feet their tops may be pinched off, and the young side shoots be left their full length. The fruit is more pointed than the English Blackberry, but in this climate is neither larger nor better in flavour. The Dorchester Blackberry, also an American fruit, is said to be larger than the Lawton; but it has not yet borne fruit. It is not more robust in habit than the Lawton.—T. R.]

### OSIERS.

PLANTATIONS, or large beds of Osiers, might be very advantageously grown in almost any soil—such as banks of rivers, drained moors, &c., and, annually cut, would produce a sum of money that I have no doubt would largely remunerate the grower. And from land that cannot otherwise be made available for tillage, notwithstanding the vicissitudes of seasons, taking good and bad under view, the writer has experimentally ascertained that an acre of Willows or Osiers will often bring the grower a larger sum of money than an acre of Wheat; and likewise from land that would be almost useless for other kinds of crops. It is rather astonishing that the growth of them is not more attended to both in England and Scotland. As regards the nature of the soil and subsoil suitable for growing them in to the best perfection, Osiers delight in banks of rivers or drained moors, and are greatly invigorated by occasional floods or irrigations. Plantations of them may also be formed, and will succeed well, on low spongy bottoms along the margin of streams, in almost any lowland district of Britain.

In the great majority of farms are to be found level, marshy, wet spots, which, by drainage, cannot well be made available for tillage, and which might be planted with the Willow, and would afterwards recompense the proprietor or farmer in a twofold way. The land might be prepared in various ways for this crop, owing to the extent and nature of the soil. Where the land will admit of being ploughed and harrowed, and has formerly undergone cultivation, I find that, at the present prices of Willow-sets or plants, and the expense of labour, it would not cost more than £8 15*s.* per English acre, allowing the plants to be planted at a distance of 28 inches by 18 inches apart. But I find that for plantations of any considerable extent for Osiers, the ground should be formed by the spade

into beds of from 8 feet to 9 feet broad, with intervening furrows or narrow ditches to carry off the water. The plantation may be made at any time between the fall of the leaf and an advanced period in spring; but the two last weeks of February and first week of March are the most proper times for planting the Willows. Cuttings 15 inches long should be taken with the knife on an upward slope from well-ripened wood of either two or three years' growth; experimental trial convinces me they grow more luxuriantly when planted about two-thirds of their length in the ground, than when they are less deeply inserted.

I can learn from frequent trials that, where depth of soil can be obtained, Osiers succeed best in a deep, moist, free soil—ground to be dug to the depth of 24 inches, with a small quantity of dung and old lime rubbish put in the bottom of the trench. When Willows are planted in stiff tenacious soils, they are much more tardy in growth, and very liable to the ravages of a brown bug, which is accompanied by a black caterpillar, often making great ravages. The ground should be hoed and kept clean: the space will well admit of this, as Osiers should in no case be planted closer than 28 inches by 18 inches apart. The expense of preparing Osier plantations by spade-work in this way of course depends much on the nature and situation of the land; but in ordinary soils drains can be cleared out to the depth of 30 inches by 22 inches broad at surface, having a scarpment, leaving it 12 inches broad at bottom. This form of a ditch can be made at from 5½d. to 6d. per perch, and the ground of an English acre, trenched and prepared to the depth of 2 feet, for £6 10s. 6d., or nearly so, and planting performed at about 18s. per English acre. The Willow, for the use of the basket-maker, should be cut every year slopingly with the knife, within three buds of the point whence the shoot issued, and will admit of being cut back once in three years for the use of the cooper, exactly to the swell of the shoot of the three years' growth, thus compressing the plant back to its ancient dwarf form, at the same time realising a handsome return.

Moreover, by treating Osiers in this way, they will last and produce well for a great many years. The ground should be deeply stirred with the hoe and kept clear of weeds; but digging with a spade around the roots of Willows often proves very hurtful to the fibrous feeders, as we often meet with a great portion of such oozing and growing very near the surface of the soil. Plantations of Osiers thus treated, notwithstanding the vicissitudes of the seasons, will bring the grower at least the sum of £12 sterling for every year after they arrive at their full growth. This sum of £12, I have minutely tested, can be at the present time realised from an English acre of Willows, after all expenses of cleaning and cutting-down the crop are adopted.

*The Best Varieties and Most Profitable Applications.*—The kinds most approved of for pollarding, coppice-wood, fuel, poles, or bark, are the Huntingdon Willow (*Salix alba*), and a variety called the Red-twigged or Bedford (*S. Russelliana*).

The best sorts for Osier grounds are—1st, the common Osier (*S. viminalis*); 2nd, The Red Osier (*S. rubra*); 3rd, The fine basket Osier (*S. Forbyana*); 4th, The Velvet Osier (*S. mollissima*); 5th, The Long-leaved Willow (*S. triandra*); 6th, The Golden Willow (*S. vitellina*). These are the sorts most esteemed for the various purposes of the basket-maker, the cooper, and the turner. The way in which Willows are most commonly disposed of, after being cut, is—they are sorted into trusses and tied into bundles of 2 feet and sometimes 3 feet in circumference; and if intended to be stripped of their bark, they are set on their thick end, immersed a few inches in standing water, and left there until the latter part of the following month of May.

It has of late been asserted by various respectable parties that as high a sum as from £13 to £14 of nett profit, and sometimes more, could be derived at the present time from an English acre of Willows, under very ordinary treatment: they succeed best in northern exposures, provided they are not over-topped. Should the ground be at all suitable for the crop, each set will produce in the first year two good basket-rods, or 24,000—worth 6d. per 100 of 120. The second year, the sets being much stronger, will produce on an average six rods, one more or less being considered a very common number—one of which may be left on each stock for hoops, and the remaining 60,000 cut for baskets, which would be worth much about £24 sterling. By the third year there ought to be at least 12,000 hoops, worth 4s. per 100 of 120, and from 28,000 to 29,000 rods, worth at least £13 10s.

These results may be obtained even by fair cultivation under ordinary circumstances: of course, it may sometimes be difficult to obtain a ready market or sale for the basket-rods; the hoops

we find to be always such, and much sought after. The greater part of those used in Ireland are imported and much sought after also, with commonly a very scanty supply. No hoops should be left by the third year on the plants, as the rods which grow under the shade of the hoops are seldom or ever strong enough. Mr. Philips, of Ely, in England, one of the greatest cultivators of Osiers at the close of the eighteenth century and beginning of the present, says that he always obtained from £12 to £18 per acre, according to the fluctuation of prices, after deducting all costs of labour, &c.; the Red Welsh Willow (*S. purpurea*), and the White Welsh (*S. helix*), being at that time the two leading and favourite sorts, they being at that time disposed of in bunches an ell in circumference, after being peeled and whitened, by compressing them in an iron hoop to this size. If the plants be not in any way destroyed by insects, to which in some years they are subject, under good cultivation upwards of £10 could, at the present time, be realised of nett profit, after deducting all expenses of labour, from an English acre of Osiers. And although an old adage in Lincolnshire, it is nevertheless still true, that "a Willow will buy a horse before an Oak will buy a saddle." As to what towns and countries they are in most request, we find them in request in a great many large manufacturing towns and seaports, more especially in Dublin. The butter trade in Ireland causes a great consumption for hoops for butter firkins throughout the season. I have witnessed hoops of Hazel and Black Sally, as it is termed, sold at 12s. and 13s. per 1000, and the cooper cut them at his own cost; and in Dublin there is the Institution for the Blind, that requires to import a great many yearly to keep their hands employed. A much greater consumption for Willows might be relied upon, were they but more extensively cultivated. In almost every seaport town of Britain, an accurate calculation has of late been made that at least 6000 acres of Willows could readily be disposed of in Scotland and England, at prices that would very handsomely remunerate the grower.—J. FORBES, *Monymusk*, in the "Transactions of the Highland and Agricultural Society."

**THE STREET MANURE.**—At a meeting of the Society of Arts some years ago, a paper was read "On the means of cleansing daily the carriage and foot pavements of the metropolis, including about 170 parishes, extending over an area of 13 square miles, or 40,874,200 superficial yards." The whole extent of carriage way included in the metropolitan districts, proposed to be cleansed daily, embraces an area of 6,246,902 superficial yards; and as one machine is capable of sweeping 19,280 yards in eight hours (say from midnight till eight in the morning), it would require 323 machines to perform the whole work daily. The price of sweeping and transporting the soil to the dépôts, or lay-stalls, would be, on an average, about 1s. 6d. per 1000 yards swept, so that the daily cost would be £468, or £170,820 per annum. The ashes from the 65,910 houses in the districts included would realise something like £100,000 a-year, so that the nett cost would be reduced to £70,820, or rather more than 20s. per house. If manual labour were employed to clean the same extent of surface, it would require 3,120 men to do the work daily. The foot pavements in the same districts extend over 1,041,150 superficial yards, which, at 1s. 3d. per 100 yards cleansed, would cost annually £23,725; and taking the whole of the carriage and foot pavements to be swept daily, the cost per house would on an average not exceed 28s. 6d. By experiment it was found, that the sale of the manure nearly compensated for the labour employed. The deposits of manure on the pavement of Oxford Street and Regent Street, on a Saturday, from seven in the morning till twelve at night, weighed, altogether, 3 tons 3 cwt. 2 qrs. and 8 lbs.

**SANDWICH.**—The English, who are profound thinkers, violent in their desires, and who carry all their passions to excess, are altogether extravagant in the article of gaming. Several rich noblemen are said to have ruined themselves by it; others devote their whole time to it, at the expense of their business, their repose, and their health. A minister of state (Earl of Sandwich), passed four and twenty hours at a public gaming-table, so absorbed in play, that, during the whole time he had no subsistence but a bit of beef between two slices of toasted bread, which he ate without ever quitting the game. This new dish grew highly in vogue during my residence in London; it was called by the name of the minister who invented it.—(*London by a Frenchman a Century ago.*)

**DICTYANTHUS CAMPANULATUS (BELL-FLOWERED DICTYANTH).**

This fine and very singular-flowered climbing plant has been said to grow in Mexico, at the foot of the Sierra Madre, near Durango, but Professor Morren, who figures it in "La Belgique Horticole," states, on the authority of M. Baumann, that it is a native of Brazil. The base of the stem is woody, with white lines or fissures in the bark, which probably becomes corky with

age. The stem is pubescent and twining; the leaves are opposite, cordate-acuminate, with a red petiole 3 inches to 4 inches long. From their axils is produced a single flower, borne on a long peduncle. The calyx has five broad lanceolate lobes. The corolla is urceolate below, and green; its limb is turned back, and prolonged into five large horns, with recurved margins; this part is

whitish, marked with innumerable small purple lines or striae, which are horizontal on the limb, and vertical at the base of the tube. The staminal crown has five large rays in the form of a star. The flowers remain open about a week. M. Baumann

has grown it in the open air during summer, and in a warm Orange-house during winter, and had bloomed it on a wire trellis, about 2½ feet high. It is the *Tympananthe suberosa* (Haskarl), and the *Stapelia campanulata* (Pavon).

## FLORISTS' FLOWERS,

THEIR DISTINGUISHING CHARACTERISTICS, CULTIVATION, AND VARIETIES.—NO. 8.

### THE AZALEA.

Few features at our great exhibitions are more striking than the noble banks of Azaleas contributed by the first growers in the kingdom; their varied and rich tints from brilliant scarlet to pure white, the complete mass of bloom that they present (for oftentimes not a leaf is to be seen), and the size of the plants, exceeding as they do any others that are sent to the exhibitions, all combined are sure to attract crowds of flower-loving visitors; and will even detain those who only come because it is the fashion, and "everybody" will be there, and the devices will be worth looking at, and the music will be charming, but who would be quite as ready to come were there not a flower worth looking at, provided you could insure the company and the dresses and the bands. I well recollect what the Azaleas used to be in old Chiswick days; and one may well be astonished at the rapid improvement that has taken place in them, not only in the style and habit of their growth, but also in the varieties which are exhibited. Loose, ragged, and dull-coloured flowers are rapidly disappearing, and their places are being supplied by new varieties, which combine most of the properties considered desirable by those who have fixed the standard in this as in other florists' flowers.

It will be seen by a reference to the figure that the circular form has been adopted as the *beau idéal* after which raisers of new varieties

were to strive; and although that has not been reached yet, Ivery's Gem being about the nearest to it, yet it is most likely that the rapid strides which have been made will be continued until the complete circle has been attained: and however much such arbitrary rules may be decried, I believe that the general taste of the public will confirm in the end the judgment of the florists.

The substance of the flower must be stout—a rule that applies to all flowers, for shape cannot be retained if the petals be flimsy. People forget this, and, if they have a flower of good shape, will allow the public the benefit of it, although it may have at the same time such an utter lack of substance as to prevent its ever being extensively grown. The flower should consist of five segments of about equal size, and be regularly placed.

The colour should be bright and clean. In Whites this is very difficult, most of those under that term coming at times with splashes of crimson, red, and rose in them. Where they are spotted, the spots should be distinct, and not muddled up together.

The plants may be grown and trained in various ways; but in whatever way, they should be so full of bloom that a leaf can hardly be seen. We are speaking, of course, of those for exhibition; but it is ever to be remembered that the same kind of treatment which produces such plants at our great shows will also produce the best for home display also.

THE CULTIVATION of the Azalea does not present any very great difficulties, but cannot be carried out successfully unless there be a house specially for them, where heat can be applied and all fear of frost removed. The best grower of them that I know (and the prize lists evidence the truth of my observations), is Mr. Charles Turner, of the Royal Nurseries, Slough; and his Azalea-house is a model of what such a structure ought to be. The sides of the house are of glass, and the sashes slide so as to give an abundance of air when required; and from this house, save for the purposes of exhibition, they never move. The plants (and what plants they are!) are placed on the floor of the house, which is composed of gravel. The house is heated by hot-water pipes running all round, and can of course be thoroughly shaded from the scorching rays of the sun. Here they grow for about six months in the year; and as I have said, even during this period of comparative rest, they are not, as in the mode of treatment

A PERFECT INDIAN AZALEA.

adopted by some, turned out of doors: this Mr. Turner considers injurious and dangerous; for he does not think heavy rains suit them, and oftentimes early spring frosts lay hold on the plants; and although nothing is seen at the time of this injury, the flower-buds are damaged, and will either drop off or come badly.

The soil in which they delight is peat, and this strengthened by about one-third of good sound loam will grow them admirably; white sand being, of course, largely used.

When the plants are done blooming a moderate degree of heat is applied (about 60°), and they will then soon begin to move. During this time they should be frequently syringed—once or twice a-day, and the house kept close, for they delight in a warm moist atmosphere, just as the Camellia does at the same period of its growth. This will be continued until the plants all over have made a vigorous and healthy stock of shoots; and then gradually they may have air given to them until the sashes are left quite open and the flower-buds are well formed. They are thus kept gently growing until the month of October. Then frosts will begin to make their appearance, and a small amount of heat must be given every night. Two years ago Mr. Turner's

prospects of successful competition were seriously endangered by a slight frost having seized some of his plants at this period. During the winter months the supply of water must be lessened, but they must never be suffered to get dry. In the spring, when they begin to swell for flowers, they must receive a larger supply of water and a little more heat.

There is one dread enemy to the Azalea which must be carefully guarded against—namely thrips, which attacks the under side of the leaves, depositing a glutinous matter or dust which soon closes up the pores; and the health of the plant is materially injured before anything is known about it. When discovered, fumigating must be vigorously resorted to; but if it has attained any head the leaves attacked are sure to drop off, and the beauty of the plant be for a time destroyed. It is not, however, difficult to prevent its progress, and prevention is ever better than cure; and if the house be properly fumigated, syringed, and ventilated, there is little prospect of its gaining ground.

Although in thus writing I have had mainly in view the larger plants for exhibition, yet the same kind of treatment will insure success for any purpose: and even where there are not conveniences for heating, and where they must be grown with Geranium and other softwooded plants, attention to syringing and fumigating will enable a grower to have some nice plants for adorning the greenhouse or conservatory.

As to *sorts*, there is, as in every flower now, a large number, and hence selection becomes difficult; but I believe the following are about the best that can be had. They will vary in price according to the size of the plant or the newness of the variety. Those more recently introduced I have marked thus \*.

*Admiration*.—White ground with broad bands of crimson; fine form.

*Ardens*.—Orange scarlet; fine bright colour.

*Beauty of Reigate*.—White striped with rose; very fine shape.

*Brilliant* (Shearman's).—Fine orange scarlet.

*Chelson*.—Orange scarlet; fine form and good habit.

*Constantia Rosea*.—Deep rosy purple.

*Criterion*.—Light salmon, margined with white, and spotted with crimson in the upper petals.

*Distinction*.—Rich salmon, white margin.

\* *Due d'Areberg*.—Salmon, white margin, and spotted in upper petals.

\* *Duchesse Adelaide de Nassau*.—Red shaded with violet.

\* *Etoile de Gand*.—White ground; upper petals strongly spotted with rose, and a broad band of the same in the centre of each petal; very fine.

\* *Flower of the Day*.—Fine habit, large; white, occasionally striped with rose.

*Gledstanesii*.—White, sometimes striped with red.

*Lateritia*.—Light orange red; good form.

*Milioni*.—Rosy lilac; fine form and habit.

\* *Perfection* (Frost).—Bright rose; upper petals thickly spotted and veined with crimson; flowers large, shape excellent. The best in this class.

*Perryana*.—Dark orange scarlet; excellent shape.

*Queen Victoria*.—Pure white, flaked with purple.

\* *Roi Leopold*.—Salmon, finely spotted with crimson.

*Sir C. Napier*.—Salmon pink; large and fine.

\* *Sir H. Havelock*.—Bright salmon; upper part of the flower beautifully marked.

\* *Variiegata superba*.—Salmon pink, spotted, with white margin.

*Vesta*.—Fine white.—D., Deal.

**CRYSTAL PALACE**.—The great excursion of the Foresters on Tuesday last, when 83,721 persons were present, passed off without the least accident to the assembled thousands, or appreciable damage to the gardens and Palace. The large excess of visitors was doubtless owing to the unusual number of excursionists from the provinces and abroad, visiting London for the International Exhibition. On Monday, Tuesday, and Wednesday, the great Poultry, Pigeon, and Rabbit Show will be held, and upwards of eight hundred pens are entered for exhibition. On Thursday, 28th, M. Blondin will exhibit on the high rope over the fountains, and he will give a low rope representation in the centre transept on Saturday, which is now a shilling day. On Friday, the great fountains will be played their full height. As each of these great displays requires upwards of 1,900,000 gallons of water, the centre jets being higher from the basins than Bow Church steeple is from the level of Cheapside, it is no wonder they

are the special admiration of all visitors. Foreigners are particularly struck with them; and it has been truly remarked, that "whatever may be the relative position of the *grandes eaux* of Sydenham when compared to those of Versailles, there can be no doubt of their positive merit and attractiveness; they are never seen to greater advantage than when the flashing waters grow iridescent in the sunshine, and then break, from a rainbow of colour, into a shower of silver drops." Besides the above special attractions, a very interesting meeting will be held on Wednesday, of the *Deutsches Turnfest*, or German Gymnastic Association. Great attention has of late been given throughout Germany to institutions connected with athletic sports and exercises, and one held last autumn created the greatest public interest, many thousands of Germans taking part in the proceedings. This will be the first gathering of the sort in this country, and is likely to excite no inconsiderable attention.

## WHAT TO LOOK FOR ON THE SEASHORE.

(Continued from page 400.)

### MOLLUSCA.

MOLLUSCS may be generally described as soft, invertebrate, inarticulate animals, mostly protected by a shell. This shell is usually composed of a single piece in the higher groups, and is bivalve in the lower. The chief office of the shell is to serve as a shield or case for the protection from injury of the respiratory organs; although it very frequently serves as a defensive covering for the whole of the soft parts. These shells are mostly so elegant in their structure, so beautiful in their colour, and so durable in their substance, that they have, until a comparatively recent date, engrossed the attention of the scientific and curious, to the exclusion of the animals they contained; and whilst naturalists devoted their time and attention to the collection and delineation of the shell, they totally neglected the no less beautiful and curious creatures those shells protected.

The following introductory sketch to the British Mollusca is partially condensed from the very admirable work of Professor Edward Forbes and Mr. Sylvanus Hanley, of Wadham College, Oxford.

The Mollusca of the British seas are abundant; the varied conformation of the coasts of Great Britain and Ireland, and of the sea-bed surrounding these islands, being peculiarly favourable for nourishing a multiplicity of these animals. The greater part of our marine Molluscs are very small species.

The Cuttle-fishes that live around us are too excursive and oceanic in their habits to be claimed as exclusively or even chiefly our own. Those, however, that frequent our sea-bed are generally of considerable size for Molluscs, and certainly among the most beautiful and wonderful inhabitants of the sea; but they are seldom seen by the casual observer.

A considerable number of our marine Molluscs are sufficiently common on the western coasts of Britain, though they are scarce in the Irish Sea, and for the most entirely absent from the German Ocean, or, at any rate, from the more central portions of our eastern coast. Several localities have species peculiar to themselves. Where the shore is rocky it is inhabited chiefly by numerous gasteropodous (belly-footed) Molluscs. For instance: the common Limpet (*Patella vulgata*), the various species of Periwinkle (*Littorina*), the Dog-Whelk (*Purpura lapillus*), the common Mussel, &c., are found in quantities on this hard rocky ground, whilst muddy or sandy shores are frequented by burrowing bivalves. Such localities are, however, frequently destitute of Testacea altogether. It may be set down as a general rule that univalve Testacea and naked Mollusca flourish most upon hard ground; whereas bivalve Testacea appear to be more at their ease on soft ground.

The Molluscous province may be primarily divided into ACEPHALA, or animals destitute of heads; and ENCEPHALA, those which are provided with heads.

These may be again divided into classes according to the modifications of their integuments or of their gills.

ACEPHALA, then, are headless animals, having simply a pharynx or beginning of the œsophagus, without jaws, tongue, or mouth properly so called, and of which the Oyster may be looked upon as the most familiar illustration.

The ACEPHALA may be subdivided into three classes—namely, 1st, *Tunicata*, from *tunica*, a tunic. This class comprises such Molluscs as have the body enveloped in an elastic tunic furnished

with at least two apertures. This class is also denominated "soft-shelled" or "shell-less," in distinction to the other Acephalous Molluscs, all of which have a bivalve shell.

2ndly, The *Lamellibranchiata*, from *lamella*, a little plate, and *branchiæ*, gills. A class of Molluscs which are bivalve, and respire by gills in the form of vascular plates of membrane attached to the mantle. The common Oyster and the Mussel belong to this class.

3rdly, *Brachiopoda*, from two Greek words signifying "an arm" and "a foot," or *Palliobranchiata*, from *pallium*, a mantle, and *branchiæ*, gills—a class so named from its members having two long spiral arms placed on each side of the mouth, which in many species can be unrolled to a considerable length, and protruded to some distance in search of aliment. They are bivalve, one valve of the shell being applied to the back and the other to the belly of the animal, which is attached by its shell, or by a pedicel to some foreign body.

The ENCEPHALA, or animals having heads, may be subdivided also into three classes, according to the modifications of the locomotive organs.

1st, The *Pteropoda*, from two Greek words signifying "a wing" and "a foot." This class consists of small, soft, floating marine animals, which swim by the contractions of two lateral, musculo-cutaneous fins; but are unable to fix themselves or creep in the sea from want of feet.

2nd, The *Gasteropoda*, from Greek words signifying "the stomach" and "the foot." This class includes those Molluscs whose locomotive apparatus consists of a muscular disk attached to the ventral surface of the body, serving either as an instrument for crawling, or, in rarer instances, compressed into a muscular membrane for swimming.

3rd, *Cephalopoda*, from two Greek words signifying "the head" and "the foot." This class has all or part of their locomotive organs attached to the head, whence they radiate in the form of muscular arms or tentacula. The Cuttle-fish is a familiar illustration of this class.

It is only in this class (the *Cephalopoda*) that we find an internal skeleton, combined in some with a shell. In the rest of the Mollusca the hard parts, where present, are external. But the integument in certain species of the *Encephalous* classes, and in most of the *Cephalopoda*, is uncalcified and flexible.

It may be mentioned here that all true Molluscs have a complete alimentary canal, with mouth, stomach, intestine, and vent, and they are provided with circulating and respiratory organs.

In the higher classes of Molluscs (*Cephalopoda*), muscles may originate from an internal cartilage; in other Molluscs they are attached to the skin, or to the shell which may be developed in that otherwise soft substance. The shell is chiefly hardened by carbonate of lime, and consists either of one or two pieces called "valves;" there are rarely more than two of these, or with accessory parts. The blood is colourless, or, at all events, it is not red. The heart is distinct and muscular, and propels the blood through a system of arteries and veins, the latter having the form of irregular lacunæ.

It is almost unnecessary to observe that as our errand lies only on the seashore, we shall take no notice of the countless land and freshwater animals which form so large a proportion of the family of the Molluscs.

We shall now proceed to notice the first class of Headless Molluscs, called TUNICATA.—W.

(To be continued.)

## PROPAGATION OF BEDDING PLANTS.

THIS now-a-days forms no mean portion of the duties, or shall I say pleasures? of all who aim at gay beds and borders throughout the summer and autumn months, and the time is now upon us when it must be set about in earnest. It is to those amateurs that are in possession of a greenhouse, vinery or pit, with the further aid of it, may be, a one or two-light common frame, or a few hand-glasses, that I propose addressing myself on this occasion, with the view of giving a few practical hints as to the best mode of autumn propagation. There are two important points to be aimed at in the case of those whose means of wintering stock is limited. The first being how to propagate so as to turn out the healthiest possible stock of plants, and the next is how to winter the greatest quantity in as small a compass as possible. In discussing these points I will not take them

up under separate heads, but shall keep both objects in mind in the few following remarks.

Throughout an experience of very considerable extent I have become more and more convinced every year that the practice of striking cuttings of Verbenas, Heliotropes, &c., in a high temperature, and plunged in bottom heat, is not only unnecessary, but the very reverse of sound practice, and results in the excessive debility of the plants; so much so, that by so striking such plants after the middle of August, it require the whole autumn to accomplish the tedious and so-called process of "hardening them off." I would advise the commencement of propagation to take place either with the closing days of July or the beginning of August. And instead of enclosing the cuttings in a steaming hotbed—deriving the heat either from hot water or fermenting material—I would say, Choose a cold frame, putting in the bottom of it a layer of half-rotten leaves or turfy loam to act as drainage. Over this place 3 inches of half sand, half finely sifted leaf mould for the reception of the cuttings; press the surface moderately firm, and commence putting in the cuttings of Verbenas, Heliotropes, Alyssums; in short, the whole fraternity of bedding plants, excepting Scarlet and variegated Geraniums, as well as yellow Calceolarias, of which more by-and-by. In taking cuttings of such things let them be short, fresh, stubby cuttings from the outsides of the beds, and see that as fast as they are made into cuttings they are dibbed firmly into the frame—prepared as above—and watered and shaded before they droop. This is a point of great importance, for cuttings once allowed to droop and be dried up with sun and wind never succeed so well. The cuttings may be inserted at about 1 inch by 1½ inch. A one or two-light box, or even a few hand-glasses at this rate hold a great quantity of cuttings, and the labour and trouble in preparing such receptacles is scarcely worth naming as compared with the crocking of pots, and the plunging and steaming into the bargain. As soon as the necessary quantity of cuttings are in, give them as much water as will wet the whole surface soil down to the leaves or turf, and then shut them up close, and shade them carefully from the sun.

Now, the first step in the process of getting fine, stocky plants that will stand the rigours of winter well, is to get these cuttings to make roots without becoming drawn and weakly. To this end let the lights be removed entirely from the frame in the evening after the sun has left it, at the same time—and to prevent any chance of the plants drooping—give them a gentle dewing through a very fine rose. Should the weather be harsh and windy, be content with simply putting on some air at the back of the frame by tilting up the lights. When the lights are removed never forget to put them on again before leaving them for the night, for a thunderstorm or a high wind would deal cruelly with them. If the cuttings are healthy when put in, they will soon root when treated so, and that, too, without making much growth or expending their life and energies. But such cuttings thrust into warm frames and plunged in bottom heat become elongated and sickly long before they are ready either to prick or pot-off. As soon as they are rooted, of course the next consideration is how best to accommodate them for the winter, so as at the same time to take up the smallest possible space, and to preserve them in health. In the case of Verbenas, I would recommend square or round pans of earthenware, the same material as pots, or wooden boxes about 5 inches deep. In preparing these it is not necessary to use many crocks; a single crock over the openings, with a few crocks finely broken over them is enough; then place above these 1½ inch of horse-droppings that have been in heap for a few months, or part of a decayed Mushroom-bed or hotbed will do perfectly well. Cowdung I object to from its sloppy nature, which makes it dangerous on the score of impeding the drainage. The pans or boxes should then be filled up to within a quarter of an inch of the top, with a compost of half loam, half rotten dung, and sufficient sand to make it sparkle. The cuttings should then be lifted carefully with their roots entire, and dibbed into these vessels, putting about forty plants into a round pan 13 inches in diameter. This transplanting process should be performed as soon as the cuttings have made roots an inch long. After all are so transplanted into the pans or boxes, as the case may be, place them in a cold frame and shade for a few days from the sun, but let the shading be discontinued by degrees, and entirely dispensed with as soon as the plants have got hold of the soil. Give more and more air every day till the lights be removed entirely, except in cases of heavy rains; go over them as soon as they begin to grow freely, and pinch the top out of every plant. Let them be

attentively supplied with water so as to prevent them ever becoming mealy dry on the one hand, or saturated on the other. Thus treated they will form masses of healthy plants by the middle or end of September, that will rustle as you draw your hand over them, and will contrast most favourably with cuttings struck in hot, close frames, in a poor, sandy compost, and allowed to stand starving in their cutting-pots till next spring.

