Messrs. DOBBIE & CO., Rothesay, N.B., and Orpington, Kent, made a grand exhibit of cut Dahlias, of Cactus and Pompon varieties; also a splendid lot of Gaillardias in much variety, Sweet Peas, Marigolds, their Wallflower-coloured Violas, early Chrysanthemums; also their new Tomato Cherry Ripe, recently certificated as a good flavoured one for dessert. The fruits are small, and generally are produced in clusters of thirteen (Small Gold Medal).

Mr. H. DEVERILL, Banbury, put up a fine exhibit of hardy herbaceous flowers, including excellent Phloxes, Gladioli, &c. (Silver-gilt Medal).

Mr. ALBERT MYERS, Sutton Lane Nurseries, Shrewsbury, had a large exhibit of greenhouse plants (Silver Medal).

Messrs. DICKSONS, Ltd., Chester, had a first-class group of cut flowers, Gladioli, *Lilium auratum*, herbaceous Phloxes, &c.; also very good floral designs, a few choice stove plants, and flower and leaves in a tank of hybrid Nymphaeas (Small Gold Medal).

Dahlias and Begonias, the former as cut flowers, and the latter as plants, were staged by Mr. B. R. DAVIS, Yeovil (Silver Medal).

Messrs. SUTTON & SONS, Reading, were awarded a large Gold Medal for a very large exhibit of flowers and vegetables. The vegetables were the more remarkable; Onions especially

were capital, and so were Tender-and-True and other Beans, and out-of-door grown Tomatoes. Then there were Gloxinias, Begonias, Achimenes, and Carnations, all showing the firm's excellent strains in these specialties.

Mr. JNO. WATKINS, Pomona Farm, Hereford, had a large exhibit of Apples, Plums, Pears, Peaches, &c., a very nice exhibit of well-coloured fruits (Silver Medal).

The best exhibit of Apples in the show was from Messrs Geo. BUNYARD & Co., Midstone. The collection was not large, but included fairly varieties of Apples, Pears, Peaches, Nectarines, &c. A new early Pear (American), named *Potée Marguerite*, promises to become a useful variety for market and other purposes (Gold Medal).

Messrs. S. SPOONER & SON, Hounslow, Middlesex, also made a fine exhibit of Apples, including about fifty dishes (Silver Medal).

Mr. ED. MICHELL, Portland Nurseries, Shrewsbury, had a large exhibit of Roses in pots, and as cut blooms, the exhibit being very gay and beautiful (Small Gold Medal).

Messrs. JONES & SONS, Shrewsbury, showed Sweet Peas.

A magnificent exhibit was made by Messrs. E. WERN & SONS, Worlesley, Stourbridge. This was composed of Gladioli, tuberous Begonias, hardy herbaceous flowers, and a collection of vegetables. Tomatoes in the most popular varieties were shown as plants (Small Gold Medal).

Messrs. PRITCHARD & SONS, Shrewsbury, showed a group of Ferns in pots embracing much variety, also plants of *Acalypha hispida*, &c.; cut flowers arranged in silver-coloured artistic receptacles.

Messrs. T. S. WARE, Ltd., Hale Farm Nurseries, Tottenham showed a group of tuberous-rooted Begonias, that was quite a reminiscence of the Temple Show. It was a first-rate group and many of the varieties were remarkable (Small Gold Medal).

Messrs. J. HILL & SON, Lower Edmonton, London, made a very large exhibit of Ferns in pots, most of them of large size and representative of choice varieties (Large Gold Medal).

Caladiums came from Messrs. J. PEEN & SONS, Roupell Park Nurseries, Norwood Road, London, who had a fine group (Large Gold Medal).

Messrs. WM. CLIDMAN & SON, Altrincham and Manchester, showed a group of Celosias in pots; and a most commendable group of Codiaeums in small pots, in very numerous varieties, including a noticeable one named *Frank Taylor* (Silver Medal).

Messrs. W. CUTRUSH & SONS, Highgate, London, N., had a collection of Ivies (Small Gold Medal).

Mr. JOHN FORBES, Hawick, showed hardy flowers, including a number of Carnations (Silver-gilt Medal).

Mr. JOHN GREEN, Norfolk Nurseries, Dereham, showed Cactus, Dahlia, Gloxinia blooms, &c. (Silver-gilt Medal).

Mr. H. PATTISON, Shrewsbury, was awarded a Silver Medal for an exhibit of Violas and Pansies.

Messrs. W. & J. BIRKENHEAD, Sale, Manchester, had a very fine group of Ferns. The "filices" were not represented, but there were British, greenhouse, and stove species (Silver-gilt Medal).

Mr. S. MORTIMER, Rowledge Nursery, Farnham, was awarded a Small Gold Medal for collection of first rate Dahlias, fancy, show and Cactus varieties.

Messrs. R. HARTLAND & SON, Cork, also showed a collection of Dahlias (Small Gold Medal).

Messrs. R. SMITH & CO., Worcester, were awarded a Small Gold Medal for a group of Bamboos, Liliums, and hardy flowers generally, in pots and arranged on the grass in the open.

Mr. H. ECKFORD, Wem, Salop, showed a fine collection of Sweet Peas (Gold Medal).

Messrs. JARMAN & CO., Chard, were awarded a Silver Medal for Dahlias.

LOCHMABEN HORTICULTURAL.

AUGUST 19.—The annual flower-show in the burgh of Lochmaben, Dumfriesshire (the pretty town called by Burns, from its surroundings, "Marjorie o' the moony lochs"), was a very successful one, and was largely attended.

In the gardeners' class there was a creditable show of flowers, Roses being particularly good. The cottagers' department was well filled, and the judges expressed the opinion that the Stocks and Phloxes could not be excelled. The show of fruit was limited, though there were good classes of Gooseberries, but the quality was excellent. There was a good display of vegetables and field produce. In addition to the exhibits shown for competition, two large tables of plants were on view from Sir ROBERT JARDINE, Bart., Castlemilk (gr. Mr. King); Messrs. T. KENNEDY & CO., Dumfries, sent a stand of Dahlias and other blooms; and Messrs. J. PALMER & SON, Annan, exhibited a collection of Roses.

Mr. G. URQUHART, Halleaths, carried off the majority of the prizes for pot flowers in the gardeners' department, obtaining 1st and 2nd for greenhouse plants, table plants, and Fuchsias, and 1st for Begonias, zonal Pelargoniums, Colons, and Liliums. He was also very successful with cut flowers, fruit, and vegetables. Mr. D. WHITELAW, Lochbarbriggs; Mr. EWEN CAMERON, Ericstane; and Mr. W. RICHARDSON, Preston House, were chief among the other winners in this department.

Obituary.

FRANK RIVERS.—It is by this name, rather than by his more correct appellation of T. Francis Rivers, that this gentleman was best known to his associates. By them the news of his death at

Sawbridgeworth, on the 17th inst., in his sixty-ninth year, will be received with deep regret. He is the second of the Victorian Medallists to be taken from us, and was certainly not the least distinguished of that select body. The first Hogg Medal was also appropriately awarded to him, and the trustees of the Veitch Memorial also acknowledged his services to horticulture. The appreciation in which the deceased gentleman was held was in a measure, but not quite justly, overshadowed by the greater reputation of his venerated father. Now they lie side by side in the quiet, peaceful churchyard at Sawbridgeworth, where, it may be, few beyond relatives will visit their graves. But their record is not that of the mortuary, but that of workers who have done good in the world, and left it richer than they found it.

Francis Rivers was not so much the head of a great and distinguished nursery firm as a genial, honourable, retiring country-gentleman, well-read, and one who had assimilated what he read. Moreover, he did much experimental work, for which his father, perhaps unavoidably got the credit. Indeed, he was the assistant and helper of his father in many of his experiments; but "Thomas Rivers, of Bonk's Hill, Sawbridgeworth," died, as the simple record on his grave-stone shows, "on October 17, 1877, aged 79 years," and the business had indeed been under the management of the son since 1872.

For twenty-seven years, then, the younger Rivers has not only followed in his father's steps, but effected much independent work, and we have but to take up a good fruit catalogue to see how great an advance has been made in the time by him. His chief aim seems to have been to prolong the season of fruits, either by securing early varieties, or by lengthening the period by the evolution of late varieties. Apricots, Cherries, Nectarines (that called "Early Rivers" ripening three weeks before "Lord Napier"), Peaches, and especially Plums and Nectarines, may be cited in illustration of these facts.

Mr. Rivers issued numerous editions of his father's excellent Manuals, and it was hoped that some of his experiences might have been laid before the Hybridisation Conference, but the cruel disease from which he ultimately died prevented the realisation of that project. He served on the Council of the Royal Horticultural Society, and was always to the fore in pomological matters, doing much to stimulate the extension and improvement of fruit culture. He gained the confidence of the public not only by what he said, but by the disinterestedness and straightforwardness which he manifested. His portrait was given in our number for July 15. His funeral took place at Sawbridgeworth on the 21st inst. Messrs. W. Paul, G. Paul, M. Hogg, and Dr. Masters, were among the horticulturists present.

We add a list of a few of the principal seedlings raised by T. Francis Rivers:—

PEARS.	
Conference	Parrot
Dr. Hogg	Red October
Magnate	St. Edmund
Marquis	St. Luke
APPLES.	
Thomas Rivers	St. Martin's
Early Rivers	Prince Edward
Rivers' Early Peach	
NECTARINES.	
Early Rivers, Cardinal. He also was really the one to send out Lord Napier, and many others.	
PEACHES.	
He has not sent out many of these, but there are several of great excellence raised by him not yet in commerce, which extend the season during which Peaches may be enjoyed:—Thomas Rivers, a very large and late Peach (First-class Certificate, R.H.S.); Duchess of York, Duke of York, Prince Edward, three Peaches of which he thought very highly—they are very early, and of excellent flavour and colour.	

PLUMS.	
Mallard	Late Transparent
Monarch	Bittern
Stint	Heron
Late Orange	Swan
Blue Rock	Primate
Golden Transparent	Admiral
The last-named received an Award of Merit R.H.S., 1898, a very late and valuable Plum	

R. WILLIAMS.—Many of our readers will learn with regret of the death of Mr. R. Williams, head gardener at Sulby Hall, Northamptonshire, which took place on Thursday, August 17. The deceased had been head gardener to the late Lady Elizabeth Villiers for the long period of thirty-eight years. He began his gardening career at Chatsworth, going thence to Moor Park, then under the care of the late Mr. Sparrow, where he stayed four years. He next obtained a situation in the gardens at Hatfield House, going subsequently to the nurseries of Messrs. Veitch & Sons, Chelsea, by whom he was sent to Sulby Hall.

THE WEATHER.

[The term "accumulated temperature indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DISTRICTS.	TEMPERATURE.					RAINFALL.			BRIGHT SUN.	
	Above (+) or below (−) the Mean for the week ending August 19.	ACCUMULATED.				More (+) or less (−) than Mean for the Week.	No. of Rainy Days since January 1, 1899.	Total Fall since Jan. 1, 1899.	Percentage of possible Duration for the Week.	Percentage of possible Duration since Jan. 1, 1899.
		Above 42° for the Week.	Below 42° or the Week.	Above 42°, difference from Mean since January 1, 1899.	Below 42°, difference from Mean since January 1, 1899.

*	5 +	173	0	+ 616	67	6	99	15.8	78	54

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing District:—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London. Principal Grazing, &c., Districts:—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending August 19, is furnished from the Meteorological Office:—

"The weather was again generally fine over the greater part of England and the more southern parts of Ireland, the only exception being on Tuesday, when sharp thunderstorms were experienced in many parts of southern, central, and eastern England. Over 'Scotland, N. and W.,' 'Ireland, N.,' and 'England, N.W.,' the conditions were much less fair, rain being somewhat frequent, and thunderstorms occurring in 'Scotland, N.' on Tuesday.

"The temperature was again above the mean, the excess ranging from 1° in 'Scotland, E.' and 'England, N.E.,' to 4° in the 'Midland Counties' and over Ireland, and to 5° in 'England, S. and S.W.' and the 'Channel Islands.' The highest of the maxima were registered on the 13th in 'England, W. and N.W.,' but mostly on the 15th elsewhere; they ranged from 89° in 'England, S. and E.,' and 88° in 'England, S.W.,' to 78° in 'Scotland, W.' and the 'Channel Islands.' The lowest of the minima, which occurred on rather irregular dates, varied from 33° in 'Scotland, N.' (at Wick, on the 19th), and 40° in 'Scotland, E.,' to 49° in 'England, N.W.,' 53° in 'England, S.,' and 57° in the 'Channel Islands.'

"The rainfall was less than the mean in all districts, although the fall accompanying the thunderstorm on Tuesday was very heavy in places. No rain whatever was recorded at any of the stations in England or the 'Channel Islands.'

"The bright sunshine was again much above the mean in most parts of the Kingdom, but slightly below it in 'England, E.' and 'Scotland, W.,' and just equal to the normal in 'England, N.E.' The percentage of the possible duration ranged from 78 in the 'Channel Islands,' 75 in 'England S.W.,' and 64 in 'England, S.,' to 37 in 'Scotland, N.,' and 31 in 'Scotland, W.' and 'England, N.E.'"

MARKETS.

COVENT GARDEN, AUGUST 24.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

s. d. s. d.	s. d. s. d.
Adiantums, p. doz. 5 0-7 0	Foliage plants, var., each 1 0-5 0

— good, cwt. bags 3 0-3 6	Peas, blue, per bushel 5 0-6 0
Cauliflowers, dozen 1 9-2 0	Potatoes, Hebrons, Snowdrops, &c. per ton 60 0-80 0
Celery, new, per bundle 1 6 —	Radishes, round, breakfast, per dozen bunches 1 6 —
Cress, per dozen punnets 1 6 —	Salad, small, punnets, per dozen 1 3 —
Cucumbers, doz. 1 6-3 0	— Shallots, per sieve 1 6 —
— ridge in pots 2 0 —	Spinach, New Zealand, per peck 0 9 —
Endive, new French, per dozen 1 6 —	— sieves 1 6 —
Garlic, new, per lb. 0 2 —	Tomatoes, new English, per lb. 0 3-0 2½
Horseradish, English, bundle 2 6-3 0	— Channel Islands, p. lb. 0 2-0 2½
— foreign, per bundle 2 0-2 6	— French, in sieve 1 6-2 0
Leeks, new, per doz. bunches 2 0 —	— boxes 1 6-2 0
Lettuce, English, Cabbage, dozen 1 6-2 0	Turnips, dozen 5 0 —
Lettuce, Cos, doz. 2 6 —	— cwt. bags 3 6 —
Marrows, Veg., doz. 0 9-1 0	Watercress, p. doz. bunches 0 4-0 6
— tatty 3 0-4 0	
— in pads or pott. 1 6 —	

POTATOES.—Hebron, Puritan, Snowdrop, Up-to-Date, &c., Cos. to 90s. John Bath, 32 & 34, Wellington Street, Covent Garden.

REMARKS.—There is now in Covent Garden Market, Maize or Indian Corn, from Jersey, selling from 1s. to 1s. 3d. per dozen, according to the size of the Cobs; this is for use as a green vegetable. Some Cos Lettuce and Cabbages, both very good, coming from Cheshire; Runner Beans are short in supply, and prices have advanced; Apples are plentiful in supply, and trade is very slow with them; the Plums quoted are all home-grown.

(Remainder of Markets carried forward to p. viii.)

ENQUIRIES.

THUNDER AND LIGHTNING.—I shall be greatly obliged if some reader will favour me with the title of some modern work dealing with the origin of thunderstorms, and the cause and effect of lightning. W. S. T.

BOWLING GREEN.—Will you kindly furnish particulars of a Lancashire bowling-green. Bowler.

A DESERTED WIFE: Antrim. We are sorry we cannot help you to find your husband, even though he did obtain a situation through an advertisement in our advertising columns. Communicate with the police.

CAMPANULA ISOPHYLLA DISEASE: Left at Office, Wellington Street. The leaves are attacked by a species of *Aecidium* (rust fungus). Sulphide of potassium at the rate of half an ounce in a gallon of water, applied with a syringe, will destroy it. Burn the affected leaves.

CATTLEYA GASKELLIANA BLOOMS: W. R. Yes, we do think them fine blooms of a good variety.

CORRECTION.—"The late Rose season," in our last issue. "Wild Rose" desires us to state that Messrs. Harkness & Sons' Nursery is at Hitchin, not at Ledbury.

DENDROBIUM: Veritas. We assume that your *Dendrobium Hildebrandi* is making a second growth, and under the circumstances you had better place it in a warm, moist house, and endeavour to make up the pseudo-bulbs sufficiently to allow of the usual cool, dry rest in winter being safely adopted.

DRYAS OCTOPETALA: Dryas. The plants succeed in well-drained, rich loam, on a rockery. If the loam or natural soil is retentive and close in texture, some peat and sand should be added. To propagate this and others of the genus, divide the roots in the spring.

FERNS AS FOLIAGE PLANTS: W. B. If there is nothing in the schedule to the contrary, you might stage a Fern among foliage plants. At the same time it is customary to exhibit Ferns by themselves. We recommend you to obey the ruling of the committee whatever it be, and to get the rule altered next year if necessary.

GRAPE: B. & Sons. In the absence of leaves and wood, we should take the variety to be Golden Hamburgh.

"HARDY HERBACEOUS FLOWERS": M. The wording of the schedule certainly does not exclude bulbs. If the committee wished to exclude bulbous plants, they should have said so. Bulbs like *Lilium auratum*, with deciduous leaves, are undoubtedly herbaceous plants, although in catalogues and books they are usually placed by themselves. The best guide to follow is the "Rules for Judging," issued by the Royal Horticultural Society, but these require frequent revision. In your case the committee, according to section 10 of the Regulations, should have acted as the court of final appeal, and their judgment, right or wrong, should be loyally accepted by exhibitors, at the time, but note taken for future guidance.

Kew: A Reader. You should have applied to the Director, and not to us. You must do that now, stating the length of time you have worked in a garden, where it is, &c., and send copies of such testimonials as you possess. You may have to wait some considerable time before a vacancy occurs, even if you are considered eligible.

KITCHEN GARDENS: An Old Cabbage Grower. You have sent us a document similar to some made use of in the Dreyfus trial; but in spite of the disguise, we take it more in the spirit than in the letter, and will attend to your hint, for which we are obliged, but we should like to know the precise grievance.

MOTH: A. Bott. The insect is the humming-bird Hawkmoth (*Macroglossa stellatarum*); a local species.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—E. T. The correct botanical name is *Leucophyta Brownii*, syn. *Calocephalus Brownii*. It is mentioned in the supplement to Nicholson's *Dictionary of Gardening*, p. 503, under the latter name.—Samuel McGredy. *Delphinium denudatum*.—W. B. 1, *Abies balsamea*; 2, *Arundo Phragmites*.—C. L. W. *Sciadopitys verticillata*; not very unusual.—P. Bicknell. *Nostoc commune*; an Alga which springs up suddenly in such situations as you describe.—J. T. *Pteris crenata*; not hardy.—A. B. Brothers. *Campanula pulla*, *Sedum populifolium*.—H. F. *Epidendrum variegatum*.—Kentish. 1, *Bocconia cordata*; 2, *Indigofera Dosua*; 3, *Olearia Haasti*; 4, *Phygelis capensis*; 5, *Abelia triflora*; 6, *Spiraea callosa*.—A. W. S. *Thymus Serpyllum*. It is not very objectionable, but a dressing of manure will probably destroy it.

NOTICE TO QUIT EMPLOYMENT: Constant Reader. The gardener being at law a domestic servant, is entitled to and must also give a month's notice in the absence of a written agreement. He may, for wilful misconduct, be discharged by his employer without any notice being given him.

PHYSALIS FRANCHETI: Physalis. This is very like *P. Alkekengi* (Winter Cherry, &c.), the fruits of which are eaten as dessert in Arabia, Germany, and other countries. They are slightly acid, but not bitter, as described in your note; but perhaps a liking for them has to be acquired. In this country, *P. Alkekengi* and *P. Francheti* are grown merely for ornament.

SEEDLESS GRAPES: J. B. We are unable to inform you of the exact cause of the imperfect fertilisation of *Gros Guillaume* and *Alnwick Seedling*. The first is always uncertain as to fruiting, some plants showing abundantly, others not at all; and the same applies to the setting of the flowers. Barron, in his book, *Vines and Vine Culture*, says that this variety does best on the long-rod system of pruning. It should be afforded as much heat as the Muscat of Alexandria; it would therefore not be suited in a vinery afforded cooler treatment. *Alnwick Seedling* is a notoriously shy setter, needing at flowering time a temperature of 70°. We should advise the use in the future of the pollen of other varieties conveyed to the bunches on a feather or camel's-hair pencil, and the maintenance of a temperature of 70° at that season.

SHADING: S. B. Mix sour milk with the whiting; or, failing that, use a very thin solution of glue instead.

TOMATO DISEASE: Grower. Do growers never read about what concerns their business? The fruit is affected with black-spot, repeatedly figured and described in our columns. The affected plants should be burnt, and the rest sprayed with Bordeaux Mixture.

WHOLESALE SEEDSMEN IN GREAT BRITAIN: C. J. Jones, Ruthven, Ontario. You might obtain the *Horticultural Directory*, price 1s., exclusive of postage, published at 12, Mitre Court Chambers, Fleet Street, London, E.C.; and likewise communicate with Mr. Bryan Wynne, No. 1, Dane's Inn, Strand, London, W.C., who publishes an exclusively advertising periodical.

WHO SHALL PAY THE GARDENERS' WAGES IN THE ABSENCE OF THE HEAD GARDENER? Interested. We should suppose that the general foreman should pay the men, he being usually considered the next in authority to the head gardener.

WILLOW, MONSTROUS: C. C. The "Rose Willow," in which the leaves are aggregated into tufts. This is the work of a fly, *Cecidomyia* (see Masters's *Vegetable Teratology*, p. 168). We did not receive the caterpillar.

COMMUNICATIONS RECEIVED.—G. Tourret Grignan (next week).—A. O'N.—Expert.—R. D.—A. C. F.—J. E.—H. H. T.—A. H.—J. W. McH.—G. G. M.—A. Dickson & Sons.—Too-good & Sons.—R. W.—H. F.—A. J.—G. R. F.—E. J. A.—T. A. H. R.—H. J. W. Lincoln, Nebraska.—R. C. B.—H. T. M.

THE

Gardeners' Chronicle

No. 662.—SATURDAY, SEPT. 2, 1899.

CARTON GARDENS.

CARTON is near Maynooth, and about ten miles from the city of Dublin, and belongs to His Grace the Duke of Leinster. One of the most pleasant ways of reaching Carton is to ride through the Phoenix Park, with its fine trees, and groves of gnarled old Hawthorns, and herds of fallow deer; and then leaving the Knockmaroon-gate to pass The Rag Well, at Wilsontown, and bear away to the right towards what is locally known as the Rugged Lodge, a quaint, Ivy-covered entrance to Woodlands, or as it is now more generally called Luttrellstown. This is a picturesque domain, with a large lake, and a turretted house draped with Ivy, now the residence of the Hon. Mrs. Barton, formerly of Straffan. There is a good garden here, and extensive fruit and plant-houses, and charming dells and woodland walks in the vicinity. The lake is naturally undulated and river-like, its margins covered with the large white Water-Lily, and it is moreover alive with fish and water-fowl. The views both ways from the bridge which crosses this extensive piece of water are most varied and enjoyable.

Leaving Luttrellstown by a side-gate, you pass through corn-fields, and along delightful country roads for 3 or 4 miles, until Carton is reached. The hedges are here and there aglow with the bright berries of the Water-Elder, the Wayfaring-tree (*Viburnum Opulus*), and with fragrant masses of Honeysuckle, the ditches here and there being filled with the white plumes of the Meadow-Sweet; while the profusion of green hips on the arching branches of the Wild Roses show how profusely they have bloomed.

It is a gloriously hot day in August, with fleecy clouds in the blue overhead, the cattle knee-deep in the pools, and the golden cornlands yellow in the sun. Now and then a robin sings its earliest song, or a yellow-hammer sounds its melancholy notes; or a wood-quost oos in the Pine trees; or the rattle of a mowing-machine comes from a sloping Wheat-field far away on the side of the hill.

We are now at Carton, and enter one of the back-lodges, and skim down the smooth drive, startling alike rabbits and pheasants that lie on the green turf in the hot sun. Through plantations of Box and Larch, and past the end of the lower lake, by the rocky banks, and the lake, and we are at Carton itself, with its noble grey mansion, flanked by Cedars and Irish Yews. It is fronted by rolling scenery and fine timber, while the enclosed flower-garden, sheltered by low Yew-hedges, is bright with hardy flowers. Hot and dusty, we glide round the great house, past a picturesque group of harvesters at luncheon under the trees, and reach the gardener's house, to find Mr. Black awaiting us with a hearty welcome. Both Mr. and Miss Black insist on

carrying out the traditions of a Scottish welcome, and then we are allowed to see the gardens and the flowers. Carton is an extensive place, and it is by no means easy to do justice by mere words to its many phases of beauty. The timber here is very fine, especially Beech, Ash, Lime, Chestnut, and Oak; and the Conifers are healthy and well-grown. Cedars perhaps predominate; but Scots Fir, Larch, Yew, and Silver Fir are all remarkable. There are some fine Yew-trees at the cottage grounds, and the largest Yew-tree in Ireland is on the estate at Maynooth, a mile or two away, its trunk at 3 feet from the ground being over 20 feet in circumference.

There is a very large lake here made many years ago by damming up the little Ryewater river, and its islands and banks being well planted with golden and red osiers, Dog-wood, Birch, Alder, Golden Elder and White Willow, there is an agreeable change of aspect and of colour all the year round. This lake is haunted by wild fowl of all kinds, especially during winter, the wild duck being extremely numerous.

A pretty little building or tea house, known as the "Queen's Cottage," stands on the bank of this lake on the opposite side to the great house, and there a charming enclosed garden, filled with Roses, Clematis, and Honeysuckles in variety. H.M. Queen Victoria visited Carton in 1848 or 1849, and took tea here—hence its name, and she sat in the ancient old carved Oak "wishing-chair," which originally stood in the hall of the old Geraldine fortress or castle at Maynooth. A fine head, with antlers, of the now extinct Irish elk is preserved over the large open fireplace in the cottage kitchen, while the sitting-room is decorated with shells, and contains some life-sized Chinese figures in native costume.

On the sloping banks near the cottage are some noble Beech-trees, and a fine *Quercus alba*, and on the lower grounds some fine Coniferæ. The lake on the other side is fringed by a high rocky bank, and is planted with *Hypericum olympicum*, *Helleborus*, *Narcissus*, *Colchicum*, *Dianthus*, dwarf *Periwinkle*, and many other hardy flowers and shrubs.

At the lower end of "the rocks" is a charming little marsh or bog-garden, through which a stream of limpid water runs from the "Violet well," and this garden has been tastefully planted with marsh-loving vegetation. In the little stream the "Water Hawthorn," or "Cape Pond-weed" (*Aponogeton distachyon*) attains a size and vigour I never saw before.

Leaving the lower garden and lower lake, here spanned by a bridge of grey limestone, on which the Scale Fern (*Ceterach officinarum*) grows, the house and garden may be reached by ascending the hill and passing upwards to "Cromwell's Tower," a square tower on the highest part of the home park, from the top of which it is said that Cromwell watched the troops in the plain below.

Lying between the mansion and the kitchen and fruit garden is a long and undulating piece of water, now devoted to Water Lilies of all kinds. *Nymphaea alba* is here by the hundred, its numerous star-like flowers resembling a Milky-way in June and July; but now, in August, we found M. Latour-Marliac's seedlings in full beauty. *N. Marliacea rosacea* (rose), *N. M. carnea* (flesh), *N. M. chromatella* (yellow), *N. odorata rubra* (deep rose), *N. Leydekeri purpurea*, and others, were blooming very freely in the hot sunshine. Mr. Black has here also the dainty sweet-scented blue *Nymphaea stellata*, flowering well in the open

air unheated water; and this is, so far as I know, the first time this Lily has succeeded in cold water without some added shelter or heat at the beginning of the season. Both here and in the lower lake the Arum Lilies (*Richardia æthiopica*) grow and flower quite freely.

One of the most striking and attractive of all the more modern features at Carton is the great pergola, erected by the late Duchess Hermione just before her death in 1894. Two low walls, having square brick piers at intervals in the total length of about 100 yards; the piers support oaken beams or cross pieces, and these again support other rustic oaken beams, so as to form an open flat roof. The floor is 9 to 10 feet wide, and is paved with bricks on edge, narrow borders being left on either side for flowering plants; and there are oaken seats at intervals on either side for repose. Outside this pergola is planted with Roses, Clematis, Spiræa, and Honeysuckles, in variety, for draping the pillars and overhead; while on the low outer walls sweet-scented shrubs and plants have found a congenial home, such as Rosemary (for remembrance), Lavender, Verbena, Musk, and Mignonette, Marjoram, and scented golden Thyme. So far as I know, there is nothing like this noble pergola out of Italy, and it will form a fitting and appropriate memorial of the Duchess Hermione in years to come. It is really a great open air conservatory, a cloistered retreat full of beauty and sweetness, a shrine sacred to the children, to the flowers, and to the birds.

The so-called kitchen-garden at Carton is enclosed by the fruit-walls, but all the borders on the main walks are so full of annuals and herbaceous plants or florists' flowers, that the vegetable quarters must be sought for if they are to be seen, so shut in and hidden are they behind the floral ramparts! Even the Vine and Peach-house borders outside are gay with Phloxes and Petunias, Sweet Pea and Zinnias, or Mignonette. The fruit-houses within are well stocked, and Vines, Peaches, Nectarines, and Figs are all heavily—not too heavily—cropped, and the produce is fine in both size and quality. In one of the houses I noted a healthy young Shaddock or Pomelo in fruit, and the Muscat of Alexandria Grapes were taking on that rich amber hue so dear to the sight of the connoisseur, but not always so easy to secure. The plant-houses are gay with *Lapageria*, *Begonia*, or *Stephanotis*, and the now rarely seen ally of the last-named, viz., *Schubertia grandiflora*, bore many clusters of its great ivory-white, Cocoa-nut scented flowers. The bright, rosy, dense masses of flower on *Begonia President Carnot*, were larger and richer than we had ever seen them before.

The Orchids were growing freely—so luxuriantly indeed, that they will soon require more extended quarters; and in the Orchid-house were also noted remarkable examples of two of the best of all the Nephentes, viz., *N. Mastersiana* and *N. mixta*. Both basal and cauline pitcher on *N. Mastersiana* were the largest and most highly-coloured I ever saw, and Mr. Black may well feel proud of them.

One charm about the garden at Carton is, that amid all the beauty of vegetation, there is room and a welcome for things interesting rather than merely showy. Many a rare alpine nestles in the rock-edgings, or under the lee of a selected boulder. The Calvary Clover is here with its spirally-twisted pods, that look, when ripe, like little hedgehogs!

Here also is the rare and beautiful *Orobancha speciosa*, a parasite readily grown by sowing its

seeds along with those of the Broad or Windsor Bean, either in large pots, or in the open ground. This seems to be the best and most showy of all the Broom-Rapes, having close-set spikes of white-purple blotched flowers, each spike being 12 to 16 inches in height.

I have had the privilege of seeing Carton and its gardens at all times and seasons, and it is always beautiful. In winter, when thousands of wild duck flutter and swirl in clouds around the lakes, and a gleam of sunshine illuminates the golden osiers and dead reeds, and gives a touch of crimson to the Cardinal Willows and the Dogwood; in spring, when Daffodils nod and flutter on the grassy slopes, or when great crimson Tulips sway and flutter in the May sunshine. Then there is a regal splendour in the time of Roses, and when Delphiniums shine forth in every shade of blue.

Now the annuals make a glorious show, the Water Lilies jewel the lake margins, and all these will in turn give place to the Torch Lilies and Pampas, to the thousand-and-one lingering blossoms that grace the waning year. *F. W. Burbidge.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA × ATLANTA.

A FLOWER of this fine Veitchian hybrid between *C. Leopoldii* and *C. Warscewiczii* (gigas), sent by Samuel Gratrix, Esq., West Point, Whalley Range, Manchester, while showing a good example of the beauties which the hybridist has developed, also gives a pointed instance of the increasing difficulties of determining positively from a single flower what any of these much-worked crosses may be. The first thought was that it might be an extraordinary form of *Lælio-Cattleya* × *elegans*, but a test of the polliniae showed pure *Cattleya*. Then the section of crosses between *Cattleya Leopoldii* and the different types of *Cattleya labiata* had to be considered, and it appeared to be very close to the natural hybrid *C. × Victoria Regina* (*Leopoldii* × *labiata*), and still nearer, perhaps, to *C. × Fowlerii* (*Leopoldii* × *Hardyana*). The rose-purple markings on the side-lobes of the lip, however, in the flower sent indicate clearly the influence of *C. Warscewiczii*, although the flower sent by Mr. Gratrix is larger than those of *C. × Atlanta* previously seen. The sepals and petals are light rose-purple, with a white median line at the base; the very showy front-lobe of the lip, and the tips of the side-lobes of a bright purplish ruby-red, the exterior of the side-lobes folded over the column bluish-white veined with rose-purple.

FLORISTS' FLOWERS.

THE DAHLIA.

ONE of the earliest notices of the Dahlia is given by Hernandez in his *History of Mexico*, published in the year 1651, who figured and described two species under the name of *Aeocotli*, as, he informs us, it was called by the inhabitants. He found the plants growing spontaneously upon and around the mountains of Quauhnahuac. It is afterwards noticed in 1787 by M. Thierry Menonville, in the history of his journey to Oaxaca, where he was despatched by the French Government upon the perilous mission of stealing the cochineal insect from the Spaniards.

In the year 1790, a plant which had been introduced into the Royal Garden at Madrid the previous year produced blooms, and was described by Professor Cavanilles under the name of *Dahlia sinuata* in his *Icones Plantarum*, published in the early part of 1791. It would seem there were two varieties in Madrid, *D. rosea* and *D. coccinea*. Upon the introduction of the plant to Madrid, the Marchioness of Bute, then temporarily residing

there, procured seeds or roots, and transmitted them to this country, but they were totally lost shortly after their arrival.

In May, 1804, seeds were re-introduced from Madrid by Lady Holland, and during the following autumn several varieties bloomed in the gardens of Holland House, Kensington. From these, M. Buonaparte succeeded in saving several seeds which were liberally distributed. The extension of sorts, however, in this country progressed tardily until the peace of 1814, when numerous importations of sorts were made from France, Germany, and Holland, where the raising and propagating of new varieties had been more successfully pursued, especially by Count Lelieur at Paris, M. Otto at Berlin, and M. Van Eeden at Haarlem. Two persons in this country were among the earliest to attempt the improvement of the flower, viz., Mr. Joseph Wells, gr. to Wm. Wells, Esq., of Redleaf, Kent, and Mr. David Douglas, gr. to Lady Grantham, of Putney Hill; and it is stated that the former raised the first double dwarf Dahlia. The most decided advance considered to have been made in those days was when Mr. Geo. Lynes, a gardener at Springfield, Surrey, in 1832, obtained that universally-admired flower, *Springfield Rival*.

At the time of the publication of the *Annual Dahlia Register*, in 1836, the production of new varieties had increased enormously, and exhibitions of Dahlias were held in many parts of the country. There were so many raisers of new varieties that it would seem invidious to particularise; however, mention may be made of Harris, of Upwey; Brown, of Slough; Wheeler, of Warminster, Leick, of Sheffield; Cox, Widnall, and others. The veteran Dodds, still living, was just commencing as a raiser, and high prices for new varieties ruled. To these, a generation after, succeeded Drummond, of Bath; Holmes, of Norwich; Bush, of Bath; Turner, of Slough; Rawlings, of Bethnal Green; Burgess, of Salt Hill; Keynes, of Salisbury; Fellowes, of Shottesham. It was the last of these, with Turner, Keynes, and Harris, of Orpington, who brought the succession of raising down to our day.

The fancy type of Dahlia originated with Count Lelieur, of Paris, who obtained from seed some striped and shaded single flowers; and from these were developed the present race of fancy Dahlias. In the early fifties, the lists of this type contained a goodly number raised abroad; but it is mainly to Keynes, of Salisbury, we owe the fine show flowers which are now grown and exhibited in this country.

The Pompon, Liliputian, or Bouquet Dahlias originated with Hartweg, of Karlsruhe, through his obtaining a double form from the single Dahlia *coccinea*. This type was greatly favoured by the Germans, who kept the cultivation and raising of new varieties pretty much in their own hands, for they were not offered in English catalogues until thirty years or so ago. The varieties of ten years earlier were of very tall growth; but Turner, Keynes, Cheal, West, Seale, and others, have so improved the type, that the plants are now dwarf and bushy, and exceedingly floriferous, and invaluable for garden decoration.

It was the late Mr. W. H. Cullingford who introduced the Mexican Dahlia, *Juarezii*, to this country about 1874. It was originally received from Mexico by M. J. T. Vander Burg of Utrecht; and among a number of subjects contained in a box, many of which were destroyed by reason of delay, was seed, or a tuber, which eventually produced *D. Juarezii*. Mr. Cullingford supplied Mr. Henry Cannell of Swanley with plants, who exhibited it for the first time in 1880; and though shunned at the onset by the admirers of the large show-types, it yet caught on, and was the means of bringing into temporary cultivation under the term of Cactus Dahlias a number of varieties of poor value. Happily the true Cactus type has been preserved and greatly developed, and at the present time there are in cultivation a considerable number showing great variation in colour and form, as well as much

amendment in habit of growth and freedom of bloom as compared with the earlier sorts. Bunches of Cactus Dahlias are now a leading and imposing feature at our Dahlia exhibitions. The work of improvement is largely the outcome of the labours of Messrs. Cannell, Keynes, Cheal, Burrell, Stredwick, West, Mortimer, Ware, and others.

The single Dahlia came to the fore about the year 1880, when Mr. Alfred Salter brought to one of the meetings of the Royal Horticultural Society *D. coccinea*, and at the same time appeared *D. lutea*, and an old variety grown sixty years ago under the name of *Paragon*. Several at once began to raise seedlings, and the varieties increased with great rapidity and were highly popular for a time, but are now much less so than they were a few years ago. The fugitive character of the blossoms unfits them for general decorative purposes. No one has more decisively left his mark as a raiser of new single-flowered forms than the late President of the National Dahlia Society, Mr. T. W. Girdlestone. He was successful in obtaining many beautiful fancy varieties of high quality; and he also originated the very dwarf-growing *Tom Thumb* race, which are approved for bedding purposes.

A single form of the Cactus type has been developed by Mr. E. J. Lowe; and the varieties have been increased by Messrs. Dobbie & Co., Rothesay. That they are more attractive from an artistic point of view than the formal single varieties there can be no doubt, but it can scarcely be said they have as yet attained to any great degree of popularity. *Florist.*

NOTES FROM A SCOTTISH MANSE.

THIS is the season of climbing flowers: the period at which they bloom most luxuriantly, and produce the grandest artistic effects. In many Scottish gardens, I regret to say, they are almost ignored; possibly because their capabilities of floral impressiveness are not adequately realised. Here they are assiduously cultivated, and receive every possible attention. What they chiefly require, especially in their initial stages—what may be called their first attempts at aspiration—is sufficient moisture around the roots and on the foliage during the warm summer months. It may be said, without exaggeration, that water (and especially rain, which has fertilising chemical properties peculiar to itself) is their very life. All of the *Tropæolums* require it in abundance during such tropical weather as we have recently experienced, and especially the extremely graceful *Tropæolum speciosum*, at present festooning a lofty Hawthorn hedge above the south wall of my garden, at a height of 13 feet. This is the brightest climber within the range of my acquaintance; and especially is its luminous beauty apparent, when, planted in such a picturesque situation as I have instinctively assigned it, its radiance is intensified by environing masses of dark or delicate green.

Such, the lover of Nature will observe, are the finely contrasted surroundings of her fairest flowers; and from the arrangements of Nature, so wise and so beneficent, reverential thinkers, to whom she has taught the deep lesson of humility, can learn much. We do not go so often as we should to the waysides or the woodlands for our gardening inspirations. Everywhere around us, in the great garden of Nature, may be heard the vast music and beheld the marvellous evidence of infinite design. For, as Cowper has so beautifully sung:

"Happy who walks with Him! whom, what he finds
Of flavour or of scent in fruit or flower,
Or what he views of beautiful or grand
In Nature, from the broad, majestic oak,
To the green blade that twinkles in the sun.
Prompts with remembrance of a present God!"

Among the climbing flowers that at present make our gardens oriental in aspect, the finest are *Tropæolum speciosum*, already and most inade-

FIG. 4.—PHARUS GUIANEENSIS ALBO-STRIATA.

quately described, for it is of a beauty that transcends all description; *T. canariense*, which, grown amid the dark purple foliage of a *Prunus Pissardi* in the centre of my "earthly Paradise" (as an olden horticultural writer, not yet quite forgotten, expressively entitled his own garden of Eden), has created a striking floral effect; *T. majus*, familiarly known as the Great Nasturtium, here covering old, messy Apple-trees with its wealth of varied bloom; the "Painted Lady," a scarlet and white runner, richly ornamental; and above all the exquisitely tinted and powerfully fragrant Sweet Peas, for the finest of which we are indebted to their great specialist, Mr. Eckford, a native of Midlothian. These I have climbing and flowering luxuriantly wherever they could be planted with any prospect of success. With the exception of the Rose, the Lily, and the Viola, there is no other flower that I cultivate so much.

I am a great lover of old-fashioned flowers, though fond of adding the latest novelties to my collections; and I anticipate much pleasure from a number of very fine perennial Asters (akin to "Michaelmas Daisies") raised mostly in Belgium, and of comparatively recent origin, though they belong to a class of flower which most of us have known from childhood, and which are therefore to memory very dear. Flowering during the months of September and October, they are of great value for late autumnal bloom. Their companions are the Dahlias, and early "garden" Chrysanthemums, whose period of floral productiveness—so long in its duration, and so memorable for its effectiveness—has just begun. Among the former, my supreme favourites are the single, the Cactus, and the decorative varieties, and I think that the last-mentioned, which are now extensively cultivated and universally admired, are the fairest of them all. In them the noblest attributes of all the other classes appear to be combined.

But for the climbing flowers to which I have alluded, our gardens would at present be somewhat lacking in brightness; for this is the intermediate season of the Rose. There are several very precious varieties that seem to flower almost without intermission; conspicuous among these are *Caroline Testout*, *Marie Van Houtte*, *Papa Gontier*, *La France*, *Madame Pernet Ducher*, and *Madame Lambard*. *A. K. Williams* is a splendid autumnal bloomer, but his second reign among the crimson Roses has not yet begun. Some very late varieties of *Duke of Edinburgh* and *Duke of Wellington* are still very conspicuous by reason of their rich colouring of velvety-scarlet and maroon; equally appreciable is an occasional dark specimen of *Sir Rowland Hill*; *Ards Rover*, one of the most recent introductions of the *Dicksons* of Newtownards, whose colour resembles that of the venerable *General Jacqueminot*, seems likely to prove a valuable autumn Rose. Roses at this season, like our old friend, *Mrs. Gamp*, in *Martin Chuzzlewit*, require a good deal of artificial stimulant to bring them into proper form for any kind of exhibition. Under the influence of the terribly exacting sunlight they come very rapidly, and as suddenly collapse. Ere long, when the atmosphere grows cooler, and the beneficent rains descend, they will acquire stronger petals, and last longer in full bloom.

The most fascinating flowers in my garden at present are *Lilium auratum*, *L. longiflorum*, and the exquisite, satiny-crimson *Lobelia cardinalis*, highly eulogised by Sir Archibald Alison, in his *History of Europe*, in an eloquent, incidental passage on the scenery of America. *David R. Williamson*.

PHARUS GUIANEENSIS ALBO-STRIATA.

THIS is a handsome tropical grass, suitable for the adornment of the stove. It has, as the illustration shows (fig. 64), broadly ovate leaves, tapering to each end, and irregularly striped with yellow or cream-coloured stripes. It has been

exhibited by Messrs. Veitch & Sons, of Chelsea, on more than one occasion during the summer. We figure the plant under the name in which it was exhibited. The species of *Pharus* are mostly natives of tropical America.

HORTICULTURAL RECIPES.*

Grafting Wax.—(1) Beeswax, 75; purified resin, 125; turpentine, 36; rape oil, 12; Venice turpentine, 25; zinc white, 25. Colour yellow with turmeric. (2) Japan wax, 100; yellow wax, 300; resin, 800; turpentine, 400; hard paraffin, 100; suet, 300; Venice turpentine, 600.

Fluid Grafting Wax.—(1) Resin, 1250; pitch, 200; linseed oil, 120; turpentine, 50; yellow wax, 130. Melt with a gentle heat, stir continually until cold, and then add methylated spirit, 400 fluid parts. (2) Burgundy pitch, 500, is melted slowly, removed from the fire and mixed with alcohol, 70 to 80. Put up in wide-necked glass bottles, or in tins. (3) Turpentine, resin, 1; methylated spirit, 4.

Manure for Indoor Plants.—(1) Sodium chloride, 10; potassium nitrate, 5; magnesium sulphate, 5; magnesia, 1; sodium phosphate, 2; mixed and bottled. Dissolve a tea-spoonful daily in a litre of water, and water the plants with the solution. (2) Ammonium nitrate, 40; potassium nitrate, 90; ammonium phosphate, 50; 2 gm. is sufficient for a medium-sized flower-pot. (3) Ammonium sulphate, 10; sodium chloride, 10; potassium nitrate, 5; magnesium sulphate, 5; magnesium carbonate, 1; sodium phosphate, 20. A tea-spoonful to a litre of water. (4) Ammonium nitrate, 40; ammonium phosphate, 20; potassium nitrate, 25; ammonium chloride, 5; calcium sulphate, 6; ferrous sulphate, 4. Dissolve 2 gm. in a litre of water, and water the plants with the solution. (5) Potassium nitrate, 20; potassium phosphate, 25; ammonium sulphate, 10; and ammonium nitrate, 35. This mixture produces a luxuriant foliage. If blooms are desired, dispense with the ammonium nitrate.

To Destroy American Blight and other Plant Lice.—The use of carbon disulphide is recommended, the affected places being daubed with a rag tied to the end of a long stick. The application must be repeated every eight days. A simple method is to sprinkle the affected parts with diluted petroleum. No ill effects have, so far been noticed from this treatment. A dilution of 1 litre of petroleum to 4 or 5 litres of water may be used as long as it is continually shaken up. The process of extinction can only be considered complete when every trace of the bluish-white web in which the insects are enveloped has been destroyed. Autumn is the best season for waging the campaign, when the trees are bare; later, in spring, the bluish-white web disappears, and the pests are then scarcely discernible. It is useless to attempt their destruction unless it can be done thoroughly, as the smallest remnant left multiplies to an alarming extent.

Destruction of Phylloxera.—Bordeaux mixture is rapidly prepared as follows:—Water, 90 litres, is put into a wooden or earthenware vessel, and copper sulphate, 2 kilos., dissolved in it; 700 gm. to 1 kilo. of freshly slaked lime is mixed carefully with 10 litres of water. This is gradually added with continual agitation to the copper solution; a turbid blue mixture results, which becomes clear on standing. If still blue, more milk of lime should be added until the solution is quite colourless. Sprinkle the Vine with this solution. The solution destroys the phylloxera, but has no lasting effect, so that the application must be repeated several times during the summer.

Shield Louse Wash.—(1) Calcium sulphide wash is prepared with unslaked lime, 18 kilos.; sulphur, 9 kilos.; salt, 6·75 kilos; mixed as follows:—A fourth part of the lime is slaked and boiled for two to three hours with the sulphur in 22·6 litres of water. The remainder of the lime is then slaked and added with the salt to the hot mixture. The whole is boiled for another half-hour, or an hour, and then diluted to 35·2 litres. The fluid is applied lukewarm when the plants are not in active growth. (2) Sodium sulphide solution, consisting of sulphur, 900 gm.; caustic soda, 675 gm. (or concentrated ammonia solution); and train oil soap, 7·5 kilos. The sulphur and the alkali are boiled in water for one hour, the soap is dissolved in 45·4 litres of boiling water. The solutions are mixed, boiled for half an hour, and diluted to 227 litres of water. Apply while warm. (3) Saponified resin solution, consisting of resin, 9 kilos.; caustic soda, 2·25 kilos.; or concentrated ammonia, 2·25 kilos.; or calcined 93 per cent. soda, 1·575 kilos.; fish or train oil, 1·4 litre. All three substances are put into a kettle, covered with 3 or 4 inches of water, and boiled from one to two hours. The mixture is then diluted with water to resemble strong black coffee. This fluid is diluted with water to 450 litres. Petroleum.—Undiluted petroleum may be used in frosty weather when the insects are not fully developed. The petroleum is painted on with a brush. Delicate Plum or Greengage trees, however, will not stand such an application. Pruning is recommended for these.

Petroleum Emulsion.—Train-oil soap, 2·25 kilos, is dissolved in 4·4 litres of boiling water, petroleum, 2·25 litres, is added, and the mixture diluted to 227 litres with hot water. Wash or spray with the lukewarm solution.

Krueger's Petroleum Emulsion.—Black soap, 250 gm., is dissolved by boiling in 4·5 litres of water, and petroleum, 9 litres, is added when the soap solution is removed from the fire. The fluid is then agitated well for 10 to 15 minutes.

Nessler's Remedies for American Blight.—(1) Soft soap, 40 gm.; amylalcohol, 50 gm.; methylated spirit, 20 gm.; water, 1 litre. (2) Soft soap, 30 gm.; sulphurated potash, 2 gm.; amyl alcohol, 32 gm., to water, 1 litre. (3) Soft soap, 15 gm.; sulphurated potash, 20 gm., to 1 litre of water.

Destruction of Thrips.—Insect powder dusted on the plants answers admirably. (2) A decoction of tobacco stalks, 500 to a paill of water, sprayed over the beds. (3) Decoction of wormwood, and dusting with a mixture of guano, gypsum, and wood-ashes.

Destruction of Slugs and Snails.—Strew plentifully with powdered lime in dry weather and repeat in half an hour.

Destruction of Moles.—(1) Place pieces of fresh raw meat, poisoned with arsenic powder, 1·15 or 1·20, into the hole immediately underneath every heap of earth thrown up by the mole, and cover again carefully without disturbing the passages excavated by the animal. The scent of the bait lures the moles to sure destruction. (2) Insert branches of Elder into the mole runs; this is sure to drive them away. (3) A few bulbs of Garlic steeped in petroleum have the same effect. (4) Hedgehogs are said to drive away moles.

Destruction of Mice.—(1) Soak Wheat thoroughly in an infusion of fresh squill bulbs, 1·5, and dry quickly; this Wheat is only poisonous to rats and mice, and an excellent vermin-killer if the infusion is carefully prepared. (2) A mixture of lard, 500; salicylic acid, 5; one onion; suet, 50-100; barium carbonate, 500; solution of ammonio-acetate of copper, or of verdigris, 50. The Onion is cut up fine and fried with the fats until dark brown. The salicylic acid is then added, and the mixture strained and stirred until the fat nearly sets. The barium is next added, and, finally, the copper solution.

Destruction of Rats.—(1) Precipitated barium carbonate, 100 gm., and tartar emetic, 1 gm., are mixed with baked flower and glycerin in 2 gm. into boluses, which are fried brown in hot fat. (2) Gypsum, 2; oatmeal 750; flavoured with anise oil. (3) Plaster of Paris and sugar, equal parts. The mixture is spread on a plate, and exposed near a vessel of water. (4) Crushed bitter almonds, 60; lard; fresh squill bulbs, equal parts, (5) powdered almonds mixed with arsenic answer well.

Rat Cakes.—A bulb of squill is cut into thin slices, dried and mixed with sugar, flour, and a little salicylic acid. Make into cakes with glycerin and with sugar, and expose them by the side of the water.

Moth and Caterpillar Lime.—Venice turpentine, 200; resin, 1,000; turpentine, 140; tar, 80; lard, 500; rape oil, 240; tallow, 200. (2) Resin, 50; lard, 40; stearine oil, 40. (3) Resin, 3; rape oil, 4; lard, 2; soft soap, 1; wood tar, 10. (4) Resin, 36, rape oil, 36; Venice turpentine, 20; wood tar 5; turpentine, 3 parts. Paint the mixture while warm on strips of paper laid smoothly on the tree-trunk about a yard above the ground. This should be done at the end of October, or the end of November, to prevent the females of the winter moth from climbing up the trees. (5) Instead of above mixture, cart grease may be used. (6) Mix melted resin with crude rape oil to form a mass of sticky consistence.

FOREIGN VEGETABLE PRODUCTS.

(Continued from p. 166.)

BORDEAUX.—*Pine Forests and Forest Fires.*—The Pine forests of the Landes of south-west France cover about 5,000,000 acres, and are apt to take fire in very dry summers. The summer of 1898 being unusually dry, was more than ever prolific in forest fires; and in August and September vast tracts were devastated by fire. On August 21, a fire broke out in the forests a few miles from Bordeaux, in which two persons lost their lives, and timber to the value of £60,000 was burnt. At the same time two other vast tracts of forest were a prey to the flames. The extent burnt by the one was in length about ten miles by about two miles in width, the loss being estimated at £40,000. All the buildings which were in the way of the fire were burnt, and a large number of cattle, sheep, and beasts of burden were destroyed.

Another fire on the same day, which was said to have been caused by lightning, burnt forest to the value of £12,000. All these were in the department of the Gironde, around Bordeaux. At the same time fires were burning the forests in the department of the Landes, one of them alone destroying 50,000 acres. A fortnight later the forest along the Southern Railway between Bordeaux and Arcachon took fire, and the Pines burning fiercely on both sides the line became a fiery way. Much courage was shown by the engine-drivers in taking their trains through the flames and smoke. An express train from Bordeaux to Arcachon arrived at the scene as the fire was at its fiercest on both sides of the line; the train was stopped, and all windows and ventilators

ordered to be closed. Then the driver put on steam, and at his best speed ran the gauntlet through an actual forest of fire. It is true that the flames did not actually cover the line, but they were burning on each side, and gave out such dense smoke that the train was literally lost in it; so dense, indeed, was the smoke, that it was found impossible to pull up at Marcheprince station, around which the fire was raging. The forest of La Teste, close to Arcachon, was no exception, and was devastated by fires.

The inhabitants of the villages around this forest enjoy feudal rights as to its use. They may cut all the live wood which they require for their households and their boats, and the dead wood is their exclusive property. The extent of this forest burnt was at least 1200 acres, and the value £16,000. After the fires, legal questions arose between the proprietors and the peasants as to whether the burnt trees were live or dead wood. The tribunal declared it live wood, and ordered it to be sold. This decision exasperated the peasants, who claimed it as dead wood, and who thereupon to the number of nearly 2000, with 300 carts, made a procession to the forest. It was as if taken by assault. The trees, still blackened by the fires, were felled in hundreds, sawn, and cut up, and loaded on the carts, which, almost breaking under the loads of timber, returned to the villages.

French Plums.—The annual blooming of the Plum-trees generally takes place during the early part of the month of March, but last year, in consequence of the low temperature, the trees did not blossom till the second week in April. Though very high temperatures prevailed during the months of June, July, and August, 1898, the maturing of the fruit was delayed, and harvesting the Plums only took place early in September, under most favourable circumstances, and terminated in the early days of October. The crop was very abundant, and reached about 1,600,000 cwt. The fruit was of average size only, from 54 to 59 Plums to the pound, up to 90 and 100. The larger sizes, 41 to 46 and 45 to 50, were scarce, and commanded unusually high prices. The largest-sized fruit, 30 to 32 Plums to the pound, were very rare. The demand from Great Britain was very active, and very important in quantity, the comparatively low prices favouring consumption, as well as, perhaps, also, the fact, that other fruits were scarce in France, and not of the usual good flavour. The Apricot and Peach crops were almost an entire failure. *J. R. Jackson.*

ANNUALS IN POTS.

THE cultivation in pots of annuals and ornamental grasses for conservatory decoration, has recently become more general, and deservedly so, for they may be easily grown, and are invaluable in many ways during the summer months. They give colour and lightness to the greenhouse, are extremely useful for cutting, and are also admirably suited to the work of the decorator and plant furnisher.

One great advantage possessed by the annuals over the perennial subjects is, that so soon as they are over, they may be cleared from the houses and consigned at once to the fire heap; but perennials, when they have flowered, still need much attention in the way of watering, pruning, &c., and they continue to occupy a large amount of ground, while generally presenting an untidy appearance. Those showy varieties of *Cinethera*, popularly known as *Godetias*, are exceedingly well adapted for pot-culture. At Ferrières-en-Brie, the domain of Baron Alphonse de Rothschild, thousands of them are thus grown annually. For out-door use, as, for instance, in floral decorations at a garden-party, nothing could be more effective.

The seed may be sown in the pots in which the plants are intended to flower, and the seedlings afterwards thinned out to the required number, or they may be sown in boxes, and when large enough, be placed eight or ten in a 6-inch pot. For this

* Reprinted from the *Pharmaceutische Zeitung* by the *Journal of the Pharmaceutical Society*.

latter operation, it is best to fill the pot very loosely with soil, even higher than the rim, and then make holes for the plantlets with the finger. When the work is completed, the soil will have become quite firm enough, and there will also be sufficient of it to nicely fill the pot.

Coreopsis Drummondii is another showy annual, well adapted for this method of culture. It remains dwarf, and produces an abundance of flowers. *Gypsophila paniculata* is rarely seen grown in pots, yet it succeeds admirably under those conditions, and is of great value as a summer greenhouse flowering plant, its habit is so light and graceful.

Of ornamental grasses, *Agrostis nebulosa*, *A. elegans*, and *Briza gracilis* (syn. *minor*), are a few of the most popular. The loose panicles of these grasses are very useful for making up with sprays, buttonholes, and bouquets. *A. nebulosa* is known as the Cloud Grass; and its fully developed flowering shoots certainly do bear some resemblance to a small cloud resting over the ground. *A. elegans* does not grow quite so high as the preceding one; it seldom exceeds 1 foot in height. *Briza gracilis*, "The Little Quaking Grass," grows wild in Britain, but is of comparatively rare occurrence. It is a charming plant of very distinct appearance.

If gathered and dried, these ornamental grasses can with advantage be made use of for vase and table decoration in the dwelling house. All the foregoing varieties can be easily raised from seeds sown in spring. Sow them in the pots in which they will flower, and thin out as becomes necessary. Cool conditions are essential to success with these plants. *H. H. T.*

MALSHANGER PARK, HANTS.

ON an elevated position, in a fine English park, is the beautiful mansion of W. S. Portal, Esq., a great admirer and planter of forest and ornamental trees. In the policies and pleasure-grounds are some grand Beech-trees, Oaks, Chestnuts, Limes, and Scots Firs; also many choice Conifers, planted in clumps of six to eight plants, in one position. They have grown freely during the past thirty years, and some of them have reached a height of 40 feet. These clumps add a rare beauty to the landscape. Mr. Portal has made many grass-walks and new woodlands through this estate. It is most interesting to note the rapid rate that trees grow when planted in deeply-trenched land. The pleasure-grounds are extensive, and contain many noble trees whose branches sweep the lawn, besides many young trees and shrubs of the choicest kinds that have been planted more recently.

The flower-garden, near to the conservatory and mansion, has been planted skilfully with numerous flowering and foliage-plants, the whole garden being a grand display of different coloured flowers and foliage. Leading from the flower-garden to the kitchen-garden is another fine grass walk, with trimmed Yew-trees on each side, and spanned by several fine arches of Vines, Roses, and Honeysuckle. This walk, which gives quite a character to the place, becomes an entrance to the kitchen-garden, which is well cultivated. It contains fine beds of Peas, Cauliflower, Celery, Carrots, Parsnips, Beet, Turnips, and some excellent white Cos Lettuce. Onions here are a special feature, and Mr. Kneller, who is one of our oldest and most experienced growers, says they are this year as good as ever he had them. The bulbs are wonderful in size, shape, and quality, and carry a growth of 3 feet, 6 inches in height. The same high cultivation is afforded all crops, whether fruit-trees, vegetables, or flowers. The glass-houses are not extensive, but they are most useful ones, and are kept in excellent repair.

The Fern-house contains useful plants for decoration; also some well-grown Palms in fine health. In the vineries there are crops of even-sized bunches of fruit with large berries. Such sorts as Alicante, Madresfield Court, Buckland Sweetwater, Black Hamburgh, and Muscat of Alexandria are grown.

The greenhouses and the stove contain many choice plants, including Ferns and Orchids.

In the Cucumber-house are some fine fruits of a large deep green Cucumber of handsome form; and without exception, I think, the finest and heaviest crop of Tomatos I ever had the pleasure to see is grown in a small house in this garden. The plants are grown in boxes 3 feet long by 1 foot wide, and 9 inches deep. The trusses of fruit are perfect in all ways, and from one box alone I was informed Mr. Kneller had cut 30 lb. of fruit, some specimens weighing 17 oz., and perfect in shape. The variety is known as Plentiful. The Tomato-house is 36 ft. in length, and 8 feet wide.

In the pits and frames are batches of many useful plants for summer and winter supplies of cut flowers. In one pit were some fine seedling Cyclamens, which ought to give a good account of themselves.

The whole of this extensive garden is under the care of the able and much-respected gardener, Mr. N. Kneller, who has been here many years, and has carried out great improvements in this charming place. *J. W. McHattie, Strathfieldsaye.*

FLAVOUR IN POTATOS.

THE question of flavour in Potatos continues to receive much attention from our correspondents. Below is a strong, but not too strong, indictment of the modern varieties. [Ed.]

"Mr. Harrison Weir and Mr. H. J. Elwes do not write one whit too strongly, but have quite understated the case against the modern Potato. "A. D." may be amused, but it is scarcely a laughing matter. Some day, when the public is less largely composed of fools—at present there are more of them eating worthless Potatos than Mr. Elwes imagines—Potatos with the Potato flavour will be again inquired for, and in vain. For at present it seems the one aim of those who are most industrious in raising Potatos from seed to eliminate all yellow colour, and with it, every vestige of flavour; and to flood our gardens and markets with coarse lumps of tasteless white starch. It may seem an invidious thing to carp at the long and patient work of the hybridiser, but I am constrained to ask a foremost firm, who write of one of their popular Potatos, that "it possesses the great advantage of being white in the flesh." Why is this any advantage? The French, who are immeasurably ahead of us in knowledge and appreciation of what is good to eat, and not merely to measure or look at, in vegetables, will have nothing to do with white Potatos. To myself this whiteness has one advantage only, it serves as an unerring advertisement of insipidity, and so simplifies the decision of summary rejection. The good Potato is yellow in colour, and in consistency of flesh a happy medium between wax and flour, like a boiled Chestnut; it should never fall to a heap of loose starch when cooked, but should dissolve in the mouth, not on the plate. It has always been a marvel to me why Messrs. Sutton did not follow up the clue of that excellent production, *Magnum Bonum*—large, prolific, disease-resisting, and with so much of the true colour and flavour of the early kidney varieties. It was the introduction and infusion of the American strains that worked the mischief; how people can grow and eat such dry, vapid, choking stuff as *Beauty of Hebron*, *et hoc genus omne*, passes my understanding. Years ago I had sent me from Guernsey, by a sympathising friend, a basket of small, round, roughly-formed, red-skinned Potatos, for all the world like the first known drawing of the Potato in old Clusius's book. They were supremely good, but the plant was a small cropper, and I grieve to say that by some mischance one year no seed-tubers were kept, and I never could obtain the thing again.

To demonstrate what a Potato should and may be in flavour, I posted some of it to the office of a horticultural paper, and with it, to serve as the drunken Helot, or awful contrast and example, the biggest tuber I could find of one of the white

American kinds. The Editor (not you, Mr. G. C.), who probably wished to gratify me, but had read my note upside down, wrote:—"We have received your Potatos; the small red kind is valueless, but the other is large, white, floury, and excellent." We still grow in this district the delicious old Walnut Kidney, unsurpassed for earliness, texture, and flavour, but a small cropper, and therefore sure to disappear before the inroad of the coarse, vulgar, valueless, modern Juggernaut Monster. If it is true—but I doubt it—that the American blood was the only possible help against the disease, and that therefore these chalk-faced starch packets are a necessity, we must endure them. But I object to the insult added to injury of being assured that these are the best Potatos that ever have been or are conceivable. It reminds me of the saying attributed to Professor Jowett, "Young men will go wrong, but it is pity when they make a theory of it." As to Tomatos, if Mr. Elwes wants them to eat and not to look at, all he can do is to fall back upon the old common (if it is still common), corrugated Red. *G. H. Engleheart, Appleshaw, Andover.*

COLONIAL NOTES.

A MARKET GARDENER IN VICTORIA.

IN a former letter (see p. 140), when making mention of land that could be taken up in this district for fruit-growing and general market-garden purposes, I omitted to give various necessary details in connection therewith.

Land that is declared auriferous, or "gold-bearing," is not let on a purchasing lease; but the selector is allowed the right to cultivate the surface by paying a small yearly rent per acre, with this risk, that miners may at any time come in and commence gold-finding operations on that area. This at first may seem a queer sort of tenure; but when this kind of land is taken up it has generally passed through its day of mining, and is just waiting the re-inspection by the mining authorities to have the area transferred to another section; and in many cases that I have known, when the Department has seen the genuine improvements made by the selector, he is at once allowed a purchasing lease under section 42 of the Land Act. Under this section, land is leased to selectors in 20 acre blocks, at a yearly rental of £1 per year, or 1s. per acre, for six years, at which time the occupier can, by paying £14, the balance of purchase-money at £1 per acre, obtain his title to the freehold, providing that he has in the meantime fenced and cultivated the land. For small allotments, miner's rights can be taken out for 2s. 6d., and the holder can peg out an acre and have it registered by paying another 2s. 6d., the qualification necessary to holding being residence for two consecutive years, when you can demand the sale of your allotment at the next Government land sale, when you or some one else can purchase the freehold. The occupier, is, however, allowed to place what valuation he thinks for improvements, thus putting probable bidders out of the running.

Within the last two or three years there has been a great increase in the acreage under fruit and garden crops generally, and now that the home-market is being catered for successfully by Victorian fruit, all those areas adapted to fruit-growing will soon be selected. Our crops here ripen when the home-market is really hungry for supplies, and most assuredly there is a great future for the Victorian fruit industry.

As I have said before, it is young men that have been trained in the practical school of English gardens that can utilise the facilities for raising and producing fruit crops in a climate that has everything in their favour, and but few of the drawbacks incidental to open-air operations in this line in England. *A. V. N., Eaglebank, Victoria, Australia.*

HONG-KONG.

The report for 1898 of Mr. Superintendent Ford

has been received, giving details of the changes in the staff and Botanic Gardens. *Nepenthes ventricosa* has been sent to Kew. *Derris Fordii* (§ *Mimoseae*) was discovered by Mr. Ford in the province of Kwan Tung, and is described as a picture of beauty; the flowers, which are produced in the greatest profusion, being white and red. *Rourea santaloides* (Connaraceae) is a lovely plant when in bloom; it is indigenous in Hong-Kong. Strawberries have been successfully grown. Six hundred and eighty-six cases of illicit tree-cutting for fire-wood have been recorded, the convictions amounting to fifty-one; but as there are only five forest-guards for the whole colony, it is not to be wondered at that the convictions are few. Forest fires are numerous and destructive, being caused chiefly by the carelessness of natives and Europeans alike, in the use of matches.

THE HERBACEOUS BORDER.

LUPINUS POLYPHYLLUS.

For some years the writer has held somewhat hopeful views of the future of *Lupinus polyphyllus*. It seemed to him hardly likely that a plant which had yielded the comparatively few varieties known until late years should not give us before long several distinct breaks. Nearly everyone interested in hardy flowers is thoroughly familiar with the blue, the blue and white, and the white varieties so often met with. Of these the best was, perhaps, that with blue and white flowers. It might look at times a little stiff and too pronounced in its contrasts, but it is decidedly effective in a large border. Most of the white-flowered plants had a bad defect in the shape of irregular spikes, caused by breaks in the continuity of the flowers, or by some of the latter dropping too soon. From what has been seen of late, one cannot but think that we are in a fair way to have many improved varieties, which will be found of the greatest value. Perhaps the greatest surprise was the introduction last year, I think, of a yellow variety by Messrs. Kelway & Son, of Langport. It is assumed that this may have originated from hybridisation with a yellow Tree Lupin; but this does not appear to be proved; and there is no reason why it may not have been the result of variation from seed. [Is it not commonly grown in France? Ed.] Last year I saw in an Irish nursery a large bed of seedling *L. polyphyllus*, among which were some very beautiful flowers in shades of blue and white. Some of the latter seemed quite perfect in their flowering. Messrs. Barr & Son have also some pretty varieties. A dark-purple form, called Purple King, was in their stand at the last Temple Show, but the way in which it was set up, hardly did justice to a plant of the character of *Lupinus polyphyllus*. Of the various breaks that I have seen, nothing has pleased me so much as a pretty pink-coloured one in Mr. George F. Wilson's experimental-garden at Oakwood, Wisley. It was different from any of the perennial Lupines with which one is acquainted, and gives a colour we have not yet had among these useful border or wild-garden plants.

IRIS PALLIDA FOL. VAR.

Garden visits are very interesting to those who admire flowers, and one often comes across plants before unknown; or, if known, sees them under quite different conditions. At Guildford, the other day, I was delighted to see a fine bed of this beautiful variegated Iris, which I had not met with before, although it is not absolutely new. It was honoured with an Award of Merit from the Royal Horticultural Society in 1896. It is quite possible that some of its effect was due to its being grown on the chalk; but, even allowing for this, it is apparent that this Iris will be invaluable to many. I was told that it liked as hot and dry a place as possible, and that it should not be watered. Such a plant can easily be accommodated in most gar-

dens, and on a wall or a reef it would apparently succeed perfectly. We ought to make greater use of such Irises as do well in these positions. Many are perfectly at home, and look far more delightful than those who have not seen them can imagine, crowning the summit of a wall or a low reef. In addition to its broad creamy-banded variegation, *I. pallida* fol. var. appears to flower freely. The effect of the beautiful blue flowers, with the distinct variegation of the leaves, is most pleasing. *S. Arnott*.

THE IMPROVEMENT OF PLANTS.

MIGNONETTE.—My earliest experience in the improvement of flowering plants was when the first plant of Mignonette was selected, which after further selections, extending over a period of seven or eight years, resulted in the fine white variety, which was known as Parsons' White (or *Reseda odorata eximia*), under which name it received a First-class Certificate from the Royal Horticultural Society. The plant referred to above, though far from being what would now be considered worth growing, was a decided advance on all the others then grown. It was one of several in the same pot, all except the one being carefully removed, and the one placed in an isolated position for seed; the same process of selecting the most distinct being carried on for several generations, during which time other varieties equally distinct were found among them, one with almost round leaves, and of very dwarf habit. Upwards of forty different selections were made, all of which except the white, and a vigorous-growing variety with more green in the flowers, were eventually discarded; the last was known as Parsons' Tree-Mignonette. It was found that to keep these true, and prevent deterioration, it was necessary to carefully select the seed-plants, and avoid the two varieties coming in contact. I might add that further selections resulted in a variety without any anthers, and a large batch reserved for seed proved abortive. The above results were obtained without any cross-fertilisation except what occurred by natural agencies. The above is only an illustration of what has occurred with many other plants which are grown from seed annually. It was from the late Mr. Geo. Parsons (who did a great deal both in selections and hybridising) that I received my first instructions, and it was not only with flowers but also vegetables that these selections were made. I have gone over large breadths of Lettuce, Cauliflower, &c., and selected the best to save seed from for own sowing.

Chinese Primulas.—Coming back to flowers, Primulas received a large amount of attention. For some time we saved only what seed was required for own sowing, and as the seed plants were carefully selected from large quantities grown for sale, steady improvement was made. The camels'-hair pencil was brought into requisition for these, and a clean pencil was used for each distinct colour. Some crosses were also made. I found that the seed parent generally sustained the habit, while the pollen parent was more responsible for the colour. Taking the Fern-leaved varieties as they were first sent out, there were two white and red; the latter was of rough habit while the white was dwarf and compact. By carefully selecting and re-crossing we had not only a red and white of good habit, but also all the intermediate shades, including the striped and mottled. The semi-double varieties also made their appearance, and although not so perfect in form and shades of colour, a gradual advance was made from year to year.

During the first years of my experience, even from the most carefully selected stock, many of the seedlings would revert to the old form with only two lobes to each petal, but eventually it was rare to find any reversion, though some would be of superior form and colour. A similar process was carried out with the—

Cinerarias, only that the main stock for seed consisted of plants of named varieties which were

propagated by divisions; additions being made annually from the most approved seedlings, and also by obtaining seed from other sources; this, though often with poor results, introduced some new breaks, and, perhaps, more sturdy growth.

Pelargoniums.—My first experiment with these proved a great failure. Although I had good material to work from, I made a grave mistake. I crossed the various colours indiscriminately, the result being that most of the progeny produced washed-out colours; this proved instructive. In my next venture, I carefully avoided crossing distinct colours, there being already sufficient of the intermediate shades. I selected of good habit and well-formed flowers, and fertilised them with pollen from those of more distinct or brighter shades, the result being much more satisfactory, but I lost sight of most of these, as the death of Mr. G. Parsons, which occurred about this time, resulted in the whole of the nursery-stock being sold off, and thus ended my first and most interesting series of experiments in plant-breeding. I was, however, able to keep sight of one of the Pelargoniums, which eventually gained a First-class Certificate from the Pelargonium Society in about the last year of that Society's existence.

Begonias.—The events referred to above, also broke off my first start in crossing Begonias, but not before I had made one very distinct cross; this was by the employment of the pollen of *B. boliviensis* on *B. insignis*, which might be considered a "hybrid," for the parents were very distinct species. Although the best of these seedlings were lost, I was able to secure a plant from a friend after I went to Chiswick, where, under Mr. Barron, I again started crossing, but the hybrid referred to above, proved, like the beautiful Gloire de Lorraine, perfectly abortive, both in regard to pollen and pistillate flowers. I made many attempts to raise seedlings from *B. Meonlight*, for although there was no pollen, the female flowers appeared perfect, yet though I took pollen from various sources, all proved a failure to raise seedlings. I was, however, more successful with the tuberous section, and the Chiswick collection at that time being one of the best, I had good material to work from, the result being that thirteen First-class Certificates were awarded at one meeting of the Committee, but all of these have now long been superseded by the magnificent varieties of the present day.

I have found in the course of my experiments that there are some varieties which prove far better as seed-parents than others, which from appearance should be equal. In Begonias, one of the earliest which almost always gave a good percentage of fairly good flowers, and was the parent of some of the best raised at that time, was *Oriflamme*; while other varieties, equally good in themselves, rarely gave good results from their seedlings. It is this point which gives these who remain in the same field so great an advantage over those who move about.

Carnations.—In these plants I have found somewhat similar results as with the Begonias. Of these I have raised some of the best came from Winter Cheer. I used the pollen of Uriah Pike on Winter Cheer long before Uriah Pike was in commerce, securing a bunch of blooms from the market for the purpose. Although it would be difficult to entirely supersede this fine crimson, I think Countess of Warwick, which proved the best of three years' re-crossing, has several points in its favour, being nearly as dwarf as Winter Cheer, free-flowering, and of a rich claret-crimson. It is a curious fact that I never was able to get a good pod of seed from our old favourite, Miss Joliffe. I have worked on a number of plants, always with the same result—failure. Even the large double flowers of the Malmaison section are more prolific, thus proving that it requires careful observation, and some knowledge of the material you are working on, to prove successful in cross-breeding of all sections of plants, and although some success may

attend first attempts, the net results will be very small compared with those who have followed a long series of observations and experiments.

One great misfortune in the raising of seedlings is, that in many instances the number of plants obtained is so great that there is a difficulty in giving them all a fair trial. The specialist knows at an early stage, to some extent, what he may discard; but it is not so with the less experienced, and although it may be very fascinating to go in for a number of subjects, those who confine themselves to some particular class or classes, as room permits, generally attain some success. *A. Hemsley.*

M. LATOUR MARLIAC'S WATER-LILIES.

No more remarkable results of cross-breeding and hybridisation have been gained than the series of

not appear to have ever been so much as thought of. On the continent, on the other hand, height-growth is the first thing the forester concerns himself about after he has planted his trees. Get height-growth, he says, and the rest will come. Height-growth has the same significance as "drawn up," an expression well known to gardeners, who seldom want height-growth in their productions, as that, as a rule, would be against the object they have in view, which is lateral development in trees and bushes and in fruiting plants, crops. The editor may perhaps remember me writing to him a year or two back on this subject, and asking for explanations of a puzzle that physiologists have not yet solved, viz., how trees in crowded woods, dells, and ravines, get pulled up at such an extraordinarily rapid rate compared to isolated trees in the open; and how more timber is produced to a given area in that way than when the trees are grown wide

projecting considerably beyond the last support, and the "spring" of the pole is worked to drive the sinking apparatus up and down, a man working the pole.

Some time ago your well-known correspondent, Mr. Burbidge, sent me a pen-and-ink sketch of a section of a ravine planted with Scotch Firs, near Newry in Ireland, that would have illustrated my meaning well, but a type-writing company lost it, to their cost and mine too. This sketch showed the Firs as tall as masts in the bottom of the gully, and those at the top, in the exposed field on each side, rough-branching specimens, unfit for anything but firewood, and about half the height of the others. That is height-growth! The Douglas Fir pole at Kew is another fine example of height-growth. It is about 160 feet high, and only just a little less in girth at the top than at the bottom. How a timber merchant's mouth would water over that pole! He could enter his saw at one end and cut one continuous plank out of it 55 yards long, with very few knots. I have twice measured the Douglas Fir specimen at Dunkeld, planted about 1845, and now containing well on for 100 cubic feet, and compared it with the Kew pole, much to the disadvantage of the former, for whereas the first represents a perfect timber tree, the other, from the same point of view, is an abortion of the candle-extinguisher pattern, having every fault that a trunk of timber can have—viz., too much taper, and a multitude of coarse knots over its entire surface. The opinions of the saw-mill man and the forester—as distinguished from the tree-lover—are sadly at variance on such subjects. When the Royal Scottish Arboricultural Society visited a certain estate in Ireland, the proprietor took pride in showing the visitors two favourite trees of the umbrageous type, more limbs than trunk; and was shocked by hearing a timber-merchant, member of the Society, whisper to another, "Two brutes!"

If only the importance of height-growth in forest-trees was better understood, there would be more glens and ravines planted than mountain-tops, and our woods would be dense everywhere. The common Alder grows about 40 feet high in the open, and is a rough tree, but attains to 60 feet and 70 feet in a plantation of the taller-growing Oak and Ash, that pull it up. The Elm is said to double its height or more under the same conditions, and the Birch does the same. The common Hawthorn, as everybody knows, does not greatly exceed the dimensions of a bush in the open field, but I have seen it 40 feet high, with a perfectly straight stem, in an old Oak wood. I left it standing, but it blew over soon after its neighbours were felled. The height-growth of all plants as well as trees is influenced by the same conditions. About twelve years ago I planted a long plantation of Firs and other species on very rough ground, where Brambles, Nettles, rag-weeds, Thistles, &c., abounded, and it has been interesting to watch the struggle for existence among the weeds and trees. The trees were planted 3 feet apart, and have not yet been thinned. The first few years the weeds and rank grass had to be beaten down to give the trees a start, otherwise they would have been smothered. After they got the lead, however, it was the turn of the weeds to fight for their existence. In many places these have quite succumbed, the ground being now bare under the trees; but the weeds named struggled on for years, and many that I measured lately were from 6 to 8 feet high—a height far exceeding their usual growth in the open. They were, of course, very attenuated, and could not have held their heads up but for the shelter the trees afforded them. The Bramble, which previously seldom rose above 2 or 3 feet from the soil, I found last year overtopping some of the trees about 14 feet high, struggling to reach the light, just like the Potato mentioned by Dr. Lindley, which, lying in a dark cellar, pushed a shoot some 12 feet long, till it reached a hole in the wall, where the light came through. The common Bracken, however, beats all other plants for

FIG. 65.—NYMPHEAS AT M. LATOUR-MARLIAC'S ESTABLISHMENT, TEMPLE-SUR-LOT, FRANCE.

hardy Water-Lilies raised and sent out by M. Latour-Marliac. We have repeatedly had occasion to call attention to their extreme beauty, and those who visited the Conference on Hybridisation at Chiswick in July last will remember the magnificent display of these flowers made by Mr. Hudson from the gardens of Baron Rothschild. We are indebted to Mrs. Hampson for the opportunity of giving an illustration showing the means adopted to propagate these remarkable plants.

FORESTRY.

HEIGHT-GROWTH IN PLANTATIONS.

THE term "height-growth" in forestry is derived from the German. Neither the words nor their meaning have ever had any significance in British forestry practice, and the importance of height-growth as a factor in the production of timber does

enough apart to develop to their utmost extent? Let me give an example or two. For over thirty years I have watched the gradual filling up of a precipitous narrow gully with trees, and marked the comparative progress of the trees on the steep sides of the gully.

At first, when the ravine was planted, a section of it would have appeared like the letter V with the plants (all then about the same size) on each side. But gradually, as the trees grew, the acuteness of the angle of the V grew less and less, owing to the trees lower down growing faster than the trees higher up, until now the tops of the trees are nearly level across the ravine. At the top edge of the cliff the trees are short, and in the bottom tall and cylindrical, and by far the more valuable. We have frequently wanted very long larch-poles for sinking purposes, for minerals, and all the poles have been got from this wood. This will show that the timber is tough and of good quality. The poles are laid over tressels with the long point

asserting itself in a crowd. I have seen it on the bleak hills of the Isle of Man, not exceeding 6 or 9 inches in height; but hereabouts it keeps pace with young plantations for years, if it can get the end of a frond out to the light. Fronds 7 and 8 feet long are common in the woods, and we once found one 12 feet long in a thicket of underwood. It was tied to a rail and taken care of as a curiosity.

A belief exists among some foresters that girth is sacrificed to height-growth when the latter is prolonged, and it is that notion that has led to such severe thinnings in this country. No doubt the drawing-up process may go on too long, but it is surprising to see how tall all species of trees are allowed to grow in German forests with exceedingly slender stems, and yet become good, thick trees before the end of the rotation period. We do not look close enough into the question of increment in our forestry practice, or we should not be so nervous and generalise so much. So long as a tree lives and has a healthy top, however small, a ring of new wood, however narrow, will be added to the trunk annually; and it is a very narrow annual ring indeed that does not produce a measurable quantity of timber over a tree of fair size. One-sixteenth of an inch to the girth is not much, apparently, but the layer goes round the tree, and over the whole surface of the trunk it means a large addition to the bulk. The telegraph-poles on the highway, and the scaffold-poles we see set up in the streets might read the forester a lesson. Mark their proportions: the 30 or 40 feet telegraph-pole, about 9 inches in diameter, is nearly as thick at the top as the bottom; some are so nearly cylindrical in shape, that the untrained eye can hardly tell the thick from the small end, yet these poles are only part of one tall tree, nearly the same girth throughout, not very old, that never had more than a small tuft of branches at the top to carry on elaboration and growth; and a close examination of a section of such a pole will show that the annual rings are of fair measurable width, and very regular.

The extent to which height-growth is influenced by situation is most frequently noticed by those who have to practice in an undulating country of hill and dale. The difference in the height of the trees and length of bole in different situations, not as regards height above the sea, but only so far as relates to the configuration of the ground, is very remarkable. Even a mere depression in the ground makes a difference, and a marked one.

Not long since I had to value and sell nearly 20 acres of Larch, growing at an altitude of about 1300 feet. The ground was very poor, and consisted of a series of hillocks or mounds, so artificial-looking in shape as to suggest that they had been raised by the hand of man. Both the heights and the hollows were planted at the same time—about seventy years ago; and when I valued them standing, the average dimensions of the trees were about 6 cubic feet, yet the trees ran from 1 foot up to 23 feet, according to the position. An average of the two extremes would have given 12 feet as the general average, but what pulled the average down was the number of stunted short trees that grew on the high and exposed knolls, these seldom exceeding 1 ft. or 1½ ft., and a careful average had to be taken in every part of the wood. The winding narrow gullies everywhere held the best and tallest trees, some reaching a height of 50 feet where they were drawn up. The total quantity of measurable timber estimated in the lot was 36,000 feet, or a little under 2,000 feet to the acre all over, and it fell just a little over the estimate, the most of it going to one consumer for pit work—for about 1s. per foot delivered, the road being bad and long. Roughly speaking, the trees in the gullies would average about 9 cubic feet, and the poor ones on the high ground about 3 feet, a difference due not to soil, but to the comparative shelter afforded in the different positions, and the pulling-up process—the height-growth. The wood had never been thinned, and the tall trees varied greatly in girth.

All were about the same height, but while some did not quarter-girth more than 3 inches in the middle, others would girth double that and more, showing that the height-growth was not due to shelter alone, but to their being drawn up in the struggle to reach the light. J. Simpson, Wortley, Yorkshire.

THE BULB GARDEN.

GALTONIA HYBRID (PRINCEPS × CANDICANS).

SEEDS from the above cross were sown less than two years ago, and already the most advanced bulb is in flower, with a fine scape 4 feet 6 inches high. It shows a hybrid which is very nearly intermediate in character between the parents. The scape evidently partakes of the greater height of *G. princeps*, while in foliage, if much difference can be detected between the parents, it partakes rather of *G. candicans*, especially in the somewhat greater glaucousness of the species.

In the flowers, hybridity is clearly evident. They are of paler green than those of *G. princeps*, and may be described as tinted all over with green. The perianth segments are less spreading than in *G. princeps*, but decidedly more spreading than in *G. candicans*. The intermediate character, or at least, the hybrid character, is easily shown by measurement. In *G. princeps*, the perianth segments are shorter than the tube; in *G. candicans* they average a quarter of an inch longer, while in the hybrid they are an eighth of an inch longer, or, it may be said, that in *G. candicans* they are half as long again as the tube, while in the hybrid they are about a fifth as long again.

Whether the hybrid will be of much horticultural value remains to be seen, but there may be those who can appreciate a plant rather like *G. candicans*, but taller and with flowers delicately tinted with pale apple green. *G. princeps* does not appear to be much cultivated. Here, it is perfectly hardy, but I find its chief use to be in the conservatory; where, in spring or early summer, several scapes from an 8 inch pot reach a height of nearly 6 feet, and are striking to all. They are distinctly ornamental, though the flowers are but green. Does anyone now cultivate *Galtonia clavata*, *Gardeners' Chronicle*, 1884, Sept. 27, p. 401? R. Irwin Lynch, Botanic Gardens, Cambridge.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Odontoglossum crispum.—In comparison with the number of growers of this popular species, those who attain satisfactory success are exceedingly few. A mistake frequently made by cultivators is that of treating the plants rather as if they were aquatics than plants which grow naturally on trees more or less bare. Complaints have been frequent this season that *Odontoglossums* have shrivelled greatly owing to the unusually hot weather, and in attempting to remedy this, many growers have given the plants too much water and shade, which, I believe, has more often than not defeated the end in view. An excess of moisture in the pseudo-bulbs is decidedly disadvantageous to the plants, but a little shrivelling is more a blessing in disguise than an injury. Now that cooler conditions prevail, the pseudo-bulbs will soon regain their former plumpness, and commence to root anew. The operations of repotting or resurfacing of *Odontoglossums* should not be performed at any one particular period. Instead of this, examine the plants repeatedly during the next two months, and select those the young growths of which are in that condition that new roots from their base may be confidently expected to follow the operation. Pots and pans of various sizes are used with success by different growers, though the larger the receptacle and the greater the body of material it contains the greater will be the care necessary in the important matter of watering. A plant that is in good health, and has room to develop, need only be relieved of a portion of the old surface material, and given fresh peat and living sphagnum-moss; but those in bad health, or

any that require more pot-room, must be repotted. Those in ill-health should be shaken out, and the roots washed in tepid water. Cut away all dead roots, and fix the plants in pots just large enough to hold them. These pots should be two-thirds filled with drainage material, and the compost about the roots of the plants may be peat and sphagnum-moss in equal proportions. Healthy plants that need be moved on merely, should be turned out of the pots, when much of the old potting material may be removed; also, any of the old pseudo-bulbs that are of no further use to the plant. Afterwards, fix the plants in clean pots that will be large enough for the two seasons following. The base of the plant should be just above the level of the pot. The drainage material may be broken much more than is generally the case for other Orchids, and the peat and sphagnum-moss should be used separately, when it will not retain moisture so long as if mixed together before using. For some time to come, the temperature must depend largely on outside conditions; and so long as the night temperature does not recede much below 50°, the ventilators may be left open. Only sufficient water to keep the sphagnum-moss alive will be necessary for some time to come. *O. Pescatorei*, *O. triumphans*, *O. luteo-purpureum*, *O. Sanderianum*, *O. odoratum*, &c., should be treated in the same manner.

Odontoglossum Rossii.—No one but the inexperienced would take exception to the bulbs of this species shrivelling during dry, hot weather, as they are subjected to such conditions in their natural habitats, and apparently are benefited thereby. The plants thrive well when grown in baskets, and suspended over the other cool *Odontoglossums*. At this season they may be removed to larger baskets, or re-surfaced only as each may require. When about to give new baskets, the bars of the old ones should be removed separately, and with great care, to prevent injury resulting to the clinging roots. Then place the plants in the new ones, and insert amongst them plenty of drainage material and a small quantity of peat and living sphagnum-moss.

Odontoglossums Erstedii and *Cervantesii* should be grown in pans and suspended. In order to obtain nice specimens mound them up as much as possible, and give extra drainage material. Excepting when rooting freely, these two species thrive best under moderately dry conditions.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Drogheda, Maidenhead.

Strawberries.—If a mulch of short manure was provided after making new plantations of Strawberries, this will help to shade the soil, and thus prevent evaporation; but waterings may be necessary also until the plants have become established. All runners that form must be pinched off immediately. In some districts mildew has spread badly over Strawberry-plants, in beds and in pots. The best remedy is to syringe the leaves, &c., with a solution of Gishurst Compound, or a mixture of soapy-water, at the rate of 2 oz. of soft-soap and 4 oz. of sulphur to 3 gallons of water. Dissolve the soap in a small quantity of hot water, and with this mix the sulphur, afterwards adding clear water to the required strength. Rain or pond-water is the best for this purpose. Some provision should be specially made now by setting out plants for furnishing runners for next season's layering, as it is not desirable to obtain these from the fruiting quarters. Young plants to the number required should be set out in a convenient position for layering next year, and each plant will probably produce at least three or four strong runners. We utilise for the purpose the borders near the margins of the paths in the fruit quarters. In the spring, the flower-trusses should be pinched out as soon as they appear. If such borders be not available, ground from which Potatoes have been lifted may be used without further preparation, other than levelling and making it firm. Plant them 12 inches asunder in lines 3 feet apart, to allow of room for the work of layering. Where forced plants of *Vicomtesse H. de Thury* and *Royal Sovereign* were planted out early, some second crop fruits will now be ripening, and if these are required for use, they will need to be protected from birds by garden netting, and the trusses of fruit should be propped up with forked sticks to keep them from the ground.

Gathering Peaches.—Now that fruits are ripening fast the trees should be looked over daily, or at least every other day, and those fruits that come away easily be gathered and placed on wadding on the shelves of the fruit-room. With a little practice those fruits that are ready may be easily selected without any squeezing or hand pressure on the fruits. Bruises soon show badly after the fruits are gathered. A box, with a sheet of cotton-wadding and soft paper in the bottom, should be taken to the trees to place the fruits in. Going over the trees in this way is less trouble than suspending netting to catch the fruits, and the flavour is usually much better than when the fruits are allowed to become fully ripe and drop from the tree.

Protecting Apples and Pears.—Of late years it has become absolutely necessary to protect by some means the choicest fruits of Apples and Pears from the ravages of Birds. Blackbirds and thrushes are the worst to Apples, but no birds are so destructive to Pears as the small tits. These small tits attack the fruits near the stem, and fly from one to another until the crop is ruined. Thin muslin or canvas bags are cheap, and may be quickly put on. If the string be fixed to the branch, the fruit, should it part from the stem, will be caught in it. Round pieces of cardboard with a small hole in the centre, and from this slit to the edge, will enable it to be slipped over the stems of Pears, and if pinned together after will keep the birds from the part usually eaten. The celluloid protectors of the Rev. Darnley-Smith, which have been figured in the *Gardeners' Chronicle*, are apparently valuable protectors, and when they can be produced cheaply will probably be much used. I am giving them a trial, and will report later. [Please do so. Ed.]

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Watering.—The last month has been the hottest and driest for many years, and flowering plants, such as Lobelias, Phloxes, Salvias, Nicotianas, Verbenas, Pansies, Violas, and late-flowering annuals, have suffered greatly, although liberally supplied with water. All moisture-loving plants, as Spiræas, Hellebores, Ferns, and many other occupants of the rock and alpine gardens, should be given an abundance of water at the roots, unless there be rain.

Narcissus.—Bulbs that were lifted in July and stowed away should be replanted as early in this month as possible, and if the present supply be not large enough, a catalogue should be obtained, and orders given without delay. Narcissus may be planted as late as November with very good results, but there is a decided advantage in planting them in September. Narcissus may be grown successfully in almost any position, and the stouter-growing varieties, such as N. Emperor, Empress, Horsfieldii, Sir Watkin, Golden Spur, Henry Irving, Grandee, Obvallaris, M. J. Berkely (very fine), Glory of Leyden, and Johnstone's Queen of Spain, have a pleasing effect when planted in grass or under deciduous trees; but in no case place them where the main roots of trees are near to the surface or above the ground. Nor is it of use to plant bulbs too near the stem of the tree, or where heavy drip may damage the flowers. In the herbaceous borders they make a pretty show of flowers in spring, when placed in irregular masses, and if the spots chosen have annuals planted near them, it will take off the bareness of the ground when the Narcissus foliage dies down, and shelter the bulbs when resting, as the roots will absorb the moisture on the surface. N. incomparabilis and the Barrii sections have star-like perianths, cups well expanded, edged with orange and orange scarlet. The Barrii section should be given a high position partially shaded, so that they may escape as much as possible from the frosts, otherwise the colours will be less brilliant. N. triandrus albus, concolor, calathinus, pulchellus, and the Bulbocodium section, citrina, and monophyllus, are gems for the rock-garden. N. odorus (the Campenelle Jonquil) is a free-flowering variety, most useful for cutting purposes, and succeeds well in the woodlands and on grassy banks.

Suitable Soil and Planting.—Narcissus will thrive in almost any good loamy soil devoid of fresh stable manure and peat; but where the soil is of a

wet, clayey nature, it is best to remove this away entirely to the depth of 12 inches, and replace with some good loam. When planting in grass, if the soil is of a dry, sandy, and poor nature, the turf should be removed, and some good bone-meal or basic slag mixed with the soil, allowing about 2 oz. of the former and 6 or 7 oz. of the latter to the square yard. The turf should then be relaid, and a hole dibbed through this to the depth of 6 inches, and filled with some good loam; then press the bulb firmly into the soil, and cover over. Thus planted, they may remain to advantage in the same soil three or four years, and if placed at distances of 5 inches or more, they will multiply readily.

FRUITS UNDER GLASS.

By W. STRUONELL, Gardener to Lieut.-Col. RALPH VIVIAN, Rood Ashton, Trowbridge.

The Early Vinery.—Strict attention must be given to supplying the necessary moisture to the borders. Those that are filled with roots, or have done duty for a number of years, will be benefited by applications of manure water, or dry manure purposely prepared for Vines and other fruits. This will strengthen the roots, and enables the Vines to store in the embryo buds material for a vigorous start in the new year. Do not allow the borders to become dry as soon as the crop has been cleared from the Vines, neither allow superfluous laterals to grow. Shorten the fruiting laterals gradually, so that the basal buds, which will be the actual fruiters next season, may derive all possible benefit from the autumn sun. During such tropical heat, Vines with roots in outside borders would be helped by a surface covering of straw manure. Borders having hard baked surfaces, need to be lightly pointed over before watering, and if a good thickness of straw litter is at once placed over this, the moisture will be retained over a much longer period. Now the Vines are free from fruit, steps can be taken to rid them of insect enemies. Water, or soap-suds from the laundry, heated to 145°, form an excellent remedy for mealy-bug and thrips, but one application alone is insufficient. The Vines should be syringed right and left, wetting thoroughly the foliage, rods and spurs. In bad cases, a little soluble petroleum would render the remedy more certain. The same remedy will destroy mildew and red-spider. A fairly coarse rosed-syringe is the best means for applying hot water. Mildew often comes from dryness at the roots, and those troubled with it ought to satisfy themselves that the roots are well soaked to the whole depth of soil from now onwards.

Later Vineries.—With continuous sunshine, it is difficult to keep down the temperature of the vinery, despite all-night ventilation. Lateral growth should be allowed to extend with little more freedom over ripe Grapes, and those nearly ripe. Roofs furnished with large squares of glass, and lightly timbered, may be given a light shading of whiting mixed with milk. Lime is neither good for the paint or the glass. Black Grapes soon lose their colour if there is not sufficient foliage to shade them; and white ones noduly exposed become shrivelled or scalded. The fullest ventilation will be required in the daytime, but reduce it slightly at night, to prevent moisture condensing on the Grapes. The night dews are heavy, and with open ventilators moisture may settle on the bunches, unless a little warmth from the pipes is given. Wasps and bluebottle-flies are becoming troublesome, and a stock of Scott's or Davis's Destroyer ought to be at hand, applying a little from a pointed stick to the partially-eaten berries. Muslin tacked over the ventilators will keep them out; but later, when the weather is less clear and settled, it tends to check the passage of air. Robins give a good deal of trouble in the autumn, and should either be trapped, or kept out of the house by means of fish-nets hung over the roof and front ventilators.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Onions.—As the land on which Onions have been grown will probably be required for spring Cabbage, the crop should be pulled, dried, and stored as soon as growth has ceased. After pulling them up, let the bulbs lie upon the ground for a few days fully exposed to the sun, turning them over at intervals

if needed. When they are properly fit for storing, remove all thick-necked ones and put them aside for immediate use. Those remaining should be laid in a dry, airy shed, or they may be roped and tied to the roof of an open shed, where they will keep sound for weeks. But never put them away whilst damp.

Cabbages.—If it is intended to cultivate Cabbages upon land that has been occupied with Onions, and the land for the latter crop was thoroughly trenched and heavily manured last winter, no preparation in the way of digging, &c., will now be required. Merely hoe and rake over the surface, and draw shallow drills. Do not omit to plant plenty of that useful early Cabbage, Ellam's. These may be put 12 inches apart in the rows, and 15 inches from row to row. The later and larger varieties should be allowed more space. Continue to water the seed-beds if it be necessary. It is not yet too late to sow seed, and plants from a sowing made now would be useful for spring-planting, to follow the earliest batch of Ellam's, which might be cut, and the ground at once cleared for other crops, leaving some of the later for sprouting purposes. A few of the red pickling Cabbage should be planted at one side, as these will have to stand till the following autumn.

French Beans.—A good batch of some of the best dwarf Beans should be sown in pots, filled three parts full with a mixture of loam and manure. They may be kept out-of-doors so long as the weather keeps warm. Small Beans will be found useful when the outside crop is over. Do not let the pods upon Beans out-of-doors become stringy before they are gathered.

Celery must be given every possible attention. Thoroughly deluge the trenches with water and liquid-manure alternately. Earth up the plants at intervals, and take great care to keep the hearts free from soil, avoiding at the same time the mistake of putting too much earth to the rows at one time. Plants that were earthed up partly some time ago will still need water, but it must be applied in such a manner that the soil will not be washed into the hearts of the plants. A good plan is to make a trench 6 inches away from the plants, and then soak them thoroughly, filling up the trenches several times before putting back the soil.

PLANTS UNDER GLASS.

By O. R. FIELDER, Gardener, St. James's House, Malvern.

Hydrangeas.—To obtain dwarf plants for flowering in late spring, cuttings should be taken at the present time; these should be selected from plants now in the open air, whether they be planted out permanently, or plants in pots which have been removed out-of-doors since flowering, and which have not yet been cut back. Choose strong shoots which, by reason of the shortness of the last few joints, indicate that flower-buds are in course of formation. Remove them below the third joint, and after taking away the lowest pair of leaves insert them singly in 3 inch pots filled with sandy soil. Place them under a handlight in a cool house, keep the air close, and afford shade during sunshine. When the cuttings are sufficiently well rooted remove them from the handlight, and in a few days transfer them to a cool frame, which should be ventilated freely. They may be wintered in any cool structure from which frost is excluded, and towards the end of January shift them into 5 or 6-inch pots. Afterwards place them in an intermediate temperature, and they may be expected to flower when from 12 to 15 inches high.

Centropogon Lucyanus.—As this useful winter-flowering plant completes its growth, it should be afforded plenty of light and air. The flowers will then be produced along the greater portion of the gracefully arched branches. When well grown the stems are sufficiently strong to be self-supporting without the aid of stakes, and the plants are most effective when thus grown; but if staking be unavoidable, use only one stick to each plant, and loosely sling the stems to this by thin strands of raffia. Being a free-rooting plant, the pots will soon become full of roots, and manure-water will be then required. When in bloom, the plants should be placed in the driest part of the house, as the flowers are inclined to damp off if subjected to a close moist atmosphere, or if the water from the syringe be allowed to fall upon them.

APPOINTMENTS FOR SEPTEMBER.

MEETINGS.

TUESDAY,	SEPT. 5	— Scottish Horticultural Association.
TUESDAY,	SEPT. 12	{ Royal Horticultural Society's Com- mittees. Royal Horticultural of Ireland.
TUESDAY,	SEPT. 26	{ Royal Horticultural Society's Com- mittees (Vegetable Competition for "Sherwood Cup").

SHOWS.

FRIDAY,	SEPT. 1	{ National Dahlia Society's Show at the Crystal Palace (2 days).
WEDNESDAY,	SEPT. 6	{ York Florists' Exhibition of Dahlias.
THURSDAY,	SEPT. 7	{ Dundee Horticultural Society's Ex- hibition (3 days). Cambridgeshire Horticultural So- ciety's Exhibition at Cambridge.
WEDNESDAY,	SEPT. 13	{ Royal Caledonian Horticultural Society's Show in the Waverley Market, Edinburgh (2 days).
TUESDAY,	SEPT. 19	{ National Dahlia Society's Exhi- bition at the Royal Aquarium (2 days)
THURSDAY,	SEPT. 28	{ Royal Horticultural Society's Show of British Fruits at the Crystal Palace (3 days).

SALES FOR THE ENSUING WEEK.

MONDAY,	SEPT. 4	{ Dutch Bulbs, at Protheroe & Morris Rooms.
TUESDAY,	SEPT. 5	{ Dutch Bulbs, at Protheroe & Morris Rooms. Clearance Sale of Stove and Greenhouse Plants and Effects, at Devonhurst, Duke's Avenue, Chiswick, by Messrs. Protheroe & Morris.
WEDNESDAY,	SEPT. 6	{ Dutch Bulbs, at Protheroe & Morris' Rooms. Great Trade Sale of Winter Flower- ing Heaths and other Plants, by Protheroe & Morris, at the Long- lands Nursery, Sidcup, by order of Messrs. Gregory & Evans.
THURSDAY,	SEPT. 7	{ Dutch Bulbs, at Protheroe & Morris' Rooms. Great Trade Sale of Palms, Ferns, &c., by Protheroe & Morris, at The Page Green Nursery, South Tottenham, by order of Mr. G. Rochford.
FRIDAY,	SEPT. 8	{ Dutch Bulbs, at Protheroe & Morris' Rooms. Imported and Established Orchids, at Protheroe & Morris' Rooms.

Remarks.—The weather has again been very hot and dry, with high winds, mostly from the south.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—60.4°.

ACTUAL TEMPERATURES:—

LONDON.—August 30: Max. 75°; Min. 61°.

PROVINCES.—August 30 (6 P.M.): Max. 66°, South Coast; Min. 56°, Shetland.

Fine—warm—heavy showers.

HENRI
VILMORIN.

THE announcement of the death of HENRI L'ÉVÊQUE DE VILMORIN on Thursday the 24th inst., in his 57th year, will come as a sad shock to his many English friends. He was one of those then young horticulturists, who, like EDWARD ANDRÉ and EDWARD PYNAERT, first became generally known to their British colleagues at the great Exhibition and Congress of 1866, when foreign visitors were present in much larger numbers than at any other subsequent time. From that time to this, HENRY VILMORIN, as he liked to be called, has been, as it were, one of us, visiting us frequently, taking part in most of our great exhibitions and conferences, speaking our language fluently, a member of our societies and clubs, a contributor to our charities. Some of us have not

HENRI DE VILMORIN trod in the paths of his predecessors, and availed himself, as he was proud to acknowledge, of their observations and of their collections. It must be pointed out, however, that these works are, some of them, mere outlines, which it has been left for the son to complete and fill in. His work, *Les Meilleurs Blés*, richly illustrated with coloured figures, is one of the most carefully elaborated volumes on the subject, and is quite indispensable to the student and experimenter.

The following note addressed to the writer of these lines, shows the principles on which he worked in his experiments on Wheats.

"I have made two series of experiments in cross-breeding Wheats. The one was initiated with a view to raise new sorts with an agricultural,

THE LATE HENRI L'É. DE VILMORIN.

only known him here, but have been privileged for over thirty years to enjoy his hospitality in his own domain, to meet him at many of the principal continental horticultural gatherings, to travel with him, and with him to visit trial grounds and seed farms in Italy and in France, and to maintain a correspondence specially relating to variation, and to the species of Conifers. In these varied circumstances, HENRI VILMORIN was always the same—high principled, conscientious, considerate, unprejudiced—a perfect gentleman.

It is only a few weeks ago that he was among us, and took part in the Hybridisation Conference, giving us the history of his successful endeavour in hybridising the annual Opium Poppy, *Papaver somniferum*, with the perennial, *P. orientale*, or *bracteatum*. He showed coloured drawings and explained the peculiarities of the plants in fluent English (see p. 56, *Gardeners' Chronicle*, July 15). That same evening he spoke at the banquet of the Royal Horticultural Society.

and, consequently, a commercial value different from and, if possible, superior to older kinds. In this line, which was only 'metisage,' as taking place between different varieties of the same species, from *T. sativum*, I obtained a good many new varieties, of which I introduced only three to commercial circulation, one being subsequently withdrawn, while two, Dattel and Lamed, are now gaining favour every year. This line is still being followed up, and I have new hybrids on hand which may be sent out if considered of sufficient merit.

"Now for the other series. Finding the process of intercrossing Wheats easier than I expected, I tried other experiments, with the object of ascertaining whether Wheats belonging to groups, generally regarded as distinct species—*T. sativum*, *turgidum*, *durum*, *Polonicum*, *Spelta*, *amyleum*, and *monococcum*—could be made to intercross, and to give a fertile offspring. The result of those experiments was on several occasions communicated to the Société de Botanique.

"There is no agricultural use whatever in obtaining a cross with the *T. polonicum*. But as I had

[From a photograph by W. Thurtle, Shifnal.]

FIG. 67.—MR. LUNT'S FIRST-PRIZE EXHIBIT IN THE GREAT GRAPE CLASS AT THE SHREWSBURY SHOW. (SEE P. 176)

The varieties in the front row, commencing above the word "Gardchron," are Muscat Hamburgh, Muscat of Alexandria, and Cooper's Black ; and those in the back row, commencing at same point, Black Hamburg, Alnwick Seedling, and Mrs. Pince. The number of points possible was 106, and those gained 96.

[From a photograph by W. Thurtle, Shifnal.]

FIG. 68.—FIRST-PRIZE EXHIBIT IN THE CLASS FOR TWELVE DISHES OF FRUIT, SHOWN BY MR. J. H. GOODACRE, AT THE SHREWSBURY SHOW. (SEE P. 177.)

failed in former attempts to cross this with other Wheats, I was glad to show that the failure had come from imperfect work, not from a physiological hindrance.

"Those people who deny the possibility of such crosses are right, if they mean that no such thing takes place by merely growing two Wheats side by side. But if they will try impregnation by hand, the stamens of the flowers to be acted upon having been previously removed, they will find that nothing is more feasible, and comparatively easier."

It would be tedious to enumerate the many contributions to the literature of horticulture and botany enshrined in the Transactions of various Societies, such as those on the Potato (*les meilleurs Pommes de terre*) and the Chrysanthemum. That he was not an even more prolific writer may be understood when it is remembered that he was the head of the largest and most historic seed firm in France, that he took a principal part in the trials and experiments at Verrières and at Antibes, where he passed the winter supervising the growth of seeds and plants which demand a warmer climate than that of the neighbourhood of Paris. At Verrières, in addition to the trial-grounds, there is a laboratory, a studio, a museum, a printing-office, as well as warehouses. At the Ferme de St. Fiacre the cultivation of the Sugar-Beet is carried on. The increase in the percentage of Sugar in this root is one of the substantial gains due to the VILMORINS.

Abroad as well as at home, VILMORIN was beloved and honoured. He was first Vice-President of the National Horticultural Society of France, a former President of the Botanical Society, an officer of the Legion of Honour and of the "Mérite Agricole." He was a foreign member of our own Royal Horticultural Society, and a recipient of the Veitch Medal in 1896.

The circumstances of his death which we glean from a communication of Mr. ARTHUR SUTTON to the Royal Horticultural Society were very sad. VILMORIN spent the day in his trial grounds at Verrières, and on returning to his house seemed to be in his usual health. In the middle of dinner, however, he complained of pains in the head, and becoming unconscious was conveyed to his room. At ten at night he rallied slightly, but unconsciousness soon set in again, and he died at 1 A.M. on Thursday, the 24th, of effusion of blood on to the brain, doubtless caused by long exposure to the sun during the day. The funeral took place on Saturday last, the only English representative present, owing to the inevitable shortness of the notice, being Mr. ARTHUR SUTTON. The relations between the SUTTON family and that of the VILMORINs have been intimate during at least two generations, and no better British representative could have been selected even had time permitted. The ceremony was very long, but very impressive. The several French Societies, Horticultural, Agricultural, and Botanical, were represented, and hundreds of friends filed past the bereaved family, first at the house, and afterwards at the cemetery, where as is the custom in France funeral orations were delivered. The trial to the family must indeed have been terrible, but it may have imparted some alleviation to them to know that they have the deep sympathy of the entire horticultural community.

THE VILMORIN
FAMILY.

HENRI DE VILMORIN, with his brother, MAURICE, offers a good illustration of the inheritance of intellectual and moral qualities. There is every reason to believe that M. PHILIPPE DE VILMORIN,

the son of HENRI, will be found to have shared the family inheritance like his father and his uncle. The grandfather of HENRI, PHILIPPE VICTOR LÉVÊQUE DE VILMORIN, was distinguished as a student and an experimentalist. To him AUGUSTE PYRAMUS DE CANDOLLE dedicated the genus *Vilmorinia*. He died in 1804. To him succeeded PIERRE LOUIS FRANÇOIS LÉVÊQUE DE VILMORIN, a Correspondent of the Institute of France, who published descriptive lists of culinary plants—*plantes potagères*—of varieties of Wheat, and of hardy flowers, the precursors of the books on the same subjects, and with the same titles, by which his son HENRI has achieved so great repute. PIERRE, or, as he was generally called, LOUIS DE VILMORIN, died on March 21, 1862, in the eighty-sixth year of his age. This was the VILMORIN who contributed to the *Transactions of the Horticultural Society*, in 1840, a paper on the "Improvement of the Wild Carrot," remarkable as showing that the effects produced by abundant nutriment were capable of transmission by inheritance. He also published notes on the improvement of plants by selection, together with considerations on heredity in plants, which are of value now when so much attention is given to the subject. The history of the remarkable arboretum created by him at Barres, and now the property of the State of France, is given in the *Memoirs of the Imperial and Central Society of Agriculture* (1862). A notice of the career and work of LOUIS DE VILMORIN was contributed by DUCHARTRE to the *Journal of the Central Society of Horticulture*, vol. vi. (1862), LINDLEY (*Gardeners' Chronicle*, April 19, 1862) speaks of him as a man of singular intelligence, with a love for scrupulous accuracy in the conduct of experimental gardening.

Madame ELISA VILMORIN, the wife of LOUIS and mother of HENRI, also enjoyed a very high reputation as an experimentalist and an observer. She not only assisted her husband, but conducted original researches, and her powers of observation, says ALPHONSE DE CANDOLLE, "were worthy of the name she bore." Her observations on the Strawberry and its history are classical, and were summarised by DECAISNE in his *Jardin Fruitier du Muséum*. They are accompanied by numerous beautiful illustrations from her pencil. She died at Verrières on August 5, 1868, venerated and beloved by all her large circle of friends for her abilities, her charm of manner, and her benevolence.

REMINISCENCES OF THE SHREWSBURY SHOW.

—This week we publish several photographs, specially taken at Shrewsbury, of some of the more important exhibits at the recent exhibition. That which represents the first prize exhibit in the commemorative Grape class may be accepted as a good illustration of the general appearance of the exhibit, with the decorations used in connection therewith. But the Grapes themselves are necessarily so greatly reduced, that their weight and the extreme finish in berry is not so evident. The information published in last week's issue, together with the photograph, will, however, supply those who were not present with a pretty correct idea of the exhibit. The other two photographs represent exhibits from Mr. J. H. GOODACRE, gr. to the Earl of HARRINGTON, Elvaston Castle, Derby, both of which won first prizes in their respective classes. We had also hoped to illustrate the magnificent group of plants arranged for effect by Mr. PETER BLAIR, Trentham Gardens, Staffordshire, but the exhibit contained so much detail that it is next to impossible to do justice to the subject. By the way, it had slipped our memory that Mr. BLAIR won the 1st prize in a similar class at Shrewsbury eight years ago, and twice previously. The 3rd

prize in this class last week was won by Mr. W. FINCH, of Coventry, and not by Mr. VAUSE, as reported last week. Messrs. ADNITT & NAUNTON have obliged us with the following details of the receipts:—Subscriptions, £420; refreshment contracts, £620; sale of tickets previous to show, £521; taken at gates, first day, £879; do., second day, £1852 (increase over best record); sundry receipts, &c., £380. It is estimated, therefore, that the income of the Society for the year will be £4672.

THE FIRS COLLECTION OF ORCHIDS.—The sale of the interesting collection of Orchids made by the late Major MASON, The Firs, Warwick, is announced to take place on the premises on Tuesday, October 11, and two following days, Messrs. PROTHEROE & MORRIS being the auctioneers. The collection contains a great number of rare and some unique specimens. Albinos were a special fancy of Major MASON's, and many of the known kinds are represented in the collection, which also includes many fine Cattleyas and Laeliocattleyas.

M. LEMOINE'S NURSERY AT NANCY.—For the following note respecting this interesting nursery we are indebted to Sir TREVOR LAWRENCE, Bart.:—"When at Nancy lately I paid a visit to my old acquaintance, M. V. LEMOINE, whom I found hale and well, and as amusing and as interested in his valuable horticultural work as ever. He has some fine new Gladioli (*Nanceanus* type), many of them running into bright violet and blue. His Montbretias, too, are striking, and among them are many large-flowered varieties I had not seen before. He has, among many other interesting plants, an outdoor foliage Begonia, a seedling from B. Dregei, it is believed, with leaves brown above and red underneath. The fruit crop round Nancy was all destroyed by the May frosts. The summer in the Vosges has been and continues the counterpart of that at home, brilliantly fine, hot, and dry, but now it is cool and pleasant."

SCOTCH-GROWN GRAPES.—How is it that the best Grapes come from Scotland? Scotsmen have claimed for years that Vine cultivation has reached a greater degree of success there than in England. Apparently, it is not that they are grown by Scotsmen, for Mr. LUNT, whose success at Shrewsbury last week entitles him to pass as champion Grape-grower for the year, has not a drop of Scotch blood in his veins. The 2nd prize also went to Scotland, and to a Scotsman. Is the air clearer, the soil more suitable, or how may the matter be explained? Perhaps our Grape cultivators in England will kindly enlighten us.

ALWAYS SOME FAILURES!—In a statistical table attached to the report of the Inspector-General in Bankruptcy, we find the number of failures under the Bankruptcy and Deeds of Arrangements Acts, among gardeners, florists, and nurserymen, in 1897, was thirty-six; and in 1898 there were thirty-five. In 1897 the total unsecured liabilities amounted to £26,238, and in 1898 the total was £27,566. It will therefore be seen that, although there was a decrease of one in the number of failures in 1898, as compared with 1897, yet there was an increase of £1328 in the amount of the unsecured indebtedness.

RISKS AT HORTICULTURAL SHOWS.—The catastrophe that overtook the horticultural exhibition in Aberdeen, as reported in these pages last week, has again reminded us of the amount of risk entailed by the exhibition of valuable plants in marquees. After every such occurrence one hears exhibitors declare that some means must be devised to minimise these risks. Horticultural shows are now so numerous that it would be absurd to hope that permanent structures could be provided in each case. There are still means, however, of protecting exhibitors in some degree. They might refuse to exhibit choice plants before a society which has not a sufficient reserve-fund to contribute

a proportion of the damage in case of disaster. Or would a new insurance society better meet the requirements of the case? The risks of a society formed to insure exhibitors against damage to plants during exhibition under tents, judging by past experience, would certainly not be greater than those at present incurred by the society which insures against damage to glass and plants by hailstorms. Perhaps this society might be prepared to take on the suggested business? But if insurance were attempted, it would probably be necessary for the Society to examine each tent before accepting liability in regard to that particular one. Some day, perhaps, the whole question may be solved by the invention of a new kind of tent—one more fitted to combat the elements, and at the same time more capable of proper ventilation than are those at present in use. No one would be better pleased at such a result than the representatives of the press.

CULTIVATED ROSES, edited by T. W. SANDERS, (London, W. H. & L. COLLINGRIDGE, Aldersgate Street). One of the difficulties attending the production of a book on Roses must lie in the

of the book, giving the name, section, date of introduction, colour, habit, requirements, adaptability, and description of the bloom of each of the best known Roses is likely to be widely consulted. The pages of the book devoted to methods of planting and cultivating Roses are perhaps less interesting, though the directions are clearly given. Insect pests are always with us, and the chapter devoted to them is worth the space it occupies. Mention should also be made of the illustrations to the book, which are numerous. A Rose must always make a pretty picture, and those portrayed are no exception to this rule, though they certainly are not specially flattered. In fact, Mr. Sanders has here put forth information acquired by him, and previously tested through the pages of *Amateur Gardening*, of which he is the Editor, and the result is an acceptable book in a handy form, which may instruct the novice, and be useful as a reference to the professional grower.

APPLE CROPS IN THE UNITED STATES.—There have been current such conflicting accounts respecting the probable yield of this fruit in the

author deals firstly with the botanical side of the question, mentioning that caoutchouc or india-rubber is found in certain families of plants, especially the Euphorbiaceæ, Moraceæ, and Apocynaceæ, contained in laticiferous vessels or tubes, which are quite closed, but which, when wounded, exude the milky latex. The trees cultivated in Ceylon include species of Hevea, Castilloa, and Manihot, and these vary, not merely in the quantity and quality of the rubber they yield, but also as regards the ease with which this can be collected. Thus, Hevea contains very pure latex, but many incisions are necessary to obtain all the milk; that of Castilloa flows more freely, but is less pure; and Manihot is inferior both in quality and quantity. Another question is, how to best draw rubber from the trees without unnecessarily mutilating them. The cuts made may be transverse, or V or X-shaped. For Castilloa the first form is sufficient, and the cuts may be further apart than in the other varieties; V-shaped incisions are recommended for Hevea. The wound made, a specially-shaped tin is affixed above it, and this receives the flow of the rubber. The main trunk and branches of an adult

From a photograph by Mr. W. H. Anonson, one of the joint secretaries.]

FIG. 69.—FIRST-PRIZE EXHIBIT IN THE CLASS FOR A "DESSERT-TABLE OF FRUIT," SHOWN AT SHREWSBURY BY MR. J. H. GOODACRE. (SEE P. 176.)

choice of a title, the number of such books making the selection of anything original far from easy. The next and far more important problem is to decide how to write such a book without giving information already repeatedly published. Happily there is an ever changing public who need telling old facts in a new form, and, as regards Roses, there are enthusiasts who can never amass too much literature connected with their hobby. Mr. SANDERS produces a favourable impression in his new book. He deals with many branches of his subject, and his writings are those of one with knowledge and authority. To quote the sub-title he gives "an alphabetical list of species and variety grown in this country, with their date of introduction, classes, colours, adaptabilities and modes of pruning; also chapters dealing with insect and fungoid pests, manures, &c." The list of Roses, classified, and with cultural notes, is valuable and up-to-date, mentioning the best of the new Roses, and as we have found by testing it, many old favourites now rarely met with, yet by no means overlooking old and tried favourites. It is so arranged that the description sought, of a Tea, a climber, a pot-grown Rose, or what not, can be found at once by seeking for it under the heading of its most prominent characteristic, or under the general name by which the class to which it belongs is known. The tabulated index of sorts at the end

United States, that we have to-day pleasure in giving a few notes from the very latest reports from the Washington Agricultural Bureau. There are but few States from which the intelligence is not even more unfavourable than those previously issued. Taking the fourteen States having 3,000,000 or upward trees bearing at the last census, there was a further decline during June and July of seven points in New York and Tennessee; three points in Pennsylvania and Kentucky; four in Missouri North Carolina and Mass.; and six in Iowa. The condition in Illinois, Indiana and Kansas underwent an appreciable change, and there was an improvement of two points in this, and of three points in Michigan and Virginia. Altogether, the outlook is a bad one.

THE COLLECTION AND PREPARATION OF CAOUTCHOUC.—The commercial value of Caoutchouc renders the selection and treatment of Rubber-trees worth every attention on the part of the growers; and the Royal Gardens, Kew, have for years taken a foremost part in all questions with the botany, cultivation, and distribution of Rubber-trees. The recent experiments carried on in connection with the Royal Botanic Gardens, Ceylon, should prove especially helpful. Mr. F. PARKIN's report upon these trials, published in the *Bulletin* of that Institution, is now before us. The

tree are still considered the most satisfactory parts upon which to operate, as experiments to obtain caoutchouc by tapping the roots, or using the seedlings or the season's crop of young shoots, have not hitherto proved successful. Proper preparation of the rubber has in time past received but too scanty attention. The plan pursued was rough, and resulted in putrefaction, mould, and imperfect dryness. Hevea-milk is now prepared by means of acetic acid or mercuric chloride, both of which have yielded good results, but the latter substance leaves some of the mercuric salt in the rubber, to the possible deterioration of its market value. As regards Castilloa rubber, the number of trees in Ceylon is, it is said, too small to make it worth while to use the centrifugal machine, but creaming yields excellent rubber at a small cost. Mould and putrefaction are guarded against by the use of antiseptics, such as creosote and mercuric chloride, and by rapid drying of the rubber on porous surfaces. Such are, briefly, the main points determined by Mr. PARKIN, and detailed in his paper. Still further experiments and investigations are to be entered upon, as those hitherto made have yielded such decided results. It is considered certain that when growers adopt the advice prepared for them, when the selection of the best varieties of Rubber-trees has been made for them, and the methods of treating these and their yields according to their separate require-

ments have been determined with certainty, and widely published, the result will be an improvement in every way. The trees will be economically managed, the rubber collected and treated antiseptically, will be purer than in time past; and, in short, the caoutchouc will be superior, and yet less costly to produce, than that which is at present in the market. These are not the days when cultivators can safely follow the methods pursued by their forerunners; they must remember the competition of the age, and join in it, and in raising rubber or any other produce must keep abreast of the times. Mr. PARKIN's paper is followed by an appendix in the form of a summary by the Director. Mr. WILLIS, who also adds a list of books and pamphlets on the general subject, which will be useful beyond the limits of Ceylon.

"THE FERN BULLETIN."—The July number of this "quarterly devoted to Ferns," is now published from Binghampton, N.Y., by the Fern Bulletin Co. The contents include the third paper, by A. A. EATON, on "The genus Equisetum with reference to the North American species;" "Trichomanes petatum in Japan," by K. MIYAKE; "How to identify Shield Ferns: variety of Dicksonia," by W. R. MASCON; "Pteridophytes of Georgia," by R. M. HARPER; and other articles appropriate to the scope of the magazine.

A MALFORMED BEGONIA FLOWER.—M. G. TOURET-GRIGNAN writes from La Varenne, St. Hilaire, the following account of a "Begonia erecta cristata (Vallerand type) cultivated in my garden and that has produced a curious flower. Two petals, the smallest, bear at the edge in the middle a small hirsute yellow cushion, exactly resembling a portion of the stigma. The flower is a male one, and otherwise normal. There is no trace of an ovary, and the stamens are normal and as numerous as in the other flowers. I have never heard of analogous phenomena, so think you will be interested to hear of these."

AGRICULTURAL RETURNS OF GREAT BRITAIN, 1899.—From a preliminary statement for 1899, issued on the 29th ult. by the Board of Trade, and compiled from returns collected on June 5, we extract the following:—

CROPS.	1899.	1898.	1897.
	Acres.	Acres.	Acres.
Wheat	2,000,951	2,102,206	1,889,161

Hops	51,843	49,735	50,363

THE CHELSEA PHYSIC GARDEN.—We record with pleasure the fact that this historic garden is now to be placed under the care of a curator, owing to the public spirit of several learned societies, and the London County Council, whose determination to maintain the garden we announced some time ago. The person appointed to the position is Mr. WILLIAM HALES, who has been, during the past three years, in the Royal Gardens, Kew, and previously in the Birmingham Botanic Gardens.

PUBLICATIONS RECEIVED.—*Anne Pratt's Flowering Plants*, Vol. 11., No. 10.—*Nuovo Giornale Botanico Italiano*, Vol. VI., No. 3, Luglio (Florence).—*Bullettino della Società Botanica Italiana*, No. 5, 6, Maggio-Giugno (Florence).—*Journal de la Société Nationale d'Horticulture de France*, July.—*Agricultural Gazette of New South Wales*, Vol. X., Part 7. This contains notes on a northern tour, taken by the Hon. J. Cook, Minister for Agriculture, for the purpose of inspecting

the farm at Wallongbar, and a tick-infested district in Queensland; the Valonia Oak, and native Food Plants (Part III.), by J. H. Maiden; Market in China for our surplus Wheat; Phylloxera in Goulburn Valley, M. Blinn, &c.—*Michigan Wild Flowers, Collected and for Sale*, by W. A. Brotherton, Rochester, Michigan, U.S.A.—*Botanical Gazette*, Chicago, July. This issue includes: Studies on Reduction in Plants, Plates I.—VI., G. F. Atkinson; Flowers and Insects, XIX., Charles Robertson; and Origin of the Leafy Sporophyte, J. M. Coulter.

NURSERY NOTES.

MR. JOHN RUSSELL, RICHMOND.

IF anyone has avoided the risk attending the carrying of all of his eggs in one basket, it is Mr. Russell. He has nurseries at Brentwood, in Essex, at Haverstock Hill, in Middlesex, and at Milford and Richmond, in Surrey. These together provide an area of about 200 acres. A week or two ago, yet another nursery was acquired, namely, that known as Spring Grove, Isleworth, which belonged to Messrs. C. Lee & Son. Fine foliage plants are to be made a specialty at Isleworth.

It is however with the establishment at Richmond that we are now concerned, a branch of the business which is under the management of Mr. L. R. Russell; the other two sons directing the business at Brentwood and Haverstock Hill. The Richmond establishment is not one nursery, but it consists of pieces of land separated from each other. The offices and headquarters face the Kew Road, and are the same that formerly belonged to Mr. Steele. There are here a number of glass-houses which are used chiefly for propagating and growing into moderate-sized specimens many species and varieties of half-hardy and hardy ornamental foliage and flowering plants; also numerous greenhouse species particularly adapted for use in furnishing. One of Mr. Russell's specialties is Ivies, grown in pots plunged in the open, so that but little check is given to plants when transplanted. A large number of Ivies is disposed of annually through the trade and to private customers. Indeed, it occasions some surprise to learn the figures, because Ivies, though the most suitable plants for certain positions, should not be planted where flowering plants will succeed. But the variety of form and colour of leaf in them offer the planter the means whereby he may make even an Ivy-covered wall or fence very interesting. Mr. Russell possesses a very pretty variety of Ivy, which bears his name. It has small lanceolate leaves, with broad, creamy-white margins. There are numerous plants also of Ampelopsis, Passion-flowers, and other climbing plants.

ASPARAGUS AND SEAKALE.

Mr. Russell has a piece of ground at Richmond that has for many years proved to be excellent for the cultivation of Asparagus and Seakale. When we recently saw the Asparagus it was looking very fine, many of the stems being more than 7 feet in height. There is a stock of 100,000 crowns four years old, and ready for disposal during the coming autumn and winter for forcing. There are, of course, successional batches to provide crowns sufficiently strong for forcing next year and the succeeding ones.

The Seakale has not made quite so much progress as usual, owing to the drought; still, there is a good stock of plants on the 5 acres under this crop. A new variety here would appear to be deserving of mention. It originated from a cabbage seedling four years ago, and in colour is between "Lily White" and ordinary Seakale. The special points of the variety are vigour of growth, and a habit similar to that of a self-protecting Broccoli,

though in lesser degree. In place of the petioles of the leaves extending at right angles to the stem, they incurve.

We noticed much Rhubarb of Early Albert and other varieties, all for disposal for forcing.

ORNAMENTAL TREES, SHRUBS, &c.

In several of the nurseries, and particularly in the larger one on Sheen Common, Mr. Russell has a large variety of ornamental trees and shrubs, including flowering species, and those possessing attractive foliage. Of Ligustrum we noted several species; the Japanese Privets for instance, varieties of *L. japonicum*. But the feature of the Privets was the large number of the golden variegated variety of *L. ovalifolium*, of which, it is estimated, there are 40,000 plants of saleable sizes.

Rhus typhina, R. Cotinus, R. glabra, R. laciniata, &c., all very pretty deciduous shrubs, were noticed in quantity. The Forsythias, including F. Fortunei, F. suspensa, F. viridissima, and a variegated variety of the last-named species, are gaining popularity, but not to the extent they deserve. Also a number of fine standards and bushes of the best of the hardy Acacias or Robinias, including about 1000 fine plants 7 feet high of the well-known *Acacia inermis*, besides *Bessoniana*, and other "Mop-headed" varieties; also *Robinia neo-mexicana*, *pyramidalis*, *hispid grandiflora*, &c. Maples were noted in considerable variety. *Acer virgicum rubrum*, a picture in spring; *A. colchicum rubrum*, most ornamental in autumn, and *A. pseudo-platanus purpurea*, with its leaves of effective purple colour on the underside, and exceedingly ornamental when disturbed by the breeze, are some of the noteworthy ones. A large stock of standard Limes is possessed for street and avenue planting, including a variety with smooth, glossy leaves, and which retains its foliage exceptionally late in autumn.

Hollies and Aucubas being plants which are greatly in request, are kept in extensive "drifts." Of Hollies, Mr. Russell says he has about 200,000; and of Aucubas we saw instances of 7000 plants in a "drift." *Ailanthus glandulosa*, the very popular *Osmanthus* in variety, *Phillyreas*, *Catalpa aurea*, *Daphne Mezereum*, *D. M. alba*, and *D. M. rubra*, *Arundo Donax*, hardy Yuccas, *Viburnums*, *Skimmias*, common and uncommon species of *Quercus*; *Olearias*, *Magnolias*, *Eurya japonica* and *E. latifolia variegata* (in large numbers), *Cratagus*, *Cerasus*, and *Berberis*; *Horse-Chestnuts*, *Cornus*, *Beeches*, *Laburnum*, *Pyrus*, *Syringa*, were also among the evergreen or deciduous species of flowering and ornamental trees and shrubs.

When speaking of the "Mop-head" *Robinia* previously, we should have mentioned a variegated form of "inermis." From present appearances it will be likely to become very popular for alternating with the green variety in town or suburban gardens.

The American plants, or most of them, are cultivated in the nursery at Milford, and these we did not see. At Sheen, among the Cedars, were some nice plants, 7 feet high, of *Cedrus Deodara* and *C. atlantica*, and a smaller batch of *C. a. glauca*, one of the most effective of all coniferous trees. Paul's double Scarlet Thorn, the merits of which are well known, is grown in pots for use in the forcing-house. The standard Planes were remarkable for their strong, smooth stems, and would make fine avenue trees.

A considerable variety of herbaceous, perennial, and other border plants was observed in one or the other nursery. The ground on Sheen Common contains a fine lot of fruit trees, and we were very much surprised to find upon these a more than average crop of Plums; the bulk of them were Victorias, and there would certainly be some hundreds of bushels. Apples were also good, and rather better than an average crop; whilst Pears were much under, excepting the variety Jargonelle.

Mr. Russell cultivates his Roses and many other plants in Essex, and of these we hope for an inspection at a future time. But one thing is very certain, the business is conducted with great enterprise, and is attended with success.

THOMAS LUNT.

THIS successful Vine cultivator, who was quite a hero in Shrewsbury last week, is the son of English parents, who removed to Scotland. He served his apprenticeship at Ardgowan with his father, under whose tuition he obtained a good groundwork in the principles of plant and fruit cultivation. Leaving his father, young Mr. Lunt gained further experience at Dalkeith, Drumlaorrig, Thoresby, Mentmore, and Crichele House, all of which are first-class well-appointed establishments. Mr. Lunt was appointed to his present position at Keir eleven years ago, and was there but a very few years before he entered the exhibition field, where he has met with extraordinary success at the shows in Edinburgh of the Royal Caledonian Society, and at the Chrysanthemum shows also in

it seems to luxuriate here (at Burford) in the open air—and so does *Aristolochia elegans*. The experience of most gardeners is, I expect, the same as mine—that we fail in growing plants more often from coddling them too much than from any other reason. This year our Iris-flowered Cannas have been a sight all through the summer, and will continue in vigour and abundant flower until frost visits us. The result of our experience is that Martin Cahusac is by far the best variety for outdoor cultivation. It is very floriferous, and bears very large heads of fine flowers, which are more persistent than those of most varieties. I have several times tried to induce the trade-growers of Begonias to introduce into this country the beautiful variety "Bavaria," which is of German origin. I first saw it in the Palm garden at Frankfurt, and being much struck by it I procured a supply, I think, from Erfurt. It is a compact, low-growing variety, vigorous and very free-flowering, with

the Kew plant has. I would suggest that other positions be tried, and a longer period of flowering should result. A most important item is to plant the seedlings out very early, not allowing them to long remain in small pots to starve. *E. H. Jenkins, Hampton Hill.*

A MONOECIOUS ARAUCARIA IMBRICATA.—I send you a photograph of a portion of an *Araucaria imbricata* growing at Pencarrow, Rodmin. The tree bears two very fine female cones, and a great number of male catkins. The second cone is just below the prominent one, but unfortunately it is hidden by the crossing of the branches. These cones contain an unusually large proportion of good seeds, due, no doubt, to the close proximity of so many pollen-bearing catkins. The tree is situated at the foot of the famous Pencarrow rockery, quite 50 yards distant from any other examples of the same species. The nearest is a fine female tree, which has over forty cones; these are rather small, and contain a very small proportion of fertile seeds. I attribute this to the distance—quite 40 yards—from the nearest pollen-bearing tree. The monoecious tree was purchased by Sir William Molesworth, the well-known Secretary of State for the Colonies, from Messrs. Knight & Perry, the predecessors of Messrs. Veitch & Co., for £25, in 1834. My employer, Mrs. Ford, a sister of Sir William, graphically describes the ceremony of planting this, at that time, most rare and curious tree. There was a large and distinguished house-party at Pencarrow, and they assembled in solemn state to witness the ceremony of planting. Among them was Mr. Charles Austin, the eminent lawyer, who after carelessly handling the plant, feelingly remarked, "It would be a puzzler for a monkey." The name "caught on," and now *Araucaria imbricata* is more generally known as "Monkey Puzzle" than by any other appellation, scientific or otherwise. *A. C. Bartlett, Pencarrow.* [We thank you for your interesting note, but do not reproduce the photograph, as a fine specimen of a Monoecious *Araucaria* was figured in our columns Mar. 1, 1873, p. 291. Ed.]

THOMAS LUNT,

Winner of the Gold Medal and First-prize in the Great Grape Class at Shrewsbury.

FLAVOUR IN TOMATOS.—I have a good deal of sympathy for those persons who are unable to find flavour in modern Tomatos. I had thought that there were cases in which, during the past ten years, appreciable advance had been made in true flavour production. Those whose privilege it has been from time to time to test the merits of the smaller fruited varieties grown at Chiswick, have been fortunate enough to find very pleasant flavour in some of them. The large ones, found so useful for market purposes and ordinary kitchen uses are not tested for flavour, as these do not display any distinction in that respect, one from the other. A less ripe fruit may be a little more acid than is an over-ripe one, and that is all. These are regarded purely for their productiveness, appearance, and solidity of flesh. Very sensible and practical requirements, as all engaged in Tomato production know. [Is it sensible to grow and sell inferior products? Ed.] But real flavour is looked for only in those which have fruits of moderate or smallish size, such as are best fitted for the dessert-table, and of these very excellent ones are Red Dessert, Golden Nugget, Red Peach, and now the New Chiswick Peach. But to get the best flavour from Tomatos, they should be gathered direct from the plant, and when the fruits are cool. Warm fruits are never so pleasant to eat. Tomatos do not, and never will, compare in flavour with what is found in the higher or standard fruits, but when palates are natural, and have not been vitiated by port, sherry, whisky, strong condiments, sundries, &c., there are less prominent flavours highly appreciated. Flavour is not always an inherent property; it depends very much also on the condition of the palate. Only the other day I was enabled to taste fruits of the Old Red Tomato, grown out-doors, and fully ripened, and I found that it was absolutely flavourless—quite inferior to newer ones. When so much is being done to seek to impart high flavour to Tomatos, it is unkind to regard such efforts as sheer waste labour. *A. D.*

BOWLING-GREENS: HOW TO FORM THEM.—In reply to "Bowler" in your last issue, I may say that this game, although enjoyed by so many, appears to be most diverse in its rules and regulations, some "greens" being flat, whilst others are raised in the centre. In Scotland the game is played by each set of players across the green, side by side, each set retaining the same plot for play. In the South of England the bowls have a greater bias, and the

pretty foliage and charming bright pink flowers, and is, moreover, a good doer. It makes a really lovely edging, and strikes everyone who sees it. *Trevor Lawrence.*

CAMPANULA MIRABILIS.—Notwithstanding the tropical heat of the past two seasons, I believe no really fine plant like that at Kew has flowered at an earlier age than three years. But this species is so unique in its aspect generally, that it is not wholly uninteresting before it flowers. I believe that the longer a plant is, before reaching the flowering stage—assuming that it is planted out, the finer is the flowering, owing to the greater degree of development of the plant. But flowers may be had each year if seeds be sown annually, and plants of different ages thus obtained. The great flat rosette of almost succulent leaves is a very remarkable circumstance in the bell flowers, if not in the whole Campanulaceae. In spite of the fact that the Kew example was one of the finest plants that have yet flowered, I am not sure that the position it is in would prove the most suitable generally. Many bell-flowers delight in a little shade, and with such environment develop even more rapidly than in the hot sunny position that

HOME CORRESPONDENCE.

CAMPANULA MIRABILIS AND OTHER PLANTS.

—I hope your readers will not be discouraged by Mr. Wolley Dod's and Herr Max Leichtlin's experiences from cultivating *Campanula mirabilis*. Out of the few plants I have, one flowered at Burford this summer, and formed a lovely mass of pale blue flowers, spreading over the ground for some distance on all sides. Experience will doubtless teach the conditions requisite to ensure it flowering. Last year, and again this, we have had a strong plant of the lovely *Solanum Wendlandi* in full flower in a warm and sheltered corner ever since the summer set in. Though a native of Costa Rica

Edinburgh, for Mr. Lunt has displayed equal skill in the cultivation of Chrysanthemums as of Grapes. In England he made his *début* at Shrewsbury last week, and at a single bound easily obtained a prize that has been discussed and coveted during the greater part of the year. There is no apology needed for publishing the photograph of so excellent a gardener.

players are divided, half of each side contending against half of their opponents, on each side or end of the green. In Lancashire, Cheshire, &c., where the game is very popular, the practice is quite distinct from either of those mentioned above, the leading player selecting any portion of the green he chooses, so that the length is over 21 yards, and the Jack not within a yard of the edge. A few particulars of the form and size of Lancashire "greens" are here given. So far as can be gathered there are no regulations as to form or size—in fact, it is most difficult to find two "greens" approaching uniformity; often the designer has no choice, but must make his "green" to fit a certain space, which may be square or irregular in outline. Size is as variable as form, ranging from 400 to 2000 square yards; therefore, the directions here given can be altered according to circumstances. The shape recommended is a long square, because of the greater variety in the fall of the land, which mean increased skill required; the following dimensions will be ample for four, five, six, or seven, sets of players (four to a set), 38 by 28, 43 by 33, 46 by 37, 50 by 41 yards. Of course, in matches it would be desirable to have fewer players. The centre of the "green" is usually termed the "crown," and varies from 3 to 16 inches higher than the corners. Of course, it will be readily understood the higher the "crown," the more difficult to play. Before commencing the work, the ground should be pegged out with boring rods. Select the centre, drive a peg level with the surface when completed, and level to each corner. Afterwards, lower the peg 1 inch to every 6 yards, so that a green 38 by 28 yards will fall 4 inches. Next, find the middle of the side and drive a peg in 3 inches below the centre peg, the middle of the ends $3\frac{1}{2}$ inches below the centre; then with the boring-rods level from the corners to the middle of the sides and ends, putting in pegs every 7 to 9 feet; from the outer pegs to the centre, insert pegs at convenient distances, which will give the level of the "green." Of course, if necessary, the ground will have to be drained, and an inch of ashes under the turf is most desirable to check worms. A couple of feet of the edge should be kept well up, as the extra rolling has a tendency to make the edge drop, so that the bowls cannot stop on near the edge. The very best turf should be selected, or the bowls will never run true; if good sod cannot be obtained, sowing with selected seeds is preferable. A gutter or channel round the edge about 6 inches wide and 1 inch deep, with a wooden edging is necessary, to stop the bowls when they run off the "green." R. G. W.

HYDRANGEA HORTENSIA.—I forward a head or two of the above, and think you will agree with me that the blue tint is far more intense than what is usually met with. The plant stands somewhat in the shade, and we always find that plants so situated are a far better blue than those in a sunnier aspect. Two years ago I had pruned this bush, as it was trespassing over the walk too much; last year it only had ten or a dozen heads, while this season it carries no fewer than 290, and measures $7\frac{1}{2}$ feet across. I think this close pruning worth repeating, even if one has to wait two years, as the quantity of flower and intense blue is the admiration of all who have seen it. J. Mayne, Bicton. [With this came specimens of a more intensely blue colour than we have ever seen before. Ed.]

A VISIT TO BIRDSALL HOUSE GARDENS, YORKS.—Quite recently I had an opportunity of seeing these gardens. The glass-houses are built on the corridor principle, which runs east and west, with span-roofed houses opening out from it. In the vineries were heavy crops of Grapes, Muscat of Alexandria and Black Alicante being chiefly grown for a late supply. The Strawberry-Grape is represented by a few canes, and is highly appreciated by Lord and Lady Middleton. Figs are grown in quantity; two span-roofed houses being devoted to them. The trees are grown in large pots, plunged nearly to the rims in a bed, and were carrying a fine second crop of fruits. Brown Turkey is the most reliable cropper, but several other varieties are grown, including Negro Largo, St. John's, Violette de Bordeaux, and Bourjassotte Grise. In one part of the garden with an east aspect is what Mr. Wadds called the Apricot-shed (fig. in *Gardeners' Chronicle*, Feb. 2, 1895, p. 133); this is like a lean-to shed with a glass roof, the front (about 3 feet high) being open. The trees are planted outside, and trained on a trellis under the

glass. Quantities of fruit had already been gathered. To anyone wishing to grow this delicious fruit, I would advise the adoption of the above system. Amongst the Apricots, here and there, I noticed several Plum-trees bearing heavy crops, the varieties being Green Gage, Prince of Wales, Kirk's, and Golden Drop. Out-of-doors fruit-trees are numerous, but this season there is not an average crop. Carnations are largely grown, especially those of the Malmaison type. A large bed of dwarf Dahlias, called "Rising Sun," was ablaze with fine blooms of a bright scarlet colour; none of the blooms exceeded 18 inches in height, but were yet quite clear of the foliage. Geo. Taylor, *Byram Gardens*

WASPS.—On a recent sunny afternoon, after the tea was cleared, it was found that a small portion of honey had been spilt on the table-cloth by the waiters, whose notice it had escaped. The attention of the writer, who, by the way, was reading the *Gardeners' Chronicle* in the same room, was attracted to the coming in and going out by one of the windows of a wasp; and upon watching its movements closely, it was found that the honey had caught its eye. The repeated visits on the part of the wasp, which were at intervals of about ten minutes, were evidently for the purpose of carrying off the dainty to its cells, for in the course of an hour every particle of the honey had disappeared. The wasp's nest must have been at no great distance. The lesson learned had reference to the amount of damage these creatures are capable of doing to fruit or anything else that is palatable to them. Geo. Paxton.

DIANTHUS KNAPPIL.—On p. 168 I read with surprise that the flower-stems of this species "scarcely ever exceed 9 inches in height." I have grown it for several years, and though it ripens seed here very sparingly, I now have some two dozen plants in flower in different positions on rockeries and raised beds. I have just been to measure their stalks, and find that they nearly all range from 12 to 18 inches in length. I regret that it is so, because their leggy stalks and their inability to hold up their heads is the great defect of this and of most of these cluster-bearing alpine Pinks, which might otherwise be fairly good rock plants. Can any of your correspondents give me recent authority for the name? I find in Nyman's *Conspectus* D. Knappii (Asch. and Kan.), a native of Montenegro, &c., given as a synonym of D. liburnicus (Bartl.); and in *Index Kewensis*, D. Knappii (Asch., in Nyman's *Conspectus*) is referred to D. liburnicus (Bartl.). In the *Kew Handlist of Herbaceous Plants*, D. liburnicus (Bartl.) is mentioned as cultivated in Kew Gardens, but not D. Knappii. I also find on reference to authority that the name D. liburnicus (Bartl.) is about forty years prior to D. Knappii (Aschers), but do they belong to the same plant? C. Wolley Dod, *Edge Hall, Malpas*.

THE TOMATO UNDER GLASS.—I have read with interest what "A Traveller" writes on p. 174. I fully agree with your correspondent as to flavour, and his remarks thereon, and equally so as to the practice of denuding the plants of their leafage, which alone may be responsible for a great deal more than even "A Traveller" would appear to claim. With the great, pinnate leaves of these vigorous subjects reduced to the veriest scrap of their strongly formed rachis, how is it possible for such mutilated subjects to properly perform the functions for which such things were by Nature intended? In not a few market places it is the common practice to plant out Tomatos at about one foot apart, then with the generous assistance of hose-pipe, an equally generous—if unfruitful growth quickly follows. Then a boy or youth, from 14 to 18 years, is set in this thicket to "let in a little light," and usually he does it with some idea of liberality. I have more than once counted from eight to ten plants across a central bed in a span-roofed house, the width of which was not more than 8 ft. or 9 ft. inclusive of brickwork. In such a space five plants would have been ample, and better still only four, so that a centre pathway could have remained in the middle. In these dense thickets of growth, light and air, the greatest essentials to free setting, never penetrate, and dozens of plants never carry a fruit. Then follows the wholesale thinning, and the work of destruction is well nigh completed. Market gardeners who have never served a days apprenticeship in any garden, are not

one bit worse than many experienced gardeners who have taken to the trade. Let the plants be grown with full light and full foliage before we say in this wholesale fashion that there are no good Tomatos to be had by cultivation under glass. Many marketed fruits are gathered half ripe, hence another reason for poor flavour. And now a word as to the single-stem system of culture. "A Traveller" refers to this as "the stupid plan of reducing the plant to a single stem by removing the lateral shoots." But your correspondent does not attempt to show how it is stupid. Is not the natural growth of the seedling the erect, single stem, or main stem? How does "A Traveller" secure his "six to ten main shoots per plant?" Not by letting the plant grow its way naturally. No; he has to stop, and pinch, and stop again, to get the number of shoots he requires, which is not a natural process, but the reverse. At the same time, this fan-shape system is a greater consumer of time—an item your correspondent appears to lost sight of—than is the single-stem, even with five plants to one. I am not denying the suitability of the fan-trained plant for low walls; this is obvious, but space for space and weight for weight, till the crop is finished, the fan-trained would not have the smallest chance with the single cordon under glass. Here, again, is only needed the reasonable and feasible to secure the obvious; and I think the strongest possible reason of all for the single-stem culture is that it is the nature of these plants to produce flowers and fruits on the main stem, between the joints, and not from axillary buds from the joint. This is a remarkable fact generally little recognised. Were it otherwise, the fruiting taking place from the axils, there would be more reason in training out the lateral branches for fruiting purposes. One decided advantage of the single stem to the cultivator is, that he thereby secures the earliest fruit the plant is capable of producing. On the other hand, by the fan-shaped method, time is certainly lost or taken up in converting the plant into the required size or shape. It is this latter that is the unnatural, because if "A Traveller" never removed the point of the middle stem, he would be quite unable to get his "six to ten main shoots" from a plant that naturally produces but one main shoot. All else is subordinate. This one rod in an extended season will readily produce from a dozen to sixteen bunches of fruit; and of good quality if rationally grown. Moreover, the Tomato is self-asserting in this way, that if you give a plant the necessary light, the first bunch will be within a few inches of the soil, the fruit touching it long before it is ripe. We see this in no other plant in the same degree, for the Melon and the Cucumber, fruiting from axillary buds on laterals, and not on main buds, do not in the least compare with the Tomato. Yet numbers of solanaceous things fruit thus, and it is here that the Tomato is unique. E. H. Jenkins, *Hampton Hill*.

RASPBERRY, FILLBASKET.—The above variety of Raspberry undoubtedly bears out its good name at Bowhill, Selkirk, N.B., and as grown by Mr. Lunt it is truly a Fillbasket. When visiting at Bowhill a few days ago, I was very much surprised to see the marvellous growth the plants have made during the present season, canes averaging from 10 to 12 ft., and of corresponding thickness. The fruiting canes, I was informed, had carried enormous crops, and judging from their present appearance they are likely to give a fine succession of ripe fruits for a considerable time. The system of training is that of tying several canes to a strong stake in the centre of each clump. The position for the plantation was wisely selected when the canes were planted six years ago. It is sheltered from the north-east by high garden walls, and on the west by some tall trees, which cast their grateful shade over the canes during the afternoon; in fact, the only direct sunshine they receive is for a few hours in the middle of the day. R. T. S.

FRUITS IN YORKSHIRE.—The three most important of British fruits—Apples, Pears, and Plums—are fewer here than they have been for ten years. The result is unquestionably due to the severe frost and cold winds experienced in May. Small fruits, excepting Gooseberries, have been a fairly good crop. Superlative Raspberry stood the drought well, and is the finest variety grown here. J. Elworthy, *Newton Hall Gardens, Yorkshire, East Riding*.

FRUIT IN CORNWALL.—Peaches and Nectarines are remarkably good in quantity and quality. The trees have made clean and healthy growth, and I have never known them to be so free from blister; but they would not mature their heavy crop without most liberal supplies of water to root and branch. Apples, Plums, and Pears are a very partial crop. Cherries a complete failure, but the trees are making good growth for next year. Strawberries, especially Royal Sovereign, very good. Bush fruits abundant, and we have still plenty to gather of Gooseberries and Red Currants from under permanent wire net protection to present date (August 27). *W. Sangwin, Trelinick Gardens, Truro.*

FRUIT IN COUNTY ROSS AND CROMARTY.—Apples and Pears are good, notwithstanding the east winds prevalent during the time the trees were in blossom. Small fruits were abundant. Plums are quite a satisfactory crop. Apricots are a grand crop, and with the good weather we have had lately, they are ripening well. *H. Henderson, Cromarty House Gardens, N.B.*

PLANT NOTES.

CORONILLA VARIA.

THIS plant is unfortunately too rambling in its growth for the ordinary herbaceous border, the roots travelling a long distance, and throwing up suckers, which soon smother other plants; it has, however, the merit of flourishing on a dry, sunny bank, where many other species would fail, and is on that account worthy of cultivation. The flowers are produced in heads similar to *C. glauca*, which they resemble with the exception of their colour, which is a pleasing shade of pink marked with white. It is strictly herbaceous, and of a spreading habit, seldom exceeding 1 foot in height; a good succession of flowers is maintained throughout the summer months. I recently saw a nice plant of it in the beautiful Abbey Park, Leicester, where Mr. Burn has introduced it into the shrubby border with success. *W. H. Divers.*

VEGETABLES.

PEA THOMAS LAXTON.

THE varieties of culinary Peas are far too numerous, and few of the later additions are equal to the older varieties; but Thomas Laxton is a variety which has afforded me much satisfaction this season. It possesses the best qualities of my old favourite, Ne Plus Ultra, with the advantage of coming into use much earlier, and grows only 4 ft. high, whereas Ne Plus Ultra grows from 6 to 8 ft. Sown on April 5, the first flowers opened on June 10, and the first pods were ready for use on July 4—that is, only two days later than Exonian, the quickest Pea I know of, and twelve days earlier than Ne Plus Ultra, sown at the same date; the pods contain eight or nine Peas, of excellent flavour when cooked, and it bears well. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

SOCIETIES.

ROYAL HORTICULTURAL.

Floral Committee.

AUGUST 25.—The Floral Committee met at Chiswick on this date, and inspected the large collection of Pompon Dahlias grown there this season for trial. Unfortunately they could not be seen to the best advantage, owing to the drought, and though Mr. Wright had done his utmost to have the plants ready for inspection, they were generally of spare growth, and only partially in bloom. The following, however, were considered worthy of three marks:—*Hypatia*, *Vulcan*, *Opal*, *Ganymede*, *Ceres*, *Claribel*, *Florence Woodland*, *Admiration*, crimson, tipped with white, specially recommended for border decoration; *Bacchus*, bright scarlet; *Captain Boyton*, one of the very best dark varieties; *Emily Hooper*, *Eurydice*, *Fabio*, *Little Sweetheart*, *Mars*, *Nerissa*, soft rose, tinted with ailver, a charming variety; *Sunny Daybreak*, *Tommy Keith*, red, tipped with white, very pretty; *Annie Holton*, *Darkness*, *Dagmar*, *Madeline*, *Irene*, rosy purple, tipped with white,

also specially recommended as a charming border variety; *Iris*, *Nancy*, *Fashion*, pale orange, one of the best; *George Bruckman*, *Grace*, *Jolanthe*, *Isenlt*, *Phoebe*, *Red Indian*, *Rowena*, *Whisper*, and *White Aster*. Another examination of the plants will be made a fortnight hence; meanwhile it is hoped there will be a fall of rain, which is very greatly needed at Chiswick for many other things. A plantation of leading varieties of *Cactus Dahlias* is not yet ready for inspection, and greatly need a good soaking of water. A *Cactus* variety named *Britannia*, should be noted as a dwarf-growing, tree-blooming sort, throwing its flowers well above the foliage, and admirably adapted for border decoration.

DRILL HALL.

AUGUST 29.—It was quite a vacation meeting that of the Committees of this Society in the Drill Hall, Westminster, on Tuesday last. In extent the display was less than has been the case for a twelvemonth, and the number of visitors just showed how few there are, comparatively speaking, in London at the present time. Horticulturists give themselves a holiday occasionally, like most other folk, and the present season is a favoured one for the purpose. Business, however, proceeds through it all, and though the show was a small one (especially after Shrewsbury), there was a show. An exhibit of *Nepenthes* from Messrs. JAS. VEITCH & SONS was worthy every praise, and certainly of a wider body of spectators, and some New Zealand plants, mostly new species, from the same firm, had much interest. The Floral Committee recommended six Awards of Merit—two to *Dahlias*, one to *Gladiolus*, one to *Robinia inermis alba marginata*, one to a *Canna*, and one to *Polygonum Baldschuanicum* (see *Gardeners' Chronicle*, Jan. 9, 1897, p. 17).

There were few Orchids, and the only award made was an Award of Merit to *Cypripedium* × *Captain Holford*. The Fruit and Vegetable Committee did less even than that, for no novelty was certificated.

The lecture announced to be given by M. GEORGES TRUFFAUT upon "The soil considered as plant food and its exhaustion," was postponed, owing to that gentleman being detained at present by his military duties.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. R. Dean, W. Howe, Jas. Hudson, C. J. Salter, Chas. E. Pearson, W. Bain, J. D. Pawle, Jas. Walker, Geo. Gordon, E. H. Jenkins, and E. T. Cook.

Mr. S. WARE, Hale Farm Nurseries, near Tottenham, made an exhibit of *Cactus* and *Pompon Dahlias*: sprays of *Cannas*, the latter of newer varieties; sprays of *Lilium speciosum*, in varieties; also many bouquets of *Helianthus multiflorus*, in as many varieties (Silver Flora Medal).

Messrs. BARR & SONS, 12 and 13, King Street, Covent Garden, London, had a few varieties of hardy flowers in bunches. Some of the choicer herbaceous *Phloxes* were represented, and *Lathyrus latifolius albus* was conspicuous; *Gladioli* in a few varieties were also good (Silver Banksian Medal.)

The most imposing group in the hall was one of *Nepenthes*, from Messrs. JAMES VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea. The plants were better than any the firm has shown this season, with finer, more-developed pitchers. Each plant was raised on a stand over a ground-work of *Adiantum Ferns*. *N. Mastersiana* × (the dark-coloured variety) had about twenty-five pitchers, and was a handsome object. Quite a different one in form and colour is *N. Chelon* ×, with globular mottled pitchers depending from the basket upwards of 2 feet, of which a very fine plant was shown. *N. mixta* × and *N. mixta sanguinea*, both from seed from the same plant, were magnificent. They have handsome pitchers almost 1 foot in length, the variety *sanguinea* being darker in colour, but otherwise much the same as *N. mixta*. The well-known *N. Hookeriana* and *N. Rafflesiana*, the latter with pitchers upon stems 2 feet or more long. *N. Balfouriana*, the new hybrid (figured in *Gardeners' Chronicle*, July 29, 1899, p. 91), was again shown, and this time with longer pitchers. *N. Amesiana* was represented by an enormous plant with abundance of pitchers. *N. Dicksoniana* ×, *N. Wrigleyana* ×, *N. intermedia*, and the pretty little *N. Sedeni*, were others shown in this remarkable group. The only species shown were the excellent *N. Curtisii superba*, *N. Burkei*, an exceedingly pretty pitcher, with peculiarly tinted rim; *N. bicolorata*, the horned species from Borneo; *N. Hookeriana*, and *N. sanguinea*, one of the brightest-coloured of any. The rest were hybrids (Silver-gilt Flora Medal).

Messrs. VEITCH had also a group of New Zealand plants in pots. These included *Pittosporum*, *Olearias nummularifolia* and *moschatii*, *Plagianthus betulinus*, a very graceful plant; *Melaleuca*, *Senecios*, and *Aciphylla squarrosa*, &c. We hope to refer to these plants again.

On the centre table was a large group of ornamental foliage plants, shown by Messrs. WILLS & SEDA, Onslow Crescent, South Kensington. Attractive features in this exhibit were the fine plants of *Alocasias*, including *A. Sanderiana*, *Thibantiana*, *Watsonii*, *Rodriguesiana*, *Seleni*, *Argyra*, *Mortfontainensis*, and *Mrs. Martin Cahauzac*. Fine plants of *Draena Goldiana*, *D. Godseffiana*, *Phrynum variegatum* (very good), *Begonia Arthur Malet* and others, *Gymnostachyum Verschaffeltii*, *Lienala grandis*, *Stevensonia grandifolia*, *Anaassa sativa variegata* (a splendidly-coloured plant), excellent *Codiaeums*, *Aralias*, *Ferns*, &c. (Silver-gilt Banksian Medal).

From Sir TREVOR LAWRENCE's garden, Burford, Dorkin

(gr., Mr. Bain), was shown a collection of cut sprays of eighteen varieties of *Lobelia cardinalis*. These offered a great variety in shade and colour, from Queen Victoria, *Ignea Firefly*, and *Amethyst*, to paler forms, as *Syphilitica*, *Orion* and others. *L. sessiliflora* has flowers of a purple shade of blue. Flowers of *Cianthus Dampieri*, grown out of doors, were also from the society's President.

Sir TREVOR LAWRENCE also showed plants of *Crowea saligna* (latifolia), a very pretty evergreen greenhouse plant (*Rutaceae*), usually grafted on *Eriostemon* or *Correa*. The flowers are beautiful clear pink, widely expanded, about 1 inch across. In habit of growth the plant greatly resembles *Eriostemon*. It deserves wider cultivation. Also *Euphorbia corollata*, a hardy slender old-fashioned plant, with small white flowers, on numerous flowered spikes.

Mr. H. B. MAY, Dyson's Road Nursery, Upper Edmonton, showed a group of plants upon one of the tables, including a number of plants of *Golden Fleece Abutilons*, a yellow flowered variety. *Acalypha hispida*, the new *Campanula isophylla*, *Mayii*, *Bouvardias*, *Begonia Dregei*, a fibrous rooted variety with abundant small white flowers, and some choice *Ferns* (Silver Banksian Medal).

Messrs. THOS. CRIPPS & SON, Tunbridge Wells, showed two plants of a golden variety of *Retinospora obtusa* named *aurea Crippsii*. It is contended that this is the only golden coloured form of *obtusa* (true), though one has been certificated under this name. The variety is very pretty and will probably be shown again with the certificated variety for comparison.

Messrs. PAUL & SON, Old Nurseries, Cheshunt, made an exhibit of cut *Roses*. The blooms filled six large exhibition boxes. Also some hardy herbaceous flowers, and sprays of *Kolreuteria paniculata*, &c. Also flowering sprays of *Tamarix odessana*, very like the familiar seaside shrub, flowers light purple (Silver Flora Medal).

Mr. PHILIP FRY, Addington, West Malling, showed several new *Fuchsias*, but none of them were noteworthy.

AWARDS.

Canna Beauté Potterine.—A very brightly-coloured variety; almost vermilion. From T. S. WARE, LTD. (Award of Merit).

Dahlia Mrs. J. H. Luscombe.—A *Cactus*-like variety, with mauve-pink flowers. From Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley (Award of Merit).

Dahlia Mrs. Stephenson Clarke.—A *Cactus*-like variety, old gold colour, tips of petals red. Very pretty variety, but rather thin flower. From Messrs. J. CHEAL & SONS (Award of Merit).

Gladiolus James H. Veitch.—A very large handsome variety, with flowers of much substance, deep salmon-rose in colour, with white about throat, which is much spotted with red. From Messrs. JAS. VEITCH & SONS, King's Road, Chelsea (Award of Merit).

Polygonum Baldschuanicum.—A Turkestan species, growing wild at an altitude of 3900 to 5525 ft., and discovered in 1882 by Dr. Albert Regel. It was awarded a First-class Certificate by the Société Nationale d'Horticulture de France in 1894, and a figure of the plant was given in the *Gardeners' Chronicle*, January 9, 1897, p. 17. It is a herbaceous species, and grows from 13 to 16 feet high. The flowers are white, or very faintly rosy, produced in long handsome trusses, and succeeded by winged fruits, white at first, afterwards red. Further particulars of this species may be found on reference to the issue of *Gardeners' Chronicle* above quoted. From Messrs. BARR & SONS, and Mr. T. S. WARE, LTD. (Award of Merit).

Robinia inermis alba variegata.—A freely variegated form of this well-known and popular hardy town tree. From Messrs. THOS. CRIPPS & SON, Tunbridge Wells (Award of Merit).

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the Chair), and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshaw, J. Gurney Fowler, A. H. Smea, H. Little, II J. Chapman, A. Outram, T. W. Bond, E. Hill, W. Cobb, J. Colman, J. Douglas, H. M. Pollett, and T. B. Haywood.

Messrs. JAS. VEITCH & SONS, Chelsea, were awarded a Silver Banksian Medal for a small group composed principally of six finely flowered plants of *Laelio-Cattleya* × *callistoglossa* var. *ignescens* (*L. purpurata* × *C. Warscewiczii*), which, together with *L. C.* × *Nysa* (*L. crispata* × *C. Warscewiczii*), some plants of which were shown, are the showiest hybrids of the season, their large, handsome flowers in each case having brilliant purplish-crimson labellums. Shown for the first time was *Phaio-Calanthe* × *insperata* (*Calanthe Masuca* ♂, *Phaius grandifolius* ♀). The change which the cross made in *P. grandifolius* was extraordinary, the plant and flowers more nearly resembling the pollen parent. The inflorescence was on an ascending scape, arranged like *P. grandifolius*, though the flowers were much nearer to those of *Calanthe Masuca*, but larger. The change from the tubular form of lip in the *P. grandifolius* to the perfectly flat form was a remarkable feature. The sepals were white, tinged with lilac, the smaller petals similar in colour, though darker; the lip light rose, tinged with orange, darkening towards the base to reddish-orange. Another remarkable hybrid was *Cypripedium* × *Janet*, said to be *C. glanduliferum* ♀ × *C. Spicerianum*, but which some thought to be out of *C. Rothschildianum* ♀ × *C. villosum*. The dark green foliage favoured the former record. The dorsal sepal was ovate, acuminate, slightly twisted, yellow, with dark purple lines; the petals extended and deflexed, wavy at the edge, yellow, with purplish markings, darker on the upper half; lip cream coloured, tinged and veined with rose. Messrs. Veitch also showed *Laelio-Cattleya* × *Phryne* (*O. Warscewiczii* ♀

L. xanthina ♂), a strong-growing plant, tinged with red-brown, and bearing flowers with pale yellow sepals and yellowish-white petals, the base of the lip being yellow, the front bright rose colour.

Sir F. WIGAN, Bart., Clare Lawn, East Sheen (gr. Mr. W. H. Young), showed *Cattleya Warscewiczii* ("Prince of Wales," a very handsome and richly-coloured variety with flowers of fine form; a very good *Cattleya* × *Hardyana*, and *Cattleya* × *mollis* (superba × *Gaskelliana*), having flowers in outline partaking much of *C. superba*, but of a much lighter tint. The sepals and petals were pale lilac; the lip, the front lobe of which was rounded and crimped, dark rose.

H. S. LEON, Esq., Bletchley Park, Bucks (gr. Mr. Hislop), showed *Laelio-Cattleya* × *Bletchleyensis* (*L. tenebrosa* × *C. Warscewiczii*), a showy hybrid with the form of *L. tenebrosa*, but more of the colouring of *C. Warscewiczii*. The sepals and petals were warm rose colour, the lip much darker; the front lobe veined and tinged with crimson.

JEREMIAH COLMAN, Esq., Gatton Park, Reigate (gr. Mr. W. King), showed *Cattleya* × *Hardyana* "Mrs. Jeremiah Colman," one of the finest of its class, the showy labellum being dark ruby-red tinged with purple; also *Houlletia odoratissima*.

H. S. SIMONDS, Esq., Woodthorpe, Beckenham (gr. Mr. Geo. E. Day), showed two good forms of *Cattleya* × *Hardyana*, that called *Symonds'* variety being especially fine.

WALTER COBB, Esq., Dulcote, Tunbridge Wells (gr. Mr. J. Howes), showed *Zygopetalum Protheroeanum*, a singular plant of the *Z. brachypetalum* class, with flowers having the sepals and petals of a dark chocolate colour, the lip being violet with reddish markings at the base. Mr. Cobb also showed spikes of a distinct light coloured form of *Epidendrum prismatocarpum*.

Mr. A. J. KEELING, High View Nursery, Cotingley, Bingley, Yorks, showed two plants of *Cypripedium* × *Bingleyense* (*Charlesworthii* × *Harrisianum*), a decided acquisition to hybrid *Cypripediums*. In form and colour the flowers resembled a good dark *C. Charlesworthii*, but they were larger. The upper sepal was green at the base, surrounded by a dark purple zone extending upwards into a fine rich rose-coloured veining running into the white margin. The petals were bright rose, tinged with brown on the lower halves; lip greenish, fluted with red; the singular triangular stamens bluish-white.

Mrs. MASON, The Firs, Warwick (gr. Mr. Lambert), showed flowers of an alpine form of *Cattleya superba splendens* and *C. Harrisoniana superba*.

Capt. G. W. LAW-SCHOFIELD, New Hall-Hey, Rawtenstall, Manchester (gr. Mr. Shill), sent flowers of *Cypripedium* × *Juno*, Schofield's var., larger than the ordinary form; and *C. Veitchii Morganii*, a decided improvement on *C. Morganii* in most respects.

Mr. ED. KROMER, Roraima Nursery, Bandon Hill, West Crondon, showed a specimen of *Miltonia Regnellii* purpurea with six spikes.

Messrs. F. SANDER & CO., St. Albans, showed *Laelia* × *pulcherrima* (*Boothiana* (*lobata*) × *purpurata*), with a fine four-flowered inflorescence, the blooms equal in size to those of *Laelia purpurata*, but with a more trumpet-shaped and showy lip. The sepals and petals were of a delicate lavender tint; the showy lip, handsomely veined with rose colour.

AWARD OF MERIT.

Cypripedium × *Captain Holford* (*hirsutissimum* & *superbissimum*?)—A very showy hybrid, with flowers equal in size to *C. Curtisii*, but clearer in colour, and with decided indication of *C. hirsutissimum* in the dorsal sepal, which is white, with a greenish tinge, and the obscure dark shading over its surface seen in *C. hirsutissimum*. The broad sepals were white, tinged with green at the lower, and rose on the upper half, the surface being closely spotted with dark purple. Lip dull rose. (From Messrs. JAS. VEITCH & SONS.)

Fruit Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. R. Parker, Jas. Cheal, Jno. Basham, Jas. H. Veitch, A. F. Barron, Alex. Dean, S. Mortimer, H. Balderson, F. Q. Lane, Geo. Norman, Robert Fife, and Geo. Bunyard.

Messrs. GEO. BUNYARD & CO., Royal Nurseries, Maidstone, showed eighteen ripe fruits of Lady Sudeley Apple. Also some fine specimens of the Wineberry, and an agreeable conserve prepared from this fruit.

Some excellent fruits of Jargonelle Pears were shown by Mr. Geo. Neville, gr. to Lord CHESHAM, Latimer, Chesham, Bucks.

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, showed plants in fruit of a new Tomato named Cheal's Prolific. It is described as a seedling from Laxton's Open Air, and recommended for outside cultivation as more prolific than Laxton's. The fruits are rather flat in form, and corrugated.

Mr. H. Brown, gr. to F. LUCAS, Esq., The Grange, New Barnet, showed some good fruits of Chemin Rouge Tomato. Mr. J. ESCOMBE, The Grove, Penashurst, showed eleven varieties of Potatoes, most of them "scabby," with particulars as to the manures used in each case, and their effect.

There were two Melons submitted for Certificate, but neither of them of extra quality.

Some fine fruits of Peach Hale's Early were shown by Mr. McGuffog, gr. to the Countess of SELKIRK, Balmac, Kirkcubright. The Peach succeeded very well in that district upon south walls, protected with 14-inch coping. In the case of the fruits shown the trees commenced to flower on March 15, and the fruits were ripe on August 10.

Samples of Tomato Jam from Mr. ROBT. FIFE, Orpington, Kent, were sweetened preserves, but retained the full flavour of Tomato.

Apple Early Victoria, a large, soft fruit, very suggestive of Lord Grosvenor, was shown by Mr. W. Cross, Wisbech, who had a dozen fruits. It should make a first-class culinary Apple, especially for making dumplings.

Messrs. HARRISON & SONS, Leicester, were awarded a Silver Banksian Medal for a collection of Onions, including thirty-four varieties. The bulbs were fine ones for use rather than of exhibition size. They were not monstrous. In the collection were noticed many very good varieties, some of the firm's own introduction, and many others.

ROYAL HORTICULTURAL OF IRELAND.

AUGUST 22.—The annual autumn exhibition was held in Merion Square, Dublin, on the above date, and in cloudless weather. The display this year surpassed in excellence any preceding one.

Deserving of note was a superb stand of forty-eight blooms of *Begonias*, shown by Lord ASHTOWN, and to which the Ashtown Cup was awarded. The Carnations exhibited by Mr. JOHN FORBES, Hawick (Scotland), were much admired. Dahlias were a very creditable show, and the Cactus section was by far the most popular. Gladioli and Sweet Peas were excellent, and Roses were well exhibited, especially by Messrs. DICKSON & SONS, Newtownards. Fruits in some classes were fine, Peaches, Apples, Plums, Melons and Grapes, but there was not much shown. Vegetables were better than usual.

PLANTS IN POTS.

Mr. GEORGE DRIMMIE displayed a fine collection of Ferns, including *Davallia bullata*, *Polypodium aureum*, and *Adiantums*. For these he was awarded 1st prize; as also for a superb collection of *Coleus*. Mrs. MOORE, Phoenix Park, was 2nd.

The Right Hon. J. T. MEADE, Ailesbury Road, Dublin, staged a 1st prize group of Zonal and Ivy-leaved *Pelargonium* ms.

For a specimen *Orchid* the 1st prize was captured by GEORGE DRIMMIE, Esq., J.P., Bellevue, with a well-grown plant of *Cattleya crispata*.

CUT BLOOMS.

LORD ASHTOWN, Darrow Castle, Darrow (J. L. McKellar, gr.), took premier honours for his stand of twenty-four blooms of DAHLIAS, the varieties including Harry Keith, R. J. Rowley, Majestica, Joe Chamberlain, Noma, Galety, Chieftain, Buttercup, Mrs. Morgan, Colonist, and Gloria de Lyon. Lord ASHTOWN, Woodlawn, Galway (Mr. A. Porter, gr.), had to be content with 2nd place.

LORD ASHTOWN was 1st for a group of Dahlias (other than show or fancy varieties); and Lord ASHTOWN was 2nd.

C. S. SPEAR, Esq., (Mr. Wm. Maher, gr.), displayed a nice stand of Cactus Dahlias, including Beatrice, Arachne, Claribel, Alfred Vasey, and Ruby.

For Pompons, C. SPEAR, Esq., was also 1st, and included Donovan, Mary Kirk, Rosea, Midnight, Irene, Euridyce, Hedwig, Polwig, and Barchus; the Right Hon. Colonel CRICHTON, Ballymore Eustace, Mullaboden, was 2nd.

Mr. WATSON, Clontarf, took the Society's Medal for a stand of Dahlias; Messrs. A. DICKSON & SONS being 2nd in this class.

ROSES.—ERNEST BEWLEY, Esq., 5, Cowper's Road, Dublin, displayed a nice stand of Roses, and took the lead with Al red, Co'omb, Kaiserin Victoria, Edith Gifford, Caroline Testout, Madame Hoste, Mrs. W. J. Grant, and Bessie Brown; Mr. GEORGE DRIMMIE followed.

LORD ASHTOWN staged a collection of Tea Roses, and Mrs. MOORE, Phoenix Park was 2nd in this class.

For Roses, Messrs. DICKSONS were, needless to say, unbeaten, and easily won the Society's Medal. Their stand included Duc de Rohan, Queen of Queens, Horace Vernet, Mrs. John Laing, Madame Joseph Combet, Bessie Brown, François Michelin, John Stuart Mill, Star of Waltham, Alfred Colomb, Etienne Livet, François de Courtin, Maréchal Niel, Sénateur Vaisse, Alice Lindsell, Her Majesty, Ulrich Brunner, and Rosieriste Jacobs. Their stand of Gladioli was also awarded a Medal.

GLADIOLI.—For Gladioli, Lieut.-Colonel JERVIS WHITE, Healthfield, Wexford, easily took 1st prize; his stand was excellent, the spikes being one mass of flowers.

BEGONIAS.—LORD ASHTOWN's stand of forty-eight Tuberous *Begonias* (Doubles and singles) was awarded the Ashtown Cup. The varieties were very choice. Lord ASHTOWN, was 2nd in that class, but showed a fine collection of hardy cut flowers taking 1st place, and the Lord Ardilaun Challenge Cup.

ASTERS were not well represented, the 1st prize collected from Mr. GEORGE DRIMMIE, were good but not exceptional.

Mrs. ARMSTRONG, Hollywood, Carrickmines, staged a magnificent group of Sweet Peas, which easily outdistanced her competitors, and besides 1st prize she also won the Toogood Bronze Medal.

FRUITS AND VEGETABLES.

LORD ASHTOWN staged a superb stand of Grapes of the varieties Muscat of Alexandria, Black Alicante, and Mrs. Pearson, six bunches in all, and was easily 1st.

Lady EMILY BURY, Charleville Forest, Tallamore, took 1st and 2nd prizes for her Muscat of Alexandria and Buckland Sweetwater Grapes, but they were not perfectly finished.

The Right Hon. J. T. MEADE won 1st prize with some excellent bunches of Black Hamburgs.

Peaches formed an excellent exhibit; the fruit was well grown. Master FRED L'ESTRANGE, with a dish of Bellegarde, took 1st prize, WILLIAM IVY, Esq., J.P., displayed a dish of

good early silver Peaches, which were grown and ripened in the open air.

For Nectarines Lady EMILY BURY, with her Downton's, was 1st.

The best Apricots were Moor Park, from Lady EMILY BURY.

Apples, including dessert and culinary varieties were good, the culinary fruits were well above the average. Mrs. MILLER, Baginbrough House, with her specimens of Peach, took 1st place in the dessert class; H. J. GILL, Roebuck House, Clonskeagh, with Lady Sudeley, was 2nd.

Mrs. MILLAR was 1st for culinary varieties with Ecklinville; Lady EMILY BURY, with Lord Suffield, took 2nd place. Currants, both red and white, formed an excellent stand; the berries were very large.

LORD ASHTOWN's stand of sixteen dishes of fruit was excellent. The Muscat Grapes were splendid; also Pears (Jargonelle), Plums (Pine-apple), Melons (Eureka), Cherries (Morello), Apples (Peach), were the leading dishes. Besides taking 1st place, he won the Hume Dudgeon Challenge Cup.

In the vegetables, the honours of both classes were awarded to LORD ASHTOWN (who took the Toogood Silver Medal) and W. GOFF PIM, Summer Grove, Mount Mellick (who took the Toogood Bronze Medal).

MISCELLANEOUS EXHIBITS.

MESSRS. CLIBRAN & SON, Altrincham and Manchester, staged a fine collection of Carnations, herbaceous plants, and ornamental trees and shrubs.

Mr. F. W. MOORE, Curator of the Botanic Gardens, Dublin, as usual, staged a very fine collection of stove plants.

Messrs. W. DRUMMOND & SONS, 53, Dawson Street, Dublin, occupied a medium-sized marquee to themselves. Herbaceous plants here formed a very creditable display. Also some very fine *Sarracenia*, China Rose, Lobelias, Montbretias. A feature in their stand was a new hybrid Rose raised by themselves from *R. rugosa* and *R. frutescens*; it fruits very freely, but the fruits in point of size are much smaller.

The display from Messrs. J. HENDERSON & SONS, Templeogue, Dublin, was divided. They exhibited a very fine collection of Cactus Dahlias, also a group of single *Begonias*, seedlings of their own strain, having both an erect flowering habit and fine blooms. Stove plants from the same firm were superb.

Messrs. HOGG & ROBERTSON, 22, Mary Street, Dublin, showed fifty varieties of Sweet Peas, forty varieties of Gladioli, and sixty varieties of hardy annuals.

Messrs. C. RAMSAY & SON'S, Balls Bridge, Dublin, exhibit suffered somewhat from want of space. Their plants comprised *Caladiums*, *Coleus*, and *Codiaeums*, also several specimens of *Draecena hispida*; also *Lilium roseum* and album. Their stand of cut blooms included Dahlias and hybrid Gladioli.

Mr. JOHN FORBES (Hawick) had an exhibit of Carnations (border), Pentstemons, and Phloxes.

Mr. WM. WATSON, Clontarf, co. Dublin, had an exhibit composed largely of Dahlias, also a very nice collection of stove plants.

Messrs. ALEXANDER DICKSONS & SONS (Newtownards), apart from their superb stand of Roses, staged a few new varieties, Beryl and Irish Fidelity, and Irish Innocence; also a magnificent collection of herbaceous plants, and a group of hardy flowers, at least 150 distinct kinds.

BRIGHTON AND SUSSEX HORTICULTURAL.

AUGUST 22, 23.—This Society was established as far back as 1853, and since then has continued to hold exhibitions each year. It is fortunate in having the Pavilion and its grounds in which to hold the shows, for the circular hall under the dome and the spacious Corn Exchange are much cooler than tents, and cut flowers especially stand better in consequence. There were also two large tents in the grounds, one occupied by plants and groups arranged for effect, and the other containing cut flowers and vegetables. It cannot be said that the exhibits generally were up to Brighton's usual form, but this was due to the drought.

GROUPS OF PLANTS.

Groups arranged for effect were somewhat flat and formal. The best came from Mr. GEORGE MILES, Nurseryman, West Brighton. There was a background of Palms and Humæa elegans, and the foreground was formed of Lilies, bright *Codiaeums*, *Caladiums*, *Acalypha*, *Gloxinias*, with *Cannas*, &c.; 2nd, W. GOODLIFFE, M.A., Worthing.

Groups of Ferns were a good feature, Mr. GEO. MILES being again 1st, with a neat and well-finished arrangement; Mr. W. GOODLIFFE was again 2nd, making use of larger specimens than Mr. Miles.

Tables of flowering and foliaged plants were very effective, arranged under the dome, where they imparted a pleasant relief to the lines of cut flowers.

The best six Ferns came from J. WARREN, Esq., Handcross Park; he had fine plants of *Davallia polyantha*, *Microlepia hirta cristata*, *Cibotium barometz*, *Adiantum sancta catharinae*, &c.; Messrs. W. MILES & CO., Hove, were 2nd.

Begonias of very fine quality were shown by Mr. W. GOODLIFFE, dwarf, well grown and flowered; Mr. T. FAIRS, gr. to R. CLOWES, Esq., was 2nd, also with good specimens. Very good *Gloxinias* for the time of year won a 1st prize for Mr. FAIRS.

CUT FLOWERS.

Boxes of cut stove and greenhouse flowers were attractive, but call for no special remark. Some good blooms of Roses

were staged by Messrs. D. & W. CROLL, Dundee. It would perhaps be well in the future to admit duplicates in a class for twenty-four blooms, shown so late in August; Mr. H. HARRIS, Dennis Park, Horsham, was 2nd.

Mr. HARRIS had the best collection of twelve Tea-scented Roses.

Gladioli were somewhat numerous shown. The best twelve were staged by Mr. H. J. STENNING, Tunbridge Wells; Messrs. R. WALLACE & Co., Colchester, 2nd.

It has probably never before occurred in Brighton experience, that show Dahlias were so few and poor, and that the 1st prize for twenty-four blooms was withheld. A really superb collection of single Dahlias, in twenty-four varieties, was set up by Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley. Equally fine was the collection of twelve bunches of Pompon Dahlias staged by this firm.

Cactus varieties were remarkably good. The best twelve bunches were shown in very fine character by Mr. J. STRUDWICK, Silverhill, St. Leonards; the collection comprised some very promising new varieties. Messrs. CHEAL & SONS were 2nd.

With twelve varieties of single Cactus Dahlias, Messrs. CHEAL & SONS were 1st.

Hardy Perennials and Bulbous Flowers, shown in bunches, are always a good feature at Brighton. Mr. G. H. SAGE, The Gardens, Bayham Abbey, Lamberhurst was 1st, with hold and striking bunches of Lilium speciosum, Tritoma Uvaria, Galtonia candicans, Gaillardia, Everlasting Pea (white), Montbretia, Gladiolus, &c.; Messrs. R. WALLACE & Co. were a good 2nd.

Annuals in bunches were a good feature. An excellent collection of twelve varieties came from Mr. W. E. ANDERSON, gr. to B. PARISH, Esq., Brighton.

FRUIT.

Fruit consisted largely of Grapes. A class for a collection of fruit arranged with plants, flowers, and foliage, contained but one collection, from Mr. T. OSMAN, The Gardens, Otter-shaw Park, to which a 1st prize was deservedly awarded.

Three very fine bunches of Muscat of Alexandria Grapes, but not perfectly "finished," came from Mr. G. DUNCAN, gr. to C. J. LUCAS, Esq., Warnham Court.

The best three bunches of any other white Grape were excellent bunches of Dr. Hogg, even and well finished, from Mr. T. OSMAN.

Mr. C. LAKEN, Horsham, had the best three bunches of Black Hamburgh, very good.

The best three bunches of any other black Grape were Madresfield Court, from Mr. MITCHELL.

There were as usual many Melons shown. The best two dishes of Peaches were Noblessa and Barrington, from Mr. F. POTTER, gr. to R. WORSLEY, Esq., Cuckfield. Mr. MITCHELL had the two best dishes of Nectarines, staging fine fruits of Pine-apple and Pitmaston Orange.

The best four dishes of dessert Apples came from Mr. G. H. SAGE, who had William's Favourite, Beauty of Bath, Quarrenden, and Mr. Gladstone. Mr. SAGE also took the 1st prize with four dishes of culinary Apples.

VEGETABLES

filled a considerable space, and were generally good, Potatoes especially. The best collection of nine dishes came from Mr. R. DRAYCOTT, gr. to Col. SAMERSON, Lindfield, who had fine Ailsa Craig Onions, Carrots, Leeks, White Celery, Syon House Potato, &c.

There were ten entries of six dishes of Potatoes, Mr. DICKER taking the 1st prize with excellent samples of Duke of York, Windsor Castle, Satisfaction, The Canon, Up-to-Date, and Prince of Tonbridge.

Onions and Tomatos were very fine; Mr. DRAYCOTT was 1st for Onions with Ailsa Craig, which was generally finely exhibited.

MISCELLANEOUS EXHIBITS.

Messrs. W. BALCHIN & SONS arranged a collection of plants from their Hassocks Nursery, forming a noble pile at one end of the Corn Exchange—Acalypha hispida, a fine central specimen of Phœnocomia prolifera Barnesii, Lilies, Codium, Palms, &c.

Messrs. JAMES VEITCH & SONS, King's Road, Chelsea, filled a large table with plants—Pitcher-plants, Orchids, cut ree-house Rhododendrons, Streptocarpus, &c.—all in fine character.

Messrs. CHEAL & SONS had fruit-trees in pots, Dahlias in great variety, Gladiolus, fruit, &c.

Messrs. WALLACE, Colchester, had a table of choice bulbous flowers.

KINGSWOOD ST. GEORGE HORTICULTURAL.

AUGUST 23.—Kingswood is a large industrial centre of Bristol; it is on the east side of the city, and occupies a portion of the ridge which takes in Balton as it stretches away to Bath. The shoe trade is the staple business of Kingswood, and the suburbs grow with astonishing rapidity. The amateur element exhibits largely and well, but the effects of the drought have been felt here, and some things were smaller in size than usual.

Mr. CYPHER, from Cheltenham, brought his stove and greenhouse plants, and took the handsome 1st prize offered for ten plants in bloom and six fine-foliaged subjects; 2nd, Mr. W. VAUSE, Leamington, who had a very good collection.

The latter beat Mr. CYPHER in the class for a 100-leaf group; and though the materials were much the same, Mr. VAUSE had a better background, and a better finished foreground.

Messrs. PALMER & SON, Fishponds, were 1st with six Exotic Ferns; Mr. Rye, gr. to Capt. BELLEFIELD, Malvern, Bristol, was 2nd.

Mr. J. ROBERTS, a local grower, was 1st for Begonias, and his plants were finely grown and bloomed, and of excellent quality; the Rev. F. FAWCETT took 2nd. Good specimens of zonal Pelargoniums were shown, and of Gloxinias; Fuchsias were quite poor.

Several special prizes were offered for amateurs, and Mr. RYE proved highly successful, being 1st for six specimen stove and greenhouse plants in flower, six exotic Ferns, and six fine-foliaged plants.

CUT FLOWERS.

Cut flowers in the "open to all" division fell below Kingswood mark, mainly owing to the drought and heat. Roses were small, the best twenty-four varieties coming from Mr. G. GARRAWAY, of Bath, and he was 1st with twelve varieties also.

Mr. JOHN WALKER, Thame, had the best stand of twenty-four show Dahlias, Mr. G. HUMPHRIES, Chippenham, was 2nd; and these two occupied similar positions with twelve fancy Dahlias. Mr. WALKER also had the best six bunches of Pompon Dahlias, and the same of Cactus.

Herbaceous Phloxes, shown in collections of twelve spikes, were good, considering the weather. Mr. A. A. WALTERS Bath, was 1st with twenty-four quilled Asters, and with the same number of French varieties.

Hardy flowers in twelve bunches made a good feature, and there were very creditable Hollyhocks, although as many as twenty-four blooms were required.

FRUIT AND VEGETABLES.

The best eight dishes came from Mr. A. CROSS, gr. to H. O. WILLS, Esq., Bristol, who had Madresfield Court and Foster's Seedling Grapes, Peaches, Nectarines, Apples, &c., and he also won a special prize with the same number of dishes, but substituting Black Hamburgh and Muscat of Alexandria Grapes. Mr. E. HALL took the second prizes in the former class. Mr. J. MARSHALL, gr. to H. STEVENS, Esq., had the best two bunches of Black Hamburgh Grapes, having Gros Maroc, and Mr. C. C. TUDWAY was 2nd with the same. Mr. T. WILKINSON, gr. to Mrs. TALBOT GREAVES, was 1st with two bunches of White Grapes, showing Muscat of Alexandria. Mr. MARSHALL, came 2nd with Buckland Sweetwater. Mr. C. C. TUDWAY, had the best fine Culinary Apples, showing fine Peasgood's Nonsuch; the best Dessert Apple was Lady Sudeley, shown by Mr. G. GARRAWAY.

Vegetables were fairly numerous, but not so good as we have seen them elsewhere.

SWANSEA HORTICULTURAL.

AUGUST 24.—The annual show of this old-established Society was held in the new Market Hall on the above date. The Market Hall is a spacious, well-ventilated building, covering about 5 acres, and suitably adapted for the purpose of exhibitions.

The Show was opened at 1 P.M. by Sir J. T. D. Llewellyn, Bart., M.P., and Mayor of Swansea. The Secretaries, Messrs. Drummond and T. FOOTS, assisted by an energetic committee, made every arrangement desirable for the success of the Show.

Although the season has been exceptionally hot and dry, the quality and number of exhibits were in advance of last year. Some fine trade exhibits were put up by Messrs. KELWAY & SONS, Langport, Somersetshire; CLIBBON & SON, Manchester; TUPLIN & SONS, Newton Abbot; PARSONS & CO., Swansea; and JAMES HARRIS, Blackpill.

The Show was in every way a great success.

MARKETS.

COVENT GARDEN, AUGUST 31.

[We cannot accept any responsibility for the unjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. En.]

CUT FLOWERS, &c.—AVERAGE WHOLESALE PRICES.

	s. d. s. d.		s. d. s. d.
Arum Lilies, dozen blooms	3 0-4 0	Oxystoglossum, per dozen	3 6-5 6

— tally	6 0 —		
— in pads or pots	1 6-3 6		

REMARKS.—Apples still continue a very bad trade. Potatoes are much lower in price, even to 55s. per ton. Snowdrops and Up-to-Date realise 70s., 75s., and 80s. per ton.

SEEDS.

LONDON: August 30.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report to-day's market thinly attended. Trifolium continues in moderate request at unchanged rates. Winter Tares and seed Rye being in brisk demand, and moderate supply favours holders. There is a somewhat improved inquiry for Mustard and Rape. Canary seed is firm at the recent advance, whilst Hempseed keeps scarce and dear.

FRUIT AND VEGETABLES.

GLASGOW: August 30.—The following are the averages of the prices recorded since our last report:—Lemons, 6d. to 1s. per dozen; Cobnuts, 4d. to 8d. per lb.; Pears, 2s. to 3s. per sieve; Plums, Dutch, 2s. 9d. to 3s. do.; Victoria, 3 1/2d. to 4d. per lb.; Apples, Dutch, 12s. per barrel, and 2s. 4d. per bushel; do., English, 14s. per cwt.; Grapes, English, 1s. to 2s. per lb.; do., foreign, 6d. to 8d. per lb.; Mushrooms, 10d. to 1s. 6d. do.; Tomatos, English, 3d. to 5d. do.; do., Scotch, 4d. to 6d. do.; Carrots, Dutch, 3s. per bag; do., Scotch, 1s. per bunch;

Onions, white, 2s. 9d. do.; Cabbages, 9d. to 1s. per dozen; Leeks, 3s. 6d. per dozen bunches; Parsley, 1s. to 1s. 6d. per stone; Cucumbers, 4d. to 5d. each; Lettuces, round, 6d. to 9d. per dozen; do., Cos, 9d. to 1s. 3d. do.; Beetroots, 6d. to 1s. per dozen; Syboes, 9d. to 1s. per bunch.

PLANT AND FLOWER MARKET: August 30.—The following are prices current during the past week:—*Ghent*: Latania borbonica, 1s. 6d. per pot; *Corypha australis*, 4s. dozen do.; do., small, 3s. 6d. do.; *Clivella*, 6d. do.; *Aspidistras*, green, 1s. 6d. do.; *A. variegata*, small, 2s. 3d. do.; *Dracena discolor*, 5d. do.; *D. rubra*, 6d. do.; *A. Massangeana*, 2s. do.; *Nidularia*, large, 1s. 7d. do.; small, 1s. do.; *Araucaria excelsa*, 1s. each; *Ficus clastica*, 6d. do. Scotch: *Roses*, *Pelargoniums*, *Fuchsias*, *Begonias*, and *Azaleas*, about 2s. per dozen; *Ferns*, 6d.; *White Heather*, 4d. bunch; *Scotch Lillim Harrisii*, 1s. 6d. to 4s. per dozen; *Arums*, 1s. 6d. to 3s. do.; *Orchids*, 1s. 8d. per dozen blooms; *Carnations*, 2d. to 6d. per bunch; *Roses*, white, 6d. to 2s. per dozen, do.; red, 1s. to 2s. do.; and boxes, 2s. to 4s.; *L. lancifolium*, 9d. to 1s. 3d. per dozen; *Asters*, 1s. to 3s. per dozen bunches; *Sweet Peas*, 1s. to 2s. do.; *Maiden-hair Fern*, 3s. to 6s. per dozen; *Gardenias*, 1s. per dozen; *Marguerites*, 1s. 6d. per dozen; boxes of mixed flowers, 6d. to 4s. per box; *Asparagus Ferns*, 6d. to 2s. per bunch.

LIVERPOOL: August 30.—*Wholesale Vegetable Market*.—Potatoes, per cwt.: Early Regents, 2s. 3d. to 3s. 3d.; Main Crop, 2s. 9d. to 3s. 6d.; Kidneys, 2s. 9d. to 4s.; Turnips, 8d. to 1s. per doz. bunches; do., Swedes, 2s. to 2s. 6d. per cwt.; Carrots, 8d. to 9d. per dozen bunches; Parsley, 6d. to 8d. do.; Onions, foreign, 4s. to 5s. per cwt.; Cucumbers, 1s. 3d. to 2s. 9d. per dozen; Cabbages, 10d. to 1s. 9d. do.; Celery, 1s. to 2s. do.; Peas, 4s. to 4s. 3d. per bushel; Beans, 1s. 3d. to 1s. 6d. do.; do., Kidney, 1s. to 1s. 3d. per peck; Scarlet Runners, 1s. to 1s. 3d. do. *St. John's*.—Potatoes, 1s. 2d. per peck; Grapes, English, 1s. 6d. to 3s. per lb.; do., foreign, 4d. to 5d. do.; Pines, English, 4s. each; Peas, 1s. 4d. per peck; Cucumbers, 2d. to 4d. each. *Birkenhead*.—Potatoes, 10d. to 1s. per peck; Peas, 1s. do.; Cucumbers, 2d. to 4d. each; Filberts, 10d. per lb.; Grapes, English, 1s. 6d. to 3s. do.; do., foreign, 4d. to 8d. do.; Pines, 4s. to 6s. each; Mushrooms, 1s. per lb.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending August 26, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.		1899.		Difference.
	s.	d.	s.	d.	
Wheat	30	7	24	7	- 6 0
Barley	27	6	26	5	- 1 1
Oats	19	3	17	1	- 2 2

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London.

Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending August 26, is furnished from the Meteorological Office:—

"The weather continued very fine and dry until towards the end of the week, when rain was experienced over Scotland, Ireland, and the extreme of 'England, W. and S.W.' At the Scotch stations the rain was accompanied by much thunder and lightning.

"The temperature continued above the mean in all districts, the excess ranging from 4° in 'England, E., and 5° in 'England, N.E. and S., to as much as 7° in 'Scotland, E. and W., the 'Midland Counties' and the 'Channel Islands,' and 8° in 'Scotland, N., 'Ireland, N., and 'England, N.W.' The highest of the maxima were recorded on the 25th over England, but earlier in the week in most parts of Ireland and Scotland. They ranged from 90° in 'England, E., S., and S.W.' (at Cambridge, in London, and at Llandoverly), and 89° in the 'Midland Counties,' to 82° in 'England, N.E., and 80° in 'Scotland, W.' and 'Ireland, S.' The lowest of the minima, which were registered, as a rule, on the 22nd, ranged from 40° in 'Scotland, N., to 52° in 'England, N.W., and to 58° in the 'Channel Islands.'

"The rainfall was again almost entirely absent from England, and much less than the mean in all parts of the Kingdom, excepting 'Ireland, S.' In this district, the fall was equal to the normal, owing chiefly to a measurement of 2.22 inches, which fell at Valencia on the 24th, and during the early morning of the 25th.

"The bright sunshine was much above the mean in all parts of the Kingdom. The percentage of the possible duration ranging from 83 in 'England, S.' and the 'Channel Islands,' and 80 in 'England, S.W., to 51 in 'England, N.E., and 49 in 'Scotland, N.'

BOOKS: R. C. D. *The Amateur Orchid Cultivator's Guide Book*, second edition, by H. A. Burberry published by Blake & Mackenzie, Liverpool, price 5s.

CELERY: W. J. If your crop is so badly attacked as you describe, we fear there can be little done to save it. When once the maggots are in the leaves, you can only get rid of them by removing the leaves. Of course, dressings are useful as a preventive. But they are most valuable early in season; and if then the foliage be made distasteful to the fly, the crop would never become so badly infested with maggots. Soot is as good as anything; but bear in mind that it is well to mature and water heavily, or do anything to encourage quick growth in the plants, as this will help greatly to save them. Miss Omerod recommended the following mixture as useful:—One part unslaked lime, one part gas-lime a month from the works, and two parts of mixed dry earth and soot. Stir all well together, and scatter liberally on the plants and the ground.

CLEMATIS: A. T. You do not say what species of Clematis it is to which you refer. If you transplant them to a position out-of-doors, and must cut them down, the work should be done early in the autumn, or in spring before growth commences. But from the filthy condition the plants are in, it would be best to destroy them.

GRAPES: J. McL. The slight disfigurement to your excellent berries of Muscat Grapes is due to some physical cause. There appears to be no fungus in the case, and so far as can be judged here in the absence of precise knowledge of the circumstances, we should suspect that there was a little "rubbing" done when the Grapes were thinned, or it may have been due to cold draughts. The injury has affected the skin alone.

INSECTS: Herts. One of the Hawkmoths.

IS CORNFLOWER (CENTAUREA CYANUS) A WILD FLOWER? A *Disqualified Exhibitor*. We think the judges were technically right. It is not a true native plant, but one that has been introduced with foreign seeds, &c. Nevertheless, it has made itself very much at home.

MELON WITH SEED GERMINATING WITHIN: Jno. McL. You ask why the seeds have commenced to germinate before the Melon was opened? The opposite question would be just as fair one. For the conditions in the interior of a Melon, or such-like fruit, are just those necessary to the germination of seeds, except that there is little air. But why in certain

instances germination does take place, and in others it does not, is not known. However, it is much more common than you suspect, and we have known instances of the like in Melons, Tomatos, Papaws, Oranges, Pernettyas, and other succulent fruits.

NAMES OF FRUITS: H. F., Moortown, Leeds. 1, Margaret; 2, Crimson Quoining.—G. H. T. Market Harboro' and Red Astrachan.—A. H. 1, Liver Pearmain; 3, Early Strawberry; 4, Evargil; 7, Radford Beauty; 8, Trumpington; 9, Pineapple Pippin; the other specimens were not in character.—R. H. W. The Grapes were insufficient to form a positive opinion upon. No. 1 was apparently Gros Guillaume; 2, Black Prince; 3, White Frontignan. Plums: No. 4, Kirk's; 5, Jefferson's; 6, Prince of Wales; 7, Violet Damask.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—F. C. W. Your Crotons are:—1, Baron Frank Seiliere; 2, Veitchii; 3, Mrs. Swan; 4, Etna; 5, looks like a seedling; 6, Interruptus elegans.—A. L. Cassinia fulvida; 2, probably Lonicera sempervirens.—C. G. 1, Phleum pratense; 2, Cynosurus cristatus; 3, Arrhenatherum avenaceum; 4, Bromus giganteus; 5, Juncus bufonius; 6, Reseda lutea.—Alpha. Cichorium Intybus.—J. R. All wretched scraps, shrivelled to tinder. We guess them to be—1, Cornus mas; 2, Ribes alpinum; 3, Viburnum Lantana; 4, looks like the Snowberry—Symphoricarpos racemosus; but the specimen is insufficient; 5, Spiraea Douglasi; 6, Kolreuteria paniculata, probably.—F. Lomas. Cannabis sativa, common Hemp.—C. H. 1, Hamanthus naltensis; 2, Crinum Mooreanum; 3, Pachyphytum species.—M. C. 1, Masdevallia Reichenbachiana; 2, Odontoglossum Lindleyanum; 3, Oncidium preteritum; 4, Cypripedium Parishii; 5, Dendrobium infundibulum.—J. F. 1, Yellow Hollyhock; 2, Delphinium cardinale; 3, Erigeron philadelphicus; 4, Arnebia echinoides; 5, Gaura Lindheimeri; 6, Stachys palustris.—W. T. Saponaria officinalis, double flower.—H. T. W. Betonica carnea.—J. C. 1, Calystegia pubescens; 2, Ecballium Elaterium, the squirting Cucumber.—Beaumont. Rhus Cotinus.

ROSE: S. Badly affected with Rose mildew; cut off and burn the affected shoots.—B. R. & Co. Robin's Pincushion; the work of a gall-fly—Cynips sp. Very common on Briers though professional Rose-growers are generally not familiar with it.

SHRUB GROWING IN THE EMBANKMENT GARDENS: S. Ray. A variety of Hibiscus syriacus, commonly known as Althæa frutex.

TOMATOS DISEASED: F. and S. The fruits sent are not sufficient to allow a correct identification of the cause of trouble. The discolouration may arise from the fungus you mention, on leaves. Spraying with potassium sulphide, and sprinkling the soil below the plants with quicklime, will probably help, at least will do no harm. If you sent specimens of diseased plants with fruit, another examination could be made.

WIREWORMS: F. W. C. Gas lime is injurious to these hardy pests, but air-slacked lime—no. In your case, the gas lime would probably injure the plants also, unless you could delay planting for a time. Many cultivators have lately used the ordinary commercial flour of mustard against wireworm, and as this substance will not injure plants, it would be well to dig in a good dressing of this. The worms would be very likely to destroy your bulbous Irises if you take no means to get rid of them.

Gardeners' Chronicle

No. 663.—SATURDAY, SEPT. 9, 1899.

THE PRINCIPLES AND PRACTICE OF FERN-CULTURE.

IN the order of Ferns we see one of the largest, and yet one of the most primitive groups of plants on the globe. In the earlier period of the earth's history, this group held a much more important position in the vegetable kingdom than it does to-day. In the late Palæozoic and earlier Mesozoic epochs Ferns must have constituted a very prominent and distinctive feature of the vegetation. This is highly probable, not only from the records handed down to us by the rocks, in which we find their remains abundantly preserved, but also from what we know of the habits and exigencies of living Ferns, and of the climatic conditions prevailing on our earth during those far-back ages. Anyone who knows anything at all about these plants is well enough aware that the prime requisites for their successful healthy life are a moist atmosphere and, as regards the majority, at least, shade; they are generally found growing in the midst of thick woods and forests, or in the weakly-illuminated crevices and cavities of damp rocks. Astronomers and geologists tell us that in the earlier epochs of the earth's history above-mentioned, these two conditions of moisture and shade were very much more prevalent than to-day. In the first place, the disc of the sun was probably immensely larger than it is now, and thus afforded a very great amount of heat to the earth's surface; this heat and the density of the atmosphere, caused by the preponderance of carbonic acid gas in its constitution, were the chief agents in retaining a very large quantity of moisture in the air at all times. This condition of the atmosphere would necessarily moderate to a considerable extent the strength of the light coming from the sun, which would be much more diffuse than in an atmosphere like that of the present day; the greater size of the sun's disc would also render the light less concentrated and calmer. All these conditions, as it seems, would be much more favourable than those prevailing at the present day for the development and extension of Fern-life. And in Carboniferous, Permian, and Triassic times this order of plants probably attained a luxuriance of which we know nothing in our own days. In those epochs, doubtless, the individual plants reached a great development. Tree-Ferns were everywhere, or almost everywhere, the typical representatives of the order, most of these being far larger in size than any we know of to-day.

FAVORABLE CONDITIONS.

In later ages, as the climate in the different latitudes of the globe became less equalised, and the heat became confined within the tropics; as the density and moisture of the atmosphere diminished, and the sun's light increased in intensity, the cycle of Fern life also proceeded *pari passu* along its downward arc. The comparatively few Tree-Ferns that remain at the present day are almost entirely

confined to the tropics; the forms which had made their home in what are now temperate regions diminished greatly in size as the ages rolled by, until to-day the severe change in conditions has caused the dwarfed descendants to seek the cover of woods and the shelter of rock-crannies to shield them from the bright sun, and to find the moisture which they love.

Ferns must be treated under cultivation as they are treated by Nature in their native habitats. They do not all demand one uniform mode of culture, but even in this apparently monotonous type of plants considerable variation of habit and habitat obtains.

TEMPERATURE.

Take the Ferns of the tropics. These will all require to be grown in conservatories, where a temperature suited to their natural needs must be constantly maintained, a temperature varying with the seasons somewhat—i.e., lower in winter than in summer, just as it would vary in the native home of these plants. Other tropical Ferns which grow at some considerable elevation on mountains, and those which inhabit regions lying midway between the torrid and the temperate zones, will be satisfied without artificial heat, or only a few degrees thereof, and will require only a cool greenhouse and sufficient shelter to protect them from cold winds and frosts.

The hardy Ferns, such as those which grow wild in this country, except such forms as the Bracken and *Blechnum*, need only to be protected from the direct rays of the sun, an illumination such as is afforded by planting them with a northern aspect, suiting them best. This protection from the sun's rays will apply to Ferns of all climates; at the same time, they must not be placed in too deep shade, for they require light as much as any other plant; although that they are partial to a certain amount of shade is shown by the fact, which distinguishes them from most other plants, that chlorophyll is present in the epidermal cells of the leaf, as also, probably, by the thin texture of the latter. The only Ferns which are fond of a tolerably thick shade are the Hymenophyllaceæ, or Filmy-Ferns, which grow in dense woods, creeping under the foliage of other plants, or by water-courses, hidden under rocks and stones; the texture of their leaves is of the thinnest in the vegetable kingdom, being, with the exception of the genus *Loxsonia*, but a single layer of cells thick. The shade such as tropical Ferns enjoy in their native glens and forests is perhaps best copied through the means of the green shading material which is painted on the roofs of stoves, whereby a diffused greenish light prevails in the house, such as would be shed through the green umbrage of a forest upon the Ferns and other plants growing in its depths.

MOISTURE.

Ferns all love a moist atmosphere, more especially those hailing from tropical forests, where a damp atmosphere always prevails, owing to the constant slow evaporation of water from the luxuriant vegetation which is protected from the direct influence of the sun's rays. Amongst the precautions to be taken, therefore, in a conservatory for the proper maintenance of healthy, vigorous Fern-life, beside a suitable temperature and adequate shading, is the maintenance and regulation of constant moisture in the air by watering the floors and stages; the foliage of the Ferns must not be wetted more than can be helped, but the water must be supplied to the roots from below. The foliage of these plants is constructed

to luxuriate in a moist medium, and if this latter lose its moisture disaster will ensue to the plants, for the epidermis of their leaves is furnished with no cuticle, as is the case with most plants, adequate to withstand desiccation, and the few cell-layers which constitute the thickness of the leaf would yield up their sap at a more rapid rate than it is supplied by the roots. And the reason why the foliage should not be watered from above is because such delicate tissues are easily soaked through—a state of things which would naturally soon cause them to decay, and induce fungus-growths.

SOIL.

Another very important factor in Fern culture is the choice of the compost in which to grow the plants. This should always be chosen with an eye to that in which the individual genera and species flourish in Nature. The natural conditions of soil found in most of the habitats of Ferns is probably best imitated by making a mixture of the various soils used in the garden, with a preponderating proportion of that substance which best suits the individual plant or plants concerned. But the majority of Ferns will thrive well in an ordinary compost of loam (especially fibrous loam), leaf-mould, peat, and sand in equal quantities. While the three former supply the requisite food-substance, the sand serves to preserve the porosity of the soil, both for the passage of air and the surplus water. For those Ferns growing in woodland habitats, where leaves would accumulate round their roots in considerable quantity, and thus constitute a very special kind of soil, an extra quantity of leaf-mould must be added to the compost above given; such Ferns are *Polypodium* and *Platynerium*. Others, such as *Osmunda*, *Marattia*, exotic *Aspleniums*, &c., which love boggy places, must be supplied with an overplus of peat. *Botrychium* and *Ophioglossum*, which grow in meadows where there is nothing but pure loam, must be treated accordingly in the garden. The *Adiantums* exhibit, apparently, a dislike to peat, so that this substance must be omitted from the compost given to them. For those which, like our British species of *Ceterach*, *Asplenium*, *Cystopteris*, and *Scolopendrium*, grow in the crevices of limestone walls and rocks, broken bits of lime in the form of old mortar, oyster shells, or gravel, should be added to the soil. The *Parsley Fern*, *Holly Fern*, and *Woodsia*, which frequent the shady crevices of slaty rocks, must be supplied with chopped bits of slate in their soil. The Filmy Ferns require a rough compost, afforded by the addition of bits of charcoal and sandstone; this is to allow the surplus moisture to readily pass through, for though these plants like a moist medium, an over-saturated soil and atmosphere such as would result from a substratum which did not allow of the very rapid passage of water, especially in the close and confined habitats of these plants, would probably induce early decay of their delicate tissues.

As regards the positions in which to cultivate Ferns, Nature must here, of course, be judiciously copied. Some hang from rocks or tree-trunks; and these may best be placed in baskets, on cork blocks, or planted on rocks in the rock-garden or fernery. The majority grow on the ground in deep, rich soil, and chiefly in glens or woods. Many prefer the dark crevices of rocks. Others, such as the *Ophioglossæ*, are actually found flourishing in the open, as in meadows, and more or less fully exposed to the sun. Each must be treated, in the garden or the greenhouse, according to its native needs.

W. C. Worsdell, F.L.S.

(To be continued.)

ORCHID NOTES AND GLEANINGS.

SCHONBURGKIA LYONSII.

ORIGINALLY described by Dr. Lindley in the *Gardeners' Chronicle*, 1853, p. 615, from material sent by Mr. J. C. Lyon, of Ladiston, near Mullingar, who could give no further information about it than that he believed he got it from the Rev. John Clowes, the habitat of this handsome species was for some time unrecorded. Subsequently Dr. Lindley met with it in Dr. Alexander Prior's herbarium, the specimen having been collected by that gentleman in the hills of St. Anne, Jamaica. That, doubtless, is the correct record for the plant, of which we give an illustration of a flower (see fig. 71), shown by the Rt. Hon. Lord Rothschild, Tring Park, Tring (gr. Mr. E. Hill), also received from that locality. The plant has fusiform pseudo-bulbs, thin at the base, and much resembling *Lælia superbiens*. The scapes are about 3 feet in height, and bear at the top about twelve to twenty flowers, each flower furnished with a long bract. The flowers are white, marked with purple. It is the showiest of its own section of the genus, and well worthy the attention of all who can obtain it. Mr. Hill finds it thrives best when grown in a similar manner to *Lælia anceps*. An Award of Merit was given for it when shown before the Orchid Committee of the Royal Horticultural Society on August 15.

ODONTOGLOSSUM CRISPUM.

The excellent remarks by Mr. W. H. Young on p. 188 of last week's issue of the *Gardeners' Chronicle* induce me to describe my own method of treatment, and the course of reasoning which led to its adoption: in the first place, as this plant grows at an altitude of 8000 feet it must always be in a free air, and as the vapour-laden clouds rise to that height they become condensed and descend in copious showers upon the plants frequently, but not constantly; and not at any time can the showers be warm. One could not imagine such a thing as a spike of bloom becoming spotted and disfigured, as one has often seen them in cool Orchid-houses.

As I grew my own plants, and had not to please another's fancy, a bold method was adopted with marked success.

The essential points are: air is always admitted (except in a wind-frost), and especially by low ventilators opposite the hot-water pipes, with sufficient top-ventilation to keep the air of the house in movement. Under such conditions damping-off is unknown. What I am now about to mention will no doubt raise a chorus of surprise and dissent. All the watering the plants get is from the cold hose-pipe once or twice a day, to imitate the cold showers they get in their native habitat. This is given overhead, as if they were so many Cabbages. If the sheaths at the base of the pseudo-bulbs are full of water, they are left so, the free ventilation puts that matter right, and the material in the pots is never soaking wet, as though we were attempting to grow bog-plants. It is remembered that *Odontoglossum* naturally grow on trees, and can only get such water as falls from above. Keep the ventilation free—not so free as in an orchard-house of course; but be bold, and all will be well. Do not coddle your plants as regards temperature, but keep it down to 60° in the summer if you can; and should it fall to 35° on a winter morning, do not faint with fright—your plants will not die, if all other conditions have proper attention. *T. L. C.*

REVISION OF THE CYPRIPEDEÆ.

One of the most interesting features in our contemporary botany, is certainly the revision of the Cypripideæ group, which was, and still is, the subject of many scientific discussions. Several great authorities undertook and discussed the matter, and I am pleased to bring forward in recognition of their valuable classification the names of Prof. Pfitzer, of Heidelberg, the well known German Botanographer, and our good friend, Mr. R. A. Rolfe, F.L.S., of the Kew Herbarium, to whom the Orchid world is so much indebted for his

special studies and monographs, amongst which "The Morphological and Systematic Review of the Apostasiæ," forms one of the most interesting records in connection with these notes.

This well known group of Linnaeus was in recent years divided into distinct sections or sub-groups. One of the first attempts was made in 1886 by Prof. Pfitzer, and established in 1888.† This new method of classification was not immediately adopted. However, it must be stated that its bases were to divide the Cypripedium group into distinct genera from a scientific, geographical and horticultural point of view.

This idea was not practically new, for Lindley in 1842‡ anticipated the necessity of separating the Indian species from their Western allies, although botany and horticulture have for another half a century kept under the same determination plants greatly different in habits, structure, and origin. In 1894 the discussion was revived, and has since reached a definite result. When Comte Oswald de Kerchove de Denterghem, President of the Royal Agricultural and Botanical Society of Ghent, published his valuable book on Orchids, *Le Livre des Orchidées*, he adopted Prof. Pfitzer's classification, which gave rise to interesting criticisms in all the leading European papers.

Time has given proof of the above necessity, and Mr. R. A. Rolfe undertook the subject and brought it to its present standard.

Linnaeus established in 1737 a special genus on a well-known European species (*Cypripedium calceolus*), and called it *Cypripodium*, a determination composed of *Kypri*, one of the synonyms of *Venus*, and *podion*, small foot [?]. Later on, this name became the subject of a slight alteration by the substitution of a single letter, which produced *Cypripedium*. Here we have the exact origin of that familiar name. But this did not describe Linnaeus' idea, which was, according to the traditions of botany, the translation of "Venus' Slipper." *Podion*, as selected by the author, was perfectly right [?]; but *podion* means plain, or level (for a small chain). This shows the defective alteration which has become so widely used in the practice which it could be extremely difficult to correct now.

Up to 1846 all species were classified amongst the Cypripideæ, but Lindley described the curious *Uropedium Lindenii* as a distinct genus of the tribe, on account of its elongated tailed lip. Eight years later, or in 1854, Reichenbach showed its affinities regarding the three-celled ovary characteristics of the Cypripideæ, as the other species belonging to the new world. He suggested with authority that the new plant was only an abnormal form of *Selenipedium caudatum* [as was afterwards proved by a monstrous specimen illustrated in these columns].

In 1892 Prof. Pfitzer, in his classification of Orchids, separated the tribe into three sections. The first included our old species, remarkable for their one-celled ovary. He called these Cypripideæ, with thin teguments to the seed. Secondly, the *Selenipedium* group was distinguishable by its three-celled ovary, deeply marked with the crustaceous teguments of the seed. The third group was composed of species having the three-celled ovary, with thin teguments, and was called *Paphiopedilum*, another derivation of "Venus' Slipper." This last generic name has been modified in the latest classification, and remains now *Paphiopedium*. Mr. R. A. Rolfe, with his authority on the matter, pointed out several overlooked mistakes, and undertook the complete revision of the Cypripideæ tribe, basing his classification on the nature of the ovary, and on the disposition of the seeds therein, which obliged the author to divide the tribe into four distinct genera, which are all characteristic of their own peculiarities. In the following classification, *Selenipedium* are reduced to only three species. *Phragmopodium* of Rolfe unites Reichenbach's *Selenipedium* with coriaceous leaves, with the *Phragmopodium* of Pfitzer.

The genus *Cypripedium* is represented by about thirty species, widely spread over Europe, temperate Asia, and the northern part of America. All the others, which are species found in Asia, Malay Archipelago, New Guinea, belong to *Paphiopedium* group. The genus is represented by about forty species, all in cultivation. These four distinct divisions or genera are grouped into two distinct groups. The first one is characterised by its three-celled ovary with axile placentas, and its valvate sepals, as it is found in Rolfe's *Selenipedium* and *Phragmopodium*. The second class comprises the one-celled ovary species, with parietal placentas and fusiform seeds, as found in *Cypripedium* and *Paphiopedium*.

SELENIPEDIUM, Rolfe, f., is a genus characterised by its plicate leaves, persistent perianth, and its sub-globose seeds, and is only represented by three typical species found in Guiana, Brazil, and Central America. Their flowers are rather small, and borne on a terminal raceme. The two first described species are remarkable by the Vanilla-like odour of their flowers.

PHRAGMOPEDIUM, Rolfe, is a genus distinguishable by its conduplicate leaves, deciduous perianth, and its fusiform seeds. It is represented in cultivation by about ten species, natives of the tropics of the new world, where they are found all along the Andes, from Guatemala to Peru.

CYPRIPEDIUM, L.—The chief distinctions of the genus are its plicate leaves, persistent perianth, and its valvate sepals.

* *Journal of the Linnean Society*, vol. xxv., pp. 221, 243, t. 41.

† *Die Natürlichen Pflanzen Familien*, von A. Engler und K. Prantl, Leipzig, Engelmann.

‡ *Botanical Register*, xxviii. snb. t. 17.

§ *Orchid Review*, vol. ii., p. 268.

|| *Orchid Review*, vol. iv., p. 330.

It differs from the old group by its one-celled ovary with parietal placentas, as previously mentioned. This genus is represented by about thirty species, but not very often met with in cultivation.

PAPHIOPEDIUM, Pfitzer.—This genus is easily recognisable by its conduplicate leaves, deciduous perianth, and imbricated sepals. It comprises all the tropical species of the Old World, and its peculiar distinction lies in having the dorsal sepal folded within the lateral ones in the bud. This genus is very well represented in cultivation, and is undoubtedly composed of the most beautiful species of the whole tribe, that is to say, that we shall soon be familiarised with this new determination.

In conclusion I might add that, omitting the *Selenipedium* group, which is scarcely found in cultivation, Cypripideæ are, from a horticultural point of view, only represented by the three latter genera. But what will happen in the case of the bigeneric hybrids, which we already have? Between the old *Selenipedium* and *Cypripedium* many crosses are recorded, but very few have flowered so far. It will be a case of "Paphiophragmopedium;" and add to this the usual determination of variety, which may be splendidissima or longifolia, &c., from a botanist, or *Mlle. Germaine Seellier de X.*, from a French raiser, which will make a pretty name of some forty to fifty letters. The nomenclature of bigeneric Orchids will then undoubtedly become the subject of special study. Condensed from a communication of A. E. P. Greigsen, in "Indian Gardening."

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES.

The March and April number of this unpretending but most useful publication, contains coloured illustrations and figures of the subjoined species and varieties:—

Cattleya Mendeli, Backh.; *Cypripedium insigne* v. *Sylhetense*, C. villosum, Ldl.; *C. callosum* var. *Sanderae*, C. *chloreneum*, Rehb. f.; *Disa Veitchii*, Hort.; *Lycaste gigantea*, Ldl.; *Odontoglossum luteo-purpureum* var. *sceptrum*, O. *maculatum*, Llav. et Lex, O. *parlinum*, Ldl.; *Oncidium excavatum*, Ldl., O. *falcipetalum*, Ldl.; *Staurosis gigantea*, Benth.; *Cymbidium pendulum*, Swartz.; *Cypripedium concolor*, Parish, C. *Belus* Reg. Young; *Masdevallia elephanticeps*, Rehb. f. et Warsc.; *Odontoglossum Edwardi*, Rehb. f., O. *excellens* var. *Hyeanum*, Hort.; *Oncidium ornithovinchum*, Kunth.; *Pescatorea Lehmanni*, Rehb. f.; *Sobralia virginalis*, F. Peeters et Cogn.; *Stanhopea Madouxiensis*, Cogn.; *Vanda corulea* var. *concolor*, Cogn.; *Warscewiczella discolor*, Rehb. f.; *Zygopetalum Mackayi*, Hook.

BEDDING BEGONIAS.

NEXT to *Pelargonium*, perhaps no class of plants is so generally useful for bedding-out purposes as the *Begonias*. A short review of some of the best older varieties used on the continent, and which have stood the test of a great many seasons, may be of interest. Before, however, naming and describing individual varieties, I may mention that thousands of *Begonias* are raised from seed annually, both of varieties which come fairly true from seed, and of strains generally, not only of the *semperflorens* class, but also of the *tuberous-rooted* section. They are then sorted up into their respective colours, and in the case of the *semperflorens*, planted out into their definite quarters for the season, whilst the *tuberous-rooted* varieties are generally grown on to make good bulbs for the next season.

For bedding out, the single-flowered tuberous are preferable to the double-flowered; the latter, although very fine at first, are disappointing afterwards when only producing single flowers, apart from the fact that on account of their weight they are more liable to suffer from wind and rain than the others.

There are, of course, some exceptions, and of these the varieties *Lafayette* and *Graf Leppelin* are among the best and most effective.

Lafayette (Lemoine) is a very fine variety, with medium-sized flowers of an intense crimson colour, and with a somewhat dark bronzy-green foliage. It is a little tedious to propagate, unless one possesses a few strong stock plants; but owing to its intense colour it is indispensable. It grows about 1 foot high, and bears its flowers well on stiff stems.

Graf Leppelin (Neubronner) is, perhaps, best described as a double *Davisi*, being very similar to it in every respect. It grows about 6 to 8 inches high, and has pretty cushion-shaped, scarlet-coloured flowers of about 1 inch in diameter, and is very floriferous. It will stand a sunny position well, and can easily be propagated by cuttings.

Of course, as I mentioned before, all double tuberous-rooted Begonias are more or less disappointing on losing their double flowers; but in the case of the above two varieties this is amply compensated for as bedding Begonias, owing to their very effective colours, and their almost total indifference to strong sunshine, especially in the case of B. Graf Leppelin.

We have now three other tuberous-rooted Begonias which, although not used to the extent of the Semperflorens and other classes, are so distinct and beautiful that they well deserve mentioning, and are found in many private gardens of note.

Bavaria, already described in these columns, a pretty little dwarf variety, with delicate pink single flowers tinted with violet, and with almost heart-shaped dark green leaves, and exceptionally free in flowering.

Bertiui, almost identical with the old B. bolivensis, having bell-shaped flowers of a cinnabar-scarlet colour. Foliage of a rich green, and the plant grows about 1 foot high. It is most useful in very sunny positions, and is easily propagated from cuttings.

and beautiful variety, best raised from seed, as plants from cuttings do not branch and form such fine plants as seedling plants. It is a cross between B. Schmitti and B. semperflorens Vernon, and has delicate rose-coloured flowers, which it produces very freely. The foliage is bright green, slightly bronzed. Altogether, for groups it is one of the best varieties cultivated. I believe it is synonymous with B. Schmittii hybr. rosea (Versaillensis) of French catalogues.

B. s. elegans.—This variety gives no seed, and generally also does not produce sufficient shoots for cuttings, but being so free in blooming, and having flowers of such a beautiful tint of deep carmine-rose, it is generally met with in public gardens, or private ones which make any attempt at a display. Foliage is of a bright metallic-tinted green, and the habit of same is dwarf.

Perle von Stuttgart and Teppichkönigin are dwarf varieties of B. Vernon, growing about 6 to 8 inches high, but in every other particulars resembling B. Vernon. They are very useful for groups, or as borders to other groups.

Bertha Befinger, carmine-rose, tinted lilac;

class that I know, is about 1 foot in height, and has flowers of a delicate coral, red or rose. These Begonias are considered the most reliable and useful from the point of view of a nurseryman who requires many thousand plants for bedding out at certain times, as they are so easily propagated from a few strong stock plants.

The first-named variety, Berthe de Châteaurocher, although often met with, has rather smaller flowers than either Abundance or Corbeille de feu, and they are of a dark red colour. It is certain to be superseded altogether by these two and other newer varieties of this class. One of their greatest advantages is that they will stand almost any amount of full sunshine. They are exceedingly effective when planted with specimen plants of Chamaerops excelsa, Dracena indivisa, Phoenix, &c., as centres to the groups, and bordered with Coleus Verschaffelti and Alternantheras. They are also very durable, and cause little trouble by way of cleaning, &c., during the whole season.

I do not presume to have given a complete list of the best Begonias grown for bedding-out on the Continent. This would be obviously impossible, as

FIG. 71.—SCHOMBURGKIA LYONSII. (SEE P. 202.)

Martiana grandiflora, a most beautiful Mexican species, grows 16 to 20 inches high in fine erect bushes. It produces its flowers all the way up the stems, and these are of a fine carmine-rose, being somewhat lighter than those of B. Bavaria. It will grow in almost any position, standing full sunshine well if hardened off when still small. It is most useful for cutting and for tall groups, and flowers late into the autumn.

Propagation is effected by means of small bulbs, which form in the axils of the leaves. These are treated the same as if they were seeds, and are sown in the spring in a warm temperature. I have seen groups of this variety edged with Pennisetum or Coleus Verschaffelti and Alternantheras, which were most striking.

BEGONIA SEMPERFLORENS.

Thousands of Begonia semperflorens are raised from seed, but of named varieties the following are most generally met with, and most useful for bedding-out purposes:—

B. s. atrepurpurea Vernon, which comes very true from seed, grows about 1 foot high, and has dark red flowers, whilst the foliage is of a glossy green colour, which assumes a dark chocolate tint when planted in full sunshine. It is very free, and makes nice bushy plants.

B. s. Erfordia (Erfurter Kind), a most useful

Helene Befinger, white, are very dwarf in habit, growing only about 5 inches high, and having very pure-coloured flowers. As pot-plants under glass they are also very useful, the flowers being naturally still purer in colour than these grown in the open. Both are very free.

Bruanti is also a variety rather widely distributed. It is dwarf and compact in habit, and best used as a border to groups of other varieties. Foliage is small, and flowers are rosy-white.

SHRUBBY VARIETIES.

Taking the shrubby varieties of Begonias, the sous-frutescents varieties of the French, the most useful and most widely distributed varieties are, Ascotensis, Berthe de Châteaurocher, Abundance and Corbeille de feu, mostly raisings of Mr. Lemoine, of Nancy.

Abundance and Corbeille de feu are really perfect as bedding Begonias. They are very free in flowering, both of very fine colour, and will stand any amount of sunshine well. In fact, I have seen them do best in the hottest positions, and on not too light soils.

Abundance grows about 1 ft. to 1½ ft. high in fine bushy plants, and has beautiful rose-coloured flowers, produced in little clusters at the top of the branches. It is very free, and best for tall groups. Corbeille de feu, the most floriferous variety of this

climatic and other conditions teed, in some places, to bring out points in some varieties, making them very effective and useful, while in another locality they will not succeed at all. The above list will be found to include many of the best and fairly representative varieties.

Improvements are being carried on both in France and Germany in Begonias as well as in all other classes of plants. Especially from Nancy may we expect good things; Mr. Lemoine's double semperflorens being the forerunners of a new class, which may in time also become very useful for bedding-out purposes.

It is a pity that this side of horticulture was not a little better represented at the Conference at Chiswick a month or two ago; it would have shown how great the improvement has generally been in summer-flowering plants. H. R. W., Clapton, August, 1899.

THE ZOOLOGICAL GARDENS, REGENT'S PARK.

THESE gardens, situate in the north-west district of the metropolis, are associated in the minds of many with animal life only, but those of us who are within easy visiting distance, knew the many floral attractions there; and in a season like the present one, when flower gardening with many of

us in the south has been a series of comparative failures, it is refreshing to see how well the many beds, borders, and squares, with their thousands of plants appear at the Zoo. Mr. Young, the head gardener, has had an excellent training in this particular department of horticulture, having served under the late Mr. McIntosh at Drumlanrig, and later with Mr. David Thomson in the same place, Mr. Thomson being an ardent lover of flowering effect, which he carried out in first-class style in the princely domain over which he ruled for so many years. Moreover, Mr. Young has had the long experience of nineteen years in the "Zoo," having been sufficiently long there to know, unfortunately, the ravaging effects of the London fogs upon Pelargoniums, and that Lobelia and Alternanthera and other such tender plants are liable to be killed off by thousands at a time when propagation should be in full swing. But as one admires the pleasant situation of these gardens, the stately trees, vigorous shrubberies, smooth lawns, conveniently intersected with paths, one is loth to remember that a thick metropolitan fog in winter often envelopes this charming picture.

On the occasion of my visit, which was made on a hot day in August, numbers of visitors were carefully inspecting the flower-beds, doubtless making mental notes for future use; but a few, note-book in hand, were conveying some of the floral combinations to paper, and I shall be surprised if some of these designs are not repeated in many gardens next season.

The effects of the long-continued drought were not very evident, except in the case of the tuberous-rooted Begonias, which were not equal to those usually seen here, nor were the lawns so verdant and soft as usual.

The following beds were extremely good:—The oval bed in front of the saloon, with Pelargonium Henry Jacoby groundwork, and Golden Privet and Acacia lophantha, had a bold and distinct appearance. Salpiglossis, so disappointing in some situations, were here the chief occupants of a large bed, having a groundwork of Harrison's Musk, and a relief of Anthericum freely dotted round the edges. The effect was at once simple and pleasing.

Mr. Young's name has been associated with the Celosia for some years, he having devoted much attention to this plant, with the result that his strain by careful selection has become perfect, and the cultivation from long experience being the best possible, the display from these showy plumes was a picture in themselves. Celosia aurea, with gigantic plumes of a lovely golden hue, formed the dot plants of a large bed having as a groundwork Anthericum variegatum, and a broad band of Alternanthera versicolor, relieved by a few bold specimens of Echeveria secunda glauca. C. rosea, having a light orange tint, was, in pleasant association with subjects such as Fuchsias, Asparagus plumosus nanus, Violas, &c., and was equally charming.

Seed of these Celosias is sown late in March or early in April, and the seedlings, as soon as they are fit to handle, are put singly into thumb-pots. From then until the middle of June the plants are encouraged to grow quickly, the aim being to produce the finest plumes possible before the planting out takes place. Liberal feeding, after they have rooted into the compost, is essential, as they are gross feeders, provided the diet is not too heavy.

It would be difficult to mention a style of bedding (excepting the carpet system, which finds no place at the Zoo) but is represented here. A charming margin to a large shrubbery was furnished with various tall-growing Hollyhocks, Larkspurs, Phloxes, &c., these being used to form an irregular outline; while the front portion was tastefully filled with Stocks, Fuchsias, Celosias, Veronicas, Calceolarias, &c.; the whole so arranged, that, while many kinds were represented, no one sort predominated.

Another shrubbery was edged with a broad band of Nicotiana affinis, and the dark-leaved Ricinus, two well-known subjects, but rarely seen to better advantage than in this particular position.

As suggestive of the bold nature of the lion, a large oblong bed, that runs at right angles with the structure devoted to the king of the forest, was planted with fine plants of the Flax-plant, Phormium tenax, Nicotiana affinis, and Standard Fuchsias, while a broad band of Veronica Andersoniana variegata separated the main portion of the bed from the edging of Thrift.

Cannas are largely used, and plantations of the choicest bedding varieties, in association with well-coloured Golden Privet and suitable ground-work, gave variety, and are certainly to be recommended where large masses are necessary, for few plants have the same noble leafage and a corresponding amount of flower.

As illustrative of the tropical heat of this season, an interesting border near the main entrance, planted with Acalypha musaica, Strobilanthes Dyerianus, Asparagus plumosus nanus, Pandanus Veitchii, all pleasantly interspersed with little Palms, from 2 to 3 feet high, looked capital.

Facing the main entrance, and lining the main path, are two borders—one contained East Lothian Stocks, 1500 of them, arranged in blocks; and that on the other side is planted with various types of Pelargoniums, with a background of Cannas, Paris Daisies, &c.

The older styles of bedding are to be seen in suitable places. There are masses of Pelargoniums, Calceolarias, Verbena venosa, Fuchsias, and Canterbury Bells.

In whichever style the plants are used, they bear unmistakable signs of great care in their production, and forethought in their distribution, such as only can be obtained after years of experience in conducting and superintending such a place. J. F. McLeod.

FLORISTS' FLOWERS.

"TREE" OR "PERPETUAL" CARNATIONS?

MANY object to the term "perpetual" in reference to this section of Carnations, on the ground that the plants are not perpetual blooming; but I consider the term to be much preferable to "tree," for the plants are not trees, and it is not possible to make them become such. "Bush" is more in keeping with the habit of growth. We use the term perpetual when referring to a certain section of Roses, and certainly Carnations are equally free or "perpetual" blooming.

Mr. A. Hemsley, on p. 163, is apparently one who favours the term "tree," and objects to "perpetual," pleading that although some flower for a long period, a succession of bloom from the same plants cannot be expected. Certainly a continual succession may not be had, and with such varieties as Uriah Pike, Duke of York, Primrose-Day, and Pride of Penshurst, one crop per annum is all that is to be looked for; but there are many really good varieties which will give a crop of fine flowers in October and November or later, and if the same plants be shortened back and repotted, they will again give a fine crop of blooms in April and May, and later from September to November, in addition to occasional blooms throughout the year.

Mr. Hemsley is undoubtedly correct in suggesting that many varieties degenerate because the stock plants are not treated with sufficient care. Only the most vigorous plants should be used as stock plants. The Americans, who are certainly the finest growers of Carnations of this section, urge that no stock plants should be allowed to flower.

VARIETIES.

Of scarlets in general cultivation nothing can compare with William Robinson, but it is a variety that pays well for thoughtful and proper treatment.

Respecting white varieties, I do not admire either of those mentioned on p. 163. They are tall growers, and the flowers are small. Pearl Beauty is immensely superior to either in size and substance of flower, in perfume, and habit of growth. Flora Hill, of American origin, is a large, handsome bloom when well grown, and is very free flowering.

The plant is of good constitution, but it will not succeed under indifferent treatment.

Of crimsons Countess of Warwick is the best, the habit of the plant being truly perpetual.

Of pink, rose, flesh, salmon, and carmine varieties, there are many that are superior to Miss Joliffe and Mlle. Thérèse Franco. As the fortunate raiser of several varieties of these colours, and of whites, it would perhaps be out of place for me to do more than mention them, but I consider the following are not anything like so well known as they deserve to be. They are all Americans, and after several years' trial have proved first-class. Triumph is a deep, rich rose-pink, quite distinct from any English variety, of large size and good substance. Victor is a lively pink, many shades lighter than the preceding. It is really a sport from the popular American variety Daybreak, and like its parent is a good grower. This variety should be much more popular than it is. Bridesmaid is also well worth growing. In the yellow varieties progress is slow, but improvements are being made. America has sent us over many, but none seem to be good. They either produce poor blooms or are shy bloomers and indifferent growers. Still, I think that before long really good yellow Carnations will be obtainable throughout the winter. W. J. Godfrey.

TREES AND SHRUBS.

PITTOSPORUM CRASSIFOLIUM.

WE are indebted to Messrs. James Veitch & Sons for sending us specimens of this handsome evergreen shrub (fig. 72, p. 205) under the name of P. Ralfii.* In the *Kew Hand List* this is given as synonymous with P. crassifolium, Solander, *Bot. Mag.*, t. 5978, and judging from the descriptions of the two plants, it seems most likely that we have to do with one species only. It is an evergreen shrub with oblong obovate leaves, tapering to a short stalk, dark green above, covered with creamy felt beneath. The flowers are chocolate-coloured, the sepals covered with white downy hairs. It will probably be hardy in the southern counties, or near the sea. It was included in the remarkable group of New Zealand shrubs exhibited by the firm at the last meeting of the Royal Horticultural Society.

CULTURAL MEMORANDA.

CODIUMS.

CODIUMS or Crotons may be propagated by cuttings or by "mossing." If cuttings are used, select nice tops, and place them singly in thumb-pots with a small stick to each, so that the leaves may be tied together. They should then be put in a propagating-case that has a bottom-heat of about 70°, and if treated with care they will soon form roots. Then a little air will be necessary, and after another week the plants may be removed to the stage until they need to be re-potted.

The second method, "mossing," is a very good plan, and especially for those who have not the convenience a propagating-frame affords. Remove three or four leaves from a point a few inches from the end of the shoot, and cut the stem in a way similar to that practised when layering Carnations. Obtain some sphagnum-moss, and mix a little sand with it, and bind it round the stem where incision has been made. Syringe this moss two or three times a day.

As soon as roots are observed to be growing freely in the moss, take off the shoots and pot them up into 2½-in. pots, keeping them in a close atmosphere, and shade from sunshine until they are established. When nicely rooted, shift them into 5-in. pots, using a compost of good fibrous loam 3 parts, and leaf-mould 1 part, with the addition of some sand, and a little charcoal broken roughly. If the loam be very heavy, a little peat may be added. Use the compost in a fairly rough state. The plants

* Pittosporum Ralfii, *Trans. N. Zeal. Instit.*, iii. (1871), p. 161.

should then be placed on the stages as near to the glass as possible. A very good practice is to cover the stage with shingle or breeze, and to stand the plants on inverted pots, which will enable you to syringe the underside of the leaves, and thus keep the plants clean. Or they may be suspended from the roof by wires. Look over the plants occasionally for insects, as thrips, red spider, and scale soon disfigure them if not quickly destroyed.

The following is a list of some of the best varieties. One of the best broad-leaved varieties

SCOTLAND.

GOOD BORDER-PLANTS.

Gladiolus.—In Scotland, the various sections of autumn-blooming *Gladiolus* mostly require special treatment in spring, by starting the corms into growth under glass, in order not only to secure the development of the flowers, but also to complete growth in the young corms. Seasons have, of course, determining effects in these matters, late ones see-

others. The plants at the same time are robust and healthy.

There are, however, some sorts of *Gaudavensis* which, as decorative plants, cannot well be dispensed with. These are more particularly late-flowering forms in shades of red, such for instance as *Le Vesuve*, and the very old *Meyerbeer*. Then for yellow varieties, which are effective for the purpose under discussion, nothing is finer than those of the *Lemoinei* section, the oldest of all, *Lemoinei*, being still indispensable.

FIG. 72.—PITTOSPORUM CRASSIFOLIUM. (SEE P. 204.)

is *C. Reidii*; this variety, grown with single stem, makes an extremely handsome plant, as it colours well. *Gordonii*, *Mortefontaineensis*, *Mortii*, *Thomsoni* (a fine yellow-coloured variety), *Evaniaus* (an old variety, but one of the best for colour), *Baron F. Selleieres*, *Alexander III.* (another good broad-leaved variety), *Queen Victoria*, *Flamingo*, *Warrenii*, *Ruberrimus*, *Sunshine*, *Bergmani*, and *Nestor*.

The following is a list of some of the best varieties for table decoration and for exhibition:—*Aigburth Gem* (a grand variety), *Johannis elegantissimus*, *Countess*, *Flambeau*, *Superbus*, *Mrs. Dorman*, *Chelsonii*, *Laingii*, *Mrs. McLeod* (a recent addition), and *Golden Ring*, a splendid variety, as it colours well, and should be in every collection of table plants for exhibition, or for the dwelling. X. Y. Z.

ing many varieties that had been artificially started into growth failing to produce spikes in time, and early seasons sometimes forwarding the plants too rapidly; but the rule is a good one, to lengthen the season of growth at its beginning. *Lemoine's Nanceianus* varieties are rather earlier to bloom than the *Gaudavensis* section, and the *Childsii* forms are equally precocious, on which account they are decided gains. The last-named is, moreover, intrinsically superior as a decorative subject to any of its congeners, and if one were confined to the cultivation of only a limited quantity of *Gladiolus*, I think the one to choose should be the above. In rich crimsons, true scarlets, and various winey shades of colouring, these are undoubtedly ahead of the

HOLLYHOCKS.

These have been producing a wonderful effect in broad borders filled mostly with herbaceous plants, the *Hollyhocks* being dotted and grouped in irregular masses instead of in lines. Ten or a dozen plants grouped together produce a feature at once bold, handsome, and attractive, while they lend a character to the whole arrangement, surpassing that afforded by any other autumn-flowering plant. In Scotland, we possess a decided advantage over southern growers, inasmuch as the plants hold on flowering till late in the season, though this year, owing to the excessive heat they do not appear capable of producing blooms so late as usual.

Twelve months ago I mentioned having sown seeds in autumn for flowering this year. I am

glad to say the time chosen—the beginning of September—was just right. I am sowing at the same time this year also, and the young plants will, as last year, be kept in a cold, dry pit until the planting season comes round. The benefits resulting from this practice is, that one secures strong flowering plants, which sowing in early spring does not always produce; and we have absolute freedom from disease among the young stock which one is never sure of when the seeds are sown in summer.

TRITONIAS.

I have several irregular masses of these, and by far the prettiest is one of *Pottsii grandiflora*, among which a few of the soft yellow *Royon d'Or* is intermixed. It is a curious fact that all the clumps which contain two or more varieties mixed together are much more effective than when the sorts are grouped separately. Another point worth mentioning is, that the more extensive the mass the better the effect, and yellow varieties surpass those that are more or less red in colouring. One of the most charming, and certainly the most distinct of *Montbretias* is the lilacy rose-coloured form called *rosea*, and this when better known must take its place as a decorative plant equally indispensable with the other sorts. It is noticeable that the admission of other plants, such, for example, as *Lilium tigrinum*, *Coreopsis tinctoria*, *Gladiolus*, and *Cape Marigolds*, is effective in breaking up the larger groups; and in the case of sorts the stock of which is limited, they may be spread over a larger area by including other plants.

Montbretias are generally considered to be hardy, but serious losses in two hard winters show that they are only conditionally so in Scotland. For that reason our stock is lifted annually and wintered in cold frames, whence the corms are transplanted in April into well-manured soil. They are planted 4 inches deep and 4 inches apart, at which distance the plants fill up nicely.

GALTONIA (HYACINTHUS) CANDICANS

is singularly effective in any way one chooses to employ it; either dotted singly among suitable low-growing plants, or grouped in large masses, or in broad lines in borders. If it were generally known that this plant may be increased with the greatest facility by means of seeds, it might be utilised more freely than it has been, as a first-rate decorative plant. My own stock, consisting of several thousands, is wholly derived from home-saved seeds, which every plant produces in great abundance. The seed is sown in April, just like Onions, in drills, and the resulting plants remain in the same place until the bulbs have attained a size sufficiently strong to bloom, which is in three to four years. The bulbs are not entirely hardy, and I lift each year in October and replant in the following April. The greater number of bulbs each produces two spikes, the one succeeding and taking the place of the other.

PHLOXES.

These are so well known and cultivated so universally that it seems almost superfluous to write of them. The full effect of the late flowering *Phloxes* is secured, however, not by means of a single specimen dotted here and there about borders, but when they are massed together twelve to twenty plants of one variety. Employed thus, I do not know any more desirable plant. There has been somewhat of a hawking after the dwarf varieties that have been so plentifully produced of late years, but for bold effect, these are altogether inferior to the tall sorts. Continental raisers have effected great improvements in the *Phlox*, both as to size of the spike, and of the individual bloom. But these are slight in comparison with the colours which have been produced. Some people would, no doubt, at once declare the various shades of scarlet, and especially those of which *Flambeau* is a type, as being the greatest gain; but the violet and plum-coloured varieties are scarcely less effective,

whilst nothing can surely be more pretty than the pinks.

They are difficult to arrange from catalogue descriptions, but it is a difficulty easily overcome if the plants are arranged when in flower—a method which not a few may hesitate to adopt. The *Phlox* is, however, one of the most accommodating of plants, and, with due care and plenty of water, they may be transplanted at any stage of growth without receiving injury. They are largely surface rooters, and in preparing ground for their reception it is well to add a thick dressing of short manure, to be thoroughly incorporated in the top spit of soil. In addition, I place annually a thick surface-dressing of manure above the stools during winter, and this affords a material aid in cases in which the ground can be enriched in no other way. *R. P. Brotherston.*

NEW RUBBER PLANTS.—We learn that the collectors for *l'Horticole Coloniale* have sent home some new and interesting "Rubbers" from hot regions, and also some seeds, which have already germinated, of a valuable species coming from cold districts where *JEAN LINDEN* discovered it sixty years ago, growing at an altitude of from 6,000 to 8,000 feet. This species yields caoutchouc the fifth year after planting, and it can readily be acclimatised in the South of Europe and North Africa. Hitherto efforts to obtain living specimens have been futile, but now a large stock has been raised which will prove a valuable acquisition, notably in the Congo plantations. We do not know whether this Rubber is the species of *Castilloa* mentioned in the *Kew Bulletin*, 1899, p. 70, or a *Hevea*. A detailed account of these Peruvian Rubbers is given in the *Bulletin l.c.*, which came to hand after the receipt of the *Semaine Horticole*. This publication for August 5, which mentions the above fact, speaks also of a tree to be shortly imported which is as powerful as *Eucalyptus* in rendering tropical swamps less noxious, and the seeds of which constitute a new febrifuge as efficacious as quinine, and infallible for snake-bites. [It may be so, but we suggest experimental proof. Ed.]

THE WEEK'S WORK.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Hollyhocks.—The old systems of propagating *Hollyhocks* by cuttings, grafting on stocks, and division, are now regarded as more or less failures, as the plants raised by these means are rarely robust enough to resist the fungus (*Puccinia Malvacearum*). If plants be raised from seeds however, they have a better constitution, and the strains of seeds now obtainable are quite equal in size and colour of flowers to the selected and named varieties of past years. The singles are preferable to the double varieties, as they throw up stronger spikes, the leaves keep healthy, and they are in every way as greatly attractive.

The seeds may be sown in January, but stronger plants will be obtained if they be sown now in pans which have been filled with a well mixed compost of fine loam, leafmould, and sand. Sow regularly and thinly, and place the pans in a warm and moist position. When the plants are strong enough, pot them off singly in thumbs using a similar compost, and when these pots have become well-filled with roots, transfer the plants to pots two sizes larger. Afterwards remove them to a pit or frame where they can be gradually hardened off and remain till spring, when they will be planted out. The smaller plants in the seed-pan should always be kept, because these, as a rule, have the best-coloured flowers.

Chrysanthemums.—Plants of the early Japanese, recurved, and Pompon varieties grown in borders and beds will now require liberal feeding with manure-water, and some neat stakes put to them to support the flowers. Where buds are forming freely, disbudding should be commenced as soon as possible, removing in the larger-flowering kinds all

growths pushing from the axils of the leaves, and the smaller buds from beneath the terminal bud. These are best removed by the aid of a pen-knife early in the morning when they are damp. The recurved and Pompon varieties will require less thinning, but should be looked over daily to destroy any earwigs or thrips.

Bulbs.—An order-list for bulbs should now be made out and sent to the tradesman, that the number necessary for the garden may be procured without delay. Thus no time need be lost in planting them as soon as the summer plants have been removed from the beds. Of the bedding *Hyacinths* the single varieties are much the best to plant. A selection of the boldest single Tulips would contain *Artus*, *Bacchus*, *Brutus*, *Dussart* (very fine), scarlet and crimson in colour; *Chrysolora*, *Ophir d'Or*, *Potterbakker*, good yellows; *Keizer Kroon*, *Duchess de Parma*, scarlet, edged gold; *Rose Grisdeline* and *Cottage Maid*, rose and white; *Proserpine* (very fine) and *Rosa Mundi*, rose; *Wouvermann* and *Molière*, rich purple; *Thos. Moore* and *Prince of Orange* are good shades of apricot. The double varieties are quite a fortnight later in flowering than the single ones, and are best adapted for planting in beds in low-lying ground. Among the best doubles are *Rex rubrorum*, *Purple Crown*, crimson; *La Candeur*, white; *La Matador*, orange-scarlet; *Duc van Thol*, scarlet and yellow; and *Murillo*, rose. The *Parrot Tulips* are excellent for borders, and may be permitted to remain in the same spot for several years together. Likewise the May-flowering varieties, such as *Bouton d'Or*, *Picotée*, exquisite for cutting; and the still later-flowering species, *Gesneriana* and *Fulgens*. *Scillas sibirica*, *bifolia*, *campanulata*, blue, and alba, succeed well under trees and in turf; and *Chionodoxa Lucilie* and *sardensis* show up superbly when mixed with the giant-flowered *Snowdrop*, *Galanthus Elwesii*.

FRUITS UNDER GLASS.

By W. STRUGNELL, Gardener to Lieut.-Col. RALPH VIVIAN, Rood Ashton, Trowbridge.

Melon-house.—Melon plants for furnishing fruits during the next few weeks must be given very careful ventilation, watering, and bottom-heat. Their roots are very tender, and a check from any cause, particularly from cold, will be serious. Only a moderate heat, however, is needed, and this should be as uniform as possible. A strong heat one day, and none, or but little, the next, is worse than no fire-heat at all. Watering is of equal importance; an excess having fatal consequences, where there is not a well-regulated bottom-heat provided. The roots now are better kept slightly on the dry side, and chilled water should be used. It is a very good practice to keep a mound of dry lime around the base of the stems, as a precaution against canker, but unless this be kept dry its presence will do more harm than good. Should canker set in, rub the affected parts with either dry quick-lime or Portland cement, continuing this daily, or more often if necessary. Close the house early in which late Melons are grown, and shade but slightly. Do not syringe late in the day, but merely damp the floors. Plants now in flower will not set unless much care is brought to bear on the pollination of the expanding blooms, and until they are swelling satisfactorily it is better not to rigidly pinch the shoots. A light sprinkling of lime over the border frequently and watered in will greatly assist the fruit to swell.

Fig Trees in pots should now be out-of-doors, where they will become fully ripened. Any that are in small pots, and need further root-room, may be given a shift at once; they will soon make new roots if the work be done while the trees have still leaves upon them. With frequent applications of stimulating manures, however, it is surprising how well and how long *Fig trees* continue to be fruitful, though confined in small pots. In potting or top-dressing *Fig-trees*, lime-rubble and bone-meal should always be included in the compost.

The Orchard-house.—Where such fruits as *Apricots*, *Plums*, *Apples*, *Pears*, and *Cherries* in pots occupy a portion of this structure, they should be removed outdoors as soon as they have ripened all their fruits. The latest-fruited varieties of *Apples* and *Pears* colour better in the open than under glass, but they will need to be protected from birds. The pots also should be protected against sun and drying winds by means of litter or a bed of plunging material; but do not put the

trees in a shaded position. If scale, red-spider, or thrips have given trouble, trees that have fruited may be conveniently syringed with an insecticide or hot water at the time of their removal. Peaches, Nectarines, and Plums required as late in the Autumn as possible, should for the present be given air constantly. Wasps, flies, and earwigs, are becoming very numerous. Earwigs may be trapped with short lengths of beanstalks, which must be examined each morning, and the insects therein destroyed. Bottles partly filled with sweetened beer attract a good many flies and wasps, and Davis's or Scott's destroyers are both useful in keeping them from ripening fruits. Shorten all unnecessary lateral growth upon fruit-trees, so as to expose the swelling fruit to the sun, and also to assist the ripening of that portion which will bear the next season's crops. Make sure that the roots do not suffer for want of water, and give stimulants to those that are pot-bound.

THE ORCHID HOUSES.

By W. H. YORNO, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Cattleya Bowringiana.—This free-flowering and easily-grown species, may shortly be expected to emit roots from the cushion-like base of the pseudo-bulbs just completing growth. If any of the plants need to be repotted or resurfaced, the work may now be given attention. Ordinary pots suit small plants very well, but for larger specimens pots or pans with perforated sides should be used, so that the drainage of water from the rooting material may be more rapid and free. A stagnant atmosphere or a constantly wet compost are very detrimental to the young pseudo-bulbs. Their peculiar convolute sheathing bracts are adapted for the retention of water, and if evaporation be arrested this will cause decay, and ultimate loss of the pseudo-bulbs. The tenacity and brittle character of the roots render great care necessary when breaking the pots and handling the ball when repotting. When the plant has been arranged in the new receptacle, place sufficient crocks round the ball to fill the pot to within an inch or so of the top, and on this pack some good fibrous peat, inserting a few heads of sphagnum-moss over the surface. Following root-disturbance, water will only be needed in just sufficient quantities to keep the material moist. As the winter approaches, and for a long time afterwards, a very restricted supply will suffice. Place the plants in a light and airy position in the *Cattleya* house. Evaporation should there be quick, but if at any time water remains in the bracts a longer time than is desirable, blow it out or remove it with the aid of a soft-haired brush. *C. x Mantinii*, the beautiful hybrid between the above and *C. aurea*, will thrive under similar conditions.

The Autumn Treatment of Orchids is, in most respects, directly opposite to that suitable in spring, for then it is wise to follow the old Latin proverb, and "hasten slowly," but now, it is necessary in many cases to hasten "quickly," so that plants which in their natural habitat complete their growth during the warmest parts of the year, may do so here under artificial conditions, and so fit themselves for the changeability of the British climate during winter. Backward plants should therefore be removed to the most favoured positions as regards light and heat; and being thus encouraged, they may develop their unfinished growths. All general overhead syringings should now cease so far as the afternoon is concerned, for owing to the cool and dewy nights, evaporation does not remove the deposited moisture quickly enough. On bright mornings, when there is prospect of a fine day, dewing the plants overhead should not result in harm during this month. Shadings now only need be employed to counteract the direct rays of the sun, removing it whenever there is not bright sunshine. Greater attention must be given to temperatures, as they will, no doubt, be considerably lower, and if not watched, may drop below the desired point. By no means employ more fire-heat than is absolutely necessary, but use enough to keep the air moving and to sustain the temperatures in early morning to the requisite degree.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Lettuces and Endive.—Plant out as soon as possible large quantities of Lettuces and Endive, choosing for them a border in a sunny position.

The Cos varieties may be planted 10 inches apart from each other, and the broad-leaved Endive at distances of a foot. Notwithstanding the showery weather, the plants will need to be heavily watered previously to lifting them; and when planted in the border, give another watering, which will settle the soil around the stems. Seeds that were sown three weeks ago have made but little progress owing to the drought, and part only have yet come up. These small plants may be lifted and put out on a warm border in rows 12 inches apart, and the plants 6 inches apart in the rows. Every alternate plant will need to be removed later. More seed may now be sown of the hardy winter kinds, but do not disturb the beds that were sown some time since; because the soil, now being damp and cooler, more of the seeds will germinate. In dry weather, when the inner leaves of those Lettuces ready for tying are perfectly dry, tie them carefully to bleach them. It is only on heavily-manured north borders that good, crisp Lettuce can be grown in hot, dry seasons.

Cauliflowers.—Attend to the young plants that will be wintered under handlights or frames. There are many who have ceased this practice, and now depend entirely on spring-sown plants raised in heat, but a few hundred plants take up but little room and attention during winter, and moreover, they can always be depended on for turning in about the middle of May. A few degrees of frost will do the Walcheren variety no harm in winter. The great evil that must be avoided is that of getting the plants too forward in autumn. From the first there should be no coddling; the plants must grow slowly, and be as sturdy and hardy as possible. In southern districts a second sowing is made, and sometimes proves the more useful.

Parsley.—Go over the beds raised from seeds sown last April and remove a good portion of the lower leaves, so that an abundance of young Parsley may be had throughout the winter. A few of the best plants may be taken up and planted at the foot of a south wall or fence. Plants raised from seeds sown in July will require to be thinned out; the young plants removed may be planted in cold frames. Parsley which has been properly prepared for winter and spring use should be kept free from weeds, and encouraged to grow freely for some time yet, and as soon as frost appears, put on the covers of the frames; but if the plants have been prepared and put out in brick pits near the glass, the lights should only be used in severe weather.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Raspberries.—Cut away all old bearing wood as soon as convenient. The principal advantage to be derived from doing this work now is that more light and air will be admitted to the young canes that are to produce next year's crop. If a greater number of these have been allowed to grow up than is required, they should now be thinned out, three or four strong ones to each stool being sufficient. Loosely fasten these to the trellis, or stakes, as the case may be, to prevent them from being broken down by wind. If the growth made has not been satisfactory, a soaking of weak liquid-manure may be helpful should September remain warm.

Pears.—Look over early varieties weekly, and gather the largest and more forward fruits a few at a time, that the season may be prolonged. Besides Williams' Bon Chrétien, which will now be nearly finished, small gatherings of such varieties as Souvenir du Congrès, a grand variety to follow the preceding; Clapp's Favourite, Doyenné Boussoch, Fondante d'Automne, Beurré d'Amanlis, and others, ripening at the same season, may be made, selecting those fruits that, from their appearance and size, should be the forwardest. If these be gathered now, those remaining will increase in size before the next gathering is made.

Out-door Vines.—Closely pinch out all surplus growths, that increased sun and air may benefit fruit and stem. The hot weather has been favourable for out-door varieties, and the Sweet-water varieties having already commenced to ripen, and should now finish well if protection is given them from wasps and flies. For this purpose thin muslin bags are best, although as a cheap makeshift I have known paper ones answer fairly well when the Grapes are as forward as they are this year. Flies seem so far to be more trouble-

some than wasps, although these are increasing in numbers. Damaged fruits, especially Plums, make good bait to trap these enemies. Place a handlight (having a square of glass taken out at the top), on four bricks, and upon this place a second handlight, making it to fit closely round the sides. The fruits being placed under the lower one attract the flies, they naturally ascend, find their way into the top light, and seldom return.

Mildew has recently become troublesome on Black Hambro, and Black Cluster Grapes growing outside, and syringing with Gishurst Compound or the Sulphur Mixture, or hot-water, is necessary. The varieties last mentioned rarely ripen perfectly outside, but the fruits may be utilised for making wine, for which purpose they answer very well.

PLANTS UNDER GLASS.

By C. R. FIELDER, Gardener, St. James's House, Malvern.

Mignonette.—A good sowing may now be made to obtain plants that will flower in late winter and early spring months. Use clean well-drained 5-inch pots, and fill these to within an inch of the brim with a compost consisting of three parts loam, one part rotten manure from a spent hot-bed, and a little silver-sand. Make the surface of the soil even, sow the seed thinly and cover it slightly with finely sifted soil. A watering should be afforded through a fine rose, and the pots placed near the glass in a cold frame. Water must be applied carefully while the seedlings are small. If the soil be kept too wet the seedlings will turn yellow and damp off. Thinning should be done directly it can be seen that the seedlings are growing freely, leaving three or four plants that are about equal in point of strength in each pot. Later it will be necessary to remove the plants to a shelf in the greenhouse or any similarly cool and light position.

Zonal and Ivy-leaved Pelargoniums should now be placed in cold frames, keeping the lights off for the present, however, save in the event of a cold night being anticipated, and during heavy rains. With a view to assisting the flowering of these and other winter blooming plants such as *Bouvardias*, *Salvias*, *Libonias*, *Manettias*, *Tecoma Smithii*, &c., weak liquid manure may be given to such as have well filled their pots with roots.

Bouvardias that have been planted out should be lifted and potted up, taking care to secure as good a ball of roots as possible, in order to prevent the plants suffering any serious check. The potting soil may consist of three parts loam, one part leaf-soil, and one part rotten manure, together with sufficient silver-sand to keep the soil porous. When potted, the plants may be stood in a cold frame or pit, and kept somewhat close and shaded until they become established, when the shading may be discontinued, and ventilation afforded, in accordance with the state of the weather. As the autumn advances, it will be necessary to place the plants in a structure where fire-heat can be obtained when necessary. Plants which are in pots, and at present out-of-doors, may be placed in cold frames. Remove the lights each morning during fine weather.

Bulbs for Pot Culture.—Continue to pot up successional batches of bulbs. For flowering before Christmas, "retarded" Lily of the Valley crowns are very satisfactory. Batches may be potted up at intervals of about three weeks, and it is best to purchase only a sufficient number of crowns for one batch at a time. About a dozen crowns may be placed in a 5-inch pot, and if the pots be watered and placed in a cold frame for a few days, and then introduced into gentle heat and watered freely with luke-warm water, they will produce flowers in from three to four weeks. *Polyanthus Narcissus* "Early Snowflake" is a very valuable bulb for very early forcing. If bulbs were purchased, as advised in a previous calendar, and potted at once, they have probably commenced to show leaves; and when this is the case they should at once be taken from the ashes and placed in a cold frame for a week or ten days, and then transferred to an intermediate-house for about the same length of time. After being prepared in this way they may be placed in a house where a night temperature of about 60° is maintained, when they will come into flower about the middle of October. Batches of *Lilium Harrisii*, *L. candidum*, Roman and show Hyacinths, Freesias, and the Van Thol varieties of Tulips should also be potted. The forcing of the above bulbs should be gradual, after the manner recommended above for Narcissus, and forcing should not be begun before the pots are well filled with roots.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

TUESDAY, SEPT. 12 { Royal Horticultural Society's Committee.
Royal Horticultural Society of Ireland.

SHOW.

WEDNESDAY, SEPT. 13 { Royal Caledonian Horticultural Society's Show in the Waverley Market, Edinburgh (2 days).

SALES.

MONDAY, SEPT. 11 { Dutch Bulbs, at Protheroe & Morris' Rooms.
Fourteenth Great Annual Unreserved Trade Sale of Plants, at Dyson's Lane Nurseries, Upper Edmonton, by order of Mr. H. B. May, by Protheroe & Morris.

TUESDAY, SEPT. 12 { Dutch Bulbs, at Protheroe & Morris' Rooms.
Great Annual Sale of Winter-blooming Heaths, and other Stove and Greenhouse Plants, at The Burnt Ash Road Nurseries, Lee, by order of Messrs. B. Maller & Sons, by Protheroe & Morris.

WEDNESDAY, SEPT. 13 { Dutch Bulbs, at Protheroe & Morris' Rooms.
Unreserved Annual Sale of Winter-flowering and other Plants, at The Nurseries, South Woodford, by order of Mr. John Fraser, by Protheroe & Morris.
Special Sale of Lillium Harrisii and Palm Seeds, at Protheroe & Morris' Rooms.

THURSDAY, SEPT. 14 { Dutch Bulbs, at Protheroe & Morris' Rooms.
Thirty-first Annual Trade Sale of Stove and Greenhouse Plants, at the Brimsdown Nurseries, Enfield Highway, by order of Mrs. F. E. Thompson, by Protheroe & Morris.

FRIDAY, SEPT. 15 { Dutch Bulbs, at Protheroe & Morris' Rooms.
Eighteenth Great Annual Trade Sale of Winter Blooming Heaths, at the Longlands Nursery, Sidcup, by order of Messrs. Gregory & Evans, by Protheroe & Morris.
Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period August 27 to September 2, 1899. Height above sea-level 24 feet.

Remarks.—The weather has been much cooler. Small quantities of rain fell on five days. The wind has been cool, and mostly from the west.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—60.4°.

ACTUAL TEMPERATURES:—

LONDON.—September 6 (6 P.M.): Max. 79°; Min. 66°.

PROVINCES.—September 6 (6 P.M.): Max. 69°, Home Counties; Min. 60°, N. E. Scotland.

September 7, London, noon: Rainy; Violent Storm on 6th.

The National Dahlia Society's Show. The Dahlia Exhibition, held at the Crystal Palace last week, was surprisingly good. That the display of all sections combined was as large or larger than at the show last year, is a very satisfactory circumstance, for the drought and heat of 1899 have been even more exhausting than the weather last season. The Show Dahlias were those that were in worst form at the Palace. They were not only less numerous than is usual at the National

poraries. The time-worn reasons of soil and district, have no doubt in some measure been responsible. Mr. C. TURNER, of Slough, the hero of so many Dahlia struggles, was unable to show a collection at all, on this occasion.

But the Cactus varieties are the better adapted for fighting such a season as the present. They were shown in the usual numbers. They lacked neither quality nor quantity, and, generally speaking, are deservedly the most popular Dahlias.

FIG. 73.—A VIEW IN DR. WINTER'S UNDERGROUND FERNERY.

(SEE P. 211.)

Society's exhibitions, but they were lacking in the symmetry and quality that the florist admires, and which, apart from the exquisite colour tints, is the only characteristic possessed by the show Dahlia that could possibly commend it to cultivators. The best blooms in this section were shown by Mr. JAS. WALKER, of Thame, who secured the leading prizes with collections that included individual blooms of a high order of merit. This exhibitor has been equally fortunate at other exhibitions held recently, and it must be capable of explanation, why in the present season, he has succeeded in combating the influences of the weather, to a degree beyond most of his contem-

Mr. J. STREDWICK'S 1st-prize collection was magnificent, and there were others of almost equal excellence. Nor were the prim little Pompons less good. Bright, neat, and very free in flowering, they are splendid "garden" Dahlias, and everyone should cultivate them.

We cannot refer to the single-flowered varieties without remembering the much-lamented President of the National Dahlia Society, Mr. T. W. GIRDLESTONE, whose decease it was our painful duty to announce a short time ago. His exertions on behalf of the Dahlia, and of the single varieties in particular, are known to most of our readers. He has raised many delightful varieties of the most perfect

form, having beautiful colouring, and an improved habit of growth. But even he proved unable to obtain for the single varieties a tithe of the popularity that was accorded them some years ago. His superb exhibits in the large classes for single flowers were greatly missed last week, but it was noticed that a few of the newer seedlings raised under his care were exhibited.

Some of the best single blooms exhibited were from Messrs. J. CHEAL & SONS, who took 1st prize

show under notice. One of these is a Welsh seedling, having been raised in Cardiff by Mr. W. TRESEDER, who won 1st prize in the class for show varieties. It is to be called William Treseder, and is the first seedling for which this exhibitor has been awarded a certificate. It is a nearly white flower, the old petals becoming pale lilac, and the centre is pale yellow. Three new ones from Messrs. KEYNES, WILLIAMS & Co. were all good. These were Mrs. J. J. Crowe, a pure yellow flower;

Chrysanthemums. It is well that the Society has no desire to encourage size—or monstrosity. Mr. Stredwick had some good Cactus varieties also; including Major Tuppeney, a large orange coloured flower, with pure yellow centre; Augustus Hare, a distinct bright looking flower of orange tint edged with crimson; Uncle Tom, deep maroon, one of the best; Major Weston and Mrs. Sanders. The last mentioned is a pure and soft shade of yellow. In colour this is a lovely variety, but the lower part of the petals being flat, and only the uppers rolled, it is not so distinctly Cactus-like as some others. Elsie is the name of a seedling shown by Messrs. J. Burrell & Co. It has a yellow ground, and is marked with lilac.

We think the Society has done well to introduce a few classes for the purpose of demonstrating the use that can be made of Dahlias in various forms of decoration. In this year of grace it is very necessary to show that a flower it is wished to popularise is one that has value when cut. Here, it goes without saying, the show varieties fail entirely. But the Cactus, the Pompon, and single flowers, can be arranged to produce a charming effect in vases, or in show bouquets. The single vase from Mr. ED. MAWLEY, one of the Society's good friends, was a picture of harmony; nor was the bouquet from Mr. TRESEDER, or the epergne from Mr. HUDSON, less attractive. The Society will hold another Show this season, and we hope with Mr. J. F. HUDSON, the Hon. Secretary, that it will be equally, or more, successful than that at the Palace.

The Naming of
Trees and
Shrubs in
Public Gardens.

A CORRESPONDENT writes us a complaint on this matter. He is always on the look-out for something pretty or valuable for his garden, and visiting the Embankment Gardens recently he found a flowering shrub which to him was new and attractive, and at once desired a specimen like to the one that pleased him. But diligent search around the shrub for some indication of its species proved ineffectual. Not the slightest information as to the name, affinity, or native home of the plant had been provided. It had been planted therefore, apparently, to beautify that particular garden, and not for educational purposes. In his disappointment, our correspondent must needs write to the horticultural press, ask the editor to walk down to the above-mentioned gardens and send him the name of the plant. But that was not all; he asks that we should censure the responsible authorities, and, like a man with a grievance, he declares that such an experience is quite common in London. Now, latterly, we have frequently found occasion to express our appreciation of the work done in relation to the parks and open spaces in London by the London County Council and othersympathetic bodies. They have not only provided, by all sorts of measures, an immensely greater area of park and garden land in our midst, but they have introduced into these a number of the best flowering trees and shrubs, some of which are fortunately proof against London's wretched fogs. We think, therefore, that where there has been an omission to attach names to the principal species of plants it is more probably due to want of thought than lack of sympathy with such flower-lovers as our correspondent. It would be undoubtedly best to make the public gardens in London as educational as possible in the manner suggested, and if a system of labelling were carried out such as is practised in botanical gardens, this might be done so unobtrusively that none of the natural effect of the grounds would thereby be destroyed.

"LESSONS FROM THE GREAT DROUGHT OF 1898" will form the subject of a lecture by Mr. E. MAWLEY, at the forthcoming meeting of the committees of the Royal Horticultural Society, on Tuesday next, September 12, in the Drill Hall, James Street, Westminster. The lecture will commence at 3 P.M.

FIG. 74.—HYMENOPHYLLUM DEMISSUM, AS GROWING IN DR. WINTER'S UNDERGROUND FERNERY. (SEE P. 211.)

in the class for twenty-four varieties. Mr. STREDWICK exhibited a seedling variety of the single-flowered section, that gained a Certificate; and Girlie, as the variety is called, will be valued for the extra good form of its flowers, which are white, each petal edged with deep red. The only other single variety to which a certificate was awarded had the appellation Flame, and was from Messrs. J. CHEAL & SONS. This also has a good circular outline, the ground colour is orange-yellow and flaked or splashed with crimson.

But it is the Cactus varieties that increase out of proportion to those of all other sections, and a dozen certificates were distributed amongst these at the

Emperor, red, tipped with purple; and Innovation, the last-named being an improvement upon the rather unsatisfactory but pretty Arachne. It has a deeper-coloured base, and stouter stems. Mr. J. GREEN, of Dereham, showed a variety named Green's White, a very deep flower, of good form, with rolled, claw-like petals. This is probably the best of the seedlings exhibited; also Zephyr, a rosy-lilac variety. His Red Rover was thought to be too large to be encouraged by the Society's stamp of merit; it is the largest and most showy scarlet Dahlia, and in comparison with others is in something like the same position Madame Carnot occupied three years ago amongst

THE WEATHER IN LONDON has been exceedingly hot upon several days during the past week. The highest temperature was on Tuesday, when it reached 89° in the shade, a remarkable temperature for the month of September. On Wednesday morning the air was most sultry and the sky dull, and about twenty minutes after noon we were visited by an unusually severe thunder-storm, which lasted rather less than half an hour. For a time, however, the rain was a deluge, flooding the streets, and, in low situations, the houses. This cloud-burst of rain was accompanied by heavy thunder and vivid lightning. In less than half an hour an inch of rain had fallen. London has received a thorough cleansing. At the time of going to press, the weather remains showery.

"STEVENS' ROOMS."—A phrase well known to sellers and buyers of plants, and objects of natural history generally, and, as seems likely, destined to be yet better known. Mr. STEVENS informs us that he has taken Mr. D. PELL SMITH into partnership. Mr. SMITH occupied for some years a very responsible position with Messrs. J. VEITCH & SONS, and it is now intended that the horticultural branch of the business shall receive special attention in the future. The business will be carried on as heretofore at 38, King Street, Covent Garden. The telegraphic address, "Auks," if not elegant, is delightfully simple, and appropriately recalls the sales by the firm of the very rare eggs of a bird not only very rare, but extinct. Indeed, for many years the greater part of the natural curiosities and collections have ultimately gravitated to these famous rooms, where their fate has been for the time at least decided by a blow of Mr. STEVENS' hammer.

TIMBER FOR CAPE TO CAIRO RAILWAY.—A Kansas City journal states that an order has been given and accepted for 500,000,000 feet of Southern yellow Pine, for use in the construction of this great line of African railway. One requirement of the agreement is that the timber must be placed on the ground within two years; and it is stated that the above is the largest single order known in the history of the American timber trade. Possibly, by the time all the timber has been worked up on the great through line, means will have been found for tapping and utilising the virgin forests of the "dark continent."

THE ROYAL GARDENS, KEW.—Below are a few condensed notes upon some of the interesting plants in these gardens at the present time.

Canada Rice.—There are now flowering in various parts of the garden plants of the stately Canada Rice, *Zizania aquatica*. It is a most elegant plant for the edges of ponds and similar localities, growing to a height of 6 to 8 feet, with narrow recurved foliage and light terminal panicles of flowers, the males above, the females beneath. The plant is an annual, and great difficulties have been experienced in former times in getting the seed to grow; so that, although originally introduced by Sir JOSEPH BANKS to this country, it has never become well established among us. The seeds are used as cereal grains by the North American Indians. *Z. latifolia*, a perennial species from Japan, has fleshy root-stocks, which are eaten by the Japanese.

Calystegia macrostegia is a woody Californian species, producing its white bell-shaped flowers in tufts. It might be tried in the southern counties.

Kirinyeshoma palmata.—An extraordinary plant with an extraordinary name is now in bloom on the rockery. It is a member of the Saxifrage family, though it would puzzle a London University examinee to detect it; and we are not sure the examiner would be any better informed unless previously coached. It is about 3 feet high with long-stalked, opposite, cordate, palmately-lobed, glabrous leaves, about the size of the palm of the hand, and loose terminal clusters of yellow flowers, each rather more than an inch long, with a shallow

cup-shaped, five-lobed calyx, and a corolla of five oblong, blunt, yellow petals, about 1 inch long. There are numerous stamens with thickened filaments, which ought to be perigynous, but have no such appearance in the specimen before us, as the stamens have all become detached from the sepals and petals. It is a native of Japan.

Coriaria terminalis.—This is a handsome trailing shrub, with terminal-stalked racemes of flowers, succeeded by yellow berries. Most of the *Coriarias* are shrubs, as this is in appearance, but we are informed it is truly herbaceous. It is a native of China, and of the Himalayas. A full account, by Mr. HEMSLEY, will be found in our pages, Feb. 19, 1898.

Argemone grandiflora is now finely in flower; it differs mainly from the ordinary mexicana in its taller habit and the larger size of its flowers.

Didierea mirabilis.—This extraordinary cardiceous plant, figured in the *Gard. Chron.*, Feb. 19, 1898, p. 110, is doing well at Kew in the pits. It is not exactly the plant for the flower garden, but for the botanist it is a great curiosity.

Halenium tenuifolium (Nuttall), is a plant that when once it becomes known, will be eagerly sought for by decorating gardeners. For the front of herbaceous borders, or for separate beds, it will be very effective. It is like a *Tagetes* in habit, with slender, linear leaves, and a profusion of yellow flower-heads. It is figured in MEEHAN'S *Native Flowers of the United States*, vol. ii., p. 37, t. 10.

The Mango.—In the temperate-house is a fine bush bearing numerous fruits well on towards ripening.

Thalia dealbata.—An elegant and striking water plant, usually grown in heated aquaria, but at Kew it may be seen at the edge of a pond forming a most beautiful foreground plant with its bold glaucous foliage and tall panicles of bluish flowers.

Silene Fortunei.—We have spoken of this pretty Chinese *Lychnis* before, but revert to it to say that at Kew there are now two varieties of it, one tall (2 to 3 feet) and early, the other dwarf and late. It is one of the plants of the future in decorative gardening.

Hippophae rhamnoides as a Standard.—Near the north end of the Palm-house is a fine bush laden with orange berries, but with a clear stem like that of a standard Holly. This has been produced by removing suckers and laterals. As there is no male plant in the vicinity the abundant crop of berries must be due to the proximity of some other *Elæagnoid* plant, of which there are several close at hand. Perhaps some interesting hybrids may result.

HYBRID CARNATION.—A correspondent from Wimborne sends us flowers of a hybrid between the Clove Carnation and a Malmaison variety. The flower sent is from a plant in bloom since Easter; it has nine growths in flower at the present time. It was layered July, 1898, at Easter; the crown blooms were 4 inches wide, with over 100 petals. The flower sent is 3 inches across, very full, rich crimson. The calyx does not split, and its lobes are broad and rounded, not pointed as in the Clove. We look on it as a remarkable cross; but as our correspondent is more especially concerned with its commercial value, we may add that it is a very fine variety, and if sufficiently hardy would make a fine border Carnation. We advise him to send flowering specimens to the Floral Committee at its next meeting on the 12th inst.

BOTANIC GARDEN, CONGO.—This is the new address of one of our young friends, the son of our much-respected colleague, EDWARD PYNAERT. It appears that the Belgian Government has decided on the establishment of a botanic garden, and of sundry experimental gardens near Stanley Pool and elsewhere. The establishment and direction of these "botanic stations" has been entrusted to M. LÉON PYNAERT, a distinguished pupil of the School of Horticulture at Ghent, and one who,

though still young, has gained experience at Kew, in Paris, and Potsdam. M. LÉON PYNAERT will visit Java and Ceylon, and study the methods of administration of the gardens at Peradeniya and Buitenzorg before proceeding to the Congo. We heartily wish him all success in his beneficent occupation.

TRANSVAAL HORTICULTURE.—Our correspondent at Johannesburg, writing in August, thus speaks of the commencement of the growing season:—"Spring weather is fast overtaking us. The night frosts have nearly ceased, and by mid-day the shade temperature rises to 70° As yet, very little rain has fallen. In May we had '65 inch, in June '12 inch, in July '34 inch, and cannot expect heavy showers until September or October. The high winds are fast stripping *Acacia dealbata* of its flowers—the ground beneath the trees is yellow with golden heads of blooms. A. cultiformis, large bushes 10 feet high, are just beginning to flower; later on we shall see the large trees of A. mollissima masses of creamy-yellow inflorescence. The very beautiful, but sub-tropical A. pubescens, finds our winter too cold to succeed in the open. *Ulex europæa* and Spanish Broom are beginning to flower, and Almonds and *Prunus Pissardi* are masses of snowy white. Early Peaches, too, show their pink flowers. *Cydonia japonica* and *Daphne indica* give materials for bouquets if grown in damp places. Our native *Buddlea salviifolia* is in bud; the flowers are not showy, but very sweet scented. *Sutherlandia frutescens* is in bloom—a long way inferior to *Clinanthus puniceus* in beauty. In damp, boggy places, *Narcissus* and *Daffodils* promise well for flower, but in ordinary dry borders these, and all other spring-flowering bulbs, are utter failures. Under glass we have *Cinerarias*, *Pelargoniums*, *Freesias*, *Lachenalias*, *Poinsettias*, and a few *Cypripediums* in bloom, with *Calceolarias*, *Cyclamens*, and *Triteleias* coming on. Under trellis sheds we grow *Camellias*, *Rhododendrons*, and Indian *Azaleas* in tubs. Thus treated they flower fairly well. Work out-of-doors just now consists in lifting, dividing, and re-planting *Cannas*, *Tuberoses*, *Dahlias*, *Pancratiums* and *Hippeastrums*, and in pruning *Roses* and all flowering shrubs. *Pinus insignis* is making rapid spring growths in advance of all other *Coniferae*, as it is ever its nature to do, and so gives us a hint (in spite of the present political situation) never to relax our efforts, but to be always preparing for next year."

"THE CENTURY BOOK OF GARDENING."—The first number of this publication is before us, and, with one exception, we have nothing but praise to bestow upon it. The cover is so dazzlingly red that in some lights it is positively painful. The present number is mainly introductory. Mrs. EARLE contributes a paper on Shrub Borders and Hardy Flowers. Then follows the commencement of an article on Annuals, concerning which, the information is too meagre. But it is the superb illustrations that are most attractive. We can hardly say too much in praise of such an illustration as that of the terrace garden at Heckfield. If all process-blocks were as good as those here given the objections which many of us have felt to them would be speedily removed.

RAGLEY GARDENS, ALCESTER.—Through the kindness of R. OLIVERSON, Esq., these gardens were again open to the public recently, and a collection made on behalf of the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund, when a sum of about £5 was obtained. The drought has been felt most severely in South Warwick, and the lawns were not looking their best; but sixty odd beds and borders of flowering plants were beautiful. The largest share of admiration was bestowed on the pyramid beds of zonal and Ivy *Pelargoniums* and *Plumbago capensis*, which were 8 feet through at base, and 6 feet high, and a mass of bloom. The gardener, Mr. CHRISTIE, had done his best to obtain a striking show,

FILMY FERNS AT DR. WINTER'S, BRIGHTON.

(See Illustrations on pp. 208, 209.)

Few things give more trouble to the cultivator of Ferns in the ordinary way, than the species known as Filmies, and yet, as with many other difficult subjects, when taken in hand by one making a special study of them and their requirements, few sections of Ferns are easier to cultivate. At least, that is the experience of Dr. Winter, who, at his residence in Mootpelier Road, Brighton, and hence in town surroundings, has succeeded in arranging an excavated Fernery extending the whole length of the garden, and in which the Filmies luxuriate, and give but little trouble. Their accommodation in this subterranean fernery, which has the additional advantage of thick glass fixed in iron frames, affords the necessary subdued light, and still leaves the garden space above available, the glass bearing any reasonable weight which can be put on it.

The tortuosities of the rockery afford charming views of the different groups of species forming its salient features; whilst throughout there runs a connecting-link of *Trichomanes venosum*, a pretty New Zealand plant; of *Hymenophyllum Tunbridgense*, *H. Wilsoni*, and others, of low stature, which have quite taken possession of such positions as are best suited to their needs; plants of *Trichomanes venosum*, more especially coming up spontaneously everywhere about the place, even in the small set of houses above the fernery in which the rarer tropical species are cultivated. The rockery throughout is formed of sandstone, the floor consisting of blocks of the same, through the chinks of which a narrow stream of water trickles, the water being supplied by means of pipes, which run the whole length of the rock at the highest point on either side, which have small openings at intervals, through which the passage of the water is regulated by means of valves. In earlier times, most cultivators of filmy Ferns thought that rain-water alone was a necessity, but this is not everywhere available, and Dr. Winter would find great difficulty in obtaining it. Experience has taught him that the somewhat hard water of the district, flowing from the chalk, has no detrimental effect on Filmies. The Killarney Fern (*Trichomanes radicans*), in its various forms afford beautiful and diverse effects. One pretty group of it rambles naturally around the opening of a grotto, above it on the left being a mat of *Hymenophyllum Tunbridgense*, on the right an equally beautiful one of *Trichomanes venosum*, and overhead and around a number of pretty species growing one into the other. But the title Killarney Fern is no longer tenable, for representatives from Madeira, Teneriffe, and other parts of the world are here, one fine plant having been collected at Trefriw, Carnarvonshire. Here also is its Jamaican representative, known as *T. speciosum*.

A simple and convenient method of propagating *Trichomanes radicans* is pursued by Dr. Winter by pressing spare lengths of the rhizomes with fronds attached into quarters of Cocoa-nut husks, the rhizomes being filled in with fine shingle, no soil being used; soon they root firmly, and become good plants.

Hymenophyllum cruentum surrounded by *H. Wilsoni* and other pretty species, form another effective natural arrangement. Among the most remarkable specimens noted were the New Zealand *H. pulcherrimum*, which has fronds of 2 feet in length, their growth being extended year after year on the same fronds, a peculiarity noted in other species. A pretty mass of it has *Trichomanes reniforme* in front, and about a dozen other species immediately around it.

Hymenophyllum demissum (see fig. 74) is equally handsome; and in the maze of diverse frondage were *H. pectinatum*, *H. parvulum*, *H. flexuosum*, *H. chilense*, *H. caudiculatum*, *H. crispatum*, *H. dilatatum*, *H. polyanthos*, *H. sericeum*, *H. lineare*, *H. cuspidatum*, *H. capillaceum*, and most of the

other species in cultivation, all arranging in the most novel and delightful manner with the many rare species of *Trichomanes*, *Todeas*, and other Filmy Ferns, the whole being a striking example of the feebleness of the single word "green," to express the colour of the many shades in the foliage, which varies from the pellucid pale tint to the dark hue seen on some sea-weeds, the same frond often giving a dozen different tints. Some of the fine specimens of *Todea pellucida* and *T. superba* are grand, being 4 feet and 5 feet across. A charming specimen of *T. pellucida plumosa* looks beautiful, with its surrounding of smaller "Filmies;" and the *T. grandipinnula*, *T. Moorei*, and *T. Fraseri*, all afford their share of variety. It was interesting to note the *T. grandipinnula* raised as a hybrid by Messrs. Veitch, which approaches closely the *T. Moorei* imported from Lord Howe's Island.

It should be stated that no artificial heat is used; and as bearing on the statement that the common water supply from the waterworks does not injure the plants, it should be observed that the plants are neither watered nor syringed, but that the general moisture of everything is secured by evaporation from the accumulated water which has trickled from the perforated pipes overhead, rising and condensing. This course practically reduces the moisture to the quality of rain-water; although it was observed that where the water from the pipes continually dripped on some of the specimens, their fronds showed no injury or in any way differed from the others not so watered.

At one end of the Filmy Rockeries is an ornamental fernery containing ordinary Ferns, and above-ground are some small neat houses, cased-in internally, and used for cultivating some of the tropical species which cannot be easily grown in the caves. Of these the downy-fronded West Indian and South American species are found to be rather difficult. Some also are here which are thriving below in the caves, among them being a great mass of *Trichomanes trichodeum*, with all the parts of its countless fronds as slender as hairs; *T. Luschianthium*, a fine South American species; *T. Lyalli*, from New Zealand; *T. maximum*, from Java; and *T. pyxidiferum*, from the West Indies. Another small house is used to acclimatise newly-imported specimens, a number of which are under treatment.

In perfecting this interesting cultivation of Filmies, &c., under conditions approaching those obtained in Nature, Dr. Winter has been greatly assisted by his sons; Dr. J. B. Winter, who has collected some of the specimens in Teneriffe and other places, taking an active interest in the matter. J. O'B.

HOME CORRESPONDENCE.

SCOTS GRAPES.—In your last issue, it is asked why the best Grapes come from Scotland, and if the air is clearer, or the soil more suitable there? The air is certainly purer. There is not the quantity of coal-getting and manufacturing going on in Scotland, in proportion to the acreage. I have served in six counties, namely, Hertfordshire, Middlesex, Staffordshire, Westmoreland, Dorsetshire, and the South-west Riding of Yorkshire, which has the worst climate of them all. The soil or loam in most of the counties mentioned required more or less lime adding when making Vine-borders. But this place is 5 miles west of Doncaster, and we are upon a very strong magnesian lime-stone formation, so strong that Vines, Melons, and Cucumbers exude it in a clear substance upon the lobes of their leaves, and unless a very great portion of porous material is used in making Vine-borders, the soil becomes like lumps of lead, and sour. In regard to air, we fare worse, as we lay due east from Barnsley, and get a large deposit of soot and sulphuric acid from there, especially in foggy weather—so much so, that there is always deposited an oily seum upon tanks and other still waters. We are very much pestered with red-spider, especially in dry seasons, which not only attacks Vines, but nearly all outdoor fruit-trees, especially Peaches and Nectarines; colonies of them can be found upon Peach-leaves when they are about the

size of a mouse's ear. Some few years ago our box edging, of which we have about 1½ miles, was nearly killed by it. My gardening friends smile when I tell them that I believe this to be its original home, and that it circulated from here over the United Kingdom. This, I may add, is a very old garden, and I have a copper coin a little larger than a halfpenny, which was found twenty-four years ago about 3 feet from the surface in trenching to clear out horse-radish roots: it is dated 1099. Wm. Chuck, Brodsworth Hall Gardens, Doncaster.

EMBOTHRIUM AND PAULOWINA IN FRUIT.—We have at present two trees bearing seed here for the first time. One of these is *Embothrium coccineum*, planted on the lawn about ten years ago; the tree is about 10 or 12 feet high, and has this year developed several good seed-pods. The other is *Paulownia imperialis*; the tree has attained a height of about 30 feet, and was planted in front of the rockery seventeen years ago. It is this year bearing seed pods very profusely. Is it not a rare occurrence for these trees to ripen seeds in the open air in this country? [Yes; we have never seen the *Embothrium* seed-pod. Ed.] Alfred King, Trevanno Gardens, Helston, Cornwall.

ARNEBIA ECHIOIDES is a plant we very seldom see, for what reason I do not know, but a finer plant for the hardy flower garden need not be wished, especially if grown so successfully as is done by Mr. Lunt, the genial gardener at Bowhill. In the cold damp climate of Selkirk it grows well and flowers continuously during the summer, and a bed of it at Bowhill is a sight. The individual flowers do not last long, but a rapid succession of blooms is kept up by the lengthening spike, which grows about a foot high. The small dark spots on each flower are pretty, and it is interesting to watch them becoming paler as the bloom ages. The propagation of this *Arnebia* is not attended with much difficulty. Old plants can be split up and replanted, or offsets can be taken off with a heel in the autumn, and planted in sand under a bell-glass. It can also be increased by root-cuttings in saucers of sand in a warm pit. R. T. S.

CAMPANULA ISOPHYLLA MAYI.—When illustrating a spray of this plant in a recent issue of the *Gardeners' Chronicle*, you remark it to be the result of a cross between *C. isophylla* variety and an unknown species. I have been trying for some years to cross-fertilise *C. isophylla alba* (which, by the way, is one of the reputed parents of Mr. May's plant), in the hope of getting a distinct form, but so far with no success. It should be remembered, too, in trying to fix the parentage of one of these *Campanulas*, that they are greatly varied of themselves when raised from seeds. Indeed, it is significant now to recall the fact that *C. isophylla alba* was itself a chance seedling raised from the typical *C. isophylla*, the plant originating at Kew when Mr. Lynch had charge of the hardy-plant department there. The typical *C. isophylla* is somewhat hirsute in the radical leaves; the white form is not so in the least, while Mr. May's plant goes quite beyond this, as it is both downy and soft to the touch, even to the tips of the flowering-sprays. So far as the flowers of Mr. May's plant are concerned, there is not the smallest evidence of any cross; they are those of *C. isophylla* pure and simple, when this latter is given good treatment under glass. The leafage of Mr. May's plant is quite distinct, altogether more woolly [and fleshy. Ed.] than anything I have ever seen. Seeing that *C. isophylla alba* is the admitted seed-parent of the present plant; there may have been foreign influence, and if this is the case I would suggest *C. Barrellieri*, or *C. B. hirsuta* as being that plant. Were it not for the woolly foliage in Mr. May's plant, I should unhesitatingly say no cross had been effected. Of the manner such plants revert to the normal type, even when a cross has been attempted, and all care taken to ensure its efficacy, I have ample proof in some seedlings now flowering; all these seedlings are blue-flowered forms, and yet are the results of an attempt to cross two white-flowered kinds, of which *C. isophylla alba* was the seed-bearing plant. Indeed, I have never yet been able to raise a white-flowered form, even when crossing with white-flowered forms on both sides. Blue seems more than ordinarily the dominating colour of *Campanulas*, and its influence is not easily neutralised. E. H. Jenkins, Hampton Hill. [From enquiries made, it would seem that if the now variety

is a hybrid, the second parent was *C. Barrelieri*, this being apparently the only other species of *Campanula* in cultivation where the new one originated. Ed.].

SUBSTITUTE FOR GRAFTING WAX.—Noticing that two recipes for this are given in the last issue of the *Gardeners' Chronicle*, I am reminded that my experience in the matter of not using a wax, either hard or fluid, may be useful to others. During the last two years I have grafted a variety of plants, and it struck me that tissue gutta-percha might answer perfectly without the inconveniences of wax. I find that such is the case, and so thin an air-tight material can be applied closely to all inequalities of the stem, and be made to prevent drying quite as perfectly as wax itself. I tie in the usual way, then wrap round a strip of tissue, and afterwards secure it with a tie of raffia. There is no question of its efficiency, nor perhaps of the nastiness of grafting wax. It may be as well to mention that I have used it only for indoor work. Would some professional grafters try it and report? *R. Irwin Lynch, Botanic Gardens, Cambridge.*

ARAUCARIA IMBRICATA.—The letter pertaining to this tree, published on p. 195, interested me greatly. There is a specimen here, 40 feet high, carrying eighteen cones larger than ordinary Pine-apples. Fifteen years ago the tree bore four cones. There are several specimens here about the same size, but they have never produced any cones. *F. Fitzwater, Bushey Lodge Gardens, Teddington.*

FLAVOUR IN POTATOS.—If Mr. Eagleheart is so anxious to secure high flavour in Potatos, irrespective of produce, why does he not, besides securing both the old Ashleaf and Walnut-leaf Kidneys, obtain the old Fortyfold, one of the best-flavoured Potatos ever grown, though a poor cropper, and terribly susceptible to disease; and Paterson's Victoria. But if these varieties were obtained, and grown with Ringleader, Conference, The Dean, Reading Russet, Windsor Castle, Snowdrop, and a good many others, I think any person would be satisfied that the superiority of quality or flavour found in the old varieties was, after all, imaginary, and that later-introduced varieties were as good. [Oh! dear no. Ed.] But it is useless to urge that the mere production of what is called flavour is all that is essential in modern Potatos. How was it that when we had varieties that were regarded so much for their flavour—and be it understood that flavour, as we understand that element, is a very infinitesimal quality in both Potatos and Tomatos—that these were nearly extirpated by the *Peroospora*, whilst others less assumedly high flavoured proved to be comparatively disease resisting? Whenever we get a bad disease—season now, the same thing is still seen, therefore we have had to breed first for disease-resisting qualities, and second for food, for the Potato is a great food product, even though it may not possess much, if any, flavour. Happily because of this breeding we have always now great crops of Potatos, and poor as well as rich can have them cheap, and in abundance. That is great gain. But that fact need not deprive those who may so desire of the privilege of growing varieties that if they have good flavour, at least have little power to resist disease, and at the best are but indifferent croppers. If we can yet add flavour to Potatos without detracting from robustness and cropping, so much the better. *A. D.*

WANTED, A GARDENERS' SOCIETY FOR NORWOOD.—Having lived for some time within a mile or two of the Crystal Palace, it is a matter of surprise to me, that in a district where there are so many gardeners there is no Society through which we can meet together for mutual improvement. The dark evenings when outdoor recreations have to be laid aside, and when books should take the place of bats and balls, and lecture-rooms that of hose and watering-cans, will soon be with us again. There is no doubt but a Mutual Improvement Association in Norwood would be a source of both pleasure and profit to gardeners and others interested in horticulture. Will not some of the more influential among us bestir themselves in this matter? If so, we shall soon have a flourishing Norwood Gardeners' Mutual Improvement Association. *King Coyle.*

KOELREUTERIA PANICULATA.—There is a splendid specimen of this tree in the gardens

of Windsor Castle, about 40 feet high; its age is considered to be between sixty-five and seventy years. The large panicles of beautiful yellow flowers are produced in great abundance every year, and remind one very much of the fine sight presented by the *Acacias* in flower in the south of France. Except that on the west, it is sheltered by the castle, its position is not otherwise a particularly well protected one. The tree is now covered with, and rendered conspicuous by, the numerous, large whitish three-lobed and inflated capsules. Within the last ten years, a much larger specimen of *Koelreuteria* than the one described, has died. This, certainly had a warm, sheltered corner, which no doubt accounted for its wonderful luxuriance. At the present time, there is one more tree of unusual size living, within the royal grounds, though not quite so fine as the specimen represented by the photograph. [The photograph does not show the flowers clearly enough for reproduction.] *H. H. T.*

A GROWL ABOUT THE SHREWSBURY SHOW.—On August 22 I journeyed from the extreme west of Surrey to a town in the Midlands, having at that time for my principal object a visit to the show at Shrewsbury. On the 24th inst., I took train to Shrewsbury and made my way to the exhibition. The exhibits were most interesting, but the dust was suffocating. Everywhere in the tents the air was charged with dust, and the dryness of the air was unpleasant. Thousands of people were forced into this dust-laden atmosphere in their endeavour to see the finest products of horticultural skill; charging their lungs with the filthy air. The most lovely and superb exhibits—grand specimens of fruit—were thick with the dust. Surely such a state of things might have been prevented. The expense of two or three men with water-cans or hose would have prevented the evil and made the atmosphere less unpleasant to visitors, and less injurious to the exhibits themselves. *H. O. Etherington.* [Our correspondent's complaint we feel sure will be given the consideration of the committee before another exhibition takes place. The crowds at Shrewsbury are enormous, but the above suggestion, if practicable, will not be ignored from financial considerations. There was no such experience on the first day. Ed.]

TRADE NOTE.

BANKRUPTCY CASE.

Re William Albert Holmes, florist, nursery gardener, and horticulturist, trading under the style of "S. Mahead & Son," residing at Earee Villa, Dryburgh Road, Putney, and now carrying on business at Dryburgh Road and 1, Railway Terrace, Upper Richmond Road, Putney, lately carrying on business at 121, Upper Richmond Road, Putney.

The debtor has filed a statement of affairs showing gross liabilities amounting to £2,934 1s. 4d., of which £1,857 7s. is due to unsecured creditors. The assets are returned at £1,617 12s. 5d., from which £118 19s. 4d. has to be deducted for the claims of preferential creditors payable in full, leaving net assets at £1,498 13s. 1d., and showing a deficiency of £1,199 7s. 11d.

Obituary.

ALFRED JOHNSON.—This gentleman, well known in the county of Lincolnshire, the head and managing-director of the firm of W. W. Johnson & Son, Ltd., seed growers and merchants, of Boston, passed away on the morning of the 2nd inst., at the age of 59 years.

The business with which Mr. Johnson was so long connected was commenced by Mr. William Wade Johnson, his father, in 1820; in the first instance as a market gardener. Gradually and surely the business grew; and in the year 1854 his son, the deceased, joined the firm, and was shortly after taken into partnership.

Early in life Mr. Alfred Johnson took a keen interest in the culture of fruit and forest-trees; but some twelve years ago, through his physical

inability to take an active personal insight of the business, he sold the entire nursery-stock, and henceforth devoted his whole energies to the selection and improvement of garden and agricultural seeds. Johnson's Wonder Longpod Bean originated years ago with the firm; and later novelties introduced by the firm are Boston Q2 Potato, Boston Unrivalled Pea, &c., and more recently, the Green Mammoth Longpod Bean, a variety of great value.

A few years ago, for family reasons, the business was converted into a limited liability company, and Mr. Johnson held the position of managing director up to the last. In July last, feeling himself unable to attend fully to business details, Mr. Johnson invited Mr. E. J. Deal, late with Messrs. Sutton & Sons, to fill the post of general manager.

Deceased was laid to rest, on the 5th inst., in the churchyard of St. Nicholas, Boston, and there were present on the occasion such old friends and business associates as Messrs. N. Sherwood (Hurst & Son), David Syme (Lawsons), A. Watkins (Watkins & Simpson), F. Calder Turner, E. J. Deal, G. Wood Ingram, &c. Mr. Johnson's last appearance in London was on the occasion of the Temple Show, in May last.

SOCIETIES.

ROYAL HORTICULTURAL.

POTATOS AT CHISWICK.

AUGUST 31.—A meeting of the Fruit and Vegetable Committee was held at Chiswick on the above date, to examine late Potatos. Many varieties, old and new, were tried. Some had grown out or "speared" very much, especially those robust late ones having luxuriant tops. But the majority gave fine clean crops of good tubers. In one case only was there material disease, and that was, in spite of the drought, a very bad instance.

Of new varieties, seven were selected to be cooked; and certainly as sent to the table in their jackets, no tubers could be better cooked than they are for the Fruit Committee's purposes at Chiswick. Let a variety at Chiswick be ever so handsome and so fine a cropper, none after being cooked pass the Fruit Committee unless they show good flavour and general table excellence. Two only thus passed the ordeal; these were The Sirdar (Hurst), a fine white round, and Ellington's Seedling, white round, with pink eyes, something like the old Cheshire Pink-eye, but finer. But Potatos vary so much according to soil, that some of the other varieties tried may prove to be excellent elsewhere. A fairly firm soil, containing a sufficiency of lime, usually gives the best flavour; but there, again, much depends on the seasons. Some of the nomenclature of new varieties at Chiswick showed that naming is of a plagiarised order, as not a few show the same appellations; whilst some older varieties—Chancellor and International, for instance—have been sent in under other appellations.

DUMFRIESHIRE AND GALLOWAY HORTICULTURAL.

AUGUST 30.—The first show under the auspices of the Dumfriesshire and Galloway Horticultural Society (founded in 1812), since its resuscitation, was held on the above date in the Drill Hall, Dumfries. Some unfortunate confusion about the date told somewhat against the attendance of visitors.

Mr. C. E. GALBRAITH, of Terregles, sent for exhibition only, a number of fine foliage plants, which were arranged to form a bank in front of the platform. Stands of plants and flowers were exhibited from the nurseries of Messrs. KENNEDY & Co., Dumfries; Messrs. KEAR BROS., Dumfries; Messrs. PALMER & Son, Annan; and Mr. W. BYERS, Dumfries.

The competition in the open class was somewhat limited; but Messrs. KEAR BROS. were the largest prize-takers. They carried off the 1st and 2nd awards for *Cactus Dahlias*, which made a particularly fine class. *Dahlias* generally were largely shown, and for the show varieties, Messrs. T. KENNEDY & Co. were 1st, and Messrs. KEAR BROS. 2nd. The latter were the only exhibitors of Ferns and Sweet Peas, and were also without opposition for the dinner-table decoration of cut flowers and foliage.

Mr. W. Caldwell, gr. to JAS. DAVIDSON, Esq., of Summerhill, obtained the Burgh of Dumfries Silver Cup for the best exhibit of horticultural produce, and also prizes for plants for Table Decoration, Bouquets, &c.

The heavy rains in the beginning of the week did considerable injury, but notwithstanding this there was an exceedingly creditable display of cut flowers. For Rose blooms Messrs. D. & W. COLL, Dundee, were the only competitors. The *Gladioli* in the open class were of a high standard; and both prizes were carried off by Prestwick exhibitors, Mr. GEORGE MUIR being 1st, and Mr. JAMES CARNEGIE 2nd.

Mr. W. Allan, gr. to JOHN PRIMROSE, Esq., Arundel House; and Mr. J. DAVY, Galloway House, were the principal prize-winners in the gardeners' classes, they being the chief competitors for fruit, which made a very good show, particularly Grapes. Perhaps the most successful competitor in the amateurs' section was Mr. J. THOMSON, Sanguinar, who showed largely in the cut-flower classes. Mr. G. W. KERR made an energetic secretary.

ISLE OF WIGHT.

AUGUST 30, 31.—The Cowes Horticultural Improvement Society held their first exhibition on the above dates in the Foresters' Hall. The exhibits numbered over 200, and were of a high standard of excellence, and the show augurs well for the future.

The show upon the second day was opened by Mr. Godfrey Baring, Chairman of the Isle of Wight County Council, who spoke of the pleasures and benefits to be derived by cultivating garden products. To encourage this work on the Island, he had great pleasure in offering for competition at next year's show three silver cups, one for cottagers, one for amateurs, and one for gardeners. A word of praise is due to the Hon. Secretary, Mr. C. E. Creighton, for the able manner in which he carried out the arrangements for this the first show.

The ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION made their last excursion of the season on the 31st ult.; Cadland Park, Southampton, was the place visited, by permission of A. Drummond, Esq. Considering the season, the gardens were in splendid condition, and a credit to Mr. Garner, the well known gardener at this establishment.

The monthly meeting of the same Association was held at Newport on the 2nd inst., Dr. J. Groves in the chair. Mr. Fred Pearson prepared a capital paper on "Butterflies and Moths, Injurious and Useful," which was read by the Chairman. The paper was illustrated by a large collection of preserved specimens which proved of great interest.

The exhibits included a large dish of Victoria Plums from Mr. J. NEWNHAM, of Wroxall, and a dish of Veitch's Golden Jubilee Tomato, and a dish of Duchess of Oldenburg Apples from Mr. A. J. Cole, gr. to G. W. RENDAL, Esq., Broadlands, Sandown. The forthcoming fruit exhibition will be held at Ryde in the first week in October.

MAIDENHEAD HORTICULTURAL.

AUGUST 31.—The twenty second annual exhibition of this Society, was held in Kidwells Park, on the above date. Although in some instances exhibits compared favourably with those of previous exhibitions, in others there was a considerable falling off; and this was especially noticeable in the fruit classes.

Groups of plants for effective arrangement were good, but there were fewer competitors than usual. The Committee would do well to make some change in the general arrangements, the exhibition being carried on from year to year with such sameness that it is becoming monotonous to visitors. For instance, groups of plants of the same shape and size, and from the same exhibitors, occupy the same positions year after year; and other plants, fruits, &c., are set up with equal methodical precision.

PLANTS.

Class 1, for twelve handsome foliaged plants in 8-inch pots, brought some nice exhibits; that from Mr. Fulford, gr. to J. D. LAMBERT, Esq., Cookham, took 1st prize.

Mr. Aitken, gr. to Colonel MEKINO, Richings Park, Slough, was the only exhibitor of six stove and greenhouse plants, and was awarded the 1st prize. This exhibitor was also 1st for six stove and greenhouse Ferns, with large specimens of *Davallia Mooreana*, *Microlepia hirta cristata* and others.

Mr. Goodman, gr. to Miss HAMMERSLEY, Abney House, Bourne End, was 1st with a flowering stove plant, having a fine specimen of *Eucharis grandiflora*. Table plants were numerous, the best six coming from Mr. Wood, closely followed by Mr. FULFORD. Fuchsias were poorly represented by two collections, the best were set up by Mr. D. Paxton, gr. to the Hon. C. S. INBY, Hitcham Grange, Taplow.

GROUPS OF PLANTS.

The groups of plants arranged for effect constitute the chief feature of the show, especially those that occupied a space 12 feet by 10 feet. Here the two leading exhibitors, Mr. D. PHILLIPS, gr. to A. N. GILBEY, Esq., and Mr. AITKEN, have fought for the 1st position for several years past, the former being the victor both this and last year. Their plants and arrangement were somewhat similar, but while Mr. Phillips' four corners were considerably elevated, his opponent preserved a more even surface, which failed to secure the light and graceful appearance seen in the 1st prize group. Both exhibitors used a *Cocos Weddelliana* for a centre, with a groundwork of *Adiantum*, other plants consisting of highly-coloured *Codiaeums*, *Pancratiums*, *Gloxinias*, *Odontoglossums* in variety, *Eulalias*, and others. For a smaller group, Mr. Richardson, gr. to G. HERRING, Esq., was 1st; Mr. FULFORD 2nd.

CUT FLOWERS.

Cut flowers, considering the very trying season, were good. Mr. JOHNSON, gr. to A. GILLIAT, Esq., Stoke, Slough, was 1st for twelve H. P. and the same number of Tea Roses.

In a keenly-contested class for Sweet Peas in distinct colours, Mr. Wood was a good 1st. Dahlias, Asters, and

Zinnias were also numerous and good. Mr. TRANTER, Henley-on-Thames, was the principal exhibitor in the nurserymen's classes.

FRUIT.

Mr. AITKEN was 1st for a collection of six dishes with good Sea Eagle Peaches, Kirk's Plum, Brown Turkey Figs, Muscat Grapes, Elruge Nectarines, and a Melon; 2nd, Mr. GOODMAN. For four dishes, Mr. Wood was 1st; and for the same number grown in the open air, Mr. JOHNSON was 1st with excellent fruits of Lord Napier Nectarines, Stirling Castle Peaches, Kirk's Plum, and a fine dish of Lady Sudeley Apples.

Mr. LANE, gr. to Miss RIDGE, Englefield Green, was 1st in the two Black Grape classes, with medium-sized bunches. Mr. FULFORD had the best bunches of Muscats, and Mr. LANE the best other white Grape, showing Buckland Sweet Water.

Mr. JOHNSON was awarded the 1st prize for a dish of Lady Palmerston Peaches of handsome appearance, but questionable quality; 2nd, Mr. GOODMAN.

Mr. HUNT, gr. to Captain FARWELL, The Priory, Burnham, had the best dish of Nectarines, large and fine Pitmaston Orange. Mr. HUNT was also 1st with a handsome dish of dessert Apples, said to be a local seedling of merit.

FIG. 75.—A "SHOWER" BOUQUET OF LA FRANCE ROSES. From a photograph sent us by Messrs. E. S. Williams & Son, 160, Piccadilly, W.

VEGETABLES.

The finest produce was found in the special classes provided by the large seed firms. For Messrs. Sutton & Son's prizes Mr. J. Gibson, gr. to R. W. HUDSON, Esq., Danesfield, Marlow, obtained the 1st award with a perfect collection.

For Messrs. Webb & Son's prizes Mr. GOODMAN was awarded 1st prize; Mr. GIBSON 2nd.

MISCELLANEOUS.

Mr. E. F. SUCH contributed a collection of Cactus Dahlias, floral decorations, and forty dishes of fruits. Messrs. OWEN, Castle Hill Nurseries, had a collection of Cannas and floral decorations. Mr. BROUGHTON, Norfolk Park Nurseries, a group of miscellaneous plants.

BATH FLORAL FÊTE.

AUGUST 30, 31.—Bath, like Trowbridge, puts the Fuchsia in the forefront of its schedule of prizes, and a considerable number of splendid plants were staged. Mr. GEO. TUCKER, Hilpertou Marsh, Trowbridge, brought some of his fine examples, which must be sent by road, as only an open railway van could take them, in consequence of their height

and dimensions. He was 1st with nine; his darks were Doel's Favourite, Charming, Bountiful, and Final; and his lights, Mrs. H. Rabbitt, Mrs. Bright, Western Beauty, Arabella and Tucker's Favourite. If anyone requires a selection of fine and distinct varieties for house decoration or bedding, there it is. Mr. G. H. WILCOX, Bath, was 2nd with some very good specimens indeed.

With six specimen ens, Mr. W. A. BURFORD, Upper Weston, came in 1st, having finely grown and flowered examples. The best light Fuchsia was Duchess of Albany from Mr. GEO. TUCKER, a charming free-blooming variety. The best dark was a very fine plant of Charming, from Mr. G. TUCKER.

There was a big plant class for twelve ornamental foliage plants, and six stove and greenhouse plants in flower; and Mr. JAMES CYPHER was 1st with six noble Palms, Crotons, a fine example of *Ixora Duffii*, *Allamanda nobilis*, a fine *Phenocoma*, &c.—a really grand lot. Messrs. J. B. WOOD & SON, Chipping Sodbury, were a good 2nd.

Groups of plants were highly effective. Mr. J. CYPHER was again 1st; and Mr. W. Sansey, gr. to R. B. CAPER, Esq., Bath, 2nd.

The best six stove and greenhouse flowering plants were from Mr. CYPHER. He had a superb example of *Ixora Duffii*, with fifteen expanded and unexpanded trusses; Mr. G. TUCKER was a close 2nd.

Messrs. W. J. STOKES & SON had the best three specimens including a fine piece of *Bougainvillea glabra*; Mr. H. POCOCK, Hilpertou, was 2nd.

In the class for a specimen stove plant there was another striking *Ixora Duffii* from Mr. J. CYPHER, while Mr. G. TUCKER had *Dipladenia Brearleyana*, the judges placing them equal 1st.

Mr. E. T. D. FOXCROFT, Hinton Charterhouse, took the 1st prize with some good double tuberous Begonias; and Mr. G. TUCKER came 1st with the same number of single-flowered plants.

With six fine-foliaged plants Messrs. E. S. COLE & SONS were 1st. The best specimen was a fine *Croton Chelsonii* from Mr. J. CYPHER. Mr. G. TUCKER was 1st with excellent specimens of Exotic Ferns; and Mr. A. P. STANCOMB, Trowbridge, was 2nd. With six specimens, the Rev. Y. FAWCETT was 1st. In all cases good examples were shown. The best specimen Fern was a fine *Gymnogramma sulphurea* from Mr. G. TUCKER.

CUT FLOWERS.

In the cut flower division a fine lot of eighteen spikes of *Gladioli* was staged by F. H. FOX, Esq., Wellington (Mr. S. Bird, gr.); Mr. J. MATTOCK, nurseryman, Oxford, was a good 2nd. With twelve spikes, Mr. G. HUMPHRIES, nurseryman Chippingham, was 1st.

The best twenty-four show Dahlias were from Mr. JOHN WALKER, nurseryman, Thame; Mr. GEORGE HUMPHRIES was a good 2nd.

Cactus varieties in twelve bunches of six blooms were finely shown by Messrs. KEYNES, WILLIAMS, & CO.; Messrs. CRAY & SON were 2nd. The latter were 1st with twelve charming bunches of Pompons; and Mr. G. HUMPHRIES a close 2nd.

Roses.—Some very good cut Roses were shown by Messrs. D. & W. CROLL, nurserymen, Dundee; Mr. J. MATTOCK was 2nd.

Mr. GEO. PRINCE, Oxford, was 1st with twelve Tea-scented varieties.

The best twenty-four bunches of stove and greenhouse cut flowers came from Mr. G. TUCKER.

Hardy annuals in twenty-four bunches made a very interesting feature. The 1st prize went to Mr. A. H. NEWMAN, Bath, who had excellent material well set up.

Tables of Sweet Peas, arranged with foliage, were somewhat flat, though they were a pretty feature. Mr. BLACKBURN was 1st; and hardy herbaceous and perennial flowers were finely shown by Mr. A. A. WALTERS.

FRUITS AND VEGETABLES.

Fruit made a good display; the best eight dishes came from Mr. STRUGNELL, The Gardens, Rood Ashton, Trowbridge, who had *Alicante* and Muscat of Alexandria Grapes, Dagmar Peach, Pine-Apple, Nectarine, Brunswick Fig, Plums, Cherries, and Melon. 2nd, Mr. T. WILKINS, the Gardens, Hembridge, Blandford.

With eight bunches of Grapes, Mr. ALDERMAN CHAFFIN was 1st with very fine examples of Black Hamburgh, Gros Maroc, Muscat of Alexandria, Madresfield Court, two bunches of each. Mr. W. MARSH, gr. to W. ALLEN, Esq., came 2nd. Mr. GEORGE SUTTON, gr. to W. A. TODD, Esq., was 1st with three good bunches of Black Hamburgh. Mr. T. WILKINSON, gr. to Mrs. TALEOR GREAVES, was 1st with three bunches of Muscat of Alexandria.

Any other white was Buckland Sweetwater, and any other black, Madresfield Court, from Mr. ALDERMAN CHAFFIN.

The best dish of Peaches was Royal George, from Mr. Tate, gr. to Mrs. STORHART, Bath. Pitmaston Orange was the best Nectarine, the 1st prize going to Mr. J. CLARKE, gr. to J. C. ATKINS, Esq.

Vegetables were very good on the whole, and especially those shown by Mr. T. WILKINS, of Hembridge.

NON-COMPETITIVE EXHIBITS.

Messrs. W. & J. BIRKENHEAD, Sale, had an extensive collection of Ferns; Mr. A. A. WALTERS, Kensington Nurseries, Begonias, &c.; THE DEVON CHRYSANTHEMUM AND NURSERY COMPANY, Teignmouth, Dahlias, in great variety; and Messrs. G. COOLING & SONS, Bath, Roses, Sweet Peas, hardy flowers, &c., in considerable variety, also trees in fruit and a collection of Apples, &c.; and Mr. G. GARRAWAY, Bath, a collection of Apples.

SANDY AND DISTRICT HORTICULTURAL.

AUGUST 31.—Where do the thousands come from to see the Sandy Show? Sandy is a village in the centre of the market gardening industry of Bedford; there is no large town except Bedford near it, but the people flock there in large numbers. It is a unique exhibition in its way, as it comprises something of many things which interest country people; there are plants, flowers, fruits, and vegetables; domestic animals and birds, needlework, wood carving, &c.—something to interest everyone; and prizes are offered to the amount of £450.

For thirty-one years past Sandy has held a show of this character; and if only the weather be fine, a great success is assured. The park of Sandy Place is in the village, within a short distance of the railway-station, and it is here the show is held. Should the park be closed to it, it is probable no show could take place.

Certain classes, about thirteen in number, are open to all comers. There is one for twelve stove and greenhouse plants in flower, and there were four collections staged. Mr. J. CYRUS was the 1st prize winner; Mr. W. VAUSE, Leamington, was 2nd.

The best group of plants arranged for effect was set up by Mr. VAUSE, and consisted of good plants artistically put together; Mr. W. FINCH took the 2nd prize.

CUT FLOWERS.

One large tent was devoted to cut flowers. Usually crowded to excess, it was not filled on this occasion, so many who had entered for competition failing to appear. Roses made a good feature, though they were rather small, but they were fresh and bright. Messrs. PERKINS & SON, nurserymen, Coventry, had the best forty-eight blooms; Messrs. HARKNESS & SON, H'thin, were 2nd.

MESSRS. HARKNESS & SON were 1st with eighteen Teascented varieties; Messrs. PERKINS & SON were 2nd.

GLADIOLI, in twenty-four spikes, were very finely shown by Messrs. HARKNESS & SON, who had massive spikes of excellent varieties.

The class for twenty-four show Dahlias, usually so well filled at Sandy, brought but one stand, to which a 2nd prize was awarded.

Fancy Dahlias in twelves were also somewhat poor. Mr. BRIGHT was 1st with twelve bunches of Pompon Dahlias, stagio admirable blooms; Messrs. HARKNESS & SONS were 2nd. Cactus varieties, in twelve bunches, were also good, Mr. BRIGHT again taking the 1st prize.

The class for twenty-four bunches of hardy herbaceous and bulbous plants brought a very fine collection from Messrs. HARKNESS & SON.

AMATEURS.

In the division closed to the trade, some good fine-foliage plants were staged; also stove and greenhouse plants in sixes, and also stove and greenhouse Ferns. Mr. W. J. EMPSON, gr. to Mrs. WINOFIELD, Ampthill, was 1st, having a fine specimen of *Adiantum Farleyense*.

Fuchsias were fairly good, Begonias past their best; some Cockscombs shown by Mr. T. LOCKIE, gr. to A. J. THORNHILL, Esq., Diddington Hall, were really superb, of great size, and high quality.

The best twenty-four cut Roses were shown by Mr. W. KINGSTON, Bedford. Mr. B. BURGIN, St. Neots, had the best twelve show and the best six fancy Dahlias.

FRUIT.

Mr. W. J. EMPSON had the best collection of eight kinds of fruit, having good Madresfield Court and Muscat of Alexandria Grapes, Peaches, Nectarines, &c.; Mr. B. CARTER, gr. to Captain DUSCOMBE, was 2nd.

Mr. T. STONE, gr. to R. A. COCHRANE, Esq., had the best six dishes.

Mr. C. J. GRIBBLE was 1st with three dishes of dessert Apples, having in good form Lady Sudeley, Quarrenden, and Irish Peach.

The best culinary Apples were Emperor Alexander, Warner's King, and Lord Suffield.

Grapes.—Two bunches of each were shown in several classes. Mr. GRIBBLE had the best two of Black Hamburgh; any other black was Madresfield Court, from Mr. STONE.

Mr. EMPSON was 1st with two excellent bunches of Muscat of Alexandria, and also with any other white, having Foster's Seedling.

Vegetables were good on the whole. Mr. T. LOCKIE won the 1st of Messrs. SUTTON & SON's and Messrs. WEBB & SON's special prizes, showing remarkably well.

ELLESMERE HORTICULTURAL.

AUGUST 31.—The thirty-sixth annual show of this society was held on the above date in the Cremorne Gardens, kindly lent for the occasion by Earl BROWNLOW. These grounds adjoin a beautiful lake of over 150 acres in extent, and are very suitable indeed for holding such shows. Unfortunately, early in the afternoon a thunder-storm came on, and the rain for a long time descended in torrents.

In the class for groups of plants arranged for effect the competition was very keen. Mr. WEST, gr. to E. BEHRENS, Esq., Bettlesfield Park, was 1st with a choice and tastefully-arranged collection of plants.

Two very good collections of Fruit were staged, Mr. WEST 1st, and Mr. PEARSE a very close 2nd. Black Grapes were

very good. The Rev. BULKELEY OWEN, Tedmore, 1st; Mr. PEARSE 2nd. White Grapes, Mr. WEST 1st; Mr. PEARSE 2nd.

There was a very nice show of plants, such as Cannas, Begonias, Fuchsias, Ferns, Pelargoniums, and stove plants.

CUT FLOWERS, such as Sweet Peas, Cactus Dahlias, and Asters, were well shown.

Some very fine VEGETABLES were shown in the gentleman's gardener's classes. Carrots, Onions, Peas, and Tomatoes, being especially fine.

Messrs. DICKSON, Chester, and Messrs. JONES, Shrewsbury, put up good collections of flowers, not for competition.

There were some interesting exhibits in the cottager's classes; for instance, prizes were given for the best home-made bread, butter, and jam; prizes were also given for children's work such as knitting, sewing, and darning, and making all kinds of garments, in which there was close competition.

BRISTOL AND DISTRICT GARDENERS'.

AUGUST 31.—The monthly meeting of members was held at St. John's Parish Room, Redland, on the above date.

A very interesting and instructive lecture on "Viola and Pansy Culture" was given by Mr. J. C. HOUSE, of Coombe Nurseries, Westbury-on-Trym. He gave the history of the plants, and explained the differences between them. He strongly urged their cultivation for bedding purposes, claiming for them the quality of blooming freely and during a long season. All the necessary cultural details were fully explained.

NATIONAL DAHLIA.

SEPTEMBER 1, 2.—The display of Dahlias at the Crystal Palace on the above date was much better than might have been expected. Growers of the show and 1st fancy varieties had given an enormous amount of attention to their plants, watering and assisting them in every way, but the extreme dryness and heat of the atmosphere largely neutralised their efforts. The show and fancy varieties were certainly below mark, in that they lacked the fine substance and symmetry of former years, and they were fewer in number than usual, so prominent a grower as Mr. C. Turner being unable to exhibit in a single class. But the very conditions which told against the show Dahlias had assisted the early development of the Cactus and Pompon varieties, imparting earliness to the one and refinement to the other, and they were both represented in fine character, and as numerous as usual. There was a decided increase in the number of entries, but some of those who entered failed to appear through the rapid deterioration of their blooms. As is usual, the show was held in the eastern nave of the building, where there was ample space. A mournful interest attached to this exhibition through the death of the President of the Society, the late Mr. T. W. Girdlestone, whose presence was greatly missed during the day.

SHOW DAHLIAS.

There were four entries of sixty show and fancy Dahlias. Mr. J. WALKER, Nurseryman, Thame, Oxon, who has been successfully exhibiting during the past month, taking the 1st prize with highly creditable flowers, chief among them Harrison Weir, Vice-President, Diadem, Frank Pearce, T. S. Ware, David Johnson, W. Powell, Maud Fellowes, Shirley Hibberd, Goldsmith, J. Hickling, Rosamond Virginate, Mrs. Saunders, Colonel, Rev. J. Goddard, John Bennett, John Walker, Duke of Fife, Mrs. Gladstone, James Vick, Victor J. C. Vaughan, &c.; Mr. M. V. SEALE, Nurseryman, Sevenoaks, was 2nd; and Messrs. M. CAMPBELL & SON, Nurserymen, Blantyre, N.B., 3rd.

With forty-eight varieties, Mr. WALKER was again to the fore, having as his best blooms Rev. J. Goddard, R. T. Rawlings, Shirley Hibberd, Maud Fellowes, Prince of Denmark, J. Wyatt, Dr. Keynes, Diadem, Colonel, John Walker, W. Rawlings, Victor, Mrs. Gladstone, James Vick, &c.; Mr. SEALE was again 2nd, and Mr. S. MORTIMER, Swiss Nursery, Farnham, 3rd.

With thirty-six blooms, Mr. W. TRISEDER, nurseryman Cardiff, was 1st, having, differing from those already named, good blooms of Arthur Ocock, Pleasance, Willie Garratt, Eclipse, Duchess of Albany, J. T. West, and Duchess of York; Mr. GEO. HUMPHRIES, nurseryman, Chippenhams, was 2nd; and Messrs. KEYNES, WILLIAMS, & CO., Salisbury, 3rd.

Mr. GEO. HUMPHRIES was 1st with twenty-four blooms.

FANCY DAHLIAS.

A class is still kept for the striped and tipped fancy Dahlias, though they are admissible in the preceding four classes. It may be said of the fancy Dahlias that they show a marked tendency to run to the self form, thereby losing their distinctness of character, and that the present season has been particularly trying to growers in this respect, and they have experienced considerable difficulty in getting a dozen well marked blooms for exhibition. Mr. J. WALKER, exhibited in much better character than might have been expected, and his 1st prize exhibit of twelve blooms, included the Rev. J. B. M. Camm, S. Mortimer, Mrs. J. Downie, Matthew Campbell, Duchess of Albany, Plintarch, Frank Pearce, Emin Pacha, &c.

CACTUS DAHLIAS.

Very imposing stands of Cactus Dahlias were shown in the class for eighteen bunches, six blooms of each. The 1st prize was taken by Mr. J. STREDEWICK, Silver Hill, St. Leonards, a builder, cultivating his own flowers, and taking great pride in them; he had in very fine character: Countess of Lonsdale, Viscountess Sherbrooke, Stella, Britannia, Mary Service, Emperor (new); Magnificent, a new and foremost variety of excellent habit, and very free; Eclipse, soft sulphur yellow, a charming new variety; Keynes' White Harmony, W. T. Balding (new), and Charles Woodbridge, the last in perfect form; Messrs. J. BURRELL & CO., Home End Nurseries, Cambridge, was a remarkably good 2nd. This collection contained several new varieties, such as Auburn, a lovely tint of colour; Olive, Elise, orange-salmon and mauve, extra fine; Ibis, Whirlwind, Britannia, Keynes' White, Emperor, &c.

With twelve bunches, Mr. S. MORTIMER was 1st, having in fine character, Magnificent, Mrs. J. Goddard, Starfish, Ebony, Keynes' White, Mary Service, Britannia, Lucius, &c.; Mr. SEALE was 2nd.

One class was for twenty four blooms of Cactus Dahlias, shown on boards in the usual way with Dahlia foliage, Messrs. M. CAMPBELL & SON were 1st with an excellent stand, and in appearance not a bit more formal than the rigid-looking bunches on the wire-frames; Mr. SEALE was 2nd.

POMPON VARIETIES.

The pretty Pompon varieties, so free and so admirably adapted for garden decoration, were seen to great advantage, because so uniformly small, clean, and neat. Mr. SEALE had the best twenty-four bunches, ten blooms of each—240 blooms in all, a very perfect collection indeed. The leading varieties were Donovan, Ernest Harper, Red Indian, Capt. Boyton, Nerissa, Ganymede, Crimson Gem, Lilian, Cherub, Douglas, Snowflake, Demon, Tommy Keith, Distinction, Emily Hopper, Phoebe, &c. 2nd, Messrs. CHEAL & SON, Nurserymen, Crawley, with an admirable collection; Messrs. KEYNES & CO. were 3rd.

With twelve bunches, Messrs. J. BURRELL & CO. were 1st, with varieties of high quality; Mr. J. WALKER was 2nd.

SINGLE-FLOWERED VARIETIES.

The single Dahlias also were very fine, fresh, and of the best quality; two excellent collections of twenty-four varieties, ten blooms of each being staged, were set up by Messrs. CHEAL & SON and Mr. SEALE, the prizes being awarded in the order of the names; Columbus, Demon, Violet Forbes, Miss Roberts, Puck, Lonisette, Polly Eccles, and Leslie Seale were among the prettiest, but all were very good.

Mr. JOHN WALKER was the only exhibitor of twelve bunches.

AMATEURS.

Then followed a number of classes for amateurs, taking the term in its widest sense.

The best twenty-four Dahlias came from Mr. F. W. FELLOWES, Putteridgebury, Luton, a nephew of the late Rev. Charles Fellowes, who thus maintains the floral traditions of the family. This stand contained several promising seedlings, which may probably be seen more fully developed later on. Mr. T. ANSTISS, Brill, Bucks, was 2nd.

The best eighteen blooms were shown by Mr. THOMAS JONES Ruabon; Mr. R. C. WEST, gr. to H. J. WIGRAM, Esq., Salis, bury, was 2nd. Mr. S. COOPER, Chippenhams, was 1st with twelve blooms; and Mr. A. STARLING, Romford, with six.

A very good stand of twelve fancy Dahlias was shown by Mr. R. C. WEST, who had Peacock, Dazzler, Goldsmith, Mrs. J. Downie, Duchess of Albany, Matthew Campbell, &c.; Mr. T. W. FELLOWES, was 2nd.

Cactus varieties in bunches of six and three blooms were well shown by amateurs; the cultivation of the Cactus Dahlia for exhibition purposes appears to be much on the increase among amateurs.

The best twelve bunches, six blooms of each were staged by Mr. R. KEEBLE, gr. to F. W. SHARP, Esq., Twyford; 2nd, Mr. JAMES HUDSON, Gunnersbury House Gardens, Acton.

Mr. H. A. NEEDS, Horsell, Woking, had the best nice bunches; Mr. JAMES BRYANT, Salisbury, was 2nd.

Mr. E. MAWLEY, the Treasurer of the Society, had the best six bunches.

MESSRS. CHEAL & SON provided special prizes for a class for six varieties, six blooms of each, for which Mr. R. KEEBLE was again 1st; and Mr. J. HUDSON, 2nd.

Pompon Dahlias were shown by amateurs in classes for twelve and for six bunches, and in two classes for singles also. Messrs. HUDSON, BURGIN, and MAWLEY were the principal prize winners.

SINGLE varieties were somewhat sparingly shown by amateurs. Messrs. HUDSON and MAWLEY were the leading prize winners.

In the classes, two in number, set apart for amateurs who had never previously won a prize at a society show, there was a brisk competition.

The pretty Fancy Single Dahlias raised mainly by the late Mr. T. W. GIRDLESTONE, were shown in a class for eighteen varieties. Special prizes were provided in this instance. Mr. M. V. SEALE was placed 1st with a charming collection, having Dorothy Seale, Jeannette, May Sharp, Phyllis, Miss Glasscock, Firefly, The Sirdar, Duchess of Marlborough, Gaiety Girl, Polly, &c. Messrs. CHEAL & SON were 2nd, having distinct from the foregoing Princess Petula, Muriel, Lord Rosebery, Shamrock, Flame, Daisy, &c.

HALF DOZENS OF ONE VARIETY.

Great interest always attaches to the nine classes in which are shown six blooms of one variety of some colour or type. The best dark was Prince of Denmark, from Mr. SEALE. The best light, not yellow, was Mrs. Gladstone, from Mr. J. WALKER; William Powell, was the best yellow, and won the 1st prize for Mr. WALKER. Duke of Fife, in fine colour, was the best red or crimson; it came from Mr. R. C. WEST. No white can beat John Walker when at its best, it was finely shown by its namesake; the best Dahlia of any colour; it is a fine, heavy-edged variety, and came from Mr. SEALE.

The best tipped Dahlia, necessarily a fancy, was Miss Browning, yellow, tipped with white, from Mr. J. WALKER. The best striped was the dark fancy Prince Henry. Miss Cannell was the best edged flower shown by Mr. SEALE.

FLORAL DECORATIONS.

composed of Dahlias always find a place in the schedule of prizes. The best epergne of Dahlia blooms and foliage, came from Mr. J. T. HUDSON. Cactus Pompon and singles were tastefully employed. Mr. R. EDWARDS was 2nd, with a pleasing and less formal stand.

The best vase of twelve blooms of Dahlias was set up by Mr. E. MAWLEY, who had a salmon Cactus variety; Mr. H. A. NEEDS was 2nd; Mr. R. EDWARDS, Sevenoaks, had the best three vases of Cactus Dahlias, using salmon and crimson varieties with excellent effect.

Mr. W. TRESEDER, Cardiff, was 1st with an attractively shown bouquet of Dahlias, amber tints of Cactus being employed; Mr. SEALE was 2nd, having a yellow Cactus.

The best floral design was a harp in crimson and white Cactus Dahlias, from Mr. W. TRESEDER; Mr. SEALE taking the 2nd prize, with a cross of white Pompon Dahlias rising out of a base of foliage.

NON-COMPETITIVE EXHIBITS.

At the sides of the naves were arranged miscellaneous collections. Mr. J. GREEN, Norfolk Nursery, Dereham, had panels of such new Cactus Dahlias as Red Rover, brilliant red, large, striking, and of true Cactus shape; Zephyr, soft pinkish rose; Clio, ruby with deep centre; and others.

Messrs. H. CANNELL & SON had a very large collection of Cactus and decorative Dahlias, some 200 bunches forming an imposing bank.

Messrs. T. S. WARE (LTD.), Tottenham, had a long table of Cactus and other Dahlias, with barely flowers in considerable variety; and Messrs. J. LAING & SONS, Stanstead Nursery, Forest Hill, a table of ornamental foliaged plants; another table of cut flowers, Dahlias, Roses, hardy perennials, &c.; and on the floor, various hardy ornamental plants of an attractive character.

A number of seedlings were staged, and some notice of these will be found in an article on p. 209.

EAGLESFIELD HORTICULTURAL.

SEPTEMBER 2.—This show, which is essentially the most important of its kind in the South of Scotland, was held in a field adjacent to the village. The entries to the show totalled 2460, this being similar to last year's numbers.

The show of FLOWERS was highly creditable after the unfavourable season. Dahlias and Asters were particularly good, and the foliage plants attained a high standard of excellence. As at other shows in the neighbourhood, the exhibits of FRUIT were not numerous, but several capital collections were forwarded, Melons and Apples being particularly good. Vegetables were well represented.

Competition in the amateur section was the most limited, though keen in certain classes; but the display of CUT FLOWERS was the best seen for several years. Asters, Dahlias, and Marigolds were exceptionally fine. Messrs. J. & T. W. ELLIOT, Langholm, and Messrs. W. & R. HORTON, Langholm, were the principal exhibitors.

The cottagers' section was, as usual, the heaviest one, all the classes being well filled.

The best CUT FLOWERS, which were numerous, were Dahlias, French Marigolds, and Asters. Mr. T. GRAHAM, Longtown, and Mr. JAMES JOHNSTONE, Ecclefechan, were among the principal prize-takers of pot plants; Messrs. T. & J. TWEEDIE and Messrs. W. & R. HORTON being again to the front among the cut flowers.

In the open class, the four latter exhibitors and Mr. EWEN CAMERON, Eriestane, Moffat, occupied conspicuous positions. Stands of Roses were sent for exhibition by Messrs. PALMER & SON, Annan, and Messrs. SMITH & SON, Stranraer.

METROPOLITAN OPEN SPACES: One Tree Hill.

—We have been informed that it has been decided—against the hopes of the dwellers around—that this favourite spot is private property, and that the golf club is entitled to possession. As streets of houses are being built in this locality, it behoves those desirous of keeping open a fine landscape and recreation ground to bestir themselves, so as to secure from the builder one more fine open space for South London.

Brockwell Park.—There are fine wooded grounds (about 40 acres) lying between the Park and Dulwich Road: all of this cannot now be acquired for the public. Twenty acres however are in the market, and if all could be purchased and added to the now charming park, it would become the finest open space in the

southern part of the metropolis. It should not be overlooked that very little interference would be necessary in fitting the grounds for immediate enjoyment. By the way there is a paucity of entrances to Brockwell Park, the number of which can only be increased, one believes, by the conversion of the woodland into pleasure ground.

MARKETS.

COVENT GARDEN, SEPTEMBER 7.

[We cannot accept any responsibility for the abjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

SEEDS.

LONDON: September 6.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report increasing activity in seeds generally. Trifolium especially moves off more freely. Winter Tares being scarce and much wanted are dearer. Rye unchanged. The Canary-seed market is strong, with stocks getting rapidly reduced. Lower rates are quoted for Hempseed. As regards Alsike White, Red, and Trefoil, values all round are higher. Peas and Haricots steady.

FRUIT AND VEGETABLES.

GLASGOW: September 6.—The following are the averages of the prices recorded since our last report:—Foreign fruit, Dutch Plums, 14s. per cwt.; do. Pears, 2s. to 3s. per sieve; Dutch Apples, 2s. to 3s. per bushel, and 4s. per half small hamper, and 12s. per small cask; Lemons, Palermo, selected, sound, 14s. to 17s. per case; do. Messina, 15s. to 18s. do.; do. Naples, sound, 25s. to 32s. do.; Grapes, Almeida, 11s. to 18s. per barrel; do. Denia, white, 4s. to 5s. do.; do. black, 7s. do.; Bananas, extra, 12s. to 13s. per bunch; do. No. 1, 10s. to 11s. do.; No. 2, 9s. to 10s. do.; French Pears, Williams, 6s. to 7s. per case; Bonne Louise, 3s. to 4s. do.; Duchesse, 3s. to 4s. do.; English Grapes, 1s. 2d. per lb.; Melons, Valencia, yellow, 24s. 7s. to 7s. 6d. per case; 36s. 7s. to 8s. do.; 48s. 7s. to 7s. 6d. do.; brooze, 24s. 7s. 6d. to 8s. do.; do. 38s. 7s. to 7s. 6d. do.; Vegetables: Carrots, Dutch, 3s. to 3s. 6d. per bag; 2s. per small hamper; Onions, 3s. 6d. per bag; do. Valencia, 4s. 3s. 9d. to 4s. 3d. per case; do. 5s. 4s. 9d. to 5s. 6d. do.; Scotch Mushrooms, 10d. to 1s. 6d. per pound; Tomatoes, English, 3d. to 5d. per pound; do. Scotch, 4d. to 7d. do.; Turnips, 10d. to 1s. per cwt.; Swedes, 1s. 10d. per cwt.; Carrots, 9d. per dozen bunches; Parsley, 7d. to 9d. per dozen bunches; Cucumbers, 1s. 3d. to 2s. 6d. per dozen; Cauliflowers, 1s. 6d. to 2s. 6d. per dozen; Cabbages, 1s. to 2s. per dozen.

PLANT AND FLOWER MARKET: September 6.—Prices for Dutch bulbs ruled rather low, considering the advance in price of Hyacinths and Tulips in Holland. Some of the prices are as under:—Hyacinths, 9d. to 1s. per dozen; small beddings, 1s. 2d. to 1s. 6d. per bag, 50 60, 72, and 100 in each bag. Tulips, 1s. per 100; single Snowdrops, 1s. 6d.; Scilla sibirica, 8d.; Crocuses 5d. to 1s.; Narcissus and Daffodils, 4d. to 2s.; Iris, English, 1s. 2d.; do. Spanish, 4d. to 1s.; Colchicum, 2s., all per 100 bulbs. Scotch: Lilium Harrisii, 2s. to 3s. per dozen; L. lancifolium, 9d. to 1s. 6d. do.; Orchids, 1s. to 3s. per dozen blooms; Carnations, 2d. to 6d. per bunch; Roses, white, 6d. to 2s. per dozen; do. red, 1s. to 2s. do.; do. boxes, 2s. to 4s.; Asters, 1s. to 3s. per dozen bunches; Sweet Peas, 1s. to 4s. do.; Maidenhair Fern, 3s. to 6s. do.; Gardenias, 1s. per dozen; Marguerites, 1s. 6d. do.; boxes of mixed flowers, 6d. to 4s. per box; Asparagus Ferns, 6d. to 2s. per bunch.

LIVERPOOL: September 7.—Wholesale Vegetable Market.—Potatoes, per cwt.: Early Regents, 2s. to 2s. 6d.; Main Crop, 3s. to 3s. 6d.; Kidneys, 2s. 6d. to 3s. 6d.; Turnips, 8d. to 10d. per doz. bunches; do. Swedes, 1s. to 2s. per cwt.; Carrots, 6d. to 8d. per dozen bunches; Parsley, 6d. to 8d. do.; Onions, English, 6s. per cwt.; do. foreign, 4s. to 6s. do. Cucumbers, 1s. 2d. to 2s. 9d. per dozen; Cauliflowers, 1s. 6d. to 2s. 9d. do.; Cabbages, 1s. to 2s. do.; Celery, 1s. to 2s. do. Beans, Kidney, 9d. to 1s. per peck; Scarlet Runners, 9d. to 1s. do. St. John's.—Potatoes, 10d. to 1s. 2d. per peck; Grapes, Potatoes, 10d. to 1s. 2d. per peck; Grapes, English, 1s. 6d. to 3s. per lb.; do. foreign, 4d. to 8d. do.; Pines, English, 4s. to 6s. each; Damsons, 4d. per lb.; Cobnuts, 8d. do.; Cucumbers, 3d. to 4d. each; Mushrooms, 1s. per pound and basket. Birkenhead.—Potatoes, 8d. to 10d. per peck. Cucumbers, 2d. to 6d. each; Filberts, 8d. per lb.; Grapes English, 1s. 6d. to 3s. per lb.; do. foreign, 4d. to 8d. do.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending September 2, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.	1899.	Difference.
	s. d.	s. d.	s. d.
Wheat	23 1	25 0	- 3 1
Barley	27 8	25 10	- 1 10
Oats	18 11	10 7	- 2 4

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DISTRICTS.	TEMPERATURE.					RAINFALL.			BRIGHT SUN.	
	ACCUMULATED.									
	Above (+) or below (—) the Mean for the week ending September 2.	Above 42° for the Week.	Below 42° for the Week.	Above 42°, difference from Mean since January 1, 1899.	Below 42°, difference from Mean since January 1, 1899.	More (+) or less (—) than Mean for the Week.	No. of Rainy Days since January 1, 1899.	Total Fall since Jan. 1, 1899.	Percentage of possible Duration for the Week.	Percentage of possible Duration since Jan. 1, 1899.

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London.

Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending September 2, is furnished from the Meteorological Office:—

"The weather during this period was much less settled than that of late, rain falling rather frequently in all parts of the kingdom, and thunderstorms occurring from time to time.

"The temperature was again above the mean, the excess ranging from 2° in 'Scotland, W.,' 'England, N.W.,' and 'Ireland, S.' to 4° in 'Scotland, N.,' 'England, E.,' and the 'Channel Islands.' The highest of the maxima were registered on August 27, and ranged from 85° in 'England, E. and S.,' to 72° in 'Scotland, E.,' 'England, N.W.,' and the 'Channel Islands,' and to 71° in 'Scotland, W.' The lowest of the minima, which were mostly recorded on August 29, varied from 35° in 'Scotland, E.,' to 50° in 'England, S.,' and to 54° in the 'Channel Islands.'

"The rainfall was rather less than the mean in 'Scotland, N.,' and 'England, E.,' and just equal to it in 'Scotland, W.' In all other districts there was an excess, that in most cases being rather large.

"The bright sunshine was less than the mean in 'Scotland, E.,' and the 'Channel Islands,' but was again in excess in all other parts of the kingdom. The percentage of the possible duration ranged from 52 in 'England, E.' and the 'Channel Islands,' and 49 in 'England, S.,' to 26 in 'Scotland, E.,' to 25 in 'Scotland, N.'"

DALKEITH GARDENS.—According to the *Journal of Horticulture*, the charge of the Duke of Buccleuch's gardens at Dalkeith has been given to Mr. J. Whytock, gr. to Earl Fitzwilliam, Cool-lattin Park, Shillelagh.

ANSWERS TO CORRESPONDENTS.

BOOKS: A. G. *Chrysanthemums and their Culture*, by Edwin Molyneux, published at 12, Mitre Court Chambers, Fleet Street, E.C., price 1s. The particular cultivation required by newer varieties is given in a practical manner by Mr. W. Wells, Earlswood, Redhill, Surrey, in *The Culture of the Chrysanthemum*, price 1s. 6d.—G. L. T. *About Orchids*, by F. Boyle, published by Chapman & Hall, Ltd.

CACTUS PHOTOGRAPHS: F. L. If you will kindly send specimens of the photographs you mention, we will consider them.

CHRYSANTHEMUM STIMULANT: J. S. Urine from horses will certainly be useful as a stimulant for these plants; and if allowed to lie for a time in a tank, and thus develop ammonia, its value will be increased. But we cannot recommend it without a caution against using it insufficiently diluted.

CINERARIAS: F. M. We are unable to say with certainty what is the cause of the plants dying. The roots are numerous and healthy, and the plant sent was a most vigorous specimen. The mischief has been at the "collar." Has it arisen from too much moisture there, or from an over rich top-dressing having burned this part before getting down to the roots?

FERNS: J. C. The insects on your Ferns is a small scale, and they are so numerous, that it would be best to cut away all the fronds, and make a fresh start. If scales attack the young fronds, sponge them with a safe insecticide before the insects become numerous, and repeat the work as often as necessary.

INSECTS ON PEAR: C. J. and G. D. White. The Pear slug-worm (*Selandria atra*). You may syringe the trees by means of a powerful garden-engine with strong soap-suds and a little tobacco-water. Or they may be dusted with soot, lime, or other caustic powder. The operation will need to be repeated, as these insects when so dusted can exude a coating of slime and thus cleanse themselves. But if another dressing be quickly given, it will be fatal to them, as they are powerless to repeat the exudation immediately.

LAWN COVERED WITH MOSS: Cretica. Break the surface by raking, and thus remove much of the moss. Then give, as soon as possible, a half-inch dressing of three parts rich fine loam, and one part powdered lime. Afterwards sow a little fresh grass-seed. This will also greatly strengthen the existing grass. In the spring, if this grass be still weak, give weak solutions of a nitrogenous manure occasionally, or one of the advertised lawn "sands."

LANTERN SLIDES: A. R. J. We cannot tell you. Probably you would have to get them made specially for you.

NAMES OF FRUITS: T. W. S., Gloucestershire. Pine Golden Pippin.—Rosefield. Court Pendu Plat.—E. A. The Cherry apple, or Siberian Crab.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—J. Laurie. *Magnolia acuminata*.—J. W. 1, *Rhamnus* sp. [?]; 2, *Pyrus Aria*; 3, *Purple Beech*; 4, *Cryptomeria japonica*; 5, *Abies cephalonica*; 6, from the scrap sent, we cannot tell whether it is a *Deodar*, *Lebaon*, or *Atlas Cedar*—probably the second; 7, *Quercus cerris*.—W. T. *Muhlenbeckia complexa*, *Polygonaceae*.—W. C. & Co. *Funkia grandiflora* (see figure in *Gardeners' Chronicle*, November 16, 1878, p. 629).—Jas. Wright. 1, *Physianthus*, or *Arauja albens*; 2, *Carthamus tinctorius*.—T. W. 1, *Eurothera macrocarpa*; 2, *Dicentra formosa*; 3, *Trachelium caeruleum*; 4, *Escallonia rubra*; 5, *Spiranthes autumnalis*, a wild Orchid, of much interest: do not dig it up; 6, *Ceanothus azureus*.—J. S. 1, *Alnus cordata*; 2, *A. imperialis*. We are sorry we cannot name these seedling varieties of Oaks; 3 and 4 we take to be *Q. Cerris*; 5, 6, and 7, we suppose are hybrids between that species and *Q. Suber*, of which the *Lucombe* and the *Fulham Oaks* are varieties.—B. K. All leaves with no flowers. 1, *Magnolia acuminata*; 2, apparently *Clerodendron trichotomum*; 3, *Gledit-chia triacanthos*; 4, *Alnus*; 5, *Calycanthus occidentalis*; 6, *Ulmus montana*—*Ilex*. A very good variety of *Cattleya* *Lodigesi*.—Robertus. *Rodriguezia* (*Burlingtonia*) *pubescens*.—G. L. T. *Oncidium dasytyle*. For other answer see under "Books."—S. J. *Origanum Dictamnus*, superficially like the Hop, but extremely different in reality.

ORCHID FLOWERS WHEN CUT: Grower. The flowers of *Odontoglossums*, *Cattleyas*, and similar orchids will travel well the distance you name provided they have been properly matured on the plant and hardened off in a

tolerably cool place. Orchid blooms should not be cut too early. They travel better, and last longer, if cut a week before they would begin to fade if left on the plant, than when cut just as the flowers are fully formed. *Odontoglossums* should never be cut until all the flowers on the spike are expanded and matured. Soft tissue paper should be used for packing. Cotton wool where it touches the flowers is very injurious.

SHREWSBURY SHOW.—Messrs. Clibran & Son, Altrincham, were awarded two Silver Medals at this show, instead of one as reported.

SWEET PEAS, &c.: M. S. Your flowers arrived in such a condition, that we could not form a proper opinion about them. So far as we can see, none are at all remarkable.

VEGETABLES AT EXHIBITIONS: J. S. sends the following query—"Judging at a local show recently, in a class for collections of vegetables, one of the exhibits contained French Beans and Scarlet Runners; they were shown as two varieties. In another exhibit Broad Beans and Scarlet Runners were also shown as two varieties. By the Society's regulations, which I enclose, they say 'distinct species,' and my colleagues and myself disqualified the collections. A dispute arose in reference to them being disqualified. Will you kindly give the verdict?"

—In a note in the schedule explaining the requirements of this class, it is stated—"For varieties in any collection of vegetables . . . distinct 'species' must be shown, e.g., one 'variety' of Potatoes, one variety of Peas, &c." The Dwarf and the Runner Beans are separate and distinct species, and the Runner Bean and the Broad Bean are more than this, as they belong to separate genera. Therefore, the judges were unquestionably wrong in not allowing the exhibits. We may add that the wording of the schedule is confusing and most unsatisfactory.

VINE BORDER: J. S., "Sunflower." Two feet of soil is ample depth for the back of the Vine-border, with a fall of 6 inches if the position is an elevated one. Unless the maiden loam mentioned be of a rich fibrous nature, a less amount than that stated should be used, and more of the top spit. The proportion of mortar-rubble is in excess of the requirements of the varieties of Grapes it is intended to grow. Rather use half the amount, and an equal quantity of home-made charcoal. We presume the exact nature of Canon Hall Muscat Grape is known to "a regular subscriber." We should much prefer in such a limited area to plant Buckland Sweetwater, as this Grape, though by no means possessing the rich flavour of the former, is a sure cropper, and, when well finished, is a Grape of fair appearance and one possessed of average flavour.

WILD SPECIES OF FLOWERS AT EXHIBITIONS: E. Midgley. We have not the schedule before us; and as the wording of schedules should always be interpreted literally, we cannot give a definite opinion in your particular case. A wild flower is generally meant to imply a native British species—one that grows wild in this country. It is still a British flower even if taken from a cultivated garden; but it is certainly against the spirit of the schedule if exhibitors cultivate wild species in their gardens for purposes of exhibition; and as plants so grown are generally entirely out of character, and unrepresentative, besides being, as a rule, less beautiful, the judges would be wise to award the premier awards to more typical exhibits. The framers of the schedule could settle the matter, by stating in relation to such classes, "that flowers cultivated out of normal character may not be shown."

HARDY WATER LILIES.

(MY STORY.)

COMING to this place in November of last year, it was my intention, and is yet, to grow some of those beautiful Water-Lilies of M. Latour-Marliac. To this end, a few years ago I dammed up a small streamlet which passes through the lower part of my grounds; a few of the common white Nymphaea which I had placed therein did very well and flowered freely during the months of July and August; but the severe drought of the summer dried up the inflow of the stream, and that which had been dammed up evaporated so much that these Lilies were left in rather an unhappy position. Finding protection in my grounds, the streamlet now swarms with water-voles (*Arvicula amphibius*), and moor-hens (*Gallinula chloropus*)—and the kingfisher (*Alcedo ispida*), is not a stranger. We succeeded in killing a few of the voles, and by the same means we caught some of the moor-hens; their numbers, however, did not seem to decrease, as they came again by way of both the upper and lower lengths of the stream. Finding these local feathered and furry fauna so difficult to exterminate, I have resolved to leave the streamlet for their own undisturbed enjoyment. In time of heavy rain, this little stream transforms itself into a formidable rushing muddy river. During these freshets no Nymphaea could hold their own and look nice; the dirty state of the leaves of the white variety now there is hint sufficient to take note of, although the flowers which show for about three or four days only are clean enough whilst they last. For these reasons I have abandoned the idea at present of running the risk of placing my Nymphaea in these waters. I have, therefore, for the reception of these Lilies been preparing a pond in the higher portion of my grounds, to which, when ready, my collection of Lilies will be transferred. This pond will be partly fed by rain-water, and when that does not come in sufficient quantity, I can keep it filled by turning on water from a never-failing deep well, which is forced up to an elevated cistern by one of those "hot-air-pumps." With this simple but clever working little engine we could, if necessary, irrigate by gravitation the whole surface of my little place of 12 acres; by its use and frequent application, coupled with deeply-trenched ground, we have passed unscathed through the trying ordeal of the late hot summer; most of our things, too, were planted late in spring, as during winter we had the ground to dig and prepare for them.

The pond, now about ready to receive the water, is surrounded with sundry shrubs, which by their shelter, and without intercepting the sun's rays, will secure placidity and the necessary warmth; under such almost unique cir-

cumstances Lilies ought to do well. To begin with, my collection is as under, viz:—

Marliacea ignea	Marliacea rosea
" Robinsoniana	" odorata sulphurea
" chromatella	" Gladstoniana
" albidia	" exquisita
" flammea	" Dr. Faunce's Seedling
	" Laydekeri liliacea

All these I had sent me by my esteemed friend, Mr. James Brydon of South Lancaster, Mass., U.S.A. His letter, which is so practical and full of Lily-love, I send for your perusal. On pp. 3 and 4 of his letter Mr. Brydon writes:—

"I have raised several new hardy ones from seed, which I think are fully the equals of M. Marliac's. Saturday, August 12, I was awarded a Silver Medal by the Massachusetts Horticultural Society for one of these seedlings, which I have named *Brydonacea elegans*. I claim the honour of being the first man in this country to raise hardy Lilies of the Marliac type, and shall continue to exhibit the same from time to time."

Before receiving the unexpected but handsome consignment of Lily-roots from Mr. Brydon, I had already written to Mr. Marliac for his priced catalogue. By a singular coincidence, this arrived by the same post which brought Mr. Brydon's letter, followed next morning by a parcel containing the much-prized roots in excellent condition. On arrival, I potted them, as advised by Mr. Brydon, in 6-inch pots, and plunged them in a tank of water which had at the bottom about 6 inches of nice slimy mud, this being the remainder of a mulch which we had been using in spring as a dip for the roots of our young trees before planting. In this situation, these precocious little plants in the course of the summer made abundance of leaves and threw up several blooms, which to us was not only pleasing but also encouraging; *Marliacea ignea* we admired much. *W. Miller, Berkswell, near Coventry.*

ORCHID NOTES AND GLEANINGS.

"DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES."

THE numbers 32 and 33 contain coloured illustrations and descriptions of the following species and varieties:—

<i>Aerides Houlettianum</i> , Rehb. f.	<i>C. Godseffianum</i> , Rehb. f.
<i>Angreum Leonis</i> , Veitch.	<i>C. Calypso</i> var. <i>Flamingo</i> , Cogn.
<i>Coleogyne Massangeana</i> , Rehb. f.	<i>C. Jules Hye</i> , from <i>Spicerianum</i> by Boxalli atratum.
<i>Cymbidium tigrinum splendens</i> , Cogn.	<i>C. Clotho</i> , Reg. Young, a cross out of <i>x C. politum</i> by Boxalli atratum.
<i>Dendrobium cynbilloides</i> , Ldl.	<i>C. Eudynion</i> , Reg. Young, a cross from <i>C. carbatum</i> by C. Mastersianum.
<i>D. e. thyrsoformum</i> , Rehb. f.	<i>C. Eyerimannianum</i> var. <i>Hermione</i> , Rolfe, a hybrid between <i>C. carbatum</i> fertilised by <i>C. Spicerianum</i> .
<i>Epidendrum inversum</i> , Ldl.	<i>C. Pollettianum</i> , Rolfe, a cross from <i>C. calophyllum</i> <i>x</i> and <i>C. onanthum superbum</i> <i>x</i> , and thus the derivative from no fewer than four species— <i>C. carbatum</i> $\frac{1}{2}$, <i>C. venustum</i> $\frac{1}{4}$, <i>C. villousum</i> $\frac{1}{4}$, and <i>C. insigne</i> var. <i>Mauldi</i> $\frac{1}{4}$.
<i>Eulophiella Elisabethae</i> , Lind. et Rolfe.	<i>C. Souvenir de Roch Jolibois</i> , Opoix, a cross from <i>C. Lowi</i> by C. Curtisii, raised by M. Opoix. Would it not be preferable to call it simply <i>C. Jolibois</i> <i>x</i> ?
<i>Masdevallia Peristeria</i> , Rehb. f.	
<i>Maxillaria nigrescens</i> , Ldl.	
<i>Mormodes Lawrenceanum</i> , Rolfe.	
<i>Oncidium cucullatum</i> , Ldl.	
<i>Phalaenopsis Denisiana</i> , Coig.	

Cypripedium Boxalli var. *atratum* and var. *superbum*.
C. Charlesworthii reticulatum.
C. C. pallidum.
C. Mastersianum, Rehb. f.
C. Appletonianum, Gower.
C. Zampa var. *Steriope*, Cogn., a cross effected by M. Vnylsteke between *C. hirsutissimum* (female) and *C. Leonardum* *x*.

In the number for March 1899, *Cypripedium callosum* var. *Sauderae* was erroneously designated as a hybrid.

LÆLIO-CATTLEYA *x* ANDREANA.

When this pretty hybrid, which was obtained by M. Chas. Maron, by crossing *Cattleya bicolor* with *Lælio-Cattleya x elegans*, first appeared, it was, like other of the medium-sized hybrids, not

generally admired. Later, it gained strength, and when shown by R. I. Measures, Esq. (gr., Mr. H. J. Chapman), it was granted an Award of Merit. Since then, with Mr. Measures and others, increased strength has intensified the beauties of its flowers.

A grand example of it with very strong pseudo-bulbs, and bearing as many as six flowers on a spike, has flowered with Henry Little, Esq., Baron's Halt, Twickenham (gr., Mr. Howard), where the *Lælias*, *Cattleyas*, and *Lælio-Cattleyas* are specially well grown. The plant in question had fine waxlike flowers; the sepals and petals cream-white, tinted with rose; and the showy lip bright claret-crimson, its form indicating *Cattleya bicolor*.

LÆLIO-CATTLEYA *x* BROOMEANA.

In the issue of the *Gardeners' Chronicle*, Nov. 11, 1897, p. 174, there appeared a description of this gorgeous natural hybrid, which was imported from Brazil by Joseph Broome, Esq., Sunny Hill, Llandudno (gr., Mr. A. C. Axtell), with whom it flowered. A splendid bloom now sent proves that all its fine characteristics are well maintained, the flower in size and in intensity of colour being even better than when it first appeared. Its general appearance is that of an abnormally fine *Lælio-Cattleya x elegans*, but the lip is larger and somewhat different in form, and all the other segments broader; the sepals and petals are of a clear rosy-mauve, with slight spotting and veining of purple. The base of the lip is white, with a crimson band running into the front lobe, the broad front lobe and about 1-inch of the front portion of the side lobes glowing crimson-purple. It was imported as a distinct hybrid, and so it has proved.

CATTLEYA GUTTATA VARIETY.

Cattleya guttata is one of the most variable of Brazilian species, and it has been still further complicated by the inclusion by some of the amply distinct *C. Leopoldi* and *C. amethystoglossa*. When the typical plant is considered, the variation in size and colour is very extraordinary; extremes of both classes often being taken for new species or hybrids when they appear among amateurs. A flower of a very remarkable example, which may be considered the starting point of the species, is sent me by Francis H. Moore, Esq., The Royal Infirmary, Liverpool. The flower is about half the size of the ordinary form, the sepals yellowish-green with a purplish tinge, and a few small purple spots; petals similar in colour to the sepals, but broader, and with a wavy margin. The lip has the side lobes white, the small, narrow, elongated front lobe which has a rugged surface, being purplish-crimson. The labellum when spread has much of the outline of *C. granulosa*, and the whole flower bears a striking resemblance to that somewhat mysterious plant shown by Messrs. F. Sander & Co., St. Albans, at the Royal Horticultural Society, September 8, 1891, as *Cattleya granulosa Dijanceana*, though in that case the sepals and petals bore scarcely any trace of spotting. *J. O'B.*

THE LAVENDER INDUSTRY.

LAVENDER comes of an odorous race; it is one of the Labiatae, or lip-flowers, which include Mint, Thyme, Rosemary, Balm, Sage, and Marjoram. But, though grown to such perfection in this country, it is not indigenous. Those excellent people, the Huguenots, when they settled in the valley of the Wandle, in 1568, are said to have brought it from its home on the hills of Naples. It is a native of Persia also, of the Canaries, the Barbary States, and of the greater part of the South of Europe; that of Mont Blanc is said to be the finest, for it affects altitudes, and has been found in North Africa growing in dry stony soil, 5000 ft. above sea-level. From the *Lavaudula spica*, grown on the Continent, oil of spike is made, now chiefly used in the preparation of pigments in porce-

lain painting. Some of the rarer members of the tribe, with divided leaves, have a place in the greenhouses. But the English Lavender is a hardy plant, which would disdain so luxurious a setting. It delights in loamy land, with a chalky subsoil, well open to the sun and air. There is warrant for saying that it will grow on ground which would not support any other crop of value. Planting goes on in September or October. When in the spring the Lavender shows signs of flower, it is ruthlessly clipped; this is done sometimes twice or three times, for it is essential to strength that no flowers be formed the first season. When a year old, they are planted out in rows, with breathing-spaces of 3 feet between. If oil is scarce and dear, they are allowed to flower the second year, but it is better to clip them again, and wait until they have reached their prime in the third year. They are at their best till the fifth; in the seventh or eighth they have served their time, are rooted up, and become brands for the burning.

The harvest falls about the end of July or at the beginning of August. A dry, warm season, with gentle showers between, suits Lavender best. If garnered in showery weather, the yield of oil is greater, whilst continued drought taints it with a rank odour. The flowers must be fully expanded when gathered. They are cut from the plants with short reaping-hooks, tied in bundles, taken from the field, and then stripped from the stalks. As the pans fill with the odorous blossoms they are transferred to the still. From half a ton to a ton of them fills the still; from twenty to thirty women will be working hard for six hours to make up the quantity. The oil is contained in glands on the calyx, corolla, and leaves, and to a smaller extent in the branches of the flower-stalks. Women work in the fields too, following the men who reap, and tying up the harvest in mats. This protects it from the sun, which would otherwise "heat" the Lavender and injure the oil. In a good year a ton will give up as much as 21 lb. of oil, at other times not more than 15 lb. or 16 lb., and in bad seasons the yield may fall as low as 10 lb.

The distillation starts at 4 or 5 in the morning, and lasts till 10 at night, continuing from about the first week in August till the end of October. Each operation takes about two and a half hours, the largest quantity of oil coming over during the first hour and a half. A considerable part of the time is taken up in filling and emptying the still. This is of copper, with a fluid capacity of about 200 gallons. The flowers are packed in tightly by treading—work to get accustomed to, for the boys employed are often stung by the bees concealed within the bunches. After a few days, however, the stings cause little or no pain. Hundreds of these bees, drunken with sweets, refuse to be dislodged either by the reapers or the trimmers, and find their way into the still, there to realise too late that enough is better than a feast, for the still is filled with boiling water, and sudden death environs them round about. The head of the still is put on, and luted with clay. It resembles nothing so much as an enormous tobacco-pipe, bowl downwards. The furnace is lighted, and the oil passes off, carried on the wings of the steam, which condenses again in the cool of the receiver, the oil floating on the top. On the removal of the water with a syphon, the oil remains behind. The head of the still is taken off, and the sodden mass of flowers taken out with long forks. They go back to the land to fertilise the next crop. Bottling the oil for a twelvemonth mellows it, takes away the harshness, and turns it from a light brown to a pale gold. Up to three years it improves, but deteriorates if kept longer. The subtle individuality of the Lavender lies hidden in the oil. This must be diluted from twenty to forty times its bulk of spirit before it is revealed. The oil is a quite impossible perfume, though the generation which four or five decades ago reeked with bergamot and patchouli might have borne it. Sometimes Lavender-water is a bouquet of scents of which Lavender is the key-

note. Commonly it is mixed with rose-water as well as spirit. Piesse, in his *Art of Perfumery*, says:—"English oil of Lavender, 4 oz.; spirits of wine, 3 quarts; rose-water, 1 pint; the filter does the rest." X.

THE FERNERY.

TREATMENT OF SICKLY FERNS.

As it often happens, even with the most careful culture, and not infrequently owing to over-care or coddling, that valuable Ferns get gradually out of health, and eventually die outright, a few hints as to treatment may be of interest. Apart from the attacks of vermin, a lack of health induced by bad colour of the fronds, and constant failure of new ones to develop properly, is more frequently due to a water-logged condition of the soil, owing to bad drainage; and if a plant so affected be shaken out, it will be found that the great bulk of the roots are black and dead—and further investigation will show that, while there is perhaps a large caudex built up of the bases of several generations of old fronds, this too is rotten at the base, and for a considerable distance upwards. In such a case the whole of the soil should be first shaken out, and then washed out under a tap, until the mass is clean. Starting then on the base of the caudex, pull away all the rotten bases, with which will come the bulk of the dead roots; then with a sharp knife trim away all the dead parts remaining, and if there be any living roots left, repot in a small pot, and keep close, when in all probability a fresh start will result. The philosophy of this procedure is simple. The vitality of Ferns is very great, and hence the plant, when handicapped by some soil which kills its old roots, devotes all its energies to form new fronds and new roots from its centre. Each new frond, however, sends forth its now particular fascicle of rootlets, and no sooner do these start out, as it were, in search of provender, than they plunge into the general rottenness around them, and soon perish for lack of sustenance, or by contagion, until finally, batch after batch succumb, and the ever-spreading rottenness reaches the plant's very heart, and it is beyond resuscitation. The process described gives the needful start, and very often not one plant, but a batch, is the result. Mr. G. B. Wollaston once told us that a very precious form of *Polystichum* went wrong, and when thus treated, yielded no less than eighty typical plants. A very curious fact in this connection is, that many Ferns have the power of forming a bud, or buds, at the point where each frond develops its particular bunch of rootlets; and so long as the core of that frond-base is green, this bud, or buds, is capable of being generated, provided—always provided—it finds itself in sweet and good soil when it is first formed. Even where the central crown has quite perished, if any greenness be visible during the aforesaid clearance process, plants may be obtained by cutting the caudex up so that each of the frond bases has a little bit of the central mass attached to it.

An old caudex may yield a score or more of good pieces if deftly-handled, and these should be inserted into small pots or pans of good sterilised soil, just deep enough for anchorage, a piece of glass placed over the pot or pan, and the whole put away in a damp corner with plenty of diffused light. Shield Fern, Lady Fern, and Lastreas are all amenable to this treatment; while as regards the Hartstongue, the frond bases do not demand the adherent piece of caudex, but every $\frac{1}{4}$ inch will yield plants, so that every base is good for at least half-a-dozen. We have, at the present moment, a pan full of young plants, some fifty or sixty, raised as follows. A finely tasselled Hartstongue went wrong, and was accidentally thrown away as dead; fortunately it fell into a box of prepared mould, hence, months afterwards, when the mould was used, the caudex was discovered still green. It

was pulled to pieces, and the pieces dropped into a tumbler containing an inch of wet sand, upon which the pieces lay loose as they fell; a glass was placed over this, and the arrangement being overlooked, was untouched for at least six months—the whole winter, in fact. The water, however, could not escape, and hence the sand constantly received again whatever was evaporated. In the spring, the little pieces were covered with whitish knobs, incipient buds, and in a few months, when put into soil, a perfect little forest of plants sprang up, rooted themselves, and the erewhile seeming corpse became a crowd of vigorous individuals. In these cases, it is clear that there is a store of nourishment laid up in the frond bases as a provision for accidents to the main axis of growth. In the Hartstongue, it has the faculty of generating bulbils at any surface point within an inch of the point of attachment to the central core; in other species, the area is limited to the immediate vicinity of the root fascicles, but in all cases the faculty of actual development seems to depend upon a considerable check to the growth of the main axis, or its entire destruction, and in the latter case frequently only those bulbils manage to develop as are freed from the dead mass, and able to reach fresh soil and the light by actual severance of its parts. In cutting up old caudices, we have sometimes remarked long thread-like attempts at frond formation, which were obviously doomed to fail by their very position, since the bulbils originate in a narrow crevice an inch or two deep. And more, the roots they form cannot consequently get into the soil, nor their fronds to the light; hence nothing results. Pull that caudex asunder, however, and they have their chance, and that is the simple philosophy of the procedure suggested.

These drastic remedies have so far as I know only been applied to our British species, but are presumably quite as applicable to many rare exotics. Each Fern frond practically is an individual plant, like the leaf of a tree, and it would appear that although the axial bud is not so patent as in the latter, a latent one exists, or is capable of being induced, through which the Fern can survive though the main axis of growth be destroyed or damaged. In culture, however, there is one essential point of difference: in raising flowering plants from leaf buds, a leaf is usually retained to help development; but with the Ferns, the frond base alone must be used, no basal bud development following if a frond be inserted complete, any remaining energy being then exhausted by the draw set up to maintain the frond's vitality. Chas. T. Drury, F.L.S., V.M.H.

THE VEGETATION OF NEW GUINEA.

I HAVE sketched out a few stray notes on the plant-life of British New Guinea, observed during a recent visit with his Excellency Lord Lamington's party to that place. First, it struck me that the plants of this large island resembled the natives in one thing, namely, as it would be hard to find one of the latter with a clean skin, all of them being more or less covered by skin disease, so the plants are nearly all infested with various kinds of insect and fungus blights. The vegetation, however, even under this great disadvantage, makes in all directions most vigorous growth, but, so far as I was able to judge, not a timber growth. I come to this conclusion from specimens which have been forwarded to me for determination during late years, from the various published accounts of other botanists, and from my own observations. Likewise, the grasses, as compared with Queensland, are few in variety, and are, for the most part, coarse kinds, the better ones only being seen here and there in small isolated plots. A large number of the trees and shrubs, as well as plants of smaller growth, are identical with those met with in tropical Queensland. These, as one might expect in such a moist climate, have in many instances

much larger foliage, and the variegated kinds are of a much brighter colouring than one meets with on the same species grown even in bush or hot-houses. My visits to the land were only close to the beach, excepting one trip for about 6 miles up the Mambare River, and here the scrub was so dense that it was quite impossible to penetrate more than a few yards from the river. The scenery was grand in the extreme, and for its striking beauty was, in a great measure, indebted to the great variety of Palms; but not being able to procure fruits, I could only guess at the genera to

growth of that historic Palm, *Nipa fruticans*, Wurmb., with fruit-heads nearly 1½ ft. in diameter, of a rich, glossy brown colour; the leaves, however, did not attain the height ascribed to them in other parts of the tropics. I could not hear of the natives using the fruit as food, but the leaves are used for thatching most of their houses on the coast. On the wide sandy beach of the bay into which the Mambare River empties, one may pick up a large collection of both flowers and fruit; but it was of only a very few that I could find the trees or shrubs from which they had

indigenous, but I have grave doubts as to others, although they may be recorded as such by botanists who have written upon the New Guinea flora. The mistakes have likely occurred owing to the missionaries, who have sent specimens to the botanists, not seeing the necessity of mentioning whether the particular specimens were taken from indigenous or naturalised plants. *Extracts from a Paper by F. Manson Bailey, F.L.S., read before the Royal Society of Queensland, August 20, 1898.*

TRAINED PEAR-TREES AT GORHAMBURY PARK.

THE ordinary garden wall is seldom built of such a height that a Pear-tree can be allowed to extend itself to anything approaching full dimensions; and a great deal of the vigour of a Pear-tree is expended in making growth, which the exigencies of space compel the gardener to sacrifice at the summer and winter prunings, and doubtless thus contribute to the loss of numerous small roots. Given, however, a higher wall, as that afforded by the blank wall of buildings of good height, as in this case, a well managed Pear-tree can be made to cover it in the course of ten or twelve years with regularly disposed, horizontal branches. These branches, should, for most varieties of the Pear, be separated from each other from 10 to 12 inches; and in the case of those that fruit on long pendulous spurs of which Jargonelle and Marie Louise are familiar examples, 14 to 15 inches is not too much. In the future, when our people more fully appreciate the numerous benefits to be derived from the *petite culture*, take up, among other things, the more general cultivation of good varieties of hardy fruits, cottage and farm-house walls, and those of country houses generally, will be clothed with fruit-trees affording gratification and profit to their owners.

The illustrations, pp. 219, 223, show a tree each of *Beurré Rance* and *Marie Louise*, 25 feet high, and 22 feet broad, growing in the gardens of the Earl of Verulam, Gorhambury Park, St. Albans, photographs of which were kindly furnished by Mr. W. Newberry, his lordship's head gardener.

PLANT NOTES.

HOYA BELLA.

THIS charming little plant is well adapted for culture in hanging baskets, having dwarf, slender branching stems, about 1 foot in length. It requires more heat than *H. carnosa*, and is distinctly different in habit. The leaves somewhat resemble the size and shape of the Myrtle, and the little umbels of flowers are very sweetly scented, being waxy white, with a rosy carmine centre. It is a native of India, and was introduced in 1847. A plant is now flowering freely here.

FRUITING CAESCIUMS.

A group of these ornamental plants form a very interesting feature in one of the houses here. The following varieties amongst others are well worth cultivating: Long Yellow, Bull's Nose, Mammoth Long Red, Tomato Shaped, Red Cherry, Long Pod Chili, and Erect Fruiting, the latter being remarkable for the erect manner in which its fruits are produced. The fruits of all are either red or yellow when ripe, and their various sizes and shapes are singular. Seed should be sown in heat early in March, and the plants grown on in the same temperature during the early stages. Then, after being gradually hardened off, they should be removed to a light, airy, and cool house. An occasional tap when in flower is all that is necessary in order to induce the flowers to set. The fruits are not only very attractive, but they may also be used in some cases for the more profitable purpose of flavouring pickles. *J. G., Botanic Gardens, Liverpool.*

FIG. 76.—PEAR MARIE LOUISE AT GORHAMBURY PARK, ST. ALBANS.

which they belonged. I was particularly taken, in more senses than one, by a grand "lawyer cane," a species of *Korthalsia*—a genus, so far as at present known, not belonging to Australia. It is in all probability *K. Zippellii*, Blume, but the plants were neither in flower nor fruit at the time. On the bank of this river I saw the only Fern-tree met with during the trip. The trunk was about 12 feet high, but after spending some time in obtaining specimens, it was found to be only a form of our common species, *Alsophila australis*, R. Br. The absence of Fern Trees along the coast is only what one would expect, as these plants are usually found in the gully scrubs, often some distance from the coast.

Near the mouth of the river was a very dense

fallen. Many, doubtless, had been brought down the river and washed up by the tides. At the time of our visit a fruit closely resembling, in colour and shape, an Orange, was very abundant. This proved to belong to *Tabernaemontana aurantiaca*, Gaud.

At the Ope River, some of the party brought on board the steamer a specimen of the "green-light fuogua," *Hiatula Wynnii*, B. and Br. This beautiful object gave out its faint green light again as soon as night set in, and was a source of wonder and delight to those who had not previously seen it. The species is not of frequent occurrence. The Papuans are evidently very fond of bright, showy colours, and we always found plants of this character planted near their houses. Some of these may be

THE MUNCHES, DALBEATTIE, N.B.

THE name of Mr. Wellwood H. Maxwell, of The Munches, has long been familiar to all interested in gardening and forestry in Scotland. For many years Mr. Maxwell has taken an ardent interest in these kindred arts, and its results are now seen in the trees and shrubs which ornament his estate, and the flowers with which the gardens are made attractive. A hot August day found one experiencing the regret that one had not gone earlier in the season, as there was now nothing to be seen in the garden. It was certainly not the best time to see hardy border flowers in perfection, but there was more than enough in the way of plant-life to fill up the time available and to make the notes taken too voluminous to permit of proper condensation.

The mansion of Munches is situated close to the River Urr, near where it flows into the Solway. The proximity of the latter gives the estate a climate favourable to many things which in other localities are often tender. The mansion is an imposing, if somewhat plain, pile of Dalbeattie granite. It stands on a portion of the site of the old gardens. On the position occupied by the old house, which was on a knoll so close to the river that it was said one could fish out of the windows, a small garden has been laid out. This is filled with hardy perennials and shrubs, supplemented in autumn by hardy annuals. The latter, as is general in S.W. Scotland this season, are far from satisfactory. The most noteworthy features at the time of my visit were two magnificent *Retinosporas*, the growth of long years. *Cornus mas* elegantissima was also exceedingly beautiful, its colouring being very fine. The borders are mostly edged with *Sedums*, and contain a good collection of *Delphiniums*, *Potentillas*, *Phloxes*, *Papavers*, and such plants, with *Alstroemeria chilensis*, *A. aurantiaca*, and others of more or less rarity. The drought was telling upon some, and, as the water supply is limited, rain was needed.

From this garden we had a look at the many trees and shrubs which have been collected and grown for so long. Mr. Maxwell has taken special pride in forestry, and one does not only see choice trees, but also the results of the care taken to give them full space for developing their true character. Conifers have always been favourites, and here are to be seen the various genera and species which supplied the specimens sent by Mr. Maxwell to the Chiswick Conference. If these delightful trees are favourites, they are not so to the exclusion of others, as other evergreens and deciduous trees are present in unusual variety. The collection is particularly rich in specimens with golden, dark, or variegated foliage, but so planted as to be without the bizarre effect often seen. Only a life-long student of arboriculture could properly appraise the comparative value of the choice trees, yet one could not but admire the noble proportions of a grand old Scots Fir, the stateliness of *Wellingtonia gigantea*, or the good specimen of *Sciadopitys verticillata*, now about twenty-five years old; *Abies Douglasii* Stairi, the white Douglas Pine, which was raised at Castle Kennedy, is a fine specimen of much beauty. *Cupressus* in variety, *Cryptomeria elegans*, and a fine *Pinus Cembra*, may only be mentioned as among the arboreal treasures of The Munches. Maples are apparently favourites, and many species and varieties are represented. There are unusually good examples of the Japanese Maples, which the climate seems to suit.

For its autumn tints, *Parrotia persica* is largely grown, and *Rhus Cotinus* is also called into use. The more popular forest trees such as the Oak are not neglected, but do well in the district. One could spend much longer among these trees and shrubs, but time would not permit of further and more minute inspection.

From the woods we passed into the gardens, where one had again evidence that their owner's tastes are somewhat eclectic. Hardy border flowers are largely used here also. In these, one observed the comparatively new *Rudbeckia*

laciniata Golden Glow, a good plant with double flowers; what had been a good spike of the shy-blooming *Gentiana lutea*, and a short row of plants of *Incarvillea Delavayi*. These deserve more than an allusion on account of their vigour. Mr. Murray, the head gardener, kindly furnished the information that the seed was sown five years ago, and that the plants, grown without protection, were improving yearly. They produced this year an average of four spikes each, and the longest of those in seed measured 52 inches. Their vigour was apparent, and the plants were the finest of this species, the writer has yet seen.

There was a brilliant display of other flowers, although the Sweet Peas had been a comparative failure in a portion of the garden. In a more open border they were quite good. *Mignonette* was in abundance, its fragrance being grateful. Beside it lines of good *Asters* and of East Lothian Stocks were effective. One noted also *Gladioli*, *Crozy's Cannas*, *Lantanas*, *Dahlias*, *Marguerite-Carnations*, and other flowering plants. *Carpentaria californica* was observed in a cool border under a wall, and *Vitis Cœngetia* was flourishing on a sunny wall.

Both Mr. Maxwell and his gardener were regretting the unsatisfactory growth of the Brassica group. This is, however, the common experience in the locality this season, though the comparative failure of Cabbages and allied plants and the prevalence of mildew on Peas has been the cause of much disappointment. A capital crop of perfectly formed and highly-coloured Tomato Eclipse was growing in pits, and a good crop of Melons in a Melon-house.

Out-door fruits have been an average crop, and those in the houses showed excellent cultivation. Grapes looked well. Pears in the orchard-house, with Guavas and the Cape Gooseberry, do not exhaust the numerous fruits grown at The Munches.

The plants in the glass structures would delight my friend Mr. Burbidge, and would require his skilled and facile pen to do them justice. They are the fruits of years of collecting, and include many usually strangers to private gardens. *Fuchsias*, *Pelargoniums*, *Begonias*, *Strelitzias*, *Nandinas*, *Strobilanthes Dyerianus*, *Ceropegia Woodii*, *Kœmpferias*, *Acalypha Sanderi*, *Datura Knighti*, *Crotons*, *Bougainvilleas*, *Cycas*, *Sansevieras*, *Achimenes*, *Hedychiums*, and *Gloxinias*, are only a few things, noted, as it were, at random, to show the varied character of the collection. Like the subjects outside, they are the result of many years of interest taken in plants. Interesting in themselves, many have special associations from having been brought from abroad or raised from seeds sent home by Mr. Maxwell or members of his family in a somewhat wide experience of travel in far-off lands. S. A.

TREES AND SHRUBS.

CRATÆGO-MESPILUS DARDARI.

IN the current fortnightly number of the *Revue Horticole* is described the above-named new flowering shrub, which is a most curious instance of the nature of a stock being influenced and changed by the grafting upon it of another species, and which occurred recently in his nursery at Plantières. He says that the new shrub is exactly intermediate between the Medlar and the common Whitethorn, and is the result of grafting the former on the latter. After many years a shoot appeared below the graft on the stock, which when it bloomed produced bunches of white flowers, sometimes as many as twelve in number, somewhat smaller in size than those of the Medlar, which always has solitary flowers. The new shrub is of vigorous growth, but the stems, instead of being nearly smooth, as in the Medlar, are very thorny. The fruit is rather small, and generally flat. This new shrub will ere long be distributed by Messrs. Simon-Louis, and from its description should, I think, be an acquisition to our gardens. W. E. Gumbleton. (See p. 226).

THE PRINCIPLES AND PRACTICE OF FERN-CULTURE.

(Concluded from p. 201.)

PROPAGATION BY VEGETATIVE MEANS.—Perhaps the most interesting feature of the cultivation of Ferns is their propagation. This is effected along two chief lines—(1) vegetatively, or (2) by means of spores. There are various ways in which Ferns may be vegetatively reproduced. Some, like *Adiantums*, *Nephrolepis*, *Platycerium*, produce tiny plants and bulbils on their roots, which, at the proper time, may be severed from the parent-plant and made to start life on their own account. Others, again, develop young plants at the tips of their fronds, such as some *Aspleniums* and *Adiantums*. These, if the parent-fronds are pegged down to the soil, will emit roots in a short time, and soon after being severed from the frond, grow into plants resembling their parents. Other *Aspleniums*, as *A. bulbiferum*, and a few other Ferns, such as *Cystopteris bulbifera*, produce tiny bulbils on their fronds. This mode of vegetative reproduction differs from the last in the fact that the young plantlets do not develop foliage-leaves until after they have established themselves as independent units, and put forth roots into the soil, and in the fact that while in the former case the offspring become fixed by their roots in the soil before severance from the parent-fronds takes place, the bulbils drop off at an early period, and having food-substance stored up in their fleshy tissues can set about emitting roots and establishing themselves, preparatory to developing into ordinary individuals, at their leisure.

APOSPORY.

There is a species of aberrant vegetative reproduction termed apospory, in which, not as in the *Asplenium*, &c., a "Fern-plant," but a sexual plant or prothallus, is produced in the place of spores. In the *Athyrium filix-fœmina* var. *clarissima* and *Pteris aquilina*, the sporangium suspends its usual function of spore-production and develops a green prothallus in their place. In *Polystichum angulare* var. *pulcherrima*, *Scolopendrium vulgare*, and *Trichomanes alatum*, the prothalli are produced quite independently of the sporangia, as outgrowths from the edges of the pinnae. An abnormally moist environment may be one of the factors inducing this phenomenon.

Ferns with underground rhizomes, such as some *Adiantums* and *Struthiopteris*, as also those with creeping sub-aërial rhizomes, such as *Davallia*, may be propagated by careful division of their rhizomes, care being taken that each severed portion is provided both with a growing-point, root, and fronds, and has not yet started into new growth. Plants such as *Adiantum cuneatum* and *A. Farleyense*, as also some of our common hardy Ferns, such as the *Polystichums* and *Lastreas*, which form a number of distinct crowns, may be easily multiplied by careful division and pulling apart of these crowns, so that each new piece which is to form a fresh plant shall be possessed of plenty of roots and leaves wherewith to start its independent existence. Lastly, the *Nephrolepis*, and a few others, send out runners or sarmenia bearing bulbils at intervals, which, eventually rooting, start life on their own account, and become severed from the parent stem.

APOGAMY.

I have spoken hitherto of vegetative reproduction (i.e., in which the special reproductive organs of this generation, known as spores, take no part as it occurs in the "Fern-plant." But in the sexual plant vegetative reproduction is also known to occur under certain conditions, in which a young "Fern-plant" is developed as an out-growth of the prothallus quite apart from, and independently of, the sexual organs. This phenomenon is known as apogamy. It must be regarded as an abnormal species of reproduction, due, probably, to the peculiar conditions to which the prothalli are subjected. Apogamy is known to occur in *Pteris cretica*, *Aspidium filix-mas* var. *cristatum*, *A. fal-*

catum, *A. frondosum*, *Lastrea dilatata* var. *cristata gracilis*, *Scolopendrium vulgare* var. *ramulosissima*, *Athyrium filix-femina*, *Todea africana*, *T. pellucida*, and *T. rivularis*. In *Trichomanes alatum* apogamy and apospory are combined, the prothalli produced on the fronds being apogamous.

In *Scolopendrium vulgare* var. *ramulosissima* and *Lastrea dilatata* var. *cristata gracilis* prothalli have been discovered assuming partially the rôle of "Fern-plants," for they bore sporangia like those produced normally on the fronds of the asexual generation.

In *Gymnogramma leptophylla* the "Fern-plant" is annual; but the prothallus is perennial, forming adventitious branches, which subsist as tubers in the ground from year to year.

In the *Hymenophyllaceæ*, or Filmy Ferns, the production of small gemmæ, or buds, from the prothallus, is of frequent occurrence, as in *Hymenophyllum* and *Trichomanes alatum*. In *Vittaria*, one of the *Polypodiaceæ*, peculiar chains of gemmæ are formed at the ends of short stalks. In all these cases, the gemmæ on germination give rise to new prothalli. This formation of gemmæ is no doubt connected with the damp habitat of the plants concerned.

It will thus be seen how Ferns, like many other plants, have adopted numerous methods of reproducing themselves vegetatively, i.e., without the aid of spores or sexual organs, whether it be by means of bulbils or tiny plants produced on the fronds, stems, roots of the asexual or "Fern-plant," or on the thallus of the sexual plant or prothallus, or by means of the lateral extension of the rhizome, whose newly-formed portions may or may not become eventually detached from the original parent stock. It would seem also, that, as in the case of many another plant, so also with Ferns, many of those species which for a long period have become addicted to this vegetative method of propagation, have, in some degree, lost the power to reproduce themselves by means of spores or sexual organs. This, however, as in the case of some of the higher plants, may be partly a result of the long treatment under cultivation to which they have been subjected.

The species with an upright caudex or stem, such as the Tree Ferns, some *Lomarias*, and many of our hardy forms, such as the Lady and Male Ferns, which are naturally incapable of having their stems divided, must always be propagated by means of spores.

PROPAGATION OF FERNS FROM SPORES.

The circumstances connected with the development of Ferns from spores, are amongst the most captivating and interesting in the whole history of plant-life. The ordinary Fern-plant, consisting of stem, roots, and leaves, so well known to everyone, can hardly, strange as it may seem to say so, be considered as representing the ordinary normal stage of the plant's life-history; the latter must rather, as in the Moss-plant, and all flowering-plants, be that in which the sexual reproductive organs are developed—organs which in the "Fern-plant," as "the man in the street" knows it, are entirely absent. The Fern-plant is rather to be regarded as a new stage—a new generation, as it were—intercalated into the life-history, when the ancestors of these plants first assumed a terrestrial habit of life. On adoption of this terrestrial mode of life, the plant, which before was a simply-built organism, gradually became a highly complex being, with strongly differentiated tissues, which eventually, in the course of ages, culminated in the "Fern-plant" as we know it to-day. The main object of this greater differentiation of the various organs, and their increase in size and number, was the production in as large numbers as possible of asexual reproductive organs, known as spores, adapted by their minute size and lightness for transportation by the wind to a great distance. But the original, simply-built sexual generation, still, of course, persisted, although it, too, assumed a terrestrial life, though confined always

to situations sufficiently moist to allow of the antherozoids, or male reproductive bodies, swimming about and reaching the female organs. Every new individual developed sexually from the simple primitive generation gives rise to the "Fern-plant," or asexual generation. Each spore thrown off from an asexual "Fern-plant" develops in its turn into a sexual plant, bearing antheridia and archegonia, and commonly termed a "prothallus." This is the highly interesting and absorbing cycle of the life-history of the Fern. The multiplication by means of spores enables the plant to spread itself widely over the face of the earth; but there must always be the constant cyclic return to sexual reproduction at a given period, or else the vigour and extensive distribution of the race could not be maintained.

The compost used on which to sow the spores should consist either of the mixture of loam, peat, leaf-mould, and sand above given, when the soil should be well sterilised, so as to destroy all spores of other Ferns or of fungi, &c., which may be lurking therein, or it may consist of finely-broken bits of peat, sandstone, brick, or loam; we used a mixture of chopped sphagnum-moss and finely-broken crocks. The surface of the compost in the pot or pan, after being moistened, should be thickly covered with spores, and the pot or pan then covered with a glass shade or lid, so as both to keep the surface moist and to prevent the entry of any foreign bodies. The pots or pans should thereafter stand in saucers, and be watered from below, so that the water rises from the saucer up through the soil to the spores on the surface, and thus constantly keeps the latter damp. If watered from above, the spores are sure to get displaced and disturbed.

After a certain period the spores will begin to develop, by the extension of its tissue, and the production of chlorophyll therein, each into a green body, the prothallus bearing the sexual reproductive organs, the antheridia and the archegonia on its lower surface. Each such sexual plant exhibits no differentiation into stem and leaf, like the asexual plant, but consists simply of a flat thallus, like a Liverwort, in which stem and leaf are united in one, and roots emitted from the lower surface of the latter. The moisture in which these prothalli must constantly be bathed by means of adequate watering from below, affords the medium in which the spermatozoids, escaping from the antheridia, are enabled to swim about and reach the archegonia, whose ova they fertilise.

Small areas of the mass of prothalli, after they have reached a certain age, must be separated, and placed in pans, and when the young Fern-plants which have developed from the fertilised archegonia have attained a certain size, they require to be pricked out in rows in pans or boxes until they are large enough to be planted in some suitable shady situation out-of-doors.

Thus we see how different must be the cultural treatment of these lowly cryptogamous plants from what obtains in the higher circles of plant-life, and a careful study of their life-history will necessarily greatly aid us in acquiring a right comprehension of the why and wherefore of their peculiar mode of culture. *W. C. Worsdell, F.L.S.*

FLORISTS' FLOWERS.

CHRYSANTHEMUMS.

PLANTS cultivated to produce large blooms for exhibition or home use will require considerable attention during the present month. Stimulants will need to be given, and the foliage must be kept free from any pest.

FUNGOID PESTS.

Mildew is capable of creating much mischief in a short time if not checked in its infancy. In September mildew generally makes its appearance, especially after an exceptionally hot and dry August. It is generally found on the underside of the leaves, and

too often has obtained a strong hold before its presence is suspected. Dry sulphur scattered over the affected parts, when the leaves and atmosphere are dry, will as a rule arrest the spread of mildew; but when it has obtained a firm hold, much more drastic measures are necessary to eradicate the pest. I have found nothing equal to the use of quicklime and sulphur, whether the mildew be upon *Chrysanthemums*, *Roses*, or other plants. Place 2 lb. of sulphur and 2 lb. of unslaked lime in 10 quarts water, and boil for twenty minutes. Use 2 wineglassfuls of this mixture to 4 gallons of clean water, and syringe the plants with it. A Vermorel sprayer, or an ordinary syringe with the jet affixed, which causes a single stream, is the best method of applying the liquid; by placing the forefinger over the orifice the liquid can be directed upwards, and spread over the plant where required. If a slight discoloration of the leaves follows from the sediment of the mixture, it will not be injurious, but can be removed, if desired, by a vigorous washing with clean water.

Although some collections of plants are badly affected with "rust" this season, there are plenty that have not yet shown the slightest trace of it. This "rust" pest is a source of much trouble if treated with neglect, but is easily combated if intelligence is brought to bear upon it at the right moment. If upon the first sign of this fungus the "rust" be touched with a small brush dipped in methylated spirit or petroleum, it will completely kill the spores, and thus check the growth before the roots have time to take a firm hold of the leaves.

"TAKING" THE BUDS.

No time should be lost now in securing all flower-buds as fast as they form. The early days of September are late enough for bud formation, even for the incurved section. Directly the buds are perceptible in the point of the leading shoots, remove promptly all growths which push from below the flower-bud, and which are really caused by the formation of this flower-bud. By an early removal of these, the whole energy of the plant will be concentrated in the development of the selected bud. But one flower on a shoot is sufficient, for thus only can the desired size, colour, and form of flower be obtained.

If the best results are wished, it is imperative that the plants be encouraged by the affording of frequent stimulants. It may be remembered that frequent doses of diluted manure are preferable to applications of strong stimulants; also that a change in the stimulant afforded is occasionally of absolute necessity. *E. Molyneux.*

THE DANGER OF OVER-FEEDING IN CULTIVATION.

AFTER a pretty wide reading of garden literature during the last fifty or sixty years, I remain impressed with the idea that many of our writers on gardening are not sufficiently guarded in their recommendations of the use of manures. The practical man who knows his business and thinks before he acts is not likely to be led astray, but in these days when so many who have little knowledge of gardening are anxious to make it a hobby, they and their assistants are open to be unfavourably influenced by the too general or too emphatic recommendations of this or that manure. I met with an instance, not very long ago, of a man watering some Rose-bushes with liquid manure from a sewage-pond, which instead of increasing the size of the flowers, as was intended, caused both flowers and leaves to turn yellow and drop off. I have often seen spots of ground on which heaps of manure had lain during winter refuse to grow anything until ridged up and well exposed to the air for a season; if plants and trees were put on them without this intervention, they dwindled and died, poisoned by over-feeding. These, I admit, are extreme cases; but there is a gradual and almost imperceptible poisoning by over-feeding often going on from day to day, year to

year, culminating in serious results at last, made manifest by an overdose, or by some peculiarity of the season. It would, perhaps, not be difficult to prove that many of our strains of florists' flowers have been brought into a delicate and tender state through over-feeding, with the view of getting large flowers. Cultivators of these should be wary in this practice; feed liberally [at sufficient intervals], but do not gorge your plants.

It is the same in the vegetable as in the animal kingdom, nutrition does not depend on what is taken into the system, but upon what is digested. I remember the Potato on a neighbouring farm prior to the appearance of the Potato-disease being an easily cultivated esculent free from disease and serious insect attacks, until it was deluged with fresh manure, and its functions of flowering and seeding also arrested with the view of adding to the number and size of the tubers. Then came disease with all its sad consequences. This I attributed principally to over-feeding, and I did not come to this conclusion without ascertaining the antecedents of cultivation of the particular crop under observation, and studying the individuals with the aid of one of Ross's best single microscopes.

If a second case in point were needed, one might quote the Hollyhock. Originally, one of the hardiest of biennials; it almost died out a few years ago, after previous years of high cultivation with the view of getting giant spikes and flowers. But numberless are the instances of debility met with during a long life, and which rise to my mind while I write, which it seems most reasonable to attribute to what is called high cultivation, brought about principally by over-feeding. *Wm. Paul, Paul's Nurseries, Waltham Cross.*

THE HERBACEOUS BORDER.

ANTHEMIS TINCTORIA (*New Variety*).

By way of distinction, I have ventured to apply the name, *Coed Derw*—that of Mr. Buxton's residence at Bettws-y-Coed—to a variety of *Anthemis tinctoria*, which originated there. [Why not call it Buxton's variety? Only a minority speak Welsh. Ed.] In 1897, Mr. Buxton, in a letter regarding other plants, mentioned this seedling as continuing longer in bloom than any others in his garden. As this prolonged blooming is, at times, the result of climatic conditions, or of the character of the soil, Mr. Buxton kindly sent me a piece of his plant, so that the test of complete change might be applied. It came into bloom last year, with the other plants of the species grown here, and continued to flower without intermission until nearly Christmas, in the open. This season, the plant again displays the same persistent flowering habit, and one is disposed to look upon this variety as quite an acquisition to those who like the *Dyer's Chamomile*. The *Coed Derw* form is, moreover, a good one from the point of view of a garden flower. The blooms are not quite so bright in their colour as *A. t. Kelwayi*, but the yellow is good enough to please anyone, and the flowers are also well formed.

It may be said with truth, that by cutting them back, almost any plants of *A. tinctoria* will produce late flowers. This is quite true, but the *Coed Derw* form does not require to have this done, and blooms on without the removal of the withered flowers, although the plant looks neater and less untidy if these are removed.

BOLTONIA ASTEROIDES.

Although a trifle too tall for my taste if grown in strong soil, *Boltonia asteroides* has been a favourite here since it was given me by a friend a number of years ago. Resembling to some degree the perennial *Asters*, it has yet some general features which, as seen in the garden, give it a distinct appearance. It is difficult to describe these, and it is equally difficult to tell why one has grown to like the plant. There is something particularly pleasing in its tall wand-like stems, clothed with lanceolate

light green leaves, and its pretty, well-formed, flesh-coloured flowers. The precise colour of these is not easily indicated by any other term than "flesh," but it is soft and pleasant to the eye. In this garden it grows to about 4 feet high, and comes into bloom early in August, continuing in flower for a long time. It is easily propagated by division, and has the advantage over a considerable number of the *Asters* that it is not inclined to run at the root, to the injury of neighbouring plants. It is one of our many North American plants long introduced, but little grown.

HELENIUM NUDIFLORUM.

So far as one knows, it does not seem to be definitely settled that this is the correct name of the plant introduced as *H. grandicephalum striatum*, but the weight of evidence is, perhaps, in favour of superseding the latter, by which the plant has found its way into gardens. It is now so well known that it does not require much said in its favour; but one is desirous of ascertaining if the differences seen in the flowers in this country are the results of soil or climate, or are due to variation among the plants themselves.

The plant grown here, which was procured soon after its introduction, always produces flowers with a large proportion of red upon the petals; these being, indeed, principally of that colour. This season they are very brilliant, but in most other gardens I have seen this season, and in stands of herbaceous flowers at shows, this *Helenium* has shown only a small degree of crimson, so small, indeed, that the flowers are only made rather dull thereby. Perhaps the Rev. C. Wolley-Dod, who, I know, has been at a great deal of trouble to find out something about *Helenium nudiflorum*, may be able to furnish some information upon the question I have ventured to raise. If the flower is to retain its place in gardens, only the best coloured forms—if such there are—should be grown. If, however, the poor colour of some of the plants seen is due to improper cultivation, we may be able to give them the treatment they require. My own plant is grown in a light and dry soil, so dry that it has required occasional soakings with water in the dry season we have just passed through. *S. Arnott, Dumfries.*

AMERICAN NOTES.

THE ANNUAL CONVENTION OF THE SOCIETY OF AMERICAN FLORISTS.

[From our Own Correspondent.]

THE 15th annual convention of this trade organisation held at Detroit, Mich., August 15 to 18, has proved to be one of the most successful that the body has held. The strange addition to the title of the Society, which was made so as to give it a semblance of being something more than a trade affair, has not apparently accomplished what was intended, and one of the most prominent members very recently alluded to the ornamental-horticulturist part of the name as an excrescence, which by its very sound and suggestion seems to imply a lurking desire for amputation or excision. But be the name what it may, and let the ruling powers be never so suave to the private gardener and amateur element, the Society of American Florists, as it is still called, remains a distinctly trade society, with its main interests centred in the commercial plant grower and raiser of cut flowers. Its end-all is in the retail florist's store. It is a great institution, which concentrates itself once a year in some prominent city, indulges in a deal of talk and amusement, and then lies low until its next convention, except so far as, occasionally, a committee may do a little work in the interim.

The Society also has a register bureau for new plants introduced into the trade, for which kindly service it makes a tax on the one registering the name. Now this register is, after all, merely a record of a name, and carries with it no manner of certificate as to the value of the plant or flower. The arrangement, however, works well, and helps to obviate the appearance on the market of several different varieties under one name.

The city of Detroit is, indeed, a favoured spot. It has grand parks, as, indeed, have most representative American cities. The city itself is only two years short of 200 years in age, and was originally French. The president, Mr. Rybn, of Chicago, is a well-known, popular and progressive florist;

his address was a strange mixture of journalistic comment on current events, and a "speech" of Queen Victoria on the opening of a parliament at Westminster. It was observed that the florist trade did not get a fair share of benefit from the experiment stations, but it was more truly added that this was due to the florists themselves. "We have neglected to make our wants known in an intelligent way, and have not accepted gracefully what little work has been done." It is alas, too true, that here, where so much is done for horticultural investigation by the public purse, that the florist has, to a large extent, not availed himself of it. There are some of them who "know it all," and are therefore bopeless; but as a younger generation is getting into the lead, an alteration is gradually being made. The president himself is a graduate of Cornell.

CO-OPERATIVE BUYING.

The society has been experimenting in co-operative purchasing, and the work of the committee in charge appears to have been very satisfactory, so much so, indeed, that it would look as though a permanent organisation will be effected for that purpose.

THE TARIFF.

Of course the working of the tariff law came into discussion, and as a result of the intervention of the Legislative Committee there is likely to be less friction between importers and the appraisers than was the case last season.

The Protectionist squeals when the shoe is on his own foot, and he can see it. As a result of a duty of 140 per cent. on glass, the cost of glazing has of late been rapidly advancing. The figure practically excludes foreign glass, and the domestic manufacturers are holding up the price at a figure that is almost impossible for florists. One man suggests a "trust" in plants. We have heard of this before, but how the selling price of such stock as a florist manufactures can be controlled by a board passes comprehension. Anyhow, the whole case seems to make a good argument for free-trade, or, at all events, for duties for revenue purposes only. The most practical suggestion—and it goes to show not only the dire straits the trade is in, but also the great capacity of the Society of American Florists for looking to its trade interests—is a proposal to start a glass-making factory of its own! It is a stock argument of the protectionist party that the foreign manufacturer pays the duty, and not the importer (= consumer). Theory is one thing and practice another, and one speaker voiced the truth when he said "When the glass tariff is reduced, the price of glass will come down." If the florists are in earnest they have their opportunity, for on the day after the subject was discussed a telegram was received offering a glass works for sale!

But these annual affairs are not all business; there is recreation in the shape of excursions, and inter-urban contests in shooting and bowling, the latter a game that has become an essential adjunct to the American florists' outing. Valuable prizes and challenge trophies are given, and now we have organised a National Florists' Bowling Association with ten cities in the league.

THE NEW PRESIDENT.

The president-elect, and who will preside at the next convention, is Edmund M. Wood, of Natick, Mass., where he is connected with the famous Waban Rose conservatories. He has been an active worker in the Massachusetts Horticultural Society for years, and since associating himself with the S.A.F., has taken a deep interest in its affairs. Mr. Wood is also concerned very largely in numerous other commercial enterprises, and is a sound business man.

THE VICE-PRESIDENT.

The vice-president-elect, Mr. Paul M. Pierson, is a well-known and leading florist and plantsman, carrying on business at Tarrytown, N.Y. He was born in Boston in 1835, and is the son of P. R. B. Pierson, one of the most celebrated of wood engravers. At the age of sixteen years, he entered the large establishment of Peter Henderson & Co., New York. His aptitude for handling and placing advertisements brought him to the attention of Mr. Peter Henderson, and he was put in charge of this very important division of the business.

When not yet twenty-three years of age, Mr. Pierson returned to Tarrytown, and commenced business on his own account as a retail florist, in a small way, in 1878. Shortly after this the *Harrisii* Lily began to attract attention in America, and Mr. Pierson was one of the first to see the commercial possibilities in this now popular bulb. A trip to Bermuda convinced him of the suitability of the islands for the successful production of the *Harrisii*, and in 1881 he entered into partnership with General Hastings for its cultivation in Bermuda. In 1895 a combination of the producers in Bermuda, under the title of the Bermuda Bulb Company, was formed, and Mr. Pierson was chosen president and distributing agent for the United States and other countries. From various causes this combination was but short-lived. He was the first to have the Lily on the market at Christmas, and for some years held a monopoly on it. The celebrated American Beauty Rose and Meteor have been largely introduced through his efforts.

NEW YORK, NEXT YEAR.

The next convention of the Society of American Florists and Ornamental Horticulturists will be held in New York City, the most available point, by-the-by, for any European friends who desire to meet a maximum of horticultural men with a minimum of travel. A three weeks' trip from London would enable one to just do it—think it over, some of you!

CULTURAL MEMORANDA.

CENTAUREA RAGUSINA.

THIS plant is very valuable for bedding purposes, where its bright silvery foliage helps to tone down the colours of flowering plants in the geometrical garden, or indeed, in any part of the flower-garden. *C. ragusina* will thrive in almost any position throughout the summer months, although it is desirable to keep it from the drip of overhanging trees. Its propagation has been

soil and sharp sand. Put one strong cutting in the centre of a small thumb-pot, or dibble several around the sides of a 3-inch pot; if the latter method be adopted, greater care will be necessary when potting them off, for the fibrous roots are very tender. If the side-shoots be pulled downward from the old plant, and afterwards carefully smoothed off with a sharp knife, there is less chance of decay setting in than would be the case from cuttings made in the usual way.

The pots containing the cuttings should be plunged in fibre or sawdust, and kept shaded and

FIG. 77.—PEAR BEURRE RANCE AT GORHAMSBURY PARK, ST. ALBANS.

(SEE P. 219.)

attended in many cases with unsatisfactory results, hence the scarcity of the plant in some gardens. The error usually made is that of affording a too copious supply of water to the cuttings; one good soaking after they have been inserted is sufficient for many days.

A good bed of leaves and stable-manure with a frame placed over it will answer admirably, but it must be allowed to become partially spent in order that any steam may pass away, otherwise the moisture will cause the woolly stems of the plant to decay. Take the cuttings in September, and select shoots that are well ripened and firm; use a compost of two parts loam, and one part each of leaf-

close, but admit a little air to the frame during the middle part of the day.

I have raised annually a good batch of plants from seed gathered when ripe, and sown immediately. As soon as the seedlings form the first rough leaf, they are potted off singly, and encouraged to make growth by placing them on a shelf in a temperate-house. They are potted on in the early part of the year, and much stronger plants are thus obtained than were the seeds not sown until spring. Plants so raised from seeds have proved true, and have generally made better plants than those from cuttings. *H. T. Martin, Stoneleigh Abbey Gardens.*

NITROGENOUS MANURES.

GREAT progress has been made in the use of commercial fertilisers in the garden during the past few years, and Prof. E. B. Voorhees, of the New Jersey Experimental Station, has done yeoman service to the cause in a recently issued bulletin of the State, by showing how to use the materials containing the plant-food elements in order to secure the largest return from their application to the different crosses. He says that while the three constituents—nitrogen, phosphoric acid, and potash—are all essential, because all are liable to exhaustion, nitrogen is the one that should receive more careful attention than the others, first, because it is the most expensive of the three to supply; second, because the forms in which it exists differ so widely in their rate of availability or immediate usefulness to the plant; and, third, because when it is applied in an immediately available form, it is so readily soluble and so completely carried in the soil-water that there is great danger of its loss by drainage.

The mineral elements, potash and phosphoric acid, on the other hand, are relatively cheap as compared with nitrogen. In the case of potash, the availability of the different forms in which it is usually obtained is not a matter of importance, since all are readily available, while in the case of phosphoric acid, the soluble and immediately available forms contained in superphosphates may be obtained quite as cheaply as many of the organic forms, as in ground-bones, which are not so immediately useful. These mineral elements, too, however soluble when applied, are fixed by the soil, and are thus not liable to rapid loss by drainage. When the gardener applies the minerals or materials containing phosphoric acid or potash in their best forms, his expenditure is not so great as for an equal amount of nitrogen; he can place his dependence upon its presence there during the growing season, and that the plants can readily obtain it, and he can readily obtain it, and he can rest assured that if the one season's growth of the plants does not use the entire amount supplied, the residues will remain for future crops, though they may be less readily acquired by them.

In the next place, the gardener should remember that the best use of nitrogen is attained when it is applied to soils in good condition, rather than to poor or worn-out soils, and he should also consider whether, even if the increased yield from its use should be as great as can be expected, there is a possibility of obtaining a profit. The soils to which high-class fertilisers are applied should possess good absorptive and retentive properties, in order that the materials applied may be held and retained for the use of the crop, and the physical character also should be such as to permit a ready penetration of heat, and an easy circulation of water, conditions which are essential in order that the activities within the soil may be unimpeded, thus making it possible for the plants to obtain their needed food. In too many cases good plant-food is wasted, because applied to mixtures of sand, clay, and other materials, rather than to soils in the true sense. *J. J. Willis, Harpenden.*

(To be continued.)

SOUTH AFRICAN NOTES.

FORESTRY IN THE TRANSVAAL.

ABOUT a year ago I propounded in a local paper a scheme which I have long pondered over, but which, from its very vastness, attracted no public notice or approval whatever. Convinced as I am, however, that there is something practical in the proposal, I crave space to restate it here.

Looking at any good map of the Transvaal, we find a tract of flat, treeless table-land, between 5,000 and 6,000 feet above sea level; and roughly speaking, 150 miles in extent from east to west, with a breadth of 100 miles from north to south,

From this collecting ground, which has an average annual rainfall of about 27 inches, all the larger rivers of South Africa may be said to take their rise. The Vaal, Crocodile, Olifants, Tugela, Sabie, Umfelozi and Maputa rivers, which water the Cape Colony, Transvaal, Free State, Natal, Zululand and Swaziland, all have their beginnings on the high Veld. This table-land is almost destitute of trees, except in sheltered valleys; and in a word I have proposed to clothe this tract of land with trees, and the certain, though distant result, will be that the whole of South Africa will reap the benefit.

At present we have a vast arid plain covered with short grass over which heavy thunder showers rush to find the shortest way to the sea. The radiation of moisture is excessive during the cloudless day, and the cold is biting at night. Cover the ground with trees, and you arrest the storm-water to a great extent, and replenish the springs. The country is as bare of clothing as the natives; such a project, if carried out, means employment and a living to thousands of people, and a settled industry for all time.

To set such a gigantic business going, the Government alone is able and long-lived enough; for as M. Bagnier remarks, in his *Elements of Sylviculture*, "The state, which is, so to speak, imperishable, is the only body which is able to produce the most useful timber, for private companies are obliged to guard against the accumulation of a large capital in the shape of standing timber."