Plants treated as described above will be comparatively easily wintered, although the most favourable position is a light, dry, and airy one. Through the winter months they must be kept carefully free from green fly, and have just enough of moisture at the root to keep them healthy and no more, or mildew or other ills may be looked for. With regard to the comparative merits of earthenware pans and wooden boxes, I give the decided preference to the former, having always observed that these plants are easier kept in health in them than in boxes.

In spring should it be desirable to increase the stock, such may be done at pleasure by the aid of a little bottom-heat. Spring-struck cuttings are much preferable to autumn-struck ones; and I propagate only in autumn to get stock from them in spring, and the ease with which the necessary stock can be worked up in spring is dependant in no small degree on a fine healthy stock to propagate from; and struck as I have described, the show of cuttings will be very different to the miserable rusty things struck in heat, and wintered in their cutting-pots. There may, however, be many amateurs who must, in the nature of things, be entirely dependant on autumn-struck plants; and, in the case of such it is all the more urgent that their stock should be fine, and I have no fear but that by pursuing the hardy manner of propagating, they will find themselves in possession of a stock that will not only cost them much less trouble and anxiety, but also of one far superior in quality.

In the propagation of the different sorts of Geraniums, both variegated and common sorts, it not unfrequently pains one to see them coddled to death by placing them inside the room window, with a blind between them and the sun, instead of placing on the sill outside in the full blaze of the sun. Amazement is very often expressed at our exhortations to bring them up so hardy, and it takes some earnestness and pains to convince that certain death would not be the result of propagating Geraniums in the hottest and most sunny place at command.

In order to make the most of space in wintering Geraniums, there is no better and easier way than that of striking them in boxes, and wintering them as they are struck. Boxes about 5 inches deep, filled with light tolerably rich soil, are all that is required for the successful propagation and wintering of the common earliest varieties. The variegated sorts are, however, more tender and do best in well-drained pots or pans. In the propagation of both sections, I know of nothing so conducive to success as the selection of large cuttings, and the placing them in an open, sunny position after they are made, and dibbed into the pots or boxes. Heavy rains should always be guarded against by having some means of covering them. I fear, however, in the face of these directions, that, should the present most ungenial weather continue, large cuttings will not be easily got early in August. Well, then, I would say, Wait a fortnight or three weeks. You will be safer with a large, firm cutting at the beginning of September, than with a soft, spongy thing at the 1st of August.

In about three weeks after the cuttings of Geraniums are put in and managed thus, they will root and begin to grow, and make fresh leaves; and as soon as they become to any extent thick, go over them and pinch the terminal bud out of each, and remove some of the leaves so as to let the air have free scope about them. They should be housed before autumn rains and frost commence; the best place to keep them safely is in the coolest and driest part of a greenhouse, vinery, or pit. Geraniums can also be successfully wintered in a spare sitting-room, coach-house, or, in fact, any place where they can be kept dry and free from frost, and have a moderate share of light.—D. T., in *Scottish Gardener*.

## EXTRACTS FROM A TOO-MUCH NEGLECTED BOOK.

**MUSHROOMS.**—September 22.—Mushrooms are springing up by the roadside and in pasture grounds; they are not so numerous as last year, however, when the fungus tribe abounded. Mushrooms are not much eaten in our country neighbourhood;

people are afraid of them, and perhaps they are right. Certainly, they should never be eaten unless gathered by a person who understands them thoroughly. In France they are not allowed to be offered for sale, I believe, until inspected by an officer appointed for the purpose. There is a good old Irish mother who supplies one or two houses in the village when they are in season, and she understands them very well.

The Indians of this part of the continent ate Mushrooms. Poor creatures, they were often reduced to great extremities for food, from their want of forethought, feeding upon lichens, *tripe de roche*, and everything edible which grew in the forest. But Mushrooms seem to have been considered by them as a great delicacy. A Chippewa, when speaking with Major Long on the subject of a future life, gave the following account of the opinions prevailing among his people:—"In this land of souls, all are treated according to their merits." "The wicked are haunted by the phantoms of the persons or things they have injured; thus, if a man has destroyed much property, the phantoms of the wrecks of this property obstruct his passage wherever he goes; if he has been cruel to his dogs, they also torment him after death; the ghosts of those whom during his lifetime he has wronged, are there permitted to avenge their wrongs." "Those who have been good men are free from pain; they have no duties to perform; their time is spent in dancing and singing, and they feed upon Mushrooms, which are very abundant." Thus, Mushrooms appear to be the choice food of the Chippewa heroes in the happy hunting grounds.

**COLOUR OF AUTUMN LEAVES.**—October 5.—The woods are very fine, under the cloudy sky, to-day. Scarlet, crimson, pink, and dark red increasing rapidly—gaining upon the yellows. So much the better; seasons where yellow prevails are far from being our finest autumns. The more crimson and scarlet we have to blend with the orange and straw colours, the gayer we are. Still, this seems rather a yellow year; for the Elms and Hickories—which often wither and turn brown, without much beauty—are very handsome just now, in clear shades of yellow, fluttering in the breeze like gold-leaf; while the Chestnuts, Birches, Wych Hazel, and many Maples, as usual, wear the same colours.

Although there are certain general rules regarding the colouring of the trees, still they vary with different seasons; some which were red last year may be yellow this autumn, and others which were dull russet may be bright gold colour. The other day we found a wood path strewed, at one spot, with pink Aspen leaves; but the general colour of this tree is a decided yellow, nor do I ever remember to have seen its foliage pink before this instance; still there was no mistake about the matter, the leaves belonged to the large Aspen, and they were clearly pink. They looked, however, as if they had first turned yellow, and then a coat of rich warm lake had been laid on afterwards. Maples frequently go through the same process.

Some of the Oaks are turning deep red, others scarlet. The Ashes are already dark purple. But while most of the foliage is gaining in brilliancy, bare limbs are already seen here and there; the Virginia Creepers are all but leafless; so are the black Walnuts; and the Balm of Gilead Poplar is losing its large leaves. Such is Autumn: prodigal in her magnificence, scattering largesse with a liberal hand, she is yet careless, and regardless of finish in the lesser details; she flings cloth of gold over the old Chestnut, and Tyrian purple upon the Oak; while the neighbouring Grape Vine hangs a dull and blighted garland of russet upon the forgotten Aspen, still green. Spring has a dainty hand, a delicate pencil; no single tree, shrub, plant, or weed, is left untouched by her; but Autumn delights rather in the breadth and grandeur of her labours, she is careless of details. Spring works lovingly—Autumn, proudly, magnificently.—(*Miss Cooper's Journal of a Naturalist in the United States*.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

**Artichokes**, cut down the flower-stems, and remove the dead leaves from the old plantation. Those made last season will probably now produce a few heads. **Basil** and **Marjoram**, to be cut and dried just as it is coming into flower. **Asparagus**, to be kept free from seed-weeds. **Carrots**, make a sowing for early spring use on a dry light soil, that is only moderately rich. **Cabbage**, continue to plant-out for Coleworts at every favourable opportunity; prick-out the young plants intended for the main

spring crop. *Cauliflowers*, sow the principal crop for keeping over the winter. *Celery*, some of the early crops will now be sufficiently advanced for earthing-up; this should be performed on a dry day. Remove all suckers, and tie each plant separately with a piece of matting to prevent the earth from getting into the hearts of the plants. The earthing-up to be proceeded with in the usual way, taking care to loosen the soil well about the roots. If they had a thorough good soaking of liquid manure the day previous, it will be of great advantage to them. *Endive*, make a last sowing for spring use; continue to transplant from former sowings when the weather is favourable. *Dwarf Kidney Beans*, if the weather is dry and hot, give them an abundant supply of water when they are in bloom. *Lettuces*, if a sowing of the various sorts to stand the winter was made last week, another good sowing may be made during this week. The former will do for transplanting in the autumn, and the latter may remain in the seed-bed to be transplanted in the spring. *Onions*, sow seed of Spanish, Tripoli, or Strasburgh to stand the winter. The Welsh may also be sown for drawing young in the spring; the other sorts are best transplanted in the spring for bulbing. Let the crop now on the ground be removed as soon as they have ceased to grow, if left longer than this on the ground they frequently get mouldy and do not keep well; to be spread out in a shed or any dry place till fit for tying in ropes. *Tomatoes*, gather them as they ripen; and where they are backward, and at the same time much in demand, gather a few of the most forward and hang them in the stove, or, where there is not this convenience, place them in a frame where they will soon ripen.

#### FLOWER GARDEN.

Look over rock plants, pruning back any that are overgrowing choice kinds, in order to give them sufficient time to break again before autumn. Keep such plants cut back as have a tendency to overgrow Box or other edgings. Tie-up Dahlias, Sweet Peas, and other border plants. Peg-down a few shoots of *Chrysanthemums* for laying in pots; this is better done after the shoot has turned up at the point. Cut-out some of the leaves from Hollyhocks to show their bloom. Keep gravel walks perfectly clean and smooth by weeding, sweeping, and rolling as may be necessary. Keep climbers on walls within due limits. Part and transplant *Polyanthuses*. Prick-out seedling *Auriculas* into store-pots or pans. Prick-out seedling *Pansies*, and plant-out the first-struck cuttings for next year's bloom. Pull-off all deformed or damaged flowers from Dahlias, and give regular attention to staking, tying, &c., that the plants may not be broken during boisterous weather.

#### FRUIT GARDEN.

Remove all superfluous shoots from wall trees, and expose the fruit of Peaches and Nectarines, but not by cutting off the foliage. Place dry beanstalks, cut in lengths of about 6 inches, among the branches, and by this means the earwigs, that are sometimes very injurious, may be caught before the fruit is ripe.

#### STOVE.

Continue former directions in this house as to heat and moisture, and, by giving plenty of air, endeavour to get your *Ixoras* and similar plants to make strong luxuriant shoots, which, if properly ripened, are sure to produce fine heads of bloom. Pay due attention to *Begonias*, *Euphorbias*, and all winter-blooming plants. Expose such plants as *Stephanotis* that have completed their growth to the full sun, so as to get the wood properly ripened, and then gradually go to rest.

#### GREENHOUSE AND CONSERVATORY.

Plants that are required to bloom late in autumn and winter should be repotted, and their growth advanced. Ply the finger and thumb vigilantly on all plants which appear disposed to make a loose rambling growth. Remove the flowers regularly from *Leschenaultias*, and assist those that have filled their pots with roots with a little weak manure water occasionally. Look sharply out for mildew on *Boronias*, *Gompholobiums*, &c., and when the slightest speck is visible dust the plants with sulphur. Pot *Tropeolums* of all kinds, giving them a free open soil, with plenty of sand and drainage, and place the pots in the open air until the end of next month. Thin-out the *Mignonette* sown some weeks back, and get in a second sowing for Christmas-blooming. Look to Violets, and keep the runners removed. *Roses*, *Lilacs*, and other plants for forcing, to be examined, and such as require it may be repotted, plunging the pots afterward, and watering when necessary.

#### PITS AND FRAMES.

Attention should now be paid to the propagation of *Verbenas*, *Petunias*, *Salvias*, *Scarlet Geraniums*, and other bedding-out plants. Use every available means to raise a sufficient stock to preserve through the winter. Where there is a comparatively small space for wintering them, boxes and square pans are recommended for that purpose. The cuttings of plants liable to be affected by aphids to be immersed in tobacco water before they are put into the boxes or pans. W. KEANE.

#### DOINGS OF THE LAST WEEK.

"It never rains but it pours," might well be said of Saturday the 16th, and Sunday the 17th inst. For from fifty to sixty hours we had a continual down-pour, without the least intermission—a grand thing for land needing ploughing and scarifying; as in this neighbourhood, notwithstanding the damp and drizzle, the soil was too dry to permit of either being satisfactorily done. A grand thing, too, for Turnips, reaching to their roots, and giving them enough to prevent their feeling the effects of drought for the season. A grand thing, too, for the corn swelling, and just needing cutting, as it will make it fill the bushel so much the better. With these benefits, the drawbacks were that it hindered the storing of grain fit to be carted, interfered with the labour of the reaper; and in our own department, though giving us just what we wanted in the kitchen garden, it gave a desolate appearance to the flower garden, as noble trusses of *Geraniums* became a mass of rottenness, looking as wretched as a lot of drowned mice, whilst *Calceolaria* blossoms were washed off in bushels. Monday afternoon gave us a little sunshine. Tuesday was a glorious day. Wednesday, sunny and cloudy by turns: and though the rains have given us labour for which we did not bargain, in picking off the worst remnants of flowers, did the sun continue to shine the flower gardens would yet be fine this autumn, as many fresh flowers begin to open, and there are plenty of buds to make all rich and beautiful. The rains have also so soaked the ground that watering to any extent will hereafter be unnecessary, whilst lawns will hardly have a tinge of brown for the season. At no time have I seen them of a richer green.

#### KITCHEN GARDEN.

Pulled up forward garden Beans for seed. Pulled Dwarf Kidney Beans close to keep them well in bearing, every pod allowed to swell seed doing more to exhaust the plant than a dozen of pods nice and crisp for the table. Planted out Lettuces, *Endive*, *Coleworts*, *Broccoli*, &c., as room could be found; also a good batch of Cauliflower for the last gathering without protection, and a bank of smaller plants, which can easily be protected a little. Tied up the seed-heads of *Sea-kale* in bundles, as the seed is ripe enough for keeping, and taking it all away will strengthen the roots of the plants. Sowed Lettuces and Cauliflowers, the latter for early spring use. Will sow again in a week or ten days. Took up Shallots and Garlic, and pulled up Onions of spring planting, leaving the bulbs exposed to the sun. Thinned and stopped Cucumber plants, Vegetable Marrows, &c. Stopped and thinned leaves of Tomatoes. Thinned Turnips, sowed more, and also Spinach and Onions for winter. Found that *Capsicums* and *Chilis* were not swelling much under glass merely; turned them, therefore, out of their pots into leaf mould and loam placed above hot fermenting matter, and where a pipe can give a little top heat when necessary. This luxury in the shape of home-made Cayenne pepper is much valued, and what is not wanted for that purpose will be pretty well as serviceable for destroying insects as *Neal's Pastils*. Put some dung round Tobacco plants, which are not growing so well as usual, owing to the want of heat in the soil. Earthed-up some *Celery*, using ashes round the stem. This, too, grows more slowly than usual this season. Peas have been in their glory, so juicy and rich. Must get the latest staked if we can find time to do so at all. Swept the surface of the older Mushroom-beds to leave them clean and solid; and will smoke the Mushroom-house with burning sulphur and sawdust, to destroy all wood lice and other vermin that may be lodging there, before we begin to make up beds for late autumn and winter.

#### FRUIT GARDEN.

Planted Strawberry plants as time could be got. Potted for forcing. Commenced clearing the rows of those to be left for next year. Gathered some of the earlier Apples that were ripe.

Removed as we could get at them the breastwood of trees, and taking now almost the whole away, and especially the second growth after a first nipping some time ago. Find wasps attacking the remnants of Figs, which have borne heavy crops—the first time we have seen the gentry this season, looking almost as if the heavy rains had turned them out, and the bright sun had enticed them to keep out instead of returning to their burrows. As a matter of precaution will place gauze over the air-openings in vineries to prevent them getting in, which is better than driving them out after they get in and do mischief. Removed all the plants from the second vinery, washed the stage, &c., so that there should be no damp or impurity about the fruit, ripe and ripening. Got Camellias, &c., out of late vinery, where colouring is commencing, for a similar purpose; and in about ten days or less will have all the other things—Begonias, Cockscombs, Achimenes, &c., also out, that the floor may be nice and dry before the autumn closes. Thinned out the laterals in these houses now, that more strength may be thrown into the branches and the wood and buds that will be wanted for another year. I regret the roof is so flat, as moisture is so easily condensed and apt to drop inside in winter, even with every care.

Watered the borders of Peach-house, from which the fruit has been all gathered for three weeks, and find we have been rather greedy in the orchard-house in leaving so many, especially Peaches; and, therefore, we do not in the earliest coming-in get the size which we will do in later ones better thinned. We are apt to err in this respect when the young fruit set as thick as they can stand, as they did merely with the protection of the glass, and plenty of air on too. Small Peach and Nectarine trees in pots have yielded good fruit and heavy crops, and we are doubtful what to do in the autumn, give larger pots or plant out; the advantage of the former being that they are so thoroughly under control. Some Jefferson's Plums in pots, ripened with air on night and day, have been much prized for their size and flavour. All these pots have had a fair allowance of manure water, and twice during the summer have had about half-an-inch surfacing of horse-droppings half rotten, partly to enrich the water that passed through them, and partly to act as mulching and keep the soil from drying so quickly. The plants chiefly were small single-stemmed maidens in the spring of 1861; the pots chiefly 12's and 8's, half plunged in the border; and some of the larger kinds of Plums have from one to two dozen of fine fruit, and the plants seem anything but distressed, giving every promise of better crops next year. We find that the roots are getting through the pots notwithstanding all the surface-mulching; but as soon as the fruit is gathered the pots will be lifted or twisted round, so that the wood shall be thoroughly ripened. Where a little labour and attention can be given we feel sure that the best Plums can thus be satisfactorily grown, and they will have a richness in flavour which they rarely have in cold places out of doors. Had we the chance we would have a little house of Coe's Golden Drop, which will rarely ripen here; as with plenty of air all the summer it would come in rich as preserves in October and November. We mean to give all Peach, Plum, &c., trees in these houses some thorough washings and smokings as soon as the wood is ripe and the leaves falling, as there is some appearance of the black fly that annoyed us so much in the spring. The green fly is nothing to it.

#### ORNAMENTAL GARDENING.

The rains have given us pretty well a week's work, which we did not bargain for, in the flower garden, cleaning and nipping off the decayed bloom. This has thrown us behind with other work that needed doing, as there was a necessity for making the grounds as attractive as possible, and if this weather continues, a few days will remove all traces of the drenching. Some visitors at the mansion would not look at the beds on Sunday or Monday, and thus escaped the morbid feeling experienced at seeing such a dreary spectacle. Much of the happiness of life consists in resolutely not looking at the black side of things. The grass, too, from the drenching gave us much additional work, rushing up like magic; but then it is so beautifully green when dressed either by the scythe or hand machine. I was afraid that

#### GREEN'S MOWING MACHINE

of 16 inches would be rather heavy for one man; but unless the grass is long, which it never should be, I hear no complaint, it is so nicely balanced. I never saw Mr. Green, but I had the pleasure of examining these machines closely on his premises, and seeing them at work. I am much obliged for his courtesy

in noticing my complaint at page 298. Several ladies and gentlemen who saw them at work, and liked them much, were horrified at the hideous noise as the machine was pulled backwards. I might have written to Mr. Green privately, but that would have been far less effectual in removing the unpleasant impression, and many now will be astonished that such a simple thing as elevating the iron rollers and allowing the weight to rest on the wooden rollers in front, enables you to draw the machine backwards with as little noise as a cat would make with its paws. All things, however, are simple, but only to the initiated. Common workmen might have plodded on for years deafening the ears of their employers without finding out such a simple thing. Of course, in those of a larger size, the moving of the lever that takes the cogs out of gear, remedies all this without any elevating of the machine.

These different operations have interfered with propagating and potting farther than getting in a batch of Verbenas in the mode spoken of last week, and we are about commencing with Scarlet Geraniums, most of which *now* will be inserted in rough wooden boxes, and, if possible, all the tenderest will get the protection of glass. Will have to hunt the sides of roads to get some fresh compost for this purpose, which answers better than any mixture of old soils or compost—if sandy, all the better; if not, to be made so. No cuttings care much for leaf mould or dung in the soil, though when the cuttings are to stand many months we often lay a little of such material in a rough state at the bottom of the boxes or pots. In all delicate affairs, the cuttings do best without, and if help is needed, a little weak manure water, when struck, would suit the most of them better. Among things rather new we will put in a good batch of the

#### GNAPHALIUM LANATUM,

a free-growing, neat, cordate, woolly-leaved plant, producing small everlasting-like flowers, that but for the white stems and the white scales round the flower, and their rather agreeable perfume would be little more attractive than the flowers of the Groundsel. Some ladies, however, like them much and say that thinly scattered they give a greater attraction to the plant as an edging. For myself I neither like nor dislike, being neutral in the matter. In some cases I might let them remain, and in others I would remove them if their yellow points did not suit what was next to them. I think either Mr. Beaton or some other correspondent spoke of its not blooming, but here it seems that from oldish plants it would bloom rather freely. I like it as an edging plant chiefly for two reasons. First, it is so accommodating that you may cut and pin it down to a broad or narrow margin of a few inches in height, or you may let it grow upright with support, so as to form a dense sloping bank of 18 inches or more in height round a tallish bed of scarlet or purple, against the shades of which colours it seems to tell the most favourably. The next attraction is one that some ladies first pointed out to me, and that is the dancing flickering shades that flit over its foliage when looked at from a little distance in bright sunshine. "Oh! what beautiful new variegated Ivy is that you have got?" several have exclaimed; and really the shades are very striking under such circumstances. This is a matter much overlooked. Mr. Hamilton, of Ham Wood, first drew my attention to the beauty in this respect of Beaton's Stella Geranium. Well, the smallest bit of this Gnaphalium will atone in sandy soil, either under hand-light or frame; and though it will not stand frost it is so hardy that you can hardly lose it in winter unless you thoroughly dry it up, or thoroughly deluge it with water. The poorer the soil, I am inclined to think, the whiter will be the foliage. As an edging plant I give it a place along with the *Cerastium tomentosum* and *Cineraria maritima*.—R. F.

#### TO CORRESPONDENTS.

\* \* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate

communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

**PRONUNCIATION OF NAMES (*Ignoramus*).**—The correct pronunciation of *Dryopteris*, *Oreopteris*, and *Polystichum*, is *Dryop-teris*, *Oreop-teris*, and *Polys-tichum*.

**INSECTS ON CUCUMBERS (*J. M.*).**—If, as we presume, your plants are attacked by red spider, sulphur vapouring at a temperature not higher than 140° or 150° may be resorted to; but you must be very cautious or you may kill your plants. In syringing employ the following liquor:—Boll a pound of sulphur and a pound of lime in five or six quarts of water for twenty minutes, pour off when clear, and use half a quart to four gallons of water. You have, probably, been keeping the house or pit too hot and dry; maintain on the contrary a moist atmosphere, and syringe frequently. If you consult our back Numbers you will find full information on the best means of destroying this tenacious pest.

**FLOWER-GARDEN DESIGN (*A Regular Subscriber*).**—We would decidedly recommend you to adopt grass; it will make your design look very much better than gravel, and would harmonise better with the bright colours of the flowers.

**REPORTS (*A Constant Reader*).**—If you refer to page 322 of our present volume, you will find a reply to your inquiry. Where so much repetition is necessary, we must draw the line somewhere. Your observation does not apply to country shows, because there the whole features and subjects are totally distinct from the metropolitan exhibitions.

**CRYSTAL PALACE (*E. M. M.*).**—You must have had a treat round the beds there. The *Commelina* is one of the oldest herbaceous plants, and has blue flowers, and there were more than two full beds of it there. But Mr. Beaton will tell us next month how they all stood the season there. For your greenhouse we would prefer a common flue; these hot stews for cuttings, from a greenhouse boiler, are like paying through the nose for one's use. Perhaps six fires will carry you through the winter, and seldom is fire needed for a greenhouse in March and April when you propagate.

**ROSE-CUTTINGS (*Virgil*).**—The best Rose-cuttings in August and September are those stiff little side shoots which are from 3 inches to 4 inches long; cut them off close from the shoots, or with a heel to them, and put them in with a little sand in pots, or in the open ground. The latter is the surest way for all inexperienced persons, and if they could put a hand-glass over them all the sure.

**BERBERIS BERBERIS (*Idem*).**—The blue berries of the Holly-leaved *Barberry* are thus prepared for sowing:—First you draw a lot of drills, as for winter Spinach, across a border; secondly, you get up before the blackbirds and thrushes, and keep them from the berries; and in the third and last place, when the berries are ripe take a blue apron before you, and gather as many as you can carry, and sow them just as they will be, and as much like spring Pea sowing as anything you ever saw; cover them up like Peas, and next April they will come up in rows just as you put them.

**GUERNSEY LILIES (*J. F.*).**—They are beyond the pale of useful cultivation in the three kingdoms, and no mode of culture will cause one of them to flower a second time in England or Scotland at all events; and if you can hit on a plan in your part of the country you might do good to some one there, and give him a share of the trade in Guernsey Lilies.

**PLANTS FOR A TANK (*H. M.*).**—The plant is *Hippophae rhamnoides*. We fear you will not do much with your water-tank that is only a foot in depth and 5 feet wide. A good plant of *Nymphaea alba* would fill it, but then you have not depth enough to do it justice. A good root would require more than a foot of rich loamy soil, and at least as much water above it. In the circumstances, we would advise plants in six-inch pots of *Apogonon distachyon*; *Butomus umbellatus*, the flowering Rush; *Menyanthes trifoliata*, three-leaved Buckbean; and two or three plants of the *Ranunculus aquatilis*. Then, for variety, you might have two plants of *Calla rethiopia*, set in the tank in summer, and moved under the protection of a greenhouse in winter. Two or three plants of *Agapanthus umbellatus* might be set round the sides in summer, the half of their pots under the water. These too should be removed under protection in winter. Suppose you use the last two in summer first, and see how you like them.

**GREENHOUSE CLIMBERS (*Gardenia*).**—We never give plans for flower gardens, but opinions on plans submitted to us. There are, however, many plans in this work and in the manuals; but every place should have an arrangement to suit itself. As the *Mandevilla* does well, we would suggest as climbers—*Kennedy*, *Marruytta*, *K. nigricans*, *Soiya heterophylla*, *Jasminum revolutum*, *Bignonia jasminoides*, *B. Cherii*. These will give scarlet, dark purple, blue, yellow, pink, and rich crimson, also fine foliage. All the Tea Roses, *Deviensis* especially, would do admirably against pillars, &c., and so would the *Rhododendron* spoken of, if it has plenty of light, and too much heat is not given.

**BOTTOM HEAT AND MOISTURE (*H. II.*).**—We do not think that for tropical plants you will have too much bottom heat, if the pots stand on the top of the cinders. If at all set on the tank, we think there will be too much. If, however, the bottom of the pots, even on the surface, get more heat than you want, you may increase the depth of ashes, or give each plant a piece of board or slate to stand upon. If so, we would prefer the ashes being covered with sand for neatness. We do not understand rightly about the open cisterns, and the tanks consuming their own moisture in winter; but if you have too much moisture in winter, the covering of the cisterns by a lid would be an advantage. The next best would be to see that no moisture escaped from the tank, by the slate covering being made vapour-proof; and the best of all would be to have part of the tank surface slate, at least exposed so as to give a dry heat in winter; and if even then the house was rather damp to be careful in watering, not using more than was necessary, and spilling none, as careless waterers are apt to do.

**FUCHSIA ON WILD ROSE (*A Three-years Subscriber*).**—Very strange things happen sometimes, but that a *Fuchsia* should grow when grafted on a Wild Rose is more than we can give credence to.

**HYDRANGEAS (*H. B.*).**—If you keep your *Hydrangeas* as much in the sun as possible, with no more heat now than they will receive in the greenhouse or out of doors, and thin the shoots or leaves where too thick, curtail water as autumn approaches, and keep the plant dry all the winter, then every prominent bud, whether on old or young plants, should produce a

flower-bud or a fresh shoot next season. We expect your plants are too hot, and that the wood has been imperfectly ripened last season. For composts, we lately said much. Fresh soil from the roadside, and a little sweet rotten dung or leaf mould will grow *Hydrangeas* well, and every other common soil-wooded plant.

**WHITE CARNATION (*M. F.*).**—The colour is pure, but the flower does not seem to be as fine as many in the same way.

**VINE-BORDER (*William Mackney*).**—You will find ample instructions in Nos. 3 and 4.

**RIGHT TO A DITCH (*Ignoramus*).**—So many circumstances control the right to ditches and other boundaries, that we cannot venture to give a decided opinion in answer to your queries. You have certainly no right to stop up the ditch by building a dung-pen in it, because a ditch, among other uses, acts as a beneficial drainage to your neighbour's field. You have a right to the contents of the ditch, but must keep it scoured out, yet you have no right to widen it. On the other hand, your neighbour has no right to fill it up by "throwing clods in at ploughing time." If he has any object in so filling it up and preventing your building a dung-pen in it, that object must be that when the ditch is filled up he may have more ploughable space. This he has no right to, and he might be mulcted for throwing in the clods. On the other hand, you must not widen the ditch; your utmost boundary is its present outer edge. As there is no ditch outside of the Quick-hedge you mention as planted on the flat, you most probably have no right to make a ditch there; for it is a reasonable conclusion, as no ditch exists, that the hedge was planted on the extreme boundary of the land it encloses.

**NAMES OF PLANTS (*S. A. P. S.*).**—The plant appears to be *Stachys lanata*, a hardy perennial, easily increased by division of the root.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

August 25th, 26th, 27th, and 28th. CRYSTAL PALACE. Sec., W. Houghton. Entries close July 26th.

August 27th. COTTINGRAM. Sec., Mr. J. Brittain. Entries close Aug. 26th.

August 30th. HALIFAX and CALDER VALE. Sec., Mr. W. Irvine, Holmsfield. Entries close August 16th.

SEPTEMBER 2nd. POCKLINGTON, Yorkshire. Sec., Mr. T. Grant. Entries close August 26th.

SEPTEMBER 4th. WAKEFIELD and WEST RIDING. Sec., Mr. J. Crosland, jun., Entries close August 23rd.

SEPTEMBER 9th. WORSLEY and ARMLEY (near Leeds). Sec., Mr. Robert Hoyle, Armley, near Leeds.

SEPTEMBER 9th and 10th. CALNE. Secs., A. Heath and F. Baily. Entries close August 28th.

SEPTEMBER 10th and 11th. MANCHESTER and LIVERPOOL. Sec., Mr. T. B. Ryder, Church Street, Liverpool. Entries close August 11th.

SEPTEMBER 25th. STAFFORDSHIRE. Sec., Mr. W. Tomkinson, Newcastle. Entries close August 25th.

SEPTEMBER 25th. MIDDLETON. Sec., Mr. T. Mills. Entries close September 10th.

DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. Sec., John B. Lythall, 14, Temple Street, Birmingham.

### CRYSTAL PALACE POULTRY SHOW.

The Summer Show of Poultry, Pigeons, Rabbits, Ornamental Water Fowl, Gold, Silver, and other Pheasants was commenced yesterday, and will be continued this day, to-morrow, and Thursday. The prizes offered being very liberal in amount, the entries in the different classes have been extremely numerous, amounting to upwards of eight hundred in number. On the whole, it is a most admirable and comprehensive Exhibition, which will doubtless prove a great attraction to those interested in the breeding and management of Poultry, Pigeons, and Rabbits; whilst, to the uninitiated in these matters, the examination of the different breeds which have been gathered together must be both interesting and instructive.

We subjoin a list of the prizes, but must defer our detailed report until next week.

Class 1.—SPANISH.—First and Second, J. R. Rodbard. Third, J. Smith. Highly Commended, M. Rake. Commended, F. Crook.

Class 2.—SPANISH.—First, J. Barry. Second, J. R. Rodbard. Highly Commended, J. Smith.

SPANISH COCKS.—First, H. Lane. Second, J. Smith. Highly Commended, J. R. Rodbard. Commended, W. H. Butler.

DORKING (Coloured).—First, Hon. W. W. Vernon. Second, J. Frost. Third, E. Tudman. Fourth, Sir J. Paxton, M.P. Highly Commended, W. G. Bannister; C. H. Wakefield; F. Waldar. Commended, A. Potts.

DORKING PULLETS.—First, C. H. Wakefield. Second, Miss M. Milne. Highly Commended, Hon. W. W. Vernon. Commended, P. A. Eagles.

DORKING (White).—First, Rev. G. F. Hodson. Second, H. Lingwood. Highly Commended, Mrs. H. Fookes; H. Lingwood.

DORKING COCKS (Coloured and White).—First, J. Simmons. Second, H. Lingwood. Third, C. Smith. Highly Commended, P. A. Eagles.

COCHIN-CHINA (Cinnamon and Buff).—First, J. W. Kelleway. Second and Third, H. Bates. Highly Commended, J. W. Kelleway. Commended, Miss V. W. Musgrove.

COCHIN-CHINA (Brown and Partridge-feathered).—First, E. Tudman. Second, P. Cartwright. Third, Miss V. W. Musgrove. Highly Commended, W. H. Beadon; J. K. Fowler.

COCHIN-CHINA (White).—First, W. Dawson, Hopton. Second, G. Lamb. Commended, R. Chase.

COCHIN-CHINA COCKS (Coloured and White).—First, J. W. Kelleway. Second, T. Stretch.

BRAHMA POOTRA.—First, Mrs. Seamons. Second, J. K. Fowler. Commended, C. Priest.

BRAHMA POOTRA COCKS.—First, J. K. Fowler. Second, Mrs. Seamons. GAME (White and Piles).—First, G. Crofts. Second, A. Ewen. Third, W. Phillips. Highly Commended, G. J. Barnett; R. R. Clayton; S. Matthew. Commended, J. Monsey.

GAME (Black-breasted Reds).—First, J. Fletcher. Second, J. Groote. Third, R. Brand. Highly Commended, Hon. W. W. Vernon; J. Fletcher. Commended, G. J. Barnett; H. C. Dear; S. Matthew.

GAME (Brown-breasted and other Reds except Black-breasted).—First, E. Archer. Second, J. Fletcher. Third, T. Moss. Highly Commended, A. B. Dyas; J. Groote.

GAME (Duckwings and other Greys and Blues).—First, Hon. W. W. Vernon. Second, F. Hardy. Third, J. Fletcher. Highly Commended, S. Dupe. Commended, W. Bentley.

GAME (Blacks and any other variety).—First, W. Dawson, Selly Oak. Second, J. Fletcher. Highly Commended, Hon. W. W. Vernon; J. Rogers.

GAME COCKS.—First, Hon. W. W. Vernon. Second and Third, J. Fletcher. Highly Commended, E. Archer; R. Swift.

HAMBURGH (Gold-pencilled).—First and Second, A. Nuttall. Third, Messrs. Carter & Valiant. Highly Commended, R. R. Clayton; J. Munn. Commended, C. H. Wakefield.

HAMBURGH (Silver-pencilled).—First, C. Moore. Second, E. Buckland. Third, S. Fielding.

HAMBURGH COCKS (Gold or Silver-pencilled).—First, G. W. Locke. Second, J. Munn. Highly Commended, Mrs. H. Sharp.

HAMBURGH (Golden-spangled).—First, G. Brook. Second, E. Smith. Third, E. Collinge.

HAMBURGH (Silver-spangled).—First, E. Collinge. Second, T. Twose. Third, F. W. Entwistle. Highly Commended, Mrs. H. Sharp. Commended, H. Carter; W. Joshua.

HAMBURGH COCKS (Gold or Silver-spangled).—First, J. Dixon. Second, J. Davies.

POLAND (Black, with White Crests).—First, G. Ray. Second, W. Newcome.

POLAND (Gold).—Prize, H. Beldon.

POLAND (Silver).—First and Second, G. C. Adkins.

POLAND COCKS.—First, G. C. Adkins. Second, J. Firth. Highly Commended, H. Beldon.

MALAY.—First, W. Hill. Second, N. Sykes, jun.

ANY OTHER DISTINCT BREED.—First, C. H. Wakefield. Second and Third, R. H. Nicholas. Fourth, J. Hope. Highly Commended, Mrs. Robinson; C. Ballance.

BANTAMS (Gold-laced).—First, T. H. D. Bayly. Second, M. Leno, jun.

BANTAMS (Silver-laced).—First and Second, T. H. D. Bayly.

BANTAMS (White, clean legs).—First, T. H. D. Bayly. Second, F. Hardy. Highly Commended, E. Holdsworth.

BANTAMS (Black, clean legs).—First, E. Hutton. Second, Miss J. Hodson. Highly Commended, E. Hutton; N. Sykes, jun. Commended, Rev. P. W. Story.

BANTAMS (Game).—First, T. H. D. Bayly. Second, J. W. Kelleway. Highly Commended, T. H. D. Bayly; E. Brown; J. Cann; W. Lawrenson; T. Moss; R. Swift.

BANTAMS (any other variety).—Prize, Rev. P. W. Story.

BANTAM COCKS (any variety).—First, M. Leno, jun. Second, G. W. Locke. Commended, T. Moss; Miss V. W. Musgrove.

DUCKS (Aylesbury).—First and Second, Mrs. Seamons. Highly Commended, Mrs. Seamons. Commended, Mrs. Seamons; W. Walter.

DUCKS (Rouen).—First, C. Priest. Second, J. K. Fowler. Highly Commended, J. K. Fowler.

DUCKS (Black).—First, W. Joshua. Second, Mr. Wolferstan. Highly Commended, Capt. R. Edgell; H. Adney; J. K. Fowler; J. W. Kelleway; T. Twose. Commended, Mrs. Beardmore.

DUCKS (any other variety).—First, T. H. D. Bayly. Second, H. Adney.

GEESE (White).—First, Mrs. Seamons. Second, W. Manfield, jun. Highly Commended, W. Manfield, jun.

GEESE (Grey and Mottled).—First and Second, J. K. Fowler.

TERKEYS.—First, R. Brand. Second, W. Wright. Highly Commended, R. Brand.

ORNAMENTAL WATER FOWL.—First, T. H. D. Bayly. Second and Third, C. Baker. Highly Commended, C. Baker.

PRESAUNTS (Gold and Silver).—First, S. C. Betty. Second, A. S. Yates. Highly Commended, S. C. Betty.

PRESAUNTS (any other variety).—First, C. Baker. Second, M. Leno, jun. Highly Commended, C. Baker; A. S. Yates.

#### PIGEONS.

POWTERS OR CROPPERS (Cocks of any colour).—First, R. Fulton. Second, T. H. Evans. Third, M. Rake. Highly Commended, Mrs. Evans. Commended, R. Fulton. *Hens*.—First, M. Rake. Second, R. Fulton. Third, Mrs. Evans. Highly Commended, T. H. Evans. Commended, Mrs. Evans; R. Fulton.

CARRIERS (Cocks, Black and Dun).—First, J. F. Mortimer. Second, Mrs. Craigie. Third, Major F. C. Hassard, R.E. Very Highly Commended,

A. L. Sylvester. Highly Commended, J. F. Mortimer. *Of any other colour*.—First, J. C. Ord. Second, W. H. Edmonds. Highly Commended, J. C. Ord. Commended, Major F. C. Hassard, R.E. *Hens, Black and Dun*.—First and Second, E. L. Corker. Third, M. Rake. Highly Commended, M. Rake. *Of any other colour*.—First and Second, W. H. Edmonds. Highly Commended, F. Esquilant.

DRAGONS (Blue).—Prize, T. W. Walker. Very Highly Commended, F. Else. Highly Commended, J. C. Ord. *Any other colour*.—Prize, W. H. Edmonds. Highly Commended, H. Yardley. Commended, T. D. Walker.

ALMOND TUMBLERS.—First, E. L. Corker. Second, M. Rake. Third, J. Percivall. Very Highly Commended, M. Rake. Highly Commended, F. Esquilant. (A good Class.)

SHORT-FACED MOTTLES.—First, E. L. Corker. Second, F. Else.

SHORT-FACED BALDHEADS.—First, F. Esquilant. Second, H. Morris.

SHORT-FACED BEARDS.—First, H. Bunce. Second, M. Rake. Commended, J. Ford; T. D. Walker.

SHORT-FACED TUMBLERS (Self-colour).—Prize, F. Esquilant.

KITES, AGATES, DUNES, AND GRIZZLES.—Prize, J. Percivall.

JACOBINS.—First, F. Esquilant. Second, H. Morris. Commended, J. Baily, jun.; G. F. Nicholls.

OWLS (Blue or Silver).—Prize, M. Rake. Very Highly Commended, H. Morris. Highly Commended, F. Else. Commended, J. W. Edge. (A good class.) *Yellow or any other colour*.—Prize, F. Else. Very Highly Commended, J. Baily, jun.; H. Morris. Highly Commended, F. Key; M. Rake. (An excellent class.)

NUNS.—First, F. Key. Second, F. Else.

TURRITS.—First, J. W. Edge. Second, G. F. Nicholls. Third, G. Fleming. Highly Commended, W. Greene.

FANTAILS (Black).—Prize, T. D. Walker. *White*.—Prize, F. Else. Commended, H. Morris. *Blue*.—Prize, H. Morris.

BARBS (Black).—Prize, M. Rake. *Yellow or any other colour*.—Prize, M. Rake.

MAGPIES.—First, E. L. Corker. Second, G. Fleming. Third, T. D. Walker. Highly Commended, G. Fleming. Commended, W. Greene.

TRUMPETERS (Black Mottled).—Prize, F. Else. *White, or any other colour*.—Prize, H. Morris.

RUNTS (Spanish and Leghorn).—First, T. D. Greene. Second, F. Key. Commended, E. Pigeon.

ANY NEW OR DESERVING VARIETY.—First, H. Yardley. Second, J. Baily, jun. Third, Mrs. C. Baker. Fourth, A. G. Brooke. Highly Commended, J. Baily, jun. Commended, J. Baily, jun.; J. W. Edge; H. Morris.

#### RABBITS.

LONGEST EARS.—First, Messrs. Guest & Coleman. Second, J. Cranch. Highly Commended, J. Angus; J. Olley; W. Howell. Commended, H. Handford; M. Taylor.

BLACK AND WHITE.—First, Miss M. Hawksley. Second, A. Stedman. Highly Commended, Messrs. Guest & Coleman; H. Handford; A. Stedman. Commended, G. Jones; G. Miller; W. J. Pope; A. Stedman.

YELLOW AND WHITE.—First, J. Morris, jun. Second, J. Hincks, jun. Highly Commended, J. Haile; H. Hinde, jun. Commended, J. Hincks, jun.; A. S. Marchant; J. Morris, jun.; G. South, jun.

TORTOISESHELL.—First, R. Cook. Second, J. Morris, jun. Highly Commended, J. Angus. Commended, J. Haile; Miss M. Hawksley; G. Jones; J. H. Wyone; C. Sellen.

BLUE AND WHITE.—First, T. Durbridge. Second, Messrs. Guest and Coleman. Highly Commended, G. Jones.

GREY AND WHITE.—First, R. Cook. Second, J. Sherwood. Highly Commended, C. King. Commended, J. Hincks, jun.

SELF COLOUR.—First, J. Hincks, jun. Second, H. Hodge. Highly Commended, J. Angus; Messrs. Guest & Coleman; J. Haile; G. Jones. Commended, Miss M. Hawksley; H. Hinde, jun.; G. Jones; J. G. Quick; C. Sellen.

WEIGHT.—First, N. Norman. Second, C. Ashdowne.

FOREIGN RABBITS.—First, C. Sellen. Second, E. J. Vipans.

JUDGES.—*Poultry*: Mr. J. Baily and Mr. Edward Hewitt. *Pigeons*: Mr. Bellamy and Mr. Hurrierson Weir. *Rabbits*: Mr. Banck, Mr. Fox, and Mr. Webster.

#### TO PRESERVE EGGS AS FRESH AS WHEN LAID, FOR SIX MONTHS.

HAVE a vessel of water boiling on the fire, put the eggs into a net, or, better, into one of those wire baskets for boiling vegetables; hold it in the boiling water for half a minute; take out the eggs and rub them all over with a little fresh lard, pack them with the narrow end downwards in a glazed crock, cover them with coarse salt. They will keep perfectly fresh for six months; but will not do for culinary purposes, as the whites will not beat up well from being in the boiling water.—(*Irish Farmers' Gazette*.)

TO PRESERVE EGGS IN LIME.—A correspondent of a contemporary gives the following recipe for this purpose:—"Take two or three limestones about the size of half-bricks, pour suffi-

cient cold water on them, and stir it up for three or four days; let it settle, then pour the clean water into an earthen vessel, in which place the eggs, and they will keep fresh for many months. Eggshells being lime, lime water strengthens the shell and keeps the air from acting on the animal matter. I have practised this for over forty years, and have always had fresh eggs as long as my stock lasted."

### LIGURIAN QUEENS.

BEING desirous of converting my stocks of black bees into Ligurians, I intend substituting Ligurian queens for the black ones. Of course, the Ligurian queens should be fertilised, and if any of my fellow bee-keepers who have got pure Ligurians would kindly supply me with a few, I should be very thankful and would pay anything in reason for them, or would exchange betwixt them and a bee-hive or wax-refiner on the same principles as those I have got in the International Exhibition. See Class 9, 8023.—JAMES BOOTHMAN.

[We regret that we are unable to name any bee-keepers who are in the habit of selling Ligurian queens. The fact is, that multiplying these queens appears a difficult and uncertain affair in this climate. "A DEVONSHIRE BEE-KEEPER" tried it very perseveringly during two seasons, but was glad to wash his hands of it in the end.]

### INTRODUCTION OF A LIGURIAN QUEEN.

OWING a Ligurian queen to the correspondent whose Ligurian misadventure was recorded in page 78 of the last volume of THE JOURNAL OF HORTICULTURE, I have only very recently been enabled to discharge the debt, and have been favoured in reply with the following interesting narrative.—A DEVONSHIRE BEE-KEEPER.

"Accept my best thanks for your kindness in sending the Ligurian queen, which arrived on the 11th August.

"I had two hives near each other, which I intended to unite for the winter. I turned an empty box, size of the hives, the open side up, covering about three parts with a cloth; removed No. 1 hive from its board on to the box partially covered. Taking out each frame in succession, I swept the bees from them back into the hive, and towards the open part of the empty box. No. 1 hive was removed and the frames replaced. No. 2 hive was then put on the box with No. 1 bees now in it, the frames taken out, and the bees swept into the box to unite with No. 1 stock, which they did quietly, being apparently too frightened to quarrel. No. 2 hive was removed, and the frames replaced; and the united bees left undisturbed nearly an hour. No. 1 was put on its board as soon as possible, and placed about midway between the old stands of No. 1 and No. 2. The bees on the wing soon crowded in. A piece of stick three-eighths of an inch thick was inserted between the back lower part of the hive and floor-board, and a spare board was put level with and against the floor-board. This preparation was to assist in finding the two queens.

Taking up the box with the united stocks in it, I turned its side on to the spare board, and from the lowest or uncovered side I swept out a few bees on to the board towards the hive. A joyful hum followed, and I soon had a living stream from the box into the hive—in fact a regular procession, which I regulated and directed with a large feather. In less than three minutes I secured one queen out of the procession, but the second did not make her appearance until nearly all the bees had left the box. I caught her and then swept out the remaining bees on to the board. I now got a piece of perforated zinc, put it on top of the hive, and on the zinc a piece of comb with a little honey run over it. The Ligurian queen and a few bees her companions were carefully got under a bell-glass placed over the comb and zinc, three slides drawn so that the smell from the hive should fill the glass. This was done about half-past seven P.M., the glass was covered with five or six folds of cloth, and the empty box over the cloth. So I left it until next evening about eight P.M., when I removed the box and cloth, shut two slides, and moved the zinc slightly and gently so that the bees in the hive could get up into the glass (anxious moment!). They rushed up, no fighting, and as it was getting dark and the glass cold I covered up again. Next morning I saw thirty or forty bees in a cluster

on one end of the comb under the glass. I thought the queen must be there, but could not get to see her. On disturbing them with a piece of wire they went down. I shut the slide and all has been quiet in the hive ever since, so I conclude her majesty was kindly received. This experiment has been very interesting in two ways—first, proving Mr. Filleul's method of uniting stocks\* to be good; and, secondly, showing how a queen can be put to a strange stock with something like a chance of being successful.

"Next spring I hope to begin the season with a strong and pure Ligurian stock.—J. N."

### ARTIFICIAL COMBS.

I HAVE just succeeded in obtaining from Germany a parcel of these very ingenious contrivances designed to assist bees in the production of combs, and insuring their being built with the greatest regularity, as well as effecting a great saving in wax, which, when elaborated from honey, is, as is well known, an enormously expensive material, since Gundelach has demonstrated by actual experiment that 20 lbs. of honey are consumed in secreting 1 lb. of wax!

Artificial combs, or, as the Germans more correctly style them, "artificial partition walls," are thin sheets of wax about the thickness of card-board which have been pressed between two metallic moulds, and thereby made to assume the exact form of a piece of comb from which the cells on both sides have been removed, leaving only the central partition indented over its entire surfaces by the bases of the cells. When used they are attached to comb-bars or frames, and hung in hives exactly like guide-combs, and are speedily completed by the bees, which excavate both surfaces, and apply the superfluous wax to the formation of cells on either side.

One of the best practical apiarians of my acquaintance assured me that these artificial appliances would most certainly fail, since he was satisfied that wax when once melted down underwent so great a change in its character that it was thenceforth useless to bees. I find, however, that he was entirely mistaken, as my bees accept the proffered assistance without hesitation, and speedily convert the indented plates into the most beautiful worker-comb.

As I am very desirous of having this contrivance thoroughly tested, with the view, if it be approved, of endeavouring to get artificial combs manufactured in this country, I shall be happy to distribute nearly all my stock at prime cost among the apiarian readers of THE JOURNAL OF HORTICULTURE. The expense of carriage from Germany is unfortunately a very sensible addition to their first cost, but I can send fifty artificial combs on receipt of a post-office order for 21s., or twenty-five for 10s. 6d.—T. W. WOODBURY, Mount Radford, Exeter, 21st August, 1862.

### APIARIAN NOTES.

PRACTICAL OBSERVATIONS ON BEES—HERR VIEBEG, POTSDAM.—Having written on the same subject fourteen or fifteen years ago, I avow myself an apiarian of the old school, and agree with Herr Viebeg, that in the end it is better to allow bees to swarm in their natural way than to torment them by too much artificial means. The use of bell-glasses, and what they term "supers," or smaller hives, to collect pure honey, and at the same time to give room to the bees, should be adopted by every bee-keeper; but among the cottagers how few of them, even in these enlightened days, are to be seen taking the trouble to carry this plan out to any extent! Mr. Woodbury, whom I designate the "Wildman" of this century, is, no doubt, an adept at all operations in the secret of artificial swarming and manipulation of bees; and it is quite refreshing to observe with what ease he manages to do what not one in a hundred of the bee-keepers of the present day attempt without failure, even by their own honest confession. For myself I own that one of the greatest and most agreeable gratifications to me as a bee-keeper, has been the wonderful mode in which Divine guidance has taught these insects to act, when their numbers are to be increased at the proper season, by issuing from their hives, headed by their queen, and hovering in the air for some minutes

\* Vide "The English Bee-keeper," page 143. This excellent little work has recently been very much reduced in price.—A DEVONSHIRE BEE-KEEPER.

previously to settling. Their devotion, also, is wonderful, as, should the queen bee fall suddenly, which is often the case, and the main body of the bees lose her, a few faithful guards will always be found near her person, and remain even after she is dead for many hours.

**LIGURIAN BEES.**—Mr. Woodbury has been unfortunate in his seasons in introducing this new and beautiful species of bee into England, as the years 1860, 1861, and 1862, have all been most untoward years. At the same time I am still of opinion, that except in being hardier, and not so sensitive of raw or dull weather, I still think the black or brown bee indigenous in Great Britain, by no means inferior to the yellow-jacketed strangers. It will be many years before the "Ligurians" become very common in Great Britain, and I still think that no benefit can arise from a mixture of the two breeds.

**THE SEASON.**—Very little honey will be saved this year except in localities where heath abounds. The pasture for bees in my neighbourhood is nearly at an end. One bee-keeper informed me yesterday (21st August), that neither his old stocks nor swarms had any honey in them, and that he should be compelled to feed immediately or lose them all. Nearly one hundred stocks are kept within six or seven hundred yards of my apiary; one of my near neighbours has more than thirty hives.

I have never noticed three seasons consecutively so bad as the last three, but in 1838, 1839, and 1840. The former two were miserable seasons, and 1840 and 1841 were very indifferent.

We may in the course of the "roster," as they say in the army, expect that the next two or three summers, or rather the bee months of May and June in these, may be much more favourable, and make some "compensation" for the past.—H. W. NEWMAN, *Hillside, Cheltenham.*

### QUEEN BEES MUTILATED BY WORKERS.

I HAVE already related my experience of this phenomenon in pages 304 and 366; but a somewhat similar instance is related by Herr Mehring in a recent Number of the German "Bee Journal," which was attended by some remarkable results. It appears that on the 3rd of last June he substituted three Italian queens for the original sovereigns of as many German stocks with perfect success, by merely presenting them to their future subjects in small boxes, from which they were released in fifteen minutes, on no signs of hostility being manifested by the bees. It was one of these queens, the effects of whose ill-treatment is thus related by Herr Mehring:—

"On the 6th of June, the third day after having introduced the queen to the hive, I observed that when laying eggs she made strikingly tortuous and dragging movements. On examining her closely, I found that instead of the right, hind, and middle feet she had only short stumps, and that it was, therefore, very difficult for her to perform the act of egg-laying—a discovery very vexatious to me. It was, indeed, very afflictive to see how difficult it was to her, being deprived of these two feet, to raise the abdomen high enough to bring its point into the chosen cell, in which however, she seldom succeeded; as on account of the missing members on one side the whole body remained in an oblique position, in consequence of which the point of the abdomen came into the next cell. If this were empty it received an egg unknown to the queen, and the missing of the cell for which it was intended had no farther consequences; but if this cell already contained an egg a second was added, and thus was produced the irregular egg-laying on which so many and very different opinions have been expressed. In this instance a bodily defect existed, but there was no deficiency of instinct.

"On the first and second days after this discovery, the irregularity in egg-laying was greater than I ever saw before. Everywhere empty cells alternated with those containing eggs, whereby several eggs were often found in one cell, and (what certainly very seldom happens), sometimes even in cells containing pollen. Once I saved the queen from inevitable death by widening the worker-cell into which her head and thorax had fallen, whilst her abdomen stuck in the next cell. Although the invalid had become quite exhausted from her efforts to free herself, not a single bee attempted to assist her, which is by no means favourable to the intelligence for which they have been so highly praised. About the third or fourth day the oviposition became more exact and afterwards quite normal. The queen had by little and little accustomed herself to a new mode of laying, and

had entirely laid aside her stiff awkward manner. She now slipped the abdomen sideways into the chosen cell, and this with a dexterity and steadiness that never missed its object—a proof that she entered the hive un mutilated. It is most probable that she lost her two feet when I first placed her in the hive, and learnt by degrees to accommodate herself to circumstances."

I can only say that I hope very few queens have to learn so hard a lesson.—A DEVONSHIRE BEE-KEEPER.

### GOLD FISH TURNING BLACK.

WE have had some Gold Fish for some months, and some of them are becoming marked in different places with black. We have been informed that it is a sign of decay. Will you please inform one of your readers whether it is so?—PETER KINSEY.

[We have had similar complaints before. Your fish will ultimately become entirely black and die. Will any of our readers give us further information on this subject, and the remedy if there is any?]

**DRYING CURRANTS.**—The Currants should be quite ripe when gathered, with the stems attached, and washed or rinsed effectually or drained off. Then stem them and wash them thoroughly, and to each pound of Currants add a quarter of a pound of good Havana sugar; then place them in a preserving-kettle over a fire until they come to a scald heat, when they are turned out into white earthen dishes, and exposed to the action of the sun until, by evaporation, they become hardened on the upper side. Then they are turned over, and there remain until they become so on the other side, and so alternately until they become of a sort of leathery texture, when they are put away in earthen jars or boxes until wanted for use. Care must be taken to keep them from the dews and rains during the process of drying; finally, the utmost cleanliness must be observed from first to last. When used, enough hot water is required to dissolve them or render them to any consistency suitable for tarts, jelly, &c. At the same time more sugar is required to make them quite palatable, which must of course be governed by taste. Currants in this way have kept well with us for three years, and the presumption is that they will keep a longer time if well cared for.—(*Horticulturist.*)

### OUR LETTER BOX.

**SELECTION OF PENCILLED HAMBURGERS (T. J. S.).**—In the selection of a Silver-pencilled Hamburg cockerel, for exhibition or as a stock bird, great attention should be paid in respect of the comb. It must stand perfectly erect on the head, but not raised too high from it, as the latter is a defect commonly called "helmet-combed." It must terminate behind in a peak curving gently upward. The peak should be perfectly plain, though the comb itself should be well covered over with points. Any hollow in the centre of the comb is a grievous defect. The earlobe should not exceed the size of a shilling, if a little smaller the better, be quite circular, and perfectly white. The whole character of the head of a well-bred bird is neat and small. All the plumage, except the flights and tail, are white, the tail-sickle feathers and outer coverts of the tail an iridescent black in a perfect bird, each feather being shaded round the edge with silver. The legs and feet must be blue. Any disposition to lop the tail on either side must be carefully avoided. It is a fatal disqualification although a somewhat frequent fault in very highly bred Pencilled Hamburgs.

**BRAMA POOTRAS (Sophia).**—As the Brahma Pootra is merely a variety of the Cochinchina differing in colour, their habits are exactly the same as that variety.

**RABBIT (L. B. S. D.).**—Your Rabbit with black ears, tail, feet, and nose, is the Himalaya.

**SIZE OF QUEEN BEES (J. E. B., Waterhampton).**—The two queens enclosed in your letter appear well developed, but dark. I do not think either of them can justly be considered small, whilst one is certainly large. In common with most apiarists I prefer large queens to small ones; but I have sometimes found a very diminutive virgin expand into a full-sized and wonderfully prolific matriarch.—A DEVONSHIRE BEE-KEEPER.

### LONDON MARKETS.—AUGUST 25.

#### POULTRY.

Poultry is fast becoming cheaper as the season declines. The last week has told the tale of the passing year and approaching autumn. The Grouse season has begun, and so far as we can judge those who prognosticated a total failure of the breed were right. They are unusually scarce.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 69.8° and 47.1° respectively. The greatest heat, 83°, occurred on the 7th, in 1843 and 1846; and the lowest cold, 28°, on the 7th, in 1855. During the period 142 days were fine, and on 103 rain fell.