I confess I have brought these facts before this Government, but hitherto without the smallest effect. All the timber used for the mines, and for building and general purposes, is imported at vast expense. Even fencing-poles of *Acacia mollissima* are now largely imported from Natal. Some time ago it was proposed to import blocks of *Eucalyptus diversicolor* from Western Australia, for paving the streets of Johannesburg, but the cost was prohibitive.

Readers of my previous notes are well aware that our soil and climate is very well suited to many kinds of timber-trees. The trees I should name as most suitable to begin with are *Eucalyptus viminalis*, *Acacia dealbata*, and *Pinus pinaster*; to be followed by *Pinus insignis*, *Casuarina tenuissima*, *Eucalyptus Globulus*, *Quercus suber*, *Acacia mollissima*, *A. melanoxylon*, and in warm, frostless places, the famous Karri Gum, *Eucalyptus diversicolor*. R. W. Aitken, Curator, Joubert Park, Johannesburg.

COLONIAL NOTES.

CALCUTTA.

THE annual report of the Government Cinchona Plantation and Factory in Bengal for 1897-98, and of the Royal Botanic Garden, Calcutta, for the same period, are now before us. As regards Calcutta—"The weather during the year was more normal than that of the preceding two years. The show of Orchids regained its old standard of excellence. During the year the gardens were improved by extensive repairs to the river banks, and repairs to the Roxburgh Avenue were also taken in hand. . . . An interesting introduction to India during the year was *Polygala butyracea*, an African species which yields an excellent vegetable oil. . . . The collection in the herbarium was increased by 10,672 specimens."

In Bengal the season was also normal as regards the weather, and there were during the season no specially marked fluctuations in the quantities of sulphate of quinine or other products of the plantation.

PLANT PORTRAITS.

NECTARINE EARLY RIVERS, *Bulletin d'Arboriculture*, &c., July, 1899.

ANSELLIA CONGOENSIS and A. CONFUSA.—These, according to M. Laurent, appear to be variations of one species, but they have very different geographical areas. Both are illustrated in the current number of the *Revue de l'Horticulture Belge*.

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By C. R. FIELDER, Gardener, St. James's House, Malvern.

Epiphyllums.—Plants which have been shaded during the growing season may now be exposed to full sunshine, and be given more ventilation. For the present an airy and light position in the greenhouse will suit them. When they are required to flower, they may be placed in a temperature of from 55° to 60°, when they will soon come into bloom, and may then be removed to the conservatory. Throughout the winter, and until growth commences in the spring, only sufficient water should be afforded as will keep the foliage plump. Avoid over-potting, but when re-potting becomes necessary it should be done in the spring just when the plants are commencing to grow. As much of the old soil as it is possible to take away without injury to the roots should be removed, and the plants potted in a compost of an open and gritty nature, such as one formed of three parts sandy loam, one part peat or leaf-soil, and plenty of coarse silver-sand, together with a little broken mortar-rubble. The pots should be thoroughly well drained. After potting the plants, place them in an intermediate temperature.

Azalea indica.—If wet weather should set in, plants which are out-of-doors should be placed in their winter quarters without delay. If tying be contemplated, let it be undertaken as soon as possible, in order to allow the foliage and buds to assume a natural position. Examine all *Azaleas* closely, and if thrips be detected prompt measures should be adopted in order to thoroughly cleanse the plants. This operation has been greatly simplified of late years by the introduction of efficient insecticides. Plants which have not been repotted may be greatly assisted now that the flower-buds are being formed, by affording them an occasional application of weak liquid-manure.

Camellias.—Any necessary cleaning may be much more readily performed before the flower-buds become prominent than afterwards. Shading may now be dispensed with, except in the case of plants growing near the glass in structures having a southern aspect, where it may be retained until the end of the month. Continue to ply the syringe freely during bright weather, and afford a plentiful supply of water to the roots.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

The Morello Cherry.—Trees from which the fruits have been gathered should be cleared of the old fruiting wood; and the young shoots still growing freely, tacked temporarily to the wall. Wash the trees with clear water, which should be applied with some force to cleanse them from dust and dirt, which generally accumulates during the time ripe fruit is hanging. Should any traces of black-fly be seen, the Quassia solution or some similar insecticide should be used to destroy them.

Peaches and Nectarines.—If the young growths have not been kept nailed or otherwise fastened, this should be done forthwith, and they will become the better matured before winter. Those trees from which the fruits have been gathered may now be relieved of the old fruiting growths that would be cut away at the winter pruning. In the case of early fruiters, such as Waterloo, Alexander and Amsden June Peaches, and Early Rivers' Nectarines that have fruited differently and made strong rank growth, it will not be too early now to set about root-pruning them, with a view to checking growth and inducing fruitfulness. If this operation be done early, a crop of fruit may be had from such trees next season. The borders should be watered a few days before root-pruning is commenced. Take out a semicircular trench at a distance of 4 feet from the base of the tree, and cut all roots clean away at this distance. Next work the soil carefully away from the roots up to a distance of 2 feet from the stem, and if strong tap-roots exist, burrow under the ball of soil until they can be reached and removed. Cut off with a sharp knife the points from all the strong roots, further reducing their length to about 2½ feet from the bole of the tree. If the soil be of a heavy nature, mix with it

some old lime rubbish, wood ashes, and charcoal before relaying the roots. I do not advise new loam to be added to the roots of fruit trees when root-pruning, as they soon make strong growth again when encouraged in this way. When returning the soil, ram it well under the ball and tread it firmly about the roots. Keep the roots in a horizontal position and near the surface, spreading them out evenly, and placing some of the finest soil about them. A day or two after the operation afford a good watering; and if the weather be dry, syringe the trees overhead occasionally to prevent flagging of the leaves. With Peach-trees that produce good crops, root-pruning is unnecessary; but young trees often require one or two such operations before growth is checked, and they are brought into a fruitful condition.

Miscellaneous.—Late Plums will require protection from flies and wasps, and for this purpose thin canvas should be spread over the trees, and tacked down closely around the edges. Coe's Golden Drop, Brahy's Late Gage, and Reine Claude de Bavay are three late varieties quite worth such protection. Ordinary garden-netting placed over the trees in five or six thicknesses is also a partial protection, and where the former material is not available, this may be used. Trees that have been budded should be looked over carefully, and the ties around the buds loosened. If the buds have commenced to grow, the surrounding shoots upon the stock may be removed, that more vigour may be thrown into the bud-growth, and the shoot produced ripened off before winter. Peaches may yet be budded. Filberts and late Cob-nuts should be gathered while they are yet firm in the husk, and if it is desired to keep them late, stored in air-tight receptacles after they have been slightly dried.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Bedding-plants.—The propagation of the chief bedding-plants should now be completed as early as possible, for if they be struck late, the losses will be heavy during the winter months. Examine boxes that have been filled with *Pelargoniums*, and if any have damped-off, or are withered, replace such with cuttings of the same varieties, allowing them to remain exposed for a few hours before being inserted. *Coleus*, *Iresines*, *Heliotropes*, *Ageratums*, and other soft-wooded plants, as soon as the cuttings have formed roots, should be afforded more air by tilting the lights; and gradually expose them to more light, so that after another month they may be removed to a coal ash-border, for if placed on shelves the soil becomes dry, and the young and tender roots soon perish. If large plants of *Fuchsias* are required for vases or beds, the cuttings are best struck at this season, and potted-off early in the new year; but if smaller plants are needed, cuttings taken from store-pots in the spring will answer the purpose equally well.

Cyclamens (Hardy).—These form delightful cushions of foliage and flowers, and blossom at a season of the year when outdoor flowers are scarce. *C. europæum* and *C. Hederaefolium* afford a continuance of flowers in the early autumn months, and they are closely followed in the new year by *C. vernum*, *C. ibericum*, and *C. Coum*. They show to advantage in a position on a north border, in shady nooks in the rock-garden, or under evergreen trees. The latter end of this month and in February are the best times to plant the corms, but the present time is preferable, as the soil is in a better working condition. Before planting, the ground must be well drained, and if the soil is of a retentive character, some leaf-mould and old mortar-rubbish should be well mixed with it, or a special compost of rich loam, leaf-mould, road-grit, and old mortar-rubbish placed to the depth of 12 inches. This should be well trodden to make it firm. From 1 foot to 18 inches apart is a sufficient distance to plant the corms, and the crown should be placed just below the surface. These usually take two seasons before they become thoroughly established; afterwards they grow to a larger size, and flower profusely. If the flowers are allowed to remain on the plants, seed will be produced, and soon form a large colony of plants. The deeper tints of red are the best to plant, as the blooms pale to a lighter colour after being out a few days. Where plants have been in the same ground for some years, afford them a light top-dressing, consisting of fine mould, with a little

soot, and Clay's fertiliser; or a weak solution of cow-manure water may be applied occasionally, when the plants are growing freely.

Roses.—Briars that were budded, should now be looked over, and the tying material removed from the buds. If any of these have started into growth, the Briar shoots should be shortened back, so that the strength may be thrown into the young shoot; but if the buds are dormant, it will not be advisable in any way to check or stop the Briar shoots, as the time is too limited to enable them to make shoots sufficiently strong to pass safely through the winter.

Miscellaneous.—Sub-tropical plants will now be at their best, and further applications of water will not be necessary. Tritomas, Pampas-grass, Acanthas, Bamboos, and other soft-growing plants, will require to be kept drier at the roots in order to afford them the opportunity to perfect the growths they have made, and go to rest before severe weather occurs. Remove dead leaves and seed-pods from Begonias, also select and label seedlings, in case early frosts should come and destroy the growths.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Potatoes.—As soon as the tops have decayed, no time should be lost in lifting the main and late crop Potatoes. In digging, care must be taken not to damage the tubers with the fork, and to choose a dry day for the job, commencing early in the day, and leaving the tubers on the ground till the afternoon. The damaged tubers, or those having a diseased appearance, should not be placed with those stored for consumption; and those of middle size, suitable for planting, should be stored apart. If there are large quantities, the bulk of the tubers may be placed in conical heaps or ridges out-of-doors, and moulded over. A ridge need not be more than 4 feet wide, and the spot selected for storage should be elevated and dry, and partly sheltered from the sun.

Cauliflowers.—The late crops of this vegetable now turning in should have the central leaves bent over the heads, in order to keep the curd white and afford a protection against early frost. After frosts set in, it is well to lift the more forward plants with a good ball of soil, laying them close together in trenches in some suitable out-of-the-way part of the garden.

Beet.—Some roots of the early varieties may be taken up and stored, although the main lot need not be disturbed for a month. When it is feared that the roots will grow too large, it is better practice to lift them than to let them grow larger, and lay them in trenches with the crown of the roots just below the level of the soil. When frosty weather comes, a covering of soil three inches thick will afford good protection. By this method of storing Beet, the roots keep sound and of good flavour till the spring.

Miscellaneous.—Now that rain has fallen generally, weeds may be expected to make their appearance everywhere, rendering the use of the hoe imperative, in fact every bit of land where a hoe can be used should be hoed in dry weather, and whilst the weeds are young. Liquid-manure should be copiously afforded to Leeks and other growing crops on soils that are of a light nature, or when extra large size is wanted. The Vegetable-Marrow beds may also require moisture, for although rain has wetted the surface, the lower part of the bed may be very dry, and require large quantities of water as well as liquid-manure to moisten it.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Aerides will now need to be watered with the utmost care, or the much-dreaded "spot" will appear upon the leaves. In the first place, if the sphagnum-moss has grown long, the tops should be picked off or the moss thinned out as may be most convenient. Thus, the water will not be retained in such large quantities. The long roots may be tied in where possible to the baskets or other receptacles. Do not continue to syringe the plants overhead, and afford them only sufficient water to keep the sphagnum-moss and drainage material in a moist condition. The species *A. Fieldingi*, *A. crassifolium*, *A. odoratum*, and *A.*

japonicum, being grown in the Cattleya-house under drier conditions than the warmth-loving species, are not as liable to suffer from "spot," but these now having ceased to grow should also be afforded a much lessened supply of water.

Saccolabiums require drier conditions than any of the Vanda tribe, their thick leathery leaves being more adapted to withstand drought. An excess of moisture at this season, when they are immature, in conjunction with a low temperature in the morning, is very harmful. *S. curvifolium*, *S. guttatum*, *S. Blumei*, *S. giganteum*, *S. premorsum*, &c., need little water during the winter months, atmospheric moisture being almost sufficient for their needs.

Vandas of the tricolor section, although rooting freely, should be treated according to the above directions, also affording them more light and air than formerly.

Vanda Sanderiana, now developing its flower-spikes, should be given a light position in the East India house; keep the sphagnum-moss moist until the flowers have been removed, which should take place soon after the buds have expanded. Few orchids suffer so much from flower-production as this species; and weak plants should not be allowed to flower at all.

Vanda cœrulea, also developing its flower-spikes, should be given a moderately cool, light and airy position, restricting at the same time the supply of water so that the material will become dry in the course of a few days. The difficulty attending the cultivation of this species is in large measure due to the varying altitudes of its native habitats and the ignorance of the cultivator as to the conditions under which his particular specimens were found. Those from the higher regions root freely and thrive generally during the autumn months when placed in a cool house, whilst those from lower elevations require much warmer treatment. If importers would only tell us more about the plants they sell to us there would be a vast gain. When growth is completed, remove all the sphagnum-moss, leaving only the crocks to hold the little moisture necessary.

Angraecums should on no account be allowed to remain dry for any lengthened period, even in the winter, but now a gradual decrease in the water supply should commence. If the plants remain dry for a day or two only, no harm will result, and the increased amount of air that will be admitted to the rooting material, will have a purifying effect.

Phalenopsis usually grows very rapidly during this month, and great care must be exercised in order to obtain an equally balanced atmosphere and temperature. A slight scratch or puncture is sufficient to produce decay and loss of one of the fleshy leaves if a cold moisture-laden atmosphere prevail. When decay is noticed at the apex, it can sometimes be checked by severing the leaf with a sharp knife below the affected part, and keeping the plant drier for a day or two. *Phalenopsis* do not require nearly so much water applied to them direct as is generally supposed. Root action and leaf development is much more free when the sphagnum-moss is allowed to become dry before affording water. But the atmosphere must not be dry, and to prevent this, the surfaces in the house may be damped as often as may be necessary. Sponge the leaves with clean water frequently, so that they may be able to perform their functions properly, and to rid them of any insects.

FRUITS UNDER GLASS.

By W. STRUGNELL, Gardener to Lieut.-Col. RALPH VIVIAN, Road Ashton, Trowbridge.

Pines.—Now that the days are shorter, and the sun less powerful, Pines will need less water at the root. Syringing of the plants overhead ought now to be done in the morning, on fine days only, so that no water will lie in the leaf-axils during the night: Ventilation, too, will require care, so that it may be adapted to the aspect of the pits, the condition of the plants, and the prevailing weather. It would be unwise to force growth by a close, stuffy atmosphere from sun or fire-heat, or the free use of the watering-pot and syringe. The treatment altogether should be modified to suit the decline of the season, and prepare the plants for steady progress through the winter. The fruiting plants may be arranged either in separate structures, or otherwise, according to their stage of forwardness.

Where separate structures do not exist for their accommodation, the only course is to grade them from the forwardest down to the latest in one house in batches, giving the warmest end to those that most require it, whether they are early fruiters or succession-plants. Those that are intended for starting in the spring of next year for summer ripening need cooler treatment for a time, so that when forcing-time comes round they will respond the more readily. These cooler conditions require that the atmospheric and root moisture be modified. Forward plants with their pots full of roots may be afforded weak liquid-manure when moisture is needed.

Pot. Vines.—Fruiting Vines produced from cut-backs ought by this date to be in a sufficiently forward state to be put out-of-doors, in order that exposure may arrest growth and complete their ripening. Place them under a sunny wall, and in the event of heavy rain falling, it will be well to lay the pots on their sides to prevent the soil becoming saturated; they must not, however, be allowed to get dust-dry. The canes should either be tied to stakes or lightly nailed to the wall. Spring-struck Vines must be treated according to their present state of foliage. If this is still green they should be permitted to remain some time longer indoors; others that are showing signs of maturity may shortly be turned out and treated the same as cut-backs. If there is any shortening of the rods necessary, this can be done now, as this will tend to lessen the danger of bleeding at starting-time. Free ventilation should be allowed Vines during the day-time after this date, with a lesser amount at night for those in a backward state.

Inarched Vines.—When this has been performed late with young Vines struck in the spring, it will be found necessary to loosen the binding, otherwise this will cut deeply into the bark. It is not safe, however, to cut away the binding and leave them without any protection, or the union between stock and scion may become broken. A tie placed at each end of the grafted portion before the ligatures are loosened will prevent such mishaps.

Wasps in Vineries.—The absence of these destructive insects until the end of August raised a hope that they were not likely to be troublesome in the fruit-houses this year; but they have become exceedingly numerous in the space of a fortnight, and the destruction they are capable of working among choice fruits can scarcely be measured. Davis' wasp-destroyer entirely fails to keep them out of the vineries, which renders necessary the closing of all open spaces against them with muslin or similar fine-meshed material. The destruction of nests is an absolute necessity, and is easily effected with cyanide of potassium, obtained in a lump or granulated state from the chemist, and dissolved in warm water. A spoonful of this poured into their nest during the daytime is instantaneous in its action, but the comb needs to be dug out and smashed up a few hours afterwards, otherwise young ones soon hatch out. This is much the simplest expedient, and although itself a virulent poison, is perfectly safe when due caution in its use is exercised.

"ALL ABOUT RUBBER."—The further title of this handbook mentions that it deals with "all varieties in all countries, with harvesting and preparation, and gutta-percha." Therefore, Mr. J. FERGUSON has launched out upon a large and important subject, with which, as editor of the *Ceylon Observer* and the *Tropical Agriculturist* he has proved himself qualified to deal. The volume is destined to be the India-rubber Planters' Manual, and it "includes the latest statistics and information, more particularly in regard to cultivation and scientific experiments in Trinidad and Ceylon." Having mentioned the scope of the book, and the fact that Mr. FERGUSON may be trusted both as regards original writing and the sources from which he draws his quotations, it is merely necessary to add that all directly or indirectly interested in the India-rubber industry must acknowledge the convenience of obtaining so much valuable information in a handy form. Publishers—London: J. HADDON & Co.; LUSAC & Co.; KEGAN PAUL, TRENCH, TRUBNER & Co. Also issued from Colombo, Singapore, and Java.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

SHOW.

TUESDAY, SEPT. 19. National Dahlia Society's Exhibition at the Royal Aquarium (2 days).

SALES.

Remarks.—For the most part the weather has been dull and misty. The temperature rose to 86.3° on the 5th inst., and was succeeded by a heavy thunderstorm on the 6th.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—56.9°.

ACTUAL TEMPERATURES:—

LONDON.—September 13 (6 P.M.): Max. 70°; Min. 40°.
PROVINCES.—September 13 (6 P.M.): Max. 65°; Scilly Isles; Min. 58°, Holyhead.

To Le Jardin of Jan. 20, M. E.

Graft Hybrids. JOUIN communicated a paper, now published separately, in which he discusses whether or not the "sports" produced in consequence of grafting are true hybrids. He instances a Medlar-tree at Bronvaux of which he gives the following account:—

"This Medlar, more than a hundred years old, is grafted midway up the stock on Hawthorn, and was brought to our notice about three years ago by M. DARDAR, a gentleman of Bronvaux, near Metz, who for some time had the tree under observation. Immediately below the graft, the stock (Hawthorn) gave birth to a branch, which we will call No. 1,

intermediate between Hawthorn and Medlar (*Mespilus germanica*), but resembling the latter more closely than the Thorn. This branch differs from the grafted part of the tree, that is to say, from the true Medlar, in that it is spiny, and instead of bearing the flowers solitary, has them united in corymbs, including as many as twelve blooms. The fruits (Medlars), are rather small, and generally much flattened.

"Close by this branch, issuing from the same point, is developed another completely different form (No. 2), the young leaves of which are lobed, downy in form like those of Hawthorn; the adult leaves on the contrary, are little or not at all lobed, rather elongated; and in fact, have a certain resemblance to those of the Medlar. The young shoots are pubescent; the flowers in corymbs, somewhat analogous to those of the Hawthorn, but rather larger and with the calyx pubescent. These flowers were rose-coloured two years ago, and sometimes now pink petals alternate with others that are white. This year we remarked white flowers only; it is true we only saw them at the end of the flowering, this may explain the change of colour. The fruits of this form are, according to M. DARDAR, elongated, brown, very small, and quite different from true Medlars.

"The same tree has further produced, also just below the graft, another very remarkable branch (No. 3). The base of this one is no other than Hawthorn, but at the extremity merges into a branch that, if not identical to No. 2, is very near to it.

"This third form, unfortunately, now exists in the mother-stem only in a dry state. Possibly we cut the branch too short when taking pieces to graft. Luckily the grafts have taken well, so that we can study the form with facility.

"This year we noted two phenomena not chronicled before. No. 1 gave rise to a young branch that is the true Medlar (with solitary flower). On the same branch a forking twig has put forth on one side an inflorescence of Hawthorn, and on the other a corymb of eight Medlar flowers. Probably every year there will be new changes which will be duly reported."

What is to be concluded from these phenomena? In our opinion, the changes are all undoubtedly due to the influence of the graft (Medlar) upon the stock (Hawthorn). The intermediate forms produced, and of which we possess sturdy specimens two years old fixed by grafting, cannot logically be called anything but hybrids; unless some other special designation be adopted for the bastards produced by grafting. Many times already has the influence of the graft upon the stock been remarked. The influence of the stock upon the graft we have not mentioned, although it is manifested by experiments made by M. DANIEL, Doctor of Science, of Rennes, and explained by him at the Pomological Conference at Rennes in 1897, and at the Horticultural Congress in Paris in May, 1898.

This year, in the nurseries at Plantières, a common Beech developed a branch with lacinate leaves. This Beech had been grafted in the spring with a variety bearing lacinate leaves, but the graft failed. The "sport" occurred much below the spot where the graft had been inserted, and this surprised us as, in analogous cases previously noted, especially with Maples, the transformed branches appeared in proximity to the graft, if not immediately below it.

The charming and widely-known *Cornus alba* Spaethi was raised—though this is little known

even among horticulturists who grow these handsome shrubs wholesale—from a branch that developed below the graft on *Cornus alba* when grafted on *Cornus alba* fol. arg. marg. M. Spaeth, who obtained the variety, is a most distinguished German nurseryman, and he attributed this variation to the influence of the graft on the stock.

The following facts, taken from the *Bulletin* of the International Horticultural Congress, held in Brussels in April, 1864, only confirm what has been said above:—

"When he was directing the Cultural Department attached to the École Normale of Lierre, Dr. RODIGAS budded a shoot of *Crataegus oxyacantha* fl. punicea on the stem of *Sorbus aucuparia*. The bud was inserted about 3 feet above the soil. This was in July. The following spring the bud sprouted to a length of from .05 to .06 met. Then the leaves withered. But, at the same time, on the opposite side, and about .18 from the point of the insertion of the graft, was developed a true shoot of *Crataegus*, the leaves of which soon reached half the normal size, and were healthy and characteristic. Now, this shoot has withered in its turn. The stem at the spot is .09 met. round. It is perfectly smooth, and no vestige of the insertion of another graft is noticeable, even under a fairly strong lens, while the cicatrix of the graft remains plainly marked as in every similar instance. The eye, otherwise, has grown, just as does an adventitious shoot. The authenticity of this fact is guaranteed.

Is it possible that a cell including in itself the vital germ of the *Crataegus* could be borne from the place of insertion to where the bud saw daylight, .18 met. below, and on the opposite side? The affinity existing between the two neighbouring genera, *Sorbus* and *Crataegus*, might have favoured the case, but we dare not say. Explanations of the matter we should be glad to receive.

In considering the cause of these changes, two circumstances not known to our predecessors must be taken into consideration. The one is the continuity of protoplasm—that is, the permeability of the cell-wall, so that the plasm may pass from cell to cell throughout the younger-growing tissues—a fact discovered by Dr. GARDINER, of Cambridge. With this means of intercommunication it is much easier to understand how the contents of one cell pass into the cavity of another than it used to be when the cell was looked upon as a closed sac. Indeed, the wonder is that phenomena like those of graft-hybridisation, instead of being exceptional, should not be more frequent.

The minute subdivisions of the nucleus of the cell, and their singular methods of dividing and of changing their position, may be expected in future to offer explanations of many problems. At present, the research into these matters is as difficult as it is intricate, but in all probability not many years of the new century will have elapsed before the physiologists will have brought their science to such a condition that practitioners will be enabled to turn it to practical account.

ANTHURIUM VEITCHI.—The view of the end of a conservatory belonging to Mrs. T. L. AMES, Boston, Mass., U.S.A., affords a good example of the decorative value of a large, well-grown *Anthurium Veitchi*. It is evidently a very fine plant, furnished with leaves which measure from 2 to 3 feet in length. Provided the atmospheric conditions of a glass-house are suitable, this species is of as easy culture

FIG. 78.—ANTHURIUM VEITCHI IN THE CONSERVATORY OF MRS. T. L. AMES, MASS., U.S.A. (SEE P. 226.)

as other Anthuriums. We may add that A. Veitchi was discovered by Mr. WALLIS in Columbia, and introduced to this country by Messrs. J. VEITCH & SONS early in the seventies, and was figured by us in the issue for December 16, 1876, accompanied by a full description of the plant. We are indebted to Messrs. SANDER & Co., St. Albans, for the photograph from which the present illustration (fig. 78) was taken.

ROSES FOR FORMING HEDGES.—A correspondent has written us requesting advice upon the varieties of Roses best suited for planting to form a hedge 100 yards long. It is an interesting subject, and one in which locality and soil must be given consideration. The chief difficulty is to obtain kinds which flower continuously, and which will be sure to make a thick hedge. Summer Roses, flowering in masses, but only once, are suitable for dwarf hedges about 3 to 4 feet in height. Yellow Scotch are first rate, and better than Harrisoni or Persian Yellow, growing closer and more compact than these. Of the Penzance Briars, the varieties Lord and Lady Penzance, planted alternately, make a charming shading of colours, and grow from 3 to 5 feet high. Meg Merrilies is a good Rose, but a taller grower; Miss Blanche Norman is a fine white-flowered hedge Rose, 3 to 4 feet in height. Of single species, R. rubrifolia is charming for its leaves and hips; it grows 4 to 6 feet in height. R. Brunonis, 6 to 8 feet, is more prolific of bloom. Of autumn-flowering Roses, the best for a dwarf hedge are common China, 3 feet; Fellemberg, 4 to 5 feet; Rugosa blanche, double, do.; Coubert, double white, 4 to 5 feet; Paul's single white, 5 to 6 feet; Alistar Stella Gray, yellow, 6 to 8 feet; Turner's Crimson Rambler, 6 to 8 feet; Carmine Pillar, 8 to 12 feet, the finest for a tall hedge (these last two are not autumnal flowerers); Viscountess Folkestone and Augustine Guinoisseau, 3 feet; Bouquet d'Or, 5 to 6 feet. Perhaps, on the whole, the best for tall hedges are Carmine Pillar, Crimson Rambler, and Alistar Stella Gray. For medium-sized hedges, Bouquet d'Or, Penzance Briars, and Double-white Rugosa. For dwarf hedges, common China, Viscountess Folkestone, Augustine Guinoisseau, and Yellow Scotch.

ECONOMIC ENTOMOLOGY.—This is a branch of science that has hitherto been comparatively neglected in this country. It is probable, however, that in the Colonies at least greater attention will be devoted to it, especially in connection with the agricultural development going on in tropical countries. Recently the Government of Ceylon has appointed an entomologist at a salary of 5000 rupees per annum; and now we learn that it is in contemplation to appoint a scientific man as entomologist to the Imperial Department of Agriculture in the West Indies at a salary of £350 per annum, and a free passage to Barbados. Hitherto the number of persons who devoted themselves exclusively to economic entomology is a singularly small one. In the United States they are far in advance of us in this matter. If, however, there is likely to be a demand for capable men at good salaries, there is no reason why this demand should not be fully met.

HIPPOPHAE AT KEW (p. 210).—We understand that the standard tree now bearing fruit near the temperate-house (not the Palm-stove, as we stated by mistake), was fertilised by hand with pollen from a male plant at some distance.

THE NEW SINGLE DAHLIA "GIRLIE."—When writing in our last issue of this beautiful variety, we were under the impression that the raiser was Mr. STREDWICK, and we therefore hasten to correct our remark, by substituting the name of the late Mr. T. W. GIRDLESTONE, as this variety proves to be yet another single-flowered gem raised by that lamented gentleman. We understand that it is hoped to exhibit other seedlings from Mr. GIRDLESTONE's garden, at the National Dahlia Society's show at the Aquarium on the 19th inst.

"BOTANICAL MAGAZINE."—The September number contains coloured illustrations of the following plants:—

Coleus thyrsoides, Baker, t. 7672.—A native of British Central Africa; raised from seed in the Royal Gardens, Kew. It is a Labiate undershrub, 2 to 3 feet in height, pilose, with shortly-stalked, cordate, ovate, lanceolate, coarsely-toothed leaves, and terminal, cymose panicles of azure blue flowers, each flower being about $\frac{1}{2}$ -inch long.

Begonia sinensis, A. de Candolle, t. 7673.—A Chinese tuberous species, with cordate, ovate, serrated leaves, and terminal cymes of small pink flowers. Royal Gardens, Kew.

Calathea picta, Hook. f., t. 7674.—A Brazilian species introduced by Mr. W. BULL, with sheathing, purple-stalked leaves of lanceolate, acuminate form, green above, purple beneath. The inflorescence is terminal with large, boat-shaped, yellowish bracts, margined with violet. The flowers are white.

Asparagus scandens, Thunberg, t. 7675.—A South African species, with small linear, curved leaves, and small red berries.

Dorstenia Philippiæ, Hook. f., t. 7676.—A botanical curiosity from Somaliland. It has a thick erect stem, 3 to 4 inches high, marked with the scars of fallen leaves. The leaves are clustered at the tips of the fleshy branches, and have short stalks with oblong, dentate blades, about $1\frac{1}{2}$ to 2 in. long. The long flower-stalks expand into a disc-shaped receptacle about 1 inch wide, from whose margins project seven to eight curved horn-like projections. It flowered in the Botanic Garden, Cambridge.

CROSSING VARIETIES OF WHEAT.—The *Bulletin* No. 62 of the Agricultural Experiment Station of the University of Minnesota contains a very valuable paper on Wheat-breeding, by Messrs. W. M. HAYS and ANDREW ROSS. It is very complete, and contains fuller information within small compass than we know of elsewhere. Considering the precarious prospects attendant upon Wheat-culture in this country, the development of new varieties better suited to our uncertain climate is a matter of vast importance. "The evidence seems conclusive," say the authors, "that better varieties of Wheat can be made at an expense which is, indeed, very small when compared with the increased value of varieties, which will raise the average yield per acre even only a part of a bushel."

SALAD PLANT.—The salad plant mentioned recently by Mr. CHRISTY has now flowered, and proves to be *Plantago Coronopus*, our Buckshorn Plantain, a common wild plant in some situations. It is sown in autumn and spring, says Vilmerin, and requires only hoeing and copious supplies of water. We have not been impressed with the merits of this plant on the Continent. Purslane, on the other hand, may be strongly recommended, and grows well in seasons like the present. In winter it may be grown on a hot bed in a frame, and is highly recommended as a salad, though one seldom sees it in English gardens.

"LES POIS POTAGERS."—(J. B. BAILLIÈRE et fils, 19, Rue Hautefeuille, Paris, and DENAÏFFE et fils, Carignan, Ardennes). M. M. DENAÏFFE's book deals first with the derivation and evolution of the cultivated edible Pea; then with the many different varieties separately. The subject matter is duly classified into sections dealing with the different types of Pea, and there is much detailed information, fully illustrated in addition to the various tables. It is not an easy task, nowadays, when there are so many sorts, thus to distinguish between them, to classify and to tabulate them; and growers of Peas on a large and also those on a small scale should welcome this handy manual which deals with old and tried forms as well as with newer introductions.

BROWN BLIGHT OF TEA.—Mr. G. MASSEE describes in the *Kew Bulletin*, p. 90, a fungus which

he calls *Colletotrichum Camelliae*, a mould which is destructive to Tea in Ceylon. Spraying with Bordeaux Mixture is recommended as a remedy.

MR. W. N. NORMAN has been appointed Curator of the Botanic Station in Antigua, on the recommendation of the Director, Royal Gardens, Kew.

MR. MURDO MCNEILL has, through the recommendation of the Director, Royal Gardens, Kew, been appointed Agricultural Instructor in St. Vincent; and Mr. A. J. JORDAN, from the same gardens, has been appointed to a similar post in Montserrat.

MEETING OF THE GHENT AGRICULTURAL AND BOTANICAL SOCIETY.—At the meeting of the *Chambre Syndicale des Horticulteurs Belges*, and of the *Société Royale d'Agriculture et de Botanique*, at Ghent, on September 4, the following awards were made: Certificates of Merit for seedling *Dracænas*, from M. G. DE COCK (par acclamation); for two specimens of *Dracæna Tolfaerti*, from M. A. TOLFFAERT (par acclamation); and for *Anthurium Scherzerianum* var. *amabilis*, from M. L. DE SMET-DUVIVIER (à l'unanimité). Cultural Certificates were allotted for: *Astrapea Wallichii*, from M. G. GYSELINCK; *Aralia leptophylla*, from M. CARELS; and *Asparagus Sprengeri*, from the same exhibitor (à l'unanimité). Certificates of Merit for Cut Flowers were given for those of *Hydrangea paniculata grandiflora*, from M. L. DE SMET-DUVIVIER; *Cactus Dahlias*, from M. F. BURVENICH, père (à l'unanimité); double *Begonias*, from M. M. DE GROOTE, frères; single *Begonias* from the same exhibitors; and *Lilium auratum platyphyllum* from M. L. BOTELBERGHE. Honourable mention was allotted for the following cut flowers: *Lilium lancifolium rubrum* and *Gladiolus* var., both exhibits from M. G. DE SAEGHER.

FLORA CAPENSIS.—Another part of this "Colonial Flora" has been published by LOVELL, REEVE & Co. It contains the continuation of the *Gramineæ*, by Dr. STAFF. His descriptions are scrupulously elaborated, sometimes occupying nearly a page to each species; while the synonymy fills up nearly as much space. *Avena* now contains only seven species, four of which are African; whilst other so-called *Avenas* are distributed in the genera *Avenastrum* and *Trisetum*.

AGRICULTURAL STATISTICS FROM IRELAND.—Under the superintendence of the Registrar-General, Dublin, general abstracts have been made and published relative to the acreage under crops and the number and description of live-stock in each county and province of Ireland in 1898-1899. The following are the results of some of the reports: The total extent under crops in 1899 is 4,627,273 acres, being, as compared with the extent in 1898, a decrease of 77,587 acres, or 1.6 per cent. Allowing for the alterations in county boundaries made by the Local Government Board under the Local Government (Ireland) Act, 1898, there was a decrease in the area under crops in Leinster of 38,496 acres, or 3.0 per cent.; in Ulster of 14,371 acres, or 0.9 per cent.; in Munster of 15,897 acres, or 1.3 per cent.; and in Connaught of 8,823 acres, or 1.4 per cent. In 1898 the extent returned under grass was 10,470,119 acres, in 1899 the amount returned is 10,575,003 acres, being an increase of 104,884 acres; the extent returned as fallow in 1898 was 16,839 acres, and in 1899 is 13,081 acres; the extent under woods and plantations was 307,661 acres in 1898, and 308,800 acres in 1899; and the extent returned under "turf, bog, marsh, barren mountain land, &c.," was 4,833,865 acres in 1898, and 4,809,187 acres in 1899, being a decrease of 24,678 acres; of the acreage thus returned in 1899, 1,196,208 acres have been entered by the enumerators as turf bog, 386,855 acres as marsh, and 2,261,046 acres as barren mountain land. Similar details are given with reference to the number and description of live-stock, showing a large decrease in horses, but an increase in asses, cattle, sheep, goats, pigs, and poultry.

MARKET GARDENING IN WORCESTERSHIRE.—

In the Evesham district there is an immense quantity of Plums and of Asparagus grown. Most of the growers have some land at any rate devoted to "Grass," and in the course of a drive such a quantity may be seen as could not be found in any other part of the country. Plums this year have generally been a poor crop, but there appeared plenty round Evesham. Victorias and other good varieties are grown in moderate quantities, but the one variety that every small and every large grower has, is the "Persnore." Who has not heard of the "Persnore Plum?" It has been condemned again and again. Its qualities the critics have declared to be poor; and growers have been advised to root the trees out, and plant others. The reasons that they have not done so are these: The "Persnore Plum" is the easiest to cultivate of all Plums. The stock can be, and is, increased by suckers, it is one of the surest of croppers, and young trees come into bearing uncommonly soon. And then the "Persnore Plum" will sell. It is not of the best quality, but for culinary purposes this large, egg-shaped Plum sells readily enough; and if the prices obtained are not so high as for better sorts, neither is the cultivation so expensive, or the risks of non-cropping so great. It is the practice to gather them just before they are ripe; and in this condition they are sent over the greater part of the country. Nevertheless, it is not a first-class Plum.

THE TRAINING OF AZALEAS.—The formal training of Indian Azaleas ceases to be pleasing after one has seen it once or twice. At the Belgian shows (as formerly at our own), a group of Azaleas so trained had the appearance of decorated dish-covers on a large scale. The pyramidal form adopted by M. CH. VUYLSTEKE, and not uncommon here, is at least a change, but a freer, more natural form would be better still, even though a few more leaves were rendered visible.

ARBOR-DAY FOR ITALY.—The Italian people have come to the conclusion that the exclusion of forestry from its rural economy is unwise. They are now learning to do well, under the guidance of the Government, at the hands of the Department of Public Instruction. An Arbor-day has been instituted, and the Japanese plan of teaching wood-craft in the public schools has been adopted. On a day yet to be named in October proximo, the youth of Italy will take their first lesson under the improvised forester. The Minister of the above-named Department has been at work for some time past engaged in elaborating the scheme now to be started, finding, as we understand, that reforestry, or replanting, could not be done by the State; and so help was asked for from every school and commune or local authority in the land; and the reply has been in favour of the new scheme. Scholars in all parts of Italy will soon be engaged in the endeavour to make their native land more beautiful and more receptive of those gifts from the clouds which, as at present, run down to the sea—wasted. In spots adjacent to centres of population, large and small, sites are being prepared for the planting of young trees, and on Arbor-day the scholars will be marched from the school-house to the embryo plantation, accompanied by their master and some one or more of the local authorities, assisted by a practical hand, and when the planting has been accomplished—after the necessary explanations on the practice—an address will be delivered on "The Moral, Social, and Economic Value of Trees." And one may be allowed to express the hope that name carving on bark may be condemned in strong terms. Doubtless during the year the youngsters will be trotted to the miniature plantations, and receive more instruction, as we believe is done in Japan; and so, year by year, the young may grow in knowledge and stature, and the rows of young trees be added to, and some transplanted to prominent positions in spots where they are most urgently required. One little feature of the scheme is not without

interest—as far as possible places celebrated in Italian history will be selected for the transplanted trees, and thus a double lesson taught to the scholars. All must wish every possible success to the new Italian Arbor-day.

TORSION IN THE LEAF.—One of the most interesting papers at the recent Hybridisation Conference was one by Professor HUGO DE VRIES, which dealt with the spiral torsion of the stem, not unfrequently met with in the stem of *Dipsacus*. The Professor has succeeded in "fixing" this mal-

FIG. 79.—TORSION OF THE LEAF OF A DANDELION.

formation, as gardeners say, and has produced a race of which a large percentage of the individuals come true from seed. The illustration here represented (fig. 79), shows the leaf of a Dandelion twisted on its axis from some cause which is unknown to us. Twisted leaves of this character are more uncommon than twisted stems. In some bulbous plants, as in some *Nerines*, this condition is normal. We are indebted to the Director of the Royal Gardens, Kew, for the opportunity of drawing this specimen.

CANADA RICE.—The following extract, from *Studies of Plant Life in Canada*, by Mrs. C. C. TRAILL, 1885, p. 103, will be read with interest in relation to the plants referred to at Kew, on p. 210. "The name of 'Rice-Laké,' is derived from the

fields of Wild Rice, *Zizania aquatica* (L.), which abound in the shallower waters of this fine inland sheet of water, and give the appearance of low verdant islands clothing its waters. When the Rice is ripened, and the leaves faded, a golden tint comes over the aquatic field; and the low Rice islands, as they catch the rays of the sun, take the form of sands glowing with yellow light. Where the water is low, the Rice-beds increase so as nearly to fill the shallow lakes and impede the progress of boats, changing the channel and altering the aspect of the waters. In the month of June, the tender green spikes of the leaves begin to appear; in July, the Rice begins to push up its stiff, upright stalk; sheathed within its folds are the delicate, fragile flowers; from the slender glumes, the beautiful straw-coloured and purple anthers hang down, fluttering in the breeze, which stirs the grassy leaves that float loosely upon the surface of the water, rising and falling with every movement. The plant grows in lakes, ponds, and other waters, where the current is not very strong, to the depth of from 3 to 8 feet, or even deeper. The grass, or ribband-like flexible leaves, are very long. I remember a gentleman who was rowing me across the lake drew up one at a chance on his oar, and measured it, the length being 11 feet, but with the culm and flower it would have measured 12 or 13 feet in length. The month of September or later, in October, is the Indian's Rice harvest. The grain, which is long and narrow, and of an olive-green or brown tinge, is then ripe. The Indian woman (they do not like to be called squaws, since they have become Christians) pushes her light bark canoe or skiff to the edge of the Rice-beds, armed, not with a sickle, but with a more primitive instrument—a short, thin-bladed, somewhat curved wooden paddle, with which she strikes the heads of ripe grain over a stick which she holds in her other hand, directing the stroke so as to let the grain fall to the bottom of the canoe; and thus the wild Rice crop is reaped, to give pleasant, nourishing, and satisfying food to her hungry family. There are many ways of preparing dishes of Indian Rice: as an ingredient for savoury soups or stews; or with milk, sugar and spices, as puddings; but the most important thing to be observed in cooking the article is steeping the grain—pouring off the water it is steeped in, and the first water it is boiled in, which removes any weedy taste from it. It used to be a favourite dish at many tables, but it is more difficult to obtain now. The grain all collected, it is winnowed in wide baskets from the chaff and weedy matter, parched by a certain process peculiar to the Indians, and stored in mats or rough boxes made from the bark of the Birch-tree—the Indians' own tree. Formerly, we could buy the Indian Rice in any of the grocery-stores at 7s. 6d. per bushel, but it is much more costly now, as the Indians find it more difficult to obtain."

USEFUL PLANTS OF SENEGAL.—Father SÉBIRE, Director of the Botanic Garden of Thibé, Senegal, has published through Messrs. BAILLIÈRE & SONS, a useful little treatise, in the French language, on the plants of economic importance in the colony of Senegal. Wild plants and introduced species are passed in review. The rainy season begins towards the end of June, and continues, with slight intermissions to the middle of October. Malarial fevers are rife at the later period. In the dry season but little rain falls, so that it is necessary to secure artificial supplies of water. The soil is mostly sandy, with some clay. Father SÉBIRE gives an interesting account of the methods of cultivation adopted by the natives, and of the results of the experiments made by the colonists and settlers. The bulk of the book is made up of slight descriptions of the various economic and decorative plants arranged according to their natural orders. Numerous illustrations are given, together with a full index and table of contents. The strictly botanical details are somewhat meagre, but the particulars as to mode of cultivation and properties are well suited for the purpose. The book, though primarily

intended for Senegal, will be useful to settlers in other parts of Africa having a similar climate. A debt of gratitude is due to Father SÉBIRE for this accurate and useful publication.

STOCK-TAKING: AUGUST.—It would seem to require a very dark cloud indeed on the political horizon to affect the energies of this section of the commercial and manufacturing world, for once again the Trade and Navigation Returns point to a heavy increase in both imports and exports. The value of the imports for the month of August is placed at £40,693,398, an increase of £3,489,213 on the same period last year, when the total value was £37,204,185. Our excerpt from the "summary" table is as follows:—

IMPORTS.	1898.	1899.	Difference.
	£	£	£
Total value ...	37,204,185	40,693,398	+3,489,213
(A.) Articles of food and drink—duty free ...	13,710,209	14,822,711	+1,112,502
(B.) Articles of food & drink—dutiable	1,910,115	1,923,291	+15,176
Raw materials for textile manufactures ...	2,880,014	3,056,428	+176,414
Raw materials for sundry industries and manufactures	6,102,167	6,512,586	+410,419
(A.) Miscellaneous articles ...	1,106,032	1,179,495	+73,463
(B.) Parcel Post ...	106,652	81,711	-24,941

It will be seen from these figures that the great increase is in articles of food and drink, and in considerable measure it indicates the healthy tone of the home labour market. The "States" and Canada figure largely for breadstuffs, bacon, and butter; and there remain over from last harvest a fairly large quantity of Wheat and flour, as per advices from Washington. Raw materials for textile manufactures show an increase in various classes. A very interesting little table this month is that made up by us from fruit, roots, and vegetables imported, and is as follows:—

IMPORTS.	1898.	1899.	Difference.
Fruits, raw:—			
Almonds ... cwt.	1,506	3,870	+2,364
Apples ... bush.	116,860	131,315	+14,455
Cherries ... "	34,535	13,780	-20,755
Grapes ... "	236,641	305,871	+69,230
Lemons ... "	71,340	144,280	+72,940
Oranges ... "	22,121	18,647	-3,474
Pears ... "	128,854	219,969	+91,115
Plums ... "	491,663	223,048	-268,615
Unenumerated ... "	433,437	440,207	+6,750
Roots and Vegetables:—			
Onions ... bush.	629,799	561,821	-67,978
Potatoes ... cwt.	90,939	119,865	+28,926
Vegetables, raw, unenumerated ... value	£207,716	£220,741	+£13,025

The unenumerated section here looms large, both in quantities and values, and the President of the Board of Trade would gain much credit by reducing these, through enumeration. Some of the tabulated totals are very suggestive, and confirmatory of harvest reports already published. The imports for the past eight months foot up £317,327,164, against £309,064,153 for the same period in 1898—a gain of £8,263,011. Coming to the

EXPORTS,

We find still another increase. The total for the month of August is placed at £22,258,538, against £20,186,016 in August, 1898—a gain of £2,072,522. The figures for the past eight months are £171,976,390, against £152,784,073 in 1898.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—We are asked to announce that the annual dinner of the above society will take

place at the Holborn Restaurant on Thursday, October 5, at 6.30 P.M. Mr. W. Y. BAKER will preside.

THE BRITISH ASSOCIATION has assembled this year at Dover, and horticulturists will feel proud that so learned and eminent a body meets under the presidency of a zealous and devoted botanist and gardener. Sir MICHAEL FOSTER, is known to our readers in various ways. Not only has he written frequently in these columns upon horticultural subjects, especially Irises, of which he has an unique knowledge, but in past years he has done a large amount of work on behalf of the Royal Horticultural Society, being one of those who took office in that society when its affairs were in a deplorable condition, and remained a member of the Council until the society was completely rescued from the helpless state into which the adoption of a wrong policy had brought it. Sir MICHAEL FOSTER, is one of the leading scientists of the present day, and his presidential speech delivered on Wednesday evening at Dover, though not specially relating to our own science of horticulture, was a masterly review of the progress of science generally during the century now rapidly approaching its close. The address was delivered in the Town Hall, which was filled to its utmost capacity. Among the eminent members of the Association present upon the platform were Sir W. T. Thiselton Dyer, Director of the Royal Gardens, Kew; Sir W. Crookes, retiring President; Lord Lister, Sir H. Roscoe, Prof. G. H. Darwin, Prof. Ray Lankester, Prof. Kronecker of Berlin, Prof. J. T. Thompson, Prof. Richet of Paris, Sir W. H. Preece, &c. During the proceedings at Dover, there will be a deputation from the French Society, and the British Association will visit Boulogne. Section K. is the one devoted to Botany, and in future issues we hope to give our readers some account of the proceedings in this section.

PUBLICATIONS RECEIVED.—*Journal of the Essex Technical Laboratories*, Summer, 1899 (County Technical Laboratories, Chelmsford).—This includes papers on Planting Fruit-trees, by C. Wakely; Destruction of Charlock by spraying with solution of sulphate of copper, by R. W. Christy and T. S. Diamond; and Check list for Botanical Ramblers, by E. Turner.—*Anne Pratt's Flowering Plants* (F. Warne & Co., Bedford Street, Strand), vol. ii., parts 13 and 14.—*Nature Notes*, September.—*Tropical Agriculturist*, August; this contains a portrait and notice of Mr. W. B. Lamont, a "pioneer" Coffee and Tea planter; articles on Rubber Cultivation in Ceylon; Coffee Cultivation in Ceylon, &c.—From the University of Illinois Agricultural Experiment Station, Urbana, July 1899, Bulletin No. 56, *Recent Work on the San José Scale in Illinois*.—*Annales Agronomiques*, August 25.—*Botanisches Centralblatt*, Band LXXIX., Nos. 9, 10.

HOME CORRESPONDENCE.

THE ROYAL HORTICULTURAL SOCIETY.—The advantages and the benefits conferred on all concerned in horticulture by the Royal Horticultural Society are too well known to require comment from me—but it has often occurred to me and probably to others that it is most inconvenient to have only one place in the kingdom to which all new plants and fruits must be sent for awards. I propose that there should be four branches, viz., North, South, East, and West. This would be to the advantage of all of those who reside at a long distance from London; moreover, the expense and loss of time, and the injury to fragile things, would be in a measure averted. If there were branches conducted on the same lines as the parent society, with committees and staff selected from the gentlemen and gardeners of each part of the kingdom, under the control of the head society—many gardeners would be glad of the opportunity thus afforded to display their productions. A. J. Long, Wyfold Court, Oxfordshire. [We do not think the proposal is feasible. Ed.]

BIGNONIA GRANDIFLORA, ETC., AT PARK PLACE, HENLEY.—This is the best of the so-called "Trumpet-ash" climbers, the other useful one being B. radicans major, which does well on a dry border against a wall or fence, and there flowers freely. B. grandiflora, however, is somewhat tender, and only in

exceptionally hot and dry summers are its flowers perfect in the open; though planted out in a cool conservatory or in a winter-garden, it flowers moderately well. As I saw it the other day, growing over the porch of the head-gardener's (Mr. Stanton) house at Mrs. Noble's, Park Place, Henley, it was beautiful. It was planted near to one of the rustic Oak supports of the porch, and, bifurcating, was carried along the front to left and right, and on the right side inward towards the house. The pinnate foliage was unusually large and handsome; and the terminal spikes of flower were no fewer than forty-two, the number of flowers on each being twelve to fifteen finely-developed campanulate blossoms, of a bright orange-scarlet colour, paling to rich warm yellow as they mature. This Bignonia evidently loves drought and heat, for I have very frequently had plants abundantly budded at the termination of the shoots and laterals, but, before opening, the flowers invariably dropped off. There are also fine Conifers here, including well-coloured specimens of Young's Golden Chinese Juniper (*J. sinensis aurea*), and the finest example of a still rarer Conifer, *Cupressus macrocarpa aurea*; at least, so named, but from its stout growth and dense habit, the shrub to me appeared more like a golden-tinted form of the Upright Cypress (*C. fastigiata*). There was also a fine piece of the lovely *Abies Engelmanni glauca*. Experience.

THE PERPETUITY OF FEEBLENESS BY HYBRIDISATION.—One result of the recent congress on hybridisation, will, I have no doubt, be a large addition to the number of those engaging in attempts to vary and improve the different forms of vegetable life. May I be permitted to suggest, with due deference, that in all efforts of this kind the parents chosen on both sides should possess, if not a strong, at the least a sound and wiry constitution. How many feeble varieties of florists' flowers, admittedly of great beauty, have been ushered into the floral world—varieties which it requires the utmost watchfulness and skill to develop fully, and which no amount of watchfulness and skill could keep in health or life over a lengthened period? This production is, we believe, generally, though not always, due to the setting up of a standard of ideal beauty, in form, colour, &c., and working for its attainment, overlooking the vital point of constitution. How disappointing and disheartening to the ordinary cultivator to have to deal with such puny things! Nature, we admit, free of man's interference, often gives us such, and disposes of them in her own way, but do not let us by our interference add to the number whose cultivation gives us more pain than pleasure, but rather strive to lessen it by judicious selection in parentage. Wm. Paul, Pauls Nurseries, Waltham Cross.

PROTECTING PEACH-TREES WHEN IN FLOWER.—Unprotected Peach and Nectarine-trees have borne heavy crops of fruits this season, though the weather during the critical period of flowering was most severe. Is the protection of the flowers by fish-netting and other light materials a fad only? I invariably find that unprotected trees bear as freely as protected trees. At Wrotham this year we have had heavy crops of fruit, and although we made use of netting and Laurel branches after registering 14° of frost, the fully-expanded flowers having been previously blackened, we obtained a heavy set of fruit; but there were trees and parts of trees that had no protection whatever, and during the frosty weather ice and snow were frozen to the branches, and yet these bore equally good crops. I visited the gardens at Woodgreen Park at the time the trees were in bloom, and I believe that upwards of 20° of frost were registered there. The flowers were miserably black, but there has been a very fine crop of large Peaches. These were protected with a single fish-net. On the same wall a Walburton Admirable that had no protection bore heavily. In my case, the unexpanded blooms proved best. But if trees bear freely after several nights in succession of severe frost, it is not always that frost is to blame for failure. What have others to say on the subject? H. Markham.

THE GROWL ABOUT SHREWSBURY SHOW.—I like a "growl"; it shows something is not perfect, or some one has a grievance. I like to investigate "growls," and do the best to prevent them in future. Our friend from Surrey complains on p. 212 of the dust in the fruit tent; so did many others. I did myself. But what could be done?

During our twenty-five shows it has occurred twice—in 1897 and this year. The reason is lack of rain. For many weeks before the shows scarcely a drop of rain fell in either year on the show-ground, which is light, consequently the soil became as dry as dust for many inches below the surface. In consequence of the enormous number of visitors going round the tents, the dust rises in proportion to the amount of traffic. Sprinkling with watering-cans is of no use. It becomes dry again in ten minutes. In 1897 we had a water-cart for an hour going round the tents without any permanent effect; the dust in an hour rose as badly as before. I should only be too glad to receive suggestions how to avoid such dust in future; but if there is no rain for ten weeks previously to the show, I can see no remedy. We have had shows where planks from tent to tent lie still buried where they sank in the mud, and ladies' boots were lost by the dozen. Some "growled" then; so did I. *H. W. Adnitt.*

"TREE," OR "PERPETUAL" CARNATIONS.—In reference to Mr. W. J. Godfrey's remarks, on p. 204, I favour neither of the above terms for this section of Carnations, but have a great objection to creating new names for old friends. Having in my previous note stated that both terms are misleading, I preferred to adopt that by which they are generally catalogued. When the term "Tree" was originally applied, there were good grounds for it, as those included had such a distinct tall growing habit. In my earlier associations with these, when we used to grow the same plants on from year to year, I have known them attain from 3 to 4 feet in height. I am very pleased to learn that there are many varieties superior to Miss Jolliffe and Mdlle. Thérèse Franco, but I have yet to make their acquaintance. If Mr. Godfrey can send me blooms to confirm his statement, I shall certainly be anxious to secure a stock of them. With reference to the American varieties, I have been disappointed with those I have tried, Flora Hill being no exception. *A. Hemsley.*

I was much interested in the remarks of Mr. Hemsley on p. 163, where he says varieties vary in different parts of the country. I have grown Primrose Day in Kent, Manchester, and am now growing it in Scotland, and do not wish for a better yellow. I have found it a truly perpetual variety, and by growing the plants a second season they flower magnificently. For this purpose, it is better to shorten all the growths at the end of May, and when they have again started into growth to put them into 8-inch pots, and stand them on a coal-ash bed out-of-doors. You may then expect a splendid crop of flowers in October, and a continuous supply through the winter. These remarks hold good in the case of all varieties generally cultivated for cut blooms. I find some of the newer introductions answer equally well. Countess Ferrars, a lovely deep flesh colour; Mrs. Clibran, a reddish-rose with a pure white edge, and powerful fragrance; Lord Armstrong, a glowing chestnut; Baron Rothschild, deep apricot, make splendid plants the second season, and flower profusely throughout the winter and spring. Countess of Warwick also does well, but I have found Flora Hill does not answer. Like Mr. Hemsley, I have not yet found a good white variety. I keep my plants at a higher temperature than most growers, and advocate 65° to 75° with plenty of air at all times. This method is now being practised in continental nurseries where Carnations are a specialty. The stock plants must be kept in a cooler house, in order to provide strong cuttings. *W. Clifford, Maxwellthugh, Kelso.*

SUBSTITUTE FOR GRAFTING-WAX.—I think that any contribution to this subject is useful as the old recipe of clay and cowdung is not only disagreeable to use but often cracks badly, thus necessitating extra labour and serving as a harbour to earwigs and other injurious insects. For the last three years I have used ordinary painters' knotting both for Apples and Pears, and the results have been entirely satisfactory. The scions are tied in the usual way, and the knotting painted over the whole with a sash tool. It quickly forms a hard, glazey, impervious coat, which is not affected by any kind of weather. Under glass I have only tried it on Oranges, for which it proved successful, and I have no doubt it would be equally effective for any kind of hard-wooded plants. Painters' knotting is the best material for painting over wounds or the cut surfaces of Vines and other plants after pruning, as it effectually stops up the injured cells, preventing bleeding or evaporation,

and the drying up of the wood. *J. H. Woolley, Leicester Frith Gardens.*

FLAVOUR IN POTATOS.—I do not know how or where "A. D." obtains his data as to what my experience of Potato-growing is, or its extent, inasmuch as it is generally thought but right to be well associated with a man before offering an opinion as to his attainments and capabilities. "A. D." seems to think this needless, and without scruple, sums up my knowledge and "experience of the Potato," cooked and uncooked, as not being large enough to render me impartial. Why, though my understanding of the Potato may be small, I am not impartial, I should like explained. Having acted as a judge at Potato shows, I hope and trust that my decisions have been impartial. This knowing of what another knows, or does not know, without even an acquaintanceship with the person, is a great gift that many would like to possess, and is seldom met with, though apparently "A. D." feels that it is well within his competence, and so in my case exercises his wonderful powers in this science. Having grown the Ashleaf Kidney more than fifty years, and after that Rivers' Ash-leaf, I can testify to its excellence, and that on some ground it is by no means a small cropper, nor with me was the old Forty-Fold, nor the Early Shaws, and the Kent Blue-Eyes (one of the very best, yet now extinct), with me none of these had "the disease." I like Sharpe's Victor and some others, but what I complain of, and still do, is that these "quality" Potatos are not to be bought, but must be home-grown for our tables. "A. D." remarks that many of the Potato consumers object to such a Potato as the Ashleaf Kidney. Here, perhaps owing to my inexperience, I must join issue, for though familiar with a vast number of people, I have never known one that decried the old Ashleaf; nor do I know at the present time a single person but what is perfectly discontented with the dry, tasteless balls of flour. Such may be good croppers, and so wrongly called good market Potatos. But of this I am certain, and that is, the Potato of the salesman is a thing to be avoided and not sought for with pleasure, as it was years before it was improved. Why a third or fourth-rate article should be considered good enough for the people is beyond my comprehension, and in this I am not alone. *Harrison Weir.*

THE CONDITIONS UNDER WHICH ODONTOGLOSSUM CRISPUM GROWS.—Having read Mr. Young's advice in the "Week's Work," on p. 188, on the culture of the *Odontoglossum crispum*, and also "T. L. C.'s" experience as regards the plant, I feel a little in doubt as to the kind of treatment the species requires during the summer months. Mr. Young says, "a little shrivelling is more a blessing in disguise than an injury;" whilst "T. L. C.," at p. 202, remarks, "as this plant grows at an altitude of 8000 feet, it must always be in a free air, and as the vapour-laden clouds rise to that height, they become condensed, and descend in copious showers upon the plants frequently, but not constantly," which certainly would not give the pseudo-bulbs any chance of shrivelling; and as *O. crispum* is growing more or less throughout the year, it is quite obvious that neither the atmosphere nor the plants themselves should be allowed to get dry at any time, so as to allow the pseudo-bulbs to shrivel. The above opinions seem to me so conflicting that I would like to solicit the advice of other cultivators of *Odontoglossums* for the benefit of others, as well as *A. Young Gardener.*

PITTIOSPORUMS.—I am very glad to see a good figure of *Pittosporum crassifolium*, at p. 205 of the *Gardeners' Chronicle*. It grows well in Ireland, and has flowered this spring at Woodside, Howth, with Dr. George Vaughan Hart, Q.C., who flowered *Olearia Forsteri*, that you figured about a year ago. I now send you a fruiting twig of *P. viridiflorum*, a nearly allied species, hoping it may be of interest. It is a plant I first saw in fruit in the old greenhouse at the Oxford Botanical Gardens, a year ago. *Pittosporum Mayi* is a good shrub here, and flowers and fruits freely. Its glistering, glossy leaves colour of a beautiful bronze in the autumn; and at Castletwellan, co. Down, there are fine specimens on the lawn, 8 to 10 feet or more in height, and perfect columnar pyramide. Though a common shrub in Ireland, its origin seems obscure. In the *New Index* it appears as "*P. Mayi*, Hort. ex. Regel Cat. Pl. Hort.

Aksakov. 112, nomen. Hab.?" no authentic description being cited. Its black twigs smell of terebinte, or turpentine, like those of a Conifer if bruised or scraped; and it is always a clean, neat, and healthy bush, far more valuable than *Ligustrum Walkeri*, which resembles it in general part, except that its foliage is of a paler green. So far as I see at present, *P. Mayi* is by far the best and hardiest of all the species of *Pittosporum* in Irish gardens, and even as a small specimen in pots or tubs it is very pretty and desirable, and its foliage is useful for cutting during autumn and winter. *F. W. Burbidge.*

SOCIETIES.

ROYAL HORTICULTURAL.

SEPTEMBER 12.—An ordinary fortnightly meeting of the committees of this Society was held on Tuesday last in the Drill Hall, James Street, Westminster, when there was a very much better display than on the last occasion. There was more of every section of exhibits, excluding Orchids, and the Orchid Committee, as will be seen below, recommended the awards of one First-class and one Botanical Certificate, and two Awards of Merit. But Dahlias were the feature of Tuesday's show, and these were exhibited abundantly, most of the trade growers being represented by large collections of blooms. Little evidence was there in these bright, handsome Dahlias of the severe drought. Seedling Dahlias were put forward for Certificates in great numbers, and seventeen of these were granted Awards of Merit, most of the varieties being identical with those certificated last week at the Crystal Palace. Chrysanthemums were shown in two exhibits, one of cut flowers, and another of plants arranged in a group.

Sir TREVOR LAWRENCE, Bart., showed a new hybrid *Eucharis*, "*Burfordiensis*," and to this novelty, and to *Retinospora obtusa aurea Crippsii*, First-class Certificates were awarded.

Mr. JAS. HUDSON showed a sport from *Begonia Gloire de Lorraine* with larger flowers than the type (Award of Merit); and Messrs. W. PAUL & SON obtained a similar award for a new Rose, "*Corallina*."

The Fruit and Vegetable Committee had a large number of exhibits before them. Three new Apples received Awards of Merit, a most unusual occurrence, as did a new Cucumber, "*Achievement*," from Lord ALDENHAM's gardens.

In the afternoon Mr. ED. MAWLEY gave an interesting lecture upon "*The Drought of 1898*."

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. H. P. May, R. Dean, Jas. Hudson, J. F. McLeod, Chas. E. Pearson, Thos. Peed, W. Bain, J. W. Barr, J. D. Pawle, James Walker, Herbert J. Cutbush, E. H. Jenkins, Chas. Blick, E. T. Cook, D. B. Crane, E. Beckett, Geo. Paul, and Ed. Mawley.

DAHLIAS.

Mr. J. STREDWICK, St. Leonards, had a number of novelties, and in addition to those which received Awards of Merit, Princess, primrose-yellow; William Jowitt, deep scarlet; Goliath, orange-red; Mrs. Sanders, soft yellow; Clara, pale orange-red; and Autumn Queen, delicate pinkish-lilac, are all of a promising character.

MESSRS. J. CHEAL & SONS, Crawley, had a large and representative collection of Dahlias, affording ample choice for those interested in the flower. There were grand bunches of the most approved Cactus varieties, Pompons, and singles in excellent character; several boards of show and fancy varieties, and a good representation of the fascinating single Cactus type, which were seen in their best character (Silver-gilt Banksian Medal).

MESSRS. T. S. WARE (Ltd.), Tottenham, had a huge bank of cut flowers, in which Dahlias played an important part, the Cactus and Pompon varieties being in strong force. Among the former was *Empress of Austria*, a rich dark crimson variety, very promising, but not in its best character on this occasion (Silver Flora Medal).

Mr. M. V. SEALE, Sevenoaks, had a box of a dozen new varieties of Single Dahlias, and in addition to the two which received Awards of Merit, there were *Gaiety Girl*, orange red, tipped with yellow; *Elsie*, pale ground, tinted soft lilac, and flaked crimson; the *Sirchar*, white, with side-edgings of maroon; and *Mona*, pale ground with slight side edgings of deep crimson.

MESSRS. JONES & CO., Shophatch, Shrewsbury, set a good fashion in the way of the effective staging of cut blooms of Dahlias; having a back-ground of shields of Cactus varieties arranged with foliage, charming shower-bouquets of Dahlias, and a basket of Cactus Dahlias arranged with Asparagus foliage, which set everyone longing to possess it (Silver Banksian Medal).

Mr. J. T. WEST, Cornwall, Brentwood, had a large collection of Cactus Dahlias in handsome bunches, among which could be seen his fine, new varieties, Mrs. J. J. Crowe and Mrs. Carter Page; and a singularly beautiful light variety of this year named *Violet Cornish*, which would have obtained an Award

of Merit had it been duly entered. In addition, there were charming bunches of Pompons, and quite an array of show and fancy varieties (Silver Banksian Medal).

Messrs. KEYNES & Co., Salisbury, had a collection of new varieties of Cactus, and of those which did not receive Awards of Merit, mention may be made of Loyalty, Fearnought, The Leader, Cornucopia, and Wisdom, as varieties with a future before them.

Mr. J. GREEN, Norfolk Nurseries, Dereham, was awarded a Silver Flora Medal for a group of choice Dahlias; and Messrs. J. PEED & SONS, West Norwood, a Silver Banksian Medal, also for Dahlias.

ROSES.

Messrs. WM. PAUL & SON, Waltham Cross Nurseries, Herts, made a fine display with cut Roses. There were something like eighty varieties staged, and many of them were represented by a large number of blooms. Some of the more prominent varieties were Queen Mab, Empress Alexandra of Russia, White Mamam Cochet, Marie Van Houtte, Papa Gontier, Kaiserin Aug. Victoria, Madame Abel Chatenay, Polyanthas Perle d'Gr, and Perle Rouge; Alexandra, a new bedding Tea-Rose, with bronzy-yellow blooms; Mrs. W. J. Grant, Enchantress, Caroline Testout, Viscountess Folkestone, Gruss aus Tepitz, a new crimson H. T. Rose, &c. (Silver-gilt Flora Medal).

Mr. GEO. PRINCE, of Oxford, had a very artistic display of cut Roses. A large number of small glassed were used of different shapes, one variety of Rose filling several of them, and all were named neatly. Many of these were placed upon shelves covered with black velvet. Some tall Bambo stands furnished with Tea Roses looked very pretty. Then there were others, in moss-surfaced boxes. So many lovely Tea-scented varieties were shown well, that we need not particularise (Silver Flora Medal).

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, in a very large exhibit of cut flowers, included a number of varieties of Roses, especially of the Noisette and Tea-scented sections. Also a fine lot of hardy herbaceous flowers. Aster sinensis was well shown, some with white flowers, and others with pink, blue, and crimson blooms; these single flowers are very pretty, and of great value for decorative purposes. Helianthus in variety and Gaillardias, a variegated form of Rosa Wichuriana, &c. Some pans containing plants in flower of Cyclamen hederifolium and C. h. album were very pretty (Silver Banksian Medal).

CHRYSANTHEMUMS.

Mr. W. WELLS, Earlswood Nurseries, Redhill, Surrey, showed a large collection of cut flowers of Chrysanthemums, representing forty varieties, from the outside border. The hot sun has been very trying to the Border Chrysanthemums this season; and probably the later-blooming varieties will succeed better. Mr. WELLS had a very pretty group of flowers.

Mr. J. W. WITTY, superintendent of the Nunhead cemetery, London, S.E., exhibited a fair-sized group of Chrysanthemums in pots, edged with Ferns, &c. Varieties of the Desgrangea section and others were well shown, but it is rather too early to bring Chrysanthemums to the exhibition, as the numerous Dahlias are much superior in brightness (Silver Flora Medal).

MISCELLANEOUS EXHIBITS.

Mr. JAS. HUDSON, Gunnersbury House Gardens, Acton, W., showed nine remarkable specimens of *Acalypha hispida* in pots. They had been planted out in a warm-house in the spring; and, after making a clear straight stem 4 feet 6 inches high they were stopped, thus inducing the production of side-shoots. These side-shoots became pendent, owing to the number of flower racemes upon them, and numerous flowers were still hanging from the upper part of the main stem. In appearance, the shape of the plants above the bare stem was like that of a mammoth bunch of Grapes. Mr. HUDSON also showed a rather dwarf compact form of *Salvia splendens* (Silver Banksian Medal).

Sir TREVOR LAWRENCE, Bart., Burford (gr., Mr. Bain), exhibited a flower of *Aristolochia elegans*, one of the pretty small species very seldom flowered out-of-doors; and a fine variety of *Lobelia cardinalis*.

Mr. JNO. WEATHERS, Silverhall Nursery, Isleworth, showed cut flowers of *Callistephus chinensis*, the species from which has been obtained all the fine China Asters, now so popular for bedding purposes. It has long been out of cultivation in England, but was re-introduced about two years since. The flowers are a shade of purple, very decorative, and will last about a fortnight after being cut and placed in water. The plants were raised from seeds sown in April.

Messrs. F. SANDER & Co., St. Albans, exhibited several handsome varieties of *Sonchella*.

Messrs. W. CURESH & SONS, Highgate Nurseries, London, W., exhibited some extraordinary trusses of flowers of *Uydrangea paniculata grandiflora*. There were eighteen trusses, and they were the largest we have seen.

Messrs. JNO. PEED & SONS, Norwood, London, showed a group of plants in pots, of a white flowered perennial Aster, named Mrs. W. Peters. The plants about 2 feet high from the ground. The variety has small flowers and foliage.

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., showed a collection of cut hardy flowers, including some of the choicer varieties of herbaceous Phloxes, Helianthus, and some of the earlier flowering of the perennial Asters.

Awards.

Begonia Mrs. Leopold de Rothschild.—This is a distinct sport from B. Gloire de Lorraine. It has similar foliage to that of the type, but the inflorescence is shorter, and the habit of the

plant more compact. The flowers are much larger; and lighter in colour, being pink rather than rose. Mr. HUDSON purchased six plants of B. Gloire de Lorraine in the spring of 1896, and the sport appeared last season. It may be described as a glorified form of the type. From Mr. JAS. HUDSON, Gunnersbury House Gardens, Acton (Award of Merit).

Eucharis "Burfordensis."—This is a very attractive Eucharis, and most likely the result of a cross between E. Stevensii and E. Mastersii. The leaves are very suggestive of those of E. Mastersii, but are narrowed in the direction of E. Stevensii. It is an exceptionally free bloomer. The flowers are rather more than 3 inches across, and about 2 inches long; not flat, like E. grandiflora, but bell-shaped. From Sir TREVOR LAWRENCE, Burford (First-class Certificate).

Rose "Corallina."—This is a brightly coloured, very showy bedding Tea Rose, raised at Waltham Cross. The variety is an extra strong grower, the maiden plants being about 3 feet in height this season. It is exceedingly free blooming, and the flowers, as seen in a bunch, are reddish-rose, passing lighter and silvery. From Messrs. W. PAUL & SON, Waltham Cross (Award of Merit).

Retinospora obtusa aurea Crippsii.—A very fine golden variety of R. obtusa, differing, as shown, from R. o. aurea previously certificated, in having a more slender, less dense habit of growth; the points of the growing shoots are pendulous. From Messrs. THOS. CRIPPS & SON, Tunbridge Wells (First-class Certificate).

DAHLIAS.

Awards of Merit were made to—

Mrs. J. J. Crowe (West), pale soft yellow, a variety highly refined, and of perfect shape; shown by the raiser, and by Messrs. KEYNES, WILLIAMS & Co., nurserymen, Salisbury.

To Cactus Innovation, which maintains its character as a glorified Arachne;

Trojanitor, bright reddish-crimson, the points of the petals cut and fluted in a novel manner;

Loalstone, dark orange-red, with a brighter hue in the centre; fine Cactus shape;

Emperor, orange-rose, suffused with purple, especially towards the points of the florets; a fine addition to the purple Cactus; and to

Pompon Cheerfulness, yellow, with an even and regular tip of bright orange-red, a charming variety of perfect shape; from Messrs. KEYNES & Co.

Cactus Red Rover, unusually large in size, brilliant red in colour, while maintaining the true Cactus shape; and

Green's White, a new white variety, fully maintains its promising character. From Mr. J. GREEN, Norfolk Nursery Dereham.

Cactus Mayor Tuppenny, the basal petals bright salmon red, with clear yellow centre; fine Cactus type, and very bright

Augustus Hare, yellow, or salmon, overlaid with brilliant red; very handsome and distinct;

Major Weston, bright crimson, with a dark shading in the centre;

Uncle Tom, the basal petals maroon-crimson, with black centre; a valuable addition to the dark varieties.

Maurice T. Walsh, the basal petals amber, with a slight tint of reddish-salmon, and soft yellow centre; novel, and pleasing. The above from Mr. J. STREDWICK, Silverhill, St. Leonards.

Fancy Dahlia Empress, a very welcome addition to a select class, having a pale ground, suffused with the most delicate lilac, striped and flaked with crimson and maroon, from Mr. G. ST. PIERRE HARRIS, Orpington.

Single Dahlia "Veronica," orange-red, each floret tipped with bright amber; fine shape, and very uniform. Also

Flume, yellow flaked, pencilled and striped with orange-red; a flower of fine shape in the way of Lord Rosebery, but distinct from it; and

Daisy, pale ground, flaked and pencilled with dark crimson and purple; novel, distinct, and of the finest shape. From Messrs. J. CHEAL & SONS, nurserymen, Crawley.

Single Dahlia Edie Obelin, a combination of gold, salmon, and mauve; a beautiful variety, of fine shape; and

Nellie Nicholson, white, the florets having narrow margins of bright rose. From Mr. M. V. SEALE, Vine Nursery, Sevenoaks.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the Chair), and Messrs. Jas. O'Brien (Hon. Sec.), J. Gurney Fowler, De B. Crawshaw, H. Little, A. H. Smea, J. Gabriel, E. Hill, J. Jaques, J. Douglas, H. M. Pollett, H. J. Chapman, W. H. Young, T. W. Bond, and C. J. Lucas.

But very few Orchids awaited the attention of the Committee; the only group being a nice display of the fine white and orange *Dendrobium formosum*, arranged with that beautiful decorative plant, *Acalypha hispida* (Sander), staged by Messrs. F. SANDER & Co., St. Albans.

Sir TREVOR LAWRENCE, Bart., Burford, showed the very pretty *Cypripedium niveum maculatum*, with pure white flowers, all the parts of which were uniformly spotted with dark purple.

FRED. HARDY, Esq., Tyntesfield, Ashton-on-Mersey (gr., Mr. T. Stafford), again showed *Sophrora-Cattleya* × *George Hardy* (*Sophranitis grandiflora* × *Cattleya Aclandiae*), a very charming hybrid, with flowers of a peculiar reddish-scarlet

tint, with yellow base to the lip. It received an Award of Merit when shown on May 10, 1898.

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), showed four flowers of *Laelio-Cattleya* × *callistoglossa*, *lagram* variety, with very bright dark purple lip.

Mrs. TEMPLE, Leyswood, Groombridge (gr., Mr. E. Bristow), sent *Cattleya Gaskelliana* Temple.

Col. R. W. SHIPWAY, Grove House, Chiswick (gr., Mr. W. Walters), showed *Cattleya* × *Hardyana*, *Grove House* variety, a very large and highly-coloured form, with extraordinary development of the front lobe of the lip.

Awards.

Cattleya Luddmanniana alba.—From W. DUCKWORTH, Esq., Shawe Hall, Flixton, Manchester (gr., Mr. H. H. Tindale). This is one of the rarest, and certainly one of the most beautiful albinos among the large-flowered *Cattleyas*. Flowers like those of typical C. Luddmanniana, but pure white, with a clear light yellow centre to the lip (First-class Certificate).

Laelio-Cattleya × *callistoglossa*, *Leon's variety* (*Laelia purpurata Leonie* × *Warszewiczii*).—From H. S. LEON, Esq., Bletchley Park (gr., Mr. Hislop). This gorgeously-tinted hybrid gives a fine example of the good results to be obtained by crossing exceptionally good varieties, the introduction of L. purpurata Leonie in this case having resulted in obtaining a form scarcely reconcilable with other varieties of the same cross. The sepals and petals were bright lilac-rose, the fine lip almost entirely of a dark claret-purple, the colour extending to the base. It was but a small plant, and therefore capable of improving even upon its present fine appearance (Award of Merit).

Cattleya × *Kienastiana* var. *Aurore* (*Luddmanniana* × *Dowiana aurea*), from C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond). The flowers in some degree resembled a light form of *Cattleya* × *Hardyana*. Sepals and petals soft rose colour, slightly freckled with cream-white; the centre and base of the lip bright golden-yellow, with dark purplish-red lines, the crimped front lobe coloured rose like the petals, and with a purplish-rose irregular blotch in the centre (Award of Merit).

Cryptophoranthus hypodiscus, Rolfe (*Masdevallia hypodiscus*, Reiche, f.).—A very extraordinary and distinct species, whose introduction is due to Consul F. C. LEHMANN. The plant is somewhat smaller in all its parts than C. Dayanus, but with the same general appearance, the flowers, like them, bearing some resemblance to a hawk's head, the eye like windows of the closed sepals showing through, as in C. fenestralis and others of its class. The exterior of the flower is rugose, the base purple, the middle portion cream-colour, and the beak-like top dark brownish-purple. It is a very extraordinary and quaint-looking species, and said to be very free-flowering (Botanical Certificate).

Fruit and Vegetable Committee.

Present: Philip Crowley, Esq. (Chairman), and Messrs. Jos. Cheal, W. Poupart, M. Gleeson, W. Pope, A. H. Pearson, Alex. Dean, S. Mortimer, G. T. Miles, Geo. Woodward, Geo. Wythes, Robt. Fife, Geo. Bunyard, W. Wilks, and Geo. Reynolds.

Mr. C. ROSS, the gardens, Welford Park, Berks, sent Apple Thomas Andrew Knight, described in the Awards; also a small one named Margeretta, but of little value; also Melon The Captain, of moderate quality.

Messrs. W. J. BROWN, Stamford, sent Apple Stamford Beauty, good sized, ribbed, and richly coloured. It greatly resembled Hollandbury, but deeper coloured.

Mr. JAS. RUTTER showed Apple Lord Kitchener, something like Potts' Seedling, but earlier and soft; but as only one fruit was sent, it was passed over.

Messrs. R. VEITCH & SONS, Exeter, had a large Melon named Taunton Hero, an old variety. This was regarded as the same as Golden Gem. It was devoid of flavour. Also from them came a plant and fruits of Tomato Abundance, of the Perfection type, and a heavy cropper. There is an Abundance Tomato already in commerce.

Messrs. G. BUNYARD & Co., Maidstone, showed Apple Bielo Boradawka, of Russian origin.

Messrs. HOBBS, Dereham, Norfolk, had Tomato Wonder of Italy, a variety that has been grown at Chiswick this season under the name of Semper fructifera, having been sent from Naples. The fruits are about the size and shape of Damsons, and borne in huge clusters. It does well outdoors, and is very nice for the dessert.

Some large and not handsome Aubergines came from the Chiswick Gardens.

Mr. J. MILLER, gr. to Lord FOLEY, Ruxley Lodge, Esher, received a Cultural Commendation for a box of very fine Princess of Wales Peaches.

Mr. G. WYTHES, Syon House Gardens, Brentford, showed green Corn-cobs in six varieties, produced in four months from seed. The cobs were more or less set with seed, but neither seemed so good as Cobbett's Corn, once largely grown in Middlesex.

Mr. S. MORTIMER, Farnham, Surrey, staged twenty-four fine Melons, grown in wooden troughs in a house. The troughs are 18 inches wide and 6 inches deep. To show what fine fruits can be thus produced, one of each of the varieties were cut and tasted, Sutton's Favourite, Hero of Lockinge, and Perfection; the two latter were of delicious flavour, the former was not quite ripe (Silver Banksian Medal).

Mr. F. WALKER, Balcombe, Sussex (gr., Mr. J. Cole), set up a neat collection of fruit, including fine Exquisite and

Walburton Admirable Peaches, Magnum Bonum and Pond's Seedling Plums, Violette Hative and Elruge Nectarines; The Queen, Lord Grosvenor, and other Apples; and Morello Cherries (Silver Banksian Medal).

Mr. Taylor, gr. to C. BAYER, Esq., Forest Hill, had a capital collection, including Alicante, Directeur Tissierande, Alnwick Seedling, and Gros Maroc, Black; and Muscat of Alexandria and Foster's Seedling White Grapes; Mr. Gladstone and Princess of Wales Peaches; Coe's Golden Drop, Primate, and late Orange Plums; Williams' Bon Chretien Pears; Cox's Pomona, good Nonsuch and King of Tomkins's County Apples, and several nice-looking Tomatos (Silver Knightian Medal).

Mr. Geo. Woodward, gr. to ROGER LEIGH, Esq., Barham Court, Maidstone, had very fine examples of Beurre Mortillet, and Triomphe de Vienne Pears, fine Sea Eagle and Nectarine Peaches, and capital Humboldt and Rivers' Orange Nectarines, all from the open wall; also fine, rich coloured Dymond Peaches from trees one year planted against a north wall, and capital Royal George Peaches from a standard in the open garden, that has fruited well for eight years (Silver Banksian Medal).

Messrs. W. PAUL & SONS, Waltham Cross, had not only forty-five dishes of fine Apples, very representative, but also eighteen trees in pots, of diverse sizes, and all heavily fruited. These included Beauty of Kent, Lewis's Incomparable, Mabbot's Pearmain, Chelmsford Wonder, Annie Elizabeth, Cellini Pippin, Small's Admirable, Lane's Prince Albert, Belle Pontoise, Peasgood's Nonsuch, and Gloria Mundi (Silver-gilt Knightian Medal).

Messrs. JAS. VEITCH & SONS, Chelsea, set up in very attractive fashion a collection of Tomato plants, in twenty varieties, all heavily fruited, just as they were pulled from the open ground. It was a most interesting collection, and fully displayed the remarkable cropping qualities of varieties this season under such culture. Very fine reds were noted in Frogmore Selected, Duke of York, Perfection, Trophy, Acquisition, Ham Green, Cherry Red, and Conqueror. Good yellows were Golden Jubilee, very fine and handsome; Golden Queen, Golden Cherry, &c. (Silver Knightian Medal).

Mr. E. BECKETT, gr. to LORD ALDENHAM, Elstree, set up a superb collection of vegetables of the highest merit. There were forty-seven dishes, and included symmetrical Model and New Intermediate Carrots, Autumn Giant Cauliflowers, Autocrat Peas, Dwarf French and Runner Beans; Satisfaction, Windsor Castle, and Goldfinder Potatoes; Model Leeks, hardy green Coleworts, specially good; Prizetaker, White Gem, and Standard Bearer Celery; The Wildsmith, Cocoa Nut, and Ailsa Craig Onions; long, white, green, and Moore's Prolific Marrows, handsome and luxuriant Cucumbers, White Turnips, and various other vegetables (Gold Medal).

Awards.

App's Ben's Red.—A variety showing rich colour; a seedling from Red Quarrenden and Farleigh Beauty. It is large and red, not unlike Mère de Ménage, but ripens earlier. From Messrs. GEO. BUNYARD & Co., Maidstone (Award of Merit).

Apple Thomas Andrew Knight.—This was raised from a cross between Cox's Orange Pippin and Peasgood's Nonsuch. The fruits are exactly of the form of Cox's, and have the rich flesh and flavour of that excellent variety; but they were more than double its size, very handsome, and well coloured. It promises to be one of the best dessert Apples in the country. From Mr. C. ROSS, Welford Park gardens, Berkshire (Award of Merit).

Apple Venus Pippin.—A medium-sized, conical fruit, smooth, and handsome. It is greenish-yellow, with soft flesh. A pleasant-eating fruit. From Mr. W. GODFREY, Exmouth (Award of Merit).

Cucumber "Achievement".—A handsome, dark, slightly spiny fruit, with a dense bloom, from Mr. BECKETT, Aldenham House gardens, Elstree (Award of Merit).

"LESSONS FROM THE GREAT DROUGHT OF 1898."

MR. ED. MAWLEY has had so much experience in relation to statistics, and more especially statistics relating to the weather, that his lecture in the Drill Hall on Tuesday last was expected to be a most interesting one; and so it was.

Amongst the items concerning the drought of 1898, Mr. Mawley stated that in the North of Scotland there was no great deficiency of rain; and in Ireland, not any at all. The North of England was not so badly hit either, the deficiency there being one gallon or less per square yard per week, reckoning from the beginning of June until the middle of October. In the southern counties the deficiency was 1½ gallons per square yard. This merely confirms what we already knew, for the condition of the soil and crops south of London last year was one that will be long remembered.

The drought was a very severe one, for during a period of sixty-eight days the rainfall was less than half a gallon per square yard per week. But it was an essentially autumn drought. Mr. Mawley, by displaying several diagrams, and by quoting figures in abundance, gave his audience facts relating to the actual rainfall during last year's drought in the different counties, and during selected periods of the drought. He compared that of 1898 with former droughts, referred to the value of summer and winter rains, respectively; quoted the number of droughts experienced for the past eighty-four years, and gave a great deal of relevant information including a little about that drought through which we have just passed.

Then turning to the practical side of the question, Mr. Mawley said that the only natural source of moisture for crops, was that obtained from rain and dew, in addition to that already stored in the soil.

To economise during drought the moisture already in the

earth, Mr. Mawley recommended (1) The good old custom of thorough trenching for flowering plants and kitchen-garden crops. The soil will then the better conserve the moisture, and the roots be better enabled to penetrate deeply; (2) Mulching with farmyard or other manure, not thicker than 3 inches; but it is well never to apply a mulching before the latter end of May, as until then, the warmth of the soil is more valuable than moisture; (3) Hoing frequently the surface of the soil to the depth of about 2 inches, and so ensure a layer of fine, dry soil, which will largely act as a conservator of moisture; (4) Well manuring the soil before planting, with farmyard animal manure, or decayed vegetable matter; (5) Water should only be applied on a large scale, when experience has proved that other means will not be sufficient. If water is afforded, the applications should be thorough and infrequent; (6) Selection of crops for the garden of species and varieties, which, by possessing a habit of rooting deeply, or an extra robust constitution, will not feel the effects of drought so severely.

Mr. Geo. Bunyard said that at Maidstone they found that cow-dung and kainit, both of which manures contain a proportion of salt, were excellent manures for dry soils. He thought also that much more use might be made of common salt for the same purpose.

NATIONAL DAHLIA.

NEW DAHLIAS AT THE CRYSTAL PALACE.

SEPTEMBER 1, 2.—One remarkable feature of the exhibition of the National Dahlia Society's show held at the Crystal Palace last week was the large number of new Cactus varieties staged, and they appear to be becoming as plentiful as the new Japanese Chrysanthemums.

Messrs. Keynes & Co., Burrell & Co., J. Stredwick, J. Green, and others are busy raising new varieties, and despite the care exercised by the committee of the National Dahlia Society in awarding Certificates of Merit, not a few new varieties were so honoured, and it is satisfactory to note that with increased variety in the flowers, and with acceptable changes in the form of the flowers, there is decided improvement in the habit of growth; the plants grow dwarfier, are more bushy in growth, bloom much more freely, and throw their flowers well above the foliage. This may not be true of every new variety; but the time has arrived when habit of growth should be considered in granting awards in the form of Certificates of Merit. The time has come when a lofty ideal should be set up, and adhered to.

Certificates of Merit were awarded to the following new Cactus Dahlias:—William Treseder, blush, the basal petals tinted with delicate lilac—a charming light variety, from Mr. W. TRESEDER. Innovation, in the way of The Clown, the fluted petals deep crimson, with white tips, and the centre of the flower white—a fine exhibition variety; Emperor, ruby, flushed with purple, and dark centre—a purple Gloriosa; and Mrs. J. Crowe, delicate yellow, a medium-sized variety of great refinement—all three from Messrs. KEYNES, WILLIAMS & Co. Mrs. Sanders, pale yellow, a soft and pleasing tint, and of the best Cactus type; Major Weston, bright crimson, with darker centre—a bold and striking variety; Mayor Tuppenny, salmon-red, with yellow centre, novel and distinct; Augustus Harc, rich orange-red, very bright and effective; and Uncle Tom, shaded maroon, with black centre, a good addition to the dark varieties—all the foregoing five were raised and exhibited by Mr. J. STREDWICK, Silver Hill, St. Leonards. To Elsie, a lovely variety, yellow ground, the petals tinted mauve-pink, from Messrs. J. BURRELL & Co., Cambridge. To Green's White, the finest white yet produced, pure, perfect in form, and a grand exhibition variety; and to Zephyr, soft rosy-pink, delicate and beautiful, and of the best Cactus type, from Mr. J. GREEN, Norfolk Nursery, Dereham. Red Rover, a large and very striking deep-red variety, of perfect Cactus shape, was passed over, apparently because of its large size; but as no authority has set up a limitation of size, and as it has all the true Cactus character, the objection was scarcely logical. Increased size is certain to appear in the newer Cactus Dahlias; it is one of the certain results of development. Two pretty single varieties also received Certificates of Merit: one, Girlie, cream, with narrow side edgings of pale red, and of fine shape, from Miss E. J. GIRDLESTONE, Sunningdale; and Flame, orange-flaked, and pencilled with orange-crimson, from Messrs. J. CHEAL & SONS, Crawley.

WARGRAVE AND DISTRICT GARDENERS'.

SEPTEMBER 6.—A meeting was held on this date, and Mr. W. H. SCOTT read a paper on "Begonia Culture." He said Van Houten was the first hybridiser, and brought the plant to the notice of the public as a florist's flower. The Begonia had a robust constitution, and would stand a certain amount of severe handling. He then described experiments he had made on the plant with various chemical manures, and gave his opinion that nitrate of soda produced the best results.

Mr. J. HASKETT followed with a short practical paper on "The Onion." The varieties, the structure of the bulb, the colour, manures, and enemies, were in turn touched upon. Soft and wood-ashes were recommended as the best manures. Potato Onions were advocated as the best cottagers' Onion, being enormous croppers, and growing anywhere.

The exhibits included some fine Giant Rocca Onion (Mr. HASKETT), Charlton's Beet (Mr. FULLBROOK), Noblesse and Royal George Peaches (Mr. GREENAWAY), and two dishes of Tomatos (Mr. POPE).

MANCHESTER AND NORTH OF ENGLAND ORCHID.

SEPTEMBER 7.—Present: Messrs. G. Shorland Ball (chairman), R. Johnson, W. Duckworth, Chas. Parker, and P. Weathers (Secretary).

Messrs. CHARLESWORTH & Co., Heaton Bradford, staged a few handsome Orchids, amongst which were *Lælia Iona*, *L. tenebrosa* × *L. Dayana*, a bright little flower, showing the parentage very distinctly; the size of *L. Dayana*, however, is maintained, thus proving somewhat a drawback to the production, *Lælia-Cattleya* × Admiral Dewey was the best plant shown by this firm, and was awarded a First-class Certificate. *Lycaste Dunningiana* was shown with one flower of good proportions, and received an Award of Merit. *Cypripedium* × Mrs. Harry Smith is one of the numerous results which are showing themselves just now of *C. Rothschildianum* hybrids, the other parent in this case being *C. Veitchi*, *Demidoff's* var.; the result is a fine bold flower, well-balanced, and handsome (Award of Merit). A very fine plant of *Houlletia Brocklehurstiana* came from the same firm, bearing upwards of a dozen fine flowers, which are sweetly scented (Award of Merit).

J. LEEMANN, Esq., of Heaton Mersey, showed a fine plant of *Vanda Sanderiana*, with a spike of fine flowers of good form and colouring (First-class Certificate).

Mrs. BRIGGS-BURY, Accrington, sent *Cypripedium* × *Leonæ* in good form, but it failed to receive an award; as did also a peculiar *Odontoglossum* which is certainly a hybrid between *O. Alexandræ* and *Pescatorei*, the latter species being traceable plainly in the labellum.

Mr. A. J. KEELING showed a good *Cypripedium* hybrid between *Veitchi* × *Morganæ*; the flower was of a remarkably pale colour, comparable to *C. T. B. Haywood* in this respect, but of much more handsome form, being like *C. Morganæ* in the droop of its petals, with the markings of *C. Veitchi*, while the dorsal sepal was almost purely *C. Veitchi* (Award of Merit). The same exhibitor showed a very good form of *R. elegans* var. *Schilleriana*, which had a magnificently-coloured lip, and splashed with rose in the petals.

The gem of the meeting was *Cattleya speciosissima alba*, a variety I think seen for the first time in this country; from the general habit of the plant one would take it for an ordinary *C. speciosissima*. The flowers (two) were of a very fine type, being strong and well formed, and of a fine opaque white. This plant was greatly admired by the amateurs present. Mr. Duckworth, possibly one of the most enthusiastic young amateurs of the day, must be congratulated in having such a treasure in his collection. The Committee unanimously awarded a First-class Certificate, and ordered the Society's artist to paint it for record.

GALLOWAY HORTICULTURAL.

SEPTEMBER 7.—After a lapse of one year, the Galloway Horticultural Society held a show in Castle-Douglas, on the above date. There was a good turn-out of exhibits, the entries being equal to those of former years, both as regards numbers and quality.

Mr. J. M. STEWART, Mollance, obtained the Lever Silver Cup offered to the most successful exhibitor, having 88 points; while Mr. J. AUSTIN, Hardgate, was awarded the 2nd prize, a Silver Medal, he having 44 points. Mr. J. M. STEWART carried off nearly all the awards in the gardeners' class, and besides took honours in the open class for Grapes and for table or pot plants (arranged for effect). Mr. AUSTIN was also the most successful exhibitor in the amateur department. Messrs. JOHN BLYTH & SONS, Castle-Douglas Nursery, exhibited a good table of plants and cut blooms. Mr. THOMAS MYERS, Gowanlea, made an energetic secretary.

BRENTWOOD HORTICULTURAL.

SEPTEMBER 7.—The autumn exhibition was held, as usual, under tents in the grounds of Middleton Hall. All the classes were for cut flowers, fruit, vegetables, and table decorations; and there was, on the whole, a very satisfactory exhibition.

Dahlias formed one of the leading features. The best twenty-four varieties, which included the leading show and fancy flowers, were from Mr. HARRIS, Chelmsford; Mr. Joy, gr. to H. RAPHAEL, Esq., was 2nd.

With twelve varieties in the class for amateurs, Mr. J. C. QUENNEL was 1st; and Mr. A. STARTING, Rosecourt, Havering, 2nd.

Cactus Dahlias were numerous shown in the class for twelve blooms. The 1st prize was won by Mr. T. BROWN, gr. to W. B. PARKER, Esq. Roses were rather sparsely shown.

A charming arrangement for a dinner-table was set up by Mrs. W. GREEN, jun., Harold Wood. Roses, Marguerites, and other flowers of soft tints, being tastefully arranged with foliage. This proved one of the most attractive features in the show.

FRUITS AND VEGETABLES.

The best collection of six dishes of fruit came from Mr. W. GREEN, jun., Harold Wood; and he was placed 1st in three classes for two bunches of Grapes, having very good examples. The best two bunches of white grapes were Foster's Seedling, from Mr. J. ELLER.

Peaches, Nectarines, Plums, in three classes; dessert and culinary Apples, Pears, and Currants were all in good character, and the competition in some of the classes was very keen.

Mr. TULLETT was 1st with nine dishes of vegetables; and the 1st of Messrs. Sutton & Sons' special prizes for six varieties was won by Mr. T. A. Beckett, gr. to Mrs. McINTOSH, Havering. Vegetables generally were good, especially Potatoes, Celery, and Onions, in which fine Ailsa Craig was prominent.

NON-COMPETITIVE EXHIBITS.

A large and representative collection of Dahlias was set by Mr. J. T. WEST, Tower Hill, Brentwood.

Messrs. SALTSMARSH & SON, nurserymen, Chelmsford, had a collection of Cactus Dahlias, Asters, Pentstemons, Zinnias, &c., and also of fruit.

WELLINGBOROUGH AND MIDLAND COUNTIES DAHLIA.

SEPTEMBER 8, 9. — Wellingborough can claim to have created a very successful Dahlia Society; and also to have called into existence a number of growers for exhibition. This was the fourth exhibition, and so decided was the increase in the number of entries, that the spacious Corn Exchange was filled to overflowing, making the work of judging somewhat arduous. Wellingborough is an excellent Dahlia growing district, and an appropriate centre for a midland exhibition.

Certain classes open to all comers brought the southern growers in strong force, and in the leading class for forty-eight show and fancy Dahlias, there were six entries; Mr. JOHN WALKER, nurseryman, Thame, adding to his triumphs of the present season by taking several 1st prizes. He was 1st in the class for thirty-six blooms, out of six competitors, having good-sized, symmetrical examples. Mr. M. V. SEALE, Vine Nursery, Sevenoaks, was a close 2nd.

With twenty-four blooms, there being seven competitors, Mr. WALKER was again 1st, and also for twelve blooms in class 3; Mr. S. MORTIMER, Swiss Nursery, Farnham, was 2nd in both classes.

The competition was remarkably keen in all three classes, and the judges regretted they could not award extra prizes.

Cactus Dahlias, staged as in the case of show Dahlias, were shown in two classes, one for eighteen blooms, the other for twelve blooms. Mr. S. MORTIMER was placed 1st in the former class, having in excellent character many leading varieties. Mr. SEALE was 2nd.

In the class for twelve blooms, there were eight competitors, Messrs. KEYNES, WILLIAMS & Co. taking the 1st prize with excellent flowers; Mr. S. MORTIMER was 2nd.

Bunches of Cactus blooms in twelve varieties, three blooms of each, were a fine feature, Messrs. KEYNES & Co. taking the 1st prize with the following in admirable character:—Mary Service, Loyalty (new), Magnificent, Charles Woodbridge, Keynes' White, Progenitor (new), quite a novel and distinct type; Mrs. Carter Page (new), Innovation (new), Loadstone (new), Starfish, Ebony, and Mrs. J. J. Crowe (new); Mr. R. Keeble, gr. to F. W. SHARPLES, Esq., Great Martins, Twyford, Berks, was a close 2nd, setting up flowers of fine quality.

Equally fine in quality were the bunches of twelve varieties of Pompon Dahlias. Mr. GEO. HUMPHRIES was 1st with medium-sized, even fresh blooms; and Messrs. KEYNES & Co. were 2nd.

Mr. SEALE was 1st with six bunches of single Dahlias, a very pretty selection, consisting of Jeannette, Alice Seale, Leslie Seale, Gullielma, The Geisha, and Trilby; Mr. J. WALKER was 2nd.

Special prizes were offered by Mr. C. Turner for six blooms of one variety of fancy Dahlia. Mr. SEALE was 1st with Professor Fawcett, a model half-dozen blooms, finely marked; Mr. G. HUMPHRIES was 2nd, with Mrs. J. Downie, in excellent character.

The best three blooms of a yellow self were those of Mabel Stanton from Mr. SEALE.

AMATEURS' CLASSES.

In the two classes for show Dahlias, Messrs. SPRIGGS, T. PENDERED, and W. PRENTICE, were the principal prize-winners. Cactus flowers shown in bunches, as well as on boards, and Pompons, were shown in good character. Messrs. KEYNES & Co. offered special prizes for twelve blooms of Cactus Dahlias sent out from Salisbury; the 1st prize was won by Mr. T. PENDERED, with very good flowers.

Messrs. WALKER & HUMPHRIES offered special prizes for Show and Fancy Dahlias exhibited by cottagers, and very creditable blooms were staged.

A Gold Medal, offered by Mr. R. DEAN, for the best eighteen blooms of Cactus Dahlias, brought a good competition, and it was awarded to Mr. J. YORK, Desborough.

There were open classes for fruit, in which good Grapes, Apples, Pears, and Plums, were staged; also, for perogues and bouquets of Dahlias, and for Asters and vegetables exhibited by cottagers; and there were brisk competitions in all the classes.

The leading growers and exhibitors present, with the judges, formed a Floral Committee, awarding Certificates of Merit to new varieties of Dahlias.

Mr. J. GREEN, sent from Dereham, a very interesting collection of new Cactus and Pompon Dahlias, among the former were the large Red Rover, Green's White, Zephyr, Grace Darling, Golden Plover, Eclair, &c., with some older varieties; this collection was highly commended; as was also a collection of twelve varieties of new seedling Dahlias, from Mr. SEALE, of Sevenoaks.

ROYAL CALEDONIAN HORTICULTURAL.

[SEPTEMBER 13 14.—The autumn exhibition of this Society was held on Wednesday and Thursday, in the vast Waverley Market, Edinburgh. At one time fruit bulked most largely among the exhibits at this show, and though it holds a more prominent position than ever, the quantity of cut flowers arranged and staged in the most attractive manner by nurserymen, as well as tables of plants suitable for decorative purposes, set up by the same public-spirited tradesmen, have now eclipsed the fruit as a show; and to these gentlemen the gardening public of the north are greatly indebted for these grand educational displays.

In order to gain a little extra time for the competitive exhibits, the following notes were made previous to the judging of the former.

NON-COMPETITIVE EXHIBITS

Among cut flowers, Mr. M. CUTHBERTSON, Rothesay, set up a very bright group, mainly of Montbretias, Cactus Dahlias, Lemoine's Gladiolus, Michaelmas Daisies, &c.

Messrs. KEIR BROS., Dumfries, has a splendid exhibition of Dahlias of all sections; and from Mr. CAMPBELL, High Blantyre, there was a large group, composed mainly of Pompon Dahlias, Border Carnations, including his new yellow variety, Miss Alley.

From Mr. JOHN FORBES came a unique collection of hardy florists' flowers, including the newer French Philoxes, Hollyhocks, Carnations, Dahlias, and a lot of herbaceous cut flowers. Mr. INVINE, Jedburgh, had a group of Pentstemons in variety, all his own raising, and characterised by brightness of colouring, along with lengthy spikes and good form of bloom.

Messrs. H. CANNELL & SONS, Swanley, Kent, along with a group of the best large-flowering Cannas, brought a superb collection of the best Cactus Dahlias, the blooms, in bunches of six, being arranged with sprays of Aster erioideus in bud.

Messrs. WALLACE & Co., Colchester, set up a nice table of various autumn-flowering Lilies, Montbretias, and Gladiolus. Mr. HENRY ECKFORD had, as usual, examples of his lovely Sweet Peas, including the charmingly tinted new form, Lady of Rinning.

Messrs. DOBBIE & Co., Rothesay, confined their efforts to an exceedingly effective and large group of all sections of Dahlias, among which none was more pretty than the starry, single-flowered Cactus varieties.

Mr. ROWATT, Glassford, staged fine Pentstemons.

Mr. S. T. S. WADE, LTD., Hale Farm Nurseries, Tottenham, staged a most extensive exhibit of double and single Begonias.

Messrs. CLERHAN & SONS, Altrincham, staged a very fine lot of Celosia pyramidalis in various colours, salmon, yellow, magenta, rose, and crimson; also a number of pots of St. Joseph Strawberry full of fruit.

Mr. DOWNIE, Princes Street, Edinburgh, had a charmingly-arranged group of decorative plants arranged on the floor of the building; while another group, equally effective, was set up by Messrs. LAIRD & SONS, who also showed collections of shrubs and cut Dahlia blooms in variety.

Messrs. CUNNINGHAM, FRASER & Co. had a nice lot of decorative shrubs.

Mr. J. RUSSELL, Richmond, showed a collection of Ivies; Mr. HILL, Edmonton, Ferns; and Messrs. H. Low & Co., Clapton, Orchids. From Mr. H. J. JONES, Lewisham, came a nice group of decorative plants, such as Crotons, &c.

COMPETITIVE CLASSES, CUT-FLOWERS (AMATEURS).

In the Competitive Cut-flower Classes, Mr. A. BRYDON, Innerleithen, had the finest exhibit of twelve spikes of herbaceous perennial flowers in a large class; Mr. HOON, Dalmore, Hellensburgh, the finest collection of twelve Tea Roses; Mr. W. MELVILLE, was 1st for twelve H. P.'s, having beautiful blooms, and he was 1st also in the class for six blooms of a pink Rose, showing fine specimens of Caroline Testout.

In a large class, Mr. ANGUS, Aberdeen, was 1st, for twelve bunches of Sweet Peas.

The finest Dahlias were from Mr. VEITCH, Carlisle; and the prizes for the best and most tastefully arranged dinner-table decoration were secured respectively by Mr. MARTIN and by Mrs. DUNCAN, Fogo.

NURSERYMEN.

In the Nurserymen's Classes the cut Roses formed a grand display, the blooms generally being large and well coloured.

For thirty-six blooms, Messrs. D. & W. CAOLL, Dundee, were 1st, and also for eighteen blooms; Mr. SMITH, Stranraer, being 2nd in both classes.

For twenty-four Roses, Messrs. CROLL were again successful. The tables of herbaceous perennial cut flowers brought out three exhibitors, Messrs. HARKNESS & Co., Bedale, Yorks, being 1st. It comprised grand masses of blooms, in the freshest condition, of the leading flowers now in bloom.

Messrs. J. COCKEN & SONS, Aberdeen, were a very close 2nd; and Messrs. KEIR, BROTHERS, Dumfries, 3rd.

The best thirty spikes of Gladiolus were shown by Mr. GEO. MOIR; Mr. FORBES, Hawick, taking 1st for eleven spikes of Hollyhocks; Mr. CAMPBELL, Blantyre, had the best twelve blooms of Carnations; and Mr. JOHN FORBES the best twelve blooms of Picotees.

FRUIT CLASSES.

In the fruit classes there was a grand collection of Grapes. Mr. T. LUNT, gr., Keir, securing 1st, both in the classes for six bunches and for four bunches; the Muscats being hardly so

well finished as those shown by the same exhibitor at Shrewsbury. In the class for six bunches, he staged Muscat of Alexandria, Mrs. Pince, and Albwick Seedling; Messrs. BUCHANAN, Kippen, were a close 2nd with Muscats, slightly green, three magnificent clusters of Alicante, weighing respectively 5½, 6½, and 7½ pounds, and a fine bunch of Cooper's Black. In the four bunch class, Mr. LUNT staged Mrs. Pince, Muscat of Alexandria, Madresfield Court, and Cooper's Black. Messrs. BUCHANAN were 2nd in this class also, a fine cluster of their oval-berried black seedling, Diamond Jubilee, being one of the four staged.

Mr. LUNT was again successful with two bunches, and with one bunch of Muscat of Alexandria, with large, fine, and well-coloured clusters.

The best two bunches of Black Hamburg Grapes were shown by Mr. A. KENACHER.

Messrs. D. & W. BUCHANAN had the finest Alicante and Albwick Seedling Grapes. The finest-flavoured Black Grapes were shown by Mr. D. MURRAY, Culzean Castle gardens. The best White Grapes for flavour were shown by Mr. LUNT; and the Grapes showing the finest bloom by Mr. GREEN.

HARDY FRUITS.

Of hardy fruit there was a very large exhibition of well-grown produce. Mr. BARNES, gr., Eaton Hall, Chester, had the best twelve varieties of Apples; Mr. WILLIAMSON, gr., Tarvit House, the best collection of dessert Plums; Mr. DAY, gr., Galloway House, Kirkcudbright, taking a like position in the culinary class.

Peaches, Nectarines, Melons, and Figs were also well shown. Mr. A. IRELAND and Mr. DAY had the best Pears.

DECORATED DESSERT TABLE, AND COLLECTIONS OF FRUIT.

For the best decorated dessert table, Mr. BARNES, Eaton Hall, was the only exhibitor, and was awarded 1st prize. The fruit staged was fine, especially the Apples, Pears, and Peaches; and the floral decoration simple. The flowers used were Odontoglossum Alexandre and Lily of the Valley, in vases.

Mr. MURRAY, gr. Culzean Castle, was 1st for a collection of twelve sorts of fruit, and included excellent Grapes, Peaches, and Nectarines; Mr. SMITH, Oxfenford, 2nd.

PLANTS.

In the plant classes, Mr. WOOD, Canaan Lane, Edinburgh, had 1st prize for a table of plants arranged for effect.

Mr. MCCARTNEY was 1st for four stove or greenhouse plants in flower.

Mr. LUNT won in the classes for six foliage plants; six foliage plants in 9-inch pots; two Crotons, Palms, and Adiantums.

The best six Ferns were staged by Mr. J. H. PEARSON; and Mr. SHARP, Freeland, Perth, was 1st for four Orchids, for one Orchid, and for three Cyripediums.

VEGETABLES.

The vegetable classes were very largely filled, in some cases as many as thirty-three, thirty-six, and forty-two entries having been made in a class.

For a collection of twelve kinds there were eight entries, Mr. J. DUNCOCK securing the 1st prize, with fine produce and Mr. J. WARDIE was 2nd.

The Floral Committee.

The first meeting of the Fruit and Floral Committees was held on the afternoon of Wednesday.

At the latter a seedling Dracena, with broad foliage, having white markings, and named The Sirdar, from Mr. ANGUS, Norwood Hall, Cults, Aberdeenshire, was recommended a Certificate; as was a golden variegated Ilex maderiensis, named Fraseri, from Messrs. CUNNINGHAM & FRASER, Comely Bank, Edinburgh; also a yellow-flowered Chrysanthemum, named Craig Millar, from Messrs. DICKSON & Co., Edinburgh; and a yellow Carnation from Mrs. WHITEHEAD, Selkirk, named Mrs. Whitehead.

The Fruit Committee

awarded Cultural Certificates to Mr. R. CAIRNS, Bahnderry, Dundee, for Apple Emperor Alexander, and Pear Pitmaston Duchess.

ENQUIRIES.

"PHYTOPHILIST" writes:—"Having noticed in your last week's issue some useful recipes for various garden purposes, it is suggested to me to write and ask you if you could give a good recipe for making some strong adhesive composition, which might be applied to strips of cloth or linen, so as to make them adhere to a wall? I find that I am unable to drive nails into a cemented wall against which I am trying to train Ivy, and I wish to bring the young-growing shoots (which are sometimes apt to grow away from the wall) into close contact with the wall. I have used some strong adhesive (sur-

gical) strapping, but it is not strong enough in its adhesive power when the shoot is somewhat twisted or perverse."

PINE-BEETLE IN SCOTS FIR.—A correspondent would be glad to know how soon after the wood has been cut down will the beetle become extinct, and when could the ground be re-planted with safety?

HORSE-CHESTNUTS AND LIGHTNING.—Is the tradition a correct one, that Horse-Chestnut trees are non-conductors of lightning, and for this reason are planted round the houses in North Wales? Does this custom prevail in other parts of the country? and is it a reliable safeguard? *L. E. E.*

TRADE NOTE.

We are informed that the partnership which existed between Messrs. Thos. Rigg and Walter Fixter, at South View Nurseries, Caversham, has been dissolved, and that in future the business will be conducted by Mr. Thos. Rigg.

BOOKS: *H. S. D.* The best is the *Illustrated Dictionary of Gardening and Encyclopedia of Horticulture*, by George Nicholson, A.L.S., published in four volumes by Upcott Gill, price about £3. Or there is *Johnson's Gardeners' Dictionary*, published in one volume by Geo. Bell & Sons, York Street, Covent Garden, London. This is a much cheaper work, and though small is worth the price.

CATERPILLAR: *A. W.* The caterpillar of the Death's-head Moth, *Sphinx Atreus*; feeds on Potato leaves, &c.

CHRYSANTHEMUM: *Mutual Friend* It is not usual to leave such a shoot when "taking" or selecting the flower-bud; nor is it necessary to do so. You may convince yourself of the better of the two methods by practising both for a time. We think you will find little difference in the mature flowers.

DISEASED CATTLEYA: *E. T.* The diseased condition shown in the bulb of *Cattleya Dowiana aurea* has become common of late years, *C. Warszewiczii*, *C. Dowiana*, and others of that class being specially liable to this disease, the contributory conditions of which have not as yet been correctly determined. Among Orchid growers it is conceded that no blame attaches to those in charge of the plants, as the disease attacks the plants grown under different kinds of treatment.

EEL-WORMS: *A. A. L. S.* Simply to dig the land one or two spits deep is not enough to destroy the worms, as they would be sure to come near the surface, and feed on the roots of whatever plants and weeds they found there. If grass-land were dressed twice or thrice a year for a number of years with nitrate of soda or other chemical manure, the worms might be destroyed. For various reasons, turf in which there are eel-worms should be cut and carted to the earth deposit in the winter, and preferably when it is not sodden with moisture. If but small quantities of pasture-loam be wanted at a time, baking it is best.

ELEAGNUS ARGENTEA: *Phytophilit.* The plant is deciduous.

GRAPES: *A. V.* The fruit is in such a condition that it is difficult to say what conditions have led to such a result. The mildew is clear enough, but this would not account for the berries cracking before ripe. Is your border well drained? Had you sent the fruit when first the trouble was noticed, an opinion might have been formed on them. But they are now a decaying mass only.—*J. J.* The berries sent are "shacked," a condition which points to something being wrong at the root, or to over-cropping this year, or earlier, and other causes. The colour is likewise not up

to the mark. Examine the border and the roots of the Vines, obtaining the advice of some good gardener in your neighbourhood in carrying out the certainly very necessary renovations.

INSECTS: *Alpha.* The exact nature of the objects you send is very doubtful. We are inclined to think that they are the eggs of some insect attacked by a fungoid growth. We should not anticipate any mischief arising from them. *C. O. W.*

LYGODIUM SCANDENS INFESTED WITH SCALE: *Phytophilit.* Try the effect of syringing the plant with water at a temperature of about 150°.

MELON: *C. W. H.* The soil is quite unsuitable for Melon-growing, and that is probably the cause of the fruits being so very small. Can you not obtain some stiffish pasture-loam, or good garden soil?

NAMES OF FRUITS: *G. W.* We must ask you for a better specimen.—*S. B.* We must ask you for a better specimen, or, which would be better, two specimens. It is unfair to present for identification an Apple that is three parts decayed.—*H. H.* 1, Dr. Harvey; 2, Scarlet Leadiogton; 3, Fairy.—*G. N., Cheltenham.* 1, Pott's Seedling; 2, Ribston Pippin; 3, Curlytail; 4, Pear Martin Sire; 5, Flower of Herts; 6, Herefordshire Beeding.—*T. R., Sussex.* The Pear was quite rotten, but resembles the Summer Doyenné; the Apple appears to be a highly-coloured Red Hawthornden or Greenup's Pippin.—*W. O., Lancashire.* 1, Calville Blanche d'Eté; 2, unknown.—*A. C.* 2, Worcester Pearmain; 3, Loddington; 4, Lane's Prince Albert. The Plum should have been packed separately.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*R. A.* A variety of single Dahlia.—*G. W.* *Odontoglossum Lindleyanum.*—*J. H. W.* *Eichornia crassipes*, figured in *Bot. Mag.*, t. 2932, as *Pontederia azurea*.—*W. W. Dicksonia* (*Cibotium*) *Barometz.*—*S. A.* 1, *Cyperus longus*; 2, *Begonia incarnata metallica*; 3, *Coreopsis tinctoria*; 4, *C. latifolia*; 5, *Othonna crassifolia*, a very pretty plant for suspending in a cool-house.—*G. W. R.* *Datura Stramonium*, the Thorn Apple, a poisonous plant cultivated for the druggists. Apply to some wholesale druggist.—*A. T. C. J.* 1, *Equisetum arvense*; 2, *Astrantia major.*—*Blyth.* 1, *Schubertia graveolens*; 2, *Diervilla* (*Weigela*) *hortensis variegata*; 3, *Abutilon vexillarium variegatum*; 4, *Codiaeum* (*Croton*) *pictum*; 5, *C. Weissmanni*; 6, *C. chrysophyllum*; 7, *C. elegantissimum*; 8, *C. variegatum.*—*W. S.* 1, *Solidago* species, not *Tarragon*; 2 and 3, varieties of *Hibiscus syriacus*. *J. Miller.* 1, *Choisya ternata*; 2, *Phyllirea angustifolia*; 3, *Andromeda* probably, send when in flower; 4, *Taxodium distichum*; 5, *Phyllanthus nivosus*; 6, *Olearia Haasti*. No label, *Keria japonica*; fruit is *Pyrus japonica*. The bark may be as you state, that of *Wellingtonia gigantea*. We see no disease; it is the natural condition of the bark.—*Cambrian.* 1, *Lepidium ruderalis*; 2, *Senebiera coronopus.*—*Turti.* 1, *Negundo fraxinifolium*; 2, *Robinia pseudacacia* var.; 3, *Quercus coccinea*; 4, *Berberis vulgaris*; 5, apparently a variety of *Laburnum*; 6, *Salix rosmarinifolia.*—*Fuchsias and Pelargoniums.* Impossible to name such specimens as you send. Send good specimens to some nurseryman who deals in such plants.—*H. G. B. H.* sends leaves only. 1, not recognised; 2, *Abutilon Souvenir de Bonn*; 3, *Crataegus* species; 4, *Colutea arborescens*; 5, *Pseudotsuga Douglasii*; 6, *Calycanthus occidentalis.*—*F. S.* 1, *Sanguiserva officinalis*; 2, *Santolina incana*; 3, *Asparagus* sp.; 4, *Russelia juncea*; 5, *Smilax* sp.—*H. Kempshall.* *Betula nana*, a Scots species.—*W. H. M., Munches.* 1, *Physalis Francheti*; 2, *Arctostaphylos uva urse.*—*C. G.* 1, *Thalictrum flavum*; 2, *Chenopodium polyspermum*; 3, *Akebia quinata.*—*T. B.* Send when in flower.

NASTURTIUM: *W. S. W.* The flowers were quite faded, so that the variety could not be determined. These plants come fairly true from seed, and they may be propagated from cuttings taken at this season and rooted in a cold frame, or from stock plants in gentle warmth in the spring.

NATIONAL DAHLIA SHOW.—In the amateurs' classes for Cactus Dahlias, at the Crystal Palace

Show, the 2nd prize for nine bunches was won by *W. G. Handcock, Esq., Kingsnorth, Ashford (gr., Mr. Smith).*

NEGLECTED LAWN: *Lawn.* If the lawn is not uneven, that which you purpose doing should suffice. You might supplement the top dressing with stiff loam, some slaked lime, and wood ashes. Turf may be laid from October to April, in mild weather.

PEARS FOR EAST WALLS, NEAR NEWCASTLE-ON-TYNE: *Matfen.* You might try *Williams' Bon Chrétien*, *Dr. Jules Guyot*, *Triomphe de Vienne*, *Pitmaston Duchess*, *Althorpe Crassane*, *Beurré d'Arenberg*, *Beurré Diel*, *Beurré Hardy*, *Eye-wood*, *Suumer Franc Real*, *Conference*, *Jersey Gratioli*, *Jargonelle*, and *Napoleon*.

ROSES FOR FORMING A HEDGE: *Cymru.* See note on p. 228.

TEA PLANTER, &c.: *F. J.* You should advertise your wants in the *Times of India*, the *London Times*, or other newspapers circulating in the East Indies; also scan the advertising columns of this and other likely journals. Some practical experience in horticulture would be an advantage, as would the possession of a little capital.

USE FOR A SPARE CUCUMBER-HOUSE IN THE WINTER: *Midland.* Naturally we should suggest Cucumber cultivation; and failing this, there are winter-flowering Carnations, requiring very little heat, *Roses* in pots or troughs, *Mushrooms*, *Rhubarb*, *Asparagus*, *Mustard-and-Cress*, all of which would fetch fair prices in the neighbouring towns.

COMMUNICATIONS RECEIVED.—*A. E. B.*—*R. H. W.*—*X. Y.*—*A. B. C.*—*H. W. W.*—*A. G. T.*—*J. I.*—*Chas. Ross* (with thanks).—*F. R.*—*Japonica.*—*T. D.*—*C. P.*—*D. T. F.*—*R. D.*—*A. O'N.*—*J. F. H.*—*E. B.*—*G. M.*—*T. W. O.*—*A. W. T.*—*J. P. K.*—*G. C. F.*—*C. Buds-Pesth.*—*T. B.*—*L. Behmer & Co.*—*R. T.*—*G. G.*—*G. F. Grindley.*

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London. Principal Grazing, &c., Districts—6, Scotland, W. 7, England, N.W.; 8, England, S.W.; 9, Ireland, N. 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending September 9, is furnished from the Meteorological Office:—

"The weather was fair or fine in all except our most northern and north-western districts during the earlier days of the week, but subsequently became very unsettled for a time, with considerable falls of rain and thunderstorms in places. Towards the end of the period the conditions had again become fair and dry over England and Ireland, S."

"The temperature continued above the mean, the excess ranging from 3° in Ireland, Scotland, and 'England, N.W.' to as much as 6° in 'England, E., S., and S.W.' and the 'Channel Islands.' The highest of the maxima were recorded on the 5th over England, earlier in the week in Ireland, and on irregular dates in Scotland; they varied from 80° in England, S., and 88° in 'England, E., to 72° in 'Scotland, N., and 'Ireland, S., and 71° in 'Scotland, W.' The lowest of the minima, which were registered on somewhat irregular dates, ranged from 37° in 'England, S.W.' (at Llandoverly), and 40° in 'Scotland, W., and 'Ireland, N., to 47° in 'England, S., and to 56° in the 'Channel Islands.'

"The rainfall was less than the mean in most districts, but more in 'England, S.' and the 'Midland Counties'; in the latter district, the fall was twice as large as the normal value. During a severe thunderstorm which passed over the metropolis on Wednesday, as much as an inch of rain fell at Brixton in about half an hour.

"The bright sunshine again exceeded the mean amount in nearly all districts; the percentage of the possible duration ranged from 08 in the 'Channel Islands,' 64 in 'England, S., and 61 in 'England, S.W., to between 41 and 38 in Ireland, and to between 35 and 31 in Scotland."

MARKETS.

COVENT GARDEN, SEPTEMBER 14.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

— White, boxes	10 6-12 0		

POTATOES.

Hebrons, Puritans, Snowdrop, Up-to-Date, &c., 60s. to 85s. John Bath, 33 & 34, Wellington Street, W.C.

REMARKS.—Good supplies all round, trade rather slow. Peas are nearly finished. Blackberries are plentiful. A few Sloes were in evidence to-day. Californian Pears are of various sorts; some of the Bartlett or Williams' Bon Chrétien are fine. Of home-grown Apples, there are plenty on sale, and prices are low.

SEEDS.

LONDON: September 13.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that the return of the drought naturally restricts the demand for those kinds of seeds required for immediate sowing for catch crops. Meantime, there is a good inquiry for Trifolium, which is getting scarce; French seed, by the way, is dearer, whilst the English samples come cheaper. Winter Tares are in short supply, and firm in value. There is no change in Rye, whilst full prices are quoted for Mustard and Rapeseed. The tendency for Haricot Beans is still upwards. Peas are strong, but quiet. Canary-seed shows no alteration; and, as regards Clover seeds, prices all round are distinctly on the up-grade. The Board of Trade Returns give the imports of Clover and grass-seeds into the United Kingdom for the eight months of this year, ending August 31, 1899, as—cwt. 173,238, value £331,267; as against cwt. 232,652, value £451,918, for the corresponding period of 1898.

FRUIT AND VEGETABLES.

GLASGOW: September 12.—The following are the averages of the prices recorded since our last report:—Fruit: Apples, Dutch, 4s. 3d. per bushel, and 4s. to 11s. per small hamper, and 9s. to 16s. per cask; do., American Colverts, 15s. to 18s. per barrel; Pears, French Duchesse, 36's, 3s. to 3s. 6d. per case; 48's, 2s. 6d. to 3s. 6d. do.; do., Louise Bonne and Duchesse, loose, 7s. to 8s. do.; do., 15s. 6d. to 3s. per sieve basket; Victoria Plums, 2d. per lb.; Irish Plums, 12s. per cwt.; Damsons, 18s. do.; Lemons, Palermo, selected, sound, 14s. to 17s. per case; do., Messina, 15s. to 18s. do.; do., Naples, sound, 25s. to 32s. do.; Melons, Valencia, yellow, 24's, 7s. to 7s. 6d. per case; 36's, 7s. to 7s. 6d. do.; 48's, 7s. to 7s. 6d. do.; do., bronze, 24's, 7s. 6d. to 8s. do.; 36's, 7s. to 7s. 6d. do.; Grapes, English, 1s. to 2s. per lb.; Almeida, 11s. to 18s. per barrel; Bananas, extra, 12s. to 13s. per bunch; do., No. 1's, 10s. to 11s. do.; No. 2's, 9s. to 10s. do.; Vegetables: Carrots, 3s. per bag; Beetroot, 2s. 6d. to 4s. per bag; Onions, Valencia, 4's, 3s. 3d. to 4s. per case; do., 5's, 4s. 6d. to 5s. 6d. do.; Tomatoes, 3d. to 5d. per pound, English; do., Scotch, 4d. to 7d. do.; Mushrooms, 10d. to 1s. 6d. per pound; Turnips, 7d. to 9d. per dozen bunches; Swedes, 1s. 10d. per cwt.; Carrots, 7d. to 8d. per dozen bunches; Cucumbers, 1s. to 1s. 9d. per dozen; Cauliflowers, 1s. to 2s. 3d. per dozen; Cabbages, 1s. 6d. to 1s. 9d. per dozen.

PLANTS AND FLOWERS: September 12.—Lilium Harrisii, 2s. 6d. to 3s. per dozen blooms; L. lancifolium, 9d. to 1s. 6d. do.; Orchids, 1s. to 8s. do.; Carnations, 2d. to 9d. per bunch; Roses, white, 6d. to 2s. 6d. per dozen; do., red, 1s. to 2s. do.; do., boxes, 2s. to 4s. each; Asters, 1s. to 3s. per dozen bunches; Sweet Peas, 1s. to 4s. do.; Maidenhair Fern, 3s. to 6s. do.; Gardenias, 1s. 6d. per dozen; Marguerites, 2s. do.; boxes of mixed flowers, 6d. to 4s. per box; Asparagus Ferns, 6d. to 2s. per bunch; Chrysanthemums, 2s. to 6s. per dozen.

LIVERPOOL: September 13.—Wholesale Vegetable Market.—Potatoes, per cwt.: Early Regents, 1s. 6d. to 2s.; Main Crop, 2s. to 3s. 6d.; Kidneys, 2s. 6d. to 3s. 3d.; Bruce, 1s. 9d. to 2s. 3d.; Turnips, 6d. to 8d. per doz. bunches; do., Swedes, 1s. to 2s. per cwt.; Carrots, 6d. to 8d. per dozen bunches; Parsley, 6d. to 8d. per dozen bunches; Onions, English, 6s. per cwt.; do., foreign, 5s. to 6s. do.; Cucumbers, 1s. to 3s. per dozen; Cauliflowers, 1s. 3d. to 2s. 6d. do.; Cabbages, 1s. 2d. to 3s. per dozen; Celery, 1s. 4d. to 2s. per dozen. St. John's.—Potatoes, 10d. to 1s. 2d. per peck; Grapes, English, 1s. 6d. to 3s. per lb.; do., foreign, 4d. to 8d. do.; Pines, English, 4s. to 8s. each; Damsons, 4d. per lb.; Cobnuts, 10d. do.; Cucumbers, 2d. to 4d. each; Mushrooms, 1s. per pound and basket. Birkenhead.—Potatoes, 8d. to 10d. per peck; Damsons, 4d. per lb.; Cucumbers, 2d. to 4d. each; Filberts, 8d. per lb.; Oranges, English, 1s. 6d. to 3s. per lb.; do., foreign, 4d. to 8d. do.; Mushrooms, 1s. to 1s. 6d. per lb.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending September 9, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

MR. ALEXANDER McLEAN, for the past three years Gardener at Ryecourt, Crookstown, Cork, as Gardener to Mrs. VESSEY, Dunleckney Manor, Bagnalstown, Co. Carlow.
MR. THOS. THOMPSON, for five years Gardener to F. A. NEWDIGATE, Esq., M.P., Weston-in-Arden, Nuneaton, as Gardener to R. WALKER, Esq., Ratcliffe Hall, Leicester.
MR. THOMAS HILL, plant foreman, Lonsdaleborough Park, Market Weighton, Yorks, as Gardener to W. H. AVKROYD, Esq., Cliffe Hill, Lightcliffe, Bradford.
MR. THOMAS KERR, late Gardener to Miss FOWLER, St. Ann's, Scillon Park, Liverpool, as gardener to WILLIAM POTTER, Esq., Moorhall, Aughton, near Ormskirk, Lancashire.
MR. D. F. DEBMAN, for the past five years foreman at Roehampton House, as gardener to R. H. BATTEN POOL, Esq., Road Manor, Bath.

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS' AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal libraries.

THE

Gardeners' Chronicle

No. 665.—SATURDAY, SEPT. 23, 1899.

JOHN STACKHOUSE AND ACTON CASTLE.

DURING the latter half of the last century a miniature mania seems to have prevailed for the erection of castles in Cornwall. About the year 1750, Stephens, a wealthy landowner in the Duchy, erected Tregenna Castle, which overlooks the beautiful bay of St. Ives; and a few years later John Stackhouse, the eminent botanist, also the owner of extensive properties in Cornwall, erected, on the opposite coast of the county, a fine castellated house, which, like Tregenna, commands a magnificent sea-view. For many years Tregenna Castle has been transformed into a big hotel; and as Acton Castle (fig. 80, p. 238) is on the point of being converted to the same usages, a brief account of its history and of the man who built it may not be out of place. Stackhouse, who was not only an eminent botanist himself, was connected, in a manner which will presently be shown, with Thomas Andrew Knight, of Downton Castle, co. Hereford, known to posterity as President for many years of the Horticultural Society of London (1811—1838).

John Stackhouse was the second son of the Rev. W. Stackhouse, rector of St. Erme, Cornwall, and was born at Trehane, in the same county, in 1742. He matriculated from Exeter College, Oxford, and was a Fellow of the College from 1761 to 1764. The writer (Mr. G. S. Boulger) of the notice in the *Dictionary of National Biography*, states that "from an early period Stackhouse devoted himself to botany, and especially to the study of Seaweeds, and of the plants mentioned by Theophrastus." He married on April 21, 1773, Susanna, only daughter and heiress of Edward Acton, of Acton Scott, Shropshire, by which he came into possession of the valuable estate of Acton Scott. Ten years before this, however, he succeeded to the Pendarves estates in Cornwall, when he resigned his fellowship, and travelled abroad for a couple of years; doing, in fact, the "grand tour," without which, at that time, no young English gentleman's education was considered complete. In or about 1775 he erected Acton Castle, which he obviously named in compliment to his wife's maiden name, and which he admittedly built for the express purpose of studying seaweed *in situ*.

The eighteenth century was a period of leisurely movements, and Stackhouse allowed just twenty years to elapse before he published the results of his studies. *Nereis Britannica sive fuci, ulve et Conferve in insulis Britannicis crescentes* was published in folio at Bath in 1795, with text in Latin and English, and twelve coloured plates from drawings by the author—coloured by a lady, whose name he does not disclose—of course, "*ad vivam depictis*." An enlarged edition, or an enlarge-

ment of the original issue, appeared in 1801, with twenty-four coloured plates; and fifteen years later it was published at Oxford in quarto size, the text considerably revised and added to, with Latin text only, and twenty folding-plates. In this work he had the friendly aid of such correspondents as Dawson Turner, T. J. Woodward, Dr. Samuel Goodenough (Bishop of Carlisle), Colonel T. Velley, and others. This very handsome book is written in the somewhat diffuse style common with scientific writers of the day, the author's theories on the sexual character of seaweeds and other allied topics being plentifully sprinkled among facts. But it is an indispensable volume in a library of books on Algae.

His next work was *Illustrationes Theophrasti in usum Botanicorum precipue peregrinantium*, which was privately printed at Oxford in 1811; it is specially interesting from an iconographic point of view, inasmuch as it contains a lithographic portrait, after an unnamed artist, of Stackhouse; this was reproduced in a smaller form, in his edition of *Theophrastus*, published in 1813. He is represented holding a plate, illustrative of *Fucus membranaceus*, drawn by himself ("J. S., del."). His edition of *Theophrasti Eresii de Historia Plantarum libri decem*, printed at Oxford by S. Collingwood, and published in 1813, in two octavo volumes, contains the Greek text, Latin notes, Greek-Latin, and Latin-Greek catalogues of the plants, is described by Mr. Daydon Jackson as "perhaps the most unsatisfactory ever published;" the bibliography of the editions of *Theophrastus*, and of the various commentaries on his works, would seem to prove that Stackhouse was a better bibliographer than editor. From this work, in 1814, he reprinted *De Libanoto Smyrna et Balsamo Theophrasti Notitiæ*, a pamphlet of sixteen leaves, with three plates; and in the following year, he privately printed *Extracts from Bruce's Travels in Abyssinia and other modern authorities regarding the Balsam and Myrrh Trees, illustrative of the Natural History of Theophrastus*; this appeared at Bath, and consisted of twenty-one pages of introductory matter, fifteen pages text, and three plates.

It is interesting to note that the British Museum copies of Stackhouse's books and pamphlets were originally in Sir Joseph Banks' library; the example of *De Libanoto*, &c., being a presentation copy, inscribed "with Mr. Stackhouse's compliments to Sir Jos. Banks."

Stackhouse was a Fellow of the Linnean Society, which was instituted in 1788, and to which he was elected in 1795, and to the *Transactions* of which, 1795 and 1798, he contributed two short papers, one of which is a description of *Ulva punctata*, and the other comprises observations on preserving specimens of plants; he was also a member of the *Société des Naturalistes de Moscou*, to the *Mémoires* of which, 1809, he contributed a paper entitled "*Tentamen Marino-Cryptogamicum*."

Mr. Boulger (*op. cit.*) mentions that Stackhouse contributed a translation in English verse of the Abbatte Alberto Fortis's *Dei Cataclismi Sofferti dal nostro Pianeta, Saggio Poetico*, from which it would appear that he occasionally relaxed from the severer scientific studies with which his name will always be honourably associated. The English title of this book is *A Poetical Sketch of the Revolutions that have happened in the Natural History of our Planet, intended as a specimen of a Philosophical and Theological Poem*. It was first published at Bath, in 1786; and a second edition appeared during

the same year in London, bearing the imprint of Benjamin White, the well-known natural history publisher, a relative of Gilbert White, whose well-known classic on Selborne was issued under the same auspices. That he was a valued correspondent of the botanists of the day goes without saying, and Sir James Edward Smith has perpetuated his memory by naming after him the genus *Stackhousia*. (See *Transactions of the Linnean Society*, iv., p. 218.)

The first volume of Lady Smith's *Memoirs and Correspondence* of her distinguished husband (1832) contains a very interesting letter from Stackhouse, dated Pendarves, September 16, 1795; it relates almost exclusively to seaweed, and in the course of it he says, in reference to his *Nereis*—"As I described every plant from Nature, and bestowed every attention in my power, I had some reason to hope it might be favourably received." He rendered considerable assistance to Coxe in compiling his *Literary Life and Select Works of Benjamin Stillingfleet*, 1811, and the notes in that interesting and varied medley of botanical and other information marked (S.), as well as the remarks on Theophrastus, are the work of "my worthy friend, John Stackhouse, Esq."

In the third edition of Withering's *Arrangement of British Plants*, 1796, the author acknowledges the "utmost liberality of John Stackhouse, Esq.," who "contributed by every means in his power to illustrate the *Fuci* and *Conferve*." A similar acknowledgment appeared in the fourth edition of the same work, published in 1801.

He died at Bath on November 22, 1819, and an appreciative notice of him appeared in the *Gentleman's Magazine*, 1820, p. 88. His third son, and eventual heir, Thomas Pendarves Stackhouse, assumed the surname of Acton at the decease of his mother, in 1834; he had married on January 28, 1812, Frances, eldest daughter of Thomas Andrew Knight, of Downton Castle, F.R.S., and President of the Horticultural Society of London.

The history of Acton Castle since Stackhouse's time can be compressed into a few lines. Shortly before the death of its original owner, the place was sold to Captain (afterwards Admiral) Bulkeley Mackworth Praed, who died here on October 6, 1852. The Admiral bequeathed it to his sister, Mrs. Smith, who almost immediately sold it to a Mr. Thomas Field, from whom it passed to Mr. Richard Lanyon, of the Kennal Powder Works; his widow, Mrs. Lanyon, occupied the Castle until a few months ago, when she died at the great age of ninety-four. *W. Roberts.*

BIRDS.

I WAS much interested a few months ago watching a Black-cap warbler (*Sylvia atricapilla*), busy taking the larvae of some moth that was feeding on a batch of Hemlock in my wild garden. Another bird of the same species was near at hand doing like service. I mention this, for few persons are aware how much use our migratory soft-billed birds are, both in the fruit and flower-garden. The white-throat (*Sylvia cinerea*), in the former, feeds on the Raspberry-maggot and on the green aphids. The chiff-chaff seeks and finds many small caterpillars; and the nightingale (*Sylvia lucina*), besides his sweet, harmonious song, takes his share of insect life. Of tits, the great tit (*Parus major*), is useful; also the coal-tit (*Parus ater*), and the marsh-tit (*Parus palustris*), are insectivorous, but fond of seeds, particularly those of the annual Sunflower. Growing these for my poultry, I found that my otherwise little friends would have taken every

seed had I not covered some of the huge flower-heads with gauze. The blue tit (*Parus coerules*), clears away much insect ova in winter, but he is naughty, indeed, when he bores holes about the stalks of my Pears; but this can be prevented by putting card collars around that portion of the fruit—the sort of thing florists put under the petals of their show Picotees and Carnations to improve them (eh?). And now to the dear old song-thrush, *Turdus musicus*. I only wish they were more plentiful in my garden, but they will not allow more than a pair to occupy a certain radius, from which all intruders are driven. One thing I have noted about the haunts of this truly gardeners' friend is, that on examining the broken snail-shells at the spot or stone chosen to break them on, I have invariably found that they are all, or very nearly so, the portions of the shells of full-sized snails, there being none of the small or

ORCHID NOTES AND GLEANINGS.

CELOGYNE UNIFLORA.

THIS singular species, which forms a good companion to the dwarf *C. Schilleriana*, was described as *Panisea uniflora* by Lindley, who afterwards referred it to *Celogyne*. Its short, clustered, flask-shaped pseudo-bulbs are of a peculiar tint of green, and its comparatively large flowers appear singly, or rarely in pairs, close down to the former. The flowers are about 1 inch in length, the sepals and petals semi-transparent whitish-green; the rather showy labellum, whitish, with some orange streaks in the centre. It is a singular-looking plant, free-flowering and attractive when well-grown. A plant is at present flowering with Mr. J. W. Moore, Cragg Royd Nursery, Rawdon, Leeds, who kindly sends flowers.

channelled leaves, with a distinct curvature, a peduncle similar to that of the type, bearing usually six flowers, which are quite as large as, but much more fragrant than those of *E. grandiflora*. The six lines running down the tube are also of a richer green. Grown side by side with the type, it is distinct in its dwarf, sturdy habit; it is also comparatively free from diseases and mite. It would prove the better plant to grow for decorative effect, as it takes up but little space, and the flowers are thrown high above the foliage. It was probably collected from a high elevation; but its exact origin cannot be traced.

E. grandiflora Lowi (see fig. 81, p. 239).—Large-flowered forms of this variety are superior to the type; it is also of much stronger growth, producing leaves fully 3 ft. long and 8 in. wide. The peduncle is relatively tall, bearing from three to five flowers, which measure 4 inches in length and breadth. The three

FIG. 80.—ACTON CASTLE, CORNWALL. (SEE P. 237.)

immature. I should much like to know if any other besides myself have observed this. This year being very hot and dry, my thrushes have been unusually busy, and therefore have given me more chances of verifying what I believe as a discovery regarding this bird's peculiar selection of his food. They are also excellent help on the grass-lawns, rising by sunrise as they do, and thus getting the early worm before he can make his "castings," and so make unlevel the grassy smoothness. How he loves a worm! How he tugs little by little, until all is drawn out, then killed; and then, after it is swallowed, what a calm self-satisfied look around he gives; and then—good bird—he searches for another. But during all the hot, dry weather, that has parched—nay, baked—our grass-plots, it has been of no use to peep forth almost before dawn to watch the doings of the early-riser, for he was away to the haunt of the snail, and there was satisfying his hungry wants and thirst. Now he is back again, and the early worm has rather a bad time of it. *Harrison Weir*.

EUCHARIS.

THE genus *Eucharis* contains six fairly well marked species, among which the well known *E. grandiflora* ranks first and foremost as a garden plant. All have white flowers of great beauty. They are natives of the Andes of New Granada, occurring at low elevations. The treatment required by *E. grandiflora* will suit the others, whether hybrids or species.

SPECIES AND VARIETIES.

E. grandiflora (*E. amazonica*). This plant is found in almost every garden. It produces arching leaves 2 feet long, $\frac{1}{2}$ foot wide; a peduncle as long as the leaves, bearing five, occasionally six or seven flowers, each from 4 in. to 6 in. span. Fine specimens of this plant have been figured in these pages. A well marked variety of this, which has been called—

E. grandiflora fragrans was introduced to our gardens four years ago. It has small, sub-erect,

inner segments are very wide and wavy, and not so fully expanded as the three outer ones. The tube is wide at the throat, and is surmounted by a short, toothed staminal cup, and slender filaments. This plant is considered by some to be a natural hybrid between *E. grandiflora* and *E. Sanderi*. Although the characters are just intermediate, I must lodge a doubt here, as I have tried to repeat the cross, and not only do these species refuse to cross, but also to produce seeds when self impregnated, although I have subjected the plants to a variety of temperatures and atmospheres to induce fertilisation; anyway, it is a beautiful and free-flowering garden plant, as also is—

E. grandiflora Moorei, appears to differ only in having smaller flowers, a fully expanded perianth limb, and "clubby" filaments.

E. Mastersii (*Bot. Mag.*, t. 6831) (see fig. 82, p. 241).—This is a much smaller plant, producing leaves 16 inches in length and 5 inches in width. The peduncle is 1 foot high, and bears an umbel

of two flowers, each $2\frac{1}{2}$ or more inches in length and width. The perianth-limb is quite spreading, the tube has the six yellowish stripes of *E. Sanderi*; and the staminal cup is small, and toothed. This is a comparatively recent introduction, and has not made its way into gardens to any appreciable extent, nor is it likely to do so when species with a greater number of larger flowers are available. It is by no means an undesirable plant for inclusion in a representative collection.

E. candida.—This plant produces eight or more flowers in each umbel. The perianth-segments are

texture of the leaves, which are four in number, the narrower and more recurved segments, and the trifold stigma. It is the only *Eucharis* in this collection that produces seeds freely, a point which stamps it as a useful parent in hybridisation. Its three-lobed, terra-cotta-coloured fruits are very striking. This plant is figured by Regel, in *Gartenflora*.

E. Sanderi.—This is a strong-growing plant, with tall leaves $\frac{1}{2}$ -inch wide, a peduncle 2 inches high, bearing four flowers, which are somewhat poor compared with others. The three inner

an-inch long. It has been called *Calliphruria subdentata*, and is a very tardy flowering-plant. The *Calliphrurias* are very difficult to flower.

A hybrid has been obtained between *E. grandiflora* and *Urceolina pendula*, called *Urceocharis Olibrani*, a figure of which is given on p. 251. I do not like the hybrid so well as either of its parents. I mention this hybrid to draw the attention of hybridists to *Urceolina miniata*, a pretty plant with bright scarlet flowers. We should probably have something good if this colour could be infused into the *Eucharis* by inter-breeding.

FIG. 81.—EUCCHARIS GRANDIFLORA LOWL. (SEE P. 238.)

acute, somewhat recurved, and half an inch wide. A prominent feature in this flower is the staminal cup, which is tubular, half an inch long, and deeply cleft between the filaments. The leaves are 18 inches long, acute, narrowing gradually to the short, stout petiole. It is a distinct and pretty species, succeeding best in a very loose compost. The roots are very liable to rot if a close soil surrounds them. It is the only species with an entire stigma.

Eucharis \times *Stevensii* (see fig. 83, p. 243), is a hybrid between this species and *E. Sanderi*, combining the characters of each.

E. Lehmanni.—This plant is very near *E. candida*, differing only in the darker colour and firmer

segments of the perianth limb do not expand so fully as the three outer, and the staminal cup is rudimentary and entire. A better garden plant would be found in—

E. Sanderi multiflora, which produces eight to ten flowers to each umbel. The flower has six green stripes down the tube, instead of yellow, as in the type. Both plants produce offsets freely.

E. subdentata.—I have not flowered this plant, nor have I seen it in flower. The leaves are acute, a foot or more long. The peduncle is described as being as long as the leaves, bearing from six to eight flowers, each with a perianth-tube an inch long, the segments being oblong, ascending, half-

[*E. Bakeriana* (see fig. 85, p. 249), is a species collected by Messrs. F. Sander & Co., in Columbia. Its flowers are distinct from others of the genus in the corona, and in having the tube of the flower of nearly equal diameter almost up to the top, being very little dilated at the throat. A full description of this species will be found in the *Gardeners' Chronicle*, April 5, 1890, p. 416.

E. x "Burfordiensis" (see fig. 84, p. 247).—We take the opportunity to illustrate the fine *Eucharis* exhibited under this name at the last meeting of the Royal Horticultural Society by Sir Trevor Lawrence, Bart., when the Floral Committee recommended the award of a

First-class Certificate. This variety is most likely the result of a cross between *E. Stevensii* and *E. Mastersii*. The leaves, while resembling those of *E. Mastersii*, are narrowed in the direction of *E. Stevensii*. Mr. Bain, who has charge of Sir T. Lawrence's garden, describes the plant as unusually free in flowering. The flowers are rather more than 3 inches across, and about 2 inches long. They are not flat like those of *E. grandiflora*, but somewhat bell-shaped. *E. Burfordensis* is likely to become a popular garden variety. ED.]

CULTIVATION.

The cultivation of *Eucharis* is not difficult if the natural tendencies of the plant are carefully observed. Imported bulbs should be carefully cleaned of all dead tissue after twenty-four hours immersion in water, and potted in a rough compost consisting of chopped turf $\frac{3}{4}$, half-rotted leaf soil, and very coarse sand or other porous material $\frac{1}{4}$. It is advisable to only cover the bases of the bulbs, so as to allow of frequent examination until leaf growth commences, when the potting may be finished off. They should be started in a temperature of 70°, and kept growing in a moist atmosphere until the leaf growth is finished, when they may have a temperature of 60° with less water, but at no time should they be without some moisture at the root.

The *Eucharis* really has no resting season; for the roots are active, or should be active, all the year round. If the plants are not grown on a large scale for the production of cut flowers at all seasons, they may remain in a growing temperature all the year round, affording them water in accordance with the amount of leafage they carry. Many of the grand potfuls of healthy plants of considerable age found in country gardens are thus treated, and grow with the vigour of a Cabbage.

Weekly applications of liquid cow-manure during active growth is the best and only manure the plants should have, and failing this, weak soot-water is the next best. The plants require light shading in sunny weather.

FORCING.

Hard forcing accounts for the bushels of diseased and debilitated bulbs one sees consigned to the rubbish-heap on most cut-flower farms every year. A writer in a contemporary a short time since stated that "Nurserymen were giving up the cultivation of *Eucharis grandiflora* because they could not force the plants into flower more than three times a year." Such expectations verge on the impossible, as the bulbs cannot be forced to flower more than twice a year consistently with good health and longevity. A third flowering season may be secured biennially with very strong plants by hastening the maturity of the leafage, maintaining a drier atmosphere, and resting the plants drier. I have found, however, that such plants take a great length of time starting into leaf-growth again.

PESTS AND DISEASES.

The Encharis or bulb-mite is the worst pest to deal with. I have tried the prepared remedies sold as efficacious, but have found them to be useless. Badly-infested bulbs are hopeless; bulbs lightly attacked will recover if they are painted with a soft-soap and petroleum emulsion of a similar strength to that generally used for destroying mealy-bug. The roots must not be touched with the preparation. The bulbs may be treated after cleansing as advised in the case of imported ones.

I am convinced that mites have origin in diseases, as I have found them on decaying bulbs of nearly every plant belonging to the Amaryllidaceae imported from every quarter of the globe. Where disease alone exists, the bulbs should be carefully washed, and dried whilst still damp with flowers-of-sulphur, planting the bulbs with the sulphur adhering to them.

An open compost, free drainage, and the removal of the black slime fungus which infests the soil in moist hot-houses, are the best preventatives of diseases or mite. Geo. B. Mallett, Isleworth.

THE AGE OF THE DWARFING STOCK.

IF one were requested to name the time when fruit-trees were first grafted on dwarfing stocks, it would be, I believe, impossible to assign a date. The *Paradise* (*l'homme de Paradis*) is mentioned in D'Estienne's *D'Agriculture*, in the sixteenth century. Markham's translation mentions it, and the reason why they were employed may be gathered from De Serres' *Théâtre d'Agriculture*, which was, that it fitted trees to grow and train as espaliers. The last-named writer has a very interesting chapter on the subject, and he shows that fruit was larger and finer off espaliers, and the trees came into bearing much earlier than standards. When he wrote (1598), all kinds of fruit-trees were trained espalier-fashion, but "Les premiers espaliers ont esté faits de Pommiers nains, dits de S. Ian. Après s'y servit on des petites Poires musquées," and by-and-by all kinds of hardy fruits followed. Writing in 1669, Worlidge has these remarks: "If you desire to raise dwarf trees, let the stocks whereon you graffe them, be of the *Paradise-Apple* for Apples; of the *Quince* for Pears; of the *Morello* for Cherries; being kept low according to the new mode, though I see but little pleasure or profit in that way." He, however, commended the "Quince-stock for the Pear, because it produceth its fruit better and fairer, and better-coloured, and the trees to bear sooner and more store of fruits." The Rev. John Laurence in his latest work, *A New System* (1726), has this interesting note on Apples:—"Everyone who hath seen the beauty and fruitfulness of those grafted upon *Paradise*-stocks, will allow that there is nothing either in the flower or kitchen-garden that can vie with it for its uncommon and pretty qualities. It is about thirty years since it was first brought over into England, and the plants were then sold at 5s. apiece." It is only fair to note that the Dutch *Paradise* may be referred to. The above must be taken for what it is worth, because we find Reid more than forty years earlier mentioning them, though he does not recommend the use of dwarfing stocks. Apples were worked on the "Paradise, or any that hath burry-knots; Codlings, Redstracks, &c.; dwarf Pears on the Quince, dwarf Cherries on the Morella, or on the common Red Cherrie, or on Red green" (Gean).

Switzer (1724) named stocks suitable for certain sorts, and adds—"The Dwarf Medlar is by some in use for dwarfing of Pears, as the *Paradise*-stock is for dwarfing of Apples, and the Bullace for Apricocks." Miller mentions the French *Paradise* as losing or having already lost its popularity as a stock in his day. The Dutch *Paradise* and Codlin were, however, still in use for dwarf trees and espaliers; the last-named having come largely into vogue during the eighteenth century for forming dividing lines between walks and kitchen-garden quarters. With the beginning of the present century, Forsythe's work on fruit-trees appeared, and in it note is made of the *Paradise*-stock for strong soils, but he does not say to which variety of *Paradise* he refers.

Dwarfing stocks appear in the works of other writers; while others again, of whom Evelyn is a notable example, are silent as to their use. It is noteworthy that the property of rooting near the surface, possessed to so large an extent by these stocks, is never once commented on; they seem to have been employed almost solely on account of their potentially dwarfing effects, and thus rendering trees more amenable to wall and espalier training, and for forming bush-trees in kitchen-gardens. These stocks were credited at an early date with the attribute of shortening the life of trees, and there appears to have been always a dislike to their employment in general; and thus it occurred that the wilding Crab, and more especially "free stocks," were all along in most favour, and similarly the wilding Pear as a stock for Pears. Double grafting, it may be added, was in use at least as early at the beginning of the eighteenth century. R. P. Brotherston.

NURSERY NOTES.

E. WEBB AND SONS, WORDSLEY.

THOUGH the name of this firm is familiar enough to most readers of the *Gardeners' Chronicle*, it is probable that few of them have visited the establishment at Wordsley. It is not near the metropolis, nor on one of the great railway routes to the North. At the same time, should anyone be in the districts of Worcester or Birmingham, they would be able to call on Messrs. Webb very conveniently by alighting at Stourbridge, or Stourbridge Junction railway stations. Upon reaching Wordsley, which is but a short drive from either of these points, they would find that this large seed establishment, with its great warehouses, offices, and other buildings, affords another object-lesson in regard to the immense demand that exists over the British Empire for horticultural and agricultural seeds.

At Wordsley, the buildings that existed a few years ago, when our last visit to this neighbourhood was made, have been increased by the erection of another great warehouse on the opposite side of the street; and several houses for the cultivation and display of Gloxinias, tuberous Begonias, and other florists' plants, have been built. At the end of August is not the best time of year to catch the seed-cleaners busy, nor to see the warehouses stocked to their capacity with seeds.

THE KINVER GROUNDS.

An hour's drive to the trial grounds at Kinver brings the visitor to as picturesque a part of the country as he need wish to see. Who, in Smethwick, Stourbridge, and other manufacturing places, in what is termed the "Black Country," has not seen or heard of Kinver Edge? Kinver is visited by hundreds and thousands of people upon their holidays, and upon Sundays. But it is a rather long drive from most of the populous centres, and at the present time there is in course of completion an electric tramway with overhead wires from Stourbridge, which will open up the country to a much larger extent. Very near to the "Edge," which is a somewhat precipitous-looking point, is Kinver Farm, and upon part of this farm are made trials of flowering plants and vegetables.

In a season such as the present has been, there are kitchen crops and bedding plants that have not been so successful as they sometimes are, but generally the trial-grounds were full of interest; here, nothing but colour as one scanned great breadths of some of the brighter bedding plants; there, a striking contrast in breadths of Cabbages, Onions, Peas, &c.

VEGETABLES, &c.

Noting the Onions first, there was a bed of a seedling variety from Ailsa Craig \times Improved Banbury, the latter one of the best Onions in cultivation. The seedling is an intermediate globe-shaped bulb, and would appear to be as it was described to us, "a good keeper, and of perfect quality." There were many Onions upon trial, but the favourite is Masterpiece, a large globular bulb with pale yellow skin. The next best is Reliance, a large cropper, excellent keeper, but not so globular in shape as the preceding, nor so flat as Improved Banbury.

Turning to Carrots there were twenty-two varieties on trial, but the best of these for most purposes is Market Favourite, rather shorter than Intermediate, growing 5 to 6 inches long, straight, thick, and of rich colour. It is a good keeper. Prize-winner and Intermediate are also Carrots to be recommended.

Parsnips have not, and never will be known, in such bewildering variety as other vegetables. We noticed a fine batch of a good strain of the old Hollow Crown.

Of Kales there were excellent types of the Perpetual Dwarf, in green and purple varieties; a Moss Curled and Curled Scotch. A seedling variety of Kale was very interesting. The type

FIG. 82.—EUCCHARIS MASTERSII. (SEE P. 238.)

appeared to be a perpetuation of a fasciated condition. In the leaves there was abnormal development of the mid and secondary ribs; the margins of the leaves were as the Moss Curled. Something good may come from a selection of this type.

Of the Cauliflowers, Early Mammoth (which is a type of Erfurt) and Peerless are the best in the collection, and they are really good. A novelty in Broccoli, purchased by the firm last year, is likely to soon gain popularity. It is known as Mont Blanc. The heads are well protected, are conical in shape, not extra large, but close, and pure white in colour. May generally be cut from January to April.

Savoy was looking very well in spite of the dry weather, and were commencing to form hard close heads. Among a large number of varieties the two best were Little Wonder and Kinver Globe. The first-named is the earliest to mature, and Kinver Globe is remarkable for its dwarf compact habit.

Cabbages occupied the greater part of a large field, and with Brussel Sprouts, &c., made quite an exhibition. The earliest Cabbage is known as First-of-All. It was new a season or two ago; it is small growing, and may be planted rather closely for affording an early spring supply. Notwithstanding that the variety Emperor is tried with a number of newer varieties, this well-known Cabbage is still the best Maincrop variety the firm possesses, and appears likely to hold its position. A red Cabbage, named Vesuvius, was noticed to differ from the Red Dutch in being much smaller and neater in habit.

Among French Beans, a seedling was pointed out to us, that should prove useful for cultivation in pots. It produces but little foliage; the leaves after the first 3 inches, are small, and the blossoms are thrown clear above the larger ones.

Peas are necessarily an important vegetable, and the varieties are so numerous at the close of the nineteenth century, that trials of them, in order to afford conclusive information, need to be undertaken upon a very large scale. There were something like 120 varieties at Kinver, and the best for all purposes was one named Senator, a variety raised some years ago at Kinver; it was a cross between Prince of Wales and Culverwell's Giant Marrow. Pioneer is a novelty, a blue wrinkled Marrow, grows about 3½ feet high, and turns in as early as Sangster No. 1; the pods are about the same size as those of Telephone. The best late Pea amongst those seen was Masterpiece. It has a long fruiting season, and sown upon the same day as other varieties, it proved to be in full bearing after those had passed; it grows about 4 feet in height, and the blunt-ended pods are deep green colour. There were many other good Peas, but we have mentioned only the three very best. It may be added that Talisman, growing 6 feet high, is especially recommended for supplying pods for exhibition purposes.

Potatoes, again, are important. The remarks respecting the Peas are even more applicable to these, for Potatoes are the most important crop of the kitchen garden; but we had not the time to examine the varieties on trial at Kinver, which would have necessitated the digging of samples of each. Suffice it to say, that all the best varieties up to date are used for comparison, with an immense amount of seedlings now on trial. Fifty unnamed seedlings, besides others, are at present at Kinver, and the best from the point of view of the firm are year by year catalogued. A new one "Motor," now on the market, is likely to be a popular free-cropping, kidney-shaped, white tuber. Several roots turned out very well under our notice.

We hope the correspondence that has lately taken place in these columns will induce all raisers and distributors of new varieties to secure as far as possible increased flavour in Potatoes, in addition to such essentials as free cropping, and disease-resisting constitution.

Of Celery, a variety named Pink Perfection was praiseworthy. Tomatoes were also under trial, but

unless in the point of improved flavour, or in that of greater suitability for out-of-door cultivation, there is little advance being made just now in regard to this wholesome fruit.

FLOWERING PLANTS.

So many of the popular kinds of bedding-plants and of hardy herbaceous species were to be seen at Kinver, that we are quite unable to refer to each fully. The Stocks, for instance, were very imposing, especially such types as Imperial Large-Flowering, and Dwarf German. The former showed a giant habit, branching away, and producing an immense number of fine flowers.

Sweet Peas in numerous varieties from many sources, and including Mr. Eckford's and Mr. Burpee's new ones, had still some flowers upon them, but they will all be reduced to the firm's large-flowering strain when seed-time arrives.

Coreopsis, Godetias, Chrysanthemums, Eschscholtias, Papavers, Achilleas, Phloxes, Larkspurs, Nasturtiums, Gaillardias, Sweet Williams, Dianthus, Mignonette, &c., were all to be seen in varying degrees of condition, some affected very much less than others by the absence of rain.

Of Larkspurs, Emperor and Empress, the former bluish-purple and the latter rose colour, are fine sorts, well worth keeping distinct. The same might be said of a variety of China Aster named Snow-drift, a dwarf, pure white flowering variety of much merit. White Queen and Scarlet King are also excellent varieties of Asters, but forms of this most popular bedding-plant are now so numerous that they are largely sold according to colour rather than to variety. A very nice free-flowering strain of Zinnia was noticed in full bloom; and no plant created a more lovely show than did the beds of Salpiglossis. These had succeeded splendidly, and the seeds were sown in spring, in the beds where the plants were now flowering.

OTHER ITEMS.

But Messrs. Webb have a very large trade in farm seeds, and the number of acres of land annually devoted to the cultivation of grain and other seeds by the firm is wonderful. We are not so much concerned with agricultural crops, however, or particulars might be given of the amount of land occupied by Wheat, Barley, Oats, as well as roots, such as Mangolds, Turnips, &c.; and of the extreme care, and variety of means taken, to ensure the crops being pure. There is one interesting fact, however, respecting the grain crops that may be stated. Harvest operations were in full swing when our visit was made, and such a bountiful yield was it, that those best able to estimate it held the opinion that a greater quantity of seeds per acre had never been reaped by this firm. The quality, too, was, of course, perfect, and though the straw was a trifle short, it was, in this respect, not comparable to that further south and in our own district.

Messrs. Webb & Sons are also Hop merchants, and the storage of Hops could not be done without spacious warehouses. Then they have manure factories at Saltney, in Cheshire, where they manufacture various artificial manures.

THE SEED TRADE.

THE GRASS AND CLOVER CROPS.—From the grass-growing districts of Germany comes information of the crops of natural grasses, which leads to the conclusion that on the whole the yield of most grasses will be below the average; in some instances the yield is so short that it almost amounts to an utter failure. The Sweet Vernal (*Anthoxanthum odoratum*) has been harvested in extremely small quantities, while *A. Puelli* shows a rather larger return. The Creeping Bent-grass (*Agrostis stolonifera*), and the Brown Bent-grass (*A. canina*), are a very short crop, and it is anticipated it will not exceed one-half of last year's yield. The latter appears to be regarded more as a troublesome weed

than a grass of agricultural value. Meadow Fox-tail (*Alopecurus pratensis*), no doubt on account of its more persistent character, has been harvested both in satisfactory quantity and quality.

The Tall Meadow Oat-grass (*Avena elatior*) promises remarkably well, and the crop will probably be both larger and better in quality than last season's, and prices will, it is anticipated, be reduced as compared with last year. The true Golden Oat-grass (*A. flavescens*) will be a good average crop.

Crested Dogtail-grass (*Cynosurus cristatus*) is expected to be a short crop this season, and prices are higher than heretofore; still, it is a little early to give a definite estimate of the quantity.

Cocksfoot-grass (*Dactylis glomerata*) is a fairly good crop in Germany, and that of North America is large and good. The New Zealand supply is less in quantity than for some time past, while the quality of the seed is below the average.

The smaller Fescue-grasses (*F. duriuscula*, *F. ovina*, and *F. rubra*) are reported to have yielded only from one-half to, at most, two-thirds of a crop, and it appears certain the crop saved must be smaller than last year, as it is difficult to procure them, and prices are rising. The weather has also affected the appearance of the seed. *F. ovina tenuifolia*, or more probably *F. angustifolia*, is a shorter crop than has been experienced for many years, and it is anticipated the growth will be poor, while the prices will be high. Meadow Fescue (*F. pratensis*) will be a small crop from the United States, something like our production in the past, induced farmers to sow less than usual. The crops in Germany are insignificant.

The Ray-grasses (*Lolium perenne*), and its continental variety (*L. italicum*), has come to hand in very fine quality of the seeds, but in smaller quantities than usual.

Of the Poas, *P. nemoralis*, the Wood Meadow-grass, has, by the smallness of the crop, disappointed expectations; and it is reported that prices for pure seed will be very high. The smooth-stalked Meadow-Grass (*P. pratensis*), is apparently a good yield, and so far prices are lower than last season. The quantity of the seed is excellent, the colour bright, and the germination good. Rough-stalked Meadow-grass (*P. trivialis*), is said to be better in every respect than last year, and prices will be easy.

CLOVERS.

Of Clovers, little can be said at present, but it appears to be certain that the crops of Trefoil and Red Clover will be very poor in Germany, and it is thought by many that there will be an entire dearth of seed of Red Clover. French reports are also unfavourable; while from many districts of Austria better results are expected, and it seems that the production of this grass in Austria is being considerably increased. Accounts have still to come to hand from Russia, though the crop derived from thence, owing to the difficulty of securing deliveries up to sample, render the crop less important than it otherwise would be.

The stock of Crimson Clover has been sold out almost completely, and prices are extremely high. The crops of Alsike are said to be very indifferent. The quality of Sainfoin is good, and it is cheap in price. It is too early to judge of the crop of Lucerne, but it is to be feared the French supply will be limited; but better reports come from other countries. *Pisum*.

BULBS FOR THE LONDON PARKS.—We understand that Messrs. JAMES CARTER & Co., Seed-merchants of High Holborn, have again received the commands of Her Majesty's First Commissioner of Public Works to supply the whole of the bulbs required this autumn in Hyde Park, Regent's Park, St. James's Park, Kensington Gardens, &c. It is also their privilege to state that they have been similarly instructed by the London County Council to furnish the whole of the bulbs required for the parks and gardens under their control.

CULTURAL MEMORANDA.

PHRYNIUM VARIEGATUM.

THIS plant, when properly grown, is a great addition to the stove or greenhouse, and for decorating or exhibition purposes, the creamy-white

well, the soil should be shaken from the roots, which should be divided, each piece being planted in 3-inch flower-pots, using a compost consisting of fibrous loam two parts, peat one part, leaf-mould and sand one part. Having potted the divisions, place them in the propagating-case, applying shade till they are established, then stand them on the

using it in a rough state, with the addition of a small quantity of rotten manure, pressing the soil moderately firm, and placing them in the stove. The plants must now be syringed two or three times a day, otherwise red-spider may spoil them. If an attack of red-spider is severe, the better plan is to sponge the foliage. A slight amount of shade

FIG 83.—EUCHARIS × STEVENSII. (SEE P. 239.)

and green leaves having a very effective appearance. To obtain good results, this plant should be treated as follows:—The plants should be rested in an intermediate-house in the winter, but not allowed to get entirely dry at the roots, but affording water occasionally. In the early spring they should be brought into the stove, and when they have started

stage. The first leaves that are made in this size of pot will be green, and may be left alone or cut down, when in the latter case the plants break from the bottom, the growths sent up will be well coloured, and the habit dwarfer than when the first growths are left. The plants should then be potted into 5-inch flower-pots, in the same kind of compost,

during sunny weather is desirable, and on no account should the plants be allowed to get into a starved condition. If big plants are required, three or four may be placed in large pots or pans, and in a short time they will make a nice specimen for placing in the cool conservatory during the summer months. X. Y. Z.

THE WEEK'S WORK.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Propagation of Roses from Cuttings.—Many of the varieties of Hybrid Perpetual and Noisette Roses grow and flower well on their own roots, and the time from this date till the end of the month of October, is the most suitable for inserting the cuttings in beds in the open. The position of the beds should be on a border facing or inclining to the north, or between other plants, where they will be partially shaded from the sun, and sheltered from the wind. The soil should be retentive rather than light, although the cuttings will make roots freely in ordinary garden-soil. Choose as cuttings, strong, well-ripened side-shoots; and if these are from 8 to 12 inches long, so much the better. The shoots should be cut with a beel, four or five leaves removed from the lower part, without however touching the buds in the axils of the leaves. Should the land have been recently dug, let it be made firm by trampling it, then make it level with a rake, and insert the cuttings in holes made with a dibber, 4 inches apart, placing them four buds deep, and fill in with some sharp road-grit or sand. Bourbon, Tea, and hybrid Tea-Roses may be propagated by cuttings, but hand-lights or cold frames should be used, protection being afforded them in frosty weather.

Violas.—Strong flowering plants for next summer's flowering may be obtained by taking cuttings not later than the end of the present month; the young shoots coming from the roots of healthy plants making the best cuttings. An empty pit or cold frame should be prepared for them by putting in first some drainage-materials, then a compost of leaf-mould, loam, and sharp sand or road-grit. Having made the bed firm and level, insert the cuttings 2 to 3 inches apart, and close the frame, affording the cuttings shade for a few days, then gradually exposing them to full light and air till cold weather sets in. If frost is likely to penetrate the pits or frames, mats or other covering should be placed over them.

Lantanas are pretty plants, easy of cultivation, which afford a pleasing contrast to other kinds of bedding-plants. Cuttings may now be put into store-pots, filled with a mixture of loam, leaf-mould, and sand, and placed in frames on a mild bottom-heat. They soon take root, and may then be subjected to the same kind of treatment as zonal Pelargoniums. Lantanas may be raised from seed sown in the spring, but it is preferable to grow a few good varieties with flowers of distinct colours, and the best are—La Neige, white; Rutilant, light yellow; Distinction, orange-scarlet; Eclat, reddish-crimson; Rayon de Soleil, very dark yellow.

Pelargoniums, Ivy-leaved.—For filling window-boxes, as trailers in plant-vases and as balcony-plants, nothing equals the varieties of *P. peltatum*. Three fine varieties for the last-named purpose, are, Sarah Bernhardt, white feathered maroon; Madame Crousse, pink; and Souvenir de Chas. Turner, deep rose. The stiffer growing varieties, Cordon's Glory, bright scarlet; Flambeau, orange scarlet; Beauty of Castlehill, soft rose and very double; Rycroft Surprise, salmon pink; and Madame Mougeot, deep red, make lovely beds, and do best when trained erect, so that the trusses may show well against plants of the ordinary zonal Pelargoniums. The single-flowered varieties are effective when seen at a certain distance, but as the petals so soon drop, the plants have a ragged look when observed at a short distance. I prefer to take cuttings at this season, putting them into store-pots, and potting them off in the spring. By doing this, the cuttings become firm at the base, and not so much wood is made in the summer as is the case with cuttings struck in February; moreover, the quantity of flowers produced is larger.

Sweet-scented Pelargoniums.—These species are deservedly coming to the fore, after having been neglected for many years. The species capitatum, Pretty Polly, Quercifolium, tomentosum, Prince of Orange, and Lady Scarborough are distinct in leaf and fragrance; and the varieties denticulatum majus, radula major, filiciforme, odoratum, and the Pheasant's-foot are of dwarf growth, with foliage resembling the fronds of Ferns, excellent for bouquet-work. Lady Plymouth and the varie-

gated Prince of Orange are pretty edging plants. All the species can be struck readily at this season in sandy loam, but the cuttings must be shorter than those of ordinary Pelargoniums, and the cutting-pots placed in the winter close to the light, and the soil kept rather moist.

Work in General.—The flower-beds must be kept free of decaying leaves, flowers, and of seed-vessels. Plants that have ceased to produce flowers may be removed altogether, and the soil raked and made clean and tidy. If the herbaceous perennials have been properly secured to stakes, the old flowering stem need not look unsightly, and that being so, they need not be removed before they have become thoroughly withered, as till that occurs they are of use to the plants.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Unseasonable growth of Cattleyas.—I have remarked this autumn that the Cattleyas have made more growth than will be good for the plants, and plants of *C. Trianei*, *C. Warszewiczii*, and *C. labiata* are in some instances making late pseudo-bulbs, and as a continuance of fine weather suitable for maturing these is not probable, their presence must be, to some extent, a source of anxiety to the cultivator. In the case of valuable varieties of the first and last-named species, it will be advisable to remove the over-sheaths, in order that the energy of the plant may be directed to the current season's growth. With the other species named this cannot be done, the flowering-stage having passed. Sometimes I have removed secondary growths soon after they had started, a course which compels the following season's growth to proceed from a back pseudo-bulb, or a second bud on the last one made, and although the result so far was satisfactory, it was a hazardous proceeding. The best course for the grower to take is to place the plants in a position calculated to induce them to develop these secondary growths, and if sheaths appear in these, to remove such as soon as practicable. *C. Dowiana*, *C. aurea*, and *C. Hardyana* have a like propensity to start growing again either before or just after flowering, which in the former case detracts from the quality of the flowers produced. Given favourable weather, these growths usually develop into small pseudo-bulbs, which, if thoroughly matured, carry on the life, but spoil the symmetry of the plants.

Dendrobiums are also similarly afflicted this season, only more so, the early-matured bulbs not only commencing to grow again, or, rather, to throw out new growths from the base, but also to develop flower-buds, which, however, instead of producing bloom, become adventitious growths, thus spoiling their chance of flowering at the proper season. The decrease of light and heat render it improbable that any secondary growth will reach full size or mature; and to retard the plants by keeping them dryer and cooler, when undeveloped growth is present, would serve no good purpose now. At this season, the only thing the grower can do therefore, is to aid development as much as possible, and hope for the best.

Oncidium varicosum.—The too abundant flowering proclivities of this species tends to shorten its life, and as the plants will shortly be in bloom, a note of warning may be of use to those who grow this lovely Orchid. That it is still abundant is shown by the large numbers imported, and as quantity determines prices it is fairly cheap, but the price of a plant ought not to weigh with the cultivator, whose object should be to grow them well, and to keep them in health for as long a period of time as he can. The removal of the flower-spikes as soon as the flowers have expanded, is a point to be observed; another, is to withhold the direct applications of water so long as the young pseudo-bulbs remain plump, and as the plant should be grown in a very cool, moist, yet airy house, this state of things may continue for a long time before shrivelling occurs. The same will apply to *O. crispum*, *O. Marshallianum*, *O. prae-textum*, *O. Forbesii*, and *O. Gardnerianum*.

Oncidium incurvum, a species now in bloom, is usually long lived when grown under the same conditions as *Odontoglossum crispum*. In the matter of repotting and top dressing, this plant usually needs attention owing to forwardness of growth almost before the flowers are passed, but being a plant of compact habit, there is no need for

frequent disturbance, provided the drainage is efficient; when, however, from insufficient pot space or other cause it becomes needful to repot it, the fibry roots should not be disturbed more than is absolutely necessary, large quantities of drainage material and a surfacing of good, lumpy Orchid-peat, and a little sphagnum-moss should be afforded. During the winter months, although the plants are then making growth, very little water should be applied.

Oncidium ornithorrhynchum is another useful autumn-flowering species that should be afforded treatment similar to the foregoing, excepting that the temperature may be slightly higher. A place on a shelf near the glass, in a house where *Miltonia vexillaria* grows, is a suitable position.

PLANTS UNDER GLASS.

By C. R. FIELDER.

Solanum capsicastrum.—Where the practice of planting out during the summer is adopted, preparations should be made to pot these plants, and in order to prepare them for the operation, the plants should be cut round at a distance of 5 or 6 inches from the stem with a sharp spade. A week or ten days afterwards the plants may be lifted, and planted in 5-inch or 6-inch flower-pots, according to their size. After potting, they should be placed in a cool-house or pit. I have always found a house with a north aspect to suit them at first, keeping the roof shaded when sunshine reaches it until the plants are established, when shading may be discontinued. The syringe should be used freely among the plants while they are becoming established, and, in fact, every care taken during the first fortnight after potting to prevent any loss of foliage. If the points of the shoots are pinched back to the first flower, the berries are more fully exposed, and they gain in size.

Chrysanthemums.—If the flower-buds on a plant are in a forward condition, and showing colour, the plant should at once be placed under glass, and preparations made to house all later plants upon the first indication of cold weather. In housing these plants, afford as much space as possible between them in order to prevent any loss of the lower leaves; and for the present afford abundance of ventilation. Do not afford manures in large amounts at one time, little and often being a safer rule, as serious loss of roots and indifferent flowers follow the reverse practice.

Show and Fancy Pelargoniums.—When these plants have made an inch or two of new growth, repotting in accordance with instructions given in a previous calendar may be undertaken. For Fancy Pelargoniums a small quantity of peat may be added to the compost there recommended for Pelargoniums, and the plants should be grown in a rather warmer house than the show varieties.

Euphorbia pulcherrima.—It is not prudent to leave these plants in cold frames after this date, but rather to place them in a house, the temperature of which is not calculated to start them into growth. A position should be found for them near the glass, in a house where a night temperature of 55° is maintained. This will meet their requirements until the bracts are about to form, when the temperature may be increased to 60°.

Caladiums, Achimenes, Nagelias, &c.—Water should not be too rapidly withheld from any plant which shows signs of maturity, but the quantity reduced gradually till the foliage has died down, and then withheld altogether, and the pcts stored away in a house where the temperature never falls below 55°.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Cardoons.—These plants will still require a plentiful supply of moisture at the roots, clear water and liquid-manure being alternately afforded, making sure that the soil is thoroughly moistened to a good depth. Tying up the plants to blanch should be done on a dry day, and the performance of this job should not be long delayed. First bind each plant with haybands, after drawing the leaves straight, and follow this by earthing-up the stalks with fine mould.

Celery.—Let a slight earthing-up of the plants be performed weekly when the weather is dry, taking care not to let any soil fall into the hearts. This

is a better plan than affording a great quantity of soil at long intervals of time. The earliest Celery may now be finally earthed-up. The later crop should be encouraged to make free growth; and since cooler weather has set in, the plants will grow fast, needing in consequence regular and constant attention to affording water, &c.

Onions.—Let no time be lost in getting the bulbs harvested whilst the weather and the soil are dry. When quite dry, let the rougher, looser outer coat be rubbed off, and the leaves twisted off by hand. The white Spanish Onions, and other varieties which do not keep sound for any length of time, should be placed by themselves, apart from the late-keepers. Tripoli Onions sown in August may now be in need of thinning, if large bulbs are wished for; but for ordinary kitchen use, the thinning is better if left till the spring, when the spare plants may be transplanted or used in various ways. Run the hoe between the rows occasionally, and dust the beds with fresh soot.

Cauliflower Plants raised from seed sown a month ago, will be in need of pricking off into their winter quarters, eight or twelve being placed under a hand-light. Those who winter their Cauliflowers in cold frames should get these prepared betimes, by affording a good bed of soil, and making it moderately firm; washing the glass, but not covering the bed till sharp frosts occur. The plants may be set out at not less than 6 inches apart. The same holds good for those under hand-lights and cloches. Large plants should not be put out, but some may be potted and wintered in a Peach-house, if they can be afforded plenty of air, light, and water.

Capsicums.—The seed-pods should be gathered as they become fit, the ripening being completed under glass.

French Beans.—A good sowing may now be made, in 7-inch pots, of Ne plus Ultra, Osborne's Forcing, &c., using a loamy soil and spent Mushroom-bed manure well mixed together. Sow half-a-dozen seeds in a pot, or, if the seed is old, sow more, and thin out to that number those which vegetate. A cold frame will suit this sowing for the present. Good gatherings may be obtained from this sowing; but there is not much to be gained by attempting to grow French Beans under glass in the last two months of the year.

FRUITS UNDER GLASS.

By W. STRUGNELL, Gardener to Lieut.-Col. RALPH VIVIAN, Rood Ashton, Trowbridge.

Strawberries in Pots.—Unless in the first instance these were placed at distances from each other that will allow the plants to make free growth, more space had better be afforded them, as Strawberry plants now need all the sunlight possible. The plants ought now to have almost or quite filled their pots with roots, and if they appear less vigorous than is desirable, they may be given weak liquid-manure or soot-water once or twice a week. An examination of the roots is necessary before such feeding is practised, because unless there are active roots, feeding will be injurious. If good turfy loam was used with other ingredients at the time of potting, there should be no need for feeding in the autumn. The plants require to be examined occasionally, even during showery weather, for the rain does not always penetrate through the foliage and the soil to the draioage. Remove runners from the plants each week. If watered from a pond, the surface of the soil may become coated with a green vegetation, and this must be removed before becoming thick enough to hinder the aëration of the soil.

The Cucumber House.—Plants for midwinter-fruiting will require careful attention in stopping and regulating the shoots. If there is no need for immediate fruiting, continue to remove the flowers so as to reserve the energy of the plants for later bearing, but in any case reduce the number of the fruits as they set. Winter Cucumbers should be planted in small beds, and then afforded weekly or less frequent surfacings of new and sweet soil. By these means the growth is not excessive at the start, nor do the plants dwindle down to straw-like stems before the winter is half gone. It is all important that the roots be kept steadily moving in new composts, applied as suggested. Later batches now growing in small pots ought to be planted permanently as soon as possible. Bottom heat for winter fruiters is indispensable, and in gardens where insects troublesome to the

roots abound, the baking of the soil will do much good. For some time hence clear water only should be afforded.

Cucumbers in frames may, with careful ventilation, a steady bottom, and sufficient atmospheric warmth, continue in bearing for some time. But they must be regularly stopped, and the foliage thinly disposed over the bed. Check green-fly by fumigation or syringing with an insecticide.

Tomatos for Winter.—The forwarder plants are already setting their first flowers, and growing strongly. Like Cucumbers, these are more satisfactory when the roots are kept active with light top-dressings of fresh soil or bone-meal. Some care is needed daily in fertilising the opening flowers, either by sharply tapping the stems at mid-day, or by the use of a camel's hair-brush. Pot on successive plants, and fruit them in 10-inch pots. When potting, allow ample space for future top-dressings, and do not over-stimulate with fertilising manures, either natural or artificial. These are better given when the plants actually need help. Plants standing outdoors or in cold pits should be removed indoors at once, but not to a house where artificial heat is much used. As long as the weather continues mild, air should be admitted rather freely during the day, and with a little warmth from the pipes it may be afforded at night. Apply clear water only, except in cases where the pots are filled with roots. For winter bearing the plants are best trained near the glass, so that they will get all the light possible. Such plants should be kept to one stem, removing the secondary shoots as they appear. If white-fly is troublesome, fumigate often with NL All.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Fruit Gathering: Apples.—There are several early Apples which should be gathered at this date, as they will now keep in better condition when stored, than if allowed to remain longer on the tree. These varieties are Lord Grosvenor, Lord Suffield, Ecklinville Seedling, Potts' Seedling, Warner's King, Frogmore Prolific, Lady Sudeley, and Worcester Pearmain. To gather these Apples now would probably save the most of the fruit that would be blown off if high winds should occur. If the fruit-room is a cool one, some of the varieties named may be kept in a sound condition for a considerable length of time. The recent extreme heat has induced early ripening in Apples, and varieties which are fit in the generality of years in October are now ready for gathering, Ribston Pippin being a notable example. The season appears to have suited this variety, the fruits being larger than usual, notwithstanding the drought, and the crops on standards and bushes are very good.

Pears need closer attention than Apples, especially early and mid-season varieties, and all the fruits of Doyenné Boussoch, Beurré de Amanlis, Louise Boone of Jersey, Thompson's, Beurré Hardy, and other mid-season varieties, may now be gathered, taking the forwarder first, and the rest a few days later. Let only perfectly sound fruits be put into the fruit-room. If it be considered desirable, a few of the earliest fruits of Marie Louise, Pitmaston Duchess, Beurré Superfin, Duchesse d'Angouleme, and others of this class may be gathered. Late varieties are best left on the trees as long as possible, or at least until frosty nights are imminent. The ripening of any of the varieties first named may be hastened by placing them in wooden boxes and standing these on a shelf in a warm-house, or in a cupboard in the dwelling.

THE APIARY.

By EXPERT.

Heather Districts.—Our fortunate friends who are within reach of these favoured spots, should prepare their bees for the journey to the hills as directed below, extracting the Clover-honey from as many unsealed sections and shallow frames as possible before starting, that they may be re-filled without the bees having to build combs to receive the honey. A main feature in ensuring success on the heath is the protection of the surplus chambers from the cold nights, so often occurring in the autumn. Warm wrappings, therefore, are very desirable. For the rest—and modifying the directions to suit circumstances—proceed as follows:—1. Prefer hives without legs, they pack

more safely and economically in the cart or waggon. 2. Any time within a week of lifting, examine all the frames, removing those containing honey only, and replacing with brood from stocks to be left. 3. Fix all frames, so as to make them absolutely immovable. 4. Supers should, if possible, have outer cases similar to the hive body below. They can thus be firmly secured from sliding about. Surplus storeys, with the hive and floor-board, are all secured together by laths nailed up the four corners. 5. Cover the top with loosely-wrought scrim, secured by strips of wood nailed round the four sides, so that it is impossible for a bee to escape. The usual quilts may be replaced over this scrim, both before and after removal; but during the journey the scrim alone should form the covering. 6. At the moment of removal, close the doorway by a strip of wire-cloth, fastened first to a lath of wood, so that two short wire-nails serve to secure it. 7. Set the hives in the cart or waggon on 2 inches or more of straw or hay. Place wads of the same between the hives and the sides of the cart to prevent rocking, and drive as fast as you please when the roads are good and the springs easy. 8. Preferably travel at night or early in the morning. Locate your stocks on their new stands, and after all are set, and quilt-rooms are placed, go round with a feather dipped in carbolic acid with which to streak the wire-cloth a moment before removal. In this way there will be no rush of bees on the door being opened; after treatment will depend on the season. If honey be abundant it may be necessary after eight or ten days to remove surplus honey, and give more storage room; if scarce, it may be good policy to give less room, leaving only one set of sections where there were two. As all supers and upper storeys may generally be removed before the bees are taken home, the latter is comparatively an easier process than taking away. The weather is cold, the combs are already secured, and the whole are less bulky than before. The same precautions as to ventilation should be observed, and a further opportunity is given on their return of making any desired change in the location of the hives, or of uniting any nuclei or weak stocks to the hives brought back.

Condemned Bees.—Where a good supply of frames of combs is on hand, these may be worked up into fine stocks if two or more are united, and fed up well by the beginning of October. Bees will unite readily just after driving, and it is only necessary to secure the best queen to head the stock. They should, if possible, be united and put into the hive the same evening on which they are driven; very strong lots will build out comb foundations if given in full sheets, but of course, ready-built combs are much preferable if they are to be had.

Feeding.—It was not thought that feeding to any extent would be required this autumn, but the stoppage of income for the last week or two has told heavily on stores in brood-chambers, and in districts where there is no Heather to rely on, immediate preparations should be made previous to the general feeding up towards the end of September. In preparing food, add one quart of water to every four pounds of sugar, boil for a minute, and after taking it off the fire stir in a dessert spoonful of vinegar and pinch of salt to each quart of food. We strongly advise that all syrup given in autumn be medicated, whether foul brood be known in the locality or not. Prevention is easier than cure, and the cost of medication is merely nominal. Feeding will not be required in such unusual quantities this year, yet many will no doubt use the "rapid" or box-feeder; indeed, we advise all with over half-a-dozen stocks to do so, in preference to pottering with small feeders; they will greatly assist in keeping down the tendency to rob, which is sure to develop when feeding is carelessly done. Besides, a good box-feeder holds about half-a-gallon of syrup, and seldom requires filling more than once to give all the food needed if set on the hive in the evening while the weather is warm. Care should be taken that the bees cannot reach the food from the outside, the feeder will be emptied in a few hours, and no excitement whatever caused among the bees. My own plan is to arrange the feeder while empty, and see that there is no access to it except for the bees of the stock being fed; I then pour in warm syrup, cover up, reduce the hive entrance to an inch in width, and leave it. The following morning I usually find the feeder empty, and the bees perfectly quiet.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

TUESDAY, SEPT. 26.—Royal Horticultural Society's Committee, at Drill Hall Westminster.

WEDNESDAY, SEPT. 27.—National Chrysanthemum Society's Floral Committee at the Royal Aquarium.

SHOW.

THURSDAY, SEPT. 28.—Royal Horticultural Society's Show of British Fruits at the Crystal Palace (3 days).

SALES.

MONDAY NEXT, SEPT. 25, and the following Tuesday, Wednesday, Thursday, and Friday, Dutch Bulbs, at Protheroe & Morris' Rooms.

WEDNESDAY, SEPT. 27.—Sale of Stove and Greenhouse Plants, at the Castle Nursery, West Norwood, by order of Mr. G. H. James, by Protheroe & Morris.

FRIDAY, SEPT. 29.—Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period September 10 to September 16, 1899. Height above sea-level 24 feet.

Remarks.—The weather has been dull and cloudy, with a few showers, and strong winds from the north and east.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—55.5°.

ACTUAL TEMPERATURES:—

LONDON.—September 20 (6 P.M.): Max. 61°; Min. 49°.
PROVINCES.—September 20 (6 P.M.): Max. 57°, Cape Clear; Min. 47°, Peterhead.

HORTICULTURISTS have not, we believe, up to the present, shown any special eagerness to display their products at the several meetings to be held in connection with the Paris exhibition of next year. We may take it as pretty certain that business motives and business motives alone, will actuate them whether they exhibit or refrain from so doing. Patriotism and zeal will, we fear, be kept entirely in the background, and the reasons are not difficult to discover.

In the first place, "business is business," and if our horticulturists do not see their way

to a profitable return for their expenditure and their trouble, it is not for others to blame them if they decline to incur the trouble and expense of exhibiting. Moreover, France is a protectionist country, and protection does not help in the promotion of international trade, but just the reverse.

Again, we know pretty well in which departments France excels us, and those in which we excel them; so that we have not much to learn in that particular.

In the second place, the very unsettled state of France, and especially of French politics, will operate most forcibly in keeping our exhibitors at home. When the elements of stability can be discerned, exhibitors will not be lacking; and this brings us to the proposal which was made in some quarters, that British exhibitors should "boycott" the Paris exhibition because, as we believe, seven officers of the French army, five, we ought to say, have pronounced what we believe to be an infamous judgment, and because some people have, as we also believe, been guilty of about the most frightful sins that human beings are capable of.

Supposing all this to be true, what has it to do with the horticultural department of the Paris Exhibition? Most of us would shun association in any way with men who, if all be true that is reported, have so far outraged the common feelings of humanity that they must be looked on as pariahs. But they are few in number, and we are not likely to come into contact with them; we do know those with whom we shall be associated, and we know them to be men like ourselves. It is silly to attempt to pass scorn on the millions of honest Frenchmen comprising, as we all know, some of the finest intellects and the noblest spirits that can adorn mankind, because some few have been base and others have been misled. What should we say if circumstances were reversed? From this point of view we greatly rejoice at the visit of the French scientists to Dover. Politics, generally speaking, are carried on in a way so totally different from scientific methods that it is quite clear that politics and science still occupy two different spheres. It ought not to be so, no doubt, and we may look forward to the time when even party politics will be controlled by scientific principles. Meanwhile, science is independent even of nationality. Science in the abstract is truth, and no nation can claim a monopoly of it.

Let us, therefore, earnestly welcome all seekers after truth, whatever be their nationality, and recognise them as brothers and fellow workers. This is high ground perhaps, but if we occupy the high ground we can the better see the plains beneath—see facts in their true proportions, and, indeed, see how childish and futile it must be to attempt to boycott a great nation because in its sun there are some notes.

We are happy to learn that since these lines were penned, the President of the Republic has seen fit to grant a pardon to Capt. DREXFUS, and thus, in a measure, assist in lessening the agitation at home and abroad that his trial has caused.

In the current number of the *Journal*, which first saw light as *Biology Notes*, some considerable amount of space is as usual devoted to horticultural matters. From the general notes we learn that the two annual senior scholarships in horticulture have been

gained by Miss ETHEL SQUIER and Mr. GEORGE PYMAN, and will be held at Swanley and the Royal Horticultural Society's Gardens, Chiswick, respectively. The number of successes (fourteen first, six second, and one third-class certificate) at the April Examination of the last-mentioned Society gained by Essex students is also given, and Mr. C. WRAGG, who obtained second place, has been offered a scholarship of £25 for two years as a result of it. The suggestion made on many occasions, and emphasised in *Nature* (July 27, p. 307), that a practical examination should be held in connection with, or, preferably, as a continuation of the Royal Horticultural Society's examination, is again brought forward in the same general notes, and the scoring of two hundred marks out of the three hundred obtainable at the written examination, is advanced as a suitable qualification for candidates who might be tested practically in the biology and operations of horticulture.

But we must point out that the object of the instruction given, and of the examinations held, is not at once to make students into practical men, but so to educate them that they may become so in the future. No scheme of education, no examination can take the place of experience, but both can facilitate the acquisition of experience, and enable the student to profit by it.

The Staff-Instructor in Horticulture, Mr. CHARLES WAKELY, contributes a seasonable article on Planting Fruit-trees. He points out that although much land is in itself suitable for such uses as the cultivation of fruit-trees, the exposure to high winds which it offers, reduces the chance of successful culture to a minimum. Abundance of gravel near the surface is another source of non-success in Essex, and defective drainage is noted as a third. After much good advice as to the preparation of the ground, into which the trees are often simply "stuck" rather than planted, and with regard to the treatment of the roots, the too general custom of buying "cheap" bundles of badly-formed trees, is pointed out, "and the plants shown in the end to be very dear."

The school garden furnishes material for several notes, and an eminently practical method, borrowed from a careful and successful grower of fruit-trees, is alluded to. The latter being to make a slight basin round the small trees, and then after these have been well watered, "the dry soil is returned over the moist surface."

A well-considered essay on "Profitable Apple Culture," comes from the pen of Mr. EDWARD MILLER, who gained the senior scholarship given by the County Council in 1897, and who is now in Kew Gardens. Previously his brother had planted and established a thriving fruit farm near Maldon, and some points in the experience of this successful student and horticulturist are well worth considering. Although a million pounds annually goes out of this country for Apples, choice English Apples well maintain their price. Last year, says Mr. MILLER, Cox's Orange Pippin fetched from fifteen shillings to twenty-one shillings per bushel in London, and the retail price of each Apple was twopence or threepence. Passing over the cultural details which are given for the benefit of fellow-students who are less familiar with the culture of this particular fruit-tree, Mr. MILLER strongly expresses himself on the subject of grading fruit, the necessity of which, and of careful packing, ought long since to have been learned by English growers from the foreigner. Choice Apples grown on cordons,

"The Journal of the Essex Technical Laboratories."

and sent to Covent Garden in boxes of a dozen, have realised from two to three shillings a box. The particular cordons, not in this case grown by Mr. MILLER, were set in rows about four feet apart, and with eighteen inches between the plants, and bore very heavily. The result, of course, being that care had to be taken to replace the trees as they wore themselves out.

The cost per acre of growing Apples as

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Fruit and Floral Committees will take place on Tuesday, September 26, in the Drill Hall, James Street, Westminster, from 1 to 5 P.M. At 3 o'clock a lecture on "Instructional Fruit Stations" will be given by Mr. E. LUCKHURST, F.R.H.S.

The Fruit Show of the Society.—The great show of British-grown fruit will take place at the Crystal Palace on Thursday, September 28, and the two following days. Entries should reach the Royal

in capital condition, the most effective of the plants in the beds being the fibrous-rooted Begonias, which are a picture of neatness, and full of bloom. *Lilium speciosum* in several large beds is now blooming freely, and many very pretty autumnal buds may be seen on the Rose-trees near to the Palm-house. The mauve flowers of the autumn Crocuses (*Colchicums*) are appearing in many spots among the grass. The greenhouse No. 4 is looking gay with the following plants in flower amongst others:—*Tibouchina* (*Pleroma*) *macrantha*, *Salvia*

FIG. 84.—*EUCCHARIS* × *BURFORDIENSIS*. (SEE P. 239)

(Shown by Sir Trevor Lawrence, Bt., at a meeting of the Royal Horticultural Society on September 12.)

estimated in the paper might perhaps be quoted with advantage:—

	£	s.	d.
Rent of Land	...	5	0
Digging same at 6d. per rod	...	4	0
Hoeing five times during summer, say, at 10s.	...	2	10
Manuring (twenty loads of dung)	...	5	0
Wheeling same into plantation	...	2	0
Cost of pruning	...	3	0
Cost of Insecticides and time spent in application	...	5	0
Cost of gathering and packing	...	10	0
Carting to rail, carriage, and commission of salesman	...	10	0
Total	£46	10	0

This sum is approximate to the cost of growing a crop which at the low figure of four shillings a bushel would realise eighty-seven pounds.

Horticultural Society's Office, 117, Victoria Street, S.W., not later than September 21. On each day of the show, after 10 A.M., Fellows of the Society, on producing their tickets, will be admitted to the Palace free. The President and Council desire special attention be paid to the notice found on p. 3 of the schedule, which will be strictly carried out, viz., "All fruit should bear its natural bloom; any polishing process disqualifies."

THE ROYAL GARDENS, KEW.—The appearance of the lawns is now much improved, and the summer bedding-plants also show the effect of the recent rains. The flower garden in front of the Palm-house, although the season is so far advanced, is

splendens, Celosias, Abutilons in variety, Begonia Knowsleyana and B. semperflorens gigantea rosea, Physalis Francheti, Balsams, a fine lot of Cannas in pots, Primula obconica, Achimenes, Plumbago capensis in blue and white flowering varieties, Rhododendrons, Maurandya scandens on rafter, Datura fatuosa, blooming well in pots of about 6 inches in diameter, and Datura Knighti. In the Begonia-house, Solanum Seaforthianum trained under one of the rafters is just a mass of lilac-coloured flowers, and several of the Begonias also are making a good show. Curcuma Roscoeana a few days ago was in flower in the stove (T range), and is worth noting by visitors, although an old plant. A figure of this Scitamineaceous plant with scarlet

flowers and bright orange bracts, may be seen in *Bot. Mag.*, t. 4667. There are naturally few Orchids in flower at the present time, but in the adjoining house is the *Victoria regia*, and this season of the year is the best to see the giant of Water-Lilies, for it is now flowering freely, and the leaves are a good size. The effect presented by the *Nepenthes-house* is exceedingly good, and the majority of the plants are carrying many well-developed pitchers.

"**SAM STEVENS.**"—Many naturalists and horticulturists in the habit of frequenting STEVENS' Rooms in years gone by retain pleasant recollections of this gentleman, who died recently at an advanced age. In his garden at Beulah Hill, he had a Pear grafted on an Apple. He, as we believe, effected the graft himself.

THE VEGETARIAN FEDERAL UNION.—The members of the Federal Union met at the Mansion House Restaurant, Poultry, on Thursday evening, the 16th inst., in connection with the Vegetarian Congress held in London last week. The chair was taken by Mr. ARNOLD F. HILLS, of the Thames Ironworks Company. The Union, he explained, was an association of such vegetarian societies and individuals as might be willing to unite for the advancement of vegetarianism, that was, the encouragement of the use of the products of the vegetable kingdom, instead of the flesh of animals. The Union is intended to act as a connecting body for foreign societies, and also to do what it can to promote the spread of the cult throughout the country.

USEFUL GARDEN RECIPES.—To destroy moles, wasps, and rabbits: pour an ounce or so of disulphide of carbon down the holes, and plug them securely with a thick sod. Care must be taken that the liquid is kept away from fire and lights.

"**THE FAIREST FLOWERS OF THE WEEK.**"—A correspondent writing to us on the 14th inst., employed the above expression in regard to a box of cut flowers he was sending. One of these was *Harpolum rigidum*, var. *Miss Mellish*, and as most of our readers are well acquainted with this variety, they will doubtless concede it to be a most valuable border plant. The rest of the flowers were varieties of Perennial Asters or Michaelmas Daisies, but these arrived in a state too withered to enable us to approximate their beauty, at any rate, from the specimens sent. The first of these was the well-known Harpur Crewe; the rest were White Queen, japonicus, Edie Lowe, versicolor, and cordifolium. Such, according to our correspondent, were "the fairest flowers of the week." He gathered them, he states, from a mixed border.

DR. S. P. BUDD.—The death is announced in his fifty-sixth year, after a prolonged illness, of Mr. SAMUEL PUNNETT BUDD, the well known Bath surgeon. He was the second surviving son of the late JOHN WREFOED BUDD, M.D., of Plymouth, the eldest of a noted west country family of seven medical men, all eminent in their profession. The deceased came to Bath in 1870, and soon found himself with a large practice. He was also widely known as an amateur rose-grower and exhibitor, and a member of the National Rose Society. He was the winner of the Jubilee Challenge Trophy at the National Rose Society's northern show in 1892; and that of the metropolitan show of the same Society in 1894.

PRESENTATION TO A GARDENER.—Since the re-formation of the Beckenham Horticultural Society in 1892, Mr. MARK WEBSTER, gr. to E. J. PRESTON, Esq., at Kelsey Park, has contributed valuable assistance as a member of the Committee, and particularly as hon. librarian. Many of his friends, therefore, who are also interested in the Society, have taken the opportunity afforded by Mr. WEBSTER's approaching marriage, to make him a presentation of a pair of easy-chairs, in dark mahogany. In one of the chairs has been fixed a suitably-inscribed medal of

the Society. This has been placed on pivots, and reverse and obverse can therefore be seen. We had occasion, some time ago, to comment favourably upon the practical and useful educational work the Beckenham Society is doing.

ANOTHER OPEN SPACE.—Islington would appear to be the most highly favoured district in the metropolis in the matter of open spaces. There are now open six extensive gardens in the parish: one is Barnsbury Square, the others Thornhill Square, Canonbury Square, Edward Square, Duncan Terrace, Islington Green; and now the largest of all is about to be opened at the Caledonian Road end of Market Road. This is a long and broad thoroughfare on the south side of the great Cattle Market, just above the gloomy-looking prison of Pentonville. At the other end of Market Road—where it joins York Road—is a fine new children's playground, which has been laid out in conjunction with the new open space. Formerly the two were almost waste ground, though used for all sorts of odd businesses, and owned by the City Corporation, who parted with it at a high figure to the Islington folks. The laying out has been done by the parish surveyor, and the garden will be open to inspection in a few days.

FRUIT, ETC., FROM THE WEST INDIES.—Some time since we drew attention to the proposals of the Government for helping the more than half-ruined producers of the West Indies, to send fruits and other products of the islands to a ready market here. To-day we note that some Glasgow people, after mature consideration, are about to solicit subscriptions from the public, in order to float the Jamaica Produce and Transport Association (Ltd.). The capital asked for is to be laid out in building four steamships, wharfage at Jamaica, a hotel, and to provide funds to enable producers to take advantage of easy loans, in growing, harvesting, and forwarding fruit and other productions for which the islands are celebrated. We cannot but wish any well-considered scheme all success.

CHARGES FOR WATER FOR GARDEN PURPOSES.—Some of our readers residing in those parts of London supplied by the New River Water Company, will be grateful for the following note on that Company's charges for water, supplied for garden purposes during the winter. We are indebted to Messrs. NOKE & NOKE, 67, Caledonian Road, King's Cross, for the information afforded: "As the season is approaching when the application of water to the garden is unnecessary, will you allow us to point out to your numerous readers that they can save one-half of the amount paid the New River Company for water for gardens, by giving notice that they will cease to use water for this purpose after 29th inst. By giving this notice, consumers will not have to pay for water for gardens until they again require to use it for that purpose—that is, until after March 25 next. This means to each householder a clear saving of one-half the sum charged by the New River Company, which charges for water for garden purposes the whole year round, although water is only used for that purpose for four or five months out of the twelve."

VINTAGE PROSPECTS IN FRANCE.—In a note from Sir WALTER GILBEY from the Château Loundenne, Medoc, dated September 13, states the *Agricultural Gazette* of September 19, he refers as follows to the vintage prospects:—"The vintage will commence in the Medoc next Monday, the 18th inst. I have regularly seen the vineyards for forty years at this season, and to all appearance the Vines never looked more promising. The Grapes on the early 'Malbec' Vines are in some cases shrivelled; rain is badly wanted during the next few days to increase the yield and improve the quality of the wine. With the many thousands of acres of vineyards in this claret district, the importance of rain falling quickly is very great, as is proved by

the fact that each acre of Vines in bountiful harvests produces nearly five hogsheads, or 236 gallons, of Grape-juice."

GENTLEMEN GARDENERS.—As showing the kind of statements which press writers sometimes afford newspaper readers, we commend the following, taken from the *Daily Mail* of a recent date. Were the statements but only half true, we fear the ranks of British gardeners would be greatly more crowded than is even the case at the present time. We should suppose that if the annual incomes quoted were divided by ten, they would be much nearer the mark:—"There never was a time when really clever and scientific gardeners were in such request as now, for it is a notable fact greatly to their credit that the modern self-made rich men, of whom there are such numbers, as a class show the greatest enthusiasm in the matter of their gardens and greenhouses. Indeed, one of our greatest authorities on the subject has said that where there was one splendidly appointed garden fifty years ago there are a hundred now. And there are hundreds of rich men who desire to shine in this way who are prepared to pay, and do pay, very handsome salaries and premiums to their head gardeners. The writer was lately interviewing a millionaire north-country baronet noted for his gardens, and he exclaimed, 'Why do not more professional men and gentlemen of small means make trained and scientific gardeners of their sons? They cannot realise what a number of comfortable berths there are in the calling, and that scores of head gardeners make from £600 to £1000 a-year, and have everything free besides.'"

SHIRLEY MUTUAL IMPROVEMENT ASSOCIATION.—The monthly meeting of above Society was held at the Parish Room, Shirley, Southampton, on Monday, 18th inst., there being a good attendance of the members, presided over by Mr. B. LADHAMS in the absence of the President. Mr. A. DEAN, London, gave an interesting lecture, entitled "Horticultural Exhibitions: their Uses and Lessons."

HAMPSTEAD GREEN.—The Tree and Open Spaces Committee of the Hampstead Vestry have issued a report stating that they have carefully considered a letter from Sir HENRY HARBEN, the chairman, intimating that upon his recommendation a lady had bought for £7,500, the Hampstead Green property recently put up to auction for the sole purpose of enabling the vestry to make up their minds what they will do with regard to the green or paddock in front of the houses standing on the property, and that if the offers were sufficient she would dedicate the paddock to the public in order that it might be preserved as an open space for ever. In the opinion of the committee the opportunity now afforded by the generous and public-spirited action of the lady of maintaining the present picturesque and sylvan approach to Hampstead from London should not be lost, and they recommend that the necessary steps be taken for the acquisition of the Green and the dedication thereof to the public. The lady referred to, who wishes to remain anonymous, has said that she will herself make a contribution to the acquisition of the Green.