CERASTIUM BIEBERSTEINI — WHITE FUCHSIAS—COCOA-NUT FIBRE.

IRSTLY, then, I must square the circle in which I have been writing last week. I wrote that I knew every plant Dr. Neill had in 1829, in answer to "AN OLD SHOWMAN," who said Dr. Neill could tell something of *Scrophularia aquatica*, which no one else could; that I sometimes assisted his gardener, Mr. A. Scott, the worthy Doctor being then the scientific director of the Caledonian Experimental Garden at Edinburgh, where I served; that Mr. Scott is now nurseryman at Chichester, "lately of Leigh Park, Hampshire, and who was at Kew, and at the Liverpool, Manchester, and Birmingham Botanic Gardens." There is where the circle is out of square: your humble servant, and not Mr. Scott, was at Kew, Liverpool, Manchester, and Birmingham Botanic Gardens, very soon after leaving the Edinburgh ones, and could tell that Dr. Neill had plants which I could not see in any of these seats of botany; but I did not recollect either of the *Scrophularias*

being then in his collection. I can tell you one thing he had in 1827, 1828, and 1829, which would be an eyesight to some fresh-water sailors of the present day. He had a real fresh-water aquarium in a glazed pit, or cold frame as you might call it, with means to keep it warm. It was a wooden tank lined with lead; one-half of it was all water, and a few under-water-growing plants, as *Vallisneria*, and a number of creeping lizards and other living creatures of strange aspects; and another part was all water below, and a thin crust of marsh-like surface of tangled vegetation, either resting on the water, floating about, or fixed as islands by having stones sunk in the water for the island surfaces to rest upon. In such ways Mr. Scott grew plants and kept water animals in a way they have not yet been done, nor one-half so naturally. It is just as natural that the Doctor might have written something about *Scrophularia aquatica*, which did not much interest the world at that time; and people of the present day need not fash themselves about old saws and sayings, but dig into a good plant, new or old, when they find it,

No. 75.—VOL. III., NEW SERIES.

or discover its properties, for such fancy works as are in the favour of fashion for the time.

This brings me on in the circle, to the beginning of last week, when we had a large pot or pan plant of *Cerastium Biebersteini* before the Floral Committee; and as one tale is good until another is told, and also as you have been made to believe that the new *Cerastium* was so much better than the old one, it is only, as an attempt at squaring the circle, but right and proper for you to be made aware of the fact that not one member of the Floral Committee thought the new *Cerastium* one single step in advance of the old one. Some of them believed it was not nearly so good as tomentosum, and to-day I appear before you as a living illustration of the adage which speaks of a man convinced against his will. The only clue I can give you for arriving at a fair conclusion of saving your money on that plant, or to spend it on it, is that there is no plant now in use in all the flower gardens of the three kingdoms, which ever had the smallest lift or encouragement from any society whatever, or from any quorum or committee of such society, except two or three for which we had given good characters last season—such as *Agathæa cœlestis variegata*, and the Foxhunter *Verbena*.

WHITE FUCHSIAS.

I never saw a bed of white *Fuchsias*, nor have I been aware, at all, of their bedding qualities; but at the head of public opinion on gardening, or say in the Floral Committee of last week, I had to make an apology to one of the members, Mr. Smith, of Hornsey Road, the raiser of so many fine *Fuchsia* and other plants, for the non-appearance of his new white *Fuchsia Conspicua* in our report of the previous Meeting, at which it had a fair and suitable award. On Mr. Smith's authority I make bold to say that this *Conspicua* white *Fuchsia* is one of the best bedders of the family; and he backed two more members of our body in affirming that the new race of white-corollaed *Fuchsias*—that is to say, those with the white inside and red outside, make famous bedders; all of the members having either had them so, or had seen them so used. It was only a few weeks before, in looking over my own collection of twenty-five kinds of the best new ones of this season, that I was congratulating myself for living to see the day when sense and judgment should come to the aid of one of the very prettiest of the flowers of my childhood—*Fuchsia coccinea*, than which there has never been a better wild *Fuchsia*, and out of its style of growth there has never been any improvement in the family, to my eye.

These new white-corollaed *Fuchsias* are just coming round in the style and habit of *Fuchsia coccinea*, and that of *globosa*, the next best-habited of the very old *Fuchsias*. Now, as the most ready way of getting up a stock of bedding plants on the instant for an experimental-bed of the different kinds of these white-corollaed beauties for next year, we who possess them must propagate a stock this autumn, and those who have them not must order a lot from the nurseries, or else arrange to

No. 727.—VOL. XXVIII., OLD SERIES.

do without them for another year. Of course, to those who cannot well afford the expense that is the best way; and by this time next year we shall be enabled, from experience, to tell a better tale, if that be possible. I do not know another family of plants from which it would be more desirable to get up three or four very distinct kinds of beds for the flower garden than the family of Fuchsia. All that I can say more in the matter is this, that there is no danger or fear but that a ready demand for bedding Fuchsias is as sure to follow as that day follows night or one season succeeds another. What I was going to remark about a stock of autumn-got plants was, that we who have not got hothouses should not go on the plan of Verbenas and Geraniums, by taking little bits of the tops or tips of the shoots for cuttings. I have a score of times got Fuchsia plants, just such plants as I anticipate now, without wanting them, or caring at all about them, in this wise: Whole rows and hedges of common Fuchsias have been cut over by the ground late in the autumn, when the pleasure ground was being righted after the bedding plants were housed, and before the spring bulbs were put in. Bundles of these would be made in sizes for staking plants with; and after being dry in the sheds, perhaps, for six weeks, they would root in the pots like Willows, till at last I was compelled not to allow them being used in-doors at all. They were, in fact, an actual nuisance, rooting and filling the pots faster than the plants they were meant to support. Every gardener in the three kingdoms of any experience is well aware of all this—aware that bare sticks of all Fuchsias will root and cause trouble the whole winter through, if they have been used fresh even for cold-frame uses, for stakes, sticks, or number-tallies. Then what is more simple than to take advantage of this living and pushing principle of Fuchsias, by pruning them, as soon as their growth is done for the season, on the close-spurring system; then to cut the prunings Rose-cutting fashion into lengths of four, or five, or even six inches, according to the strength of the shoots, parcel them into three sizes, the strongest or five or six-inch-lengths in one bundle, the middle-sized next, and the least by themselves; the assortments of cuttings to be planted in three different places, or pots, or pans—indeed, anyhow, so they be planted also Rose-cutting October fashion, all but an inch out of the ground they are in, wherever it is?

But the best way of all the ways I know of would be to get mould into one light of a cold pit, where *Calceolarias* and *Cinerarias* might be trusted in winter, then to begin at the back of the pit, and put in the biggest cuttings there as thick as they could be got in; the middle-sized cuttings to follow, and the little tit-bits to be along the front; then to damp them well with water at once, to leave off the glass till the next rain or frost, and to finish the season with them by a sprinkling of dusty dry something, if it be no other than the sweeping of the sheds. Anything will do if it is dry, or a dry mulching as one might say, and then there need be no more saying or doing about them till the middle or end of next March, when you would find them all rooted and coming away from every eye, like the sprouting of Potatoes in a cellar. If the spring was early they might be up in leaf as soon as the time here stated.

Perhaps one might like to try a hand at making spring cuttings of the tops as they rose above the surface; and if not, the best way would be to nip them off as fast as they appeared, for a certain reason, for getting rid of them out of the pit more early—that is to say, by the last week in April, if the bed or beds were ready for them. Always, and in all places of our three kingdoms united, beds of Fuchsias struck on this plan might be planted out and off-hand by the first days of May. You have seen, at least in your mind's eye, that the spring growth was all under the surface, so there would be no chance for a May frost to get hold of them. Besides, it is always a good plan to mulch over such beds as soon as they are planted—not with any mulching stuff, however, but with dry refuse soil from the back place, sifted if you could, and put on an inch thick. This is what I would call the best mode for every class and calling in society to adopt for getting up the first Fuchsia-beds; but then it might cause a rebellion if one were to insist on it, when a gardener knew well enough he could do it in another way more suitable to his own arrangements. Then the second year some would risk the Fuchsias in the beds the whole winter with something over them; and others would take them up and store them away like Potatoes for the winter, divide the plants in the spring, put the biggest pieces with the best roots in the middle of the bed, and work down to the sides in gradation of sizes, just as has been suggested for the pit cuttings.

The last way will be my own practice if I go on at all, which is doubtful. But in the autumn I would have all my Fuchsias after or just before the first frost of more than 5°—that is, as soon as the thermometer fell to 27° I would up with my beds of Fuchsias root and branch, prune to the quick at once, assort the prunings into three sizes like the comparing of adjectives in grammar—good, better, best, and keep up a fresh stock for contingencies. The old roots and the stumps pruned that way I would keep in a shed to dry partially for two or three weeks, with a bundle of something to throw over them in case of frost. I would have them then packed in sand or mould where Carrots, Parsnips, and Potatoes would keep without sprouting to the end of February. During the last week in March I would have them out; divide them in parts as strong as possible, for the centre of the beds; plant them all as soon as I could, putting the tops of the stumps within the soil; and then sow a crop of some six-weeks annual over them, as *Nemophila*; the covering for the seeds being my dry mulching.

#### COCOA-NUT FIBRE.

The next most gratifying news for propagation, which I heard of at the "top of public opinion" aforesaid, was this—that Dr. Lindley was actually the best patron down at Turnham Green for Barsham's patent "pulp," this cocoa-nut refuse. He always said his garden was damp, full of clay, and a great bother to him, and I consider it one of the most gratifying points in the history of Barsham's patent that I should be indirectly the means of getting Dr. Lindley out of a fix. That is the stuff to fix your ammonia, if you only first fix it in clay ankle deep. The first 18 inches of the surface of all the clay in Middlesex could be made with the refuse into a compost for Pine Apples, or for *Lobelia speciosa kermesina*. That I have proved with my own hands. Mr. Samuel Matthews, a well-known gentleman in Long Ditton, and well-to-do as he deserves, charged us only 14s. the load for the best clay in Claygate for the Experimental Garden loam during seven long years, and now he only charges me 10s. the load for the same. That is trade price for my being in the calling, for I never spoke to him but once. I vouch for it that his Claygate clay, where the Claygate Pearmain originated, is the most genuine article in the commerce of all England; and at the present moment I have the actual *Lobelia speciosa kermesina* growing in it in little pots, and doing as well as any *Lobelia* you ever saw, and not one particle of sand has ever been used to make it into the suitable soil. But that clay was out of a ditch for years, and the surface of it mouldered down to the very strongest loam I ever handled. It takes only four times its bulk to make it suitable for any pot plant in England, and I have not the smallest doubt but Dr. Lindley will report it, when he has used it half as long as I have done, in far better terms and with still greater confidence.

D. BEATON.

## INTERNATIONAL EXHIBITION.

### HORTICULTURAL GARDENS.

"HAVE you been to the Exhibition yourself yet?" are questions that are coming to me thick and fast." And to save other people and myself trouble, I wish to state, "Of course I have," though as yet only for one day; and I think it right to add, that owing to the kindness of my employer every man and boy in the garden has enjoyed the same privilege, making two companies of them, so that the work might be carried on to a certain extent, and nothing suffer from the holiday. The sight will be a thing to be talked about by the youngest now, when they come to have grey hairs, and to be looked back to as a sunny spot in memory's recollections. "Sad, sad is the heart that never rejoices." Wearisome must that existence be in which no bright joyous feature of the past comes as a sweet vision to delight amid the stern realities of the present. We have had gardener visitors sent up all the way from the north of Scotland; and I could discover many more by their voice and the peculiar walk in the building—a gait which to me is almost as sure a sign as any in the masonic confederacy, by which one brother easily recognises another. Once more, then, as the closing of the Exhibition approaches, allow me to urge upon the employers of gardeners who read these pages, not as a duty or a privilege, but as the means of giving a great treat to hard-working respectable men, to send up their gardeners, if at all within railway distance, to see this grand sight at least; confident that even in this, goodness and beneficence will meet

its legitimate reward in renewed and extended efforts to please and to promote their interests on the part of those thus favoured and obliged.

"But what, after all, would be the use of one day amid such a display of wonders? Anything like study of details and clear apprehension of particulars must be quite out of the question." Well, suppose we grant all that for the sake of argument; we would contend notwithstanding that a most beneficial effect would be produced on most minds—not merely from the sense of the beautiful being gratified, but in beholding the wonderfully diversified produce of our earth, and observing how that has been improved and developed by the agency and intellect of man. Humility of spirit, the wish to learn, the desire to improve, are the first steps in the ladder of advancement, and nowhere could we have better forced upon our attention the idea of individual littleness. Many a one will be bettered for life from that sight, though they might be at a loss to tell you clearly of the individual thing that produced such impressions. A country clergyman once got into conversation with a matronly peasant washing wool in a sieve in a running stream. The services of the previous Sunday formed the chief topic of their talk, and he ought to have been satisfied when the good woman told him of the comfort and happiness she derived from his sermon. But no. He wanted to know what particular head or division of the sermon afforded her so much pleasure; and because she honestly told him she could not tell him, he somewhat bluntly said he could not see how she could have been benefited if her memory was so bad and unretentive. Lifting the sieve full of wool out of the stream, she directed his attention to the patent fact that the water all fell through, and then added, "But the wool is the cleaner, sir." We would wish all the brotherhood of the spade to be placed as respects the Exhibition in the same position as the good woman's wool stood in respect to the water.

Though granting the above, yet we are also of opinion that a good general idea may be gained of the whole Exhibition in a day, if a shilling guide especially is studied a few hours previously, so as to see the most attractive objects first. I was in the building from ten to five, and though there were close on 60,000 people I cannot say I was ever crowded. The great feature as contrasted with 1851 is the picture gallery. The two lesser and distinct features are the superior and more extended machinery, and the produce—mineral, vegetable, and animal, of the numerous colonies.

I had a fine view of all the jewellery, &c., on the south side of the nave, where people could be counted by scores. Had between two and three hours in the picture gallery, and had a general run through the whole building upstairs and downstairs, with a more particular survey of the machinery, and the whole of our colonial departments; delighted I was with the grand view of their mineral, vegetable, and animal products; and I did not only make notes to please myself, but such as might have been useful to those who did not have even a day's view, but for those very nice short descriptions that have appeared in and no doubt will continue to grace these pages.

Having dined to my heart's content, with only a few minutes given for digestion, and having had an excellent cup of tea, I spent more than an hour in the

#### HORTICULTURAL GARDENS.

I would not have deferred the visit to the evening, but on wishing to go early in the afternoon, when exhausted with the noise and the heat of the machinery, I was told I could not get back again without paying afresh. Nothing could have been worse advised. But for such a foolish restriction, thousands instead of tens would have cheerfully paid their sixpence merely to breathe the sweet air, and have a walk or a seat after the bustle and heat of the building. On appealing next day to some of the great folks connected with the Exhibition and the gardens, I found, so far to my satisfaction, that in this case the garden authorities were not at all to blame; and ere long afterwards I had the pleasure of noting, that such an absurd rule was broken to the benefit of all concerned and the disadvantage of none. On that beautiful evening, with the garden at its trimmest and best—and it did look lovely—and one of the most popular bands discoursing eloquent music, not above two hundred people seemed congregated to have ear and eye alike gratified; and during the day when I looked at the gardens the visitors were few and far between.

Another drawback to visitors was the very desolate appearance

of the low piece of ground next the building. Owing, I presume, to that having been used for exhibition tents, and, consequently, the beauty of the upper terraces not being seen from the Exhibition building, there was little inducement presented for investing a sixpence for gratifying the eye out of doors, when there was so much to see within. For this I presume no one is to blame, but hundreds so turned from the refreshment-room with "Is that what is to be seen?" Such a matter is deserving of consideration on a future occasion, and also the idea, as exhibiting in these gardens is the most prominent feature, whether it would not be better to have permanent glass buildings chiefly for the purpose. At any rate, many of us gardeners and many gardens might take a useful lesson from the drapers who do adorn their windows with a care and an elegance that would shame the tawdriness and slovenliness of many parterres, knowing full well that the attractiveness of the window induces many a customer to walk in to the counter.

Shortly afterwards in the establishment of one of our greatest nurserymen I noticed a span-roofed house full of fine plants of Vines in pots. The *very very* best were clustered opposite the doorway, and on the sides near that end. Not one visitor in a hundred would think of walking round the houses. Some young gardeners, if sent with visitors, think they must especially show off all that is below the mark, just as if those visitors came on purpose to see failures; nay, sometimes they will be so honest as to depreciate what is really excellent. Our nurseryman knew better. All his Vines were up to the mark; the most excellent were placed full in view, like the chaste dress and the elegant ribbon in the window. There is no deception, nothing against sound policy in putting, so to speak, the best foot foremost. The impression that would be formed of the gardens from the Exhibition would decidedly be that of the worst foot foremost. But for the reason assigned the grounds next the building might have been as attractive as anywhere else, and thus have tempted many thousands of sixpences into the treasury.

Of the gardens as a whole, now becoming a rather controverted subject with the public, I would treat rather gingerly, more especially because I am one of the half-way sort of people that see much to admire, and also something not to admire, and just having enough of presumption to say what I think, notwithstanding the "away, then, with criticism" of our worthy coadjutor Mr. Beaton. Well, then, the grounds were everything to be desired in the way of keeping, and, on the whole, the planting and grouping were in much better order than is generally to be met with this season, and more especially the different Geraniums. For *Caleceolarias* I think the beds could have been more than matched farther north.

Then, again, as to the title "Horticultural Gardens," I believe the first person that summoned courage to criticise the title with the appendix "Royal" as totally unsuited, honoured me with a notice of his intention; and I pleaded as I now do, that the smallness of the space and the position would ever prevent it being a garden distinguished for its horticulture; but that I viewed it, and I believed the members viewed it, chiefly as a place suitable for the exhibitions of the Society, and where the results of culture at their garden at Chiswick could be made known, and also as a place where the members and friends of the Society could meet and enjoy themselves amid its parterres and conservatories.

Then, again, others complain that there are no trees to speak of, no shelter, no shade, no picturesque effects produced. To which it might be replied that the trees could not be expected to be large in a twelvemonth; and that though in picturesque effect the gardens could not compare with the Regent's Park or the Crystal Palace, it should be recollected that it was intended to be merely an artistic garden of terraces and parterres, and that this could scarcely have been departed from if the giving of the ground by the International Commissioners were dependant on flanking the ground all round with brick arches, corridors, or arcades. If the authorities were thus tied up, there is little more to be said about the general design, which left only the *artistic* to the artist or landscape gardener as a matter of necessity. If not thus tied up, the whole costly affair of as-yet-some-what-useless corridors and costly terraces, when the visitor obtains an idea of what the whole has cost, would lead him to the conclusion that the affair as a whole and for the objects contemplated was a huge mistake. It would really be a great benefit to the gardening public to know what was spent on the laying-out of this garden as it is, and the laying-out of the

garden in Regent's Park, as we would be surprised if the latter cost anything like the former, and there can be no question of the greater suitability of the latter for the object aimed at, and the greater pleasure of the visitor from the diversified scenery, and from the artists not being confined to any one school of design. Certainly, before country gentlemen who grudge their £50 or £100 for a great improvement are to be indoctrinated with the idea that these gardens are a pattern for them to follow, they ought to know something of the cost—first of making them, and then of keeping them.

Leaving these things, however, as they are, the question of greatest import is, As an artistic garden is it fitted to be a pattern to the community? If not, we will have a spurious, gimcrack system of flower-gardening poured over the country—a retrogression instead of a progression in fitness and refined taste, and already the example is being followed in but too many cases. I might have entered on this subject at large; but our friend Mr. Beaton has really done pretty well all we intended doing, and the beauty of it is, he has done it all, not in the way of fault-finding, but as an advocate of things as they are, as the best present example of Italian gardening, &c., which I do not doubt in the least, though the very best would, perhaps, not suit our purposes. It is thoroughly refreshing, after objections being scouted as so much *twaddle* and criticism disbanded "away," to find after all the ponderous club of the veteran coming down more heavily on the mixture of coloured gravels, broken bottles, and flowers than ever we should have ventured to strike for fear of breaking all up in a rough medley of confusion. "Shure and doesn't he bate me because he loves me?" was the rejoinder of the Irish lady to the kind but simple-hearted swain that tried to interpose between her and the fists of her angry husband. Our friend loves the garden so well, that he heartily drubs all its shortcomings; but woe to the other poor wight who would gently hint at a drawback. Well, it matters not, provided the evil is pointed out. I thoroughly agree, therefore, with Mr. Beaton, that though different coloured gravels, shells, ashes, broken bottles, &c., may be admissible as to ground colour—may, may come in well as pathways between beds of flowers, especially if well contrasted, that they are thoroughly inadmissible for occupying the position which a clump of flowers ought to do.

I saw the prettiest parterres of the garden last season, and the same, even with more telling effect, this season; and these patches of colour, stuck here and there, rendered the whole effect incongruous. The same style has been adopted in various parts of England, and also in Ireland; but the effect, to our eye, was constantly most unsatisfactory. It just made a sorry muddle of what otherwise would have been most artistic in design and uniform in beauty. The idea of levelness, a great charm in itself in such parterres, is completely broken. Train, peg as you may, the generality of plants will be from 9 inches to 18 inches above these little holes of mere colour. If admissible at all, the general planting should be sunk so low that the colour of the flowers should be on the same level with the shells, &c. As at present managed, whatever may be urged in favour of composition planting, the beauty of the picture is marred. Instead of leaving them, as our friend advises, as a source of warning, we would rather see the evil remedied before the incongruity is spread over the country on the authority of these gardens as an example. Nay more, not only would I plant these circles, &c., now monopolised with coloured earths, but, as rising abruptly now and then above the general level is a very different thing from sinking below it, we should be disposed to try a few pyramids of colours in some of the smallest of the circles merely as stand-points to the eye, enhancing and not reducing the general loveliness. I was delighted to observe that the pretty parterres in the Regent's Park had an additional attractiveness given to them by several of these blunt pyramids at regular distances, which, by breaking the general levelness, enhanced the attractions of the picture as a whole. There are many positions in which stand-points would be inadmissible; but, in somewhat level ground, acres of flower-beds, all uniform in height, are to us acres of boredom. Variety in height has a charm in itself, as well as variety in colour.

To the beautiful, artistic, purely composition groups, one on each side of the garden, these remarks have no reference. Entirely composed of Box and variously-coloured materials they look all of a piece, and the first sight is very striking. We should imagine the want of change would become irksome. The great beauty consists in the artistic tracings. We should be sorry, however, to see such a style of purely coloured earths ever going beyond towns or their thickly-populated suburbs. Even there

they can convey little idea of gardening or its pleasures. A carpet so coloured or a piece of calico would for a time be as attractive as these Box composition-gardens. To produce them more durably we may ere long find the carpenter, the stonemason, and the painter taking the place of the gardener. I can, however, find no fault with those who like them, though, as far as gardening is concerned, I look upon it as a step in retrogression. The largest affair of the kind I know is the huge bed in winter at Linton. I wonder what the accomplished proprietress with her refined taste would think if Mr. Robson, following this now somewhat popular mania, were to leave that huge group adorned with his coloured earths all the summer through, as a pattern of flower-gardening of the highest kind to the neighbourhood. Mind, however, I deny not the beauty and the striking effect of the artistic tracery, I merely demur to its general introduction as a feature in flower-gardening.

#### ARCADES.

"Talk of shade and shelter, why don't you go to the arcades?" growled one old gentleman to another as I was passing. "Yes, and get a stiff neck and rheumatic fever again," was the grumbling retort. Well, if they have no other good qualification about them, they are certainly breezy enough. Given a little brisk wind outside, and the visitor would have to look after the point of his nose. No wonder that exhibitors dread to have their plants placed in these corridors, even when protected with the dingy curtains in the openings, that, flapping about, conveyed anything but the idea of the "Royal." In our ramble through them we scarcely discovered a vestige of the humanities, except a single pair in a sheltered nook, busy seemingly in exchanging the sweets unutterable that can only flow from tongues that love has rendered eloquent, and charitably we gave them a wide path not to break in on their happiness.

Often these corridors have been brought under our notice by visitors, who wished to give us plain simple folk in the country some idea of the grand if not the sublime. "They give such an architectural effect to the gardens," and that is all true. "They render such a fine background to the terraces when standing in the middle of the garden." All true, no doubt. We presume that was part and parcel of the bond. Like many other things, however, these corridors seem to require this distance to lend enchantment to their view; like many other objects of attraction, like even our dearest friends at a distance, nearness and intimacy only tend to dissolve the magic of the charm. From description merely, we had formed bright visions of corridors, width somewhat larger than the reality, length going round the south as well as the east and west of the garden, so as to permit of all being seen in a wet day. Front openings furnished with glass; a low span-roof of glass, concealed if deemed necessary by parapets; the front buttresses inside covered with plants. The back wall so covered, and climbers depending from arches across at regular distances, thus furnishing in such a limited garden a vast number of growing plants to engage the attention of visitors, and of which we could see little doubt as to their thriving if the ventilators were provided with gauze to exclude the soot, and also presenting a noble background for those exhibition-tables that could not be massed in the conservatory. Although in these corridors there would not be the same massive effect as could be achieved under large tents, there would be much more opportunity for visitors examining all objects quietly in detail, whilst the uncertainty of the weather and the flapping of tents in such an artistic garden would be wholly provided against. Instead of the realisation of anything like such a vision or day-dream, which we believe would have involved little more expense, we are presented with some flapping dingy curtains, a bare unadorned back wall, an ugly opaque roof, consisting in one place of large rough timber, and in another of lath, seemingly, from which the plaster has fallen; and all so far as we can see, to procure an asphalted walk on the top, that some visitors, numbered by tens in the twelve months, may have the pleasure of looking on the garden from an eminence a few feet higher than could be obtained from the arcade inside. No doubt there is a reason for all this. No doubt it is very wrong for a person knowing little or nothing of architecture to attempt to criticise what may prove to be only half-finished work; and yet it may not be wrong to omit swelling the notes of admiration for the beauty of these arcades until we are kindly informed how they are to be finished, and what purpose of utility they can be made to answer to compensate for the heavy outlay; there being still a good many old-fashioned people who think the beautiful

not the less beautiful when associated with the useful, and who, without clear perceptions on such matters, might demur to follow even the Royal Horticultural Society in the forming of architectural and artistic gardens.—R. F.

### PRESERVING PLANTS DURING WINTER.

"A CONSTANT READER" asks in your valuable Journal of August 19, "What am I to do with my plants in winter?" I have a number of Geraniums, Calceolarias, Fuchsias, &c., and have preserved them successfully during the last two winters. The winter of 1860 was very severe, as many a gardener has reason to remember, and in that winter I lost but one plant; last year I lost none. Plants in pots are a pest in winter, unless you possess a greenhouse.

To avoid trouble, I made several boxes suitable for the window; each box the depth of an ordinary flower-pot, about 8 inches or 9 inches wide, and 16 inches or 17 inches long, well supplied at the bottom with holes for drainage, and nicely painted. A slight layer of broken crocks was then placed at the bottom of each box, and covered with coarse fibre torn from a cocoa-nut husk to prevent the mould escaping. I then turned each plant out of its pot, squaring the ball of earth a little, without disturbing the plants. They were then placed in the boxes side by side, each box holding about eight plants (eight troubles in one), and the spaces between, if any, were then filled with the spare mould. Geraniums, Calceolarias, Fuchsias, &c., were each in a box by themselves. I then kept them as quiet as I could; they were very rarely watered, did not grow lanky, and were preserved healthy to the spring. They are now mostly bedded-out, and are finer plants and more profuse in flowers than any I have purchased this year. In fine weather they had plenty of air in the daytime. They were in a back kitchen during the greater part of the winter, only being removed into a dwelling-room when the weather was very severe, and then placed as far off the fire as possible.

Be sparing with the water—comparative dryness is essential. The Calceolarias will ask plainly when they want moisture.—WM. H. STRANGE, *Hornsey*.

### FORCING VINES.

LAST year I erected a small lean-to house, and have raised some young Vines, some of which I intend planting in front to train in. Would you advise me to plant them out this autumn, or in the spring?—J. G. D.

[Vines to be forced early in the spring, or in winter in pots, should have the pots full of roots, and the wood well ripened early in the autumn. An early produce of fruit is more the object than continuous bearing. In your case, we would prefer turning out the Vines now, as the roots would progress well in the warm soil. Spread the roots well out, as practised by the best planters, and recommended by Mr. Thomson in his book on the Vine. Such roots should be protected in winter from frost, and heavy cold rains. We think you will gain considerably in thus planting-out now.]

### CULTIVATION OF THE PEACH.

MR. APPLEBY gives some plain directions for the out-door cultivation of the Peach, &c., which have found their way by this time into unknown corners, and added to the information of many a young aspirant. But I do not think, nor do I believe Mr. Appleby thinks, that the time has arrived for folding arms upon the subject; and if I desire to have a say in the matter, it is less from the fact of having anything new or useful to impart than from a desire to give my experience, which every one is invited to do, and which if done in a kindly and neighbourly manner, is conducive to good will among the gardening fraternity.