YORKSHIRE NATURALISTS' UNION.—We have particulars of the 147th meeting of this Association to be held on the 25th, 26th, and 27th inst. at Sutton, near Askeru. A fungus foray will be made from that place over Campsall, Burghwallis, and Ouston Woods. Another meeting will take place on the 28th inst., at Barnsley, for the investigation of Worsborough reservoir, Stainborough, Broom Royd, Friarail, and other woods in the neighbourhood. The Hon. Sec. of the Naturalists' Union is Mr. W. DENISON ROEBUCK, F.L.S., 259, Hyde Park Road, Leeds, but all communications with regard to the scientific business of the Mycological Committee should be addressed to Mr. C. CROSSLAND, F.L.S., Halifax, the Committee's Secretary.

HOME CORRESPONDENCE.

FIGS IN KENT.—Am I correct in thinking the Figs herewith sent to be Brown Turkey? [Yes. Ed.] They are gathered from large standard trees, which must be very old. Some of the first fruits weighed half a pound, and the flavour has been first-rate, owing, no doubt, to the very hot, dry season. When allowed to hang on the tree until fully ripe, Figs get the sweetness without which, to my taste, they are not worth eating. If it would interest readers of the *Gardeners' Chronicle*, I should be pleased to furnish particulars of the size, cropping powers, &c., of the two trees from which the enclosed fruits were gathered. *Thomas Bowie, Elmwood Gardens, St. Peter's, Kent.* [Please do. The largest of the fruits sent was a little over 5 oz. Ed.]

RUBUS ROSÆFOLIUS.—Last autumn a small plant was sent to me by a lady, who got it from France under the name *Fraisier Framboisier*, and it was said to be a hybrid between a Strawberry and a Raspberry. I do not know whether such a hybrid has ever been verified, but the characters of

H. nudiflorum, I distributed it to friends under that name provisionally, telling them if anyone disputed the name to ask the reasons, and to let me know. In this case, as in all others, I should have preferred to compare the plant with the types in Kew Herbarium, but I live too far from Kew to do this myself, and though I formerly used to get my specimens verified from this source by a local botanist on payment of a small fee for each plant, the regulations at Kew now forbid this. But even with this help garden forms are often difficult to identify, especially in the case of North American Composites, many of which hybridise readily when flowering together. Asa Gray says "*H. nudiflorum* (see *Nth. Am. Fl.*, vol. i., page 349) hybridises with *H. autumnale*," so we may very likely be discussing a hybrid. But apart from this chance, *H. autumnale* is very variable in stature and form if not in colour, and already figures in English nursery catalogues under several names, both authorised and spurious. We have *H. grandiflorum* and *H. pumilum*, authorised varietal names; and *H. superbum*, a spurious name, for which the authorised *H. altissimum*, Link., would be more appropriate. For this variegated plant, perhaps

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—The subject to which Mr. Long refers at page 230, was thoroughly thrashed out in the gardening papers sometime since, and the ultimate conclusion was that having more than one central Certificate-granting body by the Royal Horticultural Society for the dealing with flowers, fruits, and vegetables, Orchids, Daffodils, &c., would be impracticable. Things rejected by the old and experienced central body because not good enough for an award, would probably if placed before a local committee, receive an award, simply because this latter body did not possess the knowledge as to what similar products may be in existence, that the central body would possess. Of course, any local society may, if it chooses, establish its own committees, and make awards of certificates, &c., but then, how comparatively worthless would they be. The Drill Hall committee largely include members from all parts of the kingdom, but how difficult it is for the distant ones to attend the meetings! Only constant attendance will keep members up-to-date, with either committee. *A. D.*

PROTECTING PEACH-TREES WHEN IN BLOOM.

Mr. Markham re-opens a subject which has received considerable discussion in horticultural journals from time to time. It is also a subject upon which cultivators agree to differ, as these pages amply testify. I have about sixty Peach and Nectarine-trees here which are not covered at any time, and which never fail to produce good crops. This year I had to thin heavily, removing quite two-thirds of the young fruits; the trees were also practically free from blister. I have studied the behaviour of these trees during the flowering season for several years, in order to find out whether protection is absolutely necessary or not, and to arrive at this knowledge I removed an unopened bud which had been frozen black, and pulled it to pieces. I found that although the petals were destroyed the stamens and style had not been injured, as the anthers had burst without seeing the light, and pollen had been distributed over the stigma. With the view to finding out if fertilisation had taken place under these conditions, I marked several other buds which had not opened, and which were similarly frozen, by tying raffia round the stem, and removing all other buds near them. These have developed into perfect fruits, each containing what appears to be a perfect seed. This, I take it, shows that the petals, though frozen black, had afforded protection to the anthers and stigmas. This probably explains why Mr. Markham's unexpanded blooms proved best. In the case of Peaches and Nectarines, the flowers open successively; but in Apricots, which, from the reports of the fruit crops recently, have suffered most, the flowers are open altogether. In such a case it is imperative that the blooms be protected, for once they are frozen, the case is hopeless. Moreover, the Apricot seems more susceptible to a few hours' sunshine than either the Peach or the Nectarine, and may often be found carrying expanded blooms before the Peach and Nectarine flowers have burst the protecting scales. Returning to Peaches and Nectarines, I am of opinion that much may be done to save or secure crops by removing the bearing wood soon after the fruit is gathered, thereby strengthening the next season's wood, and securing free access of air and sunshine to promote ripening; also by levelling the borders in which the trees are planted so far as is possible, in order that they may not be hastened into flower too early. The additional heat absorbed by an inclined border early in the year is of sufficient importance to be noted, and this heat must be instrumental in bringing the trees into flower earlier than they would do on the level. Anyway, the plan proves to be excellent in practice. I have seen numbers of trees, which have been covered with protecting-material bearing indifferent crops, and suffering badly from blister; whilst others on the same wall without protection, have borne excellent fruits in quantity, and have been free from blister. Both soil and situation have to be considered in exposing, and apparently risking so important a crop as Peaches and Nectarines to the elements, and it is well to experiment with a single tree by planting it on the level, in a well-drained soil, noting the amount of frost registered at the flowering season, and the behaviour of the tree from year to year. In most cases I think it will be found that protection is needless, and Peaches plentiful. *Geo. B. Mallett, Isleworth.*

FIG. 85.—EUCHARIS BAKERIANA. (SEE P. 239.)

this plant were so unlike those of either reputed parent, that I sent it to be named on good authority, and find it is *Rubus rosæfolius* (Smith), a native of tropical Asia, ascending a few thousand feet into the Sikkim Himalayas; but though it lived out through last winter, and is offered as hardy in some catalogues, I do not expect to keep it out-of-doors in a hard winter. The flowers are the size of large Strawberry-flowers, uniform, pure white, and ornamental. The leaves are dark green, and very thorny at the back. The habit is elegant and prostrate, with a tendency to run underground. See *Bot. Mag.*, t. 1783, where a double form is figured; also *Loddiges' Cabinet*, t. 158, for the single form. *C. Wolley Dod, Edge Hall.*

HELENIUM NUDIFLORUM?—Mr. Arnott, on p. 222, calls upon me to settle the correct name of the plant generally known in nurseries as *H. grandicephalum striatum*. When I first got it five or six years ago from Ware's nursery, objecting as I do to unauthorised quasi-botanical names, I looked through the descriptions of *Helenium* in Asa Gray's *Flora of North America* to see if I could not find a better name. The only species there described as having rays striped with brown-purple is *H. nudiflorum*; and as the characters of this plant with striped flowers seemed in other respects to answer sufficiently well to those of

H. autumnale var. *striatum* would be a safe name, even though not authorised. *H. nudiflorum*, according to Asa Gray, ought to have sterile ray flowers; but these striped flowers appear to have the ray-flowers perfect. But whatever its name, the plant makes a very pleasing variety amongst the forests of tall North American yellow Composites which nearly fill our borders in September. *C. Wolley Dod, Edge Hall, Malpas.*

NE PLUS ULTRA RUNNER BEAN.—This fine Scarlet Runner, and the various selections made from it, *A1*, *Prizewinner*, *Best-of-All*, and *Hill's Prize*, with some others, is now being universally grown in gardens, not only because the pods are so long, straight, and handsome, but because such abundant crops are produced. Very recently, a correspondent in the West of England, wrote complaining that judges at a local show had disqualified a handsome dish of *Ne plus Ultra* because they were too long. That was an odd objection to Beans 10 inches in length. What would these sapient persons have said to the wonderful sample of *Best-of-All*, shown by Messrs. Sutton & Sons at Shrewsbury, 13 inches long. Of course, such long Beans are not required, and habitually the pods are gathered for table shorter, and for exhibition when 10 inches long. A very even green sample of such pods now constitute a common dish at shows. *A.*

THE CAPE GOOSEBERRY IN THE OPEN AIR.—I have pleasure in sending you a sample of Cape Gooseberries, *Physalis pubescens*, grown and ripened in the open air in my garden at "Oaklands," Marchwood, near Southampton. These were gathered to-day (September 18), the fruit having gone on ripening during the recent cold weather, and even to-day the plants are bearing flowers and fruit at the same time. The fruit-bearing plants are from seed sown in February last in heat, and planted out on April 15, after which sharp frosts occurred for a week, which cut down to the ground Cape Gooseberries, Tomatoes, and Potatoes. The Cape Gooseberries, as well as the others, came up again, and formed sturdier plants than those put out early in May. Strange to say, that though the plant belongs to tropical (Barbados) and sub-tropical zones, it has thriven this year decidedly better with me in the open air than under glass. I have had a fair supply of, to me, delicious fruit this year, and I hope next to have a much better one, if I can protect the roots from too much frost. *J. A. R., September 18.* [Exceedingly nice-flavoured, full-grown fruits. Ed.]

GRAPES, CLIMATE, AND ATMOSPHERE AT ALLOA, N.B.—I may say that I know the town of Alloa fairly well. In it there are nine breweries, one distillery, one manufactory of chemicals, two brickmaking-works, two potteries, one copper-work, five engineering-works, two iron-foundries, one woollen manufactory, the Alloa Coal Co.'s coal-mine, and four yarn manufactories; yet from out of the midst of this busy commercial town came the Grapes that won 2nd in the champion class, and 1st in that for four bunches of Grapes at the last Shrewsbury Show. Surely your correspondent of last week cannot maintain that the atmosphere of Alloa is as good as he would have us believe it is. *A. K.*

THE ROSARY.

MARÉCHAL NIEL ROSE.

Has any reader of the *Gardeners' Chronicle* ever tried Maréchal Niel worked on Rose Devonensis as a panacea for canker and loss of vigour after a few years cultivation under glass? If not, a market grower would recommend a trial being made, as with me the Rose has never yet shown a tendency to canker, but rather, as years go on, increase in vigour. There is much to recommend the use of Devonensis as a stock, it being vigorous, with thick bark, and tenacious of life; the flowers, though good, are not so valuable as those of M. Niel, and it is not so profuse or regular a bloomer indoors. I have tried M. Niel on almost every kind of Rose, Manetti, de la Griffère, Sweet Briar (which is a good one), Dog-Roses of the hedge-rows, and the less prickly one which grows in damp ground; Dundee Rambler, Hybrid Perpetual, Lamarque, Rêve d'Or, Cellini Forestier, and Gloire de Dijon, with interesting results; but the old Tea-Rose Devonensis takes the palm for producing the weightiest blooms. I do not mean from Devonensis on its own roots, but when worked on the seedling Briar or prepared Briar-stocks, which when established make robust growths, 10 to 12 feet long. From stocks from cuttings, excepting in the case of Gloire de Dijon, they do not reach that degree of vigour quickly, but the union with the Briar gives it forthwith.

The method of procedure is by budding and inarching; by the former, inserting the bud in the robust growths, which this variety produces liberally, from 3 to 6 inches apart, awaiting results. A man could quickly insert a few hundred, and no matter if the buds are from weak wood, on this stock the shoots develop very weighty blooms. Of course, the branches operated upon must be kept in an upward, or at least, an oblique position, or the buds will start into growth directly, as many have so done to a length of 4 to 6 feet since May. The whole of the stems can be done at one time (even now it is not too late—I put on ninety buds on September 9), or a few at a time, as the growth develops. If it is desired to have several varieties on a plant, choose Catherine Mermet, Madame Thérèse Levet, Lambard, Perle, &c., which will be attractive the whole summer. A branch treated in this

manner trained horizontally, has given many fine blooms, M. Niel having grown very freely, and the branch is now about 17 feet long, and I am still adding other buds alternately with M. Niel.

Those that start are shortened back, so as to carry from six to ten flowers, never all of them being wished for. If the shoot be bent to a horizontal position, each bud will start. After flowering, prune hard back to the main stem if a M. Niel, and other growth will follow for another year, a method generally followed with this variety. If the sap is not on the move, the application of a few pots of water to the roots will soon set up activity. If the worked buds remain dormant till the spring, the blooms are of the finest quality. I could say more about inarching M. Niel on Devonensis, Gloire de Dijon, Rêve d'Or, A. K. Richardson, and others, at some future time. [Please do so. Ed.] M. Niel worked on A. K. Richardson, bloomed freely a second time this year.

Perhaps "Growler" will ask "why all this trouble when Roses can be bought so cheaply?" Canker comes to M. Niel in many kinds of soil, and if we cannot cure it, we may try to prevent it by using a stock which is not liable to it. *J. K., Wimborne.*

AMERICAN NOTES.

THE AMERICAN ROSE SOCIETY.

A MEETING of the newly-formed Rose Society was held at Detroit during the large Convention, with the President, W. C. Barry, of the firm of Elwanger & Barry, Rochester, N. J., in the chair. The first exhibition of the Society will be held in New York next year, and the schedule will be ready in a few weeks. This show will, of course, be for varieties grown under glass, and great things are expected of the society. Its opportunities are large, and all depends upon the course of procedure that the leaders there follow out. It is really surprising how small the list of Roses in regular cultivation is—half-a-dozen at the most; Mr. Hill says three. If the American Rose Society will do for us what the English society has done on your side of the water, we shall be more than jubilant.

NEW SCALES OF POINTS FOR CHRYSANTHEMUMS.

The Chrysanthemum Society has adopted new scales of points for judging, which now read as follows:—

SCALE A.—Scale of points for bush-plants and standards, single specimen, or any number up to six, in an exhibition where the class under consideration does not form the chief feature in the exhibition-hall:—

Equality of size and form of plant	40 points.
Excellence of bloom	35 "
Foliage	25 "

Total ... 100 points.

SCALE B.—Scale of points for bush-plants; exhibits of more than six, or for any number of specimen-plants in an exhibition, where the class under consideration forms the chief feature in the exhibition-hall:—

Equality of size and form of plant	35 points.
Excellence of bloom	40 "
Foliage	25 "

Total ... 100 points.

SCALE C.—Scale of points for plants grown to single stem and one bloom. A height of not over 3 feet is recommended for plants in this class, and pots not over 6 inches in diameter:—

Compact and sturdy growth	35 points.
Excellence of bloom	40 "
Foliage	25 "

Total ... 100 points.

SCALE D.—Scale for points for specimen blooms:—

Colour	25 points.
Form	25 "
Fullness	15 "
Stem and foliage	10 "
Substance	10 "
Size	15 "

Total ... 100 points.

The changes in the latter scale were the addition of foliage to stem, and the substitution of substance for petalage.

DISCOUNTING THE ELEMENTS.

The Florists' Hall Association continues to flourish and do good work, but owing to a lack of interest the recently-circulated scheme for fire insurance on green-houses has been thrown over. The Hall Association now carries an aggregate of 11,209,865 square feet of glass, and has paid in the year just past 5,300 dol. in claims. The way a hailstorm goes and comes is "one of those things that no feller can understand," and each year there are surprises all round, but the most surprised man is he who did not insure because a hailstorm "never comes my way." There are some such individuals in both England and America, for human nature is very much the same the world over. *Our own Correspondent.*

Obituary.

WILLIAM THOMSON.—Many of the older readers of the *Gardeners' Chronicle* will be grieved to learn of the death of Mr. William Thomson, which took place at Teignmouth on Saturday, September 16, in the seventy-fifth year of his age, he having been born July 19, 1825, a day mentioned in *White's Natural History of Selborne* as being hotter than any day in the previous 100 years. From 1846 to 1851, he was curator of the Museum of Human and Comparative Anatomy, and of *Materia Medica*, King's College, London, where he was also lecturer on the "Use of the Microscope in Botanical and Zoological Investigations." In 1852-53, he was superintendent of the Natural History department of the Crystal Palace at Sydenham. This department consisted of several sections: that of the geographical distribution of plants and animals, being under the direction of Prof. Edward Forbes; that of geology, under Prof. Anstead; that of Paleontology, under Prof. Owen; and that of ethnology, under Dr. R. Gordon Latham. In addition to these varied collections, he originated a museum of raw products in connection with arts, science, and manufactures, which was subsequently carried on by Dr. David Price.

From 1856 to 1894, Mr. Thomson was secretary to the City of London Club. In the earlier part of that time there was a good deal of competition in the London Clubs in dinner-giving, which induced him to pay attention to floral decoration for the table, for which his club got considerable repute. He contributed many articles on that subject to this journal and the *Garden*. He was often in request as a judge at metropolitan and suburban flower shows in those years. In 1885, he wrote a series of articles upon "House, Area, and Window Gardening," which were published in *Cassell's Popular Gardening*. Besides his varied work in connection with horticulture, Mr. Thomson in 1856, published a book on the art of ornamental hairwork, the only one probably existing in the English language. At the suggestion of Professor Ed. Forbes, he described the researches which he had made on the lingual teeth of the British land and fresh-water Mollusca, a subject which had not then been taken up in this country. This paper was read at the meeting of the British Association in Edinburgh in 1850, and was in February, 1851, reprinted in the *Annals of Natural History*. The deceased gentleman had for several years lived in retirement at Teignmouth.

ALFRED HENDERSON.—American horticultural periodicals contain notices of the death of A. Henderson, eldest son of the late Peter Henderson, at his summer home, Spring Lake, New Jersey, U.S.A., on September 5, aged forty-seven years. After completing his education he underwent a thorough training under his father at the nursery in Jersey City and the seed-stores in New York, then Henderson & Fleming. In 1871 the firm of P. Henderson & Co. was established by his father, he and Mr. W. H. Carson being the associate partners. In 1876 Carson withdrew, Jas. Reid becoming the third member of the firm. The latter died in 1887, and Charles, the younger son of P. Henderson, was then admitted to the partnership. Upon the death of their father, in 1890, the business was incorporated, an interest being given to some old employes in charge of departments. The business capacity of the deceased was enormous, and he greatly extended and consolidated the business founded by his father.

PLANT PORTRAITS.

NERINE FOTHERGILLI AND N. EXCELLENS VAR. ROSEA.—The first is synonymous with *N. curvifolia* and *Amarylhis curvifolia*, Jacq., or *A. Fothergilliae*, Andr. Introduced from the Cape in 1788. The second is stated by Mr. J. G. Baker to be a hybrid of *N. flexuosa* and *N. humilis* major. Known also as *N. flexuosa excellens*. Introduced to commerce in 1883. Coloured plate. *Illustrirte Garten Zeitung*, August-September, 1899.

FIG. 86.—URCEOCHARIS CLIBRANI. (SEE P. 239.)

THE BRITISH ASSOCIATION. (DOVER, THURSDAY, SEPTEMBER 14.)

SIR GEORGE KING, K.C.I.E., LL.D., M.B., F.R.S., President of the "K" or Botanical Section, gave as his address a Sketch of the History of Indian Botany, of which we append the more interesting passages.

The earliest references in literature to Indian plants are, of course, those which occur in the Sanskrit classics. These are, however, for the most part vague and obscure. The interest which these references have, great as it may be, is not scientific, and they may therefore be omitted from consideration on the present occasion. The Portuguese, who were the first Europeans to appear in India as conquerors and settlers, did practically nothing in the way of describing the plants of their Eastern possessions. And the first contribution to the knowledge of the Botany of what is now British India was made by the Dutch in the shape of the "*Hortus Malabaricus*," which was undertaken at the instance of Van Rheede, Governor of the territory of Malabar, which during the latter half of the seventeenth century had become a possession of Holland. This book, which is in twelve folio volumes and is illustrated by 794 plates, was published at Amsterdam between the years 1686 and 1703, under the editorship of the distinguished botanist Commelyn. The "*Hortus Malabaricus*" was based on specimens collected by Brahmins, on drawings of many of the species made by Mathæus, a Carmelite missionary at Cochin, and on descriptions originally drawn up in the vernacular language of Malabar, which were afterwards translated into Portuguese by Corneiro, a Portuguese official at Cochin, and from that language finally done into Latin by Van Douet. The whole of these operations were carried on under the general superintendence of Caserius, a missionary in Cochin. Of this most interesting work the plates are the best part; in fact, some of these are so good that there is no difficulty in identifying them with the species which they are intended to represent. The next important contribution to the botanical literature of Tropical Asia deals rather with the plants of Dutch than of British India. It was the work of George Everhard Rumph (a native of Hanover), a physician and merchant, who for some time was Dutch Consul at Amboina. The materials for this book were collected mainly by Rumph himself, and the Latin descriptions and the drawings (of which there are over one thousand) were his own work. The book was printed in 1690, but it remained unpublished during the author's lifetime. Rumph died at Amboina in 1706, and his manuscript, after lying for thirty years in the hands of the Dutch East India Company, was rescued from oblivion by Professor John Burman, of Amsterdam (commonly known as the elder Burman), and was published under the title of "*Herbarium Amboinense*," in seven folio volumes, between the years 1741 and 1755. The illustrations of this work cover over a thousand species, but they are printed on 626 plates. The works of Plukenet, published in London between 1696 and 1705, in quarto, contain figures of a number of Indian plants which, although small in size, are generally good portraits, and therefore deserve mention in an enumeration of botanical books connected with British India. An account of the plants of Ceylon, under the name "*Thesaurus Zeylanicus*," was published in 1737 by John Burman (the elder Burman), and in this work many of the plants which are common to that island and to Peninsular India are described. Burman's book was founded on the collections of Paul Hermann, who spent seven years (from 1670 to 1677) exploring the flora of Ceylon at the expense of the Dutch East India Company. The nomenclature of the five books already mentioned is all unimmaculate.

Hermann's Cingalese collection fell, however, sixty years after the publication of Burman's account of it, into the hands of Linnaeus, and that great systematist published in 1747 an account of such of the species as were adequately represented by specimens, under the title "*Flora Zeylanica*." This Hermann Herbarium, consisting of 600 species, may still be consulted at the British Museum, by the trustees of which institution it was acquired, along with many of the other treasures possessed by Sir Joseph Banks. Linnaeus's "*Flora Zeylanica*" was followed in 1768 by the "*Flora Indica*" of Nicholas Burman (the younger Burman)—an inferior production, in which about 1,500 species are described. The herbarium on which this "*Flora Indica*" was founded now forms part of the great Herbarium Delessert at Geneva.

THE "UNITED BROTHERHOOD."

The pioneer John Gerard Koenig was a native of the Baltic province of Courland. He was a correspondent of Linnaeus, whose pupil he had formerly been. Koenig went out to the Danish Settlement at Tranquebar (150 miles south of Madras) in 1768, and at once began the study of botany with all the fervour of an enthusiast which he succeeded in imparting to various correspondents who were then settled near him in Southern India. These friends formed themselves into a society under the name of "The United Brothers," the chief object of their union being the promotion of botanical study. Three of these brothers, viz., Heyne, Klein, and Rottler, were missionaries located near Tranquebar. Gradually the circle widened, and before the century closed, the enthusiasm for botanic research had spread to the younger Presidency of

Bengal, and the number of workers had increased to about twelve, among whom may be mentioned Fleming, Hueter, Anderson, Berry, John, Roxburgh, Buchanan (afterwards Buchanan-Hamilton), and Sir William Jones, so well known as an Oriental scholar. Rottler was the only member of the band who himself published in Europe descriptions of any of the new species of his own collecting, and these appeared in the "*Nova Acta Acad. Nat. Curiosorum*" of Berlin. A little later Sonnerat and other botanists of the French Settlement at Pondicherry sent large collections of plants to Paris, and these were followed at a considerably later date by the collections of Leschenault. These French collections were described chiefly by Lamarck and Poiret. Hitherto botanical work in India had been more or less desultory, and it was not until the establishment in 1787 of the Botanic Garden at Calcutta that a recognised centre of botanical activity was established in British India. Robert Kyd, the founder of that Garden, was more of a gardener than a botanist. He was, however, a man of much energy and shrewdness. Kyd, as a Lieutenant-Colonel of the Company's engineers, and as Secretary to the Military Board at Calcutta, occupied a position of considerable influence, and his suggestion evidently fell on no unwilling ears; for the Government of Bengal, with the promptitude to accept and to act on good advice in scientific and semi-scientific matters which has characterised them from the day of Kyd until now, lost no time in taking steps to find a site for the proposed garden. Colonel Kyd's official proposal was dated June 1, 1786, and in a despatch dated August 2, the Calcutta Government recommended Kyd's proposal to the Court of Directors in London. Posts were slow and infrequent in those days, and the Calcutta Government were impatient. They did not wait for a reply from Leadenhall Street, but in the following July they boldly secured the site recommended by Colonel Kyd. This site covered an area of 300 acres, and the whole of it, with the exception of thirty acres which were subsequently given up to Bishop Middleton for an English College, still continues under cultivation as a Botanic Garden. Kyd died in 1793, and in the same year his place as Superintendent of the Garden was taken by Dr. William Roxburgh, a young botanical enthusiast, and one of Koenig's "United Brotherhood."

DR. W. ROXBURGH AND OTHERS.

In 1776 Roxburgh accepted an appointment in the Company's Medical Establishment, and was posted at Madras, where he very soon made the acquaintance of Koenig. Roxburgh was shortly afterwards transferred to a remote district, a good deal to the north of Madras, then named the Northern Circars. The station of Samuleotta, which formed Roxburgh's headquarters during his sojourn in the Circars, stands on the edge of a hilly region possessing a very interesting flora, and this flora he explored with the greatest ardour; and as part of the result of his labours an account of some of the most interesting of its plants was published in London, at the East India Company's expense, in three large folio volumes under the title "*The Plants of the Coast of Coromandel*." This was Roxburgh's earliest publication on a large scale. The first part of this book appeared in 1795, and the last not until 1819, i.e., five years after the author's death. The increased facilities afforded to Roxburgh after his transfer to a comparatively well-equipped institution like that at Calcutta induced him at once to begin the preparation of descriptions of all the plants indigenous to British India of which he could procure specimens. And so diligently did he work that, when he was finally driven from India by ill-health in 1813, he left complete and ready for publication, the manuscripts of his "*Flora Indica*" and of his "*Hortus Bengalisensis*" (the latter being an enumeration of the plants in cultivation in the Calcutta Garden). He also left admirable coloured drawings (mostly of natural size) of 2,533 species of plants indigenous to India. Seldom have twenty years yielded so rich a botanical harvest! Dr. Roxburgh was thus the first botanist who attempted to draw up a systematic account of the plants of India, and his book, which is on the Linnaean system, is the basis of all subsequent works on Indian Botany; and until the publication of Sir Joseph Hooker's monumental "*Flora of British India*" it remained the only single book through which a knowledge of Indian plants could be acquired. Roxburgh was immediately succeeded in the Calcutta Garden by Dr. Buchanan-Hamilton, a man of many accomplishments, who had travelled from Nepal in the North to Ava and Mysore in the South, accumulating materials for a Gazetteer of the Honourable Company's possessions. Dr. Buchanan was a zoologist as well as a botanist. He had published a valuable account of Mysore, Canara, and Malabar, and had collected materials for a work on the Fishes of India, besides having accumulated a large herbarium, part of which may now be consulted at the University of Edinburgh. Prior to his death Buchanan-Hamilton had begun to write a learned commentary on Van Rheede's "*Hortus Malabaricus*." Many of his Nepalese collections were described in 1825 (a few years before his own death), by Don in his "*Prodromus Floræ Nepalensis*."

NATHANIEL WALLICH AND ROBERT WRIGHT.

Buchanan-Hamilton remained only one year at Calcutta, and in 1815 he was succeeded by Nathaniel Wallich, a native of Copenhagen, who, prior to his appointment to the Calcutta Garden, had been attached to the Danish settlement at Serampore, twenty miles higher up the Hooghly. Wallich remained Superintendent of the Calcutta Garden for thirty years. In 1846 he went to England, and in 1854 he died. During his tenure of office in the Calcutta Garden, Wallich organised collecting expeditions to the then little-known regions of Kamaon and Nepal (in the Himalaya), to Oudh, Rohilkund, Sylhet, Tenasserim, Penang, and Singapore. He undertook in fact a botanical survey of a large part of the

Company's possessions in India. The vast materials thus collected under his own immediate direction, and the various contributions made by others, were taken to London by him in 1828. With these were subsequently incorporated the collections of Russell, Klein, Heyne, Rottler, Buchanan-Hamilton, Roxburgh, and Wight. And by the help of a band of distinguished European botanists, among whom may be named De Candolle, Knoch, Lindley, Meisner, Nees von Esendeck, Von Martins, and Benthams (the latter in a very special manner), this vast mass of material was classified and named specifically. A catalogue of the collection was prepared by Wallich himself (largely aided by Benthams), and sets of the named specimens were distributed to the leading Botanical institutions in Europe, every example of each species bearing the same number.

During much of the time that Wallich was labouring in Northern India, Robert Wight, a botanist of remarkable sagacity and of boundless energy, was labouring in Southern India, chiefly in parts of the Peninsula different from those in which Koenig and his band had worked. Wight was never liberally supported by the Government of Madras, and it was mostly by his own efforts and from his own resources that his collections were made, and that his botanical works were published. The chief of the latter is his "*Icones Plantarum*." This book consists of figures with descriptions of more than two thousand Indian species.

Besides this *magnum opus*, Wight published his "*Spicilegium Nilghirensis*" in two vols. quarto, with 200 coloured plates. And between 1840 and 1850 he issued in two vols. quarto, with 200 plates, another book named "*Illustrations of Indian Botany*," the object of which was to give figures and fuller descriptions of some of the chief species described in a systematic book of the highest botanical merit, which he prepared conjointly with Dr. J. Walker-Arnot, Professor of Botany in the University of Glasgow, and which was published under the title "*Prodromus Floræ Peninsulæ Indiæ*." The "*Prodromus*" was the first attempt at a Flora of any part of India in which the natural system of classification was followed. Owing chiefly to the death of Dr. Walker-Arnot, this work was never complete, and this splendid fragment of a Flora of Peninsular India ends with the natural order Dipsacæ.

WILLIAM GRIFFITH

The next great Indian botanist, whose labours demand our attention, is William Griffith. Born in 1810, sixteen years after Wight, and twenty-four years later than Wallich, Griffith died before either. But the labours even of such devotees to science as were these two are quite eclipsed by those of this most remarkable man. Griffith's botanical career in India was begun in Tenasserim. From thence he made botanical expeditions to the Assam valley, exploring the Mishmi, Khasia, and Naga ranges. From the latter he passed by a route never since traversed by a botanist, through the Hoeking valley down the Irrawadi to Raagoon. Having been appointed, soon after his arrival in Raagoon, surgeon to the Embassy to Bhutan, he explored part of that country and also part of the neighbouring one of Sikkim. At the conclusion of this exploration he was transferred to the opposite extremity of the northern frontier, and was posted to the army of the Indus. After the subjugation of Cabul, he penetrated to Khorassan. Subsequently he visited the portion of the Himalaya of which Simla is now the best-known spot. He then made a run down the Nerbudda valley in Central India, and finally appeared in Malacca as civil surgeon of that settlement. At the latter place he soon died, of an abscess of the liver brought on by the hardships he had undergone on his various travels, which were made under conditions most inimical to health, in countries then absolutely unvisited by Europeans. No botanist ever made such extensive explorations, nor himself collected so many species (9,000) as Griffith did during the brief thirteen years of his Indian career; none ever made so many field notes or wrote so many descriptions of plants from living specimens. His botanical predecessors and contemporaries were men of ability and of devotion. Griffith was a man of genius. He did not confine himself to the study of flowering plants, nor to the study of them from the point of view of their place in any system of classification. He also studied their morphology. The difficult problems in the latter naturally had most attraction for him, and we find him publishing, in the "*Linnaean Transactions*," the results of his researches on the ovule in Santalum, Loranthus, Viscum, and Cycas. Griffith was also a cryptogamist. He collected, studied, and wrote much on Mosses, Liverworts, Marsiliaceæ, and Lycopods, and he made hundreds of drawings to illustrate his microscopic observations. Wherever he travelled he made sketches of the most striking features in the scenery. His habit of making notes was inveterate; and his itinerary diaries are full of information not only on the botany, but also on the zoology, physical geography, geology, meteorology, archaeology, and agriculture of the countries through which he passed. His manuscripts and drawings, although left in rather a chaotic state, were published after his death under the editorship of Dr. McClelland, at the expense of the enlightened and ever-liberal East India Company. They occupy six volumes in octavo, four in quarto, and one (a "*Monograph of Palms*") in folio.

WILLIAM JACK, AND VICTOR JACQUEMONT.

Another botanist of much fame, who died prematurely in 1822, after an Indian career of only nine years, was William Jack. In 1814-15 Jack accompanied Ochterlony's army to the Nepal terai. He was transferred in 1818 to the Company's settlement in Sumatra under Sir Stanford Raffles, and during the four years of his residence in Sumatra he contributed to botanical literature descriptions of many new genera and species which were published in his "*Malayan Miscellanies*."

His collections, unfortunately, were for the most part lost by an accident, but those which were saved are now in the Herbarium Delessert in Geneva.

Somewhat similar to Griffith in temperament and versatility was the brilliant Victor Jacquemont, a French botanist who, at the instance of the Paris Natural History Museum, travelled in India for three years from 1829 to 1832. During this period Jacquemont collected largely in the Gangetic plain. He then entered the North-West Himalaya at Mussoorie, explored Gharwal and Sirmur, ascended the Sutlej to Kanawar and Piti (at that time unexplored), visited Cashmir, and returning to the plains, crossed northern Rajputana to Malwa and the Deccan. He finally reached Bombay with the intention of returning to France. But at Bombay he succumbed to disease of the liver, brought on by hard work and exposure.

THOMAS THOMSON.

The roll of eminent botanists who worked in India during the first half of the century closes with the name of Thomas Thomson, who collected plants extensively between 1842 and 1847 in Rohilkund and the Punjab, and again still more extensively during a Government mission to the North-West Himalaya and Tibet which was continued from 1847 to 1849. During this period Dr. Thomson explored Simla, Kanawar, Piti, Cashmir, Ladak, and part of the Karakoram. His collections, which were large and important, were transmitted to the Botanic Garden at Calcutta, and thence in part to Kew. They formed no insignificant part of the materials on which the "Flora Indica" and "Flora of British India" were founded. Dr. Thomson also published an account of his travels—an admirable book, though now jostled out of memory by the quantities of subsequently issued books of Himalayan travel and adventure.

WORK COMMENCED IN THE N.-W. PROVINCE.

About the year 1820 a second centre of botanical enterprise was established at Seharunpore, in the North-West Provinces. A large old garden near that important town, which had been originally founded by some Mohammedan nobles of the Delhi Court, was taken over by the Honourable Company, and was gradually put upon a scientific basis by Dr. George Govan, who was appointed its first superintendent. Dr. Govan was in 1823 succeeded by Dr. J. Forbes Royle, and he in 1832 by Dr. Hugh Falconer. Dr. Royle made collections in the Jummo-Gangetic plain, in the Lower Gharwal Himalaya, and in Cashmir. He was distinguished in the field of Economic rather than in that of Systematic Botany, his chief contribution to the latter having been a folio volume entitled "Illustrations of the Botany of the Himalaya Mountains." His valuable labours as an Economic Botanist will be noticed later on. Hugh Falconer was an accomplished paleontologist who devoted but little of his splendid talents to botany. His great contribution to paleontology, the value of which it is almost impossible to over-estimate, consisted of his exploration and classification of the tertiary fossils of the Sewalik range. Falconer was transferred to the Calcutta Garden in 1842.

WESTERN INDIA.

During the first half of the century, a considerable amount of excellent botanic work was done in Western India by Graham, Law, Nimmo, Gibson, Stocks, and Dalzell, the results of whose labours culminated in the preparation by Graham of a "List of the Plants of Bombay," which was not, however, published until 1839 (after his death), in the publication by Stocks of various papers on the Botany of Scinde, and in the publication by Dalzell in 1861 of his "Flora of Bombay." It is impossible in a brief review like the present to mention the names of all the workers who, in various parts of the gradually extending Indian Empire, added to our knowledge of its botanical wealth. It must suffice to mention the names of a few of the chief, such as Hardwicke, Madden, Munro, Edgeworth, Lance and Vicary, who collected and observed in Northern India; Jenkins, Masters, Mack, Simons and Oldham, who all collected extensively in Assam; Hofmeister, who accompanied Prince Waldemar of Prussia, and whose collections form the fine basis of the fine work by Klotzsch and Gareke (Reis. Pr. Wald.); Norris, Prince, Lobb and Cuming, whose labours were in Penang and Malacca; and last, but not least, Strachey and Winterbottom, whose large and valuable collections, amounting to about 2,000 species, were made during 1848 to 1850 in the higher ranges of the Kamaon and Gharwal Himalaya, and in the adjacent parts of Tibet. I cannot conclude this brief account of the botanical labours of our first period without mentioning one more book, and that is the "Hortus Calcuttensis" of Voigt. Under the form of a list, this excellent work, published in 1845, contains a great deal of information about the plants growing near Calcutta, either wild or in fields and gardens. It is strong in vernacular names and vegetable economics.

SIR JOSEPH HOOKER.

The second period of our history begins with the arrival in India in 1848 of Sir (then Dr.) Joseph Hooker. This distinguished botanist came out in the suite of Lord Dalhousie, who had been appointed Governor-General of India. The province to the exploration of which Sir Joseph directed his chief attention was that of Sikkim in the Eastern Himalaya, the higher and inner ranges of which had never previously been visited by a botanist, for Griffith's explorations had been confined to the lower and outer spurs. The results of Sir Joseph's labours in Sikkim were enormous. Towards the end of his exploration of Sikkim he was joined by Dr. Thomas Thomson, and the two friends subsequently explored the Khasia Hills (one of the richest collecting grounds in the world), and also to some extent the districts of Sylhet, Cachar,

and Chittagong. Dr. Thomson subsequently amalgamated the collections made by himself in the Western Himalaya with those made in Sikkim by Sir Joseph individually, and by them both conjointly in Eastern India; and a distribution of the duplicates after the fashion of the Wallichian issue, and second only to it in importance, was subsequently made from Kew. The number of species thus issued amounted to from 6,000 to 7,000, and the individuals were much more numerous than those of the Wallichian collection. The immediate literary results of Sir Joseph Hooker's visit to Sikkim were, (1), his superbly illustrated monograph of the new and magnificent species of *Rhododendron* which he had discovered; (2), a similar splendid volume illustrated by plates founded on drawings of certain other prominent plants of the Eastern Himalayas which had been made for Mr. Cathcart, a member of the Civil Service of India; and (3), his classic "Himalayan Journal"—a book which remains until this day the richest repository of information concerning the botany, geography, and anthropology of the Eastern Himalaya. A remoter result was the appearance in 1855 of the first volume of a "Flora Indica," projected by himself and his friend Dr. Thomson. The first half of this volume is occupied by a masterly introductory essay on Indian botany, of which it is hardly possible to overrate the importance. This remarkable essay contains by far the most important contribution to the Physico-Geographical Botany of India that has ever been made, and it abounds in sagacious observations on the limitation of species and on hybridisation, besides containing much information on the history of Indian botanical collections and collectors. The taxonomic part of the book was cast in a large mould, and the descriptions were written in Latin. Unfortunately the condition of Dr. Thomson's health and the pressure of Sir Joseph's official duties at Kew made it impossible that the book should be continued on the magnificent scale on which it had been conceived. After a period of about twelve years Sir Joseph, however, returned to the task of preparing, with the aid of other botanists, a flora of the Indian Empire, conceived on a smaller scale and written in the English language. His proposals for this work were accepted and officially sanctioned by the Duke of Argyll while he was Secretary of State for India. The first part of this great work was published in 1872 and the last in 1897. In the execution of this great undertaking Sir Joseph had the assistance of Mr. C. B. Clarke, who elaborated various Natural Orders; of Mr. J. G. Baker, who worked out Leguminosae and Scitamineae; and of Sir W. Thistleton Dyer, Messrs. A. W. Bennett, Anderson, Edgeworth, Hiern, Lawson, Maxwell Masters, Stapf and Gamble. The greater proportion, however, of the book is Sir Joseph's own work, and a noble monument it forms of his devotion and genius.

MR. C. B. CLARKE.

Since the date of Sir Joseph Hooker's visit to India, by far the most important botanical work done in India has been that of Mr. C. B. Clarke. Rather than attempt to give any appreciation of my own of Mr. Clarke's labours (which would be more or less of an impertinence), I may be allowed to quote from the preface to the concluding volume of the "Flora of British India," "Sir Joseph Hooker's estimate of them. Referring to all the collections received at Kew since the preparation of the Flora was begun, Sir Joseph writes, 'The first in importance amongst them are Mr. C. B. Clarke's, whether for their extent, the knowledge and judgment with which the specimens were selected, ticketed, and preserved, and for the valuable observations which accompany them.' Mr. Clarke has published numerous papers on Indian botanical subjects in the journals of the Linnean and other societies. He has issued as independent books monographs of Indian Compositae and Cyrtandraceae, the former in octavo, the latter in folio, and illustrated by many plates; and he is now engaged on his *opus maximum*, viz., a monograph of the Cyperaceae, not only of India, but of the whole world; and to the completion and publication of this every systematic botanist is looking forward with eager anxiety.

DR. THOMAS ANDERSON.

During this second half of the century, Dr. Thomas Anderson, who was for ten years superintendent of the Calcutta Garden, collected much; and he had just entered on what promised to be a brilliant career of Botanical authorship when his life was cut short by disease of the liver. Dr. Anderson was also the earliest Conservator of Forests in Bengal. Sulpiz Kurz, for many years Curator of the Calcutta Herbarium, also collected largely in Burma, and besides many excellent papers which he contributed to the "Journal of the Asiatic Society of Bengal," he prepared for Government an excellent manual entitled the "Forest Flora of Burma." This was published in two volumes in 1877. General Sir Henry Collett, who commanded a brigade during the last Burmese war, also made most interesting collections in that country, the novelties of which were described by himself in collaboration with Mr. W. Botting Hemsley, of the Kew Herbarium, in the Linnean Society's "Journal" some years ago. Sir Henry Collett also collected much in the Khasia and Naga hills, and in the portion of the North-Western Himalaya of which Simla is the capital, and on these latter collections, together with the materials in Kew Herbarium, Sir Henry is now elaborating a local Flora of Simla.

REPRESENTATIVES OF THE FOREST DEPARTMENT.

Five officers of the Indian Forest Department, viz., Dr. Lindsay Stewart, Colonel Beddome, Sir D. Brandis, and Messrs. Talbot and Gamble, have within the past thirty years made important contributions to the Systematic Botany of India. Dr. Stewart collected largely, and published in 1869 his "Punjab Plants," a book which gives a very imperfect impression of his acquisitions as a botanist. Sir Dietrich

Brandis issued in 1874 his admirably accurate "Forest Flora of the North-West Provinces of India," illustrated by seventy excellent plates. Between the years 1869 and 1873, Colonel Beddome issued his "Flora Sylvatica of the Madras Presidency," illustrated by numerous plates. Colonel Beddome is the only Indian Botanist of note, except Griffith, Mr. C. B. Clarke, and Mr. C. W. Hope, who has written much on Indian Ferns. His two works the "Ferns of Southern India," and the "Ferns of British India," published the former in 1863 and the latter between 1865 and 1870, practically give a systematic account, together with excellent figures, of the whole Fern Flora of India. The fourth Forest officer who has published contributions to Systematic Botany is Mr. W. A. Talbot, whose "List of the Trees, Shrubs, and Woody Climbers of the Bombay Presidency" gives evidence of much careful research. And the fifth is Mr. J. S. Gamble, who, besides amassing at his own expense probably the largest private collection of plants ever owned in India, has published a systematic account of the Indian Bambuseae, a tribe of grasses which, from the peculiarity of many of the species in the matter of flowering, had so long been the bane of the Indian agrostologist. Mr. Gamble has also published a Manual of Indian Timbers. A Forest officer who was ever ready to help in botanical work, but who never himself published, was Mr. Gustav Mann, for many years Conservator of Forests in Assam, but now lost to India by his premature retirement.

MADRAS AND BOMBAY PRESIDENCIES.

In the Madras Presidency botanical work has been carried on during this second half of the century by Noton, Perrottet, Metz, Hohenacher, Schmidt (on the Nilgiris), Bidie, and Lawson. By the efforts of the latter two a second public Herbarium was established in Madras (the first having been broken up many years ago), and in this second Madras Herbarium are to be found many of the collections of Wight, besides those of the other Madras botanists just named.

In the Bombay Presidency the only public Herbarium is at Poona. This is of recent origin, and owes its existence to the devotion of four men, viz., Dr. Theodore Cooke (late Principal of the College of Science at Poona), Mr. Marshall Woodrow (until recently Superintendent of the Garden at Guneshkind and Lecturer in Botany in the Poona College), the late Mr. Ranade (a native gentleman), and Dr. Lisboa (a medical practitioner in the Deccan)—all four enthusiastic botanists. The amount of Government support given to the Herbarium at Poona has hitherto been very inadequate. It is to be hoped that greater liberality may be extended to it now that a stranger to the Bombay Presidency has just been appointed to its charge in the person of Mr. George Gamble, hitherto employed in the Cinchona Department of Bengal.

CRYPTOGAMIC AND ECONOMIC BOTANY.

In this Address I have hitherto made little reference to Cryptogamic and Economic Botany. As regards Cryptogamic botany there is little to relate. Except Griffith, no Indian botanist of the earlier of the two periods into which I have divided my sketch ever did any serious work amongst non-vascular Cryptogams.

Economic Botany has, on the other hand, by no means been neglected. It was chiefly on economic grounds that the establishment of a Botanic Garden at Calcutta was pressed upon the Court of Directors of the East India Company. And almost every one of the workers whose labours I have alluded to has incidentally devoted some attention to the economic aspect of botany.

Tea cultivation is one of the enterprises in the introduction and development of which botanists took a very leading part. The advisability of introducing the industry was first pressed on the attention of the East India Company by Dr. Govan (of Seharunpore), and in this he was seconded by Sir Joseph Banks as President of the Royal Society. Royle in 1827, and Falconer slightly later, again urged it as regards the North-West Himalaya. In 1826 David Scott demonstrated to rather unwilling eyes in Calcutta the fact that real Tea grows wild in Assam. In 1835 Wallich, Griffith, and McClelland were deputed by Government to visit Assam, to report on the indigenous Tea. In the year 1838 the first consignment of Indian-grown Tea was offered for sale in London. The consignment consisted of twelve chests containing 20 lb. each. This first sample of 240 lb. was favourably reported upon. Last year the exports of Tea from India to all countries reached 157 millions of pounds, besides 120 millions of pounds exported from Ceylon!

THE INTRODUCTION OF CINCHONA.

The introduction of Cinchona into India originated purely with the Government botanists. As everybody knows quinine, and to a less extent the other alkaloids present in Cinchona bark, are practically the only remedies for the commonest, and in some of its forms one of the most fatal, of all Indian diseases, viz., malarious fever. The sources of supply of the Cinchona barks in their native countries in South America were known to be gradually failing, and the price of quinine had for long been increasing. The advisability of growing Cinchona in the mountains of British India was therefore pressed upon Government by Dr. Royle in 1835, and he repeated his suggestions in 1847, 1853, and 1856. Dr. Falconer, in his capacity of Superintendent of the Botanic Garden, Calcutta, made a similar suggestion in 1852; and his successors at Calcutta, Dr. T. Thomson and Dr. T. Anderson, in turn advocated the proposal. In 1858 Government at last took action, and, as result of the labours of Sir Clements Markham and Sir W. J. Hooker, of Kew, the medicinal Cinchonas were finally, in the period between 1861 and 1865, successfully introduced into British India—on the Nilgiris under Mr. Melvor, and on the Sikkim-Himalaya under Dr.

Anderson. The manufacture of quinine had hitherto been practically a trade secret. And when the Indian Government had succeeded in providing the raw material from which a cheap quinine might be made for distribution amongst its fever-stricken subjects, the knowledge of the means of extracting this quinine was wanting. Philanthropic platitudes were freely bandied about as to the immensity of the boon which cheap quinine would be to a fever-stricken population numbering so many millions. But there was a singular absence of any practical help in the shape of proposals, or even hints, as to how quinine was to be extracted from the rapidly-increasing stock of crown and yellow bark. The officers in charge of the Cinchona plantations in India had therefore to do their best to solve the problem for themselves. And it was ultimately solved by Mr. C. H. Wood, at one time Government Quinologist in Sikkim, who suggested, and Mr. J. A. Gamble, Deputy-Superintendent of the plantation there, who carried into practice a method of extraction by the use, as solvents of the Cinchona alkaloids, of a mixture of fusel-oil and petroleum.

THE FOREST DEPARTMENT AND ITS WORK.

In conclusion, I wish to make a few remarks on the third great economic enterprise connected with Botany in India, viz., the Forest Department. The necessity for taking some steps to preserve a continuity of supply of timber, Bamboos, and other products from the jungles which had for generations been exploited in the most reckless fashion, was first recognised by the Government of Bombay, who in 1807 appointed commissioners to fix the boundaries of and to guard the forests in the Presidency. This scheme was abandoned in 1822, but was resumed in a modified form during 1839-40. Seven years later a regular forest service was established in Bombay, and Dr. Gibson was its first head. Dr. Gibson in turn was succeeded by Mr. Dalzell—and both were botanists. In the Madras Presidency the first man to recognise the necessity of perpetuating the supply of Teak for ship-building was Mr. Connolly, collector of Malabar, who in 1843 established a Teak plantation at Nelumbur, which has been carried on, and annually added to, down to the present time. In 1847 Dr. Cleghorn (a botanist) was appointed to report on the conservation of the forests of Mysore (which contain the well-known sandal-wood), and the following year Lieutenant Michael (still with us as General Michael, a hale and hearty veteran) was appointed to organise and conserve the public forests in Coimbatore and Cochin. The crowning merit of General Michael's administration was the establishment, for the first time in India, of a system of protection against the fires which annually used to work such havoc. In 1850 the British Association, at their Edinburgh Meeting, appointed a Committee to consider and report upon the probable effects, from an economic and physical point of view, of the destruction of tropical forests. This Committee's Report was submitted to the Association at the meeting at Ipswich in 1851. The weighty evidence collected in this Report so impressed the Court of Directors of the East India Company that, within a few years, regular forest establishments were sanctioned for Madras and British Burma, the two main sources of the supply of Teak.

In 1856 Mr. (now Sir Dietrich) Brandis was appointed to the care of the forests of the latter province. These forests had been the object of spasmodic efforts in conservancy for many years previously. In 1827 Dr. Wallich reported on the Teak forests, and five years later a small conservancy establishment was organised, officered by natives. This, however, was kept up for only three or four years. In 1837 and 1838 Dr. Helfer reported on these forests, and an English conservator was appointed. In 1842 and 1847 Codes of Forest Laws were drawn up, but do not appear to have been enforced to any extent. In 1853 Dr. McClelland was appointed superintendent, but he continued to hold the office for only a short time. A few years after Sir Dietrich Brandis's assumption of the charge of the Burmese Forests, he was appointed Inspector-General of all the Government Forests in British India; and it is to him that we owe for the most part the organisation of the Indian Forest Department as it now exists. That organisation includes two Schools of Forestry (in both of which botany is taught), one in connection with Cooper's Hill and the other at Dehra Dun in Upper India.

Botany is taught at Cooper's Hill, and (according to the Calendar of the College) it forms one of the "special auxiliary subjects" for the Forest student. I do not wish to say a single word in depreciation of the botanical teaching at this College, which is probably excellent of its sort.

SOCIETIES.

THE ROYAL HORTICULTURAL OF IRELAND.

SEPTEMBER 12.—The council members of the above, held their usual monthly meeting on the above date, at their offices Dawson Street. There was a large attendance of members, and the chair was occupied by Surgeon-General BEAUMONT. The minutes of the last meeting were read and duly signed. A detailed report of the recent autumn show was then submitted by the secretary (W. H. HILLIARD, Esq.), and was adopted; they sanctioned the payment of £105, the cost of defraying the expenses of their last show; and the list of judges for the forthcoming winter show to be held in The Royal Dublin Society's grounds, Balls Bridge, were nominated. A. O'Neill.

MOFFAT AND UPPER ANNANDALE.

SEPTEMBER 15.—The annual show was held at Moffat, the well-known south of Scotland Spa, on the above date. The weather was, unfortunately, of a most unpropitious character, and the attendance was in consequence seriously affected.

There was an extremely good show in the horticultural department, especially of flowers. Herbaceous perennial plants were exceptionally fine in both gardeners' and cottagers' classes; and in the former the Dahlias, both Cactus and Show, were of excellent quality. Taking the dry season into consideration, the show of vegetables was quite up to former years.

The principal winners in the gardeners' classes were Mr. EWEN CAMERON, Ericstane (who, *inter alia*, took the 1st prize for greenhouse plants); Mr. WILLIAM MURRAY, Ardenholm (who was 2nd); and Mr. JOHN HAMILTON, Haywood.

Messrs. KENNEDY & Co., Dumfries, had on exhibition a table of Dahlias; and Messrs. PALMER & SON and Messrs. T. SMITH & SON, Stranraer, had stands of their Roses. R. J. A.

NATIONAL DAHLIA.

SEPTEMBER 19.—The National Chrysanthemum Society having ceased to hold their annual September show of Dahlias and early-flowering Chrysanthemums at the Royal Aquarium, Westminster, the National Dahlia Society and the Aquarium Company together arranged to hold a show of Dahlias at this place on Tuesday and Wednesday last. It was thought that such an exhibition would enable growers to exhibit seedlings and varieties that were not quite in condition upon the date of the Society's Exhibition at the Crystal Palace. The show proved very successful. Eight classes only were scheduled, but there were entries in all of them, and in some the competition was unusually large. The quality of the flowers generally was very high, and a fairly good number of seedlings were certificated. Non-competitive exhibits were very numerous, and altogether the show was as good or better than those held in the Aquarium for some years past, when Dahlias, Gladioli, and Chrysanthemums have been exhibited.

There is just now some disposition amongst the Dahlia exhibitors to find a better method of staging the blooms. Some complain (and not without cause) that the methods at present adopted in respect to the Cactus and Pompon, and even Single flowers, are as flat and formal as in the case of the show varieties, which are shown on boards. Exhibitors are wiring the Pompoms and Cactus flowers so artificially and in such symmetrical figures as triangles, &c., that a change in some direction will be welcomed. But there is such a thing as going from bad to worse, and an exhibit which professed to illustrate how show blooms might be more rationally displayed was a proof of this. A board of the usual type was used, and the cups elevated several inches on stout wire. The blooms were then placed in the cups, and a shoot from the Dahlia plant was inserted in the board where the cups should have been. The result was to bring the blooms to a higher level, but still almost as flat as before; and moreover the cups were displayed equally with the flowers, and the effect was disastrous.

SHOW DAHLIAS.

The largest class for flowers of the show section was for twenty-four blooms, and Mr. J. WALKER, Thame, Oxon, followed up his previous successes at the Crystal Palace and elsewhere by taking 1st position. Some of the prettiest and best blooms were of the varieties Goldsmith, Duke of Fife, Harry Keith, Buffalo, John Hickling, Rev. J. Gooday, Mrs. David Saunders, Victor, and Eclipse. Mr. CHAS. TURNER, Slough, was 2nd; and Mr. GEO. HUMPHRIES, Kington Langley, 3rd.

The 1st prize for a collection of twelve blooms (amateurs) was won by THOS. HOBBS, Esq., Easton House, St. Mark's Road, Bristol. His varieties were Mrs. Gladstone, Duchess of York, Harrison Weir, Eldorado, Jas. Cocker, Florence Tranter, Warrior, Muriel Hobbs, T. S. Saltmarsh, Victor, The Reverend, and Prince of Denmark. 2nd, T. W. FELLOWES, Esq.; and 3rd, Mr. R. BURGIN, St. Neot's, Hunts.

"CACTUS" VARIETIES.

The largest collection called for by the schedule was twelve varieties, and six blooms of each. There were seven exhibits, and the best of these came from Mr. JAS. STREDWICK, Silverhall Park, St. Leonard's. This exhibit was a very fine one, and the varieties were almost all of them new. The following, for instance, Major Tuppenney, Uncle Tom, Major Weston, all described on p. 232, *Gardeners' Chronicle*, September 16. Mrs. Sanders, pure soft yellow, with grand form; Eclipse, also yellow, but much paler in tint; Maurice T. Walsh (certificated on same day), Mrs. Saunders, also yellow, large flower, good petal; Magnificent, a large, full flower of orange and mauve shades, &c. Messrs. KEYNES, WILLIAMS & Co., Salisbury, showed well for 2nd place; and Messrs. J. BURRELL & Co., Cambridge, were 3rd.

The best collection of nine varieties (amateurs), to be shown in bunches of three blooms each, was from Mr. Robt. Keeble, gr. to F. W. SHARP, Esq., Waltham St. Lawrence, Twyford. This exhibit was a very pretty one, and the varieties were Starfish, Harry Stredwick, Britannia, Chas. Woodbridge,

Stella, Mary Service, Keynes' White, Viscountess Sherbrook, and J. F. HUDSON; the latter variety has flowers with petals that incur much towards centre. 2nd, F. W. FELLOWES, Esq., Putteridge Grange, Luton, Beds; none of the varieties in this stand were named, and the Society would do well to enforce disqualification in such cases. W. E. REEVE, Esq., Lyndhurst, Maybury Road, Woking, was 3rd, and there were several other collections.

POMPON FLOWERS.

The best exhibit of a collection of twelve varieties was from Mr. F. W. SEALE. The varieties, Sunny Daybreak, Ganymede, Spitfire (scarlet), Douglas, Phoebe, Snowflake, Demon, Emily Hopper (yellow), Nerissa, very beautiful mauve-pink; Hypatia, Ernest Harper, and Nellie Broomhead were all capital, making a collection of very neat, and well set up blooms. Mr. CHAS. TURNER was a close 2nd; and Mr. GEO. HUMPHRIES was 3rd.

The 1st prize for six varieties (amateurs) was awarded to Mr. J. F. HUDSON, Gunnersbury House Gardens, Acton, Secretary to the Society. Mr. Hudson staged very small, neat blooms of Eve, E. F. Junker, Douglas, Phoebe, Orpheus (a grass yellow), and Nerissa; 2nd, Mr. W. C. PAORAM, The Whim Gardens, Weybridge; 3rd, Mr. R. BURGIN, St. Neot's, Hunts.

SINGLE VARIETIES.

The only exhibit of twelve varieties of single Dahlias in bunches was shown by Mr. F. W. SEALE, Vine Nurseries, Sevenoaks. Some of the varieties were capital; others lacked form. Duchess of Marlborough, deep maroon; Yellow Perfection, Beauty's Eye, mauve; Miss Glasscock, white, petals edged mauve; Paragon Improved, Alice Seale, and The Geisha were the best.

The 1st prize for six varieties (amateurs) was won by Mr. J. F. HUDSON, his varieties being Gaielma, white, each petal edged yellow; Donna Casilda Jeannette, white, petals edged scarlet; Noemi Tighe, yellow, with red around disc; Phyllis, white or mauve, splashed with crimson; and Jack Sheppard, yellow, splashed red. 2nd, EDW. MAWLEY, Esq., Rosebank, Berkhamstead. Beauty's Eye and Victoria were very pretty in this stand.

NON-COMPETITIVE EXHIBITS.

Messrs. DOBBIE & Co., Rothesay, N.B., had a large exhibit of cut Dahlias. There was a vast number of blooms put up in huge close bunches, but only Cactus and Pompon varieties were represented (Gold Medal).

Messrs. THOS. S. WARE, LTD., Hale Farm Nurseries, Tottenham, contributed a great number of cut Dahlias, too closely staged, and their display also was confined to the same two sections (Silver-gilt Medal).

Mr. JOHN GREEN, Dereham, Norfolk, displayed many of his novelties in Dahlias, including the showy Red Rover.

Messrs. H. CANNELL & SONS, Swanley, Kent, put up a fine lot of Cactus Dahlias, relieved with cut sprays of *Aster ericoides* (Silver-gilt Medal). Also a group of *Caecus* in flower in pots (Silver Medal).

Messrs. JNO. PEED & SONS, Roupell Park Nurseries, Norwood, London, exhibited cut Dahlias, perennial *Asters*, &c. Also a group of the new white-flowering perennial *Aster*, M's. W. PETERS (Silver Medal).

THE DEVON CHRYSANTHEMUM NURSERY, Teignmouth, showed about six dozen blooms of Cactus varieties, including a number of promising seedlings, which, however, were not put up for certificate on this occasion (Bronze Medal).

Mr. F. W. SEALE showed cut flowers of Show and Cactus varieties (Silver Medal).

Messrs. CARTER, PAGE & Co., 52 and 53, London Wall, E.C., made an exhibit of cut Dahlias.

Mr. J. T. WEST, Tower Hill, Brentwood, Essex, also showed a fine lot of Pompon, Cactus, and Show Dahlias, most of them very good.

Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., decorated one of the large fountains with Ivies, Palms, Bamboos, early-flowering Chrysanthemums, Eucalyptus, &c., and the effect was unusually good (Gold Medal).

Messrs. J. BURRELL & Co. made a large exhibit of cut spikes of Gladioli in extensive variety, and were awarded a Silver Medal.

Awards.

First-class Certificates were awarded to the following varieties:—

Empress (fancy), *Maurice T. Walsh* (Cactus), *Edie Obelin* (single), all described on p. 232, *Gardeners' Chronicle*, Sept. 16, in the Royal Horticultural Society's awards.

Geo. Hobbs (show), a dark crimson or maroon-coloured flower, of good exhibition form. From Mr. T. HOBBS, Bristol.

Madame Medora Henson (Cactus), bright crimson flower, with purple shading; good Cactus form. From Messrs. T. S. WARE, LTD., Tottenham.

Mrs. Carter Page (Cactus), a large, showy crimson variety. From Messrs. KEYNES, WILLIAMS, & Co.

Hilda (single), a white flower, flushed with flesh colour, each petal having yellow margin along three parts of their length from base; very beautiful form. From Miss GIRDLESTONE.

Claribel (single), a flower with yellow centre, petals tipped reddish-rose. From Mr. ED. MAWLEY.

Sylph (Cactus), bright orange-red; petals fluted and incurved. From Mr. G. BURRELL.

Vera, a neat little soft yellow Pompon. From Mr. CHAS. TURNER, Slough.

ENQUIRY.

THE Rev. Canon Ellacombe would be much obliged if any of our readers would kindly inform him if *Aster sericeus* and *Campanula Soldanelliflora* (single or double-flowered), are in cultivation. He has grown the plants, but has not seen them for many years.

ANSWERS TO CORRESPONDENTS.

AQUATICS FOR A SMALL BASIN IN A CONSERVATORY

—TEMPERATURE OF THE AIR 80°, MAXIMUM: *R. H. R.* East Indian Lotus, *Nelumbium roseum*; white Japanese Lotus, *N. album striatum*; and striped Japanese Lotus, *N. album striatum*; and Egyptian Lotus, *N. speciosum*. *Nymphaea zanzibariensis*, *N. z. szurea* and *N. z. superba*; *N. dentata*, very free and easily grown; *Lymnorchis Humboldtii* and *Salvinia brasiliensis*, a pretty little floating plant, with leaves, almost heart shaped covered with numerous short hairs.

BOOKS: THE RENOVATION OF AN OLD GARDEN:

R. H. R. A good practical work, by a man who knew his business thoroughly, is *How to Lay-out a Garden*, by Ed. Kemp, published by Messrs. Bradbury, Agnew & Co., Ltd., 11, Bouverie Street, E.C. *Landscape Gardening as applied to Home Decoration*, by Samuel Maynard (published by Chapman & Hall, Ltd., London), would furnish much useful information. *B. J. Beckton: Dictionnaire Iconographique des Orchidées*. This serial work is printed in the French language, and the cost is 60frs. a year. Address, M. A. Goossens, Rue Quinoux, Schaerbeek, Bruxelles.

CEANOTHUS PROPAGATION: *W. P. B.* The surest means is by layering two and three-year-old shoots in the early summer in stiffish loamy soil. Cuttings of matured current season's shoots, taken with a heel, will strike in sandy loam under a hand-glass or in cold frame. This is the best month to insert cuttings. The position of the cutting-bed should be on the north side of a wall, as that does away with the need of shading.

CORRECTION: The name of the newly appointed curator of the Botanic station in Antigua is Mr. W. Norman Sands, and not Mr. W. N. Norman, as printed in last week's issue, p. 228.

FLOWER SHOW DISPUTE: *X.* The exhibitor who showed fourteen pots where the competition was "for the best two pots of Ferns," was obviously wrong, and the judges were right in disqualifying the exhibitor.

FRUITS, A SELECTION OF: *G. F. Grindley.* *Pears.* Doyenné d'Été (July); Jargonelle (August); Williams' Bon Chrétien, and Beurré Superfin (September); Louise Bonne of Jersey, Beurré Hardy (October); Marie Louise, Thompson's (November or earlier); Doyenné du Comice, and Pitmaston Duchess (December); Winter Nelis (January); Bergamotte d'Espéren (February and March); Easter Beurré (March or April).

Apples (Culinary).—For August, September, and October, Lord Grosvenor, Yorkshire Beauty, and Bismarck; November, December, and January, Ecklinville Seedling, Newton Wonder, Blenheim Orange. For continuation until May, Bramley's Seedling, Dumelow's Seedling, and Sandringham.

Apples (dessert).—Irish Peach (July), Devonshire Quarrenden (August and September), Ribston Pippin and Mother, October and November; Cox's Orange Pippin and Scarlet Nonpareil (December and January), Old Nonpareil, Allen's Everlasting and Sturmer Pippin, from February to May.

Plums (dessert).—Coe's Golden Drop, Transparent Gage, Jefferson, Guthrie's Late Green, Kirke's, and Reine Claude de Bavay. *Culinary.*—Victoria, Belle de Septembre, Prince Englebert, Diamond, Belle de Louvain, and Pond's Seedling. *Gooseberries (dessert varieties).*—Bright Venus, Yellow Champagne, Whitesmith, Whinham's Industry, Red Warrington, Green Gascoigne, Ironmonger, Early Red Hairy, and Scotch Nutmeg. Reds, for jam-making, Warrington and Whinham's Industry.

Red Currants.—Red Dutch and Comet. *White.*—White Dutch and White Versailles. *Black.*—Lee's Prolific.

Cherries.—Early Red Bigarreau (middle to end of June), May Duke, Black Tartarian (July),

Early Red Guigue (June), Bigarreau Napoleon (very late), and Governor Wood.

Melons.—Eastnor Castle, Hero of Lockinge, Earl's Favourite, and Royal Favourite.

Peaches and Nectarines for early House.—Alexander, Waterloo, Hale's Early Peaches, and Early Rivers, and Cardinal Nectarine. *Succession-house.*—Royal George, Noblesse, Grosse Mignonne and Barrington Peaches, and Stanwick Elruge, Victoria, and Rivers' Orange Nectarines. For south wall out-of-doors—Alexander, Royal George, Noblesse, Belle Beauce, Dr. Hogg, and Barrington Peaches; and Elruge, Hardwicke Seedling, Pitmaston Orange and Violet Hâtive Nectarines. (Others next week.)

FRUIT BUSHES ON GRASS LAND: *C. D.* We would advise the stations for the bushes to be taken out not less than 4 feet in diameter, trenching the soil 2 to 3 spits deep, turning the turf to the bottom, and then waiting a few weeks before proceeding to plant. When planting, if a small quantity of garden soil and rotten manure could be afforded each bush, food for the plants would be provided till such time as the turf rotted. This is not essential, but doing it would tend to early growth and re-establishment.

GARDENING JOURNALS: *B. T.* Ten, or thereabouts. Apply to a bookseller or newsagent for the titles and addresses.

GARDEN LABOUR: *Arbor.* We think that no one man could manage the garden satisfactorily without the assistance of a strong lad. It is not so much the extent of the garden as the adjuncts thereto which would demand so much of the gardener's time and attention. The wages are fair for the kind of place.

GARDEN PEAS: *E. P. F.* The gentleman you allude to, read a paper on Garden Peas at a meeting of the Royal Horticultural Society, but we are unaware that he had published a book on the same subject. You should communicate with him under the address, Messrs. Hurst & Son, 151, Houndsditch, London, E.C.

GRAPES: *H. C.* The Grape you describe as a sport from Golden Champion have very good flavour, but the berries are over-ripe, and should have been sent earlier.

GRAPES FOSTER'S SEEDLING: *A. W. T.* This is a thin-skinned variety of Sweetwater, readily decaying if the air is moist or ventilation deficient. The bunch sent shows natural decay following perfect ripening. If you have many bunches still left, cut them with a few inches of the shoots, sticking these into bottles filled with water, and place them in a cool, dry room. Under favourable conditions, the skin of this variety thickens and shrivels, and the fruit keeps a long time.

IRIS (MOOREA) ROBINSONIANA: *W. B. S.* Grow in sandy, rich soil, in a sunny, well-drained position, protecting the plants with a frame or handlight during the winter and early spring. In your part of the country this precaution might not be necessary. The plants resent root-disturbance.

LARVÆ: *A. B. C.* The grubs you send are the larvæ of the Vine-weevil, *Otiorhynchus picipes*. These feed on the underside of the roots. The injury to the stems of the *Rhododendrons* you mention is probably done by the perfect beetle. This is about half-an-inch long, dark brown; it comes out at night and hides away in the day. During the winter the roots should be examined, and some soot or other dressing used to check the larvæ. To catch the beetles, spread cloths beneath the shrubs in the day, and at night shake the bushes; the beetles will drop on to the cloths at the slightest alarm, even the light of the lantern will make them drop. They can be killed in boiling water. It would be useful to syringe the stems with water, to which a very small quantity of paraffin has been added.—*J. Warren.* Your insect is one of the *Ichneumonidae* of the genus *Ophion*. These are parasitic on other insects, and are beneficial. *C. W.*

MR. LUNT'S GRAPES AT SHREWSBURY: *Chas. Peebles and others.* The exact weights of the several bunches of Grapes exhibited by Mr. Lunt in the great Grape-class at Shrewsbury have been supplied us by the exhibitor himself. Two bunches of each variety were shown. They are as follows:—Cooper's Black, 4 lb. each; Muscat

of Alexandria, 4 lb. 4 oz. and 4 lb.; Muscat Hamburg, 4 lb. and 2½ lb.; Mrs. Pince, 4 lb. and 3½ lb.; Alnwick Seedling, 6 lb. each; and Black Hamburg, 3 lb. and 3½ lb.

NAMES OF FRUITS: We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. They should be just approaching ripeness, and they should be properly numbered, and carefully packed. A leaf or shoot of each variety is helpful, and in the case of Plums, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.—*Japonica, Berks.* 1, Hawthornden; 2, Nelson's Codlin; 3, Ribston Pippin; 4, Nanny.—*R. J. B. Taunton.* 1, Dymock Red; 2, not in character; unrecognisable; 3, Mank's Codlin; 4, Reinette Grise; 5, Greenup's Pippin; the Plum was smashed.—*T. D., Hull.* Lemon Pippin.—*F. R.* 1, Emperor Alexander; 2, Alfriston; 3, Yorkshire Greening; 4, Winter Russet; 5, Crimson Quoining; 6, Yellow Ingestre.—*A. K.* 1, Lord Suffield; 2, English Codlin; 3, Norfolk Stone Pippin; 4, Jolly Beggar; 5, Gloria Mundi.—*F. R.* White Astrachan.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—*G. W.* 1, *Panicum crus-galli*; 2, *Setaria viridis*; 3, *Calystegia sepium*.—*B. B.* *Viburnum Opulus* (Snowball tree).—*J. R.* 1, *Abelia rupestris*; 2, *Solanum jasminoides*; 3, *Mesembryanthemum multiflorum*; 4, *Eccremocarpus scaber*; 5, *Impatiens noli-me-tangere*.—*A. S.* Impossible to name specimen sent from leaves only, without further information.—*G. W., Ventnor.* *Agapanthus umbellatus*.—*F. J.* 1, *Veronica Andersoni variegata*; 2, *Linum usitatissimum*; 3, *Corydalis lutea*; 4, *Teucrium Polium*; 5, *Diplacus glutinosus*.—*J. T. S.* The frond sent appears to be of a singular form of *Scolopendrium vulgare*, but we cannot say for certain without fertile frond or some particulars of origin.—*D. E.* 1, *Polygonum cuspidatum*; 2, *Cassia corymbosa*.—*C. A. B.* 1, *Adiantum Edgworthii*; 2, *Plumbago Larpentæ* of gardens; 3, *Geranium pratense*; 4, *Asperula odorata* (Woodruffe); 5, *Nipholobolus lingua*; 6, *Lophospermum scandens*, does well out-of-doors in summer.—*W. W.* *Cymbidium giganteum*—a very good variety.—*G. P.* 1, *Chrysocoma com-aurea* (Goldilocks); 2, *Aster floribundus*.—*H. R.* *Cattleya Warscewiczii* (gigas), we have seen several malformations this season of the kind seen in your specimen.—*C. Jones.* *Salvia Horminum*.—*P., Penze.* We do not undertake to name varieties of *Coleus*. The rest of the specimens are insufficient. No. 3 is a species of *Potentilla*.

ORIGIN OF APPLES, PEARS, AND OTHER FRUITS: *S. J.* We know of no one work affording the information you require.

PLUM WITH MAGGOT: *T. W. O.* The maggot in your fruits is that of the Plum-moth, *Opadina funebrana*, and nearly related to the Codlin-moth. The eggs are deposited by the female moth during June and July upon the fruits. In a few days these become hatched, and they soon eat their way into the fruits, and leave no prominent indication that this has been done. In the winter you had better treat the bark of the trees with caustic potash and soda, and during June and July spray the trees with some insecticide that will render the trees distasteful to the female moth. When a maggoty fruit has been cooked, it has no really injurious effect upon the consumer.

PRIVET AND COMMON LAUREL: *E. W.* Privet cuttings may be put in during November; those of Laurel in October.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY'S SHOW: *Addenda.* Messrs. T. Methven & Sons, Leith Walk Nurseries, contributed a large table of decorative plants very tastefully arranged, Lilies being employed in great profusion. Messrs. Dicksons & Co., Waterloo Place, also showed a quantity of flowers, e.g., *Violas*, with decorative pot plants. *R. P. B.*

MARKETS.

COVENT GARDEN, SEPTEMBER 21.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. EN.]

CUT FLOWERS, &c.—AVERAGE WHOLESALE PRICES.

	s. d. s. d.		s. d. s. d.
Arum Lilies, dozen blooms	3 0-4 0	Maidenhair Fern, per doz. bunches	4 0-6 0
Asparagus "Fern," bunch	2 0-2 6	Odonatoglossum, per dozen	3 6-5 6
Carnations, per doz. blooms	2 6-3 6	Marguerites, p. doz. bunches	3 0-4 0

Ericas, var., per doz.	18 0-36 0	Marguerite Daisy, per dozen	8 0-9 0
Euonymus, various, per dozen	6 0-18 0	Myrtles, per dozen	6 0-9 0
Evergreens, var., per dozen	4 0-18 0	Palma, various, ea.	1 0-15 0
Ferns, in variety, per dozen	4 0-18 0	— specimen, each	21 0-63 0
— small, per 100	4 0-6 0	Pelargoniums, scarlet, per dozen	4 0-6 0

POTATOES.

Hebrons, Puritans, Snowdrop, Up-to-Date, &c., 70s. to 85s. Blacklands, 60s. to 65s. John Bath, 33 & 34, Wellington St., W.C.
REMARKS.—Grapes are plentiful, and prices generally low except for very fine fruit. The Walnuts quoted above are imported ones; home-grown fruits, which are a good crop, are not yet in the market. The Nova Scotian barrels are now coming.

SEEDS.

LONDON: September 20.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that the recent welcome rains are bringing to hand a few sowing orders for Trifolium, the stocks of which are now getting into narrow compass. Winter Tares continue in short supply, and realise full prices; but Giant Seed Rye is now obtainable on reduced terms. There is no quotable change this week in either Peas or Haricots. Canary-seed, despite its momentarily quiet sale, keeps remarkably firm in value; in Hempseed, however, the tendency is downwards. More money is asked for Linseed, and Clover seeds all round are very strongly held.

FRUIT AND VEGETABLES.

GLASGOW: September 20.—The following are the averages of the prices recorded since our last report:—Fruit: Apples, Dutch, 4s. per bushel, and 6s. 6d. to 8s. per small hamper, and 9s. 6d. to 14s. per two-mud cask; English, 7s. to 13s. per cwt.; do., American Colvilles, 15s. to 18s. per barrel; Kings, 20s. to 25s. doz.; Pears, French Duchesse, 36s., 2s. 6d. to 3s. per case; 45s., 2s. 3d. to 3s. doz.; do., Bon Louise and Duchesse, loose, 7s. to 8s. doz.; do., Dutch, 2s. per half-bushel; 1s. 6d. to 2s. per sieve-basket; Plums, Irish, 9s. 6d. per cwt.; Damsons, 20s. doz. (but falling); Lemons, Palermo, selected, sound, 14s. to 17s. per case; do., Messina, 15s. to 18s. doz.; do., Naples, sound, 25s. to 32s. doz.; Valencia, yellow, 24s., 6s. 6d. to 7s. doz.; 36s., 6s. 6d. to 7s. doz.; 45s., 6s. to 7s. doz.; bronze, 24s., 7s. to 8s. doz.; 36s., 6s. 6d. to 7s. doz.; Grapes, English, 1s. 2d. per lb.; do., Almeria, 11s. to 18s. per barrel; Bananas, extra, 12s. to 13s. per bunch; do., No. 1's, 10s. to 11s. doz.; No. 2's, 9s. to 10s. doz.; Tomatoes, English, 3d. to 5d. per lb.; do., Scotch, 4d. to 7d. doz.; Mushrooms, 10d. to 1s. 6d. doz. Vegetables: Onions, Valencia, 4s., 3s. 3d. to 4s. per case; do., 5s., 4s. 6d. to 5s. 6d. per bag; Carrots, Dutch, 3s. per bag; Beetroots, 2s. 6d. doz.; Turnips, 7d. to 9d. per dozen bunches; Carrots, 6d. to 9d. doz.; Parsley, 6d. to 8d. doz.; Cucumbers, 1s. to 1s. 9d. per dozen; Cauliflowers, 1s. to 2s. 4d. doz.; Cabbages, 9d. to 1s. 4d. doz.

BULBS, PLANTS AND FLOWERS: September 20.—The following are among the prices of the past week:—Hyacinths, 2s. per dozen; ordinary bulbs, 1s. doz.; miniature (small), 3d. per dozen, add 1s. 6d. to 3s. per 100; Scillas, 9d. to 1s. doz.; Narcissus, 3d. to 1s. 6d. doz.; Daffodils, 2s. doz.; Lilies, 4d. to 9d. doz.; Iris, various, 3d. to 1s. doz.; Fritillarias, 9d. doz.; Snowdrops, 1s. to 2s. doz.; Arum dracunculoides, 6d. to 1s. doz.; Lilium candidum, 6d.; Crown Imperials, 6d. to 1s. doz.; Polyanthus Narcissus, 6d. to 1s. doz.; Jonquils, 6d. to 1s. doz.; Lilium Harrisii, 2s. to 3s. 6d. per dozen blooms; L. lancifolium, 9d. to 1s. 6d. doz.; Orchids, 1s. to 8s. doz.; Carnations, 2d. to 1s. per bunch; Roses, white, 6d. to 2s. 6d. per dozen; do., red, 1s. 2d. doz.; do., boxes, 2s. to 4s.; Sofrano, 1s. 6d. per dozen; Asters, 1s. to 2s. per dozen bunches; Sweet Peas, 1s. to 4s. doz.; Maidenhair Fern, 3s. to 6s. doz.; Gardenias, 1s. 6d. per dozen; Marguerites, 2s. doz.; boxes of mixed flowers, 6d. to 4s. per box; Asparagus Ferns, 6d. to 2s. 6d. per bunch; Chrysanthemums, 6s. to 12s. per dozen bunches.

LIVERPOOL: September 20.—Wholesale Vegetable Market.—Potatoes, per cwt.: Early Regents, 1s. 7d. to 2s.; Main Crop, 2s. 6d. to 3s. 9d.; Kidneys, 2s. 6d. to 3s. 3d.; Bruce, 1s. 9d. to 2s. 3d.; Turnips, 6d. to 8d. per doz. bunches; do., Swedes, 1s. 3d. to 1s. 6d. per cwt.; Carrots, 6d. to 8d. per dozen bunches; Parsley, 6d. to 8d. per dozen bunches; Onions, English, 6s. per cwt.; do., foreign, 5s. to 6s. doz.; Cucumbers, 1s. to 3s. per dozen; Cauliflowers, 1s. to 2s. 3d. doz.; Cabbages, 10d. to 1s. 9d. per dozen; Celery, 10d. to 1s. 10d. per dozen. St. John's.—Potatoes, 10d. to 1s. 2d. per peck; Grapes, English, 1s. 6d. to 3s. per lb.; do., foreign, 4d. to 8d. doz.; Pines, English, 4s. to 6s. each; Damsons, 3d. per lb.; Cobnuts, 10d. doz.; Cucumbers, 3d. to 4d. each; Mushrooms, 1s. per pound and basket. Birkenhead.—Potatoes, 8d. to 10d. per peck; Damsons, 3d. per lb.; Cucumbers, 2d. to 4d. each; Filberts, 8d. per lb.; Grapes, English, 1s. 6d. to 3s. 6d. doz.; do., foreign, 6d. to 8d. doz.; Mushrooms, 8d. to 1s. doz.

CORN.

AVERAGE PRICES OF British Corn (per imperial qr.), for the week ending September 16, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

The districts indicated by number in the first column are the following:—

- 0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending September 16, is furnished from the Meteorological Office:—

"The weather remained fine over the greater part of England until towards the close of the week, but elsewhere the conditions were dull and unsettled, with frequent falls of rain."

"The temperature was again above the mean in most districts, but just equal to it in 'Scotland, N. and W.' and 'England, E.' The highest of the daily maxima were recorded during the middle part of the period, and ranged from 75° in the 'Midland Counties' and 'England, S.W.', to 66° in 'England, N.W.' The lowest of the minima were recorded on the 11th over England, and on the 15th in most parts of Ireland and Scotland; they varied from 32° in 'Scotland, W.' (at Glenlee), and from 36° in 'Scotland, N.' to 42° in 'Ireland, N.' and to 52° in the 'Channel Islands.'"

"The rainfall greatly exceeded the mean in 'Scotland, N.' and slightly in 'Scotland, E., while in 'Scotland, W.' it just equalled the normal. In Ireland and England the fall was again deficient."

"The bright sunshine was less than the normal in almost all districts. The percentage of the possible duration ranged from 48 in the 'Channel Islands,' and 42 in 'England, E.', to 25 and 28 in the Scotch districts, and to between 14 and 18 in Ireland."

THE

Gardeners' Chronicle

No. 666.—SATURDAY, SEPT. 30, 1899.

TOMATOS AS A FIELD CROP.

THE cultivation of out-door Tomatos has increased greatly in certain districts; and in others, which are apparently equally suitable for the purpose, not at all. We were lately in a district in the extreme south of England, and were surprised to find how few there are among the growers for local markets who have adopted this system of cultivation upon an adequate scale. Most of the Tomatos upon sale are brought long distances, or even imported; the few "home-grown" samples in the fruiterer's shops are grown under glass, and such cultivation is necessarily more expensive.

Some of the market-growers affirmed that Tomatos would not succeed out-of-doors in their districts, but we saw the Fig ripening its fruits upon a standard tree close by; the Myrtle was wreathed in white blossoms, and many other such plants testified to the mildness of the local climate.

A day or two later we were in Worcester-shire, in the heart of the market-gardening district of that county, and had the opportunity to see acres of Tomato plants bearing fine crops of ripe and ripening fruits. They were planted in rows across a field, nearly three feet between each row, and the plants less than two feet distant from each other; but some growers plant much more thickly than this, and recommend the practice. Each plant has a single stem only, and is supported by a wooden stake; but the most favoured varieties do not grow very tall, and are sturdy, and commence to fruit early.

Among the largest growers in the Evesham district are Mr. Masters and Messrs. White & Tillson, the latter firm, though only two years or so old, having at once made the cultivation of Tomatos an important feature in their market gardening.

It should be stated here, that anyone commencing the cultivation of Tomatos as a field crop should provide himself with several light span-roofed, moderately-heated houses. These will be necessary for the raising of young plants in the spring, and in most seasons they will be needed in the autumn to perfectly ripen late fruits that are gathered when beginning to colour.

Undoubtedly, the most popular varieties at present are Early Evesham and Early Ruby. The first-named variety is a sure cropper in a favourable season; the habit of the plant is perfect, the fruit being produced very close to the ground, and the growth this season is so sturdy that the nodes are scarcely two inches apart. Its disadvantages are in the fruits, these being, from our point of view, too flat in shape, and they are corrugated.

Early Ruby, which is almost as good a cropper, and is of good habit, has better-shaped and smooth fruits. Samples of this variety could be gathered which would equal in quality and appearance the best house-grown specimens. Indeed, when the fruits are permitted to ripen

upon the plants, those grown out-of-doors have rather finer flavour. But there were many other varieties in the fields, most of them more or less upon trial, and it was evident that some of those which give excellent results indoors are certainly unfit for profitable cultivation outside. Either the plants had made too much growth, and were therefore more troublesome, or they were poor croppers; or, as in many cases, they were very susceptible to fungous diseases.

The two locally popular sorts were quite free from "spot" in most of the fields, yet thinner skinned sorts next to them showed disease upon almost every plant. But even the two varieties mentioned above will crack, take "spot," and "sleepy" disease if they be planted in unsuitable situations, or the season be specially unfavourable. The qualities necessary in a Tomato for out-of-doors culture are a dwarf habit of growth, freedom to bloom and fruit, comparative hardiness, and a prominent tendency to early fruiting. This last-named quality is naturally a most important one, our summers being not too long for such a crop.

In such seasons as have prevailed for the past few years, each plant upon an average may be expected to produce five, six, and sometimes seven pounds of fruit, and if the produce fetch in the wholesale market not less than twopence per pound, the crop is a lucrative one. Prices are frequently much better than this, but occasionally they are not so good.

The following notes are taken from a communication sent us, since the foregoing was in type, by Mr. H. W. Ward, a well-known contributor to these pages, who describes the system of cultivation practised by some of the more successful Tomato-growers in Essex:—

"The unusually fine summer and early autumn weather we have experienced during the last three years has been most favourable to the production and ripening of Tomatos planted out-of-doors. Therefore, growers have extended their plantations of this much-valued vegetable-fruit each season.

"Some growers allow a space of 2 feet between the rows of plants in planting, and 1 foot from plant to plant in the row, while others allow 2½ feet between the rows and 1 foot between the plants in the rows, the plants in both cases yielding satisfactory crops of fruit. Dwarf, sturdily-grown plants should be used for planting out-of-doors towards the end of May or first week in June, according as the situation is early or late. Ground which slopes to the south or west is favourable to the growth of Tomatos; so also is level land which is sheltered from north and east winds. Land which produces good crops of Potatoes will prove admirably adapted to the growth of Tomatos. The plants are, as a rule, trained to horizontal wires, fixed to a series of stout sticks stuck into the rows of plants at short intervals, the top wire being about 3 feet from the ground. Soft Tomato-strings a little more than 3 feet long are in due time secured loosely one to each plant close to the ground, and then twisted pretty tightly round the individual wires, afterwards twisting the plants carefully round the strings as they require support. The side-growths are kept persistently pinched during the whole period of the plant's growth, so as to direct all the energies of the plants into the thickening of one individual stem, the production of large trusses of strong flowers, and the setting, swelling, and ripening of heavy crops of good fruit.

"When visiting a friend, who is a capital grower of Tomatos (indoors and out), in June last, his plantations of Tomatos in the open, struck me at first sight as being those of the Old Ashleaf Kidney Potato; the plants being dwarf, and furnished from the ground with small, finely-cut foliage, and strong trusses of flowers. The plants

were struck from cuttings; and in consequence of young roots appearing on the surface of the soil, my friend had some of the latter drawn up to the stems on either side, with satisfactory results. From these plants he has made large gatherings of fruits of good quality, which will be continued well into October should the weather continue sufficiently fine to ripen the fruits now swelling.

"The foliage, as a rule, remains fresh and green until cut down by frost. Where the clusters of fruit are partly hidden from the sun's rays by the leaves, sufficient of the latter should be removed to enable the sun to reach the fruit."

The following particulars are reported in a contemporary respecting an experiment made this season by Mr. Julian, Shaldon, near Teignmouth:—

"A piece of meadow-land of about 2 acres was selected that faces south-east, and forms the surface of the cliff overlooking the mouth of the river. Early in the year this piece of maiden-soil was lightly ploughed. Some 14,000 plants—raised in a small greenhouse and a few cold frames—were put in, the varieties being Sutton's Earliest-of-All and Carter's Outdoor. The plants were set out at distances of 2 feet apart, with 2 feet 6 inches between the rows. They were subjected to no special treatment, excepting that side-shoots were taken off. The plants were allowed to remain without any support being given whatever, and rested on the soil. The months following were in every respect favourable to the growth of the fruit, and the average yield was about 8 lb. of fruit per plant. Five tons of fruit were ruined by a fungus disease. [This may not have occurred had the fruits not been allowed to rest upon the soil. Ed.] The first gathering was made the second week in August, and from that date hundredweights have been picked daily, for all of which there has been a demand, either locally or in the London and Midland markets, special boxes having been made in which to pack the fruit. Had the crop escaped the disease, the total weight of fruit would have been nearly 80 tons, and there is a market for every one of them. The results go far to prove that Tomatos can be grown like weeds in and around Teignmouth."

One reason why many fail is, that they do not make the most of a short growing season by obtaining fair-sized plants, well hardened, early in spring, and plant out in the open the earliest possible moment it is safe. If they could be protected when planted for a short time, as Marrows sometimes are, the extra week gained would be of great value. At Evesham the plants are removed to the field from three-inch pots, but if five-inch were used they would be better. Then "early land," as the growers term it, is selected for the crop. Land that lies well to the sun, is sheltered to some extent from the coldest winds, and that is not heavy and cold. Such land will give a better return should the season be less warm than the one now at its close, and if the ground chosen be a newly broken-up piece of old turf, the chances of success will be greater.

What is needed of raisers of new Tomatos is that they will endeavour to obtain varieties specially suitable for cultivation out-of-doors, of strong habit, free fruiters, and as little tender as possible; if this be done, we feel sure that there is a future for Tomatos as a field crop.

ORCHID NOTES AND GLEANINGS.

ROSSLYN, STAMFORD HILL.

In the quaint, old-fashioned garden around the residence of H. T. Pitt, Esq., there is evidence that its successive owners were always lovers of the garden. In one part is a gigantic *Catalpa bignonioides*, which must have been one of the earliest of

its kind in England. In the centre of the garden is a quaint ornamental sunk portion, and all around there is evidence of changes in the methods of treating the garden, until the property passed into Mr. Pitt's hands, when Orchids were made the leading feature. *Odontoglossums*, *Cattleyas*, *Lælias*, and showy hybrid Orchids, were favourites; but the collection contains many pretty and rare species of the class usually spoken of as botanical, and some of the species generally considered difficult of cultivation, grow successfully here, especially since they have been in the charge of Mr. Thurgood, who has been for some time head gardener at Rosslyn. Among the plants in grand health were noted a goodly number of the leafy section of *Zygopetalum*, known in gardens as *Bolleas*, *Pescatoreas*, and *Batemannias*, a few of which were in flower or bud. In the same warm moist house, *Miltonia Phalenopsis* grows with unusual vigour, and flowers freely; also a large number of *Miltonia Roezli* and *M. vexillaria*, one fine plant of *M. v. Leopoldi* sending up four stout flower-spikes. On the other side of the house was a pretty arrangement of Orchids, mingled with *Anthurium Andreanum* in variety. Suspended overhead were *Nepenthes*, and some singular looking *Bulbophyllums*, *Cirrhopetalums*, and the smaller-growing *Angraecums*, the curious and pretty *A. Scottianum* being in bloom, also *Dendrobium revolutum*, and a few other uncommon species.

Another division of the range had on one side a selection of the larger *Selenipediums*, and on the other hybrid *Cypripediums*, both sections having a fair show of bloom. The end division had a good display of *Odontoglossum grande*, including the unique *O. grande Pittianum*, with wholly bright yellow flowers of two shades, and without the usual brown markings. Here also in bloom were some *Oncidium Forbesii*, *O. incurvum*, *O. tigrinum*, *O. prætextum*, *Masdevallia Bella*, *Paphinia cristata*, *Cypripedium Charlesworthi*, *Sophronis grandiflora*, and among the *Cymbidium*s a fine plant of the *Armanvillier's* variety of *Cymbidium x eburneolowianum*, with fine stout spikes in the course of formation.

THE ODONTOGLOSSUMS

are the greatest favourites, and the collection includes some very fine spotted forms of *O. crispum*, a magnificent set of varieties of *O. Wilckeanum*, *O. x W. Pittianum* being the best known; and some grand *O. x excellens*, and other hybrids. All were thriving well, and a few plants were in flower.

In the next intermediate range was a good show of *Calanthe veratrifolia*, a fine old white-flowered Orchid now seldom seen well grown; some nice spikes of *Vanda suavis*, *Miltonia Clowesii*, *M. candida*, *Cattleya granulosa*, and other showy kinds. At the end of the house were three very remarkable and handsome plants in flower, viz., a form of *Cattleya x Hardyana*, flowering for the first time, with a noble inflorescence of three very large flowers, the cream-white sepals closely veined with rosy-lilac, the broad flat petals of a bright purplish-rose, and the very large and spreading labellum of a dark purplish ruby-red, the base and centre of the lip veined with bright yellow, running into the side lobes. It is distinct, because the side lobes of the lip are of a bright purple, and the sepals and petals do not reflex as in the ordinary *C. x Hardyana*. The next was *Cattleya x Maroni* (*velutina x aurea*), with handsome Indian-yellow tinted flowers with a slight bronzy veining, and a distinct crimson veining and marbling on the lip. The third species, *Oncidium Retemeyerianum*, though "botanical," was no less attractive. It has thick, coriaceous leaves like *O. Cavendishianum*, and a long, branching spike of flowers, each nearly 1 inch across. The sepals and petals are white at the base, and cinnamon-brown on the outer portion; the singularly-formed labellum, bright-yellow at the base, the centre bearing some dark-purple lobes; the front, shining chocolate-brown.

The houses in the kitchen-garden contained in one division of the first range, a very fine show of flowers on the many plants of *Dendrobium Phalenopsis Schroderianum*, which thrive here so well; the

back shelf having a profusion of white and orange-flowered *Dendrobium formosum*. In the next division, was a goodly number of the different species of *Phalenopsis* doing remarkably well, suspended over a bed of *Eucharis*, &c.; and in the end division was a newly-started bed of *Vanda teres*, with a fine lot of *Dendrobium Johnsoniæ*, *D. atrovioleaceum*, and others, suspended under the roof. Then followed a house of imported *Odontoglossum*, another of varieties of *Cypripedium insignis*, and the large span-roofed range, containing the larger *Cattleyas*, *Lælias*, &c.; at the entrance a very handsome form of *Lælio-Cattleya x elegans*, and a few others were in bloom. J. O'B.

FOREIGN CORRESPONDENCE.

CATTELEYA LAWRENCEANA.

OF the tolerably extensive collection of *Cattleyas* which I have cultivated for many years, *C. Lawrenceana* is one that I like the most. The species is a native of British Guiana, and more especially of Roraima that mighty mountain and landmark standing between the states of Venezuela, Brazil, and British Guiana. It is highly interesting to read the description of this district and its inhabitants, by M. Appun, who was sent by the British Government on a journey of discovery, and who visited Roraima in the course of his journeyings. It is there that *C. Lawrenceana* is found, and so far as I know of nowhere else, although in all probability, its habitat is not so circumscribed as this. The transportation of plants through the colony to Roraima is a matter of extraordinary difficulty, and impediments of all kinds are met with, and as will be readily understood, the species in question is rarely exported. Moreover, the Government of the Colony forbids the exportation of native species of Orchids, therefore few plants reach Europe as compared with the often immense importations of other species of *Cattleya*. The species is the more valued, irrespective of its beauty, for its freedom to bloom, and the season at which it blooms. In fact, *C. Lawrenceana* fills a gap in the *Cattleya* season between the period of *C. Trianaei* and that of *C. Mendeli* and *C. Mossii*.

The plant is of easy culture, but it must not be subjected to the ordinary rules of cultivation without certain matters receiving attention. An essential factor is a temperate, very light glasshouse, and it must be stood near the glass, and the plant must be often sprinkled or syringed, so that the leaves and pseudo-bulbs do not suffer from dryness. The compost must be kept in a moderately moist state constantly—not wet at one time and dry at another.

When growth begins, the plant should be carefully watched, and no water permitted to remain in the same, otherwise it is greatly to be feared that decay will occur. The growths should be cleared of water in the evening, as moisture during the night is very injurious to the young growth, as is also a high temperature. When the growth is complete, the compost should be maintained in a drier condition, only as much water being afforded as will avert shrivelling of the pseudo-bulbs and leaves; and with this intent these may be dipped in a vessel of water, but the compost should not be wetted. This operation should take place in sunny weather.

Beyond these small details, cultivation is simple. The plant, having made its growth, should be afforded rather more air, in order to mature completely. The blooms appear in the month of April, and on well-established plants these come in bunches of three to six, which, as a result of their arrangement and rich colouring, have a particularly pretty effect. These have a resemblance to those of *C. Skinneri* and *C. Bowringiana*, to which species *C. Lawrenceana* may be nearly related, although it is undoubtedly a veritable, distinct species, and not regarded merely as a variety of a type. My experience of the plant is that it grows better in a pot

than in a basket. It is found in its native habitat of mossy rocks, in open forests, and on the banks of streams. The roots extend horizontally, and, like the crown of the plant, they are not exposed to the air. It serves no purpose to use much peat as compost; on the contrary, the layer of soil should not be more than 1 inch thick, which should overlay a pot filled with crocks; sphagnum-moss cannot be recommended, only clean-washed peat-fibre. Several varieties have been imported, which exceed the type in beauty of form, size of the flowers, and in rich and dark tints. I cultivate a variety under the name of *C. Lawrenceana* var. *splendens*, which has larger flowers, the sepals broader than the type, and of a richer tint, the lip a fine dark purple-carmine. The finest form, however, that I have observed, excepting that superb variety which M. Jules Hye, of Ghent, possesses, under the name of *C. L. superba Hyeana*, of which the entire bloom is of the richest dark carmine, is *C. L. superba*, whose beauty consists mainly in the magnificent large lip of the richest and most gratifying shade of carmine. In beauty this variety is excelled, in my opinion, only by the unequalled *C. L. superba splendens*, whose beauty, unfortunately, is concentrated only on a few blooms, and which is a plant that is rarely seen in flower. The best time to repot *C. Lawrenceana* is when growth commences and new roots appear, and repotting is only needed when the peat has become actually decayed and sour, i.e., every alternate year. The root-mass must not be afforded water before the roots have well developed, the pseudo-bulbs and foliage only being refreshed by immersion in water, or by syringing. Otto Froebel, Zurich.

A NEW PACKING-MATERIAL FOR FRUITS.

AN interesting experiment has just taken place in the matter of packing fruits in the colony of Victoria for shipment to England.

As is pretty generally known, Apples and Pears are now brought from the Cape of Good Hope and from the Australian colonies in boxes holding a bushel, which are stored on board ship in cool chambers. These chambers, or refrigerators, have been provided by the steamship companies at a considerable outlay of money. The fruits are merely wrapped in tissue, and placed in the boxes.

Under this system, Apples have for the most part come very successfully; but Pears have been less satisfactory. Occasionally, there have been Pears from the Antipodes that have reached this country in a sound condition, but numerous consignments have proved to be of little value, and the commission-agent is never able to speak of such fruits or to gauge their value until they have been unpacked. The freight per bushel from Victoria to London for Apples or Pears so packed and stored on board ship in cool chambers is 3s. 9d.

Such are the circumstances of the present system, and the amount of freight paid for passage.

And now for the experiment, for intelligence of which we are indebted to Mr. J. B. Thomas, a well-known fruit salesman in Covent Garden, to whom the fruits which have been the subjects of experiment were addressed.

Instead of packing the Apples wrapped in tissue only, in the case of several bushels that have recently arrived in London by the s.s. *Wakool*, a quantity of asbestos or a preparation of this substance has been used. The fruits were wrapped in tissue as formerly, and afterwards embedded in the asbestos, each fruit being perfectly surrounded by this substance. Upon unpacking the case, the asbestos appeared to be caked, but it was easily broken up, and then appeared almost like flour. We should suppose, therefore, that the fruits would be airtight under such conditions, and this will account for the fact that as we saw them they were perfectly sound, and in excellent condition, although five months had elapsed since they were packed in the boxes. The Apples were grown by Mr. J. R.

Warren, Mount Alexander Orchard, Harcourt, and Mr. J. M. Ely, Rosehill Gardens, Harcourt, both large Victorian fruit growers. They were packed and brought to this country under the direction of Mr. Geo. Pontin, Church House, Yapton, Sussex. The Apples were gathered and packed previous to

"hold" of the ship, and the freight per bushel-case will be 6*d.* instead of 3*s.* 9*d.*; but as the packing material will displace a quantity of the fruits in each package, it may be well for present purposes to describe the future freight of the fruit as 1*s.* per bushel.

FIG. 87.—APPLE THOMAS ANDREW KNIGHT

May 5 last, but owing to some objection, we believe, on the part of the s.s. companies, there was a delay of two months or more before shipment, and even then they travelled by the Cape route. The companies, naturally perhaps, object to the intro-

It must be remembered also that the asbestos is a valuable material in England, and it will be sold here to as much advantage as will the Apples. The result will be that the asbestos and fruit would be brought to England for less money than is now paid

FIG. 88.—SECTION OF APPLE THOMAS ANDREW KNIGHT.
(SHOWING THE CORE.)

duction of a new system of packing fruits that may render unnecessary the cool chambers that have cost so much money to provide. But such objections will, no doubt, be overcome, and if a syndicate be formed, as is now proposed, the system will be given a conclusive trial. The new system, should it answer to expectations, will possess several advantages. The fruit may then be stored in the

for the fruits alone. The Apples will travel as well or better, and it is thought they may be preserved after arrival here for weeks if necessary, providing that the cases be not opened in the meantime. And beyond the other considerations, it is hoped also that Victorian Pears by this system may be placed on the English market without much risk of loss by decay.

THREE NEW APPLES.

ON the occasion of the Royal Horticultural Society's meeting on September 12, the following varieties of Apples were distinguished by the Fruit and Vegetable Committee by Awards of Merit:—

THOMAS ANDREW KNIGHT.

This handsome and splendid variety has been raised by Mr. Charles Ross, Welford Park Gardens, Newbury, Berks, from a cross between Peasgood's Nonsuch and Cox's Orange Pippin. The fruits are exactly the form of Cox's, and have the rich flesh and flavour of that excellent variety; but they are more than double its size, very handsome, and well-coloured (see fig. 87). It is the best dessert Apple that has been raised for many years. As may be noticed on reference to fig. 88, the fruits have remarkably little core, which is a great advantage.

BEN'S RED.

This Apple was shown by Messrs. Geo. Banyard & Co., Maidstone, and is the result of a cross between Red Quarrenden and Farleigh Beauty. It is of large size, solid, and very red in colour, and not unlike Mère de Ménage, but it ripens earlier than that variety (see fig. 89, p. 261). It will doubtless make a capital Apple for culinary purposes.

VENUS' PIPPIN.

This Apple was shown by Mr. W. J. Godfrey Exmouth Nurseries, Devonshire, who has informed us that the variety has been known to him for thirty years past, and it appears from information obtained in the district that almost a century ago "Plunderitz" (a local name) was a popular West-country Apple. But be that as it may, the variety is new to commerce to-day, and it will be welcomed by all who enjoy a juicy, soft-fleshed, peculiarly refreshing Apple.

Our illustration (fig. 90, p. 261) represents a small fruit, but Mr. Godfrey states that he has had them weighing from 12 ozs. to 14 ozs. each. On parts of the tree exposed to the sun the fruits become very slightly flushed with crimson. The stalk is about 1 inch long, set in a cavity of considerable size, one side of which is russety. The eye is moderately open, and set in a deep, small basin. It would make an excellent sauce Apple; and as a dessert fruit, the flesh is so soft that it is unusually easy of mastication. The tree is a prolific bearer, and seldom fails to carry a crop.

BOOK NOTICE.

THE STRAWBERRY MANUAL. By Laxton Bros., Bedford.

In the publication of the *Strawberry Manual* Messrs. Laxton Bros. have performed a useful service, for with all the abundance of horticultural literature the Strawberry has not received its full share of attention. The fruit is a general favourite, and its cultivation has extended greatly within the past quarter of a century; as a consequence there is a constant demand for information both from amateur and professional growers. In our own paper valuable articles have appeared from the pens of the most successful cultivators of this fruit; but a condensed and practical review of the principal points connected with Strawberry growing was urgently needed. All this has been satisfactorily supplied in the work now before us. The name of Laxton has been so long associated with the improvement of this popular fruit, both father and sons having laboured during a period of about forty years in the cross-breeding and raising of new varieties, that it is especially appropriate that such a manual should emanate from them.

The book comprises 139 pages (crown octavo) of information dealing with the origin and history, hybridisation, crossing, and seedling-raising, cultivation in private gardens, and for market. Forcing, also, has a chapter devoted to it, in which a *résumé* is given of the facts concerning which it is needful

to be informed. An interesting and instructive chapter is devoted to manures, and other portions of the work deal with Strawberry enemies, experiments with Strawberries, and descriptive notes on some of the principal varieties in cultivation, together with select lists of varieties suitable for different purposes and various soils.

The "manual" is clearly printed on good paper, and is bound in cloth, constituting a really cheap and useful shilling book; but we should have liked to see a few more illustrations to brighten the pages, though readers of technical works of this character are more concerned with the "matter," and this is of a character that should give general satisfaction. Some small errors have escaped notice, but they are not of a serious nature. For instance, on p. 28, "the end of the nineteenth century" evidently refers to the eighteenth century. On p. 102, "Lord Roseberry" is a misprint for Lord Rosebery; and there are a few other oversights of minor importance which do not affect the value of the book. With regard to the species of *Fragaria*, it has only been attempted to deal with that part of the subject in a popular manner; but it is worthy of a fuller exposition. A condensed work somewhat in the way of the admirable *Histoire Naturelle des Fraisiers*, by M. Duchesne, brought up to date, would be acceptable to many.

NITROGENOUS MANURES.

(Continued from p. 223.)

NITROGEN FOR PARTICULAR CROPS.—The influence of the kind of crop in determining the possible profits from the use of the materials applied affects more particularly the constituent nitrogen. For example, the liberal application of materials containing nitrogen to crops which possess a low market value may result in a maximum production, that is, as large an increase in yield as it is possible to obtain; yet because the nitrogen is so expensive, the value of the increased yield may not be equal to the cost of the nitrogen applied.

On the other hand, its application to crops of a high market value, though not causing so large a proportionate gain in crop, may result in a larger profit, because the cost of the nitrogen, though considerable, is relatively a small item when compared with the increased value of the crop obtained from its use.

The adjustment of the fertiliser to the kind of crop is not a matter of indifference. In the one class of crops, only a small application can be afforded, while in the other case even an excessive application may be profitably made, if by the excess a maximum crop is obtained.

MOST SOLUBLE FORMS OF NITROGEN.

In the next place, the form of nitrogen used is very important, particularly in the culture of early market-garden crops, or such as are improved in quality, and thus increased in value by virtue of quickness of growth. Market-garden crops, as Turnips, Beets, Lettuce, Tomatoes, and others, in order to be highly profitable, must be grown and harvested early. At this season the natural soil agencies are not active in the change of soil-nitrogen into available forms; and the plants must, therefore, be supplied artificially with the active forms of nitrogen, if a rapid and continuous growth is to be maintained. Their edible quality is dependent to a marked degree upon this rapidity of development; hence a supply of plant-food in reasonable excess of ordinary demands is essential, in order that unfavourable conditions of season may in part, at least, be overcome.

Nitrogen exists in commercial products in a form that is immediately available, namely nitrates; yet the fact that a nitrate is extremely liable to loss for the reasons already given, makes it desirable to determine—first, whether this most available form is in actual practice of greater or less service than those other forms which are rapidly changed into this active form, but which before their change

are not liable to be lost from the soil. For example, the nitrogen in nitrate of soda is immediately available to the plant: if it is applied before or at the time of seeding in such quantity as to meet the entire demands of the crop, an opportunity is afforded for loss previous to the time that the plant has thrown out its roots and is able to gather it from the soil, and also during its early growth, when it is unable to gather it rapidly. Sulphate of ammonia or dried blood are forms which change very rapidly into the nitrate form, but which previous to that change are readily held by the soil.

In the use of any of these forms of nitrogen, therefore, the conditions which prevail between the time they are applied and the time that they can be used by the plants, would determine their relative usefulness. *J. J. Willis, Harpenden.*

(To be continued.)

NURSERY NOTES.

BUCCLEUCH NURSERIES, HAWICK, N.B.

MR. JNO. FORBES' establishment is situated 800 feet above sea level, and hardy florists' flowers succeed admirably. When visiting the place in the early part of September, Antirrhinums were very showy. For producing the best effect in beds, the excellent variety White Bedder, which grows 1 foot high, and Yellow Bedder and Crimson Bedder, a few inches taller, but showy and effective, are very valuable.

Begonias are extensively bedded out, and if they do not give such a wealth of flowers as under greenhouse treatment, they are a welcome change to the Pelargoniums. Under glass there were the best and newest of the tuberous-rooted section. A few of the best doubles are Albert Crousse, deep salmon-red; Apricot, salmon-apricot; Bernard Cowan, scarlet; Chieftain, beautiful pale rose, shaded salmon; Madame de Didier, yellow; Mrs. A. Forbes, pale salmon; Olga, pure white; and Satin Rose, a deep rosy-scarlet. Of the singles, Aurora, deep scarlet; Alexander, bright rose; Candida, pure white; Conquerant, cerise-scarlet; Favourite, golden-bronze; Iris, bronzy-yellow; and Model, pink, suffused buff; are among the best.

Carnations, especially the border varieties, have been very showy on a steep slope of the nursery, where they succeed to perfection. Not the slightest trace of disease in any form was to be found among the many varieties which are here grown. A few among the many worthy of note are:—Artemis, scarlet, flaked lavender; Foxhunter, crimson-scarlet self; Professor Gerts, steel-blue with scarlet; Queen of Holland, terra-cotta; Brochlin, yellow, with purple edge; Corunna, golden-yellow; John Forbes, rich canary-yellow, edged with rosy-scarlet; Primrose League, yellow, edged and splashed with red; Waterwitch, blush-white; and Scarlet Gem. Yule Tide is grown under glass in quantity, to meet the demand for such a splendid winter-flowering variety.

Hollyhocks were gorgeous, and anyone who can grow them to the same perfection as they are done here is fortunate. Year after year the plants enjoy entire freedom from disease. There is great advantage in growing Hollyhocks in this district, that is, the scarcity of the wild Mallow. When living in the south, it was impossible for me to keep the plants clean for any length of time (seedlings or otherwise), owing to their becoming contaminated with disease from the wild Mallow, which grew in abundance in the district. Varieties are too numerous to mention, but a few good ones are alba superba, pure white; Archibald Forbes, blush, suffused pink; David Henderson, light rosy-crimson; Gem of Yellows; Grace Darling, rosy-salmon; Lord Decies, dark crimson; Octoroon, pure purple; and Robert Ryle, carmine-red.

Herbaceous Lobelias are grown in many varieties, and I think the variety Firefly is the most brilliant of them all.

Montbretias are delightful when arranged with their own sword-like foliage. I think, from the profusion of the flower-spikes here, they prefer a damp situation.

Pansies find a congenial home in very stony soil, and grown as they are, quite in the open, they delight in their position. Violas are finer here than I ever have seen them; they have been quite smothered with their neat, and in many cases, sweet-scented flowers all the summer, and promise to maintain the display through the autumn. Varieties are so numerous and good that it is needless to enumerate any of them.

The show of Pentstemons is worth going a long way to see, and it is interesting to examine the varied shapes and markings of the different varieties. A great many are grown in pots and forwarded in greenhouse temperature, so as to lengthen the flowering season as much as possible. They make fine, showy pot-plants for conservatory decoration. Among the finest varieties are Miss Dawson, rich rose with white throat; Mrs. William Cruden, brilliant scarlet, pure white throat; William Bain, rosy-scarlet, white throat, margined crimson; Jean Mace, scarlet, white throat, marbled crimson; President Carnot, scarlet, white throat; Lord Ravensworth, rosy-purple, large white throat; and Scorpion, clear violet, with purple blotch in the throat.

Proceeding along the main walk, we found it bordered on the one side with herbaceous perennials, and on the other by Phloxes, which are mostly of the newer dwarf type. Among the scores of varieties to be seen here, there are some to suit the tastes of all both in height of plant and colour of flower. Pot-culture is called to the grower's help also for extending the flowering season of the Phloxes, and well they repay any such attention given them. A few varieties may be mentioned as exceptionally good, namely—Bouquet-tist, orange-scarlet, purple centre; Fedora, rose, slightly suffused pink; Crepuscule, silvery-white, with dark centre, and white edges; John Forber, pink, dark crimson eye; Lord Raleigh, dark violet, purple centre; Le Mahdi, violet-blue, suffused bronze; Le Siècle, salmon-rose, lilac, white centre; Liberté, orange-salmon, carmine centre; M. C. Carpentier, pure white; Suffrage, lilac-mauve, rose centre; and William Robinson, rosy-salmon, violet centre.

East Lothian Stocks are among the leading plants at this nursery, and a piece of ground planted with several hundreds of these beautiful sweet-scented plants in full flower was a feature. They are not grown here as in most gardens. In the spring the plants are put into 6-inch or 7-inch pots, and plunged in the open ground, watered occasionally during the summer, and on the approach of frost they are taken up, and placed in a light, airy house, where they prolong the display for a considerable time. So far as I could see, there would be about 20 per cent. of singles. They are represented by seven varieties, purple, crimson, scarlet, rose, and white, and white and crimson wallflower-leaved. I have always thought most of the white and crimson varieties grow with more freedom than the others. Where East Lothian stocks stand over the winter outside, they make a fine show in the months of May and June following.

Another very useful and ornamental plant is the Dunrobin Bedding Fuchsia, which grows about one foot high, and flowers with the greatest freedom, making a fine hardy plant for the flower garden as a front row to a shrubbery.

Of hardy Chrysanthemums there is the usual selection, but a variety I noticed much earlier in flower than any other was named Golden Shower. It is in colour a golden-yellow, and grows 18 inches high. There is also a quantity of Chrysanthemums in pots, which are grown for the supply of cut flowers. Dahlias were in bloom, but Delphiniums were all past. Of herbaceous plants in general, their names and qualities are legion, and the borders are very gay from early summer till late in

the autumn. *Gypsophila paniculata*, and *Statice* in their many varieties are fine plants, and *Pyrethrum* are represented in their best varieties.

MISCELLANEOUS FEATURES.

The glasshouses are principally used for propagating purposes; but the large centre conservatory

a pale shade of green, with good wiry stems and small pinnules. It is only from well-established plants that good fronds can be obtained, but after they attain to a useful size, the same plants will continue to supply good material for a considerable length of time. I have known the same plant to afford a good supply for several years

a less number of plants when given plenty of room than is the case where they are crowded together. Liquid-manure may be used when the plants start to make new fronds, but after they are well developed it should be discontinued.

The most difficult months in which to have good fronds of Maidenhair are those of February and March. To ensure good material for this period, plants that have been rested during the summer should be started in the autumn; if they have not been entirely dried off, they should have all the old fronds removed. If the plants are too dense damping-off may give trouble. Old fronds will sometimes cause this, or it may be caused through letting the plants get too dry at the roots. When allowed to get too dry, the under-fronds shrivel up, and as soon as moisture settles on them, decay and damping-off are the result.

In growing Maidenhair for furnishing fronds for cutting, it may be necessary to afford some slight shade during the summer, but the more the plants can be exposed, the better; and if water be carefully afforded, it will only be during the very bright, hot weather that any shading need be used.

Adiantum elegans, the fronds of which are larger than *A. cuneatum*, is now being grown to some extent; it also lasts longer in the winter. Plants of this variety which have been rested during the early part of the winter will start into new growth, and come in much earlier than the old favourite. *A. Hemsley*.

FIG. 89.—APPLE BEN'S RED.
(SEE P. 259.)

contains some large specimen Camellias, which, I have no doubt, Mr. Forbes would gladly part with, as they take up a good deal of valuable space; but there is not much demand for hard-wooded plants of this description.

At present, there are several new glasshouses in course of erection; some for holding the hardier class of plants, and others for stove plants. *R. T. S.*

without being repotted. When necessary to increase the stock, division may be recommended in preference to seedlings, as the latter produce a number of small fronds with short stalks (or stipes).

In growing on a stock for cutting from, they should be potted in a good loamy compost, pressed fairly firm, and good drainage should be afforded.

FIG. 90.—APPLE VENUS' PIPPIN.
(SEE P. 259.)

MARKET FERNS.

FERNS SUITABLE FOR CUTTING.

ADIANTUM CUNEATUM.—Although not so popular as formerly, there is still a demand for good Maidenhair Fern, especially during the winter months. To meet with the approval of florists, it must be of

When starting with young plants, they may be grown on in a good heat, and treated liberally; it is only after the pots get well filled with roots, and the plants have been well exposed to light and air, that they make desirable hard wiry fronds. They should be grown on an open stage, giving them plenty of room, so that the air may pass freely among them. More good fronds may be cut from

HOME CORRESPONDENCE.

COLCHICUM AUTUMNALE.—At the present time (September 23) this plant affords a welcome touch of colour to the herbaceous borders, and the plants are flowering more abundantly this year than usual. Planted in fair-sized clumps in the front row—as we have it here—there is plenty of green foliage near to it; it is also well separated from the yellow-flowered *Helianthus* and allied genera, which give the prevailing tone of colour to the herbaceous garden at this season, otherwise the two colours would be inharmonious if near together. The variety *C. a. maximum* is much superior to the type, and to *C. Parkinsoni*, but all are welcome at this season of floral scarcity. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

MARÉCHAL NIEL ROSE.—Referring to remarks on the above Rose, by "J. K., Wimborne," I have two trees that I budded many years ago on a *Rosa Banksia* stock; they are growing in a cold house, and have never shown any sign of canker. It appears that *Rose Devonensis*, or any other stock will do that yields a good flow of sap. I do not know if fruit-trees obey the same law, but clearly the stock in every case should yield sap as fast as worked *Rose* or fruit requires it. *P. V. Hadlow, Buxted, Sussex.*

PEACH PRINCESS OF WALES.—I am sending for your inspection a photograph of a Peach-tree of this variety, growing on a south wall in the gardeus, which was taken in August, 1898, when the tree was carrying 274 fruits of large size. The fruits were over at the date of the Fruit Show at the Crystal Palace last year, or I should have exhibited some of them. This year the same tree is carrying over 100 fine fruits. *Peach Princess of Wales* succeeds here, and is one of the best late varieties we have. [The photograph was, unfortunately, too small for our purpose. *Ed.*] *T. H. Stade, The Gardens, Poltimore, Exeter.*

GENTLEMEN GARDENERS.—The *Daily Mail* is noted for its surprises, but I never had a greater shock than when I read the note with the above heading. After an experience of over a quarter of a century amongst many of the leading gardeners, I have never heard of the "scores of places" where such handsome remuneration is given. No one knows better than the Editor of the *Gardeners' Chronicle* how the market is already overcrowded with these so-called "scientifics." Where the supply falls short is in sound, practical men, who have done their seven years at the bottom before attempting to mount the ladder. Perhaps your enlightened contemporary may be induced to name one only of the twenty he refers to, as I should like to know him. *D. McDonald.*

ALLIUM ROSEUM.—During the parching month of August last, this plant was conspicuous in the herbaceous borders by reason of its fresh appearance among so many other plants that were withered or dried up. Fortunately, it does not possess the strong aroma of *A. Moly* and other species. The plant grows about 1 foot in height, and its slender stems are surmounted by a head of flowers about 1½ inch in diameter, of a pleasing shade of soft rose, tinted with purple. It is easily increased by division. *W. H. Divers.*

THRUSHES AND BLACKBIRDS, ETC.—In your last issue, p. 238, Mr. H. Weir, writing of the song-thrush, says he should like to know if any other person had observed the habits of this bird which he had noticed. It so happens that the song-thrush is a favourite of mine; a good singer, and a gentle, innocent bird. Of course, it is very fond of small fruit when this can be got, but they can easily be kept away from it by nets, and it does not attack large fruit on trees and walls, and tear up mulching, as the blackbird does. By keeping down the blackbirds, which, when numerous, chase off the thrushes and take their worms from them, I have a large and happy family of thrushes here. On three sides this manse is surrounded by grass, a lawn, flower-garden, Rose-garden, and bowling-green. On these, I can see the thrushes every morning, and in summer time, not only at sunrise, as Mr. Weir says, but long before. When there is only the faintest streaks of light, and before any blackbird appears, I have often noticed them hopping over the green in quest of their morning meal. After the grass has all been searched many times over, and later in the day, I have frequently seen them, especially in dry warm weather, searching the rockery and secluded or sheltered nooks, disappearing under Ferns and other plants, and then emerging with a large shell snail, and making for one of the garden stairs (stone), where the milling process was instantly started on the shell. In fact my attention was first drawn to this habit of the bird, many years ago, by hearing a deal of tap, tap, tapping going on, on the stairs, and when I went and looked at the place I saw Mr. Thrush busy at his banquet, and the debris of many a rich repast scattered over the steps. In regard to the blue or tom-tit, he is certainly a most destructive little rascal; not for what he eats, but for what he destroys. Provided with a strong neck and a sharp bill, he seems to take a delight in puncturing fine Pears. They are very numerous in this part of the country, and if the trees were unprotected they would injure every Pear here. To put a collar on every Pear, as Mr. Weir suggests, would certainly be a troublesome and tedious process where Pears are at all numerous. I cover mine with nets. As a gardener's assistant, I venture to think the tit is an over-rated bird. Anyhow, last winter we reduced the number here as near to nothing as we could, and my fruit-trees, despite the dry and warm summer, never were free of insect pests. *J. Hart, The Manse, Aberlady, East Lothian, N. B.*

BULBS, ETC.—An article by someone of genuinely practical experience, specifying which, among the rarer bulbs, can be successfully grown in the grass in England, would be very interesting. By such rarer bulbs or tubers, I mean *Adonis*, *Alstromeria*, *Anemone Robinsoniana*, *palmata*, *blanda*, *Camassia*, *Chionodoxa*, *Erythronium*, *British Fritillarias*, bulbous *Irises*, *Leucjum*, *Lilium*, *Trillium*, exotic *Tulips*, and such-like. I understand that even on the mound at Kew most of these things have to be replanted each year. Some interesting things have turned up here this year. *Campanula rupestris* from the Peloponnese has not yet flowered, but its deeply-cut, tomentose foliage, lying on the ground in rosettes, is far more effective than *C. mirabilis*; its hardihood is not yet proven. This last remark also holds good for a most charming *Linum* from Chili, with orange flowers and bright scarlet-tipped buds, of which I have not yet been able to send a plant to Kew for identification. *Lathyrus magellanicus* has returned to cultivation, but the flowers have not the beautiful azure-blue of Sweet's illustration. They are fairly large, lilac in colour, with a red base. It ripens a fair proportion of its seed, and the seed germinates at once. Few people seem to grow *Perowskia atriplicifolia*. After *Salvia angustifolia*, that true queen of the autumn, I know of nothing so effective among the late flowers; but the flowers are individually small, which might not suit some tastes. *Ranunculus Lyalli*, in some quantity, seems

quite happy in stiff soil, under a north hedge, and well sheltered from winds. It flowered this spring, after going through the winter unprotected. It is also to all appearances contented, though quite dwarf, on the north side of a fearfully windy rockery. *Rodgersia pinnata*, which I have not yet dared to trust outside, is putting up dark-brown, hairy leaves, which are very taking. Dr. Henry tells me that when it was in full flower among the cliffs, at 8000 feet altitude, in Yunnan, it was a magnificent sight. Gardens are evidently going to be greatly enriched with *Meconopsis*. Besides the well-known *cambrica*, *nepalensis*, and *Wallichii*, and the less well-known *simplicifolia* and *aculeata* (this latter, perhaps, the most beautiful of dwarf spring flowering plants), seed of two new Himalayan species has germinated, viz., *grandis* and *paniculata*. Seed of the perennial Himalayan *M. bella* also reached Europe, but unfortunately it failed to germinate. Dr. Prain, the chief Director of the Calcutta Botanic Garden, told me that he has for years been endeavouring to secure seed of this fine species. Last year a lot of seed was obtained, but, as ill-luck would have it, a rat got at the seeds en route between Sikkim and Calcutta. The wretched creature showed unerring penetration. It might have glutted itself on *M. Wallichii* and *M. nepalensis*, but it preferred to devote itself to this choice *M. bella*, and devoured almost every seed. Only a few imperfect seeds reached Calcutta, and none of them has germinated. By-the-by, cultivators of *Meconopsis* must prepare for some changes of nomenclature. The true *M. nepalensis* (now being raised from seed) is apparently quite a different thing from the beautiful sulphur-flowered species generally known under that name. Besides these Himalayan species, we may shortly expect to gain, through the enterprise of Messrs. Veitch, who have sent a collector to tap the extraordinary riches of Western China, the superb *M. integrifolia*, whose great flowers are understood to be some 4 inches across. All lovers of hardy plants must heartily wish success to Messrs. Veitch in an enterprise which is bound to so greatly enrich our gardens. Beyond these above-mentioned Asiatic species, and several others unmentioned, there is yet another in the Californian *M. heterophylla*, which was so exceedingly beautiful this spring in the alpine-house at Kew. The worst news I know is, that Dr. Henry, our only first-class botanist actually in the field in China, has been moved to a spot wholly out of reach of the high mountains, where alone hardy things can be got; so at present outdoor gardeners in England will have to wait. *A. K. Bulley, West Kirby, Chester.*

CROCUS SPECIOSUS.—A large bed of this species is now a mass of beautiful blue flowers, and will continue in beauty for several weeks. Like many other early-flowering bulbs, it flowers whilst devoid of foliage, but scattered clumps among the herbaceous plants add much to the nice appearance of a border at a time when few others are in bloom. If left undisturbed, it increases readily from self-sown seed, and also flowers more satisfactorily than it does when transplanted. *W. H. Divers.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart. Clare Lawn, East Sheen.

Fire-heat and the Necessary Temperatures.—Artificial heat will now be necessary in order to maintain the temperatures in most of the Orchid-houses, and although care is always needful in the employment of fire-heat, it is doubly so now, when most Orchids are approaching their resting season. The man deputed to attend to the fires and heating of the houses at night should be one qualified to read ordinary signs of the weather, so that the house temperature in the morning may be as nearly right as possible. The temperatures for the various departments should approximate to the following figures, though, if the weather continues mild, the minimum readings need not be strictly adhered to, providing fire-heat be not largely used:—

	Morning.	Noon.	Night.
East Indian and Phalaenopsis-house...	68°	75°	70°
Cattleya-house	63°	68°	65°
Mexican-house	67°	68°	63°
Intermediate-house	58°	63°	60°
Masdevallia-house	53°	58°	55°
Odontoglossum crispum-house ...	50°	55°	53°

On bright sunny days the noonday temperatures

in the first four houses may be permitted to rise considerably above the figures given. It should be clearly understood that these figures are intended to apply to temperatures obtained by artificial means, and they serve only as a guide; atmospheric influences and local conditions may render modifications advisable.

Shading may be dispensed with so far as the East Indian, Cattleya and Mexican houses are concerned, but the Phalaenopsis and plants in the cool houses may need for some time longer a small amount of shade during sunnier hours. Owing, however, to the very brilliant weather this season, the most delicate plants will stand stronger direct sunlight than would otherwise be good for them at this season. All permanent shading on the ends and sides of the houses should be removed at once, also any that has been employed on the roof-glass.

General Remarks.—*Bletia hyacinthina* should now be taken indoors and placed in a dry, cool position, and afforded no more water until the new year. If space is limited they may be placed under the stage, where no drip will reach them. *Thunias* also may be laid beneath the stage in an intermediate-house as soon as the leaves have fallen away. Arrange them so that the pseudo-bulbs will not lie flat upon the ground, and afford the plants no water whilst occupying this position. A light and dry position on a stage in a moderately cool house would be preferable. Continue to remove *Dendrobiums* to a cooler and drier position so soon as the new pseudo-bulbs show that growth is finished. Repot or re-surface such *Cattleyas* and *Laelias* as are emitting new roots from the base of the last-made pseudo-bulbs. The water supplied afterwards should be limited in quantity. *Celogyne cristata* and its varieties now forming pseudo-bulbs should be afforded every encouragement to further their development. *Anguloas*, the deciduous *Lycastes*, and others that have matured their growth will now only require sufficient water to keep the latter in a sound and plump condition.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Tender bedding plants.—Cuttings of these that have made roots and are still out-of-doors must now be placed in cold frames, but for the present the lights need be used only during the nights. If sufficient cuttings have not been obtained of the tricolor or golden-leaved varieties of *Pelargonium*, it will be well to lift the old plants, and when they have laid out for a few days to dry, pot them up, putting three plants into a 6-inch pot. Place them in a cool and airy position.

Specimen trees in tubs.—Standard Oranges and other half-hardy trees in tubs should be removed to their winter quarters; and hardy trees in tubs, such as Portugal Laurels, Sweet Bays, and *Rhododendrons*, should be placed in a situation sheltered from rough winds. *Cannas*, *Melanthus major*, *Acacias*, *Aralias*, and *Aloes*, may be permitted to remain out for a few weeks longer, as a few degrees of frost will not harm them.

Calceolarias.—The propagation of these should be carried out in the course of next week. Few failures need occur if the shoots selected are firm, not showing flower, and come from near the base of the plants. The cuttings should be from 3 to 4 inches long, cut just below the joint, and a few of the lower leaves removed. They succeed better in a cold frame than in pots or boxes. Thorough drainage must be afforded, and the soil should be made up evenly and firmly to within 8 inches of the lights. The best compost to use is one consisting of loam, leaf-mould, wood-ashes, and sand. The cuttings may be dibbled in about 4 inches apart from each other, sprinkling the surface with silver or river-sand. A light spraying overhead in the mornings is beneficial, but the frame must be kept close for a few days so as to prevent flagging; after which, plenty of air will be necessary. No covering is needed except during frosts.

Gazania.—The two varieties, *G. splendens variegata*, and *G. splendens aurea*, make very pretty bedding-plants, especially when mixed with a blue *Viola* or a *Lobelia*. Cuttings taken from the tips of the shoots, and placed in boxes containing a light (not too rich) compost, soon make roots, and when thoroughly established, they may be wintered in a cold frame from which frost is excluded.

Chrysanthemum frutescens.—The white-flowered variety, *coronarium*, *coronarium grandiflorum*, and

the yellow-flowered Etoile d'Or, grow and produce flowers during the whole season. Cuttings of these strike readily if inserted around the edge of the pots, and the latter plunged in a little bottom-heat; but the cuttings should be taken from these plants that have been cut back, or from the sides of stems that have not produced flowers. Chrysanthemums are subject to the attack of a small fly, *Tephritis oenopordinis*, which lays its eggs on the leaves, and the resultant maggot mines between the upper and lower surfaces. A careful examination should be made for these, and as a preventive, the cuttings, before insertion, should be dipped in tobacco-water.

Carnations.—It is rare that the yellow, yellow-ground, and other delicate varieties of Carnations survive the winter if planted out in the open, or allowed to remain in the situations in which they were layered. The layers should, therefore, be carefully lifted with a good ball of earth, and potted singly in 5-inch pots. Good drainage may be secured by putting some soft broken brick and half-inch bones at the bottoms of the pots. Place a small piece of fibrous turf over this, and use for potting a compost of good maiden loam, and sand. The plants may then remain outdoors for a few weeks before removal to a cold pit or frame for the winter. The hardier and stronger-growing varieties may be planted out in borders or beds. Before doing this, dig into the ground some maiden loam, and well decayed manure, and some soot. Having made the beds and borders firm and level, put out the layers at a not less distance than 15 inches apart.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Trenching the Land.—When considerable areas of kitchen garden are to be trenched, advantage should be taken of the dry state of the ground to wheel and neatly stack the manure that will be used on the plot, or on some convenient spots, so as to expedite the work. Refuse, or potting-bench soil, and garden-refuse of all kinds, excepting wood, should also be wheeled on to the land in readiness. This rough sort of rubbish is very useful in lightening heavy soils; but it must be put in two or three spits deep. Trenching should always be carried out piecemeal over the entire garden, in order that good vegetables may be grown, and provision made against a season of drought.

Celery.—The rainfall has been very slight in this district, and not sufficient to reach the roots of Celery in any useful quantity. If no heavy rains fall soon, good applications of water will have to be made, taking care in doing the work not to wash the soil into the hearts of the plants. Furrows should be made along the rows at about 8 inches distant from them, and water poured into these twice or thrice in succession. Continue to mould-up the plants when the stalks are thoroughly dry, and the heart-leaves are a few inches out of the soil. The plants, since the cooler weather has set in, are growing fast.

Turnips.—The plants from the last sowing will require to be singled, and the whole plot stirred with the Dutch-hoe. The bulbs on warm, dry soils, have not been very plentiful, and the flesh has been far from tender and sweet; but on cool, retentive soils, they have been excellent.

French Beans.—Let the useable pods be gathered on alternate days, as frost may come now at any time, and cut off the plants. The rows growing on warm borders for affording a late supply of Beans, should now be protected with hoops and mats, or in other ways. Bracken, if come-at-able, should be stored in quantity for covering Lettuces, Endive, Cauliflowers, cold frames, &c.

Tomatos.—Gather daily all slightly coloured fruits, and lay them thinly in a vinery to ripen. The Tomato crop out-of-doors this year has been a heavy one of good quality; and those raised from early-sown seed, and grown on as single-stemmed plants, have ripened fruit up to a good height.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Late Plums.—The weather having now become cooler and the atmosphere moister, the greater part of the late dessert Plums still hanging on the trees may be gathered, and laid out thinly on the shelves of the fruit-room; or if boxes be used to

gather the fruit in, and they be placed thinly in these, which should be put into a dry and cool place. The fruits should be quite dry at the time of gathering. Before Plums are quite ripe, a few at a time may be brought on successively if placed in a vinery or other warm, dry house. Kitchen Plums, as Monarch and Grand Duke, may remain some time longer on the trees if desired, but if rainy weather sets in it will be better to gather them. Such dessert Plums as Coe's Golden Drop, Brahy's Late Gage, and Reine Claude de Bayay may be kept in good condition for several weeks if preserved carefully as described above.

Blackberries.—The old fruiting growths should now be cut away in a manner somewhat similar to that practised in the case of the Raspberry. The common Blackberry has fruited abundantly in a wild state during the past month, and where these are plentiful there is not the same necessity for cultivating such varieties as *Rubus laciniatus* and others. But as fruit for dessert, the common Blackberry, as grown wild, is not so good. Young strong growths for next year's fruiting should be tied to poles or a trellis, and allowed to hang in a semi-pendulous manner, and should not be shortened. The variety grown by Mr. Mitchell, of Farnham Royal, which received an Award of Merit at the Drill Hall last year, appears to be an improved form of the common Blackberry, producing larger fruits, which are borne profusely on strong pendulous growths.

Preparing Ground for Planting Fruit-trees.—The long drought has made digging and trenching difficult, and where it is intended to do a considerable amount of planting, the necessary double digging of the land must wait for a heavier rainfall. Avoid the practice of taking out circular holes of medium size to plant trees in, while the surrounding soil is left hard and in a state difficult for the roots to penetrate. The ground should be trenched throughout, and if the soil be of a heavy nature it will be necessary to have a good dressing of lime, or lime-rubbish and wood-ashes, incorporated as the work proceeds. If the varieties to be planted have been decided upon, the trees should be obtained from the nurseryman well in advance of planting time. If the selection be made at this date, the condition of the trees may be noted before the leaves fall, and the purchaser will know precisely the kind of trees he will receive as soon as it is possible to lift them in October or early November.

PLANTS UNDER GLASS.

By G. R. FIELDER.

Stephanotis floribunda.—Plants which have completed their growth should be afforded as much air and light as is possible without causing injury to other plants occupying the same house. This is necessary for the thorough maturing of the shoots, upon which successful flowering largely depends. The shoots should be thinly disposed upon the trellis, and where there is crowding the weaker growths should be removed.

Allamandus.—Plants which flowered early may be placed in a house where the temperature does not fall below 55°, in order to rest them. The ends of the shoots should be shortened slightly, which will allow the air and light to reach the remainder of the wood more readily. The amount of water should be gradually reduced until the plants are quite at rest, when they should be kept dry at the roots, or at the most should only receive water occasionally. It is not safe to rest Allamandus in a temperature lower than 55°. Late-blooming plants trained to balloon trellises should receive the final tying-in when the flower-buds can be discerned upon the ends of the shoots. At this season, they should be afforded a position in the stove where they will be fully exposed to the sun, otherwise the flowering will be unsatisfactory. Plants whose pots are filled with roots should be afforded weak manure-water once or twice a week.

Anthurium Scherzerianum.—When these plants have finished their growth they should be placed at the cool end of the stove in order to rest, or still better in an intermediate-house having a minimum temperature of 55°. While resting in this lower temperature the amount of water afforded to the roots must be considerably reduced, otherwise loss of roots will occur. Plants which have been rested in this way during the winter come quickly into flower when they are again placed in heat.

Gardenias.—Cuttings may be inserted to form plants for flowering in small pots in the late spring. Strong cuttings with not too firm a base should be selected, and inserted singly in small pots filled with sandy soil, and plunged in a moist, warm propagating frame, where they will strike readily. The plants should then be potted, and placed near the glass in the stove, and the points of the shoots pinched out occasionally, in order to produce bushiness. As soon as sufficiently well rooted, the plants should be shifted into pots one size larger, and subsequently into 5-inch or 6-inch pots, in which size they may be allowed to flower.

FRUITS UNDER GLASS.

By W. STRUGNELL, Gardener to Lieut.-Col RALPH VIVIAN, Rood Ashton, Trowbridge.

The Early Peach-house.—The foliage being nearly matured on those trees which were started at the end of last year, it may be detached by lightly brushing the shoots in an upward direction with a new birch-broom. If any planting or re-arrangement of the trees is to be carried out this year, the present affords the best time for the work. It is not advisable to transplant trees that are still in active growth, or the leaves may drop prematurely, and the trees be weakened. In any case, much care should be taken to preserve the roots from damage, and to afford water copiously at the time of planting. The formation of new roots is greatly assisted if a few leaves are left on the trees. If a tree be removed from out-of-doors to the Peach-house, or is merely lifted in the house while still in leaf, it should be shaded during the day, and syringed often in order to keep the foliage fresh. In removing large trees from the open to early Peach-houses, a trench should have been dug out round the ball some time ago, and partially filled in with light soil. Alexander and Waterloo, although they are fine early Peaches, are untrustworthy for forcing early, but are good varieties for starting slowly in February, or better still in March. When forced early, the buds drop in a most disappointing manner. Amsden June Peach, though smaller than either, is a more satisfactory variety as an early forcer; and Hale's Early and Early Gross Mignonne are good for succession. Alexander and Waterloo are very quick in ripening after stoning, and they may be forced hard after the fruits are well developed. In the maintenance of a continuous supply of early fruit it is not well to plant the early division with too many of the earliest kinds. This is only advised when there is a number of houses which may be started at short intervals of time. Every early Peach-house should include a tree of Cardinal, Early Rivers, Lord Napier, or Elruge Nectarines. If the wood of a Peach or Nectarine-tree has a tendency to grossness, now is the time to root-prune. Young trees are very prone to make much robust wood, especially in newly-made borders. As soon as the leaves are removed, pruning and training may begin, then the roof should be cleaned, and the walls lime-washed. If scale, mealy-bug, thrips, or red-spider, have been present, hot-water and petroleum may be employed at the temperature and strength previously directed, and in bad cases a dressing of some approved insecticide should be applied. Finally the surface-soil should be removed from the border, not, however disturbing the roots, and a quantity of new soil—turfy loam if it be procurable—or some good garden-soil, together with a sprinkling of charred garden refuse, and mortar rubble substituted for it. In the case of old trees, a dressing of artificial manure may be spread on the bare surface before the new soil is spread. The house should be thrown open for some weeks longer. If any plants in pots are placed in the early Peach-houses, they should be such as will endure continuous ventilation without harm.

Other Fruit-houses.—Where shading has been employed, this may now be removed, and the trees fully exposed to sunlight. If the borders are suspected to be deficient in moisture, remove the surface-soil forthwith, and afford water copiously so as to reach the bottom, and run from the drains.

A NEW GAZETTEER.—A cheap edition, in sixpenny weekly parts, is about to be issued of Cassell's Gazetteer of Great Britain and Ireland. The work is very fully illustrated from authentic photographs, and will contain sixty maps in colours. Part 1 will be ready on October 4.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR OCTOBER.

MEETINGS.

THURSDAY,	OCT. 5	Annual Dinner of the United Horticultural Benefit and Provident Society, at Holborn Restaurant.
TUESDAY,	OCT. 10	Royal Horticultural Society's Committee. National Rose Society's Committee. Royal Horticultural Society of Ireland.
TUESDAY,	OCT. 24	Royal Horticultural Society's Committee. National Chrysanthemum Society's Floral and Executive Committees.
SHOWS.		
TUESDAY,	OCT. 10	National Chrysanthemum Society's Exhibition at Royal Aquarium (three days). Taunton Chrysanthemum and Fruit (2 days). Southampton Chrysanthemum (two days).
TUESDAY,	OCT. 31	Wolverhampton Chrysanthemum Society's Exhibition (three days). Torquay Gardeners' Association: Chrysanthemum Exhibition (two days). Teignmouth Chrysanthemum.

SALES FOR THE ENSUING WEEK.

MONDAY,	OCT. 2,	and the following Tuesday, Wednesday, Thursday, and Friday, Dutch Bulbs at Protheroe & Morris' Rooms.
TUESDAY,	OCT. 3.	Important unreserved sale of thousands of bedding and hardy border Plants and Bulbs in immense variety, at the Hale Farm Nurseries, Tottenham, by order of Messrs. Thomas S. Ware, Ltd., by Protheroe & Morris, at 11 o'clock.
TUESDAY,	OCT. 3.	Important unreserved sale of Nursery Stock at the Matlock Nurseries, Matlock Bank, by order of Mr. C. H. Harris, by Protheroe & Morris at 12 o'clock. Two days.
WEDNESDAY,	OCT. 4.	Annual important unreserved sale of Nursery Stock at the Tunbridge Wells Nurseries, Tunbridge Wells, by order of Messrs. Thos. Cripps & Co., by Protheroe & Morris at 12 o'clock. Two days.
THURSDAY,	OCT. 5.	Important sale of Freehold Land in large and small lots on the New Hall Estate, Hockley, by Protheroe & Morris, at 2 o'clock.
FRIDAY,	OCT. 6.	Important and Established Orchids at Protheroe & Morris' Rooms.

FRUITS AT
THE CRYSTAL
PALACE.

We have frequently remarked that in an exhibition such as that now being held at the Crystal Palace, one does not obtain a perfect illustration of the extent or quality of the year's fruit crops. Other sources of information, and the returns furnished by our correspondents and published in these columns on August 5, prove the crops of Apples, Pears, and Plums throughout the country to have been very much below the average. But this is not so much evident at the show. There are as many exhibitors this season as on the last occasion, though the number of entries from these exhibitors is a little less. In the single dish classes, the falling off that was recorded last year is continued this season to a greater degree, but there are more entries in classes for collections. It is curious that Pears are shown quite as well as Apples. But be the season never so unfavourable, it is always possible to make a fairly good display at an exhibition; and although the quality of Apples and Pears is not so good as we have previously noted at the Palace, the difference is only such as would be noticed by a fruit cultivator after careful observation. Grapes were not specially remarkable. There were some excellent exhibits, but some classes were weak.

The good effect that such exhibitions may have in the promotion and encouragement of high-class fruit cultivation may be imagined from the fact that the show is visited by nearly 29,000 people annually. A debt of gratitude is therefore due to the Royal Horticultural Society, the Crystal Palace Company, and to the gentlemen who in the aggregate have subscribed the £100 which the Society stipulates must be guaranteed each year before it will accept the responsibility of the Show.

Sir TREVOR LAWRENCE, Bt., presided over the Gardeners' Luncheon, and there being so many gardeners present, the opportunity was taken to publicly present to Mr. JAS. DOUGLAS the Victoria Medal of Honour.

As we have previously announced, Mr. DOUGLAS has been chosen by the Council of the Royal Horticultural Society to fill the vacancy in the sixty Medallists caused by the regretted death of Mr. MALCOLM DUNN.

In making this presentation, Sir TREVOR LAWRENCE paid a very deserved tribute to the memory of this eminent Scottish gardener. Not only was he a good friend to ourselves, to horticulture, to the Royal Horticultural Society, but he was a friend to all gardeners. But to whatever extent we may have cause to regret such losses, the duty remains to carry on the work that those we mourn were engaged in, and to fill positions that they have relinquished. The selection of Mr. DOUGLAS will be a very popular one. He would doubtless have been included in the first sixty had he not at the time been a member of the Council of the Royal Horticultural Society.

In former days Nature was supposed to be "absolutely perfect" in all her ways, and everything had its use, and was used. Anything like waste was thought to be impossible, as unworthy of her methods of procedure. A more careful investigation shows that waste is really enormous. By waste, I mean loss of structures which evince some definite purpose, are produced in profusion, but yet in innumerable instances they have no opportunity of being put to their uses, and perish.

The cases most evident are connected with the reproductive organs; roots and leaves are put forth in response to stimuli arising within or without the plant, and scarcely fall under this category; but regarding flowers, fruit and seed, as the means of propagation, it is among these that probably few persons realise the vast amount of energy displayed in their production compared with the feeble results which often ensue.

It was on the assumed superabundance of offspring produced, that the theory of natural selection, as a means in the origin of species, was based; but few statistics were forthcoming to test the truth of the hypothesis—or if it were true in some cases, whether it was true in all. Let us consider a few instances, and first, with regard to the quantity of pollen produced. It is believed that the nucleus of a single pollen-grain can impregnate a germ-cell, and so give rise to an embryo in a seed. But numerous flowers bear but one seed in the ovary-cell, as of the largest families, Composite and grasses. In each floret of the former there are five stamens, and each of which produces an abundance of pollen-grains. Labiate and Boraginaceae produce at most four seeds in each flower, accompanied by four or five stamens respectively; the Spurge-Laurel bears one seed and has eight stamens; and so all through the flowering world, numerous other examples may be mentioned, especially perhaps, among the Conifere, the pollen of which is often wafted away, as from a Fir-tree, like a cloud of sulphur, and is lost in the breeze.

Again, although a plant, herb or tree, may bear a profusion of flowers, the proportion of fruit is often almost infinitesimally small compared with it. Take our Horse-Chestnuts, Lilacs, Elms, and Limes, what a wealth of blossom they bear, yet on each spike or cluster of the first two, one or two fruits remain to bear witness to their former glory, while the half-formed fruits of the last two fall without perfecting a seed. Especially is this the case with Orchids. Mr. FITZGERALD records the observation that in a particular plant of *Dendrobium speciosum* (the "Brisbane Lily") there were no less than forty thousand flowers open at the same time on that plant; but though the plant was growing in the open air, and was open to the visits of insects, only one flower produced a seed-pod.* Mr. FORBES and Mr. RIDLEY both observed that it was the self-fertilising species of Orchids which alone can be trusted to set any quantity of seed.†

Few of us were aware of the great preponderance of abortive fruits and seeds borne by many plants, and Dr. J. W. HARSBERGER ‡ has done good service in calling our attention to this matter, and correcting our erroneous and preconceived notions on the subject. During several summers he has taken statistical observations, in order to determine what was the successful termination of the act of fertilisation. He did not take into account all of the factors concerned, such as the weather, which, of course, influences seed-production, nor how far the plants were shaded, which condition reduces the flowering process; nor, again, the number of insect visitors, &c. Still, his tables possess much value.

Taking a perfect fruit as one well matured, and an abortive fruit as more or less shrivelled and seedless, he found that in *Ariseia tri-*

SARDON

A. S. S.

FIG. 91.—FRUIT-TREE ARCH IN THE GARDENS OF W. M. CAVALLET, ESQ., FAIRLAWN PARK, TONBRIDGE, KENT. (SEE P. 266.)

phyllum, Torr., of thirteen plants there were one hundred and forty-four perfect, but five hundred and thirty-seven abortive fruits, or only twenty per cent. of the former.

Of *Rhododendron* (*Azalea*) *nudiflorum*, Torr., there were only four perfect fruits on two plants, but there were ninety abortive.

Of *Cornus florida*, L., of thirty-four clusters on one bush there were two hundred and eighteen perfect, and four hundred and fifty-three, or a little over thirty-two per cent., of good seed.

Of *Yucca filamentosa*, L. (Adam's Needle), the author observes:—"This Liliaceous plant is of considerable interest from a biological standpoint, owing to its dependence upon the moth *Pronuba yuccasella*, Riley, which passes part of its larval existence in the capsule of the plant, feeding upon the seeds. The moth, previous to depositing its eggs in the soft ovary, pollinates the stigma by placing a ball of pollen from the same flower between the three stigmatic lobes. This insures the production of good seeds, on which the larvæ feed." In the tabulation of the results in which, besides the numbers of good and aborted seeds, he gives the number devoured, &c., the final result of observations upon eight capsules, each of which contains six rows of seeds, is that about thirty-five per cent. remain good for propagation.

Of *Pimpinella integerrima*, Benth. & Hook., six plants were examined, carrying one hundred and seventy-four umbels. Of these about eighty per cent. of good seed was the result. Lastly, of *Hibiscus moschatatus*, L., as in the last instance the preponderance was in favour of good seed, being about seventy-five per cent.

Horticultural
and Agricultural
Exhibition at
Buda-Pesth.

THE HUNGARIAN AGRICULTURAL SOCIETY, we are informed, would have held an exhibition last year under the patronage of the Minister of Agriculture, but owing to the sad death of the Empress ELIZABETH, it was postponed for a year. We now learn that an exhibition has been arranged by the Committee of the Hungarian Agricultural and Horticultural Society of Hungary for fruit and garden productions, and that the undertaking will receive the utmost amount of support from H. V. DARANYI, the Minister of Agriculture. It is arranged to take place from October 7 to 15 of the present year in the Halls of the Commercial Museum, Buda-Pesth. The exhibits may comprise fresh and preserved fruits and vegetables, flowering ornamental plants and bushes, fruit-bushes and trees, cut flowers, Roses, samples of the bouquetists' art, Grapes, worked Vines, and fruit-trees in pots. Hungarians may take part in all of these competitions; but one of the objects of the exhibition being the improvement of the fruit trade of the country, there will be an international section for machinery and implements of use in the manufacture of fruit conserves of all kinds, and the like products, in which section foreign manufacturers may likewise take part. In this section there may be exhibited fruit-drying ovens, fruit-boilers, cider and other fruit-mills and presses, fruit-peeling and cutting-machines and instruments. The prizes to be awarded in this section consist of gold, silver, and bronze State medals, given by the Ministry, besides silver and bronze medals of the Society. No charge will be made for stands, but the exhibitor has to look after his own exhibits, and

pay the costs of transit. When the exhibition is at an end, a sale of the various productions and articles will take place.

Applications for space must be made to the Exhibition Committee, in Ungarischen Landesgarten Bauverein, IV. Ker. Koronaherczeguleza 16, Buda-Pesth.

FRUIT-TREE ARCH AT FAIRLAWN, TONBRIDGE.

—Our illustration on p. 265, shows an extensive fruit-tree arch in the gardens belonging to W. M. CAZALET, Esq., Fairlawn Park, Tonbridge, Kent, the photograph being taken when the trees were in full bloom last spring. The splendid bearing condition of the trees is seen by the number of fallen petals that strew the path; the trees being at the same time wreathed with blossoms. The archway was made about 1873, shortly after the present gardener, Mr. FENNELL, had succeeded Mr. CHAS. ROSS, now at Welford Park. Such archways as that illustrated may be recommended as a means of cultivating the choicer kinds of Apples, and almost all varieties of Pears. Better finish, colour, and size may be obtained in fruit so grown, than on bush trees, indeed, they rank next to a brick wall as an aid to fruit growing. Another advantage possessed by espalier trees over the bushes is that the fruits are not liable to be blown off, and they can be easily gathered. If cordon trees be used, a large space may be soon furnished with wood; and if the trees are planted intelligently and in a suitable situation, they will bear enormous crops of fruit of the finest quality. But we would not in respect to these arches or any trellis advise that cordons be crossed over each other, to form trees known as the "Diamond" cordon. It may be mentioned also that a fine fruit-tree arch is a pleasant feature in a large garden, and a feature much prized in some of our oldest and best fruit-growing establishments. At Barham Court, Maidstone, Mr. WOODWARD prefers to allow his trees more freedom of growth than such a system permits; but his garden is in such an unusually favourable situation as to be quite an exception. We shall publish further notes upon Fairlawn Gardens in an early issue.

A COMPLIMENTARY DINNER has just been given to the heads of the firm of Messrs. ED. WEBB & SONS, Wordsley, Stourbridge. The event, which took place in the Talbot Assembly Rooms, Stourbridge, was very largely attended by influential gentlemen of the district, the chair being taken by Sir H. FOLEY LAMBERT, Bart. The cordiality that characterised the proceedings illustrated the respect entertained for Lieut.-Colonel W. G. WEBB and Mr. EDWARD WEBB, and the firm generally.

PUTNEY, WANDSWORTH AND DISTRICT CHRYSANTHEMUM SOCIETY.—The approaching show of this flourishing suburban Society will be held on November 9 and 10 at Putney. In addition to numerous money prizes, there will be offered a Challenge Cup for the best collection of sixty blooms. Mr. J. F. McLEOD, gardener, Dover House, Roehampton, is the Hon. Sec.

FREDERICH ABEL, Secretary to the Imperial Royal Horticultural Society of Vienna, celebrated his fortieth year's jubilee as a gardener on the 18th inst.

GASTON TISSANDIER.—The death is announced of M. GASTON TISSANDIER, the author of a number of scientific works, and the founder of *La Nature*. He was a member of many scientific societies in France, and a vice-president of the French Meteorological Society.

THE SURVEY OF LAKE TANGANYIKA.—The *British Central African Gazette* (July 24), published at Zomba, announces the arrival at Nyasa of Mr. J. E. S. MOORE, who visited Lakes Shirna, Nyasa,

and Tanganyika in 1896, under the auspices of the Royal Society, to survey the basin of Lake Tanganyika, to collect specimens of the aquatic fauna and flora, and to study the geological history of this portion of Central Africa.

ANALYSES OF SOIL.—We learn from *Nature* that the Dorset County Council has set a good example in arranging for a series of reports with analyses of the soils of the county. The work has been carried out in Reading College under the superintendence of Mr. DOUGLAS A. GILCHRIST; and the soils have been analysed by Mr. C. M. LUXMOORE and Mr. A. M. RYLEY. The results so far obtained and published in the journal of the College are full of interest, and likely to prove of much practical importance.

THE ABERDEEN BOTANIC GARDENS.—A visit to these gardens the other day showed that fair progress is being made everywhere. Thanks to the assiduous attention of Dr. TRAIL, Professor of Botany in Aberdeen University, the Curator of the Gardens, assisted by Mr. STRACHAN, the gardener in charge of the whole place, and whose flower and market garden has been absorbed in the formation of the Botanic Gardens, matters are now assuming a very favourable appearance. The propagating garden shows a large selection of plants in a very fair condition. Included in the collection are some fine Conifers, Ivies, &c. A rockery is being formed alongside the main walk at the entrance. Rows of trees are to be planted round the propagating garden, and shrubberies are to be formed in triangular sections in the eastern portion of the public garden. Progress is being made with the new Botanical Museum, which is now approaching completion. Besides the new specimens which are to find a home here, the fine botanical collections at present in Aberdeen University are to be removed thence. It is expected that possession of the museum will be taken on Whitsunday, 1900.

JAMAICA PRODUCE, ETC.—In our last, we briefly noted the fact that an association had been projected in Glasgow for the purpose of assisting in the development of the fruit trade between Jamaica and this country, and for other objects in connection with the revival of industries in the ever-beautiful islands of the West Indies. With the commercial aspect of the matter we have nothing to do, but it is pertinent to the subject to ask if all has been done for the Sugar industry that it is possible to do? This has been denied, and it is affirmed that, properly managed the Sugar planters of Jamaica, &c., need have no fear of bounty-fed sugar—that the West Indies can give the European Beet-grower the difference of the bounty, and beat him in the race for a paying market. The late Mr. J. C. MORTON used to say, that what the arable and pasture-land in the old days stood in need of was brains! perhaps cane-land and Sugar-making stand to-day in need of the same. There are not wanting men in the West, and here in the East, who affirm that, with a better variety of cane, thrice the quantity of juice could be expressed, and placed on the consumers' table at far less cost than now obtains. A cleaner, better manured soil, a better variety of Sugar-cane, more powerful machinery in central mills, with good roads, and better steam service—these, it is claimed, would revolutionise the trade and the island! What has been done for and by the farmer and grazier here, should be done in degree for and by the planter in the Sugar-growing districts. What is the prize to be striven for? The favourite place and highest price on the British market, with peace and content to all engaged in the business.

IS IT ELECTRICITY?—An extraordinary phenomenon has been noticed with regard to the Chestnut trees in the Avenue Louise, Brussels, since the installation of the electric trams. Their foliage begins to turn brown and drop early in August, and the trees to bud, and even to blossom

again in October. The trees on the opposite side to the tramway behave like ordinary trees, for they lose their foliage in the late autumn, and do not put forth fresh blossom until the spring. Intelligent persons are inclined to believe that the cause of this singular state of things is due to the electrical current which passes underground acting upon the roots of the trees, which are otherwise quite healthy.

CACTUS DAHLIAS AT CHISWICK.—A somewhat large and representative collection of Cactus Dahlias has been grown at Chiswick, but as the plants were not put out until the end of June, through being received so late, and, further, as the effect of the hot weather was to arrest development, the plants were unusually late in developing flower-buds; and when on the 22nd inst. the Floral Committee made a visit of inspection to Chiswick, they found but little expanded bloom, though were the next fortnight or three weeks to be fine and warm, there would doubtless be a rare display of blossom, but at that late season of the year the habit of growth of the varieties could not be correctly estimated. The Floral Committee agreed upon a recommendation to the Council that a further trial of the leading varieties of Cactus Dahlias should be attempted next season; that raisers should be requested to send new varieties so that they may be compared with the older ones; and that those sending varieties for trial should be requested to do so as early as possible in the month of May, so that the plants may be potted and grown to a good size before planting them in the first or second weeks of June.

PUBLICATIONS RECEIVED.—*Journal of the Society of Arts*, September 22.—*Queensland Agricultural Journal for August*.—*Phanerogamae et Pteridophyte Japonice Iconibus Illustratae*, by T. Makino, Imperial University, Tokio. Text in Japanese, with some woodcuts.—*Cryptogamae Japonice*, by J. Makimura and M. Miyoshi, Imperial University, Tokio.—*The Journal of the Board of Agriculture*, vol. vi., No. 2. This issue contains articles on manuring of Potatoes, as carried on in various places in England and Scotland. The detailed schemes of the trials at the four centres were directed, *inter alia*, to the elucidation of, 1st, the influence on the Potato crop of supplementing dung with artificial manures; the effects of using artificials alone and in combination with dung; the effects of the omission of nitrogen, phosphoric acid, and potash, respectively, from a complete manure containing all three; the effects of increasing nitrogen, phosphoric acid, and potash respectively, in a complete manure; and the relative values of sulphate of ammonia and nitrate of soda. Other articles deal with Tree-root Rot, the Ash and its Cultivation, Imports of Cereals, Marketing of Eggs.—*Georgia State Board of Entomology*, Bulletin No. 1, 1899.—*On Biastrepis in its Relation to Cultivation*, by Hugo de Vries, Professor of Botany in the University of Amsterdam.—*The Tropical Agriculturist*, Colombo, A. M. & J. Ferguson.—*Anne Pratt's Flowering Plants, &c., of Great Britain*, Nos. 15 and 16, vol. ii.—*Journal of the Society of Arts*, September 15.—*Transactions and Proceedings of the Botanical Society of Edinburgh*, parts i., ii. and iii., vol. xxi.

SOCIETIES.

ROYAL HORTICULTURAL.

SEPTEMBER 26.—A meeting of the Committees of this Society was held on Tuesday last in the Drill Hall, James Street, Westminster, and considering that it was almost the eve of the fruit show at the Crystal Palace, there was a good display of exhibits. Orchids were not numerous, and the Orchid Committee recommended only two awards to novelties: one of these to a variety of *Cattleya* from T. W. THORNTON, Esq., Weedon; and the other to a variety of *Odontoglossum*, named "Bassano," from WALTER COBB, Esq., Tunbridge Wells.

The exhibits before the FLORAL COMMITTEE included a very extensive exhibit of *Codiaeums* from Mr. H. B. MAY, Edmonton; a group of well grown fine foliage plants from Sir HENRY TATE's garden at Streatham; several exhibits of Dahlias; a few cut blooms of *Chrysanthemums* from Mr. WELLS; a group of Ferns from Messrs. HILL & SONS, and some miscellaneous exhibits. Awards of Merit were recommended to two Cactus Dahlias—*Augustus Hare* and *Madame Medora Henson*, and to *Caryopteris mastacanthus*, a very pretty hardy flowering shrub.

The FRUIT and VEGETABLE COMMITTEE recommended an Award of Merit to *Pear Triomphe de Vienne*, a variety that has been in commerce several years, and of which Mr. GEO. WOODWARD, Barham Court Gardens, Maidstone, sent excel-

lent fruits; and to two new Potatoes that had previously been tried at Chiswick.

In the afternoon, a Lecture by Mr. E. LUCKHURST upon "Instructional Fruit Centres" was read by the Secretary, Rev. W. WILKS, M.A. Mr. Luckhurst's paper described a deal of useful educational work that has been done in Derbyshire under the auspices of the County Council.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. C. T. Drury, H. B. May, R. Dean, W. Howe, C. J. Salter, J. Jennings, Chas. E. Pearson, J. W. Barr, T. W. Sanders, E. H. Jenkins, E. T. Cook, Harry Turner, Geo. Paul, H. M. Arderoe (Cape Town), H. Selfe-Leonard, D. B. Crane, and George Gordon.

FINE FOLIAGE PLANTS.

A group of fine foliage plants, which covered a large area of the floor space, was shown by Mr. W. Howe, gr. to Sir HENRY TATE, Bart., Park Hill, Streatham Common. The large specimens of Bamboos, *Codiaeums*, Palms, *Cordylines*, *Aralias*, *Asparagus*, Ferns, &c., all showed the effect of first-class cultivation. It would have been of use to visitors to the hall had names been attached to the varieties of *Codiaeums* and *Cordylines* (Silver-gilt Banksian Medal).

A magnificent collection of *Codiaeums*, in 5, 6, and 7-inch pots, was shown by Mr. H. B. MAY, Dyson's Road Nursery, Upper Edmonton. This exhibit filled the whole of one side of one of the long central tables, and included as many as sixty varieties. There was one new one called *Golden Gem*, with leaves about 1 inch wide, the centre of each golden yellow, with mottled-green and yellow margins. The petioles of the younger leaves are bright red in colour, and this affords a pretty effect. In a few instances the margins of the leaves have wavy outlines. Of the narrower-leaved varieties specially noticeable in the collection were the varieties *Mrs. Dorman*, *ruberrimus*, distinct in that it affords more red colour than other varieties; *superba*, *Imperialis*, *aurea*, *Flambeau*, and *Aigburthensis*. Of the broader-leaved varieties we noticed *Sunbeam*, *Flamingo*, *Baron Frank Selliere*, *Mortii*, *Thomsoni*, *Reidi*, &c. (Silver-gilt Banksian Medal).

MESSRS. F. SANDER & CO., St. Albans, showed a number of plants of *Dracaena Sanderiana*, and *D. Godseffiana*, *Acalypha hispida*, *Linospadix Patrickiana*, &c.

DAHLIAS.

Mr. JAMES STREDWICK, Silverhill Park, St. Leonards, showed eighteen very choice varieties of Cactus Dahlias, the blooms being of fine quality. Some of the most charming were *Autumn Queen*, a mauve flower; *Mrs. Sanders*, pure yellow, large well-formed flower; *Augustus Hare*, crimson, with purple hue; *Magnificent*, Countess of Lonsdale, and *Mary Service*, orange colour and mauve (Bronze Banksian Medal).

Mr. S. MORTIMER, Rowledge Nurseries, Farnham, Surrey, showed some capital Dahlia blooms. There were 120 show blooms of much merit, and nearly fifty bunches of Cactus blooms (Silver Flora Medal).

Mr. THOS. S. WARE, Ltd., Hale Farm Nurseries, Tottenham, made a display, showing *Pompon*, *Decorative*, *Single*, and *Cactus* varieties. Also many of the perennial Asters were exhibited by Mr. Ware (Silver Banksian Medal).

CHRYSANTHEMUMS, CANNAS, CARNATIONS.

Mr. W. WELLS, Earlswood, Redhill, Surrey, showed fine cut blooms of some of the best early-flowering varieties of *Chrysanthemums*. *Victor Mew*, a pale sport from *Mrs. Hawkins*; *Mlle. M. Massee*, *Jules Mary*, *Market White*, a valuable novelty of last season; *Madame Leger Ligneau*, a yellow Japanese variety that should be valuable, &c.

Mr. W. J. GODFREY, Exmouth, showed plants in flower of *Carnation Mrs. Geo. Foster*, a large yellow, winter-flowering variety, but with rather indifferent calyx. Mr. GODFREY also showed a few plants of a yellow sport from Lady Fitzwigram *Chrysanthemum*.

The newer strain of large-flowering Cannas was well illustrated by a collection of cut flowering sprays shown by Mr. A. H. BICKWOOD, gr. to the Dowager Lady FRAKE, Fulwell Park, Twickenham. There were upwards of forty spikes in this collection, which included such varieties as *Burbank*, *Austria*, *Alemania*, and the fine spotted variety *L. E. Bailey*.

MISCELLANEOUS.

MESSRS. J. HILL & SON, Lower Edmonton, London, showed a handsome group of Ferns upon the floor of the hall. The plants were fine specimens of varieties of *Asplenium nidus*, and the largest plant particularly, with its large, broad leaves, and deeply-coloured, prominent rib, had a grand effect. It is a fine species for decorative work where space is not greatly limited. A few *Adiantums* and *Selaginella* interspersed between the specimens afforded relief (Silver Flora Medal).

MESSRS. W. H. ROGERS & SONS, Ltd., Bassett, Southampton, showed plants of *Retinospora pisifera aurea*, and *R. p. a. Rogersii*, the latter as shown, being more golden in colour. Also a variety of *Skinimia oblata*.

MESSRS. JAS. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, showed plants of *Caryopteris mastacanthus*, with pretty blue flowers; *Hydrangea Hortensis Mariesii*, and *Nandina domestica*. The latter is a Berberidaceous plant, hardy in warm situations; it produces berries about the size of Peas, and the compound leaves at this season are of a reddish tint, being very attractive.

MESSRS. BARR & SONS, King Street, Covent Garden, London, made a fine show with hardy Perennial flowers. Some of the Asters were well represented; also *Kniphofia Pfitzeri*,

K. Leichtlini var. *distachya*, *K. corallina superba*, *K. hybrida nana*, and the large-flowered "Triumph;" also early-flowering *Chrysanthemums*, and a variety of hardy flowers. Messrs. BARR & SONS showed plants in flower of *Zauschneria californica* and *C. splendens*.

MESSRS. HUGH LOW & CO., Bush Hill Park Nurseries, Enfield, showed varieties of *Statice prostrata*, in pots. Also a few plants of the elegant *Palu*, *Kentia (Zonia) Veitchii*.

Awards.

Caryopteris mastacanthus.—A half-hardy Verbenaceous flowering shrub, growing about 2 feet high; a very old species, having been introduced from China in 1844. The leaves are about 2 inches long, ovate, oblong, toothed or serrated, and downy on the under surface. Flowers violet, or violet-blue, produced in axillary, many-flowered peduncles. Shown by Messrs. BARR & SONS and Messrs. JAS. VEITCH & SONS (Award of Merit). (See fig. 30 in *Gardeners' Chronicle*, February 2, 1884.)

Dahlia Augustus Hare (Cactus).—A fine flower, with slightly incurving petals; colour scarlet or crimson, the shade of colour of different flowers varying very considerably. From Mr. J. STREDWICK (Award of Merit).

Dahlia Medora Henson (Cact. s.).—A bright crimson flower, with purple shading; good form. From Messrs. T. S. WARE, Ltd., Tottenham (Award of Merit).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. J. Gurney Fowler, De B. Crawshaw, S. Courtland, J. Gabriel, W. H. Young, H. J. Chapman, F. J. Thorne, E. Hill, J. Jacques, W. Cobb, J. Colman, and Jas. O'Brien (Hon. Sec.).

Orchids formed the prominent feature of the meeting. Messrs. J. VEITCH & SONS, Ltd., Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Flora Medal for a very fine group, in which hybrid *Cattleyas*, *Laelias*, and *Laelio-Cattleyas*, of their own raising, were to the fore. As at several recent meetings of the Society, the varieties of *Laelio-Cattleya* × *callistoglossa* (*L. purpurata* × *C. Warscewiczii*), of which there were many specimens, including the handsome *L. C. × callistoglossa ignescens* were the most showy. We may also mention the pretty novelty, *Cattleya* × *Chilce*, a plant with a nearer resemblance to *C. bicolor*, one of its parents, than to the other, which is *C. Bowringiana*. The sepals and petals are of a rosy-purple tint; the comparatively small side lobes of the lip, a light rose; and the front lobe, a bright purple colour. Other remarkable plants in the group were *Laelia* × *splendens* (*crispa* × *purpurata*), *Laelio-Cattleya* × *Fortuna* (*L. C. Schilleriana* × *C. Mossiae*), *Cattleya* × *Patrocinii*, a pretty plant introduced as a natural hybrid, but apparently identical with *C. × hybrida* flowered by Messrs. Veitch in 1854 from a cross between *C. Loddigesii* and *C. guttata* var. Some good *Cattleya labiata*, *C. granulosa*, *C. bicolor*, *C. Loddigesii*, *Dendrobium Phalenopsis Schroderianum*, *D. superbiens*, *D. Dearii*, *Zygopetalum maxillare*, *Houlletia Brocklehurstiana*, *Brassavola nodosa*, *Angraecum articulatum*, and a number of fine *Cypripediums*; both hybrids and species were shown by Messrs. VEITCH.

C. H. FEILING, Esq., Southgate House, Southgate (gr., Mr. Canham), was awarded a Silver Banksian Medal for a very tastefully-arranged and extensive group, in which many well-flowered plants of *Dendrobium Phalenopsis Schroderianum* were a marked feature; also *Cattleya Gaskelliana*, *C. guttata*, and other *Cattleyas*, *Miltonia Clowesii*, *Laelia pumila*, *Dendrobium formosum giganteum*, and a number of good *Cypripediums*, &c., were shown.

MESSRS. HUGH LOW & CO., Clapton, staged a fine group, in the background of which were two *Oncidium Marshallianum*, some fine blue *Vanda cerulea*, *Oncidium phymatorhizon*, *O. Cartaginense*, and other tall-growing species. Fronting them were nice plants of *Oncidium incurvum album*, a rather rare variety; *O. ornithorhynchum album*, *Cattleya Gaskelliana*, of a pure white; and also some well-coloured forms of *C. labiata*, *Laelio-Cattleya* × *elegans*, *L. C. × Schilleriana*, *Cattleya* × *Minucia*, *Odontoglossum grande*, and other *Odontoglossums*, *Cypripediums*, &c. A Silver Banksian Medal was awarded.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed *Cattleya* × *Hardyana* "Rosslyn" variety, a very large and handsome coloured flower, of fine form.

The Rev. F. FAYNT, Stoke Hill, Guildford (gr., Mr. Cooke), sent a fine yellow form of *Odontoglossum grande*, in which the usual chestnut-brown colour seen in the species was absent; also a *Laelio-Cattleya* between *L. C. × elegans* and *C. Lawrenceana*, which closely retained the form and colour of the first-named.

WALTER COBB, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes), showed *Cattleya* × *Hardyana*, "Cobb's" variety, with very brightly-coloured flowers, showing a rich colouring of yellow on the lip; also *Odontoglossum crispum* "Bassano." R. I. MEASURES, Esq., Cambridge Lodge, Cumberwell (gr., Mr. H. J. Chapman), showed *Cypripedium* × *Lachmea* (*ciliolare* ♀, *superbiens* ♂), having a large flower with the colouring of *C. superbiens*.

HENRY LITTLE, Esq., Baron's Hall, Twickenham (gr., Mr. Howard), showed the fine *Laelio-Cattleya* × *elegans* *Littleana*, which secured a First-class Certificate when first shown by Mr. Little, in August, 1885. The variety is distinguished by its brilliant colour, and the more ample and trumpet-shaped lip. The exhibit on this occasion was interesting, as affording another instance that Orchids need not degenerate if taken care of. Mr. LITTLE also showed *Cypripedium Sanderianum*.

T. B. HAYWOOD, Esq., Woodhatch Lodge, Reigate (gr., Mr. C. J. Salter), showed the fine *Cypripedium* × *Fowlerianum*, Haywood's var. (*Harrisianum* superbum × *bellatulum*), together with flowers of both plants.

Major JOICEY, Sunningdale Park, Sunningdale (gr., Mr. F. J. Thorne), showed a finely grown plant of *Dendrobium taurinum* amboinense, a remarkable colour variation of the type; originally imported by Messrs. J. Veitch & Son. The plant bore a fine inflorescence of large, Indian-yellow coloured flowers with a bronzy hue.

W. M. APPLETON, Esq., Tyn-y-Coed, Weston-super-Mare (gr., Mr. J. H. Brooks), showed *Cypripedium* × *Julia* (Lawrenceana × *exul*), flowered from seeds sown January, 1895; and *C.* × *Entfieldense*.

Awards.

Cattleya × *Weedoniensis* (Mendeli × *granulosa* Schofieldiana).—A very fine hybrid; the inflorescence bearing three large flowers, in outline partaking mostly of *C. granulosa*, but with all the segments more broadly developed and showy. The sepals were greenish-white, tinged with lilac; petals cream-white, with a greenish tinge on the midrib, the whole surface closely veined with purplish rose. The labellum had the acute side-lobes as in *C. granulosa*, pale yellow, darker on the inside; the conspicuous front-lobe crimped and toothed, of a bright purple colour, showing lighter tints between the veining. Raised and shown by T. W. THORNTON, Esq., Brookhill, Weedon.

Oncotoglossum crispum "Bassano".—A fine flower, of perfect form, white, with a cream-coloured tinge on the flesh, sepals, and petals; the column marked with red-brown, and a large blotch of the same colour on the labellum. From WALTER COEN, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes).

Fruit and Vegetable Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. Jas. Cheal, W. Iggulden, W. Poupert, A. F. Barron, P. C. M. Veitch, A. H. Pearson, Alex. Dean, S. Mortimer, W. Farr, J. W. Bates, Geo. Wythes, F. Q. Lane, G. Norman, J. Willard, Geo. Reynolds, and Robert Fife.

Seedling Melons were sent by Mr. ALLEN, Guntton Park Gardens, Norwich; Mr. D. HARRISON, London Road, Brighton; and Mr. R. DOE, Knowsley Gardens, Prescott, but no awards were made to these.

Mr. Jas. Day, gr. to the Earl of GALLOWAY, Galloway House, Garliestown, N.B., exhibited a collection of thirty-six dishes of Apples, of popular varieties. The fruits were not equal in size to exhibition fruits from the home counties, but they were very clean and bright in appearance, and extremely creditable to the cultivator, as they were grown so far North as Wigtownshire (Silver Knightian Medal).

Mr. Beckett, gr. to Lord ALDENHAM, Aldenham House, Elstree, Herts, again made a magnificent exhibit of vegetables, similar to that shown from the same establishment at the last meeting, when a gold medal was awarded the collection. The exhibit on Tuesday last was shown in competition for the "Sherwood" Cup, and it is now pretty certain that Mr. Beckett will gain this important prize. The exhibit on the last occasion was described in our issue for September 16, and we shall not cite varieties now, because it is not so much the merit of the varieties, as the superb manner in which Mr. BECKETT exhibits them; suffice it to say, that there were as many as forty-seven distinct varieties, and the collection was not only a most exemplary one, but it was exhaustively representative.

Messrs. D. & W. BUCHANAN, Forth Nurseries, Kippen, showed two bunches of a Black Grape, already shown in Edinburgh, and other places, under the name of Diamond Jubilee. The appearance of bunch and berry is handsome and very suggestive of Madresfield Court. The committee is however inclined to be cautious in regard to the variety, and no award is recommended on the present occasion. It has rather a thick skin, and is of good average quality.

From Mr. R. W. GREEN, Wisbech, fruits were shown of Early Victoria Apple, to which an Award of Merit was recommended on August 15. From the evidence of several fruit growers in that district it would appear that the Apple has been known for many years as Emmett's Early, and stock is common; at the same time it is not denied that the Apple is distinct from Lord Grosvenor and all others in general commerce, and its value is admitted. The same Apple, when shown before the Fruit Committee of the Royal Horticultural Society about a dozen years ago, was rejected, as being too nearly alike to Lord Grosvenor. The name under which it has been generally known should have been retained.

The Rev. DARNLEY SMITH, Landseave Vicarage, Ashburton, showed samples of the Fruit Protector, figured in *Gardeners' Chronicle*, March 18, p. 173, and Pears and Apples that had been protected by such means during ripening.

Awards.

Potatoes *The Sirdar*, from Messrs. HURST & SON; and *Ellington Seedling*, from Messrs. ELLINGTON & CO. (Awards of Merit). Both of these varieties were described in these pages, September 9, p. 212, in a report upon the trial of Potatoes at Chiswick.

Pear *Triomphe de Vienne*.—A large, handsome, bluntly pyriform-shaped Pear, russety, of very rich flavour. The trees grow vigorously, and are very free-bearing. This Pear has been in commerce several years, and generally ripens in September. Capital fruits were shown by Mr. Geo. WOODWARD, Barham Court Gardens, Maidstone (Award of Merit).

BRITISH-GROWN FRUITS AT THE CRYSTAL PALACE.

(See also p. 264.)

September 28, 29, and 30.

THE sixth show of British-grown fruits under the auspices of the Royal Horticultural Society, since in 1894 this Society succeeded in establishing an autumn show at the Crystal Palace, in place of the one held for many years previous to that date but which fell through, was opened on Thursday last.

Owing to the exhibition of the Article Club, which is still at the Palace, the whole of the exhibits were confined to one half of the nave, and some of the minor competitive classes, and many of the miscellaneous exhibits, were necessarily pushed into inconvenient positions. Sir TREVOR LAWRENCE, who presided over a very large gathering at the luncheon, said that he had just returned from the Continent. He had been in large towns, villages and small places, but during the whole time he had not seen a dish of good fruit.

In proposing the toast of the judges and referees, Sir TREVOR coupled the toast with the name of Mr. J. MCINDOE, who briefly replied.

The Chairman was pleased to think that the Crystal Palace Company had entered upon happier circumstances than they had experienced for a long time. He regarded the Crystal Palace as a place of education and of innocent amusement, and were the building in Hyde Park as it was once, the company would know nothing but success.

Mr. GILMAN, in replying for the Crystal Palace Company, spoke very hopefully of the future. Occasion was taken of this gathering to present to Mr. J. DOUGLAS a Victorian Medal of Honour.

The Show was a most satisfactory one for such a fruit season as that of 1899. The arrangements, as usual, were good, and everything passed off very successfully. The majority of the work connected with the exhibition falls upon the Secretary, Rev. W. WILKS, M.A., and upon Mr. S. T. WRIGHT, and his assistant, Mr. HUMPHREYS, from the Society's Gardens at Chiswick.

Mr. WOODWARD, of Barham Court Gardens, Maidstone, made no exhibit whatever, chiefly owing to the injury inflicted some time ago by a disastrous hailstorm. Mr. J. MCKENZIE, of Liuton Park Gardens, near Maidstone, had a good number of exhibits of first-class fruit.

Below is given a report of the whole of the competitive classes. Our notes upon Division II., the Nurserymen's exhibits of fruit and other non-competitive exhibits, we must hold over until next week.

DIVISION I.

FOR GARDENERS AND AMATEURS ONLY. COLLECTIONS OF FRUIT.

The large class in this division was for a collection of nine dishes of ripe dessert fruit, and it was well won by Mr. G. MULLENS, gr. to Lady HENRY SOMERSET, Eastnor Castle Gardens, Ledbury. He had excellent Gros Maroc and Muscat of Alexandria Grapes, the former being the better, the Muscats not being perfectly "finished"; a fine specimen of Countess Melon; Peaches Barrington and Lord Palmerston; Nectarine Albert Victor; extra fine Pears of Pitman's Duchess; Apple, Ribston Pippin; and Plum Coe's Golden Drop. For 2nd place, Mr. J. McIndoe, gr. to Sir J. W. PEASE, Bart., M.P., Hutton Hall, Guisborough, Yorks, beat Mr. J. H. GOODACRE, gr. to the Earl of HARRINGTON, Elvaston Castle, Derby, who was a very successful exhibitor at Shrewsbury. Mr. McIndoe's Grapes were Foster's Seedling and Gros Maroc, both varieties of medium quality; a fine specimen of Queen Pine, Scarlet Premier Melon, Prince of Wales and Sea Eagle Peaches, Humboldt Nectarine, Souvenir du Congrès Pears, and Bryanstone Gage Plums.

Mr. GOODACRE had excellent Muscat Grapes of extra colour and finish, and the rest of his fruit was good. Throughout the class the quality of the exhibits was high.

The smaller class for a collection of six dishes was won by Mr. MAXIM, gr. to Col. H. WALPOLE, Heckfield Place, Winchester. His Cooper's Black Grapes were very fine, but the Muscats, although of good quality, were a little past the exhibition stage. Apple, Lady Sudeley; Nectarine Peach;

Albert Victor Nectarine, and a Melon were of fair quality. Mr. Jas. Dawes, gr. to M. BINDULPH, Esq., M.P., Ledbury, was 2nd. He had a capital dish of Ribston Apples, Williams Bon Chrétien Pears, and moderate Princess of Wales Peaches. His Gros Maroc Grapes were good; 3rd, Mr. W. Tidy, gr. to W. K. D'ARCY, Esq., Stanmore Hall, Middlesex. There were two other exhibitors.

GRAPES.

The first prize for six varieties, two bunches of each, included, in addition to the money offered by the Society, a Challenge Cup, value 25 guineas, presented by Messrs. W. WOOD & SON, Wood Green, to celebrate the Jubilee year of their firm. There were four entries, and the champion of these proved to be Mr. J. H. GOODACRE. He had two mammoth bunches of Barbarossa, very good Black Alicante and Alnwick Seedling, and moderate bunches of Muscat of Alexandria and Gros Maroc. Two bunches of Mrs. Pince were good. The 2nd prize was won by fruit cultivated in the neighbourhood of the Crystal Palace. The exhibitor was Mr. W. TAYLOR, gr. to C. BAYER, Esq., Tewkesbury Lodge, Forest Hill, S.E. His Black Alicante, Madresfield Court, and Muscat of Alexandria were the best of the six varieties, the others being Gros Colman, Mrs. Pince, and Gros Maroc. The only other exhibitor was Mr. F. COLE, gr. to Sir CHARLES RUSSELL, Bart., Swallowfield Park, Reading. The varieties Foster's Seedling and Mrs. Pince appeared in this exhibit.

In the class for three distinct variations, the only collection staged was one from Mr. J. DAWES. He had really fine bunches of Gros Maroc, and Black Alicante, but his Muscats of Alexandria were rather poor.

The best collection of three bunches of Black Hamburg were well finished and coloured bunches from Mr. W. MITCHELL, gr. to J. W. FLEMING, Esq., Chilworth Manor, Romsey. The berries were rather small. Mr. F. COLE followed, and Mr. J. H. GOODACRE was 3rd. There were five entries.

Mr. W. MITCHELL was 1st again for Madresfield Court, having a creditable exhibit. The remaining two collections in this class were distinctly discreditable and unworthy this magnificent variety.

Mrs. Pince was shown as well as it is ever seen. Mr. W. MITCHELL had very heavy bunches of good berries. A little more colour would have made them superb illustrations of this rather difficult grape. 2nd, Mr. N. W. TAYLOR, gr. to C. BAYER, Esq., Forest Hill.

Muscat Hamburg was represented by one exhibit only, and that from Mr. GOODACRE. They were not remarkable except for nice colour.

Black Alicante is such a general favourite that the class devoted to this variety is generally a strong one. The best on the present occasion were shown by Mr. W. ALLAN, gr. to Lord SUFFIELD, Guntton Park, Norwich, and were heavy well-shouldered bunches of large, finely coloured berries, very typical of the natural type of this variety. Mr. F. COLE showed well for 2nd place, and M. W. MITCHELL was 3rd. There were nine entries.

Lady Downes was shown by five exhibitors, and two prizes only were offered. The 1st prize was taken by Mr. W. MITCHELL who had splendidly finished bunches; and the 2nd by Mr. W. TAYLOR, of nearly the same type.

The best variety in the "Any other Black" class was Gros Maroc, from Mr. W. ALLAN. They were superb in size and finish of berry; 2nd, Mr. Arthur Sadler, gr. to Mrs. TULK, Cowley House, Chertsey, with the same variety, also very good; 3rd, Mr. A. MAXIM, gr. to Col. H. WALPOLE, Heckfield Place, Winchester, who had Cooper's Black. There were eight entries.

The Muscat of Alexandria class was not specially strong, there being but four collections, and one of these was very poor in respect to finish. The best were very good specimens indeed, and were shown by Mr. G. DUNCAN, gr. to A. J. LUCAS, Esq., Warnham Court, Horsham; 2nd, Mr. Ed. SKELTON, gr. to JOHN BARKER, Esq., The Graperies, Bishops' Stortford, and Mr. A. MAXIM, 3rd.

Mrs. Pearson brought three exhibitors, and the 1st prize was awarded to three large unripe bunches from Mr. T. OSMAN, gr. to L. J. BAKER, Esq., Ottershaw Park, Chertsey; and the 2nd to three bunches of moderate size but much more fit for table, from Mr. W. J. EMPSON, gardener to Mrs. WINGFIELD, Amphilil House, Amphilil. The judging in this case was open to much criticism.

The best of "any other White" proved to be Dr. Hogg, nice specimens coming from Mr. T. OSMAN; Foster's Seedling came next from Mr. F. COLE, and were the best specimens of the variety in the show.

PEACHES.

There were ten exhibits in a class for a single dish, and the best were from Mr. A. MAXIM, who showed very fine samples of the Nectarine variety. Only two prizes were given, and the 2nd was awarded to Sea Eagle, from Mr. W. MITCHELL. There were good dishes staged of Admirable, and Walburton's Admirable.

Only three dishes of Nectarines were staged from indoors, and the best of these was Spenser from F. W. THOMAS, Esq., Wauchock, Polegate, Sussex. The variety Victoria was 2nd, from Mr. W. H. BACON, gr. to Sir MARCUS SAMUEL, Mote Park, Maidstone. The other variety staged was Pitmanston Orange.

PLUMS.

There were two exhibits only of three dishes of dessert Plums or Gages from under glass, and the best were shown by Mr. J. Hudson, gr. to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton. He had Golden Transparent Gage, Transparent Gage, and a sport from Coe's Golden Drop, the colour of the fruits being inclined to purple. Mr. J. McINDOE had Reine Claude de Bavay, Bryanston Green Gage, and Late Transparent Gage.

FIGS.

There were only three exhibits of one dish of Figs, and none of these was thought to justify a 1st prize being awarded. The varieties were Negro Largo and Rond Noir.

COLLECTIONS OF HARDY FRUIT

GROWN ENTIRELY IN THE OPEN.

The best exhibit of thirty-six dishes was from Mr. R. Potter, gr. to Sir M. W. COLLETT, Bt., St. Clare, Kemsing, Sevenoaks. The best of the Apples were Lady Henniker, Cox's Orange Pippin, Warner's King, Bramley's Seedling, Gloria Mundi, Mère de Ménage, Ribston Pippin, Emperor Alexander, Peasgood's Nonsuch, Stone's, Worcester Pearmain, &c. Of Pears, Conseiller de la Cour, Nouveau Poiteau, Triomphe de Vienne, Pitmaston Duchess, Conference, Beurré Bachelier, &c. There were Reine Claude de Bavay, Pond's Seedling, Cox's Golden Drop Plums, Figs Negro Largo; Peaches, Nectarine, Lady Palmerston and Ospraly, also Nuts Kent Cobs. The exhibit was one of much general excellence.

The only other exhibit was one from Mr. J. Dawes, and in this there was greater variety. Fewer Apples and Pears were staged, but there were Nuts, Medlars, Morello Cherries, Peaches, Siberian Crabs, Damsons, Quince, Imperatrice and other Plums, Red Dutch Currants, Sweetwater Grapes, Figs, Mulberries, &c.

FROM THE GLASSHOUSE.

There was only one exhibit of twenty-four dishes of hardy fruit, grown partly or entirely under glass to illustrate Orchard House culture, Grapes excluded. The varieties shown were Apples: The Queen, Lady Henniker, Peasgood's Nonsuch, Stone's, Jefferson's, Gascoigne's Scarlet Seedling, Ribston Pippin, and Cox's Orange. Pears: Van Mons Léon de Clere, Beurré Steekmans, Durondeau, Duchess d'Angoulême, Beurré Bachelier, Beurré Hardy, Doyenné du Comice, Beurré Baltet. Peaches: Lady Palmerston, Nectarine, and a Seedling. Plums: Transparent Gage, Kirke's and Reine Claude de Bavay. Figs, Negro Largo and Rond Noir.

DIVISION III.

OPEN TO MARKET GROWERS ONLY.

The classes in this division are intended to attract exhibits that will illustrate the best of the present systems of packing hard and soft fruits for market, and to encourage systems not generally known. The points of view from which the exhibits are judged, in addition to the quality of the fruits, are packing, grading, and the suitability for travelling and for market purposes of the box, basket, or other receptacle in which the fruit is shown.

Grapes, Hamburg, a single layer weighing not less than 12 lb., in a "Baby-basket." The above class, brought but one exhibit, and this very poor, and no award was apparently made.

In the next class, corresponding with the above, but the Grapes to be white, The Frome Flower and Fruit Co., proprietor Mr. IGGOLDEN, was awarded the 1st prize, for a basket of handsomely coloured Muscat of Alexandria; 2nd, Mr. W. GREEN, Harold Court, Harold-wood, Essex. Mr. IGGOLDEN'S Grapes were tied to the side of the "Baby-basket," and the latter was stood in a square bushel-flat hamper, similar to those used by Watercress-growers, and tied at each side to prevent its moving; the lid is tied down and labelled "Grapes, with Great Care." This seems to be a perfect way of sending baskets of Grapes: those of Mr. IGGOLDEN having travelled some distance, and opened in excellent condition.

For Grapes of any variety sent in any other way than the above, Mr. GREEN was 1st with a basket of fine Gros Colman. In this instance, an ordinary cross-handled basket had been lined inside with paper; and the bunches of Grapes tied around the top edge—some twigs were bent across the top over which brown paper had been tied. This arrangement seems to be as good a one as possible to use for the purpose; Mr. IGGOLDEN was 2nd with a similar package.

Class 28 was for four varieties of cooking Apples, about 42 lb. net of each, packed in baskets or boxes. Here Messrs. POUPART & SONS, Marsh Farm, Twickenham, were 1st with Peasgood's Nonsuch, Bismarck, Warner's King, Lane's Prince Albert, packed in ordinary bushel sieves, lined with blue paper, and paper between each layer of Apples; the 2nd prize was awarded to Mr. E. BASHAM, Bassaleg, Newport, Monmouth, for four varieties packed in boxes, with a small quantity of wool between each fruit.

For a similar number of packages of dessert Apples, 20 lb. net, Messrs. POUPART & SONS were again 1st, the fruits being packed in a similar manner to those mentioned above. The 2nd prize was awarded to Mr. A. WYATT, Hatton, Middlesex, for baskets similarly packed, minus the paper between each layer of fruits.

For a single package of cooking Apples, Mr. GEORGE TEBBUTT, Isleworth, was awarded 1st prize for a fine basket of Lady Henniker, but the fruits in this basket were raised considerably above the rim of the basket, and could not be considered an ideal market package, as the raised fruits must become bruised when sent with a number of packages for market; Mr. WYATT was 2nd.

With a single package of dessert Apples, Messrs. POUPART & SONS were easily 1st with fine Cox's Orange Pippin, packed as described in their former exhibits; 2nd, Mr. MARCHANT, Somerfield Plantation, Maidstone. There were seven competitors, and Messrs. POUPART'S arrangement and packing seems to be perfect in a market sense.

About 42 lb. net of Apples was asked for in any improved form of package for market, and here Mr. BASHAM gained the 1st prize, for a basket (square) of Bismarck, each fruit packed between a thin layer on each side of wood-wool; and with the same kind of packing and hamper the same exhibitor took the 1st prize in the next class for a similar quantity of Apples of the variety, and showing any improved system of packing.

Messrs. POUPART & SONS were successful with packages of Pears, winning the 1st prize for two varieties, in two packages of about 20 lb. each. The varieties were Pitmaston Duchess and Calabasse Bosc, and the system adopted was similar to that described for Apples; Mr. WYATT was again 2nd.

The last-named exhibitor was 1st for twenty-four to forty-eight fruits (Pears) of one choice variety, suitably packed in one package for market. Here, a stout box, holding twenty-eight fruits was used, the bottom lined with wood-wool, and each fruit wrapped partly in pink paper, leaving the upper half of the fruit exposed, a sheet of paper being folded over the top under the lid. Mr. MARCHANT was 2nd, the Pears being packed in wood-wool only.

For twelve varieties of Apples and six of Pears, distinct, eighteen fruits of each to be laid flat on the table without dishes or baskets, six competed, making a large display. Messrs. POUPART & SONS were 1st, and noticeable among their varieties were Peasgood's Nonsuch, Warner's King, Mère de Ménage, Bismarck, Cox's Orange Pippin, and Ribston Pippin Apples, and Pitmaston Duchess Pears; Mr. WYATT was 2nd.

In the Plum competition a basket or box of 28 lb. of fruit, for cooking purposes, Messrs. POUPART & SONS were 1st with a basket of Monarch. These were packed similarly to the Apples, and were in good condition; Mr. TEBBUTT, 2nd. There was no exhibitor of a basket or box of dessert Plums.

Twenty-four fruits of one or more varieties of Peaches, packed in a suitable box, brought but two exhibitors. Mr. GORE, Polegate, Sussex, gained the 1st prize. His fruits were wrapped individually in tissue-paper, so that the upper part of the fruit was visible, and packed in wood-wool. Messrs. POUPART were 2nd, cotton wadding being the packing material used by them.

Mr. GORE was 1st for a basket of Tomatos, a cross-handled basket as for Grapes being used, and a layer of paper between the fruits.

DIVISION IV.

FRUITS GROWN IN THE OPEN AIR.

(Gardeners and Amateurs only).

APPLES.

In this Division the colour of the fruit, especially in the dessert varieties, was a striking feature, and despite a season that was thought would have proved hostile to the development of fine fruit, there was really fine. Some ordinary sorts, as well as leading dessert varieties, were in brilliant form.

In Class 41, for twenty-four dishes (sixteen cooking and eight dessert), there were seven entries. Mr. J. McKenzie, gr. to F. W. CORNWALLIS, Esq., M.P., Linton Park, Maidstone, was 1st with a fine, clear, bright collection, consisting of Tyler's Kernel, very fine; Gloria Mundi, Emperor Alexander, very fine; Loddington Seedling, Mère de Ménage, Hornmead's Pearmain, Peasgood's Nonsuch, very fine; Tower of Glamis, Bismarck, well-coloured; Golden Noble, Brabant Bellefleur, Warner's King, Alfriston, Golden Sire, The Queen and Stirling Castle; dessert: Autumn Pearmain, very fine; Gascoigne's Scarlet, St. Edmund's Pippin, Baumann's Red Reinette, and fine Wealthy, brilliant in colour; Allington Pippin, Fearn's Pippin, in very fine form; and grand Ribston Pippin. Mr. R. Parker, gr. to the Duke of Richmond and Gordon, Goodwood, Chichester, was a very close 2nd, also having some grand fruit, such as Grenadier, Lady Henniker, Peasgood's Nonsuch, Gloria Mundi, Stone's, very fine; Lane's Prince Albert, very fine; Warner's King, Bramley Seedling, King of Tomkins's County, Yorkshire Beauty, very fine; Cox's Pomona, Golden Spire; and of dessert, Blenheim Orange, finely coloured; Royal Russet, Gascoigne's Seedling, very fine; Ribston Pippin, very good; Cox's Orange Pippin, Worcester Pearmain, &c.; 3rd, Mr. King, gr. to J. COLMAN, Esq., Gattin Park, Reigate, also with admirable fruit, a very fine, even lot.

In Class 42 there were also seven entries. Here Mr. A. Maxim, gr. to Col. H. WALPOLE, Heckfield Place, Winchester, was 1st, with brilliant fruit of the following twelve varieties of cooking Apples, having Lady Henniker, Cox's Pomona, Peasgood's Nonsuch, very fine; grand Cellini Pippin, Bramley's Seedling, Emperor Alexander, Newtown Pippin, and Alfriston; and four dishes of dessert, as follows:—Ribston

Pippin, Cox's Orange Pippin, Gascoigne's Scarlet (highly finished), and King of Pippins. Mr. G. Mullins, gr. to Lady HENRY SOMERSET, Eastnor Castle, Ledbury, was a good 2nd; he had, of culinary sorts, Tyler's Kernel, Lord Derby, Peasgood's Nonsuch, Lord Suffield (very fine), Cox's Pomona, &c.; and of dessert, Claygate Pearmain, Ribston Pippin, Baumann's Winter Reinette, and Cox's Orange Pippin. 3rd, THE SOUTH-EASTERN AGRICULTURAL COLLEGE, Wye, near Ashford, Kent.

There were four entries in Class 43, for six cooking and dessert. Mr. J. Dawes, gr. to M. BIDDULPH, Esq., Ledbury, was 1st with excellent fruit, with Warner's King, Tyler's Kernel, Lord Suffield, Peasgood's Nonsuch, Royal Jubilee, and Beauty of Kent; dessert, Cox's Orange Pippin, Worcester Pearmain, and Ribston Pippin. 2nd, Mr. W. Jones, gr. to J. R. BROUGHAM, Esq., Wallington Bridge, Carshalton, who had as his leading cooking varieties, Lady Henniker, Peasgood's Nonsuch, Hollandbury, and Bramley's Seedling; and as dessert, Ribston Pippin, Blenheim Orange, and Cox's Orange Pippin. 3rd, Mr. W. Wallace, gr. to H. G. SMITH, Esq., Mount Close, Roehampton, with a good representative collection.

There were six entries of six dishes of cooking Apples, the 1st prize was awarded to H. H. HURNARD, Esq., Gurney's Manor, Higham, Norfolk, who had very fine fruit of Peasgood's Nonsuch, Mère de Ménage, Bramley's Seedling, Lane's Prince Albert, very fine; Warner's King, and Emperor Alexander; 2nd, Mr. R. M. WHITING, Credenhill, Hereford, his leading sorts were Frogmore Prolific, Lane's Prince Albert, Bramley's Seedling, and Stirling Castle. In this and the following classes, no 3rd prize was offered.

There were seven entries in Class 45 for three dishes of cooking Apples; Mr. G. Fennell, gr. to W. M. CAZALET, Esq., Fairlawn, Tonbridge, was 1st with Peasgood's Nonsuch, Castle Major, a very fine variety; and Lord Derby. Mr. J. Dawes, Ledbury, was 2nd with finely-coloured Tyler's Kernel, Peasgood's Nonsuch, and Warner's King.

There were only two collections of six dishes of dessert Apples in Class 46, Mr. KING, Gattin Park, coming in 1st with a superb lot, consisting of Ribston Pippin, Cox's Orange Pippin, Worcester Pearmain, rich in colour; Blenheim Orange, Allington Pippin, and King of Pippins; 2nd, Mr. H. COOK, Knowle Gardens, Sidmouth, his leading varieties were Cox's Orange Pippin, Rosemary Russet, Autumn Pearmain, and Lady Derby, very fine.

There were fifteen entries in Class 47 for three dishes or dessert Apples. The 1st prize went to Mr. G. H. SAGE, gr. to the Marquis of CAMDEN, Lamberhurst, Kent, who had Washington, Cox's Orange Pippin, and Ribston Pippin, all very fine, and nicely set up with Vine-leaves, a practice to be commended at such an exhibition. Mr. W. H. GODDEN, gr. to P. W. BUXTON, Esq., Cashibury, Sawbridgeworth, was 2nd, having very good fruits of Cox's Orange Pippin, Blenheim Orange, and Ribston Pippin.

PEARS.

In Class 48, for twelve dishes of dessert Pears, Mr. R. Potter, gr. to Sir M. W. COLLETT, Bart., St. Clare, Kemsing, Sevenoaks, was 1st with remarkably fine fruits of Duchesse d'Angoulême, General Todleben, Pitmaston Duchess, Beurré Alexandre Lucas, Nouveau Poiteau, Madame Treve, Madame Chady, Beurré Rance, Durondeau, Beurré Diel, and two unnamed. Why at such an important show as this did the judges allow this to go unchallenged? Mr. W. H. BACON, gr. to Sir M. SAMUEL, Mote Park, Maidstone, 2nd. He had fine examples of Triomphe de Vienne, Pitmaston Duchess, Williams' Bon Chrétien, Doyenné du Comice, Durondeau, Souvenir du Congrès, Beurré Superfin, &c.; 3rd, Mr. W. E. HUMPHREYS, gr. to A. H. SNEE, Esq., The Grange, Hackbridge, Surrey.

There were three entries in the class for nine dishes of dessert Pears. Mr. W. JONES, gr. to J. R. BROUGHAM, Esq., Wallington Grange, Carshalton, was 1st with good fruit of Pitmaston Duchess, Beurré Diel, Beurré Bachelier, Souvenir du Congrès, Madame Treve, Beurré Superfin, Maréchal de la Cour, Louise Bonne de Jersey, and Urbaniste; 2nd, Mr. H. COOK, Knowle Gardens, Sidmouth, who had in good character Doyenné Boussoche, Marie Louise, Ickworth Park, Doyenné du Comice, Durondeau, &c.

In Class 41, for six dishes of dessert Pears, there were seven entries. Mr. G. H. SAGE, Bayham Abbey Gardens, was 1st, with excellent fruits of Souvenir du Congrès, Gansell's Bergamot, Beurré Bachelier, Admiral Todleben, Pitmaston Duchess, and Doyenné du Comice; 2nd, Mr. W. A. COOK, gr. to Major HENEGGE, Compton Bassett, Wilts, who had very fine Louise Bonne de Jersey, Marie Louise, Pitmaston Duchess, and Doyenné du Comice.

There were ten collections of three dishes; Mr. R. EDWARDS, gr. to G. H. FIELD, Esq., Beechinglees, Sevenoaks, was 1st with excellent fruit of Pitmaston Duchess, Madame Treve, and Doyenné du Comice; 2nd, Mr. J. RICK, gr. to G. H. HADFIELD, Esq., Monastor, Ross, Hereford, who had fine Souvenir du Congrès, and Marie Louise.

Three dishes from Mr. A. MAXIM were highly commended. In Class 52, for three dishes of cooking Pears, there were four entries. Mr. W. E. HUMPHREYS, The Grange Gardens, Hackbridge, was 1st, with Uvedale's St. German, Triomphe de Jodoigne, and Catillac; Mr. H. COOK, Sidmouth, was 2nd, with Beurré Clairegout, differing from the foregoing.

There were fifteen single dishes of cooking Pears. 1st, Mr.

R. POTTER, St. Clere, Bellissime d'Hiver; 2nd, Mr. C. Rose, gr. to Captain CARSTAIRS, Welford Park, Newbury, with Uvedale's St. Germans. The latter with Catillac were the principal varieties grown.

PEACHES.

Class 54 was for three dishes grown in the open air. Mr. MAXIM, Heckfield Gardens, was 1st, with finely-coloured fruit, of Sea Eagle, Gladstone, and Princess of Wales. Mr. J. SPARKS, Upper Grove House Gardens, Roehampton Lane, Putney, was 2nd, with very good fruit of Sea Eagle, Princess of Wales, and Late Admirable. Mr. S. Osborne, gr. to the Duke of FIFE, East Sheen Lodge, was 3rd, he having, with Sea Eagle, Royal Ascot, and Walburton Admirable, three capital dishes.