I took charge some eight or nine years ago of a collection of very old trees, which were trained to a very old wall, in a very old garden. The trees were not only well stricken in years, and the wall so indented with nail-holes that not a square inch presented a plane surface, but they also seemed to be in no very healthy condition. By midsummer the leaves had acquired a yellowish tint, and were infested with thrips; and although the trees bore a fair crop of fruit, which ripened tolerably well, I did not like the starved appearance nor the quantity of dead

wood they made. It was never in my nature to let well alone if I could better it, and after my experience of the first season I considered what had best be done. If I could have had my own way entirely I should have taken out every other tree, planted a young one in its place, and kept the remainder of the old trees in bearing till the young were sufficiently advanced to depend upon for a regular crop, when the rest would have been replaced as the others were; but I could not do this, so I resolved on what I considered the next best plan. In the following March I pruned them in rather hard, nailed them up, and allowed them to flower and set their fruit, which they did in a satisfactory manner.

I must here state that the border in which the trees grew was 12 feet wide, the soil a very light loam, deep, and rich, but had evidently been worked in a very superficial manner. I concluded that in addition to the lightness and porosity of the soil, the roots had spread near the surface; consequently the heat of the sun and rapid evaporation of moisture from the light soil caused a deficiency of that most essential article, and that this was the reason of the starved appearance of the trees during the heat of the summer. This might have been remedied easily by mulching, but I had not the material; and as I was obliged to crop the border, I could not have used it properly if I had. It might also have been remedied in the manner spoken of by Mr. Appleby—that is, by opening holes at the foot of each tree and filling them with water; but there were reasons why I could not do this. Water was not sufficiently plentiful, nor could I spare the time, as to do the whole of the trees in this way and carry the water a long distance would have been a good day's work each time it was done, and I had many other things to attend to.

The plan I adopted was effectual and more permanent than either of the above, and I would recommend others who find their trees in a like condition to try the same remedy.

I procured several loads of good stiff loam, the stiffest I could get—somewhat approaching clay. I then, taking the stem of each tree as a centre, marked out a crescent or half-circle a yard each way from the stem. The soil within this half-circle was then dug out to the depth of 10 inches, and a foot of the loam put in its place and trodden down firmly. This was done about the middle of April, before the sun had affected the trees that season. Nor were they ever affected afterwards in the way they had been before. Instead of the leaves turning yellow they preserved a healthy greenness, and have done so every season; and I have never known them from that time to be infested with thrips or any other pest, except here and there where a shoot may be occasionally troubled with aphids, but not enough to disfigure a tree. The roots and the collar of the trees were shielded from the scorching and drying influence of the sun by this bed of loam, which by maintaining a uniform degree of moisture and regular temperature, had a most beneficial effect. Old trees seemed to have taken a new lease of life; they made vigorous shoots, soon covered the wall, and bore regularly every season a uniform crop.

But there were two spaces still which it was desirable to fill up, and I procured two young trees and planted them in a good mixture of loam and dung. The following autumn two young trees were planted in the place of a very large Peach tree, of a sort inferior to the others, which I was ordered to destroy. These I planted by merely making holes for them and without giving any additional soil. The difference now between these two and the two planted a year previously is remarkable. The first two that were planted rooted into the rich stuff and grew vigorously, too vigorously to be fruitful; and in spite of root-pruning, they are still far less fruitful than those that received no manure or extra soil at the time of planting. The latter have borne regularly from the third year after planting, and always produce a good supply of fruit-bearing wood, proving in my opinion that planting in strong or stimulating soil is not conducive to fruitfulness, either in wall trees or indeed any others; and if the soil is tolerably good in the first place, it is not advisable to add any stimulating manure until the trees come into bearing: it may then be applied advantageously either as a mulching or dressing to the border.

With regard to making holes at the foot of the trees as above referred to, I think a better plan might be adopted for applying water, provided neither mulching nor my plan of easing the main roots with loam is thought advisable. That is, instead of making holes and filling them up each time after watering, let good-sized flower-pots be sunk bottom upwards just where the

holes would be made, and let the bottom of the pots be on a level with the surface of the ground. These pots may be filled with water as often as you please without the trouble of digging holes every time. A piece of slate may be placed over the hole to exclude the light after filling. Eight-inch pots I think a very good size for the purpose; at least that is the sized pot I have seen in use, and found it an excellent plan for introducing water or liquid manure to the roots of plants in sufficient quantities to be beneficial, without the inconvenience of disturbing the ground excepting in the first operation of sinking the pots.

Another good method I have seen in operation as applied to a Vine-border, is to lay perforated pipes a foot under the surface, and have a tube leading to a convenient place for mixing liquid manure, which is poured into a funnel, and thence conducted directly to the roots of the trees, where it becomes of immediate effect. The same system might be applied to the whole length of a Peach-wall; and the pipes filled once or twice a-week would keep the trees in full vigour and add considerably to the size and flavour of the fruit. The first expense of laying down the pipes is saved in labour, as they will last as long as the wall, and the time it takes to fill them is nothing. It would be a grand thing if the owners would see the advantage of such appliances, and the benefit they might reap from them in a long course of seasons—to say nothing of the credit of gardeners, who, as a rule, have to work against numerous impediments, that with a few pounds judiciously spent in the first instance might be removed. In the management of wall trees particularly I have known instances where gardeners have been brought to discredit for what in reality was no fault of their own. Sometimes a ten-foot wall has a border 2 feet wide. This border is usually skirted by a gravel path, presenting an impenetrable barrier to the extension of the roots, which are consequently confined to that narrow compass of border. No wonder, then, if the trees do not bear regularly, or that they do not yield good-sized or well-flavoured fruit. Yet as regards quantity, I have known heavy crops produced in such situations; and had the roots been well supplied with liquid manure during the swelling of the fruit, I believe it would have been all that could be desired as regards size and flavour.

In speaking of the culture of wall fruit, writers of any note would seem to imply that it can be properly managed only in gardens that are kept up in style, or of some extent;—an erroneous opinion altogether, as every jobbing gardener about London knows. Many suburban residences are built in continuous blocks, sometimes of considerable length, with long strips of gardens, divided by walls averaging 7 feet or 8 feet high. These walls are never lost; every available space is planted with Peaches, Nectarines, Vines, &c., wherever there is a southern aspect, and Cherries, Plums, &c., on the north. Thus many hundreds of these trees are grown in the space of a few acres. In such places I have known crops that would do credit to the most skilful growers in the country; and many a cold, frosty day in winter, and many a hot day in summer, have I spent in the training process, going from one garden to another, and got over a number of trees during a single season that would surprise many a country gardener.

I am led to make these remarks from what Mr. Appleby states in speaking of the winter treatment of wall trees. He says, "To prevent breaking or loosening the wall in the process of drawing the nails, give each a gentle tap;" a thing that would seem extraordinary to one who has taken a pair of pincers, and, giving each nail a gentle twist, has drawn bushels of nails and shreds just before pruning time. In giving a nail a tap with the hammer, be it ever so gentle, is as likely to break the nail off as to loosen it; and even the claws of the hammer are not so convenient for drawing the nails as a handy-sized pair of pincers, which every one who undertakes the training of wall trees should be provided with, and have slung in a loop fixed to the nail-bag for the purpose.

Again, Mr. Appleby recommends scalding the shreds, and oiling and cleaning the nails before using them a second time. These precautionary measures I have never practised—in the first place, because they take up too much time; and in the second place, I do not think that much importance need be attached to them. I will answer for it that the trees I have attended the last nine years are as clean and free from every insect pest as need be; yet I never syringed or lmed them, or ever had occasion to use one of the numerous remedies for thrips, aphids, cuckoo-spit, &c., and my trees are as innocent of Gishurst Compound as they possibly can be, yet I use the same nails and

shreds as long as they will last. How, then, am I to believe that insects deposit their eggs in them? If they do they come to naught. As regards repairing the wall and stopping-up nail-holes, I think it a very wise rule to be observed, and should never be neglected; the more so because I have known the inconvenience of training trees properly and neatly where it has not been done. But as to taking so many precautions on account of the eggs, &c., of insects, I think too much stress is often laid upon a fact of which I have never known any positive proof. Far more I believe depends on the condition of the trees. And this brings me to an old theory I have long entertained—viz., that insects, where they appear in considerable numbers, are not the cause but the effect of ill health; that they prey on the unhealthy juices of a diseased tree or plant in preference to those of one in a healthy state; and that while either is in a thoroughly healthy state neither thrips, aphids, nor red spider will be found upon it: therefore, see that the soil of the border is tolerably good, and that the roots are never either dried up or soddened with wet, that the trees are pruned in a timely and judicious manner, and that they are never exhausted by being overburdened with fruit. Attend well to these points, and the trees will be kept in health, and insect pests will not annoy you by infesting them.—F. CHITTY, *Stamford Hill.*

### EXPERIENCE OF THE AMARANTHUS RUBER MELANCHOLICUS.

I RECEIVED twelve plants of the above at the end of June from the grower. They were planted out round a bed of Calceolaria, the Perilla-border being removed to make room for them. They were fine healthy plants, but the second day began to droop. I wrote to the Messrs. Veitch, who suggested shelter with pots for a short time. This had been already done from the third day. In a few days half of the number died off from the collar. The gardener then took up the rest and repotted them, placing them in a cool frame. Three out of the number are now doing well. Can any correspondent suggest a cause?—H.

### ROYAL HORTICULTURAL SOCIETY.

AUGUST 26TH.

FLORAL COMMITTEE.—It occupied two hours to discuss the merits of the collection of novelties which were sent up for adjudication—*Gladiolus*, bedding *Geraniums*, *Petunias*, *Verbenas*, *Begonias*, *Hollyhocks*, *Achimenes*, a *Gloxinia*, *Ceraium Biebersteini*, a tricolor *Heath*, many *Dahlias*, new *Pyrethrums* from Mr. Salter, lots of *Fuchsias*, the new *Zinnia aurea*, *Phloxes*, a *Fern*, and some other plants, all of which were not considered of sufficient merits above their kind and kindred to deserve the honours aimed at. But the best *Dahlia* that ever was seen and the newest to the florists of the day was there, and took your reporter by the eye like the flash of a firefly. It was from Mr. Keynes, of Salisbury, who named it Charles Turner in compliment to Mr. Turner, of Slough; and it had the First-class Certificate by the unanimous lifting-up of hands in admiration of the beauty of the flower, which is of a peculiarly rich orange ground colour, and edged, tipped, and shaded throughout with a peculiar tint of soft, rich, mellow purple—a perfect model of a lady's fancy in the combination of colours in one flower.

Cut flowers of a new *Verbena* from the Messrs. Downie, Laird, & Laing were equally admired by all present, and had a unanimous vote for a First-class Certificate. It is named Lord Craven, and the colour is a compound of dark plum colour and Bishop's purple—the finest purple *Verbena* yet seen.

Another *Achimenes* from Mr. Parsons had a unanimous vote for the highest award on account of the substance, shape, and size of the flowers. They are as thick, as stiff, and of as much substance as those of the stoutest *Gloxinias*, and larger than any of the race. It is named Mauve Queen after the fashion of the dress of 1859, when every shade of blue to violet and lavender was called mauve, when no mauve was in the market.

The *Dahlias* Countess of Shelburne and Lord Dundresry brought First and Second Certificates to Mr. Turner. The Countess of Shelburne is a very pretty new colour in blush tipped and lightly punctured.

*Lobelia kermesina*, from Messrs. J. Carter & Co., had a Certificate of Commendation, as a likely kind to produce a new strain of purple *Lobelias*.

The new *Zinnia aurea* is a bright orange yellow, but was said not to be very suitable for beds.

Mr. Bull had a Second-class Certificate for *Anthurium leuconeurum*.

There were many plants from the Messrs. Veitch, beginning with a fine specimen of *Lapageria rosea* with upwards of twenty blossoms open, for which a Special Certificate was awarded. Then *Rhus vernicifera*, the tree from which the celebrated lacker of the Japanese is manufactured. To this a First-class Certificate was given, in consideration of its having been reported to be hardy: and another First-class Certificate was given to an entirely new form of *Cryptomeria*, which in a young state has much the look of the old *Diosma cricoides*; and a fine hybrid from *Rhododendron jasminiflorum*, which is as pure in white as the original, and four times its size; and another plant of the great gilded Lily of Japan with one large flower.

**FRUIT COMMITTEE.**—Thomas Rivers, Esq., in the chair. Mr. Rivers brought several varieties of Peaches and Nectarines grown on pot-trees in an orchard-house. Like all the fruit this season, they were very inferior in flavour, and came far short of the qualities they usually present. *Violette Hâtive*, which is generally a first-rate and delicious Peach, was not good, flat, and without much flavour. *Montagne Précoce*, another excellent variety, was acid and inferior in flavour. *Early Albert*, one of Mr. Rivers' own seedlings, was rather better, but still had more acidity and coarseness in its flavour than is usual. *Early Grosse Mignonne* was in better condition than any of the others. In the collection was a variety raised from a stone of the White Nectarine, and which was, in fact, a White Peach, equally as white as the White Nectarine, and with the flesh pale to the stone—not a trace of colour either outside or inside. It had a brisk flavour like the White Nectarine, and no doubt in a good season will be in very much better condition. Crawford's *Early*, a fine large Yellow American Peach, was past, and had become mealy.

Mr. Rivers also brought specimens of his Orange Nectarine, a seedling from Pitmaston Orange, which has kidney-shaped instead of round glands on the leaves, but is in other respects the same.

Of Plums and Cherries Mr. Rivers brought the following:—Prince Engelbert Plum is a large, oval, dark purple variety, admirably adapted for all kitchen purposes, and an immense bearer. Mitchellson's Plum, less in size, but of the same colour, is also a great bearer. Columbia, a large, round, purple Plum; is also fit only for kitchen use; the flesh is coarse, and of an ordinary plum flavour. Rival Cherry is a variety recently introduced from the continent. It is a small Black Bigarreau of the race of Belle Agathe, only the latter is a Red Bigarreau. It has the good properties of hanging late and bearing abundantly, as Belle Agathe has. Planchoury is a form of our Late Duke, or Anglaise Tardive as the French call it, and if not identical with that variety, is so like it that the one can hardly be known from the other.

Mr. E. Pierce, nurseryman, Yeovil, exhibited a Seedling Nectarine called the Cricket Nectarine. It was raised from a stone of Royal George Peach, and is very highly coloured, as much so as *Violette Hâtive*, and has a deep yellow flesh. Unfortunately, the unfavourable season influenced this variety also, and the specimens exhibited did not come up in flavour to the requirements of a first-rate fruit. It exhibited, however, the properties of a good fruit, and the Committee recommended Mr. Pierce to produce it again another season. It is said to be remarkably hardy, the maiden trees having for the last three winters withstood the severity of the season when every other variety was killed in the Yeovil Nursery.

Mr. Rust, gardener to Lawrence Sullivan, Esq., Putney, sent a seedling yellow-fluted Peach, which was of a very bitter flavour, and a seedling Nectarine with hard flesh, and with not much flavour.

Mr. Cunningham, gardener to the Bishop of London, Fulham, sent a dish of each Red and White Alpine Strawberries in very fine condition. The fruit of both was large and handsome, and the flavour all that could be desired.

C. Roach Smith, Esq., of Strood, sent a branch of the Cluster Damson, a variety growing in his garden, which is an immense bearer, and which this season has produced enormous crops, while other Damsons in the neighbourhood have failed.

Richards Headley, Esq., Stapleford, near Cambridge, sent a seedling early culinary Apple. It is of small size, being similar in appearance to a small Dumelow's Seedling. It has a fine

tender flesh, and a brisk acidity—in fact, the true "Wellington flavour." It is ready for use early in August, and in this respect is valuable. The Committee awarded it a First-class Certificate as a valuable early kitchen Apple.

Mr. Rivers, of Sawbridgeworth, exhibited samples of the Royal Ashleaved Kidney, a new variety raised by the late James Ashwin, Esq., of Bulerton Hall, Evesham. It is much more luxuriant and prolific than the old Ashleaved Kidney, and eight or ten days earlier. When cooked it is a mass of flour, and of excellent flavour.

Mr. Loney, gardener to W. G. Prescott, Esq., Roehampton, sent fruit of a seedling Melon, which was of very good flavour.

Mr. Parsons, of Welwyn, exhibited a branch of Gondouin Currant, an enormous bearer, and a variety well worth growing.

Mr. Myatt exhibited fruit of Standard of England Plum, and Mr. Dancer the Goodenough Apple.

## NOTES WHILST RESTING.

(Continued from page 412.)

ON the north-west side of the island is Vazon Bay, and beneath its widely-extended, firm, pebbleless sand is a peatified forest. A notice from the governmental authorities forbids this fuel being dug up nearer to the sea wall than the half-tide mark. This stratum of peatified forest extends, however, much further inland; for a fisherman, resident in a cottage not far from the shore, told me he found this peat when digging the garden behind his cottage. In some places there it is very near the surface, but in others it is much deeper. His son brought a specimen on a spade from the garden, wet, but otherwise the same as the lumps won from the sea, kept dry for fuel in a heap near the cottage. In all the specimens I examined were pieces of not-entirely-decayed wood and leaves. Birds' nests, acorns, and hazel nuts, with the kernels still within them, have been found embedded in this peat. One of the guide-books intensifies this discovery by adding, "The Hazel, like the Beech, has disappeared from this island; and it may not be out of place to state that the Filbert, on many occasions imported into Guernsey from a good stock, though subject to the same culture and pruning as prevails in Kent, cannot be brought to bear fruit." Both these statements are contrary to existing facts. I have seen fine Beeches growing here in St. Martin's; and I am informed by Mr. Carey that in his garden at Le Vallon, in the same parish, he has grown Filberts, and that at his brother's, Woodlands in Catel parish, they have grown for many years, are still growing, and bear abundantly every year.

Although the existence of the peatified forest had been long known, and though dried seaweed had been the chief fuel of the poor, and is still in other parts of the island, yet this forest was not rendered useful until the year 1817. In the December of that year a violent gale, impelling a spring tide, upheaved large masses and bore them to the shore. These masses were immediately employed as fuel, their value duly appreciated, and the winter being severe it received, and retains, the name of *Corban*, corrupted into *Garban*, a gift—a name forcibly reminding one of the similar word of like meaning mentioned in the 7th chapter of St. Mark's gospel.

It is interesting to have an approximate knowledge of the date when this forest was overwhelmed, and we have such knowledge from Mr. Lukis, a well-known authority resident in the island, who says "that there were found pottery and stone instruments, the tools and vessels of the first inhabitants, materials in character coexistent with our cromlechs and their contents, formed of the same substances. It is also reported that several hundred Roman coins were discovered in the peat some years ago."

Noting this peat formation, reminds me how forcibly and continuously I am struck by the courtesy even of the poorest of these islanders; for even that poor, half-naked, tattered fisher's boy whom I have mentioned, seeing my hands dirtied by the peat, fetched for me, unasked, a bowl of water and a fragment of coarse towelling.

I have already glanced a passing observation, I think, at the market of St. Peter's Port; but whether I have or not, having now seen it in all its glory—namely, on a Saturday morning, my notes can be more full and more worthy of its excellence. I have spoken in the singular; but in truth there are four markets, all abundantly supplied, all thronged by purchasers, the majority of them carrying a basket in which to bear home their bargains—for bargains they are, inasmuch as the female vendors have the

reputation of asking for a commodity sixpence when they will not reject the fourpence bid. On this point I will not volunteer an opinion, for they all looked upon me so benignly that bargaining would have been ingratitude.

The Fish Market I estimate to be more than 200 feet long, and full 20 feet wide, very lofty, and well lighted. There are twenty double stalls on each side, and two at one end. Each stall is formed of a slab of polished black, white-veined marble, has a tap of water, and is formed so that the surplus does not overflow, but is conveyed away by a pipe in the central front-supporting pillar.

I shall only mention some of the fish which were there when I made my visit. The most plentiful supply and most readily sold were crabs, both the common and the spider. The price of the largest and heaviest was 1s. 6d., and in London would have had affixed more than double that price; mackerel, a dozen for 6d.; red mullet, just in season, 6d. each; gore fish, if that is correct orthography; large craw fish, or rock lobsters, 6d. a-piece; and many other kinds, as bream, rock fish, red gurnet, bass, conger in large quantity, cut into pieces, but I am told this fish will be more plentiful next week. The only fish in the market peculiar to the island was the *Ormer*, a contraction of *Oreille de Mer*, or Sea Ear, which name is descriptive, for the form of its univalve shell approaches very closely to that of the human ear. Its scientific name is *Halotis tuberculata*. By its shell-less side it adheres to the rocks, probably by the same vacuum-power which makes the wet leather of the boy's toy adhere to a stone. Beaten to render it tender, and then stewed, it is said to have the flavour of a veal-cutlet. Uncooked, and lying with the unshelled side uppermost, they look much like a small scollop of oysters. The emptied shells are exported in large quantities to England, and especially to Birmingham, their pearly, iridescent, internal surface being familiar to us in *papier maché* and other 'spanned ornamental work.

The fish usually purchasable, but which were either not in season or absent when I was there, are turbot, whiting, white mullet, john dory, soles, brill, plaice, cod, smelt, and sand eel.

The Butchers' Market runs parallel, and is annexed to the Fish Market, and comprises about forty small rooms, lined within and without with the usual joints, the only peculiarity of which not-very-provocative-of-appetite exhibition was the extreme smallness of the veal. This, I am told, arises from the greater value of the butter and milk inducing the early killing of the calves.

On a projecting ledge outside the Butchers' Market, and in the open air, sit some thirty or more countrywomen with their very uniform white-clothed baskets of butter and eggs. That butter and those eggs are unsurpassable, the vendors thereof being unexceptionable models of elderly neatness; so I turned over in my mind why they were all elderly, and it would have been a mystery until this day, had not my eyes rested upon one young, fair, and jocund—then was it a mystery no longer, for I had to say, "Hadji, thou art advanced in years, yet thou art looking upon the damsel rather than upon her commodities."

Before these decorous butter-vendors, exposed to the open air, is the spacious, well-supplied Fruit and Vegetable Market. There were all the usual vegetables, and about which I saw no peculiarity except that the Broad Beans were shelled and sold by the pint. Among the fruit were good Peaches, 3d. each; Moorpark Apricots, the finest I ever saw, 2½d. a-piece; Apples, Pears, and Plums very various and abundant; purple and white Figs; and Cob nuts, from France, 3d. per quart. There were also a few Raspberries, and still fewer Mulberries. Strawberries, of course, were not there; but I must mention that I am informed that the old Pine variety of this fruit, rarely met with now in England, is the most prolific here, and, consequently, is that chiefly cultivated for sale. When in season the market-supply of it is most abundant, and often sells for no more than 1½d. per pound. The Cabbages exposed for sale are all of the Drumhead kind, and only the extreme heart of them is cooked for table use. I conclude that the reason for preferring this variety is, that it is that which is most useful as food for the cows, with an eye to which all the cottage gardening is conducted. Every spare space where cultivation can be carried on is occupied either with these Cabbages, or Mangold Wurtzel, or Parsnips. A red variety of Onion is universally cultivated, and, I think, it is James' Keeping Onion; except a stray instance among these now and then, I have not seen a white Onion in the island.—*QUIT.*

(To be continued.)

## BREAKING UP A PASTURE FIELD FOR MARKET-GARDENING PURPOSES.

I HAVE upwards of five acres of grass land which I intend converting into a market garden. The soil is peaty; in some parts peaty to the thickness of 2 feet or 3 feet, resting on a fine yellow clay. It is at present imperfectly drained. How would you advise it to be drained well? and how would you dispose of the sods—bury them, or pile them up in heaps to rot? And also, would you advise a good application of gas lime on breaking it up?—*FEAT.*

[First of all drain it well; then break it up as early in the autumn as you like, and about 2 feet deep, burying the turf about midway, or just so near the top as to insure it not growing through; rough dig it once or twice during slight frosty weather in winter or when it is dry; and in spring plant a good breadth of it with Potatoes, for such a soil as you describe is just the one we have seen Potatoes do best in. The wants of the neighbourhood will determine what other crops are advisable; and if you contemplate doing anything in the hot-bed or Grape-house way, save several loads of turf which will be wanted there. Perhaps that taken off the part intended for walks might be set aside for such uses; but unless the turf be full of couch grass or other noxious weeds bad to kill, it had better be trenched into the ground at once. If you determine on planting any autumn crop as Cabbage or the like, immediately after trenching a good dressing with gas water may be useful in killing wireworm and other enemies; but it ought to be given some days before planting and the ground dug again. If, however, it lies in fallow through the winter, and receives one or two diggings during that time, it is likely these pests will in a great measure be destroyed; and we are no advocates for gas water in cases where it can be done without, as it does not impart any useful ingredient to the composition of the soil.]

## READING HORTICULTURAL SHOW.

THOSE accustomed to the great metropolitan exhibitions of flowers and fruit, but who are ignorant of what many of our provincial horticultural societies can effect in this way, are apt to under-estimate the importance of country shows, and to imagine they are not worth attending. This is a great mistake; for in some of the principal towns horticultural exhibitions are held, which, though not of course equal in extent to those at South Kensington or the Crystal Palace, nor offering such inducements to exhibitors from a distance, are yet of no small magnitude, are well arranged, well attended, and thoroughly enjoyable. Of such the shows of the Reading Horticultural Society are amongst the best and most attractive, from the extent of the display and the place where they are held—among the ruins of the old abbey, in the midst of a well-kept public garden, which, except on such occasions, is freely open to the townsfolk.

Another advantage which the ancient and historical borough of Reading possesses, is that of its being readily accessible from all parts of the kingdom by means of three principal lines of railway.

The second and last Show for the season took place on Thursday last; and about £115 being offered in prizes for plants, cut flowers, fruit, and vegetables, an extensive and creditable exhibition was the result.

The various productions exhibited were ranged in a large tent, hollowed out on a similar plan to that formerly adopted at South Kensington, with turf stages down the middle and at one end for cut flowers, with others more elevated at the sides for plants: thus a very good view could be obtained of nearly every part of the tent.

In class A, 8 Stove and Greenhouse Plants, the first prize was awarded to Mr. Ingram, gardener to J. J. Blandy, Esq., High-grove, Reading, who had a large and well-trained *Stephanotis floribunda*, a fine specimen of *Rondeletia speciosa*, *Vallota purpurea* in fine bloom, and nice plants of *Vinca rosea* and *alba*, *Tetratea verticillata*, *Leschenaultia formosa* *superba*, and *Statice brassiceifolia*. Mr. Good, gardener to E. Majoribanks, Esq., Henley, had a good plant of *Rondeletia speciosa* *major*, though rather past its best in point of flower; nice plants of *Vinca alba* and *rosea*; *Tetratea verticillata*; *Heterocentrum roseum*; *Crowea stricta*; a fine *Ixora coccinea*; and *Clerodendron fallax* in excellent condition. To this collection the second prize was awarded; the third going to Mr. Miller, gardener to

Miss Hobson, Shinfield, whose collection contained *Statice brassicifolia*, *Begonia prestoniensis*, a fine plant of *Gesnera zebрина splendens*, *Stephanotis floribunda* (good, but not equal to Mr. Ingram's either in size or beauty), and *Leschenaultia formosa*.

In class B, 10 Variegated or Foliage Plants, the exhibitors were Mr. Ingram; Mr. Robinson, gardener to R. Benyon, Esq., M.P., Englefield; and Mr. Moles, gardener to W. Banbury, Esq., Reading, who respectively gained the first, second, and third prizes.

Mr. Ingram had a nice little *Alocasia metallica*, a large and beautifully grown specimen of *Coleus Verschaffelti*, a fine *Croton variegatum*, a tall *Dracena ferrea*, *Cissus discolor* (large and so perfectly clothed with leaves as not to show any stems), *Philodendron pertusum*, *Sansevieria javanica*, and two *Caladiums*.

Mr. Robinson's collection contained a small *Cyanophyllum magnificum*, tall plants of *Dracena draco* and *ferrea*, *Maranta zebрина*, *Alophila anstralis*. And Mr. Moles had two handsome specimens of *Coleus Verschaffelti* and *Blumei*, 4 feet across; a small *Croton*, two *Dracenas*, two *Begonias*, and three *Caladiums*.

In class C, 10 Ferns, the first prize was awarded to Mr. Robinson for his exhibition, which contained a fine *Dicksonia antarctica*, a handsome *Pteris tremula*, as well as well-grown plants of *Pteris argentes*, *Gymnogramma chrysophylla*, and *Cibotium Barometz*. Mr. Ingram obtained the second prize for a well-grown collection, which included some excellent specimens of *Asplenium* and *Pteris*, *Gymnogramma argyrophylla* and *Platyterium alciorne*. Mr. Moles was third, and an extra prize was given to Mr. Fabray, gardener to W. S. Darter, Esq.; the only other exhibitors being Messrs. Ivery, of Dorking, who had a large collection of hardy British Ferns, some of which were exhibited in this, and the remainder in the Miscellaneous class.

The succeeding class, D, was for 6 Lycopods, and as in the case of the Ferns, the whole of the exhibitions were good samples of cultivation. The competitors were Mr. Ingram, first; Mr. Robinson, second; and Mr. Good, third.

In class E, 6 Achimenes, the first award was taken by Mr. Ingram, who had a fine pan of *Sir Treherne Thomas*, and *Lengiflora major*. Mr. Lanaway, gardener to R. Henborough, Esq., was second, who had *Ambroise Verschaffelt*, *Dr. Buenzood*, and *Sir Treherne Thomas*, in good flower; and Mr. Miller came in third, having among his six good examples of *Sir Treherne Thomas*, *Lengiflora major*, and *Carl Woolfurth*.

Of *Fuchsias*, in sixes, class F, the first prize was given for a beautiful set, among which were *Venus de Medici*, *Sir C. Campbell*, *Little Bo-Peep*, *England's Glory*, *British Sailor*, exhibited by Mr. Baskett, gardener to Miss Sheepshanks. These plants, being tall and covered with flowers, were placed in an elevated position near the principal entrance to the tent, where they had a very pretty effect, being covered with their beautiful pendulous flowers. Mr. Foster, gardener to J. Lodge, Esq., Reading, who was second, had good plants of *Fair Oriana* and *Wiltshire Lass*; and Mr. Castle, gardener to Miss Sowden, third.

In class G, for Balsams, there was no competition; and in class H, 8 Cockscombs, Mr. Bailey, gardener to T. T. Drake, Esq., Shardeloes, Amersham, gained the first prize with some well-grown specimens; those of Mr. Hawes, gardener to J. W. Rhodes, Esq., Henley, who was second, not having such regular heads.

The next class, I, was for 8 branching Cockscombs, and here Mr. Good was successful in obtaining the first award with plants which were generally well flowered; and Mr. Prior, gardener to G. May, Esq., Reading, was second; an extra prize being given to R. Webb, Esq.

In class J, 6 *Lilium lancifolium*, Mr. Ingram, exhibited album and rubrum grandiflorum, three of each, all of them being large, handsomely grown, and beautifully in flower. To this exhibition the first prize was awarded; the second was given to Mr. Baskett for nice plants of the same kinds well flowered, but of much less size.

In classes K and L, 6 Bedding and 6 Variegated Geraniums, Mr. Baskett was first, and Mr. Miller second; and in the Miscellaneous class prizes were awarded to Mr. Good for three *Vallota* and one *Eucharis amazonica*, all of them creditable specimens; to Mr. Ingram for a mixed collection of flowering and fine-foliage plants, for *Anectochilis*, and for *Desfontainia spinosa*; to Mr. Robinson for *Caladiums*, miscellaneous plants, aquariums, and some neatly-prepared skeleton leaves; and to

Mesara. Ivery for hardy British Ferns. Awards were also made to Messrs. Webb, Miller, and Bragg.

The exhibition of Cut Flowers was very good, but we should have liked to have seen more Roses.

In class N, 24 Dahlias, Mr. Turner had a magnificent stand which distanced all competitors in the size, colour, and regularity of the blooms, which were perfect models. The sorts were Mrs. Bush, Lord Palmerston, Lady D. Pennant, Mr. Stocken, Delicata, Privateer, Goldfinder (a splendid bloom), George Brown, Cygnat (lovely), Criterion, Lord Cardigan, Umpire, Beauty of Hilper-ton, Golden Drop, Captain Harvey, Hugh Miller, Bob Ridley, Mrs. W. Piggott, Earl of Shaftesbury, Lady Popham, Madge Wilkfire, Juno, Lord Derby, and Lady Elecho. To this exhibition the first prize was, of course, awarded. The second was taken by Mr. Terry, Castle Bromwich, who had also some very good blooms in his stand; and Mr. Bragg was third.

In the Amateurs' class, O, 12 varieties, there were several very good stands, Mr. Perry coming off first, Mr. Hopkins, of Brentford, second; and Mr. Fruin, Foot Baldon, third.

The Fancies, class P, were likewise very good, Mr. Turner and Mr. Perry being again first and second. The exhibition of the former contained some remarkably fine blooms of *Lady Paxton*, *Queen Mab*, *Gem*, *Pauline*, and *Miss Jones*. In the succeeding class, Q, exclusively for Amateurs, Mr. Perry and Mr. Fruin were first and second respectively. Seedlings, for which there were no prizes offered, were shown by Mr. Turner and Mr. Perry; those of the former were *Caractacus*, *Dundreary*, and *Countess of Shelburne*, which have already been stamped with the approbation of the Floral Committee.

Of Hollyhocks there were several fine stands, that of Mr. Turner taking the first prize; and in *Roses*, 24 varieties, three trusses each, he was the only exhibitor, but well merited the highest award. *Miss Crawshay*, of Caversham Park, had a very good stand of twelve in the Amateur's class, gaining the first prize; and a similar award was made to C. Worthington, Esq., for single blooms.

Asters, both French and German, were in most instances very fine, though the setting-up in a few cases was susceptible of improvement. Mr. Betteidge received the first prize for both kinds; Mr. Millett being second in French; Mr. Beasley holding the same position for the German quilled varieties; Mr. Baskett and Mr. Bailey obtained third prizes, and several extra ones were given besides.

In *Verbenas*, 18 varieties, fine trusses were exhibited by Mr. Perry and Mr. Turner, between whom the competition was very close, who respectively obtained the first and second prizes; the stand of the former was very tastefully arranged with regard to colour.

Mr. Bailey was first in the class for 12 varieties, with a fine stand; Mr. Baskett and Mr. Jacob being second and third. There were several other exhibitions, which were also of great merit.

Of Miscellaneous Cut Flowers there was an excellent display, which contributed much to setting off the end of the tent which they occupied. Mr. Millett and Mr. Moles were first; Mr. Baskett and Mr. Mearing receiving second prizes.

Of Fruit there was an excellent display, quite as good as we have seen at a London exhibition. Grapes, especially of the *Black Hamburg* kind, were fine, the bunches regular, the berries generally large and well coloured, and the bloom not rubbed. *Muscats*, of which several large bunches were shown, were not sufficiently ripe.

Pines were not so numerous as could be desired, but were generally well grown and of fair size; and here we would suggest that in future the names as well as the weights should be attached to each.

Excellent collections of eight dishes, from Mr. Turner, Mr. Good, and Mr. Robinson, received first, second, and third prizes.

In *Quecu Pines*, Mr. Johnson, gardener to the Duke of Wellington, was first. A *Ripley Queen*, from Mr. Robinson, came next. Mr. Bailey was third with a good *Moscow Queen*; and in the class for "any variety," he obtained the highest award for a *Queen*, apparently about 4 lbs. weight. Mr. Robinson was second with a *Smooth-leaved Cayenne*; and Mr. Johnson third.

The best *Black Hamburg Crisps* were from Mr. Ingram; and Mr. Dwerrhouse, gardener to Lord Eversley, who was second, had also large and well-coloured bunches, and the competition among the other exhibitors being close, several extra prizes were awarded.

Muscats large but not sufficiently ripe were sent by Mr. Ingram, Mr. Webb, Mr. Johnson, and Mr. Turner, those of the latter being very fine as regards size, and prizes were awarded in the order in which the names stand.

White Muscadines, from Mr. Turner, were the best in the next class for any other White Grapes; Mr. Cording coming in next with Sweetwater, and Mr. Good third with good bunches of the Royal Muscadine.

Large and well-ripened Royal George Peaches were exhibited by Mr. Johnson and Mr. Good, who were first and second; and in Nectarines and Apricots the best came from Mr. Turner and Mr. Johnson, both of whom received equal first prizes for fine fruit of the Moorpark variety.

In Melons Mr. Good was first, Mr. Bousie second; and in Plums, three dishes, Mr. Bailey received the first prize for fine fruit of the Washington, Prince of Wales, and Denyer's Victoria.

Among the Miscellaneous Fruit, we noticed a beautiful dish of Red Astrachan Apples from R. Webb, Esq., and some of the finest Oranges we have ever seen grown in this country from Mr. Robinson, who had also some excellent Lemons. Nor must we omit to mention eight Apple trees, in 13-inch pots, from Mr. Webb, which were loaded with large fruit. They were grown out of doors without protection, being merely plunged in the ground.

Of Vegetables there was likewise a very creditable exhibition, both in the Gardeners' and Cottagers' classes, and numerous awards were made; but we cannot afford space to particularise them. The Cucumbers were fine, especially those which gained the first and second prizes, and so were the Carrots and Potatoes.

The arrangements were excellent, and even if we had the disposition to do so we could find no fault, everything was arranged pleasantly, and good humour was the order of the day. During the afternoon the subscribers to the Society and numerous visitors examined the Exhibition, which, but for a counter-attraction in the band of the gallant 16th Lancers from Aldershot, would have been even too crowded.

We may mention that the ride to Reading by the South-Western railway is just now very interesting, the line being bordered by waving fields of corn ready for the sickle, whilst the banks are in many places purpled with Heath, now in full bloom.

### WINDOW-GARDENING IN IRELAND.

In the introduction to "A Few Days in Ireland," Mr. Fish noticed a fine box of Geraniums in a certain street in Dublin, which seemed to stand alone in its loveliness. He has had a hint that it has been equally fine this year. He and the helpers in THE JOURNAL OF HORTICULTURE would be glad to hear of window plants being more prevalent in Dublin, and would be greatly obliged to "A CONSTANT READER" to forward that object, and we take also this opportunity to state that all inquiries bearing on this subject will meet with the most prompt attention; and if these inquiries are beyond our depth, we will at once confess our incompetence to answer them, so that information may be got from a different quarter. "A CONSTANT READER" may also rest assured, that neither he nor his fellow townsmen would for a moment be considered deficient in brains. On the contrary, much kindness received would prompt to the attempt to show all kindness and courtesy in return.

Now, to the purport of this last note. Until lately we have had a cold, drizzly season here, and we fear it has been much the same in Dublin, and that would influence the foliage of some of the tenderer variegated Geraniums, as we find that ours in beds needed more picking than usual. The leaves sent were much withered. The variegated Scarlet Geranium we presume to be Lady Plymouth, which likes plenty of sun and not too much water. The variegated Geranium we think to be one of the Peltatum kind, as Pink Cup, and to have that nice requires not only plenty of sun but plenty of moisture. Hitherto we have had plenty of the latter, but until lately not enough of the former, and the flowers have been more scanty than usual; but now they are coming better. The Calceolaria-heads had much the appearance which the Prince of Orange Yellow presents in May and June, when there has been a little frost. At this season it hardly ever appears in any Calceolaria, unless there is a deficiency of moisture and support.

To produce the best effect individually, then, would be to follow the hint given the other week, and grow such plants in separate boxes; or else take such care in the watering, that whilst you

drench Calceolarias well, you give but little to the Geraniums in general, except the Pink Cup referred to. As the Tropæolum elegans is healthy, arrest growth by taking off more than half of its foliage. This will give room to and encourage the flower-buds. Do not be afraid of disleafing considerably; the succulent stems when grown as yours, will be a sufficient store-house of nourishment. Wreaths of Nasturtiums, unless grown on the most hungry soil, will do no great things without this disleafing. Go over them again whenever the foliage becomes too dense. If your Scarlet Geraniums are very strong, and the flowers not thick enough, remove not only any faded leaves, but some of the strongest and largest of the green ones, to throw more strength into the flower-truss, and at this season you may with advantage pick out the terminal bud on each shoot with the point of a penknife. This arrests mere extension, and throws more strength into the flower-stems. The thinning-out of the leaves also puts the stems in a better position for standing the winter. Of course, though not stated the other week, all young Scarlet Geraniums raised from cuttings this autumn must be kept growing, and have light inside of a window all the winter; and hence require much more care than old ones, such as those in the boxes now. These boxes will want much less water than Calceolarias; but if they show signs of want of vigour, a little weak manure water, or a moderately rich top-dressing will set them all right. Small variegated Geraniums will, in general, need more moisture and heat to do well. The Calceolarias should have the decayed points removed, and plenty of moisture and a little top-dressing will cause the blooms to open freely. For Senecios the season has been too moist. A very poor hungry soil would have suited best, and then in very dry weather a mulching could have been given. In such a season as this has been here, the Tropæolums, Senecios, and the larger Scarlet Geraniums, would have bloomed better if plunged in their pots. There is even then no necessity for the pots being the same in size. We are glad that Fuchsias and Ivy-leaved Geraniums do so well. We shall always be glad to hear of successes as well as failures.

### ORCHARD-HOUSE TREES AT BURTON-ON-TRENT.

THE visitors to the Burton-on-Trent Flower Show, August the 27th, appeared highly pleased with the display of flowers, fruit, and vegetables, which was very good indeed; but the Peach trees in pots, sent by A. Bass, Esq., attracted marked attention. These would have been highly creditable to any gardener, but as the result of a lady's skill were quite remarkable. The house in which they were grown is 60 feet by 20 feet, a double-roofed one, handsomely painted in the way of the Crystal Palace, and nicely paved. Mrs. Bass, with the exception of such work as could be done by any labourer, has entirely managed them herself, and has reason to be proud of her success. The first season she had a good crop: this year almost every tree was full. Though so late in the season that most of the fruit was gathered, and such as remained would hardly bear touching, yet some fine specimens were exhibited. When staged three plants had thirty or more fruit each, besides those which had fallen, and the others had quite as much fruit as they were calculated to bear. It was amusing to see the faces of one or two persons who have always contended that Peaches could not be fruited in pots. So much interest was excited by this Exhibition that it was proposed by some members of the Committee to have the Show a little earlier next season, and make fruit trees in pots one of its principal features. If this is carried out, some of the gardeners in the neighbourhood stand a fair chance of again being beaten by a lady. I hope it may be so—it will have a very stirring effect. Why does not the Royal Horticultural Society of London offer a good prize for orchard-house trees? The result would be novel and attractive.—J. R. PEARSON, *Chillwell, Notts.*

### MARTYNIA FRAGRANS.

HAVE any of your readers ever noticed the intoxicating or soporific effect which the leaves of this plant have on flies and caterpillars? I find quantities of flies dead or "drugged" on them; and a day or two ago I remarked that some large green caterpillars, which had dropped on them from a plant above, were "lousised" most completely. Would the plant be of any value to duggists?—W. X. W.

## EPIDENDRUM REPLICATUM.

THE accompanying is a full-sized representation of one of the branches of the flowering panicle of this pretty Epidendrum.

The pseudo-bulbs are crowned by the ensiform, or narrowly-clongate lance-shaped leaves, from between which proceeds the flower-scape, 4 feet long, the upper half forming a large branched panicle. The flowers though not gaudy, are very pretty, and being numerous, they render this species ornamental. The sepals are cuneate-spatulate, with a mucro dull yellowish-brown; the petals are spatulate, narrowed below, mucronate above, of the same ground-colour as the sepals, and marked with a large chocolate-coloured blotch at the broad apex. The lip is white, veined with purple, three-lobed, the two lateral lobes large, oblong-ovate, appressed to the column at the base, spreading above; the middle lobe is cordate-acuminate, folded together backwards, and having a waved margin.

It is a stove epiphyte, and requires the same kind of treatment as other tropical orchidaceous plants.

A FEW WORDS ON ROSES  
IN 1862.

Now that all the bustle and din of the contest is over, the arena been swept, and fresh sawdust been put down, we may sit quietly down and consider what has been the result—who have most deserved the palm—whether Fortune has favoured the brave or been blind to her devotees. Doubtless we shall find, as in every contest, some cherished names have failed to fulfil their promise; reputations that seemed to stand on a sure basis have been scattered to the winds, and names hardly ever heard of before have assumed a prominent position. We may criticise both the combatants and the field of battle—may find fault as the lookers-on at a game of chess so well can do with moves in which they had nothing to do; and, undazzled by the glare and glitter, may be able to give an impartial opinion on matters connected with the fight.

Three great exhibitions have been held during the year—at Kensington, the Crystal Palace, and Birmingham; the date of the former one, June 26th, being somewhat too early, especially as the weather preceding it had been very sunless. The Birmingham one was, as far as my judgment went, the best; although, fine as the Town Hall is, it is not so suitable for this purpose as for some others. The tents at Kensington were excellent; but for ease, comfort, and general advantages the Crystal Palace must bear the palm. With the difficult task that judges have to perform, it was satisfactory to find that only at Kensington was there any fault found, and that only in one section; while the difficulty that was felt in getting a view of the flowers only shows how unceasing is the popularity of this favourite flower—a popularity which I imagine will be progressive.

The general character of the flowers exhibited was excellent; but I must take exception to what seems to be a too prevalent thing—viz., to cultivate so highly that colour is entirely sacrificed to size. There were flowers as large and as coarse as *Pæonies*, and others as flat as a breakfast-saucer, and quite as dull as they could well be. That this is an evil I feel every lover of the flower will agree in, although they will tell you that they are compelled to grow them to that size because others do; just on

the same principle that people will not close their shops early because others keep them open. Unquestionably if you could get flowers as large as Anna de Diesbach, of the shape and refinement of Comtesse Cécile de Chabillant, or with the brilliancy of Général Jacqueminot, they would be a sight worth looking at, but as it is coarse and large it ought to take a low place. Thus, I would say, if twelve blooms of Comtesse Cécile de Chabillant, and twelve of Anna de Diesbach were put up for competition,

even though the former might be somewhat inferior in quality to its ordinary character, I should give it the prize; for in all florists' flowers I hold that shape is first, colour next, and size last, and I believe if such a principle came to be acknowledged generally, it would tend greatly to the advantage of Rose-fanciers.

It is somewhat curious to see how the fortune of war changes, the ever-shifting hue of victory resting now on one and then on another. Hertfordshire, which seemed to be the home of the Rose, has been dead beaten this year by Essex; for the two most successful exhibitors in nurserymen's and amateurs' classes have been Mr. Cant, of Colchester, and Mr. Hedge, of Reed Hall, close to the same town. The universal admiration that the stands exhibited by these gentlemen elicited, shows how completely they have attained the foremost places as growers; not only, however, were their flowers well grown, but great taste was exhibited in the manner in which they were set up. The contrasts in colour were excellent, and neatness pervaded all their stands. This, let me say to exhibitors, is not a trifle. The best box may be marred by a want of it, and I have seen myself stands passed by which half an hour's skilful handling of wood have made presentable, and, perhaps, achieved honours; for great advances have been made in this, as also in the method of naming the flowers. The stand of ninety-six, exhibited by Mr. Mitchell at Kensington, was the best-named collection, I think, that I saw the whole year.

But that which has signalled the season of 1862 above all its predecessors, is the introduction of seedling Roses of English growth, heralding a new era in their history. It may be we shall be independent by-and-by of foreign growers, who, although they have given us a vast number of beautiful Roses, in fact well nigh all we possess, yet do manage to freight it with such an intolerable quantity of rubbish, that growers are out of heart at the apparently hopeless task before them; while the probability is, that Roses raised at Ipswich or Cheshunt will be better able to stand the variations of our climate than those produced at Angers or Lyons. In the earlier part of the season Mr. William Paul exhibited some very taking blooms of his seedling Beauty of Waltham, which fully justified the award given to it by the Floral Committee of a first-class certificate; while at the Rose Show on June 26th, "John Hopper," raised by Mr. Ward, of Ipswich, fairly took the "fancy" by storm. It was so grand, so rich, so vigorous, that there could be no doubt of its value. There was another, exhibited by Mr. George Paul, of the Old Nurseries, Cheshunt, which we think will prove a good addition to our catalogues, "Lord Clyde," but which was not brought forward with that *empressement* which it deserved; had it been better set up it would have claimed more attention. At Birmingham it excited a good deal of attention, and thus we have three good English Roses in one year. Those who have been thus successful will hardly be contented with these honours, but will look for still further ones, and we doubt not but that they will succeed. Out of the large number of foreign Roses there are a few which will, I think, be considered worthy of cultivation for some years. I do not think that one can go wrong in ordering the following:—François Lacharme, Olivier Delhomme, Marechal Vaillant, La Brillante, Souvenir de Comte Cavour (Margottin's), Alexandre Dumas, Duc de Rohan, Maurice Bernhardt, Madam Charles Wood, and Mademoiselle Julie Daran—all these are H.P.'s. Gloire de Bordeaux and Comtesse Ouravoff, are good Teas—at least, the latter is, and the former has been shown well. It seems a shy bloomer as yet, but this it may probably get out of. One may be, of course, mistaken in one's opinion of new Roses, but I do not think there are many in the above number which will be found indifferent.

And now may I ask a favour? I have endeavoured in my blundering way to give what little information I could on this subject, and I should be very much obliged if any one will tell me *how to grow Roses*. Yes, I mean it, here at least. My plants look well in the spring and bloom fairly, but in the summer black blotches (of mildew I suppose), appear on the leaves, and towards September many of my plants are left without a leaf. My situation is very open and sunny. My soil a rich, open, friable garden loam, which will grow almost anything; but I am baffled by this black enemy. I tried sulphur; it may do good, but prevention is better than cure. Would the addition of clay to the soil be of any use? or what would do good. I hope some kind Rose-grower will come to my rescue, and let me have the pleasure of seeing my Roses as they ought to be.—D., Deal.

## PRIMULA FARINOSA.

In your Number of the 17th of December last "RUSTIC ROBIN" recommended me to save seed for the purpose of raising varieties. I have just gathered my seed. Does "RUSTIC ROBIN" recommend me to sow it now, or to keep it until next spring? I am disposed to sow it now, because Nature certainly intends it, for the seed is evidently ready to be scattered from the gaping capsules by the first rough wind. I often think that we should be much more successful in raising plants if we took the hints given us by Dame Nature. It must be quite evident from the way in which the seed-capsules of many plants burst as soon as the seeds are ripe, that the seeds ought to be sown as soon as mature—for instance, the Delphiniums, the Digitalis, and the Salvias, as soon as ripe the slightest touch or breath of wind scatters them abroad; whilst others, if we may judge from the retentive character of their capsules, are not intended to be sown so soon, probably not until a drying frost has split or cracked their hard case. Perhaps this may be theoretical; at any rate I throw it down for consideration and discussion.

I may mention that my British *Cypripedium* has some seed-pods on it this season. Whether it will ripen them I know not yet; but when should they be sown? "RUSTIC ROBIN" will find *Achillea millefolium rubra* in a well-known garden at Todmorden; it is, I think, also sold elsewhere under another name.

By-the-by there is a strange peculiarity about the word *Todmorden*—*Tod* means a hill, *mor* also a hill, and *den* a hill, in three distinct languages—Runic, I think, and two others; so that two races have adopted the name given to it by their predecessors, and have added their conviction that it is a hill.—W. X. W.

## WHAT TO LOOK FOR ON THE SEASHORE.

MOLLUSCA—(Continued from page 417.)

### ACEPHALA TUNICATA, OR HEADLESS TUNICATED MOLLUSCS.

THE TUNICATA, as before observed, are Molluscs which have no true shell, but are enveloped in a coriaceous tunic or mantle, whence they derive their name. This mantle takes the form of a sac with two apertures, or in some instances is shaped like a tube, open at either end; within this tunic are the viscera, which consist of well-defined organs of digestion, circulation, and respiration, with a nervous and muscular system. They have no distinct head, nor any organs serving the purpose of hands or feet. Occasionally they are free, occasionally and more frequently fixed; but in every case they are free during a portion of their existence; and they are all inhabitants of the sea.

The Tunicata, of which we possess British specimens, may be divided into two orders—the *Ascidia*, from a Greek word signifying "a bottle," from the creature's resemblance to a leathern bottle; and *Salpa*, from a kind of fish called "Salpe," the outer tunic being elongated, compressed, and open at both extremities.

We will commence with the ASCIDIANS, which have been subdivided into compound, social, and simple *Ascidia*.

COMPOUND ASCIDIANS.—"If"—we quote from the "History of British Mollusca" by Messrs. Forbes and Hanley—"if, when walking on the seashore about low-water mark, we turn over large stones or look under projecting eaves of rock, we are almost sure to see translucent jelly-like masses of various hues of orange, purple, yellow, blue, grey, and green—sometimes nearly uniform in tint, sometimes beautifully variegated, and very frequently pencilled as if with stars of gorgeous device—now encrusting the surface of the rock, now depending from it in icicle-like projections. These are compound *Ascidians*."

They are otherwise known as *Botryllidae*, so called from a Greek word (*Botrys*), which signifies "a cluster of grapes," to the likeness of which a mass of these creatures very nearly approaches. It would well repay the curious observer to secure a bunch of these strange Molluscs, and after placing it in a vessel of sea-water to subject it to a minute and careful examination. In this examination, however, the naked eye will not be sufficient to assist him, he must call in the aid of a rather powerful microscope, when he will plainly perceive that that which appeared to be simply a mass of coloured jelly is in reality a cluster of many individual animals, each one possessing an independent and remarkable organisation; and torpid, motionless, lifeless as they appear to the naked eye, he will remark an energetic system of vitality carried on chiefly by the absorption and expulsion of the surrounding water, which double action, if

the creatures be disturbed, is increased to a considerable degree of violence. This arrangement is contrived so as not only to answer the purposes of respiration, but that it may serve also as the means of propelling into the stomach of the Ascidian such minute particles of food as the necessities of the creatures may require. The internal structure of these little Molluscs is as perfect as it is curious; but the scope of our work does not permit us to examine it in detail, it is sufficient to say that it is surpassed by but very few of the inferior forms of animal life.

**APLIDIUM FICUS** (*The Sea Fig*).—This Ascidian has received its somewhat singular appellation from the resemblance it bears to a fig when cut open. The name was, doubtless, originally given to it by the fishermen to whom it was a common object, and who ordinarily give a sufficiently expressive title to such creatures as come under their notice, being directed in their nomenclature by the likeness which they perceive in the animal named to some object familiar to their everyday experience.

The *Sea Fig* is of a fleshy substance and of a dusky olive colour when divided and examined, which must be done with the co-operation of a microscope. It is found to contain a large quantity of little yellowish bags or eggs, somewhat resembling in mass the interior of a fig. These bags are filled with a thick transparent liquid which emits a very offensive odour.

**SEPTOCLINUM MACULOSUM**.—This Ascidian is common to most parts of our coast, and occurs plentifully at the roots of *Laminaria*, in Belfast Bay, and the north of Ireland generally. It may be easily recognised by its thin, hard, leathery crust, which is variegated with white and blue. The substance of which the crust consists is composed of needle-like crystals.

**BOTRYLLES**.—This compound Ascidian is very common on stones and seaweeds near low-water mark all round the British islands. It is thus described by Messrs. Forbes and Hanley:—"Mass, a thick, gelatinous, semi-transparent, glaucous crust, with yellow marginal tubes. Systems numerous, composed of from ten to twenty or more individuals. Yellowish and reddish. Branchial aperture white, surrounded by a circle of broad ferruginous spots, a red spot on the centre of each individual. Mass often measuring several inches across; individuals one-twentieth of an inch in diameter."

There is also the *Botryllus violaceus*, the tunic of which is of deep blue; and the *Botryllus smaragdus*, where it is a deep green; both these are common on the coast of Cornwall. There is a third, again, very common at Falmouth, which has an intensely red integument.

**SOCIAL ASCIDIANS**.—These are intermediate forms between the compound and simple Ascidians. The Social Ascidians are individuals and groups connected by creeping root-like prolongations. The Ascidians arising from these have long, erect, and more or less stalk-supported bodies. The branchial and anal orifices are destitute of rays. The exterior tunic is smooth and transparent, and the thorax generally marked with coloured lines.

**CLAVELINA LEPADIFORMIS**.—This creature is abundant in many places, on rocks and stones at low water. It is most common, however, on the west coast of Scotland. Mr. Alder says, "It is very generally diffused. I have met with it on the Devonshire, Cornish, and Northumberland coasts, and in Lamah, Rothesay, and Oban bays, in Scotland." It is thus described by Messrs. Forbes & Hanley. The thorax forms one-third part of the length of the adult individual, and is marked with yellow lines. The stomach is of a bright orange, placed near the middle of the abdominal portion of the animal, part of the intestine being of the same colour. Its usual length is from one-half to three-fourths of an inch.—W.

(To be continued.)

## EXTRACTS FROM A TOO-MUCH NEGLECTED BOOK.

**A VETERAN IN THE WILD WOODS**.—October 10.—Mild. Showery morning, bright afternoon. Pleasant walk on the lake road. The Pines are clear green again, having cast their rusty leaves. A few cones also are dropping, but many hang on the trees through the winter.

A few years since, those who followed this road, along the lake shore, frequently met an old man coming and going in this direction, whose venerable appearance would probably have attracted a stranger's attention. His head was white with the honours of fourscore and upwards, yet his tall, slender figure was

erect and active, showing few marks of age; and his face was remarkable for a kindly, benevolent expression, a bright, healthy eye, and ruddy complexion.

This old man led a singular life, partaking of the retirement and simplicity of that of a hermit with the active benevolence of a different class of men. With children living in the village, and calling the house of a daughter his home, he loved the quiet solitude of the fields; and, unwilling to be idle so long as he had strength to work, the good old man applied to the owner of the land in this direction for a spot to till; his request was complied with, and he chose a little patch within a short walk of the village. Early in the morning, before sunrise, he would go out into the woods, frequently remaining out the whole day, only bending his steps homeward towards evening.

Often he might be seen at work with his spade or his hoe, about the little field which he was the first man to till; he made a fence of the decayed logs lying about, collected the rubbish and brushwood and burned it, then ploughed and planted Maize and Potatoes. Often, when missed from his field, he has been found sitting among the bushes reading his Bible or his hymn-book, or kneeling in prayer. On the hill side, at no great distance from his little clearing, there is a shallow cave, well known in the neighbourhood, and many a summer morning before the village bell has rung for sunrise, the good old man has been kneeling there in earnest prayer for the people of the sleeping town at his feet. Much of his time was passed in prayer, in reading the Holy Scriptures, and singing pious hymns with his pleasant old voice.