There were eleven single dishes of Peaches in Class 55. Mr. Geo. Wythes, gr. to the Duke of NORTHUMBERLAND, Syon House, Brentford, was 1st, with splendid Sea Eagle; 2nd, Mr. T. H. Slade, gr. to Lord POLTIMORE, Poltimore Park, Exeter, with excellent Princess of Wales. Barrington and Walburton Admirable were also finely shown.

NECTARINES.

There was no entry in Class 56 for three dishes; and in the class for a single dish, they fell much below the Peaches in point of quality; Mr. J. SPARKS, Upper Grove House Gardens, Roehampton, was 1st with Victoria; and Mr. C. Earl, gr. to O. E. d'AVIGNOR GOLDSMID, Esq., Somerhill, Tonbridge, was 2nd with Prince of Wales.

PLUMS.

There were three collections of four dishes of dessert Plums. Mr. H. Folkes, gr. to C. E. STRACHAN, Esq., Gaddesden Place, Hemel Hempstead, was 1st with well coloured fruits of Cloth of Gold, Jefferson, Washington, and Reine Claude de Bavi; Mr. R. Chamberlain, gr. to P. M. LONERGAN, Esq., Cressingham Park, Reading, who had Cox's Golden Drop, Transparent Gage, Jefferson, and a small, late, yellow variety, unnamed, was 2nd.

There were six dishes of one variety of dessert Plums, not Gages. Mr. THOS. SPENCER, gr. to W. H. C. MOFFATT, Esq., Goodrich Court, Ross, was 1st with fine Cox's Golden Drop. Mr. A. Wright, gr. to J. G. DEARDEN, Esq., Walcot Hall, Stamford, was 2nd with the same; in both cases the fruit was bright and clear. With the exception of the purple Imperiale de Milan, all the dishes were Golden Drop.

There were six dishes of Gage Plums; Mr. G. Duncan, gr. to C. J. LUCAS, Esq., Warham Court, Horsham, was 1st with Transparent Gage; and Mr. Rick, Monaston Gardens, Ross, 2nd with the same, Purple Bryanston Gage and Purple Gage.

There were three entries of four dishes; and Mr. J. McIndoe, gr. to J. W. PEASE, Bart., Hutton Hall, who had a very fine form of Archduke, Magnum Bonum, Grand Duke, and Pond's Seedling was 1st; 2nd, Mr. H. FOLKES, the Gardens, Gaddesden Place, who had Prince of Wales, not shown by any of the other exhibitors.

The best single dish in Class 62 was Pond's Seedling, from Mr. W. E. COLEMAN, gr. to T. L. BOYE, Esq., Tonbridge. Mr. H. H. HURNARD, Kingham, Norfolk, was 2nd with the same. Monarch, was also shown in good character, and Diamond.

In Class 63 there were two collections of Damsons, Prunes, and Bullaces. Mr. T. CLINCH, Sittingbourne, obtained the 1st prize, having the Crittenden and Cluster Damsons, the Prune, and Shepherd's Bullace. Mr. G. FENNELLY, Fairlawn Gardens, Tonbridge, was 2nd, he had the Old Cheshire and Cluster Damsons, and a Yellow Bullace.

DIVISION V.

SPECIAL DISTRICT COUNTY CLASSES.

(Open to Gardeners and Amateurs only.)

The first of these classes is one for six dishes of Apples, four culinary and two dessert; the second for six dishes of dessert Pears. In the order of competitors KENT came first, the 1st prize in the former class, Mr. W. T. STOWERS, gr. to C. H. DEAN, Esq., Whitehall, Sittingbourne, who had grand samples of Bramley's Seedling, Warner's King, Prince Albert, and Peasgood's Nonsuch; and of dessert, Cox's Orange Pippin and Worcester Pearmain. Mr. G. H. SAGE, The Gardens, Bayham Abbey, was 2nd. He had very fine Peasgood's Nonsuch, Warner's King, Bismarck, and Lord Derby; his dessert varieties were Cox's Orange Pippin, very fine, and Ribston Pippin.

There were four collections of Apples, and the same number of Pears. In this class Mr. G. H. SAGE was again 1st, showing very fine fruit of Beurré Jongmans, Pitmaston Duchess, Beurré Bachelier, Souvenir du Congrès, Doyenné du Comice, and very fine Gansell's Bergamot; 2nd, Mr. R. EDWARDS, gr. to G. H. FIELD, Esq., Beechy Lees, Sevenoaks; he had Doyenné du Comice, Durondeau, Gansell's Bergamot, and Madame Treve, in fine character.

The next division was for the counties of Surrey, Sussex, HANTS, DORSET, SOMERSET, DEVON and CORNWALL. There were six collections of six dishes of Apples, and Mr. W. CAMM, gr. to the Duchess of CLEVELAND, Battle, Sussex, was 1st, with very fine and bright specimens of Warner's King, Peasgood's Nonsuch, Stone's, Mrs. Barron, and of dessert, Washington and Ribston Pippin. Mr. KINO, Garton Park Gardens, was 2nd, having Bismarck, Beauty of Kent, and Cox's Orange Pippin, very fine.

There were four collections of Pear, the 1st prize going to Mr. W. Mancey, gr. to A. BENSON, Esq., Upper Garton Park, Merstham, who had very good Beurré Hardy, Souvenir du Congrès Pitmaston Duchess, Durondeau, Bon Chrétien, and Marguerite Marillat. Mr. KING, Garton Park, was 2nd. Chief among them, Doyenné, Boussoch, Brockworth Park, and Souvenir du Congrès.

The counties of WILTS, GLOUCESTER, OXFORD, BEDS, HERTS, and MIDDLESEX came next. There were five collections of Apples, Mr. W. STRUGNELL, gr. to Col. VIVIAN Rood Ashton, Trowbridge, was 1st, with very fine Peasgood's Nonsuch, Warner's King, Rambour Frane, Bramley's Seedling, Cox's Orange Pippin, and Ribston Pippin. Mr. R. CHAMBERLAIN, the Gardens, Cressingham Park, Reading, was 2nd; he had very fine Peasgood's Nonsuch, Golden Noble, Emperor Alexander, and the two same dessert varieties.

There were five collections of Pears. Mr. W. A. COOK, the Gardens, Compton Bassett, Wilts, was 1st with Pitmaston Duchess, Doyenné du Comice, Bon Chrétien, Marie Louise, Beurré Diel, and Louise Bonne of Jersey; Mr. R. CHAMBERLAIN was a close 2nd with very fine Doyenné Boussoch, Bon Chrétien, Beurré d'Amanlis, and Clapp's Favorite.

The next group of counties was ESSEX, SUFFOLK, NORFOLK, CAMBRIDGE, HANTS, and RUTLAND. There were three collections of six dishes of Apples, the 1st prize falling to H. HURNARD, Esq., Higham, Norfolk, who had in very fine character, Cox's Pomona, Emperor Alexander, Lord Derby, Peasgood's Nonsuch, Ribston and Cox's Orange Pippin; 2nd, Mr. A. ANDREWS, gr. to the Hon. W. LOWTHER, Wickham Market, Suffolk, whose culinary varieties were superb, he had Lane's Prince Albert, Mère de Ménage, Bramley's Seedling and Peasgood's Nonsuch, with Cox's Orange and Ribston Pippins.

There were three collections of Pears, the 1st prize going to Mr. W. ALLAN, gr. to Lord SUFFIELD, Guntton Park, Norwich, who had fine fruit of Pitmaston Duchess, Beurré Diel, Bon Chrétien, Marie Louise d'Uccle, Thompson, Marie Louise, very large; 2nd, Mr. A. ANDREWS, the Gardens, Wickham Market, who had Durondeau, Doyenné du Comice, Pitmaston Duchess, Emile d'Heyst, in good form.

Next in order came the counties of LINCOLN, NORTHAMPTON, WARWICK, LEICESTER, NOTTS, DERBY, STAFFS, SHROPSHIRE, and CHESHIRE. There were three collections of six dishes of Apples. Mr. A. WRIGHT, the Gardens, Walcot Hall, Stamford, had very fine Mère de Ménage, also Warner's King, Peasgood's Nonsuch, Lord Derby, Cox's Orange Pippin and Worcester Pearmain; 2nd Mr. W. H. DIVERS, gr. to the Duke of RUTLAND, Belvoir Castle, Grantham, who had what we thought to be remarkably fine fruit for the district, consisting of Peasgood's Nonsuch, Stirling Castle, Bismarck, and Warner's King, Cox's Orange Pippin, and Worcester Pearmain.

There were two collections of Pears, and from this district they were relatively smaller than from any of the preceding counties. Mr. A. WRIGHT, Walcot Hall Gardens, Stamford, was 1st with Bon Chrétien, Durondeau, Van Mons Léon le Clerc Beurré Diel, Marie Louise, and Louise Bonne of Jersey. Still, with a good even lot, Mr. W. H. DIVERS was 2nd; he had Bon Chrétien, five Beurré Clargau marked not a dessert Pear, Louise Bonne of Jersey, Fondante d'Automne, and Doyenné du Comice, certainly the best quality of fruit as far as development is concerned.

The counties of WORCESTER, HEREFORD, MONMOUTH, GLAMORGAN, CARMARTHEN, and PEMBROKE furnished fine bright fruit. The 1st prize for six dishes of Apples going to Mrs. BLASHETT, Hereford, who had very bright examples of Warner's King, Golden Noble, Peasgood's Nonsuch, Emperor Alexander finely coloured Adams, Pearmain, and Cox's Orange Pippin. 2nd, Mr. R. M. WHITING, Credenhill, Hereford, with Bramley's Seedling, Stirling Castle, Peasgood's Nonsuch, Cox's Orange Pippin, and Egremont Russet, very fine.

There were three collections of Pears, the 1st prize going to Mr. JOHN RICK, Monaston Gardens, Ross, who had in fine character Pitmaston Duchess, Souvenir du Congrès, Conseiller de la Cour, Durondeau, Marie Louise, and Beurré Hardy. 2nd, Mr. T. SPENCER, Goodrich Court Gardens, Ross, whose leading varieties were Beurré d'Avalon, Durondeau, Souvenir du Congrès, and Duchess d'Angoulême.

Other counties in Wales furnished but two collections of Apples, and those of an inferior character. The best came from Mr. R. T. JONES, gr. to R. D. HUGHES, Esq., Denbigh, who had Blenheim Orange, Norfolk Beaufin, Warner's King, Ribston Pippin, Dutch Mignonne, and Wareham Russet; 2nd, Mr. H. AUSTEN, gr. to L. P. POOT, Esq., Abermarde, Aberystwith, who had fine Warner's King and Alfriston, the others poor. There was but one collection of Pears and no award was made.

The six NORTHEN COUNTIES of England and the ISLE of MAN furnished but one collection of Apples from Mr. GARSDIE, Larbrick Gardens, Gt. Eccleston, near Garstang. These were of fairly good character, and consisted of Grenadier, Annie Elizabeth, Scotch Bridget, Lane's Prince Albert, Worcester Pearmain, and one unnamed.

SCOTLAND.

From Scotland came two collections of Apples, the best from Mr. J. DAY, The Gardens, Galloway House, Carlisle, N.B., and consisted of good, clean, well coloured examples

of Warner's King, Yorkshire Beauty, Mère de Ménage, Peasgood's Nonsuch, Lady Sudeley, and James Greive, a handsome dessert kind.

The 2nd prize was awarded to Mr. J. McKinnie, gr. to H. MILLAR, Esq., Roundwood, Crief, the best being Stirling Castle and Ecklinville Seedling.

There was but one collection of Pears, this also came from Mr. DAY, all the varieties of good character, consisting of Souvenir du Congrès, Jersey Gratioli, Marie Louise d'Uccle, Doyenné Boussoch, Pitmaston Duchess, and Madame Treve.

IRELAND.

No contribution came from Ireland, and so no comparison could be afforded between Irish fruit, and that of Scotland and England.

DIVISION VI.

SINGLE DISHES OF FRUIT FROM OPEN AIR.

DESSERT APPLES.

First of these came Adam's Pearmain, in four lots, all nice samples, Mr. CORNELIUS, gr. to H. A. WILLIAMS, Esq., Truro, coming 1st; with Mr. CAMM, gr. to the Duchess of CLEVELAND, Battle Abbey, Sussex, 2nd.

There was only one dish of that poor Apple Allen's Everlasting, and a poor sample at that.

Then came Allington Pippin, a far superior one, with six dishes, the best coming from Mr. ROSS, gr. to Captain CARSTAIRS, Newbury. This fruit carries a nice bloom.

Banmann's Red Reinette, in three dishes, made a good show of colour, Mr. ROSS being again 1st here.

Then came twenty-one lots of that grand Apple Blenheim Pippin, but there were only two prizes to award. There were large and small, as well as a superb, medium samples; but really small fruit for the variety were awarded the prizes, whilst the public were wondering why. Mr. Chamberlain, gr. to F. M. MORGAN, Esq., Reading, was 1st; and Mr. EARL, gr. to O. E. d'AVIGNOR GOLDSMID, Esq., Horsham, was 2nd.

There were but four dishes of Brownlee's Russett, and the same number of Claygate Pearmain, whilst there were but three dishes of Cocker Pippin.

Then of Court Pippin Plat there were six, the best examples coming from Mr. LINTOTT, gr. to WALFOLE GREENWELL, Esq., Marden Park, Surrey, very handsome fruits.

That grand dessert Apple, Cox's Orange Pippin, was represented by no fewer than thirty-two dishes, but there were only two prizes to award, where there should have been many more. Here, oddly enough, quite large fruits for the variety—certainly handsome ones—were selected, these coming from Mr. KING, gr. to J. J. COLMAN, Esq., Garton Park, Reigate; Mr. SLADE, gr. to Lord POLTIMORE, Exeter, was 2nd.

The Duke of Devonshire found representatives in six dishes, but one half of these were poor. Mr. JOHN RICH, gr. to C. H. HADFIELD, Esq., Ross, was 1st.

There were eight dishes of Egremont Russett, Mr. WHITING coming 1st; and thirteen lots of Pearmain Pippin, generally good in colour. Mr. SLOWERS, gr. to C. H. DEAN, Esq., Sittingbourne, being 1st; Mr. MCKENZIE, gr. to F. S. W. CORNWALLIS, Esq., Linton Park, Kent, coming 2nd.

Very brilliant was the colour of Gascoigne's Scarlet, smallish, high-coloured fruits, taking the Awards, C. H. DEAN, Esq., Sittingbourne, again was 1st here. Some over-looked fruits were superb samples.

There were but three of Gravenstein, the 1st prize lot coming from Battle Abbey, but much the finest from Hackfield Place, Hants.

There were but two dishes of Jas. Greive, the raiser, Mr. DAY, of Galloway House, N.B., coming 1st.

King of the Pippins had fifteen dishes to represent it, distinctly poor samples for the variety, being placed 1st, from Mr. MCKENZIE; Mr. SLOWERS coming 2nd with larger samples. The judging here has been greatly commented upon.

King of Tomkin's County had few representatives, Mr. MAXIM bringing the best, apparently well grown, from Heckfield. It is a poor Apple for this country.

Mabbott's Pearmain, a very handsome Apple, had but three dishes; and there were but five lots of Mannington Pearmain, the best coming from Linton Park.

Margil was better shown, there being thirteen dishes. Mr. CAMM had very handsome samples of these.

Of American Mother Apple, eight lots being staged, smallish samples seemed to be most favoured, very fine samples being overlooked. Mr. WHITING was 1st with the variety.

There came no fewer than thirty-six dishes of the fine old Ribston Pippin, showing how very much this grand variety is alive. Mr. KING was 1st, with medium-sized high-coloured fruits, two of which were weak. Mr. SAGE came 2nd, with fine samples, very even and clean, but less highly coloured. Some capital samples obtained no award.

There were six dishes of the late Rosemary Russett, and two only of Ross Nonpareil, with only one of the old Scarlet Nonpareil, that coming from Mr. J. HUBSON, of Guonersbury House Gardens, very handsome samples, that might in a free competition have been regarded as too large.

Sturmer Pippin brought six, and Wealthy but three dishes, whilst the rich-coloured Worcester Pearmain was represented by eighteen dishes, of which Mr. KING and Mr. DUNCAN, gr. to C. F. LUCAS, Esq., Horsham, had the richest.

There were no Winter Quarrendens staged, in spite of Messrs. Pearson's prizes.

Finally, with any other variety, eighteen dishes being shown, Mr. Ross captured the 1st prize easily, with his beautiful new seedling, Thos. Andrew Knight; Golden Russet, from Mr. Wythes, Syon House Gardens, Brentford, being 2nd.

CULINARY APPLES.

Kitchen Apples were generally fine, the classes starting with Alfriston, Mr. Spencer, gr. to H. C. Moffatt, Esq., Herford, being 1st, with fine clean samples.

Beauty of Kent had but five dishes, only moderate samples. In the class for Belle Pontoise, Mr. McKenzie had superb fruits.

Bismarck brought only eight dishes, and none high-class. The best came from Mr. S. W. Sweet, Ipswich.

Bramley's Seedling, for three prizes offered by Mr. MEADWEATHER, of Notts, brought sixteen generally grand samples, Mr. Cock, of Sidmouth, coming 1st, and Mr. Short 2nd, with splendid fruits; the 3rd went to Mr. A. H. Snee, Hackbridge.

Cellini Pippin was poorly represented by six dishes; but Cox's Pomona was better with eleven lots. Mr. Stowers was 1st with fine clean fruit; and Mr. King 2nd, with smaller and more highly-coloured ones.

Dumelow's Seedling, *alias* Wellington, brought fifteen dishes, Mr. Camm coming 1st, and Mr. King 2nd.

Ecklinville Seedling very much showed its speckled character. Mr. Stowers had the best samples. Emperor Alexander brought superb fruits, that from Mr. McKenzie and Mr. Stowers taking the prizes. The former was also 1st with handsome Golden Noble, of which there were nine lots, but there were but one of Golden Spire and four of Grenadier staged.

The best of New Hawthornden came from Mr. Herbert, gr. to J. P. Charlesworth, Esq., Redhill; whilst Mr. Stowers was 1st with grand Prince Albert, and Mr. Cross was very near, also with fine samples.

The samples of Lord Derby were very fine, especially those from Mr. Stowers; Mr. Whiting was 2nd.

There were but five lots of Lord Grosvenor, Mr. Whiting taking 1st, and Mr. C. Herring, Dropmore, 2nd prizes.

There were also but five dishes of Lord Suffield, only moderate samples; and but six of Mère de Menage, but the fruits shown by Mr. Ross and Mr. McKenzie were grand samples.

Messrs. Pearson's prizes for Newton Wonder from northern counties brought but four dishes, the best coming from Mr. H. H. Turner, Fincham, Norfolk; and Mr. Divers, The Gardens, Belvoir Castle.

In the class for the same variety grown in southern counties, handsome samples were shown, Mr. Cock, of Sidmouth, was 1st with very fine ones, and Mr. Potter, gr. to Sir Mark Collett, Sevenoaks, was 2nd. There were eleven dishes of Peasgood's Nonsuch, Messrs. McKenzie and Stowers, taking the prizes with handsome samples. Mr. McKenzie was again 1st with good Pot's Seedling. There were but three dishes of Royal Jubilee, and seven of Sandringham, the 1st award going to Mr. McKenzie; and Mr. Gage was 1st with Spencer's Favourite, only two dishes being staged. Stirling Castle, was represented by some fine fruits from Messrs. Whiting and Ross, the latter having the best Loddington Seedling. Mr. Stowers had the best, and Mr. Maxim, the second best lots of Queen, out of nine dishes. There were but four dishes of Waltham Abbey Seedling. Then came that popular variety, Warner's King, with ten dishes, Mr. Harris, gr. to P. Crowley, Esq., Croydon, having very fine samples. Finally, in any other variety, grand fruits of Tyler's Kernel, from Mr. Dawes, gr. to M. Biddulph, Esq., Ledbury, and Mr. Ross, with large Wiltshire Defiance, were 1st and 2nd Yorkshire Beauty, and Gloria Mundi, were fine in this class.

DESSERT PEARS.

Thirty-five classes were devoted to dessert Pears in single dishes, and in several of the classes the competition was very keen, and the exhibits generally of good quality.

The first class, that of Buerré Bosc, comprised seven dishes, all good, the 1st prize being taken by Mr. J. Friend, gr. to the Hon. P. C. Glynn, Rooknest, Godstone; 2nd, Mr. A. Smith, The Convent, Roehampton Lane, S.W.

Buerré d'Angou brought a small number of dishes, Mr. R. Chamberlain, gr. to F. M. Loneragan, Esq., Cressingham Park, Reading, coming 1st with finely-coloured fruits; 2nd, Mr. Sage, gr. to the Marquis Camden, Bayham Abbey.

Five good dishes of Buerré Diel were staged. 1st, Mr. W. Allan, gr. to Lord Suffield, Gnaton Park, Norwich, with large fruits; 2nd, Mr. Wythes, Syon House Gardens, with nicely-coloured fruits.

Buerré Fouquier, two dishes only. 1st, Mr. Sage, with very fine fruits; 2nd, Mr. Hudson.

Four competitors staged good fruits of Buerré Hardy. 1st, Mr. J. Allan, gr. to G. HANBURY FIELD, Esq., Ashurst Park, Tunbridge Wells; 2nd, Mr. T. Stower, gr. to G. H. Dean Esq., Sittingbourne.

Buerré Superfin brought the same number of exhibitors. 1st, Mr. Rickwood, gr. to the Dowager Lady FRAKE, Fulwell Park, Twickenham.

Comte de Lamy,—1st, Mr. T. W. Herbert, gr. to J. T. Charlesworth, Esq., Nutfield Court, Redhill; 2nd, Mr. W. Allan.

Conference.—1st, Mr. HUDSON, Gunnersbury; 2nd, Mr. FRIEND.

Conseiller de la Cour.—1st, Mr. CHAMBERLAIN; 2nd, Mr. Ross, gr. to Captain CARSTAIRS, Welford Park, Newbury.

Some very fine dishes of Doyenné du Comice were staged, Mr. W. H. Bacon, gr. to Sir MARCUS SAMUEL, Mote Park, Maidstone, coming 1st with a large and nicely coloured dish; 2nd, Mr. W. Harrison, gr. to Col. ARCHER HOGBON, Bishop's Stortford.

But one dish was forthcoming of Duchesse de Bordeaux, a good one, from Mr. E. Coleman, gr. to T. L. Boyd, Esq., North Firth, Tonbridge.

Eight highly coloured lots of Durondeau were staged, the 1st very fine, from Mr. W. H. Bacon; 2nd, Mr. Spencer, gr. to H. C. Moffatt, Esq., Goodrich Court, Ross.

Easter Beurré and Emile d'Heyst, brought each but two exhibitors, for the former Mr. W. Jones, gr. to J. R. Brougham, Esq., Wallington Bridge, Carshalton, was 1st; for the latter, Mr. W. Allan.

Fondante d'Automne,—1st, Mr. W. H. Godden, gr. to F. W. Buxton, Esq.; 2nd, Mr. W. Allen, gr. to Lord BRASSEY, K.C.B., Normanhurst, Sussex.

Glen Moreau was a poor exhibit of three fairly good dishes, the best coming from Mr. SPARKS, Grove House Gardens, Putney.

Six dishes were staged of Josephine de Malines, the best coming from Mr. W. Jones; 2nd, Mr. Ross.

Mr. W. Jones was the only exhibitor of Le Lectier, and was awarded the 1st prize.

Eleven exhibitors staged Louise Bonne of Jersey, a very even lot. The 1st prize was awarded to Mr. Wythes for a very fine and highly coloured lot; 2nd, Mr. W. A. Cook, gr. to Major HENAGE, V.C., Compton Bassett, Wilts.

Marie Benoist was poorly represented, the best dish coming from Mr. W. H. Godden. The popular Marie Louise brought but five dishes, 1st, Mr. WM. ALLAN; 2nd, Mr. MOORE, Babington, Bath.

Three very fine dishes of Marguerite Marillat were staged; 1st, F. W. Thomas, Esq., Polegate; 2nd, Mr. Slade, gr. to Lord POLTHORPE, Exeter, with more highly coloured fruits. Nouvelle Fulvie, 1st, Mr. THOMAS; 2nd, Mr. WYTHES.

Two dishes of Olivier de Serres only were staged, the best came from Mr. C. Harris, gr. to O. A. Smith, Esq., Hammerwood Lodge, East Grinstead. Pitmaston Duchess brought the strongest competition in this division, seventeen handsome dishes being staged, Mr. C. Morgan, gr. to S. J. Du Croz, Esq., Oaklawn, Weybridge, coming 1st with a very heavy lot; 2nd, Mr. WEBB.

The pretty little Seckle was well shown by Mr. Ross, who was a good 1st; 2nd, Mr. SPARKS.

Some very fine specimens of Souvenir du Congrès were staged by four competitors: 1st, Mr. HERRIN, Dropmore Gardens; 2nd, Mr. THOMAS.

Six competed with Thompson's, the best coming from Mr. W. ALLAN; 2nd, Mr. HUDSON.

A similar number of Winter Nelis were staged, Mr. CHAMBERLAIN coming 1st; Mr. J. WEBB, 2nd.

In the last class, that for any other variety, seventeen dishes were staged, the winning variety being a fine lot of Williams' Bon Chrétien from Mr. W. ALLAN; 2nd, Mr. W. H. Stower, with Duchess d'Angoulême.

BRITISH ASSOCIATION.

SEPTEMBER 18.—Various papers interesting to botanists were read in the Botanical Section during the day. Mr. F. DARWIN, F.R.S., contributed a paper "On the Localisation of the Irritability of Geotropic Organs," which in some respects was a continuation of the work undertaken by CHARLES DARWIN and himself on the movement of plants. Professor DOUGLAS CAMPBELL next gave the results of studies in Araceae; and Mr. J. C. WILLIS followed with a paper, entitled, "Studies in the Morphology and Life-history of the Indo-Ceylonese Podostemaceae." In the afternoon, Professor F. O. BOWER, F.R.S., read a valuable paper on "Fern Sporangia and Spores," in which he gave a general account of his interesting researches in Ferns. Mr. A. C. SEWARD, F.R.S., then spoke on the Jurassic Flora of Great Britain. In the course of his remarks, he said that the lower oolite rocks exposed in the cliff sections between Whitby and a few miles south of Scarborough had long been famous as affording rich collections of fossil plants, which enabled us to form a fairly accurate idea of the chief characteristics of the Jurassic flora. The Ferns, Cycadean genera, constituted a large proportion of the vegetation, with an abundance of one or two species of Equisetaceae and a few Conifers; no trace of undoubted Angiosperms had so far been discovered. The account of the flora included a description of the more important types, a general comparison of the English species with recent plants, and remarks on the characteristics and distribution of the Lower Oolite floras. Miss E. DALE read a paper which dealt with the intumescences of *Ilbiscus vitrifolius*.

The Effects of Sea Water on Land.—At the meeting on this day, a paper by Mr. T. S. DYMOND and Mr. F. HUGHES, on "The Chemical Effect on Agricultural Soils of the Salt Water Flood of November 28, 1897, on the East Coast," was read. On that occasion, about 30,000 acres of land in Essex alone were flooded. By analysis made after the water had run off, but before an appreciable quantity of rain had fallen, the

soil was found to contain 0.2 per cent. of salt, or about twenty times the normal quantity. This was insufficient to produce plasmolysis of the root-hairs, and it therefore was not directly injurious to growing crops. The immediate injury appeared to be chiefly due to the entire destruction of earth-worms. In the following season (1898) very few crops were worth harvesting. The soils were re-examined this spring (1899). It was found that nine-tenths of the salt had been washed down by rain and removed by drainage, and that young worms had again made their appearance. The condition of the soil was, however, very unsatisfactory, and while on some farms there was promise of fair crops, on others the crops had failed. When shaken with water, the soil was no longer quickly deposited, but remained partially suspended for several weeks, evidence that the clay had become gelatinous. This was also shown by the higher percentage of water of hydration in the air-dried clay from the flooded soil. The retentivity of the soil for water had not become greatly altered, but percolation of water through the flooded soil was just half as rapid as through the unflooded.

BOSTON DAHLIA AND CHRYSANTHEMUM.

SEPTEMBER 21.—Boston, following upon the lines of Wellingborough, has started a Dahlia and Chrysanthemum Society, with every prospect of success. An exhibition of Dahlias took place in the Corn Exchange on the above date, and aided by the presence of several of the leading southern growers and their blooms, an excellent exhibition of the flower in its various types resulted. Several local growers also exhibited, and the result appears to be that another year an extended schedule of prizes of greater value will be issued. The southern cultivators are worthy of great praise for the self-denying support they gave to the new venture.

The first six classes for Dahlias were open to all comers. There were as many as six entries of twenty-four blooms of show and fancy varieties. Mr. S. MORTIMER, Swiss Nursery, Farnham, took the 1st prize; Messrs. KEYNES, WILLIAMS & Co., nurserymen, Salisbury, were 2nd; and Mr. GEO. HUMPHRIES, nurseryman, Chippenham, was 3rd. With twelve show varieties, there being eight entries in this class, these exhibitors took corresponding positions. Mr. MORTIMER was in remarkably good form for so late a part of the season; he had really fine blooms of Shirley Hibberd, Sunbeam, Victor, one of the finest dark varieties, extra good; Mrs. Gladstone, J. B. Service, John Walker, Duke of Fife, Virginale, John Hickling, R. T. Rawlings, Rebecca, Rev. J. Godday, Duchess of Albany, Perfection, and Chieftain.

Cactus Dahlias shown on boards, in collections of twenty-four varieties, brought ten entries. Here Messrs. KEYNES & Co., came to the fore, with an excellent selection; chief among them being Clown, Charles Woodbridge, Mrs. Carter Page, Mrs. J. J. Crowe, a new variety, which has been consistently good all the season; Loyalty, Lucius, Progenitor, in its best form; Britannia, Fusilier, &c. Mr. R. Keeble, gr. to F. W. Suarpe, Esq., Twyford, Berks, was a very good 2nd. There were also ten entries of twelve blooms; Messrs. KEYNES & Co. were again 1st; Mr. KEEBLE, 2nd.

The finest feature of the show was the class for twelve bunches of Cactus, three blooms of each, there being seven entries. Messrs. KEYNES & Co., and Mr. R. KEEBLE, showed in such excellent form that the most careful pointing of the blooms brought both collections out as exactly equal, and eventually equal 1st prizes were awarded; Messrs. KEYNES & Co. had in perfect character such varieties as Clown, Innovation, J. F. Hudson, one of the most distinct of the newer varieties; Mrs. Carter Page, Loyalty, Mary Service, Mrs. J. J. Crowe, &c. Mr. KEEBLE had J. F. Hudson, remarkably well coloured; Lucius, Keynes' White, Mary Service, Viscountess Sherbrooke, Etarish, and Alfred Vasey, extra fine. Mr. S. MORTIMER came in a close 2nd.

Pompon varieties were also shown in collections of twelve bunches, and there were six entries; Messrs. J. BURRELL & Co., were 1st in the varieties of medium sizes, fresh, even, and perfect in form; among them, Red Indian, Eurydice, Dr. Jim, Emily Hopper, Bacchus, Douglas, Mary Kirk, &c. Messrs. KEYNES & Co., were 2nd.

Special prizes were also offered in a few classes, and the 1st in a class for twelve blooms of Cactus, was won by Mr. KEEBLE; and he also won the 1st of Messrs. KEYNES & Co.'s special prizes for 12 blooms of Cactus varieties sent out by themselves; and also a special prize by Mr. R. DEAN, for the best bloom of any type, having a remarkably fine one of Cactus Magnificent.

There was a series of classes for amateurs residing in the county of Lincoln; and for cottagers.

Miscellaneous exhibits filled a considerable space of tabling. Mr. J. GREEN, Norfolk Nursery, Dereham, had a large bank of Cactus Dahlias in bunches, including his new varieties, Red Rover, Green's White, and Zephyr; also Pompon Dahlias in variety, and Tomatos. This was awarded a Special Medal, offered for the best miscellaneous exhibit.

Mr. W. COCKS, nurseryman, Donnington, had a very interesting collection of Lincolnshire-grown Apples, generally in fine character, some of them brilliantly coloured; also a select collection of Pears, the variety Fertility being very good.

Messrs. W. & J. BROWN, nurserymen, Stamford, had illustrations of standard, dwarf-trained, and bush-fruit trees, Apples, Dahlias, &c.

Messrs. PENNELL & SON, nurserymen, Lincoln, had a collection of blooms of Dahlias.

Mr. T. B. DOLBY, nurseryman, Boston, had stove, greenhouse, and hardy cut flowers, Dahlias, Apples, &c.

Mr. F. WAITE, seedsman, Boston, had a collection of about fifty dishes of Apples.

Mr. C. T. CHATTAND, Floral Gardens, Boston, had a collection of blooms of Cactus and Pompon Dahlias.

NATIONAL CHRYSANTHEMUM.

SEPTEMBER 27.—A meeting of the Floral Committee of this Society was held in St. Stephen's Hall, Royal Aquarium, on Wednesday last. There were very few exhibits.

Mr. W. J. GODFREY, Exmouth, showed a perfect yellow sport from Lady Fitzwigram; Mr. WELLS, Earlswood, had a fine yellow Japanese named General Paquin; Mr. A. G. DAVEY, Oakhurst, Burgess Hill, showed an early-flowering Japanese variety, with broad petals, named Miss Burton, flowers ivory-white; and Messrs. CARNEGIE & BAXTER, Ayr, N.B., sent a rosy-cerise coloured sport from the well-known early-flowering variety Madame Marie Massee. No awards were made. Sufficient members of the Committee were not present to form a quorum.

Obituary.

JAMES MARTIN.—We regret to announce the sudden death, at three o'clock on Wednesday morning, after four hours' illness, of Mr. Jas. Martin, the well-known hybridist, who was for over forty years the faithful servant of Messrs. Sutton & Sons, of Reading. His death was entirely unexpected, he having retired to rest in his usual health on Tuesday night.

VARIORUM.

THE FIBRES OF THE PHILIPPINES.—By far the most important of the fibre plants growing in the Philippines is Manila Hemp, or Abaca. At first sight this plant might be taken for an ordinary Plantain, or Banana-tree, but its fruit is much smaller than the Banana, and is not edible. According to a recent report of the United States Department of Agriculture, the Manila Hemp crop comes chiefly from the provinces of Albay and Camarines, on the island of Luzon, and from the islands of Marinduque, Leyte, Cebu, Mindoro, Samar, Mindanao, and the southern part of Negros. The finest quality of the fibre is called "Lupis," or "Quilot," and is of a pearly lustre. Other grades are distinguished by their colour and consistency. Nearly the whole crop is placed on foreign markets. The average yearly shipments amount to nearly 1000 tons, and form the most important item in the Philippine export trade. The United Kingdom and the United States receive the largest shipments, although considerable quantities are also sent to Spain, Australia, China and Japan. Cotton occupies a peculiar position in the Philippines. It was the first raw fibre used locally in the manufacture of textile fabrics, but it has recently lost much of its former importance, partly because of the excessive taxation that has for some time been imposed on the textile industry of the islands, but principally because of the competition of British fabrics. The Cotton plants cultivated in the Philippines are chiefly of the herbaceous varieties. They yield a fine white staple, of superior quality and strength. One variety, however, known under the name of Cayote, produces a cinnamon-coloured fibre. There is also a species called Bubuy, that grows like a shrub; the fibre it produces cannot be employed in weaving, but is used in stuffing mattresses, pillows, cushions, &c. Another textile plant that occurs is the Amray! This plant is found only on the Batanes Islands, north of Luzon; it closely resembles Ramie, and yields a fine white fibre of great tensile strength. Various other fibre plants are found in the Philippines, such as the Pita (a kind of Aloe), the Balihago, the Dalanot, or Tree-nettle, the Pine-apple, and the Cabonegro (a species of Palm-tree), as well as many other varieties more or less unknown outside the Archipelago. *Indian Gardening*, August 31, 1899.

ANSWERS TO CORRESPONDENTS.

APPLE AND PEAR-LEAVES DISEASED: *F. C.* The spots on the Pear-leaves are caused by a fungus (*Fusicladium pirinum*), which attacks both leaves and fruits; on the latter causing the "Pear-scab," see figures, *Gardeners' Chronicle*, November 5, 1898, p. 341. The disease on the Apple-leaves is in part due to a similar fungus, but at least two others are present, all assisting in destroying the leaves. As to remedy, the first thing is to satisfy yourself that the trees are in a good situation, and properly treated. The disease may be successfully combated as follows. During the winter the trees should be well washed down with copper-sulphate (1 lb. in 15 to 20 gallons of water). Then spray with Bordeaux Mixture, first, as the flower-buds begin to open; then immediately after the petals fall; and finally, about two weeks after the second application. The strength of the mixture, given in *Gardeners' Chronicle*, May 20, 1899, p. 328 (see also August 21, 1897, p. 118), is about the best. This is the method recommended by the United States Department of Agriculture. The disease is important enough to warrant the trouble (the expense is very little), because of the injury it causes to the fruit. This year we have seen whole trees bearing fruit which was of no market value, because scabbed.

BOOKS: *C. A. British Flora*—that by Bentham & Hooker; price 10s. 6d., 5th edition. *Illustrations* to the same, 10s. 6d. (L. Reeve & Co., London).

CATALPAS BEARING SEED: *G. Burt.* The result, doubtless, of the last two very warm summers.

CREEPERS FOR COVERING A DWELLING: *A. B.* *Ampelopsis Veitchii*, *A. purpurea*, *Vitis Coignetiae*, *Ceanothus azureus*, *C. stricta*, *Bigoonia grandiflora*, *B. capreolata*; *Crimson Rambler*, *Ayrshire*, and other rambling Roses, *Banksian* Roses, white and yellow; *Magnolia grandiflora*, *Pyrus japonica* in variety, *Smilax aspera*, *S. laurifolia*, *Wistaria sinensis*, and *Clematis* in variety.

CUCUMBER LEAVES BURNED IN SPOTS: *H. P. R.* Due to scalding, from lack of air, bad glass, &c. No disease.

CUCUMBERS DISEASED: *W. K.* The disease is a form of mildew. Allow a free circulation of air amongst the plants, and, if need be, raise them slightly above the ground. In America the spraying of outdoor Cucumbers with the Bordeaux Mixture resulted in a better supply of healthy fruit than from unsprayed parts of the same field. In spraying, the underside of the foliage must be thoroughly wetted.

EUCHARIS SANDERII, CORRECTION: On p. 239 of our last issue, the second line under *E. Sanderi* should have read "with tall leaves $\frac{1}{2}$ foot wide, a peduncle 2 feet wide," not inches.

FRUITING OF THE CAMELLIA: *Stanley Jordan.* A common occurrence on single and semi-double-flowered varieties, and less common on double-flowered ones.

GRAPES: *G. H.* A sudden access of water to the border after a period of drought has caused the cracking of the fruits, and too much humidity in the air is responsible for the decay, in so far as it follows on the cracking of the berries. There is no disease beyond a little shanking.

HOP PLANT: *S. J.* *Humulus Lupulus*.

LAND AND FIXTURES: *Beeston.* If the buildings have foundations that are fixed in the ground, you must leave them standing unless your agreement states that you may remove them. In regard to the whole matter it will be prudent to take legal advice.

NAMES OF FRUITS: We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. They should be just approaching ripeness, and they should be properly numbered, and carefully packed. A leaf or shoot of each variety is helpful, and in the case of Plums, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.—*H. H.* 1, Margaret; 2, not received; 3, Norfolk Stone Pippin; 4, Yorkshire Greening; 5, Hawthornden; 6, Calville Rouge d'Hiver.—*C. A. C.* 1, Crimson Quoining; 2, Scarlet Tiffing; 3, White Paradise; 4, Hubbard's Pearmain.—*R. F. I.*,

Stamford Pippin; 2, Scarlet Nonpareil; 3, Golden Spire; 4, Hawthornden; 5, North End Pippin; 6, not known—probably a local variety.—*T. W. S.* Apple Golden Noble.—*A. C.* Plum, Red Magnum Bonum. You did not follow instructions given above. It is necessary that wood and leaves should be sent with all stone fruits, but particularly with Plums and Peaches.—*X.* You have not attended to the instructions given in this column relative to sending fruits for name; we have therefore selected the following six varieties from those received:—3, Mank's Codlin; 4, Stirling Castle; 6, Keswick Codlin; 9, Margaret; 10, Devonshire Quarrenden; 11, Duchess of Oldenburgh.—*B.* Dume-low's Seedling.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*W. B.* *Populus canescens*—probably; you should have sent shoots with catkins in the spring.—*Percy Bicknell.* *Fraxinus excelsior* var. *simplicifolia*.—*W. H. M.* *Cassia corymbosa*.—*J. R.* *Villenoj.* 1, completely withered; 2, *Polystachya* species; 3, *Odontoglossum cariniferum*.—*B. B.* 1, *Caryopteris mastacanthus*; 2, *Polygonum cuspidatum*; 3, *P. orientale*; 4, *Vitis laciniata*; 5, *Mentha pulegium*.—*P. H.* *Camb.* *Lælia Dayana*, sometimes called *Lælia pumila Dayana*.—*Constant Reader.* 1, *Begonia incarnata metallica*; 2, *Polystichum angulare*; 3, *Cyrtomium caryotideum*; 4, *Adiantum capillus-veneris*; 5, *Pteris longifolia*; 6, *Clematis vitalba*.—*S. G. S.* 1 and 2, *Cypripedium bellatulum*; 3, *C. Charlesworthii*; 4, *Epipendrum radiatum*; 5, *Brassia signata*.—*T. B.* 1, *Brassia caudata*; 2, *Gomeza planifolia*.—*A. E.*, *Ascot.* 1, *Pteris argyrea*; 2, *Gymnogramma ochracea*; 3, *Blechnum occidentale*; 4, *Davallia dissecta Mariesii*; 5, *Pteris Mayi*; 6, *Cyrtomium falcatum*. Some of the tickets were wet and scarcely decipherable.

OAK LEAVES WITH GALLS: *E. Bros.* The leaves are covered with the Oak spangles, the work of an insect—*Diplolepis lenticularis*, figured in the *Gardeners' Chronicle*, p. 52, 1843, together with *Cynips Quercus tiare*, the Silk Button Gall.

RAISING WATER TO A HEIGHT: *Riga.* We should suppose that an American windmill would suffice to pump the water to a height of, say, 15 to 20 feet, and it would be greatly more economical than a steam-engine. An hydraulic-ram would be very suitable if sufficient water be available to work it.

THE ROOTS OF POT PEACHES, &c.: *T. B.* There will be no injury done to the trees if you remove the longer roots in moderation, performing the operation at this season. A sharp knife should be used, and a somewhat oblique cut made. Next year numbers of roots will be emitted from the callus formed at the edge of the wounds, which will collect and afford more nourishment to the plant than the long, somewhat bare roots removed.

TRAVELLER IN FRANCE AND GERMANY: *T. K.* You should advertise your wants in the *Gardeners' Chronicle*, which has a considerable continental circulation; or in *Möller's Gärtner Zeitung*, Erfurt, and *Le Moniteur d'Horticulture*, 14, Rue de Sevres, Paris.

VINERY IN THE SHADE: *A. B.* You might get over the difficulty encountered in ripening the crop of Grapes, by starting the Vines early in the month of March, and thus afford them a longer period of warm weather in which to mature.

COMMUNICATIONS RECEIVED.—*A. Child.*—*A. D.*—*F. W. R.*—*J. C. & Sons*, Rochester, New York.—*J. H. P. W.*—*W. E. E.*—*D. T. F.*—*S. J. T.*—*W. Cobb.*—*W. R.*—*D. McKinnon.*—*V. R.*—*H. B.*—*D. IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal libraries.

(For Markets and Weather, see p. x.)

THE

Gardeners' Chronicle

No. 667.—SATURDAY, OCT. 7, 1899.

FAIRLAWN PARK, TONBRIDGE, KENT.

THIS fine park, the residence of W. M. CAZALET, Esq., is situated some $3\frac{1}{2}$ miles from Wrotham Station on the London, Chatham, & Dover Railway, and about 5 miles from Tonbridge, on the London & South Eastern line. Either way there is a pleasant drive through leafy country lanes and apparently prosperous villages. On the Tonbridge side the scenery is as diversified as it is beautiful; and though at the time the visit was made the drought was being severely felt, yet hedgerow, field, and tree were in the full flush of their summer glory. One of the glories of Fairlawn are the splendid trees which form the framework of a picture, which is typical of many another southern English scene, nestling in the shade of Limes, Beeches, and other big trees.

Fairlawn was in ancient times accounted a manor, though it has long since lost that appellation. It was the seat of the family of the Bevants, afterwards of the Colpepers till the end of the reign of Henry VI., when it was alienated to one Chown, whose descendant, Sir George Chown, resided at Fairlawn in the reign of Henry VIII., till ordered by the King to confine his possessions within the county of Sussex, he alienated Fairlawn to Sir Harry Vane the elder, whose son, Sir Harry, became a prominent Roundhead. On the Restoration of Charles II., Sir Harry Vane was exempted from the general pardon, and executed on Tower Hill in 1662. He was succeeded by his second son, who improved the estate by means of extensive planting, &c., and who was created Lord Barnard in 1698.

Fairlawn remained in the Barnard family till 1789; and then, after several minor changes of proprietorship, it was purchased by the father of the present owner in 1871, by whom, and also by his son, the present proprietor, many considerable additions have been made both to the mansion and the grounds.

Lord Barnard, who owned Fairlawn during the latter part of the seventeenth century, did the chief part of the planting in the grounds and park, and there is a record of his having planted a singular arrangement of Yew trees in what is known as the Wilderness in 1684. Very little in the way of improving and planting had been done on the estate from that time until J. Ridgway, Esq., purchased the property in 1848. He, shortly after coming into possession, laid out the flower-garden in its present form, and made and planted the American walk, the older of the specimen Conifers, including a fine specimen *Sequoia gigantea* in the park near the American Walk, which is now 60 feet in height, and 110 feet in the circumference of the branches. The veteran, Mr. Charles Ross, now of Welford Park, Newbury, was gardener here at that time, and he has never lost a warm interest in the place he did so much to embellish. The American Walk,

leading to the Wilderness, is straight, and 200 yards in length, and the *Rhododendrons*, *Kalmia*, *American Azalea*, &c., with which it is planted, must form an attractive mass of colour in early summer.

Mr. Edward Cazalet, the father of the present owner, purchased the estate from Mr. Ridgway in 1871, and entrusted the gardens to the care of Mr. George Fennell, who still holds the position of head-gardener. During the past twenty-eight years Mr. Fennell has carried out numerous alterations and improvements, formed drives, &c., and made a terrace-garden on the west front of the house. In 1872-73 improvements were made in the huge sloping bank of trees and shrubs in which Lady Vane's well is situated, and below which is Lady Vane's pond. Many interesting traditions have gathered about the place in the past, and some ghostly legends abound in the neighbourhood, and probably centre about the fact that the body of the beheaded Sir Harry was brought here, and interred in the church of Shipbourne close by; and his ghost is still supposed to haunt the wilderness, carrying his head under his arm. Lady Vane's spirit is represented as haunting the spot where her well is situated. Just above the well, tower up some tall and majestic Lime-trees of prodigious proportions, the roots of which are probably watered by the springs which appear to be here, or perchance have found their way into her ladyship's well.

The covered walk of Apples and Pears in the kitchen garden [figured in our last issue. Ed.] was planted about this time. In 1876, glass-houses and a fruit-room on modern principles, were erected. In 1882-83, Mr. Fennell enclosed, laid out, and planted a new lawn, $4\frac{1}{2}$ acres in extent, on the eastern side of the American walk. In 1896 a range of three-quarter span-houses was added to the kitchen garden. In 1898 a spacious conservatory was erected by Messrs. McKenzie & Moncur, access to which is obtained from the dining-room of the mansion.

The gardens of Fairlawn may be said to be laid out upon a series of levels; the gardener's house, elaborately constructed, with swimming-bath and other offices, occupying the higher ground. The plant and forcing-houses form a compact whole, though from the nature of the ground, broken up as it is into sections; and in walking about the visitors come suddenly upon varied and beautiful views. What strikes the visitor is the orderliness and tidiness found on every hand.

There are early, mid-season, and late vineries, and near these are plant-houses filled with useful decorative plants. Tuberous and fibrous-rooted *Begonias* are made great use of in various ways; the brilliant *B. corallina* being especially noticeable. We remarked a number of Melon plants growing in inverted Seakale-pots, and doing well.

The early vineries are on a lower level than the plant-houses, and near them are old walls covered with Fig-trees and other plants; and on a north wall the Japanese Honeysuckle, *Lonicera aureo-reticulata* covers a large amount of space. There are several Peach-houses, in one of which a grand specimen of the old French variety, *Belle Beauce*, planted by Mr. Charles Ross some forty years ago, is still in existence. A venerable Fig-tree on an outdoor wall is said to have been planted in the time of Sir Harry Vane, the tree being imported direct from Turkey.

Some very fine specimens of *Cypripediums* were noticed in one of the houses; there were also Carnations, fine flowering examples of

Ruellia macrantha, and *Richardia Elliotiana*, which Mr. Fennell said he made a point of drying off, the plants succeeding capitally under this kind of treatment.

Then comes the walled-in garden, with its well-managed Apple, Pear, and Plum-trees. The leading feature is the arcade of Apple-trees running athwart the garden. The principal varieties consist of Cox's Orange Pippin, Cox's Pomona, Lord Derby (which does specially well), Gloria Mundi, and Peasgood's Nonsuch. The direction of the walk is from north to south; thus enabling the fruits to colour well on two sides.

Then comes the raised flower-garden on the east side of the mansion, with a venerable hedge of Laurel affording shelter from wind and sun. Dotted about the gardens are standards of various Hollies, with green and variegated leaves. From this garden there is a descent to the south front, and the spacious new lawn fenced in on certain sides by a bank of shrubbery and the new conservatory. Among the occupants of this building are some fine Kentias; and a delightful fernery has been made at one end, with an appropriate waterfall.

From the east side of the mansion, splendid trees of *Sequoia gigantea*, *Cryptomeria japonica*, a pair of magnificent *Acacias*, and lines of towering Limes, reported to be 200 years old, become visible. On the front line of the terrace are stone vases filled with plants; and alternately with these are lamps, with Crimson Rambler Rose trained to each standard. Then on by Lady Vane's pond, I noticed fine specimen *Sequoias* and *Thuyas*; and so round by Ross' monumental *Sequoia* to the American Walk, and past this to the Wilderness, a quiet and reposeful place.

A grassy walk leads to a circle of Yews, planted, it is supposed, two hundred years ago; and from the centre of which radiate in all directions several walks lined with Yews, and forming a circle at the termination of each. The question will always be asked, What did, or does, this arrangement of Yews indicate? From here, by a shady walk, a return is made to Mr. Fennell's abode. Of the trees which abound in these grounds, mention may be made of English and Turkey Oaks, these very fine; Elm, Lime, Beech, *Pinus sylvestris*, of which there are some splendid specimens; and there are good examples of Wych Elm. R. D.

NEW OR NOTEWORTHY PLANTS.

LÆLIO-CATTLEYA × *ETHELWALD* (C. GASKELLIANA × L. BOOTHIANA).

THIS, while not being so showy as some of the other *Lælio-Cattleyas*, is an attractive flower, somewhat resembling *L.-C.* × *Gottoiana*, and not unlike some of the varieties of that natural hybrid. The sepals and petals are like those of *Cattleya labiata* Gaskelliana, and of a pale rose-lilac, with silvery midrib at the base. The lip well displays the influence of *L. Boothiana*, known in some gardens as *Cattleya lobata*, Lindl. It is of the same colour as the petals, the base in the inside being red, changing to orange colour towards the centre, the front lobe bearing a showy purple veining, and connecting tinge, the rosy margin finely crimped. It flowered with the Rev. F. Paynter, Stoke Hill, Guildford (gr., Mr. Cook).

CYPRIPEDIUM × *HELVETIA*.

A flower of a very pretty and distinct hybrid, purchased in Switzerland as a probable cross between *C. Chamberlainianum* and *C. Lawrenceanum*, but which the Manchester Orchid Committee

decided was *C. Chamberlainianum* × *philippinense* (a decision with which I agree), is sent by J. Leemann, Esq., West Bank House, Heaton Mersey, (gr., Mr. Edge).

The flower, which well displays itself, has the dorsal sepal broadly ovate acuminate, pale apple-green with a white margin, about a dozen distinctly-blotched chocolate-purple lines radiating from the base. The petals, which are decurved and reflexed at the tips, are 3 inches in length, twisted, and with undulate margins bearing ciliate warted protuberances; the ground colour greenish-white profusely spotted with chocolate-purple. The lower sepals, which are two-thirds of the size of the upper one, are greenish-white with fine purple lines; the lip, pale-yellow at the base and edges of the side lobes, is spotted inside with purple, and tinged outside with rose-colour. The very singular-looking cushion-like staminode, which, with the petals, gives the best indication of the presence of *C. philippinense*, is emerald-green shading off to yellowish-green at the edges, which latter bear a conspicuous fringe of blackish hairs. It was acquired from M. Otto Froebel, who, while not accounted an Orchid specialist, yet grows many reputedly difficult Orchids better than anyone else. *James O'Brien.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA × HARDYANA, OAKWOOD VARIETY.

In August, 1877, Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne (gr., Mr. Wm. Murray), crossed a fine form of *Cattleya Dowiana aurea* with the pollen of a good *C. Warscewiczii*, and a year later the seeds were sown. On September 8, 1896, two of the plants were shown at the Royal Horticultural Society, and occasioned much interest on account of their proving the correctness of the surmise that *C. × Hardyana* as imported were natural hybrids. The plants have gained strength, flowering regularly every year, and proving equal to good forms of imported *C. × Hardyana*, but with distinct peculiarities in the form and colour of the lip. A fine example has been sent with sepals and petals, of a bright rose-purple colour, and with a delicate veining of silvery white. The tint of the lip is Indian-red, from the base to the centre, with orange-lines running into orange blotches on each side of the tube. The upper portions of the side-lobes are of a purple tint, and the showy front-lobe is of purplish-crimson.

SOPHRONITIS GRANDIFLORA.

Again the time of flowering of this charming scarlet-flowered autumn and winter-blooming Orchid is commencing, and several exceptionally fine forms have been received. By far the best is a magnificent flower sent by Geo. C. Raphael, Esq., Castle Hill, Englefield Green (gr., Mr. H. Brown), which has almost the whole surface of the flower filled in by the various parts, thus making it nearly circular, and 3½ inches across. The labellum is marked with light orange colour, and there is a pale violet flush over the bases of both sepals and petals. Few plants of such small size bear such large and showy flowers as do the best varieties of *Sophronitis grandiflora*, and an additional advantage is that they thrive in any warm greenhouse if properly tended.

A TRAVELLER'S NOTES.

CHALONS SUR MARNE.—This is the head quarters of the Aij champagne district, but the passing traveller sees no Vines in the immediate neighbourhood. Indications of a warmer climate than ours are however presented in the public garden, the Parc du Jard, as it is called; Jard, being an abbreviated form of Jardin. The ornamental garden occupies the slope of a valley, at the bottom of which a clear-green stream runs. The area is small, but it has been so cleverly and artistically

managed, that it appears to be much larger than it really is. It is remarkable for its fine trees, but as usual, these have been allowed to spoil one another for want of timely thinning. Taking the trees at random as I find them in my note-book, I notice the finest *Acer Negundo* I have ever seen, but I am unable to give precise dimensions. A lofty *Gleditsia triacanthia* (?) was covered with its long, flat pods. *Sophora japonica* was a mass of bloom; and the weeping variety is used very effectively, a group of three or four together giving the undulated appearance of a "swelly" sea. Another tree of similar habit is the weeping variety of the

before, viz., an Alder copse on the top of a dry chalk down, with no water-course near. This is to be seen on the road from Chalons to Notre Dame de l'Epine. Gardeners and botanists are not wholly engrossed with plants when out on an excursion, so that the suggestion that they should, when occasion serves, visit the exquisite architectural gem above-named may be acceptable. It is a gothic cathedral of the thirteenth and fourteenth centuries, perfect and uniform in style and detail. Together with the very interesting churches of Chalons it is full of interest to the architect, and a delight to the mere tourist.

FIG. 92.—FLOWERING SPRAY OF *CAMPANULA MIRABILIS*. (SEE P. 275.)

Mountain Ash, which one does not often see at home. *Ailanthus*, with reddish flowers and twisted seed-vessels, was very conspicuous; *Kölreuteria paniculata* a sheet of golden bloom.

Tulip-trees and Liquidambars have not yet begun to change colour (September 18). *Euonymus latifolius* is covered with its crimson-lilac seed-pods. Magnificent *Paulownias*, with their noble foliage, are covered with capsules (which we very rarely see in England), and *Catalpas*, with their long, narrow pods, indicate a warmer climate. It seemed strange to see *Tamarisks* overhanging the water, as one generally associates these bushes with a dry situation (the sea-coast excepted). In any case, they droop very gracefully over the stream. This reminds me, too, of an association I never saw

BEDDING LOBELIA, &c.

Much use is made in Swiss town-gardens of a very beautiful *Lobelia* of the cardinalis type, with dark purplish-red foliage, and abundant flowers of a rich, bright, rose-pink colour. We may have it at home, but I was unable to procure its name, and think the colour more beautiful than in any variety I have seen. *Begonias* of the *sempervirens* type do excellently well as bedders; and those of the tuberous-rooted section are, on the whole, better this season than *Pelargoniums*.

CLEMATIS MONTANA.

Over a nurseryman's house at Vevey may be seen in letters, 18 or 24 inches long, the title of his establishment—"La Rosière." The whole front

of the house is covered with *Clematis montana*, which is allowed to roam at will, except where it is made to do duty as a sign-board. It is pretty, one is bound to admit, though on principle one ought to object to it; and when the flowers are out, it must be prettier still.

FRUIT-TREE PROTECTORS.

Fruit-trees have to be protected from other enemies besides birds. Featherless bipeds often do more mischief than those bedecked with feathers. To prevent this, they encircle the trunk of the tree in some parts of Switzerland with two or three coils of barbed-wire. This is hard on the boys, and recalls Leech's sketch of the poor boy bemoaning the fact that "they had been an' spiked the postes," so that they could no longer be overlept by his vaulting ambition.

CAMPANULA MIRABILIS.

We have already had more than one occasion to refer to this species, but the plant is so remarkable that we gladly avail ourselves of the permission of the Director of the Royal Gardens, Kew, to reproduce a photograph taken by Mr. Rose, of Ross Villas, Richmond. The general character of the plant is shown in the illustration (fig. 93), which is rather less than one-third the natural size. The broadly-ovate leaves are fleshy, and marked at the edges by fine spines; and the flowers are of a pale blue colour. It is a native of the Caucasus, where it was found by our late correspondent, M. Alboff. Some difficulty has been experienced in its cultivation, as recorded, but the plant at Kew, planted in a narrow border against a wall, was, in August, laden with flowers, and apparently in vigorous health.

FIG. 93.—*CAMPANULA MIRABILIS*, AS IT FLOWERED IN THE ROYAL GARDENS, KEW.

SPRAYING.

The Americans make much more use of this procedure than we do, or the Swiss either. Not a single Pear that came to our notice in the latter country was free from the maggot (*Carpocapsa*). It may be that this was an indication of the excellence of the fruit; but one would rather get that information in another way.

THE VINTAGE

here (Lake of Geneva) will be late and scanty, but the natives say the quality will be good. This seems hard to credit, for neither in the Jura districts nor here have I seen a single perfect bunch in the vineyards. In the shops may be seen fine bunches of "table" Grapes, coming, I am told, from the Valais, but about here the berries do not seem to have set; not a fourth were, as it appears, properly fertilised, and they are now shrivelled and mouldy, with only a good berry here and there. The foliage, though small, looks healthy, and shows no mildew so far as I have seen.

THE ROSARY.

THE PLANTING SEASON.

As the month of September draws towards its close, we are reminded by various signs, such as the arrival of catalogues and letters from correspondents, and the aspect of our own gardens, that the time for planting is at hand. We are never certain in our treacherous climate what weather we may have, and therefore in the first fine time after October 1, operations should be commenced. We ought to have decided in our minds what Roses are to be discarded and what new ones introduced. But there is one subject of importance to be first considered—what is to be done with our old-established plants. Some people advocate the lifting of the entire stock, and replanting them at once. I, however, say—No; let them be undisturbed, provided you have adopted the course best calculated to give good results. One good Rose-grower, who takes a large number of prizes at the National and

other shows every year, tells me that many of his cut-backs are from 12 to 15 years old; but then he adopts the plan I have a long time advocated of cutting out all the old wood and all spindly shoots in the autumn. As the plants are dwarf-budded on either the Manetti or Briar, it is more than probable that they have been budded low down, so that roots have pushed out both from the stock and scion, and it seems to me a pity to disturb them. The shoots which have been left on the Rose are simply those which have been pushed up from the lower part of the stem during the present season, and I therefore think that this is the plan which ought to be adopted now—at any rate, with hybrid perpetuals and hybrid Teas; and where you have long shoots of this year's growth, it is better to shorten them somewhat, so that high winds will have little power over them. There is another advantage in adopting this plan: it is that you will not have so much to do when the ordinary pruning season in March and April demands your attention; and in spring there is always a quantity of work to be got through, and everything that will save work then ought to be adopted.

Every few years there are changes made in our Rose-gardens, and many flowers which we once valued as exhibition and decorative Roses have to give way to newer and better varieties, and the National Rose Society comes to the help of all Rose-growers in this matter—it will publish a new and revised catalogue very shortly. The Catalogue Committee, consisting of some of the most experienced Rose-growers, both amateur and professional, have been engaged on its composition, and their great experience is to be relied upon; but while we are waiting for that, and the planting season has arrived, I will pen a few notes which may be helpful to Rose-growers.

Of course, after six years there are many Roses which appeared in the catalogue then which you very seldom see on the exhibition-table now. Who cares much now for Mary of Cambridge? for example; and how seldom do we see Duchess of Valombrosa, Mrs. H. Turver, Alphonse Soupert, Marguerite de St. Amand, or Madame Lacharme! We may have valued them in their day, or they would not have found their place in the catalogue; but these and several others we want no longer. Of those which may be added to our collections, several are the products of our own raisers. Tom Wood, Bessie Brown, Killarney, Mrs. Edward Mawley, and Ulster will, I think, be found valuable additions. With regard to hybrid Teas, I do not care to say much; there are some persons who are so enamoured of this section, that if a Rose only bear the character of a hybrid Tea, they are ready to take off their hats to it, and I dare say they will be ready to acclaim any candidate as an addition to its ranks. Of the pure Teas we have had very few claimants for public favour. It is true that we have a great many very beautiful varieties in the various shades of colouring that pervade this class; therefore, it is not easy to produce something which would be considered an improvement. The two most conspicuous are *Empress Alexandra of Russia* and white *Maman Cochet*; the former is one of those dark-coloured Teas which some people admire—but which I, for one, think spoil the chaste and delicate beauty of the stand in which it appears.

I think one of the great charms of the Tea Rose is its delicacy and refinement, and these very high-coloured flowers greatly interfere with that characteristic. The white *Maman Cochet* is very beautiful, and promises to be a very useful flower; the type is a great favourite now, and most people are glad to welcome a really good white variety. Of new garden Roses, there are many which growers will gladly welcome. I may mention *Purity*, *Dawn*, and *Psyche* amongst others, but doubtless many have taken notes during the past season of varieties which they would like to introduce into their gardens. When the revised catalogue of the National Rose Society is issued, I may have something more to say on this subject.

With regard to the method of planting, I do not think much need be said. Rose-growers know pretty well their business in this matter; and to those who are novices, the "Hints on Planting" published by the National Rose Society will afford them all necessary details. There is one point, however, one would like to insist upon after this long period of drought, when the soil is what in this part of the world we call "hover" (that is very light, and apt to run from the fork), viz., firm planting; at all times it is necessary, but doubly so this season.

We have had amongst the newer Roses a great many of light shades, pink and rose, and therefore in filling up the beds it would be desirable to see a little bit of bright colour amongst them. Such Roses as Victor Hugo, Jean Soupert, Prince Camille de Rohan, Charles Lefebvre, Duke of Edinburgh and Duke of Connaught should be liberally employed for this purpose, and it is to be earnestly hoped that some of our Rose-growers who are engaged in raising seedlings will devote more attention to the production of such varieties, which moreover have the advantage of being very sweet scented. I think it is becoming more and more the wish of Rose-growers to stipulate that their Roses should be on either the seedling Briar or Briar cuttings, though I think that in some soils the Manetti is still a favourite.

To those who are particular about Tea Roses, the half standard Briar is still the most favourite stock, and probably the best exhibition Roses are produced from it; but then it shares the risk of all such Roses of being cut off by frost, whereas when dwarfs are used, should the plants be severely punished by frost, fresh shoots come up from the bottom, and the plant is preserved. In all directions I hear, both from nurserymen and amateurs, glowing descriptions of the healthiness of the plants, so that those who are intending to add to their stock will do so under favourable conditions; and when the plants arrive let them beware of leaving the roots exposed to the sun. I have seen all the contents of a package laid out on the beds, and probably a couple of hours elapse before planting is finished—it is wiser to heel them in at once, and then take them out as required. These little matters if attended to or neglected involve very often success or failure. *Wild Rose.*

SPECK IN APPLES.

THE following communication appeared in *Indian Gardening*, October 20, 1898, and is forwarded to us by Dr. J. F. Duthie, of the Botanical Department, Northern India, under date of August 29 last. "A. C.," a resident of Mussoorie and Dehra Dunn, is an enthusiastic cultivator of Apples and other fruits, and a very successful one.

"A. C.," Mussoorie, writes on the 8th inst. :—"What is the cause of speck in Apples, and is there any cure for it? More than half of my Apples have been specked and useless. I have been trying all kinds that are supplied from the Ranikhet Nursery to see which kind suited the climate of Mussoorie, and I expected that some would do better than others; but I did not expect so many to fail as there have been.

"I have been looking up in all the books on fruit-growing that I can get, but with the exception of Bunyard's *Fruit Farming for Profit*, which mentions, under the head of Wellington, that it is apt to speck in a cold season, I cannot find any references to this matter of specking. I have several trees of Dumelow's or Dumelow's Seedling which are said to be the same as Wellington, and these speck very badly. Some I have cut down and grafted with Red Astrachan, which hitherto have done well here. Margaret, or Red Juneating, planted in December 1888, fruited in 1897, the fruit seemed good and the tree vigorous, and fruited early. I planted a number in November last. This year, this tree had a good crop of beautiful fruit—to look at—but the inside of the

Apples were all specked, some with only a few reddish-brown specks; but in others, with great patches of decay in them; other kinds are also affected. I see in a former issue of your paper, that Mr. Barron, of Kulu, transplants his Apple-trees when the fruit specks, due, he says, to the roots going down to the cold sub-soil. This may do when the trees are young, but even then it seems a very troublesome operation. Would not root-pruning do instead of transplanting the tree bodily? Is it the want of something in the soil that causes the specking, and could not this be given along with the manure? The trees are exposed to the north-east; the sub-soil is good loam, rather clayey; it makes good bricks. There is plenty of leaf-mould on the surface, and the ground being on a hill side, is well drained; the rock is dolomitic limestone."

(We shall be glad to have the experience of some of our readers on this subject.—ED. I. G.)

"M. R.," wrote in the *Indian Gardening* of Nov. 3, that in his opinion, it was a fungus closely allied to that which is attacking the Sugar-cane in southern India; he had found that transplanting into entirely fresh soil, liberal manuring and copious watering, have often cured the tree—but if the fruits are badly attacked, then he would recommend the entire destruction of the trees. Lime mixed with the soil has often cured trees.

In *Indian Gardening* of Nov. 24, Mr. Gollan writes that he does not agree with "M. R." that the speck is caused by a fungus, nor that the disease is caused by an insect, and that the fungus is an after effect; he mentions several insects, but the editor says that on reference to the Indian Museum authorities that though the insects named have been recorded as attacking Apples in Europe, that they have not so far been reported from India. Mr. Gollan asks what about the ubiquitous mosquito, but I think from what you have seen of my Apples, that you have no doubt that it is a fungus.

"M. R." could not copious water the trees here, but the rain in general does so after June 15, and so far as I can make out, it is then when the Apples are swelling that the speck commences, but it may be that the germs get in during the dry weather, and do not become visible till the rains.

[Without having seen the diseased fruits, we cannot indicate the fungus which is the cause of the specking; but we would refer "A. C." to an article on *Oidium fructigenum* with illustrations, (both of which were supplied by Mr. W. G. Smith), appearing in the *Gardeners' Chronicle*, July 11, 1885, which seem to fit "A. C.'s" case in most particulars. We should advise the use of the Bordeaux Mixture twice during the season of growth, and the burning of a small quantity of sulphur in the fruit-room before and after storing the fruit. ED.]

WROTHAM PARK, ITS VINES, &c.

As many of our older readers are doubtless aware, the gardens at Wrotham Park, Barnet, afforded an excellent example of gardening in its various features, and more especially in the cultivation of the Grape-vine when the late William Thomson had charge of the gardens from the year 1837 to 1855. The Vines were of great age when Thomson went there, as the following particulars, furnished by Lady Susan Byng to Mr. Markham, the present head gardener, will show :—"In the reign of Queen Anne, about the year 1710, the Lord Strafford of that time was British Minister in Holland, and the Dutch were then the greatest gardeners in Europe; so Lord Strafford sent home to his mother, who lived at Twickenham, a piece of a Vine, and in 1785 his great-nephew planted at Wrotham, a slip from the Twickenham Vine, which was then getting old. That is the story of it, and I believe the Hampton Court Vine is no older. The berries certainly are not so good as the Wrotham ones."

As Thomson states in his *Practical Treatise on the Grape Vine*, sixth edition, "The Vines in the very large vinery at Wrotham and the other vineries, were in a very unsatisfactory state, and it was determined that the Vines and borders of three of them should be renewed at once. But the large vinery in question was not one of those; it was 65 feet long, 22 feet wide, and 7 feet high in front, and the back-wall was 16 feet high. There was a row of strong cast-iron pillars running along the centre of it to support the rafters, and against these the Vines were planted, twisting round them like enormous snakes. My employers were loath to have these old Vines destroyed, and wished me to make an effort to renovate them if possible. I made a careful examination of the state and position of their roots, and found that none of them was within 1 foot of the surface of the soil. It was the custom to keep all the bedding-plants standing on the floor of this house, and the constant watering and treading had made the whole surface, which had not been broken up for years, as hard as asphalt. This I had picked up, and removed from the house to the depth of 1 foot. I then got hold of the leading-roots, and traced them as far as possible. When they could be pursued no further, without going to a great depth, I cut them, and coiled them round the pillars that supported the stems, till in this way I had raised some eight or ten of the roots of each Vine; not one of which so far as I traced them had any live rootlets on them. I had mats put round these bundles of roots, and kept them damp for the time being. I removed six old Peach-trees that grew as standards in the house, the Vines been confined to the rafters. I took out a large pit where each of these stood, and in doing so cut many of the roots of the Vines. I then filled the pits for the Peach-trees with the best turfy loam I could get, and planted them, and laid 6 inches of the soil I had prepared for the new Vine-borders all over the surface of the border of this house, with a considerable allowance of good rotten dung. I then laid out all the roots on this bed of new soil, making a regular set of incisions with the knife, right and left, at about 9 inches apart, along their whole length, covering them over with 6 inches of the same compost, and giving them a good watering with warm water. This was done in March, just as their buds were beginning to swell. They broke as weak as straws, and looked very miserable till about the end of July, when they showed some signs of making second growths of a more vigorous character than the first. This was in the summer of 1838, and in 1839 they broke comparatively strong, showing a fair crop of fruit which they brought to perfect maturity. In 1840, and for seven or eight years afterwards, they bore first-rate crops of excellent Grapes, colouring well; they were Black Hamburgs. In 1848 they were on the wane again; and as the vinery had to undergo extensive repairs, I removed them all to make way for a new border and young Vines, except those Vines at the west end of the house, which I kept, partly as a memento, and partly to experiment upon." So far, W. Thomson's methods of renovating a Vine-border fell but little short of what we now advise and practice fifty years later. These mementos are still in existence, and we may suppose that the successive gardeners at Wrotham have in most instances done their utmost to maintain their vigour and fruitfulness, for when I saw them in August last the remains of a crop of very fair bunches of good colour and size were to be seen upon them.

The present gardener intends to curtail the tops of these old Vines, clear out the other Vines by degrees, planting new Vines in their place, and making a new outside border, and later renewing the inside border, and thus afford the young Vines plenty of feeding space.

The other vineries are filled with Vines of great age, but not so old as this one, and doubtless they must all undergo renovation at Mr. Markham's hands, he being a gardener very thorough in his

methods, and not readily satisfied with mediocre produce. His efforts in renovation in general will be much in demand, the gardens apparently having been under rather indifferent management for some years past.

The fruit walls are well built, and mostly of good height, ranging from 11 to 20 feet; but they are but poorly covered with trees. The kitchen gardens—there are several divisions, walled in and

above the ground level, about 10 feet in diameter, and there are others but little less in girth.

A fine feature of the vegetable garden is a wide border planted with a good selection of herbaceous perennials, many of which were in full bloom. A magnificent *Magnolia grandiflora* clothes a wall 20 feet high, and has a breadth nearly as great. The situation being warm, and sheltered by a vineyard on one side and a high wall on the other,

FIG. 94.—FOQUIERA COLUMNARIS.

communicating—appear to consist of a productive soil, excellent crops being obtained when it is deeply dug or trenched and suitably manured, as was observed on the occasion of my visit. Choice plants were not much in evidence, except in a large isolated conservatory on the lawn near the mansion. A goodly number of robust, promising Chrysanthemums were remarked; and the forcing-pits contained nice crops of Melons, Cucumbers, Tomatos, table-plants, &c. Some magnificent specimens of Lebanon Cedar are scattered about the gardens and park, one of the trees being just

the plant ripens its wood thoroughly, consequently it blooms finely.

The flower-garden, once furnished with numerous beds, is now much curtailed in size, the beds having been turfed over in great numbers, and flower-gardening as such is greatly reduced. The entire place is rich in evergreen shrubs and Conifers, but singularly destitute in deciduous flowering subjects, suffering as a consequence a dearth of those beautiful effects in the spring and early summer months, which the latter afford when planted in quantity, and suitably cultivated. *A Traveller.*

FOQUIERA COLUMNARIS.

AMONG the many curiosities at Kew likely to interest the plant-lover, but to be passed over with scant appreciation by the unlearned, is the very singular looking plant, of which we are privileged to give an illustration (fig. 94), by the courtesy of the Director. It looks like a plant, adapted by its construction, to live in hot, desert places where water is scarce, and the supply intermittent and precarious. The stem is pyramidal, succulent, deeply wrinkled, and emits thin, straggling branches, beset with scattered slender spines. These spines are called by Baillon (*Dict. Bot.*, ii., 638) abortive leaves, in whose axil is developed a tuft of small fleshy leaves. The flowers are paniculate, and their construction such as to indicate an affinity to the Tamaricaceae. The plant is a native of Mexico.

CHRYSANTHEMUMS IN JAPAN.

IN the gardens of the Mikado, Chrysanthemums are trained in surprising fantasies. The imperial specimens are of enormous size, sometimes as large as trees; their numerous branches ranging with perfect symmetry around one central stem. At the end of each branch is to be seen a fully developed flower, never faded, never deformed, and always at the same stage of expansion. When once picked, these flowers keep twice as long as do the Chrysanthemums of Europe; and that, thanks to the very simple manner in which the Japanese cultivate. In place of overworking the plants and forcing the buds, the plants are well fed—not excessively—and constant, but not excessive care is bestowed upon them. The Japanese have two precious factors for the culture of the Chrysanthemum which growers in other countries lack, namely, camphorated earth (presumably humus surrounding Camphor-trees, *Camphor officinarum*), and special flower-pots in which to grow their stock.

In the culture of the Chrysanthemum, the camphorated earth replaces our loam. Being at the same time as rich as the latter, owing to its fecund properties, it thoroughly prevents the invasions of worms and insects. Besides this, it constitutes the right amount of nourishment, which seems particularly adapted to the development and well-being of the Chrysanthemum. The camphorated earth is not unknown in France. Its very cheapness seems to place it among important necessities for the culture of flowers.

M. de Loverdo gives in *L'Agriculture Nouvelle* a very complete description of the system of culture obtained from M. Oasma, gardener to a former Emperor of Japan:—

“The soil destined to receive the young plants, no matter of what consistency, demands a previous preparation. By the aid of a spade, a bank is made, 35 centimetres* in thickness, heaped up to one side. The bottom of the excavated part is covered with from 8 to 10 centimetres of pebbles. Before being filled-in, the soil which has been removed is mixed with camphorated earth at the rate of 4 kilos. of that per cubic metre of soil. The quantity removed from a surface of 3 square metres corresponds to 1 cubic metre. This mixture, which is well incorporated, is placed on the pebbles, and the trench filled up, the soil left over is made use of for cultivation of Chrysanthemums in pots.

“Upon the soil thus prepared the newly-rooted plants are set out, 40 centimetres each way. At a distance of 3 centimetres from each plant Bamboo supports are placed, the surface being then covered with moss, save immediately around the plants. Around these a trench is dug of about 20 centimetres. The object of these trenches is to keep off all larvæ, earwigs, snails, and other known enemies of the Chrysanthemum. The wall thus formed is sprinkled with pure camphorated earth, on which also is applied lime-wash, which forms a kind of collar of protection around each plant. This done, winged insects only have to be feared, and these can easily be kept away by sprinklings made with a solution of camphor.” *La Semaine Horticole.*

* A metre equals 1 $\frac{1}{4}$ yard; a centimetre is rather less than half-an-inch; a cubic metre equals 35.32 cubic feet; a kilo. equals 2.2 lb.

ARDDARROCH, N.B.

BEAUTIFULLY situated on the shores of Loch Long, and bounded on the west by its waters for a considerable distance, Arddarroch enjoys in many respects a favourable position. The mildness of the climate allows many plants to grow and thrive outside that will not live through the winter in scarcely any positions north of the Tweed. The Orchids are, and have been for years, one of the chief objects of interest to the owner of the estate, R. B. White, Esq., and large sums of money have been spent, and special collectors engaged to secure the best possible varieties, especially of *Odontoglossums*. The greater part of the Cattleyas were disposed of some time ago to make room for constant additions to the cool section. Numerous fine varieties of *Odontoglossum crispum* have flowered, and the collection is equally rich in the best crosses, some of which the writer has seen in flower; and for the rest, paintings by Mr. McFarlane are ample proof of their merit. Among the varieties are *O. c. Andersonianum pulchellum*, with flowers having intensely purple edges, and the spotting yellow on a white ground; *O. excellens*, three plants, one flower measuring $3\frac{1}{2}$ inches across; *O. Chestertonii*, a beautifully-formed flower, finely spotted. Another curious variety, *O. egregium*, is curiously spotted all over with small spots, very pretty. The plants of *O. Andersonianum*, *O. Ruckerianum*, *O. Wilekeanum*, and *O. Mulus Holfordianum*, are very fine.

Some of the *Odontoglossums* have received certificates from the Royal Horticultural Society of London, among them *O. crispum* "Starlight," a beautifully heliotrope-tinted variety, finely spotted. *O. crispum* "Northern Beauty," an appropriately named variety, with very distinct spotting; *O. c. Arddarroch* variety, having a slightly darker ground than "Starlight," and larger spots; *O. c. lilacinum*, a gem, and as its name implies, intense lilac in colour; *O. c. "Twilight,"* sepals lilac, petals white, finely spotted; *O. c. "Sunset,"* another deeply-tinted, finely-spotted variety. Paintings of two varieties arrived while these notes were being taken, viz., *O. c. Aurora*, and *O. c. Lady Helena Carnegie*, both finely-spotted varieties; in the former the colour was purple-brown, and in the latter chestnut-brown. In *O. c. dulce* we have another fine solid, heavily-blotched flower. But perhaps the best form of a typical white ground *O. crispum*, a fine round flower, regularly and heavily spotted all over, is found in *O. c. White's* variety. Very few *Odontoglossums* were in flower, but here and there a spike appeared, as might be expected where thousands of plants are grown. I was just in time to see the finest form of *O. madrense* I ever saw, the colouring being very deep. Several good spikes of *O. crispum*, a few good forms of *O. Cordinei*, with *O. tripudians*, complete the list.

Cattleya gigas made the end of a house still devoted to this class very gay. A number of semi-established plants of *C. Mendeli* suspended from the roof were growing away freely, and close by *Oncidium ornithorychum* was finely in flower. Among the *Cypripediums* in flower were *C. Curtisii*, *C. Chamberlainianum*, and several plants of *C. bellatulum*; and here we have a gem in *C. bellatulum album*, Bank House var., not in flower, but the foliage at once denotes a distinct break from the type.

Suspended from the roof of a Palm-stove was a fine batch of *Dendrobium nobile* and hybrids; some of the baskets with the potting material bristling with seedlings showed that *Dendrobiums* are by no means neglected here. In another house I was shown a fine lot of seedling *Dendrobiums* in various stages, in a division specially fitted up for and devoted entirely to their culture.

In a cool division, a fine piece of *Cochlidium Neetzliana* was finely in flower, while *Oncidium macranthum* and *Odontoglossum Edwardi* had flower-spikes well advanced. A small batch of *Masdevallias* in flower were very pretty.

In a house originally devoted to Grape-culture, several plants of the new *Acalypha hispida* (Sanderi),

well grown and flowered, were telling objects among other plants, and in an adjoining greenhouse a monster plant of *Abutilon Boule de Neige* on a back wall, was carrying hundreds of flowers.

At the west end of the principal range of glass, a division is set apart for the cultivation of Carnations, chiefly varieties of *Souvenir de la Malmaison*. These presented a picture of health, and were finely flowered. A welcome sight in an adjoining division was that of some large plants of *Phenocoma prolifera* in full bloom; also several plants of *Boronia* in variety, unobtrusive, but very sweet, and far too seldom seen in gardens.

On leaving the glasshouses, we passed out into the kitchen garden below, and noted a series of arches forming a covered way several yards in length, clothed with Turner's Crimson Rambler Rose, which, being a mass of bloom, presented a glorious sight. To the right, a large circular bed, filled with *Anemone japonica* was very effective; and to the left, beds of Carnation Ruby Castle and Duchess of Fife were very showy. General bedding is not carried out here to any extent; herbaceous plants being more favoured.

In what is usually called the American garden, I admired the huge *Rhododendrons*, in clumps and single specimens, some of them upwards of 20 feet in height. Also large masses of hardy Azaleas. There are several large plants of *R. Nobleianum* on the lawn near the mansion, and it is nothing unusual for these to be in full bloom at Christmas. A large piece of *Spiraea arifolia* near the gardener's cottage, in full bloom, was a striking object; and as I turned to leave I was pleased to note the unabated vigour of the two fine trees of *Araucaria imbricata*, and of an equally fine one of *Cryptomeria elegans* beside the walk leading to the houses, the three having been planted about half a century ago by the late superintendent of the Glasgow Public Parks, Mr. D. McLellan. *Visitor*.

PLANT NOTES.

LYCIUM AFRUM.

This plant belongs to an extensive genus of hardy deciduous and evergreen shrubs of which but few are cultivated in English gardens, excepting the European species, *Lycium barbarum*. A short time since, on the occasion of a visit to an old garden near Guildford, I came across a remarkable specimen of *Lycium afrum* growing on a wall with a south-east aspect. This plant was 10 feet in height, and 12 feet in width, and completely covered with flowers and red fruits. Judging by the size of the shrub, it must be many years old. This species was introduced from Northern Africa in 1712, but it is rarely seen in cultivation. It is of erect growth, somewhat spiny, and of straggling habit. The leaves are linear, fasciculated, obtuse, pointed at the base, and of a deep green colour; the flowers are of a deep violet tint, solitary, drooping, axillary, and produced in great profusion during the months of June, July, and August, being succeeded by coral-coloured, elliptical fruits, about half an inch in length, which contain about twenty seeds. Owing to the decorative character of the flowers and fruits, the plant deserves the attention of planters. The plant may be readily propagated from cuttings taken in the spring, or by layers and suckers in the autumn. This species is described in the *Botanical Register*, p. 354; and in Sweet's *British Flower Garden*, p. 324. *E. S., Woking.*

CAMPAULA VIDALI.

Some fine examples of this rather singular perennial *Campanula* are now flowering in pots here. Like *C. colorata*, it is not perfectly hardy; hence, it requires frame protection during the winter. The flowers are racemose and pendulous; corolla pure white, with a remarkably broad disc, which is surrounded by thick orange-coloured annulus. Its leaves are oblong, spatulate, coarsely serrated, and

of a bright green colour. The plant is of dwarf, compact habit, and may be employed in the herbaceous borders during summer. It was introduced from the Azores in 1851. *P. Bolt, Wentworth Gardens, Barnsley.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Root-pruning Apples and Pears.—After the trees have been cleared of fruits, operations may be commenced on any trees that may need root-pruning. This applies more especially to such as are grown in the form of bushes, pyramids, cordons, or wall trees. Until now the soil has been too dry in most parts of the country for such operations to be undertaken. Early root-pruning, that is, before the leaves fall, has much to recommend it, for the ground being still warm favours early re-establishment, and large roots that have been severed soon callus, and are ready to push forth new roots when the spring arrives. The cooler weather is an advantage when hard pruning has to be done, the trees suffering very little in such weather, and more especially if showery. Large trees should be root-pruned to the extent of only one-half, the other half being treated similarly next autumn. The first thing to be done is to throw out a trench as deep as the lowermost roots, at a distance of 3 to 4 or even more feet from the stem of the tree according to its size, and gradually work the soil away for 2 feet towards the stem, or closer if deemed necessary for young trees, burrowing under the ball, and severing or lifting all descending or tap-roots met with. All the roots should be brought upwards as much as possible, and the stronger ones shortened to within 3 feet of the stem, the cuts being made from below upwards. If the land is inefficiently drained, brick rubble may be placed in the bottom of the trench to the depth of 6 inches, then return some of the soil, and proceed to lay and spread out the roots radially and evenly in one, two, or three horizontal layers, and having covered them with some of the finer portions of the soil, make it firm by trampling as the filling-in proceeds. The loose soil under the unmoved portion of the root-mass should be made firm with a rammer. If the soil is deficient in lime let some mortar rubbish be mixed with the staple, but do not add any manure. Finally, afford water plentifully if the soil is not sufficiently moist, and apply a mulch of stable-litter. Only trees which make strong growth, or those whose fruit is indifferent, need this kind of treatment. If the work is carefully carried out, flower-buds will form in place of wood-buds as hitherto, and fruitfulness once induced will tend to keep the tree fruitful. Several bushes on the Paradise-stock of Blenheim Pippin, and some others which I treated in the above manner early last autumn, have this year borne excellent crops of fruit of a moderate size, as well as abundance of fruit-buds for next year.

Colour in Apples.—The change in the colour of Apples since cooler and showery weather set in has been very noticeable; as notwithstanding the bright sunshine previously experienced, Apples in general possessed very little colour in the skin. This was very remarkable in Cox's Orange Pippin, Cox's Pomona, and Blenheim Pippin. Mid-season and other varieties may now be gathered, later ones being left upon the trees so long as the weather permits.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westcumbirt, Tetbury, Gloucester.

Planting Bulbs.—When the summer bedding-plants have been removed, those beds it is intended to plant with bulbs should be deeply dug or trenched, and if any of them are apt to become very damp in winter, such will need to be thoroughly drained. For this purpose remove the soil to a depth of $2\frac{1}{2}$ feet, and put in at least 1 foot deep of broken bricks at the bottom of the trench. Should the staple soil be poor, an addition of some well-purified loam, leaf-mould, road-scrappings, or sharp grit, well mixed together, will effect good. Manure, unless it has been kept for at least two years, should not be used. In situations where the soil is naturally of a retentive nature, and apt to become sodden and sour, bulbs will succeed better

if some other plant be used with them, such as *Myosotis*, *Violas*, *Daisies*, *Aubrietias*, and other early spring-flowering plants, which will absorb a great deal of the surface-water. *Myosotis dissitiflora* mixed with the White Swan Tulip, or a ground-work of the double-crimson Daisy, dotted over with the bright yellow Tulip *chrysolora*, make excellent combinations for occasional beds on lawns. When planting Tulips, the distance allowed between each bulb must vary according to their size. They need not be planted more than 4 inches deep, but if they are put too near the surface, the bulbs are apt to rise. The end of October is a good time to plant Tulips; they will not then show shoots until spring, and will thus escape hard frosts. Single-flowered Hyacinths will last longer in bloom if planted in beds partially shaded; they require the soil to be made much firmer than for Tulips, and are best when planted in poorer soil, and given stimulants when making growth in the spring.

Crocuses may be left undisturbed for several years, and should be planted rather deeper in beds than the generality of bulbs, or under grass.

Amaryllis Belladonna, &c. (the *Belladonna Lily*).—Charming is this "Lily" in the autumn, it throws up its strong spikes with umbels of when beautiful white flowers, much flushed and tipped with rose. To succeed perfectly, this species should be planted in a warm, sunny position facing south, and at the foot of a wall. Dibble in the bulbs about 5 inches deep, and 1 foot apart, in a deep, well-drained, loamy soil. They may then remain undisturbed until the bulbs become overcrowded. *Sprekelia formosissima* (*Jacoba Lily*), with rich, dark crimson flowers; and *S. glauca*, bright crimson-scarlet, succeed under the same treatment.

Scillas.—Both the blue *Squills*, *S. sibirica* and *S. bifolia*, make a fine display in spring, when planted in large clumps in the grass, or alternately with *Snowdrops*. The flowers soon fade if planted in too sunny a position. Bulbs placed 2½ inches deep and 3 inches apart in a deep rich soil or sandy loam and leaf-mould, will only require to be re-planted once in three years. *S. italica*, flowering in May, with beautiful bright blue flowers borne on stems 10 inches high, is excellent for cutting purposes, and attains perfection when grown in sandy or light soil. *S. hispanica* is a very strong-growing bulb, and its light blue flowers contrast finely when planted with the variety *alba*.

Muscari (the Grape Hyacinth).—The culture of these is very simple, and if planted in good soil they rapidly increase. *M. botryoides* succeeds well in grass, and flowers at the same time as *Narcissus nanus* and *N. bulbicodium*. *M. monstrosum*, *moschatum*, *grandiflorum*, *concinnum*, *racemosum*, and *Elwesii* are distinct, and well adapted for the herbaceous border, or for bold positions in the rock-garden.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart. Clare Lawn, East Sheen.

Preparation of the Houses.—Sunlight being of vital importance to most cultivated plants, and seeing that in the winter it is not of long duration here, the glass should be made clean and bright, and efforts made to keep it in this condition until spring. The cleansing of an Orchid-house requires some care and forethought on the part of the gardener or his assistants, the crowding together and removal of the plants, unless carefully done, are operations likely to produce more harm than would result if the house were to be left in a dirty state. A commencement should now be made with those houses the occupants of which require much light, viz. the *Cattleya*, Mexican, and *Dendrobium*-houses. In these let the glass, all woodwork, the stages of whatsoever material, and all pots and pans be well washed with hot soap-suds; then sponge the plants, and arrange them in the most suitable position. The outside of the glass need not be washed as yet, unless very dirty. Where there are tanks to receive the rain-water falling on the roof, the dirty water from the washing should not be allowed to enter them, or harm may be done to the plants.

Plant-cleaning.—Having cleaned the glass, &c., the leaves of the plants should be sponged with soft-soap and rainwater, and where there are no insects, with water. A day or two previously,

lightly fumigate the house with Richards' XL All Compound. *Cattleyas* and *Laelias* are frequently infested with a small, white scale, which, if not soon removed, cause the infested parts to turn a yellow tinge. These insects hide beneath the basal sheathing bracts, and are likely to remain undiscovered unless the plants be closely examined. To remove them, use a pointed stick or a stiff hair-brush and soft soap-suds.

Staging the plants.—Epiphytical Orchids, when grown in pots or pans, seldom have a thrifty appearance when stood on the stage, and it is now the custom to stand them on another trellis-work stage, 6 inches higher than the main stage; or place them on inverted pots, thus insuring good drainage and a better circulation of air among them. Nothing has come under my notice that is better than this, excepting Murray's Orchid-stands, which are made of wire, and are neat, safe, durable, and well adapted for small plants. They may be used for suspending the plants from the roof, or when inverted, as plant-stands. In arranging the plants, give them as much space as possible, and place the younger plants in the lightest places. When plants are suspended from wires attached to the rafters, they should be so arranged that the drip falling from them does not fall in or among the young leaves of plants standing underneath, more especially if these be *Phalenopsis*, *Vandas*, *Aërides*, and such-like. If it cannot be avoided, the moisture must be collected in the morning with a piece of sponge fastened on a small stick. This is very necessary in old glasshouses with numerous sash-bars. Many instances have come under my notice of plants receiving injury through being suspended from nails driven into the sash-bars, the drip being thus brought down to the plants.

PLANTS UNDER GLASS.

By O. R. FIELDER.

Plant-houses.—With the approach of mid-autumn and comparatively sunless days comes the necessity of taking steps to obtain as favourable conditions as possible for the welfare of the plants in the glass-houses. To this end an effort should be made to cleanse the glass and woodwork of, at least, the interior of the houses. Structures which are infested with mealy-bug should be thoroughly washed with petroleum. Stages and floors, and any portion of the house which cannot be got at with the scrubbing-brush, should be forcibly syringed with petroleum and hot soap-suds. All brickwork should then be limewashed, adding half a pint of petroleum to each pailful of wash, and keeping it well stirred while applying it. If any whitewash or other shading material remains on the glass, it should be cleaned off; and all blinds not required for the protection of the house during severe weather should be taken down and stored for the winter after being well dried.

Ferns.—Species of *Adiantum* which have been grown in a close, moist house for the purpose of affording fronds for cutting, should be given more air and light as the growth approaches completion, in order to harden the fronds; otherwise, when cut they will quickly wither. A better plan when plants are required for this purpose is to grow them in a moderately cool house, which is not heavily shaded. The fronds of *Adiantums* produced under such conditions are of a much firmer texture, and the colour a softer shade of green, while they last well when cut.

FRUITS UNDER GLASS.

By W. STRUGNELL, Gardener to Lieut.-Col. RALPH VIVIAN, Rood Ashton, Trowbridge.

Late Figs Fruiting in Pots.—For use in the dessert in late autumn Figs are invaluable. Given a sufficient number of trees established in pots or tubs, and an efficiently-heated house in which to grow them, there is not much difficulty in obtaining an occasional dish until late in the year. *Negro Largo* when suitably prepared is one of the best autumn fruiters, as also *Nebian*, with fruits above medium size, pear-shaped, skin greenish-yellow when ripe, a delicious Fig. There is a greater certainty of a regular crop being obtained from rather small trees, as two or three plants growing in small pots may be accommodated in the space required by one of a large size. This point should be borne in mind by gardeners having to supply Figs at this season. A stock of young plants should be kept up by purchases in the

autumn, or by spring propagation at home. It is not advisable or easy to obtain autumn Figs from old planted-out permanent trees. A fairly brisk temperature is needed at this season, with ventilation in accordance with the weather. Top-dressings of bone-meal will maintain activity in the surface-roots, but it must be applied only in small quantities, at intervals of a week or ten days. Liquid-manure and clear soot-water may be employed as long as such are necessary. Atmospheric moisture in a Fig-house at this season is better generated by damping of the floor and between the pots than by overhead syringing, and even this should be modified to suit external conditions.

Late Melons.—The syringing of the foliage should entirely cease, and a brisk bottom and top-heat is necessary in houses or pits where there are half-matured fruits in order to prolong the activity of the roots of the Melon plant. For this purpose light dressings of loamy soil, with a slight addition of decayed manure, lime-rubbish, and burnt refuse will be a great help. Let this dressing be made firm by hand pressure, a firm soil being an important matter in Melon-culture. Keep the soil immediately surrounding the stems of the plants dry, as a preventive against canker. Afford water at a slightly higher temperature than that of the house, but do not apply it over abundantly, the amount being governed by the conditions under which the plants are growing. Beds overlying chambers heated by hot-water pipes will naturally require more frequent applications than others which have beds of tree-leaves or manure beneath them. A large bed of soil is decidedly objectionable where late Melons are desired. Growth will not be freely made now, nor is it necessary, the primary leaves on plants that have set two or three fruits being quite enough, without encouraging laterals.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Late Cauliflower and Early Broccoli.—As night frosts may now be expected, it is a matter of prudence to lift such of Cauliflowers and Broccolis thrice a week as are of a useable size, and lay them in somewhat close together on a sheltered border to be protected with fern or litter when frost seems imminent. It is easy to maintain a constant supply of heads by this method, till the first week in February. Pits and frames, Peach-houses, &c., may also be used for storing them, and they may be kept for several days in a fresh condition by merely suspending in a not too airy shed. The stumps of those which have been cut, and all decaying leaves, should be removed from the quarters. Autumn Giant Cauliflower, and Self-protecting and Snow's Broccolis, afford heads in succession.

Sea Kale.—The plants which have been prepared for forcing, should be stripped of the dead leaves, and the soil freed from weeds, so that the crowns may mature without hindrance, the well-ripened crowns forcing more readily than ill-matured ones. In order to obtain very early Sea Kale, the crowns should be dug up fully a fortnight previous to placing them in heat, taking care of the young roots or "thongs," which may be cut off the proper length, sorted into different sizes, and placed in boxes of light soil in readiness for planting in the spring.

Beetroot.—The roots may now be taken up and stored for the winter, either in soil or sand, in sheds or pits. The roots require careful handling, the adhering soil should be rubbed off by the hand, and the leaves twisted off. If the shed or cellar is frost proof, it is sufficient to merely cover them with a small quantity of straw. Another method is to lay the roots closely together in deep furrows dug out with a spade on a border, burying the crowns of the roots about 2 inches deep; throw some bracken or long litter over them in frosty weather.

Mushrooms.—The temperature of the Mushroom-house may be kept between 55° and 60°. No artificial heat will be made use of for the present, the warmth arising from the new beds keeping the temperature sufficiently high. Lose no chances of collecting stable-manure. Throw it into heaps and ridges, and turn these at intervals of a week to sweeten and free it of the excess of ammonia. Beds which have been spawned and cased with loam, should receive a light covering of hay or litter.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

TUESDAY, OCT. 10.—Royal Horticultural Society's Committees.
National Rose Society's Committees.

SHOW.

TUESDAY, OCT. 10.—National Chrysanthemum Society's Exhibition at Royal Aquarium (three days).

SALES.

MONDAY, OCT. 9, and the following Tuesday, Wednesday, Thursday, and Friday, Dutch Bulbs at Protheroe & Morris' Rooms.

TUESDAY, OCT. 10.—Sale of The Firs (Warwick) Collection of Established Orchids formed by the late Major Mason, J.P., by Protheroe & Morris, at 12.30 o'clock. Three days.

TUESDAY, OCT. 10.—Clearance sale of Enonymus, Palms, &c., at the Saxe-Weimar Nursery, St. Edward's Road, Southsea, by order of Mr. T. J. Short, by Protheroe & Morris, at 12.30 o'clock.

WEDNESDAY, OCT. 11.—Great Annual Sale of Fruit-trees, at the Nurseries, Perry Hill, Cliffe, near Rochester, by order of Mr. W. Horne. Two days.

FRIDAY, OCT. 13.—Clearance Sale of Greenhouse and other Plants at the Clay Hill Nurseries, Enfield, by order of Messrs. Elwell & Pitcairn, by Protheroe & Morris, at 2 o'clock.

FRIDAY, OCT. 13.—Imported and Established Orchids, at Protheroe & Morris' Rooms.

Remarks.—The weather has been cold and showery, with a thunderstorm on the 27th, and a heavy fall of rain on the 29th.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—52.1°.

ACTUAL TEMPERATURES:—

LONDON.—(October 4 (6 P.M.): Max. 59°; Min. 51°.

PROVINCES.—(October 4 (6 P.M.): Max. 67°, Exeter; Min. 43°, Orkney.

The feeling of the meeting called together at the Crystal Palace to support, as far as possible, the horticultural department of the great exhibition to be held in Paris next year will, we hope, be fully reciprocated by the horticulturists of this country. The idea of "boycotting" the Exhibition, which was mooted in some quarters, seems to us to be extremely silly and childish; and now, at any rate, there can be no reason for the adoption of any such puerile practice. It is true that in the times of our forefathers the French boycotted us pretty severely, but we managed to survive, and are none the worse for it now. In a sense, the French still boycott us by their protectionist enactments, which they consider necessary for the welfare of their agri-

culturists and manufacturers. We could send them plenty of Grapes for one thing, of which they would be glad, but the protectionist system forbids the Frenchman from obtaining what he would like to have and pay for at market rates, and compels him to purchase from his own compatriots articles of inferior quality or of higher price. Still, anyone who travels in the north of France at this season, can judge of the magnitude of the interests involved in the cultivation of Beet, and in the manufacture of sugar from that root. Whatever may be his views on fiscal matters, everyone must admit the enormous difficulties and dangers of unsettling existing arrangements. The proper course for us is to increase the production and quality of the Sugar-cane in our West India islands, and other sugar-producing colonies. The discovery of the seedling Sugar-cane opens up great possibilities in the way of selection and cross-breeding. Capital and patience are of course indispensable, as well, probably, as improved machinery. At any rate, in the person of Dr. MORRIS, the Imperial Commissioner for Agriculture in the West Indies, the Government can rely on the application of sound, scientific principles to the practice of tropical agriculture in whatever form. This digression really leads us back to the Paris Exhibition. We shall go there not merely to exhibit our own products, but to learn what our neighbours are doing, and, where necessary and permissible, of taking a leaf out of their book. Even in the matter of sugar manufacture, which has been given up as unprofitable in this country, we are not at all sure that our failure might not be converted into success by the development of a root containing a larger percentage of sugar.

To turn to matters more within our own special department, we know that in some points, and for certain classes of plants, France has a great advantage over us in her climate. But that applies chiefly to the south. In the north the climate is little, if any, better than our own. In the centre it is worse, in that it is subjected to more violent extremes. In the west, and especially in the south, France has the advantage, and, speaking generally, she has more of that precious element, light.

With the introduction of the electric light into horticultural practice, which would have been done long ago were we not so incurably conservative and apathetic, that difference would be lessened. Those few of us who, several years since, saw the marvellous results produced by Sir WILLIAM SIEMENS in what seemed a miraculously short space of time, felt assured that in the application of the electric light the horticulturists of the future would have an enormous advantage within their grasp if they chose to avail themselves of it. Our American cousins have already adopted it for commercial purposes, and we might do the same. At the Paris Exhibition, doubtless, we shall have opportunities of seeing how this may be done.

Our horticulture on the whole, and considering the conditions under which we work, is in advance of French gardening. High-class gardening is at a much higher level here than in France; and in fruit-growing, and even in vegetable-growing (with few exceptions), we are able, we believe, to more than hold our own. At any rate, let us take the best we have, and let us go and see whether we are to be subjected to the salutary practice of having the conceit knocked out of us, or whether British gardening does not, as we believe it does, take the lead when all circumstances are considered.

CATLEYA WARSCEWICZII.—In consequence, probably, of the past torrid and bright summer, the plant which is commonly called *Cattleya gigas* is flowering exceptionally well in most gardens, and in some places it is producing most extraordinary flower-spikes. In the Rt. Hon. Lord ROTHSCHILD's gardens, Tring Park, his lordship's gardener, Mr. E. Hill, has secured one of the finest shows of *Cattleya Warscewiczii* he has ever had, some of the flower-spikes having each six very large and handsome flowers. Plants of *C. aurea* and *C. x Hardyana* have also flowered well. A grand spike, with six fine flowers, is sent by Mr. T. W. Bond, gr. to C. L. N. INGRAM, Esq., Elstead House, Godalming, who remarks that it is the finest he has ever seen. Our illustration (fig. 95, p. 281), represents a noble spike of *Cattleya Warscewiczii*, bearing seven very finely-coloured flowers, some of them nearly 10 inches across, which was sent by Mr. R. Cairns, gr. to J. M. WHITE, Esq., Balrundry, near Dundee. The fact that these extraordinary flower-spikes have appeared in several gardens this year seems to prove that some seasons are more suitable to certain species than others.

PARIS EXHIBITION, 1900.—On Thursday last, at the Crystal Palace, there was a meeting of the Horticultural Section of the British Commission to consider the subject of a representation of British horticulture during the great International Exhibition in Paris next year. Sir TREVOR LAWRENCE occupied the chair, and explained the objects of the meeting. Mr. HARRY VEITCH and Sir W. T. THISTLETON DYER also supported the Chairman in the hope that the horticulturists of the United Kingdom would be animated by a feeling of public spirit such as would show the world of what they were capable. The questions were reviewed and discussed by Mr. JOHN WRIGHT, Mr. MCINDOE, Mr. HUDSON, Mr. GEORGE MUNRO, and others. Monsr. MAXIME CORNU, of Paris, was present, and spoke in high appreciation of the Fruit Show he had seen that day at the Palace, laying special stress on the quality of the Apples and the Grapes, which he thought were very fine, and assured the meeting that his countrymen would feel very pleased to have English exhibitors amongst them. Further details or schedules can be obtained at the offices of the Royal Commission Paris Exhibition, 1900, St. Stephen's House, Westminster, S.W.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Floral and Fruit Committees will be held on Tuesday, October 10, in the Drill Hall, James Street, Westminster, from 1 to 5 P.M. At 3 o'clock a lecture on "The Injurious Scale Insects of the British Isles" will be given by Mr. R. NEWSTEAD, F.E.S.

NATIONAL ROSE SOCIETY.—A meeting of the Committee will be held at the rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Tuesday, the 10th inst., at 3 P.M. The agenda consists of 1, report of Catalogue Committee; 2, programme for 1900; 3, to consider any suggestions for the alteration of either bye-laws or regulations; and other business. H. HONYWOOD DOMERAIN and EDWARD MAWLEY are the Hon. Secretaries.

NATIONAL CHRYSANTHEMUM.—Mr. R. DEAN writes:—"In your report of the meeting of the Floral Committee of the above Society on the 27th ult., which appears on p. 272, you say, 'Sufficient members of the committee were not present to form a quorum.' Six members form a quorum of the Floral Committee, and eight members were present on the 27th; but a quorum of ten members must be present to award a Certificate of Merit, and then the voting must be unanimous; and if more than ten members are present, a majority of three-fourths is necessary." It was, of course, in respect to the granting of Certificates that our remark was made. At subsequent meetings much inconvenience may be caused to country exhibitors if no steps be taken to prevent such a circumstance happening again.

HORTICULTURAL CLUB.—The first monthly dinner and *conversazione* for the session 1899-1900, will take place on Tuesday, October 10, at 6 P.M., at the Hotel Windsor, Victoria Street, S.W. The subject for discussion on this occasion will be British wild flowers suitable for garden-culture, to be opened by Mr. GEORGE BUNYARD, V.M.H.

becomes a matter of importance to gardeners. The professor remarked that "with regard to buds in plants there is reason to believe that they share in the growing-old of the parent. That is to say, if we suppose the average life of the individual to be a hundred years, a bud removed at fifty, will be fifty years of age, and be able to live on the graft for fifty more years."

development and structure of the embryo; the anatomy of the seedling and adult plant; and a comparison of Ginkgo with other genera, and its place in the plant kingdom. The paper also contained a general consideration of the evidence available towards an account of the past history of Ginkgo and closely allied plants; a comparison of Ginkgo with various fossil types from Palaeozoic, Mesozoic, and Tertiary strata; and the geographical distribution of Ginkgo during the Mesozoic and Tertiary epochs.

PRESENTATION.—Mr. D. JOHNSTON, who for two years past has been head gardener to H.H. Prince HATZFELDT, at Draycot Park, Chippenham, Wilts, was presented on Thursday last, by the *employés* under him and a few friends, with a very handsome Meerscham-pipe and a portmanteau, on the occasion of his leaving the Prince's employ, as a slight recognition of their appreciation of his services. Mr. JOHNSTON suitably acknowledged the compliment, and general regret was expressed that Mr. JOHNSTON was severing his connection with the estate.

SEED GUARANTY IN FLORIDA, U.S.A.—In Florida it is now unlawful to offer for sale any garden-seeds, unless the same are in packages bearing on the outside in plain letters a guarantee certificate of when, where, and by whom the seeds were grown.

FLOWERS IN SEASON.—As showing the lingering floral beauties of a Devonshire garden, and for that matter of other gardens situated in the southern counties, Messrs. ROBT. VEITCH & SON, Royal Nursery, Exeter, send flowering shoots of *Desmodium pendulifolium*, with numerous flowers and unopened flower-buds; *D. japonicum*, with light purple-coloured flowers, more showy than the former; *Caryopteris mastacanthus*, its shoots covered with cheerful-looking, bright blue flowers; *Calycanthus occidentalis* syn. *macrophyllus*, with large fresh foliage and terminal, crimson orange-tinted flowers; some shoots of *Clerodendron trichotomum*, showing opening flowers; *Spiraea Watereri*, with deep crimson corymbs of bloom; *Ceanothus Gloire de Versailles*, one of the best and brightest varieties, colour pale blue; and *Buddleia intermedia*, with thin ribs of violet flowers. Shoots bearing seed consisted of *Koeleria paniculata*, well furnished with its triangular-shaped green and coppery-red seed-vessels; *Euonymus latifolius*, with expanded scarlet capsules, very showy; *Sorbus aria* and *Catalpa syriaca*.

MR. CHARLES HERRIN.—Our old correspondent, Mr. C. HERRIN, who at the present time is furnishing the calendar for the Hardy Fruit Garden in these columns, is, as we learn, about leaving Dropmore; and we trust that so good an all-round gardener will soon meet with a suitable appointment.

THE DEVON AND EXETER GARDENERS' ASSOCIATION.—As will be seen below, an excellent syllabus has been arranged for the autumn session of this Association. On Wednesday, October 11, Mr. FLETCHER, gardener to Colonel HALFORD THOMPSON, J.P., will read a paper entitled *Dahlia*s; on Wednesday, October 25, Mr. G. STILES, gardener at The Grove, Teignmouth, will give a practical lesson on dressing *Chrysanthemum* blooms for the exhibition table; on Wednesday, November 8, Mr. W. CHARLEY, Wonford House gardens, will read a paper on garden walks and drives; on Wednesday, Nov. 22, Mr. W. MACKAY, Royal Nurseries, Exeter, will discourse upon cut flowers and their arrangement; on Wednesday, December 6, Mr. J. REYNOLDS, gardener to Sir CHARLES D. CAVE, Bart, Sidbury Manor, will give a lecture on winter-flowering plants—the *Cyclamen*, the *Carnation*, and the *Euphorbia*; and on Wednesday, December 20, Mr. F. W. E. SHRIVELL, F.L.S., Thompson's Farm, Tonbridge, Kent, will read a paper on further experiments with chemical manures in kitchen and market gardening. The President of the Associa-

FIG. 95.—*CATTELYA WARSCEWICZII* WITH SEVEN FLOWERS UPON A SPIKE, IN THE GARDEN OF J. M. WHITE, ESQ. BALRUDDERY, NEAR DUNDEE, N.B. (SEE P. 280.)

SENILE DECAY AND REJUVENESCENCE OF ORGANISMS.—In dealing with the question of the renewal or reparative processes continually taking place in the organism, Professor SEDGEWICK, in the course of his opening address on Zoology at the meeting of the British Association, stated as his opinion, that there is no reason to suppose that the reparative process of any organism is sufficiently complete to prevent senile decay. If this be so, the age of a plant from which grafts are taken

GINKGO BILOBA.—Mr. A. C. SEWARD, in conjunction with Miss J. GOWAN, contributed a paper at the meeting of the British Association, on the Maidenhair Tree (*Ginkgo biloba*, L.). The chief points dealt with in the paper were the history of our knowledge of Ginkgo; its external features and peculiarities; the variability in form and structure of the leaves; the structure and morphology of the male and female flowers; the pollination and fertilisation of the ovule; the

tion is EDWARD A. SANDERS, Esq., J.P.; Hon. Secretary, ANDREW HOPE; and Hon. Treasurer, W. MACKAY.

AFFORESTING IN IRELAND.—After repeated requests to reafforest some of the denuded vales and mountains of Ireland, the Rathmines Commissioners have yielded, and are giving a slight practical impetus to this much desired question; they have recently started planting several thousand trees in the hills adjoining the suburban parts of Dublin, their labours being principally confined to their waterworks and the country contiguous; the largest number of trees are to be planted at Bohernabreena (co. Dublin); the kinds include Larch, Spruce, Scots Pines, &c. The work is under the able supervision of Mr. CRANMER, their foreman gardener.

BOTANICAL MAGAZINE.—The number for the present month contains illustrations and descriptions of the following plants:—

Lonicera Hildebrandtiana, discovered by Sir H. COLLETT, in the Shan Hills, at an elevation of 5000 feet. The flowers change with age, and have been figured and described in the *Gardeners' Chronicle* as a brilliant flame colour, and as orange-scarlet. In the Kew plant the buds are white, faintly tinged with pink; the fully-opened flowers golden-buff, passing into yellow-brown in age. A tall, woody, glabrous climber, with terete branches and branchlets. Leaves broadly ovate, broadly cuspidate, 5 to 6 inches long, bright green above, paler beneath, marked with a few brown glands. Flowers geminate on a stout terete peduncle; corolla 7 inches long; tube 4 inches; lip revolute. Fruit an inch long, ovoid.

Kalanchoe thyrsiflora.—Introduced from the Cape of Good Hope by Commendatore HANBURY, La Mortola, by whom seeds were distributed to various botanical gardens in 1891; a very stout, erect, pale glaucous-green, glabrous herb, 1 to 1½ ft. high, with an erect sessile cylindric thyrsiform densely-flowered panicle 6 to 12 inches high and 3 inches in diameter. Flowers short pedicelled, about ½ inch long, corolla tube ovoid-oblong, glaucous-green, lobes small, spreading and recurved, bright yellow within.

Stylidium crassifolium.—A native of south-west Australia. Plants have been raised at the Royal Gardens, Kew, from seeds received from Quartermaster-Sergeant B. T. GOADBY, of the West Australian Engineers. A greenhouse plant producing in spring racemes nearly 2 feet high. A tall, rigid, nearly glabrous herb, with radial leaves 4 to 8 inches long, and a narrow inflorescence scape, with the sub-paniculate raceme, erect or inclined; calyx tube ¾ of an inch long; corolla of four spreading oblong pink lobes in opposite spreading pairs.

Berlandiera tomentosa.—A native of the Pine barrens of N. Carolina to Florida, and westward to Arkansas and Missouri. Seeds were sent to Kew by the Rev. L. H. LIGHTHIE, of Jacksonville, Fla., in 1898, plants from which flowered in a cool greenhouse in May and June this year. The flowers proved very persistent. A slender, sparsely-leaved perennial, 12 to 24 inches high, more or less hoary or glabrate; lower leaves oblong, obtuse, crenate, narrowed into a petiole about 2 inches long, which is winged about the middle; flower-heads few, in a terminal corymb, 1½ to 2 inches in diameter; disc flowers, enveloped in green bractioles, dark red-brown; ray flowers about eight, orange-coloured.

Rhododendron dilatatum.—Discovered early in the century in Japan in the mountains of Okayama and Hakone, in the province of Sagami, Nippon. A small, much branched, nearly glabrous bush. Branches very slender, leafy at the tips only, covered with a very dark brown bark; young branchlets red. Inflorescence terminal, flowers geminate; corolla 2 inches in diameter, deeply two-lipped, bright rose colour, fading to white at the base, tube very short; stamens five, declinate and incurved; filaments very slender, rose-red; style slender, and stigma minute.

PUBLICATIONS RECEIVED.—*The Photogram*, Vol. vi., No. 70: the number containing studies from the nude; examples of photographing flowers; notes on the fading of prints; some methods of measuring shutter speed; and a variety of technical matter.—*Bulletins* Nos. 71-77, inclusive of Vols. ix. and x., from June, 1898, to March, 1899, of the Purdue, Indiana, U.S.A. Experiment Station.—*Twenty-second Annual Report of the Connecticut Agricultural Experiment Station for 1898* (Lockwood, Brainard & Co., Harting, Conn.).—*Report of the visit of Essex Agriculturists to Holland, May and June, 1899.*—*A Nocturne. Scene, a Village Church in a broad and pleasant Valley of Dartmoor.*—*Transactions of the Massachusetts Horticultural Society, for the year 1899* (Boston, printed for the Society), Parts i., iii.—*Century Book of Gardening*, part v.—*Catalogue of the trees and shrubs in the Arboretum and Botanic Gardens of the Experimental Farm, Ottawa, Ontario, Canada* (Government Printing Bureau, Ottawa).—*Die Natürlichen Pflanzenfamilien*, parts 190 and 191 (Leipzig: Wilhelm Engelmann, Bookseller).—*Journal of Botany*, part xxxvii.—*Bulletin de la Société Botanique de France*, 30 series, tome vi.

THE BULB GARDEN.

HYACINTHS IN THE HOUSE.

THOSE who grow Hyacinths in glasses (and the art of doing so is a very pleasant indoor recreation), should not be in too great a hurry to place their bulbs in water. I think failures often result from this course. I would certainly say select the bulbs as soon as possible, taking care to secure sound ones, and then lay them by in a cool, dry place in the light, until the base of the bulb where the roots issue begins to swell, and a coronal of embryo root-fibres, bright and fervent, are ready for development. This can be seen by the middle or end of October, and then the bulbs can at once be placed in glasses.

As to the best type of glass, that with the broad, flat base, which G. P. Tye introduced a half century ago, is still the best, because the weight of water in the bottom of it, and its broad base, prevents any probability of its toppling over, and destroying both glass and plant, as the old chimney-glasses of our forefathers used to do, and as some of the elegant, upright glasses of the present day are apt to do.

Clean glasses are indispensable. It may appear to some to be unnecessary, but it is wise to scald the glasses well inside with water to make sure they are perfectly clean. Clear, fresh rain-water is best, but water drawn from the cistern used for domestic purposes will do. Having filled the glass, place two or three lumps of charcoal in the water, and then the Hyacinth bulbs, allowing the water just to touch the base, and then put them away in the dark to ensure a downward root-growth, which comes soon and in full measure, if the base of the bulb has the indications above-mentioned.

Failure with Hyacinths arises from various causes; one is using tainted water at the outset: some injurious quality of the water communicates itself to the roots; they perish through the water becoming offensive, and there is failure. This result will sometimes arise from bulbs which may have some wound in them, yet it is of but very rare occurrence. But the chief cause of failure is lack of attention; so many start well, then interest in the work declines, and an easy descent to neglect follows. Successful Hyacinth-culture in water means a round of little attentions constantly given, keeping the waste of water by evaporation and the necessities of the bulb supplied, shading from the hot sunshine at midday, which often comes in early spring, removing the glasses from the window at night when there is a danger of frost reaching them—a calamity which has happened to any bulbs over and over again. There is, in addition, the duties of keeping the glasses in the light, where air can circulate about them, and the occasional sponging of the leaves from dust, so that the conditions of development shall be healthy.

And for those who do not care to grow bulbs in water, there is a valuable mixture of finely-sifted Cocoa-nut fibre and powdered charcoal, in equal proportions, which is a very useful compound indeed for our purpose where good, sweet soil cannot be had. With such pots, glasses, jardinières

—all the various vessels which have been called for by some feature of indoor gardening, many bulbs may be grown, and pretty floral pictures for the house. R. D.

BELLADONNA LILIES.

We find the above-named handsome Liliaceous plant to succeed well with us in Yorkshire, and wonder sometimes that they are not more commonly grown in gardens. Their culture is simple in suitable positions. We have two rows of them, one about 90 feet in length, in front of what was once a range of Pine-pits; the other, not quite so long, in front of a plant-stove and a warm Orchid-house. Both positions face due south. This season there are, and have been, hundreds of flower-spikes, each are with from seven to twelve flowers and buds upon them. The first-named lot have been planted in their present position three years; the others were planted some fifteen years ago. When we lifted a part of this border three years since, the whole space of some 18 inches in width was quite a mass of massive bulbs. Now is a good time to plant if fresh bulbs are purchased, as soon as they have finished flowering being a good time to do this if home-grown bulbs are to be used. We usually dig out the soil to a depth of 20 inches, and 18 inches from the base of the wall outwards; then put in some broken bricks or clinkers for drainage, over this put seds grassy side downwards, and then fill up with a compost of sandy-loam, three-parts to one-part Mushroom-dung, and leaf-soil. If fresh loam is not at hand, old potting-soil from worn-out Chrysanthemums or forced Strawberries will answer very well if properly broken up and turned over once or twice.

I ought here to mention that we put an edging of pieces of thin limestone or bricks set on their ends at the outer edge of the border. This allows of the border in which the bulbs are planted to be raised up a few inches above the alley that runs in front of it. Our object in doing this is to gain an increased temperature in the soil during the early summer months, when the bulbs are forming their flower-spikes. When putting in the soil, use care in spreading it equally, not throwing it in by spadefuls; as is well known to many, the mechanical condition of the soil for outdoor subjects has quite as much to do with their success or otherwise as in, say, potting Orchids. Firm the compost either by treading if not too wet, or by using a small rammer. Do not plant the bulbs too deeply; if covered, say, 2 inches from the apex of the bulb, it is quite enough. If the soil is at all dry, afford a good soaking of water, and mulch with old Mushroom-dung to keep out frost in winter. Not many flower-spikes will come up the first year after planting; after that, they should bloom annually, and continue to do so for many years. The only after attention is to prick up a few inches of the surface of the border with a hand-fork after the flowering season, and give a good mulching of fresh soil and Mushroom-dung in equal parts. When the early part of the summer is dry and hot, two or three good soakings of diluted sewage should be afforded. Last autumn, with a view to increasing the length of the flowering season, I planted some big bulbs against the back wall of a lean-to Peach-house; and I found that they bloomed very little, if any, earlier than the outdoor-grown bulbs. I am sending you herewith some flower-spikes of Belladonna Lilies. H. J. Clayton, Grimsdon, Tadcaster. [These were very fine corymbis indeed. Ed.]

PLANT PORTRAITS.

GUSTAVS DAUBERAPPEL (Longkeeper).—Several large trees of this variety were discovered growing in loamy soil in the vicinity of Bodensee, near Constance. The fruit is of pyramidal form, not unlike Maux Collin, of a bright crimson colour; middle size; eye open, set in wrinkled, shallow cavity; stalk half an inch long, set in a funnel-shaped basin of the same depth, and woody; flesh firm, yellowish, juicy, flavour sweet, vinous, and the fruit keeps in good condition from December to May. It has yet to be ascertained if the variety is suitable for light or sandy soils. Supposed to have originated from the Wurtemberg Apple, Kleinen Fleiner; and it assumes its finest colour after being stored. *Gartenflora*, September 16, 1899.

CHANGE OF SEX IN BEGONIA.

SINCE Messrs. Laing and M. Lemoine began their wonderful proceedings with the Begonia, we have had all sorts of eccentric conditions arising. Some of these excited much comment in these pages many years ago, and formed the subject of comment by C. Darwin, Sir Joseph Hooker, and others. One of the most frequent changes is the change of male to female flowers, or *vice versa*. In the case before us, kindly forwarded by Mrs. Soane, the male flower, or what should have been the male flower, has assumed the characteristics of the female. The stamens, in fact, as may be seen from the illustration (fig. 96), have assumed the guise of ovaries bearing ovules. The case, then, may be classed under pistillody of the stamens.

HOME CORRESPONDENCE.

CLEMATIS GRAVEOLENS.—This climber which may be likened to a yellow-flowered Clematis flammula, is a native of the temperate Himalayas, on the borders of Tibet. I am at a loss to find how it deserves its name, for if I gather half-a-dozen flowers together, I can perceive very little scent, and that not disagreeable. Four or five years ago a plant grew, and perhaps still grows in a large mass on the terrace of the Colwyn Bay Hotel, just above the shore. Thinking it ornamental, I obtained two plants, of which one now grows over the arch of a garden-door, and spreads on to the roof of a garden-house, where its abundant yellow-flowers, with purple stamens, and elegant pendent growth, last till late in the autumn, and are succeeded by the white beads, so familiar in the Traveller's Joy. The other grows up the stem of an Apple tree, and hangs from the lower branches. I do not know what Apple growers may think of this, but in the mixed arrangements of Edge garden, where fruit-trees grow in the flower borders, I utilise their trunks in this way, planting against them not only Clematises, but Climbing Roses, and Penzance Sweet Briars, and whether the trees like it or not, they continue to bear quite enough Apples for my use. C. Wolley Dod, Edge Hall, Malpas.

PEACHES FROM A STANDARD TREE IN THE OPEN AIR.—I saw recently a fine healthy Royal George Peach growing as a standard tree in Barham Court gardens, Maidstone. Mr. Woodward, the gardener there, informed me that he had removed it from an unheated orchard-house ten years ago, because it used to suffer from mildew. It has now made a fine head, measuring about 15 feet by 9 feet, and is about 10 feet in height. Fifteen dozens of fruit were gathered from it this year; and one of the last which I ate was of excellent texture and flavour, and weighed about 8 oz. The growth of this tree is perfectly healthy, and under the excellent methods of culture adopted by Mr. Woodward, it affords a crop of fruit every year. The tree was planted temporarily in a bed of coal-ashes and rubbish, and some loam was added to the bed after the tree began to show signs of succeeding. It occupies a sheltered position between some unheated fruit-houses. W. H. Divers.

PROTECTING PEACH-TREES WHEN IN FLOWER.—Mr. Markham's note on the above subject, in your issue of September 16, p. 230, will doubtless lead to much evidence for and against the protection of Peach and other fruit-trees in the flowering season. I fear that in this regard, unless the trees during the entire period of flowering are kept under close observation, but few facts of any value will be obtained. The ordinary observations which I have been enabled to obtain seem to show that frost does destroy the reproductive organs of the Peach-blossoms, but seeing that the Peach takes about fourteen days in developing the whole of its flowers, and as it is very seldom that sharp frosts occur on as many consecutive nights, many flowers may escape injury, even when no protection is used; and again, on healthy trees fifty flowers will be produced on a space where only one or two fruits would be left to furnish a fair crop. Therefore, a tree may produce a good crop of fruit after being left unprotected during the flowering period, notwithstanding sharp frosts may have occurred, and numerous flowers been destroyed. As far as my observations have gone, ordinary spring frosts cause no injury to the unexpanded blossoms or

young fruits, provided they are set perfectly. But I have noticed that when the pollen is ripe, and the stigma in a fit condition to receive it, a few degrees of frost are sufficient to fatally injure the flowers. The cause of this I have thought to be that the style might contain a small quantity of the viscid secretion which is found on the stigma, and when a frost is experienced during that critical period, the channel of the style, if I may so describe it, by which the pollen is conveyed to the ovules, bursts open, and is thereby unable to perform its functions. The Peach-trees in this garden are protected in the spring with a board coping, from which doubled fish-netting is suspended. The upper halves of the trees this year carry an abundant crop of fruit, but the lower portions have hardly a fruit. A coping of either wood or glass acts as a good protector against frost, and keeps the flowers dry, and consequently less liable to be injured by frost. Geo. Woodgate, Rolleston Hall Gardens, Burton-on-Trent.

OUR FEATHERED FRIENDS.—I was much taken up with Mr. Harrison Weir's note on birds (pp. 237, 238), and moreover was glad to learn he can count

FIG. 96.—MALE FLOWER OF BEGONIA TRANSFORMED INTO A FEMALE BLOSSOM BY PISTILLODY OF THE STAMENS.

among his garden friends the nightingale; further, he does not condemn the tits, which go occasionally for his Sunflowers and Pears. This state of things "can only be" for some eight or ten weeks in the year. On what do our non-migratory feathered friends subsist for the remaining weeks, i.e., until fruit-harvest comes again? Is it not good they do in devouring countless numbers of insects of all descriptions, and seeds of pernicious weeds which, by-the-way, mature their seeds in hedgerows, shrubberies, woods, and places where the eye of man never penetrates? I notice in districts where birds are most encouraged, insect pests are least troublesome in the garden or on the farm. Has Mr. Weir taken note that the song-thrush invariably repairs to one and the same stone, if it serves well the purpose for his delicate repast? I remember seeing a good representation of the song-thrush and worm on a grass plot as a sketch in a paper, the name of which I do not recollect, some time ago, in three acts, namely, (1) Eh? (2) Oh! (3) Ah! Mr. Weir will see the drift of the sketch when he calls to mind the attitude taken up, and satisfaction shown by the bird in the different acts. The thrush is hopping across a lawn, and spies a worm half-way out of its burrow, and exclaims (1) Eh? Tugs a little; breaks it in twain. (2) Oh! and tugs again at the other fast disappearing half; this time is successful in drawing his prize. (3) Ah! And with a self-satisfied look starts off in search for another. M. G.

CORTADERIA LAMBLEYI?—When I sent you the photograph reproduced on p. 335 of your issue for May 27, 1899, I gave it the name received with it many years ago when sent me from a London nurseryman, but as to the correctness or accuracy of which I had for some years entertained strong doubts. Having recently received from a nurseryman at Orleans a plant of a variegated-leaved Pampas-grass named Cortaderia Wesselinghi, which is now in flower, it is evident to me, that it is identical in every respect with what I have hitherto known as Cortaderia Lambleyi. I think, therefore, that the latter name should henceforth be dropped, discontinued, and forgotten, and the name by which it is known on the Continent (where nice plants of it can be obtained for a few pence) adopted as the correct name of the plant. I consider it to be a most desirable variety, being of a dwarf and compact habit of growth, perfectly hardy, and exceedingly free-blooming; as my plant, though only of medium size, is now bearing no fewer than thirty-three perfectly-developed spikes of its distinct and pretty inflorescence. Another, even whiter and more perfectly variegated variety, with pure white plumes, was sent me at the same time from France under the name of C. Steoackeri, which every lover of grasses should grow. W. E. Gumbleton, Belgrove, Cork.

THE FRUIT-PACKING CLASSES AT THE CRYSTAL PALACE.—Having been requested to act as one of the judges in connection with a portion of these packing classes, I can but express my regret that the conditions annexed to them should be of so imperfect a nature that no stress is laid on the method of transit. Indeed, no evidence that the packages have been sent by rail as ordinary consignments of fruit to a market was shown or required. That was a particularly weak feature of the case. Hence we saw fruit, and I readily grant very fine fruit indeed, sent to the Palace in ordinary London bushels and half-bushels, with just a lining of thin blue paper next the sides, or in some cases barely so much, conditions of packing that would not only be disastrous were the fruit sent per rail as an ordinary consignment, but which would cause them to be almost unsaleable in the market. It was evident that the bulk of the packages had been sent in vans to the show by the different competitors, and had not been on the rail, or else they had been brought by the exhibitors to the show as personal luggage; conditions of transit, in either case, that are no test of the methods of packing at all. That my colleagues, as metropolitan market-men, were satisfied with examples of the common method of sending fruit to market from a near area, and per van, was but natural. They especially regarded quality of fruit as thus presented as of the first importance, because of its market value. But I preferred to chiefly regard the method of packing as of the first importance, because it is in relation to fruit sent a long distance by rail to market that the late James Webber, and Mr. George Munro, our referee, unfortunately, and not fellow-judge, at the Palace, laboured so much in the past by prizes and by admonition to improve. The packing conditions which suit metropolitan market-growers who send their fruit in their own vans will not answer at all for growers, who must send by railway, and it is this class whose case and interests should be considered. The two most perfect examples of long-distance packing were found in the cross-handle baskets of Grapes, the flats or squares being the most cumbersome and unsatisfactory things; and these same squares packed with Apples or Pears in wood-wool, as presented by Mr. Basham for his method of long-distance travelling, seemed to be absolutely perfect. In the case of Mr. Tebbutt's Lady Heniker Apples referred to in your report as altogether too highly piled in the basket, quality of fruit was held to outweigh this undoubted defect. But it is of no use to complain because of what was done; it is too late. Another year I hope that whilst there may be classes for metropolitan growers or exhibitors, there will be classes specially for country growers, who shall be requested to send their fruit by railway, and have them delivered in the companies vans at the Palace as they would deliver to the market. A. D.

MARÉCHAL NIEL ROSE ON VARIOUS STOCKS.—I was pleased to read the remarks on p. 250 by "J. K.;" and still more so, that we are promised more of them. With all its faults, Maréchal Niel is still our best yellow Rose, and could we only prevent or cure the swelling or canker, and strengthen its flower-stalks, it would be as near

perfection as possible. I have tried a great variety of stocks in order to cure the first two maladies—budding it on the climbing *Devoniensis* or climbing *Niphetos* on their own roots, with more or less success; but have not tried treble budding, first on the Briar, second with *Devoniensis*, and finally with *Maréchal Niel*. How the Briar stock, budded with the normal *Devoniensis*, which is by no means very robust, should have fostered such strong growth as in this case, is rather mysterious. It must be quite a remarkable experience to grow a shoot of the *Devoniensis* Rose 17 feet long, and strong enough to receive buds. Surely, "J. K." has got hold of the Climbing *Devoniensis*. By the way, *Maréchal Niel* Rose lived longer, and did well on the *Devoniensis* stock on its own roots, although it did not wholly escape its special malady. And this is the great boon your correspondent promises through double grafting! As to blooming a second time, when worked on W. A. Richardson, a second or more frequent blooming is more a matter of cultivation and of site than of double or multiple budding or grafting. For years I was seldom without *Maréchal Niel* Roses on their own roots, or on the Dog Rose stock and a great variety of other stocks, growing them on walls and in the open quarters and beds, and in all aspects, besides pruning the plants at different seasons. But I intended only to thank "J. K." and to say how eagerly many of us await his further revelations, and how gladly we will double or treble bud, graft, or inarch to rid our favourite Rose of the disease that shortens its life in so many gardens can be kept at bay. Perhaps "J. K." would state the age of his oldest double-worked *Maréchal Niel* in his next—as even the length of their life and their freedom from disease is a very variable matter when on their own roots. The alternating of other vigorous Roses such as *Gloire de Dijon*, *Réve d'Or*, and W. A. Richardson, with *Maréchal Niel*, may enable these stocks to be better nourished, and as a consequence, better fortified against the disease. At all events, it is a charming method of giving interest and variety to Roses, and Rose-growers who may not be able to afford space for monstrous plants of *Maréchal Niel*s, either under glass or out-of-doors, carrying five-hundred or one-thousand blooms. By inoculating the sap of *Maréchal Niel* itself with that of canker-proof Roses, we may, it frequently seems as if we did, enable it the better, and the longer to resist the plague of canker. *D. T. Fish*.

CAPE GOOSEBERRY.—With reference to the Cape Gooseberry (*Physalis pubescens*), mentioned in the *Gardeners' Chronicle* of September 23, the plant has been grown in the open air at Ewhurst Park, near Basingstoke, for the last three years, ripening a good crop of fruit each year. The roots are quite unprotected in the winter. The plants are set out against a south wall. *A. C.*

FLORISTS' FLOWERS.

CHRYSANTHEMUMS.

The plants now housed in early vinerias or Peach-houses will need much attention. The shoots upon the Vines should be shortened a little, and every means adopted to make these and other structures as light as possible. The plants will require an abundance of air both night and day, especially when they are first housed. Each plant should be given as much space as it is possible to afford. During bright weather, syringe the plants once or even twice daily for the first fortnight after housing them. They will seldom require to be afforded water more than once a day, as evaporation will be much less than when the plants were out-of-doors. Afford sufficient water on each occasion to thoroughly moisten all the roots, the water being applied in the morning. If the plants are standing on stone, brick, or cement floors, it is prudent to mop up all waste water from the floor.

Shading will be required when the petals commence to unfold, but it should not be applied earlier. The best system of shading is that provided by roller-blinds outside the house, which can be rolled up when not required. The use of shading preserves to a great extent the petals from damping, and improves the colour of the blooms.

Where temporary shading is not possible, then a permanent shade must be put upon the glass. Mix lime and clay in equal quantities with milk or painter's size, and coat the glass with an ordinary paint brush. By constantly removing the dead leaves from the plants and keeping all sweet and clean, the risk of damping will be much reduced. If mildew shows signs of spreading, dust the affected leaves with flowers-of-sulphur.

Continue to feed the plants until the blooms are fully three-parts expanded. Some writers advise that the use of manures be stopped directly the blooms show colour; but it is at that stage that the plants need assistance. Any plants that appear backward may be hastened by affording them weekly, sulphate of ammonia at the rate of half an ounce dissolved in one gallon of weak liquid manure. Continue the use of such manures as have been employed during the summer, as, for instance, liquid made from cow or sheep-droppings, soot, or any of the advertised ones. The main rule to observe is to apply weak doses often rather than strong ones seldom. Stand here and there in the houses among the plants, 8-inch pots filled with quicklime, to absorb the atmospheric moisture.

Plants that have been unduly fed, and grown in loose, rich soil, are much more liable to the damping of the florets when expanding than others. A lack of maturity in the wood and leaves is chiefly the cause of damping. Inexperienced cultivators think that if they produce extra strong stems and leaves, good blooms will be assured. Plants cannot be too strong if the growth is at the same time perfectly matured by proper conditions, such as a firm soil and full exposure.

Should a spell of dull, wet, or cold weather set in which would render the atmosphere damp, the hot-water pipes should be made warm both day and night, so that a little air may be admitted, which will keep the atmosphere buoyant. *E. Molyneux*.

WEED-KILLER AND THE SALE OF POISONS.

WE have repeatedly had to call the attention of our readers to the evils attendant on the sale of poisons by unqualified persons, and to the careless manner in which weed-killer and other poisonous preparations are stored by the users. The following letter from the solicitor to the Nursery and Seed Trade Association points out the penalties the actual seller of poisons incurs, if he be not a qualified chemist or druggist:—

"As the report of the argument and judgment in the action by the Pharmaceutical Society against Mr. White, of Worcester, has been distributed amongst members of the nursery and seed trades, it may be beneficial if their attention be drawn to the following decisions which are not mentioned in the report.

"The Pharmacy Act, 1868, makes it unlawful for any person to sell or keep open shops for retailing or dispensing, or compounding poisons, unless such person is a pharmaceutical chemist, or a chemist and druggist within the meaning of the Act, or is registered under the Act. In the report of the action by the Pharmaceutical Society v. The London & Provincial Supply Association, Limited, in which the ultimate appeal went to the House of Lords in 1880, and is reported in the *Law Reports Appeal Cases*, vol. v., p. 857, it appears that one of the shareholders in the Association was a duly registered pharmaceutical chemist, and was a salaried servant of the Association, and his especial business was that of superintending the sale of chemicals, and he personally sold the chemical containing poison, in respect of which the action was brought by the Society to recover the penalty. It was decided that, under the circumstances, the 1st and 15th sections of the statute did not apply so as to make the Association (being a company, who would not be registered under the Act) liable to the

penalty; but the actual seller must be a qualified person, which was the case in this particular case. Lord Selborne in his judgment states, 'I will add that with regard to the mischief which beyond all controversy the Act was intended to prevent, leads necessarily to the same conclusion, viz., that he who sells, whether he be master or servant, whether he be the principal or a person to whom the conduct and management of sales is delegated, is struck at by the fifteenth section, because otherwise a very wide door would be opened to the evils which the Act was intended to guard against.'

"In the case of the Pharmaceutical Society v. Wheeldon, and reported in the *Law Reports, Queen's Bench Division*, vol. xxiv., p. 683, decided in 1890, it was decided that an unregistered chemist's assistant who, in the absence of his master, sold a packet of "Battle's Vermin Killer" which contained strychnine, was liable to the penalty under the Pharmacy Act, 1868, notwithstanding that he effected such sale on behalf of his master, and that his master was a duly registered chemist.

"I submit that these two decisions show most conclusively that the actual seller, viz., the person who takes the order and accepts it, and thereby effects a sale, whether for himself or another person or a company, must be a qualified registered chemist, and that every member of the trade not being a qualified chemist who sells or accepts an order for a weed-killer containing poison is liable to be fined." *Chas. Butcher, Solicitor to the Nursery and Seed Trade Association, 30, Wood Street, Cheapside, London.*

BOOK NOTICE.

NATAL PLANTS.

THE second part of the first volume of this excellent work by J. Medley Wood, A.L.S., Curator of the Natal Botanic Gardens, Durban, and Maurice S. Evans, M.L.A., F.Z.S., and which is published under the auspices of the Natal Government and Durban Botanic Society, is just to hand, and proves to be in every way worthy of its predecessor. The number contains fine illustrations of fifty species, their parts drawn with the most accurate attention to detail—a circumstance which renders the work of the highest value, both to the casual observer and to the student. The greatest praise is due to the authors, draughtsmen, and publishers, for the prompt manner in which each has attended to his work, for by the records accompanying the descriptions no time has been lost, many of the illustrations having been prepared from specimens collected in May, 1899. Full and accurate descriptions are given of each of the plants illustrated, their habitats, economic value, native names, &c.; and under these headings are many particulars which are of general interest, and serve to make the work acceptable to others besides the botanist. For example, in the letter-press reference to the illustration of our old garden friend, *Leonotis leonurus* (Lion's Tail), it appears to possess purgative properties, and is used in the form of a decoction as an emmenagogue, and also in chronic skin diseases. It is also reported to enter into the composition of a patent medicine which is sold in England. By the Hottentots it is smoked like Tobacco, and by the natives in Natal it is used as a remedy for colds. The whole of the plant except the root is used in decoction as a tonic for calves, and is said to be very efficacious. The plant is boiled with water until the decoction is the colour of brown sherry, and the dose is one pint twice or thrice a week. Dr. Andrew Smith says that it is used in the Cape Colony as a remedy for snake bites; he also says, "The Kaffir name, umfincafinane, is taken from the sugar-birds sipping the sweets from the bottom of its long trumpet-shaped corollas. Before the mouth of the corolla opens, which it does when the stamens are mature, the

nectar is intensely bitter, but at the moment of opening the sweetness is developed. This means that nature does not wish insect marauders who cannot carry the pollen where it is required, to come and rob the nectary."

Under *Rhus longifolia*, Sonder, is the following curious statement: "The tree is known to the natives as *isi-Fuca*, and they use the gum which exudes from the bark for fixing the blade of the assegai to the shaft. As a depilatory they simply smear their fingers with the gum so as to enable them to take a firm hold of the hairs which they pluck out by the roots"—probably more efficacious if a trifle more painful than the quack preparations advertised in places considered more civilised.

The note under the scientific description of *Loranthus Kraussianus*, Meisn., says:—"It is closely allied to *Viscum*, one member of the genus, viz., *Viscum album*, is the common Mistletoe of Europe. The flowers of the above-described species are visited by the 'sun-birds,' principally by the olive sun-bird (*Cinnyris olivaceus*), which inserts its long bill in the slits of the unopened corolla causing it to open suddenly, bursting the anthers, and scattering the pollen, not upon the stigma of the same flower, but upon the head of the sun-birds, who carry it to other flowers. Experiments made by covering many flowers with nets show that thus protected from the birds no seeds set."

Obituary.

THE LATE JAMES MARTIN.—As announced in our last issue, Mr. Jas. Martin, an old and distinguished servant of Messrs. Sutton & Sons, Reading, died suddenly, after four hours' illness, on the morning of the 27th ult. Those who have had occasion to visit the Reading establishment frequently, know how thoroughly enthusiastic Mr. Martin was in the work in which he has been engaged so long and with such success. By his decease horticulture loses a most devoted plant-lover, and distinguished worker in the improvement of plants by cross-breeding and selection. In *Cyclamens*, *Gloxinias*, *Chinese Primulas*, and *Calceolarias* especially, Mr. Martin obtained good results, and he not only gave the world better strains of these plants, but in the Reading establishment he exhibited such cultural skill as has not been excelled. If he obtained a new type, he was as well, or better, able than anyone to show that type in its best condition. And how freely did he converse to anyone interested, of the methods by which he worked, and of the principles that guided him in seeking to obtain a particular form, colour, or other characteristic in a plant that it did not previously possess! His geniality was extended most freely to all who had sympathy with the aims of the cross-breeder, and we have heard him explain with the utmost care, and in detail, the principles that underlie such work to persons who, until meeting Mr. Martin, had never given the question any serious study.

In June, 1894, Mr. Martin was presented with a Veitchian Medal in recognition of the success that had attended his work, and we cannot do better than reproduce the following note, and the photograph which then appeared in these pages. "Gardeners will recognise the excellent cultivation of the *Cyclamens*, the *Chinese Primulas*, the *Begonias*, and other specialties for which the Reading firm is famous, and will feel that the raiser of *Gloxinia 'Her Majesty'* has indeed a claim on the admiration of his colleagues. But what is specially interesting about Mr. Martin, and what is, of course, not known to many, is the circumstance that his labours in cross-breeding and hybridising have been, to a very large extent, based upon and regulated by the teachings of Charles Darwin. Whilst other hybridisers and cross-breeders are content to follow the old fortuitous methods, Martin has sought the guidance of established principle, and the results are shown not only in the excellence of the 'strains,' for which he is responsible, but also in the relative quickness with which he obtains his results, and in their general uniformity."

SOCIETIES.

ROYAL HORTICULTURAL. THE SHOW OF BRITISH-GROWN FRUIT.

(SEPTEMBER 28, 29, 30.)

In our last issue a report was given of the whole of the fruit exhibition at the Crystal Palace excepting the collections of fruit shown by nurserymen, and a few miscellaneous groups of plants and flowers. Of these we now give some description. Until this year the collections of fruit from the trade were either entered in competitive classes open only to themselves, or they were non-competitive, and were awarded Medals at the discretion of the Council. On this occasion, the competitive classes, with 1st, 2nd, and 3rd prizes, were discontinued, and in their place four classes were reserved to the trade, three for fruit grown out of doors, and one for Orchard-house fruit and fruit trees. Any collections entered in these classes were subject to certain published conditions, and in cases of failure to observe these, no award was made. Exhibitors were permitted to adopt any method of staging they

appeared to be filled with fruit, for there were more than 200 dishes, and a considerable number of baskets, each of which held a large number of fruits. But the effect of the exhibit would have been more pleasing had the fruit been relieved by a few plants or other features. A row of large baskets were placed along the middle of the exhibit, and excellent Apples and Pears were displayed in them. Of fine quality, we noticed the following varieties of Pears: *Duchess d'Angoulême*, *Williams' Bon Chrétien*, *Pitmaston Duchess*, *Triomphe de Vienne*, *Marie Louise*, *Beurré Fouquieray*, and *Doyenné Boussoch*. But the Pears were not of such excellent quality as the Apples. Of Peaches, we noticed *Late Devonian*; of Plums, *Cox's Golden Drop*, &c. Amongst a bewildering variety of choice Apples, we were specially struck by the fine quality of *Cox's Orange Pippin*, *Hanwell Souring*, *Peasgood's Nonsuch*, *Ribston Pippin*, *Cellia*, and others.

Messrs. VEITCH & SONS, had also some capital specimen-plants fruiting very freely of the perpetual fruiting Strawberry *St. Joseph*.

Mr. H. BERWICK, Sidmouth Nurseries, Devon, made a nice display of gathered fruits. Apples were especially good, of the varieties *Autumn Pearmain*, *Hollandbury*, *Grenadier*, *The Queen*, *Gascoigne's Scarlet*, and many others (*Silver-gilt Knightian Medal*).

CLASS TWENTY-TWO.

(THIRTY-TWO FEET RUN OF SIX FEET TABLING.)

There were many exhibits in this class, and the highest medal awarded was a *Silver-gilt Knightian*, that was won by an exhibit from Jersey. There seems no good reason why the Jersey cultivators should not be permitted to exhibit in a special class in the district county section. At present, no one from Jersey may exhibit in the strictly competitive classes, yet in this professedly competitive class the highest medal awarded was one to fruit from the sunny island. This appears to be paradoxical.

THE ROYAL JERSEY AGRICULTURAL AND HORTICULTURAL SOCIETY sent a collection of fruit contributed by about a score of members of the Society. There were some extraordinary Pears, the largest fruits being of the famous Jersey kitchen variety, *Belle de Jersey*. Others little less in size were *Callabasse*, *Chaumontelle*, *Pitmaston Duchess*, *Doyenné du Comice*, *Beurré Diel*, *Duchess d'Angoulême*, and very good fruits of many other varieties were shown. Of Apples there were also some fine dishes, especially of *Golden Noble*, *Alfriston*, and others. The exhibit was under the care of the Secretary to the Jersey Society, Mr. HOWELL, and included specimen bottles of dry and sweet Cider, the manufacture of Messrs. NEEL & LE QUESSNE, Jersey (*Silver-gilt Knightian Medal*).

Mr. JNO. WATKINS' exhibit from Pomona Farm, Hereford, was one of exceptionally highly-coloured Apples. *Lady Sudeley*, *Crimson Devonian*, *Beauty of Kent*, *Wealthy*, *The Queen*, *Gascoigne's Scarlet*, *Red Bietigheimer*, *Transparent Codlin*, *Peasgood's Nonsuch*, *Tyler's Kernel*, and *Hitchin Pippin* had really wondrous colour (*Silver Knightian Medal*).

Mr. J. B. COLWILL, Sidmouth Nurseries, Devon, made a splendid exhibit of Apples, Pears, Peaches, Medlars, and Plums; the Apples being by far the most remarkable, and the popular varieties were represented by samples that did credit to the county. Plums *Late Orleans* and *Golden Drop* were also good (*Silver-gilt Banksian Medal*).

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, had an exhibit in this class, and obtained a *Silver Banksian Medal*. The exhibit consisted wholly of Apples, and a very fine general collection of the choicer varieties, especially of those that succeed best in Sussex, were shown.

Mr. GEO. MOUNT, of Canterbury, staged a fine lot of Apples, some Pears, Plums, &c. A *Silver Banksian Medal* was awarded to this exhibit, which contained splendid samples of such Apples as *Peasgood's Nonsuch*, *Gascoigne's Scarlet*, *Mère de Ménage*, *Bismarck*, *Lane's Prince Albert*, and many others.

Messrs. PAUL & SONS, The Old Nurseries, Cheshunt, obtained a *Silver Banksian Medal* for an exhibit in this class, which showed that Hertfordshire, although some parts of the county are exposed and cold, is nevertheless capable of producing good Apples and Pears, the former especially.

CLASS TWENTY-THREE.

(SIXTEEN FEET RUN OF SIX FEET TABLING.)

That Monmouth is a first-class fruit-growing county was strikingly illustrated by an exhibit from Mr. JOHN BASHAM, Fair Oak Nurseries, Bassaleg, Newport, Monmouthshire. This excellent fruit grower was awarded a *Silver-gilt Banksian Medal*. His Apples were as good or superior to any in the exhibition, many of his varieties being equal to the best from Kent. Such were *Lane's Prince Albert*, *Peasgood's Nonsuch*, *Newton Wonder*, *Mère de Ménage*, *The Queen*, *Emperor Alexander*, *Tyler's Kernel*, and *Cox's Pomona*; and equally good were the smaller varieties—*Cox's Orange*, *Allington Pippin*, *Ribston Pippin*, *King of the Pippins*, *Gascoigne's Scarlet*, *Gravenstein*, an Apple greatly prized by Mr. Basham; *Adams' Pearmain*, *Jefferson's*, &c. There were some magnificent specimens of Pears: *Fertility*, *Williams' Bon Chrétien*, *Conference*, *Pitmaston Duchess*, and *Beurré d'Amabilis* (extra fine).

Messrs. RIVERS & SONS made a fine exhibit in this class, their table being laden with first class fruits, most of them approaching ripeness. There were large punnets of such Apples as *Collins*, *St. Martins*, *Mère de Ménage*, *Yellow Ingestre*, *Peasgood's Nonsuch*, *Worcester Pearmain*, *Cox's Orange Pippin*, *Emperor Alexander*, *Gascoigne's Scarlet*, *Fearn's Pippin*, *Lady Hensleigh*, *Marshall's Seedling*, and others; also Plums *Autumn Compôte* (red), *President*, *Primate*, *Admiral*, *Late Orange*, *Pond's Seedling*, *Black Orleans*, and *Wyedale*. Of Pears, there were excellent speci-

THE LATE JAMES MARTIN.

wished, subject to reasonable reservations, but it is much to be regretted that there was very little attempt made to introduce novelty.

CLASS TWENTY-ONE.

The space allotted to exhibitors in this class was 48 feet run of 6 feet wide tabling.

A Gold Medal was awarded to Messrs. GEO. BUNYARD & CO., Royal Nurseries, Maidstone, for a magnificent exhibit of nearly 300 dishes and varieties of fruit. In the centre was a handsome wicker stand, about 6 feet high above the table. This stand bore eight wicker-trays, four near the base, three above, and one at the top. Most of the exposed parts of the stand was decorated with sprays of *Myrsiphyllum*, and a very fine effect, indeed, it made. On the stand there were approaching three dozen fruits in each cone, and such varieties of Apples as the following were given the greater prominence in the exhibit: *Cox's Orange Pippin*, *Lady Sudeley*, *Barchard's Seedling*, *Mabbot's Pearmain*, *Dartmouth Crab*, &c. The collection of Apples and Pears in baskets and dishes also were of high quality. Of Apples, the following were prominent: *Allington Pippin*, a variety distributed by Messrs. Bunyard, which is rapidly gaining popularity; *New Hawthornden*, *Tyler's Kernel*, *American Mother*, *Crimson Queen*, *Yorkshire Beauty*, *Gascoigne's Scarlet Seedling*, a great favourite with Mr. Bunyard, and a capital and handsome dessert fruit in December; *Queen Caroline*, *Cox's Pomona*, *Ribston*, *Bismarck*, *Washington*, *Worcester Pearmain*, *Newton Wonder*, an Apple that does well in the Midlands, but never so well as in Kent; and scores of others. Pears were good, but not of so fine quality as the Apples. *Rivers' Princess*, *Marie Louise d'Uccle*, *Easter Beurré*, *Marguerite Marillat*, *Passe Crassane*, *Jersey Gratioli*, *Doyenné Boussoch*, &c., were prominent.

Messrs. JAS. VEITCH & SONS, LTD., Royal Exotic Nurseries, King's Road, Chelsea, obtained a *Silver-gilt Knightian Medal* for a magnificent lot of fruit. The space allotted to this firm

mens of Doyenné du Comice, Fondante d'Automne, Louise Bonne de Jersey, Doyenné Boussoch, Severn, Princess, Magate, Jersey G'atoli, Beurre Hardy, Pitmaston Duchess, Souvenir du Congrès, Bergamot, and Fertility. The dishes were covered with wood-wool, and a few decorative plants were interspersed among the dishes (Silver Knightian Medal).

Messrs. S. SROONER & SONS, Howsloew Nurseries, Middlesex, won a Bronze Banksian Medal for an exhibit of fruit, the major portion of which consisted of Apples. The varieties that showed to most advantage in this exhibit were Worcester Pearmain, Alexander, Washington, Emperor Alexander, Bismarck, Wealthy, Royal Jubilee, and Potts' Seedling.

Messrs. W. & J. BROWN, Stamford, Peterboro' and Grantham, staged a nice lot of Apples and Pears. The dishes were placed on green-baize. The margins of the tables were fringed with sprays of Myrsiphyllum, and many small decorative plants were interspersed among the fruits. Apples were shown best in this exhibit, and amongst the best of these were Barnack Beauty, Grenadier, Allington Pippin, Lord Derby, New Hawthorn, Stone's Seedling, Wadhurst Pippin, Betty Gesson, Peasgood's Nonsuch, Warner's King, Bramley's Seedling, and Blenheim Orange (Bronze Banksian Medal).

A Bronze Knightian Medal was awarded to a collection of Suffolk-grown fruit from Mr. R. C. NOTCUTT, Wood's Nursery, Woodbridge. The fruits were shown upon plates, covered with Berberis foliage, Bramley's Seedling, Mère de Ménage, Lord Derby, The Queen, Stirling Castle, and other good kitchen as well as dessert varieties of Apples were noticed.

Messrs. PEWTERESS BROS., The Old Nurseries, Tillington, Hereford, staged a fine lot of Herefordshire fruit, some of the Apples being of extraordinary size and colour, and a Silver Banksian Medal was awarded. Some of the more noticeable Apples were Emperor Alexander, Peasgood's Nonsuch, Lord Derby, Warner's King, Beauty of Kent, Cox's Pomona, of high colour; Blenheim Orange, rather small, but highly coloured; Tom Pott, some of the specimens of which were of a crimson colour throughout; Lane's Prince Albert, one of the finest of Apples; Stone's, Cox's Orange, Knight's Russet, a russet dessert Apple, not in commerce. This nursery is the same that was once the scene of Thomas Andrew Knight's labours in raising improved varieties of fruit.

Messrs. JOHN PEED & SONS, Roupell Park Nurseries, Norwood, Surrey, were awarded a Silver Knightian Medal for a fine lot of Apples and Pears. Some of the popular sorts were staged in large baskets, and were therefore the more displayed.

CLASS TWENTY-FOUR.

(ORCHARD-HOUSE FRUIT AND TREES.)

In this class, the space allowed each exhibitor was 32 feet run of 6 feet tabling. Messrs. T. RIVINS & SON, Sawbridgeworth, Herts, made one of their magnificent exhibits of fruit-trees in pots, each carrying an abundance of fruits. We noticed of Apples, the varieties Bismarck, Newton Wonder, and Bijou. Of Pears, Beurre Bachelier, Pitmaston Duchess, St. Luke, Conference, Louise Bonne de Jersey, Doyenné du Comice, and Durondeau; Plums, Rivers' Late Orange, President, Belgian Purple, Primate, and Monarch. Of Peaches, Lady Palmerston and Golden Eagle. In addition to these fine trees, a quantity of splendid fruit was shown in baskets and dishes, most of them of the same varieties as the trees. But in addition there were of Apples, Cox's Orange Pippin, of extraordinary size and fine colour; Mannington Pearmain, Worcester Pearmain, Emperor Alexander, Peasgood's Nonsuch (a dozen extraordinary fruits); and The Queen. Of Pears: Parrot, one of Messrs. Rivers' raising, and a good variety; Duchess d'Orléans, Lebon, Souvenir du Congrès, Beurre Superfin. Of Peaches: Sea Eagle, Golden Eagle, Princess of Wales, and Late Rivers. And of Plums: Late Prolific and Transparent (a Hogg Medal was awarded Messrs. RIVERS).

Another fine exhibit was made by Messrs. GEO. BUNYARD & CO., Maidstone, for which a Silver-gilt Knightian Medal was awarded. There were about two dozen trees of Apples, Pears, Plums, &c., in pots, all of them vigorous in appearance and well cropped. Some of the most attractive were, of Pears: Doyenné du Comice, Dr. Joubert, Durondeau, Marie Louise d'Ucelle, Brownlee's Russet, &c.; of Plums, there were Pond's Seedling, Reine Claude de Bayay, Wyedale, Cox's Golden Drop, &c.; Lady Palmerston, and other Peaches, Sweet Oranges, Figs, and Apples. There were also as many as ninety dishes of gathered fruits, and these were of the finest orchard-house quality. Apples and Pears were abundant, and of the choicest varieties. Grapes, Tomatos, Plums, Cherries, &c., helping to make this exhibit most attractive and complete.

MISCELLANEOUS.

Messrs. JOHN LAING & SON, Forest Hill Nurseries, London, S.E., made an exhibit of gathered fruit and trees in pots. Amongst the latter were a few Vines and varieties of the Apple and Pear. Gathered fruits were shown numerously, and included fine Apples and Pears, Melons, Pine-apples, Peaches, Plums, Tomatos, Grapes, &c. Messrs. LAING & SON had also a group of Conifers in pots.

Mr. WILL TAYLER, Osborn Nursery, Hampton, showed fruits of some of the most popular varieties of Apples, as Gascogne's Scarlet, Cox's Orange Pippin, Cellini, Worcester Pearmain, Emperor Alexander, Warner's King, &c.; and bunches of Reine Olga Grapes, grown out of doors.

From the HORTICULTURAL COLLEGE, Swanley, Kent, fruits were exhibited, which included Grapes, Apples, Pears, Plums, &c., of very creditable quality and size.

Messrs. RIVERS & SON, in addition to their collections of fruit in the above classes, arranged on a small table a score of wondrous fruits of Peasgood's Nonsuch Apples, and twelve superb bunches of Black Alicante Grapes. A few Golden Queen Vines in pots were included in this exhibit.

Messrs. H. CANNELL & SONS, Swanley, Kent, put up a large and splendid group of Cannas in pots. This group faced the centre path between the fruit tables, and was exceedingly attractive. A large number of varieties was represented.

Mr. H. J. JONES, Rycroft Nursery, Hither Green, Lewis-ham, had a nice group of pot-grown Chrysanthemums in flower; a quantity of single and double flowers of tuberous-rooted Begonias, arranged in glasses, and relieved with Adiantums. Also a splendid group of splendidly-coloured Codæums, with a few plants of Dracena Sanderiana, and other foliage species of plants. The groups were backed with Bamboos and Palms, and altogether made a very pretty exhibit of considerable extent.

Messrs. CUTBUSH & SONS, Highgate, London, had a collection of Apples and Pears, and a group of Shrubs, in pots. THE JADOO COMPANY, LTD., Exeter, had an exhibit of fruit-trees, &c., that were grown in "Jadoo," in pots.

Messrs. A. W. YOUNG & CO., Stevenage, showed hardy flowers; as did Mr. MAURICE PRITCHARD, Christchurch, Hants; Messrs. J. CHEAL & SONS, Crawley, showed a large exhibit of Dahlias, and some fruits.

Messrs. W. PAUL & SONS, Waltham Cross, Herts, had an abundance of Roses, including many of their newer varieties, such as Corallina, that was recently given an award of merit by the Royal Horticultural Society.

Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, had a pretty group of foliage plants, and some Orchids and Gesneras in bloom.

Mr. T. S. WARE, LTD., Hale Farm Nurseries, Tottenham, showed Begonias in baskets. Apparently the plants, which were full of bloom, and arranged to colour, had been lifted from the open ground.

Mr. JNO. RUSSELL, Richmond, Surrey, had a group of Ivies in pots, showing a large number of varieties.

Messrs. GAYMER & SON, Norfolk, exhibited samples of their cyder from that county.

Messrs. R. SMITH & CO., Worcester, were also exhibitors in this class. The Apples and Pears in the exhibit were of good quality, but lacking colour, and the dishes were thinly arranged over pink tissue, which between the dishes was ornamented with sprays of Ampelopsis and Berberis folage, beside a few small decorative plants.

Messrs. C. H. GLOVER & CO., Old Kent Road, London, had some very convenient boxes for storing and packing fruits.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

SEPTEMBER 21.—The Committee ordered a letter of condolence to be written and sent to Mrs. Henry Greenwood upon the death of her husband, who was a member of the Committee from the time of the Society's formation.

T. STATTER, Esq., Stand Hall, Whitefield (gr., Mr. R. Johnson), showed two forms of Cattleya granulosa; one called "Stand Hall var." received an Award of Merit.

G. SHORLAND-BALL, Esq., Ash Field, Wilmslow (gr., Mr. Gibbons), sent a magnificent form of Cattleya Gaskelliana alba, receiving a First-class Certificate.

Mrs. HENRY GREENWOOD, Vine House, Haslingden (gr., Mr. Gill), staged Lælio-Cattleya × "Henry Greenwood," a magnificent cross between Lælia elegans and Cattleya × Hardyana, that well deserved the First-class Certificate which it obtained.

T. BAXTER, Esq., Morecambe (gr., Mr. Roberts), showed a nice form of Cattleya × Hardyana.

R. ASHWORTH, Esq., Newchurch (gr., Mr. Pidsley), sent a very fine Cattleya × Maroni, a cross between C. vatiana and C. aurea, receiving a First-class Certificate.

Mr. J. CYPRER, Cheltenham, showed a Cattleya, a cross between C. bicolor and C. aurea, showing the characters of both parents (First-class Certificate). From the same nursery came a form of Dendrobium Phalenopsis, called "Distinction," to which was given an Award of Merit.

Messrs. CHARLESWORTH & CO., Hatton, Bradford, sent a fine form of Cattleya × Hardyana, and received an Award of Merit.

An Award of Merit was made to Mr. ROBSON, Altrincham, for a variety of Cypripedium Charlesworthii var. magnificum.

BRISTOL & DISTRICT GARDENERS'.

SEPTEMBER 28.—The monthly meeting of the Association was held on the above date at St. John's Parish Room, Redland. Mr. C. Lock presided over a good attendance.

The subject for discussion was Salads, and it was opened by Mr. E. Binfield, gr. to Francis Tagart, Esq., Old Sneed Park. The aim of the essayist was to show how a supply of the principal salads could be maintained through a greater part of the year. A short discussion, chiefly on the culture of Beet, and best means to combat the Celery-fly, followed the reading of the paper.

THE CHARLTON GRAPE.

At a venture of their reaching you in good condition, we send you this day (September 18), per American express, samples of our new Grape, the "Charlton" (Brighton × Mills), to show its quality as well as its capacity to travel long distances. It is the produce of a cross between two other crosses, the features of each parent being shown in its fruit. It is a strong grower, always ripening its

fruit, and wood also. It has perfect stamens, and always sets full bunches of fruit; a merit not conspicuous in one of its parents, and which failing we strived to overcome, and have succeeded perfectly in doing.

Our object in sending over these Grapes is to learn if it would meet with recognition in the English markets. We ourselves, think it a long step forward in quality over all other American Grapes at present grown here.

In western New York we have suffered much this summer from lack of rain, it being the driest season we have experienced in twenty-six years. John Charlton & Sons, Rochester, New York. [The Grapes came over to this side in an ordinary cross-hatched trug or basket made of thin wood and fitted with a cover, quite uninjured, excepting that about one-sixth of the berries had dropped from the bunches. The bloom was perfect, although the bunches had been simply wrapped in soft paper, and there was no other packing material used. The colour is purple with a reddish tinge; the pulp far less viscid than that of some other American varieties we have tasted, and the flavour very pleasant and sugary, reminiscent of the Strawberry and Black Currant. The skin is tough, and the variety should keep a long time after ripening. Not a berry had decayed upon arrival. Ed.]

BRITISH ASSOCIATION.

GENETIC VARIATION.—Asexual reproduction is a phenomenon comparatively rare in the animal kingdom, and when it does occur it is exceedingly difficult to investigate from this particular point of view. In the vegetable kingdom, on the other hand, it is quite common. All, or almost all, plants possess this power, and in a very great many of them, the result of its exercise can be fully followed out, and contrasted with that of sexual reproduction. Let us follow it out in the Potato-plant. The Potato can, and does, normally propagate itself asexually by means of its underground tubers. As you will know, if you take one of these and plant it, it gives rise to a plant exactly resembling the parent. If the tuber (seed, as it is sometimes erroneously called) be that of the Magnum Bonum, it gives rise to a plant with foliage, flowers, and tubers of the Magnum Bonum variety; if it be of the Snow-drop, the foliage, flowers, habit, and tubers are totally different from the Magnum Bonum, and are easily identified as Snowdrops. In this way, a favourable variety of Potato can be reproduced to almost any extent with all its peculiarities of earliness or lateness, pastiness or mealiness, power of resisting disease, and so forth. By asexual reproduction, the exact facsimile of the parent may always be obtained, provided the conditions remain the same.

Now let us turn to the results of sexual reproduction—the seeds, i.e., the real seeds, which, as you know, are produced in the flowers, are the means by which sexual reproduction is effected. They are produced in great quantity by most plants, and when placed in the ground under the proper conditions they germinate and produce plants. But these plants do not resemble the parent. Try the seed of the Magnum Bonum Potato, and raise plants from it. Do you think that any of them will be the Magnum Bonum, with all its properties of keeping, resisting disease, and so forth? Not a bit of it. The probability is, that not one of your seedling plants will exactly reproduce the parents; they will all be different. Again, take the Apple; if you sow the seed of the Blenheim Orange and raise young Apple-trees, you will not get a Blenheim Orange. All your plants will be different, and probably not one will give you Apples with the peculiar excellence of the parent. If you want to propagate your Blenheim Orange, and increase the number of your trees, you must proceed by grafting or by striking cuttings, which are the methods by which such a tree may be asexually reproduced; and so on. Examples

might be multiplied indefinitely. Every horticulturist knows that variety characterises seedlings, i.e., sexual offspring, whereas identity is found in slips, grafts, and offsets, i.e., in asexual offspring; and that if you want to get a new plant you must sow seeds, while if you want to increase your stock of an old one, you must strike cuttings, plant tubers, or proceed in some analogous manner.

An apparent exception to this rule is afforded by so-called bud variation, but it is not certain that this is really an exception. In so far as these bud variations are not of the nature of acquired variations produced by a change of external conditions, and disappearing as soon as the old conditions are renewed, they are probably stages in the growth and development of the organism. That is to say, they are of the same nature as those peculiarities in animals which appear at a particular time of life, such as a single lock of hair of a different colour from the rest of the hair,* the change in colour of hair with growth,† the appearance of insanity or of epilepsy at a particular age. There is nothing more remarkable in a single bud on a tree departing from the usual character at a particular time of life, than in a particular hair of a mammal doing the same thing. Address by Adam Sedgwick, M.A., F.R.S.

* Darwin, *Variation*, vol. i., p. 449.

† As an example I may refer to the Himalayan rabbit Darwin, *Variation*, vol. i., p. 114.

ANSWERS TO CORRESPONDENTS.

APPLES AND PEARS: A. F. Pruning should not take place at this season till the functions of the leaves have ceased—that is, when the leaves turn yellow, and are about to drop. Neither early nor late pruning has any advantage in the formation of fruit-buds. The production of these follow the hard cutting-back of summer shoots in the autumn or winter, and pinching of the young shoots in June and July. Flower-buds may develop the following year, which produce fruit a year later.

ASPARAGUS SEEDLINGS: S. Not truly dioecious, although Kuntz calls them so; but as Mr. J. G. Baker states in his monograph on *Asparagus*, p. 517, "He probably means polygamous." In A. officinalis, this polygamous tendency is carried out to its fullest extent; there are always filaments and rudimentary anthers in the female flowers, and a small, three-celled ovary (which sometimes contains an ovule or two) in the male flowers. The perianth in the two kinds is entirely different in size; that of the male flower being much larger than that of the berry-bearing flower.

CHRYSANTHEMUM DISEASED: *Anxious*. Attacked by some species of fungus. Syringe the leaves with sulphate of potassium and water, $\frac{1}{2}$ oz. of the former to 1 gallon of the latter.

CORRECTION: BULBS, &c., p. 262, before *British Fritillarias* read "non-"; and after *Dr. Prain* delete "chief."

CUCUMBERS: W. H. Clarke. Yours is a very bad case of eel-worm. These nematoids are microscopic in size, but the injury they are capable of effecting upon Cucumbers, Melons, Tomatos, &c., is such, that success can only be attained by ridding the houses of the pest. For the next crop you had better try to obtain the compost from a fresh source; or, failing that, to bake it, thus destroying the worms, &c. Be very careful to clear out every bit of old soil, lime-wash the pit, and to grow on the new plants in baked soil.

ECKLINVILLE SEEDLING APPLE, SPOTTED AND PITTED: D. S. The appearances on the fruit sent are similar to those noticed, figured, and described by the late Mr. J. Berkeley in the *Gardeners' Chronicle*, August 12, 1856, under the name *Gloeosporium fructigenum*, not *Oidium fructigenum*, a species that attacks Grapes, Pears, Plums, and other fruits. On the removal of the rind numerous brown spots of incipient decay were found, which in a short time would coalesce, rendering the flesh uneatable. The remedy would be to apply the Bordeaux Mixture to all trees whose fruit have been similarly affected, beginning with the dressings when the fruit is of the size of a marble, and repeating them twice or three up to the end of June.

GALLS ON LEAVES OF THE LIME: *Lime*, Durham. The leaves are capital examples of the injury that can be caused by a mite (*Phytoptus*). The

growths produced by the punctures of this insect are called nail-galls. We do not know if the insects do much harm, but in any case the leaves should be raked up and burned, as a few eggs might be harbouring in the galls.

GROWING BRASSICAS FOR SEEDS: E. W. The plots of plants must be a mile or two apart, or intercrossing is certain to occur between those which flower at one and the same time, the pollen being carried by the wind, bees, and other insects. As a rule, the plants flower when rather more than a year old.

THE GARDENERS' ORPHAN FUND: We have to acknowledge 2s. 6d. from T. Bye; and 1s. from X. Y. Z., which sums have been sent to the Treasurer of the above-named charity.

HYBRIDITY BETWEEN CONIFERS: G. B. M. It might be possible under very guarded conditions with monoecious genera, by removing the male catkins, and strict isolation. In the case of dioecious genera, by keeping male and female plants miles apart. We know of no artificial crosses having been made. Existing varieties of any species of Conifer are mostly sports, or such variations as always occur among seedlings.

LAPAGERIA SPRAY: F. G. S. By no means uncommon; we have seen much larger ones.

NAMES OF FRUITS: We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. They should be just approaching ripeness, and they should be properly numbered, and carefully packed. A leaf or shoot of each variety is helpful, and in the case of Plums, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.—R. H. W. 1, Beurre Benoit; 2, Van Assche; 3, Serrurier; 4, Louise Bonne of Jersey; 5, Bergamotte Mico; 6, Beurre Duval.—S. W. Pear Pitmaston Duchess.—J. M., North Wales. 1, Radford Beauty; 2, Ribston Pippin; 3, Cox's Orange Pippin; 4, Hornet's Pearmain; 5, French Crab; 6, Adams' Pearmain.—A. G. Probably the Old Nonsuch.—C. B. 1, Loddington (Stone's Apple); 2, Nelson Codlin; 3, Queen Caroline; 4, Scarlet Pearmain; 5, Cox's Pomona; 6, American Crab.—C. L. D., Derry. 1, Carlisle Codlin; 2, Tyler's Kernel; 3, Melon Apple; 4, Springrove Codlin; 5, Cox's Pomona; 6, Calville Rouge d'Automne.

S. W. 1, Bedfordshire Foundling; 2, Scarlet Leadington; 3, Fearn's Pippin; 4, Waltham Abbey Seedling.—G. E., Birmingham. 1, Old Pearmain; 2, Early Harvest; 3, Adams' Pearmain; 4, Cox's Orange Pippin; 5, Cox's Pomona.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—*Nimrod*, Conifer, *Sequoia gigantea*—the red fruit; *Euonymus europaeus*; the flower, *Colchicum autumnale*.—C. G. 1, *Cornus sanguinea*; 2, *Amaranthus Blitum*; 3, *Sison amomum*; 4, *Atriplex patula*.—W. Bamber. *Solanum rostratum*, a native of Mexico.—T. W. R. 1 and 2, *Crataegus coccinea*; 3, *C. coccinea* var. *indentata*. There are innumerable forms of this Thorn that are not important enough to have names; 4, *Alnus glutinosa* var.—R. Watson. 1, *Populus canescens*; 2, *Alnus glutinosa* var.; 3, *Salix nigricans*.—H. J. Clayton. *Fraxinus pennsylvanica*. *Jutt.* 1, *Tilia cordata*; 2, *Ulmus montana*; 3, *Platanus acerifolia*; 4, *Cornus alba*; 5, *Betula alba*; 6, *Viburnum Opulus*.—C. W. *Euphorbia Lathyris*, *Caper Spurge*.—W. T. P. *Pittosporum Eugenioides*; a greenhouse New Zealand shrub, growing in its native country to a height of 20 to 30 feet.—*Ibez*. Both ordinary varieties of *Cattleya Loddigesii*.—J. W. All fine varieties of *Cattleya Loddigesii*.—F. G. G. The plant which is inquired for, and which has ash-grey leaves, is probably *Gnaphalium lanatum*.—*Anxious*. *Crataegus tanacetifolia*.—R. Milner. 1, *Garrya elliptica*; 2, *Buddleia* species, send when in flower; 3, *Eriobotrya japonica*, Loquat.

OAK LEAVES WITH FUNGUS: *Quercus*. Oak spangles—see reply to E. Bros in our last issue.

PEAR GRAFTED ON APPLE AND VICE VERSA: S. Excepting as curiosities and examples of the grafter's art, such unions have no value to the pomologist.

PEAR-TREES FLOWERING BUT NOT FRUITING: C. G. S. Unless frost destroys the blooms, we are unable to account for the absence of fruit. It may be due to the larvæ of *Anthonomus Piri*, a

very lively creature, doing much damage in some places to the blossoms of the Pear; to *Rhyctites Bacchus* and *R. æquatus*, both of which bore holes in the buds and stalks of the flowers. The larvæ of the Pear-sucker (*Peylla pirisuga*), live on flower-buds and flower-stalks. You should send some blossoms to us for investigation another year. Scarcely another kind of tree has so many insect enemies as the Pear. Meantime it would be advisable to replant the tree in a better kind of soil, being careful to afford it good drainage. If the flower-buds are very numerous, that would be a source of weakness in so young a tree, and the cause of weak growth. Remove half of them forthwith.

SEEDS: A. S. Those of a species of *Medicago*—British.

"STRAWBERRY" GUAVA: *Tory*. The species probably meant, is *Psidium Cattleianum*. Fruits of a deep-claret colour; skin, pitted; flesh purplish-red, white at the centre. Fit to eat when it falls from the tree. P. guava and P. aromaticum have yellow fruits.

VEGETABLES: G. F. G. Of much excellence are the following:—

Tomatos (4).—Frogmore Selected, Hackwood Park, Conqueror, and Chemin. Cuttings struck in September, or seeds sown in the present month, would give fruiting plants in March.

Strawberries (3, forcing).—Anguste Nicaise, Empress of India, and La Grosse Sucrée. The plants require from ten to twelve weeks to bring them into fruit in the winter.

French Beans (2, forcing).—Superb Early Forcing, and Mohawk. Sow in the second week of the new year, and at fortnightly intervals till the beginning of April.

Potatoes (2, forcing).—Royal Ashleaf, and Sharpe's Victor.

Carrots (2, early).—Early Nantes, and Early Gem. These may be forced slightly; and for early work out-of-doors, choose the first, and the Carentan.

Hardy Lettuce for winter (2).—All-the-year round, Cabbage variety; and the black-seeded Bath Cos var.

Rhubarb for forcing.—Royal Albert, for outside work; Hawke's Champagne, Kershaw's Paragon, and Myatt's Victoria.

MARKETS.

COVENT GARDEN, OCTOBER 5.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

POTATOS.

Hebrons, Puritans, Main Crop, Up-to-Date, &c., 56s. to 80s.; Blacklands, 40s. to 50s. John Bath, 32 & 34, Wellington Street.

REMARKS.—The frost in the Thames Valley on Friday morning last seriously injured the Dwarf and Runner Beans; also Vegetable-Marrows. The late rains in the same district have been most beneficial to Brussel Sprouts, Savoys, &c. English Endive and Lettuces are invariably sold by the score of twenty-two. Those imported are usually sold by the dozen.

SEEDS.

LONDON: October 4.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that notwithstanding the thin attendance on to-day's market, Clover-seeds all round were exceedingly firm, with an active inquiry in progress. Higher prices are asked, meantime, for Italian Rye-grass. Winter Tares and Seed Rye keep slow in demand, at unchanged rates. The trade for Bird-seed is quiet just now; sowing Rape-seed, however, owing to some heavy export orders, is dearer, as also is Mustard. Blue Peas and Haricot Beans are held for more money.

FRUIT AND VEGETABLES.

GLASGOW: October 4.—The following are the prices realised since our last, but here we may note that some Apples from County Meath—one lot grown on Dutch trees—realised 17s. per cwt., or about double the price of ordinary Irish Apples. Apples: Canadian, Kings, 20s. to 24s. per barrel; Gravensteins, 15s. to 20s. do.; various sorts, 14s. to 18s. do.; Americans, Kings, 15s. to 18s. per barr.; selected, 18s. to 24s. do.; Greenings, Fall Pippins, Cranberry Pippins, &c., 13s. to 17s. per barrel; Pears, French Duchesse, 36s. to 48s. 3s. to 3d. per case; Bonne Louise, 4s. 6d. to 5s. per case; Lemons, Malaga, 14s. to 20s. do.; do., Palermo, 5s. to 8s. do.; Pomegranates, Malaga, 9s. to 12s. do.; do., Valencia, 120s. 6s. 6d. to 7s. do.; 180s. 7s. to 8s. do.; 240s. 8s. to 9s. do.; 300s. 8s. 6d. to 9s. 6d. do.; 360s. 9s. to 9s. 6d. do.; Bananas, extra, 12s. 6d. to 14s. 6d. per bunch; do., No. 1's, 11s. to 12s. do.; do., No. 2's, 9s. to 10s. do.; Grapes, Almeida, 12s. to 20s. per barrel; do., English, 9d. to 1s. 9d. per lb.; Mushrooms, 10d. to 1s. 3d. do.; Tomatoes, English, 3d. to 5d. do.; do., Scotch, 4d. to 8d. do.; Onions, Valencia, 5 in a row, 5d. to 6s. 6d. per case; do., 4 in a row, 4s. to 4s. 6d. do.; Turnips, 7d. to 9d. per doz. bunches; Carrots, 7d. to 9d. do.; Parsley, 6d. to 8d. do.; Cucumbers, 1s. to 2s. 3d. per doz.; Cauliflowers, 10d. to 1s. do.; Cabbages, 9d. to 1s. do.; Celery, 9d. to 1s. do.; Mushrooms, 1s. per lb.

BULBS, PLANTS AND FLOWERS: October 4.—The following are some of the prices realised at sales since our last notice:—Dracenas indivisa, 1s. 6d.; do. D. discolor, 3d. and 6d.; D. rubra, 6d.; D. amabilis, 1s.; D. B. nanti, 6d. and 1s.; D. canifolia, 2s.; Asparagus tenuisima, 1s. 2d.; do. small, 6d.; Maranta Kerchevel, 6d.; Ficus elastica, 8d. and 12s.; Latania hyacintha, 2s.; Phoenix reclinata, small, 9d. each. Bulbs: Hyacinths, 1s. to 2s. per dozen; Tulips, 1s. to 2s. per 100; Crocus, 2d. to 9d. do.; Polyanthus Narcissus, 6d. to 4s. do.; Narcissus, 3d. to 2s. do.; Scilla sibirica, 8d. to 1s. do.; Snowdrop, single, 2s. 2d. do.; Crown Imperials, 6d. to 1s. 6d. per dozen; Iris, 3d. to 1s. per 100; Sparaxis and Ixias, 3d. do.; Arum draucunculoides, 8d. per dozen; Hyacinthus candicans, 3d. do.; Lilium pomponium, 2s. do.; L. umbellatum, 6s. do.; Gladiolus Colvillei alba, 6d. per 100; G. byzantium, 1s. per 100. Flowers: Lilium Harrisii, 2s. to 3s. 6d. per dozen blooms; Orchids, 1s. to 10s. do.; Carnations, 6d. to 1s. 6d. per bunch; Roses, white, 6d. to 2s. 6d. per dozen; do., red, 1s. 2d. do.; do., pink, 1s. 2d. do., boxes, 2s. to 4s. each; Lilium lancifolium, 9d. to 1s. 6d. per dozen; Chrysanthemums, 3d. to 1s. 2d. per bunch; Lily of the Valley, 9d. to 1s. 6d. do.; Maidenhair Fern, 3s. to 6s. per dozen; Gardenias, 9d. to 1s. do.; Marguerites, 2s. 6d. do.; boxes of mixed flowers, 6d. to 3s. per box; Asparagus Fern, 6d. to 2s. per bunch.

LIVERPOOL: October 4.—Wholesale Vegetable Market. Potatoes, per cwt.: Sutton's Abundance, 2s. to 3s. 10d.; Giants, 2s. 6d. to 2s. 10d.; Main Crop, 3s. 6d. to 4s. 6d.; Bruce, 2s. 9d. to 3s. 6d.; Turnips, 6d. to 8d. per dozen bunches; Swedes, 1s. 6d. to 1s. 10d. per cwt.; Carrots, 8d. to 1s. per dozen bunches, and 3s. 9d. to 4s. per cwt.; Parsley, 6d. to 8d. do.; Cucumbers, 1s. to 2s. per dozen; Cauliflowers, 10d. to 1s. do.; Cabbages, 10d. to 1s. do.; Onions, English, 5s. to 6s. per cwt.; do., foreign, 4s. to 4s. 3d. do.; Celery, 8d. to 1s. per dozen. St. John's.—Potatoes, 10d. to 1s. 2d. per peck; Grapes, English, 1s. to 3s. per lb.; do., foreign, 4d. to 8d. do.; Pines, English, 4s. to 6s. each; Damsons, 3d. per lb.; Cobnuts, 10d. do.; Cucumbers, 3d. to 4d. each; Mushrooms, 1s. per lb. and basket. Birkenhead.—Potatoes, 10d. to 1s. per peck; Cucumbers, 2d. to 4d. each; Filberts, 10d. per lb.; Grapes, English, 1s. 6d. to 3s. per lb.; do., foreign, 4d. to 10d. do.; Mushrooms, 10d. to 1s. per lb.

CORN.

AVERAGE PRICES OF British Corn (per imperial qr.), for the week ending September 30, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.	1899.	Difference.
s. d.	s. d.	s. d.

GARDENING APPOINTMENTS.

Mr. J. HAMMOND, late Gardener at Tigrith Manor, Woburn, Bedfordshire, as Head Gardener to H. J. TORRE, Esq., Norton Curlien, Warwick.

Mr. A. JEFFERIES, formerly of Hatherop Castle, and Warren House, Stanmore, &c., and for the past five years Foreman at King's Walden Bury, near Hitchin, Herts, has been appointed Head Gardener to JOHN BALFOUR, Esq., Moor Hall, Harlow, Essex.

Mr. A. EMPSON, for the last eleven years Head Gardener at The Quinta, Brobury, Hereford, has removed to Holme Chase, Bletchley, with the same employer, P. B. GILES, Esq.

Mr. THOS. KIPPING, for the last two-and-a-half years Foreman at Apley Park Gardens, Bridgnorth, as Gardener to J. STRANGE, Esq., Denham Court, Winchester.

Mr. J. P. CONNOR, late Second Gardener for three-and-a-half years at Dalnair, Drymen, N.B., as Gardener to Mrs. WILSON, Balrae House, Killearn, Stirlingshire.

Mr. J. T. DICKSON, late Foreman Dover House Gardens, as Head Gardener to J. J. SMITH, Esq., Southwood House, Eltham, Kent.

Mr. G. BARRELL, for the past two years Foreman in the Gardens, Adare Manor, county Limerick, Ireland, as Gardener to the Earl of DUNRAVEN, Dunraven Castle, Bridgend, Glamorganshire.

Mr. C. S. JONES, late Foreman at Orleans House Gardens, Twickenham, as Head Gardener to C. W. PERRYMAN, Esq., Bifrons, Farnborough, Hants.

Mr. T. BYE, for the past five years Foreman to the late L. T. CAVE, Esq., at Ditcham Park Gardens, Petersfield as Head Gardener to CHARLES J. P. CAVE, Esq., at the same place.

Mr. G. W. LUDDIARD, for the past three years Foreman at Tatton Park Gardens, Knutsford, Cheshire, as Head Gardener to JAMES DIXON, Esq., Edenhurst, Sevenoaks, Kent.

Mr. D. S. LOUPON, for the past eighteen months as Outside Foreman in the Gardens, Hallyburton, Coupar-Angus, N.B., as Gardener to Miss RONALDSON, Howick Grange, Leshury, R.S.O., Northumberland.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DISTRICTS.	TEMPERATURE.				RAINFALL.		BRIGHT SUN.

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E. 4, Midland Counties; 5, England, including London. Principal Grazing, &c., Districts—6, Scotland, W. 7, England, N.W.; 8, England, S.W.; 9, Ireland, N. 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending September 30, is furnished from the Meteorological Office:—

"The weather during this week was extremely unsettled and much rain fell in all parts of the kingdom, accompanied at times by thunder and lightning. In many parts of England, however, there were frequent intervals of bright sunshine.

"The temperature was below the mean, the deficit ranging from 1° in the Channel Islands, to 4° in Scotland, N., and 5° in Scotland, E. The highest of the maxima were registered, as a rule, on the 25th, and ranged from 60° in 'England, S.' to 58° in 'Scotland, N.' and 57° in 'Scotland, W.' The lowest of the minima were recorded during the latter half of the period, and ranged from 29° in the 'Irish districts,' 20° in 'England, N.E.' and 'Scotland, W.' and 31° in several other districts, to 37° in 'England, S.' and to 47° in the 'Channel Islands.'

The rainfall exceeded the mean in all districts, the fall in most cases being more than twice as much as the normal value.

"The bright sunshine exceeded the mean amount in 'England, E.' the 'Midland Counties,' and 'England, S.' and just equalled it in several northern districts; elsewhere there was a deficiency, that in 'Scotland, N.' and the 'Channel Islands' being large. The percentage of the possible duration ranged from 46 in 'England, E.' and 41 in 'England, S.' to 21 in England, N.E., and to 19 in 'Scotland, N.'

THE

Gardeners' Chronicle

No. 668.—SATURDAY, OCT. 14, 1899.

FROM THE LAKE OF GENEVA TO THE ALPS BY TRAIN.

STARTING from the moist, warm shores of the Lake of Geneva, the waters of which are of a tint of blue, that to describe would involve a charge of exaggeration, the traveller may in the course of two or three hours pass from climate and scenery which are Italian in character, to the grandeur of alpine rock and precipice. The journey is effected by a combination of hauling and pushing up a slope as steep in some parts as 1 inch to 1½ inches. This is a convenient way of making ascents—it saves time and fatigue; and, in spite of Mr. Ruskin, it does not materially disfigure the landscape, being quite insignificant in relation to the colossal masses of rock it scales and perforates, whilst it allows many appreciative folk to study and admire what otherwise they would be unable to do. The way up lies through the vineyards, where the vintage is just commencing, and the leaves to put on their autumnal robes of splendour. Lizards bask on the terrace-walls supporting the Vines; big snails, and bigger slugs, suggest that the pasturage is good. And then we come to the Chestnut woods, with their dark green foliage, and their dense masses of bristly capsules, which one thinks must puzzle even the lithe squirrels which bound and leap across the track. Beyond the Chestnuts, the line passes through pastures studded just now with the flowers of the Colchicum, and then it plunges into the woods; at first, mainly of deciduous trees, the colours of the Beech contrasting vividly with the dull, black-green of the Spruce.

The colour of the Aspen Poplar is also noteworthy, the leaves being of a rich purplish or puce colour. Up—up, always up! among the Spruces, with here and there a Silver Fir in association. The Spruces are heavily laden with cones, but not a cone is to be seen on the Silver Fir. By-the-by, is it not unusual to find Silver and Spruce growing together in this way? We have not our Pliny at hand, but memory recalls the substance of a passage wherein he says that the Spruce grows on the loftier elevations, and the Silver Fir at the lower levels; and this holds good in most cases. May not the absence of cones indicate that the tree is not quite at home at these great elevations?

Presently we get above the level of the trees into a stony wilderness, with the boldest and grandest of rocks and cliffs—some stout, thick, rounded, as if nothing could wear them down; others thin, and pointed to a degree that they actually suggest the cardboard rocks one sometimes sees on the stage! Frost, ice, water, and other agencies have weathered the rocks into pinnacles and serratures, and every streamlet that follows on a rain-shower, or on the melting

of the snow, deepens and widens the gully, which now becomes a watercourse, and is destined in due time (but not computable) to form a lateral valley! The alpine pasture at the base of these rocks is doubtless a vast flower-garden in spring. Just now there is only a belated Gentian or two (*G. campestris* and *G. pneumonanthe*); but if floral colour is lacking, that of the foliage forms no inadequate compensation.

Some of the "Alps" are flecked with the bold, broad, decaying leaves of *Gentiana lutea*, like so many pieces of cloth of gold spread out upon the grass; whilst the rocks are often glowing with the brilliantly golden colour of the two alpine Willows, relieved here and there by patches of purple *Cotoneaster*, and the grey-green of *Juniperus nana*. The colouring of the Willows is indeed magnificent in the sun, and the rocks gleam with a colour which is oriental rather than alpine. We are not going to say a word about the distant view of mountains and lakes, the peaks, passes, and glaciers, they are beyond the limitations of pen and ink, and are not horticultural in character. This latter statement requires some modification, for, see, a sign-post points to the "Jardin Alpin"! This is too tempting to be resisted, and so I clamber up a path which runs round a deep, bowl-shaped "combe," and there, between two huge projecting rocks, we pass from the north to the south side through a chasm, which leads to a ravine facing due south, and reminding one (with a difference *bien entendu*) of the cliffs at the Warren between Folkestone and Dover, and especially of a rock-cleft known at Lydden Spout. In this gully M. Correvon has planned an alpine garden—indeed, the plan is partially carried out; well-stocked beds and pockets for the reception of alpine plants may be seen lining the sides of the ravine, and the vertical clefts are filled with Saxifrages, Sedums, Dianthus, Iceland Poppies, and we know not what beside, for on October 5 we do not expect to find much in bloom at this elevation, 7000 feet. Moreover, sheep and chamois find the herbage toothsome, and many plants are nibbled down to the core. We saw some indications of means being taken to prevent these incursions, but if they can keep out the sheep, it is not so easy to prevent the chamois from leaping the fence, and enjoying the salad provided for their use, as they think!

It is easy to see the intention of the designer of this unique garden, and as funds increase, a devious way, flower-lined on either side, will lead the visitor down the face of the rock to the "Alp" below. At every turn there will be something attractive, so that the visitor will be puzzled in which direction to look. In front of him there is an enchanting Alpine panorama; behind him rocks, wonderful rocks; and on all sides flowers—and yet more flowers. As has been said, this was not the season for flowers, and the chamois prove bad gardeners. Nevertheless, the active creatures are not so troublesome as some students who amuse themselves by removing or transposing labels, for they are good enough not to uproot the plants, and these tallies serve in a measure to indicate the richness of the collection.

Perhaps at some other time we may be enabled to give an illustration of a garden which, though not of long-standing, is well placed, well designed, and well stocked. The reader who cares to know more of its whereabouts may be told that it is at the Rochers de Naye, and that it is easily accessible by mountain railway from Montreux.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM HARRYANUM HYBRID.

M. C. VUYLSTEKE, of Loochristi, Ghent, has kindly forwarded two flowers as examples of his success as a raiser of hybrid *Odontoglossums*, an honour which even many of our keenest hybridists are still lacking. The beautiful hybrid is doubtless of the same parentage as *Odontoglossum* × *Rolfsee* (*Pescatorei* × *Harryanum*), though in this instance it may be the result of the inverse cross to the original, both having been crossed and raised by M. Vuylsteke. The finely-formed flowers are 3 inches across, their ground colour a cream-white, the apical end of each of the sepals and petals being heavily stained with purple, which shows through at the front. Inside the margins of both sepals and petals are some rich purple blotches, with clusters of blotches of the same colour in the middle of each. The lip is yellowish-white, spotted with dark-red at the base, the front being unspotted. The spiny yellow crest bears pandurate lips, which are well intermediate between the parents suggested.

THE FINE FLOWERING OF CATTLEYA WARSCIEWICZII.

Probably the fine bright autumn of last year had something to do with the extraordinary flowering of the *Cattleya Warscewiczii* this year, by getting the growths well ripened. We had good strong breaks, and the sunny weather finished them off well, making the flowering of the plants this season quite out of the common. We had 96 per cent. of our plants in flower, and many with seven blooms on a spike, a great many with five and six, very few having less than four large blooms. *H. Reed, Cassibury, Watford.*

PROTECTING PEACH BLOOM.

THE greatest diversity of opinion would appear to prevail among gardeners as to the need for defence against frost in the flowering period.

Apart from purely local circumstances, as, for example, a damp low-lying situation, the presence of water at no great depth, a heavy clayey soil, or shade from tall trees, I am inclined to attribute success or non-success to latitude, and the influence of the Gulf-stream. My gardening experiences were gained in Gloucestershire, Warwickshire, Surrey, Dorsetshire, Hants, and Northumberland; and in three only of these counties was there any need to afford protection, viz., Surrey, Warwickshire, and Northumberland; i.e., in those the farthest removed from the influence of the Gulf-stream. Northumberland has a notoriously inclement spring climate, frosts commonly occurring at night during the greater part of the flowering season, with very cold bright days, that help to forward the bloom on wall-trees very rapidly. In gardens in this county at a distance from the ameliorating influences of the sea, it is seldom that the Peach ripens its wood thoroughly, unless the walls are provided with flues, when no difficulty in this respect need arise; and is equally rare to secure a good, or even a fair, crop of Peaches or Apricots if no protection be used. In some years the wood is so immature that no blooms are produced.

In Surrey and Warwickshire there is no difficulty in getting the wood matured, but spring frosts being often severe renders the protection of the flowers very necessary. In Surrey the summer warmth is sufficient to ripen Nectarines and Peaches on walls facing east and west; in fact, these fruits are the better in some hot, dry localities for being planted on these aspects than on a southern aspect, the fruits on the last-named often getting scalded by sun-heat when much exposed.

In Dorsetshire, Gloucestershire, and Hampshire, the Peach ripens its wood perfectly, except perhaps in a few gardens situated at great elevation, and there is but little need to afford spring protection. The chief difficulty that I had with

Peach-trees in two of these counties, was the controlling of the growth, any failure to effect this invariably resulting in a few years in the utter unfruitfulness of the trees. This state of things is mostly due to an abundant rainfall, the frequent occurrence of sea-fogs, and the mildness of the climate. The only cure was triennial lifting and root-pruning, shallow planting, and a restricted use of manures, either solid or liquid. I do not remember ever having occasion to afford water or manure-water to any Peach-border during a residence of ten years in these three counties.

In a garden in Dorset, of which I had charge for about six years, I was informed by the out-going gardener that he had had no fruit from his Peach and Nectarine trees for many years! And yet they were in point of training and in general appearance perfect; but a close inspection showed that what should have been the bearing-wood was gross sappy, almost wholly green, and destitute of flower-buds. The causes and the remedy were evident, and by transplantation, root-pruning, and shallow planting, fruitfulness returned to all of the trees in a couple of years. That occurred many years ago, before the practices referred to had had time, as I may suppose, to travel so far South. It would, therefore, appear certain that no one formula can be made to fit all the climatic conditions of this little island, and that gardeners must be guided, in his as in other matters connected with their business, by the climatic conditions prevailing in that particular part of the country in which the garden is situated, and not by that which others in different parts of the country find appropriate in theirs. *A Traveller.*

TERREGLES, DUMFRIES, N.B.

THE name of Terregles is not unknown to readers of Scottish history. Its owner, Sir John Maxwell, was one of the faithful followers of the ill-fated Mary, Queen of Scots, and it was at Terregles Tower that she passed a night before embarking for England after the disastrous battle of Langside. It was from Terregles, too, that the brave Countess of Nithsdale set out for London in her daring and successful attempt to effect the escape of her husband from the Tower. The place is still pointed out in the garden where, tradition says, the title-deeds of the estate were concealed before she departed on her hazardous errand. More might be told of the associations of Terregles were it not that one seeks to tell of it from the horticultural and not from the historical point of view.

Like many other gardens, those of Terregles have suffered from several causes. One of the most potent of these has been the changes caused by death, through which the place has been let, and occupied by different tenants. At present, Terregles is the property of Mr. Maxwell-Stuart of Traquair, and is occupied by Mr. C. E. Galbraith, who, until recently, lived at Ayton Castle, Berwickshire. Mr. John McKinnon, the head-gardener, came with his employer from Ayton, and to him I am indebted for much courtesy on the occasion of a visit in the beginning of September.

Terregles possesses many natural beauties. Some of these have been utilised, but others, on account of the changes already alluded to, remain partially undeveloped. Among the latter are several lakes, which would add greatly to the charms of the estate were they tastefully planted with aquatics and margined with moisture-loving plants. It is not improbable that this may be taken in hand.

One of the most conspicuous features is the Italian garden, which occupies a broad terrace close to an apparently artificial ravine. The plan of this garden is more simple than many of the Italian gardens one sees, and it is planted in a suitable manner. Zonal Pelargoniums are largely used, the dry soil and position making them more suitable than Begonias. The whole effect is very good, though slightly marred by the presence of some large specimens of *Rhus typhina*, which appear to have been in the position for several years. The terrace-garden is connected with the other side of

the ravine by a rockwork bridge of a picturesque character. The high, clipped Yew hedges are quite in consonance with the style of a terrace-garden.

The greater number of the flowers needed are grown in and about the kitchen garden. Here a considerable space is taken up with flowers of value for cutting, but at the same time regard is had to the general effect of the garden. One cannot without trespassing too much upon space, detail the plants grown in the borders. Herbaceous flowers are cultivated in considerable quantity. Great use is made of early Chrysanthemums and Dahlias. Violas do well at Terregles, and Mr. McKinnon is happy in being the possessor of several of Dr. Stuart's new varieties, not yet available to the flower-grower in general. The beauty and fragrance of the Sweet Pea is fully recognised, and some sixty varieties are grown. Other annuals are cultivated in great numbers. Carnations are much in request, and seedlings are preferred because of their greater floriferousness. One must not omit the Violets, which are exceptionally well done. The variety California, in particular, was remarkably fine for the district. One or two other varieties of the same type are being tried, and several of the older Violets of proved worth are equally well cultivated.

In the glass structures, which are numerous, although not too many for the requirements, decorative plants for the mansion and flowering-plants for cut bloom are finely grown. The conservatory, at the time of my visit, was brilliant with a varied collection of flowers. Some plants of the old *Heliotropium peruvianum* filled the atmosphere with its delicious perfume, and Lilliums, Fuchsias, Hydrangeas, Pelargoniums, and many others added their charms to the display. The Fernery contains a nice collection of exotic Ferns. One also observed a capital lot of *Eucharis*, as healthy as any one could wish to see; with a number of fine Crotons, Marantas, Palms, and other plants decorative either in flower or leaf. Good Grapes, Peaches, and Tomatos, also showed that indoor fruits receive due attention.

Outdoor fruits, as Mr. McKinnon reported in the *Gardeners' Chronicle*, are not an average crop, but many a gardener would be glad to have such a crop of Apples in the gardens under his charge.

With the exception of the Brassica family, vegetables were generally good. Carrots were very fine, and this is attributed to a dressing of soot, lime, and mustard refuse, applied soon after the seedlings appeared.

About 900 Chrysanthemums are grown, including a good proportion of single-flowered varieties.

The mansion of Terregles is a large building, but its exterior has not an ornate appearance. Its chief interest lies in its having been referred to in one of Robert Burns' poems. In the grounds adjoining there are some fine Conifers and deciduous trees. Among the most noteworthy of these are a fine Douglas Fir, a good *Pinus sylvestris*, a fine *Abies Menziesii*, and a Spanish Chestnut of great age, and of magnificent proportions. *S. Arnold.*

THE ARABIAN DATE-TREE IN INDIA.

AFTER all the supposed failures regarding the introduction of the Arabian Date Palm to India, and after all the adverse criticisms regarding the unsuitability of the climate of India for the successful cultivation of this tree, it is gratifying to read in the *Indian Gardening*, September 7, 1899, the following. In a review of the annual report of the Saharanpur Gardens, for the year ending March 31, 1899, it says:—

"Strange as it may appear, the Arabian Date Palm has at last consented to bear fruit plentifully, and of good quality, at Saharanpur, and Dr. Bonavia may yet be able to point with pride to the realisation of his idea of the Arabian Date Palm being naturalised in this country."

I never had any doubt that this Palm could be successfully and advantageously grown in some part or other of India, from what I had seen of its progress in Lucknow.

Many people perhaps might suppose that India is about as big as the five letters of which its name consists! while in reality it is about as big as Europe without Russia, and with a great variety of climates and soils. As a matter of fact, it has been naturalised for centuries in Mooltan, where it contributes to the people's food.

The Date-tree is not like Apple and Pear-trees, which come to a bearing age in a few years. It takes many years of cultivation before it displays its worth; and it is hoped that the Government of India will persevere in this important experiment, which should have for one of its objects the discovery of the most suitable tracts of country for the cultivation of this most useful tree. When once it "consents to bear fruit plentifully and of good quality," it may go on doing so perhaps for a century or more. If it can give a successful crop in Saharanpur, there can be no reasonable grounds for doubting that it would do better in more favourable localities. As it is not a wildling—although the wild Date-tree grows all over India—it would require some attention and cultivation to enable it to do its duty well, even under the best conditions of soil and climate.

If some of the native chiefs were to employ a Date-grower from the Persian Gulf, there is good reason to suppose that its proper cultivation, and the proper curing of its fruits, would be readily taught to the natives, and in time this important tree would spread. It can be readily propagated both by offsets and by seeds. The latter might in time produce varieties which would be perfectly suited to the soils and climates of various localities. *E. Bonavia, M.D.*

LILIUM HARRISII FOR MARKET PURPOSES.

THIS season's crop of bulbs of this beautiful Lily is now on the market, and if required for flowering at Christmas and New Year, the bulbs should be procured at once. What I have seen this year, are in good condition. They are put on the market in three sizes, 5 to 7, 7 to 9, and 9 to 11 ins. in circumference. The two latter sizes are the best for growing, either for private or market growers. If growing for market, it is as well so to manage as to have them in bloom at Christmas and Easter, and as at these seasons the flowers fetch the highest prices, I am of the opinion that it does not pay to have them in bloom unless a grower has a retail connection. The bulbs should first be inspected, and the decayed scale removed, and when they are potted, some sand should be put at the base of the bulb, or a little sulphur dusted over them. A good compost will consist of three-parts fibrous loam, leaf-mould and rotten manure, with enough sand as will give porosity. The bulbs should be put into 5-inch pots, and should be placed about 1½ inch below the rim, so as to allow of a top-dressing being afforded when required, but leaving the crown of the bulb above the soil. They should then be placed in a cold frame and afforded water, and when this has thoroughly drained away, cover them with a layer of Cocoa-nut fibre refuse, about 5 inches thick. When the bulbs are well rooted and growth is observed coming through the refuse, the latter should be removed, and the plants placed in the greenhouse. As soon as the upper roots begin to grow, a top-dressing and a small quantity of Clay's fertiliser may be afforded. Each plant should then be staked, and placed on the stage. They may then be syringed twice daily, care at all times being very necessary in applying water, too much being very injurious, soon causing the roots to rot. It is better to raise the temperature of the house gradually than to place them in a high temperature all at once. Keep a good look out for green-fly, and if any are observed fumigate forthwith. When the buds are observed some weak manure-water may be afforded. As fast as the flowers open, the anthers should be removed in the morning, as the pollen is apt to spoil the look of the flower. *X. Y. Z.*

A FUNGUS PARASITE ON ALOE.