He always had a smiling, friendly greeting for his acquaintances, and expressed a very warm interest in the children and grandchildren of those he had known in earlier days; he never met a young person of his acquaintance without some solemn words of good advice, and a blessing given with earnest sincerity. Occasionally he would visit his different friends in the village; and although his object was generally of a charitable or religious nature, yet he loved to talk of past times with those whose memories went back to the first years of the little colony. He had been a miller by trade, and came into the county at an early day, and, of course, knew much of the history of this rural community. But he had also other recollections of a more ambitious nature; for he had begun life as a soldier during the troubles of the Revolution, having belonged to the "Jersey line;" and it was with some latent pride that he would relate how he had, more than once, stood sentinel before the tent of General Washington, and seen "His Excellency" go in and out. His recollection of the battle of Long Island, and the celebrated retreat across the East River, was particularly good; his old cheek would flush, and his mild eye grow brighter, as he told the incidents of that day and night; while the listener must needs smile to see the young soldier thus getting the better of the peaceful old solitary.

His activity was unusual for such advanced years: a great walker, he never used horse or wagon if he could help it; and at the age of eighty-two he walked forty miles in one day, to visit a friend in the next county. He ate only the simplest food, and never drank anything but water, or a bowl of milk now and then; and this temperance, added to regular exercise and light labour in the fields, with a mind at peace, were no doubt the cause of the good health and activity he enjoyed so late in life. This excellent man was a striking example of what the Holy Scriptures alone may do for the honest, simple heart, who endeavours faithfully to carry out the two great commandments—loving our Maker with all the heart, and doing unto others as we would have others do to us.

Full of simple piety and benevolence, temperate, frugal, and industrious, single-minded, and upright in word and deed, his conduct in all these respects was such as to command the respect and veneration of those who knew him. It was like a blessing to meet so good a man in one's daily walks. Such an instance of honourable integrity and simple piety was a strong encouragement to perseverance in duty, among the many examples of a very opposite character—examples of weakness, folly, and sin, which hourly crossed one's path.

Not long since, during the cold weather in winter, the village heard with regret that their venerable old neighbour had fallen on the ice, and broken a leg; from that time he has been compelled to give up his field labours, having become quite infirm. Bowed down with age and debility, his mind often wanders; but on the subject nearest his heart he is still himself. He may be seen occasionally, of a pleasant day, sitting alone in the lane

near his daughter's door, scarcely heeding what passes before him; his eyes closed, his hands clasped, and his lips moving in prayer. If one stops to offer him a respectful greeting, he shakes his head, acknowledging that memory fails him, but he still bestows a blessing with his feeble voice and dim eye—"God bless you, my friend, whoever you be!"

The little patch of ground enclosed by logs, just within the edge of the wood, and the frequent turning-point in our walks, was the good man's clearing. It now lies waste and deserted. A solitary Sweet Briar has sprung up lately by the roadside before the rude fence. This delightful shrub is well known to be a stranger in the forest, never appearing until the soil has been broken by the plough; and it seems to have sprung up just here expressly to mark the good man's tillage. Tall Mullein stalks, Thistles, and weeds, fill the place where the old husbandman gathered his little crop of Maize and Potatoes; every season the traces of tillage become more and more faint in the little field; a portion of the log fence has fallen, and this summer the Fern has gained rapidly upon the Mulleins and Thistles. The silent spirit of the woods seems creeping over the spot again.—(*Miss Cooper's Journal of a Naturalist in the United States.*)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

*Broccoli*, where there has not been sufficient planted, large plants may yet be put out with success; to be laid-in with a spade in a slanting direction. Earth-up the advancing crops. *Cardoons*, earth-up for blanching in favourable weather. *Celery*, the crops that have not yet been earthed to be abundantly supplied with water. *Endive*, continue to blanch, and plant-out from successional sowings. *Lettuce*, another sowing of the various sorts may be made. It is always better to have a superfluity in the spring than a deficiency. *Mushrooms*, beds may now be made either in sheds or in the open air. *Parsley*, thin the summer sowing while in a young state; the plants will have time to gain strength to stand the winter. A portion of the spring sowing to be cut down.

### FLOWER GARDEN.

The propagation of half-hardy plants should still be carried on as directed last month until all be completed. See that there is an abundant supply of everything for next year's operations. Root a good stock of *Maurandias*, *Lophospermums*, Ivy-leaved *Geraniums*, and other climbers that add so much to the beauty of the pleasure grounds; also *Salvias*, *Lobelias*, *Ageratum*s, *Campanulas*, &c. Continue to plant-out *Pinks* as they strike root. Besides keeping every part of this department in the neatest order, the propagation of the stock for supplying next season's demand will engross all the time and attention that can be spared. In all cases the number of plants which it will be necessary to provide should be noted down, allowing a wide margin for losses, &c. The early-struck cuttings to be potted-off, placed in a frame, and shaded, and after they become established to be placed out of doors in an open situation. No delay should now be made in the propagation of the more delicate bedding *Geraniums*; for if they have not sufficient time to well fill their pots with roots before winter, many will be lost. Attention should also be given to the amount of accommodation for them during the winter, which, whether in the shape of frames, pits, or larger structures should be got in readiness for their reception before bad weather sets in.

### FRUIT GARDEN.

Apples and Pears require constant attention now. Gather the various sorts as they ripen, and let the operation be performed with as much gentleness as possible; for wherever an Apple or Pear is bruised, it lays the foundation of premature decay. Peaches and Nectarines to be looked over daily and gathered as they ripen, as a fall, even when nets are suspended to receive them, is fatal to their flavour and appearance if they have to be kept a day.

### STOVE.

Plenty of atmospheric moisture and plenty of air are still the essentials, increasing the air and inuring them to more sunlight as the wood progresses to maturity; shading will, therefore, be dispensed with, except during very bright sunshine in the middle of the day. Continue to pay every attention to such useful plants as *Allamandas*, *Stephanotis*, *Dipladenias*, *Echites*, *Eu-*

*phorbias*, *Luculias*, &c. Shift on a good stock of *Gesnera zebra*; it delights in equal parts of good fibrous loam, heath soil, and leaf mould. If the plants are then placed for a time in a gentle bottom heat, shaded from bright sun, and syringed occasionally, they will make beautiful growth.

### GREENHOUSE AND CONSERVATORY.

Any of the inmates of these structures which have not been placed out of doors would still be much benefited by being out even for a fortnight or three weeks. If drenching rains should occur, any plants likely to suffer damage should be taken in-doors again. Where *Camellias*, Chinese *Azaleas*, and the hybrid Indian *Rhododendrons* were not potted in the spring and require shifting, the present is the most favourable time, as the young wood is now getting somewhat firm and the flower-buds are perceptible. As these plants require a liberal supply of water during their season of growth drain the pots well, and use very turfy peat and sand, adding an equal portion of fibrous loam for the *Camellias*. Pay attention to *Chrysanthemums*; they must not be stopped later than this to have fine heads of bloom. Climbers will always require attention to keep the shoots in their proper places. Take care in training that the parts of the trellis or stakes nearest the bottom do not get bare of flowering shoots, as the beauty of these depends upon being clothed with foliage and flowers from the rim of the pot upwards. Pot-off seedling *Cinerarias*, Chinese *Primroses*, and herbaceous *Calceolarias* into small pots, and keep them close in a frame for a few days, and when established to be exposed to the autumn dews, which are of great service to all young stock in a healthy condition.

W. KEANE.

## DOINGS OF THE LAST WEEK.

MUCH the same as the week previously; in fact, the work of the one resembled the other as much as two peas lying close together in the same peacod. In the kitchen garden, clearing, hoeing, and forking, were the order of the day, and watering fresh-planted vegetables. The week since the 20th has been the most beautiful and sunny of the season, and gave a chance for settling a host of the weeds that the heavy rains had encouraged. Tied-up herbs for drying, early Onions in bunches, &c.

### FRUIT GARDEN.

Proceeded as last week with Strawberries, fruit trees, &c., cutting down the used-up canes of Raspberries, and thinning and shortening the wood of Currants and Gooseberries, from which the fruit had been gathered. Find it necessary to keep what remains under netting and bunting, to keep birds and wasps out. The latter threaten to be troublesome with Peaches, &c., and where no other protection can be given must resort to traps and other devices to entice the marauders. Every damaged or decayed fruit is useful as a decoy, as they seldom go to a fresh fruit when they get a broken or injured one. Will be obliged to gather Morello Cherries from the wall to save them from such devourers. As yet we have been able to discover no nests. This plague is just one of those incentives to activity that keep us gardeners always alive and active.

### ORNAMENTAL GARDENING.

Moved plants, fresh-potted *Cinerarias*, and should have been deep in the mysteries of propagation but for noticing that from the heavy rains we required to go over all the flower-beds again, to remove yellow leaves and fading flowers, and now the trusses of bloom are as good as the plants presented before the drenching rains. It is no trifle to get a large lawn and a great many beds all in good order up to a certain day, and to do this many things must be neglected. The most we have done in the way of preparation is to get some fresh sandy loamy soil from the sides of the highway; and some days before our readers peruse this, we shall have some thousands of cuttings in, going a-head with almost everything, except *Calceolarias*, which we shall leave to the last. That new beginners may go along with us, we will mention what we deem most important to success at this season. First, Fresh sandy soil with little or no manurial matter of any kind; the roughest to be placed at the bottom of the pots or boxes. Secondly, A sprinkling of sand on the surface to prevent the air getting too freely into the soil. Thirdly, Watering the cuttings when inserted, and never allowing them to flag afterwards; keeping close or shading all that will not stand the sun during the day. Fourthly, Preventing damping and mere elongation upwards, by less or more air according to circum-

stances, from the time the sun leaves them on an afternoon until it reaches them next morning. Fifthly, Frequent skills from the syringe just to damp the foliage, if that will prevent the necessity of shading. And, lastly, At present using no bottom heat or artificial heat whatever, for the generality of bedding plants, as though thus they take longer to strike, the plants are more hardy and stubby afterwards from being struck in cold pits or frames alone. It is too late now to strike the generality of Geraniums even out of doors; at any rate they will be none the worse of the protection of glass. The more succulent Scarlets will do well enough out of doors in the first fortnight of September. Ran a small Dutch hoe round the outside of flower-beds to prevent cracking, as there is little more than the outside exposed now.—R. F.

### TRADE CATALOGUES RECEIVED.

Select List of Hyacinths, Gladioli, and other Bulbs for 1862, by *William Paul, Waltham Cross, N.*  
A Catalogue of Bulbous Flower Roots and Tulips, by *C. Turner, Royal Nurseries, Slough.*

### TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

FLOWER GARDEN (*A Constant Subscriber*).—There is no fault to be found with the flower garden if it suits the place and pleases you. One side consists of a group of circle in centre and four oblong beds round it (the space between the circles and beds being as wide as the width of the latter beds, which will give relief), and a long S-shaped bed. The other side consists of two groups each with a circle in the centre and eight clumps round it, four of these being circles, and four rounded four-sided figures. Nothing is told us of the size of these clumps. Two ideas strike us:—first, the size of the paths between the outer row of figures is too small; and if the figures are not large the planting will be too crowded. No simpler combination could be adopted; but with the exception of the S figure there is no attempt at the artistic. We can hardly make out the pencil writing on the tissue paper; but so far as we do so, we can find no fault with the individual clumps if training is well attended to. As far as we can see, the aim is to have every clump distinct in itself, whilst in such groups we would prefer a centre and the beds being balanced in pairs. This is not attempted at all, nor is regard seemingly paid to height and size. For instance: In one group of G the centre bed is edged with Cerastium, the higher bed opposite with Cineraria maritima, and the lower opposite with Centaurea, thus giving in a line three beds with white edgings. Besides this, the bed on one side of the one edged with Cineraria is to be filled with Verbena Mrs. Halford, also white, without any other white bed to balance it. So much for balancing. Many who aim at so much variety get confusion. Then as to size. We find in the centre clump rings of Baron Hagel, followed outside by Mangiesi and Campanula, which will be apt to smother it if not kept well down. We also find variegated Arabis as near the centre, with plants outside that will overtop it unless well kept down. It is important to avoid much of the pegging and clipping if possible. This has been a trying reason in this respect. In "Doings of the Last Week" it would be seen that "R. F." had been disappointed in the growth of some things. In relation to Putteridge Gardens we may state that the last day in which they were open to the public was Wednesday the 27th ult. At other times no admission is given without application to the gardener. On the north side Hitchen is the nearest station, 6½ miles; on the south, Luton, 3½ miles, per Great Northern by Hatfield. By North Western from Leighton to Luton.

WENTWORTH GARDENS (*A Gardener and Subscriber*).—No such place in Surrey as far as we know.

LOBELIA (*H. H. T.*).—White varieties of blue Lobelias have not been rare; but a really good one has not yet been out. The beautiful new one at the Crystal Palace, called Paxtoniana, is as much a white as it is a blue, and the fellow to it, called Gordoniana, is a particularly good white one with a little blue. Both these will be out next spring. A good white one has been sent to us from a gardener in the country, but the smoke round London would not allow us to judge it fairly, so we sent it down to Mr. Beaton, and we are daily in expectation of hearing from him about it. That is all that is on the card just now about white Lobelias. You ought to save yours and not work it too hard for cuttings in the spring, and try it against the rival white. We have seen these at the Crystal Palace and they are really an acquitition.

BOOKS (*O. R. J.*).—The book on training is published, and we think the price is 6s.

CARNATION SEEDS (*Christine*).—"Inoculation" is the grand secret for getting double Carnations. If you got the right thing to "inoculate" with. We should like to be in the secret. As to the "advantage" of sowing the seeds as soon as they are ripe, there is no secret; it is and has been of the utmost advantage ever since the flood, when the span of life was cut down to threescore years and ten. No man now, and much less a woman, can lose a single day in sowing experimental seeds like your inoculated Carnations. Sow them in pots quite thinly, and only just round the sides of the pot, and then they will not lose an hour, for they will not want transplanting or re-potting at all; then in April turn out the ball on the bench and make a slit in it on the top side the whole length of it; next take one side of the cut in each hand, and open the ball out into a flat network of roots, and put it on a board, and take the board to an open trench, and the transplanting is done without ever touching a leaf from first to last. This is our secret for gaining on old time.

POLYANTHUSES (*Annetta*).—The luxuriance of "ANNETTA" seedling Polyanthuses is a sure sign of her own luxuriance in garden experience; some cannot keep a leaf alive on their seedling Polyanthuses in June, July, and August. But to keep them as "ANNETTA" keeps them is just the way to give them the disposition she aims at—a disposition to bloom, which they have not shown yet. But every one of them will bloom next April if they are done exactly as they have been hitherto, and then what a quantity of new flowers and strange faces you will have.

PROPAGATING RHOPALAS (*Medicus*).—The best answer is this. When a party has to ask how such difficult things are to be effected, to tell him or her in plain words that he will not succeed in the first six trials; but if "MEDICUS" can get cuttings of M. de Jonghe's Rhopala, and of the one named after the great mountain Corcovado, on the north-west of the town of Rio Janeiro, he will very probably succeed in the seventh trial—seven being a lucky number. First, he must visit some one of the great London nurseries, and see the propagating department, for that kind of knowledge cannot be taught by books; secondly, imitate the ways of such London firms to the very letter, then almost any half-ripe joint of these Rhopalas will root at the seventh hit as sure as a Rose-cutting of Manetti.

BEE PLANT (*A. H.*).—Your plant is Centaurea nigra. Bees gather both honey and pollen from it.

GRAPES CRACKING (*A. K.*).—It is a peculiarity of the variety, unless the Vines are grown in a shallow border, and kept moderately dry at root when the fruit is ripening.

FERNS (*Patelin*).—The Ferns might live, but it is not a good place for them. Try the commonest and freest-growing sorts you can get—such as Nephrodium molle, Pteris serrulata, &c. Why not put in a layer of soil and plant it over with Lycopodium denticulatum, which would grow and look green and neat?

NAMES OF PLANTS (*Patelin*).—1, Polystichum angulare; 2, Athyrium filix-femina; 3, Lastrea filix-mas; 4, Blechnum spicant; 5, Adiantum setosum. (*B. B. T.*).—Stachys lanata. The sport of variegated Alyssum is not uncommon, and it will not maintain that colour. (*C. T.*).—1, Polygonum amphibium; 2, Ceanothus fistulosa; 3, Pteris aquilina; 4, Artemisia vulgaris. (*J. D.*).—1, Bartsia odontitis; 2, Origanum vulgare; 3, Aster trifolium; 4, Tanacetum vulgare. (*F. H. A.*).—1, Tropaeolum speciosum; 2, Tropaeolum pentaphyllum. They are increased by cuttings, or occasionally by seeds.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### POULTRY SHOWS.

SEPTEMBER 2nd. POCKLINGTON, Yorkshire. *Sec.*, Mr. T. Grant. Entries close August 26th.  
SEPTEMBER 3th. WAKEFIELD and WEST RIDING. *Sec.*, Mr. J. Crosland, jun., Entries close August 23rd.  
SEPTEMBER 9th. WORSLEY and ARMLEY (near Leeds). *Sec.*, Mr. Robert Hoyle, Armley, near Leeds.  
SEPTEMBER 10th and 11th. MANCHESTER and LIVERPOOL. *Sec.*, Mr. T. B. Ryder, Church Street, Liverpool. Entries close August 11th.  
SEPTEMBER 25th. STAFFORDSHIRE. *Sec.*, Mr. W. Tomkinson, Newcastl. Entries close August 25th.  
SEPTEMBER 25th. MIDDLETON. *Sec.*, Mr. T. Mills. Entries close September 10th.  
OCTOBER 28th and 29th. CALNE. *Secs.*, A. Heath and F. Bailey. Entries close October 15th.  
DECEMBER 1st, 2nd, 3rd, and 4th. BIRMINGHAM. *Sec.*, John B. Lythall, 13, Temple Street, Birmingham.

### CRYSTAL PALACE POULTRY SHOW.

HUMAN nature is an odd thing. Man has been called a reasoning biped. Buffon says truly he is the only animal in creation that walks upright, and that his God-like gift of reason places him at the head of all beings. Others complain that he is crooked, and made up of angles and sharp corners that have to be rubbed off or down before he is half so approachable as he should be. There is a real superiority that raises its possessor, makes him indulgent to those who know less than himself, or do not agree with him. This would induce him to forward the enjoyment of others in the same spirit that a very learned man, a parent, will, like Henry IV. of France, crawl on all fours to be his children's horse, or patiently toil at the construction of a pyramid of cards. Others, superior men also, believe their pursuit alone to be worth notice, and affect a feeling between pity and contempt for those who are content with humbler things. This is well described in the humorous piece of "Sir J. Banks and the Butterfly." The great man visiting at hi

friend's house can hear nothing but the praise of tulips; he is taken to see them in the morning; he hears their names, their value, and their peculiar merits. He is perfectly satisfied his friend is mad, and wishes him and his tulips at the bottom of the sea. But a butterfly passes. "An Emperor! by Jove," says Sir Joseph, and rushes in pursuit, overturning and trampling all the flowering treasures. "Mad," says his friend, "to tread down my tulips in pursuit of a trumpery butterfly."

We are led to make these remarks from the fact that in some quarters the poultry pursuit has been disparagingly spoken of in connection with this Show. Those who do so are generally utterly ignorant of it, and require elasticity in their sympathies. The poultry fancy is inherent in some people, however high their rank may be, and they carry it out. In others of the humbler class a few fowls, or a few Pigeons, or Rabbits are the only objects within reach of their means or their accommodation. In them is centred the natural desire to be the owner and breeder of stock. Many of those who turn up their noses at beautiful specimens of animated nature cannot contain their joy at the acquisition of a spotless teapot of undoubted antiquity. They will resort to all sorts of shifts and contrivances to "pick up" a cracked cup and saucer, and are in ecstasies at the unrolling of a mummy. Many a young man spends days in blackening a pipe. We might continue for hours, but it would not help us. We only want to show that all have their hobbies. We may if we like laugh good-humouredly at any of them, and we grant them the same privilege.

"Or, puisque chacun a les siens,  
Nous avons tous les notres.  
A votre trésorier les miens,  
Et je rirai des vôtres."

As it has been notoriously a bad season for poultry-breeding we were not prepared for large entries, not so large as we found. We have not only had trying weather, but we have had new diseases. We have had such a demand for poultry for the table, and owing to its scarcity it has been dear; the temptation to sell it has been so great that promising early chickens died because "the bird in the hand is worth two in the bush." For these causes we looked with interest to the Crystal Palace Show, to show us what we might expect during the autumn. We will give the result of our expectation in our review of the classes.

Mr. Rodbard's *Spanish* pens were very good ones, and Mr. Lane's young cock deserves notice. Some young cocks had the sprigs of their combs removed so clumsily it would have been better had they remained.

All the classes of *Dorking* were beautiful, and no plea of weather, season, or disease was necessary. Given all things in their favour, they could not be better. The Hon. W. Vernon's was a beautiful pen, the pullets rather better than the cock. It would also be unfair not to mention Messrs. Frest and Tudman, and Sir J. Paxton. Mr. Wakefield's Pullets in Class 5 were perfect; the same may be said of those exhibited by Miss Milne, and of the Whites shown by the Rev. G. F. Hodson and Mr. Lingwood.

The class for *Single Cocks* was a noble one. We must point out two things which interfered in some instances with success, and will interfere if it is not guarded against—the first is swelled toes, and the second the growth of the spur on the outside instead of the inside of the leg, both these will cause failure where the competition is close.

The Buff *Cochins* were excellent, and the prize birds among the best we ever saw in the month of August; we would especially mention those belonging to Mr. Kelleway, with respect to which we have not a fault or shortcoming to remark upon. The Whites were not very good. The Grouse were excellent, but they show better when older. It was a hard run between Messrs. Tudman, Cartwright, and Musgrove.

The *Cochin Cocks* were weak. It is well to remind exhibitors that crooked or falling combs are fatal to success in these classes.

The *Brahmas* were very good.

Among the *Game* fowl there is always a larger entry of White and Piles at the Crystal Palace than elsewhere. The present was no exception, and the prize birds, especially those of Messrs. Crofts and Ewen, deserve especial commendation. The next class of Black Reds was equally good. Mr. Fletcher distanced all others, although eight pens were mentioned in the prize sheet, and he was distanced in Class 16 by Mr. Archer, who showed a pen of exquisite birds, achieving an easy victory in a highly meritorious class. Mr. Vernon's Duckwings were very good; they deserved their first prize. This gentleman was successful in the *Single*

*Cock* class; he was here hard run by Mr. Fletcher, who took second and third.

We now come to that which we believe to be the best show of the breed ever seen at this season of the year. There were twenty-four entries of Golden-pencilled *Hamburgh* chickens, many of them perfect; Mr. Nuttall performed no mean exploit in taking first and second prizes. Many of the pullets were perfectly marvellous in their markings, every feather in the tail being as well pencilled as a body-feather. We can say little for the Silver-pencilled; there is nothing to remind us of Mr. Archer's days in this class. Messrs. Locke and Munn showed good *Hamburgh Cocks*. All the Spangled were good; but, reversing the order of things, the Silver were better than the Golden. Messrs. Brooke and Collinge deserve special notice.

The *Polands* were not numerous. Mr. Ray showed an excellent pen of Blacks, Mr. Beldon a very good pen of Golden. By far the strongest class were the Silvers, and our old exhibitor, Mr. Adkins, was successful in taking prizes both for pens, and also for the best bird in the *Single Cock* class.

It is enough to say the *Mulays* were excellent.

The "Various class" was very strong. Mr. Wakefield headed it with the best pen of Crève Cœur chickens we have seen. The Silkie were excellent, and the Black *Hamburghs* sufficiently numerous to be judged as a class.

Mr. H. D. Bayly took nearly half the prizes offered for the different breeds of *Bantams*. The Game formed a very good and numerous exhibition. Eight pens were in the prize sheet, and Mr. Kelleway well deserved his second prize. In the *Bantam Cocks* Messrs. Lenox and Locke were successful.

Mrs. Seamons' first-prize pen of *Ducks* weighed 22 lbs., her second 19 lbs. Mr. Fowler took all the prizes for *Rouens*; but even he has not succeeded in getting these to large weights. The feather is now understood, and we hope the weight will be accomplished. The Blacks or *Buenos Ayrean Ducks* proved this class to be a success; eight pens figured in the list.

Mrs. Seamons' first-prize *White Geese* weighed 47½ lbs., Mr. Manfield's second, 40½ lbs.; Mr. Fowler's first-prize *Greys*, 48½ lbs.

Three first-prize *Turkey* poults weighed 29½ lbs., the second 23 lbs.

The "Various classes" showed *Sebastopol*, *Egyptian*, and *Chinese Geese*.

The *Pheasants*, *Calege*, *Bohemian*, *Chinese*, *Gold*, *Silver*, and *Pied*.

It was a most successful Show, and, as usual, well managed in all respects by Mr. Houghton. The sales were numerous, and there was one singular event—the whole of the pullet class of *Dorkings* was sold on the first day. It was matter of general regret that the numerous entries of a French exhibitor arrived too late for competition.

Mr. Hewitt and Mr. Baily were the Judges.

## PIGEONS.

THE Pigeons at the Crystal Palace Show numbered rather less than two hundred pens, divided amongst twenty-nine classes.

The *Pouters* as usual headed the list, and were exhibited in two classes—namely, single cocks of any colour and single hens. The first prize for cocks was awarded to a very fine Blue of Mr. Fulton's; the Mealy cock of Mr. Evans' that took first here on a previous occasion being second. Mr. Rake's Red Pied that won the third was a very promising young bird, long-limbed and clean-thighed. In hens Mr. Rake won with a magnificent Blue hen, Mr. Fulton being second, and Mr. Evans third with a Yellow Pied. As an example of the chances of the exhibitions, we may state that a very long-feathered, slender, and long-limbed Mealy hen of Mr. Evans', that won here last year, was not even honoured by a commendation on this occasion.

The *Carriers* were about as poor a class as was ever seen at a large show. In the cocks, Major Hassard's third-prize Dun was a very fair bird. The second prize was awarded to a mean-looking broad-skulled animal that was scarcely worth thirty pence, and was only priced at so many shillings, at which sum it found an unfortunate purchaser. As *Carriers* good enough to win at a large show realize readily from £10 to £15, the value of the character of the bird in question may be imagined from the price.

From the general condemnation of the *Carrier* classes, we must except that for Dun and Black hens. Mr. Corker's first and second prize hens were magnificent in head, beak, and eye.

The carriage of the second-prize bird was much the best, and though not so stout some judges would have transposed their position. Mr. Rake's two hens were also very good.

*Dragons* are always an uncertain class, varying from the sheary character of the Skinnum to the heavy style of a half-bred Carrier. No two fanciers exactly agree as to what constitutes their points of excellence, and, consequently, the decisions are ever varying. The present awards were to rather heavy birds, wanting in that racehorse-looking style we ourselves admire; and the hooked beak of the Yellow prize cock was still less to our taste.

In Almond *Tumblers*, Mr. Corker won with the birds that we have remarked upon before, as owing much to nature and a little to the early training of their wonderful heads and beaks. The same exhibitor also took the first prize in *Mottles*, with a very good pair of *Blacks*.

The best pair of *Beards* in the class, belonging to Mr. Esquilant, were disqualified from a snip in the wing having been used to mark one of them. If such a rule is enforced it should be rigidly carried out on all alike. Mr. Esquilant has some ground of complaint at losing his prize, when the prize *Powter* cock had both his wings cut; and Mr. Baker's *Brouzewings* that took a prize in the "Variety class," had marks tied around their legs.

The *Owls* were a splendid collection; the Blue cock in Mr. Rake's prize pen being the best for shortness of beak and roundness of head that we have seen for years. The little White and Black African birds were also very excellent—in fact, this class of little Toy Owls is rapidly superseding the older larger variety; but no Bluea have yet been imported.

*Nuns* were good. In this class was shown a very good pair of White-barred *Black Priests*.

*Turbits* were also good; the first-prize Reds were sold directly at £3 10s. The round owl-like head of the third-prize Yellow hen wanted altogether the frog-like appearance so characteristic of the class. The *Fantails* were good. *Barbs*, as a whole, very poor. *Maggies* numerous and good. *Trumpeters* showed a sad falling-off, both in Whites and *Mottles*. Mr. Morris's self-coloured *Blacks* were singular, and also good. *Runts* were about as usual.

The "Variety class" was numerous, and very interesting. The first prize was awarded to the same Silvered Chequered birds that won at Sheffield last month; the second to Blue *Priests*; the third to Australian *Bronzewings*, a very tame and good-plumaged pair; and the fourth to a pair of Australian *Wonga-Wonga Pigeons*. It would be interesting to know if these have bred or ever laid, as the Acclimatisation Society have them down on their list of *desiderata*. Several birds from Mr. Charles Bocquet, a Parisian dealer, arrived too late for competition, amongst which may be mentioned two pairs of small *Owls*, under the title of *Cravates de Smyrne*, and a huge pair of Roman *Runts* entitled *Romains Figres*, very tall, heavy, and scanderon-like.

Considering the time of the year (the worst that could be selected, as every bird, old and young, is in moult), the Show was very good. Mr. Harrison Weir's first appearance at the Crystal Palace in the character of Judge was satisfactory to all who value the opinion of an enthusiastic fancier, whose practised artistic eye enables him to detect alike beauties and blemishes that would be overlooked by an ordinary observer.