A VERY remarkable parasitic fungus has just been forwarded to the *Gardeners' Chronicle* for determination (fig. 98). It was communicated by Mr. Thos. Rogers, Manchester, who states that it occurs on the leaves of an Aloe that is common on the hill-sides in Cape Colony, S. Africa. As only small portions of leaves were received, the host-plant cannot be determined with certainty, although the material at command suggests *Aloe platylepis*, Baker.

When fully developed the fungus forms black, convex circular patches, varying from 1 in. to 1½ in.

tually rupture, and appear on the surface; hence, in a developing patch the central portion is quite black, whereas at the circumference the patch is silvery-white, due to the dead epidermis not yet being ruptured, while between these two points the stroma may be seen just bursting through the epidermis.

This method of extending from a central point in concentric circles is similar in origin to the formation of fairy-rings in pastures by the fairy-ring Mushroom or Chantrelle—*Marasmius oreades*; only in the latter instance a single ring is formed each season by the extending mycelium present in the soil, and this ring disappears before the forma-

laria, superficie tuberculata, atra, 4–5 cent. lat., 6–8 cm. alt., epidermide diu velata; loculis semiextertis, parvulis; ascis ebevatiss vel subglobois, 60 × 40–45μ, octosporis; sporis tristictus, cylindraco-fusiformis, utrinque obtusatis, medio 1 septatis, ad septum constrictis, demum triseptatis, 30–32 × 6–8μ, e hyalino fusciculis. *Geo. Massee.*

NOTES FROM A SCOTTISH MANSE.

OUR gardens undergo a considerable change at this period of the year. Autumn is gradually receding into winter; we almost feel, in moments of saddening anticipation, as if we were already standing beside the death-bed of Nature's bloom. Many of our fairest garden treasures that flowered so luxuriantly during the summer and early autumn are disappearing by imperceptible gradations from our gaze. One by one the flowers of the *Viola*, so precious for their fragrance not less than for their capability of floral effectiveness, are passing away; only a very few blooms of *Violetta* remain to charm us still. *Phloxes* and *Delphiniums*, whose season has this year been of marvellous duration, in this region at least, have at last reached the confines of their well-won repose. Here the latter, whose shades of purple and deep blue are especially valuable, in association with other beauties, for artistic effect, have bloomed twice in succession during the autumnal months, thereby revealing a perpetual tendency which I have hitherto regarded as being in such instances exceedingly rare. But the term "perpetual" is quite a misnomer as applied to hardy flowers; it might in some special cases be sufficiently expressive had we, like Michael Bruce's cuckoo, no winter in our year. But our flowers would have to be translated during that rigorous and exacting season, like the cheerful bird in question, to summer climes, to accomplish this; so that the term, if literally interpreted, is hardly admissible. The French word *remontantes*, as applied to

ROSES,

is much more intelligible, and many of them are, unquestionably, worthy of the name. The atmospheric influences to which during the last month our Hybrid Perpetuals, Teas, and Hybrid Teas are subjected have been abnormally severe; day after day they have been assailed by severe tempests, strong enough to blow down branches from the surrounding trees; and desolating rains often mingled with fierce hail. Yet in their strongly-protected enclosures many of them have survived the shock, and with wonderful facility—I had almost said equanimity—are blooming still. Conspicuous among these are Margaret Dickson, an extremely strong-growing and grandly productive Rose, which should be included by the cultivator in every collection that is worthy of the name; her fair Irish sister, Mrs. Sharman Crawford, a dangerous rival of Mrs. John Laing; though the latter fine variety, even more valuable for exhibition by reason of its somewhat more imposing dimensions, still maintains its popularity.

Among Tea Roses that continue to flower surprisingly at this season of transition are Marie Van Houtte, recently eulogised by Dean Hole in a letter to myself, written from Cauntton Manor in Nottinghamshire, his ancestral home, where he still cultivates with his olden love for its beauty, his favourite flower. Madame Lambard, whose buds are produced with almost equal freedom, and by reason of their substance, last longer when in bloom; Madame Hoste, the most refined in aspect, and most reliable of the pale yellow Teas; though Medea, raised by Mr. Paul, of Waltham Cross, is, while not achieving so much in late autumn, a Rose of stronger petals, and richer hue; Innocente Pirella, an almost pure white variety, of exquisite texture, and, though of small stature when compared with some of its statelier contemporaries, a most attractive Rose. Of the Hybrid Perpetuals that have of late been conspicuous among their less active companions,

FIG. 98.—FUNGUS PARASITE ON ALOE.

1, Portion of an Aloe-leaf showing two patches of the fungus, nat. size; 2, Section through the fungus, nat. size; 3, Ascus containing spores, magn. 400; 4, Free spores, magn. 400.

in diameter. In some instances the fungus occupies a corresponding position on both surfaces of the leaf; in others it is present on one surface only, a corresponding depression forming on the opposite side of the leaf.

The stroma, or fruit-bearing portion of the fungus, first shows on the surface of the leaf at the central portion of the diseased patch, under the form of detached but closely packed black spots, the increase of the patch being due to the continued growth of the black spots grouped in concentric rings round the oldest central portion. The rings spring from the mycelium of the fungus, which radiates in the tissues of the leaf equally on every side from the point of infection. The black patches of the stroma of the parasite are developed below the epidermis of the leaf, which they eventu-

ally rupture, and appear on the surface; hence, in the Aloe fungus the rings are persistent, and consequently at maturity the patch consists of a considerable number of crowded concentric rings, the central one of which is the oldest, and the external one the youngest. The external surface of the stroma is minutely warted, each wart covering a cavity containing a cluster of asci, each ascus in turn containing eight spores. A solution of potassium hydrate extracts a deep purple colouring matter from the stroma of the fungus.

An allied fungus, *Montagnella uberata*, Sacc., is parasitic on leaves of *Aloe abyssinica*, in Abyssinia. As the fungus proves to be a hitherto undescribed form, the following diagnosis is appended:—

Montagnella maxima.—Stromata epiphylla vel amphigena, innato-erumpentia, pulvinata, orbicu-

are Cheshunt Scarlet, A. K. Williams, Captain Hayward, and Marquis of Salisbury; though, by reason of the weather they have recently experienced, their achievements have not been equal to those in previous years. The Hybrid Teas, under the conditions to which I have already alluded, are much more reliable. Almost the only Noisette varieties that bloom in my own garden at this late season of the year, are Bouquet d'Or, which has already exhausted its resources; and the picturesquely-clustering Aimée Vibert, which is flowering profusely still, at a height of 15 feet. An occasional fine bloom of splendid colour may still be discovered on that venerable climber, Gloire de Dijon, and its beautiful daughter, Belle Lyonnaise.

ORIENTAL LILIES.

Of oriental Lilies, whose somewhat late appearance always give them, in my estimation, a peculiar value, like that which the last of the Cactus and decorative Dahlias possess, are *Lilium auratum* platyphyllum, the grandest representative of the gorgeously-coloured family of Liliums to which it belongs (and which I have sometimes seen at Logan House, in this parish, towering amid environing Cedars and Larches to a height of 9 feet); and the white and red *L. speciosum*, *L. album*, *L. rubrum*, and *L. Kraetzerei*, all of which are delicately fragrant, and richly decorative, but of which the variety last-mentioned is undoubtedly the loveliest, with its snowy-white flowers, and tender green shading at the base of the petals, so exquisite in effect. The majority of Japanese Lilies are too tropical in their perfume to be perfectly appreciable; but here is a species whose fragrance is fascinating, because it is refined. *David R. Williamson, Kirkmaiden, N.B.*

THE WHEAT CROP OF 1899.

IN my report on the Rothamsted experimental Wheat crop of 1898, published in the *Gardeners' Chronicle*, November 5, I stated that owing to very unfavourable weather, which laid the crops of many of the plots about the time of blooming, the results could not be taken as representing the average yield of the country, as in all but very abnormal seasons they had done so remarkably for many years past. It was further stated that, if the estimate given in the *Times*, of 35 bushels per acre (of indefinite weight?), and said to be founded to some extent on the yields of the thrashing-machine, were confirmed, the requirements from stocks and imports for the harvest year would amount to from 21 to 22 million quarters. The actual amount of net imports was, according to the "Trade and Navigation Returns," 22,800,148 quarters; and as it is estimated that the increase of stocks amounted at the end of the harvest year to about 1½ million quarters, this would bring the amount of foreign grain consumed to something over 21 million quarters. The subsequent estimate of the Board of Agriculture was 34.75 bushels of indefinite weight, for the United Kingdom, which, adopting the probable average of 61½ lb. per bushel for the home crop, would be equivalent to 35.6 bushels per acre at the official weight of 60 lb. per bushel; and calculation shows that the available home produce so reckoned, together with the actual imports, less the increase of stocks, would supply the population with almost exactly 6 bushels per head at 60 lb. per bushel—that is, assuming that the consumption of home produced Wheat, old and new, approximately represented the available home crop.

Turning now to the Wheat crop of the present year, let us first consider the characters of the season. There was a great deficiency of rain in September (1898), and some deficiency in both October and November; but an excess in December, January, and February. The autumn was therefore very favourable for working the land and sowing the seed; but the seed-bed was rather too light. In each of the six months—September, 1898, to February, 1899—the temperature was considerably higher than the average; and with this, and more

than average rainfall in December, January, and February, fear was entertained that the Wheat would be what is called "winter-proud." In March there was a considerable deficiency of rain, with great fluctuations of temperature, which was, upon the whole, lower than the average. In April and May, however, there was again an excess of rain, with fluctuating temperatures, but, upon the whole, lower than the average.

The general characters of the season so far were, therefore, conducive to over-luxuriance during the winter, and to a continuation of vegetation with little maturing tendency in the spring. In each of the months of June, July, and August, there was a great deficiency of rain, with considerably over average temperature, especially in July and August; whilst in each of the three months, the number of hours of bright sunshine was much in excess of the average of the preceding seven years. The period was, in fact, generally very favourable for the ripening of Wheat; though, in some cases, spring-sown corn crops ripened too quickly. Farmers may also be congratulated on having had harvest-weather as nearly perfection as they could desire, and if the yield does not reach that of the remarkable crop of 1898, they may still consider that they have a Wheat-crop which is over average in both quantity and quality of grain, and also an abundance of straw.

The following table shows in the usual form, the produce on the selected plots in the experimental Wheat-field at Rothamsted in 1899, which is the fifty-sixth year of the successive growth of the crop on the same land. It also gives, for comparison, the average produce of the same plots over the preceding 10, 37, and 47 years, 1852–98, inclusive.

* Equal to 31 bushels at 60 lb. per bushel.

† Equal to 29½ bushels at 60 lb. per bushel.

‡ Equal to 27½ bushels at 60 lb. per bushel.

§ Equal to 27½ bushels at 60 lb. per bushel.

The continuously unmanured plot gave in 1899 a produce of 12 bushels per acre, at 61½ lb. per bushel, an amount which is slightly below the average of the preceding ten years. The farmyard manure gave 42½ bushels, which is above the average of either the ten, the thirty-seven, or the forty-seven years. The mean of the three artificially-manured plots is 36 bushels, the highest of the three reaching 39½ bushels. Referring to the quality of the grain as shown by the weight per bushel, it is seen that there was great uniformity among the five experiments, all showing 61 lb. or more, and none reaching 62 lb. The unmanured and the farmyard-manured produce show, however,

the highest weight per bushel; and in the case of each of the five plots the weight is, with one trifling exception, higher in 1899 than over the ten, the thirty-seven, or the forty-seven years.

All the manured crops were characterised by large and much more than average produce of straw. On one of the artificially-manured plots (8), the amount of straw was within a few pounds of 3 tons per acre; on the dunged plot it was more than 2½ tons, and in each of the other cases it was much more than the average of the ten, the thirty-seven, or the forty-seven years.

Calculating the average produce of the selected plots in the usual way, that is, taking the average of plot 3, plot 2, and the mean of the three artificially-manured plots, the result is a produce of 30½ bushels, at 61½ lb. per bushel; which, reckoned at the official weight of 60 lb. per bushel, gives an average of 31 bushels. Assuming this fairly to represent the average produce of the country at large, the result would be as follows:—The area under Wheat in the United Kingdom was rather over two million acres (2,052,840), which at 31 bushels per acre (of 60 lb. per bushel), gives a gross produce of rather under eight million quarters (7,954,755). Deducting from this 2 bushels per acre for seed, the estimated available home produce is rather less than seven and a half million quarters (7,441,545), or not far from one and a half million quarters less than last year. The average population for the current harvest year is estimated at 40,807,717; and taking the consumption per head at 6 bushels, of 60 lb. per bushel, the total requirement for the harvest year will be 30,605,788 quarters. Deducting from this the available home produce of rather less than seven and a half million quarters, there remain rather more than twenty-three million quarters (23,164,243) to be provided from stocks and imports.

Wheat has this year been grown in two other experimental fields at Rothamsted. In one case no cereal crop has been grown on the land for many years, it having been devoted to the continuous growth of various leguminous crops; and during the last few years seven different descriptions have been so grown side by side. The land under this treatment having become foul, it was decided to summer-fallow it, and then to take a crop of Wheat. As might be expected, some of the leguminous crops left more manurial residue in the land than others. Indeed, in some cases the Wheat was so luxuriant that it was laid flat quite early, whilst in others it stood up well. In two of the seven cases the produce was between 39 and 40 bushels, but in the others it ranged from 42½ to more than 45 bushels; whilst the weights per bushel of the grain ranged from 63.6 to 64.4 lb.; and the amount of straw was in only one case as low as 2½ tons, and in the other six it averaged about 2½ tons. The other field has been devoted to experiments on the ordinary four-course rotation of roots, Barley, Clover (or Beans), and Wheat, both without manure, and with different descriptions of manure.

The experiments were commenced in 1848, so that 1899 is the fifty-second year of their continuance, and the Wheat just grown is the fourth crop of the thirteenth four-yearly course. Taking for illustration the results obtained on the plot, which has been unmanured from the commencement, and from which the whole of the crops have been removed from the land, the general result (omitting that of the first course), is as follows: Under this exhausting treatment, the Turnips gave practically no crop at all after the first course. The produce of Barley has also declined very much, the crops averaging considerably less than half as much over the last four as over the preceding eight courses. On the other hand, the yield of Wheat was in this favourable season 30½ bushels at 63.2 lb. per bushel, which is about 4 bushels more than the average of the preceding eleven courses. These results illustrate the remarkable capability of Wheat to collect its food from what is, agriculturally speaking, exhausted soil, provided that the land is well-cultivated and kept clean. This

capability is, in fact, of great importance to bear in mind when we consider the increasing number of the world's population consuming this grain. *J. B. Lawes, Rothamsted, October 5, 1899.*

BULBOPHYLLUM MANDIBULARE.

BULBOPHYLLUMS are a curious race of Orchids, and as a rule they do not find great favour in the eyes of gardeners. So far as singularity is concerned, the subject (fig. 99) of the present note is no exception to the rule, but the large size of its flowers entitle it to some attention. It is a native of North Borneo, where it was discovered by Mr. F. W. Burbidge; and it first flowered with Messrs. Veitch & Sons, of the Royal Exotic Nursery, Chelsea, in 1882. It again appeared in the collection of Sir Trevor Lawrence, Bart., M.P., and received a Botanical Certificate from the Royal Horticultural Society.

The sepals and petals (the latter being much smaller) are greenish-yellow, striped with brown, and the curious lip has a mass of purple hairs or prickles on a pale ground. *J. W.*

MARKET GARDENING.

MARGUERITES.

THERE are few more profitable plants than Marguerites to grow out-of-doors for supplying cut-flowers during the summer and autumn months; the beautiful golden-yellow flowers, and undeveloped buds of Feu d'Or, and of the white-flowered type, always command a ready and remunerative sale. No time should now be lost before putting in the necessary hatch of cuttings of both yellow and white varieties. Take cuttings of about 4 inches long, and insert them at a distance apart of 3 or 4 inches in a cold frame or pit. The bed should be only 10 or 12 inches from the glass, and the soil will need to be made fairly firm about the cuttings. All the trimming the cuttings need is the removal of the bottom pair of leaves with a sharp knife before inserting them in the soil, which should be light rather than heavy. The sashes should be put over the cuttings until they have emitted roots, after which they may be drawn off on every favourable occasion in the daytime so as to ensure a sturdy, dwarf growth in the plants, replacing them, however, at night. The plants are fairly hardy, but require slight protection from frost by means of mats, rough grass, straw, or bracken. The Marguerite may be struck and wintered in much the same way as the bedding Calceolaria.

CARNATIONS AND PINKS.

The present month is a good time to make plantations of select varieties of Carnations and Pinks for the production of flowers next summer. The ground may be given a dressing of short manure, which should be dug or ploughed into it prior to planting. The land must be harrowed and rolled, in order to pulverise the soil before setting the layered plants therein in rows 15 inches apart, and at the same distance from plant to plant in the rows. Insert each plant well down to the foliage, and make the soil firm about the roots. Of varieties, Germania, soft yellow colour, and strong growing; Yellow Queen, a yellow, and beautifully-scented variety, the flowers being well formed, full, and of good substance; Mrs. Turner, fine pure white; Ruby Castle, clear soft salmon-pink, with a serrated edge; Ketton Rose, Sandringham Scarlet, a very bright scarlet, fine full flower, and very free growing, are six good all-round Carnations. It is true Germania has no scent, but it deserves a place on account of its lovely colour. Mrs. Sinkins and Albino are two of the best Pinks to grow, the flowers of both being of good size, fine form, pure white, and deliciously scented. Bunches or individual flowers of Carnations and Pinks, garnished with their own foliage, always sell easily. The process of disbudding the

flowers repays for the trouble involved, owing to the flowers thus obtained being so much larger and finer in every respect than unthinned flowers. *H. W. Ward.*

PACKING AND GRADING OF TOMATOS, CUCUMBERS, AND GRAPES FOR MARKET.

Generally complaints are heard throughout the season from growers of the bad prices that are obtained for their produce, but it is not always the fault of the commission-agent, as it sometimes rests with the growers, viz., in not grading and packing their produce to the best advantage. Growers

tissue-paper (the colour of which indicates the quality of the fruit) placed so that when the fruit is packed it may be folded over it. Where large quantities are grown, the fruit can be graded into extra best, best, extra seconds, seconds, and thirds. Different coloured tissue-paper is used to denote the quality, pink for extra best, blue for best, pink and blue extra seconds, white for seconds, and blue and white for thirds. *Extra best* should be fruit of the best shape and colour, averaging four or five fruits to the lb.; *best*, good fruit, but which is not of such a good shape; *extra seconds*, small fruit, but of good colour and shape, averaging about eight or nine to the lb.—these very often fetch as much as extra best; *seconds*, large and medium-sized fruit that are marked or disfigured in any way; *thirds*, all very small fruits that have not been properly fertilised. Before packing the three first sorts, they should have their stalks clipped right close to the calyx, as by so doing there is no fear of the fruit being damaged by the stalks penetrating the fruits below when placed in the baskets. They will then be ready for market, if travelling by road; but if they travel by rail the baskets will need a lid, or a covering of hay laced with twine, and in this case a piece of tissue-paper, indicating the quality packed, so that it can be seen without disturbing the fruit.

Cucumbers.—With regard to winter Cucumbers, and when they are fetching a high price, it is best to pack them in trays containing one dozen fruits, as at these periods large quantities, as a rule, are not required by buyers, but as they get cheaper, and the demand is greater, they may be packed in flats. In packing winter Cucumbers, it is best to take the trays and pack the fruit in the house in which it is grown, as if the fruit is taken through the cold air into the packing-shed it will soon become soft, and this will militate against good prices being obtained for it. The trays should have a small quantity of hay placed in the bottom, this being covered with a sheet of tissue-paper, and the fruit placed on the paper, covering with another sheet and some hay. They should then be tied in lots of three trays together, and are then ready for market. In packing the fruits in flats, hay should be placed in the bottom, a sheet of tissue, a layer of fruit, then tissue and hay, and so on, till the flat is full. Each flat will take four layers of fruit, and the quality is determined by the amount of fruit in each flat, namely, 2 dozen, 2½ dozen, 3 dozen, 3½ dozen, and 4 dozen; or as some growers grade, special, best, firsts and seconds. When packing in flats, which should be done in the packing-shed, it is best to cut the fruit and lay it in trays in single layers, a method which is much better than piling the fruit one on top of another, which only does damage to the fruit. But in each case the fruit should, as near as possible, be of the same length, colour, and thickness as they can be got. In handling the fruit, lift them by the collar, taking care not to knock the bloom off, as the better condition the fruit is put on the market, so much better will be the return for it.

Grapes.—These are graded into three sorts—special, best, and seconds, and can be packed either in shallows (or, as they are generally called, baby-baskets), or in cross-handle baskets. In packing in shallows, the baskets should first be lined with fine wool and this covered with soft tissue-paper. Before placing the bunches in the basket, all shanked and bad-coloured berries should be removed, taking care to place the fruit at once in the position it is to occupy in the baskets, as moving it about removes the bloom and spoils its appearance. Each bunch should be tied with twine to the sides of the basket. Before placing the bunches in the flat, they should be gone over with the bellows, which will remove any dust, &c., that may have rested on the berries. The lids of the flats should be covered with a sheet of paper, which will protect the fruit from rain, &c. The shallow should be tied to the flat. In sending the fruit in cross-handle baskets, they should be lined similar, and the fruit tied in securely, taking care that the shoulders of the

FIG. 99.—BULBOPHYLLUM MANDIBULARE.

should not top their baskets, that is, place good fruit at the top and smaller and indifferent fruit below, as by doing this the custom of the best buyers, who are generally willing to pay a higher price for fruit that can be depended on, is forfeited. It does not matter whether the price is high or low, the same care should be exercised in packing and grading the fruit, and there will always be a demand for it when it is in the market.

Tomatos.—These are generally put on the market in strikes, that is, baskets containing 12 lb. of fruit. Strips of brown paper should be placed round the inside of the basket, and a little hay or wood-wool in the bottom, and two half-sheets of

bunches are just below the rim of the basket, and not to fill the centre of the basket, as this tends to remove the bloom. The baskets should then be laced with twine on two or three light pieces of cane placed across the top, placing some tissue next, and covering the whole top with newspaper, tying down securely and taking care that each basket is labelled "Grapes with Care." In grading, always choose your bunches as near as possible of one size, and as near to one another in colour as they can be got. X. Y. Z.

COLOUR-TREES.

As it will soon be the time for transplanting trees and shrubs, perhaps a few notes on bright and dark-foliaged trees may not be out of place, the more so as most are singularly ornamental, producing some pictorial effects that are very nearly, if not quite, charming, and in this sense they are neglected, or but one or two, perhaps more, selected, and doing duty almost everywhere, with and without combination with their green-leaved brethren. Of these, the *Acer fraxinifolia* (Negundo) albo-variegata, though very beautiful, is becoming so common in place and out of place, that now only too often, instead of pleasing, it absolutely affronts the eye; and are mostly planted in such manner, that one is rather uncertain whether he has not strayed into a shrub nursery rather than a garden or "pleasance." These "foliage" trees are like jewels, which show to better advantage when well, skillfully, and artistically set, and thus the "setting" enhances the value, at least to the eye of the beholder, if not intrinsically and commercially. As it is said there is wisdom in "looking before you leap," so it is wise to be sure that you are beautifying before you plant your trees.

On a ground-plan of the garden the stations might be dotted in their proper colours, always of course having due regard to the height, sturdiness, habit, or other manner of growth. A small-leaved tree looks smaller when in front of a large-leaved one; and it must also be borne in mind that some, though at first they are somewhat of a light red hue, change to a deeper or greener tint, while others grow in intensity. Of trees, the Purple Beech is bright in the bud, then comes to a rich deep purple; but towards autumn the normal colour asserts itself, and before "the fall" it is a dull and heavy green. Of a lesser growth is the purple Filbert, fine in foliage, that at some periods is perfectly rich and brilliant; but now, with me, there is a sort of sullen dulness, that almost offends. Many others are of this character, such as the purple Birch, which now is of a deep green, though the wood is brownish-crimson; but of all the most reliable is the purplish red-foliaged Plum, *Prunus Pissardi*. In the spring it is lovely, when decked with its light roseate blooms; further on it is dressed in such vivid colouring as to again charm the eye. And now, with the cold nights, the heavy rains, the boisterous winds, it holds its own, and more than its own, in beauty, having leaves of red-brown, and others of purple tints; thus it is, for certain positions, unsurpassed. Then how seldom we see *Acer platanoides* Schwedleri, yet at some seasons how lovely it is, with its brilliant carmine branch and shoot tips!—my small one has been much admired this year, and so showy was it that at a distance the orange-red leafage told like inflorescences. The crimson, purple and brown-tinted Japanese Acers have all "gone green;" yet still alone in its comely loveliness, my *Prunus Pissardi* attracts, takes, and keeps the admiration that its superiority not only demands, but merits. Perhaps, if thought useful, at a future time I may call attention to some of our golden, silver, and variegated foliage trees. [Yes, do please. Ed.] It is these, perhaps, more than the foregoing that light up our border shrubberies, and give a living brightness and a charm, when our floral beauties have done their best, and left but their legacy of fruits and berries to gladden and feast our well-loved feathered friends, when "winter old brings frost and cold." *Harrison Weir, Idlesleigh, Severnside.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart. Clare Lawn, East Sheen.

Lælia anceps and its Varieties are now fast developing their flowering-spikes, and as leaf and bulb growth has practically finished, less water must be afforded the roots, but until the flowers are past, the plants should not be permitted to become excessively dry between each time that water is afforded. Most varieties of the white-flowering section have done well this season. Other Mexican *Lælias*, such as *L. albida*, *L. autumnalis*, *L. Gouldiana*, &c., are likewise showing their spikes, and should be treated as described above.

Lælia Perrini is a useful autumn-flowering species that generally succeeds under ordinary cultivation. The most suitable time to repot any plants that require more root-room is soon after they have flowered, allowing them a week or so to recover from the weakening effects of flowering. Whether the plants be disturbed or not, they will need much less water after flowering until the following season's growth has commenced, and they should be exposed to as much light as possible, and as much heat as is obtainable in the Cattleya-house. The white varieties *L. P. nivea* and *L. P. alba*, also the blue one, *L. P. leucophæa*, are not so robust, and, being very valuable, should be given even greater care. If the plants are small, as it is probable they are, they will succeed best if put into pans and suspended from the roof. There are several good cheap and useful hybrids of which *L. Perrini* has been one of the parents, as *Lælio-Cattleyas* Decia, Lady Rothschild, and Statteriana. These need the same sort of cultivation as that just described.

Lælia majalis.—Plants of this lovely species have now completed their growth, and should be given a position near the roof-glass at the cool end of the Cattleya or Mexican-house. No water need be given them, unless to prevent the pseudo-bulbs shrivelling. Failure with this species is generally owing to the using of too much rooting material about the base of the plant, or to over-watering during its natural period of rest in the winter.

Odontoglossum grande.—As the plants pass out of bloom, they should be encouraged to rest, affording them only sufficient water to prevent the young pseudo-bulbs from shrivelling. O. Insleyi and O. Schlieperianum may be treated similarly.

Oncidium tigrinum may not produce flower-spikes so freely as the vigour of the plants would seem to promise. In most cases this is due to not giving them a sufficiently long period of rest by withholding water. If proper treatment has been given the plants, they will now be in or about to flower. A moderate supply of water may be given them until the flowers are past, but afterwards a long period of drought will be necessary. Repotting and resurfacing may be done when new roots commence to appear at the base of the new pseudo-bulbs. A large quantity of drainage material is necessary, and a small quantity of peat and sphagnum-moss. Make the compost moderately firm. A light position in an intermediate-house generally suits the plants so far as temperature is concerned.

Cymbidium giganteum, *Hookerianum*, and *Tracyanum*, which are now in a cool moist house, and developing their flower-spikes, should be removed to another position where there is more light and heat, otherwise development will be slow and unsatisfactory. A weak stimulant, in the form of diluted farmyard drainings, should still be afforded the plants until the flowers are about to expand.

PLANTS UNDER GLASS.

By O. R. FIELDER, Gardener, North Myms Park, Hatfield.

Primula obconica.—The earliest plants raised from seed sown in the spring months should now be strong ones, and established in 5-inch and 6 inch pots. Any of them that may be exhibiting flower-spikes will require to be kept in a house having a temperature of 45° to 50°, in which they will flower throughout the winter.

Primula sinensis.—These plants should not be left in cold frames except in the warmest counties after this date, but should be removed to a cool, airy house, protecting them from damp and frost. A shelf in the greenhouse, vinery, or Peach-house, will suit them. The flower-stems will be pushing

upwards in the earliest plants, and it will be well to afford the plants some weak manure-water occasionally. Plants intended for spring flowering, which are established in 3-inch pots, if well rooted may be transferred to pots 2 inches larger in diameter. If required for any purpose, some of the plants may remain in 3-inch pots, in which, if afforded manure-water they will prove very useful for many decorative purposes.

Double-flowered Primulas.—These should be afforded a position near the glass in a house, the night temperature of which is 50° to 55°, and the atmosphere rather dry. With suitable attention the plants will produce a succession of bloom throughout the winter.

Mignonette.—Plants intended for flowering during the winter which have been standing outside should now be placed under glass. Mignonette plants should at all times be kept as close to the glass as possible, and for the present a position in a cool pit or upon a shelf in an early vinery, or Peach-house where the leaves have fallen from the Vines, &c., will be a suitable place. Later, in order to keep the plants growing, afford a little more warmth, such as that found at the warmer part of a cold greenhouse.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmors, Maidenhead.

Preparations for Trapping the Winter Moth.—The caterpillars of the winter moth (*Cheimatobia brumata*) are among the most injurious insects infesting fruit trees, and pre-eminently the Apple, and next to that tree the Plum and Pear. The past spring being throughout somewhat cold and damp, the eggs of this moth did not hatch out in such numbers as in the two preceding years, when the spring weather was warm and dry, and of a nature favourable to the increase of pests of this kind. With a view to prevent the spread of the caterpillars in spring and summer, it is now generally recognised that any measures to be effective must be taken from about the middle of the present month, extending over November and December (and occasionally a late development of the moth in spring has been known), to prevent the female moth ascending the trees to deposit her eggs from which the caterpillars are hatched in spring and summer. The female being wingless, or merely furnished with wings too small to be of any service in flying, the plan of banding the stems of the trees near the base with some sticky substance, on which the moths are captured when creeping up the bole, has been adopted with much success, and is now invariably carried out in the Evesham and many other large fruit-growing districts. As the moths are known to emerge from the chrysalis-cases, in the ground or crevices beneath the trees soon after this date, and commence to creep up the stems of the trees to lay their eggs in the crevices of the bark, and on the buds and twigs, the banding of the trees should be taken in hand forthwith. Several substances have been used for this purpose of a more or less greasy or sticky nature, Horne's fruit-tree dressing, as advertised in these columns, being a good preparation for this purpose, and instructions for applying are furnished with it. A mixture known as "Evesham Grease," a kind of preparation very similar to cart or axle-grease, of which tallow forms the base, is also used in the district bearing that name. Old orchard-trees, with thick, corky bark, may be smeared with these substances close to the ground, and of a width of 6 to 9 inches all round the stem. If the constituent parts of the sticky or greasy banding are suspected of being of an injurious nature, it will be safer to first place a band of grease-proof or Willesden-paper round the tree, and over this place the smeared band; young trees must always be so treated. See that the paper fits closely to the bark; and if the bark be corrugated, shave it down smoothly, securing the band round it with one strand of matting, allowing the edges of the paper to overlap an inch or so before placing the smeared paper on it. The moths in creeping up the stems are caught on these sticky bands; but care must be taken to keep them sticky, for if allowed to become dry, the insects crawl over them, and so on into the crown. Young trees that are supported by stakes, should have the latter coated with tar or the sticky substance, otherwise these will afford a ready means for the moth to pass over the protected part of the stem, and thence into the crown of the trees.

Gathering Pears.—Most varieties of Pear are now fit for gathering, except the latest, and these may remain a week or two longer on the trees if the weather is mild, their keeping qualities being generally improved thereby. In gathering Pears, lift them in an upward direction, and if matured, they will part easily from the spurs; place them carefully in single layers in the basket, and carry them by hand, or on a hand-barrow, to the fruit-room, storing them in single layers. Very fine examples may be suspended in the fruit-room by their stalks.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Endive.—The best developed plants should be tied up in quantity sufficient to meet the requirements of the place, doing this when they are dry. Frost must be guarded against, as the tender inner leaves are readily injured by a few degrees of frost. Do not tie them up too tightly, but merely collect the outer leaves and secure them with a strip or two of bast, folding them loosely over the heart. In ten days to a fortnight afterwards the plants are will be for use, when another batch may be similarly treated. Endive, when in a half-grown stage, may be dug up with a good ball of earth, and planted in frames for late uses. [The moss-curl variety is readily blanched under pieces of roofing-tile or slates, the tips of the outer leaves just showing beyond the edge of the tile, &c. Ed.].

Lettuce.—Cos and Cabbage varieties of Lettuce being nearly always in demand, strong plants of various ages and sizes should be lifted and planted in cold frames, Peach, and orchard-houses, affording them full ventilation, and keeping the leaves dry. Lettuces may be used in a quite young state if seeds be sown thickly in boxes or on beds of soil in a warmth of 60°. Raised in this manner, the leaves when cut close to the ground are useful as salad at times when blanched Lettuces are not plentiful.

Mustard and Cress.—Seeds should be sown frequently in shallow boxes in quantity according to the demand, rich soil being used, pressing it firmly before the sowing is made, gently pressing the seeds into the soil. Although almost any kind of soil may be used to fill the boxes or coat the seed-beds, I have always found that fresh soil without sand is best. Not any water should be afforded till the soil has got dry, nor should the boxes be stood in a house or pit, the air of which is very humid.

Potatoes.—Late varieties should now be taken up and stored or pitted, after removing all decayed tubers from the bulk. As the ordinary Potato-disease is prevalent this year amongst late varieties, careful inspection should be made. Any tubers taken up some time since, should also be examined for diseased ones. Let all tubers required for sets another year be stored separately in a cool dry place that is safe from frost, or which can be made safe.

Globe Artichokes.—The latest heads should now be removed from the plants, and placed in a cool damp position. Having done this, the flower-stalks may be cut down and removed to the rubbish-heap. In the case of young seedlings which have borne heads, the best should be marked with a label or a stake, and all that are inferior removed forthwith to the rubbish heap. Let the whole of the plants be mulched with rich farmyard manure, packing it in well about the roots. The Globe Artichoke cannot well receive too much manure at this season, and nothing is more productive of large succulent heads in due season.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Planting Evergreens.—Now that sufficient rain has fallen to moisten the ground, no further time need be lost before lifting and planting evergreen trees and shrubs. It is decidedly advantageous to plant them as early as possible, so that they may form new roots, and become semi-established before severe weather occurs. In the case of large specimens, afford the roots water copiously two days before it is intended to remove them, the soil will then the better adhere to the roots. Before moving the trees, sufficiently large holes should be dug out, so that a good-sized ball of earth may be removed with the tree. All fibrous roots should be carefully preserved, and in cases where

the branches are numerous and long, a few may be cut away or shortened, to make removal easier, and tax the roots less. The stem or collar of the tree should be placed slightly above the level of the ground, and the roots laid carefully out and covered with some fine leaf-mould and soil; then fill up with the coarser particles of earth, and after treading this down firmly, lighten the surface with a fork, and complete the job by staking firmly to prevent the trees being loosened by wind.

Tigridias.—As the leaves of *T. pavonia*, *conchiflora*, *alba*, and others, die down, the bulbs will be sufficiently ripened to lift; and though in some light sandy soils they prove hardy, it is always the safer plan to lift and remove the bulbs to a cool, airy place till they have thoroughly dried, when they may be stored away in Cocoa-nut fibre refuse or silver-sand until spring.

Wallflowers.—If plants of these were raised in the manner advised in a previous Calendar, they may now be planted out into the beds or borders intended for them. They are very effective when planted in masses of one colour. Though the strains of Wallflowers have been greatly improved in size and richness of colour in the flowers, the broader leaves contain more moisture, and as a rule they are not so hardy as the older kinds. It is therefore inadvisable to add manure to the soil, but the plants may be liberally fed with liquid-manure when growth commences in the spring.

Dahlias should now be properly labelled and named before they are cut down by the frost, and as new and improved varieties of the Cactus type are raised annually, it would be well to discard the inferior ones in order to make room for the best. Night and Ranji are among improved dark varieties; Alfred Vasey is very choice and pretty; Capstan, brick-red, tinted apricot, very distinct; Standard-bearer, bright, fiery-scarlet; Daffodil, yellow; E. J. Deal, scarlet, are all worth planting. When the stems of Dahlias have become blackened by the frost, they should be cut away, but the roots may be allowed to remain a fortnight longer before they are lifted, to be thoroughly dried and stored away.

Michaelmas Daisies (Asters).—These beautiful autumn-flowering plants will repay one for the little cultural care they require. They resist early frosts, form fine masses of colour, and are most useful and pretty for cutting purposes. Space cannot always be given to a large selection of them, and those who may be forming a collection will find the following varieties very distinct:—*alpinus*, with large pale blue flowers; *amellus* *bessarabicus*, large, Marguerite-shaped blue flowers; *corymbosa*, white, with yellow centre; *Chapmani*, azure-blue; *discolor*, rose; *ericoides*, the most graceful of all, with small white flowers; *lavis*, tall, pale blue flowers, yellow centre, very fine; and *Mrs. Peters*, white, very large. Small pieces taken from the plants at this time of year, or early in spring, will soon form fine clumps; or propagated by cuttings, they will produce fine spikes of bloom. If Asters be planted with the white Japan Anemones, they make a very pretty display.

FRUITS UNDER GLASS.

By W. STRUONELL, Gardener to Lieut.-Col RALPH VIVIAN, Rood Ashton, Trowbridge.

Ripe Grapes.—Houses that are not proof against drip will need to be very carefully watched, or the Grapes still hanging on the Vines will soon show signs of decay, particularly in the case of large bunches, and of thin-skinned varieties. Where there is a Grape-room, the fruit can be more easily kept in this structure than upon the Vine after they have become fully ripe, particularly the varieties Black Hamburg, Foster's Seedling, Early Alicante, and Gros Maroc. This is the more necessary should the houses be required for autumn and winter flowering-plants, the moisture arising from the soil being most injurious to them. A genial atmosphere must be obtained by the moderate use of fire-heat, and a careful watch set upon the ventilators in order to prevent the deposition of moisture on the bunches. It is a mistake to allow the temperature to drop at night; the berries then become cold, and in the morning when the temperature within the house rapidly rises, moisture condenses on the skins, and this, permitted only for a brief period, will spoil the fruit. A tendency to dryness in the border will both help to keep the atmosphere dryer and warmer, and the berries will remain sounder. If there is not a Grape-

room proper in which to store ripe Grapes, a dry and cool fruit-room or room in the dwelling may serve the purpose, the latter being often the better adapted. Damp and cold are most to be guarded against in the preserving of ripe Grapes. When required for immediate use, the bottles may be simply filled with clear water, being careful in the insertion of the stems that the water does not overflow, and pass into the centre of the bunches of fruit. The same care must be taken not to spill water on the floor, and a box of fresh lime is an excellent means for arresting any excess of atmospheric moisture, but it should be changed as soon as it is slaked and moisture-charged.

The Orchard House.—If Plums, Pears, or Apples are still ungathered, the ventilation of the house must be carefully attended to, and nets put across all air-inlets, in order to keep out the tits, thrushes, and blackbirds. Plums are liable to spoil with damp, and a little artificial warmth in rainy or damp weather should be applied at night. By day the ventilators should be opened widely when there is sunshine, and wholly or partly closed at night, in accordance with the weather. As fast as trees in pots become cleared of their fruit, they should be stood out of doors on a bed of coal ashes. Water at the root will seldom be required by these trees, the rain sufficing to keep the soil moist. If, however, the rain should keep off for a week or two, water must be applied, if any green leaves remain on them.

The Re-potting of the Trees.—Trees which may have occupied the same pots for a year or two should be afforded a top dressing, or re-potting into larger-sized pots, according to the state of the soil and the roots. If the soil has got into an unwholesome condition, or is much exhausted of its fertilising properties, or if the roots are much matted together, then re-pot. In treating the first-named case, clear away as much of the soil as can be got at, remove unhealthy roots, and re-pot in the same sized pot; and in the second case, shave off an inch or thereabouts from the ball of roots and soil all round, or prick away the soil only, and re-pot into the same size or a larger one, as may seem advisable. A small, double drag-hook is a very suitable tool wherewith to disentangle the roots and loosen the soil. The soil used in potting and surfacing must be firmly rammed, and the top finished off smoothly. It should be rather dry than wet when used—a wet soil being liable to be rendered impervious to water if much compacted. Those trees in small pots will require to be afforded a small shift, slightly disentangling the roots before putting the tree into the new pot. Drainage materials should be sufficient without being excessive in quantity; one fairly large crock, with the concave side downward, will always afford a free exit for water if broken clinkers, smaller crocks, and coarse particles of charred siftings be placed over these. Too much drainage dries the soil too rapidly, and renders the application of water a very burdensome task in the season of growth.

THE APIARY

By EXPERT.

Extracting Boxes of combs after the honey is extracted must be given to the bees to clean up before being stored away till next year; some care is needed in getting this job completed without disturbance, and a little trouble will be well repaid. The combs should be given to a few stocks only, two or three colonies doing all the cleaning up for the whole apiary. Give the wet combs after nightfall, taking special care that no strange bees get at the combs from the outside. Full instructions for removing surplus honey will be found in *Gardeners' Chronicle*, page 129.

Robbing.—The great thing to be guarded against is what Americans call a "robbing-loom," and although so much mischief may arise if this occurs, it is nearly always brought about by carelessness. Avoiding beginning to rob, is the main point, and to do this feed only in the evening; keep entrances reduced in width; see that no syrup is within reach of flying bees; if hives are threatened with special attack, smear carbolic acid round the entrances; do not open hives oftener than can be helped, and do it in the evening if possible; pay special attention to weak stocks, and join two together before feeding up; finally, feed, and feed well. It will pay to do so.

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

MONDAY, Oct. 16, and the following Tuesday, Wednesday, Thursday, and Friday.—Dutch Bulbs, at Protheroe & Morris' Rooms.

MONDAY, Oct. 16.—Clearance Sale of Glass erections, Utensils, and Stock, at the Cumberland Park Nurseries, Willesden Junction, by order of Messrs. Collins & Collins, by Protheroe & Morris, at 12 o'Clock.

TUESDAY, Oct. 17.—Clearance Sale of Stove and Greenhouse Plants, Orchids, &c., at Cricklewood House, Cricklewood, by order of Madame Roper, by Protheroe & Morris, at 1 o'Clock.

TUESDAY, Oct. 17.—Important Sale of well-grown Nursery Stock, at the Sunningdale Nurseries, Sunningdale, Berks (late Charles Noble's), by Protheroe & Morris, at 12.30 o'Clock.

WEDNESDAY, Oct. 18.—First Trade Sale of Stove and Greenhouse Plants at The Cambridge Nurseries, Northcourt Road, Worthing, by order of Mr. W. Goodliffe, by Protheroe & Morris, at 12 o'Clock.

THURSDAY, Oct. 19.—Unreserved Sale of Stove and Greenhouse Plants, Euonymus, &c., at Welsford's Nurseries, South Lambeth, by order of Protheroe & Morris, at 12 o'Clock.

FRIDAY, Oct. 20.—Sale of the Leasehold Nursery, Lawrence Road, Enfield Highway, by Protheroe & Morris, at the Mart, E.C., at 2 o'Clock.

FRIDAY, Oct. 20.—Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period October 1 to October 7, 1899. Height above sea-level 24 feet.

Affording Water to Plants.

AMONG the troubles that harass what would otherwise be the almost idyllic existence of the gardener, not the least are the difficulties he experiences in connection with the application of water to the plants under his charge. No zealous and attentive gardener can rest in contentment whilst his plants are oscillating in different degrees between shabbiness and mediocrity, the average standard of ordinary plant-culture in these days having been gradually raised greatly above the point of, say, a quarter of a century ago; and though the present degree of excellence is not impossible of attainment by anyone who possesses intelligence and industry, at the same time it cannot be reached without these qualities. True it is that the majority of plants now largely cultivated in pots call for less skill in the cultivator than the Cape Heaths of a former period; still, it should not be forgotten that the subjects of the plantsman's care to-day are largely increased alike in

variety and in quantity, and perhaps the difference in the amount of skill necessary is not really so very great after all. Now, as then, the proper application of water has a most important bearing on successful cultivation.

Broadly speaking, there are three types of workmen who alike render success impossible. The one errs in invariably affording too little water, another in applying too much, and the third saturates the soil, and then allows it to become over-dry before the next application, passing by droughty subjects over and over again. In the case of the first two, there is room to hope for an adjustment of their ideas, and a recognition on their part of the true value of a plant's requirements. The last is truly hopeless, and no one need expect plants to thrive under the care, or to speak more correctly, the lack of care, of such a one. One of the distinguishing marks of a true gardener, be he professionally trained or an amateur, is to be found in the consideration bestowed upon the proper application of water. Mistakes are undoubtedly made even in the case of these, but it is almost always an initial mistake soon rectified and never again perpetrated.

The teaching of the art of applying water is almost beyond human capacity. Hints may be given, but like the arranging of cut flowers, the individual will accept the hints, and work them out according to the bent of his own tastes. There are, however, a few broad facts or reasons connected with affording water to plants which are worth recapitulation. It may be sufficient therefore to mention the necessity of moisture in soil as indispensable to the life of most plants, that an insufficient quantity at certain periods of growth checks nutrition, and too great a quantity either deprives the soil of its fertilising constituents; or, if water be afforded too frequently, the soil is rendered inert, cold, and incapable of sustaining healthy roots.

The happy medium for the gardener to hit upon is not to abstain from affording water till its absence affects root-action injuriously, and to mete out the quantity afforded so as to just moisten the soil throughout. The first-named condition is the least hurtful to plants immediately after repotting; and in the same way the latter practice exhibits its most baneful effects at the same conjunction. But at all stages of plant life they are to be taken into account and avoided; the immediate effect of over-dryness, and which, by the way, it is impossible absolutely to overcome, being a loss either of root-hairs or root-fibres, quickly renewed no doubt, but not so rapidly as to hinder an upset to the plant, and afford an opening for the attack of injurious insects. Excessive watering, a common mistake, is followed by roots making their way into the drainage, and thence outside the pot altogether before the soil itself has been occupied by them. This is an invariable result of soil saturation brought about almost always by applying more than the requisite amount of water at one time. It seems to be a result of a desire to "soak" the soil and save labour. If a soaking were equivalent to a moistening of the soil, no harm would ensue; but it is accepted as meaning to render the soil wet, which is a condition that ought to be guarded against rather than to be sought for. But were wetness innoxious as a condition of the soil, it would exert a deleterious effect, because the roots produced in it are lacking in vigour, and more easily destroyed than those produced under more careful treatment. Some plants

sooner resent this excessive application of water, and more particularly those whose roots are very minute, or which produce root-hairs abundantly. Heaths and Azaleas may be cited as examples of the former, and Carnations and Cinerarias of the latter. On this account, root-coolness, as tending to reduce the frequency that water must be applied, is always beneficial to these plants. Another class of plants which are not so prolific of fine roots, and which coil, and cross, and intercross the whole mass of soil, and of which the Chrysanthemum is a good example, may be watered more copiously. But even in the case of these, experience has proved that a careful application of water always yields the best results in the size and quality of the flowers. Most plants possess great adaptability to varying circumstances; hence the possibility of being able to treat soil in such a manner as not to damage the plant it supports.

Plants, whether flowering or foliage, for employment during the winter season require to have water carefully afforded during the autumn months. No one, we imagine, will gainsay the fact that *Codiaeums* grow more rapidly if the soil is kept continually in a condition approaching wetness; but the leaves of these plants neither colour so well, nor are they as capable of passing through a course of "decorative" handling during the winter with so little damage as those which, while getting sufficient water, get no more. The quality, as distinct from mere size, of Chrysanthemum flowers is largely influenced by the treatment as regards watering accorded to the plants. And the many plants, *Pelargoniums*, *Marguerites*, *Carnations*, &c., which are expected to keep on flowering during the months of winter succeed in accordance with the amount of water applied and correctly gauged.

Gardeners who have had experience in widely separated localities know how greatly treatment differs from this cause alone. But it is a difference of degree only. In cold districts water must be applied less often than in those having greater warmth, but the quantity afforded at any given time need not vary. Hard-water is condemned by all, and it is the most harmful when applied cold. Water, whether from a spring, river, soft, or rain, is always best when well aerated, but stagnant water should be shunned. It requires a larger quantity of cold than warm water to moisten soil. Water much colder than the air of a house is usually bad for the health of plants, and the practice of warming the water used in hot plant-houses is one to be commended. The warmer the water, the more quickly it moistens the soil; hence, any valuable plant that has been allowed to get very dry at the root should be afforded water at 120° Fahr. By this means the soil is moistened forthwith, and without any need of applying more than is requisite for the purpose. House-plants, either singly in vases, or grouped for effect, should also be afforded water in the same manner, and largely for the reason that the least possible quantity is required to moisten the soil.

Manure-water may sometimes be superseded with advantage by a dressing of mineral-manure. The former exerts a beneficial influence, however, in the case of some plants, such for example as *Richardias*, and such foliage-plants as *Alocasias*; but in many instances where it is still largely employed, as in Strawberry culture, as good results are obtainable by two or three slight applications of a suitable artificial manure.

VERONICA COOKIANA (*Armstrong*).—For the opportunity of illustrating this New Zealand shrubby species (fig. 100), we are indebted to Mr. LYNCH, of the Cambridge Botanic Garden. The leaves ($3\frac{1}{2}$ by 2 inches) are nearly sessile, slightly puberulous; the flower-stalks are axillary, about $\frac{1}{2}$ inch long, puberulous, and bear dense, elongated (3 to 4 inches) pyramidal racemes of small, white flowers. It has been confounded with *V. Macroura*, which differs materially in the size and form of the leaves.

to *Coccoloba uvifera*, shown by M. L. DE SMET-DUVIVIER (à l'unanimité); honourable recognition for good cultivation to *Kentia Fosteriana robusta*, shown by M. A. VAN BEERLERE. Stands of decorative varieties of Dahlias were shown by M. A. GALLET.

THE GROCERS' EXHIBITION, which terminated on Saturday last at the Agricultural Hall, Islington, is the means each year of bringing together a great number of novelties in foods. The gardener

that the grocers should take up the sale of English-grown Grapes in the place of the comparatively worthless ones imported in barrels. This would be a gain to the consumer as well as to the market-gardener. Of the new proprietary foods was one called "Shredded wholemeal Wheat-biscuit," a preparation imported to this country by a firm at Worcester, Mass., U.S.A. These biscuits take something of the shape of a scone, and are already sufficiently cooked. They are very light and crisp, and if immersed in hot milk for a few seconds are ready for

FIG. 100.—*VERONICA COOKIANA*, FROM THE CAMBRIDGE BOTANIC GARDEN.

ROYAL BELGIAN HORTICULTURAL SOCIETY.—At the meeting of this Society on Sunday, October 1, at the Casino, Ghent, Certificates of Merit were awarded to Cactus Dahlias of the year 1898-99, shown by M. GALLET (à l'unanimité); to *Begonia Président Bruneel*, raised from seed this year, shown by MM. F. & C. DE COCK BROS. (à l'unanimité). Certificate of Merit for a variety of *Cattleya Brevigiana*, shown by M. le Marquis DE WAVRIN. Certificate of Merit for good cultivation to *Ixora Morsei*, shown by M. L. DE SMET-DUVIVIER (by acclamation); a Certificate of Merit

would be interested in the great variety of bottled and dried fruits exhibited by many of the best-known fruit-preservers; but the only collection shown of fresh fruits produced in England was one from Mr. GEO. MONRO, of Covent Garden, agent for the English Grape-Growers' Association. There were fine Grapes in this exhibit from such growers as Mr. THOS. ROCHFORD, Mr. JOS. ROCHFORD, Mr. PETER KAY, and others, which included excellent bunches of Canon Hall Muscat, Black Alicante, and other varieties; Tomatos, Nuts, and Melons were also displayed. Mr. MONRO is evidently desirous

consumption. They are very palatable, and there are many purposes for which they might be used; but a trial is the best recommendation of this or any other machine-made food.

THE SURVEYORS' INSTITUTION.—The Council, acting on powers conferred on them by By-law 55, have extended the Session 1898-99 by fixing an ordinary general meeting to be held on Friday, October 20, 1899, at 3.45 p.m., for the special purpose (and no other) of reading a balloting list for the election of new members. The first

ordinary general meeting of the Session 1899-1900 will be held on Monday, November 13, 1899, when the President, Mr. THOMAS MILLER RICKMAN, will deliver an opening address. The chair will be taken at 8 o'clock. The first of four meetings of examinees and students authorised (subject to certain conditions) by the Council to be held during the present Session, will take place on Monday, November 20, 1899. The chair to be taken at 7 o'clock. All inquiries with reference to the junior meetings should be addressed to Mr. A. NORMAN GARRARD, 8, Frederick's Place, Old Jewry, E.C.

THE DEVON AND EXETER GARDENERS' ASSOCIATION held its annual meeting last week in the Guildhall, Exeter, and a very satisfactory event it was. The report showed that the Society by means of a series of useful lectures, and in other ways, has entered upon a course of steady, unpretentious work that cannot fail to be of great value to horticulture in the Exeter district. Most of the officers were re-elected, and their enthusiasm for the interest of the Society is unabated. Mr. ANDREW HOPE is the Hon. Sec.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual dinner of members of this deserving Institution was held at the Holborn Restaurant on Thursday evening, the 5th inst., and was presided over by Mr. W. Y. BAKER, proprietor of the Thames Bank Iron Company, and Chairman of the management of the Gardeners' Royal Benevolent Institution. There was a capital company present, and the proceedings were markedly enthusiastic, most of the speeches, including those of visitors, being full of appreciation of the worthy aims the Society has set itself, and of the manner in which the management has carried on the Society's business. Through the kindness of many friends who contributed fruits and flowers, the tables were very prettily decorated. The Chairman, in proposing the toast of "Continued Success to the Society," explained the work that was being done, with special reference to the sectional funds, and congratulated the Society upon the satisfactory state of the finances of each. The convalescent fund was warmly praised, and Mr. N. N. SHERWOOD's and Mr. VEITCH's handsome donations to it from time to time suitably acknowledged. The exceeding small cost incurred in the management of the Society, details of which were given in these columns, March 18 last, p. 175, is a striking feature of the Institution, and was the subject of the Chairman's highest praise. Mr. JAS. HUDSON, the popular treasurer, responded, and incidentally remarked that 96 per cent. of the Society's funds were subscribed by the ordinary members, and only 4 per cent. by honorary members. The toast of the honorary and life members was given by Mr. THOS. WINTER, and was responded to by Mr. GEO. BUNYARD, who suggested that nursery and seedsmen might help the Society by publishing the name and objects of the Society in their catalogues. Mr. R. DEAN proposed the toast of "The Craft," and made a very sympathetic speech, which was responded to by Mr. S. T. WRIGHT, Superintendent of the Chiswick Gardens. Other toasts included that of "The Chairman," proposed by Mr. W. ICETON, of the Granard Nursery, Putney; and "The Secretary," moved by the Chairman. The subscription-list for the evening amounted to £40 18s. 6d., including 15 guineas given by the Chairman. Any information respecting the Society can be obtained from the secretary, Mr. W. COLLINS, 9, Martindale Road, Balham, S.W.

QUEENSLAND.—We have received from the Queensland Government some interesting items of information in regard to the industrial development and general progress of the colony, says the *Times* of Sept. 26. Of these it may be noted that no less than 644 artesian bores are now supplying water throughout western Queensland, the maximum quantity from any one bore being 4,000,000 gallons a day. The discovery of these artesian resources is said to have thrown open to grazing a vast area of some 460,000 square miles, consisting chiefly of

undulating downs covered in good seasons with rich pasture. The developments of fruit-growing in the colony are noticed, and the advantages of the Orange, Pine-apple, and the Olive, especially dwelt upon.

STOCKTAKING: SEPTEMBER.—To such of those who observed the signs of the times in the world of industry by the aid of such publications as the monthly issues of the *Trade and Navigation Returns*, it came with no sudden shock of pleasant surprise that the Chancellor of the Exchequer's stocktaking for the first half of the financial year was a wonderful revelation of financial progress. But that is now history. To-day we have to deal briefly with the last issued part of the trade table, that for the month of September. And here we find that the imports of all kinds show an increase of £3,163,591 over those for September, 1898. The total for the past month was £38,721,079 against £35,557,488 for the same period in 1898. Here are a few extracts from the summary table:—

IMPORTS.	1898.	1899.	Difference.
	£	£	£
Total value ...	35,557,488	38,721,079	+3,163,591
(A.) Articles of food and drink—duty free ...	12,187,428	13,454,951	+1,267,523
(B.) Articles of food & drink—dutiable	2,668,844	2,575,331	—93,513
Raw materials for textile manufactures ...	2,617,136	2,750,820	+133,684
Raw materials for sundry industries and manufactures	5,706,649	5,826,760	+120,111
(A.) Miscellaneous articles ...	1,261,991	1,322,978	+60,987
(B.) Parcel Post ...	84,573	80,769	—3,804

In all the sections there are but two very small decreases; but still, bread is rising in price. The largest items of increase are to be found in those recorded above, and in metals, manufactured articles, raw materials for textile manufactures, and sundry other industries and manufactures. As to the figures for the nine months just ended, we find an increase of £11,424,473, the figures being, for the past nine months, £356,019,390, against £344,594,917 for the corresponding period in 1898. And now we come to the returns relating to—

FRUITS, ROOTS, AND VEGETABLES.

IMPORTS.	1898.	1899.	Difference.
Fruits, raw:—			
Almonds ... bush.	20,440	20,340	—100
Apples	248,126	263,449	+15,323
Cherries...
Grapes	274,835	280,108	+5,273
Lemons	68,410	92,538	+24,128
Oranges	37,255	4,312	—32,943
Pears	169,064	179,563	+10,499
Plums	257,492	143,236	—114,256
Unenumerated... ..	328,793	301,788	—27,005
Roots and Vegetables:—			
Onions ... bush.	664,376	718,062	+53,686
Potatoes ... cwt.	77,721	117,105	+39,384
Vegetables, raw, unenumerated ... value	£162,987	£144,989	—£17,998

There has been a glut of Melons, Bananas, Apples, out-of-doors Grapes, Pomegranates, Tomatoes, nearly all of excellent quality, and cheap. We fancy that our Canadian friends could find as good a market for their Grapes here as at home, though it is difficult to move trade out of old grooves. The concluding items of interest to be noted here are those connected with—

EXPORTS.

and here again an excess has to be recorded over those for September of last year, amounting to £2,429,722, the total being £22,374,807, against £19,945,085 for the corresponding period in 1898. The above relates to articles of British and Irish

manufacture. There was a large export of foreign goods, but they do not count. The nine months' report shows an excess of £21,622,039 over the total for the same period of last year—£194,351,197 for the past nine months, against £172,729,158 for the nine months of 1898.

PUTNEY AND WANDSWORTH CHRYSANTHEMUM SOCIETY.—The special "tradesman's prizes" to be offered this year at the Putney show, will be for the best collection of thirty-six blooms. The first prize will be £10, and the fourth, £3. No challenge cup is for competition in place of that won last year by Mr. Hunt.

BEGONIAS AT THE CRYSTAL PALACE.—In addition to the non-competitive exhibits at the Crystal Palace Fruit Show, described in last week's issue, Messrs. JOHN LAING & SONS, Forest Hill Nurseries, London, S.E., had a collection of cut blooms of double-flowering tuberous-rooted Begonias of excellent quality for so late a date of the season.

CHRYSANTHEMUMS IN THE LONDON PARKS.—We have received information from the London County Council that the annual Chrysanthemum shows in Southwark and Finsbury Parks have already been opened to the inspection of the public. Those at Victoria and Waterlow are to be opened to-day (Saturday), and that at Battersea on the 25th inst. These fine shows of the autumn queen provided by the Council for the free use of the public are deservedly popular.

THE STRUCTURE OF THE CUCUMBER.

THE quantity of work that has been expended in explaining the conformation of the fruits of the Cucurbitaceae is somewhat considerable. It is, however, now generally admitted that the outer portion of the fruit belongs to the axis; that it is, in fact, a dilatation or swelling of the flower-bearing branch surrounding and partly incorporated with the carpels. This view is confirmed by the curious specimen forwarded to us by the courtesy of the Director at Kew from Dr. Groen of Windsor. The two long-stalked leaves must necessarily arise from a branch. In the specimen (fig. 101) before us the sepals have also assumed the form and consistence of leaves.

HOME CORRESPONDENCE.

ROSES, MARECHAL NIEL AND DEVONIENSIS.—

Having written on p. 250 respecting budding *Marechal Niel* on *Devoniensis*, I will now give my experience of "inarching." The plants of which I write are planted in a span-roofed Peach-house 60 feet long and 14 feet wide, running east to west. Three plants of *Marechal Niel* and one of *Devoniensis* alternate with the Peach-trees on the south side, to fill up the space until the Peaches are over. But the Roses have proved to be by far the most valuable crop. Each grew vigorously and yielded good blooms; the four plants covered the whole south front in three years, and two of them covered part of the north side. These were layered in the border after cutting the bark through at a joint; but only one, after seven years, is to-day free from canker, and it covers nearly half of the house. One of them showed canker at the end of two years, but from what cause I cannot conceive. Knowing what would follow, and not wishing to lose all the good flowers from this plant another year (cankered plants always produce small flowers), I inarched the end of a long shoot into the main stem of a

are *M. Niel* and *Devoniensis*. Unite them when and how you will in the growing season, vigorous growths will result. For instance, a long length of *Devoniensis* growing from the right, and carrying different coloured flowers, and a *M. Niel* from the left are united where they meet. When the union is complete, the stem of *M. Niel* is severed above the canker, and inarched on another growing length of *Devoniensis*; the sap flows freely through *M. Niel* and *Devoniensis* alike, as if its course was not altered. Now *M. Niel* inarched on *W. A. Richardson* is very different. Two plants are growing opposite to each other in a span-roofed house, each makes for the ridge; the *M. Niel* grows the quicker, and meets the other about half way up the rafter on the other side. By inarching they are united; but instead of flowers increasing in size, they are smaller for the union; nor is the growth so sturdy. The *Marechal Niel* roots are cankered, but with the assistance of *W. A. Richardson* it affords a good many dozens of blooms of a good tint in the spring-time, and flowers a second time in August. The *Gloire de Dijon* Rose, good as it is to bloom, is of no use for sale. This variety has been worked upon and with different Roses, but with little success,

makes a water-tight joint. Any man may repair a broken square, and from the inside. No outside painting is necessary, neither is putty. The first cost is much less than that incurred by the putty system, *G. G. Taylor*. [The method seems feasible, and if it be water-tight and safe against heavy winds, it is one that might be generally adopted, especially by the trade. *Ed.*]

WISTARIA CHINENSIS.—A *Wistaria* on a south wall here by the end of the glass-houses has been in flower for the past two weeks, this being the second batch of blooms the plant has produced this season. We have had the most peculiar season I remember. There have been periods of three weeks or a month of either cold, or wet, or excessive heat, and now we have one of the wettest harvests experienced for years. *J. Fraser Smith, Cullen House Gardens, Cullen, N.B., October 3.*

PERENNIAL ASTERS FROM SEED.—Your information that Mr. C. Herrin is leaving *Dropmore* reminds me of a very good "hit" recently made by that able gardener. Many of the species and varieties of *Aster*, we know, are highly ornamental for garden and room decoration, and for these

FIG. 101.—ABNORMAL GROWTH OF THE CUCUMBER. (SEE P. 298.)

plant of the *Devoniensis* Rose, and in April it was in bloom. The method of procedure with the stock is the same as that of budding; a T-shaped cut is made in the bark, and the scion cut sloping and slipped in this cut. These were merely tied with strong matting. The sloping cut of the scion must, of course, be made immediately under an eye, or, as with me, a flowering bud. Union was soon complete, and on cutting back the flowering shoot, a long growth as thick as one's little finger was produced the same year, followed next season by one as thick as one's thumb, and 15 feet in length, which produced the largest blooms of *Marechal Niel* I have ever placed on the market. But to return to the long growth inarched. After the blooms were cut and each shoot pruned close to the stem, it broke again freely and strongly; the shoots were thinned out, leaving only one, as is done in Vines. It soon became evident from what source the extra strength came, as the wounds caused by bruising healed over from the side next the *Devoniensis*, and all growths drew away from the point inarched. This led me to sever the whole length from the cankered plant, and mother *Devoniensis* never even allowed it to flag. The vigorous growth to-day shows there is no canker or lack of vitality. This one plant, by means of inarching and budding, now covers a great deal of space, and is doing the work of three plants, so thoroughly in harmony

except in the case of *M. Niel*, which grows liberally, and produces fair blooms. But it requires to be cut severely after flowering each year, or the flowers are small. Duke of Edinburgh upon *Gloire de Dijon* has not moved at all, though it is as fresh as when inserted five years ago. The old variety of *Niphetos* does well on this variety at Parkstone Nurseries near here. Let me tell "Growler" this may not be new to him and many others, but I have been persuaded to write the above for the benefit of a few Rose-growers, who, like myself, have had canker destroy their *Marechal Niels* just when they have covered the space allotted to them. *K. W.*

A SYSTEM OF GLAZING.—I beg to send you a sample of my system of glazing, for which I am seeking a patent, and I shall be pleased to hear what you think of the same. The house may be made any desired shape, and the vertical work also may be glazed on this principle. Rafters or principals are fixed at proper distances, and these support purlines, which run in parallel lines. The whole may be of wood or iron. The glass is recessed or slotted, and when laid on, forms an aperture, through which a pin or clip is passed, and this is secured on the inside of the purline by a screw or nail, thus holding the glass firmly. The clip is cork or rubber-lined, and when fastened to the purline

purposes they are invariably increased from named kinds. It struck Mr. Herrin, however, that very good results might be got from seed, and in this view he proves that he is fully justified. He has a long row of seedlings, which vary from white to various shades of colour, and the effect of the mixture, in line, is most charming. Not only so, but the forms themselves are good, and provide considerable variety for the purposes for which they are grown. Some of the seed was gathered from a form called *Nancy*; but the point of the matter is, that the seed was produced by a good deal of natural crossing, and thus gave rise to a progeny of great variety and interest. The experiment has not, perhaps, been made before; but sooner or later most of our floral improvements, as they become fixed, are raised from seed, so that we no longer rely exclusively upon the propagation of known individuals, and this experiment is one certainly well worth repeating. Given a few good and distinct varieties, and no bad ones, the result is sure to be good. In this case the seedling plants were apparently much more graceful than those propagated by division. *Perigrinator*. [A very charming lot of plants, as we ourselves can testify. *Ed.*]

AWARDS AT THE GREAT FRUIT-SHOW.—I notice in the report of this show in last week's issue of the *Gardeners' Chronicle* that in Class 22 you

state there were many exhibits. I would like to ask those who were responsible for the awards in this class if it was fair to the other exhibitors in the class, and who adhered to the rules of the schedule, that the Jersey exhibit should have been awarded first place, seeing that it was a collection from some twenty members of the Royal Jersey Agricultural and Horticultural Society? That, and the fact of their showing duplicate dishes to the extent of seven and eight, really disqualified them according to the Society's schedule, which plainly states, "No duplicate baskets or dishes of fruit, and no awards of any sort will be made to nurserymen who do not conform to the regulations;" but whilst admitting that the Jersey collection deserved recognition, perhaps to the extent of a gold medal, as much as some of those that got such an award, I must take exception to the action of the Council or judges in not upholding the rules and regulations as published in the schedule. The Council of the Royal Horticultural Society can hardly shut their eyes to the fact that it is the nurserymen who make the show; for, take them away, where is the great fruit show? Nurserymen are but human; and all they ask is a fair field, and no favour. Critic.

NURSERY NOTES.

MESSRS. JAS. VEITCH AND SONS' FRUIT-TREE NURSERY.

In an indifferent fruit season, it is some satisfaction to find that there are cases in which the local conditions and circumstances have been of such a nature as to neutralise to a large degree the influences that have, over the greater part of the country, tended to produce an unsatisfactory result. The year 1899 has been a poor Apple, Pear, and Plum season, chiefly from the injury to the fruit blossoms, inflicted by frost in May. Yet how many exceptions there are! In the London district especially, regarding the London district in the widest sense, there have been numerous instances where the Apple crop has been very much above average. And so in Messrs. Veitch & Sons' nursery at Langley, near Slough, the Apples escaped the May frosts sufficiently to produce a fine crop of fruits. This circumstance, and others akin to it, are doubtless capable of explanation; but this would be beyond our present purpose. The prolonged drought also, has had prejudicial effects upon fruit-trees this season, but many localities have escaped without suffering severely. At Langley, Messrs. Veitch have a piece of land where there is a very good depth of soil, and in the sub-soil there is much clay, but we were, nevertheless, greatly surprised upon a recent visit to find that the fruit-trees, forest and ornamental trees, and most of the other plants in this nursery, so little reflected the chief characteristics of the season now at its close. From the nurseryman's point of view, there is, doubtless, some little cause for regret that the "maiden" trees of Apples, Pears, and Plums, have not made such a long growth as generally characterises a more genial summer; but even in this direction, the falling off is by no means so much as might have been expected, or as is actually the case in many districts. From the buyer's point of view, that is not any disadvantage; he will get trees with a moderate current season's growth upon them, hard, well-ripened, and preferable to trees with willow-like, less perfectly matured shoots that are produced by a damp, growth-hastening season. The Langley nurseries include from seventy to eighty acres of land, a good part of which is occupied with young fruit-trees, the remaining portions being devoted to the seed trials, herbaceous plants, and ornamental trees and shrubs.

APPLES.

A visitor, after a careful inspection of the stock, could hardly fail to agree with the remarks made above. He would probably first turn his attention to some "brakes" or "drifts" of Apple-trees near the entrance to the nursery, where there are grand batches of two-year-old trees upon the Paradise

stock. The growth these have made this season, in our opinion, is satisfactory, if not remarkable. Cox's Orange Pippin, and Lane's Prince Albert, the one the acknowledged king of dessert Apples, and the other hardly less valuable as a kitchen fruit, are particularly noticeable amongst these two-year-old trees. But proceeding, the visitor would next see a large number of four-year-old trees, also upon the Paradise, and including such excellent varieties as Bismarck, Blenheim Orange Pippin, Wadhurst Pippin, Sandringham, King of Tomkins County, Hoary Morning, Rymer (not so good this season), Lamb Abbey Pearmaio, Baumann's Red Reinette, Barnack Beauty, and Schoolmaster. The two varieties last-mentioned are worth special attention; Barnack Beauty is a good grower, a free cropper, and a long keeper, the fruits are highly coloured, and it is less well known, or at any rate planted, than it deserves to be; Schoolmaster is a capital keeper right on into late spring, and it will succeed in certain districts in which Dumelow's Seedling gives considerable trouble, and is liable to canker.

It was the batch of three-year-old Apple-trees, however, that were the most remarkable for the extraordinary growth they have made in that time, and never have we seen better specimens. Such free-growing varieties as Ecklinville Seedling, Bramley's Seedling, and Blenheim Orange were the most conspicuous; and it was interesting to compare these with the slower-growing King of the Pippins, and the still slower Gladstones. Anyone unacquainted with the habits of the varieties would find it difficult to believe that they are all of the same age, and were, in fact, budded upon the same day. Lane's Prince Albert was again noticeable in the three years' old, and Newton Wonder, of which it is almost impossible to speak too highly. Trees of the last-named variety were well cropped with their fine solid fruits, and they make also a good sturdy growth.

Of newer or little known Apples, Royal Late Cooking is so far fulfilling the promises the variety gave several seasons ago, when it was recognised by the Fruit Committee of the Royal Horticultural Society. Messrs. Veitch believe that it will supersede Alfriston, itself a good Apple; but Royal Late Cooking, while resembling in some measure Alfriston, is a much better grower, and the large, fine fruits will keep in excellent condition until May. There are two good dessert Apples that have done well this season, and are less known than is desirable. Lord Burghley one of these is sometimes deficient in size, but they are not this season, and being a pretty and highly coloured fruit that keeps well until late spring, they will be valuable. Jonathan is another late dessert that can be given an unqualified recommendation, although a little weak in growth. In flavour, colour, and size, the fruits are perfect, and the tree is a good cropper. St. Edwin's Pippin, and King Harry are good dessert Apples also, and some fine fruits of these, as of many other excellent sorts, were shown us in a covered shed in the nursery. Most of the Apple-trees are trained for forming bushes and standards, but cordon trees are also kept for particular purposes.

In a border containing stock-trees of 310 varieties of Apples, the following were jotted down as being most fully cropped at the time:—Norfolk and Hereford Beefings, Beauty of Stoke, Beauty of Kent, Barnack Beauty, Blenheim Orange, Woodstock, Cornish Aromatic, Court Pendu Plat, Court of Wick, Dutch Mignonne, Farleigh Pippin, Fearn's Pippin, Gascoigne's Scarlet Seedling, Sandringham, and Sturmer Pippin.

PEARS AND PLUMS.

There is a fine collection of Pear-trees, and the remarks above upon the growth made by Apples this season are in most part applicable to Pears. Bush and pyramidal trees of various ages, from maidens up to six and even eight years old, and standards, were all looking well. In the case of Pears, however, there is a large demand for trained trees for walls, arches, trellis, &c., and for all these

purposes there are trees exactly suitable. The double and treble cordons are excellent systems of training, and are apparently becoming more popular than single cordons. Some two-year-old cordons, with growths 6 feet high, were admirable. Apart from the trees for sale there is a collection of stock trees of about 180 varieties, and looking over this collection, we took the following names of varieties that have fruited most freely this season, and the fruits still remained ungathered—Beurré Bachelier, Beurré Diel, Beurré de Rance, Comte de Lamy, Emile d'Heyst, Glout Morcean, Marie Guise, Napoleon, Nouveau Poiteau, Prince Consort, Alexandre Lambre, Zephirin Gregoire, and Forelle.

Of Plums, we saw some splendid standard trees, especially of the first-rate variety, Early Rivers—clean-stemmed, vigorous-growing trees, that should give most satisfactory returns when transplanted to other gardens or orchards. There is a fine lot of espalier-trained trees of Plums, and they have made very remarkable growths in the two and three years they have been budded.

PEACHES, CHERRIES, GOOSEBERRIES.

Of Peaches, the stock naturally consists of trees trained for planting against walls, fences, or trellises. Probably when the new nursery at Feltham is thoroughly established, the Peaches and other of the stone-fruits will be cultivated there.

Cherries succeed splendidly in the deep, stiff loam at Langley, and there are some magnificent trees of various shapes. The espaliers and the standards alike make clean, vigorous growth, indicative of the best possible health. Fan-trained trees, three years old, and twice trained, were magnificent.

Gooseberries are also done grandly. They are trained as cordons, cup-shaped, or gridiron, all of them good systems, and illustrations of which were given in *Gardeners' Chronicle*, July 31, 1897, p. 73. The two newest varieties in the collection are Langley Gage and Langley Beauty, both of which were raised on the place. An illustration of the latter was given in *Gardeners' Chronicle*, August 8, 1896, p. 155. They are both choice dessert fruits.

SOCIETIES.

ROYAL HORTICULTURAL.

OCTOBER 10.—The first meeting of the Committees of this Society after the great Fruit Show, was not a very large one. Not only was it held less than a fortnight after the Crystal Palace Show, but upon the same day the National Chrysanthemum Society opened its first exhibition for the present season in the Royal Aquarium, Westminster.

At the Drill Hall Show, the Orchid Committee recommended Awards to three novelties, and had before them a few collections of plants and blooms.

The Floral Committee awarded only two Awards of Merit and no First-class Certificate. The two Awards were to varieties of the perennial Aster, which were included in a magnificent exhibit of Michaelmas Daisies, from the gardens of F. A. BEVAN, Esq., Trent Park, Barnet. Messrs. JAS. VEITCH & SONS exhibited a group of Chrysanthemums in pots; and Mr. W. WELLS, Earlswood, made a capital exhibit of border varieties of Chrysanthemums.

The Fruit and Vegetable Committee recommended the award of a First-class Certificate to the new Apple raised by Mr. Ross, and that recently was given an Award of Merit. The Committee also recommended an Award of Merit to Pear Marguerite Marillat, a variety of fine quality that has been in commerce for some seasons.

There were several fine collections of fruits shown by amateurs, including first-class exhibits from ROGER LEIGHT, Esq., Maidstone; MARTIN R. SMITH, Esq., Hayes, Kent; and F. A. BEVAN, Esq., Trent Park, Barnet.

Floral Committee.

Present: Chas. E. Shea, Esq., Chairman, and Messrs. Owen Thomas, H. B. May, W. Howe, Jas. Hudson, Jno. Jennings, Thos. Peed, J. T. Bennett Poe, J. D. Pawle, E. H. Jenkins, Chas. Blick, Harry Turner, Chas. Jeffries, and W. Marshall.

CHRYSANTHEMUMS.

MESSRS. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, put up a group of Chrysanthemums in pots. There were such varieties as Louise, Soleil d'Octobre, Mutual Friend, Eastman Bell, Madame Gustave Henry, A. H. Fewkes, James Bidentope, Reginald Godfrey, a very valuable early-

blooming Japanese variety with dull red flowers. The group was edged with *Adiantum* Ferns, and was very good for the date of season.

Messrs. JAS. VEITCH & SONS, also showed cut blooms of their *Rhododendron Javanico* × *Jasminiflorum* hybrids, that seem to appear more attractive and bright as the days are less sunny. From the Coombe Nurseries of Messrs. VEITCH, an exhibit was made of sprays of hardy shrubs showing autumn tints (Silver Flora Medal).

Mr. W. WELLS, Earlswood Nurseries, Redhill, Surrey, contributed a magnificent display of *Chrysanthemums*. The bunches of flowers were exceedingly good, and they were staged tastefully, and with good effect. Two dozen or so trusses of each variety were stuck into globular balls of moss enclosed in wire, each truss thus forming a huge bouquet. Some of the more attractive of the varieties included were *Ambrose* Thomas, red; *Edmund Duval*, white; *Sam Barlow*, pink; *Coral Queen*, De la Guille, yellow and orange-yellow; *Jeannie Guillermot*, crimson; *Madame E. Lefort*, a magnificent yellow and reddish Pompon; *Mytchett Beauty*, yellow; *Fiberta*, small yellow Pompon; *Mrs. Hawkins*, yellow, &c. There were also some good blooms of large-flowering varieties, including *Rayonnante*, R. Hooper Pearson, Kathleen Rogers, &c. (Silver-gilt Banksian Medal).

HARDY FLOWERS.

Messrs. BARR & SONS, King Street, Covent Garden, London, made an exhibit of hardy flowers, the greater part of the display consisting of a collection of varieties of perennial Asters. There were nearly fifty varieties of these; a variety named *Mrs. J. F. Ryner*, had pretty rosy-purple flowers. The brightest flowers in the exhibit were several varieties of *Kniphofias*, and a number of varieties of border *Chrysanthemums* were included, as were sprays of *Physalis Francheti*. There were several small, well-flowered plants of *Caryopteris mastacanthus*, hardy *Cyclamens*, *Colchicums*, &c.

SHRUBS IN POTS.

"London Shrubs" was written on the label attached to a group of hardy evergreens to pots, shown by Messrs. J. PEED & SONS, Roupell Park Nurseries, Norwood, London, S.E. It included varieties of *Eucynimus*, tree and climbing *Ivies*, green and golden-leaved *Privets*, *Hollis*, evergreen Oaks, *Cedrus Deodara*, Portugal and Common Laurels, *Veronicas* *Hendersoni* and *Traversii*, *Buxus*, *Ceanothus dentatus*, *Aucuba japonica*, English Yew, *Berberis aquifolia*, *Yucca recurva*, &c. The specimens were good ones (Silver Banksian Medal).

ROSES.

Roses were shown by Messrs. PAUL & SONS, The Old Nurseries, Cheshunt, who had quite a nice display of varieties that linger in bloom to the last. There were *Madame A. Chateau*, *Paul Neron*, *Nanan Cochet*, *Madame P. Duher*, *Mrs. W. Grant*, *Viscountess Polkstone*, *Kaiserin A. Victoria*, *W. A. Richardson*, *Mrs. John Laing*, *La France*, *Caroline Testout*, *Victor Hugo*, &c. Some of the species of *Rosa* that produce ornamental berries were shown also (Silver Flora Medal).

MISCELLANEOUS EXHIBITS.

Two *Acalyphas* were shown by Mr. WELLS, Wingfield, Berks. One of these was named *Wellsiana*, the other *Novelty*. The former had large, ovate-acuminate leaves, variegated or mottled, of two shades of green and yellow. *Novelty* had smaller leaves, less regular in outline, harrier, and in appearance a good variety for withstanding the ill effects of cold and draughts.

Messrs. F. SANDER & CO., St. Albans, showed plants of *Dracena Sanderiana* variety *viride*, the leaves of which are intense green; and a few plants of the pretty little *Palm Calamus asperianus*. The *Dracena* has the same habit as *D. Sanderiana*, but the variegated form will probably be the more highly prized.

One of the most representative collections of perennial Asters ever staged in the Drill Hall was exhibited by F. A. BEVAN, Esq., Trent Park, Barnet (gr., Mr. W. H. Lees). There were nearly one hundred varieties staged, and each was represented by very fine bunches of flowers. The exhibit offered a splendid opportunity for visitors not familiar with the varieties to compare them one with the other, and to choose the best (Silver-gilt Flora Medal).

Mr. H. B. MAY, Dyson's Road Nurseries, Upper Edmonton, showed a group of plants, in which *Salvia splendens* was a conspicuous feature. There were also choice Ferns, *Bouvardias*, &c. (Silver Banksian Medal).

Messrs. W. CUTBUSH & SON, Highgate Nurseries, showed a group of plants, in which were fine specimens in flower of *Erica caffra*, *E. gracilis*, *Nerine Fothergilli majus*, a new variety of *Mahonia* named *Lady Ulrica*; and such foliage-plants as *Aralia elegantissima*, *Araucaria excelsa*, *A. compacta*, &c. (Silver Banksian Medal).

Miss ARMISTEAD, Daddon, Ross, showed sprays of a *Gypsophylla*, said to be a hybrid between *G. paniculata* and *G. elegans*, the former a perennial, the latter an annual species.

Awards.

Aster Amellus "Distinction."—A fine showy variety, with flowers about 2 inches across, violet or violet-purple in colour. From F. A. BEVAN, Esq., Trent Park, Barnet: gr., Mr. W. H. Lees (Award of Merit).

Aster N. B. Robert Parker var. *nanus*.—A valuable variety, as it is said to grow 2 feet high only. The flowers are of moderate size, and of a pale lilac-purple colour. From F. A. BEVAN, Esq. (Award of Merit).

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair), and Messrs. JAS. O'Brien (Hon. Sec.), T. B. Haywood, E. Hill, J. Jaques, J. Douglas, J. Colman, A. H. Smee, H. Little, H. J. Chapman, W. H. Young, and T. W. Bood.

J. BRADSHAW, Esq., The Grange, Southgate, was awarded a Silver Banksian Medal for a bright group, in which was a finely-grown plant of *Cattleya* × *Mantini nobilior* (*Bowringiana* ♀, *Dowiana aurea*), with two spikes each of seven richly-coloured flowers; *Cattleya* × *Maroni* (*velutina* × *aurea*), with flowers of a remarkable shade of yellow, with the front lobe of the lip effectively veined with crimson; a fine *Odontoglossum crispum guttatum*, and another good, unspotted form; a handsome dark-coloured *Cattleya labiata*, *Cynoches chlorochilon*, with three fine flowers, &c.

Messrs. HUGH LOW & CO., Enfield, showed a group composed of *Cymbidium Tracyanum*, *Cattleya* × *Mantini*, *C. Gaskelliana* alba, *C. labiata*, &c., there being in the centre a plant of the singular hybrid *Cypripedium* × *Olivia* (*niveum* × *tonsum*), together with plants of each of the parents in flower. The hybrid had well-formed flowers, somewhat resembling those of *C. × T. B. Haywood*, cream-white, tinged with pale rose.

W. THOMPSON, Esq., Walton Grange, Stone, Staffordshire (gr., Mr. W. Stevens), sent *Odontoglossum crispum Katea*, with strong spikes of rather narrow petalled white flowers, profusely spotted with purple; *O. crispum* Queen Empress, a grand flower of large size and fine substance, white, with a clear pink flush; and *O. c. Daphne* (see awards).

HENRY LITTLE, Esq., Baronshalt, Twickenham (gr., Mr. Howard), showed a fine inflorescence of the originally certificated *Cattleya* × *Mantini nobilior*, still the most brilliantly-coloured form of that hybrid. The sepals were bright amethyst crimson, the showy lip was of a dark ruby-purple with golden lines. With regard to this form, the problem is how the introduction of the yellow-petalled *C. aurea* could intensify and make darker the purplish-crimson colour to be expected from *C. Bowringiana*. Mr. LITTLE also showed *Cattleya granulosa* Little's variety, in which the purple-tinted blade of the lip bore a broad fimbriated white margin; also *Cattleya Dowiana aurea*, Little's variety.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, showed their new hybrid, *Cattleya* × *Minerva* (*Bowringiana* ♀, *Loddigesii* ♂). The plant had much of the habit of *C. Bowringiana*, the flowers in form more nearly resembling those of *C. Loddigesii*; sepals and petals dark, bright lilac-rose; lip with a bluish-purple veining in the centre, and a light yellow disk. Two plants were shown, the one much lighter in colour than the other.

FRED HARDY, Esq., Tyntesfield, Ashton-on-Mersey (gr., Mr. T. Stafford), showed a pan of three plants of the pretty *Sophro-Cattleya* × *George Hardy* (*Sophrontitis grandiflora* × *Cattleya Acklandiae*), all the plants varying in tint, the prevailing colour being reddish-scarlet. Mr. HARDY also showed *Laelia* × *Euterpe*, Tyntesfield variety, *L. Dayana* × *L. crispata*, with bright lilac sepals and petals, and rich, dark purple lip, with claret-coloured veining.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke), showed *Cattleya* × *Hardyana*, Crawshay's variety, a very distinct light form, in which the sepals and petals are cream-white, the petals faintly freckled with lavender colour. The showy lip was glowing crimson-purple, the base yellow, with red lines, the sides of the middle portion of the lip having each a fine blotch of bright yellow. Mr. CRAWSHAY also showed *Laelia pumila* Lionel Crawshay, a very large and richly-coloured form.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed the singular *Bulbophyllum grandiflorum* and *Saccolabium calceolare*.

Messrs. F. SANDER & CO., St. Albans, showed a small group of the pretty *Natal* terrestrial Orchid, *Stenoglottis longifolia*, each with five or six elegant spikes of pale rose flowers; also a plant of the singular *Bulbophyllum grandiflorum* with two flowers and a bud.

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, sent *Epidendrum Laucheanum*, the long raceme having numerous brownish flowers.

Awards.

Cattleya Dowiana aurea, Little's variety.—From HENRY LITTLE, Esq., Baronshalt, Twickenham (gr., Mr. Howard). A large and finely-formed flower with clear yellow sepals and petals, and very broad labellum of a rich, claret-purple colour, closely veined with orange almost to the margin (Award of Merit).

Odontoglossum crispum "Daphne."—From W. THOMPSON, Esq., Walton Grange, Stone (gr., Mr. W. Stevens). A very remarkable and distinct variety, in which the sepals are almost entirely tinted bright light purple, the tips and margin only being white, which contrasts curiously with the white petals, which only bear a few purple blotches; and the labellum, which has a large cinnamon-brown disc (Award of Merit).

Odontoglossum grande, Pitt's variety.—From H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood). A handsome variety, in which the brown colour usually seen in the species is suppressed, the sepals and petals being of two tints of yellow, the lip white, with two or three yellow blotches.

Spathoglottis Fortunei.—From the Royal Botanic Gardens, Glasnevin, Dublin. Several sprays of pretty yellow flowers were sent of this well known species (Botanical Certificate).

Fruit Committee.

Present: Philip Crowley, Esq., chairman; and Messrs. JAS. H. VEITCH, W. Poupard, A. H. Pearson, A. F. Barron, W. Wilks, J. Wright, Alex. Dean, S. Mortimer, J. W. Bates, Geo. Woodward, Geo. Wythes, C. Herrin, W. J. Empson, F. Q. Lane, Geo. Reynolds, Jas. Smith, Robt. Fife, J. Willard, Geo. Bunyard, H. Balderson, W. Pope, and Jas. Cheal.

Mr. Geo. Woodward, gr. to ROGER LEIGH, Esq., Barham Court, Maidstone, made a grand exhibit of Apples and Pears. Together there were upwards of 120 dishes. Kitchen and dessert varieties of Apples were equally good. The Pears were very fine; some of them unusually large. Of these the most remarkable were *Marguerite Marillat*, a newer Pear, of excellent quality, and of French origin; *Durondeau*, Gansell's Bergamot, Brockworth Park. *Beurre Superfin*, Fondante de Thirriott, Conference, Doyenné de Merode, Duchesse d'Angoulême, Pitmaison Duchesse, General Totleben, Emily d'Heyst, Bergamot d'Esperen, Prince Consort, &c. A Silver-gilt Knightian Medal was awarded this splendid collection of fruit.

A very fine exhibit of thirty-six dishes of Pears was made by MARTIN R. SMITH, Esq., Hayes, Kent (gr., Mr. C. Blick). The fruits were very fine in quality and size. Some of the more attractive being *Louise Bonne* of Jersey, *Souvenir du Congrès*, *Marguerite Marillat*, *Pitmaison Duchesse*, *Beurre Superfin*, Conference, *Buerre Brown*, Fondante d'Automne, *Parrot*, *Marie Louise d'Uccle*, *Magnate*, Conference, *Duchess d'Angoulême*, *Doyenne Boussuet*, &c. (Silver-gilt Banksian Medal).

Ten dishes of fine kitchen and dessert Apples were sent by J. KEY ALLEN, Esq., Bitterne Park, Southampton (Bronze Banksian Medal).

Another very admirable exhibit of hardy fruits, consisting of Apples and Pears in nearly eighty dishes, was shown by F. A. BEVAN, Esq., Trent Park, Barnet (gr., Mr. J. Lees). Dessert and culinary Apples as well as Pears were exceedingly good, especially for a district so near to London (Silver Knightian Medal).

A magnificent collection of Potato tubers was exhibited by Mr. R. W. GREEN, Wisbech. The collection included about fifty popular varieties, and all of them were exceedingly clean, bright-looking tubers, of a moderate size—indeed, perfect specimens for the table (Silver Knightian Medal).

Mr. O. THOMAS, gr. to HER MAJESTY, Royal Gardens, Frogmore, brought a fine lot of fruits and stems bearing fruits of *Tomato Epicure*, a smooth, moderate-sized fruit, very free in bearing, and the result of a cross between *Frogmore Selected* and *Suttons' Dessert*.

Eight fine fruits of a new Melon, named *Salmon Queen*, were shown by Mr. W. BESWICK, Walton-on-Thames. It is a handsomely netted fruit, with scarlet flesh, but the flavour was not sufficient to induce the committee to grant an Award.

Mr. W. J. EMERSON, Amptill House Gardens, Amptill, also showed a seedling Melon, named *Bounty* of Amptill, a white-fleshed variety. Both of these Melons and one from Mr. Wythes are to be shown again in the spring. There were three seedling Apples shown, but none of them gained Awards.

Awards.

Apple Chas. Ross (Thomas Andrew Knight).—This excellent Apple, raised by Mr. CHAS. ROSS, from a cross between *Cox's Orange Pippin* and *Peasgood's Nonsuch*, and figured and described in our issue for September 30, p. 253, was recommended a First-class Certificate. Since the fruits were shown and recommended an Award of Merit, it has been decided to alter the name of the variety from *Thos. Andrew Knight* to *Charles Ross*.

Pear Marguerite Marillat.—An excellent variety of French origin, and pretty generally known. It is very large, colour yellow and brown, flavour distinct.—From Mr. Geo. Woodward (Award of Merit).

Lecture by Mr. R. Newstead, F.E.S.

In the afternoon a lecture upon "Injurious Scale Insects of the British Isles" was delivered by Mr. R. NEWSTEAD, of the Grosvenor Museum, Chester, and one of the greatest authorities upon this subject. The lecture was illustrated with nearly eighty lantern-slides, and Mr. Newstead gave a few words of explanation upon a large number of species. The lecture will be a most valuable one when printed in the *Royal Horticultural Society's Journal*, but on Tuesday the limits of time prevented Mr. Newstead from reading one of the most practically useful portions of his paper, that upon "Insecticides and their Application." Sufficient was said, we hope, to induce those present to spare the natural enemies of these scale insects, among them being the common and Golden-crested Wren, the long tailed and other Tits. The chair was taken by R. McLachlan, Esq.

CRYPTOGAMIC SOCIETY OF SCOTLAND.

SEPTEMBER 26, 27, 28.—The twenty-fifth annual conference of this Society was held at Helensburgh on the above dates.

There was a good attendance of those who take the greatest interest in the Society's work; and the members had the pleasure of welcoming Dr. Plowright, President, and Mr. Carleton Rea, Secretary, of the British Mycological Society; Mrs. Rea accompanied the party. Excursions were made on the several days to Rosneath, the seat of the Marquis of Lorne; to Rosslyn, the property of Sir James Colquhoun; and to Buchanan Castle, the seat of the Duke of Montrose. The grounds and woods, and the beautiful scenery of the Gareloch and Loch Lomond, were generously thrown open to search.

At Roseneath, two magnificent specimens of Silver Fir "Adam and Eve," attracted special attention. "Adam," at 3 feet from the ground, measures 22 feet in circumference. Both are in perfect vigour of branch. Buchanan Castle boasts of the largest specimens of Abies Douglasii to be met with in Scotland. They have not been thinned with age, and are grand in their proportions.

At the business meeting, Mr. Carleton Rea was elected a corresponding member of the Society. Dr. Plowright is one of the original corresponding members. Dr. Plowright gave an interesting account of *Milesia polypodii*, B. White, which he considered identical with *Uredinopsis Scolopendri*, Rosl., and pointed out that Buchanan White's generic name, *Milesia*, had the priority of *Magnus medionipais*.

The weather was peculiarly favourable, three fine days having occurred between two storms of wind and rain. Owing, however, to the heat and drought of the summer, fungi were not so plentiful as could be desired. A few good things were met with: notably *Nancoria eriantha*, Fr., on Beech-sticks; *Torrulia capitata*, Tul., on *Elaphomyces granulatus*; *Hypocrea delicatula*, Tul.; *Geoglossum viride*, P.; *Agaricus algidus*, Fr., var. *atro-cornutus* on Willow; *Nidularia pisiformis*, Tul.; *Sphaeria mutabilis*, P.; and *Puccinia valeriana*, Carst., on *Valeriana officinalis*, which last is new to our flora. The curious *Chroolepus Arnottii*, Hook., of the English flora, was also found on the trunks of Yew-trees. The meeting was in every respect a most enjoyable one.

The next Annual Conference will take place at Rothiemurhus, or Bannoch, as may be arranged. We hope again to welcome our friends of the British Mycological Society, who will have an opportunity of investigating the flora of the native Pine-forests of Scotland. *J. S., Glomis.*

SCOTTISH HORTICULTURAL.

OCTOBER 3.—A crowded meeting was held in the Society's room 5, St. Andrew Square, Edinburgh. Mr. JAMES GRIEVE was in the chair, and ten new members were nominated. Several interesting exhibits of ripe fruits of the Logan-berry, and a fine sample of Emperor Alexander Apples, and what looked like a large Cox's Orange Pippin were made.

Mr. Todd showed a choice vaseful of the Mytchett White Chrysanthemum. Messrs. LAIRD had samples of Stirling Castle, a fine Red Tomato, and Golden Emperor, both grown in the open air at Eccles, Kelso. The red had ten fruits in the cluster. The same firm had half-a-dozen trusses of zonal Pelargoniums. Among these Oliver was one of the brightest scarlets; Dorothy Burroughs, a delicate pink; Barbara Hope, pink; Scarlet Cerise, and May Riffon, a lovely pink.

EARLY FLOWERING CHRYSANTHEMUMS.

Mr. M. MACKENZIE, of the Wattiston Nurseries, who was the lecturer for the evening, on "Early-flowering Chrysanthemums," exhibited a rich collection of some of the older and newer sorts in illustration of his subject. One great object of this informing Lecture was to show the great advance that has been made among early Chrysanthemums within the last thirty years. Floral decorators throughout the autumn and early winter, would be poor indeed now without early-flowering Chrysanthemums. And yet it is only about fifty-four years ago that Robert Fortune was sending the first of them in some form of Christmas Daisy; and the Japanese varieties followed in 1862, some thirty-seven years since. Some of the first were lost, but he managed to bring home seeds, and through these, and sports in profusion, we have got an infinite variety of form, size, and colour in our early and other Chrysanthemums.

One of the earliest notices of early-flowering Chrysanthemums was a list of thirteen varieties, given by Mr. Henry Taylor in the *Gardener's Magazine* in 1876. In Nov., 1851, Mr. Mackenzie said that he grew in the nursery various Chrysanthemums on a south wall, protected by mats. They were the small or Pompon varieties. Mr. Munro credits Mr. Wm. Handyside, of Musselburgh, with introducing the first set from France in 1868 or 1869, and presented a set soon afterwards to Mr. James McNoble, Curator of the Edinburgh Botanic Gardens. Mr. McNoble mentions receiving another set from Mr. Parker, of Tooting, about 1876. Of these early introduced varieties, *Précocité*, *Frederick Peel*, *White Queen*, *Little Bob*, and *Scarlet Gem* are still grown. Later followed Mr. Munro's collection, with, among others, *La Petite Marie*, *La Vierge*, *Blushing Bride*, *Mrs. Pitcher*, *W. Percy*, *Golden La Petite Marie*, *Madame Desgranges*, and its golden sports. These two sufficed to make the fortune of early Chrysanthemums. The following are some of the more notable varieties named by Mr. Mackenzie:—

Whites.—Mytchett, White Queen, Madame Carmeaux, La Petite Marie, Lady Fitzgibbon, the finest early white; Queen of Earlies, and La Vierge.

Pinks.—Gustave Grunerwald, Madame Cassinier Perier, Madame Alfred Normin, Elsie Wright, Strathmeath, Blushing Bride, Madame Marie Masson, and Francis Willemot.

Yellows.—Golden Shaw, Golden Fleece, Sbarra, George Vermig, Piercy's Seedling, Arthur Crepey, Mrs. Hawkins, one of the best of all the yellows; Canary, Madame Pouchet de Caril, Orange Child, Norbert Severs, and Golden Salmon, a great favourite.

Scarlet, Crimson, and Purple.—Little Bob, Frederick Pile, Crinsson Queen, one of the best of the time and colour; Nellie Brown, Roi des Précoces, Harriet Home, and General Hawkes.

Several other early Chrysanthemums were sent out last year, but most of them threaten to bloom in November rather than from September onwards, as we know these beautiful

and useful flowers. Among these are Mytchett Beauty, Doris Pell, Mrs. George Hill, &c.

In a society of practical gardeners, Mr. MacKenzie thought it useless to give details of propagation, culture, &c. He only added, in a sentence or two, that culture needed caution and care; avoiding all extremes of heat, water, and manure; not rushing the cuttings, but keeping them in a cool pit or house. Place them ten or twelve in a pot or pan, or place them in boxes near the glass. The plants may be grown out-of-doors, planted out in April or May, and potted-up in August or September in 5½, 6, or 7-inch pots, or glass sashes placed over them in September or October. By far the best mulch is moss-litter, as it holds the manure and moisture better and longer than farmyard manure, and cannot be easily blown off the surface. It is a good plan to lift batches from the open for blooming in succession indoors.

CARDIFF GARDENERS'.

PRESENTATION TO THE HONORARY SECRETARY.

OCTOBER 3.—The Session of 1899-1900 was opened by a meeting at the Temperance Club, St. John's Square, Cardiff, on the above date. There was a large attendance, and the Society promises this winter to enter upon a very successful season. The syllabus for the session just opened is before us, and the subjects arranged for discussion are practical, and directly associated with horticulture.

The President is Councillor S. A. Brain, and the list of Vice-Presidents includes the names of Alfred Thomas, Esq., M.P., Councillor J. M. Gerhold, J. Lynn Thomas, Esq., F.R.C.S., Councillor J. W. Courtis, Mr. A. Pettigrew (gr. to the Marquis of Bute), and W. W. Pettigrew (Superintendent of Parks, &c., Cardiff Corporation).

The CHAIRMAN called upon Mr. Graham to make a presentation to Mr. John Julian (the Hon. Sec. of the Association), of a beautiful silver-mounted Malacca-cane walking-stick, with a suitable inscription. In doing so, Mr. GRAHAM spoke in eulogistic terms of Mr. Julian's services to the Association as Hon. Secretary.

Subsequently Mr. T. COOMBER, gr. to Lord Llangatcock, read a paper on "Root-pruning of Fruit-trees," dealing with his subject in a pleasing style (1) the class of roots to prune; (2) how and when to perform the operation; (3) and the after-treatment, the class of soils best suitable for fruit-production.

A MIDDLESEX AGRICULTURAL FRUIT SHOW.

OCTOBER 6.—After receiving a note expressive of great expectations, we went to Ashford full of high anticipations, seeing something exceeding that which even a Crystal Palace fruit show could satisfy. Alas! for the faith thus displayed, for the consummation was indeed disappointing.

The show cut a sorry figure. Possibly it may have been thought good by the farmers and labourers that flocked to the field where the show was held, but gardeners and market growers smiled ironically. Happily we know, after what was seen at the Crystal Palace, that Middlesex can do far better things than was presented at Ashford. Could the metropolitan county do no better than was there seen, then would its fruit-growing reputation be in a poor case. Cannot the market-growers and gardeners of the county do something to rescue its reputation, so far as fruit production is concerned, from such very poor representations? We think if Middlesex did try, it might make a really great fruit-show, we will not say the grandest, as that is a term that only sanguine enthusiasts would employ.

The competitive classes for fruit, chiefly laid out on tables, included the following:—

Twelve dessert Apples, prizes two guineas and one guinea.—These should have brought strong competition, but only nine lots were staged, and really but six in competition, as some exhibitors entered two lots. Messrs. W. & S. PHILL, Harlington, were 1st, with a very large and handsome sample of Cox's Orange Pippin, the most meritorious dish in the show; Mr. C. NEWMAN, Harlington, was 2nd, with high-coloured, handsome Worcester Pearmain, though of less market value than the nice Cox's Orange that were Highly Commended from the same exhibitor. There were five lots of Cox's Orange Pippin staged, one King of the Pippins, one Ribston Pippin, and one of Hanwell Sourcing.

With twelve culinary Apples, Mr. E. P. NEWMAN was 1st, with Warner's King, fine, but some fruits much spotted; Mr. C. NEWMAN being 2nd with Ryner, very ripe, and light. Other varieties were Lady Henniker, Blenheim Orange Pippin, Lord Derby, Wellington, and Lane's Prince Albert.

Mr. E. P. NEWMAN had in a separate tent a very good show of Apples and Pears in slices, the best Pears being Louise Bonne, Pitmaston Duchess, and Uvedale's St. Germain; and of Apples, Prince Albert, Lord Derby, Gloria Mundi, Warner's King, and others; also, good Walnuts, Cob-nuts, and Filberts; Cox's Golden Drop and Belle de Septembre Plums, Tomatoes, Grapes, &c. Various ornamental Gourds were also very pretty and interesting.

Some Potatoes shown in classes were exceptionally large and dirty. It does seem, according to an admission freely made, that great laxity prevails as to how fruit for competition is obtained, and it was stated by an exhibitor that one fine lot of Kitchen Apples was purchased for him at the Crystal Palace. If that rule prevailed in one case, in how many others might it not also? Evidently exhibition morality is at these gatherings none too high; and the sooner the executive committee deal with such proceedings drastically, the better for fruit-culture under the Society's auspices.

NATIONAL CHRYSANTHEMUM.

OCTOBER 10, 11, 12.—The first show of the present season by the National Chrysanthemum Society was held in the Royal Aquarium, Westminster, on the above dates. It was by no means a record exhibition, nor equal to a few of the best that have been held in October previously; but the quality of the blooms, and the number staged, were equal to last year's show, which was an average display. The weakest classes were those for Pompons, which failed in almost every case. The Japanese varieties were strongest, and of these were excellent flowers in some of the exhibits. The displays made by members of the trade were a great advantage to the show.

There were excellent collections of vegetables staged in competition for prizes offered by Mr. H. DEVERILL. The heaviest bulb of Ailsa Craig Onion exhibited was 3 lb. 5 oz. and the heaviest dozen weighed 31½ lb.

GROUPS.

The space allowed for groups of Chrysanthemums, arranged for effect was 72 feet. The 1st prize was won by Mr. J. SPINK, Summit Road Nurseries, Walthamstow. All the Chrysanthemums in this exhibit had single stems only, and most of the blooms were very large. Some of the most effective were Madame Gustave Henry, Soleil d'Octobre, Annie Provost, Mrs. W. Seward, R. Hooper Pearson (the new yellow Japanese of last season), and others. There were not many foliage plants used, and these were of the highest character possible; the 2nd prize was won by Mr. Wm. Howe, gr. to Sir H. Tate, Bart., Park Hill, Streatham Common, London, S.W., whose exhibit differed very greatly from that already noticed, a more free use having been made of foliage plants. Some very pretty specimens of *Codiaeum* were included; the 3rd prize exhibit from Mr. E. Dove, gr. to H. E. Fry, Esq., Bickley Hall, Bickley, Kent, consisted of Chrysanthemums grown with single stems, and in its general features was somewhat after the manner of the 1st prize exhibit, but of less good quality; and it had not the imposing appearance of that to which the 2nd prize was awarded.

CUT BLOOMS (JAPANESE).

The 1st prize in the class for twenty-four blooms in eighteen varieties, was won by Mr. Jas. Brookes, gr. to W. T. NEWMAN, Esq., Totteridge Park, Totteridge, Herts. These were fine blooms, but the exhibit lacked colour, too many of the varieties being white or shades of yellow. Some of the more noticeable blooms were Pride of Malford, Mrs. Barks, Middle. L. Brossillon (soft-yellow Japanese), Mr. W. H. Lees, Reine d'Angleterre, Soleil d'Octobre, Lady Byron, Madame M. Ricard, Pride of Exmouth, E. Silsbury, and Werther. The 2nd prize was awarded to Mr. F. Fulford, gr. to F. D. LAMBERT, Esq., J.P., Moor Hall, Cookham, Berks. In this stand we noticed fine blooms of Dorothy Seward, Elthorne Beauty, Mrs. J. Lewis, and Mrs. G. W. Palmer. 3rd, Mr. W. J. Drevett, gr. to C. ARTHUR PEARSON, Esq., Frensham Place, Farnham, Surrey. The best exhibit in this class was one from Mr. M. Gleeson, gr. to A. Von ANDRÉ Esq., The Warren House, Stanmore, N.W., whose blooms were very much better in size, and especially in colour, than those of any other collection; but he had inadvertently included sixteen varieties only.

In the class for twelve Japanese blooms, distinct, there were four exhibits, and the 1st prize was awarded to Mr. M. GLEESON. His varieties were Mons. Chenon de Leche, Madame G. Bernard, Henry Weeks, Ella Curtis, Mutual Friend, Emily Towers, Australia, Elthorne Beauty (very fine in colour), Mrs. Weeks, Thos. Wilkins, Simplicity, and Joseph Brooks. The 2nd prize collection of blooms were smaller, and were shown by Mr. JAMES BROOKES. Pride of Malford was good in this exhibit, its colour being very characteristic; Mrs. J. Lewis, Pride of Exmouth, Mrs. Barks, and Soleil d'Octobre were noticeable. 3rd, Mr. C. Cox, Brickenden Grange, Hertford. There was one other exhibit, and this was awarded an extra prize.

The class for six blooms, distinct, brought nine exhibits, and the 1st prize was won by one from Mr. W. Meredith, gr. to GEORGE WILDER, Esq., Stanstead Park, Emsworth, Surrey. The varieties in this collection were Australia, Edith Tabor, Madame Philippe Revoire, Mrs. D. Dewar, J. Bideneope (this bloom had a weak centre), and Oceana. The 2nd place was taken by Mr. C. Payne, gr. to C. J. WHITTINGTON, Esq., Elm-hurst, Bickley Park, Kent. He had very fine blooms of M. Gustave Henry and Mrs. Coomber. 3rd, Mr. F. VALLIS, Bromham Fruit Farm, near Chippenham, Wilts, whose stand contained excellent blooms of the varieties A. H. Hall and R. Hooper Pearson. The difference in quality between either of these exhibits and that which obtained 1st prize was small.

The best collection of six blooms of any Japanese variety was one from Mr. R. Gladwell, gr. to S. SMITH, Esq., Werndee Hall, South Norwood, London. He had half a dozen excellent blooms of Australia. The 2nd prize was taken by the variety Madame Gustave Henry, shown by Mr. W. Paton, gr. to Mrs. HARMSWORTH, Poynter's Hall, Totteridge, Herts; and the 3rd prize to Phœbus, exhibited by Mr. A. Page, gr. to A. L. REYNOLDS, Esq., Ravenscroft, Moss Hall Grove, near Finchley. There were seven exhibits in the class.

INCURVED BLOOMS AND POMPONS.

The best collection of six blooms, incurved, was from Mr. R. Jones, gr. to C. A. SMITH-RYLAND, Esq., Bartold Hill, Warwick. The varieties staged were M. R. Bahuant, D. B. Crane, Globe d'Or, Ada Owen, and Lord Coleridge. Mr. Thos. Robinson, gr. to Mrs. LAYBENCE, Elsiefield House,

Hollingbourne, Kent, who had three very fine but undeveloped blooms of Duchess of Fife, 3rd.

There was one exhibit only in the class for twelve Pompons, but it was a very meritorious collection from Mr. T. L. Turk, gr. to T. BOVEY, Esq., Southwood House, Southwood Lane, Highgate, London, N., and the 1st prize was awarded to this.

AMATEURS.

The best collection of twelve Japanese blooms was one from Mr. R. Gladwell, gr. to S. SMITH, Esq., Wendee Hall, South Norwood. He had fine blooms of Louise, Werther, Suzie (a high-built flower, of pale lemon colour, as shown), Hairy Wonder, Phœbus, Australia, and Joseph Brooks. This exhibit was a very satisfactory one, coming as it did from an amateur. The 2nd prize was won by Mr. W. Perrin, gr. to C. W. RICHARDSON, Esq., Fairgreen House, Sawbridgeworth, Herts, who had also a very creditable collection; 3rd, Mr. A. Page, gr. to A. L. REYNOLDS, Esq., Ravenscroft, Moss Hall Grove, near Finchley.

The best collection of six blooms was also shown by Mr. GLADWELL; his varieties were Louise, Madame R. de Massy, M. Chenon de Leche, Werther, Oceana, and Emily Silsbury; all of them were of good quality. 2nd, Mr. W. PERRIN; and 3rd, T. L. TURK. There were five other exhibitors.

The best collection of twelve blooms of Japanese, in not fewer than six varieties (exhibitors in the above classes excluded) was from Mr. W. G. PAUDEN CLARK, York Road, Hitchin, Herts. The varieties Mutual Friend, Oceana, and Gustave Henry, were of good quality in the exhibit. 2nd, Mr. MARTIN SILSBURY, Providence, Shanklin, Isle of Wight.

VASES AND EPERGNES, ARRANGED WITH CHRYSANTHEMUM BLOOMS.

In an open class for two vases, each to contain twelve large flowering blooms, a 1st prize was won by Mr. Jas. Brookes, gr. to W. J. NEWMAN, Esq., Totteridge Park, Herts; and the class for a vase of Pompon blooms, arranged with suitable foliage, was won by Mr. T. L. TURK.

There were several pretty exhibits to a class for three epergnes or stands of Chrysanthemums suitable for table decoration, and the 1st prize was won by Mr. C. B. COLLE, The Vineyard, Feltham. A very pretty effect was produced by the use of small flowering varieties, and suitable drapery and relief in the way of Asparagus, Codium leaves, Physalis, &c.; 2nd, Miss W. GREEN, Florist, Harold Wood, Essex, whose flowers were yellow ones. Mr. D. B. CHANE, who won 1st prize in the class last year, on this occasion showed an exhibit of one epergne, and two low serpentine vessels, not more than 2 inches high. The exhibit showed exceptionally good arrangement of the flowers, but the novel means employed found no favour with the judges.

The best single vase of flowers was from Miss EASTERBROOK, The Briars, Fawkham, Kent; and Mr. E. H. CHITTY, gr. to S. HARRY, Esq., Cholmeley Lodge, Highgate, was 2nd.

NON-COMPETITIVE EXHIBITS.

Mr. W. J. GODFREY, Exmouth Nurseries, Devon, had a large exhibit of cut Chrysanthemums, including a number of novelties. Also plants in flower of a yellow sport from the early-flowering variety Lady Fitzwilliam, and plants and cut blooms of Ettie Mitchell, a chestnut or reddish-yellow decorative variety, raised at Exmouth, that promises to be a sterling market variety. A few blooms of winter-flowering Carnations were included also, and perennial Asters (Silver-gilt Medal).

Mr. H. J. JONES, Ryeoort Nursery, Hither Green, Lewisham, made a really fine exhibit of a group of Chrysanthemums in pots, and on either side of this were smaller groups of Codium and Cordylines. Most of the Chrysanthemums were grown with single stems, and carried fine blooms. But for an edging of Myrtlett White, and a few similar varieties, those in the group were whole large-flowering sorts, and included some of last season's novelties, such as May Mauser, a primrose-coloured flower, with much deeper centre; and R. Hooper Pearson, rich yellow Japanese, &c. The groups of Cordylines and Codium were composed of splendidly cultivated plants, and were set up with the most admirable taste (Gold Medal).

Mr. NORMAN DAVIS, Framfield Nurseries, Sussex, staged three blooms of a fine white Japanese, incurved, named Miss Alice Byron, raised by Mr. H. Weeks. The flowers are large, handsome, pure white, and the petals broad and of good length.

Messrs. DOBBIE & Co., Rothesay, N.B., and Orpington, Kent, were awarded a Silver-gilt Medal for an exhibit of cut blooms of border varieties of Chrysanthemums; also of single Dahlias.

Messrs. H. CANNELL & Sons, Swanley, Kent, staged a group of Canas in flower in pots of similar effect to that shown at the Crystal Palace. There were too many varieties of merit for us to indicate them, but specially bright and attractive were Souvenir d'Antoine Crozy, Queen Charlotte, Amie Pichou, Burbank, Madame La Baronne, P. Thierard, aurea, President Kruger, Doyen J. Liabaud, Sunset Glow, and Madame Perrin des Isles (Silver-gilt Medal).

Messrs. R. & G. CUTHBERT, Southgate, Middlesex, exhibited a group of plants of the decorative Chrysanthemum Mrs. Wingfield, a pink-flowered variety of much merit for cutting from.

Mr. H. DEVERILL, Banbury, exhibited cut blooms of perennial Asters and other hardy flowers; also some fine Onions, &c. (Small Silver Medal).

Mr. ERIC F. SUDN, Royal Berkshire Nursery, Maidenhead, made an exhibit of cut flowers of perennial Asters, early-flowering Chrysanthemums (Small Silver Medal); and Mr. S. MORTIMER, Rowledge Nurseries, Farnham, made a most attractive exhibit of Dahlias, including Cactus, show, and decorative varieties, that were as bright as any exhibit in the building (Silver-gilt Medal).

Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, showed a group of cut flowers, composed of Dahlias and perennial Asters (Silver Medal).

Messrs. JNO. LAING & Sons, Forest Hill Nurseries, London, S.E., had much the finest exhibit of fruit, and were awarded a Gold Medal. In the centre was a raised trophy, set with very fine fruits, and which gave a distinct effect to the exhibit. The quality of the fruits throughout, no less than the artistic taste in which they were displayed, was worthy great praise. Messrs. LAING had also an exhibit of Box and Yew trees trained to various imitative shapes.

Messrs. S. SPOONER & Sons, Hounslow Nurseries, were awarded a Silver-gilt Medal for a collection of hardy fruits; and another similar exhibit was made by Mr. W. J. Prewett, gr. to C. ARTHUR PEARSON, Frensham Place, Farnham (Silver Medal).

Messrs. CUTBUSH & Sons, Highgate, London, N., also showed a fine exhibit of fruit upon a table (Silver-gilt Medal).

Mr. W. T. WILLIAMSON, 24, Bury Street, Lancashire Hill, Stockport, exhibited another method for adjusting the height of the cups in exhibition stands for Chrysanthemums. The cup is fixed upon a wire which is placed in a socket containing a screw, which will fix the cup at any desired height (Commended).

MR. H. DEVERILL'S PRIZES FOR VEGETABLES.

The class for a collection of eight kinds of vegetables was won by a grand exhibit from Mr. Ed. Beckett, gr. to Lord ALDENHAM, Aldenham House, Elstree, showing produce of similar quality to that which gained a Gold Medal at a recent meeting of the Royal Horticultural Society. Mr. R. Lye, gr. to Mrs. KINGSMILL, Sydmonton Court, Newbury, was 2nd; and Mr. W. Pope, gr. to the Earl of CARNARVON, Highclere Castle, Newbury, 3rd.

The six largest and handsomest specimens of Onion The Aristocrat were from Mr. Jno. Masterton, gr. to Earl CAMPERDOWN, Weston House, Shipston-on Stour.

Mr. J. BOWERMAN, Hackwood Park gardens, Basingstoke, had the best collection of twelve, and six specimens of Onions, Ailsa Craig or Cocoa-nut, showing in each instance magnificent specimens of Ailsa Craig.

Oxonian Leeks, in a class for six specimens, were seen best from Mr. J. BOWERMAN; and Mr. J. LYE had the best twelve specimens of Mid-Ilton Park Favourite Beet.

Splendid Parsnips were shown by Mr. BECKETT, who won 1st prize in a class for twelve specimens of Improved Hollow Crown. The same exhibitor won the best among five in a class for Aylesbury Prize Red Celery, and in another class for twelve fruits of Glenhurst Favourite Tomato.

TRADE NOTE.

J. C. WHEELER & SON, LIMITED.

A COMPANY has been registered, with a capital of £20,000, in £10 shares, to acquire and carry on the well-known business of J. C. Wheeler & Son, nurserymen, seedsmen, and seed-growers, of Northgate Street, New Inn Lane, Worcester Street, and Kingsholm Nurseries, Gloucester. It may be remembered that the sole surviving partner of the firm (Alderman J. C. Wheeler) died in January of this year. The first directors (to number not less than five, nor more than seven) are: T. Nelson Foster, G. Peters, T. Blinkhorn, G. N. Walker, J. H. Jones, and S. Gibbins, all of Gloucester. The directors' qualification is fixed at £500, and the remuneration at £250 per annum. The registered office is 99, Northgate Street, Gloucester.

Obituary.

DR. A. WALLACE.—The news of the death of Dr. Alexander Wallace, which occurred at his residence, St. John's Terrace, Colchester, on Sunday afternoon, Oct. 7, will be read with regret by many of our readers. The deceased gentleman, who was seventy years of age, has been ailing since the spring, and in July he went to Harrogate for a change, but returned worse, and was attacked by jaundice. Dr. Wallace was born in Guildford Street, Russell Square, London, his father being a barrister. He was educated at Winchester and Trinity College, Oxford, where he graduated M.A. The deceased came to Colchester, where he has practised successfully ever since as a consulting-physician. For some twenty years he did splendid work as an unalarmed physician to the Essex and Colchester Hospital. To horticulturists, Dr. Wallace will be best known for his extensive collection of Lilies, Calochorti, and Brodiaeas, which were cultivated at the Kilnfield

gardens, Colchester. The firm of Wallace & Co. imported numerous novelties of these genera from Japan, Colorado, California, and other countries. The deceased gentleman was for many years an ardent entomologist, and made silkworm culture on a large scale his hobby. He wrote several prize essays upon this theme. His knowledge of botany was also extensive, and he wrote and published a work *Notes on Lilies and their Culture*. Dr. Wallace leaves a widow, one daughter, and six sons.

MARKETS.

COVENT GARDEN, OCTOBER 12.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

POTATOS.

Hebrons, Puritans, Main Crop, Up-to-Date, &c., 60s. to 80s.; John Bath, 32 & 34, Wellington Street.

REMARKS.—The season for Beans and Vegetable-Marrows is now practically at an end. French Beans from the Channel Islands have commenced to arrive; also Tomatos from the Canaries. The Apple trade is slow, except in the case of fine samples of good fruit. Blackberries also are slow trade at the price quoted above.

THE WEATHER.

The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

- 0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

ANSWERS TO CORRESPONDENTS.

A MODEL GARDEN: *H. H. M.* Thin wood supports and cardboard would do for the ground, picked moss or fine wood-wool dyed green for the grass plots, sand or fine gravel sprinkled over thin cement "slip" for the walks, and trees and shrubs according to taste.

APPLE DISEASED: *T. S.* The Apple is attacked by the "Brown Fruit-rot (*Monilia fructigenum*), the spores being found in the freshly opened core and at the tip end. This disease attacks the flowers, thus finding its way into the fruit. Another case was reported on to the Royal Horticultural Society's Scientific Committee recently (see *Gardeners' Chronicle*, August 5, 1899). No remedy has yet been sufficiently tested, but we might suggest the treatment given in this column for a somewhat similar disease on September 30. Begin by washing down the tree or trees during winter with the copper sulphate solution, then spray with Bordeaux Mixture as directed.

APPLE TREES IN HEDGEROWS: *H.* When trees are planted at the same time as the hedge, it is an easy matter to make special provisions for the trees, so that they may have a good start. In old hedges, it is better to prepare 3 feet square holes a little distance from the hedge, and fill these with good soil made quite firm; and means must be taken to cut off yearly the roots of the hedge plants that are sure to find their way into the good soil. The trees would require annual top-dressings of dung, and a little slaked lime and potash; these last two not together, but in different years.

BOOKS: *H. B.* *My Gardener*, by H. W. Ward (Eyre and Spottiswoode, East Harding Street, London, E.C.).

CUTTING BACK MODERATELY THE SUMMER SHOOTS OF H.P. and Tea Roses: *V. R.* The practice is not harmful if only the very strongest shoots are slightly pruned, and all weak and flowerless shoots taken from the inner parts of the head.

FRENCH MARIGOLDS: *F. M.* The varieties are not new, but they are very pretty, and being dwarf of stature would be capital plants for forming edgings to, and filling beds in the garden.

GALLS ON OAK LEAVES: *W. B.* Oak spangles.

GRAPES RUSTED: *F. J.* We cannot say from which of the well-known causes of rust in Grapes your berries have been injured, but it is not from syringing them with water containing charcoal. Cold draughts, especially if the berries are damp at the time, will "rust" the berries; or rough handling of the bunches in spring when thinning is done. In any case, the berries are directly affected, and the injury is not, as you suggest, a symptom of any root trouble, or unsuitable border.

GRASS: *Phytophilit.* We cannot indicate the species without the awn being sent us; but you may extirpate the plants by manual dressings, and the sowing of the finer lawn-grasses and clovers along with loamy soil; these will in time smother the weeds.

GREEN TOMATOS: *Dictamnus.* The fruits will not ripen; but they would make a sort of marmalade.

GROWING AND EXHIBITING VEGETABLES: *S.* The gardener you name has written a book on the subj. et. It is published by Simpkin, Marshall, Hamilton, Kent & Co., Ltd., London.

LILY ROOTS DESTROYED: *F. Smith.* Before deciding, we should like to inspect some bulbs of the Lily, also roots of Cabbage, Carrot, &c. It may be that what you have seen with the naked eye are centipedes (*Julus*), which feed on decaying tissues of plants, &c.

NAMES OF FRUITS: We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. They should be just approaching ripeness, and they should be properly numbered, and carefully packed. A leaf or shoot of each variety is helpful, and in the case of Plums, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.

T., Birmingham. Apple Tower of Glamis.—*Danetree.* Pear, Souvenir du Congrès; Apple, Rambour Franc.—*D. S., Cork.* 1, Duchesse de Bordeaux; 2, Beurré Hardy.—*J. J. & Co.* Nineteen varieties of fruit in one consignment is considerably in excess of our regulations. As you have taken some care in packing, and the fruit is sound, we will endeavour to oblige you by naming a few at a time. 1, Bergamotte d'Automne; 2, Durondeau; 3, Fondante d'Au-

tomne; 4, Seckle; 7, Louise Bonne of Jersey. *Belmont.* If the miniature fruits received from you are fair samples of the varieties, they are not worth a place in a garden.—*Yorkshireman.* We should like to see the foliage from the branches which bore the two fruits sent. Variation in the form of fruits from the same tree is frequent, but it is unusual that one should be ripe more than a month in advance of the other. It often happens that buds are inserted in established Pears to fill vacancies caused by the loss of branches, especially in trained trees. What form is the tree?—*J. McL.* 4, Durondeau; 17, Délices de Froyennes; 19, Royale d'Hiver; 36, Aston Town; 40, Fondante Van Mons; 41, Beurré Benoit.—*C. B.* 1, Bergamotte Reine; 2, Comte de Lamy; 3, Nouvelle Fulvie; 5, Williams' Bon Chrétien.—6, an imperfect specimen, not recognisable; 7, Bergamotte Bufo.—*S. A.* 1, Brown Beurré; 2, Duc d'Aumale; 3, Beurré Bronze; 4, Doyenné Gris; 5, Althorp Crassane.—*G. E. P.* 1, Loddington; 2, Kentish Pippin; 3, Glory of England; 4, Tom Putt; 5, Royal Russet; 6, Adams' Pearmain.—*W. T. Rolyer.* Winter Greening.—*W. M. B.* Glory of England.—*K.* Flemish Beauty; known also to French pomologists as Fondante des Bois; and it has at least twenty other names.—*Amateur.* Mank's Codlin.—*Constant Reader.* Your Apple resembles Green Tiffing, which is much grown in the North of England.—*J. F. S.* Winter Greening.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—*E. S. S.* Panicum capillare.—*T. G.* Phytolacca decandra.—*G. C. W.* Solanum rostratum.—*A. T. C. J.* Immature barreau fronds of 1, Lastrea dilatata; 2, may be a very young frond of Lastrea filix-mas; 3, Polypodium dryopteris (Oak Fern), all British.—*D. S., Co. Cork.* Muehlenbeckia complexa, a pretty rock plant for outdoors, and a graceful basket-plant for the conservatory.—*Willow.* Epilobium hirsutum, common Willow-herb.—*J. J.* 1, Ophiopogon Jaburan variegatum; 2, Cyrtanthus Mackenii.—*S. J. A.* The Tasmanian climber will require greenhouse treatment. We cannot say what it is without seeing a flower.—*J. R. P. & Sons.* Acer dasycarpum var. laciniatum.—*H.* Quercus sessiliflora var. cochleata.—*T. W.* Orchid Zygopetalum Mackayii. Conifers next week.

SIX VERY LARGE DESSERT GOOSEBERRIES: *Clara Elliott.* Broom Girl and California (yellow), Companion and Crown Bob (red), General Markham and Green Overall (green).

VIOLETS DISEASED: *Enquirer.* Your plants are affected by a fungus, *Æcidium depauperans* (see fig. and description in *Gardeners' Chronicle* for September 16, 1876). Apply, at intervals of two to three weeks, a wash of $\frac{1}{2}$ oz. of sulphate of potash in 1 gallon of water.

VINES: *T. K.* The proper course would have been to cut back the Vines the year of planting down to the wall-plate, or, say, 2 to 3 from the ground, letting them then run up to the top of the house. The next year to cut them at 5 or 6 feet higher up the roof, and the following 2 to 3 feet more, and so on. It is only in the third year that they may be allowed to carry half a dozen bunches, and the next year ten bunches. We imagine you have let the Vines crop too early and too heavily.

VINE-BORDER SOIL: *J. F. D.* The soil sent is inert, compacted, and generally unfit to sustain the Vines. What few roots were found in it were dead. Clear it out, make a new border, and plant new Vines.

COMMUNICATIONS RECEIVED.—*J. G., Liverpool.*—*H. W. E.*—*D. Roberts.*—*H. W. W.*—*E. Newman.*—*W. Hurlstone.*—*T. Coomber.*—*T. P. Fawcett.*—*C. J. Stewart.*—*London.* County Council.—*J. THE

Gardeners' Chronicle

No. 669.—SATURDAY, OCT. 21, 1899.

IMBER COURT, THAMES DITTON.

OF the numerous historical houses that cluster round London, and are so fast being absorbed by the ever-extending suburbs of our great city, few can claim a longer descent than Imber Court. Its records go back to a remote antiquity—to a time, indeed, when the advent of William the Conqueror was still a current topic, and when our ancestors were not much more civilised than the Zulus of to-day. A thousand years ago it got its name when the River Mole on which it stands was still called by its celtic appellation Y-Mylin. It was known as Imleworth then, and so difficult did the "Doomsday" clerks find its pronunciation, that the nearest they could get to spelling it was "Limeurde." In the twelfth century the name had been shortened to Imworth, and its dignity increased to that of a manor. For generations it belonged to a family of De Imworths or De Immewerthes, as they preferred to call themselves. They had died out by Edward the First's time, and it came to the D'Aguilars, and so through the great land-owning family of De Braose to the Duke of Norfolk, the leader of the Opposition in Wolsey's time. When the Cardinal fell, and Henry the Eighth seized Hampton Court, the Duke let him have Imber by exchange to add to the chase of Hampton, and it remained royal property till Charles the First's time. Henry the Eighth leased it to the Sir John Dudley afterwards Duke of Northumberland, who lost his head over the Lady Jane Grey affair. Charles the First granted it to Sir Dudley Carleton, the famous diplomatist of the time of the Thirty Years' War, together with the other manors of the Hundred of Emley Bridge that had always gone with it. The house was then a rambling Tudor mansion, much out of repair. Indeed, the Hall was so dilapidated, that Sir Dudley resolved to pull it down, and, like the man of taste and fashion that he was, he got "Mr. Jones," as he calls the renowned Sir Inigo, to design him a little palace in the new Italian style to replace it. This Sir Dudley was so much the foreigner, that nothing purely English was good enough for him, and his un-English ways were for a long time a bar to his becoming Secretary of State. Thus it is that the present house looks so much more modern than it is. For the style, though common enough in Italy where Sir Dudley had served most of his time, was not general in England till the reign of Queen Anne. When Sir Dudley's abilities finally forced him into the ministry, he took his title from his new acquisition, and became Baron Carleton of Imber Court, and afterwards Viscount Dorchester; for by this time the name had again changed. In the dialect of the people, Imwerth naturally became "Immer," and this the pedantic fashion of the day clothed with a classical dress as Imber, and so it continued till, in the eighteenth century, it became corrupted into Ember. Carleton, besides his designs for the

house, greatly improved the grounds, and two grand old Lime trees still exist of an avenue he planted with saplings brought from the Hague. Thus beautified, it became a favourite resort of Charles the First when he had fallen so deeply in love with his wife, that they could hardly get him to attend to State affairs; and once at least we know (from the 12th volume of the *Historical Manuscripts Commission*) that the Council could not sit because "the King and Queen went to Imber Court, as soon as they had dined, to a banquet and entertainment prepared for them by my lord of Dorchester." The Civil War was close at hand then, and it is certain that some of the last happy hours Charles and Henriette Marie ever knew were spent at Imber Court.

Lord Dorchester died before the war broke out, and never lived to see his fine new house completed: but it was finished in 1638 by his nephew and heir, the second Sir Dudley Carleton, clerk to the Council. But he could not live there long. He had, like many other cavaliers, to compound for his estates, and was forced to sell the place to find the money. Merchants and "nabobs" now took the place of the old courtiers, till it came into the hands of Arthur Onslow, the great Speaker of the House of Commons, by his marriage with Anne, daughter and co-heir of John Bridges, Esq., of Thames Ditton, and niece of Henry Bridges, Esq., of Imber Court. For the thirty years he held the office he lived at Imber, and once more it became one of the most fashionable houses round London. Politics, art, letters—all flocked there, and there is hardly a name in that great time that is not connected with it; and most interesting of all, perhaps that of Samuel Richardson, the novelist. When Onslow was raised to the peerage, he became Baron Onslow, of Imber Court, and Viscount Cranley. He died in February, 1768. His son, Lord Cranley, sold the manor in 1784 to a Mr. George Porter, who shortly afterwards sold it to Sir Francis Ford, the first baronet, a Member of Council in Barbados, and an M.P. of the British Parliament. Its next owner was a Mr. Robert Taylor, on whose death it devolved on Sir Charles Sullivan, Admiral of the Blue, in right of his wife, the only daughter of Mr. Taylor. Whilst it was the property of the Sullivan family, it was for a few years the residence of Sir Francis Burdett, the stormy petrel of politics in the earlier part of this century. He did much to revive the social glories of the place, and died in 1844. Frederick Cornwallis, Archbishop of Canterbury, and the Duc d'Aumale, also resided at Imber Court. Slowly but surely the flourishing suburbs that surround the place have gradually shouldered it out of its old dignified and isolated position. In 1862, the property was purchased by the late Mr. Charles J. Corbett (who died in 1882), and in consequence of the death some time ago of his widow, the place has again changed hands, having been sold by Messrs. Farebrother, Ellis & Co., in July last, whilst the entire contents of the mansion were dispersed under the hammer by Messrs. Phillips as recently as September 18-20, of this year.

The gardens and shrubberies have been well cared for during the last few years, and the mansion is well sheltered by some magnificent trees, notably a splendid specimen tree of black Mulberry (*Morus nigra*), probably one of the finest to be found in the vicinity of London; *Taxus aurea variegata*, *Sequoia gigantea*, *Abies cephalonica*, *Cedrus Libani*, *Quercus Cerris*, *Cupressus Lawsoniana*, a noble specimen of the Plane (*Platanus orientalis*), Horse-chestnut, and others which thrive with native luxuriance and vigour. The south side of the house is shaded by a fine example of *Magnolia grandiflora*, and by *Periploca græca*. All the trees have Smith's conspicuous metal labels attached, although some of these seem to have got misplaced—for instance, the label of *Thuia Vervæiana* is attached to a beautiful specimen of the common Hawthorn!

What, it may be asked, is to be the future of this fine old place? There can be but little hope that it will much longer exist as the quiet Tusculum it has been for so many centuries. Yet still, with its wandering river, its giant trees, its fishponds, and its level setting of meadows where the plover still whistles, and the snipe's cry is heard, there is no spot, perhaps, which has so peacefully resisted the restless growth of the capital, or where a jaded man within but 14 miles of Hyde Park Corner can so easily forget that such a place as London exists. But the jerry-builder, who has done so much to make the London suburbs hideous, seems to have Imber Court almost within his remorseless grasp, and its ancient history will pass into tradition; even its actual site may become a fruitful source of quarrels with the antiquaries at the end of the next century. *Sic transit gloria mundi!* W. Roberts.

ORCHID NOTES AND GLEANINGS.

CATTELEYA × HARDYANA VAR.

ONE of the enchantments which natural hybrid Orchids—which often get imported together with species—have for Orchid amateurs, is the great variation found in varieties of the same kind. *Cattleya* × *Hardyana* has been one of the most productive, all the forms being beautiful and fragrant, and scarcely two of them can be found that are exactly alike.

In the collection of the Rt. Hon. Lord Rothschild at Tring Park, *Cattleya aurea* and *C. × Hardyana* are special favourites, and many fine varieties have flowered there, including the extraordinary *C. Dowiana aureo-marmorata*, which has a true *C. Dowiana* lip with a conspicuous rose-purple marbling on the sepals and petals. Among others, a very distinct form of *C. × Hardyana* is now in flower at Tring Park, obtained among some plants of Messrs. Charlesworth & Co.'s importation of *C. aurea*. The plant is bearing two spikes, each with three finely-formed flowers. Its most striking feature is a much brighter tint than that possessed by other forms; the marking of its lip resembles very nearly the handsome *C. × Hardyana* *Luciani*, figured in the *Lindley*, x., p. 37, though the sepals and petals are even lighter than in that variety, being white with a faint lavender flush and delicate veining of very pale rose colour. The broad wavy-edged lip is bright-yellow, fading to white towards the blotches on each side; the centre streaked with purple; the front lobe rose-purple with lilac margins. There is an indescribably attractive marking of pure rose-colour on the outsides and margins of the side lobes.

BULB-PLANTING ON TURF.

I AM induced by Mr. Bulley's remarks on this subject to pen the following notes. It may be premised that many desirable bulbous and tuberous plants succeed when planted on the turf provided the soil is in a condition to promote and support a vigorous growth. In poor or sandy soils, where the grass makes poor growth, it is doubtful if any species of bulbs, &c., other than the commoner *Crocus*, *Galanthus*, *Chionodoxas*, and *Scillas*, will grow satisfactorily for any length of time. If it is desired to plant under such conditions, the soil must be improved, which may be done in the following manner: Strip off the good turf and loosen the soil, digging it deeply with a fork, mixing kitchen-garden soil and cow-manure with the staple; some soot would also be beneficial. When the soil has been dug over, it should be made moderately firm by trampling it; afterwards, proceed to plant the bulbs, corms, and tubers just below the surface, and lay the turf on the top of them. Where the turf is much worn, it would be found better in the long run to dig it in, and sow the plot with lawn-grasses. Soil that is in good condition will only require to be loosened with a fork beneath the grass, without breaking up the surface, the bulbs being planted whilst the ground is still loose by

means of a dibber, and the holes filled in with some light kind of soil, a roller being passed over the plot at the finish.

BULBS AND TUBERS SUITABLE FOR LAWNS.

Generally speaking, all the *Anemones* to be afterwards mentioned require to be established in boxes

light fibrous material before planting out, the tubers being somewhat difficult to start, even under favourable conditions. They would enjoy the addition of leaf-soil. *Anemones nemorosa*, *A. n. Robinsoniana*, *A. sylvestris*, and *A. blanda*, grow well in grass without much trouble. *A. apennina*,

Cypella Herberti, an Iridaceous plant, with orange-yellow, fugacious flowers, and *Herbertia pulchella*, a similar plant, with satiny, dark blue flowers, will thrive during the summer in grass; but the slender, much branched, almost leafless stems are poor foils to the beautifully-formed flowers. I have counted fifty-six flowers borne consecutively on one tiny plant of *Herbertia* this year. The bulbs of both plants should be lifted on the approach of winter, and stored in sand in a frost-free place.

Zephyranthes candida, with white, *Crocus* like flowers on stems a foot high, succeeds in sheltered situations; it grows well in dry or moist soils, pre-

I have not seen it grown thus. *Triteleia uniflora*, *Allium roseum* and *A. Schœnoprasum* (Chives), make effective displays of white, rose, and blue flowers. These plants increase at a rapid rate, and will withstand any rough kind of treatment. All are readily raised from seeds. *Leucojum vernum* is already largely planted in grass, and is most effective. *L. æstivum* should also do well if freed from coarse grass. It flowers in the summer.

Recesses between specimen shrubs and odd corners of lawns are excellent places for *Tulipa macrospeila*, *T. Didieri*, *T. suaveolens*, *T. retroflexa*, and *T. sylvestris*. *Tulip Proserpine* and

FIG. 102.—RHODODENDRON KINGIANUM: COLOUR DEEP CRIMSON.

and its varieties would also grow well if the leaves were freed from grass. *Fritillarias pyrenaica*, *armena*, *pallidiflora*, *Meleagris*, and its varieties will also thrive. *Galanthus Elwesii*, *robustus*, and the smaller *byzantinus* are also suitable plants; they are, however, much more expensive than *G. nivalis* and its double form, which are indispensable. *Gladiolus nanus* is rarely, if ever, seen planted in grass; yet, it is of surprising hardihood, and cheap enough for extensive planting. It likes a sunny place, and should be planted in September, choosing a site with a dry subsoil. There are many beautifully-coloured varieties, rivalling the *Orchids* in the delicate tints of colour and effective form.

ferring the latter. *Z. Andersoni*, and *Z. gracilifolia*, small, bulbous plants from Uruguay, are quite hardy, and grow better in grass than anywhere else. The former has copper-coloured flowers, and the latter rose-tinted, tubular ones. Moist places would suit *Orchis maculata* and *O. foliosa*, *O. mascula*, &c.; whilst drier places, with the addition of a little chalk, would suit *Ophrys apifera*.

Agapanthus umbellatus minus and *A. Mooreanus*, in white, lilac, and blue colours, are extremely enduring plants, quite hardy in Britain, and thriving where few others will grow.

Camassias Cusicki and *esculenta* are suitable for occasional planting; *C. Leichtlini* may also do, but

several other florists' types are of considerable hardihood, and will last for years if left undisturbed. *Colchicum autumnale* is another useful plant for such places; and *Iris histrio*, *I. reticulata*, and var. *histrioides*, will all grow well on a sunny bank. *G. B. Mallett, Islworth.*

(To be continued.)

RHODODENDRON KINGIANUM.

This is one of several new species of *Rhododendron* which were found on the high mountains of Manipur by Dr. Geo. Watt whilst on a collecting expedition in that region in 1882. He sent seeds of it to the Royal Gardens, Kew, from which a plant

was raised (fig. 102), which flowered for the first time in the Himalayan-house in May this year, where it is planted out along with numerous other species of Himalayan Rhododendrons. It has grown slowly, compared with its nearest ally, *R. arboreum*, its height being only some 6 feet, and its branches are thick and woody. The leaves are crowded, remarkable in being somewhat bullate, with recurved margins, and of a dark green colour. The flower-head and characters of the flowers closely resemble those of *R. arboreum*, whilst in colour they are a rich blood-crimson. The plant was named by Dr. Watt in honour of Sir George King, late Superintendent of the Royal Botanic Gardens, Calcutta. A figure and description of it by Sir Joseph Hooker will shortly appear in the *Botanical Magazine*. W. W.

VEITCH'S CLIMBING FRENCH BEAN.

Each year since this Bean, known also as "Tender-and-True," was put into commerce by Messrs. Robert Veitch & Son, Exeter, it has increased the good opinion which growers formed of it. It follows admirably for winter cropping, the autumn crop of Tomatoes. When the Tomato plants are removed, if the soil is considered to be exhausted, some short manure should be incorporated with it, and the whole made fairly firm with the fork in the process of digging. This done, make holes about 3 inches deep with a dibber in the exact spots previously occupied by the Tomato plants, deposit one bean in each, and fill up with soil. Place a small stick about 10 or 12 inches high close to each bean, and to these secure the Tomato strings (still suspended from the

utilised for growing Mushrooms during the four or five months following without in any way interfering with the welfare of the Vines. Houses from which Tomatoes and Cucumbers have been cleared in October or November may also be turned to good account in this way. All that is necessary is to obtain the desired quantity of peat-manure—that is, manure consisting of peat and horse-droppings, mainly of the latter. This should be turned over a couple of times before being taken indoors, in order to let the rank heat or steam escape therefrom before forming it into beds in the houses. Two truck-loads of manure (about 12 tons) will be sufficient to form a flat bed, about 5½ feet wide, on either side of the central pathway the entire length of a house 150 feet long and 15 feet wide. The manure should be turned over once or twice (according to its condition) after it is taken indoors, and before it is formed into beds of a uniform depth. When the heat in the beds has declined to about 75°, spawning may be done. Each brick of spawn having been broken into seven or eight pieces, these should be inserted barely under the surface, at about 9 inches apart all over the beds. The latter should then be soiled over to the thickness of about 1 inch when beaten down with the back of a shovel, so as to present a firm and smooth surface. In forming the beds for the reception of the spawn, the manure should also be made firm. In the event of the soil encasing the beds getting dry or approaching dryness, it should be afforded water by means of a rosed-watercan, and afterwards covered with long litter, straw, or rough hay. The beds must remain covered, and the house kept moist by damping the floors. If all should go well, Mushrooms may be expected a few weeks after spawning the beds. H. W. Ward, *Rayleigh, Essex*.

ODONTOGLOSSUM CRISPUM "DAPHNE."

AMONG the attractions at the Drill Hall on the occasion of the meeting of the Royal Horticultural Society, on Tuesday, October 3, was a plant of *O. crispum* "Daphne," surmounted by a flower-spike consisting of sixteen flowers. The plant was shown by W. Thompson, Esq., Walton Grange, Stone, and it received an Award of Merit. The fully expanded blooms measured individually 4 inches in diameter, and were of good form, as shown in our illustration (fig. 103); their chief beauty lay in the colouring. The petals were white, with a few pale purple spots; and the sepals were, over the major part of their area, of a light purple tint, bordered irregularly with white; the lip filled, and with the central area of a lighter brownish-purple hue than that of the sepals, and margined with white.

THE ROSARY.

VARIETIES OF ROSES TO PLANT.

THE time for ordering Roses is again drawing near, and those who have not a large experience, and who think of exhibiting at the next year's shows, as well as those more experienced, will find the following list well worth conning. It is taken from the reports published in the *Gardeners' Chronicle* of the last three exhibitions held at the Crystal Palace, the numbers indicating how often the particular Rose has been mentioned as being of special merit. I have not included garden varieties, or those that were only mentioned once or twice in the three years, except in the case of new varieties. The list is also interesting as showing what a small number of varieties are run on for the highest class of blooms. We cannot all grow Comtesse de Nadaillac in such perfection or the number required to produce such a grand display as that made by Mr. Prince last July, but we can all do our best to produce blooms of the highest quality, and it maybe our efforts will be so far successful that they will be rewarded by a prize at the Crystal Palace or other important Rose show in 1900:—

FIG. 103.—ODONTOGLOSSUM CRISPUM "DAPHNE."

MARKET GARDENING.

DAFFODIL FORCING FOR MARKET.

ON October 1 of this year we potted up the following distinct varieties, simply as a matter of trial, to see which would flower the first. They will be all treated alike, and no forcing adopted, simply cool treatment up to the middle of December. The varieties are:—Ard Righ, Cervantes, Countess of Annesley, Golden Eagle, Golden Plover, Golden Spur, Henry Irving, John Bright, King Umberto, Maximus Superbus, Mina Troy, "Early Bird" (this will be the Derby winner), Princess, spurius, Tottenham Yellow, Tuscan Bonnet, obvallaris, obvallaris pallidus (Buttercup), Saragossa, Irish cernuus, pallidus præcox, Princess Ida, and double Von Sion (the latter Irish grown). At the start I put in the following for a place, and in the order of finish:—1, Early Bird (late North Star); 2, Ard Righ; 3, pallidus præcox. Any grower of Daffodils for market knows well the advantages of a week's early market, and it is on this account that the experiment is undertaken. I have had Early Bird from the open always in January. The varieties are all of Irish growth. W. Baylor *Hartland, Ard Cairn, Cork, October 12, 1899*.

roof of the house) in readiness for the plants to attach themselves when they begin to spindle.

From beans thus planted, that is, in rows at, say, 22 inches asunder, and at 1 foot from plant to plant in the rows, a good crop of pods may be secured. A house say, 100 feet long and 15 feet wide, would contain about 650 plants, and putting the average yield at 2 lb. of beans per plant, this would give 1300 lb., which at 1s. per lb. would give a sum total of £65 for the crop. A minimum night atmospheric temperature of 55° to 60°, with a rise of 5° with fire-heat by day, should be aimed at, running it up to 90° with sun-heat, and plenty of moisture being distributed in the house at the same time. Indeed, a uniformly moist atmosphere should be observed in the house; also in the soil in which the plants are growing, from the time the plants appear above ground until they cease to bear. It may be as well to state that in the open air the Climbing French Bean under notice attains to a height of 8 feet under generous treatment.

MUSHROOMS.

These esculents, under proper management, pay well under glass during the winter and early spring months. Vineries from which the Grapes have been cleared in September, or earlier, may be

FORESTRY.

THE DECAY OF TREES.

(Continued from p. 123.)

TAKING a general review of various causes which operate for or against longevity in trees, we are forced to the conclusion that physical and mechanical influences play as great, if not a greater part, than physiological, in hastening or retarding decay. A healthy state of soil and sub-soil, a root system out of the reach of the temporary peculiarities of climate, give a tree advantages which go far towards ensuring it a lengthened spell of life. Dry soils, by favouring the production of well-ripened wood in autumn, and the consequent increase of vitality in the following year's growth, also favour longevity in temperate climes. But the most important factor of any, is the ability to resist that great enemy of tree-life, wind; and this ability, as we have seen, decreases with the height of the main stem, and the more the crown counter-balances in weight and leverage the resisting-power and anchorage of the roots. The constantly-increasing weight of crown and large limbs, which goes on in proportion to the vigour and health of the tree, is, in itself, the most frequent cause of its destruction, for fresh demands are annually being made upon the elastic and cohesive strength of the wood to resist the law of gravity which the side branches are so inclined to set at defiance. The English Elm is a good example of what takes place when these side branches get too heavy for the elastic strength of the wood-fibres at the fork, or in the neighbourhood of their base. Every summer, numbers of large limbs drop off in the calmest weather, and the decay which sets in on the surface of the broken stump, gradually eats its way into the heart of the tree, and weakens the strength of the main stem. The same thing occurs on a more limited scale with spreading and wide-crowned Beeches, or with trees of any kind which possess timber of a brittle nature.

In gales, again, large limbs are frequently torn off, and while the loss of such limbs lightens the crown to a great extent, it also renders it top-heavy on one side, thus increasing its leverage upon the roots. In many cases, the loss of large side-limbs in this way ultimately results in the top being broken completely off at the point where decay has eaten into the trunk; and although spoiling the tree as an arboricultural specimen, it frequently lengthens its life by relieving the roots of the strain which would otherwise be put upon them. In the neighbourhood of London, and other towns, Elms and other trees are frequently lopped and topped for safety or sanitary reasons, and if properly done, the lives of the trees are probably lengthened by the process. We doubt, however, if this is the case when the lopping takes the form so commonly seen of periodically shredding off all the side branches to within a few feet of the top, leaving the trees useless for shade purposes, and certainly more ugly than ornamental.

There is little doubt that in judicious topping and pruning we have a means of increasing the longevity of trees to an enormous extent, and which, if taken advantage of at the right time, may prove of great service in ornamental, if not economic, forestry. In parks and public resorts the rearing of young trees is a troublesome and frequently unpicturesque process, and under the most favourable conditions it never gives us anything resembling those grotesque relics which are so universally admired as the remains of a bye-gone period. A well-shaped tree is a pleasing object, but we do not want all our trees of one particular type or shape, however good it may be in itself. Yet judging from the method invariably adopted of rearing young park timber throughout the country, the day will come when an English park will exhibit as little variety as the different fields of a grazing farm. Our old park timber was probably reared under conditions which prevented it from ever growing into anything of great com-

mercial value, and in its earlier stages would present a similar appearance to those stunted and mis-shapen individuals which are so unhesitatingly removed by the modern forester wherever they appear. The result is obvious. Picturesque antiquity will soon be a thing of the past, unless we resort to methods which resemble to some extent those by which the patriarchs of tree life were produced. Constant nibbling by cattle, or lopping for the sake of the brushwood, seems to have marked the career of many of our old specimens, and without which they would probably never have obtained their present shape and age. Theoretically the most favourable objects for parasitic attack, they appear to have withstood it with comparative impunity, although they may only represent a small surviving proportion out of a large number.

Certain parasitic fungi we know are capable of attacking and destroying perfectly healthy trees, for instance *Trametes radiciperda* on the Scots Fir; but in the majority of cases, it would seem that some predisposing or aggravating influence must be at work before the destruction of trees can be accomplished by any but our most virulent parasites, although their value as timber may be quickly lost, and their power to withstand wind decreased to a dangerous extent by the decay of the main roots. *A. C. Forbes, Calne, Wills.*

AMERICAN NOTES.

AMERICAN POMOLOGICAL SOCIETY.

THE twenty-sixth biennial session of the American Pomological Society was held in Philadelphia, September 6, 7. There were present 130 accredited delegates from 22 States, and 100 others, most of whom are members of the Society. Among the older members present were Thomas Meehan, Germantown, Pa.; P. J. Berckmans, Augusta, Ga.; S. B. Parsons, Flushing, L. I.; T. V. Munson, Dennison, Texas; Robert Manning, Reading, Mass.

President Watrous' address, the feature of the first session, was received with marked attention, the reading of it being often interrupted by expressions of approval. The president urged the necessity of systematic scientific breeding of American fruits. The time had gone by when we could afford to place dependence upon varieties brought from without. The division of the country into well-defined life zones was now accomplished, and suitable fruits must be bred up to fit these divisions. The next fifty years should see fruit breeding as systematically carried out as stock-breeding now is. Pomologists must supply the material for the several stations to work upon, and then, at the meeting of the Society, which was a court of last resort, the facts could be sifted out. Already the good work was begun. In the Mississippi Valley hybrid Plums had already taken their place, and the development of the northern Grape awaited such work as Munson had done in the south. Garden herbaria, such as that now in the New York station, should be kept in all sections. A national herbarium of pomology would act as a check upon frauds. Fruits originated in their own botanical districts, and it was the duty of the Society to teach that such varieties were most likely to succeed there. Thousands of dollars had been wasted in the endeavour to introduce foreign varieties. Isothermal lines rather than territorial divisions should be looked to. The Society's best work was to be done for the mass of the American people, but it certainly could not wholly guide the public taste, and if men will buy Ben Davis instead of Grimes' Golden, the pomologist must plant that—he must go in for what pays.

The committee on the address fully endorsed the president's remarks, and recommended the appointment of two commercial fruit growers, one representing the east, and one for the west, to present papers on marketing at the next session of the society, to see if some means of avoiding glut

could not be devised. They further recommended that the Department of Agriculture prepare and issue a bulletin relating the connection of the experiment stations with pomology, and setting forth plainly just what each station had done, and was doing along that line.

THOMAS MEEHAN'S REMINISCENCES.

Thomas Meehan sketched the work done in Philadelphia and the surrounding district in early days. American pomology, he said, is the admiration of the world, and the American Pomological Society has had more to do with that eminence than any other. Europeans were amazed at the profusion of fruits, the poor enjoying them with the richest. The poor abroad grow fruit, but it goes for titles and taxes, and others enjoy it. This Society is responsible for the difference here. Mr. Meehan reviewed the beginning of Grape culture in Philadelphia, and its spread; following with the Pear and the Apple, and telling of the attempts at

of Catawba and Isabella, was set out near Wissahickon, but it too gave out; the men did not realize that the phylloxera was at work, which pest, he believed, Penn had brought from Europe. All this failure of imported stock led to the cultivation of the native Grape, and Philadelphia laid claim to that. The Pennsylvanians had decided taste in those days, and when the advent of Concord was announced from Massachusetts, the committee which went to investigate, came back with "diphtheria in their throats." Such was the reception given to the one Grape that was crowded out all others. The Grapes which emanated from Philadelphia included Bartram, Bense, Alexander, Archer, Bland, and Maxitawny, which was the first really good white Grape. In Pears, Bartram, Petrie, Brandywine, Penn, Tyson, Seckel, Washington, Ledger, Catherine, Early Wilmington, Chancellor, Jones, and Kieffer, belong to Philadelphia. There were also thirty-eight varieties of Apples, all prominent in their time, that had arisen about

name was merely a designation, not a variety nor an advertisement. Publication was essential to the proper security of a name, and this could be done in anything that bore a date—a nurseryman's catalogue offered a suitable medium.

T. V. Munson, Denison, Texas, urged that the Secretary of Agriculture prepare an authoritative list of all fruit names. This to become a legal standard list, and to which all catalogue makers were to be compelled to conform under penalty of exclusion from the mails. Further, in order to protect the purchasing public, it was advisable that State laws be enacted to punish such people as gave out false, overdrawn descriptions of new varieties, which thus become a sort of fraud. New varieties of fruits to be submitted to the United States Pomologist, and to be described by him before they become subjects of interstate commerce. Legislation protected the sale of pure butter, and why not of fruit?

MALFORMED TULIP-BULB.

IN the curious Tulip-bulb, illustrated (fig. 104), the old bulb has done its part by producing stem, leaves, and probably flowers; whilst the new one, a lateral production, has lengthened into a stalk, and then, as if tired of growing in length, has suddenly contracted its energies and formed a bulb on the end of the stalk. The outermost coat of this bulb is prolonged into a long, horn-like appendage. It is difficult to surmise what could have been the causes of this singular production, but probably we shall not be wrong in attributing it to some injury sustained during growth.

GOOD BORDER PLANTS.

CHRYSOCEMA LINOSYRIS.—This is, I am afraid, a neglected plant, and largely so because its merits are of a nature that do not flaunt themselves in one's face. Its greenish-yellow inflorescence fails to evoke rapturous approval, while its weakly stems, loaded by the expanding flowers, which bend the former in all directions, render it an object of pity to those people who like every plant to grow upright as a Hollyhock, and out of mistaken kindness, they bundle the stems together till they are much like the handle of a broom, and the flower-heads have the resemblance of a mop. The value of the *Chrysocoma*, or Goldielocks, as it was prettily designated by people long ago, is largely due to its gracefully recurring habit of growth, which sticking or tying of any kind inevitably spoil. Its general effect in garden decoration is restful, though it is not without colour value when planted in combination with, say, *Aster bessarabicus*. It is useful either dotted singly or grouped in masses of several plants. None of the plants should, however, be nearer than 2 feet from the edging, otherwise, when closer than that, the flowers will sprawl over on the gravel or grass. From the time of Gerard, this plant has had many names, and at present it is resting among the *Asters*.

Eupatorium Fraseri (Ageratoides).—Since the advent of so many fine white *Asters*, this distinct-looking plant is not, perhaps, wanted so much as it was a few years ago, when there was a difficulty to provide sufficient white flowers in late autumn. I find, however, that it would be a mistake to dispense with it, as it fills a place that even such a grand *Aster* as Mrs. Trevelyan fails to do quite so effectively. This year I have confined the *Eupatorium* to one irregular group, and it is now clear that it could with advantage have been more largely employed. It is no doubt best fitted to plant singly among low-growing subjects, though in many cases on account of its compact habit it would be unwise to plant it closer than about 4 feet from the front. The plant requires no staking, though a hand of string is not without advantage in protecting the outer stems during high winds.

FIG. 104.—STALKED LATERAL BUD OF TULIP.

importation and the destruction by rats in the held, and the law which gave no redress if there was a cat on board. Philadelphia had become a horticultural centre because of the desire for wine. Penn had established the city where it was because he had concluded it was a good place in which to grow good wine, and he sent to France for his Vines, which he grew in what was now a part of Fairmount Park. His efforts partly failed, so he sent for French vineyardists, but as failure still followed, they concluded Philadelphia was not hot enough, so they took up the Reading Grape, which gave a wine that Franklin said was as good as the foreign wine. But they were not satisfied, and sought the native Grapes till they got the Alexander—considered a great advance, but it was greatly inferior to the Concord. Bartram also tried to grow for wine, and introduced a Grape from Virginia, almost equal to Delaware, but it failed too, and so the Susquehanna was searched till a Grape known as Susquehanna was discovered. It was as good as the Delaware to-day, but that failed too, after a time. Later a vineyard, 3½ acres

the city. Mr. Meehan insisted that the wrong man often got credit for a variety. It is not always the finder who deserves the credit, but he who puts it before the public—the man who knows when he sees a good thing. The Seckel Pear owes its distribution to Dr. Hosack of New York; so, too, the Kieffer was not recognised by the man whose name it bears—it was W. Parry who saw it at the Centennial Exhibition who really merits the honours in this case.

NOMENCLATURE.

Professor F. A. Waugh urged the necessity of a stable nomenclature on a scientific basis. This was a necessity before there can be a scientific pomology. No botanist pretended to know the names of all the plants, but he had a system which made him acquainted with them in a general way, and that was what we wanted in our fruits. The American Pomological Society was not in a position to impose arbitrary rules—no society is big enough to force a rule, it can only formulate a principle. As to selection of names, it must be remembered that a

Boltonias.—In addition to what Mr. Arnott wrote in a late issue of *B. asteroides*, it may be permitted me to add that it is a plant that always attracts attention, on account of its delicately fragile appearance. It is best dotted among low-growing plants, where its good qualities readily become apparent. The later-flowering *B. glastifolia* is of less value for garden decoration, and seems to be about as uncommon in gardens as the first-named. The flowers, in large, irregular clusters, are exactly like single Daisies, and I have cultivated the plant for many years as being indispensable in the late autumn. The glaucous foliage is distinct throughout the whole season of growth.

Helianthus "Miss Mellish" is undoubtedly the finest introduction of late years among autumn flowering plants for the border. Its only fault is the amazing rapidity with which it overruns neighbouring plants. This is, however, a fault which can be corrected by means of a sharp spade, and by lifting and replanting annually, which appears to be the best kind of treatment. The most effective way to plant it is in large groups, not necessarily confined to the back part of borders; but in the case of wide ones, they may be allowed to extend to within 3 feet of the front. Pieces with four or five growths are a size suitable to plant, and they should be set at a foot apart, but single bits dibbled equally over the ground to be planted do quite as well. Five or 6 inches apart is a good distance to place the latter. It is a plant, moreover, that ought to be put in unmanured ground, as its tendency to shoot up is considerably strengthened by manure, which yields no counterbalancing advantages.

Its decorative effect is very largely due to the bright colouring of its flowers, which from the point of view under discussion may be called glorified examples of *Helianthus "Stella,"* or of *Coreopsis tinctoria*, but distinct and altogether superior to these.

Salvia patens.—Judging from the number of times one finds this flower portrayed during the thirties, it must have been in considerably greater repute at the time immediately succeeding its introduction than it is now. It is no doubt the finest of all the Sages, though less effective than *S. splendens*, and in border-planting the position it occupies should be, I think, somewhat out of line with the general mass of plants, but at the same time so placed that, in passing, one can fully distinguish its splendid wealth of blue flowers. If allowed to assert itself, lovely as is the tone of blue, it has to me a decidedly depressing effect, as it does not readily harmonise with other colours. At the end of a series of beds on grass I have this year the two outside ones planted with a white-eyed, light blue *Lobelia*, among which dwarf plants of this *Salvia* are closely dotted. The arrangement in this case is pleasing, and produces a sort of "Willow-pattern" effect as regards colouring, but I must confess it is a case of sailing very near the wind. Unfortunately, the plant is here not quite hardy, but the roots are as easily preserved as those of Dahlias. Young stock is raised with facility from cuttings in spring, which again are secured from roots started in heat. The plants are rendered compact and bushy by pinching, and the spikes as they go to seed must be removed.

R. P. Brotherston, Tynningham, N.B.

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By C. R. FIELDER, Gardener, North Myms Park, Hatfield.

Flowering Shrubs, &c., for Forcing, at present plugged in the reserve ground should be examined, in order to ascertain which of the plants are sufficiently well furnished with flower-buds to be profitable if forced, so that fresh plants may be purchased from the nursery to supply the deficiency. With few exceptions, shrubs cannot be successfully forced for two years in succession, and if the plants are plunged in the reserve ground each year after being forced, with a view to employing them for

the same purpose again, they should be divided into two batches and forced in alternate years. Lilacs and Guelde's Roses which were forced last winter, will not have made growth sufficiently strong to flower again this winter, and these plants should now be cut hard back, leaving only one or two eyes at the base of the current season's growth. Turn them out of the pots, and after partially reducing the balls, place them in pots sufficiently large to afford the plants a good shift. The pots should be well drained, and the compost of good fibrous-loam and one-seventh part manure, must be pressed firmly round the balls. Plunge the pots again in the reserve ground, keeping the rims well below the surface of the ground. Plants plunged in this manner will only need to be watered in very dry weather. The Lilacs will root out of the pots into the soil at the surface, but the roots may be cut away at lifting time without injury to the plants. The remarks concerning repotting (but not pruning) will apply also to other shrubs which were forced last winter, but take care to afford peat to such species as require it, among which would be included *Rhododendrons*, *Ghent Azaleas*, *Azalea mollis* and its hybrids, *Kalmias*, *Andromedas*, *Clethra alnifolia*, &c. The list of plants now available for winter-flowering is quite a lengthy one; and in addition to those named above, nurserymen supply specially-grown plants of *Staphylea colchica*, *Deutzias* in variety, *Hydrangea paniculata grandiflora*, *Spiraea confusa*, *S. flagelliformis*, *S. arguta*, *S. Thunbergiana*, *Prunus sinensis*, fl.-pl.; *Viburnum plicatum*, double-flowered Cherry, and others.

Dielytra spectabilis, *Solomon's Seal*, and herbaceous *Spiraeas*, which were planted out two years ago, should be strong enough for forcing this winter, and may be lifted and potted-up in readiness as soon as the foliage has died down.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart. Clare Lawn, East Sheen.

The Winter Treatment of Masdevallias.—The necessary use of fire-heat at this season often induces undue growth in many species of *Masdevallias*, and every precaution should be resorted to, such as using as little artificial heat as possible, ample ventilation, and keeping the plants and the atmosphere much drier, so that the growth already made may mature and rest. The members of this genus are, more often than not, affected with unsightly black markings and spots on the under surface of the leaves, which may be induced in various ways, extremes of heat and cold, in conjunction with a saturated atmosphere, being the more frequent causes. With few exceptions *Masdevallias* may be grown permanently in one compartment if devoted solely to them, but where this cannot be done suitable positions have to be found for them elsewhere than in the cool-house during the winter months. The warmest part of the latter house is suitable for such as *M. Harryana*, *Liudeni*, *igneus*, *Veitchi*, *Chelsoni* ×, *Pourbaixi* ×, *muscosa*, *Wagneri*, and allied kinds; but those comprising the *Chimera* group, with *Peristeria*, *cucullata*, *torta*, *elephanticeps*, *macrura*, *Shuttleworthi*, and the lovely *tovarensis*, require a few degrees more warmth than can be afforded in the cool-house. *M. Wendlandi* should be grown with the warm *Cypripediums*. Without exception all *Masdevallias* need considerably less water at the root at this season than when growing, for although it would be unwise to allow any plant to remain dry for a length of time, it is to their advantage to permit the compost to become dry before affording water. Where any of these are suspended, be sure cold draughts do not blow directly upon them; in other respects a free circulation of air among them is essential.

Affording Water to Cypripediums.—The majority included under this genus may be watered overhead during the summer months without harm resulting, when evaporation carries away water that may lodge among the leaves; but now more discretion must be used by the grower, or disasters may occur. Such *Cypripediums* as *C. Argus*, *barbatum*, *Curtisii*, *Lawrenceanum*, *Mastersianum*, *purpuratum*, *insigne*, *superbiens*, *venustum*, and others of a similar nature, may still be so watered, likewise the hosts of hybrids derived from one or other of the above; but in the cases of *C. Charlesworthii*, *exul*, *Haynaldianum*, *Lowii*, *levigatum*, *Parishii*, *Rothschildianum*, and *Stonei*, and those comprising the *Selenipedium* and *concolor* groups, extreme care

should be exercised, when applying water, to prevent any of it lodging in the axils of the leaves. To ensure success with the latter group, and hybrids claiming descent from either of its members, the plant receptacles should be dipped only to their rims, and if by chance water gets on the leaves, it should be removed forthwith in order to prevent decay being set up. Having thicker leaves than others of the "slipper" family, they may, with advantage, remain dry for a week or more at a time, a slight wrinkling of the leaves always indicating when water is needed.

Oncidium cheiroporum.—This dwarf, cool-growing species is far too rare in collections, and even when obtained it is generally ruined by too much water being afforded during the winter months. The plant is now sending up its tiny, though floriferous spikes, after completing its leaf and bulb growth, and it should be kept moderately dry in consequence. During the dull months, it should be either suspended from the roof, or placed on a shelf near the glass; but in the summer a place on the stage, further away from the light, and where moisture is more abundant, is the best for it.

Treatment of Orchids in Flower.—Exhibition houses are best for the effectual display of Orchids when in flower, for everyone will admit that Ferns and other greenery greatly add to their effectiveness. But where their health is the chief consideration, it is better to let them flower where they have grown, or at least in the same house. For the better preservation of the bloom, both the plants and the atmosphere should be kept moderately dry; and although shrivelling may appear, a thorough soaking should not immediately follow the removal of the flowers, for more often than not the shrivelling is due to exhaustion than to lack of moisture at the root. The two most effective Orchids flowering at the present time are *Dendrobium Phalaenopsis Schroderianum* and the autumn type of *Cattleya labiata*, both of which need a long period of rest, commencing with the expansion of their flowers.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Half-hardy Plants.—These plants should now be lifted, and potted in pots of a size no larger than will accommodate the roots. They may be wintered in a cool and airy structure, kept free from damp, and from which frost is excluded. Alpines growing in pots, and plants of small size, may be plunged in beds of coal ashes, with an ordinary garden frame over them, further protection being afforded in very severe weather. *Echeverias*, *Sempervivums*, and other succulents, in the case of large specimens, may be potted; and in the case of small plants, these may be placed in cutting-boxes filled with loam. Place them all in a structure where they may be well ventilated and kept dry. Under such conditions the plants are enabled to withstand several degrees of frost without injury.

Begonias with Tuberous Roots.—Frost having now destroyed the flowers of these plants, the stems may be cut down to within 4 inches of the ground, and the tubers taken up with a moderate amount of soil attached to each, choosing a dry day for the job. Let them then be spread out on mats in a cold frame, or on a vinery-border, to dry them gradually. In a fortnight the stems will readily separate from the tubers; but if they do not readily fall, they should not be forced to do so, otherwise the tubers will shrivel, and they may decay. As soon as dry, embed them carefully in trays or boxes with finely-sifted leaf-mould, putting the crowns just below the surface. *Begonia* tubers keep in good condition in a cool, dry room or cellar, to which frost has not access.

Begonias with Fibrous Roots.—Cuttings of these soon form roots if placed in pots filled with sandy loam and leaf-mould, and stood in a stove. If that be not done, a few of the old plants may be potted-up, in order to furnish cuttings for the spring.

Cannas.—Though in some light dry soils *Cannas* may be wintered out-of-doors if afforded the protection of a covering of leaves, it is safe to take up the roots with such soil as hangs to them, and place them close to one another on a Vine-border or in a dry shed, where they should remain till the stems become dry. When the latter being cut back to

within 4 inches of the crown, and the labels tied to them, may be placed in flat plant-baskets, and covered with leaf-mould. In this way the roots may be readily examined in the winter, and if found not to be keeping satisfactorily, can be easily removed to more suitable quarters.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

The Turnip Crop.—Owing to the drought, Turnips have been hitherto a short crop generally, but the late sowings bid fair to make good bulbs rapidly. The Extra Early Milan is equally useful at the end of the season as at the beginning, coming into use fully three weeks before any others, and thus filling up a gap at this season. Beds of the Chirk Castle and Red Globe should be kept free from weeds, and the plants encouraged to grow by frequently hoeing between the rows.

Brussels Sprouts.—Those plants which were set out early in the summer have Sprouts fit for use. The beds of these and of later sowings and plantings should be cleared occasionally of the decayed lower leaves, but do not remove or bruise the healthy leaves. This vegetable should be grown in a sunny position, and ample space given between the plants, crowding always leading to early and great loss of leaves, with the result that the Sprouts are small and inferior. The rows of late-planted Sprouts should be moulded up with the hoe; and if the land is not in good heart, liquid-manure should be applied.

Carrots.—These plants being more tender than the Parsnip, the main crop should be taken up at an early date, and wintered in a damp shed or cellar, or laid in thickly in deep trenches, as was recommended in the case of Beetroots, burying the crowns 2 inches deep, and leaving all the leaves on the roots. When lifting the crop, put aside all undersized and deformed roots. Some litter or bracken sprinkled over the ground in very severe weather will keep frost from entering the ground and spoiling the roots. Horn Carrots should remain in the beds where sown, and there protected with coal-ashes, soil, or litter.

French Beans.—The plants should be kept growing in a house having a temperature of 60°, syringing them once or twice daily with tepid water. Weak liquid-manure may be applied alternately with clean water when podding commences. Let the plants be kept near the glass, and admit air to them in favourable weather. Their chief foe is red-spider, which must be kept in check by a humid atmosphere and daily syringings, together with sufficient root-waterings.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCOTE, Esq., Dropmore Maidenhead.

Peach and Nectarine-trees.—Where the purchase of additional varieties, or a re-arrangement of the existing trees is contemplated, operations may be commenced when the leaves begin to fall from the trees. With a view to keeping the walls fully furnished with fruiting trees, it is usually advisable to remove some old trees each year, choosing those which are in the least satisfactory condition. A Peach-wall thus gradually renewed will have fresh trees coming into bearing each year. Young trees, or those of middle age, produce, as a rule, the finest fruits, and are the most vigorous and healthy. Wherever the spaces between the bearing trees permit of it being done, young trees of the Peach and Nectarine may be planted for drawing upon in future for forcing-house and open air cultivation. Such young trees can be moved early in the autumn, and in a better condition than nursery-trees. If a young dwarf-trained tree from the nursery be planted in a temporary position this year, it will be in a suitable condition for removal into a permanent one next season, and will probably benefit by transplanting. In selecting nursery-trees, it is of very great importance that the stocks upon which they are budded should be young, clean, and vigorous. Trees which have branches bearing traces of having been several times cut-back, should not be accepted. The Peach and Nectarine require a warm position on a wall, and well-drained land; and when a tree is planted on the same site as one that has been removed, the soil should be thoroughly trenched to a depth of 1½ to 2 feet. Take away every bit of root and a portion of

the old soil, and add new loam, together with a small quantity of wood-ashes and lime-rubble substitute for it, and well mix in with the staple. Lime-rubble, in a finely-pounded state, should be afforded in considerable quantity if the soil is deficient in lime, and in much less quantity if the underlying stratum is chalk or greensand. Where the subsoil is retentive, even though it be drained artificially, a 6-inch layer of brickbats or other similar material should be placed about 2½ feet below the surface-soil; a covering of turves, with the grassy-side downwards, being placed on these; or failing turves, coal-ashes may be used as a thin layer. Walls having a south and west aspect may be planted with Peach and Nectarine-trees in all the southern counties, but in others, a south aspect is the only suitable one. In the warmer counties, standard trees of such early varieties as Waterloo, Alexander, and Amsden June may be grown in the absence of walls, these carrying a crop of fair-sized fruits with tolerable certainty if the spring weather is favourable to the setting of bloom. Such has been my experience during several seasons preceding the present one, which is the worst experienced for Peach culture during the past four or five years.

Varieties to Plant.—Of Peaches, the earliest to ripen are Waterloo, Alexander, and Amsden June. Second Early: Hale's Early, Condor, Early Silver, Violette Hâtive, Grosse Mignonne, Royal George, Stirling Castle, Bellegarde, and Dymond. Late: Barrington, Sea Eagle, Nectarine Peach, Princess of Wales, Walburton Admirable, Exquisite, and Gladstone. The five last-mentioned should only be planted on a south aspect. Nectarines: Early Rivers, Lord Napier, Elruge, Humboldt, Pitmaston Orange, and Victoria.

Root-pruning.—The fruits having been cleared from the trees, the roots of such as have made rank and unfruitful growth this year should be pruned in the manner advised for early-fruited varieties in a former Calendar.

FRUITS UNDER GLASS.

By W. STRUONELL, Gardener to Lieut.-Col. RALPH VIVIAN, Road Ashton, Trowbridge.

The Orchard House.—Trees that have made this year too much branch-growth, should be root-pruned even when not re-potted, and this may be performed whilst they are still in leaf. The same remarks apply likewise to such trees as may be planted on the border, every thong-like root that penetrates the lower stratum of soil being severed. In filling in the soil over the roots of such trees it is an advantage to add old mortar-refuse, or slaked lime in small quantity to the staple. The same degree of firmness as is given to the soil in a pot or tub is not required in a border, but it must be made firm about the roots if the trees are to do well. If the border is dry, as it probably will be, have water applied copiously. Trees that show signs of failing, may be assisted by taking out a semi-circular trench 5 or 6 feet away from the stem, preserving all roots met with during the operation, and removing the old soil inwards towards the stem, undermining always, and gradually extracting the roots to a distance of 2 feet from the stem. Having done this, and thrown out the exhausted or soured soil, bring up and prune back the stronger roots, spread out the whole of the roots radially on a bed of fresh loamy-soil of a turfy nature made very firm, and cover them with similar soil. Do not omit the application of lime in some form, or burnt refuse, if you have it. Artificial fruit-tree manure may be also mixed with the loam, but no farmyard dung. Apply water, as in the case of pot-trees.

Bananas.—The only means by which to obtain a regular supply of fruit is to have several plants in different stages of growth. There is no gain in trying to retard, or unduly hurry the fruiting of plants, from which an early show of fruit is expected. A regular and steady artificial heat, supplemented by sunshine, is needed by the plant, and without it, it is scarcely worth the attempt to cultivate it under a coolish or varying temperature. They are a long time on hand, and their season of fruiting most uncertain. The temperatures maintained in the general plant-stove is very well suited to the Banana if plenty of atmospheric moisture and of water at the roots be afforded. Where final potting of successional fruited is not yet completed, let them be potted without delay, as they should get rooted in the new soil before the

winter actually sets in. Remove any promising suckers, and pot them for succession; but in detaching them, disturb the roots of the parent plants as little as possible. Suckers taken at this date will make good plants for re-potting in the spring of next year. Pots and tubs may answer the gardener's purpose, but brick-lined pits or circumscribed borders are better, growth being stronger and the fruit-clusters larger; moreover, there is less labour in affording water. This method cannot be adopted in low glass-houses, as the plants attain a height of 12 feet. Let a temperature of 65°, min., be maintained in the house in which there are plants showing for fruit, as well as in those in which there are ripening fruits. Afford manure-water once or twice a week to plants that are in a forward state, particularly those which are pot-bound or have a limited rooting space. Farm-yard drainings and soot are suitable aids to growth, and artificial-manures may be alternately afforded, or employed entirely, as may best suit the cultivator. A soil which suits the plants is rich turfy loam, which should be roughly broken, and if this is obtainable, animal manures may be dispensed with. With the soil neither too wet nor too dry, the ramming-stick may be used freely when potting the plants.

Peach Houses.—The earlier the trees are planted after this date the better, as they will get partially rooted in the new soil in the course of the next four weeks. A tree may require removal because it is worn out, or it is an unsuitable variety, or there are too many fruits coming in at about one season, or there is a lack of variety. Transplantation may be required by such as have made too much wood and too little bloom this year, and which it is feared may become quite unfruitful. Usually a number of trees are grown on open walls for the purpose of taking the places of those in the forcing-houses, and in such cases it is an easy matter to keep the houses furnished with large fruiting-trees. The trees may be transplanted whilst still in leaf, and by the time forcing must begin, they will be partly re-established. Amsden June is an excellent Peach for the early house; the Early Grosse Mignonne, Early Alfred, Hale's Early, Dr. Hogg, and Royal George are likewise also good varieties and good forcers. Alexander and Waterloo are better in later houses, and they must not be started at such high temperatures as those previously named. Cardinal, Early Rivers, and Lord Napier Nectarines may be grown in the early houses; Bellegarde, Dymond, Dagmar, and Violette Hâtive Peaches form good successional fruited, as also Pine-Apple, Dryden, Humboldt, Downton, and Spencer Nectarines which make capital maincrop varieties indoors. New trees should not be planted in the soil which has been occupied a long time by old trees, and if a new border cannot be made for them, at the least a good proportion of new loamy soil should be provided. This is not absolutely necessary, because any good kitchen-garden soil which has not borne trees for some long time will answer the purpose. A fair proportion of charred garden-refuse or lime rubble should be mixed with whatever kind of soil is made use of. Trees arriving from a nursery with their roots in a dry state should be placed in water for an hour or two before planting them.

THE APIARY

By EXPERT.

Bee-houses.—For the establishing of apiaries, bee-houses are specially to be recommended, as then everything can be kept secure from molestation, and any extra appliances stored ready at hand even in exposed or badly-fenced situations. The bee-keeper must sometimes of necessity keep his stocks in a house. The objections urged against their use are, chiefly, want of room for manipulations, want of room for supering, want of ventilation, entrances too near each other (this encouraging young bees to enter the wrong hive, as well as young queens when out to get mated), and risk of disturbing all the hives during operations. In most cases all these objections may be removed. My experience of bee-houses has been fairly extensive, having in use some of several shapes and sizes. My first attempt was, however, unsatisfactory, for I had one made to hold twelve hives, almost identical to the one used by the late Rev. H. Raynor. In practice, I found that the entrances were too near each other, and there was a want of room for supering purposes; consequently I discarded it after trial.

(To be continued.)

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

TUESDAY, Oct. 24.—Royal Horticultural Society's Committee.
National Chrysanthemum Society's Floral and Executive Committees.

SALES.

MONDAY, Oct. 23, and the following Monday, Tuesday, Wednesday, Thursday and Friday.—Dutch Bulbs at Protheroe & Morris' Rooms.

TUESDAY, Oct. 24.—Unreserved Sale of Orchids, Greenhouse Plants, Glass Erections, &c., at the Victoria and Paradise Nurseries, Upper Holloway, by order of Messrs. B. S. Williams & Son, by Protheroe and Morris at 12 o'clock (three days).

WEDNESDAY, Oct. 25.—Great Sale of Lilium longiflorum, from Japan, &c., at Protheroe and Morris' Rooms, at 5 o'clock.

WEDNESDAY, Oct. 25.—Sale of Nursery Premises and Nursery Stock, at 14, Mayfield Road, Wimbledon, by Mr. Herbert Wm. Rendell, at 12 o'clock.

THURSDAY, Oct. 26.—25th Great Annual Sale of Nursery Stock, at Holland's Nurseries, Groombridge, Tunbridge Wells, by order of the Executors of the late Mr. Edward Holland, by Protheroe & Morris, at 12 o'clock (two days).

THURSDAY, Oct. 26.—Important Unreserved Sale of Established Orchids, Stove and Greenhouse Plants, &c., at the Assembly Rooms, Saville Row, Bath, by order of the Rev. E. Handley, by Protheroe & Morris, at 12.30 o'clock (two days).

FRIDAY, Oct. 27.—Imported and Established Orchids at Protheroe & Morris' Rooms.

Dull, foggy, cool.

PROVINCES.—October 18 (6 P.M.): Max. 62°, south-west Ireland; Min. 52°, Shetland.

If we make exception of our Pomology. Fruit Committee, which does good work in an unostentatious way, and of our annual Fruit Show at the Crystal Palace, it cannot be said that Pomology is at all well or adequately represented in this country. From the Duke of BEDFORD's fruit farm near Woburn, we may in future expect great things, for there, experiments are carried

out on a well thought-out plan and with as much scientific precision as circumstances permit. Fruit-growing has no doubt made progress in response to the energetic efforts of the Royal Horticultural Society; but scientific pomology, if we may use such a term, has slumbered since the memorable fruit conferences held at Chiswick some years since. Yet there are many questions still awaiting full solution, in particular the question of spraying. How, when, and how often should it be done? Will it pay?

These questions the Americans have answered for themselves, but our growers are either very uncommunicative, or they do not practise it. We are inclined to believe the latter is the truth, for out of a large number of Pears recently cut open, only one or two were free from maggot. Of course, this is not to be taken as a general case, but at all events, it may serve as an indication. In France and Switzerland the state of things seems little or no better. Systematic and purposeful hybridisation is almost unknown among our pomologists, yet the prospects of success are by no means indifferent.

Then there is the question of varieties suitable for special localities and aspects—a question not half sufficiently considered, as anyone may see if he inspects the dreadful rubbish exposed for sale at relatively high prices in the greengrocers' shops. Some of us who are in the habit of seeing the magnificent fruit exhibited at the Royal Horticultural Society and at the principal local shows imagine, and rightly so, that such samples are superior to what may be seen on the continent. On the other hand, the fruit and vegetables offered for sale in the markets of provincial towns in France and Italy are much superior, as a rule, to what we see in our own shops. That this is so there is no manner of doubt, and it is a question of cardinal importance for the fruit-grower to set this matter straight. Our growers produce at once the finest and the worst samples. The former we see on the exhibition-tables; the latter we, as consumers, are obliged to purchase in default of better. Surely in this, as in other matters, there is a middle course to follow, which would give more general satisfaction than our present policy of extremes.

The American Pomological Society, whose meeting in Philadelphia is alluded to in another column, has taken great interest in all these matters, and for a time was carried on with a zeal and energy that excited our envy as much as the right-mindedness and eloquence of its late President, MARSHALL WILFER, stirred our imagination. Since his death, the Society seems to have relapsed somewhat into a state of dormant energy! Conditions have changed, as our American correspondent states, and the Society has not at present fully adapted itself to new circumstances, but that it will do so we cannot doubt. The appended letter from our correspondent will be read with interest, and may furnish hints for our own use:—

"The passing of the semi-centennial of the American Pomological Society leaves one full of reflections, full of hopes, and full of questionings. The Society has had an eventful—almost a romantic career. During the early years of its existence it held large meetings and remarkable fruit-exhibitions, which attracted all the leading fruit-growers of the day. It was the centre of horticultural thought—the summit of horticultural ambition. Much attention was paid to the study of new fruits, and to judging the merits of hundreds of varieties originated on this continent or imported from Europe. A great influence was exerted by the Society, and much good accomplished.

"In recent years, however, conditions have changed enormously. American fruit-growing has changed from the amateur type to the commercial type. Pomology has passed from the experimental stage to the stage of high refinement and severe competition. The different lines of work have been highly differentiated, so that one man can no longer be an authority on all fruits, but each must confine himself to his specialty. No society or committee can longer pass final judgment on varieties for commercial growing. Meanwhile the country has been filled with local experiment stations which go far to usurp the functions formerly exercised by the American Pomological Society. Interest in the meetings has flagged, the attendance has been scant, and it has become a question whether or not the society could live in the new environment which had grown up about it.

"The twenty-sixth biennial meeting recently held at Philadelphia was expected to answer this question. But, while this meeting was highly successful, it has been only a partial answer. There is not room here to discuss this whole question, although it is of the highest importance to American pomology. At all events, we hope for the best. At the recent meeting, there was a large and very representative attendance, coming from all parts of the continent. The meeting of so many eminent and able men was sure to be in the highest degree pleasant and profitable. The fruit exhibit was good, but not remarkable. The programme was well carried out, but was made up largely of second-hand material, which we had all heard before. There was no notable discussion of any topic, though there was a most notable omission of all reference to the San José scale. This insect has utterly ceased to be a terror to American fruit-growers.

"The American Pomological Society still lives, and we still hope to keep it with us as a strictly representative organisation of American fruit-growers and fruit-lovers."

THE above-named Society has now completed its arrangements for a Show and Conference to be held at Lyons on November 3 and following days. M. VIGER, Minister of Agriculture, will preside. The programme of the proceedings is an attractive one, the social aspect being none the less looked after than the educational. On the first day of the show, the Floral Committee will meet to adjudicate upon the novelties; then follows the judging. At mid-day there will be lunch. At 2 P.M. the Show will be opened, and this will be followed by a meeting of the Conference. Dinner will be served at 7 P.M., after which there will be a reception by the syndicate of the Lyons nurserymen.

On the following day there will be a second meeting of the Conference, a lunch at mid-day, and then a visit to the Park of Tête d'Or and the municipal greenhouses. In the evening a grand banquet. On the third day other arrangements are made of a similar nature. The subjects to be discussed at the Conference are, among others, Fertilisation, Maladies and Parasites, Wintering Chrysanthemums, Manures and Composts, &c. To show the way that popular interest has been aroused in this young and flourishing Society, it need only be mentioned that although this is only the fourth year of its existence, it counts already over 560 members, many of whom are Chrysanthemum celebrities resident beyond the borders of France. A very pressing invitation has been extended to members of the English National Chrysanthemum Society, but unfortunately the dates of the Aquarium and Lyons shows are too close to allow many of those who are interested to be present at both.

SINGLE CHINA ASTER (CALLISTEPHUS HORTENSIS).—The China Aster (*Aster chinensis*, of Linnaeus), which, by the way, is not an Aster any more than a Water-lily is a Lily, was introduced from China to France by a missionary 170 years ago, since when horticulturists have so modified and diversified its characters that we have almost as many forms of it as of the Chrysanthemum.

we are again indebted to a French missionary in China, are of opinion that as an ornamental garden-plant it is superior to most of its garden descendants. At Kew it has been largely used this year as a group-plant in the herbaceous-borders, and during September and October it has been as much admired by visitors as any plant grown there. It is more elegant because

poses. The illustration here given (fig. 105) was prepared from a specimen exhibited at the Drill Hall recently by Mr. J. WEATHERS, of Silverhall Nurseries, Isleworth, who has been very successful in its cultivation. *W. W.*

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Fruit and Floral Committees of the

FIG. 105. —*CALLISTEPHUS HORTENSIS*: COLOUR OF THE FLOWERS PALE ROSE-MAUVE, AND BRIGHT YELLOW DISC.

Mr. BARRON prepared a list of the China Asters specially grown at Chiswick in 1888, in which he enumerated no fewer than seventeen sections, bearing such names as Quilled, Peony, Pyramidal, &c. That so great a degree of variation has been obtained within the limits of one species without hybridisation is remarkable. Probably many who have seen the wild type as here represented, for the re-introduction of which, a year or two ago,

looser and taller than the double-flowered forms, its height being 12 to 18 inches, freely-branched, and clothed with healthy, dark-green foliage and numerous flowers, from 3 to 5 inches across, coloured pale rosy-mauve, with a broad, rounded, bright-yellow disc. The plant ripens seeds freely, and the flowers last a week or more if cut and placed in water. Market-growers of flowers look upon it as a very promising plant for their pur-

Royal Horticultural Society will take place on Tuesday, Oct. 24, in the Drill Hall, James St., Westminster, 1 to 4 p.m. A lecture on "Growth of the Fruit Trade" will be given by Mr. GEO. MUNRO, V.M.H., at 3 o'clock. The War Office having asked for the Drill Hall of the London Scottish Volunteers (in which the meetings of the Royal Horticultural Society are held), to be placed at its disposal for the temporary accommodation of 300 soldiers on

route for South Africa, it is probable that the Society's meeting on October 24 will have to be held in the Drill Hall of the Queen's Westminster Volunteers, which adjoins that of the London Scottish, being actually the next door. If this should be the case, Fellows and exhibitors are requested to make the best of an unavoidable inconvenience, which it is hoped will not have to be repeated. The following dates have been fixed provisionally for meetings in 1900: January 9, 23; February 13, 27; March 13, 27; April, 10, 24; May 8, 23, 24, 25 (Temple); June 5, 19, 27 (at Richmond); July 3, 17, 31; August 14, 28; September 11, 25, 27, 28, 29 (Crystal Palace); October 9, 23; November 6, 20; December 4, 18; January (1901), 15, 29; February 12. Gentlemen willing to lecture on any of these dates are requested to communicate with the Secretary, 117, Victoria Street, S.W., at once.

TRIALS WILL BE MADE AT CHISWICK IN 1900 WITH THE FOLLOWING SUBJECTS:—

1. Tulips for outdoor decoration; twelve bulbs of each should be sent at once to the Superintendent, Royal Horticultural Society's Gardens, Chiswick, W. Each variety should be marked with its colour, and an indication of its season, early, mid-season, or late.
2. Phlox decussata.—Two plants of each should be sent on or before March 1.
3. Cactus Dahlias.—The 1899 trial will be repeated. Any new varieties, two plants of each, should be sent in April.
4. Potatos, new varieties.—Twenty tubers to be sent before February 1; also, a trial of distinctly Early Potatos, both old and new varieties, requested.
5. Tomatos, for outdoors only.—Seed before February 1.
6. Peas.—Half-a-pint to be sent in January.
7. Celeriac.—Seed in January.

EXAMINATIONS IN HORTICULTURE.—The Royal Horticultural Society will hold its next examination in horticulture on Tuesday, April 17, 1900. For Syllabus, apply to the Secretary, R.H.S., 117, Victoria Street, S.W., enclosing a stamp.

KINGSTON CHRYSANTHEMUM SOCIETY.—This old-established Society, which holds its annual show on November 29, has, like some others, dispensed with the old challenge cup, and its difficult and unequal class for twenty-four Japanese and twenty-four incurved; and has instead arranged a champion class for thirty-six Japanese, with valuable money prizes.

FOREIGN CHRYSANTHEMUM SHOWS.—During the present season there will be abundant evidence of the continued popularity of the Chrysanthemum. We hear that a society has recently been formed in Denmark. The French National Chrysanthemum Society holds its show on November 3, at Lyons; the Italian National Chrysanthemum Society at Milan on November 9, Paris on November 8. Other towns, viz., Voiron, Bourges, Havre, Limoges, Bordeaux, Cambrai, Pan, and Le Mans will follow.

THE RECENT SALE OF ORCHIDS AT "THE FIRS," WARWICK.—As showing the remarkable value which Orchids fetch at sales, the following particulars of prices paid for notable plants at the sale of the late Major Mason's collection on October 10, 11, and 12, are interesting. The sale was conducted by the well-known firm of Protheroe & Morris, Cheapside, and was well attended. By far the highest prices obtained were realised for varieties of Cypripedium, and the most valuable of these was *C. insigne giganteum*, for which £147 was paid. *C. Lawrenceanum* Hyanum, figured in our pages January 16, 1897, fetched £89 5s. The plant had two growths. Another specimen of the same variety was sold for £76 13s. *C. insigne* Sanderi sold for £54 12s., and a smaller plant for £35 14s.; *C. Aylingi*, with three growths, for seventeen guineas; *C. callosum* Sanderianum, £73 10s.; *C. insigne* Maulei, yellow variety,

£32 11s.; *C. insigne* "Dorothy," with eight growths, £29 8s. Of *Dendrobium*, a plant of *D. Phalenopsis* album, with five old and one new pseudo-bulb, was sold for £52 10s.; *D. Wardianum* album, with nine pseudo-bulbs and three buds, 11 guineas; *D. × Gemma*, with three pseudo-bulbs, 13 guineas; and *D. Ballianum*, a fine specimen plant, 15 guineas. Of *Cattleyas*, a plant with seven pseudo-bulbs of *C. × Ferdinand Denis* fetched 17 guineas; *C. Mossiae* Wagneri, £27 6s.; *C. Louis Chaton*, 11 guineas; *C. Mantini* nobilior, 11 guineas; *C. Parthenia speciosa*, 17 guineas; *C. labiata* alba, with four pseudo-bulbs, £63; *C. Mossiae bellissima*, 17 guineas; *C. Skinneri* alba, 17 guineas; *C. Mendeli* "Miss Little," 19 guineas; *C. × Lord Rothschild*, £26 5s.; and *C. intermedia* alba, £22 1s. *Laelias* and *Laelio-Cattleyas* sold for good prices. *L. anceps*, "Bull's White," fetched 15 guineas; *L. purpurata* Backhouseana, 16 guineas; *Laelio-Cattleya* "Iolanthe," 18 guineas; *L. purpurata* Littleiana, £21; *L.-C. eximia*, £21; *L.-C. Bertha Fournier*, £31 10s.; *L.-C. Pallas superba*, 16 guineas. Seedling and hybrid Orchids that have not yet flowered fetched considerable prices, and the total amount realised by the three days' sale was £3110 13s.

FRUITS GROWN AT THE CAPE.—The condition of affairs in South Africa holds the first place just now in public attention, and we have thought the time opportune for the production of the latest published figures in connection with the growth of the various fruits suited to soil and atmospheric conditions of this old colony and outlying districts, such as East Griqualand, Tembaland Trans-Kei, Pondoland, Walfish Bay, and Bechuanaland. It would appear that, notwithstanding the drought which prevailed for several years, and the visitation of locusts, increasing attention is paid to fruit-culture—the larger number of Plum, Orange, Lemon, and Naartje-trees is very noticeable. The following are the figures for 1896, for the purpose of comparison:

Fruit Grown.	Trees.	Fruit Grown.	Trees.
Peach	1,377,472	Plum	166,624
Apricot	233,175	Orange	197,220
Apple	353,611	Lemon	28,468
Pear	339,672	Naartje	20,352

These figures may easily be used in comparison as the following table is scanned, the items being for the crop of last year:—

Fruits grown.—1895.	Planted.	Standing.
Peach	98,597	1,696,922
Apricot	34,672	298,232
Apple	48,339	384,733
Pear	39,653	334,466
Plum	52,908	247,832
Fig	34,160	920,062
Orange	37,814	253,922
Lemon	3,099	33,076
Naartje	4,239	26,376
Vine-stock	6,259,154	83,759,031

The number of "deaths" in Vines owing to pests, drought, chills, &c., was very numerous; but the advance all round was very marked. It is to be hoped that the horrors of war may not interfere with the process of fruit-production at the Cape.

GRAPE LADY HUTT.—This new white Grape, judging from the examples Mr. HUDSON has grown at Gunnersbury House this season, bids fair to become our most valuable late white Grape. Mr. Hudson himself thoroughly believes in a future for this variety. It sets well, is as fine-looking as Gros Maroc, and has been found to hang and keep well, and its quality is excellent. Its companion variety, the black Appley Towers, is likely to supplant the Alicante as a late variety; for like its white companion, it sets well, forms a handsome bunch, and hangs for a long time. Some new Grapes of the past quarter of a century

have failed to maintain the position they were expected to occupy; but the two above-named seem destined to exhibit all the good qualities with which they were credited when they were distributed.

NEW ZEALAND SPINACH.—While in the London market gardens (a correspondent writes) the Vegetable-Marrow plants are blackened by frost, and the Runner French Beans are much injured from the same cause, the New Zealand Spinach is green and flourishing, presenting to view masses of healthy green foliage. One market-gardener near Gunnersbury has about 2 acres at least of this Spinach, and market-gardeners appear to be alive to the importance of a crop of this vegetable in such dry summers as those of 1898 and 1899. The somewhat light ground is deeply ploughed and heavily manured, and the plants appear to revel in it, and make a prodigious growth. The density of growth of the New Zealand Spinach covers the soil, keeping it cool and economising moisture, decided advantages in a dry season.

GRAPE-JUICE IN BEVERAGES.—A Canadian expert, with the knowledge that Grapes fetch only £4 and £5 per ton in Canada, suggests that it might pay to introduce Grape-juice, unfermented, to drink with Apollinaris-water &c., believing, as he does, that no drink in warm weather is more refreshing, or so soothing as that. It should be stated that the Californians have quite taken to this new form of beverage, and doubtless it would soon become a favourite in this country. In Switzerland it forms a refreshing beverage, but too sweet to suit English palates.

CALIFORNIAN V. CANADIAN PEARS.—Some doubts have been expressed as to the superiority of Californian Pears over those sent home from various districts in Canada, but it should be borne in mind that the Canadians reach England in fewer than twelve days, and the Californian in not much less than twenty. A well-known authority, Mr. ROGERS, states that the Californian Pears are tough in fibre, and not so fine in flavour as those of the Old Dominion, and it would seem that if the time occupied in transit could be reduced by a third, the highest prices would be obtained for Pears, Peaches, and Tomatos.

THE POTATO CROP IN GERMANY.—According to the official statistics, the crop is a medium one. The low grade Potatos suitable for starch and spirit manufacture are below an average crop; but eating Potatos, such as Magnum Bonum, Imperator, Saxonia, and other good descriptions, are above the average.

THE SAN JOSÉ SCALE.—Two years ago we were told that the United States of America would be overrun by this insect, and that unless restrictive legislation were obtained in the States and at Washington, the orchards would be ruined. A draft bill was actually prepared with this object by certain over-zealous entomologists. That bill was dropped, and its promoters were obliged to meet the nurserymen in annual convention, and listen to the opinions of representative men in the nursery trade. The result was a federal bill of far different mien. The San José Scale has not spread as promised, excepting under the most favourable conditions for its so doing; and with general vigilance on the part of cultivators of orchards it is not probable that it ever will. It is not a new creation, but has existed for countless ages, and is no more likely to do great injury to orchards than the insects that are peculiar to the Orange, Olive, Grape, &c.

HYACINTHS IN GLASSES.—Those who cultivate Hyacinths for the decoration of the dwelling-rooms or conservatory, usually like to have a few of these in glasses. They do not produce such strong flower-spikes as those in moderately rich soil in pots, but they are interesting because the development of the roots may be studied as conveniently as the growth of the leaves and flowers, and they are more cleanly and less trouble. We have just

received specimens of a glass for this purpose from Messrs. STEVENS & WILLIAMS, Brierley Hill. These are of a very pretty design, in shape like a vase with a crimped top, narrowed to form a base upon which the bulb may rest. The glasses are ribbed, and prettily engraved with Fern-fronds and flowers. Altogether they are much more ornamental than the ordinary glasses, and if we could suggest an improvement it would be that the base should be made larger, so that when the Hyacinths are in bloom, the glasses would be perfectly secure from turning over.

KIDDERMINSTER AND DISTRICT HORTICULTURAL SOCIETY.—The usual monthly meeting of this Society was held on Wednesday, October 11. The chair was occupied by F. HUGHES, Esq., when, before a large attendance of members, Mr. A. YOUNG, gardener to Lord DUDLEY, Witley Court, gave an instructive address on the cultivation of

but it should be noted that, if the £150 of prize-money had had to be paid, there would have been a deficit for the year of about £110. The balance now standing at the credit of the Society to carry forward to next season is £195 14s. 6d. During the past year the Society has received intimation of two bequests, viz., a sum of £200 from the late Mr. George Angus, merchant, Aberdeen; and one of £50 from the late Mrs. Catharine Murray, or Paterson, Aberdeen, the former to be applied 'for the purpose of elevating the taste of the working-classes, and encouraging working-men and their wives and families to spend their leisure in attending to horticulture;' and the latter 'to be given in prizes spread over fifty years, to be called the Samuel Paterson Prize, to amateurs in plant-growing.' The £50 legacy has been received, and as soon as the other has been paid over, it is suggested that this sum of £250 should be invested in good heritable security. The directors are very

the sale, and the whole realised excellent prices. There were some remarkably fine specimens of the *Picea nobilis*, some of which stood 7 feet high; there were also some very choice plants of *Abies Hookeriana* and *A. Menziesii*. Mr. D. P. Laird, of Edinburgh, was auctioneer.

DEVELOPMENTS IN THE AGRICULTURAL DEPARTMENT OF ABERDEEN UNIVERSITY.

At a meeting of the joint committee on Education in Agriculture, held in Marischal College, Aberdeen, on Friday, Dr. James W. H. Trail, Professor of Botany in the University, submitted a report upon the class of botany to teachers during the autumn, in which special notice was drawn to the fact that this class, started in connection with the University, anticipated, and exactly meets the requirements of the new article as to "Nature Knowledge" in the code. Applications, it was mentioned, had come to the County Technical Instruction Committee from county teachers, inquiring as to facilities to enable them to qualify for this new provision in the code, and intimation had been sent to them that the necessary instruction is already being provided in connection with the University. In view of the new provision, special interest attaches to the following statement from Professor Trail's report:—"The treatment of the subject was strictly practical, being designed to assist the schoolmasters to acquire the methods of observation and reasoning, that would enable them to utilise the materials for teaching botany in their schools, either from the wild flora, or with the aid of plants, easily grown in gardens. The instruction was restricted to what could be seen with the unaided eye, or with an inexpensive lens, and the apparatus employed for the dissection of the plants, and other simple physiological experiments was such as would cost but little. Information was also given as to the collection and observation of suitable materials for a small school museum. Three excursions were made to enable those at the class to become acquainted with the commoner plants of their district, thus permitting more complete knowledge to be gained of their various adaptations to the surrounding conditions of life."

The committee were gratified to learn that these autumn classes were supplying to rural teachers instruction necessary under the new clause in the code.

DRACENA VICTORIA.

OUR illustration of this beautiful variety was taken from a group exhibited by Mr. William Bull at the last Temple Show. It is an importation from Brazil, and resembles *D. Lindenii*, but retains its golden variegation as it grows older. The recurved lanceolate leaves taper to each end, and are of a bright golden-yellow, with a central band of green, marked with narrow, cream-coloured linear streaks. It is one of the handsomest of its class (fig. 106).

NURSERY NOTES.

MESSRS. THOMAS RIVERS AND SON.

THE name of Rivers, Sawbridgeworth, is of world-wide repute, and we may justly claim for Thomas Rivers, and for his son, the lately deceased head of the firm, T. Francis Rivers, the credit of having introduced to commerce more meritorious new fruits than any one living in this country, or on the Continent. In the case of the Plum, which next to the Apple is of the greatest importance in this country, the Rivers—father and son—by their introduction, lengthened the season during which Plums can be enjoyed in the fresh state by nearly six weeks at both ends. In this connection we may name Early Rivers syn. Early Prolific, which ripens at the end of July—a culinary variety; and Monarch and Late Orange, two excellent dessert varieties, ripen-

FIG. 106.—*DRACENA VICTORIA* (W. BULL).

Chrysanthemums, together with hints as to their artistic arrangement for exhibition and house decoration. A hearty vote of thanks was accorded the lecturer, and a discussion on the subjects treated of took place among those present.

SCOTLAND.

ROYAL HORTICULTURAL SOCIETY OF ABERDEEN.

The following is the report by the directors of the Royal Horticultural Society of Aberdeen to the annual meeting of the members to be held to-day (Saturday, 14th inst.):—"The exhibition of 1899 will long be remembered by those concerned for the great disaster which attended it. The directors wish to take this opportunity of thanking those members of the Society who so willingly came forward after the disaster, and by their efforts assisted in making the show a very fair one after all, from a horticultural point of view. The directors report that the financial result of the year is that there is a balance of income over expenditure of £379s. 7d.,

grateful for these bequests, and hope that this is only a beginning, and that others will follow. The thanks of the Society are due to the Town Council for their kindness in having, as formerly, granted the use of Duthie Park on the occasion of the exhibition."

GREAT NURSERY SALE AT ABERDEEN.

During this last week there was held at Messrs. Ben Reid & Co.'s Nurseries, Granitehill, Aberdeen, one of the most important sales of nursery stock that has taken place in Scotland for several years. The sale was rendered necessary by the expiry of Messrs. Reid's lease of the ground. The whole of the plants disposed of were of the choicest description, and buyers attended from all parts of the country, and although these were principally factors, foresters, and others belonging to estates in the northern counties, there were buyers from the south of Scotland and from England. There were altogether 5145 lots to dispose of, consisting of hardy ornamental Conifers, ornamental evergreen and deciduous trees and shrubs, transplanted forest trees, plants for game coverts and hedges, Roses, &c. There was a keen demand throughout

ing late in September and October; and Late Rivers, the latest good Plum in season, in November.

Of Peaches raised at Sawbridgeworth, which ripen very early, are Early Beatrice, Early Louise, Early Rivers, and Early Victoria, juicy, good-flavoured varieties, with in some cases a very hardy constitution. Lady Palmerston, Osprey, and Nectarine Peaches may be mentioned as varieties extending the season of Peaches at its termination; and there are many more as good. In our climate, very late Peaches are better when grown in pots or borders in an orchard-house, and if the same be furnished with hot-water pipes for use in ripening the fruit, expelling dampness, or protecting the bloom from injury by very severe frosts, so much the better. This remark holds good of late Plums and of Pears, which, except in the finest of summers, do not mature with us.

With the raising of varieties of the Nectarine which should supersede older ones, the firm has been extraordinarily successful, no fewer than twenty being enumerated in the catalogue for 1899-1900. We need only mention Early Rivers, raised by the late proprietor, a splendid-looking fruit, ripening three weeks before the well-known Lord Napier, itself Riversian in origin. The size is for a Nectarine extremely large, and the flavour exquisite. Cardinal is a still earlier-ripening Nectarine, of high colour, and fine and distinct flavour, forming a compact sturdy tree, that bears freely. Rivers' Orange, Stanwick Elruge, Advance, and Spenser are fine varieties, mostly ripening in the month of September. The acquisition of Apples has not been pursued with the same amount of energy, at any rate with success equalling that displayed in breeding Pears, Peaches, Nectarines, and Plums; for we only know of about five varieties, viz., Thomas Rivers, syn. Rivers' Codlin, a cooking variety, of rich flavour, fit for use in the middle of September; Early Rivers, a fruit in shape and colour resembling Lord Suffield, which ripens a week earlier, the flavour sharp and good—it makes a prolific bush, and is not liable to canker. Early Peach Apple is an earlier ripening "Irish Peach," and does not bear its fruits at the ends of the branches; St. Martin's, a richly-flavoured dessert variety, is in season from November to February, and resembling Besspool; and Prince Edward, in season during the same period—a bright yellow fruit, with tender, melting flesh, and brisk flavour.

Much of the interest felt in visiting the Sawbridgeworth nurseries arises from the fact that we see the processes of cross-breeding carried on under our eyes, and survey results at first-hand. The parents of certain varieties were shown to us, and the reasons given for effecting such and such crosses; and in some instances the actual first seedling, as in the case of Rivers' Prolific Plum, is to be observed, showing the effects of age certainly, but still likely to serve as a living witness of successful breeding for some years longer. This variety, in the hands of some nurserymen, would have made a very respectable fortune, but the late Mr. Rivers parted with it to the trade and private customers soon after its good points became generally known, for, as he said, the good of the country.

In looking through the glasshouses, two long, narrow spans were noted, filled with Orange, Lime, and Lemon-trees in pots, and planted in the borders. Many of these are of great age, but the roots being confined to limited areas, the plants are removable without damage or root-disturbance. A considerable number of young trees was observed in another house to meet the demand for this fruit, and the collection is extensive. We noticed Sustain, a nice flavoured St. Michael's; Silver of Plata, Egg. St. Michael's, and varieties of it; blood and oval Malta Oranges, Navel, Tangierine, and Seville; five varieties of Lemons, besides Limes, Shaddocks, Citrons, &c. In some of the houses were Apple-trees in pots, loaded with fruits, most of which had that exquisite colour and bloom not attainable by fruits grown out-of-doors. To preserve the, in many cases, weighty fruits from falling, they were

secured by pieces of bast fixed round the stalks, and the spur or shoots on which they grew. This is done long before the fruits are ripe, in order to prevent losses. King-of Tomkins County, a favourite Nova Scotian and Canadian variety, and one largely imported into this country, brings fine large, high-coloured fruits under glass, although it is useless out-of-doors. We noted very fine Peasgood's Non-such, Ribston, Blenheim Orange, and Cox's Orange Pippins, growing on trees in pots. Several large span-roofed houses were filled with young Peach-trees for fruiting next year, and thus early bereft of leaves, which proved how well matured is this year's wood. A houseful of the largest pyramidal Peach-trees in the world is to be seen here, many of them being 10 feet high, and 5 feet in diameter at the base. Some late varieties were heavily loaded with fair-sized fruits not yet ripe, especially good being the Salway Peach, which can only be obtained at its best from trees grown under glass.

The Fig is largely grown as bushes in houses set apart for it, as are Grape-vines in pots, the stock of which is in capital order, large of cane and wonderfully ripened. The large vineries in which grow the varieties of Vines cultivated for sale, which are allowed to fruit after yielding their quota of "eyes" to the propagator. These old Vines, consisting of all the best varieties, black and white, including La Tisserande and Mrs. Pearson, were carrying more than ordinary heavy crops of well-coloured large bunches, and without a trace of shanking. The earlier varieties were in some cases cleared off the Vines.

Pears were more numerous than Apples in pots, and could be found in some of the glasshouses and in sheltered spots out-of-doors, the pots in the latter case, embedded in soil or coal-ashes. The quantity of fine fruit borne by these pyramidal trees would astonish those unacquainted with the possibilities of pot-culture carried on either in or out-of-doors, for most of the Pear-trees go outside after there is no longer any danger from frosts in May. In the sheds, the re-potting of Peach, Nectarine, and Plum-trees, was in full swing.

OUTSIDE DEPARTMENT.

The area under cultivation amounts to about 200 acres, and this chiefly consists of orchards of bush trees and breaks of young stocks of varying ages. That which bore originally and for many years the young nursery stock is now planted up as orchards, with either bush or low standard Pears, Apples, or Plums, the returns from which are very large, the fruit being superior in size and general appearance, owing to the trees being at the present time at their best. The young stock occupies land which until recent years was under ordinary farm crops.

In surveying the breaks at close quarters, one could not but be struck by the firm, vigorous growth made by the Apples, Pears, Plums, Peaches, Nectarines, and Cherries, in spite of the droughty weather of the past summer; and the thoroughly ripe condition of the wood. In the case of one-year cut-back Pears, so ripe was the wood that the leaves were ready to fall, and had quite lost their vitality. Apples on the Broadleaf and Nonsuch varieties of the Paradise stock have made as good growth as others on the wilding stock. All trees worked on these dwarfing stocks are pruned and trained for pyramids, bush trees, or some form of cordon. The breaks of Peaches and Nectarines worked last year consist of fine stuff.

Of Apricots very fine breaks of maidens and trained trees were observed; the wood of just the right size, neither too gross nor too weak, and well matured. Pears trained as double cordons, cups, horizontal, for covering walls and fences, &c., were excellent.

The new land brought within the boundary of the nursery is of a heavy, loamy nature, admirably adapted for fruit-trees, and one in which they can defy drought with impunity, a condition of the trees prove this year.

The title of the firm, Thomas Rivers & Son, will be kept up by the present owners, Messrs. T. A. H. Rivers and H. S. Rivers, sons of the late T. Francis Rivers.

HOME CORRESPONDENCE.

SENILE DECAY OF ORGANISMS.—On reading a note taken from Professor Sedgwick's address at the meeting of the British Association at Dover, on p. 281 of the *Gardeners' Chronicle*, I had carefully to scrutinise the page and verify the date, lest I had stumbled on a very venerable back number. Some of us who have read the *Gardeners' Chronicle* from its first number had hoped that such notions had not survived to this day. For years before 1841 eminent horticultural authorities believed in senile decay, and the wearing out of species and varieties. Even Thomas Andrew Knight seemed disposed at one time to give up such popular varieties of the Apple as the Golden and Ribston Pippins, as being at that date less fruitful and vigorous. Possibly few gardeners will quite grasp the Professor's meaning when he says that there is no reason to suppose that the separative process of any organism is sufficiently complete to prevent senile decay. If this be so, then is Nature but a poor evolutionist after all. I have not so read the life, the laws, and the work of Nature. To me there is abundant evidence that the recuperative processes of every organism are not only sufficiently powerful and complete to prevent senile decay, but to develop yet higher, stronger, better, and more durable developments. [Do not Oaks and Wellingtonias, as well as Ribston Pippin trees, grow old, and at last perish entirely? Ed.] This is how I have read Darwin's theory of evolution, and is not his view and teaching shown in our improved fruits, flowers, and vegetables? Some of the older vegetable physiologists went so far as to assert that neither seeds nor buds were likely to live longer than the plant from which they were taken. Thus not a few expected to lose the Ribston Pippin root and branch when fruit had been amongst us for a century. And here we have the old doctrine in a new setting by Professor Sedgwick, as we find him virtually saying on p. 281 we cannot prevent senile decay. The age a plant from which grafts are taken becomes a matter of importance to gardeners. And he goes on expressly to say that with regard to buds, they share in the growing old with the parents. This is simply a truism. But if the Professor means, which is evident from the context, that the buds share in this senile decay of the parents, then the experience of practical men, and the vigorous life of hosts of old species of trees and plants, disprove of any such theory. I thank the Professor for lucidity and incisiveness of his closing sentence in the *Gardeners' Chronicle*, as if we suppose the average life of the individual to be a hundred years, a bud removed at fifty will be fifty years of age, and be able to live on the graft for fifty years more. But science and experience prove this absolutely. A bud fifty years old is inconceivable. The life of the average bud is seldom more than a year. In growing into a flower, a leaf, a fruit, a branch, a stem, it ceases to be a bud, and may be subject to different laws. Even the ages of individual plants and trees are wholly empirical. On what principles of logic or collection of facts shall we measure the life of an individual by a thousand years, and of an Apple-tree at a hundred years? Neither can the theory of a natural twist or bend towards senility or decay hold water. We have thousands of facts throughout the closing century pointing the other way. Through the use of improved dwarfing and other stocks, stronger or more concentrated manures, improved soils, and greater cultural care and skill, our seeds, buds, scions, and cuttings have been vastly strengthened and improved. The age of senility, if it ever existed, has ended, and a new era of strength and higher evolution has set in. Nowhere is this more visible than among our older Apple-trees, such as the Ribston Pippin. Go where we may among young, well-grown trees, we note no sign of decrepitude in root or stem, or branch or fruit; and never were so many fine Ribston Pippins grown in Britain as to-day. And yet, according to the latest theories, the parent buds of these model Ribstons have already seen their fifty, sixty, seventy, eighty years out of their possible hundred years of life. Yes, and their progress during the last fifty years at least has been upwards and onwards, and not downwards. D. T. Fish, F.R.H.S.

GARDENERS' ORPHAN FUND.—With your consent I should like to make a suggestion in reference to the above-named fund. What I am wishful to

allude to is, the possible use of the very excellent little booklet issued some time ago to many if not all subscribers thereto. To my mind, the idea of the booklet is a very good one. It contains twenty receipts with counterfoils, each one to represent a sum of 1s. or upwards. The time is at hand when horticulturists of all sections will meet in large numbers at the many Chrysanthemum exhibitions held all over this country. After the various exhibits have been examined and criticised, there usually comes a time when they form into groups to discuss the varied subjects of interest to the craft. Without trespassing on the means of visitors, anyone interested in the Orphan Fund can then suitably use his or her booklet to advantage. To those who may not have one by them, I have no doubt a post-card sent to the Secretary, Mr. Wynne, No. 1, Dane's Inn, Strand, London, W.C., would at once be attended to. Collectors get one vote at the annual election for each 5s. sent to the head office. Let us hope a good number of booklets may be sent up before the year ends. *Northern Subscriber.*

ROSA CAMELLIÆFLORA.—I am not sure if this Rose is known to English growers, nor am I able to give its origin or the name of the raiser, as I have seen only one truss of it, and that was quite enough to fire one with a desire to possess it. I take it to be a Hybrid China; the flowers are large, full, double, and of a finely-cupped form; the colour purple, shaded-crimson. But then it is very highly fragrant, which suggests that it possesses the blood of this fragrant group; the flower stems are strong and rigid; the buds long and pointed. As a late-flowering fragrant Rose it is invaluable. Can anyone give information as to its origin? *R. D.*

BLACKBIRDS, ETC., AND FRUIT.—I have been much interested with the several notes appearing of late with reference to "our feathered friends," but more especially concerning the thrush. In Mr. J. Hart's note of September 30, he says, "The thrush is a gentle, innocent bird, and that he does not attack large fruit on trees and walls." My experience is that he does attack large fruit on trees and walls, and very much so. As for netting fruits, I have tried it in a good many different ways, and for all kinds of fruit, small and large, but have never been successful in keeping out thrushes and blackbirds. It may be very well in a small garden containing a few fruit-bushes or a small plot of Strawberries, but in a large place where everything has to be netted, I find that after the net has been put on it is necessary for someone to be on the spot the whole of the time if the birds are to be kept out. Apart from the small fruit, they are most destructive here amongst the Plums, Apples, Pears, and Figs. In these gardens we have several very large old Fig-trees growing in the moat; the largest of these trees, a Brunswick, had a fine crop of about twelve dozen fruits this season, which were bagged in the ordinary course, as we have to put all Figs just previous to ripening into bags made of a brown, coarse muslin. Out of the twelve dozen fruits we managed to get less than four dozen; besides these, were five dozen new bags being pecked to pieces to get at the fruit, and the other trees were served nearly as badly. The wholesale destruction of the Figs and bags, and labour thrown away, I have to place chiefly to the credit of the thrush, which, apart from a very small bird unknown to me, which took a few of the earliest fruit before the bags were put on, is the only depredator. On several occasions I have watched him pecking his way through the bag and coolly devouring the Fig; and no ordinary amount of commotion seems to frighten him, and then only to return again as soon as one's back is turned. On two occasions this season I have found Mr. Thrush in the vinery eating the Grapes. Granted the thrush makes off with a quantity of worms and snails, &c. But what are they compared with the wholesale destruction of which he is capable? In conclusion, I fail to recognise the thrush as a gentle, innocent bird from a gardener's point of view. *C. Dales, Walmer Castle Gardens, Kent.*

TEA-SCENTED ROSES.—In the *Gardener's Chronicle* of October 7, p. 275, we noticed the following remarks on Tea-scented Roses:—"The two most conspicuous are Empress Alexandra of Russia and White Maman Cochet. The former is one of those dark-coloured Teas which some people admire, but which I, for one, think spoil

the chaste and delicate beauty of the stand in which it appears. I think one of the great charms of the Tea-Rose is its delicacy and refinement, and these very highly-coloured flowers greatly interfere with that characteristic." We thought by the introduction of this exquisite Rose with its distinct and beautiful colour of red and orange, we were offering to the public an original long sought-for desideratum; and that others thought so too was made manifest by the Award of Merit it obtained from the Royal Horticultural Society, and the large sale it met with. But does the presence of a dark beauty "greatly interfere" with the "delicacy and refinement" of her fairer sisters? We think it will be said by some—nay, rather it tends to heighten and adorn them. Be that as it may, we venture to predict that we shall now shortly acquire a host of high-coloured Tea-scented Roses which many lovers of this flower have long sighed for, but sighed for in vain. *Wm. Paul & Son, Waltham Cross.*

HELENIUM AUTUMNALE VAR. STRIATUM is correct. All of our Compositæ vary, and many distinct forms can be had by selection. Hybridisation among North American Compositæ is rare, though it sometimes occurs. Dr. Gray, in his *Synoptical Flora*, notes its occurrence in a species of *Vernonia*, a fact I have demonstrated by actual experiment. Often what are considered hybrids are variations, nothing more. The opportunities for cross-fertilisation in our Compositæ are rare, chiefly confined to cases where the ligulate corollas are female only. A curious fact is, that when pistillate ligulate flowers become tubular, they change to hermaphroditism. *Thos. Meek, Germantown, Philadelphia.*

LILIUM CONCOLOR VAR.—I have a quantity of bulbs of a form of this Lily which were sent me about twenty years ago from China by the late Consul Swinhoe, which, during the whole of that time have refused to flower in my garden, though I have tried it in various places. I shall be happy to send bulbs to any Lily-growers who would like to try it. I expect a warmer and wetter climate is what it wants. Apply to *H. J. Elwes, F.R.S., Coleshorne, Andoversford, R.S.O., Gloucestershire.*

LATE NESTING OF THE SONG-THRUSH.—There is at the present date (October 17) in the pleasure-grounds here a song-thrush sitting upon four eggs. Is not this an unusual occurrence? *William Coomber, Houghton Hall Gardens, King's Lynn.*

THE NATIONAL CHRYSANTHEMUM SOCIETY'S FLORAL COMMITTEE.—The new rule which recently came into force has caused a good deal of "feeling." Rule 4 now reads, "and no certificate shall be awarded to any new variety unless it receives the support of three-fourths of the Committee present, but if not more than ten members [are present] the voting must be unanimous." On the 28th ult. I sent a basket of plants of a yellow sport from Lady Fitzwigram, and because only eight out of a possible eighteen members had sufficient interest in their work to attend the meeting, the trouble and expense of packing and sending the plants 200 miles and back again was in vain, and I may grow another batch for next September with a like result. But the meeting of the 10th inst. gave us an example of the working of this ridiculous rule. At 1 o'clock, the time appointed, not a member was present; shortly afterwards the Secretary was in his place; later on, a few of the Committee joined him, but all waited to see if the number necessary to do business would attend. The Secretary sees a few stragglers and calls them to the table, and business commences. Only two varieties were presented for certificates. Being interested in one of these, I will pass on to the variety staged by Mr. H. Weeks. It was proposed that a Certificate be awarded, and a majority supported the proposition, but as it did not receive the support of three-fourths of the Committee the Certificate was lost. Then a farce was played. Very few of the Committee were aware of the new rule, and wanted to know when such a "ridiculous regulation was made," &c. Explanation followed, and the proposition for the Certificate was put again, and more hands were held up in its favour but still not sufficient. Then more Committeemen appeared, and the matter was explained to them. Again the proposition was put, and still not sufficient votes were recorded to make it absolute. More discussion followed as to the wisdom of the rule. Finally, and some thirty minutes late, another member of the Floral Committee was seen

to be hurriedly approaching the table, and the blooms were handed to him for his opinion. Wonderful to relate, the Chairman again put the proposition for a Certificate to the meeting. Result: 11 for, 4 against; and in the words of a Committeeman "the Certificate was lost by the third of a man." Ultimately, amid high words, the Chairman dissolved the meeting. No one can object to the action of the minority of four, who conscientiously voted against the Certificate. As a protest, it is at present my intention not to place any blooms before the Floral Committee for the whole of the coming season. *W. J. Godfrey, Exmouth.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

OCTOBER 10.—*Present:* Dr. H. Müller, in the Chair; with the Rev. W. Wilks, and the Rev. G. Henslow, Hon. Sec.

Potatoes with Scab.—A number of samples were received with the descriptions of the matures supplied. They were forwarded to Dr. Smith for examination and report.

Fungus on Chrysanthemum Leaves.—Some leaves badly spotted with a brown fungus were received and forwarded to Dr. M. C. Cooke for further examination, who reports as follows:—"The Chrysanthemum disease is the 'rust,' which I refer to *Uredo Hieracei*; but I cannot tell for certain until the Puccinia is found. I had it two or three years ago on leaves sent from Slough. It is capable of spreading, and I should destroy all the infected leaves by burning, if sprinkling with Condy's Fluid prove ineffective. It is better to sacrifice the entire plants, than for it to establish itself as a permanent pest, like the Hollyhock disease (*P. Malvacearum*), to which it is allied. It is impossible to give the cause, but probably infection from other plants."

Five-nerved Eucharis.—A blossom of this plant, with its whorls regularly arranged in series of fives—most unusual for a monocotyledon—was received from Mr. E. Escombe. An examination revealed the fact that it originated in the coherence of twin flowers. The stem a short distance below the base of the inferior ovary contained very numerous and scattered fibro-vascular cords. Nearer the flower they became thirty in number, and so entered the base of the twin ovaries. These were united by a common wall, in which two of the cords normal to the ovaries were suppressed. Hence the superficial cords were now reduced to ten only. This number, therefore, laid the foundation of the supply for the four whorls (perianth and stamens) of five parts each. Apart from the two united ovaries of three cells each, and six rows of ovules in each cell, no trace of the twin origin was visible.

Chrysanthemum arrested.—Mr. E. H. Jenkins, of Hampton Hill, sent branches of the variety *Madame Desgranges*, in which the majority of the flowers were very small, with yellow petals on short stiff branches. There had been great difficulty in expansion from the bud. This was considered to be due to the excessive drought. The later flowers were nearly normal on slender pedicels. It was remarked that various kinds of Chrysanthemums had behaved in the same manner elsewhere, as well as other Compositæ, such as *Rudbeckias*. The cultural care had been quite correct, but while one plant was a failure, another in the same pot was normal. Such cases are not uncommon, some individuals succumbing to a disease, while others, under the same conditions, may resist it. Mr. Jenkins asks if the form represents the original type. It does to some extent, being like the double form of the small *C. indicum* cultivated at the beginning of the century, and figured in the *Transactions of the Royal Horticultural Society*. It shows a tendency to arrest and reversion. The actual cause is obscure, but it would seem to be most probably climatal.

BRITISH MYCOLOGICAL.

OCTOBER 2 TO 7.—The Annual Meeting of the above society was held this year at Lyndhurst, Hants. Three of the members attended the meeting of the Scottish Cryptogamic Society the week before, for distance is no object when fungi are in view. These meetings of mycologists themselves testify to this. But some of your readers may ask, what is a mycologist? Gentle reader, mycologists are beings who appear only in the autumn, generally somewhat shabbily-dressed, but wearing stout, well-nailed boots. They carry baskets or tin boxes, and when two of them meet, converse with great vivacity in a language quite their own, in which the words *Hymenomyces*, *Fries*, *volva*, *Agaricus*, *pileus*, and *mycelium* frequently occur.

The excursions on this occasion were under the guidance of the Rev. W. L. W. Eyre, who, duly equipped with baskets, waterproofs and whistle, led the party on the first day through some fine young Fir plantations. *Tremellodon gelatinosum* was the first find, followed soon after by a *Polyporus* on fallen Fir trunks; *P. spongiosus*, Fr., and *P. amorphus* quickly followed. In vain the leader blew his whistle, every dead stick and every rotten stump had to be examined. Miss Annie Lorrain Smith, of the Cryptogamic Department of the British Museum, who acted as referee for the "Micros,

lighted upon a bed of *Mycena Iris*, Berk., while another of the members was to be seen in the centre of a Bramble-bush calmly collecting the leaves, which, he maintained, were infected with *Phragmidium albidum*, a Uredine recently added to our flora. *Rhizopogon rubescens* was found in abundance on the pathway in company with great quantities of *Lactarius deliciosus* and other Fir-wood species. The visit was paid in the forest in the nick of time as far as fungi was concerned, recent heavy rains following a comparatively prolonged season of drought had brought fungi up in great profusion. The large number of Boleti found was a special feature of this meeting. Twenty species were met with, including several uncommon ones, such as *B. duriusculus*, *tenipes*, and *calopus*. Two species the present writer had never met with before, viz., *Boletus candicans*, Fr., figured by Saunders & Smith, t. 17, and *B. aereus*, Bull.

Wednesday (October 4) proved a wet day, and the party consequently got thoroughly soaked. It was none the less a successful day, for Mr. Eyre lighted upon that truly beautiful—*Mycena*, M. aurantio-marginata, a plant of extreme rarity. *Cortinarius milvius*, Fr., was also met with, as well as *Sparassis crispa*; but what seemed to arouse the enthusiasm of the moist mycologists most was a magnificent crop of *Poronia punctata*. This is not so very rare a fungus, but is one none of us had seen growing in anything like such perfection before. On the subsequent days *Cortinarius raphanoides*, *Leptonia formosa*, *Russula corulea*, *R. lactea*, Fr., var. *incarnata* were found. Mr. and Mrs. Rea, unable to tear themselves away from these Elysian fields, stayed a few days longer, and found *Boletus flavidus*, *Irpex obliquus*, *Complidius gracilis*, *Hydnum cinereum*, *Poria umbrina*, *Polyporus Schweinitzi*, and many other good things.

In the evenings papers were read. First, of course, the address of the President, of which great things were expected—but it turned out (in his own opinion, En.) a terribly dry affair, although it was listened to with respect, and will no doubt find a prominent place in the *Transactions*; still, the summary of ten years' work amongst the Uredinee is not a very lively topic for an after-dinner audience; but those who want to know what new species have been added to our flora, what life-histories have been worked out and so forth, will have to buy the forthcoming number of the *Transactions*.

Dr. M. C. Cooke was not able to be present: this we all regretted, because many of us were anxious once again to meet him and to let him know how we at least appreciated his half-century's work on this branch of science. He sent a poetical retrospect of old Woothean memories of—

"The years that are gone
When friendships were many and defections none."

In this the various members who used to attend these historical fungus forays were referred to, beginning with—

"The genial Doctor, everywhere so known,
Alas! too soon the Master claimed his own."

And Mr. C. E. Broome, so many years the colleague of the Rev. M. J. Berkeley—

"Learned and wise, but taciturn and slow
To offer judgment when he did not know."

And the

"Dear Canon, such a jovial parson he,
Like jolly monk of sage antiquity;
Canon and pipe are silent now. Alas!
Whom the Gods love—"

Dr. Cooke's communication, however, finished in a somewhat less pathetic strain—

"So fill your glasses for another toast,
Don't let the opportunity be lost,
Let it be bumpers as you close the book,
And just another hip for poor old Cooke."

Mr. Crossland's paper on "*Mollisia cinerea* and its Varieties," was a very carefully-prepared account of this obscure and difficult problem. Mr. T. Howse read a paper on "*Fungi in the Alps*," which made us all wish we were there under his guidance to gather some of the treasures he had found. Fortunately, the Rev. W. L. W. Eyre's "*Notes on Hampshire Fungi*" came as a corrective. He kindly had copies printed, which he distributed to the members, of his list of the fungi found by him in the county—and such a list it was! We felt after all there was no place like home.

It was decided that the invitation of the Scottish Cryptogamic Society should be accepted, and our next meeting be held under the presidency of Professor Marshall Ward, F.R.S., somewhere in the far North in the Pine-forest of Rothiemurchus. C. R. P.

THE LOUGHBOROUGH GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

OCTOBER 3.—The third annual exhibition of fruits and flowers was held in the Corn Exchange, Loughborough, on the above date, and a very fine display of "Hardy Fruits," in 385 dishes, was made by the members and other residents of the district.

Mr. H. MERRYWEATHER, of Southwell, Notts, staged forty dishes of Apples of great merit, amongst them being fine specimens of Peasgood's Nonsuch, Bramley's Seedling (very fine), Gascoigne's Scarlet Seedling, Prince Albert, Gold Medal, Royal Jubilee, The Queen, Bismarck, Lady Sudeley, Ecklinville, Cox's Orange Pippin (of very large size), and Lord Derby.

JAMES ELLIS, Esq., The Gynsills, Leicester (gr., Mr. Needham), showed sixty-five dishes of orchard fruit, and made a

useful object-lesson to fruit-growers, the fruit being of much excellence.

Amongst the members of the Association who contributed collections of fruits were the Rt. Hon. Lord BELPER, Kingston Hall, Derby (gr., Mr. W. English), seventy-four dishes Apples and Pears; HUSSEY PACKE, Esq., J.P., D.L., Prestwold Hall, (gr., D. Roberts), fifty-two dishes Apples and Pears—of the latter, Pitmaston Duchess, General Todleben, Uvedale St. Germain, and Catillac, being very noticeable fruits; C. T. PARKER, Esq., J.P. (gr., J. Powell), fifty-five dishes of Apples, Pears, Siberian Crabs, and Plums; J. CLARKE, Esq. (gr., Mr. C. Hartis), contribute twelve dishes of excellent Apples, and very fine Marie Louise Pears. Messrs. Fitterton, Hickling, Smith & Son, and Tucker & Son contributed fruit to the Exhibition.

Messrs. J. SMITH & SONS, Derby Road Nurseries, showed a very fine lot of Pompon and Cactus Dahlias, backed up with good, well-bloomed early-flowering Chrysanthemums, all making a most effective display. The Dahlias consisted of the most modern varieties, put up in triplets.

Mr. H. HECKLING staged *Gladiolus* spikes, eighteen varieties of Cactus, and thirty-six varieties of show Dahlias, the latter being of great excellence, especially the varieties Mrs. Saunders, Perfection, Mr. Chamberlain, Colonel, Mont Blanc, John Heckling, Mrs. Langtry, and Mrs. Kendal.

In the evening Mr. E. A. Merryweather delivered a lecture upon "The Incidental Care of Fruit-trees, in order to produce the best Results." The lecturer dwelt on the proper preparation of the soil, its nature; planting, staking, and pruning, both root and branch; manures, insects injurious to fruit-trees; storing, and grading fruit's for sale.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT.

OCTOBER 4.—The sixth annual exhibition of fruit and honey was held at Ryde Town Hall on the above date. The exhibits consisted of over 400 dishes of fruit, which showed a marked improvement in quality over last year's exhibits.

The Hall was given a very nice effect by the intermixing amongst the dishes of fruit, plants of *Dracenas*, Palms, Ferns, &c., kindly lent by Mr. JOHN DUMMICK of Ryde. The exhibition, which was non-competitive, gave every exhibit an opportunity of receiving an Award according to its merit.

The principal exhibitors were Admiral Denison, Woodside, Wootton (gr., Mr. W. Taylor); J. J. Thornycroft, Esq., Steyne, Bembridge (gr., Mr. T. Collier); Lady Daly, St. Wilfred's, Ryde (gr., Mr. Geo. Honeybourne); Lady Atherley, Langard Manor, Shanklin (gr., Mr. S. Banks); J. O. Brook C.C., Ryde (gr., Mr. W. Spragg); W. H. Chatfield Clarke, Esq.; C. A. Cleveland, Niton (gr., Mr. H. Jacobs); and Messrs. I. Webber, W. Hillier, F. Orchard, R. Coleunt, J.P.; G. Lipscombe, G. H. Bart, T. Gibbs, C.A.; and Geo. Williams. Silver Medals were awarded to the exhibits of Admiral Denison, Mr. Thornycroft, Lady Daly, and Lady Atherley. A Bronze Medal was awarded to Mr. Geo. Williams.

A First-class Certificate was awarded Messrs. J. CHEAL & SONS, of Crawley, for a fine collection of fruit, consisting of over eighty dishes of Apples and Pears.

EDINBURGH FIELD NATURALISTS AND MICROSCOPICAL.

OCTOBER 7.—On the above date the members of this Society held their annual fungus foray in Niddrie grounds by the permission of the proprietor, Major-General Wauchope. A large number of ladies and gentlemen turned out for the occasion. The weather being fine, the woods looked lovely, dressed in their autumn tints. Owing to the dry summer, fungi were rather scarce, yet about twenty species were gathered.

Among the rarer of these were *Lepiota rhacoles*, *Pluteus cervinus*, *Agaricus personatus*, *Polyporus hispidus*, *P. giganteus*, and *Lycoperdon saccatum*. The rarest of all, however, was the Jew's ear fungus, *Hirneola auricula Nida*, which was growing in profusion on Elder-trees. The fungus, in appearance somewhat like a human ear, is seldom found in Scotland, at least in the eastern part of the country. How the popular name of Jew's ear arose is not quite certain. It is said to be a corruption of Judas' ear, and the fungus is usually found on the Elder, generally on old trees. According to medieval tradition, Judas hanged himself on an Elder, with the result that his ear in the form of this fungus has been found on it ever since. It is also supposed that the name originated in the days when hatred against the Jews was a mania. The kings of England knew how to get money from the Jews when their Christian subjects refused it. At such times, the protection of the Crown was suspended from these money-lenders, and a Jew's ear was a very common adornment of the pillory. Then, when people came across this remarkable fungus sticking out from the bark of a tree, and having such a striking resemblance to the human ear, what more natural than they should liken it to the ear of a Jew, lopped off and nailed to the tree?

In dry weather the fungus shrivels up, and becomes hard and horny, but in wet weather it is soft and elastic, almost gelatinous. This sponge-like quality, combined with its edibility, has given it a value as an article of commerce. The Chinese, fond of all kinds of gelatinous animals and plants, from which they make their soups, are particularly fond of Jew's ears, and they import large quantities of an allied species from New

Zealand and the South Sea Islands. The quantity of this fungus exported to China is enormous, the annual value being upwards of £25,000. The plant requires no preparation for market beyond collecting and spreading it in the open air or in sheds for a few days to get rid of the moisture. When dry, it is packed in bags and shipped to China by way of Sydney and San Francisco.

Several fine old trees and some beautiful Conifers were observed in the course of the ramble over Niddrie estate.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

THE opening meeting of the autumn session of the Reading and District Gardeners' Mutual Improvement Association was held last week, when an interesting hour was spent on the subject of "Successes and Failures of the past Season."

This was opened by Mr. H. WILSON, gardener at Lower Redlands, and from the experience elicited from Messrs. Neve, Stanton, Bound, Townsend, Exler, Chamberlain, Woolford, Alexander, and Hinton, a good opinion was formed of the crops in the neighbourhood. Early Peas were good; the later crops in most places a failure. Beans fairly good, Potatoes good, Carrots good, Cauliflowers nearly a failure, Turnips similar, Lettuce poor, Onions very good, Spinach a failure, but a splendid substitute when this crop fails was found in Spinach-Beet. Fruit of better colour, and clearer than usual. Peaches (outdoor) very good, Plums very good, Pears very good, Apples very good, Cherries very good, Currants and Gooseberries excellent; Strawberries, some varieties, very good indeed. The best flowers to withstand the drought proved to be fibrous-rooted Begonias, Godetias, Nemesia, Antirrhinums, Verbenas, Petunias, and Phlox Drummondii.

The exhibits consisted of a splendidly-flowered Orchid, *Miltonia candida*, shown by Mr. LEVER, gr., Hillside; a bunch of Sutton's Scarlet Queen Salvia, by Mr. E. FRY, The Gardens, Greenlands; and a grand specimen of Alfriston Apple, weighing 1 lb. 10 oz., by Mr. FARLY, Balmore Gardens.

As it was the first meeting held by the Association since the death of Mr. James Martin, who had been a member since its formation, the President, Mr. C. B. Stevens, referred to the great loss the Association had sustained by his death, and said that he had become one of the most practical men in his profession; there might be greater theorists, but more practical men none. He was a friend to every gardener, and it was his characteristic to impart to them the knowledge he had obtained. His death was a great loss to their Association, and to the great firm by whom he was employed. Messrs. Woolford, Stanton, Neve, Macdonald, and Dore also spoke to the great interest shown by the deceased in all things appertaining to their profession. It was suggested that some memorial should be raised, and it was decided to bring the matter forward at the next meeting.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

OCTOBER 13.—The members of the Committee present on the above date were Messrs. G. Shorland Ball, W. Thompson, J. Cypher, W. Stevens, W. B. Upjohn, R. Johnson, and P. Weathers, Sec.

S. GRATIAX, Esq., Whalley Range (gr., Mr. McLeod), showed *Sophro-Cattleya* × *Cleopatra* (*Sophronites grandiflora* × *Cattleya Leopoldi*), the flower in size was nearly as large as those of the latter parent, and was of an intensely dazzling bright crimson colour (First-class Certificate). *Cypripedium insigne* Gratiarum, from the same collection, was simply a good form of *C. insigne*. *Cypripedium tessellatum* porphyreum, a portion of the original plant, received an Award of Merit; I have seen much darker forms, but the plant had been in flower for some time, which possibly accounted for its pale colour. *Cattleya* × *Ingrami* was also good, though it did not show the influence of *C. aurea* in the lip so well as I could have wished (Award of Merit).

W. THOMPSON, Esq., Walton Grange, Stone (gr., Mr. Stevens), had a magnificent *Odontoglossum* called *O. crispum* var. *Daphne*, which received a First-class Certificate. Mr. Stevens thinks there is the blood of *O. × Wilckeannum* in this plant. The markings are quite extraordinary, being a kind of brick-red, in which there is a tint of violet (see fig. 103, p. 307).

J. LEEMANN, Esq., Heaton Mersey (gr., Mr. Edge), sent two *L. × Cattleya* hybrids, receiving an Award of Merit for *L. × C. Antimachus*, *C. gigas* × *C. Dominiana*.

G. SHORLAND BALL, Esq., Wilmslow (gr., Mr. Gibbons), sent a collection of plants, amongst which were some well-grown examples of *Oncidium tigrinum*, with huge growths and flower-spikes. A Cultural Certificate was awarded for these, and a First-class Certificate for a pretty plant of *Oncidium ornithorhynchum album*.

Mr. J. CYPHER, Cheltenham, showed *Cypripedium* × *Memoria Moensii*, which has already been awarded a First-class Certificate. This is certainly one of the best and most striking hybrids in cultivation, and it is a pity its exact parentage is not known.

Mr. A. J. KEELING exhibited a fine form of *Cypripedium Charlesworthii*, called *splendens*; a form of yellow *C. insigne*, which was not sufficiently developed to determine; and a fine form of *Laelia prestans magnifica* (Award of Merit).

Mr. W. B. UPJOHN, Worsley, showed a fine spike of *Cymbidium Tracayanum*, a form identical with that in Baron Schroder's collection, and much superior to most varieties of this species. P. W.

MARKETS.

COVENT GARDEN, OCTOBER 19.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

— lancifolium rubrum, per doz. 3 0-4 0	

POTATOS.

Hebrons, Puritans, Main Crop, Up-to-Date, &c., 60s. to 90s.; John Bath, 32 & 34, Wellington Street.

REMARKS.—Brussels Sprouts and Cabbages are coming very good. Grapes and Walnuts are plentiful and good, at moderate prices. Apples remain about the same price, excepting superior samples. There were on sale to-day some home-grown Red Currants, of good sample, but there is no demand for them. The Cranberries in cases are of the Cherry shape; those in kegs the Russian, and are similar to Red Currants.

SEEDS.

LONDON: October 19.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that there were but few buyers on to-day's Seed market, and but little business was transacted. Meantime, Clover-seeds, all round, although quiet for the moment, keep remarkably steady in value. The most interesting feature this week is a further sharp rise in the price of Italian Rye-grass. Full quotations are maintained for Mustard, Rape, and Linseed. Canary seed, with a strong undertone as regards value, is just now slow in demand; whilst Hemp-seed, with arrivals of new seed close at hand, comes cheaper. For Blue Peas, Haricot Beans, and Spanish Lentils, the tendency is upwards. The Board of Trade Returns give the imports of Clover and Grass-seeds into the United Kingdom for last month as cwt. 14,916, value £21,857, as against cwt. 16,590, value £32,805, for the same month of last year.

The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.)

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

GARDENING APPOINTMENTS.

- Mr. E. YOUNG, Foreman, Wadhurst Park Gardens, Sussex, as Gardener to W. PARROTT, Esq., Biddlesden Park, Brackley.
- Mr. R. BURTON, formerly of Norbury Hall, Derby, Woodside Garden, Darlington, and for the past three and a half years General Foreman at Spring Grove House Gardens, Isleworth, as Gardener and Bailiff to G. A. HODGSON, Esq., Smallwood Manor, Staffs.
- Mr. THOS. SHARPE, late outside Foreman at Cullen House Gardens, N.B., as Gardener to R. M. LAMB, Esq., Cleadow House, near Sunderland.
- Mr. T. R. CUCKNEY, recently Gardener at Cloverley Hall, Whitechurch, Salop, and previously Gardener at Elen Hall, Penrith, as Gardener to the Earl of DARNLEY, Cobham Hall, Gravesend, Kent.
- Mr. B. CALVERT, for the past five years Head Gardener at Hallingbury Place, Bishop's Stortford, as Gardener to Mrs. FLETCHER, Oak Lawn, Edenbridge, Kent.
- Mr. F. COMLEY, late Gardener to HERBERT WESTROP, Esq., of South Lodge, Enfield, as Gardener to G. J. GRANT, Esq., Beaumont Manor, Wormley, Herts.
- Mr. C. ALLEN, late Foreman at Berry Hill Gardens, Taplow, as Gardener to Mrs. MIDDLETON, Haselbeech Hall, Northampton.
- Mr. CHAS. DAVENPORT, late Gardener at Marshalls Park, Romford, Essex, as Gardener to Mrs. GOAD, Hackbridge House, Carshalton, Surrey.
- Mr. T. T. SHEPPARD, formerly in the gardens at Belvoir Castle and Welbeck Abbey, as Gardener to A. B. MARKHAM, Esq., Stuffwood Hall, Mansfield, Nottinghamshire.
- Mr. A. HAMSHIRE, for the last fourteen years Head Gardener at Beaumont Park, near Loughborough, Leicestershire, has been appointed by the Asylum Committee of the Corporation of Leicester to the management of the gardens, farm, and grounds of the Borough Asylum, at Humberstone.
- Mr. ALEXANDER MCVINISH, late Gardener at Lockington Hall, Derbyshire, succeeds Mr. Hamshire as Head Gardener at Beaumont Park, Loughborough.
- Mr. PETER HARPER, late Head Gardener at Aithorpe, Inverness, and in a similar position previously at Westerlie, St. Andrews, and D. Janan Ali Rais, El Biar, Algiers, as Foreman Gardener to MALCOLM INGLIS, Esq., Montrose, Donnybrook, Co. Dublin.
- Mr. ROBERT MILNE, late Foreman in the gardens of Montrose, Donnybrook, as Head Gardener to Sir JOHN DILLON, Bart., Lismullen, Navan, Co. Meath.
- Mr. W. FLOOD, for the past fourteen years Head Gardener at Wichnor Park, Burton-on-Trent, as Head Gardener to E. A. LEATHAM, Esq., Milsard Park, Cirencester, Gloucestershire.
- Mr. EDWARD REID, formerly at Houndswood, Capel Manor, and Wood End Gardens, as Gardener to S. J. GIBBONS, Esq., Grove House, Northfleet, Kent.
- Mr. A. SUTHERLAND, for the past two years outside Foreman at Houston House, Renfrewshire, N.B., as Gardener to Surgeon Lieutenant-Colonel JOHNSTONE, Newton Dea, Aberdeen, N.B.
- Mr. J. A. ROERS, several years Foreman and Decorator in the gardens for Mr. A. DE ROTHSCHILD, has succeeded Mr. HERRIN as Head Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead, Bucks.

AREA OF LAND TO PROVIDE VEGETABLES AND POTATOS FOR FIFTY PERSONS: W. H. N. Nothing under 6 acres. Number of men: five men, and in summer two women or boys. If horse implements be used in cultivation, three men would suffice, provided there are no wall-trees, glass-houses, or much forcing to be done.

BANANA CULTURE: *Anxious*. See our Calendar for "Fruits under Glass" in the present issue.

BEGONIA GLOIRE DE LORRAINE: J. B. Your plants are now showing bloom, or should be, and may therefore be removed to a light house, having an intermediate temperature. This beautiful Begonia delights in considerable heat and moisture during the period when growth is being made. The amount of syringing done now must be determined by circumstances, but you are more likely to do harm than good by frequent applications. You may shade from bright sunshine.

BOOKS: W. T. W. We are unable to advise you. Why undertake to give lectures when you know so little of the subject?—C. A. B. Watson's *Cactus Culture* (Upcott Gill); *Manures*. By A. W. Crews, the Field Office; and *Artificial Manures*. By Alf. Sibson, to be met with at the second-hand book-shops. There is no modern work on table decorations that we know of. The best forestry work is Dr. Schlich's *Manual of Forestry*, four vols.; then there is *The Forester*, by Brown & Nisbet, published by W. Blackwood & Sons; and for Orchid cultivators get Williams' *Orchid Manual*, published by the author, Paradise and Victoria Nurseries, Upper Holloway, N.

CHRYSANTHEMUM: T. B. P. P. You selected the buds rather early—a circumstance that usually

tends to coarseness in the flowers; but the difference is not sufficient to wholly account for the condition of your plants. It is a very delicate matter in the culture of such plants as the *Chrysanthemum* to feed as highly as possible without bringing about the penalties attending "over" stimulation.

CORRECTION: In Mr. Young's *Orchid-house Calendar*, in our issue for October 7 last, he was made to say that the *Orchid-pots* should be washed with soft-soap and hot water. This we desire to correct, soft-soap being rather injurious to the roots of *Orchids*, and scrubbing hardly less so.

CUCUMBERS: *Old Subscriber.* Assuming that you are that which you sign yourself, and have read your *Gardeners' Chronicle* carefully, you should not stand in need of any instruction in cultivating the *Cucumber*. Pray examine back numbers for calendarial directions. The cultivation of the plant is, in the main, the same in private as in market gardens.

CYCLAMEN: *H. E. G.* The grub eating your *Cyclamen* is that of one of the weevils. They are extremely destructive, and difficult to catch. You might try the effect of applying clear lime-water. The soil used is infested with them, and should be baked before making use of it in potted plants.

EXHIBITIONS FOR POTATOS: *J. N.* You may exhibit tubers in competition at many of the larger *Chrysanthemum* shows to be held during this month and next; for instance, at the National *Chrysanthemum Society's*, to be held at the Aquarium on November 7, 8, and 9 (for prizes offered by nurserymen); at Edinburgh, November 16, 17 and 18; Birmingham, Southampton, &c. In each number of *Gardeners' Chronicle* we give a list of shows for the week; and at the commencement of each month a list is given of the principal shows that will occur during that month.

FERTILISATION OF ASPIDISTRA FLOWERS: *T. J. D.* The fertilisation is effected by slugs.

FRUIT-TREE STOCKS: *C. A. B. K.* See issue for March 9, 1889. Mr. G. Bunyard's paper, read at Rochester Farmers' Club, Maidstone. The most important papers on this matter appeared in the *Gardeners' Chronicle* on the following dates, April 24, 1869; June 28, 1873; and April 23, 1874.

NAMES OF FRUITS: We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. They should be just approaching ripeness, and they should be properly numbered, and carefully packed. A leaf or shoot of each variety is helpful, and in the case of *Pears*, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.—*G. J.*, Maidenhead. 1, Tower of Glamis; 2, Minshull Crab; 3, Golden Winter Pearmain. Pears: 1, Fendante de Malines; 2, Beurré Bosc.—*G. W.* 1, Caroline; 2, Winter Greening.—*M. A.* 1, Unknown; 2, Norfolk Beefing; 3, Siely's Mignonne; 4, Broughton; 5, Yorkshire Greening; 6, Calville Malingre.—*G. I.* 1, Prince Albert; 2, Round Winter Nonsuch; 3, Mère de Ménage; 4, Winter Greening; 5 and 6, not in condition, they will be named later if the specimens mature.—*X.* 1 and 5, probably local varieties; 2, Broad-eyed Pippin; 3, Ribston Pearmain; 4, Greenup's Pippin; 6, Calville Blanche d'Hiver.—*G. S.* 1, 2, and 3, quite rotten; 4, Beurré Duquesne; 5, Forelle.—*J. S.* Winter Queen, the Reine Sophie of continental growers.—*R. W. R.* Not Glou Morceau; it is a poor example of Beurré d'Aremberg, which is sometimes confounded with the above variety.—*H. H.* 1, Cobham; 2, Alfriston; 3, Tower's Glory; 4, Golden Russet; 5, Golden Pippin; 6, Winter Strawberry.—*G. H.* 1, Such a small, imperfect specimen cannot be identified; 2, Hoary Morning; 3, Graham; 4, Golden Russet; 5, Parry's Pearmain; the Pear was decayed.—*A. G. B.* 1, Reineette Carpentier; 2, Yellow Ingestre; 3, Not known; 4, Herefordshire Pearmain; 5, Ross Nonpareil; 6, Dr. Harvey.—*G. R.* 1, Beurré Luizet; 2, Beurré Blanc des Capucines; 3, Comte de Flandres.—*J. K.* Yellow Admirable Peach.—*G. H. P.* 1, Herefordshire Beefing; 2, Duchess's Favourite.—*A. C. C.* 1, Lemon Pip-

pin; 2, Herefordshire Beefing; 3, Bess Pool; *C. H.* Your fruits resemble the Sack or Spice-apple.—*G. T.* 1, Pitmaston Nonpareil; 2, Lord Derby.—*Monmouth.* 1, Golden Harvey; 2, Petworth Nonpareil; 3, Not known; 4, Nonpareil; 5, Radford Beauty; 6, Hoary Morning. *W. T.* 1, Pineapple Pippin; 2, Castle Major; 3, Nonpareil Russet; 4, Dumelew's Seedling; 5, Greenup's Pippin.—*Enigma.* 1, Tyler's Kernel; 2, The two fruits sent under this number differ in so many characters that we shall keep them until we hear from you that there has been no confusion; 3, which you say is "a seedling on its own roots," appears to us to resemble Caroline—not Queen Caroline, which is a distinct variety. If you are writing again please describe the habit of the tree.—*N.* 1, Golden Winter Pearmain, generally known as King of the Pippins; 2, Hornmead's Pearmain; 3, Lord Derby; 4, Scarlet Nonpareil.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*Young Gardener.* *Pyrus Aria* (white Beam-tree).—*H. Watson.* 1, *Myrica cerifera* ♂; 2, *M. carolinensis*; 3, *Populus tremula*; 4, *Viburnum Opulus*; 5, *Crataegus tomentosa*.—*Thos. Wakeford.* 1, *Zygopetalum Mackayi*; 2, *Platanus acerifolia*; 3, *Cedrus atlantica glauca*; 4, *Abies Pinsapo*; 5, *Cupressus macrocarpa*; 6, *Cupressus*, probably *macrocarpa* also, a vigorous top-shoot.—*A. B.* 1, *Cupressus nootkatensis*; 2 and 3, forms of *Thuja orientalis*; 4, *Thuja occidentalis*; 5, *Cupressus Lawsoniana*; 6, *Juniperus virginiana* (a state of).—*Eaton.* 1, *Crataegus orientalis*, probably, send fruits; 2, *Pavia* (*JEsculus*) *macrostachya* fruits; 3, *Caryopteris mastacanthus*.—*W. C. L.* *Acer platanoides*, the Norway Maple.—*A. C. B.* 1, *Pinus Montezumae*; 2, *Abies grandis*; 3, *Picea Morinda*; 4, *Cupressus* (*Retinospora*) *obtusata*; 5, *C. Lawsoniana*; 6, *Retinospora plumosa* of gardens, a form of *Cupressus pisifera*.—*G. B.* *Solanum jasminoides*.—*X. I. R.* 1, *Galega officinalis*; 2, *Hippophae rhamnoides*; 3, *Pyrethrum serotinum*; 4, *Leycesteria formosa*; 5, *Veronica Teucrium*; 6, *Crataegus coccinea*.—*Enquirer.* 1, *Solanum jasminoides*; 2, *Buddleia Lindleyana*.—*A. J. L.* *Yucca gloriosa*.—*T. W.* *Datura Stramonium*, a poisonous weed used in medicine. It frequently comes up with foreign seeds.—*A. B.* One of the varieties of the Japanese *A. polymorphum*.—*X.* We name some of the enclosed specimens as well as we can from the miserable scraps sent, but remind the sender that he has transgressed two rules; first, in requiring an answer by post, and next in sending more than six specimens. It would be impossible to conduct the *Gardeners' Chronicle* if these rules were systematically disregarded. The specimens sent are not only bad, but more than one bear the same name. A donation to the *Gardeners' Orphan Fund* would be some compensation for the trouble and loss of time occasioned. 1, *Pseudotsuga Douglasii*; 2, *Abies excelsa*, probably; 3 and 4, *Cupressus Lawsoniana*; 5, *Thuja gigantea*; 6, *Acer Negundo variegatum*; 7, *Veronica Traversii*; 8, *Ligustrum lucidum*; 9, *Lonicera Xylestium*; 10, *Thuja gigantea*; 11, *Crataegus coccinea*; 12, *Eleagnus hortensis*; 13, *Prunepitys elegans*; 14, *Cupressus Lawsoniana*; 7, *bis*, *Phillyrea angustifolia*; 9, *bis*, *Spiraea Douglasii*; 15, *Cerasus lusitana*; 16, *Cupressus Lawsoniana*; 17, *Spiraea opulifolia*; 18, *Ribes aureum*; 19, not found; 20, not recognised; 21, *Spiraea* sp.; 22, *S. Thunbergi*; 23, *Acer circinnatum*; 24 and 25, *Spiraea callosa*; 26, *Spiraea* sp.; 27, not found; 28, *Tsuga canadensis*; 29, *Acer platanoides*; 30, *Lonicera flexuosa*; 31, *Cupressus Lawsoniana*.—*C. S.* 1, *Aralia* sp.; 2, *Harpallium rigidum*; 3, *Helianthus* species; 4 to 10, perennial *Asters*. Impossible to be named from memory; take them to some nursery where there is a named collection; 11, *Spiraea Douglasii*; 12, ?; can you not send other specimens? Those before us are withered beyond recognition. Never send more than six. It is not our business to name plants, though we are anxious to oblige so far as we can consistently with our duties.—*Ben. Reid & Co.* Not recognised.—*E. M.* *Crataegus coccinea*.

PINE-SHOOTS DESTROYED: *R. S. Margets.* The injury is the work of the Pine-beetle, *Hylurgus piniperda*. The beetles propagate in decaying brushwood and thinnings, consequently such rubbish should be cleared out of all Fir planta-

tions. The beetles ascend the trees and commit great ravages; dressings of bark, trimmed from felled trees should not be left in the plantations, but should be burned forthwith. Sickly trees, likely to harbour the insects should also be removed. The plantation being a young one, you might try what a syringing with Paris Green would do in clearing the trees, in the proportion of 1 lb. to 120 gallons of water, keeping it stirred constantly whilst being used.

PLANTS FOR A WARM BORDER: *W. H. R.* All kinds of Lilies, *Gladiolus*, early and late-flowering species and their varieties. *Tritomas* in variety, including *Leichtlini*, *nobilis*, *cerallina*, *Pfitzeri*, *Reoperi*, *Uvaria* and *U. glaucescens*; *Verbascum Chaixi*, *V. olympicum*, and *V. phoeniceum*; *Trellius* of species, with yellow and white flowers, good for the front row; *Tradescantia virginica*, *Spiraea filipendula* fl.-pl., *S. palmata*, *Sedum spectabile*, *Scabiosa caucasica*, *Romneya Coulteri*, florists' var. of *Pyrethrum*, and *Potentilla*, many species of *Primula*; *Plumbago Larpenae*, *Polemonium Richardsoni*, *Polygonum* of species, *Pentstemon* species, and florists' var.; prostrate *Phloxes*, and florists' var.; *Monarda didyma* and *M. fistulosa*, *Oenothera Pilgrimi*, *E. Youngi*, &c. *Megasea* of species, *Lychnis* of species, *Incarvillea Delavayi*, and *I. Olga*; *Lathyrus* of species, and *Malva moschata alba*, *Iberis coriifolia*, and others; *Hemerocallis* in variety, *Eremurus Bungei*, and others; *Erigeron* species, *Doronicum* species, *Dielytraspectabilis*, *Crinum capense*, *C. Powellii*, and others; and many more plants equally suitable. The summer display could be helped out with *Annals*, such as *Aster* of various types, *Sweet Peas*, *Coreopsis*, *Scabious*, *Salpiglossis*, *Stocks*, &c. *Cannas*, *Dahlias*, *Chrysanthemums*, *Pelargoniums*, tuberosus *Begonias*, &c., could be employed.

POTATOS: *W. H. S.* The tubers have probably been attacked by a mite, the irritation caused by which has induced the formation of the corky warts on the surface.

SHOWER BOUQUET: *Anxious.* A figure of a shower bouquet is given at p. 213 of our issue for September 9, 1899.

THE QUANTITY OF GRAVEL REQUIRED FOR COVERING A WALK ONE INCH THICK: *Celsa.* Multiply the length and breadth in inches, and divide by 46,656, the number of inches in 1 yard.

TOMATO DISCOLOURED: *X.* A single Tomato gives little chance of accurately determining the cause of yellow patches. In this instance the fruit was sound, even where yellow, except at the insertion of the calyx. There a fungus-mycelium was present, and slightly affected the tissues. The fungus has probably come from the stems of the plant, but in absence of any stems, leaves, or roots, nothing more can be said. All parts of a plant must be seen before recommending treatment.

VINE-LEAVES TO PRESERVE WITH THE GREEN COLOUR INTACT: *Grape Leaves.* This cannot be done. The leaves must be taken when full grown and matured, but not possessing the autumnal tints. They must be exposed to the fumes of sulphur in a close box, having an air inlet to allow of the combustion of the sulphur, which latter, after burning a quarter of an hour should be withdrawn and the inlet closed. The next day the leaves should be taken out of the box and laid flat on sheets of paper, and dried gradually under pressure. To prepare a green colour, dissolve in ten quarts of boiling water 150 grammes of alum, and then the colouring matter in quantity so as to give the desired tint, together with a small quantity of Picric acid, according to the shade required. The leaves must be laid on a wooden float and allowed to simmer till the desired tint is obtained. Picric acid is poisonous, and affords a beautiful shade of yellow, and is useful for giving the required shade to the green dye. This sort of work requires a good deal of practice to enable the operator to obtain satisfactory results.

THE Gardeners' Chronicle

No. 670.—SATURDAY, OCT. 28, 1899.

FRIAR PARK, HENLEY.

THE RESIDENCE OF FRANK CRISP, ESQ.

SOME of the most picturesque and lovely views obtained on the Thames, are in the district on either side of Henley, a town known by name at least over the whole world in connection with the greatest and most fashionable of British regattas. It is not a matter of surprise, therefore, that the district contains some magnificent gardens.

The natural advantages possessed by the neighbourhood have in a large measure been utilised by the erection of country-houses, that in their turn render this beautiful Oxfordshire valley further interesting from our point of view. Thus, there is Park Place, the delightful residence of Mrs. Wilson Noble; Greenlands, the home of Mr. W. F. D. Smith, M.P.; and others.

Friar Park, the particular establishment with which for the present we are concerned, is the residence and property of Mr. Frank Crisp, the genial and popular Treasurer to the Linnean Society of London—a gentleman whose liberality is as great as his capacity and enthusiasm for work are astounding.

To reach Friar Park from the Henley railway-station, you must needs turn your back upon the Thames, and walk or ride, the former preferably, through the quaint little town, and part of the way up a considerable bank. When you have come barely more than half a mile, there may be seen a carriage-drive upon your right. On a bank by the important-looking gates may be noticed some well-coloured specimens of Golden Privet, and immediately through the gates on the left is an imposing lodge—one of the prettiest from an architectural point of view that we have seen. This handsome little house is occupied by Mr. Crisp's steward and gardener (Mr. Philip O. Knowles), who, when Mr. Crisp bought this place, came to Friar Park, eleven years ago, from Greenlands, and for his first responsible charge has had the making, under the direction of Mr. Crisp, of one of the most remarkable gardens in the country. The proprietor of Friar Park is nothing if not thorough. He is not content with any second-rate production, and if there arises a suspicion when something has been completed that the work would have been better done by another method, or that a better effect was possible, the work is most likely commenced again without hesitation. It is whispered that the house at the entrance-gates was not always as it is to-day, and that it has been twice built. Be that as it may, it should be some satisfaction to Mr. Knowles that his house is so far removed from the reproach of the jerry builder, that it was constructed at an expenditure of something like £3000.

THE MANSION.

But if the entrance-lodge is so remarkable, what shall we say of the mansion? It is reached from the road by a twice-curved and

ascending broad drive, which approaches the house on the south side. There are few such buildings as that at Friar Park, and if Mr. Crisp is proud of it, so ought he to be. We could not, and fortunately we need not attempt to, describe its florid architecture, which is in the late Gothic style, carried out in part stone and part brick, but delightfully relieved and adorned by skilfully-carved stone, because in our Supplementary-sheet is reproduced an excellent photograph of the building, taken by Messrs. Marsh & Son, of Henley, who have taken all the photographs illustrative of this article. From that illustration our readers may form a very good idea of the general effect, and even of the more important details of Mr. Crisp's residence. But of the very numerous representations of friars in stone upon parts of the building, a knowledge could be obtained only by a careful inspection of the building itself, and such an inspection would not only prove to be very fascinating, but by its means, one would see reflected in the figures, and in certain remarkable instances of optical delusion that are illustrated by carved stone, the humour characteristic of the proprietor of Friar Park.

GENERAL FEATURES OF THE GARDEN.

At the time the building of the mansion was completed, Mr. Crisp did not possess the amount of land around the site that he now owns, and this circumstance explains a number of alterations that have been made in the gardens during the past five years. At various times additional meadows have been purchased, until at this date Mr. Crisp has ninety acres surrounding his residence.

Not all of this, however, has yet been laid out as a garden, and a small part of that most recently acquired is upon the opposite side of the public road. But the garden is now, and will be when the improvements that are being made have been completed, sufficiently large, varied, and interesting to be a fitting "setting" for such a mansion. Of variety, scarcely more could be provided than Mr. Crisp's love of completeness has already caused to be represented there.

A huge rockery, carried out in accordance with Mr. Crisp's desires, is more than sufficient in spring to interest a sympathetic visitor for the whole of one day. A pinetum that includes about 100 varieties of Conifers has been formed; a collection of Conifers also that have been trained and cut into endless imitative and fantastic shapes, and interspersed with an unique collection of old sun-dials from all sorts of sources. A formal Dutch flower-garden, as prim and model-like as possible, and a delightful herbaceous garden, just as homely-looking as the Dutch is cold in appearance; bowers, arches, and wigwags, covered with Roses; a beautiful lake, and its associate, a bog garden; a maze that when a little older will be sufficiently puzzling for the best of us; shady walks; a Rhododendron-garden planted as will be described presently; plenty of choice trees and shrubs, as specimens and as small groups, placed in positions dictated by good taste and experience; a kitchen garden sufficient to supply the needs of the family; hot-houses for the cultivation of fruits and plants; and last, but not least, a series of wonderful caves that form a fitting complementary feature to the rockery. All these stamp the place with a degree of interest to the bulk of visitors which is lacking in most gentlemen's gardens.

When making an inspection of Mr. Crisp's

garden, after passing through the gates to the drive, the visitor turns along a path to the right, along an exceptionally shady walk quite overhung with Chestnut and other trees, leading to a "root walk," or a path lined with great roots, and near to a high bank that has been made there.

THE LAKE, &c.

Presently the bog-garden comes into view, here Irises and other semi-aquatic species of plants and Ferns have been planted, but this feature will be largely extended.

The bog-garden adjoins the lake (see fig. 107, p. 322), a pretty piece of water, containing an island that adds very considerably to the charms of the scene. The outlines of island and lake are informal, and the planting that has been done accentuates the points of beauty. The Bamboos will be very appropriate when they have grown to a greater size, and in a sheltered situation a group of plants of *Eucalyptus Globulus* have been unharmed during three winters. To-day the lake is a conspicuous and effective feature of the gardens, and it takes one by surprise to be told that it is quite of artificial make, and that upon the same site was once a private residence. The change has been brought about by the well-known firm of Messrs. Pulham & Son, of Brompton, who are responsible for several very artistic pieces of work at Friar Park, both with the famous Pulhamite, and in other matters relating to water and rockwork.

HERBACEOUS FLOWER GARDEN.

Near to the lake a charming flower-garden is entered, followed by another, not prim or formal ones, but gardens of herbaceous perennials, where the beds are full of Roses, Lavender, Tritomas, Lupins, and other hardy plants. Very narrow gravelled walks intersect some of these beds, and they are edged with Box, a somewhat curious feature in so charming a garden. The site was evidently at one time a fruit-garden, and some of the fruit-trees have been wisely left, for it is absurd to suppose that where usefulness exists there can be no beauty. The walks are very interesting, because of the curious manner in which they have been designed to lead the visitor unsuspectingly to certain corners and features, almost as a series of "surprise packets." If there is anything particularly charming, be sure you will not discover its existence until you are quite upon it, for it is not intended that you should do so.

In one of the gardens just described is the iron or wire archway, illustrated in fig. 108, p. 323. The arches form a cross, with a dome in the centre, and although they were only erected about three years ago, the greater part of the frame-work is now nicely covered with Honey-suckles, *Clematis montana*, Roses (especially the variety William Allen Richardson, a favourite Rose of Mr. Crisp's), and Turner's Crimson Rambler. Our photograph was taken from the end where Crimson Rambler has been planted, and when the exceedingly vigorous plant is in flower the prodigal display of crimson bloom produces an effect not easily forgotten.

SUN-DIALS AND CLIPPED CONIFERS.

What a change there is from the garden just described to that of the old English garden, full of Conifers and other trees trained in imitative and grotesque shapes, and interspersed with old and curious sun-dials! The latter are perhaps more remarkable than the trees, for it is doubtful if a larger collection exists. One of

these bears the date 1657. Another one, apparently very old, consists of a stone slab, supported by an American eagle; whilst a third is said to be made from a piece of old London Bridge.

The illustration on p. 325 (fig. 109), shows a few of the clipped trees, but these are not more than a fifth part of the collection. In the illustration there is a very fine specimen of a spirally-trained tree, and two representations of sheep. In the whole collection there are endless varieties of shapes, such for instance as afternoon tea-tables, peacocks, presentation-cups, columns, pyramids, and ovals. There are excellent specimens of standard plants of *Retinospora* worked upon 5-feet high stems of *Cupressus Lawsoniana*. The shape of the tree thus worked resembles that of an umbrella. It is a fact that many gentlemen who have lately made new gardens have included larger or smaller collections of fancifully-cut trees, and nurserymen have received unusual demands as a result of this tendency to re-introduce into English gardens a feature that was at one time exceedingly popular, but that was subsequently the object of almost universal ridicule. But a long period must elapse before such a garden recently planted will give effects similar to those at present existing at Levens Hall or Elvaston Castle.

THE PINETUM AND RHODODENDRON DELL.

The collection of Conifers is planted on a slope to the north, and from this site there is a glorious view of the surrounding country, where the counties of Berkshire, Oxfordshire, and Buckinghamshire meet. Part of the range of the Chilterns forms a prevailing feature in this landscape, and in the nearer valley there is an old dyke that runs from Oxford, as well as a road from Henley to Oxford, which is perfectly straight for a mile of its length, and passes through an avenue of fine Elm-trees. From the same point of view may also be seen the cottagers' allotments, upon a piece of ground lent by Mr. Crisp to the town of Henley for a period of fifteen years. It will be in future years that the Pinetum will be most interesting, for as yet the plants are all young, but in the one hundred or so species and varieties that have been planted there are some very choice ones, that will make the collection remarkable. We hope that the Conifers will succeed, and there is no doubt but they have been planted on the best available spot.

From the top of the pinetum there runs a "Pine-walk," dividing this from the herbaceous garden. The path between these hardy old Pines is only about 6 feet wide, and the walk is near upon 200 yards long. What a glorious retreat from a midsummer's glaring sun!

The Rhododendron-garden forms a pretty bank on one side of a dell, and the plants are succeeding admirably. We saw them when some of the choice varieties were in bloom, and the effect was gratifying. A path commences at the top of the bank, and winds backwards and forwards until the base is reached; and as the Rhododendrons are planted on either side this path, it is possible to conveniently inspect each of the plants without traversing any part more than once. The effect of the whole garden can be seen equally well from the top or at the foot.

THE FLOWER-GARDEN AND EAST FRONT.

There is a primly-designed flower-garden at the east front of the house, and being contiguous to the architecture of the magnificent building, there is the less reason to criticise its pronounced artificial characteristics. The geometrical flower-beds, each edged with Box, and the walks red with finely-broken bricks, may be less tasteful to some of us than the herbaceous garden already mentioned; but as a feature merely of the whole garden, and as the means of bridging over the

extremes shown by the architect and the "free-hand" gardener, this more formal style may be admired.

There are, happily, no rude inconsistencies in the present case, and nothing to mar the harmony of the view. During the summer the beds have been bright with showy, neat-habited, flowering plants, that Mr. Knowles has attended to exceedingly well. In this garden there is a very beau-

than this, the system of construction is a bold one, such as will give its best effect when it has existed for some years. This is no ordinary rock-garden with a path down the centre, and banks on either side; it is more like a model "Alps;" it stretches over a great space of ground, and there are represented in it mountains of greater and lesser height, valleys, mountain-passes, the stepping-stones of which may be seen in the illustration;

FIG. 107.—VIEW OF THE LAKE AT FRIAR PARK (SEE P. 321.)

tiful fountain carved out of Portland stone; while the east front is further decorated with two great copper cranes.

THE ROCKERY.

The thoroughness that has characterised all the work at Friar Park is very conspicuous in the construction in so fine and complete a rockery. If the reader turns to the illustration of this on our Supplementary-sheet, it may possibly be thought that it presents a somewhat unfurnished appearance. It must be remembered, however, that the Rockery has been made and planted but recently. More

rustic alpine bridges, overlooking quite formidable precipices; a waterfall, &c. The waterfall commences at the highest point in the rockery, and after winding and twisting in innumerable directions, for a moment conspicuous, then hidden for a time, at last runs into a small pool surrounded by a little greensward at the lowest point. The rockery has a range in height of from 30 to 40 feet. Then, as remarked above, the construction is bold, and not of comparatively small stones or artificial stone, that can be hidden by a season's growth. It is made with good solid Yorkshire stones, and over

2000 tons have been brought to Friar Park from Leeds. One of these stones that weighs $6\frac{1}{2}$ tons is a somewhat conspicuous object, and in a rockery will remain such for some years. But the manner in which the stones have been placed—a most natural one—and the method adopted in planting, will in time bring about a fully furnished appearance, and one that would not be possible in the case of less bold construction. Fortunately a common error in the formation of rockeries has been avoided; there has been provided ample space

intendence of Mr. Knowles, and for this work the Guildford Hardy Plant Company have been called upon to supply an immense number of plants, including all the choicest species this firm could furnish. It says something for the nurseries from whence the stock has been obtained, as it does also for the manner in which the planting has been done, that all of the species so far as our observations went, are flourishing to a surprising degree. We were struck with the evident vigour of numberless plants, and

feet in breadth. The collection of plants is so large, that it would serve no purpose to enumerate a portion of them in this general description. The choicest as well as the commonest species have been planted, including some of the best of the hardy Orchids. We may add, however, especially in the light of what has been said respecting the bold construction of the rockery, that situations have been found for Sweet Briars, Cistus, Polygonums, Acacia hispida, Opuntias, and quite a number of evergreen shrubs that are slow

FIG. 108.—VIEW IN MR. CRISP'S GARDEN AT FRIAR PARK, SHOWING A WIRE ARCHWAY SUPPORTING ROSES, HONEYSUCKLES, CLEMATIS, ETC.
(SEE P. 321.)

for the plants, in which they will be able to develop into the largest size of which they are capable. The Japanese and other dwarf-growing Conifers will have a splendid effect in such a rockery as this. It is situate to the north of the mansion, and the oldest portion, which is nearest to the house, was partly or wholly the work of one of the best-known firms in the country, Messrs. Backhouse & Son, of York. This firm has since supplied a large number of plants for the other parts of the rockery and for the pleasure-grounds, particulars of nearly 500 varieties being now before us. All the planting has, however, been carried out under the super-

an instance may be given in the popular Edelweiss, which occurs again and again in equal condition to the plant shown in fig. 110, p. 331. The Gentianas and a considerable number of other species that are usually difficult of cultivation succeed admirably.

The scale upon which the rockery has been erected, admits of the plants being cultivated in batches, so that the hardy Primulas, Thymus coccinea and T. Serpyllum, Campanulas, Tropaeolums, Veronicas, Papavers, Potentillas, Dianthus, Cheiranthus alpinus, Saponarias, and all similar species, may each be seen in batches several square

to make growth, or that never become too large for such a rockery. Much, very much more might be said upon the plants in this rockery were there no limit to our space; but our present task has been rather to describe the rockery itself. It should be added before passing, that there are splendid patches of one of the prettiest of the Sempervivums, S. arachneoidum.

THE CAVES.

From speaking of the rockery it is but natural to pass to the caves, and especially as one of the entrances to these caves is from the rockery. They are the most wonderful artificial caverns we

have ever seen, and they extend under part of the rockery and up to the dwelling-house.

Following one of the mountain-passes previously mentioned, one comes to a sliding iron door, amidst the most natural-looking environs, so that even the door itself, set in a dim recess, is not suspected to be other than stone. But pass through this doorway and the first cave comes into view. This is the "Vine" Cave, and over its roof and around the pillars is represented a Vine with leaves and fruit, as natural-looking as possible under such extraordinary circumstances. The berries are really of glass, and in each is an electric light, which, when turned on by the pressing of a button, has an indescribable effect upon the various and curious formations of tufa. From this chamber there are roomy passages that lead into a second cave, and again into others—the Wishing-Well cave, another containing examples of optical delusions, and the most charming of all, the Water-cave.

We shall not attempt on this occasion to describe these caves with any degree of fulness, as there are so many interesting features at Friar Park that this article has already become of greater length than was intended. Unfortunately our photographer after repeated efforts was unable to obtain a photograph that would have shown the interior of one of them. The series of caves, however, are well worth a visit from anyone who is at all interested in such a feature, and they are undoubtedly an excellent testimony to the skill of Mr. T. B. Harpham, Church Street, Edgware Road, London, their constructor.

In the Wishing-Well there are various optical delusions, and by pressing a button one can see his future wife or husband. The bewilderment and delusion effected by the display of mirrors set at various angles is perfect. Marguerite approaching the church door, followed by Faust, is the subject of a very pretty optical delusion. But the prettiest effect is that obtained in the Water-cave, and there one can take a boat and row under the earth in electrically-lighted caverns of wondrous fascination, and in several lights of extraordinary colour. Means exist for heating all these caverns with hot water when necessary, and the electric-light is provided by a generator on the place.

CONCLUDING ITEMS.

There is nearly a score of glass-houses, where Peaches, Grapes, and other choice fruits are cultivated, and which contain good collections of Orchids and Cactaceous plants, besides other decorative and flowering species. All of these are cultivated in a manner creditable to Mr. Knowles, who each year has been able to show as good a batch of herbaceous Calceolarias as could be seen anywhere.

The kitchen-garden and its fruit-trees have the same satisfactory appearance.

Friar Park and its gardens is open to visitors one day each week, and we think no one would be other than delighted by a visit there. A charge of sixpence each person is made, and half the proceeds are given to the Gardeners' Royal Benevolent Institution, and half to the Mayor of Henley, for the assistance of the local charities.

In concluding this notice of Friar Park and its gardens, we are full of appreciation of the liberality and enthusiasm that Mr. Crisp has displayed in the development of an establishment that to-day promises to become a place of horticultural interest to an unusual degree, and we fervently hope that he and his gardener may have health for many years, so that the proprietor may not only see the completion of his ideas, but also enjoy the pleasure that should follow their realisation.

NEW OR NOTEWORTHY PLANTS.

SELENIPEDIUM × GERALDA (LINDLEYA-NUM × CAUDATUM).

Mr. OAKES AMES, in the issue of *American Gardening* for September 23, 1899, records this interesting cross, which was made by Mr. Wm. Turner,

gardener to W. D. Rockefeller, Esq., Rockwood, Tarrytown, N.Y., the new arrival being dedicated to Mrs. Rockefeller. The flowers are said to be rather smaller than those of *S. × grande*, to which the description points to its bearing some resemblance.

Cypripedium × tonso-purpuratum and *C. × tonso-Arthurianum* are also recorded by Mr. Oakes Ames in the issue of the same journal for September 30, the former also being represented by a drawing which shows the characters to be distinctly intermediate between the parents named.

ORCHID NOTES AND GLEANINGS.

MASDEVALLIA × DORIS.

CAPTAIN HINCKS, of Terrace House, Richmond, Yorkshire, with the assistance of his gardener, Mr. Rushton, has been very successful in cross-breeding *Masdevallias*, two excellent examples of which he kindly forwards. *Masdevallia "Doris"* is derived from *M. triangularis*, and crossed with *M. racemosa* (Crossii). The seeds were sown in the summer of 1890, and the first flowers appeared at the end of 1893. The plant has flowered profusely, after the manner of both its parents, and the flowers have shown much improvement as the plants gained strength. The examples sent each bear two flowers on scapes, 4 inches in length. The flowers, which take the form of those of *M. triangularis*, are 1½ in. across the equally expanded perianth lobes, each of which is furnished with a tail half an inch in length. The flowers are nearly the same in colour as *M. racemosa*, and a marked improvement on the yellow and brown tints of *M. triangularis*. The ground-colour is of a peculiar tint of orange, and the surface of a reddish-scarlet hue. Each lobe bears three light rosy-crimson lines.

MASDEVALLIA × RUSHTONI (M. IGNEA ECKHARDI ♀ M. RACEMOSA ♂).

This cross appears to be one of the brightest and most floriferous of hybrid *Masdevallias*. The scapes are nearly 6 inches in length, and each is furnished with two flowers, borne away from each other on foot-stalks, about 2 inches in length. The form and the colour of the flowers resemble those of *M. Veitchiana*, except that they are smaller. The colour is brilliant scarlet on orange, and the lower perianth lobes, which are 1 inch in length, constitute the showier portion of the flower.

CATTLEYA SUPERBA VAR. SPLENDENS.

A flower of the ordinary form of *Cattleya superba*, and another of a very large and brilliantly-coloured form, is sent by Geo. C. Raphael, Esq., Castle Hill, Englefield Green (gr., Mr. H. Brown). The flower of the variety "splendens" is over 6 inches across, and all the segments are of considerable breadth and of stout substance. The sepals and petals are bright rose-purple; the lip dark crimson-purple and showy; and the disc of a bright yellow tint. The plant thrives suspended near the roof of a moist, warm house. Abundance of rain-water should be afforded the plant when making its growth. Like *Oncidium Lanceanum*, *Epidendrum bicornutum*, and some other plants, reputed difficult to grow, it thrives better in an ordinary plant-stove than in the Orchid-house proper.

LYCASTE DENNINGIANA.

A flower of this rare and handsome Ecuadorian species is sent by Mr. Fred. J. Thorne, gr. to Major Joicey, Sunningdale Park, Sunningdale, who considers it a very desirable plant, especially as it may be had in flower at this season. The flower-stem is nearly as thick as an ordinary cedar-pencil. The expanded flower is 6 inches across, sepals and petals creamy-white, tinged with green. The showy labellum is bright orange-scarlet, deepening towards the centre, and the fimbriated margin is of a bright yellow tint. The column is ivory-white, and altogether it is a striking flower, and very attractive. Mr. Thorne says it thrives well with the *Anguloas*, which he blooms so profusely in an

intermediate-house, and some of which are in flower with him at present. *L. Denningiana* was illustrated in the *Gardeners' Chronicle*, October 2, 1897, p. 231, from a specimen which flowered at the Royal Botanic Gardens, Glasnevin, Dublin.

LELIO-CATTLEYA × SCHILLERIANA GIGANTEA.

When one of the earliest imported plants of what was then known as *Laelia elegans* flowered, Mr. Robert Warner bloomed out of them a few which were so far superior to the others, that he named that form *Laelia "gigantea,"* and it was illustrated in *Warner's Select Orchidaceous Plants*. Since his time many varieties have been imported, but very few of them have attained the size of flower of the original. But now, out of an importation made by Mr. Joseph Broome, of Sunny Hill, Llandudno, one has flowered which is a long way in advance of the type, and exceeds in size and in the breadth of the petals most of the varieties of *Laelia purpurata*, which it more closely resembles than ordinary forms. The petals are 7 inches across; both sepals and petals are flat and of fine substance, white with a pearly-pink tinge and a few light pencillings of rose. The broad lip is white at the base, veined slightly with purple; the front lobe magenta-purple, changing to rose at the apex.

CATASETUM MACROCARPUM CHRYSANTHUM.

This pretty variety first flowered with Messrs. Linden, of Brussels, by whom it was figured in *Lindenia*, vol. v., p. 13. Another example bloomed in the gardens of C. R. de la Salle, Esq., Enbridge Lodge, Newbury, Berks (gr., Mr. Geo. E. Ellwood). This plant bore two flower-spikes, one consisting of seventeen, and the other of ten flowers. The large and fleshy labellum is of a bright yellow tint, the sepals and petals of creamy-white, the sepals having a slightly greenish tinge on the reverse side, and the petals some small red-purple spots. J. O'B.

PLANT NOTES.

CHIOGENES SERPYLLIFOLIA, THE TRUE SNOWBERRY.

I HAVE just received a plant of this curious and most distinct Ericaceous trailer, sometimes called *C. hispidula*, a native of North America and Japan, from Mr. Lemoine, of Nancy. It is nearly allied to the Cranberry, and was introduced so far back as 1760, by Mr. Laycock, who grew it at Halifax, in Yorkshire, where it produced fruit abundantly. It was there planted under a north stone wall, shaded by high trees, in a border of sandy peat from an adjoining moor. The flavour of the fruit is agreeable to some, being strongly perfumed like Noyau, or bitter Almonds, and mixed with a pleasant acid. It grows wild in swamps. Knight of Chelsea cultivated it with great success. It has also been described by different botanists under the various names of *Vaccinium*, *Arbutus*, *Gaultheria*, and *Oxycoccus*; it seems to have a much stronger and more valid claim to the English name at the head of this note than the shrub which now bears it, *Symphoricarpos racemosus*, as it flowers and fruits in its native country soon after the melting of the snow; and its fruit is pure white. W. E. Gumbleton.

INDIA.

THE RECENT EARTHQUAKES IN DARJEELING.

PERHAPS the accompanying extracts from a letter just received from my son, written two days after the catastrophe, or rather series of catastrophes, in the Darjeeling district, may be interesting to some readers of the *Gardeners' Chronicle*. The scene is the Government Cinchona Plantation at Mungpo, at an elevation of between 3000 and 4000 feet, and about 17 miles distant from Kurseong and Darjeeling. W. Botting Hemsley.

"On Sunday night we were visited by a terrible storm, in fact a cyclone. Several lives have been lost, and enormous damage done to our own plantation and the neighbouring Tea-gardens. Up to the time of writing, I have heard of the loss of twenty-two lives by houses being overwhelmed by landslips, brought about by the very heavy rainfall of Sunday. Thirteen inches fell during the twenty-four hours ending 6 A.M. on Monday. Of this, 11 inches fell during the space of five to six hours on Sunday night.

"The consequence of this heavy fall was that the streams and rivers rose enormously, overflowed their banks, and uprooted huge trees, which were

after gust came, causing the bungalow to tremble and groan. On the side exposed to the storm a quantity of thatch was carried away, letting the water into the rooms, but this was all, and very fortunate I was, for if any small portion of the roof itself had gone it would have been good-bye to the rest and a lot of my property. Many of the poor coolies were not so fortunate, as in many cases where they escaped with their lives, they lost almost their all, in the shape of houses, cattle, or crops.

"With the bridges gone we are almost completely isolated; two roads only are open, and those only for foot passengers, as they are in a

BULB-PLANTING ON TURF.

(Concluded from p. 306.)

PLANTS for wild gardening must necessarily be very tenacious of life, robust in growth, and of considerable stature. Such, for instance, is *Eremurus himalaicus*, with massive spikes of greenish-white flowers, and *E. robustus*, with rosy-tinted flowers in tall spikes. I have grown these plants in very poor soil indeed, with some success. With good treatment, noble spikes of flowers are secured, which appear at their best when seen with a suitable background of dark-green foliage. The roots should be planted in October, four inches below

FIG. 109.—SOME OF THE CLIPPED TREES IN MR. CRISP'S COLLECTION AT FRIAR PARK. (SEE P. 321.)

carried down stream, levelling everything before them in the shape of bridges, &c. The fine suspension-bridge over the Ryang river, just at the point where it flows into the Teesta river, is gone! Mr. Pantling's suspension-bridge, finished only a few months back, is gone! The Rungbu-bridge, on the lower Darjeeling road, gone! Most of the small bridges over streams on the plantation, gone! Paths, gone! Cinchona plants, houses, cattle, crops, &c., gone! These losses have occurred in the vicinity of what were small streams, but which became raging torrents, causing landslips everywhere.

"Accompanying the rain was a terrific wind, which threatened to overturn my bungalow, so violent was it between 10.30 and 12.30 on Sunday night, when it was at its height. But the bungalow stood, though I spent an anxious two hours as gust

shocking state, impassable in parts [for ponies. One of these roads leads to Darjeeling, and the other to Kurseong. The latter I have got orders to repair in a day or two, taking some forty to fifty coolies with me. I expect I shall stop at Suricl whilst the job is on, which will possibly last for five or six days. I am going to stop in my present bungalow for at least another year, the bricks for my new bungalow having to be made this cold weather for use next cold weather. Mr. Pantling, however, is putting up cloth ceilings, and is going to have a bamboo mat made for the sitting-room to go under my carpet. This will make the bungalow much warmer during the ensuing cold weather. Although this is being posted at the usual time, it may get stuck, as the railway is blocked in places, so you may receive it a week late. *Oliver T. Hemsley, September 9, 1899.*"

the surface, covering the newly-stirred soil with grass or bracken to keep out severe frosts. A mulch of well-rotted manure is almost necessary for the first season. The grass should be mown over with a scythe as the leaves die down, to promote ripening of the tuberous roots. Other species may probably do quite as well as these, but I have not tried them.

The Crown Imperials, *Fritillaria imperialis*, are very good plants for the "wild" garden; they are most effective in groups of several, occurring at intervals. They like a tolerably rich soil. Lilliums of the *speciosum*, *Martagon*, and *croceum* types, will grow almost anywhere, especially the former. I have recently rooted out some fine bulbs of *L. speciosum* and var. *album* from a shrubbery border filled with the roots of Privet; from the appearance of the soil, I should think they had been

without water for two years at the least, yet the bulbs had flowered well, and were firm and of good size. I noticed that the roots at the base of the flower-stems were unusually numerous and near the surface, where a little moisture was to be found. Funkias and the stronger-growing deciduous Hellebores are suitable plants for shady places. Alstroemerias are doubtful subjects for growing in grass; they are too big for short grass, and in longer grass the sessile leaves, so essential to the building up of a fertile stem, are liable to get smothered. A. aurantiaca may succeed, it is not particular as to soil, situation, or associations; but this species, as with others, is a long time getting over the check of removal, and is likely to be pushed out of existence by strong-growing grasses. Iris xiphium and I. xiphoides are, perhaps, the best Iris for our purpose; they are rich in variety, and are very cheap. Given a good soil, they will last for years. A very wet winter, followed by severe frosts, will thin them out considerably. They should be planted in September at the latest. In boggy soils Iris Kämpferi is one of the best plants to grow. It has been said that wet winters destroy this also, but I have not found this to be the case. I have planted this Iris extensively on the margins of a lake on a sub-soil of yellow clay; these have withstood the last four winters without loss. Geo. B. Mallett.

GOOD BORDER PLANTS.

(Continued from p. 310.)

PENTSTEMONS.—For the first time, I have employed these somewhat profusely in borders of mixed flowers, in every case planting them in good-sized groups, close to the edge of the border, though in some instances allowing them to reach to a few feet of the back. They equal in good effect any plant we grow, while the length of time—from July till the end of the season—they continue producing spikes, is not the least of their good qualities. It is, however, essential, in order to keep them in good condition, that the flower-spikes, as they get past, should be removed. I am growing the strain sold by Mr. Forbes, of Hawick. The seeds must be sown not later than one of the first days of February, and the seed-pans placed in a temperature of 55° to 65°, till the seedlings have gained strength. As soon as the latter can be handled, quite tiny things, they are pricked out into boxes, by which means growth is greatly facilitated. After staying a while in cold frames, they are ready to plant out in the end of April or in May. It is most important that early sowing, followed by pricking out the seedlings when quite small, should be closely followed. The colours range from white, shades of light blue, and pink, to dark maroon, scarlets, and crimson; many are white-throated, numbers striped, and others have large blotches—these of all being, perhaps, the most fascinating. R. P. Brotherston, Tynningham, N.B.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. YOON, Orchid Grower to Sir FREDERICK WIGAN, Bart. Clare Lawn, East Sheen.

Odontoglossum crispum.—This plant is usually imported in quantity during the late autumn and early winter months, and it is a commendable practice to purchase some of each reputedly good importation, if only for the sake of obtaining greater variety in the flowers. There are those who profess themselves expert enough to pick out from the mass, good varieties and natural hybrids, such as *O. Andersonianum*, *Ruckerianum*, *Wilckeanum*, &c., but I cannot do this, and the only thing that I can recommend a cultivator to do is to secure good pieces, not necessarily large ones, but those with sound bulbs and dormant eyes, as the buds are termed. Speaking generally, it is from amongst the small pieces that the spotted and other high priced forms appear. Having acquired a quantity, it is a matter of some doubt with many how to proceed to procure the best results, and in their anxiety and haste to see their recently purchased treasures break into life, they are placed in warm and over-moist houses, and urged into activity before they have recovered from the ruthless treatment received at the hands of the native collectors. Where a small number only has to be dealt with, the more rational course is first to clean away all dead and

decaying portions, but not to entirely denude the pseudo-bulbs and rhizomes of their enveloping bracts, or some of the sound eyes may be injured. Then select pots just large enough to accommodate each piece, fill them to the extent of two-thirds with rather small crocks, and in order to hold the pseudo-bulbs in position, pack around it a few lumps of peat. The pots should be placed on a stage in a cool, fairly moist, but not very light house. Keep the stage under the pots moistened, but do not apply water directly to any plant until growth has advanced an inch or more, even then it is not prudent to afford water frequently, but simply to wet the peat and crocks. When roots push forth, fill the remaining spaces with peat and living moss, place the plants in a lighter position, and treat similarly to a newly-potted plant. These remarks apply to most Ecuadorian *Odontoglossums*.

Odontoglossum Londeboroughianum, which few growers can induce to flower, should now, i.e. on the completion of its pseudo-bulbs, commence a long and severe period of drying off. During this period the plant should be suspended in a house having an intermediate temperature, and once the leaves have fallen, no water will be needed until there is a renewal of life.

Odontoglossum Kramerii is about the only member of the family which needs the heat and other conditions prevailing in an East Indian-house. The plant requires rather dense shade and a saturated atmosphere. It has finished growing for this season, and is now about to flower, consequently much less water at the root will be needed, and until growth recommences, only water should be given sufficiently often to prevent any undue shriveling in the pseudo-bulbs.

Fogs of a more or less deleterious nature will prevail during the next few months, and the usual precautions have to be taken to prevent injurious effects so far as is possible. Near large towns it is the moist, smoke-laden fogs that injure vegetation most, and when these occur, our aim should be to have the plants and the atmosphere fairly dry, and the temperatures no higher than the recognised standard. Again, when smoke-laden fogs occur during frosty weather, drier conditions should prevail, and the temperatures allowed to drop a few degrees below the normal. No air should be admitted by opening the ventilators whilst the fog lasts; and where the blinds are in position they should be run down at night, in order to prevent heat escaping from the houses, and the fog gaining an admittance to any great extent. As soon as the fog lifts, air should be admitted to all departments. When there is no immediate prospect of its return, let all dry spaces be well damped, but afford water to the plants sparingly. The roofs of all Orchid-houses should be cleaned, and if fog-deposits render it necessary, they should be washed after each visitation.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucestershire.

Erythroniums (Dog's-tooth Violets).—These plants are very pretty in the spring, when they have developed their beautiful mottled leaves and variously-coloured flowers, and if planted in a sunny position in the rock-garden, or in small borders in sandy loam and peat, placing each bulb 6 inches apart, and 8 inches deep, they will require but little subsequent attention. Should the bulbs appear fleshy and white, they should be planted as soon as possible after being lifted or purchased.

Calochortus (Butterfly Tulip).—These are exceedingly pretty when in flower, and show to the best advantage if a position on a sunny border be chosen for them. It is essential that the soil be well drained, and is naturally comparatively dry during the winter months. Prepare the soil thoroughly by mixing with it some good sandy loam, leaf-mould, and plenty of sharp grit. The present month is the best time to procure the bulbs, and these should be planted not more than 4 inches deep. Afterwards cover them 6 inches deep with Cocoa-nut fibre, and place over this some fine meshed wire-netting to prevent the birds from scratching. The *C. venusta* group contains some very vigorous growing and fine flowering varieties, and they are the cheapest. If these be found to succeed, other varieties which are more expensive may safely be planted.

Autumn Tints.—Nothing can surpass the beautiful masses of colour that many of the deciduous trees and shrubs afford this month, before shedding

their leaves. The following are some of the most suitable species for planting in the park, woodlands, and pleasure-grounds, with a view to obtaining autumn effect:—*Crataegus coccinea*, *C. c. maxima*, *C. corallina*, *C. crus-galli* punifolia, which form fine heads, and the broad leaves turn to a lovely gold and crimson colour, and last for a considerable time. *Acer pennsylvaticum*, *A. platanoides*, *A. colchicum rubrum*, *A. dasycarpum*, *A. rubrum*, *A. palustre*, bright yellow; *A. Ginnala*, *A. campestre*, *A. vitifolium*, rich claret red; *Carpinus americana*, bronzy-red and gold; *Catalpa bignonioides*, *C. speciosa*, massive leaves of golden-yellow; *Fraxinus excelsior jaspidea aurea*, distinct and beautiful yellow; *Juglans lasiniata*, lovely cut leaves of a bronzy colour; *Parottia persica*, gold and crimson-tinted on the edge of the leaves; *Pyrus aucuparia*, bronzy-yellow; *Liquidambar styraciflua*, variously tinted, and very lasting; *Quercus coccinea*, *Q. c.* Watereri variety, intense crimson; *Q. palustris*; *Q. rubra*, red; *Q. conferta*, yellow; *Tilia platyphyllos aurea*, *T. p. lasiniatus*, *T. p. rubra*, very beautiful tints of red and gold; *Rhus glabra coccinea*, intense dark crimson; and *R. typhina*, deep blood-red. Of the smaller trees and shrubs, those most suitable for the dressed grounds comprise the brilliant Japanese Acers, among which are *A. septemlobum*, *A. s. elegans*, *A. palmatum*, *A. decompositum*, intense deep crimson, blood-red, and yellow; *Euonymus atropurpureus*, *E. alatus*, *E. europaeus*, *E. latifolius*, red and pink shades; *Amelanchier arbutifolia*, *A. canadensis*, *A. florida*, *A. sanguinea*, rich fiery crimson; *Berberis Thunbergi*, *B. virescens*, rich crimson; *Cotoneaster affinis*, *C. frigida* intense red; *Spiraea Bumalda*, *S. callosa* vars., and *S. Fortunei*.

Pelargoniums.—Cuttings of these that were struck in boxes and pots should now be taken from the cold frames, and placed in their winter quarters. If there be no special house for wintering them, they may be put upon a shelf or trellis in a coolinery near to the light, and where fire-heat can be applied in the event of frost or fog. Water may be afforded them when they show signs of flagging, and all dead leaves and flowers should be removed promptly.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Raspberries.—Where the planting of new quarters is contemplated, an early preparation of the ground is necessary. As Raspberries are usually allowed to occupy the same site for a number of years, the ground should receive a heavy dressing of rotten manure, more especially if the staple be light; whilst clayey soils should receive a dressing of one of half-rotten manure, crushed bones, and mortar-rubbish well incorporated with the staple in the progress of the trenching. After allowing the land to settle, planting may take place; and early planting results in a strong start being made in the spring. The method of planting Raspberries is various: some gardeners plant against a strained wire-fence espalier fashion, the rows of wires being 5 feet apart; or three or four canes may be planted in triangular clumps at 4 feet apart in the row and trained upright to stakes, or arched over from right and left, so that one stake serves for half the canes from two clumps by tying them at the crown of the arch. Either of these methods serves the purpose of securing the canes. One of the best varieties is Superlative, which is far in advance of others in size, and the flavour quite fits it for the dessert table. The variety is almost a perpetual bearer, as it produces a few fruits well into the autumn from the lower growths which form near the base of the canes. Other good red-fruited varieties are Baumforth's Seedling, Carter's Prolific, and Semper Fidelis, the latter a very sharp-flavoured fruit, good for preserving. The yellow-fruited varieties are Magnum Bonum and Antwerp; while larger and newer varieties of yellow are found in Guinea and Golden Queen, both of which partake of the size of the Red Superlative, which in each case formed one of the parents.

The Gathering of Apples being near its finish, only fruits of late varieties, as Sturmer Pippin, should be allowed to hang as long as the weather will permit, as only by so doing will they keep fresh and plump till late in the spring.

The Cloister Fruit-Protector.—Having given these patent celluloid protectors a trial, I will, as requested, give my opinion of their uses and general suitability for the purpose of protecting

fruits, more especially Apples and Pears, from birds and other enemies. I confess I was much disappointed with them owing to the difficulty experienced in fitting them on to the fruits, the time to fix one taking about as long as that required to place on a dozen bags, and in many instances, unless the fruits stood out individually and well away from the branch, it was impossible to get a protector on to them—and especially was this the case with Apples; and there was considerable danger attending the fixing, as unless extreme care was used the Apple was forced away from the branch. As far as causing any speck or spot on the fruits through the perforations of the protector there was none, but fruits of Cox's Orange Pippin enclosed in them were less highly coloured than others on the same tree unprotected. One advantage that the celluloid has over bags, is in standing out stiffly from the fruits, so that wasps or birds cannot pierce them as they sometimes do in the case of canvas-bags when the latter rests on the fruit. With Pears there was some difficulty in fitting the fruits to the protectors, the latter being too small towards the stem for most varieties, and I should not recommend anyone to purchase largely before first experimenting with a few, as taking into consideration the time that is occupied in fixing them, the price, and other drawbacks, I prefer the thin canvas-bag.

FRUITS UNDER GLASS.

By W. STRUONKELL, Gardener to Lieut.-Col. RALPH VIVIAN, Rood Ashton, Trowbridge.

The Early Vinery.—Vines which are usually started at the end of the month of November or early in December, having shed most of their leaves, may be pruned and put in order for forcing. As bunches of large size are not expected from these early Vines, short-spur pruning is that commonly adopted. The laterals previously shortened, should be cut back to two stout buds. Anything left of greater length becomes in time unsightly, and is, moreover, of no more use for Grape production than a short spur. If long spurs are desired for a particular purpose in any one year, it is not afterwards difficult to prepare a shoot coming from its base for future fruit-bearing, and to which it should be cut back after it has served its purpose. The basal shoot ought not to retain more than four leaves. If mealy-bug or scale are present on the Vines, wash the rods with hot-water, to which Fir-tree oil, Gishurst Compound, or other insecticide has been added, having first stripped off the loose bark. Any greater denudation of bark is not to be advised, although in the case of Vines greatly overrun by bug or scale, it is necessary. Before proceeding with this kind of work, cloths or bast mats should be spread on the floor of the vinery, &c., in order to catch the bark and insects, these being removed and burnt. The Vines being bundled up out of the way, the roof, stages, hot-water pipes, and wall should be washed with hot soapsuds, and having done this, the surface-soil may be removed, and be replaced with fresh loam, lime-rubble, &c. Finally, the Vines may be dressed with some approved mixture if insects have been present on them. The wounds on Vines that are pruned early soon heal, and there is not much danger that "bleeding" will occur. Until the time has arrived for starting the Vines, the greatest amount of air should be allowed, and no plant should therefore be placed in the vinery that will suffer from full ventilation.

Winter Cucumbers.—The cutting of cucumbers from hot-bed frames will soon be over, the supply of fruits obtained from plants in the Cucumber-houses duly prepared for fruiting in the winter. In order to utilise these plants for as long a time as possible, they should be cropped lightly, and all crippled and unnecessary fruits being removed whilst they are quite small. The amount of forcing employed in mild weather should be very moderate, or weakly growth will result; and everything must be done at this season to keep the plants vigorous. Sufficient warmth must, however, be kept in the bed of soil as will prevent any chilling of the roots, and the air temperature well maintained, so as to develop healthy growth. Do not crowd the growths, but regulate, remove, and stop these once a week. Every leaf that is left on a plant should have full exposure to sunlight. Afford a dressing of new loamy soil frequently, and in small quantities. Succession Cucumber plants may be brought on in accordance with the demand for Cucumbers, not permitting fruiting till they have acquired strength, and the earlier plants show signs of giving out. The

ventilation of these houses needs much care, and it must soon be afforded only during the brief portion of the day when the sun shines. The syringing of the plants must likewise be modified to suit the season, it being dropped excepting once daily on warm days, a damping of the floors, walls, and other surfaces taking its place. To do this is absolutely necessary if red-spider and thrips are to be kept in check. If thrips or aphids appear on the plants, recourse must be had to fumigation with the XL-All vaporiser. The evaporating troughs on the hot-water pipes may be kept filled with diluted farmyard manure. The water afforded the plants, or used in damping down, should be warmed to 80°.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Asparagus.—The stems having assumed a yellow tint may be cut down, all seedlings extirpated, and the beds hoed and raked clean. Having done this apply a heavy top-dressing of rich, decayed manure, and then mark out the beds anew and bank up the sides neatly with soil taken from the alleys. In doing this last piece of work, do not dig deeply, so as to disturb the roots of the plants. Any preparations of the land needed for forming new beds in the spring should be made as time permits. A bed of Asparagus should not contain more than three rows, or gathering the produce becomes very laborious work. If the land is unsuitable to the growth of the plant, much may be done to make it suitable by the addition of fresh soil, road-scrappings and ditch-clearings, sea-sand, &c. The land should be trenched 2 to 3 spits deep; and if wet, drains should be cut to carry off the water. Plenty of rich manure and leaf-mould should be buried during the trenching if the land is stubborn. On land of this sort large quantities of fresh soil should be brought in, so as to raise the level, which, however, is not necessary on well-drained land.

The Jerusalem Artichoke.—The stems may now be cut down and removed, and a fortnight afterwards the tubers may be dug up, the sets separated from those kept for consumption, and the smallest tubers given to the pigs. The tubers may remain in the ground if, in frosty weather, they are protected with long litter. A fresh plantation should be made yearly, and the old plantation cleared away.

Cabbage Plots.—Let all vacancies be made good, and stir the land with the draw-hoe at frequent intervals. If slugs are troublesome, apply fresh soot and quicklime together in the evening. Let a large quantity of all the varieties grown be planted rather thickly together on a sheltered border for the purpose of making good any vacancies occurring in the rows, and for planting-out in March.

Lettuce.—Lift Lettuce and Endive from outside beds, and plant in frames and pits. Cos Lettuce may also be potted to the number of five in 10-inch pots, keeping them near the rims. Strong plants lifted at this date will prove very serviceable in late autumn and early winter. They should be afforded water sufficient to moisten the soil throughout, and be housed in a peachery or unused vinery. All these salad plants must be afforded plenty of air at all times except during frosty weather.

PLANTS UNDER GLASS.

By O. R. FIELDER, Gardener, North Myms Park, Hatfield.

Eucharis grandiflora.—These plants which are intended to flower during the late part of the autumn and throughout the winter, should be forthwith removed from the stove to another house having a temperature of from 55° to 60°, so as to rest them. Here they may remain for a few weeks. The season of flowering is prolonged when the plants are placed in cooler quarters in small batches, at intervals of a fortnight, and reintroduced into heat in the same order, or in accordance with the requirements of the establishment. With a sufficiently large stock of these plants, and with due attention paid to resting them in successive batches at suitable intervals, flowers may be obtained throughout the year. Before the plants are placed in a lower temperature, they should be allowed to become somewhat dry at the root, and be kept in that condition till they are returned to the stove; nevertheless, the dryness should not be such as to cause the foliage to flag, or the plants will be injured. In addition to lengthening the season during which flowers may be obtained, a certain amount of rest is essential to the health of the plants.

Cyclamens.—If seeds were sown early in the month of August, the seedlings will now be strong enough to prick off into pans, or pot singly into thumbs, if that method is preferred. The plants should be placed close to the light, in a moist pit or low house, where a temperature of from 50° to 55° is maintained. Last year's seedlings will now be coming into flower, and may be afforded a temperature of from 45° to 50°, unless early-flowering is wished for, in which case they may be placed in a temperature 5° higher than this. The plants must likewise be kept near to the glass, otherwise the foliage and flower-stems will become weak and drawn.

Herbaceous Calceolarias.—In order to have healthy and strong specimens, the requirements of the plants must be promptly met, being careful not to repot them too soon, nor yet permit them to become pot-bound, but repot when the roots have permeated the new soil. The proper moment may always be determined by turning out a few of the plants. Calceolarias should not be afforded a large shift at one time, otherwise by the time the plants arrive at the flowering-stage, they will be growing in pots of a disproportionately large size. Throughout the winter, and till the sun gains power in the spring, the plants must not be shaded, and they should be kept close to the light. A brick-pit, furnished with the means of excluding frost, and expelling damp, is a very suitable structure for them. If it were not for the excessive condensation of moisture upon the foliage that takes place in cold pits during frosty weather, when the lights have to be closely covered, these plants might be very well grown without the aid of artificial heat. The plants should be protected from slight frost by covering the pits with mats, &c., and artificial heat only resorted to when absolutely necessary. A temperature ranging between 38° and 45° will be sufficient. Air must be afforded whenever possible. Grown in this manner, the Calceolaria gives but little trouble. Aphids can be kept in check easily by fumigation with tobacco, by dusting them with tobacco-powder, or removing them with a small brush.

THE APIARY

By EXPERT.

Bee-houses.—I have several bee-houses in use, in which stocks have wintered better than in single hives. Each house holds four hives; entrances are placed as far apart as possible, and the hives can be worked on either the storifying or combination principle. The roof is hinged to lift up; the back opens outwards by two doors, thus giving plenty of "elbow-room." The inside is simply two long trough-like frame-hives, and each stock is kept apart by division-boards. To those who do not wish to go to greater expense, I would recommend these houses, which, for the price of materials, do not exceed the cost of a weather-proof single frame-hive. The size of each is 4 feet long by 4 feet high by 20 inches wide. Materials required to make one, are four corner-posts, 2 in. by 2 in.; cross-beams, 2 in. by 4 in.; bottom and centre shelves (strictly speaking, the floor-boards), of $\frac{3}{4}$ jointed flooring; four boards $\frac{1}{2}$ in. by 9 and 4 ft. long, for hive sides; all the other wood of $\frac{3}{4}$ jointed and beaded lining; and roof covered with canvas, and painted, to make all secure. For some years I have had in use at an out apiary, 2 miles from home, another house, which holds twenty-two hives. The size is 9 feet long by 6 feet wide, and 7 feet high. The hives are arranged in two rows, eight on each side, and six on the front or end; the door being at the other end, all manipulation can be carried on from the inside of the building. There is no floor in it; the bottom row of hives rest on the ground, the top row rests on two stout rails. I work this house on the non-swarming principle, and frequently have had stocks in it 3 feet 6 inches in height. My experience of the house is, that all that is necessary to make it complete is to have it on wheels, so that it could be removed from one locality to another. The advantage of having bee-houses on wheels requires only to be known to be more adopted; and very often it happens that in one district bees would have better foraging ground, that it would pay to shift them, were it not for the trouble and hard work involved in packing and unpacking hives. The greatest objection to bee-houses on wheels is the cost, but there are chances that one might be able to secure cheaply a second-hand lorry, or the wheels and springs of a waggonette, or carriage-wheels and springs, which, with the cost of putting on sides and a top, to make it into a suitable bee-house, would not exceed more than a few pounds.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS.

TUESDAY,	OCT. 31.	Chrysanthemum Shows at Wolverhampton (3 days), Southampton (2 days), Tannock (2 days), Teignmouth and Torquay (2 days). National Chrysanthemum, Floral Committee Meeting. Exmouth Chrysanthemum Show (2 days). Kent County Chrysanthemum Society's Show at Blackheath (2 days). Chrysanthemum Shows at Leyton (2 days), Penarth (2 days), Portsmouth (3 days), Bristol (2 days), Horsbarnham (2 days), Streatham (2 days), and Highbridge (2 days).
WEDNESDAY,	Nov. 1.	Devon and Exeter Horticultural Society's Chrysanthemum Show (2 days). Chrysanthemum Shows at Highgate (2 days), Sevenoaks (2 days), Maidenhead (2 days), Woolwich (3 days), Beaumont and Leamington (2 days).
THURSDAY,	Nov. 2.	Chrysanthemum Shows at Evesham, Swindon (2 days), and Battersea (2 days). Loughborough Chrysanthemum Show.
FRIDAY,	Nov. 3.	North of Scotland Vegetable and Root Exhibition. Stockport Chrysanthemum (2 days).
SATURDAY,	Nov. 4.	Chrysanthemum Shows at St. Neot's and Totnes. Royal Horticultural Society's Committee. National Chrysanthemum Society's Exhibition at Royal Aquarium, Westminster (3 days). Chrysanthemum Shows at Birmingham, in Bingley Hall (3 days), Coventry (2 days), Brighton (2 days), Croydon (2 days), Yeovil, Plymouth (2 days), Southend (2 days), Truro (2 days), and Stratford-on-Avon (2 days). Scottish Horticultural Association Meeting.
MONDAY,	Nov. 6.	Chrysanthemum Shows at Kingston-on-Thames (2 days), Cambridge (2 days), Bournemouth (2 days), Ware (2 days), Chesterfield (2 days), Bromley (2 days), Lowestoft (2 days), Stoke Newington (2 days), Cardiff (2 days), Hanley (Staffordshire) (2 days), Bath (2 days), Great Yarmouth (2 days), and Bristol (2 days).
TUESDAY,	Nov. 7.	Chrysanthemum Shows at Putney (2 days), Colchester (2 days), Gloucester, Northampton (2 days), Stirling (2 days), and Weston-super-Mare.
WEDNESDAY,	Nov. 8.	Chrysanthemum Shows at Leicester (2 days), Blackburn (2 days), Stockport, Eccles (2 days), Folkestone (2 days), Derby (2 days), and Huddersfield (2 days). National Chrysanthemum Society's Floral Committee Meeting. Ulster Horticultural Society's Chrysanthemum Show (2 days). Leeds Paxton Society's Chrysanthemum Exhibition (2 days). Loughton (Staffs.) Chrysanthemum Show (2 days). Royal Horticultural Society of Ireland Meeting. York Florists' Chrysanthemum Exhibition. Aberystwyth Chrysanthemum Show.
THURSDAY,	Nov. 9.	Tanworth Chrysanthemum Show (2 days). Carlisle and Cumberland Horticultural Society's Chrysanthemum Show at Carlisle (2 days).
FRIDAY,	Nov. 10.	
MONDAY,	Nov. 13.	
TUESDAY,	Nov. 14.	
WEDNESDAY,	Nov. 15.	

THURSDAY,	Nov. 16.	Edinburgh Chrysanthemum Show (3 days). Ludlow Chrysanthemum and Fruit Exhibition. Manchester Botanic Society's Chrysanthemum Exhib. (3 days).
FRIDAY,	Nov. 17.	Bolton Horticultural Society's Chrysanthemum Exhib. (2 days). Bradford Chrysanthemum Show (2 days).
MONDAY,	Nov. 20.	Cheltenham Chrysanthemum Exhibition (2 days)?
TUESDAY,	Nov. 21.	Royal Horticultural Society's Committee Meeting. National Ross Society's Committee Meeting.
WEDNESDAY,	Nov. 22.	National Chrysanthemum, Floral and Executive Committee Meet.
THURSDAY,	Nov. 23.	Dundee Chrysanthemum Show (3 days).

SALES FOR THE ENSUING WEEK.

MONDAY, Oct. 30, and the following Tuesday, Wednesday, Thursday, and Friday, Dutch Bulbs, at Protheroe & Morris' Rooms.

MONDAY, Oct. 30.—Clearance Sale of General Nursery Stock, at the Cockmanning Nurseries, St. Mary Cray, Kent, by order of Messrs. G. & J. Lane, by Protheroe & Morris, at 11.30 o'clock.

TUESDAY, Oct. 31.—Important Annual Sale, by order of Messrs. Thos. S. Ware, Ltd., at The Hale Farm Nurseries, Tottenham, by Protheroe & Morris, at 11 o'clock.

FRIDAY, Nov. 3.—Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period October 15 to October 21, 1899. Height above sea-level 24 feet.

Remarks.—A week of dense, smoky fog, which has left a thick deposit of snail on outdoor vegetation, and caused the leaves of some hardwood plants under glass to fall. No rain has fallen since the 12th.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—45.7°.

ACTUAL TEMPERATURES:—

LONDON.—October 25 (6 P.M.): Max. 61°; Min. 48°.

Foggy-dull, fine.

PROVINCES.—October 25 (6 P.M.): Max. 59°, Valentia; Min. 50°, north-east Scotland.

The Neglect of Systematic Botany.

On turning to the volumes of the *Gardeners' Chronicle* published some five-and-twenty or more

years ago, it will be seen how frequently complaint was made at that time of the relative neglect of vegetable physiology, and of the minute anatomy of plants. So little was done in the way of original investigation at that time, that the workers might be counted on the fingers of one hand. The botany of the Cryptogamia was in an equally neglected condition, so much so, that the Rev. M. J. BERKELEY, the "M. J. B." of these columns, felt constrained to apologise and write in terms of deprecation when he published what was at the time the

most masterly summary of the knowledge of Cryptogamic botany in existence!

Botanical teaching in the metropolis at that time, and for some time previously, consisted of a series of lectures, compiled from DE CANDOLLE, LINDLEY, and later J. H. BALFOUR, illustrated with diagrams and with as many fresh specimens as residence in London would allow. Microscopical preparations in some, but not by any means in all the colleges, were shown to the students. Those who could afford to do so bought illustrative examples from the dealers, and a few really interested in the subject contrived with the aid of a friendly demonstrator or senior student to make preparations for themselves; but there were no laboratories for students in those days, and no microtomes. Staining materials were limited to carmine, and that was chiefly used in animal physiology, whilst nothing like systematic practical teaching in microscopic work was attempted. At Oxford the case was still worse.

The morphology and classification of the higher plants were thus almost the exclusive subjects of study; lecturers mostly confined themselves to those subjects, and, as we have said, the students had little or no means of studying the other departments of the science.

At that time botany formed an integral portion of the curriculum for all medical students; and the medical schools offered almost, if not all, the instruction that was to be had. What the students were expected to do and to learn in three short years, was ridiculously in excess of what they could properly do in the time. Botany was generally about the most unpopular item in the endless series of lectures. As taught, it did not appeal to the students, by most of whom it was looked on as a useless superfluity, and neglected accordingly. These circumstances led to the abolition of botany as a subject of medical education, and at present, with few exceptions, there is hardly a school or college where the study of the natural orders is conducted in any but the most elementary fashion; and as for the young gardener, unless at Kew, the means of instruction in a subject of such great importance to him are entirely inadequate.

In olden times, in spite of deficient methods of tuition, those who cared for the subject, and were interested in it really, did manage to acquire a considerable working knowledge, which was most useful in after-life. Look at the labours of that splendid roll-call of Indian botanists referred to by Sir GEORGE KING at the recent meeting of the British Association at Dover; labours as remarkable for their practical consequences and their direct benefit to mankind, as for their influence in the extension of knowledge. Almost all those men had been taught the details of botanical classification on the benches of the medical schools; so had ROBERT BROWN. Others, like Sir WILLIAM HOOKER, LINDLEY, BENTHAM, obtained their botanical instruction on similar lines, if not in the lecture-room of a medical school.

One-sided and imperfect as their education was, we do not suppose that their successors will be able to surpass them in their degree, nor that they will be enabled to contribute in larger proportion to the advancement of their science.

The pendulum has swung violently in the opposite direction; and whereas we had frequent occasion at one time to lament the little attention paid to vegetable physiology, and anatomy, as taught in this country, now we have equal reason for deploring the scant

attention paid to systematic botany, and the too exclusive attention to matters which, important though they be, are little likely to concern the future gardener, forester, or doctor in his daily life-work.

We are far from wishing to decry any branch of science, or to hold up one as more worthy of pursuit than another. Still, it is impossible to withhold sympathy from Sir GEORGE KING's lament as to the imperfect equipment of the students sent to India as forest officers, and we may add as doctors. We have had abundant evidence of the truth of Sir GEORGE KING's general conclusions in other departments than the Indian forest service. We have seen students make the most beautiful preparations, and known them to be familiar not only with sieve-tubes and "synergids," but with the "chromosomes" of the nucleus, and such-like recondite subjects, and who were yet unable to recognise the natural family to which the commonest plants belong, or to give clear, first-hand information as to the differences between Crucifers and Cucurbits, or as to the medicinal or other properties to be found in the plants of particular natural orders.

Classification is by some looked at askance as being at its best arbitrary, and unworthy the attention of philosophical students. We have no need to say how ridiculous such an assumption is. Everyone admits now that "natural systems," in proportion as they are natural, have a phylogenic basis. Classification is not a mere haphazard collocation of plants that are more or less alike, but it is in essence a genealogical statement, expressive of the line of descent from less highly organised predecessors. True, we know vastly little of the exact lines of evolution, especially among flowering plants, but it is interesting to see how the judgment of our great botanists as to the affinities of plants is borne out by later researches. We may never succeed in tracing the exact stages of descent in every case, but the principles acted on by systematic botanists, such, for instance, as the recognition of the relative degree of importance to be attached to this or that "character," must surely be essentially the same as those which underlie the labours of the phylogenist. We imagine, however, that Sir GEORGE KING had specially in view the practical applications of botany, and from that aspect it is a glaring anomaly that we send out explorers, foresters, and doctors, to our various colonies, without having previously given them the means of turning their opportunities to advantage. We have not too many botanical laboratories, but we have vastly too few opportunities for the study of morphology and classification.

LINNEAN SOCIETY.—The first meeting of this society for the forthcoming session will be held on Thursday, November 2, at 8 P.M., when the following papers will be read: Rev. Prof. HENSLOW, M.A., F.L.S., "On the Proliferous State of the Awn of Nepal Barley." Dr. W. G. RIDEWOOD, F.L.S., "On the Hyobranchial Skeleton and Larynx of the new Aglossal Toad, *Hymenochirus Boettgeri*." Mr. HAROLD WAGER, F.L.S., "On the Eye-spot and Cilium in *Euglena viridis*."

DUNN MEMORIAL.—A meeting of the committee in charge of this fund was held on the 18th inst., and it was decided to close the fund on December 1 next. Any of the secretaries will be glad to receive subscriptions:—P. MURRAY THOMSON, Secretary, Royal Caledonian Horticultural Society, 5, York Place, Edinburgh; JAMES A. TERRAS, Assistant Secretary, Botanical Society of Edinburgh, 21, Teviot Place,

Edinburgh; ROBERT GALLOWAY, Secretary, Royal Scottish Arboricultural Society, 5, St. Andrew Square, Edinburgh; ROBERT LAIRD, Secretary, Scottish Horticultural Association, 17, Frederick Street, Edinburgh.

JOHN LINDEN.—The inauguration of the monument erected in commemoration of JOHN LINDEN, and its presentation to the city of Brussels, will take place in the Parc Leopold in that city on Sunday, November 5, at 11 A.M.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—A concert in aid of the Gardeners' Royal Benevolent Institution will be given in the Constitutional Hall, Chertsey, on Thursday, November 2, 1899, under the patronage of the Rev. E. R. PARR, M.A. (Vicar), Lady LILFORD, Mrs. TULK, LAWRENCE J. BAKER, Esq., and Mrs. BAKER, Captain F. B. HARRISON, and others. The names of the artists who will assist afford promise of a very excellent entertainment, and it is hoped that the gardeners and amateurs residing at Chertsey and in the vicinity will attend in good numbers, and thus assist this most deserving benevolent institution. Mr. A. J. BROWN, Hon. Secretary, Jessamine Cottage, Eastworth, Chertsey, will afford all information on application being made to him.

PRESENTATION TO A GARDENER.—On the 3rd inst. a presentation was made to Mr. F. TOPHAM by numerous friends he has made during the three years he has been gardener to H. S. H. LACON, Esq., Ormesby Hall, near Yarmouth. The presentation took the form of a handsome timepiece, accompanied by an illuminated address. Mr. TOPHAM left on the 10th inst.

PRODUCE OF HOPS.—Preliminary statement, showing the estimated total production of Hops in the years 1899 and 1898, with the acreage and estimated average yield per statute acre in each county of England in which Hops were grown:—

The Board of Agriculture, 4, Whitehall Place, S.W.,
October 19, 1899.

A NEW DEPARTURE BY THE ROYAL HORTICULTURAL SOCIETY.—It is announced in the Richmond local papers that the Council of the Royal Horticultural Society has agreed to a proposition made to them by the executive of the Richmond Horticultural Society, to hold one of their ordinary meetings, viz., that on the last Wednesday in June next, in conjunction with the annual exhibition of the Richmond Horticultural Society in the Old Deer Park. This is an entirely new departure, and has been made at the suggestion of one of our correspondents, put before certain of the Richmond executive last summer. That it will be a popular one with the Royal Horticultural Society's Committees there can be no doubt, as a change from the somewhat sombre surroundings of the Drill Hall to the bright sunny cheerfulness of the Old Deer Park, just for once, at least should be very enjoyable, particularly as the Deer Park adjoins the Royal Gardens, Kew. Perhaps it may be unwise to suggest too much; still, the new

departure on the part of the Royal Horticultural Society may be productive of important results, and further invites of a similar nature may in time be given. No doubt, as Richmond is always so great in that direction, generous hospitality will rule. There can be no doubt also but that the trade will, as is always the case, readily follow where the Royal Horticultural Society leads.

ADVENTITIOUS BUDS.—"An observation of some interest in connection with recent discussions on heredity is recorded by M. CASIMIR DE CANDOLLE in a paper read before the Société de Physique et d'Histoire Naturelle de Genève. He points out a constant difference between the normal and the adventitious buds of trees. The latter he regards as new individuals of the same species as the tree from which they spring, or as apogamic embryos, while the former are simply organs for prolonging the life of the individual. It is quite common for the first leaves of a woody plant to differ in form and structure from the later leaves. Examples are given in *Eucalyptus Globulus*, the Walnut, the Horse-Chestnut, and the Hornbeam. In all these cases, the first leaves from adventitious buds resemble, not those from normal buds, but the first leaves of the young plant." *Nature*, October 5, 1899, p. 550.

MR. A. HAMSHIRE, OF BEAU MANOR PARK GARDENS.—After years of faithful service as Head Gardener to Mrs. PERRY HERRICK, of Beau Manor Park, Loughborough, Mr. A. HAMSHIRE has been engaged by the Asylum Committee of the Corporation of Leicester as Manager of the Gardens, Farm, and Grounds of the Borough Asylum at Hummerstone. He entered upon his duties on Oct. 27. Upon Mr. HAMSHIRE leaving Beau Manor, the foreman, young gardeners, and garden-labourers, presented him with a mahogany umbrella-and-hat-stand as a mark of their esteem and goodwill.

JAPANESE GARDENERS IN FRANCE.—Preparations for the great International Exhibition to be held in Paris next year are being made actively, and as horticulture will play a prominent part in the festivities, it is only natural that they should conclude with a Chrysanthemum show. An international congress will be held, under the auspices of the National Horticultural Society of France, in the Palace of Horticulture which is in course of erection at the exhibition. Probably the first of the intending exhibitors are actually on the spot, or at any rate, as near it as they can get at present. Some Japanese gardeners, according to the *Nord Horticole*, have taken up their quarters in the municipal nurseries, to make preparations for a display of Oriental gardening. Chrysanthemums are to be included, and of these a thousand cuttings have already been sent from Japan as a first instalment. Others are to follow, and the plants that result from the year's cultivation will be shown by these ingenious gardeners from the far-east, and will, no doubt, excite great curiosity, especially if they adopt some of the quaint, fantastic methods of plant-culture such as are in vogue in the Imperial gardens, where huge pyramids with hundreds of blooms on each, curious fan-shaped plants, effigies, and other extraordinary specimens of their handicraft are indulged in.

WARGRAVE AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—An ordinary meeting of the Society was held on Wednesday evening, October 18, Mr. W. POPE being in the chair. Mr. BAZELEV, of the Twyford Nurseries, who had promised a paper on Violets, was unavoidably absent, and a discussion on general gardening matters therefore took place instead.

THEFT OF A COLLECTING-BOX.—We have received the following communication from Mr. S. M. THOMSON, of the firm of W. THOMSON & SONS, Clovenfords:—"For several years past we have had two boxes fixed up in prominent positions in our vineries, to receive contributions from visitors in aid of the Royal Gardeners' Orphan Fund. These boxes we have been in the habit of opening once a year,

sending the contents to the secretary of the Fund. To our great regret and indignation, we find that the box fixed in the principal range of vineries has been forcibly removed. We are doing all we can to find the thief, but without much hope of success. That such a very deserving charity should suffer causes us keen regret."

THE VIRTUES OF THE TOMATO.—DR. TRUE, of Philadelphia, has made extensive experiments with the juice of the red Tomato, for the purpose of discovering its virtues as a medicine. Dr. TRUE's investigations have led him to adopt the juice of the Tomato in cases in which the blood needs toning up. The United States Government and the German Government have also made experiments, and many facts have been discovered. During the recent war with Spain, the juice of the Tomato was utilised extensively as a health-preservative among certain bodies of troops, with results which were eminently satisfactory.

ILFORD RECREATION-GROUND.—The first prize of 50 guineas for the best design for laying out the Green Lane recreation-ground at Ilford, has been awarded, as they inform us, to WILLIAM BARRON & SON, landscape gardeners, of Elvaston Nurseries, Borrowash.

EFFECT OF ARSENIC ON PLANTS.—According to M. R. BOUILHAC (*Bull. Soc. Bot. France*, 1899, p. 64), a number of freshwater Alge which he enumerates can absorb a certain amount of arsenic acid in the form of arseniates without injury; these salts partially taking the place of phosphates. Among the Alge which possess this property are *Ulothrix tenerrima*, *Protococcus infusum*, *Dactylococcus infusum*, and *Stichococcus bacillaris*. With *Schizothrix lardacea*, arsenic acid appears to have even a more favourable effect on its growth than phosphoric acid.

LAWN PLANTS WHICH ARE PROOF AGAINST DROUGHT.—It is well known how difficult it is in very hot dry soils and seasons to maintain the pleasant green appearance of the lawn. In Miramar and in Abazzia, Fiume, as well as in Florence, *Ophiopogon japonicum* is employed with great advantage in forming lawns and "grass" plots. Another enduring plant, *Carex alba*, is recommended by Professor DE LA BASTHIE in the *Revue Horticole*; and some years ago M. ED. ANURE advised the planting of *Carex divulsa*.

STOCKS ON WHICH TO GRAFT THE LILAC.—In recent years many beautiful varieties of Lilac have been raised on the Continent, and to enable nurserymen to increase their stock of plants by grafting, stocks of *Syringa vulgaris* and *Ligustrum vulgare* have been employed. An admirable stock for standards is found in the common Ash—*Fraxinus excelsior*—which, like *Syringa*, belongs to the order Oleaceae. This stock being a stronger grower than *Ligustrum*, affords a better stem for standards; moreover, it attains a much greater age, and does not fall a prey to the grubs of the hawk-moth and wood leopard-moth. Budding as well as grafting may be employed. *Wiener Illustrirte Garten Zeitung*.

"LATER EXTINCT FLORAS OF THE UNITED STATES," left unfinished by the death of Professor NEWBERRY, is to be completed by Dr. ARTHUR HOLLOCK.

WINE A FIRE EXTINGUISHER.—A correspondent draws our attention to what he terms a new form of fire extinguisher—viz., wine. He states that last month a fire broke out on premises attached to a large wine store in one of the great Californian vineyards. Unfortunately, no water was to be had, but the quick-witted manager at once led the hose to the great wine-tubs, turned it on to the flames, and quenched them. This quenching was accomplished at the sacrifice of some forty thousand gallons of wine. Our cynical correspondent adds, "Looking at this from a broad humanitarian point

of view, perhaps this was not all a sacrifice—maybe it was a blessing in disguise!" But was it not really adding fuel to the flames?

FUMIGATION OF TREES.—The fumigation of orchard trees for the destruction of insect-pests is being extensively practised in California and other parts of the U.S.A. The tree to be treated is covered with a tent, and is subjected for nearly an hour to the fumes of hydrocyanic acid and potassium cyanide. A gang of four or five men can fumigate from thirty to forty medium-sized tents, and cover from 4 to 6 acres of orchard in a night. We should imagine that the using of such deadly poisons is attended with grave dangers to the workmen.

FIRST IMPRESSIONS.—Vendors of fruit of nearly all grades, both at home and in the colonies, are learning the lessons afforded by Continental growers and exporters in the art of presenting fruit to the eye of the purchaser, and acting upon them. The services of the gentler sex are now called in to assist in procuring a profitable market for fruits grown in the open and under glass. The training-class provided for girls in sundry Board Schools is well suited to training the eye in the production of effect, and it has been placed on record that the nimble fingers of little girls, directed by the trained eye of their instructors "tells" on the market. Great advantage is being taken of the facilities afforded by railway companies to carry and deliver small packages of fruit at a low rate of charge. Those who are engaged largely in this extending branch of business, might with advantage make a note of this, also provincial school authorities.

NYMEGEN.—It is proposed to hold an international horticultural exhibition in this city in 1901.

PUBLICATIONS RECEIVED.—*Journal de la Société Nationale d'Horticulture de France*,—*Queensland Agricultural Journal*, for September, 1899 (Brisbane: Edmund Gregory, Government Printer).—*The Century Book of Gardening*, part vii.

BOOK NOTICE.

FRUIT-GROWING IN NATAL.

IN the beautifully got-up Handbook to the Colony, by J. Forsyth Ingram, there is some very interesting information in regard to fruits grown in the South African Colony, from which we compile the following notes respecting the road from Durban to Pietermaritzburg, as a proof of the genial character of the climate. One colonist has in his grounds flourishing specimens of trees from nearly every country in the world. At Bellair, as at Umbilo, fruit-culture is greatly in evidence. As far as the eye can range over the hills, fruit-plantations are to be seen. The country around is pleasingly varied—field, dale, and wood combine to make up a perpetual series of charming views. The district of Malvern, 9 miles from Durban, is one of the most important fruit-producing depôts in Natal. The soil and climate are suitable for the production of all kinds of sub-tropical fruits; farms are much sought after, and a large proportion of the land in the district is under cultivation.

Bananas appear to be the staple production, and it is estimated there are about 500 acres under them, each acre carrying about 500 plants. Pine-apples of a superior variety have recently been introduced—the Natal Pine. Lemons form the staple, and can hardly be surpassed for flavour, though much smaller in size than some others. A considerable trade in the latter fruit is done in this district. "Naartzes" and Oranges flourish most luxuriantly. These trees come into bearing in their fifth year, and continue until their thirteenth; and as the tree ages, the fruit becomes small. By cultivating the soil, or feeding the roots, its life may be renewed, and the fruit improved. The culture of the Naartzes and Oranges is an item of considerable importance, but the industry has not been systematically carried out.

PLUM, COE'S GOLDEN DROP.

If care be exercised in gathering and storing this most useful Plum, it is possible to keep it in good condition for dessert until Christmas. The fruits should be perfectly dry when gathered, and on no account must the fruit be severed from the stalk, or decay will soon set in where the union existed. A good plan is to cut them from the tree with a pair of scissors, laying them carefully in a tray or basket lined with some soft material, and then carrying them carefully to a dry fruit-room.

In some seasons, it is necessary to cover the trees with tiffany until the fruit is ripe, to protect the fruit from wasps and large flies, it being essential that the skin be not broken. Such protection has not been necessary here this season. The trees are against a wall with a west aspect, and yield a good crop most years. They are of considerable age, and this has, doubtless, something to do with their productiveness, for I have not seen young, vigorous-growing trees of this variety fruit so freely and regularly.

Some growers wrap each fruit in tissue-paper for the purpose of keeping them sound, and I have done this, but have failed to discover any special advantage in the system, whilst extra watchfulness is necessary in such cases to detect and instantly remove any unsound fruits. It is my opinion that first-class varieties of Plums should be planted more extensively even than now, against walls, for the supply of fruits for dessert. The flavour of a well-grown dessert Plum will bear comparison with almost any fruit usually grown against walls in this country. By a careful selection of varieties, a constant supply can be maintained during many months of the year. In some gardens, room cannot be found for many Plum-trees because the space is required for other fruits, generally considered superior to the Plum.

Peaches are planted against west walls, and very rarely do they succeed, but much time is spent, and wall space lost, in pruning and training them. Such an aspect is most suitable for Plums, and given good cultivation they will yield fine and useful crops. *H. T. M., Stoneleigh Abbey Gardens, Kenilworth.*

HOME CORRESPONDENCE.

TOMATOS.—Several instances have occurred this season of luxuriant growth on sewage farms of Tomato-plants produced from seeds that have passed through human bodies. Not only has there been such growth, but good crops of fruit have been produced. That such has been the case, is doubtless due to an unusually warm season. But the growth of such seeds shows all the same the remarkable vitality of the seed in the passage through the human body. Should the birds take to devouring the attractive-looking fruits, as some day they may, it would be little short of a national catastrophe, seeing how the cultivation of the Tomato has extended, and how difficult it would be found by the gardener to protect this crop in the open. Moreover, the plant would then become a troublesome weed, springing up from the seeds voided by the birds. I thought it bad enough when the other day in a large garden, noting that literally thousands of leaves had to be put into muslin bags; and Apple-trees in all directions netted over to save the fruits from the birds. When such precautions are needful, what wonder will it be if brilliant red and golden Tomatos should become the prey of these predators? *A. D.*

TOMATOS AS A FIELD CROP.—From the interesting notes on this subject at p. 257 of the *Gardeners' Chronicle*, it would appear that those persons who reside in [some of] the most favoured parts of England are slow to recognise the advantage of planting Tomatos out-of-doors. Yet I am inclined to think that it is previous experience which deters growers from venturing far in this direction, for it is upwards of twenty-six years ago that one grower in the Worthing district suffered a heavy pecuniary loss through the failure of some acres of Tomatos. It was the first year that any disease made its appearance. I have seen some very good

crops this season, and no doubt those who have planted Tomatos out-of-doors will be tempted to venture still more another year; but it will always be a doubtful crop in this country, except in exceptionally dry sunny seasons. Previous to diseases making their appearance, Tomatos were extensively cultivated in the open in the neighbourhood of Worthing. I believe Messrs. Pullen & Berry, of Sompting, were among the first to grow them to any extent; and although it is generally supposed that the cultivation of the Tomato in England is quite a modern institution, it dates much further back than is generally supposed—and it must be at the least thirty to forty years ago since the above-named firm cultivated them extensively. They were also grown by other Sussex market-growers. Among my earliest

GENERIC VARIATION.—With reference to your extract on p. 286, from Prof. Sedgwick's address to a section of the British Association, and especially to the remarks on bud variation, I cannot perceive any parallelism between bud sports and abnormal characters presenting themselves at particular times in the life of an organism. Prof. Sedgwick states: "thus there is nothing more remarkable in a single bud on a tree departing from the usual character at a particular time of life than on a particular hair of a mammal doing the same thing;" but surely there is an immense and vital difference between the two phenomena. In the first place, it is altogether new to me that bud variation is in any way associated with particular times of life; and in the second place, there is the fact that such bud sports may, and indeed usually do, involve a

growth and development," they should surely appear on all individuals which flourished and fulfilled their life career. I have in my mind, especially, certain varieties of Ferns which bear prolific buds. As a rule such buds reproduce the parent plant exactly, but occasionally the resulting plants are distinctly different, as the result of asexual bud variation; but this is an absolutely different case from that of Ferns which do not assume certain characters until they are adult plants, which characters are true "stages in the growth and development," while the others, the new ones, are departures. It is, furthermore, a moot point as to how far such variations are induced by environment. Prof. Henslow holds that they are the outcome of change of environment, a view which my experience of wild varietal finds renders it difficult for me to accept, though in the records of cultural selection of abnormal forms, it seems certain that close culture can induce, and permanently fix, fine dissection and fimbriation in the new sports resulting thereunder; while if the views that a Fern-spore is of the nature of a bud be accepted, my examples could be extended indefinitely. In short, if "the particular (varied) hair of a mammal" could be grown on into a complete mammal, varied to suit, the parallel between it and a permanent bud variation would be complete, but, as I venture to think, not otherwise. Surely, too, the assertion "that sexually-produced plants do not resemble the parent," is open to many exceptions, as well as that "by asexual reproduction, the exact facsimile of the parent may always be obtained." In most normal plants the seedlings are practically undistinguishable from the parental forms—at any rate, they cannot possibly be said "not to resemble them;" while, as we have seen, bulbils may produce varieties which differ materially. *Chas. T. Druery, F.L.S., V.M.H.*

HELIUM AUTUMNALE STRIATUM.—It may, perhaps, be permitted me to thank Mr. Meehan for his note on p. 317 of the *Gardeners' Chronicle*. Soon after this plant was introduced into this country under the name of *Helenium grandicephalum striatum*, I stated in the columns of a contemporary my opinion that it was a form of *H. autumnale*. As other opinions were held by some whose views were entitled to more consideration than mine, I did not care to assert my view too forcibly. This plant is very unlike the *Helenium* sent out under the name of *H. grandicephalum* only a short time before the striped variety of *autumnale* appeared in commerce. It is quite probable, in view of what Mr. Meehan says, that the reason of the variation in the colouring of *H. a. striatum* is to be found in the differences caused by raising the plants from seed. It may be hoped that compilers of nursery catalogues as well as writers for the horticultural press will take note of the statement of so distinguished an authority upon the native plants of the United States. *S. Arnott, Carsethorn-by-Dumfries.*

THE SINGLE-FLOWERED CHINA ASTER.—On my recently visiting the gardener at Ty Coch, a fine lot of plants of this Aster was pointed out to me. Mr. Kennedy, the gardener at Ty Coch, said that he had been cutting flowers from these plants for several weeks, and they appeared likely to afford blooms for several weeks longer. The seed was obtained from the Continent. *C. Tyler, Parkia Gardens, Carnarvon.*

SALVIA PATENS.—My interest in the article on "Good Border Plants" by Mr. Brotherton, in the *Gardeners' Chronicle* of October 21, was enhanced from having had the opportunity of observing the plants in bloom at Tynningham. If one may be permitted to express an opinion upon the beds of *Salvia patens* and blue *Lobelia* referred to by your contributor, it is that Mr. Brotherton has, with characteristic modesty, hardly done justice to his arrangement. The beds in question were very pretty, and did not in any way mar the skilful planting of which it formed a part. The reference to this *Salvia* not proving quite hardy at Tynningham leads me to remark that this is the general experience in Scotland. It has been included in stands of hardy herbaceous plants at shows, but these exhibits have caused considerable discussion among those interested. One of my plant-growing friends holds the view that there is a hardy variety of *Salvia patens*, but after trying it I am satisfied that its standing the winter is really due to the character of the garden or the season. I do not dispute that there are some gardens in the west of

FIG. 110.—VIEW OF PART OF THE ROCKERY AT FRIAR PARK, SHOWING THE EDELWEISS IN FLOWER. (SEE P. 321.)

recollections of nursery work, cleaning Tomato-seed is, though, not the most pleasant, vividly retained, for it often happened that the fruits were in an advanced state of decay. While on the subject of Tomatos, I may mention that I have visited several establishments in this neighbourhood where they are extensively grown under glass, and find that the old style of growing them on the extension system is not quite obsolete, though the best growers confine them to a single stem, the height of which varies according to the capacity of the houses. The heavy cropping varieties (selections from the old red) are mostly in favour, though the great difference in the prices realised for these this season, compared with the smooth round-fruited varieties, may lead to a change. I have seen some very good crops of the round-fruited (a selection from Chemin) grown in pots, and although the weight would fall somewhat short compared with the corrugated varieties, I think the returns would be quite equal. *A. H., Worthing.*

permanent change, not in a mere excrescence of limited growth, but in a new and independent individual whose reproductive powers are also modified to enable it to reproduce its own particular type, and that not at any defined period of its existence. How can such bud variations be "probably stages in the growth and development of the organism?" In the history of such variations, we find that generally an immense number of the normal forms of the parent organisms have run the normal course of existence, from youth to old age, without presenting the new features or any trace of them at any period of their individual existences. Suddenly a solitary bud appears, it may be on a young, or it may be on an old plant, and it is found to be much modified in foliage, flower—and what is more, seed. Furthermore, one and the same species may produce on different individuals, or even on the same, as witness the recorded origin of the Moss Roses, widely different sports. If such variations were "stages in the

Scotland where this *Salvia* is hardy, but the general experience is that of Mr. Brotherston. *S. Arnott, Carsethorn-by-Dumfries, N.B.*

SEEDING OF RARE SHRUBS IN IRELAND.—Owing, I presume, mainly to the fine, dry, warm summer we have been favoured with this year, the following rare and beautiful shrubs have ripened seed here, most of them for the first time: *Chimonanthus grandiflorus*, on a very large specimen bush in an angle of my walled-in garden, which is covered with its deliciously-fragrant blooms every Christmastide, is extremely shy to set seed, and only produced two or three pods and nine seeds, which take eight or nine months to ripen, but germinate pretty freely if sown at once when ripe. *Eucryphia pinnatifolia*, resembling a pure white *St. Johnswort*, a most free-blooming and beautiful shrub, ripened a fair amount of seed, and should be in every choice collection; *Adenocarpus decorticans*, the beautiful Furze-broom from the Sierra Nevada, a most free-blooming and beautiful shrub, has produced seed in former years, but though it seemed plump and good, none of it ever came up. I hope I may be more fortunate with it this year. I do not know why it bears the descriptive name it does, as its bark does not peel off to anything like as great a degree as, for instance, *Olearia ilicifolia*, often grown under the erroneous name of *O. macrodonta*, and sent out as *O. dentata*. *Hamamelis Zuccariniana*, the pure yellow-flowered Japanese species, which is very seldom met with in shrubberies, but is most free-blooming, and well worth growing. The beautiful Chinese shrub, *Xanthoceras sorbifolia*, though it bloomed most profusely and beautifully on one of my walls, did not set a single one of its large, Horse-chestnut-like seeds. *W. E. Gumbleton.*

THRUSHES AND BLACKBIRDS, AND FRUIT.—The statement of your correspondent, Mr. J. Hart, in the issue of the *Gardeners' Chronicle* for September 30, must be taken *cum grano salis*, as we all know that thrushes and blackbirds will get at large fruit—indeed, any kind of fruit—unless well protected with herring-nets, and these must have every mesh perfect, and be made secure at the margins, or the birds are sure to get in. In netting wall-trees this is very important; moreover, the net must be kept at the distance of $1\frac{1}{2}$ ft. from the face of the wall by means of shoots of Willow or Hazel, made with a slight notch or slit at the end to receive the threads of the meshes. *F. M.*

AMATEUR GARDENING.—In potting-off my *Pelargoniums* from the garden, I have come across two (distinct varieties), which have grown on one stem, i.e., the root of the one has grown on to the stem of the other, and is deriving its nourishment through this other's stem. Is this a freak, and is the bloom from this "twin" likely to be a novelty? *R. G. Bassett, 2, May's Villas, Fools Cray, Kent.* [This is probably a "sport," and not a union of two plants. *Ed.*]

FRUITING OF SCHUBERTIA GRANDIFLORA.—I do not remember to have read any mention of the fruiting of *Schubertia grandiflora*. At the present time, there is a fruit upon this plant in the stove at Prestwold. In appearance, it resembles a Gherkin, is about 4 inches long, and has prickles similar to those of a Gherkin. The fertilisation of the flower was not assisted in any way. I should be glad to hear if this stove-climber has previously fruited in this country. *D. R., The Gardens, Prestwold, Loughborough.* [This plant is now regarded as a form of *Aranja graveolens*. *Ed.*]

EXTRAORDINARY CROPPING OF POTATOS.—It may be interesting to readers of the *Gardeners' Chronicle* to know that two crops of Potatos can be had in county Cork within a year by sprouting "Early Bird" in December, and planting the sets out in warm borders in February. This year, an experiment was made in the following manner: The sets were started as mentioned, and new Potatos were to be seen in the warehouse window the first week in May. The 1899 seed got sunned naturally, and in June were again planted in a warm border, the result being that Potato-tubers of full size were dug last week and the plants were in blossom until the frost of the 6th inst. I remember before the blight of 1846, seeing the old white Quarry Potato being dug from the soil in May, and in the same field the same month, the old Mignon and Crow Potatos were being planted; there was no blight then, and the stalks kept green

until cut down in October and November by frost. Possibly, this may be done in the Channel Islands and in Cornwall. The "Early Bird" is a Potato of my own introduction. *Wm. Bayler Hartland, Ard Cairn, Cork, Oct. 16, 1899.*

FLORISTS' FLOWERS.

AUSTRALIAN CHRYSANTHEMUMS.

It is only a few years ago since the Chrysanthemum growers of our Australian colonies started the raising of seedlings. A few of these were imported into this country, and when grown by capable cultivators proved to be of exceptional merit, some of them rivalling in point of size and colour the best of the leading continental varieties. Last season there was a large influx of these colonial novelties, and judging by the success that they met with it was only fair to assume that more would be heard of them again this year.

A visit to Mr. Wells, of Earlswood, recently, confirms this, and in his extensive and interesting collection, which comprises novelties from all sources, the visitor cannot fail to be struck with those he has received from Mr. Thomas Pockett and other Australian growers. Few raisers have done so much in so short a time as Mr. Pockett to enrich our collections, and the following, both old and new, appear to me to be in very satisfactory form this year:—Nellie Pockett, beautiful glistening white, a Japanese, with long, narrow, twisted, grooved florets; Mermaid, pure white, a Japanese, slightly flushed, rosy pink; Janet Lady Clark, very large blooms, Japanese, long quilled florets, colour deep rosy-mauve; Wonderful, also a Japanese, colour golden yellow, inside deep chestnut-crimson; Pride of Stokell, crimson; Wattle Blossom, very globular, florets long, twisted, and grooved, colour deep lemon yellow; J. R. Upton, deep yellow; Australian Belle, very long tubular florets, slightly hairy at the tips, very large, colour lilac-mauve; Miss Ida Barwood, a large, fine white Japanese; John Pockett, fine crimson, seen last year; Silver Queen, rosy-pink, very pretty long florets; Mr. T. Carrington, &c. *C. Harman Payne.*

IRELAND.

THE DUBLIN MUSEUM.

THE herbarium of The Dublin Museum has been enriched by a munificent present, the entire herbarium of the late Lord de Tabley having been presented to the Botanical Department by his sister, the Hon. Lady Leighton. The botanical collection is mainly confined to British plants, and was of great service to the deceased Lord de Tabley in the compilation of his recently-published *Flora of Cheshire*. As yet, the specimens are confined to their boxes; Professor Johnson is only awaiting the completion of some cases when he will be enabled to place them at the disposal of the many students who frequent the well-filled corridors of his department. The actual numbers of sheets of specimens is still undetermined, but a low estimate places this collection at least at 20,000 plants. This gift is actually due to the recommendation of Sir W. Thiselton Dyer, Director of Kew, who states that the herbarium will be useful to active working botanists in the Irish metropolis.

TREES AND SHRUBS.

PINUS BALFOURIANA VAR. ARISTATA.

WHEN at Welbeck recently, I was agreeably surprised at the fine specimen of the above, which stands out so conspicuously on the greensward near the Abbey entrance. At last I thought I had found a genuine specimen of the species; but, alas! on procuring a cone, it turned out to be the variety *aristata*, the cones of which have conspicuously

hooked scales, and which you figured lately from specimens collected by me at Watford.

The Welbeck tree, though a larger tree than the Hertfordshire specimen, bears much smaller cones, and, curiously enough, the leaves are as often in fours as in fives.

Can anyone tell me where the true species may be seen growing in this country? The tree seems quite hardy wherever I have come across it, and the curiously arranged foliage—fox-tail in appearance—of the softest shade of green, might well make the tree a favourite with lovers of Conifers. I should be very grateful for a cone of the true *P. Balfouriana*. *A. D. Webster, Greenwich Park.*

NURSERY NOTES.

J. CHEAL & SONS, CRAWLEY.

WE were disappointed on visiting the Lowfield Nurseries, near Crawley, on October 12, to find that the Dahlias had already been blackened by frost. In the London district our own were fresh and bright, but 7° of frost are too much for the Dahlia, and the thermometers in the Crawley district had fallen thus low. They are fine, broad plantations of Dahlias, are those from which Messrs. Cheal obtain the fine blooms for exhibition. The visitor sees at once that the Dahlia is a specialty of the firm, and those of us who have attended the summer shows have seen excellent collections of blooms from Crawley. The firm have been successful during the present season in obtaining awards for five Seedlings, including three single-flowered and two Cactus-flowered varieties. The singles are Flame, a yellow flower, flaked and striped with orange-red, of fine form in the way of Lord Rosebery, but distinct from it; Daisy, a pale flower, flaked and pencilled with dark crimson and purple, a novel and distinct variety of finest form; and Veronica, orange-red, each floret tipped with bright amber. The two Cactus-flowered varieties are Mrs. J. H. Luscombe, of a mauve-pink tint; and Mrs. Stephenson Clark, "old gold" colour, the petals tipped with red. Except in the case of Flame, which has been distinguished by the Royal Horticultural Society and the National Dahlia Society, the awards obtained have been those of the Royal Horticultural Society.

But if the Dahlia season was practically finished, there was abundance of interesting circumstances to be observed in—

THE FRUIT NURSERIES

at Lowfield. The season has been a capital one for Apples. With such a strong, clayey soil as Messrs. Cheal's, a prolonged drought inflicts but little injury to the trees, and more than this a hot season brings many a variety to greater perfection than it attains in an ordinary summer. Many of the varieties of Apples were still ungathered, and there were particularly heavy crops upon the following amongst others: Bess Pool, a capital Apple for late cold districts, because, blooming exceptionally late, it escapes spring frosts. Cellini Pippin, Emperor Alexander (exceptionally good fruits of this first-class culinary Apple); Ringer, a very pleasant Apple when taken from the tree, but not included in many collections; Golden Reinette, extraordinary crop; Hornead's Pearmain, a grand Apple extensively cultivated in Sussex, where it is much prized, and Royal Jubilee. The last-mentioned variety is a capital Apple for kitchen use until December. Messrs. Cheal regard it as one of the best of the newer varieties, being a strong grower with compact habit of growth, very late in blooming, and seldom, if ever, failing to carry a good crop of fruits. The fruits are Codlin-like, pale-lemon in colour, and keep much longer in good condition than one would judge from their appearance. Royal Jubilee is therefore worth almost the same attention that planters have at last given the variety Bismarck, whose extraordinary cropping qualities are again demonstrated in

the Lowfield Nurseries, upon the fine three-years, two-years old, and even maiden trees. Another good kitchen Apple that meets with favour in Sussex is Schoolmaster, but the fruits keep good only until about the end of November. Several good cultivators in widely-separated districts have spoken well recently of this variety. Golden Reinette, one of the most delicious of dessert Apples, was carrying an extra crop of fruits; Margil, a grand variety for bushes; and Duke of Devonshire, a dessert Apple that deserves to be much more frequently planted than is the case at present—it succeeds capitally in any form of tree. There were handsome fruits of Lord Derby, on some two-years-old transplanted trees, and it is worth remark that this and a few other Apples that are more or less angular in outline when grown in this district, lose this characteristic to a considerable degree.

These are only a few of the varieties of Apples in Messrs. Cheal's collection, which is replete with all the best new ones and standard varieties, including Armorer and Atalanta, two dessert varieties raised by Mr. C. Ross, and distributed from the Lowfield Nurseries. These were figured in the *Gardeners' Chronicle*, March 4 and March 11, 1893.

But Messrs. Cheal & Sons are not engaged in growing fruit for market. Theirs is a fruit-tree nursery, and a fine lot of trees there are for planting during the season now commenced. The stock is clean, naturally grown, free from the effects of an excessive use of manures, and the growths are thoroughly matured. They should lift very well even now, and better still if more rain should fall.

The forms of tree the firm is making a specialty of are half-standards and bushes. For these, it is said, there is a great demand. The half-standards are budded at from 3 feet to 4 feet high, and they commence to fruit early. Specimens of these and of bushes were in capital condition. But other systems of training are practised, to suit the individual tastes of the cultivators, whether it be for the large standards for orchard-planting, pyramids, or single and double cordons. Pears are not less numerous than Apples, and the 5000 or so maidens are looking very well, and have made a very satisfactory growth.

There are also in one batch about 5000 two years old Pear-trees, capital specimens in about twenty choice varieties, and some of the trees already showing bloom buds.

Cherries, either as bushes, pyramids, or cordons, are cultivated, and meet with a ready sale, as also do Plums. The one and two years old Plums have made this season the best growth of all the fruit-trees. There are excellent Plum-trees trained upon the fan system, for planting against walls.

Peaches and Nectarines seem to thrive capitally as trees, and the growth they make is as satisfactory as possible. The 1500 specimens of trained trees were a picture to behold. As previous notes in the *Gardeners' Chronicle* have described, Messrs. Cheal's nursery is divided into small fields or plantations by great hedges of Hornbeam, 10 or 12 feet high, and these are of great value to the young trees by protecting them from rough winds.

FOREST AND ORNAMENTAL TREES.

Whilst Mr. Alexander Cheal is employed in superintending the work in the nursery, his brother, Mr. Jos. Cheal, assisted by his son, carries on a very considerable business as a landscape gardener and designer. The rate at which this part of the business has increased, has led the firm to grow an increased number of hardy trees and shrubs for furnishing of new places laid out by the firm. Consequently, about half the land at Lowfield is covered with these trees, and beautiful many of them were looking in their autumn tints.

But our visit was one more especially connected with the fruit, and we must refrain from discussing this subject in detail. We cannot help remarking, however, that a bed of *Berberis Thunbergi* created such a magnificent patch of colour as we are never likely to forget,

FOREIGN CORRESPONDENCE.

GALTONIA CROSSES.

THE article in your issue of September 2 on a hybrid between *Galtonia candicans* and *G. princeps* was very interesting to me, for I have made the same cross, and have the plant now in flower. They are very accurately described in the article referred to. My object in writing is to say, that both this year and last the bulbs came into blossom about two weeks earlier than either parent, and to ask whether the same is the case at Kew. *W. E. Endicott, Canton, Mass., U.S.A., September 18, 1899.*

Obituary.

SYDNEY COURTAULD.—We learn with great regret of the death of this gentleman, on the 20th inst., at Bocking Place, Braintree, Essex. His amiable disposition, uniform courtesy, benevolence, and enthusiastic love of horticulture, endeared him to his associates. He was an active member of the Council of the Royal Horticultural Society, and

THE LATE SYDNEY COURTAULD.

whilst specially interested in the cultivation of Orchids, by no means confined his attention exclusively to those plants. His name is commemorated in *Masdevallia Courtauldiana* (*M. rosea* × *M. caudata* Shuttleworthii), raised by Mr. Norman Cookson, of Oakwood, Wylam-on-Tyne.

In our number for October 4, 1890, will be found a detailed account of his garden, which illustrates his fine taste and catholic sympathies as regards plants. Mention is also made therein of the public garden presented to the inhabitants of Braintree by "Sydney Courtauld and Sarah Lucy Courtauld, his wife." An illustration of Mr. Courtauld's garden was also given in our number for Feb. 21, 1891. Mr. Courtauld was in his sixtieth year.

GRANT ALLEN.—The death of this eminent writer and enthusiastic naturalist is announced to have taken place on the 25th inst. Gifted with a picturesque and fluent literary style, he did good service in popularising the teachings of Darwin and Herbert Spencer. His vivid imagination and the fluency of his style, however, led him to treat plausible hypotheses as if they were demonstrated facts, so that his natural history studies, attractive as they were, were somewhat lacking in scientific caution. Mr. Allen was a Canadian by birth, having been born at Kingston in 1848. He

was educated at Merton College, Oxford, and afterwards engaged in educational work in Jamaica and elsewhere. His early writing brought him neither fame nor funds, but subsequently the brilliancy and lucidity of his literary style secured him a hearing as an essayist, and later as a prolific writer of fiction. Mr. Allen, who had long been in ill health, died in the fifty-second year of his age.

LAW NOTES.

ALLEGED LONG FIRM FRAUDS.

AT the Lambeth Police Court, on Oct. 17, James Piggott, 45, a decently-dressed man, who described himself as a florist, and refused to give his address, was charged on remand with obtaining £5 from John Leather by means of a certain false pretence, and with intent to cheat and defraud. The prisoner was arrested on a warrant by Detective-Sergeant Long, who found him at a house in Great Dover Street, Borough. Mr. John Leather, a florist, of Mitcham, stated that on August 25 he advertised in the *Gardeners' Chronicle* for a quantity of *Pelargonium* cuttings. In reply, he received a letter from a person giving the name of Shuttleworth, and an address in the Kennington Road, offering to sell a large number of cuttings. He eventually forwarded a cheque for £5 to the address in the Kennington Road, but he failed to get an acknowledgment, and the cuttings did not arrive. He then wrote cancelling the order, and stopped payment of the cheque. He afterwards found that the address in the Kennington Road was a shop at which letters were taken in. Further evidence was given, showing that on September 12 or 13 the prisoner cashed Mr. Leather's cheque at the "Old Nag's Head," at Mitcham. The landlord, Mr. J. R. Cheshire, cashed the cheque readily, because Mr. Leather was a personal friend of his own. Detective-Sergeant Long mentioned that the police had received nineteen or twenty complaints concerning the prisoner. Mr. Hopkins directed a further remand.

DISPUTE ABOUT NATIVE LARCH-SEED.

On Thursday, October 12, at Jedburgh, Sheriff Baillie gave his decision in the action and counter-action between J. & A. Smith, seed collectors, Forfar, and Charles Irvine, seed merchant, Jedburgh—the former suing for an account for a supply of native Larch-seed, and the latter claiming for loss owing to the seed being faulty and unproductive. The Sheriff held it proved that the seed was bad; and, in regard to the averment of non-warranty made by the Messrs. Smith, he said the onus of proof on this point, which lay upon them, had not been discharged by them. He gave decree only for items in the claim that were not disputed; and, in the counter-action by Irvine, he gave decree for £6 10s. for the loss he had sustained, and found him entitled to expenses. *North British Agriculturist, Wednesday, October 18, 1899.*

SOCIETIES.

ROYAL HORTICULTURAL.

OCTOBER 24.—An announcement made in our last issue by the officials of the Royal Horticultural Society to the effect that the Drill Hall at James Street, Westminster, would probably be unavailable for the fortnightly meeting of the Society on Tuesday last, happily proved to be incorrect. The Hall was not full of the Queen's soldiers, but, instead, very nearly full of *Chrysanthemums*. There were several groups of plants in pots, and a number of extensive exhibits of cut blooms. The season may now be said to have well commenced, and already many of the recognised *Chrysanthemum* specialists are able to say definitely when their particular collection will be at its best. But the season is a late one. Awards of Merit were recommended to five varieties, *Florence Molyneux*, *Miss Edith Pilkington*, *Le Grand Dragon*, *Miss Alice Byron*, and *R. Hooper Pearson*. The Floral Committee also recommended an Award of Merit to a variety of *Adiantum* named "Burnii," a variety with drooping fronds, that will be very suitable for the furnishing of suspended baskets. From

Hawick, N.B., Mr. JNO. FORBES exhibited a white flowering sport from Begonia Gloire de Lorraine, that will make a pretty companion for that excellent winter flowerer. There was a considerable display of Orchids for the date of the season, and a few awards were made to novelties.

THE FRUIT COMMITTEE had before it an unusual number of collections of hardy fruit, most of them from amateurs, but some from the trade; and excellent collections of vegetables were shown by Mr. W. Pope, gr. to Earl of Carnarvon, Highclere Castle, Newbury; and Messrs. CANNELL & SONS, Swanley, Kent. Awards of Merit were made by this Committee to a hardy Grape, Reine Olga, exhibited by Mr. WILL TAYLOR, Hampton; and to Apple Panquet, from Mr. BOSS, Welford Park Gardens, Newbury. In the afternoon Mr. GEO. MONRO gave a lecture upon "The Development of the Fruit-trade," and in illustration of the subject exhibited a large collection of the choicest market fruits.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. C. T. Drury, H. B. May, R. Dean, W. Howe, Jas. Hudson, John Jennings, J. F. McLeod, H. Selfe Leonard, D. B. Crane, J. Fraser, Chas. E. Pearson, Chas. Jeffries, C. R. Fielder, George Gordon, Chas. E. Shea, E. H. Jenkins, E. T. Cook, E. Beckett, Owen Thomas, Thos. Feed, R. B. Lowe, and H. J. Cutbush.

CHRYSANTHEMUMS.

Mr. H. J. JONES, Ryecroft Nursery, Hither Green, Lewisham, put up an extensive group of large-flowering Chrysanthemums in pots, including a number of last season's novelties. On either side of this group was a smaller one, in the one case composed of finely-cultivated specimens of Codicums, and in the other Cordylines. The Codicums especially were remarkable for their fresh appearance and fine colour (Silver-gilt Banksian Medal).

Mr. NORMAN DAVIS, Framfield Nurseries, Sussex, made a magnificent display of Chrysanthemum blooms. These were cut with long stems, and were arranged in handsome vases and other receptacles, a few trumpet-shaped glasses being about 4 feet in height. Very large blooms were shown, and also smaller ones of a decorative size. As a rule, one variety only was used in each vase. There were handsome blooms also displayed upon stands, including Mutual Friend, Mrs. White Popham, Lady Phillips, Mrs. Coombes, a lilac or mauve-coloured flower, of very refined appearance; Miss Alice Byron, a large white Japanese incurved, &c. The exhibit showed much taste in arrangement, and the quality of the blooms was good (Silver-gilt Flora Medal).

Mr. W. J. GODFREY, Exmouth, Devon, had a collection of cut blooms, for which a Silver Flora Medal was awarded. There were some excellent blooms in the stand: Le Grand Dragon was represented with half-a-dozen specially good flowers; Martin H. Tucker, crimson Japanese with gold reverse, was fine; also Mrs. White Popham, Ettie Mitchell, and many others were very good. A few decorative varieties were put up in Bamboo stands, and were very pretty in appearance (Silver Flora Medal).

MESSRS. W. WELLS & CO., LTD., Earlswood Nurseries, Redhill, showed a nice lot of blooms of the border variety, Nellie Brown, a dark sport from Ryecroft Glory; also, Mychett Beauty, and others. There were capital blooms in this stand of many exhibition varieties. The rich yellow Japanese R. Hooper Pearson, was shown grandly; Sir Redvers Buller, crimson Japanese, with buff reverse, is very promising; Kathleen Rogers and M. Fatzer, both novelties of last season, were well shown. Yellow International, a sport from the type, and a number of other varieties, were capitally shown (Silver Banksian Medal).

MESSRS. H. CANNELL & SONS, Swanley, Kent, showed a collection of cut Chrysanthemums, including some fine blooms of Mutual Friend, Edith Tabor, Mrs. S. C. Probyn, General Paquie, Ella Curtis (very nice), and Madame C. Ferrier, a new Japanese variety, rosy-lilac with silvery reverse. Lady Audrey Buller, a seedling from Sunshine, promises to be a very pretty yellow Japanese; and Mrs. Frank Gray Smith, a new Australian variety, Japanese incurved, with a chestnut appearance, is promising. A plant was shown of White Quintus, a white sport from O. J. Quintus, and a useful variety for cutting from.

A Chrysanthemum named Amitié de L'Agriculture was shown by Messrs. ROET, VEITCH & SONS, Exeter. It is a yellow Japanese, and the florets are striped in varying degree with crimson.

Mr. THOS. S. WARE, Hale Farm Nursery, near Tottenham, showed a very fine group of Chrysanthemums in pots. These were all border or decorative varieties, and were abundantly flowered, making quite a floral picture (Silver Banksian Medal).

MISCELLANEOUS.

MESSRS. J. FRED & SONS, Roupell Park Nurseries, Norwood Road, London, S.E., staged a group of fine foliage plants. Choece green and variegated species were shown in clean, well-cultivated specimens. There were excellent Cordylines and Codicums, the pretty Leea amabilis, some of the choicer species of Palms, Aralias, Sonerilas, including a free-growing silver-coloured variety of the latter, named Souvenir de Louis Van Houtte.

Begonia Gloire de Lorraine was again shown as beautiful specimens by Mr. H. B. MAY, Dyson's Road Nurseries, Upper Edmonton. The plants were in 5-inch pots and abundantly bloomed. A few of the small white-flowered B. Dregei were included, and the whole were delightfully relieved with excellent specimens of Adiantum cuneatum (Silver Banksian Medal).

From J. WARREN, Esq., Handcross Park, Sussex, were shown several new varieties of Cordylines, all of them narrow-leaved. They were called Offeri, Warreni, and Marchamiana; C. Offeri, as shown, was the prettiest, and had the most colour.

MESSRS. W. CUTNISH & SONS, Highgate, N., were awarded a Silver Banksian Medal for a pretty group of berry-bearing plants, such as Pernettyas and Skimmias.

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, showed flowers of Nerine Leichtlini and N. var. Lucy Douglas. This latter is a hybrid raised at Glasnevin, and has large very singularly coloured flowers, shades of lilac and salmon.

A white flowered sport from the Begonia Gloire de Lorraine named Caledonia, was exhibited by Mr. JNO. FORBES, Hawick, N.B. It had a group of these plants in small pots. In habit and in all other respects but colour, the variety is apparently identical with the type, and for use in connection with the well-known pink bloomer it will doubtless be much valued.

N. R. HOFFMANN, Esq., Thurlow Lodge, West Dulwich, S.E. (gr., Mr. Thos. Tomlinson), showed a group of seedling Cistidiums in 3-inch pots, most of the plants having made four or five leaves. They were all raised from seeds obtained from a single pod, and were the result of a cross between the varieties Mrs. Harry Veitch and Alfred Bleu. The flower was pollinated on April 3 this year and the seeds were sown on May 17. The plants showed great variety in the colour of the leaves.

MESSRS. J. CHEAL & SONS, Lowfield Nurseries, Crawley, exhibited sprays of hardy shrubs showing autumn tints.

MESSRS. JAS. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, again exhibited flowers of their hybrid Rhododendrons, R. Javanico x Jasminiflorum. Notwithstanding the almost continuous fog that blackened London for a week previous to the meeting, these Rhododendrons were admirable. Especially were the varieties Exquisite (yellow), Hercules (buff), and Amabile (pink), of extraordinary beauty.

MESSRS. JNO. LAINO & SONS, Forest Hill, London, S.E., showed a group of clipped Yews and Box-trees, also variegated Conifers, &c.

Awards.

Adiantum Burnii.—A graceful variety, with drooping fronds, exceptionally suitable for planting in baskets, and the fronds, when cut, for drooping over the exterior of vases. It might be described as like A. amabile, with much-extended fronds. From Mr. W. J. BURN, the Nurseries, Cromer (Award of Merit).

Chrysanthemum Le Grand Dragon.—A yellow Japanese, fine deep bloom, solid, abundance of florets. From Mr. W. J. GODFREY, Exmouth Nurseries, Devon (Award of Merit).

Chrysanthemum Florence Molyneux.—A very large, globular, white-flowered Japanese incurved; a very high-built flower, of bold appearance, and wide florets. From Mr. N. MOLYNEUX (Award of Merit).

Chrysanthemum Miss Alice Byron.—See description on p. 336. From Mr. H. Weeks gr. to Lord BYRON, Thrumpton Hall Gardens, Derby (Award of Merit).

Chrysanthemum Miss Edith Pilkington.—An immense-flowered, lemon-yellow Japanese, showing suspicion of red towards centre. The florets are wide, and the variety is undoubtedly a very fine one. It is described as a very strong grower. From Mr. N. Molyneux, gr. to J. C. GARNIER, Esq., Rookesbury Park, Fareham (Award of Merit).

Chrysanthemum R. Hooper Pearson.—A deep yellow-coloured Japanese, resembling, except in colour, the variety Mutual Friend, and figured in *Gardeners' Chronicle*, Nov. 19, 1893, p. 369, when it was awarded the National Chrysanthemum Society's First-class Certificate. It is richer in colour than any yellow Chrysanthemum, and was sent out last season by Mr. H. J. JONES. At the Drill Hill there were excellent specimens shown by Messrs. WELLS & CO., Earlswood, Redhill (Award of Merit).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. J. Gurney Fowler, De B. Crawshaw, H. Little, E. Hill, J. Jaques, H. J. Chapman, W. H. Young, J. Douglas, H. Ballantine, F. J. Thorne, and Jas. O'Brien (Hon. Sec).

The Orchids made a very bright display, of which *Cattleya labiata* in variety formed the chief feature.

MESSRS. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Flora Medal for a group in which were a new and pretty hybrid *Cattleya*, a new *Lælia*, and *Lælia-Cattleya*, for which see list of awards. Older Veitchian hybrids represented of remarkable beauty were *Cattleya* x *Eurydice*, a fine wax-like bright roe-coloured flower; C. x *Wendlandiana*, a very bright and showy hybrid; *Lælia-Cattleya* x *Epicasta*, a fine large form of L.-C. x *Wellsiana*; L.-C. x *Hermione*, and the showy little *Sophrone-Cattleya* x *eximia*, with bright, purplish-red flowers, the labellum of a dark ruby-red. Among the *Cypripediums* were a good specimen of C. x *venustum* superbum, the favourite C. x *canthum* superbum, with three, and the pretty C. purpuratum, with five flowers; C. Charlesworthi, a good selection of *Cattleya labiata*, *Oncidium Forbesii*, O. varicosum, &c.

J. BRADSHAW, Esq., The Grange, Southgate, gr., Mr. Whiffen, was awarded a Silver Flora Medal for a very bright group, in which were some remarkable *Cattleya labiata*, and notably the singular blue-tinted C. *labiata* glauca, the pink and white-lipped C. l. *leucochila*, and a fine white form with very bright purple blotch on the lip. In the group also were

a remarkable nearly white-lipped *Oncidium tigrinum*, *Lælia autumnalis* atrobubens, with nine flowers on a spike; good plants of *Cattleya* x *Mantini*, *Lælia pumila*, &c.

F. KNIGHT, Esq., Thundersley, Essex (gr., Mr. E. Marston), staged a good group of excellent forms of *Cattleya labiata* and *Dendrobium Phalenopsis Schroderianum*, D. formosum giganteum, and *Cypripedium Charlesworthi* (Silver Banksian Medal).

Mr. ED. KROMER, Roraima Nursery, Bandon Hill, Beldington, secured a Silver Banksian Medal for a group that consisted chiefly of representatives of his importations of *Cattleya labiata*. The dark-coloured forms were especially fine, that named Bandon Hill variety having very fine flowers, and a lip almost wholly of a dark rose-purple tint. One fixed abnormal form, with pale lilac flowers, was very interesting, the petal-like lip being reduced to a narrow, ovate blade. About thirty varieties were represented. Besides these were some plants of *Lælia pumila*, L.-C. x *Schilleriana*, *Cattleya granulosa*, C. *guttata*, and other *Cattleyas*; *Sophroneitis grandiflora*, with twin-flowered inflorescence; and the remarkably-natural hybrid *Cattleya* x *venosa*, &c.

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), sent *Lælia-Cattleya* x *Gottoiana* var. *marmorata*, a very singular form with large flowers, more highly coloured than the original, and with sepals and petals of a light rose colour, marbled with rose-purple. The fine plant bore a five-flowered inflorescence. *Lælia pumila* magnifica was also shown by Sir F. WIGAN.

Her Grace the Duchess of NORTHUMBERLAND, Stanwick, Darlington (gr., Mr. Higgle), sent a fine inflorescence of a good form of *Vanda corulea* with twenty-two flowers, for which a Vote of Thanks was passed.

EDWIN STANLEY CLARK, Esq., Oak Alyn, near Wrexham (gr., Mr. Edwards), showed *Cattleya* x *Mantini* nodiflor.

Mr. J. W. MOORE, Cragg Royd Nurseries, Rawdon, near Leeds, showed a singular form of *Cypripedium Charlesworthi*, with white dorsal sepal, and pale greenish petals and lip—an approach to an albino, or colour suppression.

HENRY LITTLE, Esq., Baronshalt, Twickenham (gr., Mr. Howard), showed two spikes of *Cattleya Bowringiana* with many flowers.

H. TATE, Esq., Allerton Beeches, near Liverpool, sent a flower of a hybrid Orchid, supposed to be between *Lælia tenebrosa* and *Cattleya* x *Hardyana*, and which resembled a small L.-C. x *Schilleriana*.

Awards.

Lælia x *Mrs. M. Geatrix* (cinnabarina ♀, Digbyana ♂).—From Messrs. JAS. VEITCH & SONS, Chelsea. A remarkable hybrid, with flowers about five inches across. The lanceolate sepals and petals are yellow, with a very slight rose tint. The distinctly three-lobed lip also yellow, the side and front lobes tinged with rose colour, and curiously edged with an irregular fringe imparted by L. Digbyana (Award of Merit).

Cattleya x *Princess* (Trianel ♂, Luddemanniana ♀).—From Messrs. JAS. VEITCH & SONS. A grand flower of the typical C. *labiata* form, but with all the parts, and especially the petals and lip, very broad. Sepals and petals very pale rose colour; lip bright reddish-purple, with diverging orange coloured lines from the base to the centre (Award of Merit).

Lælia-Cattleya x *Duchess of York* (*Lælia crispa* ♀, *Cattleya Gaskelliana* ♂).—From Messrs. JAS. VEITCH & SONS. A close approach to the famed L.-C. x *Exoniensis*. Sepals and petals white, with a slight pearly-pink shade; lip white at the base, changing to lemon-yellow towards the disc; the elongated front lobe of which is bright ruby purple (Award of Merit).

Fruit Committee.

Present: Philip Crowley, Esq., in the chair; and Messrs. W. Wilks (Rev.), R. Parker, Jos. Cheal, W. Poupard, M. Gleeson, W. Pope, A. Dean, S. Mortimer, J. W. Bates, C. Herin, Jas. Smith, F. Q. Lane, Geo. Reynolds, R. Fife, and Geo. Bunyard.

Mr. O. TUDOR, Head-gardener to Her Majesty the QUEEN at Frogmore, Windsor, exhibited a large and very superior collection of hardy fruits, consisting chiefly of Apples and Pears. The fruits were remarkable for size and high colour, and freedom from blemishes of any sort. Notable dishes for form, size, or colour, were seen of Cox's Orange Pippin, Ribston Pippin, Allington Pippin, new; Wellington, Max Codlin, Nonauch Codlin, Yorkshire Beauty, Wealthy, new; Bismarck, Queen Caroline, Newton Wonder, of very large size, and handsome; Nelson's Glory, Lord Derby, Transparent du Crocnelles, the handsome Edmund Jupp, Beauty of Stoke, Golden Noble, Stone's, Adams' Pearmain, Dr. Harvey, and Sandringham.

Of Pears there were, among numerous varieties, very fine examples of Thompson's, Van Mons Leon le Clerc, Beurré Baltet Père, Olivier de Serres, Beurré Diel, Beurré Bosc, Maréchal Vaillant, Conseiller de la Cour, Duchesse d'Angoulême, Vicar of Winkfield, Doyné Dufais, Forelle, Doyné du Comice, Gratin, Beurré Sterckmans, Prince Consort, Marie Louise, very fine; Monarch, and Beurré Six. A Gold Medal was awarded.

LORD LANGATOCK, The Hendre, Monmouth (gr., Mr. T. Coomber), showed a very nice selection of varieties of Apples, including Frogmore Prolific, of large size; Egrement Russet, Hornead's Pearmain, blenheim Orange Pippin, Sandringham, Newton Wonder, Peasgood's Nonsuch, Belle Pointoise, and Lane's Prince Albert, all of which were of very fine fruits, and of a high degree of colour. Of Pears, there were Beurré Hardy, Doyné du Comice, Beurré Fouquier, Louise Bonne de Jersey, Beurré Diel, Durondeau, and Beurré Bosc (Gold Medal).

T. B. FORTESCUE, Esq., Dropmore, Maidenhead (gr., Mr. C.

Herrin), showed an excellent lot of fruit, mostly consisting of Apples of large size and good colour, and free from blenheim (Silver Knightian Medal).

MESSRS. JNO. LAINO & SONS, Forest Hill Nurseries, London, S.E., made an exhibit of fifty dishes of Apples in the more popular varieties. A good collection of excellent fruit (Silver Banksian Medal).

Another excellent collection of one hundred dishes of hardy fruits, including a fine lot of Apples and Pears, was shown by JOHN WARREN, Esq., Handcross Park, Crawley (gr., Mr. Offer), and a Silver-gilt Knightian Medal was awarded.

A similar award was given for a collection of one hundred dishes of hardy fruits shown by Mr. Geo. Wythes, gr. to the DUKE OF NORTHUMBERLAND, Syon House, Brentford. There were forty dishes of Pears, and amongst them were some very fine fruits, especially of Pitmaston Duchess, Doyenné du Comice, Beurre Bosc, and many others. The sixty dishes of Apples were capital, and dessert varieties particularly so.

MR. GEO. MONRO, salesman, of Covent Garden, London, exhibited a splendid lot of fruits, consisting of Grapes, Apples, Pears, Peaches, Tomatoes, &c., as sent to market, a collection which admirably illustrated Mr. Monro's interesting lecture.

A splendid collection of vegetables was shown by Messrs. H. CANNELL & SONS, Swanley, Kent, for which a Silver-gilt Knightian Medal was awarded. There were forty dishes of Potatoes, fine tubers of popular varieties. Cannell's Defence Cabbage was especially good; Carrots First Prize and Prize-winner; Cauliflower Autumn Giant; Savoy Drumhead; Parsnip First Prize; Onion Ailsa Craig, &c., and a collection of small-fruited Gourds were the principal exhibit. A tuber of Up-to-Date Potato shown weighed 28 oz.

THE EARL OF CARNARVON, Highclere Castle, Newbury (gr., Mr. W. Pope), showed a collection of superior vegetables, including Tender-and-True Parsnips, a well-shaped white root; very large Prize-taker Leeks; Early Gem and Perfection Carrots; a fine-looking solid Cabbage, of the Drumhead form; Blood-red Beet; and some nice Potatoes, in several varieties (Silver-gilt Knightian Medal).

Awards.

Apple Parakeet.—A very highly coloured fruit, deep and narrow in shape. From Mr. C. Ross, Welford Park Gardens, Newbury (Award of Merit).

Grape Reine Olga.—A hardy Grape, that produces fair-sized bunches of reddish, round berries, with a flavour very satisfactory for out-of-door grown fruits. From Mr. WILL TAYLER, fruit-grower, Hampton, Middlesex (Award of Merit).

The Lecture by Mr. Monro.

In the afternoon a very interesting lecture was given by Mr. Geo. Monro, V.M.H., upon the "Growth of the Fruit Trade." Mr. Monro's position in Covent Garden affords him exceptional means of knowing the details concerning the extraordinary development that has taken place in the fruit trade during the past twenty-five years, a development that he himself has been the means of assisting in a large measure. In 1871, said Mr. Monro, there were only three regular fruiterers in the city. During the summer, when there were soft fruits to be sold, there were additional vendors, but only three maintained a trade throughout the year. In the west-end, things were little better, and most of the trade was carried on in the Central Avenue, Covent Garden. In those days, Oranges formed the bulk, and almost the whole of the trade; then there were Apples from America and other fruits. In 1880, the Haymarket Stores commenced a fruit department, and afterwards the number of fruit-salesmen soon began to increase. In 1860, Oranges, which were first sold in Pudding Lane, formed by far the greater part of the fruit to be sold, and Apples were the next largest supply. Mr. Monro described how afterwards Newtown Pippin Apples were imported from New York; then Canada sent us some, and later Nova Scotia. Subsequently, supplies came from Australia, and these were very acceptable, because they ripen in our winter.

Regarding English-grown Apples, Mr. Monro said that the supply had increased greatly, and in some cases the cultivators were to be congratulated upon the improved quality of the fruits, and the better systems of packing and grading that had been adopted. But much of the produce was bad, and it was sent to market in a very careless manner. Mr. Monro quite agreed with a remark made in an article in the *Gardeners' Chronicle* last week to the effect that British fruit-growers grow the best and the worst samples to be seen anywhere.

Respecting Pears, Mr. Monro said that the bulk of good samples is imported. In this country, and despite the fact that excellent Pears are produced here, the changeableness of the weather renders the crop an uncertain one. Next was described the extraordinary growth in the Banana trade, which was commenced about 25 years ago. A large quantity of Bananas now come from the Canary Isles, which are practically market gardens, since the Cochineal industry was killed.

In 1870, all the Pine-apples obtainable for sale were grown in English hot-houses, but since then a tremendous trade in them has been developed with the Azores.

The trade in Grapes has been completely revolutionised by the immense development of Vine cultivation at home. Thirty years ago there was only one Grape-producing establishment in Jersey, and none in Guernsey. In England, Vine-cultivation for market purposes first commenced at Worthing, where there are now 100 or more Grape-growing establishments. Scotland also used to send a supply to Covent Garden, especially of late Grapes; but Grape-growing has increased so much in the London and other districts, that more is sent North of the Tweed than we receive from there.

The greater competition brought down prices, until the margin of profit was reached, and the present prices would pay only in the best and most economically-managed gardens. In the week preceding last Christmas, Mr. Monro's firm alone sold forty tons of hot-house grown Grapes, including a few tons sent to Manchester. Mr. Monro remarked that it is said that the market growers studied only appearance and weight. This was not the case, but it is true that they have to study these qualities in a large degree, because the public will not buy any fruits that have not a satisfactory appearance. It was their endeavour to unite these two qualities with that of high quality.

Interesting particulars were next given respecting the trade in soft and small fruits, special reference being made to the importance of the large jam-making industry of the present day, which 25 years ago was scarcely commenced. Strawberries, said Mr. Monro, are fruits for which the home cultivator will be always able to hold his own; and for forced Strawberries in particular there exists an excellent demand.

In the sale of Tomatoes, more growth has been made than with any other fruit. Twenty-five years ago, in the trade, a Tomato was something of a novelty; now there are thousands of tons grown annually in Britain. The development in the growth of Tomatoes at home has all but killed the "tin" trade, and fruits imported in a fresh state must be of very fine quality in order to command a sale at all.

The important matter of distribution, in which Mr. Monro has played a very important part, was next mentioned, and Mr. Monro again took the opportunity to offer a few remarks upon the necessity of proper packing and grading.

The facilities for transit have increased to all parts of the kingdom, though the question of railway rates still leaves something to be desired. Fruits are exported to America, Sweden, and other countries, even including France, but in the last-mentioned country the duty imposed by the French Government upon Grapes (2s. per lb.) was almost prohibitive. Means had been taken to insure a quick delivery of fruit to every part of the United Kingdom, and there were millions of persons engaged exclusively in its sale.

Mr. Geo. Bunyard, who occupied the chair, endorsed all that Mr. Monro had said, and added that Pears were admittedly an uncertain crop in this country, and those who intended to invest their money in the fruit-growing business should take care that they do not plant more than a fair proportion of these fruit trees.

DEVON AND EXETER GARDENERS'.

OCTOBER 11.—The opening lecture of the present Session was read at the meeting held in the Guildhall, Exeter, on the above date by Mr. F. J. FLETCHER, gr. to Colonel HALFORD THOMPSON, Eastcliff, Teignmouth, the subject being—

DAHLIAS.

The qualification of the lecturer to speak on the subject may be inferred from the fact, incidentally mentioned, that two or three years since, when in business near London, he used to send out about 10,000 plants, and plant out for stock for market work and for exhibition, from seven to nine acres of plants annually. He claimed for the Dahlia that it was essentially, and by right, the queen of autumn flowers, as the Rose in summer and the Chrysanthemum in winter. It was also essentially a modern flower. The great variety that exists in Dahlias to-day is the work of the present and the preceding generation of florists. Formerly there were but the single and double forms. The Cactus—double and single—and the Pompon are very modern creations. Speaking of its origin and its name, he traced its history from its first introduction from Mexico, when it was treated as a hot-house plant. In 1803 the two species known were *D. pinnata* and *D. coccinea*. The flower was named in honour of André Dahl, a Swedish botanist, and the lecturer claimed that the proper pronunciation of the name was not with the long "a," as in "dale," but with the short, as in "yacht." He explained the difference between the "show," or self-coloured Dahlia, and the variously-tipped, or "fancy," as recognised at exhibitions. For a really first-class dozen of varieties of the "show" section, he would name Colonist, Duke of Fife, Harrison Weir, Harry Keith, John Walker, Major Cornwallis West, Mrs. Gladstone, Mrs. Langtry, Mrs. Peter McKenzie, Pioneer, Warrior, and Majestic. For a second choice, or to complete a twenty-four, the following would be his selection: Arthur Ocock, Cardinal, Ethel Britten, George Rawlings, Gloire de Lyon, Joseph Ashby, J. B. Service, Muriel, Mrs. Wyndham, Pandora, Prince Bismarck, and Volunteer. The Fancy Dahlias are only to be found in a proportion of about one to eight of the "Show" section; but here is a good selection for exhibition: Buffalo Bill, Chorister, Conte de la Saut, Comedian, Dazzler, Dandy, Gaiety, George Barnes, Rebecca, Jessie McIntosh, Matthew Campbell, Mrs. Saunders, Peacock, Professor Fawcett, and J. B. M. Camm.

Size is not everything in Dahlias, as symmetry and form are far before it. What growers should seek after ought to be flowers of the style of Mrs. Gladstone, where beauty of form, compactness of build, and beauty of colouring combine to make an almost perfect flower. Then, we want two or three more good whites of the quality of John Walker, and yellows like R. T. Rawlings.

For cutting purposes, Mr. Fletcher thought the Pompon the most useful of all. It carried its flowers well, and did not bid them among the foliage. Among the best of them he mentioned White Aster, Brinkman, Mars, Dora, Brunette, Red Indian, Night, Jungker, Flora, and Fashion. As regards single Dahlias, their short endurance on the plants, and their tendency to shed their petals as cut-flowers, militated against them.

The single Cactus varieties have greater lasting powers, and in the near future may, when paid more attention to, become very popular. Among the best of them are Queen Mary, Maid of Bute, Meg Merrilies, Alice Lee, Sir Walter, and Bruce. Tracing the Cactus Dahlia from the original Juarezii, the essayist spoke in the strongest terms of recommendation of the usefulness of this race. He mentioned Exquisite, Starfish, Britannia, Runji, Magnificent, Gloriosa, Ernest Glasse, Breme, Mrs. S. Vickery, Porcupine, Regulus, Mary Service, Matchless, and Loreley, as among the best of them. What we want is one or two more whites and pale pinks, and roses of the form of Starfish or Britannia; and he thought it quite within the range of possibility that one day we may see a Cactus Dahlia rivaling the form of a Japanese Chrysanthemum! From one seed-pod of Starfish and one of Night, sown in February, ten distinct varieties have resulted, running through shades of crimson, scarlet, violet, maroon, cream, and rose; all of them being above the average in quality.

The remainder of the lecture dealt with the cultivation of the plant, which, being pretty well known to all gardeners, we may omit from our correspondent's résumé.

TORQUAY GARDENERS' ASSOCIATION.

OCTOBER 13.—The opening meeting of the eighth session of the Torquay and District Gardeners' Association was held at the Abbey Road Lecture Hall on the above date. The President, Dr. R. HAMILTON RAMSAY, occupied the chair, and there was a large attendance of members.

The President, in his opening address, expressed his pleasure at being called upon to open the eighth session of the Association. He was persuaded that members heartily approved the excellent suggestion of the Mayoress, Mrs. Beavis, as to improving the larger Bath-salon by its adornment with numerous Palms. The public gardens in general in Torquay were treated with excellent taste, and were beautifully kept. The Royal Terrace Gardens were very fine, and the view from the terrace of the blue waters of Torbay, and the line of hills beyond, formed a seascape of great beauty. Across the road there was another sight, sad to the eyes of a lover of beautiful shrubs. There *Cupressus macrocarpa*, which when allowed to grow naturally, was such an ornament at Torquay, was tortured into a miserable-looking hedge, apparently to hide what was one of the loveliest views in Torquay. That appeared to him to be the sole exception to the good taste prevailing in the case of the public gardens of Torquay.

The Palms at Torquay had done well this hot year, and a fine *Corypha australis*, which was, at the end of September last year to feet high, this year is over 18½ feet, loaded with fruit, and with numerous self-sown seedling Palms at its foot. Another interesting group of sub-tropicals rejoicing in this year's sunshine were the *Cordylines*, most frequently called *Dracenas* in gardens. The President has two specimens of *australis*, and two good specimens of *C. indivisa vera*. The first *Cordylines* at Torquay were a gift of six plants by Sir Thomas Acland, Bart., grandfather of the present baronet. Three of these he gave to the late Mr. Edward Vivian, who planted them at Woodfield, where two at any rate are now alive; and three others to the late Bishop of Exeter, Dr. Phillpotts, who planted them at Bishopstowe, where they flourished until a few years ago. The finest plant he ever had, divided into five great branches, each one carrying a splendid head of leaves. *Dracenas* did not mind frost even when rather severe, if not too prolonged; but snow, seldom if ever seen in New Zealand in their valleys, was likely to injure them. By tying the leaves over the centre, the fatal results could be guarded against, but, as his Duncan House garden was intended mostly to testify to Torquay's climate, that was not done by him. *Extract from Torquay Times*.

JERSEY HORTICULTURAL CLUB.

OCTOBER 19.—The monthly general meeting of the above Club was held on this date. The Chairman, Mr. A. Smith, presided. Mr. P. F. Le Sueur read a paper upon "Personal Reminiscences of Horticultural Exhibitions." Mr. Le Sueur was the pioneer in the matter of showing fruit from sunny Jersey; and owing to the recent exhibit of Jersey fruit at the Crystal Palace, his remarks at this juncture were all the more interesting.

Messrs. A. Smith and F. Boobyer then gave some very interesting details of their visit to the Crystal Palace Fruit Show, and also an instructive account of Messrs. F. Rochford & Sons' market-growing establishment at Turnford, Hertford.

Mr. Hamill thoroughly endorsed many of Mr. Le Sueur's remarks, especially as to the marked inferiority of the Channel Islands grown Grapes as compared with the English and Scottish grown.

HIGHGATE AND DISTRICT CHRYSANTHEMUM.

OCTOBER 25.—A meeting of the Floral Committee of the above Society took place on the above date, when First-class Certificates were awarded to Mrs. A. Jones, Japanese, a seedling from E. Molyneux, exhibited by Mr. A. Jones, gr. to Mrs. WYBURN, Hadley Manor, Barret; also to Mrs. J. J. Tilley, Japanese, exhibited by Messrs. H. CANNELL & SONS, Home of Flowers, Swanley; Madame Lucie Reccora, from the same exhibitors, which the Committee desired to see again.

The next meeting of the Floral Committee will be held on November 2, at 3 p.m., at the Northfield Hall, Highgate.

NATIONAL CHRYSANTHEMUM.

OCTOBER 25.—A meeting of the Floral Committee of this Society was held at the Royal Aquarium, Westminster, on the above date. There were not a great many varieties before the Committee. The following were awarded a First-class Certificate:—

Florence Molyneux.—From Mr. N. MOLYNEUX, Rookesbury Park Gardens, Fareham (see description on p. 334).

Miss Alice Byron.—A pure white incurved Japanese flower of large size, good petal, and much refinement. This variety will surely become a popular one. From Mr. H. Weeks, gr. to Lord Byron, Thrumpton Hall, Derby.

Miss Edith Pilkington.—See description on p. 334. From Mr. N. MOLYNEUX.

Miss Gedsmark.—A large incurved flower, with characteristic petals. Its colour is coppery or buff, and the petals are slightly hirsute. It should make a fine large incurved when well built up. From Mr. ROBERT OWEN, Maidenhead.

Mrs. A. H. Hall.—A seedling or sport from the variety Edith Tabor, sent out by Mr. Jones. The flower is larger than that of Edith Tabor, and is bronzy-coloured instead of yellow; the florets droop and curl. From Mr. R. KENYON, Monkham's Gardens, South Woodford.

In addition to the varieties certificated, Mr. WEEKS had a fine mauve-coloured Japanese with silver reverse, and good petals. The Committee wished to see this variety again.

Mr. R. OWEN showed two good Japanese Incurveds, both of them white, with suspicion of yellow towards the centre. One was Madame Gabrielle Dabrie, and the other Miss Elsie Fulton.

Messrs. H. CANNELL & SONS, Swanley, showed a white sport from O. J. Quintus.

GARDENING APPOINTMENTS.

MR. FRANCIS ROBERTS, late Gardener at Amondell, Mideaider, as Head Gardener to Sir JAMES KING, Bart., Carstairs House, N.B.

MR. G. HERRIDGE, late of Fairmile Hatch, as Head Gardener to W. B. WILLIAMS, Esq., St. Peter's Hill, Caversham, Oxon.

MR. A. HALLETT, for the past seventeen years Head Gardener at Chad House, Birmingham, as Head Gardener to E. M. PEARSON, Esq., Edstone Hall, Wooten Warwen, Warwickshire.

MR. A. McVINISH, who for seventeen years filled the post of Head Gardener at Lockington Hall, near Derby, as Head Gardener to Mrs. PERRY HERRICK, Beau Manor Park, Loughborough.

MR. PETER HARPER, as Head Gardener to MALCOLM INGLIS, Esq., Montrose, Donnybrook, co. Dublin, and not Foreman Gardener, as stated in our previous issue.

MR. ANDREW BROWNE, late General Foreman at Dunardagh Gardens, Blackrock, as Head Gardener to RICHARD PIM, Esq., Stradbrook Hall.

MR. NEIL McADAM, late Head Gardener at Stradbrook Hall Gardens, as Head Gardener to F. C. PILKINGTON, Esq., J.P., D.L., Westbury, Stillorgan, Co. Dublin.

CATALOGUES RECEIVED.

PLANTS, BULBS, SEEDS, FRUIT AND OTHER TREES, SUNDRIES, ETC.

G. SPRINGTHORPE, West Leigh Nursery, Leicester.

AMOS PERRY, Hardy Plant Farm, Winchmore Hill, London, N.

WILHELM PRITZEN, Stuttgart, Germany.

JOHN JEFFERIES & SONS, Market Place, Cirencester.

P. LAMBERT, Treves.

A. TRUFFAUT, 40, Rue des Chantiers, Versailles.

W. SMITH & SON, 18, Market Street, Aberdeen.

M. M. LEVEQUE ET FILS, 60, Rue de Liegat à Ivry-sur-Seine, près Paris.

R. C. BARTLETT & Co., 24, Hivell Street, Cumberland London, S.E.

WM. WATSON & SONS, Clontarf Nurseries, Dublin.

WOOD & INGRAM, Huntingdon.

CHRYSANTHEMUM EXHIBITION STANDS: *W. Crossman*. The following information, taken from the National Chrysanthemum Society's schedule, will guide you: "Exhibitors must have their stands made of the following dimensions, viz., stands for twelve incurved blooms to be 24 inches wide from left to right, and 18 inches deep from back to front, with holes 6 inches apart from centre to centre, to stand 6 inches high at back, and 3 inches high in front. Two "twelve-boards" may be used for twenty-four blooms, three for thirty-six blooms, and so on. The stands for six incurved blooms to be 12 inches wide from left to right, and 18 inches deep from back to

front; for twelve Japanese blooms to be 28 inches wide from left to right, and 21 inches deep from back to front, the holes seven inches apart from centre to centre. Stands for six Japanese blooms to be 14 inches wide from left to right, and 21 inches deep from back to front. The height at the back to be 7 inches, and 4 inches in front. All stands and their supports to be painted green, and the supports must be secure."

CHRYSANTHEMUMS DISEASED; *E. T.* The plants are affected by the now well-known destructive rust, *Puccinia Hieracii*, figured in *Gardeners' Chronicle*, October 8, 1898, p. 269. See also p. 295, October 15, same volume, for reputed remedies.

DISEASED GRAPES: *Disease*. Your Grapes are affected with spot (*Glaeosporium*). It is too late to do anything now, but next season spray the berries two or three times at weekly intervals before they are ripe with weak Bordeaux Mixture.

FRUITING OF STEPHANOTIS FLORIBUNDA: *F. W.* Not an uncommon occurrence in this country. The fruit is poisonous.

GRAPES GOING OFF: *F. E.* The fruit was over-ripe, like that which has been exposed to too much warmth after reaching maturity, hence, it is in a fit condition for parasitic organisms to invade it, although none was visible. The bloom was likewise entirely absent from the berries. We should advise another year the use of flowers-of-sulphur in the houses, on the hot-water pipes, in combination with lime-wash, and in pans of water placed about in the houses. The Vines should not be started earlier than will allow of the crop being eaten before it spoils, and if the weather is very hot when the Grapes are ripe, it will be advisable to bottle them, and store in a cool room.

INSERTING MUSHROOM SPAWN IN PASTURE LAND: *J. M. B.* The season is immaterial. We should, however, give preference to the summer.

NAMES OF FRUITS: We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. They should be just approaching ripeness, and they should be properly numbered, and carefully packed. A leaf or shoot of each variety is helpful, and in the case of Plums, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.

D. R. J. 1, Napoleon; 2, Winter Nellis; 3, Dr. Trouseau; 4, Fondante du Comice; 5, Scarlet Nonpareil.—*E. C. E.* 1, Brabant Bellefleur; 2, Hanwell Souring; 3, Tibbett's Pearmain; 4, Flower of Kent; 5, Winter Greening; 6, Royal Russet.—*D. G. P.* 1, Belle Julie; 2, Jersey Gratioli; 3, Ah! Mon Dieu, or D'Amour of some pomologists; 4, Summer Strawberry; 5, Duchess' Favourite; 6, Nelson Codlin.—*F. H.* 1, Scarlet Pearmain; 2, Jolly Beggar; 3, Tower of Glamis; 4, Whiting Pippin; 5, Aromatic Russet; 6, Scarlet Nonpareil.—*G. J.* The two Pears omitted in the reply to your enquiry are as follows—5, Besi Espere; 6, Castelleine.—*J. E. A. B.* 1, the ripe Pear was smashed by contact with the Apples; 2, Nanny; 3, Golden Spire; 4, Nelson's Codlin; 5, Cobham; 6, Plum Red Perdrigon.—*J. J.* 1, Cellini; 2, Fair Maid of Taunton; 3, Ecklinville; 4, Winter Greening, also known as French Crab; 5, a poor example of Flower of Kent.—*A. L. B.* 1 and 3, not received; 2, Scarlet Nonpareil; 4, Downton Pippin; 5, Hormead's Pearmain; 6, Gloria Mundi.—*C. L.* 1, Pearson's Plate; 2, Irish Reinette; 3, Carlisle Codlin; 4, New Hawthornden; 5, Winter Quoining; Pear quite decayed.—*F. H.* 1, Seek no Further; 2, decayed and almost unrecognisable, but it resembles Madeleine; 3, Scarlet Leadington.—*C. E. T.* 1, Striped Beeding; 2, Transparent Codlin; 3, Fillbasket, distinct from that known as the Kentish Fillbasket. Some of your specimens had the labels fixed to the eye by a piece of wood forced into the centre of the Apple. This is a bad method, as the important characters derived from that part of the fruit are thus destroyed.—*G. E. P.* We believe this to be a highly coloured fruit of Bees Pool. There is an old variety known as Tulip, or Dutch Tulip, but it is a dessert variety, and quite distinct from that sent; 2, Lewis's Incomparable; 3, Hawthornden; 4, Harvey's Wiltshire Defiance.—*P. W. H.* The fruits arrived

in very bad condition, being partly decayed, but they appear to be as follows: 1, Manx Codlin; 2, Lord Suffield; 3, Ecklinville.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—*Alfred Gant*. *Veronica austriaca*, var. *prenja*.—*M. C.* *Sedum pulchellum*.—*E. M.* *Crataegus coccinea*.—*X.* 1, *Viburnum Opulus*; 2, *Acer campestre*; 3, *Potamogeton heterophyllus*.—*W. C. & Co.* *Lycium barbarum*.—*P. C.* 1, *Juniperus virginiana*; 2, *Thuya orientalis* var.; 3, *Juniperus Schottii*; 4, *Pinus excelsa*; 5, a *Pinus* without cones; it is impossible to name—perhaps *P. contorta*; 6, *Cryptomeria japonica*.—*L. H. F.* 1, *Eranthemum variegatum*; 2, *Eranthemum atropurpureum*; 3, *Fittonia argyoneura*; 4, *Fittonia Pearcei*; 5, *Cyrtodeira fulgida*; 6, *Selaginella involvens*.—*J. H. S. H.* So far as we can judge without seeing fertile frond. It is a form of *Lomaria gibba*.—*V. & B.* *Nantwich*. The specimen is one of the garden forms of *Pteris* obtained between *P. tremula* and *P. serrulata*, probably.—*C. G.* *Lycesteria formosa*.—*J. J. If you send a fragment of a leaf we can tell you more certainly.

SERVANTS' TAX: *E. M.* If the men are gardeners, and not merely labourers, you are liable to pay 15s. for each per year.

SHAMROCK: *F. B.* What you send is a species of *Oxalis*. What is sold in London as Shamrock is *Trifolium repens*.

UNEARNED INCREMENT: *Correspondent*. Your proposal that the Royal Horticultural Society should share in the financial advantages accruing from the bestowal of First-class Certificates is, to our thinking, most undesirable. It would degrade the Society, and be of no use to the public. You might as well suggest that the horticultural press should benefit by the reports of the meetings, or by the insertion of illustrations of the objects exhibited. What amount of faith or respect could the public be expected to have if the Society or the press received commissions of this kind, secret or otherwise.

USES FOR EMPTY HOTHOUSES: *B. D.* You might grow Dutch bulbs, Tulips, Hyacinths, Narcissus, and force them in boxes; also, Lily of the Valley crowns, *Lilium longiflorum* Harrisii, Roses, Selaginellas, Maidenhair Feros, Tuberoses, Mustard-and-Cress, Rhubarb, blanching it partially under a covering of clean straw; Seakale, in darkened boxes, or under Seakale pots; French Beans, and even Mushrooms. See article on the subject in our issue for October 21, p. 307.

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, considerably

MORE THAN DOUBLED.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets and Weather, see p. xii.)

THE

Gardeners' Chronicle

No. 671.—SATURDAY, NOV. 4, 1899.

SHAKESPEARE AS A GARDENER.

SAYS Carlyle:—"I confess I have no notion of a truly great man that could not be all sorts of men. The poet who could merely sit on a chair, and compose stanzas, would never make a stanza worth much. . . . The grand fundamental character is that of Great Man; that the man be great. . . . The great heart, the clear, deep-seeing eye; there it lies; no man whatever, in what province soever, can prosper at all without these. Petrarch and Boccaccio did diplomatic messages, it seems, quite well—one can easily believe it, they had done things a little harder than these! . . . Shakespeare—one knows not what he could not have made, in the supreme degree."

One profession he might have adopted, O sage of Chelsea, with results that would have satisfied the most fastidious cultivator of Eden—the craft of Adam. Poet as he was, the practical culture of fruit and flowers was well understood by him, as his plays bear witness. We recommend all true gardeners to the study of Shakespeare; not only is the advice he gave of no small commercial value even to-day, but readers will perceive in the strain of natural philosophy that clothes his observations, some of the very thoughts which often come to themselves whilst tying, pruning, watering, or planting; and they will exclaim, as many others of diverse callings are compelled to do, "Why, that's just what I was thinking yesterday! what a marvel Will Shakespeare was?"

Every intelligent gardener resembles Shakespeare in this respect, according to his cerebral capacity. It is the fashion of Nature-lovers to connect external facts with their ethical significance. We knew a worthy old gardener, a second Mr. Oldacre, who regarded the floral world in the same manner as a human race; nay, we rather believe that flowers were more real creatures to him than his own kind, for he lived in a quaint universe of his own creating, a man to whom we delighted to listen for hours. Chrysanthemums were an abomination to him; he grew them only under constraint of orders, and the blooms failed annually! "Fantastic foreign fal-de-lals" was his contemptuous term for them. Zonal Pelargoniums he abhorred also, "gaudy wenchies, a shame to any modest garden," he averred. Mignonette he loved, yet could never hold a sprig in his hand without causing big tears to roll down his tanned cheeks, and his whole frame to quiver. "My little girl's favourite blossom," he would say, chokingly, "we called her Mignonne, too! A Frenchified name, but her mother willed it. We gave her back to God twelve years ago." Roses were his chief joy, and wonderful was the skill with which he tended these "honest English lasses." In such fashion did our noble old friend follow humbly after Shakespeare's natural philosophy, and weird, whimsical enchantment.

We have not sufficient space in a single paper to quote the numerous instances of our world-poet's fitness to qualify as a certificated gardener; it will, indeed, be a pleasant task for each to search out proofs in his magic pages; they are plentiful enough, and come upon us with a spontaneity at once charming and astounding. Where Shakespeare learned the craft is open to guessing; our own conclusion is that gardeners, like poets, *nascuntur non fiunt*, and that he is another proof of the fact. We will conclude with one short extract from Richard II., act iii., scene 4, which forms a good example of both practical knowledge and ethical comparison. Richard's queen overhears the head gardener and his two assistants—

Gard. Go, bind thou up yon' dangling Apricocks,
Which, like unruly children, make their sire
Stoop with oppression of their prodigal weight;
Give some suppittance to the bending twigs.

* * * * *
You, thus employ'd, I will go root away
The noisome weeds, that without profit suck
The soil's fertility from wholesome flowers.

1st Serv. Why should we, in the compass of a pale,
Keep law, and form, and due proportion,
Showing, as in a model, our firm estate?
When our sea-walled garden, the whole land,
Is full of weeds; her fairest flowers choked up,
Her fruit-trees all unprun'd, her hedges ruin'd,
Her knots disorder'd, and her wholesome herbs
Swarming with caterpillars?

Gard. Hold thy peace:
He that hath suffer'd this disordered spring
Hath now himself met with the fall of leaf.
The weeds that his broad-spreading leaves did
shelter,
That seem'd in eating him to hold him up,
Are pluck'd up, root and all, by Bolingbroke;
I mean the Earl of Wiltshire, Bushy, Green.

1st Serv. What, are they dead?