## SELLING CATALOGUES BEFORE THE AWARDS OF THE JUDGES ARE MADE.

I was at Driffell Show a month ago, and walked up with the Judge, whom I met after leaving the station, and they were examining the catalogues in the street. The Judge might buy one if he chose, and know the name and number of every exhibitor, and he might as well be set to judge by catalogue at once. I do not care for my part, because I give our judges, generally, credit for honesty as well as integrity in their decisions, and make some allowance for the hurry of the moment—the difficulty sometimes of judging twelve to twenty pens of birds of the same kind, where a very small trifle, perhaps, makes the difference between first and highly commended. But then, we must confess it, however loth to do so, the little weakness of our nature may lead us astray, and our judges are but men, and if six had the same work to do there would be three or four different decisions, perhaps. Many people stumble at these things, and perhaps a

word or two from you condemning the practice (unless approve of it) will put it right.—J. R. JESSOP.

[The practice is decidedly wrong, and should be at once put a stop to.—EDS.]

## COTTINGHAM POULTRY SHOW.

THE annual Exhibition of Poultry, Pigeons, and Rabbits, was held at Cottingham, on the 27th August. About two hundred pens were entered, and in many of the classes there were specimens of great merit. The Show is only for Chickens of 1862, except in the classes for Single Cocks, Pigeons, Guinea and Pea Fowls.

The *Spanish* class was represented by some fair birds. In *Dorkings* there was some rather close competition, all the birds entered receiving prizes or high commendations. In the class for *Dorking Cocks*, the prize went to a fine bird from Capt. Hornby's yard; and two others were highly commended. The *Cochin-China* classes had some beautiful Whites, and some fair Buffs, but they, as a class, were hardly of average merit. In the *Game* classes, Mr. Adams as usual brought out some good birds, but he had to be content with a first and third position, as there was more competition in this class than in any other in the Show. Among *Polands* there was nothing calling for remark, most of them being Silvers. There were some really good specimens among the Golden *Hamburghs*, and some capital cocks, as may be inferred from the fact of two extra prizes being awarded in the Spangled Cock class. There were some good pens also among the Silvers. We thought the Laced *Bantams* inferior; but there were some nice *Game Bantams*, and some good Whites. The Extra Stock class for "Any other distinct variety," was composed of *Brahmas*, *Black Hamburghs*, and *Malays*. There were some good-sized and good-looking useful birds among the farmyard crosses. The best, to our fancy seemed to be a cross between *Game* and *Hamburghs*.

Only one pen of *Pea Fowl* and two of *Guinea Fowls* put in an appearance on the Show day.

The prizes in *Turkeys* went to some beautiful Whites, and the other two pens were highly commended.

In *Goslings*, Mr. Tate secured first prize with some White Embden. The second going to a pen of Toulouse belonging to Mr. Jessop, only twelve weeks old. The two birds weighing 26 lbs.; and the third to Embden.

There were some good *Aylesbury* and Rouen *Ducklings*, and in the "Any other variety" class there were a pen of *Carolinias*, three pens of *East Indians*, and some cross-bred Ducks. We thought the owners must be under some mistake with regard to the points of *East Indians*, as they looked more likely to compete with *Aylesburys* for size and weight, if, as a lady once said to us, "they could only be painted white."

Among the *Pigeons* there were some very good birds, but *Croppers* were nothing remarkable; and in *Carriers* we should not like to say that one prize pen did not contain two cocks. The first prize in *Trumpeters* went to a pair of *Mottles* with a very good purl; Mr. Key coming second with a good pair of young ones with heavily-feathered feet. The *Jacobins* were very good, and also the *Fantails*; the first-prize birds having very good tails and carriage. The *Tumblers* and *Barbs* were not first-rate; and in *Nuns* there was no competition. In the "Any variety" class the first prize was given to a pair of White *Dragons*, and the second to some Blue *Owls*, about twice as large as we should like them. *Turbits* and *Maggies* made up the class.

There were some good *Rabbits* shown.

The weather was all that could be desired, and there was a good attendance of the neighbouring gentry and others. The arrangements seemed to be very good; and there is only one particular to which we take exception—and that is, that two or three days before the Show a catalogue of the entries was published and sold to any person who was disposed to buy it. We know of another case in the East Riding where the catalogues are sold prior to the Show, and we humbly think the practice of selling catalogues before the Judges have made their awards is bad in principle and likely to cause a little more petty jealousy among exhibitors, of which there is sadly too much already.

SPANISH.—First, J. Holmes, North Cave. Second, H. A. Hudson, York. Third, R. Tate, Driffell. *Single Cock*.—Prize, R. Tate.  
DORKINGS.—First, W. Watson, Bishop Burton. Second, Mrs. Maw, Eppleworth. Third, F. Key, Beverley. Highly Commended, O. A. Young, Driffell; W. Stanton, Cottingham. *Cock*.—Prize, R. M. Stark, II. Highly Commended, Mrs. Maw; O. A. Young.

**COCHIN-CHINA** (Black or White).—First, R. Tate. Second, and Third R. Loft, Woodmansey. *Cock*.—Prize, R. Loft.

**COCHIN-CHINA** (any other variety).—First, R. Tate. Second, E. Witty, Cottingham. Third, Mrs. White, Shearman. *Cock*.—Prize, R. Tate. Highly Commended, E. Witty; T. C. Trotter, Sutton.

**GAME** (Black-breasted and other Reds).—First and Third, H. Adams, Beverley. Second, R. Tate. *Cock*.—Prize, H. Adams. Highly Commended, Mrs. Patrick, Beverley; D. Pickering, Hull.

**GAME** (any other variety).—First, H. Adams. Second, H. Merkin, Driffield. Third, W. Walker, Lockington. *Cock*.—Prize, H. Adams.

**POLANDS**.—First and Second, R. Loft. Third, Mrs. Proctor, Hull. *Cock*.—Prize, R. Loft.

**HAMBURGONS** (Golden-spangled).—First, W. Cannon, Bradford. Second, W. Charter, Driffield. Third, R. Tate. *Cock*.—Prize, J. Murgatroyd, Bishop Burton. Extra Prize, H. A. Hudson and R. Tate. Highly Commended, T. Ross, Cottingham.

**HAMBURGONS** (Golden-pencilled).—First and Third, J. Bilton, Cottingham. Second, R. Voakes, Driffield. *Cock*.—Prize, J. Widdall.

**HAMBURGONS** (Silver-spangled).—First, W. Cannon. Second, S. Campion, Cottingham. Third, W. Johnson, Bishop Burton. *Cock*.—Prize, S. Campion. Highly Commended, R. Tate.

**HAMBURGONS** (Silver-pencilled).—First, J. Falkner, Hammanby. Second, W. Charter. *Cock*.—Prize, R. Tate. Highly Commended, J. Falkner.

**BANTAMS** (Gold or Silver).—First, R. Tate. Second and Third, G. Stephenson. *Cock*.—Prize, W. Charter.

**BANTAMS** (Game).—First and Third, R. Tate. Second, R. Voakes. *Cock*.—Prize, R. Tate. Extra Prize, J. Bilton.

**BANTAMS** (any other variety).—First and Second, Mrs. Foster, Beverley. Third, withheld. *Cock*.—Prize, T. Gawan. Highly Commended, R. Tate; C. S. Brittain.

**EXTRA STOCK**.—First, J. Pares, Leicester (Brahmas). Second and Third, R. Tate (Black Hamburgs and Malays). *Cock*.—Prize, H. Adams (Black Hamburg).

**FARMYARD CROSS**.—First, G. Bromley, Cottingham. Second, R. Loft. Third, Mrs. White. *Cock*.—Prize, Mrs. White. Extra Prize, J. Bilton. Highly Commended, R. Tate.

**PEA FOWLS**.—First, Mrs. Haworth, Hull Bank. Second, no competition.

**GUINEA FOWLS**.—First, H. Merkin. Second, R. Tate.

**TURKEYS**.—First and Second, O. A. Young. Highly Commended, Miss Wallace.

**GEES**.—First, R. Tate. Second, J. R. Jessop, Hull. Third, O. A. Young. Ducks (Aylesbury).—First, R. Tate. Second, O. A. Young. Highly Commended, R. M. Stark.

**DUCKS** (Rouen).—First, R. Tate. Second, O. A. Young. Commended, R. M. Stark.

**DUCKS** (any other variety).—First, J. Kingrose, Cottingham (Carolinas). Second, T. Ellington, Woodmansey. Highly Commended, Miss White; O. A. Young.

**PIGEONS**.—*Croppers*.—First, H. Yardley, Birmingham. Second, T. Ellington. Highly Commended, W. Witty. *Carriers*.—First, T. Ellington.

Second, J. A. Richardson, Hull. Highly Commended, H. Yardley. *Trumpeters*.—First, J. R. Jessop. Second, F. Key. Highly Commended, T. Ross. *Jacobins*.—First, T. Ellington. Second, W. Carlton, Howden.

*Fantails*.—First and Second, T. Ellington. *Tumblers*.—First, J. A. Richardson (Almonds). Second, T. Ellington. Highly Commended, W. A. Summers; H. Yardley; R. Bell. *Barbs*.—First, W. Witty. Second, T. Ellington. *Nuns*.—First, Miss Charter. Second, no competition. *Any Other Variety*.—First, W. A. Summers (White Dragons). Second, R. Moll (Blue Owls). Highly Commended, W. A. Summers, H. Yardley.

**RABBITS**.—First, J. E. Eglington. Second, T. Rousby.

The Judges were Mr. Blyth, of Birmingham, for Poultry; and Mr. Ferguson, of Walkington, for Pigeons.

## BEES DESERTING THEIR HIVES.

THE cause, a very small parasite. The remedy, new hives, floor-boards, &c., and no communication allowed with old hives, houses, &c.—AN OLD WATERLOO PENSIONER.

[This is a novel statement to us. Bees will desert their hives when overpowered by wax-moths, but we know of no minute parasite that will cause them to do so.]

## TRANSFERRING AND UNITING STOCKS— HIVING A SWARM IN A FRAME-HIVE.

BEFORE troubling you with a few more questions, allow me to offer my sincere thanks to the Editors, and their correspondent "A DEVONSHIRE BEE-KEEPER," for the very full reply to my former letter in your number of July 8. The answer was exactly what I wanted, practical and particular, giving just the minutia so necessary to a beginner, though so simple to an old hand. I have already acted on some of the advice given. I have bought indiarubber gloves, but I doubt if they be of the right kind. I fancy they should have been real indiarubber like the tobacco-pouches, but I could only get some covered with an indiarubber coating. Also, when I was in town for the Exhibition, I got a glazed bar-super and a bar-frame-hive at Messrs. Neighbours'. Now, I want to know, 1st, whether I can make use of the latter this autumn, or had I better wait for a swarm in the spring. The bees in my King's box, concerning which I consulted you, were soon after attacked by robbers, and for a day and a half the battle was most fierce; I therefore fumigated,

and found only a very few bees, little honey, and no brood. This box is, therefore, empty. I have now a Neighbour's cottage, a bar-box, and four common straw hives, all very strong in point of numbers. I do not care to keep quite so many stocks, and I wish to get some honey.

Please advise on query 2. Shall I keep my old stock and one other in straw hives, and destroy two new straw in the old way? It strikes me, as this has been such a prolific year, but so bad for honey-gathering, it would not be wise to join two strong stocks with small stores.

Query 3. In hiving a swarm into a bar-frame-box is it necessary or advisable to remove all the frames and insert them when the bees are in? It strikes me they would make it difficult to get a large swarm in.

Query 4. The bees in a common straw hive lately cast out heaps of grubs. I added a super and the destruction ceased. Was this from want of room?—A. W. B.

[We have never been able to obtain gloves made entirely of indiarubber, but use those covered with vulcanised caoutchouc, and manufactured for photographers.

As you appear to have two surplus stocks in straw hives you may transfer one of these at once into your new frame-hive. If the latter is fitted with "compound bar-frames"—i.e., bars which can be detached from their frames, turn to page 149 of our present volume and provide yourself with a reel of binding-wire, a score of zinc clips, and half that number of trough-shaped slips of wood, each 12½ inches long, for the purpose of supporting the combs in the manner therein described. If, on the other hand, yours are simple frames, you will only need the score of zinc clips, and a few slips of wood, each 13½ inches to 14 inches long, five-eighths of an inch wide, and one-sixteenth of an inch thick. These are required to support such combs as are not deep enough to fill the frames from top to bottom, and are to be sprung in between the sides in the form of an arch, the crown of which supports the comb in such a manner as to keep its upper edge in close contact with the underneath side of the top bar. Having provided these little requisites, drive all or nearly all the bees out of their straw hive into an empty one, in the manner described in pages 45 and 46 of "Bee-keeping for the Many;" and, having placed them on their original stand, convey their old domicile in-doors out of the reach of robbers, and there carefully extract all the combs, without breaking, and cut them to fit your frames, in which they must be fastened and supported by means of the zinc clips, &c., and hung one by one in the box as completed. If any be crooked they may be slightly warmed before the fire and set straight; and if any are too thick the projecting parts must be pared down. Having completed the job to the best of your ability, convey the hive to the apiary and put it on the old stand, shifting that containing the bees on one side; then remove the crown-board, and by a smart blow dislodge the cluster of bees from their temporary domicile on the top of the exposed bars. They will "skedaddle" between the combs with as much alacrity as the Yankees did at Bull's Run, or the Federal ironides on the Mississippi at the approach of the Arkansas, so that you will find no difficulty in replacing the crown-board. In forty-eight hours all artificial supports may probably be removed, and if the combs are firmly fixed, a sufficiency of food may then be administered to last the winter.

Do not on any account set your workmen so bad an example as to destroy stocks in the old way. If any one thing relating to bees has been proved beyond cavil, it is the fact that two or more stocks united in the same hive consume scarcely any more food than one of them would do if suffered to winter single. All reliable apirians proclaim this from the time of Jonas de Gelien down to the present day, and amongst them our correspondent "A DEVONSHIRE BEE-KEEPER," whose experiments to prove this fact are detailed in THE COTTAGE GARDENER of the 3rd of May, 1859. The best mode of uniting bees is by driving, as described in the before-mentioned pages of "Bee-keeping for the Many." It is somewhat doubtful if stupefaction by means of fungus is not ultimately quite as fatal as the murderous brimstone-pit.

When placing a swarm in a frame-hive the frames should not be removed; the bees must be hived at first in a common straw skep, and then either knocked out upon a sheet spread on the ground in a shady place close in front of the frame-hive, which should be raised about an inch on wedges, and into which they will speedily enter; or the crown-board may be removed, and the cluster knocked out on the exposed bars, between which they will rapidly disappear, and allow the crown-board to be

replaced. The last-mentioned plan is the one we adopt, whilst the first is recommended by Mr. Langstroth.

The discarded grubs were probably embryo drones; if workers, the loss is much to be deplored, and may probably be traced either to cold or starvation, not want of room.]

### PASTOR DZIERZON AT HOME.

THE following sketch is translated from the "Gartenlaube," an illustrated periodical published at Leipzig, of which 150,000 copies are sold weekly. It is a graphic description of an unpretending country clergyman, who has succeeded in elevating bee-keeping in Germany to an importance which it never before attained, and whose discovery of parthenogenesis in the honey-bee and thorough insight into the hidden mysteries of bee economy proclaim him the worthy successor of the illustrious Huber, and undoubtedly the first apiarian of the age.—A DEVONSHIRE BEE-KEEPER.

#### THE GREATEST BEE-FATHER IN THE WORLD.

WHEN arriving either from the east or from the west at the Brieg station on the Upper Silesian Railway, and there crossing the Oder, we are in the country of the water Poles. Having travelled over poor sandy plains and through dark pine forests about two miles and a half,\* we reach the Polish village of Karlsmarkt. This little village, with its small Catholic parsonage, has been for the last ten years the destination of travellers from all parts of Europe—and even from the new world, for from hence went forth a reform in bee-keeping which has elevated this branch of agricultural science to a height which it never before attained.

Crowded in the parsonage garden are hundreds of bee-hives of different descriptions, some of them being of a perfectly novel form, whilst the air is filled with thousands of humming bees. Walking about amongst them, attired in a simple house-coat and skull-cap is a plain active man, as unconcerned as if surrounded by tree-blossoms only. Bees are resting on his neck and back, his breast and his hands, and even in the sleeves of his coat, but that does not disturb him in the least; he takes them off gently here and there and lets them fly, smiling if his visitors run from the bees, or cry "Ach!" or "Web!" at a bee-sting. Him they scarcely ever sting; and, if they do, he cares no more for it than for the sting of a gnat. His attention is constantly directed to the hives and the flying bees, and if his visitors ask questions, his answers are generally very short. One must know how to ask interesting questions if one wishes him to enter fully into the subject. He who would there profit by his great knowledge of bee-keeping, must first see and observe so as to understand the man himself whose face is full of kindness, and, if somewhat commonplace, not without a certain spirit, whilst his demeanour is modest, almost to shyness unless more than ordinarily interested.

This is Dzierzon, the Pfarrer † (curate, as they call him here) of that place, the name of which has already designated him as belonging to the Polish nationality; one who understands bees as well as if he himself were a bee—who knows how to train them, as it were. What he wishes, they must do; if he wants honey, they must collect honey; if he wants wax, they must make wax; if he wants more bees, they must be busy with the increase of their species. This power over his bees he has obtained by a thorough knowledge of their nature. By means of this knowledge he makes use of their instincts and inclinations, avoids everything which is contrary thereto, defends them from their enemies and from the inclemency of the weather, takes care of them in disease, and, so to speak, makes their life comfortable. It follows from all this that they are able and willing to work for him with all their might, like workmen in a manufactory whose master cares for their welfare like a father. One must have seen Dzierzon watching his little darlings to have a perfect picture of the "bee-father," as he ought to be. Nothing escapes him; whether it be necessary to add to or to alter his hives, or whether shelter from rain or from sun is required. Every tired bee which he sees he takes up carefully and conveys it to its hive. In cold mornings he carries a queue-cage with him, in which he gathers chilled bees from the ground and warms them on his person. His activity in this way is not a little remarkable, as he has other apiaries besides that at Karlsmarkt, all of which he superintends with the same zeal.

\* 2½ German miles are equal to twelve miles English.

† Anglic, parson or minister.

When inspecting them, he takes in his hand hammer and saw, gimlet and pliers, and improves and repairs his hives and utensils in the most workmanlike manner.

Bee-keeping conducted after the manner of Dzierzon, as indeed it ought to be conducted, may be termed the very poetry of agriculture. Wherever there are trees and flowers, Dzierzon thinks there should be bees to animate and complete every such rural scene. He is also certainly right in his assertion that intercourse with bees improves a man, incites him to order and diligence, and keeps him from idle conversation. But without mentioning this, the poetical side, which is always worthy of notice, bee-keeping is also of great material value. First, the productiveness of a country is increased by it to an incredible extent since the fertilising pollen is divided and widely distributed by bees in a far more equal and lasting manner than by the wind. Next are honey and wax, so necessary and valuable, that by their universal production the national prosperity is very much increased. As a good stock may gather 10 lbs. of honey, † and make a proportionate quantity of wax, it may be observed that such produce is clear profit, since bees, unlike other domestic animals, do not require to be provided with food.

Sagacity and power of observation are two qualifications which Dzierzon possesses in a degree that is seldom equalled. By means of these he has penetrated so deeply into the mysteries of bee-life that very little if anything essential remains to be discovered.

### UNITING BEES—COMB BEE-FEEDER.

I ALWAYS feel interested in reading over the different articles which appear from time to time about bees, but must confess that for the most part they are too scientific for us countrymen who rarely see anything but the common straw hive, and, therefore, would be glad of a little of your valuable advice.

I kept three stocks through the winter, one of which seemed very weak as regards bees, not many to be seen at any time, but was always as heavy as both the others. This stock swarmed on the 5th of May, and again on the 17th; the others swarmed once each, so that I have now seven in all, and like most of my friends in these parts (Gloucester), find they have little or no honey, the old heavy stock being the only weighty one among them. Now, I only want to keep three stocks through the winter, and would be glad to know if I had better keep the old ones and destroy the young, reserving the comb in the hives for next year to put in fresh swarms, or could I unite them to be of any advantage. They are in straw hives, with wooden tops 8 inches or 10 inches diameter, with a hole 1½ inch through.

I send you my plan of bee-feeding as it differs from your other correspondents', and I find it answer the purpose very well. I save some empty combs (of which, since I began bee-keeping I have had too many), cut off the cells on one side, then cut it round the size of a basin or flower-pot saucer, make a hole through corresponding with the one in the top of the hive, lay in on the top, and, with a spouted jug, fill the cells with syrup, and turn over the basin or saucer, then put on the covering. If fed a few times regularly, they will come up when you give it them as ready as a lot of fowls. I need hardly say the holes are corked up at other times. I find they are very fond of sweet cider—that is, cider before it is fermented, with a little addition of sugar.—G. C. UPTON.

[By all means unite your condemned bees to your other stocks by driving, as recommended in pages 45 and 46 of "Bee-keeping for the Many." Yours is a good contrivance for feeding, but we believe no feeder is equal to the inverted bottle recommended by—A DEVONSHIRE BEE-KEEPER.]

### WINE-MAKING.

AS the season is approaching when attention will be turned to making wine, many people may be glad to obtain information in regard to the process which will insure the best article.

It is not always that a fine table grape will make a good wine; indeed, there are many excellent wine grapes which are unfit for the table, and many of the finest table grapes are unfit for wine. A good wine grape should give an abundance of good colour, with astringency enough to give character and tone to

† About eleven English pounds—not a very large honey harvest from a good stock.—A DEVONSHIRE BEE-KEEPER.

the wine, but not so much as to give it a disagreeable flavour. It should contain sugar enough to make the wine keep well; but this is not indispensable, for sugar may be added if the grape possess the other qualities proper to a good wine.

I will state the method I pursue in making wines from grapes containing the proper qualities for that purpose, and will show in another place by what methods excessive harshness may be ameliorated, and unpleasant flavours removed, or so qualified as to yield a palatable and wholesome wine.

The first necessity in wine-making is to prepare your casks. These should not be new, for the new wood would give an unpleasant flavour to the wine. It is better to use casks which have already held wine or spirit; they should be perfectly clean and sweet, well made and strong. The press—which should be a strong screw press—must be perfectly clean, and care must be taken to keep it so during the whole process. Few grapes are so tender as to yield their juice without bruising; you will therefore need a mash-tub and a long wooden pestle to break them. I do not strip the grapes from the stems, for I believe they give to the wine a tonic property and make it keep well. The grapes should be gathered in a dry day; gather and press them as rapidly as possible, remembering that fermentation never goes back, and it is important to have the whole body of your wine start at one time if possible, lest a portion of the must should grow sour before the rest is fermented into proper wine. The grapes should be ripe, but not over-ripe; green berries should be removed; they give to the wine a sour taste which is a long time in passing away. A bushel of grapes should give four gallons of juice; but few grapes, however, yield so much as this, the product varying from two and a half to four gallons. It, however, they are rich in wine-making properties, the measure may be made up to four gallons by the addition of water and sugar. Sugar must be added to the must from grapes grown in this latitude, for although a sound light wine may be made from some of our best wine grapes, the proportion is never sufficient to make a full-bodied wine which will keep well; 24 per cent. is the least the new beginner should allow, but 20 per cent. and even 15 per cent. will allow a skilful operator to make a sound wine; the sugar should be the best refined white, as brown sugars give a coarse taste to the wine. If you have not got a proper instrument to ascertain the per-centage of sugar contained in the must, add the sugar until the must will float a new-laid egg with about one-quarter of its diameter above the surface. It is much better to have a little excess of sugar than to take the venture of the wine running into acetous fermentation for want of enough sugar to save it.

Fermentation, as I have said, never goes back, but it is liable to fluctuations through changes of temperature; you should therefore, if possible, have the temperature under control. This can only be accomplished by having a stove in the pressing-room. With the aid of this you may keep the heat at the point necessary to secure active fermentation, and it should always be active, and to gradually increase the temperature to 80° or 85° at the close, bearing in mind that the more active the fermentation ("stormy," a German friend calls it), the sooner it will be completed and the better will be the wine. Keep the air from the must as much as possible, and when the fermentation subsides put in the bung, and if there is any strain on the cask, relieve it by taking out the spigot occasionally. After the wine is still, keep it as cool as you can until it is convenient to put into your cellar. Take this occasion to draw it off from the lees; throw these away, rinse out the cask, and replace the wine. If the fermentation has been thorough, the wine will probably be clear; if otherwise, it will be likely to ferment again in the spring, when it must again be racked-off, and, if necessary, fined.

To refine wine you may use isinglass or the white of an egg; one-quarter of a pound of isinglass is sufficient for a barrel of wine. Dissolve it in a little hot water, and mix it with five or six gallons of wine which you have drawn from the cask for that purpose; then return it to the cask, stirring it well into the wine and stop the cask tightly. In a week or two it will be perfectly fine, then draw it off, throw away the lees, and return the wine to the cask. If you use the white of eggs, take seven eggs for a barrel of wine, whip the whites thoroughly, mix with the wine as above, whipping it with a clean whisk, and return to the cask. The wine is now made, and should be kept in the cask until ripe. It will be fit for use in two years, but will improve with age. It should not be bottled—that is, it should not be taken out of the wood, where it ripens much more

rapidly than in glass, unless it is so light as to make it necessary in order to save it from going sour.

I now propose to show by what measure the harsh flavour—commonly called foxy—of our wild grapes may be ameliorated, and a good wine obtained from them.

The wild grape contains much more acid, and a tougher and more mucilaginous pulp than the wine grape. The excess of mucilage causes a violent fermentation which it is difficult to check, and it is necessary to dilute the acid to make a palatable wine. The proportions of acid, sugar, and water which are found to give the best wines, are as follows:—in 1000 parts, 240 sugar, 6 acid, 754 water. All these proportions fail in the wild grape. It contains more acid, less water, and less sugar. With the aid of proper instruments and experience in the manipulations, one can restore these proportions exactly; but as this article is written for those who have neither time nor inclination for critical experiments, but would be glad to be able to make a good and wholesome wine out of the wild grapes of their fields, I offer them the following formula:—

To every gallon of the grape juice add a gallon of pure water. Take the cheese or pressing from the press, and restore it to the mash-tub, and bruise it thoroughly again; then add to it as much water as you got pure juice from it at the first pressing; let it stand for an hour or two and press again; then put the liquid into your cask with the first pressing and the water which you have added to it. To every gallon of this mixture add three pounds of the best white sugar, let this be dissolved in the water before you add it to the grape juice, and give it a thorough fermentation. Keep your cask full if possible, and let the yeasty substance work over at the bung, for this is the best way to get rid of the excess of mucilage, taking care to fill up the cask frequently with the must saved for that purpose. If, however, you have not a sufficient quantity of must to fill your cask and supply the waste from the bung, the following method may be adopted:—

Take strips of cotton cloth, half an inch wide and 12 inches or 15 inches long, wet them and dip them in flowers of sulphur, light them at one end and put them into the cask, one end being secured at the bung; when the cask is filled with the vapours of the sulphur, pour in the must until the cask is about one-third full; put in the bung and roll the cask until the vapour is thoroughly mixed with the wine; repeat the process until all the must is in the cask; this will throw down the mucilage and colouring matter in which is contained the offensive taste and odour; as soon as this takes place, which will be in two or three days, draw off the must carefully, clean out the cask, replace the wine, and proceed with the fermentation as above.—(*Boston Cultivator.*)

OUR LETTER BOX.

FEEDING CHICKENS (*A Subscriber, Bray*).—Your chickens have been properly fed, but we suspect the wet weather has been against them. If they have been kept on a cold, damp floor, that would account for your loss.

FEEDING DUCKS FOR EXHIBITION (*A Constant Subscriber*).—The food generally used for fattening these birds is tallow-chandler's greaves, and oat and barley-meal. The great weights read of are the result of long feeding, and he who wishes to show Ducks weighing from 8 lbs. to 9 lbs. must always have that object in view, and never allow them to fall off in condition. In order to keep the bills pale, they must never go into pond-water. Small pebbles, called "grit" in familiar language, must be put in the water they have for drink and food; and they may be allowed on cold mornings, when the white frost is on the grass, to go out in search of food.

ROUEN DRAKE (*Old Subscriber*).—The colour of a Rouen drake's bill should be exactly that of a wild Mallard. It is neither orange nor olive; the former is too bright, the latter too green. It should be a sort of yellow, washed over with a very pale green. There is more latitude allowed in bills of drakes than ducks; but if not a disqualification, an orange bill must be a disadvantage.

FOREIGN SONG BIRDS (*W. A.*).—You will probably find the information you require in "Bechstein's Song Birds."

LONDON MARKETS.—SEPTEMBER 1.

POULTRY.

The trade at Leadenhall is fast sinking to the low ebb of September; and if we have not to chronicle a glut, it is because the unusual demand has thinned the yards as fast as their denizens were fit for market. Grouse remain scarce, and we see nothing to alter our opinion that it is a very bad year for them.

Large Fowls .....	3 0 to 3 6	Ducks .....	2 0 to 2 6
Smaller do .....	2 0 ,, 2 6	Hares .....	0 0 ,, 0 0

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-five years, the average highest and lowest temperatures of these days are 68° and 46° respectively. The greatest heat, 86°, occurred on the 12th, in 1858; and the lowest cold, 25°, on the 11th and 12th, in 1860. During the period 137 days were fine, and on 168 rain fell.