Gard. They are; and Bolingbroke
Hath seiz'd the wasteful king. O, what pity is it
That he had not so trimm'd and dress'd his land
As we this garden! We at time of year
Do wound the bark, the skin of our fruit-trees,
Lest, being over-proud with sap and blood,
With too much riches it confound itself;
Had he done so to great and growing men,
They might have liv'd to bear, and he to taste
Their fruits of duty.

H. Grimshire Bennett.

[Our readers will hardly need reminding of Canon Ellacombe's "Plant Lore and Garden Craft of Shakespeare." Ed.]

NEW OR NOTEWORTHY PLANTS.

CATTLEYA LABIATA "MRS. R. I. MEASURES."

A FEW years ago, R. I. Measures, Esq., Cambridge Lodge, Camberwell (gr., Mr. H. J. Chapman), was fortunate enough to flower a very handsome and distinct pure white form of *Cattleya labiata*, the front of the labellum being veined with clear pink colour, and which was described in the *Gardeners' Chronicle* as *C. labiata* "R. I. Measures." Nothing quite like that form has been imported since; but the same gentleman now has the good fortune to flower out of plants secured from Mr. Ed. Kromer's importation, another grand white *C. labiata*, which is in every point a worthy companion to the earlier acquisition. The flowers of the new arrival are of fine shape and substance, the sepals and petals pure white, the petals having a slightly crimped margin. The labellum is sulphur yellow on the inside of the tube, streaked with fine oblique lines of purple. The front lobe of the lip is white with a central blotch of glowing velvety purple, which looks all the more vivid for its broad, white crimped margin. *James O'Brien.*

ORCHID NOTES AND GLEANINGS.

"DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES."

THE numbers of this useful little publication for July and August, 1899, contain coloured illustrations of the following species and varieties:—

July.—1. *Ada aurantiaca*, Ldl.; 2. *A. a.* var. *maculata*, Hort.; 3. *Cochlidia Noezliana*, Rolfe; 4. *Cymbidium Lowianum* v. *concolor*, Rolfe; 5. *Dendrobium pendulum*, Roxb.; 6. *Epidendrum Frederici-Guilielmi*, W. & R. f.; 7. *Masdevallia leontoglossa*, Rehb. f.; 8. *Odontoglossum excellens* var. *nobilior*, Hort.; 9. *Oncidium crispum* var. *Lionetianum*, Cogn.; 10. *O. leucochilum*, Batem.; 11. *O. Carthaginense*, Sw.; 12. *Phalenopsis Manni*, Rehb. f.; 13. *Vanda teres*, Ldl.

August.—1. *Cattleya Mossiae* v. *æerulea*, Cogn.; 2. *C. Gaskelliana*, Rehb. f.; 3. *C. G.* v. *alba*, Will.; 4. *Compactia macroplectron* v. *punctatisimum*, Cogn.; 5. *Cypripedium selligerum*, Rehb. f.; 6. *C. supercilare*, Rehb. f.; 7. *Epidendrum vitellinum*, Ldl.; 8. *Masdevallia Harryana* v. *longiflora*, Cogn.; 9. *Odontoglossum luteo-purpureum* v. *Vnylstekianum*, Hort.; 10. *Phalenopsis sumatrana*, Korth.; 11. *Renanthera matutina*, Ldl.; 12. *Vanda Parishii*, Rehb. f.; 13. *V. P. v. Marriottiana*, Rehb. f.

LINDENIA.—The two last parts, issued in one, complete the 14th volume of this important publication. They comprise illustrations and descriptions of the following plants:—

Cypripedium bellatulum var. *Chotekæ*, t. DCLXV. —The spots on the perianth segments are of a brownish-rose colour.

Odontoglossum Wilckeanum (Rehb. f.) var. *ginotiana*, t. DCLXVI. —Flowers large, perianth flat, segments stellate, lanceolate, undulate, pale yellow, whitish at the base, heavily blotched with chocolate spots; lip obovate, oblong acuminate, white edged with yellow. It is a natural hybrid between *O. crispum* and *O. luteo-purpureum*, and has been produced artificially by M. Leroy of Armainvillers.

Cattleya Loddigesii (Lindley) var. *Harrisonia*, Veitch, t. DCLXVII.

Cypripedium Haumonti × (Linden), t. DCLXVIII. —A hybrid out of *C. Harrisonianum* ×, by pollen, as is supposed, of *C. Crossianum* ×; if so, it inherits the qualities of *barbatum* and *villosum*, the parents of *Harrisonianum*, and of *venustum* and *insigne*, the progenitors of *Crossianum*.

Aspasia lunata (Lindley), t. DCLXIX.

Cypripedium Parishii (Rehb. f.), t. DCLXX.—Flowers in racemes of four to six; standard obovate-oblong, pale green, with darker streaks; petals linear, 10–13 cents. long, contorted, deflexed, purplish-brown, with a few hairy warts on the edge; lip green, flushed with brown.

Odontoglossum Ruckerianum (Rehb. f.) var. *Gour-nayana*, t. DCLXXI. —Flowers racemose, each about 10 cents. across; perianth flat, stellate; segments narrowly lanceolate, whitish, heavily blotched with purplish-brown spots, and flushed in the centre with pale rose; lip elongated, with a raised crest at the base, clear yellow.

Odontoglossum Schlieperianum (Rehb. f.) var. *xanthina*, t. DCLXXII. —Flowers racemose, perianth 10 cents. across, stellate; segments oblong-acute, pale yellow, with pale brown blotches; lip with a narrow stalk, obovate, pale yellow.

CYPRIPIEDUM CHARLESWORTHII.

Flowers of the two extremes of this useful Orchid, render it difficult to believe them to belong to the same species. A flower comes from Captain Holford, Westonbirt, Tetbury (gr., Mr. A. Chapman), of a superb and richly coloured variety, and of the largest type. The dorsal sepal is 2½ inches broad, of a bright rose colour, changing to white towards the apex, the lower part being purplish-rose, which spreads upwards in feathered lines. The petals are of a pale green tint, and closely

veined with brownish-purple; the lip is tinged also with brownish-purple, and the staminode is pure white. The other extreme has flowered with J. W. Moore, Esq., Cragg Royd Nurseries, Rawdon, near Leeds, which may be described as an albino, or a form in which the colouring is suppressed. The flower is at present small in size, as also is the plant. The petals and lip are of a pale green, the dorsal sepal and staminode clear white—a very singular variety.

CATTLEYA × LORD ROTHSCHILD.

A flower of this fine hybrid, sent by Norman C. Cookson, Esq., Oakwood, Wylam (gr., Mr. Murray), from a plant raised at Oakwood, well represents its fine qualities which combine the best features of both parents. In general appearance it resembles *C. × Hardyana*, but the lip is broader and rounder in outline than in that variety. The petals measure 7 inches across, and $2\frac{1}{2}$ inches wide. The sepals and petals of a bright rose colour, small freckles of creamy-white appearing between the veining; and the base of the lip is of orange colour with a reddish tinge, and striations which extend into the bright crimson-purple colouring of the front lobe. On each side of the centre of the lip are bright blotches of clear yellow, which extend into the front portion of the side lobes. The side lobes as well as the front are finely crimped. It was obtained from *C. Gaskelliana* ♀, *C. aurea* ♂.

ONCIDIUM VARICOSUM INSIGNE.

In the year 1897, several very distinct and richly coloured examples, all bearing the same characters, were taken by their possessors to be of a new type. They appeared in an importation of Orchids. Ultimately, the form, which appears to be fixed, was described by Mr. R. A. Rolfe, in the *Orchid Review*, January, 1898, p. 27, as *Oncidium varicosum* var. *insigne*, a name which, to those who know the plant, will be more reliable than the varietal name *Rogersii*, applied to another section of this species. A fine inflorescence of the true plant has been sent by Captain Holford, of Westonbirt, the individual flowers of which are as large as those of the best forms, but they are of a much darker colour; the prominent feature is a bright red-brown mask surrounding the crest. The sepals are of a dark reddish-brown tint, with a few small greenish-yellow markings.

FRIAR PARK, HENLEY.

In our last week's issue, a descriptive and illustrated article upon the gardens at Friar Park was given. Our illustration at fig. 112, was taken on the east front of the mansion. It represents a wigwam, with the entrance to it visible from the dwelling-rooms. Crimson Rambler Rose has climbed over this little "rest," and almost screens its outlines from view. When our photograph was taken, the Rose bore myriads of crimson flowers, and the "Wigwam" had an appearance even much prettier than may be imagined from a photograph, however successfully it be taken.

THE CULTURE OF MALMAISON CARNATIONS.

It is rare to find this variety of Carnation healthy and vigorous, and I am within the mark when I say that no one has yet found a royal road to its cultivation. I have found that the chief causes of failure are too much warmth and excess of water at the root. Let the gardener obtain healthy plants in August or September, pot them in 3-inch pots, using a heavy loam, a small quantity of sand and leaf-soil. Put them in a cold frame, and keep them shaded; and when the roots touch the side of the pots, shift them into 5-inch pots, using the same kind of compost; place them in a cold frame or house, and be very careful in affording water—indeed, the soil should get almost as dry as dust; then apply rain-water copiously. The air of the house should be dry.

A damp atmosphere is the chief cause of the

spread of disease among this tribe of Carnations. The plants should be placed in slight warmth in the month of March, and be afforded water more often, not being allowed to get so dry as in the winter months; and applications of soot-water and sheep manure-water will now be necessary, the plant requiring a good deal of aid to support its very large flowers. The buds should be reduced to three, and the plants shaded at all times from the bright sun. These young plants will possess from six to eight growths, if they are properly treated; and if large specimen-plants are required, shift them, when they have done flowering, into 8-inch pots, using the same kind of compost as that before advised, but much rougher—about the size of walnuts. Pot the plants rather firmly, and stand them in a shaded place, on a coal-ash floor, out-of-doors till the end of the month of September; then

"Malmaisons," of which many have been introduced to commerce during the past six years, it may be said that they need far less care, for being the offspring of crosses with hardy garden varieties, they resist the diseases so common to those, but whilst giving us variety of colour from white to deep crimson, they do not possess the same beauty as the true *Souvenir de la Malmaison*.

The raisers deserve unstinted praise for these, among the best of which are the Churchwarden and the Shah, deep crimson; Albion, dark salmon; Lord Rosebery, dark rose; Mrs. M. Smith and Lady Rose, bright rose; King Oscar, bright crimson; Prime Minister, Mrs. de Satge, Horace Hutchinson, brilliant scarlet; Nautilus, flesh; and Nell Gwynne, white. These varieties may be afforded more warmth than the true *Malmaison*, and thus be brought into flower earlier in the

FIG. 112.—WIGWAM IN THE GARDEN OF F. CRISP, ESQ., HENLEY.

remove to a cold house, and treat as before for young plants. These plants will show a quantity of flowers at a little earlier date than the young plants.

Fumigation must be well attended to, or the leaves will get badly marked. Tobacco-powder used on the foliage at intervals of ten days is generally sufficient to keep green-fly away, and this is the only insect-pest which troubles these plants. The livid blotches and spots that are generally to be seen on the leaves are the results of puncture by green-fly in its early stage, and they are thought by some persons to be a disease; but if kept clean, the plants will not show any spots or marks whatever. Should the fungus, *Helminthosporium echinulatum* make its appearance, the plants should be dipped or sprayed with a solution of sulphate of copper; a wineglassful to a gallon of soft water. While writing these notes, I have in my mind the old blush and pink varieties, and the striped Lady Middleton. Of the newer varieties of so-called

season. If flowers are wanted in the autumn and winter, remove flower-stems in the spring, and afford the plants a shift into pots of a larger size when necessary, and keep in a cool house throughout the summer. The plants will flower from October onwards. To sum up, the requirements of these plants are a cool rather heavy loam, to be grown in the shade and a dry airy atmosphere, and kept at all times on the dry side, not treating them as tender plants, as a few degrees of frost will benefit rather than injure them. W. Clifford, Maxwellthorpe, Kelso, N.B.

NOTES ON SOME AUTUMN FLOWERS.

COLCHICUM SIBTHORPI.—This large and handsome Meadow Saffron well deserves to be brought more prominently before those who care for the dwarfier flowers of autumn. It is particularly valuable for the rock-garden, which is, at this season, less

attractive than earlier in the year. It is, I believe, the largest of the Colchicums, with well-marked tessellations. Its flowers are also of better form than those of the Meadow Saffron generally grown as *C. variegatum*, although less distinctly chequered. The general effect of the combination of the shades of coloration is that of a soft rosy-purple.

Here, I find this Colchicum a perfectly hardy plant, and a most free-flowering species, besides having the merit of increasing quickly. The light soil at the base of a rocky suits it in this garden, and in a few years the solitary corm with which I commenced, has become a good clump, producing some thirty flowers. As the leaves of Colchicum

that there must be some other reason for its non-success. The plant is seen growing and flowering well in gardens with strong and rich soil. On such, if it will grow at all, the Scabious will give larger flowers. The white variety, which comes in very usefully for cutting, does not always grow well, even where the coloured form succeeds. I have, however, been much impressed with the free way in which both grew and flowered in several gardens in and about Edinburgh this autumn. In one nursery I saw a large number of the coloured and the white forms, and both were very fine indeed. In a bed of seedlings I observed several plants of superior quality, and well worth selecting and

specimen, which was about 2½ feet across, one was pleased to see it so good in one of the ordinary beds in the arrangement for the use of those studying botany. Here it made quite a picture with its mound-like form, composed of little leaves covered with the small, white Lobelia-shaped flowers. In such a place one could also see, better than in an ordinary rock-garden, the creeping habit of the plant. This New Zealand *Pratia* is quite hardy, but it may be lost in times of drought unless it is liberally supplied with water. It is occasionally met with as *Lobelia littoralis*.

CROCUS ZONATUS.

As a rule, *Crocus zonatus* is not the earliest of the autumnal species to flower in this garden. This year, however, it has been in advance of all others. Whether early or late, it is ever welcome, with its soft-coloured, delicate-looking flowers. We have, indeed, few to equal it in chaste colouring among the fairly numerous autumn bloomers. *C. speciosus* and *C. byzantinus* are larger, but they have not the refined and attractive colour which makes the zoned *Crocus* so charming. It is of a soft, rosy-lilac, veined internally with a few purple lines, and showing at the base of the interior of the flower a pretty zone of orange. The anthers are white, the filaments yellow, the style branches being yellow also. It is a *Crocus* which grows freely in this garden, where it blooms annually. Readers of the *Gardeners' Chronicle* may remember the excellent illustration from a photograph by Mr. Siehe, which showed a mass of *Crocus zonatus* in its native habitat in Cilicia (Feb. 5, 1898, p. 85). We cannot all have it in such profusion, but many of us could enjoy the beauty displayed by a clump of this pleasing member of an invaluable genus. *S. Arnott, Carsethorn-by-Dumfries, N.B.*

CYPRIPEDIUM × OLIVIA (TONSUM × NIVEUM).

OUR illustration (fig. 113) represents the pretty hybrid *Cypripedium × Olivia*, shown by Messrs. Hugh Low & Co. at the meeting of the Royal Horticultural Society, October 10. The introduction of *C. tonsum* as one of the parents, has produced the effect which was expected of it, by producing an attractive flower of fine substance, all the segments being well rounded. The flowers are cream-white, tinged over the face of the labellum, and the dorsal sepal with pale rose-colour, all the parts also bearing more or less heavily dotted purple lines, the dorsal sepal having pale greenish area at the base.

PLANT NOTES.

SAINTPAULIA IONANTHA.

THIS pretty plant, of dwarf growth, is adapted either for pot-culture or for planting-out in borders of the stove or conservatory, and the deep blue flowers are produced very freely during the summer and autumn months. It is easily raised from seed sown in the spring, and may also be increased from leaf-cuttings.

TILLANDSIA CARINATA, SYN. VRIESIA BRACHYETACHYS.

This beautiful Bromeliad deserves to be more generally cultivated, even in establishments where these plants are seldom represented. It is a remarkably free-flowering plant, and, like all of the Bromeliaceous family, it is of easy culture. Probably the scarlet, boat-shaped bracts, from which the yellow flowers protrude, are more attractive than the flowers themselves. The flowers do not last many days in perfection, whereas the bracts, which are arranged in two rows at the top of the flower-spike (which is about 5 or 6 inches in height), remain fresh for a considerable time after the flowers have disappeared. Being a winter-flowering plant, it should be useful, by way of variety, for furnishing small vases where table-decoration is carried out. *J. G., Botanic Gardens, Liverpool.*

FIG. 113.—CYPRIPEDIUM OLIVIA = *C. TONSUM* AND *C. NIVEUM*.

Sibthorpi, like those of the other autumnal Meadow Saffrons, are not produced until spring, the appearance of the flowers is enhanced if they rise above a carpet composed of a plant of dwarf habit. I find some of the *Aceras* very suitable for this.

SCABIOSA CAUCASICA.

One finds much difference in the behaviour of *Scabiosa caucasica* in gardens. In some, it never seems to thrive, and dwindles away without apparent cause. In others, it grows not only with freedom, but even with comparative vigour. In some gardens, also, even where it grows well, it fails to produce perfect blooms, nearly every flower having one or more imperfect petals. Nor can I ascribe this defect to any observable cause. At one time I considered that *S. caucasica* preferred a rather light soil, but after seeing a good many gardens of that nature in which it was no happier than in others, I was driven to the conviction

propagating from. In my own garden, I find that *S. caucasica* needs good feeding, and has a considerable liability to suffer from drought.

PRATIA ANGULATA.

During a visit to several gardens in and around Edinburgh in the middle of September, no other alpine flower gave me so much pleasure as *Pratia angulata* in the Royal Botanical Gardens there. As may be supposed, it is not a plant new to the writer. It is a flower which is not, however, too often seen, and then rarely so fine as the Edinburgh plant. In my dry garden it is a difficult subject, as it seems to resent having to grow in a very dry soil. Indeed, I am inclined to envy one of my friends the freedom with which *Pratia angulata* thrives in his rock-garden. I do not recollect having met with a specimen equal to that in Edinburgh in any of the numerous gardens it has been my privilege to see. Apart from the size of the

FERN-PROTHALLI.

RECENT research into the phenomena of Fern life in its inconspicuous form of the prothallus, and especially the investigations of Dr. W. H. Lang, recorded in his monograph *On Apogamy, and the Development of Sporangia upon Fern Prothalli*, issued by the Royal Society, throw so much additional light upon the subject, that a short summary may merit a space in the columns of the *Gardeners' Chronicle*, especially as the monograph itself is likely to be far more limited in its circulation.

The prothallus of a Fern is the first product of the spore, and, normally, is destined to produce organs of two classes, which are practically equivalent to the stamens and pistils of flowers, and by the interaction of whose contents there results the fertilisation of an ovum, which thereafter develops into a Fern capable of bearing spores again, and so completing the life cycle. That cycle is first spore, then prothallus, archegonia and antheridia (male and female organs), fertilised ovum, and spore-bearing Fern.

Professor Farlow, however, in 1874 discovered that this cycle was shortened in some cases, *Pteris cretica* to wit, by a simple vegetative bulbil or bud being produced on the prothallus without any sexual action at all, though this bulbil arose precisely where a fertilised ovum would have occurred. The cycle was thus reduced to spore, prothallus, spore-bearing Fern, and spore again, a very short cut indeed, and peculiar in the fact that generation after generation is produced without fertilisation of any sort being apparent. I am careful to say "apparent," because certain phenomena have been observed with regard to the nuclei of some of the cells on these apogamic or non-fertilising prothalli, which indicate the possibility of nuclear combination in the cells without the antecedent formation and connection of external organs, the result being the direct formation of a bud. In this connection, when we consider that it is the one primary cell in the spore which, by multiplication by fissure and growth, produces, eventually, both the archegonia and antheridia, and the antherozoids contained in the latter, which, to cause normal fertilisation, must traverse a space and combine with the ovum at the archegonial base, it does not appear an unlikely thing that among other vagaries, certain cells may arise in which both potencies exist in the shape of modified or double nuclei, and thus another short cut be found practicable; the non-fertilisation being merely apparent, but not actual. At present, however, this is only theory, though it certainly indicates a line of research well worth pursuing.

SPORE-CASES AND SPORES ON THE PROTHALLUS.

The most striking fact observed by Dr. Lang, was the production of sporangia and spores on the prothalli of more than one species of Fern, the prothallus itself thus fulfilling the entire life cycle, shutting out altogether the foliaceous spore-bearing phase by which Ferns are recognised as such, and reducing highly-developed species, such as the Hartstongue and *Lastrea dilatata* at one stride to the level of a *Marchantia*, i.e., always presuming that spores so engendered inherited the peculiarity, and were only capable of producing sporiferous prothalli in their turn. Here, the life cycle is reduced to spore, prothallus, spore, which seems an absolute minimum; only equalled by that of a Fern which is both aposporous and apogamous, like *L. p. m. cristata apospora* (D.), whose life cycle is Fern, prothallus, Fern, the frond tips bearing prothalli which produce non-sexual bulbils yielding Ferns again. In Dr. Lang's examples, however, of these sporiferous prothalli, this minimum life cycle can hardly be regarded as established as the selfsame prothallus displays its versatility by producing the usual sexual organs of both classes, in addition to sporangia; and to crown the edifice literally, the fleshy excrescence in the indentation of the heart-shaped prothallus scale, which bears all these reproductive bodies, actually buds out at the top into

a Fern of the spore-bearing generation, in the particular case in view, a Hartstongue. We have therefore all varieties of reproductive energy represented within the space of about $\frac{1}{4}$ inch: first archegonia in numbers, but obviously frustrated in attempts at fruition, since no fertilised ovum appears; next, a bunch of sporangia containing spores, and by their presence cutting out the Fern proper altogether; and then as if by way of protest, the Fern proper appears after all as a final and successful attempt of the prothallus to do its reproductive duty somehow. In this particular prothallus, therefore, we have really three concurrent life cycles, first the normal already described, second the extreme short cuts also described, finally the apogamic short cut of spore, prothallus, spore-bearing Fern, and spore again.

APOGAMY.

In Dr. Lang's cultures, of which over eighty illustrations are given, there are numerous cases of apogamy developed in various ways, and the eccentricity of the prothallus is shown to be limitless, in some cases thick fleshy hairy roots proper being developed in lieu of plants by way of a novelty. Undoubtedly much of this eccentricity and of the resulting abnormal modes of reproduction are due to the mode of culture adopted, moisture only being afforded from below which is assumed to check fertilisation, since in the absence of overhead flooding the antherozoids fail to be conveyed or to make their way to the archegonia. My experience is, however, opposed to this view, it being my practice never to water cultures overhead, but only from below by soakage; fertilisation, however, takes place freely, and as the cover-glasses are usually wet with deposited moisture (though never to dripping point), there is no doubt that a similar deposition occurs on the under side of the prothalli in sufficient degree to permit the antherozoids to swim in it and reach the archegonia. I am therefore inclined to impute the non-fertilisation, which seems to be a condition precedent for the abnormalities observed, to some other cause than overhead dryness, say, a super-saturated soil or defective light, both of which might interfere with healthy, normal growth, and induce a plethoric condition, tending at once to non-fertility and abnormal vegetative growth. Curiously enough, some years ago, in my little book, *Choice British Ferns*, I enumerated the vagaries then known to occur, and suggested that spore-bearing prothalli were alone required to complete the possibilities.

THE PROTHALLUS AND ITS POTENTIALITIES.

These have now turned up, and it seems to me that the prothallus has now proved itself capable of all the functions of Fern life, and, in principle, has exhausted all possible variations, since it is seen to be capable of producing further prothalli by buds, spore-bearing fronds by buds, and last, but not least, recur to its own starting-point, and breed its own spores. The Fern proper, on the other hand, associates bulbils with its spore-heaps, bears them in its axils and elsewhere, develops them from cut surfaces, and in all these ways ousts the prothallus from its life cycle; next it develops prothalli instead of spores, or from its apical points, and so ousts the spore from the life-cycle, and in the younger stages of *Scol. v. Drummondia*, the frond-tips bear sexual organs, and thus usurp the functions of the prothallus. Thus all the formerly presumed hard-and-fast lines are set at naught, and all possible variations in principle would appear to be discovered as existent.

Finally, I may remark that the bulk of these interesting facts have been discovered in connection with marked varietal forms of our native species; two, especially *Scolopendrium vulgare* var. *ramulosissimum*, and *Lastrea dilatata cristata gracilis* (Roberts), yielding prothalli upon which, not merely in one but in numerous cases sporangia were developed. *Chas. T. Druery, F.L.S., V.M.H.*

EAST THORPE, READING,

THE RESIDENCE OF ALFRED PALMER, ESQ., J.P.

THIS charming and compact place, pleasant at all times, but particularly so at the end of April and early in May, when the spring flowers are at their best, is situated on the rising ground on the south side of Reading, and is flanked on the east by the Redlands Road, towards which the mansion faces. It is built of red brick, with terra-cotta facings, from a design by Mr. A. Waterhouse; and commenced in 1880, it was completed in 1882. The gardeners' residence is on the north side, the offices and glass-houses are in the rear. The grounds, with pleasure-garden, houses, &c., comprise about three acres of land. The houses are numerous, generally of medium size, well adapted for their several purposes, but for lack of space packed somewhat closely together, and running from north to south or east to west.

Taking the houses in their order, as seen in the spring, first comes a span-roofed building for flowering purposes, gay with Hyacinths, Tulips, Daffodils, and other spring-flowering plants. Daffodils are great favourites for cutting purposes, and the collection is increased year by year, the long Trumpet varieties and the old double varieties being greatly esteemed for various decorative purposes. Some climbers are overhead—a purple-flowered Swainsonia, the Nash Court variety of *Lapageria rosea*, the white variety also, and *Manettia bicolor*, which flowers freely, and blooms for a considerable time, the blossoms bright scarlet at the lower portion and the tube yellow. This house is 48 feet by 32 feet, and is kept furnished with Richardias, Carnations, Astilbe, Deutzias, Hippeastrums, Primula sinensis, Azaleas, Cinerarias, &c.; with Cannas, Streptocarpus, Gloxinias, &c., coming on in batches for succession, with zonal Pelargoniums, &c. A good specimen of *Rhododendron Countess of Haddington* in fine bloom was a feature.

From this house a descent is made into a sunken fernery, the walls of which are lined with tufa, and planted with Ferns, handsome-leaved Begonias, &c., with fine specimens of *Cœlogyne cristata* planted near the top. From this a further descent is made to a small house of cool Orchids, constructed so as to shut out the view of a rubbish-heap. There is a good collection, and the house proves very useful for late *Cypripedium insigne*, &c. Below the stages the walls are faced with tufa, and planted with Ferns, &c.

Next comes a span-roofed, cool greenhouse for flowering plants, and here, coming on into bloom, were Liliums, decorative and zonal Pelargoniums, Astilbe, Deutzias, &c., for succession. For general decorative work, and indeed for all purposes, Mr. J. Woolford, the gardener at East Thorpe, thinks the old *Astilbe japonica* the best.

Pelargoniums form a great feature at East Thorpe in June and July, and in 48-size pots Mr. Woolford produces really wonderful examples, fully 2 to 3 feet in diameter, laden with large and bold trusses of bloom. There is no tying-out of branches, but simply a small stake placed here and there to support them. Some of the leading varieties are Blue Beard, very fine in blossom and colour; Martial, a plant fully 2½ feet through, in colour brilliant crimson, and very free; Alice, creamy-white, with deep blotch; Mrs. Coombs, pure white, with carmine spots, a beautiful variety of the finest shape; W. C. Boyes, of a pretty shade of salmon; Goldmine, rich deep orange, fine in colour; and Edward Perkins, deep orange, with maroon blotches. Very fine indeed are the zonals: chief among them being Ethel Lewis, pink; Lord Chesterfield, bright scarlet; Proserpine and Lady Chesterfield, shades of scarlet; Lady Brooke, white, with pink spots; Princess Maud of Wales, a very pretty shade of pink; Charles Mason, bright crimson-scarlet; Lord Rosebery, deep crimson; Juliet, rich salmon-crimson; Sir Percival and White Lady, two whites, the latter the better of the two; and some excellent double-flowered varieties. We are accustomed to the wonders accomplished with a 48-sized

pot in market nurseries, but here is a private gardener rivalling the cultivator for market.

Then comes a stove-house, in which a general assortment of suitable plants is grown, and also some Orchids, *Dendrobiums* principally, viz., *Dalhouseianum*, *nobile*, *crassinode*, &c.; *Cattleyas*, *Lælias*, *Peristeria*, *Angulea Clowesii*, &c.; an interesting collection, in good character and condition, being well managed. Some specimens of *Anthurium Scherzerianum*, *Begonia falcifolia*, &c., were very fine. The Orchids occupy the north end of the house, so as to give them, as far as possible, something of an intermediate temperature. At a right angle to this is built another stovehouse that is kept a little warmer, and here may be seen an example of *Cyrtodeira fulgida*, with crimson flowers and finely-

and zonal *Pelargoniums*, among the latter, *Enid*, rosy red, of a very soft pleasing shade; *Snowdrop*, pure white; *Dr. E. Rawson*, fine crimson; and others. In all, there are eight plant-houses besides many pits and frames. The former are all provided with spacious water-tanks, and that rain water is appreciated is seen in the fact that it is utilised to the fullest possible extent. Water is also laid on in various parts of the grounds from the Reading water-mains. There are also two Vineries, each in three divisions, in which Grapes, Tomatos, and Strawberries are cultivated, with considerable success. Tomatos are cultivated in pots, for an early crop; *Ruby* and *Earliest-of-All* being the favourite varieties. In addition, there is a walled-in kitchen garden, distinct from

2000 acres at West Park, Surrey, where he shoots in the season. Since the death of his father, the late Mr. George Palmer, a portion of his estate, which is near to East Thorpe, is also cultivated by him.

Of the pleasure-grounds which adjoin the mansion of East Thorpe, it may be said they are irregular in shape, largely surrounded by a belt of trees and shrubs, in which Lombardy Poplars are prominent. The site of these grounds was formerly an old garden, and one prominent feature on the lawn is a large specimen of the Devonshire Quarrenden Apple. At the south-east corner there is a small garden of hardy plants. Spring and summer gardening is well carried out by Mr. Woolford, and as the grounds abound in evergreens, there is always an appropriate background of foliage to the floral arrangements.

Mr. J. Woolford, who took charge of the gardens in 1880, laid out the grounds from a sketch-plan provided by the architect of the mansion, and though the site was originally level, he was able to provide some gentle undulations, which afford diversity to the garden. The gardens, as well as the Shinfield estate, are under his charge, and in order to work them in a satisfactory manner he has a competent foreman at each place.

As East Thorpe ranks as one of the best-kept places near Reading, it goes without saying that every part of it is in perfect order, for on every hand there are evidences of thorough supervision and excellent culture. As an exhibitor of plants, &c., Mr. Woolford has taken many honours at the Reading shows, and his grouping especially affords excellent object-lessons to young gardeners. R. D.

FIG. 114.—THE RESIDENCE OF ANTHONY TROLLOPE.

veined leaves; and such Orchids as *Cycnoches chlorochilon* flowering successively from a strong growth; *Catasetums*, *Dendrobium Phalenopsis Schröderianum*, *D. Devonianum*; *D. eburneum*, a species which requires special treatment; the warmth-loving *Cypripediums*, including *C. caudatum* with a great length of tails; the curious hybrid *C. Perseus*, *Oncidium papilio*, *O. Kramerianum*, *Cypripedium Chamberlainianum*, *C. grande*, with three fine flowers; *C. Lawrenceanum*, &c. *Ceropegia Woodsii* was also to be seen here. A small propagating-house situated at the end of this house contained a number of seedling plants of *Clerodendron fallax*, a species which grows freely from seeds.

There are several small greenhouses in which may be seen a collection of *Streptocarpus*, in which there are very fine varieties which are valuable for table decoration, being very effective on a white cloth; also decorative

the home grounds, but near to them; it is nearly square, with the sides facing the cardinal points. Here, are glass-houses, in which stone-fruits and Pears are cultivated in pots, which, at the time of our visit, in April, were promising well. It may be said that Mr. Alfred Palmer is very fond of his garden, taking a lively interest in all departments of it, but more particularly in the cultivation of fruits. About eleven years ago he commenced the culture of Apples on one of his estates situated at Shinfield, some 4 miles away. About 3 acres were planted with popular varieties on the Paradise-stock, and about two years later two more acres were planted with trees on the Crab-stock as low standards. Root crops are also grown at Shinfield; also crops to augment the vegetable supply, and some general farming is carried on, including poultry-rearing on a small scale.

Mr. Palmer has also a fine wooded estate of some

THE SITE OF THE OLD HARTLAND NURSERY.

"THE residences of celebrated men always have an interest to their fellows, which increases as time rolls on." In fig. 114 we depict the spot where the late Anthony Trollope lived in the years 1847, 1848, and 1849, writes Mr. Baylor Hartland, of Cork. Here he penned his first two novels, viz., *McDermott*, and *The Kellys and O'Kellys*. "There was a lovely old-fashioned garden at the back of the house, planted and formed by my grandfather in the end of the last century. There were three detached houses, the centre one being rented from my mother, with the recreation of the old garden. The Weeping Ash-tree seen in the foreground of the picture is now very old. It is planted where the limestone rock comes near the surface, so does not obtain much nutriment. Several celebrated Englishmen came to live at Mallow at that time, to avail themselves of the Spa waters. The land at the back of the house formed a nursery, and is situated about 1 mile outside the town, in a lovely country, with the river Blackwater, the second largest river in Ireland, running through it on its way to the Atlantic by Lismore, Fermoy, and Youghal. My grandfather built three houses, living in one of them after coming from Kew; and he furnished and let the others at £60 or £70 each to English visitors. I think, from the historical point of view, the pioneering work of an Englishman, together with his efforts at tree-growing in Ireland 130 years ago, should be of interest to your readers. The lodge seen between the trees was a general garden and farm seed-store."

This land is still, as Mr. Hartland tells us in his characteristic style, in his occupation as a nursery, where he grows Tulips and other bulbs as good as those of Holland.

CERASTIUM ARVENSE.—Professor J. C. ARTHUR, in a recently published *Bulletin* of the Purdue Agricultural Experiment Station, advocates the use of this species as a bedding-plant. The variety employed is *C. arvense* var. *oblongifolium*. The species is common in this country, but as we should have thought, too "weedy" to be used for decorative purposes.

INDIA.

THE GREAT RAINFALL AND LANDSLIPS
IN THE DARJEELING DISTRICT ON
SEPTEMBER 24, 1899.

THE following additional notes from Mr. O. T. Hemsley show that the damage is much greater in the neighbourhood of the Government Cinchona plantations than was known when he wrote two days after the events, and several of the coolies belonging to the establishment perished:—

Sureil Bungalow, October 2, 1899.

"By the above, you will see that I have changed my place of residence, and as long as I am repairing Kurseong Road, Sureil will be my headquarters.

Last Tuesday Mr. Pantling asked me when I could get some work done, which I then had in hand, in connection with the factory. I did not expect to finish till some time on Thursday, but by working hard, I got all my factory and laboratory work finished by Wednesday night. I then received orders to go off next morning and take up my quarters here, and at once proceed with the repairs to the Kurseong Road, which was very extensively damaged by the recent cyclone, as no doubt you have already learnt from the papers.

Up to yesterday, we in Mungpoo were completely cut off in every direction. This I did not know last week when I wrote, as I thought the Kurseong and Darjiling Roads were open. Such, however, is not the case; the Kurseong Road especially having been most seriously damaged, completely carried away indeed in places, leaving often absolutely perpendicular faces to the rocks. These breakages have occurred where there were watercourses, which became in a few hours awful torrents, causing by their scouring and undermining action huge landslips, extending for hundreds of feet up the mountain side. Unless you could see them you could hardly realise what sights these slips present. Huge trees, and masses of rock weighing hundreds of tons, deposited here and there.

Some time after the storm had burst, Mr. Pantling heard from Calcutta that Mr. and Mrs. Cave were starting at a certain time for the plantations, as it was not known in Calcutta how much we had suffered. Mr. Pantling immediately replied that they were to stop in Calcutta till further notice, as all the roads were impassable. But the Caves started before his letter was received, and the next we heard was, 'Have arrived at Kurseong; am awaiting orders.'

I must explain here, that although the roads were so bad, some natives, by making *détours* and climbing here and there, got through to Kurseong and Darjiling, but it took them a very long time.

Here was a to-do! Mr. and Mrs. Cave were at Kurseong, and had to get to Mungpoo somehow. This was done by sending up about 130 men on Friday and Saturday, and sixty more on Sunday, to cut a way over the impassable parts, in order to allow a pony to be sent over without a rider, so that they could ride over the passable parts and walk the rest. To help them as much as possible to-day, I sent breakfast out to a place about 5 miles from Sureil, and 9 from Kurseong, and then rode 3 miles up through the forest to meet them. I found that the roads, though passable, were in a dreadful state. Mr. and Mrs. Cave were nearly four hours doing these first 9 miles. We then had something to eat, and two hours' more travelling brought them to Sureil, where I had tea ready. A rest of an hour here, and then they entered on the last three miles to Mr. Pantling's bungalow, which, I suppose, they would reach all right, as the road from here to there is undamaged.

Mr. Pantling has been up this morning, and we inspected together the five miles of road which constitute the first section I am to repair. He has considerably modified his instructions to me, in consequence of the slips being very dangerous and still going on. I am to thoroughly repair such parts of the old road still remaining, and connect the severed portions by small paths 3 feet wide,

across the most accessible parts of the watercourses where the slips have occurred. This necessitates making very steep zig-zag paths in many places; easy gradients, unfortunately, cannot be made for the want of room.

I have not the regular garden coolies working on the road, but the 'busti-wallas' (native settlers or farmers, who pay rent for their holdings), have been ordered to turn out, one from each house. At present, I can only muster about forty, but in a day or two, I hope to have over a hundred at work.

Altogether we had five people killed by the landslide, and portions of them were found, as a leg of one and an arm of another.

All the factory buildings, water-mains, tanks, &c., were uninjured, and also the bungalows with the exception of mine, which had a quantity of thatch blown off, thus letting in the rain."

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD,
Wrotham Park, Barnet.

The Mushroom-house.—Those beds which were spawned about six weeks ago will be coming into bearing, and need an examination at short intervals of time. If the covering of soil is found to be in need of moisture, let water be applied of 80° warmth. The litter employed to maintain uniform conditions in the beds may be taken away when the Mushrooms reach the "button" stage, provided the temperature of the house can be maintained at 60°. If this cannot be done, some dry, fresh hay or stable-litter should be employed to cover the beds. Prepare materials for forming other beds by turning and mixing them twice or thrice, and throwing them together into a heap each time. Do not expose the stable-dung too much, or the valuable ammonia will escape, rendering the manure almost useless for the purpose of a Mushroom-bed. If stable-manure is not plentiful, Chestnut or Beech-leaves may be used in about equal proportions to the manure, the whole being mixed, turned, and heated a few times, as in the other case.

Cauliflowers.—These plants should be afforded plenty of air, the lights not being made use of till sharp frosts appear imminent. The Walcheren Cauliflowers raised from late sowings will winter satisfactorily if transplanted on to a sheltered border if not too large when planted, and the winter is not very severe. Such plants sometimes go through a winter in better condition than plants which have been wintered in frames, which get drawn. They are also less liable to "button." Those plants which were potted should be kept fully exposed out-of-doors, and they should be afforded plenty of space, in order to prevent drawing.

Herbs.—Chervil is in some families an article in common request, and where that is the case, a bed or two should be grown on a border, and some handlights or a garden frame placed over it. In many gardens it is almost a weed, springing up from self-sown seed. Some roots of Tarragon and Mint should be potted or boxed in quantity for forcing purposes, and stood in cold frames for the present. For convenience-sake, pot-herbs should be grown all together on a border convenient of access, so that time is not lost in going from one part of the garden to another when herbs are wanted by the cook.

Horse-radish.—The best sticks are obtained from beds not older than three years, and with a view of thus meeting requirements, a new bed should be planted every year and an old one grubbed up. The present affords a suitable season for taking up a bed or portion of one. Let every bit be got out selecting what roots are fit for use, and laying them in close together on a border. The thick thongs with a crown and ends of roots should be laid in separately for making into sets later on, and the smallest pieces thrown on to the smoulder heap, not the garden-refuse heap. Some gardeners prefer to plant crowns, that is, small roots surmounted by a bud, and of a length of 9 inches, dropping this into a hole 1½ ft. deep made with a dibber. The crown should be pared off for ¼ of an inch, so as to remove the mass of buds that would otherwise push

from that part. Land for this crop should be heavily manured and deeply trenched, the whole of the manure going to the bottom of the trenches.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore
Maidenhead.

The Planting of Fruit Trees.—As the present is a very suitable season for planting, I purpose to give in this calendar a list of desirable varieties of Apples and Pears, which may be of some assistance to beginners who may be contemplating the formation of an orchard, or adding to a collection already existing. The varieties I shall recommend are generally trustworthy in diverse localities given a favourable blossoming season. I shall refer on this occasion to such varieties as are the best adapted for garden culture, leaving orchard-planting for another time. For garden-planting, no form is better for Apples than the bush or pyramid on the Paradise stock; and horizontally-trained cordons for lining the paths, &c.

Dessert Apples, Early.—Mr. Gladstone, Beauty of Bath, Irish Peach, Devonshire Quarrenden, Kerry Pippin, Lady Sudeley, and Worcester Pearmain. Mid-season for use in October, November, and December. In this class, no Apple can be compared with Cox's Orange Pippin, which should be included in the smallest collection. The new variety, Charles Ross, is almost equal to it in flavour, but somewhat larger, partaking in this respect of the character of one of its parents, Peasgood's Nonsuch. This variety is sure to be largely planted in the near future. Others are Ribston Pippin, King of the Pippins, Blenheim Orange Pippin, Gravenstein, Margil, Adam's Pearmain, Claygate Pearmain, and Golden Reinette. The latest are Scarlet Nonpareil, Hubbard's Pearmain (although rather small, a good keeper of excellent flavour), Fearn's Pippin, Cockle Pippin, Wyken Pippin, Court Pennu Plat, Sturmer Pippin, and Allen's Everlasting.

Kitchen Apples.—Early: Lord Grosvenor, a very sure cropping variety that rarely fails to produce a good crop, succeeding where Lord Suffield is often unsatisfactory; Pott's Seedling, Ecklinville (a fine cropper with large but rather soft fruits), Stirling Castle, and Grenadier a grand September variety. Mid-season: Stone's, Warner's King, Peasgood's Nonsuch, Lord Derby, Beauty of Kent, Golden Noble, Tower of Glamis, Blenheim Orange, Mère de Ménage, and Bismarck. Late: Lane's Prince Albert, Dumelow's Seedling, Newton Wonder, Bramley's Seedling, Alfriston, and Northern Greening.

Pears for Wall Culture.—Early: Jargonelle, Beurré Giffard, Margaret Marrillat, and Fondante d'Automne. Mid-season: Louise Bonne of Jersey, Pitmaston Duchess, Marie Louise, Beurré Superfin, Beurré Diel, Conseiller de la Cour, Doyenné du Comice, one of the best; and Beurré d'Anjou. Late: Marie Benoist, Beurré du Buisson, Easter Beurré, Nouvelle Fulvie, Olivier de Serres, Le Lectier, Passe Crassane, Beurré Rance, Winter Nelis, Beurré Sterckmanns, and Duchess de Bordeaux.

Pears for Bush or Pyramid Culture.—Williams' Bon Chrétien, Clapp's Favourite, Souvenir du Congrès, Beurré d'Amanlis, Doyenné Boussoch, Triomphe de Vienne, Fondante d'Automne, Durondeau, Louise Bonne of Jersey, Thompson's, Marie Louise d'Uccle, Pitmaston Duchess, Beurré Superfin, Doyenné du Comice, Beurré Diel, Beurré du Buisson, Josephine de Malines, and Bergamotte d'Esperen.

Pears for Stewing.—Beurré Clairgeau, General Tottleben, Bellissime d'Hiver, Catillac, and Uvedale's St. Germain.

PLANTS UNDER GLASS.

By G. R. FIELDER, Gardener, North Mymms Park, Hatfield.

Lilium longiflorum var. Harrisii, and other bulbs.—When an examination shows that growth has taken place to the extent of 1 or 2 inches, those bulbs which were placed in beds of coal-ashes or Cocoa-nut fibre-refuse should be removed to a cold-frame or pit without delay. This will apply to all species of bulbs when covered with these materials. In order to prevent serious injury, a few pots in each batch should be examined at intervals of a week or ten days. If the soil in the pots is dry, a good application of water should

be afforded, and the soil kept in a moist condition for the future. A batch of *Lilium Harrisii* may be placed in a house having a night temperature of 50°; and as during the next few weeks the flower-stems will grow rapidly, a light position for the plants is very essential. Let air be admitted on all favourable occasions, to prevent the plants becoming drawn. Batches of early Tulips, Narcissus, and Roman Hyacinths, may be introduced into a similar degree of warmth, in such quantities and at such intervals of time as the requirements of the place demand, the temperature at the end of a fortnight being increased to 55°. No bulb should be forced which is not well furnished with roots, and the forcing should be gradual, any attempt to hurry them into flower usually ending in failure.

Pot Roses.—If any of these were not repotted at the usual time, no time should now be lost in top-dressing the plants now instead of repotting them. After putting the drainage in good order, remove the surface soil with a pointed stick to the depth of about 3 inches, and replace it with a compost consisting of good fibry loam, rotten manure in small quantity, well burnt garden-refuse, with bone-meal at the rate of a 6-inch potful to one wheelbarrowful of the compost.

FRUITS UNDER GLASS.

By W. STRUGNELL, Gardener to Lieut.-Col. RALPH VIVIAN, Road Ashton, Trowbridge.

Pot Vines.—Those canes which are intended to fruit in the late spring should have been stood outside for some short time, in order to mature and rest before being forced. Younger ones grown from "eyes" this year should also be standing outdoors, arranged preferably in the front of a sunny wall. The weather of late has been such in this part of the country, that an occasional application of water has been necessary in order to prevent the premature fall of the leaf; but from this date, however, no more water will be needed. Those that are shortly to be started may now be repotted or top dressed accordingly as they may need, having regard to their condition, age, and size of pot. The compost employed should be of the best, but not necessarily rich in animal or chemical manures, but sufficiently so as to afford nutriment as soon as the plant needs any; more being afforded in the form of liquid-manure and manurial top-dressings when the growth becomes active. If scale, mealy-bug, &c., have been present on the Vines, be careful to wash the canes with hot water, to which Gishurst's Compound-soap, in not greater quantities than 3 ozs. to one gallon of water, Fir-tree oil, or some other suitable insecticide has been added; and if necessary, a further dressing may be afforded before the plants are placed in the forcing-pits. Pot-Vines early started are the better for bottom-heat being provided, either by a bed of fermenting tree-leaves and dung, or hot-water-pipes. The proportion of stable-dung to leaves may be one wheelbarrowful of the first to three of the second, and the whole should be got into a sweet and warm state, fit for use when the Vines are started. The use of this mixture in close-fitting pits and small houses needs much care, as the rise of heat is sometimes very rapid in mild weather, and it may do much harm to the roots if it be not watched. It is safer to partly plunge the pots in the bed at the first.

Early Figs in Pots.—Many of the foregoing remarks apply also to early varieties of Figs grown in pots. With a suitable house and the proper kind of treatment, Figs in small pots may be made to give a large quantity of fruit. The St. John's Fig, and the variety Pingo de Mel, from Portugal, are excellent for forcing for the earliest crop; moreover, their fruits are not so liable to be cast as are those of most of the other varieties. Potting, or repotting, will have been performed whilst the plants were in growth, but with care these operations may still be carried out. The soil in which the Fig is potted should be made firm, and it should contain an eighth part of lime-rubble, plaster, &c. The insects which infest the Fig are mealy-bug and scale. It is, however, not a difficult matter to clean Figs when the leaves have fallen. Scale-insects, both brown and white, adhere partly to the rind. The leaves should be gathered up as they fall, and burnt, and the stems and shoots sponged with warm soap-suds, in which petroleum, in the proportion of 1 to 200 has been mixed. In the case of mealy-bug, every part of a plant should be examined, and washed with the same. The immature tips of the

branches require careful treatment, being easily injured. Until the house is ready for their reception, Figs are the better for being left out-of-doors, or in a cool-house or shed, where they are merely protected from rain and snow.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart. Clare Lawn, East Sheen.

Lælia (Brassarola) Digbyana.—Since the flowering of the lovely Lælia-Cattleya Digbyana-Mossie, this curious but otherwise unattractive Orchid has leapt into popular esteem as a subject for the hybridist. It is a plant fairly easy to grow for a few years after being imported, but to keep it in a sound and vigorous condition for an indefinite period requires very careful treatment during the present—its resting period. It may be grown in shallow baskets and pans, or on bare blocks of wood, the only drawback to the latter method being that when the block decays, it is no easy matter to substitute another for it. How, or in whatever receptacle it may be placed, the chief care is to guard against any stagnation of moisture at the base of the plant. Water in abundance is essential when it is growing freely, but the rooting materials should be so scanty that dryness should occur readily and often. At this season, although the basal buds show activity to a small extent, but little moisture other than that obtained from the air of the house should be afforded. The plants should be suspended in a light position in the East Indian-house permanently.

Cattleya superba.—In many respects this bright-flowering species requires similar treatment to the plant previously named, especially during the winter. It grows the best in perforated pans, suspended in the same house, and in the same position. Severe drought will do less injury than affording too much water, which generally causes decay of the roots, or of the last pseudo-bulbs formed.

Cattleya Lawrenceana is another unsatisfactory subject to deal with during the winter months, and, in fact, at any time, without the greatest care on the part of the cultivator. As growth does not occur until late in the season, a warm position in the East Indian-house has to be selected for the plants, so as to encourage the growth and finish it before the hours of sunshine get very short. Having now about finished to grow, the plant should be removed to the warmer part of the Cattleya-house, where every ray of sunshine reaches it, and the atmosphere is dry. Let water be afforded only when the shrivelling of the young pseudo-bulbs is feared.

Lælia flava and longipes.—There being found in most collections of Orchids many more favoured Lælias, *L. flava* and *L. longipes* are seldom found in any number in the generality of collections. Being small, compact-growing plants, they occupy but a small amount of space; moreover, their requirements are few. The plants succeed when fixed to rafts of Teak, with a thin layer of peat and moss under them. The rafts should not be suspended in a horizontal position, moisture being then retained for too long a period, but they should slightly incline to one side. The best place for *L. flava* and *L. longipes* will be found at the coolest part of the Cattleya-house. Let the plants be afforded abundance of water when rooting, but at the present season, growth having ceased, a small quantity now and then will keep their pseudo-bulbs plump.

Lælia cinnabarina and L. harpophylla should be accommodated in pots. The former requires the temperature of the Cattleya-house, and all the light obtainable; and the latter succeeds with much less warmth. *L. cinnabarina* having matured its pseudo-bulbs, an occasional application of water will keep them from shrivelling too much; and *L. harpophylla* having thin reed-like pseudo-bulbs, should not be allowed to remain dry for any length of time.

Oncidium macranthum, undulatum, loxense, and others of this section, usually thrive in the coolest department, where moisture and shade are abundantly afforded during the sunnier portion of the year. In many instances the long, trailing spikes will be in course of development, and to keep these within bounds two or three neat stakes should be stuck in each pot, and as the spikes lengthen twining them round the stakes and making them secure. Any plant emitting roots may, if conditions warrant it, be afforded equal proportions of fresh peat and moss; water being then afforded rather sparingly till the days begin to lengthen. Plants which

have not been disturbed will need just sufficient water as will keep the materials moist.

Oncidium insculptum (metallicum) is another cool-growing species, and one that likes a rather drier atmosphere than the foregoing, especially during the resting period. On one occasion, here, a long spike was trained to a wire near the roof-glass of a very cool house, and when the side branches had developed their buds, a severe frost ensued, and a coating of ice formed on the inside, in which, for the space of a week, the tips of numerous flower-buds were embedded. These, strange to say, afterwards developed satisfactorily, and without being injured. The plant itself was 4 feet distant from the glass.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucestershire.

Anemones.—If a stock of Anemones has not been raised from seeds, bulbs should now be procured, and if planted at once in good rich soil, they will form roots before winter, and flower profusely in spring. Failures are often due to inserting the bulbs too close together; a distance of 10 in. at least should be allowed, and 12 in. between each row, planting them at a depth of 3 inches. The Giant French Poppy Anemones produce the largest blooms, have a great range of colour, are very free flowering, and not so apt to produce double flowers as the St. Bridget variety. The ordinary single forms are very pretty, and are most useful for cutting purposes, especially the white variety (The Bride). The single Peacock Anemones (*A. stellata*) flower early when planted in a sheltered position, but in cold seasons many of the blooms are damaged by the late frosts. *A. apennina*, *A. alba*, and *A. blanda* are pretty planted in clumps in the rock garden; *A. pulsatilla* (the Pasque-flower), is very pretty in borders, but requires 2 feet deep of soil.

Spring Bedding Plants.—All the plants for furnishing the beds should be planted soon after this date, according to the latitude of the place, early planting tending to early establishment in the new quarters, and the consequent ability to resist frost, and to produce flowers early in the spring. The flowering season is so very short, that there is very little time for growth. Let only good masses of each plant be put out, and these so placed that they cover the bare earth at once.

Foremost amongst these are the Primroses, known as Dean's Superb Strain, which withstand well our severest winters. They are very effective in geometrical beds when massed in diverse colours. Before planting them it is advisable to add plenty of cow-manure and a slight sprinkling of soot to the staple, substances that favour rooting and prevent flagging in dry, windy weather, and during strong sunshine, tending also to the production of robust flower scapes, and preventing exhaustion from excessive flowering. The new blue Primrose G. F. Wilson is a very pretty and suitable variety for making small beds, or massing in the borders, but the aspect chosen for it should by preference be a shaded one, or the flowers soon pale. *Primula rosea*, for the short time it lasts in flower, is deserving of a place in the rock garden, but it requires a moist position in order to thrive. The double-flowered forms of *P. vulgaris* in their different shades of white, purple, red, and rose do not lend themselves to bedding, but in the rock garden, in shady and moist nooks, where special treatment can be afforded, they are very handsome when in bloom.

Violas.—In order to make a fine show of these plants, healthy, good-sized clumps should be planted in the beds or borders which later on are intended for the reception of Begonias, Violas lasting in perfection, till at the least, the commencement of June, and will then not need to be disturbed for the other occupants. They may also be employed as a groundwork to beds of Tulips, but, in order to make them flower at the same time, the plants must be wintered in a cold frame, and planted just before the Tulips open their flowers.

Routine.—After this date the mowing of lawns should cease, but in order to keep them in good condition a weekly sweeping will be necessary to scatter the worm casts. If the surface be tolerably even, it need not be rolled much, and the surface-water will then pass quickly through it. See that all fallen leaves are swept together and cleared away, as, if allowed to remain on the grass, they are apt to ferment and destroy it.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, Nov. 4	Loughborough Chrysanthemum Show. North of Scotland Vegetable and Root Exhibition. Stockport Chrysanthemum (2 days).
MONDAY, Nov. 6	Chrysanthemum Shows at St. Neot's and Totnes. Royal Horticultural Society's Committees. National Chrysanthemum Society's Exhibition at Royal Aquarium, Westminster (3 days). Chrysanthemum Shows at Birmingham, in Bingley Hall (3 days), Coventry (2 days), Brighton (2 days), Croydon (2 days), Yeovil, Plymouth (2 days), Southend (2 days), Birkenhead (2 days), Truro (2 days), and Stratford-on-Avon (2 days). Scottish Horticultural Association Meeting.
TUESDAY, Nov. 7	Mr. J. J. King's Exhibition of Roots, Cereals, and Vegetables, at Coggeshall, Essex.
WEDNESDAY, Nov. 8	Chrysanthemum Shows at Kingston-on-Thames (2 days), Cambridge (2 days), Bournemouth (2 days), Ware (2 days), Chesterfield (2 days), Bromley (2 days), Lowestoft (2 days), Stoke Newington (2 days), Cardiff (2 days), Hanley (Staffordshire) (2 days), Bath (2 days), Great Yarmouth (2 days), Asot (2 days), and Bristol (2 days).
THURSDAY, Nov. 9	Chrysanthemum Shows at Putney (2 days), Colchester (2 days), Gloucester, Windsor (2 days), Northampton (2 days), Stirling (2 days), Llanecston (2 days), and Weston-super-Mare. Chrysanthemum Shows at Leicester (2 days), Blackburn (2 days), Stockport, Eccles (2 days), Folkestone (2 days), Derby (2 days), Sheffield (2 days), Altrincham (2 days), and Huddersfield (2 days).
FRIDAY, Nov. 10	

SALES.

MONDAY, Nov. 6, and the following Tuesday, Wednesday, and Friday.—Dutch Bulls at Protheroe & Morris' Rooms.
TUESDAY, Nov. 7.—Clearance sale of Nursery Stock at the Nursery, Grove Park, Lee, by order of Mr. G. Hind, by Protheroe & Morris, at 11.30 o'clock.
WEDNESDAY, Nov. 8.—Clearance sale of stock at the Old Park Nursery, Buckland, Dover, by order of Messrs. G. & A. Clark, by Protheroe & Morris, at 11.30 o'clock.
WEDNESDAY, Nov. 8.—Great Sale of Japanese Lilies, Continental Decorative Plants, Carnations, &c., at Protheroe & Morris' Rooms.
WEDNESDAY, Nov. 8.—Clearance Sale of Nursery Stock, Glass Erections, &c., at 206, Goldhawk Road, Shepherd's Bush, by order of Mr. Thomas Budge, by Protheroe & Morris, at 12 o'clock.
FRIDAY, Nov. 10.—Imported and Established Orchids, at Protheroe & Morris' Rooms.

Remarks.—Another week of dull, sunless, mild weather, with thick fogs during the first three days.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—43° 8'.

ACTUAL TEMPERATURES:—

LONDON.—November 1 (6 P.M.): Max. 59°; Min. 47°.

November 2.—Rain—mild.

PROVINCES.—November 1 (6 P.M.): Max. 56°, S. Counties; Min. 49°, E. Counties.

A suggested cause of sporting in Chrysanthemums.

M. GHYS* suggests a new cause of sporting in this flower. Alluding to the frequency of colour-sporting in Chrysanthemums, and to the method of propagating them, as follows:—"All the shoots are cut off excepting the one carrying the sport; then as this shoot develops buds, it can be propagated by them, as each will reproduce the sport in question;" he observes that no flower, excepting the Azalea, presents such frequent cases of dimorphism as the Chrysanthemum; that while one variety will give a white flower if it blossom in September, and a rose-coloured one in October, another will have shown glabrous flowers from the first crown buds, and downy ones at the terminal buds. Hence, M. GHYS considers the seasons as well as the positions of the buds as influencing the form and colour.†

As to the predominating colours of sports, he noticed that if the normal flower be of a composite colour, one shade may become accentuated, thus overpowering the others. Thus, in Mrs. H. Payne, Madame E. Teston, red predominates; while in Madame L. Rémy it is white. Sports of a pronounced red are rarer. Pure white varieties only give yellow sports. But he mentions Annie Clibran, a sport from Mdle. Lacroix as an exception, in being of a rosy tint on expanding in complete sunshine.‡

A feature worthy of remark is, that varieties which, as Louis Boehmer, contain several dimorphic representatives, pass gradually to white, finally terminating in yellow. This, the author observes—as we have also done—is probably due to atavism, or reversion to the primitive colour, from which the name Chrysanthemum is derived, *chryso* being the Greek for "gold;" and he adds that a pure yellow Chrysanthemum, obtained either by seed or sport, will no longer give a red-tinted, or white.§

M. GHYS then asks—What are the causes of dimorphism? A change of climate and soil are usually suggested; but he thinks there is another very important factor, and that is the taking cuttings from a plant in full vigour. "I have always been surprised," he remarks, "at the rarity of sports observed by amateurs, and at their complete absence among those who renew their collections every year by the division of the old plants (presumably by dividing the root). M. DELANOV has upwards of 450 varieties, and has never had a sport since 1832." The author's procedure is as follows:—The plants, as soon as they have done flowering and are still full of sap, are cut down to furnish the first shoots. An endeavour is then made to keep the plants vegetating, which should normally have been in repose. As soon as the young shoots appear, the points are removed; the new lateral shoots undergo the same treatment.

The vegetative growth out of its proper season, and the sudden arrest of the sap produced by the repeated amputations, are two factors of which account must be taken. Following the cuttings through their course of development, they soon become well-rooted in

appropriate soil, and make a good start. As soon as they enlarge, and grow stronger day by day, and cover themselves with foliage, if all of a sudden the flow of sap be stopped by cutting a strong part of the plant, a profound disturbance in all parts of the plant is inevitably induced; and the equilibrium between absorption and evaporation of water is disturbed. Now it is in these conditions that sports are not infrequently produced.

New varieties are more prone to dimorphism than those which have been established for many years. Thus it is, that Madame A. Cordonnier and Madame Deis have given M. MONTIGNY, of Orleans, a sport in the first year they were sent out.

"Does it not explain why all the most approved varieties, as Viviani Morel, Mrs. C. H. Payne, Madame Carnot, and L. Behmer, have given rise to a number of sports, by reason of the great demand for these varieties, and in consequence, their greater multiplication?"

Without excluding other causes, the author gives the following conclusions:—

1. That the cutting taken from an important part of a Chrysanthemum, when in full vigour, is a cause which induces dimorphism.

2. That a new variety has a greater aptitude than one of long standing for giving rise to sports.

EUCHARIS ELMETANA ×.—In a recent illustrated article on the species and varieties of *Eucharis*, presumably accidentally reproduced in the *Semaine Horticole* without acknowledgment, E. Elmetana × was omitted. By the courtesy of Messrs. SANDER & Co. of St. Albans, who forwarded us a specimen, we are now enabled to give an illustration (fig. 115, p. 345) of this variety. It was raised by Mr. BONSAILL, gr. to H. KIRSON, Esq., Elmet Hall, Leeds, and is stated to have been raised from E. Sanderi crossed with E. grandiflora. It is stated to grow more freely, and to be of easier culture than E. Sanderi, and to be well suited for "button-holes" and the formation of wreaths. It was introduced into commerce by Messrs. SANDER in 1896, the first mention of the plant being in their catalogue for that year.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Fruit and Floral Committees of the Royal Horticultural Society will be held on Tuesday, November 7, in the Drill Hall, James Street, Westminster, at 1 to 4 P.M. A lecture on some of the plants exhibited will be given by the Rev. Prof. G. Henslow, M.A., V.M.H., at 3 o'clock.

AMPELOPSIS HOGGI.—We have had frequent occasion to warn gardeners against a climber which was unfortunately sent out as an *Ampelopsis* by oversight. The plant so called is generally nothing else than *Rhus toxicodendron*. We hear that a son of Mr. SMITH, of Newry, has suffered severely from handling some cuttings. The autumn coloration is so beautiful that it is unfortunate it should have such evil qualities. Some people are more subject to its virulence than others.

ROYAL GARDENERS' ORPHAN FUND.—At the usual meeting of the Executive Committee on the 27th ult., Mr. WILLIAM MARSHALL, presiding, the following special contributions to the fund were announced:—Wimbledon Horticultural Society, sale of flowers, £6 10s.; Sandringham Estate and Cottage Garden Society, per Mr. MAKELLAR, £5 5s.; Betchworth, Brockham, and Buckland Horticultural Society, £4 6s.; The Rev. A. Lowe, The Vicarage, Rangemoor, Burton-on-Trent, collection at harvest festival, £4 10s.; Mr. A. D. CHRISTIE, half of the amount collected through throwing open the gardens at Ragley, near Alcester, £2 9s.; Worcester County Council, one-third of the amount realised by the sale of fruit at the annual Exhibition of Art and Technical Work in

* *Le Chrysanthème, au point de vue du Dimorphisme: Bull. de la Soc. d'Hort. de Loir-et-Cher (Troisième trimestre, 1899, No. 35, p. 9).*

† See Rev. Prof. HENSLOW's paper on "Chrysanthemum Sports," *Journ. Roy. Hort. Soc.*, read Dec. 14, 1897.

‡ That yellow is frequent from white, was known, nineteen cases being mentioned; but it is not exclusively so, as Cedo nulli gave rise to a yellow, lilac, brown, and two whites. Three cases of sporting from white to pink are mentioned. *l. c.*, p. 543.

§ No such sports occurred here either; but three bronze from yellow are mentioned. *l. c.*, p. 540.

connection with the above, £1 17s. 4d.; and sale of flowers at Chislehurst Show, per Mr. J. LYNE, £4 6s. The annual general meeting of subscribers to the fund was fixed for Friday, February 16, 1900. A hearty vote of thanks was passed to those contributing the foregoing special donations, and also to the chairman for presiding.

PARIS UNIVERSAL EXHIBITION, GENERAL OFFICIAL CATALOGUE, 1900.—Mr. C. WILKES, 29, Ludgate Hill, London, has been appointed General Manager and Sole Agent for the British Empire (Canada excepted), for all English advertisements

decorative, being stocked with Palms, Crotons, Orchids, and other ornamental plants. The centre of the house is to be furnished as a boudoir, reception-room, or smoking or billiard-room, the plants being grouped down the sides and at the ends. The name of "Five o'Clock" has been given to this conservatory because it is peculiarly well adapted as a lounge in which to serve the afternoon meal of which foreigners have adopted the above designation. Daintily furnished and stocked with the taste peculiar to our Belgian and French neighbours, the Five o'Clock is an elegant and comfortable salon or winter-garden, and finds much favour.

to the man of science; it absorbs the scanty funds of his libraries, and steals away his poor hours of leisure. . . . As the wise man said: "Hardly do we guess aright at things that are upon earth, and with labour do we find the things that are before us."—Dr. Langley, in *Transactions of British Association, Dover*.

DEATH OF A PATRIARCHAL ORANGE-TREE.—The great Bourbon, as the oldest of the Orange-trees at Versailles is called, died last year at the age of 477 years, as we learn from a French contemporary. The seeds of a particularly flavour-

FIG. 115.—EUCHARIS ELMETANA × : HORT. SANDER. (SEE P. 344.)

or publicity in the General Official Catalogue of the Paris 1900 Universal Exhibition; also for the French and English guides and other publications issued by Messrs. LEMERCIER & Co., Official Contractors to the French Government and Exhibition Board.

THE "FIVE O'CLOCK HOUSE."—The *Bulletin d'Arboriculture, de Floriculture, et de Culture Potagère* for September, describes a greenhouse planned and erected by M. OMER VAN LIERDE, in the garden of the Ghent Exposition Provinciale. This building is modelled somewhat on the lines of an English conservatory; that is to say, it is not intended for propagating purposes, but to be solely

THE IMPERFECTIONS OF SCIENCE.—Those who have occasion to enter into the depths of what is oddly, if generously, called the literature of a scientific subject, alone know the difficulty of emerging with an unsoured disposition. The multitudinous facts presented by each corner of Nature form in large part the scientific man's burden to-day, and restrict him more and more, willy-nilly, to a narrower and narrower specialism. But that is not the whole of his burden. Much that he is forced to read consists of records of defective experiments, confused statement of results, wearisome description of detail, and unnecessarily protracted discussion of unnecessary hypotheses. The publication of such matter is a serious injury

some Orange were sown in 1421 by LEONORA DE CASTILLE, Queen of Navarre. In 1499, Queen CATHERINE sent a specimen to ANNE of Brittany this specimen was passed on to the Constable DE BOURBON at the Château de Chantelle, whence FRANCIS I. moved it to Fontainebleau in 1531. LOUIS XIV. had it transplanted from Fontainebleau in 1684, and placed in the orangery at Versailles, where it remained until its death recently.

CLASSIFICATION OF PLANTS.—"There will be much difference of opinion as to minor points, for many smaller groups, through lack of adequate investigation, had to be "lumped," but in the

judgment of the reviewer the main lines of evolution suggested will stand, which are in brief as follows: A passage from the spiral arrangement and indefinite numbers to cyclic arrangement and definite numbers; of naked flowers to the differentiation of calyx and corolla; of apocarp to syncarp; polypetaly to sympetaly; hypogyny to epigyny; actinomorphy to zygomorphy. That cases of "reduced flowers" occur there can be no doubt, but that the great majority of so-called cases of reduction are really primitive in character seems hardly less doubtful." *J. M. C., in Botanical Gazette (a review of Engler's Pflanzenfamilien).*

F. W. LOUDON, a well-known American raiser of fruits, who brought out the Strawberry Jessie and Raspberry Loudon, died on October 2 in Jamesville, Wisconsin, U.S.A.

J. BRIGNOT, an amateur gardener, the raiser of the favourite section of "Brignot" Pansies, died on September 15 last at Saint Briene, France.

WHAT VARIETIES OF APPLE ARE SUITABLE FOR PLANTING AS BUSHES?—There are a few varieties of the Apple which crop so heavily for years together that their growth of shoots is greatly restrained in development, and as a consequence they are not so well adapted for forming standard trees, but form shapely bushes by a sparing use of the knife. Many of these varieties will occur to our readers, and we may mention the Red Calville, Hawthornden, Frogmore Prolific, Manx Codlin, Hoary Morning, Downton Pippin, Yellow Ingestre, and Cellini.

IMPORTATION OF PLANTS, SHRUBS, ETC.—The importation of plants, shrubs, trees, and flower-roots into the United Kingdom has been steadily increasing during the past twenty years; in 1879 the value of these imports was returned at £137,000, in 1884 it reached £212,000, in 1890 £308,000, whilst in 1898 it was £436,600. Of this last-named sum the imports from Holland accounted in 1898 for more than half, viz., £221,800; Belgium, France, and Germany each sent goods valued at between £40,000 and £50,000; the importations from Japan, the United States, Colombia, and the Channel Islands were each returned as worth over £10,000; while Brazil and India sent shipments valued at £6,300 and £4,900 respectively. The figures given above do not include cut-flowers, which were imported in 1898 to the value of £219,000, so that the combined value of plants and flowers imported into this country in the past year amounted to over £650,000. The countries to which plants and shrubs of British production exported are sent are not separately distinguished, but the total value of these exports in 1898 amounted to £35,500, whilst the re-exports of foreign plants amounted to £10,805. *Journal of the Board of Agriculture.*

ESSEX FARMERS IN HOLLAND.—We have already alluded to the visit of certain Essex farmers to their brethren in Holland. They were received with the utmost cordiality, and were struck with the thrift which they consider to be at the root of Dutch prosperity. This is shown in the preservation and use of manure, the utilisation of every inch of land, the clean cultivation, absence of weeds, and care in packing for market. In some districts the market-gardeners and fruit-growers combine into a co-operative society, which publishes price-lists, and circulates other useful information. Attached to the inn in every village is an auction-room for the daily sale of market-produce. What is not sold by private contract is sold in the evening to buyers from the great towns. These marts have been of the greatest service to the growers, and it would be well if something of the kind were organised here. In matters relating to education, both general and technical, the Dutch, like most other nations, are well ahead of us.

"THE PROFITABLE FARM AND GARDEN."—This is the title of yet another gardening paper. Its object is sufficiently indicated by its name. Its price is one penny weekly, and it is published by

Messrs. COLLINGRIDGE, Aldersgate Street. When we say that it is edited by Mr. W. T. SANDERS, we have said enough to prove its value to the cultivator who has to make a living out of the land. Old-fashioned farming has gone, or is useless as a profit-making business. The cultivator must in future adopt the practices familiar to the gardener.

NOMENCLATURE.—We are glad to find M. COGNIAUX, the editor of the very serviceable *Dictionnaire Iconographique des Orchidées*, and a botanist of large experience and great judgment, shares our opinion as to the inconvenience of attaching more than one word as a specific name. The great simplicity of the Linnean nomenclature resides in the adoption of one name for the genus and one name for the species. When speaking of a species, the two words, generic and specific, cannot be detached; they really form one name, and each is incomplete without the other.

M. RODIGAS.—As a sequel to the fêtes held in commemoration of the fiftieth anniversary of the Ghent School of Horticulture, M. RODIGAS has been promoted to the dignity of Officer of the Order of Leopold. Those who know with what energy and perseverance M. RODIGAS has worked in and for horticulture for a long series of years, will feel that this honour has been more than well earned.

DELASAU.—This name is familiar to us as one belonging to a family of French refugees established in Canterbury at the time of the revocation of the Edict of Nantes. It appears from the *Revue de l'Horticulture Belge* that the name is now written in France as Delasaulx or Dussaulx, and that it originally meant "of the Willow," from the Latin, *salix*; French, *saule*. The Flemish equivalent is Verwyghen. We do not think the translation of names from one language to another is desirable if the results are to be like those cited.

NATIONAL ROSE SOCIETY.—A meeting of the Soil Analysis Committee will be held at the Rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Tuesday, the 7th inst., at 2 P.M., to consider Dr. BERNARD DYER'S report on the analyses of five different Rose soils. H. HONYWOOD D'OMERAIN, EDWARD MAWLEY, Hon. Secs.

MR. MALCOLM DUNN.—The library of our lamented correspondent is to be sold by auction on November 16, at Dowell's Rooms, Edinburgh.

HOME CORRESPONDENCE.

PROTECTING PEACH BLOOM.—A correspondent under the signature "A Traveller," redirects attention on pages 289, 290 of the *Gardeners' Chronicle* to this important matter. In a couple of sentences he puts some of the more potent causes of failure and of cure, thus:—"In certain districts an abundant rainfall, frequent sea-fogs, and the mildness of the climate. The only cure was triennial lifting, root-pruning, shallow planting, and a restricted use of manures. Experience has proved these to be hindering processes; both checking the vitality of the trees, and husbanding time. Lift, root-prune, transplant Peach, Nectarine, and Apricot trees early in October, and we hold back growth for a month or more; and this forcible interregnum of growth often proves more than sufficient to save our fruit blossoms from destruction." I quite agree with "A Traveller" so far as he goes. Triennial lifting and root-pruning are likely to save the bloom every third year from destruction. But the principle and practice of the forcible holding back the flower-buds of stone-fruits, root-pruning and lifting, and a spare diet, may surely be applied oftener than once in three years. [Usually it is sufficient for the purpose, Ed.] Not a few of our best growers have so educated these trees into portable ways that they move many of them annually [?], and thus not only delay the flowering season and secure the maturity alike of wood and flower-bud. The restricted use of manure, either liquid or solid, is beneficial in restraining the energies of the trees until such time

as the period of spring frosts be passed by. Nor must it be forgotten that local circumstances are a very potent factor in the safe setting of Peaches and other stone fruit. It will sound strange for those whose lot has been cast in East Anglia to read "A Traveller's" experience in the counties which he enumerates, "that he had never to water a Peach-border either with clear-water or manure-water during the ten years of his residence in these three counties." How often have residents in dry counties had to flood their borders during the same period? But then we may have a forcing season to contend with, as well as multitudes of flower-buds allured into bursting by great sun-heat in the spring. Can we do anything to check the energy of the latter? We can. At first sight it might seem more possible to divert the Gulf-stream. But through the simple and sensible expedient of changing the aspects of our walls we may moderate the energy of our solar heat sufficiently to keep back the opening of fruit-buds to safety-point in our fickle spring. Apricots, Nectarines, Peaches in some districts, are safer in the spring months on an east than on a south wall; while in most districts they are safer from injury by frost on a west than on a southern wall. Why? Simply because the fruit-buds are several weeks later in opening. When in bud, Peaches, Nectarines, and Apricots defy spring frost. Keep them closed by surrounding them with a cooler local atmosphere, root-pruning, lifting, or under-feeding, until danger of frost is past. It will be quite easy to supply all their needs afterwards, and grow these fine stone-fruits in the open air, as well or better than our forefathers could grow them. *D. T. Fish.*

STARWORTS (ASTERS) AT STONELEIGH ABBEY, KENILWORTH.—The large number of plants of the perennial Asters now flowering profusely in these gardens present a gorgeous, yet graceful sight; the gardener, Mr. H. T. Martin, makes a specialty of them. On entering the kitchen-garden by the main entrance from the abbey, the visitor sees a bed containing between fifty and sixty distinct species and varieties, all of which are well grown and vigorous. Although due regard has been paid to the disposing of the tallest of the species at the back, yet they are so arranged that any degree of formality is entirely absent. The habit of these now popular plants is most diverse, and the numerous shades of colour and general contour of the plants are best displayed by a system of massing. Mr. Martin has many plants in the herbaceous borders dotted here and there among other subjects, and these are very effective; but it is when seen in a mass that the full beauty and utility of the plants for the embellishment of a garden in autumn is seen to best advantage. *M. D., Leamington Spa.* [Our correspondent sent with the above note a list of the best varieties in bloom at the time. Ed.]

APPLE, RIBSTON PIPPIN.—Enquiries were recently made by a correspondent in the *Gardeners' Chronicle* respecting our tree of the Ribston Pippin whether it was still living. I send you with this note four fruits from this tree; it bore about five dozen this year. It is getting very old, and is a sucker from the original tree which was raised here from a pip sown in 1709, and blown down by wind in 1834. The sucker has never been shifted, and stands in the park on a slope facing south. *John McClelland, Ribston Hall Gardens, Wetherby.* [Very good specimens from such a veteran. Ed.]

GREEN TOMATOS.—At this season there are many green Tomatos left on the plants which have been grown in the open. The utilisation of these remnants is of some importance. It is already known that they can be turned into a very nice jam, resembling somewhat that of Greengages. But here are two other modes of utilising them:—(a) Simply cut them in halves transversely, and fry them in lard with a sprinkling of finely-chopped Garlic and Parsley. Thus treated, they are very nice, and in flavour resemble that of fried Aubergines. Of course, they require longer cooking than ripe Tomatos. (b) Parboil them first, then cut away the stalk-top, and scoop out their interior. Make a mince of any left meat or fish, or of sardines; fry it slightly in butter with some finely-chopped Onion, and a chopped clove of Garlic and some chopped Parsley (in the absence of Parsley, Thyme or Sage will do); add pepper and salt, and let it cool. Then mix up with it a beaten egg and

some bread-crumbs, fill the green Tomato receptacles with this stuffing, and bake them in a dish smeared over with lard. They can also be stewed in a little savory stock. *E. Bonavia, M.D.*

AN ASH-TREE STRUCK BY LIGHTNING.—I have noticed what seems to me rather a curious occurrence. An Ash-tree growing here was struck by lightning, the electric fluid running from the top to the bottom of the bole. This happened in September last year, and the leaves dropped off it in about three days afterwards, and we thought that it was killed. This year, however, the tree bore a very large crop of good seeds. I do not know why it should bear such a wonderful crop of seed-vessels, as the leaves are not of the natural size of the Ash, but very much smaller; in fact, the leaflets of the compound-leaf are no larger than those of an ordinary Dog-Rose. I have noticed something similar in a case of a Laburnum-tree: it never used to have much bloom on it, but one day some goats got into the shrubbery where the tree was growing, and gnawed off the bark with the exception of a strip of about 1 inch in breadth. However, the following year it bore a numerous blossom, and after ripening its seeds died. *Observer.* [These are examples of the contrast between the vegetative and the reproductive energy: check the one, the other has an opportunity of developing. *Ed.*]

THE SONG-THRUSH.—I see from your columns that the character I gave of the colony of thrushes that frequent the garden and grounds here, and which appeared in your issue of September 30, has been received by some of your correspondents with incredulity or suspicion. To make the matter perfectly clear, perhaps I should have said I was speaking of the song-thrush. Well, all I said of these birds, as they have come under my observation here is absolutely true. What they may do or not do in other and distant parts, and under different conditions of life, I do not pretend to know. I only speak what I know, and testify of what I have seen, and I can say that the song-thrushes here have not injured a Pear or Apple on standard, pyramid, espalier, or wall, though quite unprotected, for twenty years. At the same time, they have not been slow to claim a share of Currants, Gooseberries, Strawberries, and Raspberries; but the large fruit, including Apricots and Peaches, they have never touched. As for blackbirds, I find that whenever they are a little time about a place, or become familiar with it, they go, especially in dry weather, full tilt at everything. But these black thieves have been kept thoroughly down here, at much trouble and not a little expense. This has freed my darling thrushes from evil companions and their bad practices. Whether it has had anything to do with their good behaviour I am unable to say. It may be, however, in the feathered, as in the unfeathered biped, that evil communications corrupt good manners. *John Hart, The Manse, Aberlady, East Lothian.*

TOMATOS AS A FIELD CROP.—The notes on Tomato-growing in the *Gardeners' Chronicle* of last week, are both interesting and instructive, and there is no doubt, that given a favourable season, there is more or less profit to be derived from Tomato-culture in the open fields in the warmer districts of the south and south-west parts of England, even when grown at a distance from the markets in the large towns. If the prices which have ruled the market here in Hawick held good in other towns, then ought there to be a decided balance on the right side this year, at any rate. The lowest I have seen priced in the fruiterer's windows this season was 8d. per lb. One thing I would warn would-be growers of, and which is well worth consideration in what may seem to be a favourable district for their cultivation. That is sea-fogs, which on some of our coasts are frequent and dense in the autumn. When living near the mouth of the Severn, where the soil is admirably adapted for Tomato-cultivation, I found in several seasons that we got very dense fogs early in September, and sometimes the whole month more or less, which brought on the disease in a wholesale manner. I have seen the plants loaded with moisture three-parts of the day for several days in succession in the open garden, but not quite so badly against the walls. Their cultivation in that district was attended with no difficulties except the one mentioned, and even in a wet season we secured a plentiful set of fruit, only to be swept off in quantity during the time mentioned if we had a visit

of the fogs. Some seasons we would escape, and were able to pick first-rate fruit in quantity well into November. I have tried many varieties, but Conference was the most trustworthy, being a freer setter than some of the larger-fruited sorts. Some of the individual fruits of the large varieties I have seen turn the scale at 1½ lb., but I do not think varieties which produce such weighty fruit are nearly so profitable as those of which Conference is the type. *R. T. S.*

SALVIA PATENS.—I can fully bear out Mr. S. Arnott's statement at p. 331, that this beautiful blue-flowered Salvia is one of the most effective of plants in the flower-garden. Every good garden should possess a bed of it, and if this is furnished with a white edging, either white leaves or white flowers, the effect is much enhanced. I edge with white-leaved Pelargonium; I prefer seedling plants, sowing the seed early in February, in heat, and prick off the seedlings into cold frames early in the month of April, and in the middle of May I take them up with good balls, and plant in the beds. As soon as they begin to cover the ground, I peg down the shoots. The beds were masses of beau-

EUGENE BEEKMAN

tiful blue flowers all the summer. I have never found it to be a hardy plant; I take up the old roots and put them into boxes filled with sand, in which they remain till March, and then pot them, and as soon as the shoots are large enough to make cuttings, I strike a quantity of them in bottom heat. *Wm. Smythe, Basing Park Gdns., Hants.*

AWARDS OF MEDALS TO HARDY FRUITS AT THE DRILL HALL.—I scarcely expected that there could be room for complaint with respect to the exhibiting of collections of Apples and Pears at the Drill Hall, where very few conditions are imposed on those who take such collections there, beyond the exclusion of duplicate dishes, and the condition that the space filled be that duly allotted. But a grower of high reputation, I find from a note from him, referring to his own experience on some occasion, states that when medals are awarded for the various collections, the Fruit Committee seem to be impressed with those where large dishes or baskets of a variety are shown, rather than by the average excellence of the samples displayed. In that respect I feel an error is committed, as on the last occasion, when medals were awarded the smaller collections of Apples and Pears from The Hendre, Monmouth, a very remote place, was, although the various dishes were each of about six

fruits, placed equal in the award of a Gold Medal to the much larger collection of 100 dishes from Frogmore. My correspondent does not object to nurserymen showing as many fruits in a dish as they like, but I think that if the awarding of medals is to be assumed to carry with them any competitive aspect—and there is undoubtedly some such aspect about them when several collections of these fruits are staged—that nurserymen may be restricted to twelve large fruits or eighteen small ones of each variety; and private growers to six large ones or nine small ones of each variety; and without doubt such restriction, whilst enabling the grower from a distance to keep his hampers of a moderate weight and dimension, would all the same cause the average samples to be of higher excellence. Of course, the matter is one for the Council to determine, and judging by what was observed at the last meeting, when every inch of table space was crowded, such proposal merits attention even on the ground of economy in table space. *A. D.*

GALTONIA HYBRIDS.—I am interested to learn that like myself, Mr. W. E. Endicott, of Canton, Mass., has raised a hybrid between *G. candicans* and *G. princeps*, and in reply to his inquiry whether my hybrid was in flower before the parents, I beg to say that it opened later than *G. princeps*, but earlier than *G. candicans*. There is the difference of about a fortnight in the flowering of the two species here, but the one lasts until the other is well in bloom. Mr. Endicott, in referring to Kew, makes a mistake for Cambridge. *R. Irwin Lynch, Cambridge.*

LIQUID AIR AS A REFRIGERATOR.—This method of preserving fruit, &c., would appear to be making way in California—in those parts especially where sub-tropical fruits are in the ascendant. Thus we learn that Mr. Bobrick, of Los Angeles, has visited Professor Tripler's laboratory in New York city, and says that after some twenty-five day's study thereof, he has come to the conclusion that liquid air will replace ice just as gas and electricity have replaced the old oil lamp—it is only a question of time. Oranges were placed in liquid air and frozen solid, then pulverised like a piece of marble. After thawing somewhat, the juice was extracted by squeezing, then concentrated by cold produced by liquid air in the following manner:—First, Mr. Tripler froze the water contained in the juice, and removed it as ice. Certain acids contained in the juice froze at a lower temperature, and these also were removed in the form of ice. Subsequently the purer juice itself froze at a still lower temperature, leaving an acid which required a much lower temperature for freezing. The acid was poured off, and the frozen syrup, absolutely pure, in a concentrated state, was used for making ice-creams, &c. No statistics connected with first-cost have come to hand. *E. Cottam, 86, Cowcross Street, E.C.*

HYBRIDS AND THEIR RAISERS.

AMONG the many distinguished hybridisers whose portraits we have given in the present volume, there are few better entitled to a place than M. Eugène Beekman. This gentleman has had charge of the hybridising department of M. Linden's establishment, now called "L'Horticulture Coloniale," at Brussels, for the last twenty years. During that time he has carried out all the important work connected with that subject; and many more promising hybrids raised by him are yet to come.

Of plants of Mr. Beekman's raising, mention may be made of *Cypripedium* × *Beekmanii*, figured in *Lindenia*, xiii. p. 51, said to be raised from *C. bellatulum* × *C. Boxalli superbum*, which obtained great admiration, and led to some discussion as to the parentage; but in any case it is one of the finest of the hybrid *Cypripediums*; *C.* × *Wineqzianum* (*Harrisianum* × *Haynaldianum*), also a fine variety; *C.* × *Wiertzianum* (*Lawrenceanum* × *Rothschildianum*), very fine, figured in *Lindenia*, xiv. p. 43.

These are, we think, among the best, but there were several other meritorious crosses, most of which are known to visitors to the meetings of the Royal Horticultural Society, who have seen them when shown there, including the singular bigeneric hybrid *Zygobatemannia* × *Mastersii* and *Batemannia* Colleyi × *Zygopetalum crinitum* (see *Lindenia*, xiv. p. 69).

CHRYSANTHEMUM NOTES.

NONIN'S CHRYSANTHEMUMS.—It is only during the past two or three years that this French grower's name has become familiar to English cultivators. During the present season several of his novelties have been met with, the most promising being *M. Raymond Desforest*, a large, solid, compact, incurving flower, with grooved florets, colour reddish velvety-crimson, with deep golden-yellow reverse; *Madame F. Daupais*, pure white Japanese, incurved, with broad grooved florets; *M. Gatellier*, dull terra-cotta, golden straw reverse; *Corcoran*, very deep in build, a Japanese incurved with grooved, pointed florets, colour pale blush-pink, shaded deeper, something in the style of *Lady Isabel*; *Jules Bernard*, very large Japanese, velvety, deep rosy-amaranth, reverse silvery-pink.

MORE AUSTRALIAN CHRYSANTHEMUMS.

The French seedling raisers have had many competitors in their day, but none seem to be more formidable than our cousins in the Australian Colonies. To-day I have just seen a new batch of Colonial novelties, many of which are from a firm of growers in Melbourne. Of these, *Sydney Brunning*, a large Japanese, with long, broad florets, slightly incurving in the centre, colour deep reddish terra-cotta, with bright golden reverse, is a striking flower. Then *Marjory*, a pretty bright rosy-pink flower, with narrow florets, comes next. *Sir H. H. Kitchener* has flat, medium-sized florets, is a bright reddish-crimson, with a golden reverse. *Hector Brunning* is a Japanese, colour dark, deep, velvety crimson, with a metallic reflection; reverse golden. *Mrs. Frank Gray Smith* is a large, globular flower, with narrow grooved florets, close and compact—deep golden yellow, shaded crimson. *Admiral White*, something like *Old Avalanche*, is another. *C. H. P.*

WOODHATCH LODGE, REIGATE.

The continued interest in the cultivation of the Chrysanthemum, exhibited by such amateurs as *Mr. T. B. Haywood*, of Woodhatch Lodge, is an indication that the popularity of the plant is not decreasing.

The Woodhatch Lodge collection is always one of much interest, and exhibits the same high class cultivation, as do other plants in this well-managed garden. The number cultivated each season varies little, but the collection from year to year differs more or less, according to the number of varieties added or discarded.

The flowers will be just at their best when this note is in the hands of our readers.

Of the new white ones, that of *Annie Prevost* is very promising. It is a Japanese incurved, pure white, except a slight lemon tinge in the centre, and reminds us of the build of *Western King*.

But there are older and excellent white Japanese, more or less pure in colour, in *Madame Philippe Rivoire*, which makes a very deep and fine exhibition flower; *T. B. Haywood*, rather too early as a rule, for the November shows; *Mrs. H. Weeks*, remarkable for its broad florets and bold build; *Mrs. J. Lewis*, *Madame Gustave Henry*, *Mutual Friend*, *Pride of Exmouth*, *Souvenir de Petite Amie*, *Madame Carnot*, *Mlle. Thérèse Rey*, *Madame Louis Rémy*, &c. Against such varieties as these and others equally good, now white ones must be exceedingly good to find a place. There is another new one, however, that promises to become valuable: its name is *Nellie Pocket*, an Australian seedling. It grows barely 5 feet high, has a grand habit, and is a first-class Japanese incurved.

Of the yellow Japanese, the richest coloured of all, and possibly the largest, is the new one of *Mr. Jones*, *R. Hooper Pearson* (see *Gard. Chron.*, Nov. 19, 1898; fig. 108, p. 369). *Mr. C. J. Salter*, who so skilfully cultivates *Mr. Haywood's* plants, has several exceptionally good blooms of this glowing variety, and he describes it as a capital "doer." Another new yellow variety, but widely distinct from that just mentioned, is *Le Grand Dragon* (*Calvat*). Its colour is more orange-yellow, and

when well shown, the florets are more or less lined with red; it produces an immense flower, and is of good habit. Some fine flowers of *Phœbus* and *Edith Tabor* were nearly developed at the date of our inspection, and of *Oceana* and others. When speaking of yellow varieties, mention may be made of *Lord Ludlow*, a variety shown last season by *Mr. Wells*. It is a very deep flower of a soft, yet rich shade of yellow, and the florets should be margined with red; the tips of the petals are spoon-shaped, and the build of the flower generally is most attractive. Cream-coloured flowers were represented by fast-developing blooms of *Mrs. Mease*, the sport from *Madame Carnot*. Of pink Japanese incurveds, *Mrs. S. C. Probin* and *N. C. S. Jubilee* were both good, but the latter, from our point of view, is the more refined flower.

Madame Boudoin (*Calvat*), white Japanese, marked rosy-purple; *General Paquie*, a smooth-petalled, very distinct coppery-red coloured flower; *Beauté Grenoblois*, white, shaded violet; *Mrs. White Popham*, and *Mrs. Barka*, are novelties that are doing well. Of better-known sorts, *Australie*, *Charles Davis*, *Chenon de Leché*, were especially good. High coloured varieties included *W. Seward*, *Werther*, *Ed. Molyneux*, and the novelty *H. J. Jones*, which at present we have not seen so fine as when shown by *Mr. Weeks* at the Aquarium late last season. There is an exceptionally bright crimson seedling (Australian) in *Mr. Salter's* collection. The tips of the florets are incurved, and have a buff reverse, and should our opinion of it be correct, its value will be great.

The truly incurved varieties, and the *Anemones*, though later than the Japanese, were developing satisfactorily, and *Mr. Haywood* had a very fine display to exhibit to his friends who were invited to Woodhatch on Thursday last.

The Orchids and other choice plants are looking very well; and it is a pity that the fog a fortnight ago should have injured the splendid show of zonal *Pelargoniums* in pots, which, but for this, would have been exceptionally fine. In the vinery were hanging splendid bunches of *Black Alicante Grapes*, and the well-stocked fruit-room indicates that the Apple crop this season at Woodhatch has been a capital one.

C. ETOILE DE FEU.

Those who want a very bright, good decorative Chrysanthemum for supplying blooms for cutting, or to be used as decorative plants in a group, will do well to procure *Etoile de Feu*, a continental variety we saw recently in *Messrs. Wells' nursery* at Earlswood, Surrey. From terminal buds the flowers are bright red, exactly the colour to produce effect when interspersed with white and yellow varieties. They are quite large enough on the terminal bud, but if the crown bud be selected, the effect of the flower is spoiled, as half the florets are likely to be gold-coloured. In the best coloured terminal flowers, the gold colour also shows itself a little upon the reverse of the rolled florets in the centre. The habit of the plant is good.

MRS. WHITE POPHAM.

This new, large Japanese incurved is proving quite equal to the promise it gave last season, and some extraordinary blooms may be anticipated at the large shows to be held on Tuesday next.

HOME-RAISED CHRYSANTHEMUMS.

are coming greatly to the front. If present appearances are maintained, in a season or two many of the best novelties will be varieties raised in England from English-grown seeds, or Australian introductions.

LONDON COLLECTIONS AND THE RECENT FOG.

With a view to seeing how far the fog of the third week in October had injured Chrysanthemums in the river district of London, we visited the collection at *Dover House Gardens, Rochampton*, the property of *Mr. Pierpont Morgan*. As was only to be expected, we had not far to seek for the fog's baneful influence. The best cultivated collection of Chrysanthemums *Mr. McLeod* has had, has been

in a measure crippled. A week's fog that hardly lifted during that period, at a time when the fast-opening florets need every bit of sunlight possible to develop good colour, was sure to inflict a check upon them, and this, despite every effort of the cultivator. But it is interesting to find that whilst certain varieties were greatly injured, others were much less so. The flowers of the Australian *John Pockett*, were spoiled, and the florets withered as by a flame. Even as far removed from London as is *Swanley*, the same variety was cut down after the fog as useless for the season. The effect upon many other varieties has been much less direct, being that of a general check to the plants, causing the florets to open less kindly, and many of them to "damp."

But *Mr. McLeod's* collection is a very fine one, and the plants have a healthy appearance and carry an abundance of fine foliage. The large flowered varieties are grouped in a vinery and Peach-house, and, though the plants are not by any means excessively tall, the trellis-path has been raised, so that now the flowers can be inspected with easy convenience. The back wall is covered with *Myrsiphyllum asparagoides*, and the effect is pretty. A few days ago the bush-grown plants were still out of doors, and in several of the other houses were additional large-flowered varieties developing bloom.

In the two show-houses the following varieties were represented by fine exhibition blooms—*N.C.S. Jubilee* and *Mrs. S. C. Probyn*, very similar Japanese incurveds, the former the prettier; *M. Chenon de Leché*, *Madame Rosette*, reddish-purple, Japanese, the florets spoon-shaped at tip; *Edith Tabor*, much damaged by fog, but is usually very good in this collection; *Pride of Maidenhead*, a fine white Japanese, with long drooping florets; *Madame Philippe Rivoire*, a white Japanese, very deep flower, and especially well grown; *Dorothy Seward*, a brown shade of red Japanese incurved, with buff reverse, a pretty variety, and possessing a good habit; *Australie*; *Lady Oporto Tait*, a deep yellow Japanese, with very wide florets, a variety distributed by *Messrs. Cannell & Sons*; *Le Grand Dragon*, with four large well-developed blooms of this fine novelty upon one plant; *Madame M. Ricord*, deep, solid blooms of a beautiful shade of pink; *Lord Brooke*, uncommonly good; *Sunflower*, in typical character, and rich golden-yellow; *Vivian Morel* and its sports, *Mutual Friend*, *Madame S. Bruant*, *Mrs. H. Weeks*, *G. C. Schwabe*, and many others. The incurveds are a little later, but several varieties were building up very satisfactory.

THE CHELSEA COLLECTION.

None of the nurserymen have to grow their Chrysanthemums under less satisfactory conditions than do *Messrs. Jas. Veitch & Sons*, *Royal Exotic Nurseries*, *King's Road, Chelsea*. It is easy enough for them to raise good stock, and to cultivate first-class plants; but, when the month of October has run its course, the subsequent weather that past experience has taught us to expect in this locality is the very worst possible for the flowers. Even October itself is not always a "good" month in the heart of London, and this year the third week was remarkable for heavy fogs.

In spite of all this, however, *Messrs. Veitch* do contrive to obtain a nice show of bloom, and that for the present season is just looking its best. Its purpose is to serve as an index of the very best varieties up to date, whether old or new, and therefore it is very representative. Representative, that is to say, of all sections of the Japanese varieties, for incurved, pompons, anemones, and single-flowered varieties, are not cultivated for the production of large blooms, though stock is kept of all. Speaking broadly, the Chrysanthemum is an excellent "town" plant; that its blooms will not sustain without injury a London November fog is no proof that it is not so.

But there are certain varieties that are much more likely to succeed under these unsuitable con-

ditions than others, and the following varieties, we judged from the collection now on view, to be among the best. Our conclusions are borne out by Mr. Weeks, who has had charge of the collection for some years:—Mrs. C. Blick, Nellie Pockett, Mrs. Weeks, Mrs. J. Lewis, Lady Byron, Chatsworth, all white, or nearly white, Japanese varieties; Louise, M. Chenon de Leché, Mr. T. Carrington, Mrs. Falconer Jameson, Souvenir de Petite Amie, and N.C.S. Jubilee. The black list includes Thomas Wilkins, Joseph Chamberlain, Madame Carnot, and all its sports (it being impossible to preserve the foliage upon these), Col. W. B. Smith, which generally "damps," and John Pockett. These, and especially the last-named variety, seldom succeed even moderately in similar districts to Chelsea. Some of the newest varieties have done very well here this season, and will possibly do so in succeeding ones. These include Annie Prevost, a fine white Japanese; Mrs. Barkley, a pink Japanese, raised by Mr. Weeks, of Thrumpton Hall Gardens, R. Hooper Pearson, Rayonnante, a very distinct variety, with fluted, ray-like florets of pale mauve colour; Reginald Godfrey, a flat-petalled red Japanese, with orange reverse; Emily Towers (white), a dwarf and good-habited plant; Hon. W. F. D. Smith, a variety sent out last season by Mr. Wells, a red flower with buff reverse. The first florets appear fluted, but later ones are flat; Hugh Crawford, a sterling Japanese, distributed by Mr. Jones two seasons since; &c. A promising new incurved variety is Major Mathew, bright rosy-purple in colour. The new green-coloured Japanese, Madame Edmond Rogers, had two blooms of considerable size.

Another house contained a fine lot of bush-plants, exactly the kind of specimens for the furnishing of dwelling-rooms, &c. The old reflexed variety, Emperor of China, figured well amongst these, and is suitable for the purpose, and for cultivation in the out-door border.

EXHIBITIONS NEXT WEEK.

In our list of appointments on p. 344 there are particulars of upwards of forty Chrysanthemum shows to be held next week, and this does not include a large number of minor shows in various parts of the country. Tuesday next will be especially busy, for, as last year, the Royal Horticultural Society's Committees will meet upon that day; the National Chrysanthemum Society's Exhibition will be opened at the Royal Aquarium, and there will be large shows at Birmingham, Plymouth, and other places.

LAW NOTES.

STOLEN CONTRIBUTORS' BOX.

THE man who stole the Gardeners' Orphan Fund Box at Tweed Vineyard, Clovenfords, N.B., has been caught. He pleaded guilty at the Selkirk Sheriff's Court, and was awarded due punishment. It is some satisfaction to Messrs. Thompson that some of the stolen money has been recovered.

ACTION AGAINST A MARKET GARDENER.

AT Brentford County Court on Tuesday, Oct. 31, before His Honour Judge Bagshawe, Q.C., and a jury, Wm. Waller, of Frogmore, Wandsworth, sued John Smith, of Grove Park Gardens, Chiswick, market gardener, and Robert Beach, his foreman, for £50 damages for false imprisonment.

Mr. Percival Smith was for the plaintiff, and Mr. W. A. Bird for the defendant.

Plaintiff was a crane-driver engaged in the operation of filling up some marshland on the banks of the Thames, to which defendant's garden adjoined. On July 12, he took a pail and went along the marshland to pick the Mushrooms which grew wild there, and Beach, who had been on the watch, jumped out on him and charged him with stealing Mr. Smith's Mushrooms. He dropped his pail and ran, and Beach, by means of a whistle, called P.C. Owen across the river from Barnes. When the

constable saw the dropped pail was on the marshland, and was told the plaintiff dropped it directly he was caught, he refused to take the charge; but eventually Beach got another policeman to take plaintiff to the Chiswick Station, and thence to the police court. The charge was dismissed, but plaintiff was put to £7 expenses, he lost time, and suffered indignity.

The defence was that the defendant Beach had reasonable and probable grounds for arresting the plaintiff. He saw plaintiff come into Mr. Smith's garden with the pail and pick the Mushrooms, and then called to him. Plaintiff ran off, and dropped the pail when he got near his crane, and the reason P.C. Owen would not arrest him was that it might endanger life if the crane-driver was away from his engine.

A mass of evidence was taken on both sides. His Honour left it to the jury to decide the questions of fact whether plaintiff was in defendant's garden picking his Mushrooms, whether Beach had reasonable ground of suspicion, and the amount of damages. The jury found for the defendants on these issues, and judgment was given for them with costs.

Obituary.

RICHARD MOORE.—We regret to have to announce the death of Mr. Richard Moore, Western Sub-divisional Magistrate of Rangoon, late Officiating Assistant Superintendent S. Shan States, which took place on August 18 last, at the age of thirty-nine years. The *Rangoon Gazette*, September 4, says: "It is presumed that the Red Sea passage proved too much for him. He had been in bad health for months past—suffering from attacks of malaria, and went home (to England) in May on a three months' leave. Mr. Moore came out from home about eighteen years ago as teacher in the Rangoon College High School. There he remained for some years under the late Mr. Gilbert and in 1888 was appointed to the Subordinate Commission. Much of his service was in the Shan States. Four years ago he came to Rangoon as Magistrate of the Western Sub-division. Mr. Moore had made a special study of Orchids, and knew the Orchids of Burma probably as well as any man."

Later intelligence gives the information that Mr. Moore was ill from fever when he left England. This was intensified by a chill caught by sleeping on deck in the Red Sea, and heart trouble caused further complications.

To most Orchid growers Mr. Moore is known for his discovery of the *Cypripedium Charlesworthii* and its albino; also *Cypripedium bellatulum album*, *Vanda* × *Moorei*, and the introduction of fine types of many of the showy Burmese Orchids, which he sent to his brother, Mr. J. W. Moore, of Rawdea, near Leeds.

GEORGES WAROCQUÉ.—The issue of *La Semaine Horticole* of October 28 announces the death of M. Georges Warocqué, which took place at Pekin, China, where he was journeying, and at the time when he was about to return home. M. Georges Warocqué was well known throughout Europe for the active part which he took in horticultural matters, and the cultivation of plants, more especially of Aroids and Orchids, of which he had one of the most extensive collections in Belgium, and which supplied the grand group which he staged in opposition to M. Jules Hye Leysen at the Ghent Quinquennial Show, April, 1893.

His gardens at the Château de Mariemont, near Charleroi, were described in the *Gardeners' Chronicle*, November 29, 1890, p. 631.

The death of M. JOSEPH MAWET, a member of the firm of Mawet & Postula, of Liège, is announced.

The death of M. ED. DE LANGHE, of Ghent, is also recorded.

SOCIETIES.

WILD FLOWERS IN THE GARDEN.

THE subject which I am allowed to introduce to-night was suggested by an incident which occurred last summer. A foreign visitor to my nurseries in the leafy and floriferous month of June remarked frequently, when specially beautiful objects were brought to his notice, "Yes, pretty; but weeds, mere weeds."

Well, "weed" is, after all, but another name for a plant which is out of place in garden and farm crops, however beautiful it may appear in its own element; and it then struck the floricultural part of my conscience that we as gardeners had neglected many beautiful British subjects in our eagerness for exotics for enriching our gardens, which "foreigners" were, of course, weeds in their native lands. Then a vision of many lovely combinations in Dame Nature's landscape gardening rose before me; for instance, next to my farm is a Chestnut wood, on sandy soil, where the background was the tender young foliage of the Spanish Chestnut, while the foreground was a mass of the wild Hyacinth—the Bluebell of one's childhood—which for some three weeks kept up its lovely and enchanting display, and as it faded a graceful crop of *Campion* (*Lychnis diurna*) succeeded it, and formed an equally charming effect. In another case, for some half mile ahead, while travelling in Wilts, I saw a mass of rosy-purple peeping out between the dark green foliage and nut-brown boles of a Scotch Fir grove. Here, to my surprise, the ground was covered with *Epilobium angustifolium*, and my driver said it was thus glorified every season. These are but two examples of many hundreds, as before a body of horticultural experts I need hardly mention the Buttercup fields, and the Primrose and Anemone woods.

I shall rather call to mind some wild British plants that seem to me deserving of garden culture, if not in the herbaceous border, yet as masses in the wild garden and woodland walks, where often masses of introduced exotics seem to mock the natural sylvan beauty. It has been noticed that masses of the same colour frequently follow each other, yellow being the prevailing late spring colour, while blue is the first in the series, and yellow returns again in autumn. One reason for the neglect of wild flowers is doubtless the difficulty of collecting the plants at the right season for transplanting, when many are lost among the surrounding herbage and grasses; but probably the best method would be to collect their seeds and sow them in nursery beds for transplanting afterwards. One knows from experience that very few plants collected on holidays ever come to perfection.

It may be as well to start with spring flowers, among which the blue Hyacinth before-named holds a conspicuous place and may well be massed in the front portions of shrubberies, or underneath deciduous shrubs, as they will there be at home, and will not in any way interfere with garden-flowers. The Primrose can be naturalised in any moist position, and should not be shocked by contact with the coloured garden kinds, as its simplicity and its modest beauty need only its own foliage as a relief. We must not omit Violets and the later Dog Violets; while the Germander Speedwell (the Cat's eye of the children) is a weed with striking blue flowers, and patches on the rockery will not be out of place. The yellow Nettle (*Lamium galeobdolon*) is one of our first spring flowers. I have noted in a park entrance large masses of the Bugle (*Ajuga*) produce a pleasing effect, and I have noted a white form, and one of a pinkish shade.

While on the subject of woodland drives and grassy-edged roads leading to mansions, I may mention that much of the beauty of the natural flora is destroyed by too close mowing, and would suggest that a 12-foot bordering is enough to be mown; and beyond that, if cut over or cleared once a year, the natural flowers would flourish in the grass, and lead a charm to the scenery, and in a small way reproduce an alpine meadow. Here Cowslips, Cuckoo-flowers (*Cardamine*), the Centaury, Bugle, and Primella, with the Primrose and yellow Toad flax, are seen to advantage with patches of wild Heather and Foxgloves.

In summer the wild Orchises give us both striking flowers and interesting species for massing in special positions. *O. mascula* and its numerous varieties are good, and I have seen *O. maculata* in Scotland called *O. magnifica*, which was specially grand. The Butterfly Orchis (*Habenaria*), with its elegant spikes of pale scented primrose flowers, delights in a shady nook. The Twayblade, the Man Orchis, and the less common *O. fusca*, *O. pyramidalis*; while *Ophrys apifera*, *O. muscifera*, and *O. latifolia* are worth close inspection, and for shady places the *Epipactis* are well worth prepared stations in the garden, affording them leaf-soil, chalk, or sandy loam as required. *Trollius europæus* is already an established garden favourite, while the Foxglove (*Digitalis*) is one of our grandest natives, and can be easily propagated by seed, and forms glorious masses for backgrounds. The Mulleins are worthy of culture, with their flannel-like foliage, and long conspicuous flowering spikes of yellow blooms. The Teazle is a bold subject for a bed, and is not only pretty in flower, but fine subjects for winter decoration are provided by its honeycomb-like head of seed-vessels. What shall I say for the Corn Poppy, with its glorious scarlet flowers all too evanescent? We must always have a tender remembrance of this as the parent of our super-elegant Shirley Poppies. In the west the

yellow Welsh Poppy is frequent near streams; and there is nothing in rich blue flowers that can approach the Viper's Bugles—seen in masses on sand and shingle near the sea it is superb, and deserves a prepared spot in the garden, where its gorgeous racemes can be thoroughly enjoyed. For a border plant *Geranium pratense*, with its lavender flowers, is well known. The various Hawkweeds—mouse and cat's ears—are pretty yellow and primrose flowers. The Wild Palm is a fine subject for banks, and runs into many varieties. For positions under trees the Periwinkles, major and minor, are suitable, and look well all the year round; while *Melanopyrum sylvaticum*, the Wood Cow-Wheat, is fine in masses. In North Wales there seems to be a larger variety than is found in Kentish woods. The Woodruffe also makes a pretty carpet plant, and in early spring the yellow Celandine is very bright.

Among the Thistles are many worth a position in gardens, some for foliage, as the Carline Thistle, others for noble growth, and others for flower. All can be readily raised from seed, and if care is taken to remove the flower-heads before they become downy they will not become a nuisance. There is also the Musk and Plume Thistle. Columbines are not infrequent on our chalk hills, and are attributed to the Romans, who esteemed the plant because the upturned flower resembled eagles nestling. Among maritime plants the Sea Holly and the horned Poppy take readily to gardens, and are distinct both in foliage and flower; while *Mathiola incana* is a lovely subject, with its lavender-pink flowers. The Thrift is well known as a neat border edging, and the white Popweed, *Silene inflata*, is useful. For hanging vases, the small Bindweed, and the Creeping Jenny or Moneywort are worth attention. Among the low-growing gems of our flora, the yellow Cistus holds a first place for arid soils and rockery, and the various coloured forms of the Milkwort claim our attention. *Hypericum humifusum* is also a small pretty subject. The Eyebright (*Emphrasia*) is interesting, and the pink Celandine (*Eythrea*) always strikes me as a good garden flower. The Sea Campion just named, with its white flowers, is not averse to rock-garden culture.

For sandy soil the Rest Harrow, with its rosy flowers, is worth culture, under which it assumes a bush form. The yellow Anthyllis and its relatives, the Hippocrepis, with *Lotus corniculatus* (Bird's-foot Trefoil), and *Tormentilla*, are admirable creeping plants for chalky soils. Saxifrage granularis is one of our best subjects for dry, sandy banks. *Chlora perfoliata* (yellow) is a gem on the chalk in August. The Chicory is a grand blue flower, and will succeed in any dry soil. *Campanula glomerata* is not uncommon on downs; while for old walls the common Celandine is a good subject, its apple-green foliage being light and elegant. The Harebell is always a welcome flower, and the Ivy-leaved Lettuce (*Lactuca*), with the yellow Wallflower, and some of the Stonecrops and native Sedums, all make an old wall interesting. Nor must we forget the red Valerian, which is quite at home where nothing else can grow; also the Cornish Moneywort. The wild Roses, either the Sweet Briar of our hills, or the small bushes of single Burnet Rose (*R. spinosissima*), which are common on all our chalk hills, are well worth culture; and few subjects in our wild garden are more esteemed than our Dog Rose, elegant in its simple flowers, and striking when its haws become ripe. For a climber, few subjects equal the Woodbine or wild Clematis (*C. vitalba*), and those who have seen the way it grows at Belvoir Castle grounds over the gardener's house and surroundings can never forget the pleasing effect produced; it is at all times beautiful in leafage and flower, and especially when set with its silvery-grey masses of feathery seed-vessels in autumn. The Honey-suckle, Bryony, and the climbing Vetch are all good trailers while the white *Convolvulus* (Moonflower) is a fine subject, running over shrubs and low trees.

It is, however, I fancy, when we come to our natural aquatic and riparian plants that we find especially striking subjects suitable for embellishing our streams and pond margins and the damp spots in our gardens. The glorious Loosestrife (*Lythrum*), the pink *Epilobium hirsutum*, with its pretty but evanescent cup-shaped flowers; the long spikes of *Lysimachia vulgaris* (Moneywort), the Tansey, with its handsome foliage and golden umbels of flowers; our Water Forget-me-not (*Myosotis palustris*), with its amethystine umbels, are all universal favourites. There are also the Yellow Flag (*Iris*), Water Plantain, Figwort, the flowering Rush (*Butomus*), with its head of rosy-purple flowers; the Bog Bean, the elegant Arrow-head, and the glorious Beel Mace or Bulrushes. The white and yellow Water Lilies, the Water Hyacinth (*Hottonia*), with its soft bluish spikes resembling some choice Orchid, are worth care to establish. The white Water Ranunculus is a striking floating plant. The tall masses of the Meadow Sweet (our native *Spiraea*), the King Cup (*Caltha*), with its golden masses of intense yellow flowers set on showy green heart-shaped leaves, are all beautiful for water gardens. All these water-loving subjects respond to careful treatment, and many of them are freely used—but why not more?

In autumn, *Hypericum perforatum*, with its foliage and golden flowers, is one of our best plants; and in sandy wastes the Ragwort is quite a feature, equal to many cultivated plants of its colour. The tall *Campanula Trachelium* is handsome, and the rosy-bloomed Soapwort (*Saponaria officinalis*) is a grand subject for masses, and flowers over a long period. The Mallows are also striking, and the tree form does well near the sea; while the Musk Mallow makes a grand show, and the commoner striped *M. sylvestris* is not to be despised. The Marsh Mallow is also suited for the bog garden. *Achillea millefolium* (Milfoil), as a red garden plant is well known, and the wild forms range from white through bluish to rose colour. The Scabiousa tribe are very good border plants, and affect our chalk-hills in the species *S. arvensis* and *S. columbaria*; the Devilsbit Scabious (*S. succisa*) is a feature with its tall stems and blue flowers. The Harebells continue to flower until

October. *Spiraea filipendula* is often found on upland pastures. The blue Cornflower (*Centaurea cyanus*) is in flower all the summer and autumn; and the yellow Corn Marigold is a showy flower. *Conyza squamosa* (Shepherd's Spikenard) is very striking on chalk or clay pastures, and rises some 3 feet, covered with pretty yellow starry flowers. All these come to us annually, and we welcome them as old friends. May we not hope to see them tended and cared for in our flower-gardens, where they will respond readily to loving care and attention?—Lecture delivered by Mr. George Bunyard, F.M.H., at a recent meeting of the Horticultural Club.

DEVON AND EXETER GARDENERS' ASSOCIATION.

DRESSING CHRYSANTHEMUM-BLOOMS.

OCTOBER 25.—A large attendance assembled at the Guildhall, Exeter, on the above date, to witness a demonstration on dressing Chrysanthemum-blooms for exhibition. The manipulator, Mr. GEO. STYLES, gr. at The Grove, Teignmouth, is a well-known exhibitor at West of England exhibitions, and during the time he has been competing—about ten years—has been the winner of numerous leading prizes. He had before him about twenty blooms, all of them more or less defective. He passed round to the audience a few of the roughest of them, and then explained wherein they were defective from an exhibition point of view. After that he "dressed" the blooms at the table, in order to show the audience how it was done, and when a show-board had been finished, filled with the blooms, it was passed round to show the improvement effected. The meeting was strictly confined to the members of the Association, and, as an object-lesson, was quite a success. Councillor Ham, an honorary member and well-known amateur, presided, and introduced a profitable discussion. A hearty vote of thanks was passed to Mr. Styles for his demonstration and instruction.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

OCTOBER 26.—On the occasion of the meeting of the Committee, on Thursday, A. WARBURTON, Esq., Vine House, Haslingden (gr., Mr. T. Lofthouse), exhibited a distinct variety of *Odontoglossum crispum*, called "Sir Redvers Buller," to which the Committee awarded a First-class Certificate. In form the flower is of middle size, and of the round type; it is peculiar in its markings, being evenly spotted with bright crimson all over the petals. The same exhibitor sent *Cypripedium* × *Milo*, a hybrid remarkable for the richness of the colouring of the dorsal sepal (First-class Certificate).

T. STATTER, Esq., Stand Hall, Whitefield (gr., Mr. R. Johnson), showed a plant of *Cattleya* × *Wendlandiana*, *C. gigas* × *C. Bowringiana*, a not very remarkable hybrid, which shows the traces of its parentage very plainly.

J. LEEMANN, Esq., West Bank House, Heaton Mersey (gr., Mr. Edge), showed a fine group of plants, amongst which were many good hybrids, nice forms of *Cattleya labiata* autumnalis, *Odontoglossums*, *Cypripediums*, &c. *Lælio* × *Cattleya* × *Ada* (*L. elegans* alba × *C. Luddemanniana*) was awarded a First-class Certificate. It is a pretty flower, in which the characteristics of *L. elegans*, one of the parents, predominates, and it is easy also to discover traces of *C. Luddemanniana* or *speciosissima*, the colour throughout being of a soft rosy tint, and with a pale citron tinge in the throat that enhances the beauty of the flower. Other good plants from this exhibitor were *L. C.* × *Nysa*, *Cattleya Martini* superba, *Cattleya Bowringiana* "Hardy's var.," and a fine plant of *Angreum articulatum*. The group was awarded a Silver Medal.

G. SHORLAND BALL, Esq., Ashlands, Wilmslow (gr., Mr. Gibbons), sent a good variety of *Cypripedium Charlesworthi* var. *rubescens*, and a choice cross in *Cypripedium* × *Actæus* (*C. insignis* Sanderae × *C. Lecanum* superbum). An Award of Merit was made to this cross. *C. × Milo* also came from this exhibitor, and, in common with Mr. Warburton, it was awarded a First-class Certificate. Mr. Ball also exhibited a grand form of *C. × Lathamianum* magnificum, in size and character superior to anything hitherto shown of this type. No award was given.

R. ASHWORTH, Esq., Newchurch gr., Mr. Pidsley, exhibited an *Odontoglossum crispum*, var. "Ashlandense," which received a First-class Certificate. The colours are bright, and the sepals stained right through by the colouring.

Mrs. BRUCE-BUAY, Bank House, Accrington (gr., Mr. Wilkinson), showed a wonderful plant in *Cattleya labiata*, var. *autumnalis*, var. *Peetersii* var. *marmorata*. It is distinct from the rare *C. L. Peetersiana*, and possesses better proportions, although the colouring is not so deep. The plant has a decided purplish tint in its foliage, which should be a good guide to purchasers of new importations of this plant. The plant was awarded a First-class Certificate.

W. THOMPSON, Esq., Walton Grange, Stone (gr., Mr. W. Stevens), staged a group of about one dozen *Odontoglossums*, among which was a plant of *O. crispum*, var. *Katie*, with about thirty-five flowers on a branched spike (Vote of Thanks).

MESSRS. JAS. VEITCH & SONS, London, staged a set of hybrids, principally *Lælio* × *Cattleyas*, and a plant of *L.-C. Wellsiana* (*C. Trianae* × *L. purpurata*) received an Award of Merit. *Lælio* × *Mrs. M. Gratrix* (*L. cinnabarina* × *L. Digbyana*) was perhaps the most interesting plant of the collection.

Hitherto hybrids of *Lælia* and *Cattleya*, in which *L. Digbyana* figured, have been welcomed; but this, the latest one observed, whilst showing an enlarged cinnabarina flower, has a lip that is scarcely of a proportionate size. Still, we may see some good forms of this cross which will be welcome Award of Merit). *Cattleya* × *Princess* (*C. Luddemanniana* × *C. Trianae*) received an Award of Merit. A Vote of Thanks was awarded for the group.

Mr. JOHN ROBSON, Altrincham, staged a large plant of *Epidendium vitellinum*. F. W.

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

THE fortnightly meeting was held in the club-room of the Old Abbey Restaurant, when Mr. C. B. STEVENS presided over a good attendance of members. The subject of the paper for the evening was "How to keep a greenhouse gay from Oct. 1 to March 31," by Mr. Blake, foreman, East Thorpe Gardens, Reading.

It was unanimously decided by the members that a Memorial should be established to the memory of the late Mr. James Martin, and that it should take the form of providing for a child, to be placed on the Gardeners' Orphan Fund, and to be known as the "James Martin Memorial Orphan." A Committee was formed to carry out the scheme.

During the evening Mr. William Baskett, for many years head gardener to the late Mr. W. I. Palmer, was made a life-member of the Association, this being the first occasion the life membership rule had been acted upon.

ROYAL HORTICULTURAL OF SOUTHAMPTON.

OCTOBER 31, AND NOVEMBER 1.—Brilliant weather favoured the opening of the Chrysanthemum show, which was held, as usual, in the Skating Rink, a building especially suitable for such a purpose. The entries were numerous throughout, and the classes for cut blooms were well filled. Admirable arrangements had been made by the courteous secretary, Mr. C. S. FRINGER, and exhibitors at the Southampton shows can have little to complain of in regard to the arrangements for their exhibits.

PLANTS.

For the best collection of Chrysanthemum plants grown in pots, occupying a space 10 feet by 6 feet, Mr. E. BROWN, jun., New Alma Road, Southampton, an amateur, was well to the front, with a splendidly-arranged group of plants, carrying blooms of high-class quality, and of fresh appearance. Especially noticeable were the varieties *Pride of Malford*, Mrs. Coombes, Mrs. White Popham, Lady Hanham, Mr. Weeks and Louise. Mr. HOSEY, gr. to J. C. E. d'ESTERRE, Esq., Elmfield, Southampton, 2nd.

The competition in the class for a central conservatory group having Chrysanthemums as a prominent feature, was good. Mr. E. WILLS, nurseryman, Shirley, was a good 1st. Mr. Peel, gr. to Miss Todd, Shirley, 2nd.

CUT BLOOMS.

Cut blooms were very numerous, and the general quality was good. In the class for twenty-four Japanese, in sixteen varieties, Mr. N. H. MOSE, Belmont Nursery, Sholing, led with splendid examples of *Edith Tabor* (2), *Mutual Friend* *Suzie*, *Phœbus* (2), *V. Morel* (2), *Australie*, *Madame Carnot* (2), *Chenon de Leche*, *Madame × Rey Jouvin*, *E. Molyneux* *N. C. S. Jubilee* (2), *Pres. Nonin* (2), *Duke of Wellington* (2), *Pride of Exmouth*, and *Lady Ridgway*. Mr. J. WASLEY, gr. to J. B. TAYLOR, Esq., Sheffield Manor, Basingstoke, was a close 2nd, showing in fine form *Chenon de Leche*, *Océana*, *R. Powell*, *Australie*, Mrs. White Popham, and *Lady Ridgway*. Mr. G. HALL, gr. to Lady ASHBURTON, Melchet Court, Romsey, 3rd.

For eighteen Japanese, distinct, Mr. MOSE again led, with finely-finished and well-coloured blooms of first-class varieties. Mr. WASLEY was 2nd; and Mr. J. ACATE, Havant, 3rd.

The entries in the classes for incurveds were less numerous than usual. For eighteen varieties, Mr. W. NEVILLE, gr. to F. W. FLIGHT, Esq., Cornstiles, Twyford, Winchester, was 1st with *Globe d'Or*, *C. H. Curtis*, *Jeanne d'Arc*, Mrs. J. MURRAY, and *Perle Dauphonoise* as his best. Mr. J. ACATE, Havant, 2nd.

For twelve incurveds (distinct), Mr. N. H. MOSE led with fine blooms of Mrs. N. Molyneux, Prince Alfred, and Mrs. Coleman. Mr. G. NOBBS, gr. to Her Majesty THE QUEEN Osborne, 2nd; and Mr. J. ACATE, 3rd.

In the class for twelve Japanese (distinct), Mr. J. WASLEY, Mr. G. HALL, and Mr. G. NOBBS, were placed in the order named.

For six yellow Japanese blooms in two varieties, the competition was keen. Mr. J. KING, gr. to H. J. G. LLOYD, Esq., Itchel Manor, Crondall, was 1st with *Edith Tabor* and *Océana*. Mr. H. H. LEES, 54, Cedar Road, Southampton, was a very close 2nd with *Phœbus* and *Mons. Pankoucke*.

For six whites, Mr. L. DAWES, gr. to Mr. OGLIVIE, Rosecroft, Hambledon, was 1st, with Mrs. J. Lewis and *Mutual Friend*; and Mr. Goss, gr. to W. G. RAY, Esq., Marchwood, 2nd.

AMATEURS.

The section confined to gentlemen's gardeners and amateurs produced some good blooms. For eighteen blooms, Mr. A. J. MARSH, gr. to M. HOBSON, Esq., Kingsworthy, Winchester, was placed 1st with first-rate blooms of *Lady Hanham*

Phoebe, Chenon de Leché, Aust. Gold, and Mrs. Coombes; Mr. J. KINO, 2nd.

In the same section for twelve Japanese in eight varieties, Mr. E. BROWN led with well finished and highly coloured blooms.

In the class open to amateurs only, for twelve Japanese blooms, distinct, a silver cup was presented by Mr. E. BROWN, jun., and this trophy was secured by Mr. H. H. LEES, who showed excellent examples of Lady Hanham, Oceana, Phoebe, N. C. S. Jubilee, Mutual Friend, and Mrs. W. Mease; Mr. E. BROWN, was 2nd; and Mr. J. T. ROBE, Oak Road, Woolston, 3rd.

For six Japanese, distinct, Mr. LEES again led, and Mr. BROWN, was 2nd.

MISCELLANEOUS.

The miscellaneous classes, and those for fruits and vegetables, gave additional interest to the show, and some capital collections of vegetables were shown for the prizes offered by Messrs. Webb & Son, Stourbridge; and Messrs. Fidler & Son, Reading.

Mr. J. KEY ALLEN, F.R.H.S., exhibited a capital collection of culinary and dessert Apples, not for competition, which gained a well merited Certificate. *W. H. L.*

NATIONAL CHRYSANTHEMUM.

NOVEMBER 1.—A meeting of the Floral Committee of this Society was held at the Royal Aquarium, Westminster, on Wednesday last. There were not many exhibits, and the only award made was that of a First-class Certificate to the following variety:—

Chrysanthemum Lady Temple.—An Anemone-flowered variety, flower 5 inches across, pale red in colour, good cushion, in which the pale yellow reverse is evident. Shown by Mr. R. OWEN, Maidenhead.

Mr. OWEN also exhibited a large white Anemone-flowered variety, with pale lemon cushion. It is named Mrs. Chas. Trinder. Also two large-flowering Japanese varieties, one named George Stanton, and the other Lord Cromer.

Mr. H. WEEKS, Thrumpton Hall Gardens, Derby, exhibited a Japanese incurved, named Mrs. Bagnall Wild, almost identical colour of N. C. S. Jubilee.

A number of single-flowered varieties were shown by Mr. H. REDDIN, gr. to G. W. BIRN, Esq., Manor House, West Wickham, Kent.

Several other promising Japanese varieties were submitted to the Committee by different raisers.

BRIXTON AND STREATHAM HILL CHRYSANTHEMUM.

NOVEMBER 1, 2.—The fortieth annual exhibition of this Society was held in the Streatham Town Hall, which, although a capacious building, was not any too large for the occasion. The quality of the exhibits was good throughout. The exhibits of foliage plants, both large and small, add greatly to the general appearance of these autumn shows, and this Society sets an admirable example in this respect.

For a Group of *Chrysanthemums*, to occupy a space of 8 feet by 6 feet, plants not to be over 6 feet in height, and every bloom to stand clear, Mr. HOWE, gr. to Sir HENRY TATE, Bart., was an easy 1st with an extra-fine group, the tallest not exceeding the limit in height, whilst the front plants were no more than 1 foot, with foliage down to the pots. Almost every flower was fit for an exhibition-stand, whilst all the plants were grown in 6-inch pots, from spring-struck cuttings; the best were *Souvenir de petite Amie*, W. Shrimpton, *Gustave Henri*, Vivand Morel, and Chas. Davis, the new R. Hooper Pearson, deep yellow, being also specially fine; 2nd to Mr. MURSELL, gr. to Mrs. BURTON, whose group also contained some fine blooms, whilst others were not well developed.

Plants.—Pompons, four plants: 1st to Mr. GIDNER, gr. to Major SAUNDERS, with plants of medium size, and well flowered.

For Japanese varieties, Mr. WESTON was 1st with freely flowered examples. For six plants not trained, Mr. MURSELL stood 1st with capital decorative, well flowered examples.

CUT BLOOMS.

Mr. HOWE was 1st for twenty-four Japanese varieties, distinct, with solid blooms, very fresh and bright, the best being R. Hooper Pearson, extra fine; Madame Gustave Henri, Mrs. Mease, Mrs. Harman Payne, Modestum, Louise, Mrs. G. W. Palmer, Emily Silbury, and Lady Hanham; 2nd, Mr. MURSELL.

For twelve varieties of broad-petalled, incurved Japanese, Mr. MURSELL was a good 1st; the best being Lady Byron, Australia, Mrs. Weeks, and Duke of Wellington. 2nd, Mr. W. HOWE.

For twelve blooms of any Japanese, Mr. H. BANKS, gr. to J. C. COVELL, Esq., was 1st with fine fresh flowers.

With two vases, five blooms in each, with own foliage (a suggestive class), Mr. MURSELL, gr. to Mrs. BURTON, was easily 1st with one vase of whites, and another of yellows. The other competitors in this class mixed their flowers, the effect not being so good.

For twelve cut blooms, to be shown as grown, with stems not less than 15 inches in length, Mr. HOWE again stood 1st, the foliage adding greatly to the effect.

For six blooms, any white variety, Mr. MURSELL won rather easily from Mr. HOWE, both of whom staged Lady Byron, the premier lot being specially fine.

For six blooms, any variety except white, Mr. HURST was 1st with Australia, in very fine form.

INCURVED FLOWERS.

The exhibits in this section were very limited, no exhibitor competing in the larger class. Mr. HILL, gr. to G. W. RYDER, Esq., was 1st for twelve varieties, with moderate blooms of the standard varieties.

Mr. HOWE was 1st for six blooms any variety, with Chas. Curtis, very good flowers; and Mr. HILL 2nd with Baron Hirsch, very good examples.

OTHER CLASSES FOR CUT BLOOMS.

For six cut blooms of Japanese varieties, to be shown as grown in glasses or bottles, Mr. H. BANKS was a splendid 1st, with well-developed flowers.

Mr. BANKS also showed well in a class for twelve varieties Japanese (both of these classes being for single-handed gardeners).

Basket for Effect, with Ferns and Grasses, &c.—1st to Miss CROOK, Palace Road; this lady depended upon one variety only, W. Seward, with which the autumn-tinted foliage blended well.

A miscellaneous exhibit, not for competition, by Mrs. KNIGHT, florist, Streatham, calls for special comment, a basket of yellow *Chrysanthemums*, with sprays of *Quercus coccinea*, being very effective.

MISCELLANEOUS.

Orebirds are always shown well at this exhibition. On this occasion the best six came from Mr. RANSOM, gr. to J. T. GABRIEL, Esq., who had *Liparis longipes*, excellent. The best three were from Mr. Fulbrook, gr. to B. B. BAKER, Esq., who was also 1st for a single specimen with *Cattleya labiata*, with about twenty flowers. Palms and other foliage plants, Ferns, &c., helped to give a better effect. These were shown best by Mr. Chalk, gr. to A. NORMANOV, Esq.; and Mr. HILL (foliage plants); Mr. Wright, gr. to J. A. WILLARD, Esq.; and Mr. HILL (Ferns); and Mr. FULBROOK (Palms).

Fruit and vegetables were worthy of a country show, rather than one in a suburban locality. Grapes were shown best by Mr. MILSON and Mr. HOWE: Apples and Pears by Messrs. MORGAN, HOWE, and PEARCE.

Mr. W. RUFFELL, the energetic and practical Hon. Sec., is to be congratulated upon the results of his labours. It is not an easy matter, as many know, to keep a society fresh and vigorous after forty years' existence. *H.*

MARKETS.

COVENT GARDEN, NOVEMBER 2.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. *Ed.*]

POTATOES.

Hebrons, Puritans, Main Crop, Up-to-Date, &c., 60s. to 90s. John Bath, 32 & 34, Wellington Street.

REMARKS.—In our last report Schwetzer Plums should have read per basket, not barrel, the capacity of the basket is about two-thirds of a bushel; the fruit is in shape like the nussel. There is a limited supply of good home-grown Pears, of Calabasse, &c., but it is not regular. Brussels Sprouts and Cauliflowers or Broccoli are down in price, and the supply of vegetables, such as Sprouts and Cauliflowers is quite equal to the demand. Chestnuts and Walnuts of foreign growth in bags and sacks of various size are coming in large quantities.

SEEDS.

LONDON: November 1.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that there were but few buyers on to-day's market, with very little business passing. Meantime, Clover-seeds all round, although quiet just now in demand, keep steady in value. Some good samples are showing this week of new English Cow-grass. To-day's cablegram from Canada ask more money for Alsike. Italian Rye-grass, in spite of being less active, is firmly held. There has been a good trade going in new Königsberg Tares. The tendency of sowing Rape-seed is upwards; whilst Mustard-seed is strong. Bird-seeds move off slowly on former terms; but Blue Peas and Haricco Beans favour holders.

CORN.

AVERAGE PRICES OF British Corn (per imperial gr.), for the week ending October 28, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.	1899.	Difference.
	s. d.	s. d.	s. d.

Barley	28 8	27 4	- 1 8
Oats	16 8	16 3	- 0 5

(For remainder of Markets and Weather, see p. xii.)

GARDENING APPOINTMENTS.

Mr. GEORGE S. CAST, for more than two years Gardener to Mrs. TAYLOR, Asbdown, Apperley Bridge, as Head Gardener to EDWARD ACKROYD, Esq., at the same place.

Mr. WILLIAM F. PALMER, for a number of years General Foreman in the Gardens, Dalkeith Gardens, N.B., as Head Gardener to the Earl of WARWICK, Warwick Castle.

Mr. J. DAVIS, late ladsore Foreman at Dowsdale, Stoke-Bishop, as Gardener to H. THOMAS, Esq., Iva House, Redland.

Mr. H. MALE, late Out-of-door Foreman, Downside, Stoke-Bishop, as Gardener to T. DAVEY, Esq., Bannerleigh, Leigh Woods, Bristol.

Mr. W. BARKS, for the past four and a half years Foreman in the Gardens at Heckfield Place, Winchester, Hants, as Head Gardener to Sir THOMAS C. MEYRICK, Bart., C.B., Apley Castle, Wellington, Salop.

ASTER SEEDLING: J. G. Varieties have become so numerous that we cannot undertake to name them. Send them to some grower.

BOOKS: T. Lewis. *Manual of Coniferous Plants*, by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea; and the Conifer Conference Report, contained in the *Journal of the Royal Horticultural Society*, 117, Victoria Street, S.W.

CHRYSANTHEMUM-BUDS: Grower. There is no evidence of external injury, and the defects are due to the development of the plants having received a check from some cause. Exercise extreme care in the application of manures.

CORRECTION.—On p. 321, column 1, in our last issue, for Mrs. Wilson Noble, read Mrs. John Noble.

GLADIOLUS THE BRIDE: Pomona. These may be brought on, if in pots, in cold frames at first, and taken in the greenhouses afterwards. Gladiolus will not stand much heat in the winter, and it is better not to afford much. When required early, the corms should be planted as soon as they are obtainable, preferably in the open ground, afterwards covering them with ordinary garden-frames, successions being planted at intervals. Such frames may be lined with stable-dung if very early flowers are wanted. Those which you have in pots may now be brought on in the greenhouse, and when roots have formed in some quantity, the plants may be introduced to warmth of 55°, night maximum. This variety is a form of *G. Colvillei*, itself a cross of *G. gandavensis* and *G. tristis*.

HARDY ASTERS: H. B., Godstone. Your communication was acknowledged under initials "H. B." in our issue for October 14. See reply to J. G. this week.

LILY BULBS, CARROTS, ROOTS OF HARDY PRIMULAS, &c.: S. S., Giffaas. The items sent show that the soil abounds with numerous insects injurious to roots and bulbs, which might be extirpated or much reduced in numbers if radical measures were taken. There are *Julus* (false wireworms), the true wireworms, grubs of weevils of species, the second and the last-mentioned pests being the worst offenders; *Julus* merely feed on any kind of decaying vegetation. We would advise the removal of all the plants from the affected area, and then to dress the land heavily with unslaked lime or with gas-lime and salt, trenching it as deeply as it will bear, and let it lie fallow for half a year. Do not apply any manures, it being, as it seems to us, too much manured already; rather stir more unslaked lime into the surface-soil some time during the winter. If ducks, fowls, or gulls were put on the land and the surface stirred twice a month myriads of the insects would be devoured by them. The insects live mostly at or near the surface of the ground, and when the latter is trenched these go to the bottom of the trenches with the top shovellings and the first spit; still, very many do not, and these the liming will destroy, and the birds secure. For some years after replanting depend more on dressings of loam that has been in clean stacks for one or two years, than on farmyard or other animal manures.

LILY OF THE VALLEY: H. J. Ross, Florence. The corms are treated on what is known as the retarding method, i.e., whilst still dormant they

are placed in a cold store, such as is used to keep meat in a fresh state, and thus the growth of the plants is quite arrested. They are taken out in batches and forced into bloom at any time from June to the end of the year. It is not a new practice in England.

LOAM: C. W. H. We should certainly prefer the stiffer sort for making the Melon bed, for although retentive, it contains plenty of fibre, which, on decaying, would afford passage for the water applied which need not be much, and of nutrient likewise. The lighter sample would do admirably for Cucumber-growing.

MARKET GARDEN: Midland. Plant Larch, Austrian Pine, and pyramidal Poplar, and common or Portugal Laurel as an undergrowth. The Conifers may stand 6 feet, the Poplar 12 feet, and the shrubs 3 feet apart. They should go nearer the boundary line than 12 feet, if the house does not belong to you. *Richardias*, "Arum Lilies." These if well rested after making early growth, may, if pot plants, be started in warmth of 50° maximum at night, and 55° by day. No bottom heat is needed. Let the temperature be increased weekly by 1°. Remove to a cooler house when the spathe show. If you hurry them much they will be spoiled.

NAMES OF FRUITS: We are most desirous to oblige our correspondents as far as we can, but we must request that they will observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. They should be just approaching ripeness, and they should be properly numbered, and carefully packed. A leaf or shoot of each variety is helpful, and in the case of Plums, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. We do not undertake to send answers through the post, or to return fruits. Fruits and plants must not be sent in the same box. Delay in any case is unavoidable.—*Pomona*. Cornish Aromatic. — W. E. M. Pear, Swan's Egg.—R. E. C. 1, Horsham Russet; 2, Wheeler's Russet; 3, Knobbed Russet; 4, Hawthornden; 5, Greenup's Pippin; 6, Calville Rouge d'Hiver. — A. R. E. 1, White Doyenné; 2, Beurré Bosc; 3, Fondante de Nees; 4, Surpassé Virgouliou; 5 and 6, not in condition for determination, but they will be kept for future reference. — T. J. & Sons. Early Spice. — W. C. Your fruits were excellently packed and conveniently labelled, the best example of careful attention to this matter that has come under our notice; in fact, you have only overlooked one of the points in our instructions. As a guide to other correspondents your method is here described. A layer of fine wood-wool surrounded by tissue-paper was wrapped round each fruit, a label was tied by string to the stalk and brought outside the packing material on to top of the respective specimens. The fruits were packed firmly crown upwards in a single layer in a shallow box. The varieties were as follows:—1, Striped Reinette; 2, White Westling; 3, Bess Pool; 4, Scarlet Leadington; 5, Herefordshire Beefing; 6, Acklam's Russet.—S. B. 1, Louise Bonne of Jersey; 2, Comte de Lamy; 3, Paradise d'Automne; 4, Autumn Bergamot; 5, Golden Russet; the Apple is Lord Suffield.—C. P. 1, Caroline; 2, Winter Greening; 3, rotten, no characters distinguishable.—*Enigma*. You have missed the point of the remark. The statement was not questioned that both fruits came from the same tree, but that we should like to see leaves and wood of the branches which bore the respective fruits.—A. M. F. 1, Norfolk Beefing; 2, Hollow Core; 3, Golden Pippin; 4, Lord Suffield; 5, Calville's Malingre; 6, Scarlet Nonpareil.—E. D. M. 1, Summer Pearmain; 2, Belle Bonne; 3, Golden Noble; 4, Rymer.—M. A. G. 1, Nelson Codlin; 2, Lewis's Incomparable; 3, De Neige or La Fameuse; 4, Calville Blanche d'Hiver; 5, a pale coloured Tyler's Kernel; 6, Benwell Pearmain.—J. B. 1, Gansell's late Bergamotte; 2 and 3, decayed and unrecognisable.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—One who wants to know. 1, *Adiantum cuneatum* elegans; 2, *Pteris serrulata cristata*; 3, *P. argyræa*; 4, *P. cretica albolineata*; 5, *P. cretica variegata*; 6, *Crataegus pyracantha*. — J. Coupland. *Polyporus intybaceus*. — J. J. C. *Juglans nigra* (black Walnut). — H. Watson. *Taxodium distichum*. — Old Subscriber. *Aloe socotrana*. — H. C. *Sevenoaks*. *Epidendrum cochleatum*. — T. R. *Gomesa recurva*. — Young Gardener. Not *Ficus*, but 1, *Codiaeum elegantissimum*; 2, *Codiaeum longifolium*. Turfy loam

suits them best.—H. W. *Taxodium distichum*. — W. R. J. H. *Encephalartos horridus*, syn. *Zamia horrida*. — Enquirer. *Bupleurum fruticosum*, a shrubby Umbellifer.—*Scoticum*. 1, *Cineraria maritima*; 2, *Ruellia Portellæ*; 3, *Cotoneaster affinis*; 4, *Tsuga canadensis* (Hemlock); 5, *Cephalotaxus pedunculata*, fastigate variety; 6, A scale insect, which we will endeavour to name next week. Burn the plant.—A Farmer. A species of *Oxalis*, with a tuberous root like the *Oca*, once recommended for cultivation instead of the Potato.—J. A. 1, *Viburnum Opulus*; 2, *Cupressus Nootkatensis*; 3, *Juniperus Scholtii*; 4, *Potamogeton heterophyllus*; 5, *Alisma plantago*. — Edinburgh. *Cattleya Loddigesii* var. *Harisoniæ*.

NOTICE TO LEAVE EMPLOYMENT: J. L. The gardener being in law a domestic servant is entitled to and must give a month's notice. If he must quit forthwith, his employer must pay him a month's salary, and if he have a cottage and perquisites, the value of these for that period must be paid him. The gardener may, for misconduct, be discharged at a moment's notice.

ORCHARD-HOUSE FRUIT: J. Best. Question 1; the flowers set as well as out-of-doors, no better, and they are protected by the glass against injury by frost. During the flowering period, a large amount of ventilation must be afforded night and day, when there is no frost. 2; the trees carry heavy crops for their size—too many usually. 3; the flavour is better from outside trees, except in the case of some few varieties of late maturing Pears, Plums, and Peaches.

PARIS WHITE COS LETTUCES FORCED IN A HEATED GREENHOUSE: A. J. F. Doubtless the plants would grow satisfactorily, provided there be ventilation afforded in accordance with the state of the weather, that the house or at the least the border has plenty of sunshine, and the warmth at no period of the winter and early spring exceeds 55° at night and 65° to 70° by day.

STRAWBERRIES AND PEAS AT CHRISTMAS: Anxious One. If you have a stock of the new perpetual bearing Strawberry, St. Joseph and can get the blooms to set in November, you might have ripe fruits at the time named. Peas forced thus early are not productive by reason of the blooms not setting.

TREATMENT OF CARNATION BED INFESTED WITH EELWORMS: Carnation. Our advice to bake or scald the soil was intended for soil to be used in pots rather than that of a bed in the open air. It would be a rather big job to bake or apply scalding water in such quantity as would clear the soil of the eelworms. Quicklime dug in at the rate of $\frac{1}{2}$ peck per square yard, would do some amount of good, but it is not calculated to destroy the whole of them; nor have we any more faith in the use of gaslime, except after repeated applications. We should advise the planting of the Carnations in quite another part of the garden.

Continued Increase in the Circulation of the "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

TREBLED.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle

No. 672.—SATURDAY, NOV. 11, 1899.

RICHARD WESTON, Esq., AUTHOR.

AMONG the numerous books of the last century on husbandry and gardening, Richard Weston's *Tracts on Practical Agriculture and Gardening* (1769) takes a high position. This is only a part of the title, which is of the descriptive style common at that period. As a matter of fact, the first edition appeared anonymously, by a "Country Gentleman;" but a second, enlarged edition, was published in 1773, under the author's name. It is an octavo of 298 pages, with a bibliographical appendix of 136 pages, and a catalogue of 36 closely-printed pages of books on agriculture, gardening, &c. Both editions are in the Kew library [and the first edition is in the Lindley Library]; but what follows relates to the latter volume. Although entitled "Tracts," this work consists of a series of chapters partly on agriculture and horticulture generally, and partly on special operations in husbandry.

The author was a practical man, who had "made gardening and farming his principal study and amusement for many years." Much of what he wrote holds good to the present day, and might well be repeated. He strongly recommended the formation of societies, in every county, to promote proper methods of husbandry, and formulated plans for raising funds for this purpose. On the subject of improved cultivation on the farm he says:—"What I mean more particularly to show is, that husbandry will never arrive at half the perfection that it is capable of, till the garden-culture is more imitated in the field; nor has this principle hitherto been attended to, though it has been recommended in a very strong manner so very long ago, by that great friend and patron of agriculture, Sir Richard Weston." Our author does not claim kinship with his namesake, who published a *Discourse of Husbandry Used in Brabant and Flanders, shewing the wonderful Improvements of Land there; and serving as a Pattern for our Practice in this Commonwealth*. The first edition of this small work was issued in 1645, and Richard Weston, the second, after praising it very highly, adds, that the Royal Society, in their *Transactions*, have made the following encomium on it: "That England has profited in Agriculture to the amount of many millions by following the directions laid down in this little treatise."

The author continues his advocacy of garden-culture in the field in a chapter on planting fruit-trees on a large scale. He gives full instructions on all operations, their cost, and the probable returns, based on a low average. Respecting the cultivation of aromatic and other medicinal herbs in the neighbourhood of London, he says the profits were incredible; and he concludes a list of those he recommends for cultivation with "any other sorts that our modern quacks in phisic introduce into fashion!" The next chapter gives an estimate of the yearly expense of a stove 40 feet long; improvements in the management of Pines and

Strawberries; a convenient oven; and an expeditious method of watering the plants. This is followed by a chapter on raising forced Peas in a pit, and Asparagus, Melons, and Mushrooms. It opens with, "All sorts of early or forced crops pay so exceedingly well that there are none so worthy of either the gardener's or the gentleman-farmer's attention." Passing the directions as to how the results are to be attained, we come to the outlay and income. The yearly expenses of a pit, 100 feet long, we are told, will be nearly as follows:—

Rent of about $\frac{1}{2}$ acre of ground	£	s.	d.
120 bushels of tau, at 1½d. per bushel	0	15	0
50 loads of dung, if bought, will cost about 5s. per load	12	10	0
20 loads of loam, and carriage, at 2s.	2	0	0
A gardener's attendance, about 18 weeks, at 9s. per week	8	2	0
Seed Peas, 20s.; seed and pots for the Melon-plants, 10s.	1	10	0
Asparagus-roots, 10s.; fifty mats, 50s.	3	0	0
				£29	2	0

The produce, moderately reckoned, will be:—

50 pottles of Peas, at 21s. per pottle	£	s.	d.
40 hundreds of Asparagus, at 5s.	52	10	0
200 Melons, at 3s.	30	0	0
The dung will be worth at least	7	10	0
				£100	0	0

The foregoing is a very neat little piece of reckoning, to which the author adds, that the Lettuce, Radishes, &c., have not been included; "and after the Melons shall have been off, this pit will serve to raise Collyflowers on, to be planted out under bell-glasses, before it be wanted for Peas again." He also explains that the dung may eventually be used for raising Mushrooms, "which will be found very advantageous for sale, and of great use in the country."

The prices reckoned for the vegetables and fruit thus raised would please growers of the present day, though they have to pay their gardeners more than 9s. per week!

Under the head of "a moveable greenhouse," is the following interesting paragraph:—

"At Pit Place, in Epsom, lately Mr. Belchier's, is a grove of thirty or forty Orange and Lemon-trees, planted in the open ground; it is entered from an elegant drawing-room, by a pair of large glass folding-doors, and two rows of trees fill each side of the walk. In winter, a case, entirely of glass, for the front, the roof, and the other end, is put over them. On the left hand is a wall, which at once defends them from the frost and the north winds; this is planted with Vines."

Another chapter, and a most interesting one, is thus headed: "Improvements in Cyder, Perry, and made Wines, to render them equal to several foreign sorts; the Profits of Planting Fruit-trees for Wine."

I have already mentioned the bibliographical appendix. This is exceedingly well done, and evidently the work of a person who knew his books. It is entitled "A Catalogue of English Authors who have Written on Husbandry," but it might well have been called a descriptive catalogue. This is, perhaps, the most interesting part of the work, as it contains an account of some extremely rare and curious books, the authors and titles of which are not in any other botanical or horticultural bibliographies with which I am acquainted. The arrangement is chronological, beginning with the *Mirror of the Worlde*, by Hugh Bryce, 1480, or forty-six years earlier than the oldest English book in the Kew library. According to Weston, it is a translation from the French, and was printed by Caxton, at the expense of Hugh Bryce, an Alderman of London. It consists of one hundred

leaves, and among other subjects it treats "of the trees that ben in ynde, and of theyr fruyt;" "of nature, how she werketh, and what she is;" "of the diversytes that ben in Europe and Affryce," &c. Bishop Grosheide's *Treatise of Husbandrie*, 1500, is another translation from the French, and was printed by Wynkin de Worde. Then followed the *Grete Herbal*, the first edition of which appeared in 1516. This is a translation from the French *Grande Herbar*, published 1499, and was printed by Peter Treveris at the sign of the Wodowes (i.e., Wild men), in Southwark. Sir Anthony Fitzherbert was one of the first (if not the very first) authors of a printed work in English on husbandry. It is stated that he followed husbandry as a recreation for forty years, and his first work concerning us was *The Book of Husbandry, very Profitable and Necessary for all Persons*: London, 1532. Five or six other editions followed at various dates; and there was a second work on husbandry, called *The Book of Surveying and Improvements*. But his writings on law were numerous and perhaps more important.

Altogether, Richard Weston's book is one of the most interesting and instructive of its period. *W. Botting Hemsley.*

NEW OR NOTEWORTHY PLANTS.

GRAMMATOPHYLLUM RÖEMPLERIANUM, *Rehb. f. ? = EULOPHIELLA PEETERSIANA.*

Is the *Gardeners' Chronicle* for 1877, i., p. 240, the late Professor Reichenbach described *Grammatophyllum Rœmplerianum* from a faded specimen furnished by M. Luedemann, of Paris, and obtained by him from M. Rœmpler, of Nancy, who had imported a few plants of it from Madagascar. The author was enthusiastic in his praise of the stately novelty, but was unable to give the colours or finer details of the structure by reason of the indifferent quality of the flowers on which he based his description. About the same time M. Rœmpler sold his plants, all of which were in very poor condition, in London, and some half-dozen of the large pieces, consisting of elongated, conical pseudo-bulbs, curving upwards distantly from stout rhizomes, came into my hands. The growth-buds of all were black and, as I found afterwards, dead; but I succeeded in keeping the stems alive for between three and four years, hoping that from some portion of them a growth might proceed, but the hope was never realised. I assume that all of the importation failed likewise, for I never heard of one which grew. In the *Gardeners' Chronicle*, March 20, 1897, p. 182, Dr. Kränzlin described as *Eulophiella Peetersiana*, from material sent by M. Peeters of Brussels, and Messrs. F. Sander & Co., St. Albans, a giant Orchid which had been discovered by M. Mocoris in the island of Madagascar. The description at once reminded me of my troublesome subject *Grammatophyllum Rœmplerianum*, and on seeing the plant in flower in Sir Trevor Lawrence's collection, I had no doubt that it was the same thing, for it is scarcely likely that two such plants, distinct from each other, can exist in the same locality. I therefore place my ideas on the subject on record in the hope of giving some assistance in determining the specimen in Reichenbach's herbarium named by him *G. Rœmplerianum*. *James O'Brien.*

ORCHID NOTES AND GLEANINGS.

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES.

THE September number contains illustrations of the following plants:—1, *Anguloa Ruckeri*, Ldl.; 2, *Cattleya Luedemanniana*, *Rehb. f.*; 3, *Cypri*

pedium Drurio-Hookeræ, Veitch; 4, *C. conco-villosum*, Hort.; 5, *Dendrobium superbum*, Rehb. f.; 6, *Epidendrum atropurpureum* var. *roseum*; 7, *Lælia Dayana*, Rehb. f.; 8, *Lælio-Cattleya Highburyensis*; 9, *L. Massangeana*, Cogn.; 10, *Masdevallia Amesiana* var. *McVittiae*, Hansen; 11, *Odontoglossum crispum* var. *Mrs. Peeters*; 12, *Phalenopsis Luddemanniana*, Rehb. f.; 13, *P. Schilleriana*, Rehb. f.

An important announcement is made, that in consequence of the necessity for progressing speedily with the monograph of the Brazilian Orchidaceæ in the *Flora Brasiliensis*, the editor of the *Dictionnaire* finds himself compelled to lighten his labours by publishing the parts of the *Dictionnaire* every other month, instead of monthly, as at present. The subscription price will be correspondingly reduced. The first part of the new series (the fourth) will be issued during the present month.

The issue with the present part of an index to the various genera, species of which are represented, will enable the readers, if they prefer it, to bind their copies, and save the inconvenience of having to untie and retie the little portfolios every time they are consulted. This is not a small matter to those who, like ourselves, have to make frequent reference to this useful publication.

PLANT NOTES.

SOLANUM PIERREANUM.

In the current number of the Paris *Revue Horticole*, Monsieur E. André gives a description of the above-named highly ornamental fruiting *Solanum*, which he recently saw in full fruit at the Botanic Garden at Montpellier. This plant is a native of the Gaboon, and was sent to France by the late Monsieur Pierre, director of the Colonial Garden of Libreville. Messrs. Paillex & Bois, who received it, named it after the sender. The plant is of a shrubby habit of growth, its branches are cylindric, of a deep violet colour, covered with a reddish down; the leaves are of a deep green, both above and below; the white flowers are small, with a violet calyx, which is also woolly.

The fruits are borne singly or in pairs at the ends of the branches, and have the peduncle refracted and swollen at the summit. They are berries of from 3 to 4 centimètres in diameter, rounded, ribbed, and depressed at their base; and at their apex, umbilicated and laterally furrowed. But what is most curious about these berries, and what gives to the plant all its singularity, is their colour. When young, they are green, striped with deep-violet, then they pass to an ivory-white, then to a golden-yellow, then finally, to an intense vermilion-scarlet. On this varying ground-colour, the longitudinal violet stripes remain all through with great persistence. The plant bears at one and the same time, berries of all these various shades of colour, which produce a most curious and charming effect. *W. E. Gumbleton, Queenstown.*

A DISEASE OF ORNAMENTAL CONIFERS.

Twigs of *Biota orientalis* showing partial withering were recently received from a correspondent. The disease merits some attention, because it is common on various Conifers, including species of *Thuya*, *Cupressus*, *Chamaecyparis*, *Juniperus*, and their cultivated forms. The most evident symptom is the withering of twigs or branches here and there on apparently healthy trees. At the base of such a withered part, the bark will be found discoloured, and, as a rule, split round the branch so that the wood is exposed. This break in the bark, and the drying up of the wood, is the cause of the gradual withering of the green parts above. If the broken edges of the bark be examined, a fungus (*Pestalozzia funerea*) is frequently present, as indicated by minute black specks, and the same fungus may be found on the withered twigs. The natural conclu-

sion is that this fungus causes the disease. This was the view adopted by Boehm in 1894, but unfortunately his research wanted the clinching proof that the fungus-spores could produce the disease on healthy trees; his experiments to do this failed to convince Tubeuf and other experienced plant-pathologists.

The view that *Pestalozzia funerea* is a parasite receives support from the fact that another species (*Pestalozzia Hartigi*) was proved by Tubeuf and others to kill young plants of Silver Fir and Spruce, as well as seedlings of Beech, Ash, Sycamore, and other trees. This fungus attacks and kills the bark near the ground, and gradual withering follows. There is thus a distinction between *P. Hartigi* which kills young plants at their base, and *P. funerea*, found on older plants in places well above the ground. The necessity of knowing more about this disease of ornamental Conifers is evident when one comes to consider remedies. If an insect or caterpillar makes the first prick or injury on the bark, thus making a dead place on which the *Pestalozzia* fungus lives, then washes for insects would, in all probability, be a successful remedy. If again the fungus can attack and kill the living bark, the remedy is of quite another kind. Since all ornamental Conifers are not attacked, it seems probable that defective cultivation, unsuitable soil or climate, renders the trees liable to attack; for instance, Junipers with *Pestalozzia* were found by Tubeuf to have a root-fungus attacking them. In our climate frost may first kill the twigs, while the fungus only follows on this. To throw light on this subject, there is obviously need for growers to make careful observations. If specimens require to be examined for fungi or insects, this can easily be done by forwarding them to the Editor. *W. G. S., Leeds.*

NOTICES OF BOOKS.

CALENDAR OF FLOWERING TREES AND SHRUBS.

By Henry Hoars. (Richard Flint & Co., 48, Fleet Street.)

Is this book a presage that hardy trees and shrubs, so terribly neglected, are to experience a revival? We hope so; for there are no more interesting plants, and none in suitable situations more decorative. In the present volume we have first of all a list of the shrubs which may be expected to bloom in each month. Then follows a general description of each species, together with cultural notes.

This portion of the work is arranged alphabetically, and it is a pity that it was not a little more expanded, as the descriptions are mostly too meagre to enable us to recognise the species. The curious flowers of *Hamamelis* deserve a fuller notice, and if some inkling were given of the significance and purpose of the flowers generally, the interest of the book would be greatly enhanced. The diocious condition of *Hippophae rhamnoides* is not mentioned—a circumstance that may lead to disappointment, as not all nurserymen even are aware of it. Lists of species that thrive in particular soils and localities are given, and the book shows that it is not merely a compilation, but that its author has considerable practical knowledge of the subject on which he writes.

MR. MALCOLM DUNN'S LIBRARY.

THE interesting and comparatively large library of arboriculture, horticulture, and botanical works of the late Mr. Malcolm Dunn, of Dalkeith, will be dispersed on the 18th inst., the date having been changed, at Mr. Dowell's rooms, George Street, Edinburgh. Mr. Dunn's reading, however, was not exclusively special, and his taste was sufficiently catholic to include such diverse spirits as Baedeker and Father Prout, Cervantes and Robert Burns, Canon's various records of certain distinguished regiments, and *Cassell's Bible Educator*. Of books relating to Scotland, of course, he had a very large number,

which covered an infinite variety of subject. On subjects which come more directly within the limits of this journal, Mr. Dunn appears to have provided himself with most modern publications of approved merit. Of some of the older works he was also an occasional purchaser. Bradley's *Ancient Husbandry and Gardening*, 1725, was in his collection; so also were two much rarer works, *The Solitary Gardener*, 1706, described in the auctioneer's catalogue as "by Gentil" (a purely fictitious name, for the author's name, so far as I know, has never been disclosed), and Hale's *Vegetable Statics*, 1727. There is a copy of Thomas Hill's *Treatise on Husbandry*, 1760, and one of his *Treatise of Fruit-trees*, published eight years later; and also of the inevitable *Switzer on The Practical Fruit Gardener*, 1724. Both of W. Speechly's pioneer works, dealing respectively with the Vine and with the Pine-apple, are in this library. Earlier in date than any of these are the copies of J. Reid's *Scots Gard'ner*, published at Edinburgh in 1683, and T. Hill's *Profitable Arte of Gardening now the thirde time set forth*, 1574; and the very curious little treatise entitled *Diverse new sorts of soyle not yet Brought into any Publique Use for Manuring*, published in London, 1594, and of which there does not appear to be a copy in the British Museum. Periodicals relating directly or indirectly to gardening are also numerous, and included the *Botanical Register* for 1815 to 1844, the last thirty years of the *Gardeners' Chronicle*, some of the earlier volumes of the *Cottage Gardener*, and so forth. *W. Roberts.*

VERONICA CHATHAMICA.*

FOR the opportunity of giving an illustration of this species (fig. 117, p. 355) we are indebted to Mr. R. Lindsay, of Murrayfield, Midlothian. Our correspondent speaks of it as an excellent plant for draping rockwork, a purpose for which its prostrate habit and free-growing qualities render it peculiarly suitable. The flowers are purple (and sometimes white). It passes unscathed through ordinary winters, but it is liable to be injured in severe seasons.

SOUTHGATE HOUSE, SOUTHGATE.

THE gardens surrounding the massive, Ivy-clad residence of C. H. Feiling, Esq., are among the best-known in the suburbs of London. From them, when in the possession of Mr. Micholls, the gardener then there, Mr. Thomas Baines, brought forth those immense specimen stove and greenhouse-plants which were the admiration of all at the flower exhibitions of the day. The present owner and his gardener, Mr. Canham (since unfortunately deceased), confine themselves to what may be described as all-round gardening, and have succeeded in making the gardens, both indoors and out, very interesting. All have been re-arranged since Mr. Feiling took possession; large banks of choice flowering and evergreen shrubs have been planted; herbaceous borders arranged as fronts to shrubberies, and elsewhere, still have a good show of flowers. The pleasure-grounds have an area of 58 acres, and they are studded with giant Chestnuts, Oaks, and Elms, now beautiful in their autumn garb. Always a collector of objects

* *Veronica chathamica*, Buchanan, in *Trans. N. Z. Institute*, vol. vii., 1875; tab. xiii., p. 338 = *V. Fosteri* Mueller var. *elliptica*.

"A small prostrate rambling shrub. Branches wiry, $\frac{1}{2}$ in. diameter, pubescent. Leaves spreading, irregular in size, sessile $\frac{1}{2}$ to $\frac{1}{2}$ in. long, $\frac{1}{2}$ to $\frac{1}{2}$ in. broad, obovate oblong or ovate oblong, acuminate, entire, flat, scarcely coriaceous. Racemes, few or many, 1 to $1\frac{1}{2}$ in. long, subterminal at the ends of the branches, and axillary to the uppermost leaves, orbicular or ovate. Flowers numerous, closely set; peduncles $\frac{1}{2}$ in. long, pedicels, and lanceolate bracts equal in length; sepals $\frac{1}{2}$ to $\frac{1}{2}$ in. long, linear lanceolate ciliate; corolla large dark purple, tube short; capsule imperfect.

"This beautiful shrub has been cultivated by Mr. Travers in his garden in Wellington, N.Z., where the profusion of its dark purple flowers and prostrate habit have proved a most showy addition to those plants adapted for the ornamentation of rockwork or earth-banks."

of art, as is shown by the wonderful collection of curiosities in silver, ivory, and other materials, the rare pictures, &c., which make some parts of the residence look like a museum. Mr. Feiling, about three years ago, turned his attention to the acquirement and cultivation of Orchids, a pursuit he has so energetically followed up, that at the present day he has many rare species and hybrids among an extensive collection of these plants, which is still increasing in size and interest. The first Orchid-house entered, a lean-to, contains a large number of *Odontoglossums*, chiefly *O. crispum*, the greater part of which have not yet flowered in England, though some are now sending up spikes. These plants stand on the front stage. On the

imported pieces soon making vigorous specimens. Here, as in some other places where the best results are obtained, the whole of the centre bed of the house is occupied by large specimen *Crotons*, *Palms*, &c.; and the *Dendrobiums* are suspended overhead. Arranged with the *D. Phalenopsis* are well-bloomed plants of the white *D. Dearei* and *D. formosum giganteum*, *D. bigibbum*, a very fine selection of good forms of *Lælia pumila* and *Cattleya labiata*, some of them being very richly coloured; *C. aurea*, *C. Loddigesii*, *Oncidium varicosum*, *O. excavatum*, *Epidendrum vitellinum*, *Vanda cœrulea*, *Miltonia Clowesii*, *M. spectabilis Moreliana*, and other showy things. The other side has a number of fine *Cypripediums*, among which in flower or

grand blooms, the side stages being brightened with scarlet *Salvias*, flowering *Cannas*, *Pelargoniums*, &c.; the roof bearing a very dark-coloured form of *Lapageria rosea*, and other climbers. Another house is full of well-grown *Cyclamen persicum*, well set with buds, and in other houses are *Azaleas*, *Ferns*, *Primulas*, *Cinerarias*, and other showy flowers.

The vineries have been very successful this year, there having been a continuous supply of Grapes since May, and enough remaining to carry into the new year.

The fruit-room gives evidence of a fair supply of Pears and Apples, and the extensive kitchen gardens neatly kept, and satisfactory.

FIG. 117.—VERONICA CHATHAMICA. (SEE P. 354.)

main stage are a fine lot of *Cypripediums* in about 140 varieties, some *C. Charlesworthi*, *C. ænanthum*, and *C. Victoria Mariæ*, among others, being now in bloom, the last-named plant having flowered continuously since the middle of March last. The fine specimens of forms of *Cypripedium insigne* now profusely sending up flowers are kept in an adjoining greenhouse, occupying the whole of the end of the house, the remaining portion being filled with greenhouse decorative plants.

The main show of flowers is in the large span-roofed intermediate-house, in which the greater part of the staging is filled with fine examples of Orchids in flower. In the arrangement are scores of well-flowered plants of *Dendrobium Phalaenopsis*, *Schroderianum*, whose graceful spikes arch over in every direction, the flowers varying from pure white, with a slight lilac tip to the petals, to bright rose, and darker tints of rosy-purple. These plants thrive admirably here, even the smallest

bud were a grand plant of *C. × Chas. Canham* (named in honour of the brother of Mr. Canham, the late gardener at Southgate House, formerly Orchid-grower to Messrs. Veitch), with three noble flowers; *C. × Arthurianum*, *C. Schlimi*, *C. × leucorrhodum*, *C. calurum*, several fine *C. tonsum*, *C. Spicerianum*, *C. × Leeanum* varieties, *C. Charlesworthi*, *C. Curtisii*, &c. On a shelf at the end is a quantity of *Lælia autumnalis*, sending up spikes; and among the rarer *Cattleyas*, the gorgeously-coloured *C. Mossiæ* Mrs. C. H. Feiling is among the most prized. There are a number of plant-houses and vineries at Southgate House, and in any of them thought to be suitable, some Orchids from time to time are placed, and the *Cœlogyne cristata* are thriving admirably in a frame in which small Ferns and other decorative plants are grown.

The other plant-houses are devoted to the culture of flowering and ornamental plants. In one is a very fine display of *Chrysanthemums*, bearing

ORCHIDS AT THE GRANGE, SOUTHGATE.

Cattleyas, *Lælias*, and hybrid *Cattleyas*, *Lælias*, and *Lælio-Cattleyas*, together with *Odontoglossums*, form the bulk of the remarkably well-grown collection of Orchids carefully got together by J. Bradshaw, Esq., and skilfully grown by his gardener Mr. Whiffen. The well-constructed *Cattleya*-house contains the principal show of flowers, and the numerous and varied forms of *Cattleya labiata* give the greatest proportion of blooms. Among the many in flower are some very handsome dark-coloured forms, closely imitating *Cattleya Warneri*, and of the six forms with pure white sepals and petals, one is in flower already, the bloom being pure white, with a chrome-yellow disc to the lip, and a purplish-crimson blotch in the centre. Another very curious form of *C. labiata* is wholly of a pale lavender-blue tint, the markings on the lip being darker, and of a slate-coloured hue. One pretty light form has the

lip almost wholly cream-white and light-rose, the usual dark-crimson blotch being reduced to an almost invisible spot. The great charms of this useful *Cattleya* are, that it flowers at a season when its blooms are the most desirable, and their great variation gives them additional interest. Still more showy are three fine specimens of *Cattleya* × *Mantini*, one bearing three grand heads of rich, rose-purple flowers, the dark, ruby-red lip, veined at the base with orange colour. This is one of the best of hybrids, and very free to grow and bloom. Also in bloom are the fine yellow *Cattleya* × *Maroni*, a number of handsome *Lælia pumila*; and among other things, a very handsome and distinct form of *Oncidium tigrinum*, which has the labellum nearly white or cream-white, the yellow usually seen in the species being nearly suppressed. The sepals and petals also are much lighter than usual, and the plant altogether an interesting variation. Among the hybrids are several crosses, with the fringed *Lælia Digbyana*; also *Lælio-Cattleya* × *Thorntoni* (*C. Gaskelliana* × *L. Digbyana*), of which there are two good plants. This season, the many white forms of *Lælia-anceps*, which here thrive admirably, are sending up numerous spikes; though scarcely so many as they have had some seasons before.

The new *Odontoglossum*-house, nearly 60 feet in length, seems to suit the plants admirably, and many are sending up flower-spikes, some of them being of the batch which has already produced some remarkably handsome natural hybrids.

A goodly number of scarlet *Sophranitis* are in flower, and many *Odontoglossum Rossi majus* and other species about to expand the earlier of their blooms.

During the past hot summer, Mr. Bradshaw has reaped the advantages of having had his Orchid-houses properly constructed, the cool-house having a rain-water tank from end to end on the one side, the opposite side beneath the staging being planted with Ferns, Begonias, &c. This arrangement, aided by the staging on which the plants stand, being of moisture-holding, porous red tiles, has played an important part in preserving a temperature as cool as possible, and getting the plants through the trying hot time in fine condition.

THE EFFECTS OF FOG AT CHISWICK.

THE fogs which hung over Chiswick during a great part of last month, and which, during the two days preceding Sunday, the 15th ult., and the day following, were of great density, have joined to other antagonistic agencies in giving emphatic notice to the Royal Horticultural Society to quit Chiswick. What the deleterious substances were, can to a considerable extent be discovered by their effects on the glass and on vegetation. The glass on houses and frames alike have an opaque, gummy-like substance adhering to it with the persistency of a coating of size, which the storms of Sunday night and Monday morning failed to remove to any great extent. The effects of the fog on vegetation have been extraordinary, although, strange to say, the high-road of Chiswick was comparatively free from it. Mr. S. T. Wright states, that never before has he witnessed such baleful effects from fog.

Some of the Ferns felt the effects of the fog sharply: the points of the fronds of *Adiantum cuneatum* are fading away as if scorched; and the thicker and more leathery pinne of *A. formosum* are equally affected. The plants of *Cannas* look almost as if fire had passed over them.

A casual visitor, knowing nothing of these fogs, might imagine the injuries were due to gross neglect, and thereby do Mr. Wright a great injustice. There must have been an immense volume of sulphurous or other deleterious acid to effect so much destruction in so short a time. The zonal *Pelargoniums* in the *Canna*-house have been well nigh denuded of their leaves. Even in the lean-to propagating-house, the fog has injured some young plants of *Begonia Gloire de Lorraine*.

The southern end of the Muscat-house shows much the same effects as that which the *Cannas* occupied. What wind there was during the fog period was in the east, and every time the door at the south end was opened, the fog entered the house, and a Vine of Mrs. Pince, just in the inside on the left hand has leaves as if scorched. Up in the roof and along the sides for some distance there are areas of scorched leaves, and there is a perceptible deposit on the bunches. Mr. Wright takes a desponding view of the Vines, seeing that the leaves are, as it were, paralysed, whilst fresh and in good health.

On the north side of the large vinery the same effects can be witnessed. Every variety of Grape is more or less "scorched," and mostly so in the neighbourhood of loose laps.

Apple-trees appear to have escaped with little injury, but Pears are badly hit. The hedgerows of Golden Privet are lustreless; and the flowers of the *Chrysanthemums* are so sooty that they had to be removed. The new garden of the Society must be far enough away from the centre to be outside the fog radius, if good work is to be carried on in the interest of horticulture generally. R. D.

NICOTIANA SYLVESTRIS AT HIGHCLERE CASTLE GARDENS.

THE figure given of a group of this decorative species of *Nicotiana* affords a good illustration of the value of the plant from a decorative point of view. Its flowers bear resemblance to those of *N. affinis* in shape, but they are more abundantly produced, and have not the drawback of that species of closing in the morning, and during cloudy weather. They are fragrant like those, and pure white; the plant, moreover, possesses stronger and more abundant foliage, and is less weedy in appearance.

Our illustration (fig. 118, p. 357) is a reproduction of a photograph taken by our valued correspondent, Mr. W. Pope, head-gardener to Lord Carnarvon at Highclere Castle, Newbury.

CHRYSANTHEMUM NOTES.

(Continued from p. 349.)

CALVAT'S CHRYSANTHEMUMS.—This eminent grower appears, as is usual, to be well represented at most of the trade displays this year. Among his own countrymen there seems to be but little competition, except some very good additions which M. Nonin has sent over. Up to the present, M. Calvat is represented best by M. Fatzer and President Bevan, both very fine incurving Japanese of varying shades of yellow; President Lemaire is a dark velvety crimson with golden reverse; Melusine, Madame Ferlat, Werther, Le Grand Dragon, Madame G. Bruant, N. C. S. Jubilee, are all fairly well known, and are much in evidence; Zepherin is a quite new Japanese, with flat pointed florets, a very full flower of a pure pale golden-yellow. Soleil de Decembre is rather too early to justify its name, but is a promising yellow; M. H. Martinet is a fine crimson and gold Japanese; Eliane is also new, it has long strap-shaped florets of medium width, pointed at the tips, colour golden-yellow; Lydia is new, colour bright rosy-amaranth, with reverse of silvery-pink. Other but older sorts, such as Marie Calvat, big but coarse; Perle, fine; Beauté de Grenoble, Madame Couvat de Terrail, Souvenir de Moulins, Madame Carnot, and many more besides are numerous and well grown.

VARIETIES FOR THE BORDER.

To anyone not having glass accommodation, but desiring to have a few *Chrysanthemums* in the borders for cutting, there are some excellent showy varieties, which, if smaller than the big exhibition blooms, are, nevertheless, very useful. Most of the old early-flowering varieties were Pompons, but thanks to the efforts of some of the French

raisers, there are in cultivation now-a-days some pretty little varieties of Japanese form that are very attractive.

Grown freely in bush-form, and without any attempt at disbudding, such flowers are always welcome, and among some of the best I have seen this season are Paul Valade—rather large, with broad florets, the centre ones incurving, colour pale ochre-yellow, slightly tinted darker; Amiral Avellan, rather short, flat florets of good width, bright golden-yellow; Market White, long, loosely-arranged florets of medium width, colour white; Pergolèse, small in size, but very attractive, colour deep velvety dark crimson; Ami Baumann, rather short, flat florets, pale lilac-mauve; Triomphe de Lyon, broad florets, blooms of good size, colour pinkish amaranth, centre golden; Madame Liger Ligoeau, largest of all, colour very pure shade of pale canary-yellow; Molière, flat florets of medium width, lilac-mauve, prettily shaded in the centre with old-gold. One variety in particular in my garden has attracted much attention: it is called Château St. Victor, a plant that has received no attention since planted in the spring; it has only a single stem, but forms a very fine bushy plant, bearing several hundred flowers of a pretty shade of pinkish-amaranth. Crimson Pride is another border variety for those who like high tones of colour. C. H. P.

THE SWANLEY COLLECTION.

Messrs. H. Cannell & Sons have ever been in the forefront in the cultivation of the *Chrysanthemum*, and Mr. Cannell, senior, is one of the very oldest cultivators of the plant, his experience extending back for nearly half a century. He is therefore just what he claims to be, "one of the old school," with an admiration for the incurved type of flower, his favourites among the Japanese being also those with incurving, or twisted florets. But the selection at Swanley is a most up-to-date one, and representative of all the types—the useful decorative sorts, the single-flowered, as well as those whose primary value is for exhibition. The plants are grouped in the extensive span-roofed structure at the top of the nursery, which for some years has been used for the purpose, and at the present time the interior view is one of a mass of bloom of exceeding showiness. All the best novelties, by whomsoever raised and distributed, are to be seen, and amongst them varieties that at present are only to be found there, so far as Britain is concerned. Most of the latter are contributed from three sources—Continental, Australian, and seedlings raised at Swanley. In addition are a few varieties of American origin. Of the Americans, a Japanese variety, with flat florets, and named Spotswood, is very pretty. The flower is white, but has a butter-coloured centre, which is very full, and this colour casts a cream shade over the larger white florets. It would probably be sufficiently large for exhibition when grown another season.

Home-raised seedlings include Mr. W. C. F. Gillam, a promising red-coloured Japanese, with pale reverse; Colonel Baden-Powell, a large incurved flower of rosy-lilac colour, the reverse silver and pale mauve. This should make a flower that will be valuable in the exhibition-stand. Mrs. J. J. Tilley, a most promising Japanese, in which the conspicuous colours are yellow and red; and others. Several of the Australian seedlings, now blooming for the first time here, have a promising appearance, but a more certain estimate of their value will be possible next season.

Mrs. Frank Grey Smith at once reminds one of Col. W. B. Smith, and in appearance is hardly distinct from that variety; but whilst Col. Smith is notorious for "damping," the newer one of the same type is said to be as little susceptible to this affection as the generality of varieties. Margery is a Japanese seedling from Madame Carnot, and its first blooms are a pretty mauve colour; Mabel Brunning, also a Japanese, has crimson florets, with gold-coloured reverse; Sir H. H. Kitchener is crimson, with bronze reverse; and Mermaid, a white Japanese, or possibly, when well developed,

florets marked with mauve; Sydney Brunning, a red Japanese, with buff reverse, is another promising Australian Japanese.

Among the continental novelties, Jules Bernard (Molin), a deep crimson Japanese, with silver and red reverse, should be valuable; also M. Jacob Holtzer, a yellow Japanese—no bloom of this was fully developed, but it appears to have an immense number of florets. Madame F. Daupias, a pure white seedling from Madame Carnot, greatly resembling that variety in build, and a grand exhibition variety; Mdlle. Gabrielle Debie, a Japanese

curved Japanese, red, with silver reverse, the reverse colour predominating, &c.

Turning to decorative varieties for a moment, a continental variety, Gorgones, with yellow flowers, all of the florets twisted as in a whorl, will make a grand variety to be grown as a bush plant. None could be more effective. Rayon d'Or, deep orange-yellow, also fine for a bush-plant, are two excellent novelties. The fine variety Mrs. Wingfield was also well represented; and Dr. Masters (Owen), a flat-petalled, reddish-crimson variety, very telling in a mixed bouquet; and Mrs. Vere Freeman, of

enterprise he has expended upon Chrysanthemums during the past ten years has been wonderful, and to this fact it is doubtless due that he has obtained such a popular reputation in the "mum" world as he to-day possesses. The number of first-class exhibition varieties distributed from the Ryecroft collection has been very remarkable. Only a few seasons since there was Chas. H. Curtis, now generally acknowledged the best yellow incurved variety, and one that will be popular for many years to come. Last season the yellow Japanese, R. Hooper Pearson was distributed, and this is just as likely to remain a standard yellow variety for a long time. The collection now in bloom at Ryecroft includes a large number of plants of the latter variety, in a number of sizes, and in different sized pots, but it matters little, comparatively, whether the bud "taken" was an early or late one, the flowers are "good," by which is meant that the centres are never exposed or thin, though there is necessarily much difference in the size of some of them. Lionel Humphrey, another of last season's novelties, will also prove to be a first-class exhibition flower, when well grown upon a terminal bud. It is a Japanese flower, the florets are reddish-crimson with gold or buff reverse, and a colour that will tell greatly upon the exhibition stand; but it is little good from first crown buds, owing to a want of colour. Mr. A. Barrett, of the type of Mrs. C. Harman Payne, but quite distinct in colour, may also be popular with the exhibitor, it will cover so large a space; but it is not a refined or attractive flower. Fair Maid is a pretty pink-coloured Japanese incurved—distributed last spring; and in J. E. Clayton, which is a beautiful yellow sport from Eva Knowles, we have a charming flower. By the way, the variety just mentioned is one of a batch raised by Mr. W. Seward Hanwell, and distributed by Mr. Jones this last spring. Mr. Seward's varieties are remarkable for their high-coloured flowers, and this is a point to which raisers and exhibitors do not attach sufficient importance. Mr. Seward's novelties, like H. J. Jones, Mrs. W. Seward, and Helen Shrimpton, are some of the brightest-coloured flowers. It has always been a difficulty, and so it remains, to obtain flowers with brilliant colours, and that have sufficiently long petals to render them valuable to the exhibitor. But already this season we have seen Fair Maid figure very charmingly in exhibition. Perhaps another season's cultivation will prove others of this most desirable class to be capable of much longer petals than we should credit them with at present.

Among other varieties distributed by Mr. Jones last season we observed Mr. A. G. Miller, a very beautiful pink-coloured Japanese incurved; Mrs. J. Bryant, a Japanese incurved with bright pink flowers of a similar type to *Australie*; Mrs. J. C. Waterhouse, a light yellow Japanese with wide florets—a seedling like the splendid bronze variety, Mrs. A. H. Hall, from Edith Tabor; and Eastman Bell, a bright crimson sport from President Borel, very fine. We noticed a few fine novelties in this collection which were distributed from other establishments, for of the 7000 plants cultivated in pots, there are not more than 1000 that are not very recent varieties; Jane Molyneux, Annie Prevost, Madame Gabrielle Debie, Queen of the Exe, and others.

Of varieties not yet in the trade it would be too early to speak; and before forming an opinion upon new seedlings raised at Lewisham, it would be more satisfactory to have them cultivated in a less populous district. The collection now in flower has suffered terribly from thick fogs and storms of soot, many of the flowers being half-smothered with these smuts. If a variety is good enough to obtain a Certificate when grown in such conditions, of what will it not be capable! But a town situation has its advantages. Chrysanthemum "rust" will not—or, at any rate, "does" not—thrive in London, and Mr. Jones proudly declares his large collection of plants, including

FIG. 118.—NICOTIANA SYLVESTRIS. (SEE P. 356.)

incurved, shrimp-coloured, or similar to the colour of a *Malmaison* Carnation, but paler—this is a magnificent flower, deep, with fine, bold, drooping florets, of considerable length, and incurving spirally. Madame Raymond Desforest promises to make a true incurved; its colour is coppery-yellow, and in size will leave little to be desired. Amateur J. de Chapilais is a red Japanese incurved, with buff reverse, one of the closer incurved type, and very promising.

Of better-known varieties of recent introduction by various raisers, fine blooms were seen of General Roberts, too small for exhibition, but marvellously good in colour; Mrs. Coombes, a pink-coloured Japanese, one raised by Mr. Weeks; and Le Grand Dragon; Samuel C. Probyn (Davies), a fine in-

the same type as Dr. Masters, but deeper crimson, with very full centre.

After an inspection of the Chrysanthemums, Mr. Cannell showed us the zonal Pelargoniums in full bloom. And what a glorious display of bright colours these afford! The *Sirdar* appears to be the brightest of all. Subsequently a drive to Eynessford, enabled us to visit the fruit-trees and plantations, where lifting is in progress: and the new seed warehouse, where cleaning of the home-grown Aster and other flower and vegetable seeds was in progress.

THE "RYECROFT" COLLECTION.

One of the most enthusiastic of Chrysanthemum-growers is Mr. H. J. Jones, of the Ryecroft Nurseries, near Lewisham. The amount of energy and

thousands upon thousands planted in the field, and which are now being lifted to produce shoots for propagating in the houses, to be absolutely free from "rust."

Nevertheless, we think that Mr. Jones' enterprise will lead him to remove his plants another season to a district where purer air and clearer light will give them a better opportunity to produce exhibition blooms than is afforded at Lewisham.

CROPS IN NATAL.

WITH regard to fruit culture in Natal, the colony may be roughly divided into three districts, viz., first, the coast; second, midland; and, third, upland districts. The first consists of a strip of land along the coast, extending some 20 miles inland, and is suitable for all kinds of tropical fruits, but especially Bananas, Pines, and all Citrus fruits. The second district consists of a belt of land parallel to the coast-belt, of about equal width, in which some tropical fruits grow to perfection, and some of the European kinds, such as Apples, Pears, Quinces, Figs, Peaches, and Plums, Apricots, Grapes, and a small quantity of wine is produced. The upland district represents the remainder of the colony, and is suitable for all kinds of European fruits. In portions of this district Vines grow very well, and produce large quantities of Grapes; but there are no vineyards. The Tea plantations are confined to the coast belt, and are all within a few miles of the sea. The growing of Aloes (*Agave americana*) for fibre has lately been undertaken in the coast district, where for many years this plant has been known to grow extremely well, the leaves attaining a great length, and the fibre being of remarkably good quality.

By-the-way, the present nble Agent-General for Natal informed the writer that in his garden at Durban, when there resident, it was customary to pass from the drawing-room to one of the borders and cut a Pine-apple to form part of the dessert. This must have been a treat unknown in Olympus!

The Agricultural Report for last year, to hand, notes respecting the Sugar-cane that the efforts of the planters to cope with the locust visitation have so minimised the loss from this cause that the crop proved a record one for the colony. There is a tendency towards better cane cultivation rather than increase of area, natural and artificial manures being more largely used than formerly. As to Tea cultivation, this industry has experienced a successful year, and the present outlook is a good one. As to the growth of the plant, it is believed that certain varieties will be found to succeed in the more elevated portions of the colony; experiments will prove this either way.

The Natal Departmental Reports form excellent reading for those interested in the various subjects. One of the reports for 1898 reads: "One wild leopard, value £10." *E. C.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart. Clare Lawn, East Sheen.

Pleiones.—These plants, which may be more properly considered as deciduous *Cœlogyne*s, are amongst the few species that require repotting during the present month. Few Orchids can be grown with less trouble than these so-called Indian *Crocuses*, and their attractiveness should recommend them to all growers of Orchids. *P. maculata*, *P. lagenaria*, *P. præcox* (*Wallichiana*), *P. Birmanica*, and *P. Reichenbachiana*, should be repotted as soon as the flowers fade; the flask-shaped pseudo-bulbs being removed from the soil, and freed from the old, useless roots and the membranous covering, removing the latter so as not to injure the young roots and growths. Pans are more suitable for *Pleiones* than pots, and the size of these will depend on the number of pseudo-bulbs placed in them. Pans of about 8 inches in diameter and 4½ inches in depth will provide space for about twenty pseudo-bulbs. A pan should be provided

with drainage materials to within 1½ in. of the rim, with a layer of moss above these, and over all place the compost, which should consist of equal parts good fibrous loam and peat, a little chopped moss, a small quantity of dry, powdered cow-dung, and as much silver-sand as will render the whole sufficiently porous. When the pans are filled, take a pseudo-bulb, and with a little moss, and the old roots left on, and form a ball, then fix the bulb securely in the compost. The pseudo-bulbs should be so arranged over the surface that the growths as they advance have ample space in which to develop. The compost should be brought above the rim of the pan, and be slightly rounded in the centre. The soil must be firmly pressed around each pseudo-bulb, but not so much so, as to make it hard. When the work is finished, *P. maculata* should be placed on a shelf, or suspended in a light position in the Cattleya-house, and the others in similar positions in a cool house. The advantages of a shelf are, that no water can reach the plants when damping down is done, and every ray of sunlight reaches the plants. Not any water should be applied for six weeks, and then the cultivator should immerse the pans to the rims in a vessel of tepid rain-water, and afford no more water for a similar period of time; and this method of affording water should be followed till about the month of April, when more frequent applications will be required. *Pleione humilis* blooms in February, and the plant is, at this season, in a state of rest in a cool house, requiring only an immersion now and then in order to keep the pseudo-bulbs from shrivelling.

Cœlogyne (Pleione) Schilleriana.—This species, which has very small pseudo-bulbs, comes from Moulmein, and a lower elevation, and enjoys therefore more warmth than do the *Pleiones* before named, which are natives of the Indian mountains, and the plant thrives on a teak-wood raft, hung up in a warm house during its season of growth, and rested in the Cattleya-house during the winter. The old roots and leaves do not die on the completion of the growth as do those of *Pleiones*, and should therefore be left intact so long as a plant has space to extend itself, and is in a healthy state. Only as much water should now be afforded as will keep the pseudo-bulbs in a firm condition.

Cœlogyne cristata and its varieties.—These plants are now showing their flower-spikes, and will need a very small quantity of water, which should be so applied that the sheaths of the scapes do not get wetted, or the loss of the flower-buds may follow.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucestershire.

Myosotis.—The variety *disitiflora* is the earliest to bloom, and it succeeds well when planted in beds containing plenty of leaf-mould. *M. sylvatica* with its very bright blue flowers is distinct; while both the blue and white varieties of *M. alpestris* make a pretty contrast when planted alternately in beds. The variety *M. alpestris Victoria* is very dwarf in habit, and the best for forming borders, but it is rather late in flowering. When planting these, with the exception of the last, they require at least a space of 9 in. from plant to plant, otherwise they get much crowded in the spring. Very effective beds may be formed by planting *Valerian Phu* 18 in. apart, and filling in with a groundwork of *Myosotis*, the blue flowers of the latter contrasting well with the golden leaves of the former.

Later Flowering Plants are *Saponaria calabrica*, *Aubrietias*, *Collinsias*, *Limnanthus*, *Alyssum maritimum*, *A. saxatile compactum*—all lovely spring plants, but unfortunately flowering too late for bedding purposes, and often having to be removed when in perfection to make room for the summer occupants. However, in clumps in the shrubbery border, or in nooks near walks, they form lovely masses of colour, and flower more freely if the compost they are planted in is of a poor nature.

Roses.—Whether these are intended to be planted singly or otherwise, the preparation of the ground should soon be undertaken. The Rose being a plant of somewhat unsymmetrical habit, is not an attractive object in geometrical beds; but if planted in groups or large clumps at a distance from the roots of trees and large shrubs, or in rows in open borders, it shows to great advantage. For affording

flowers for cutting, *Roses* may be grown in the kitchen garden, the reserve nursery, or in a field, provided direct sunlight reaches them. The best kind of soil for the Rose is a well-drained, retentive loam. This should be trenched to the depth of 2 feet, incorporating with it during the course of the work some half-inch bones, decayed nightsoil, pig, or farm-yard manure. If the soil be tenacious, charcoal, charred soil, or wood ashes may be stirred into it; and soils of a contrary nature are benefited by adding decayed, stiff turfy loam, crushed bones, charcoal, and road grit. After being dry, the land should be made firm by the feet.

Planting.—In light soils, *Roses* worked on the Manetti stock are the best, as the roots of this stock go deep into the soil; but on heavy ones the seedling Briar makes the best kind of stock; and on their own roots *Roses* succeed even better, as the roots keep near to the surface. *Roses* should be planted at a moderate depth, so that in the case of worked plants the few buds of the scion that are buried may start beneath the soil and form roots. When planting *Roses*, the operator should study the habit and strength of each bush and variety, for no specified distance at which to plant can be given; still, it is well to plant them rather closely together, and apply artificial and liquid manure when the bushes have become large and are in need of assistance.

Standard Roses succeed admirably when, as may be sometimes done, they are budded on the stock on the spot where they are to remain. Should planting on the turf or in back rows of borders of herbaceous perennials be contemplated, only those with fine large crowns should be selected for the purpose, as such plants possess fibrous roots in abundance, and are therefore well fitted for holding their own amongst other plants. In lifting *Roses*, a digging-fork should be employed, so as to avoid injury to the roots. All *Roses* should be carefully examined on being dug up, and if any roots are found that thicken as they spread from the stem, these should be removed, such being the sucker-growths, which, if left, will give a lot of trouble afterwards. The holes made for the reception of the bushes and standards should be made firm at the bottom, and the roots should be spread out naturally, and covered, at the first, with some of the fine particles of soil, and then with the rest of the soil. Having planted the tree or bush, make it secure temporarily to a stout stake; and shorten back those shoots which, owing to their length, are likely to be weighed down by snow or broken off by the wind, the actual pruning being postponed till quite late in the spring.

Tea and H. T. Roses are undoubtedly the best sections to plant where space is limited. Most of the varieties will succeed in light soils, in which the hybrid perpetuals so often fail. A great deal depends upon the altitude of the situation in which they are grown, for in low-lying or damp situations they suffer much from frost. Should the stock of these varieties be insufficient, it is advisable to procure them from the nurseryman not later than the end of the present month, but when they are raised and grown at home, planting may be left, even, till the spring.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Broccoli.—In ordinary winters there is no need to afford protection to these plants, more especially if the land on which they are planted is firm, and ample space is given from plant to plant; but our winters are not always mild ones, and it is prudent to "heel over" a goodly proportion of the crop, with the heads inclining towards the north. Let this work be undertaken in fine weather. The better plan is to open a trench at the northern end of a row of plants, and press them over to that side, disturbing the roots as little as possible. If the land is wanted for some other purpose, the plants may be dug up and replanted elsewhere, burying the stems up to the leaves, or nearly so. A ball of earth should accompany each plant; and although the heads may not grow, they will be found of useful sizes.

Seakale for Forcing.—This plant does not respond readily to very early forcing, unless specially treated by clearing away decayed leaves so as to expose the crowns to the sun; and only young plants afford the best returns, so that a good-sized plau-

tation should be planted every year, to enable the gardener to possess suitable roots for early forcing. The roots should be dug up several days before they are put into heat, and left quite exposed to the weather. When trimming the roots, let the best of the young thongs be trimmed off and reserved as sets, cutting the top end square across, to avoid confusion at planting time. These pieces may measure 6 inches in length, and be tied up in small bundles, and laid in soil or coal-ashes till required for planting. Forcing in the open by means of stable-dung and tree-leaves is a rather laborious proceeding, and one that is practicable only where these materials abound. These should be mixed well together and thrown into large heaps to heat, turning the materials twice before using them in covering the Seakale-pots. Attention must be paid to the degree of heat in the beds, uncovering them slightly if the heat be higher than 75°.

Rhubarb.—The roots of Rhubarb should be similarly exposed before forcing is begun. The roots may be forced in any sort of place having a warmth of about 60°, packing them close together and covering with leaf-mould, putting over all a quantity of clean straw. Afford water before the soil gets dry. In the open ground, large boxes may be put over the Rhubarb crowns, and heat afforded in the same manner as is practised with Seakale.

French Beans.—It is of little use to sow French Beans at this season, the plants rarely yielding pods in paying quantities. Plants which may now be in flower and in pod, should have careful attention with regard to water, heat, and ventilation; syringing being done occasionally, and only in sunny weather, and then but once a day. The temperature should range from 60° to 65° by night, and 70° to 72° by day.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Orchard-planting.—Where the land has been trenched and utilised for some light kind of crop, it will be in good condition for planting. On land which has been under the plough, I would strongly recommend the planting of bush or pyramid trees, which have an advantage over standards on wilding stocks of coming into bearing much sooner; moreover, choicer fruits are obtained from such trees. An orchard as we usually see it is a grassy-plot, planted with standard trees, and grazed by cattle or sheep. Under this method we cannot hope to obtain fine samples; and, indeed, large-fruited varieties are not unsuitable for being grown as standards, as the fruits are readily blown down, or bruised by contact with the branches. The trees are also many years before a paying crop of fruit is obtained in return for the original outlay. Bush-trees, on the contrary, crop early, but being planted at less distances apart, a greater number is required, making the outlay for trees rather greater than in the case of standards. As circumstances will determine the system adopted, this is a matter that has to be decided by the planter. Due regard must be given to the position of the orchard, and to shelter on the north and east; and if land with a slight slope to the west can be selected, so much the better.

The Distance at which apart to Plant.—Apples and Pears as bushes or pyramids need to be planted at 12 feet apart, and for some few years small bush-fruits or Strawberries may be grown beneath and between the rows. Most of the varieties enumerated in last week's Calendar are suitable for this style of planting. Orchard standard trees should not be planted closer together than 24 feet each way; and those of a strong-growing nature, that form spreading heads, as Blenheim Orange Pippin, should be given a space of 30 to 36 feet apart. A selection of varieties for the orchard should include, for cooking, Keswick Codlin, Beauty of Kent, Dummelow's Seedling, Blenheim Orange Pippin, Greengarden, Newton Wonder, Bramley's Seedling, Tower of Glamis, Dutch Mignonne, and Northern Greening. For dessert: Cox's Orange Pippin, Kerry Pippin, Devonshire Quarrenden, King of the Pippins, Gravenstein, Fearn's Pippin, Adams' Pearmain, Sturmer Pippin, and Allen's Everlasting.

Pears are an uncertain crop, and few varieties are adapted for this kind of culture. Some of the more reliable are Williams' Bon Chrétien, Bûre de Capiaumont, Beurre Clairgeau, Fertility, Louise Bonne of Jersey, Beurre Rose, and Hazel. For

stewing purposes, Bellissime d'Hiver, Catillac, Verulam, Vicar of Winkfield.

Apricots.—A selection should comprise Breda, a medium-sized early variety; Hemskirk, large and hardy; Moorpark, a good variety and very generally planted; and Late Peach.

Plums, cooking.—Archduke, Rivers' Early, Magnum Bonum, Victoria, Pond's Seedling, Prince of Wales, Diamond, Gisborne's, Prince Englebert, and Monarch.

Plums, dessert.—Early Green Gage, Dennistoun's Superb, Oullin's Golden Gage, Old Green Gage, Transparent Gage, Jefferson, Kirke's, Coe's Golden Drop, Braby's Late Gage, Reine Claude de Bavay, the latter not to be planted in a cold situation.

Cherries, dessert.—Bigarreau de Schrecken, Knight's Early Black, Elton, May Duke, Black Tartarian, Bigarreau, Bigarreau Napoleou, a good late variety; and St. Margaret's or Tradescant's Heart, a late black wall Cherry.

Cherries, kitchen.—Kentish Red, Morello, and Belle de Magnifique, a prolific bright-red coloured Morello-like Cherry.

FRUITS UNDER GLASS.

By W. STRUONELL, Gardener to Lieut.-Col. RALPH VIVIAN, Rood Ashton, Trowbridge.

The Late Vinery.—The Grapes in this division should be fully ripe by this date. If the color be not satisfactory, nothing the gardener can do now will improve it. The vinery should be afforded air with much judgment, or the bunches of Grapes will suffer greatly in appearance from loss of berries by decay, induced by low temperature and damp. Fog, of course, must be kept out of the vinery as much as possible, and its effects counteracted by the use of fire-heat, and by affording air in fine weather. No plants should be allowed to stay in this vinery unless it be those in a state of rest, and needing no water at the root; and no water should be spilled on the border. Let the leaves as they fall from the Vines be gathered up frequently, the more so if insects of any kind have infested the Vines. Examine the bunches at short intervals of time for decaying berries. Vines with their roots in outside borders should be protected from the weather, or great loss of fruit will ensue. One of the best kinds of protection is a covering of tree-leaves, but close-fitting boards, or corrugated sheet-iron, afford a better one.

Muscot of Alexandria Vines.—The fruit on these Vines must be closely looked after, in order to preserve their good appearance, the berries being more easily injured than thicker-skinned varieties. Let a gentle warmth circulate through the heating apparatus, and pay close attention to the ventilation. If a dry Grape-room is available, the bunches would be safer if they were cut and placed in bottles of water. The Vines could then be thoroughly exposed, and perfect rest induced. If insects have infested these Vines, the hot-water cure could now be brought into use without fear of doing harm to the Vines. In order to make their destruction surer, an insecticide should be added to the hot-water.

The Early-forced Peaches.—Those trees which will furnish fruit for the table next April will, ere this appears, have been started, and preparations made for starting the second peachery. In doing this sort of work, let all pot-plants be cleared out, and having done this, pruning may be performed. Then the trees should be washed, and every insect destroyed; and having completed this job, let the side-lights be cleaned, then finish the training and securing of the trees to the trellis. It is always good practice to entirely free the trees from the trellis, and refasten every shoot, &c., anew. The pruning is exactly a counterpart of that pursued with the Peach out-of-doors. It may be remarked that weak shoots have usually but few wood-buds, and if the points are cut away, there is nothing to draw the sap upwards, and many blossoms drop off as a consequence. The crowding of the shoots must be avoided, but each shoot should have space for an extension shoot, and one from the base for future bearing; and let the shoots be at such a distance apart that the foliage does not overlap. The borders may require attention, remembering that trees which have borne a heavy crop of fruit need more assistance than young trees that have not been heavily

cropped. The best materials to afford a tree are fresh loam, lime, rubble, and charred ballast. Trees of vigorous growth should not be afforded anything more than a sprinkling of fresh lime on the surface. The surface soil should always be removed with a digging-fork before any additions are made, taking little or much of it away according to its condition. Trace all suckers to their place of origin, and then remove them. The trees should be dressed with an insecticide if scale be present on them, otherwise washing with hot water will suffice.

PLANTS UNDER GLASS.

By O. R. FIELDER, Gardener, North Myms Park, Hatfield.

Bouvardias.—These choice, winter-flowering plants grow and bloom well in a house having a night temperature of about 55°. Ranging in colour from the purest white to the brightest crimson, the value of the different varieties as cut-flowers and for conservatory decoration can scarcely be over-estimated, therefore every means should be adopted in order to perfect and prolong the flowering. As good a position as possible should at this season be afforded the plants, either in a light house, or in a pit sufficiently deep to allow of a few inches of space between the tops of the plants and the glass. Air should be afforded on all favourable occasions, and in dull, damp weather the atmosphere of the house should be kept somewhat dry, in order to check the tendency to damp off that the flowers of the double varieties suffer from. Decayed blooms should be removed from the flower-trusses with a pointed pair of scissors. Plants which have been grown in pots throughout the season will be well furnished with roots, and in that case they would be benefited by being afforded weak manure-water; but there is not the same necessity for affording stimulants to plants which were planted out at the beginning of the autumn. Strong plants of several of the varieties will afford a very useful second crop of blooms if the old flower-trusses are cut off, and the amount of water afforded and of stimulants continued, instead of drying the plants off.

Clivias (Imantophyllums).—Now that these plants have finished growing, they should be afforded water less frequently, and the soil kept in a moderately dry condition. The decaying of the tips of the leaves, which is so frequently observed at this season, is chiefly caused by over-watering. Until the plants begin to show their flower-trusses, it will only be necessary to afford sufficient water as will keep the foliage plump.

Cinerarias, &c.—An early opportunity should be taken to remove these from the cold frames to a shelf in a Peach-house, or similar cool structure, from which frost is excluded. As in the case of herbaceous Calceolarias, the excessive amount of moisture which is deposited upon the foliage of these plants when kept in cold frames till late in the season, is liable to cause the leaves, and sometimes the stems of the plants to damp off. Where the convenience for housing the plants in good time exists, it is unnecessary to run the risk of injury by leaving them in cold frames after the middle of this month. Plants in need of repotting should be afforded a compost consisting of three-parts loam, one part leaf soil, and a small quantity of rotten manure and sand. Too rich a compost, and light potting, is not to be recommended, as tending to the production of gross, flabby foliage, which will flag with the least exposure to sunshine. Plants which are showing their flower-trusses should, however, be assisted with frequent applications of weak manure-water. As the plants approach the flowering-stage it is more than ever necessary that they should be quite free from aphids, and to insure this being so it is advisable to carefully fumigate them several times in succession at short intervals.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	Nov. 13	National Chrysanthemum Society's Floral Committee Meeting. Ulster Horticultural Society's Chrysanthemum Show (2 days).
TUESDAY,	Nov. 14	Leeds Paxton Society's Chrysanthemum Exhibition (2 days). Longton (Staffs.) Chrysanthemum Show (2 days). Royal Horticultural Society of Ireland, Meeting. York Florists' Chrysanthemum Exhibition. Aberystwyth Chrysanthemum Show.
WEDNESDAY,	Nov. 15	Tamworth Chrysanthemum Show (2 days). Carlisle and Cumberland Horticultural Society's Chrysanthemum Show at Carlisle (2 days).
THURSDAY,	Nov. 16	Edinburgh Chrysanthemum Show (3 days). Ludlow Chrysanthemum and Fruit Exhibition. Manchester Botanic Society's Chrysanthemum Exhib. (3 days).
FRIDAY,	Nov. 17	Bolton Horticultural Society's Chrysanthemum Exhib. (2 days). Bradford Chrysanthemum Show (2 days).

SALES.

MONDAY,	Nov. 13,	and the following Tuesday, Wednesday, Thursday, and Friday, Dutch Bulbs, at Protheroe & Morris' Rooms.
TUESDAY,	Nov. 14,	Sale of Nursery Stock, at the Horsell Nursery, near Woking, Surrey, by order of Messrs. H. and C. Cobbett, by Protheroe & Morris, at 12. (Three days).
TUESDAY,	Nov. 14,	Clearance Sale of Nursery Stock, at the Oak Nurseries, Kensal Rise, N.W., by order of the Great Eastern Railway Company, by Protheroe & Morris, at 12.
WEDNESDAY,	Nov. 15,	Dutch Bulbs, Continental Plants, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	Nov. 15,	Clearance Sale of Nursery Stock, at The Nurseries, Kensal Rise, N.W., by order of Mr. W. Goodenough by Protheroe & Morris, at 12 o'clock. (Two days).
FRIDAY,	Nov. 17,	Orchids, at Protheroe & Morris' Rooms.
FRIDAY,	Nov. 17,	Clearance Sale of Nursery Stock, at the Rivercourt Nursery, King Street, Hammersmith, by order of Mr. T. F. Turner, by Protheroe & Morris, at 1 o'clock.

Remarks.—The weather has again been dull, mild, and very wet.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—42.2.

ACTUAL TEMPERATURES:—

LONDON.—November 8 (6 P.M.): Max. 58°; Min. 50°.

Rain—wind—fine.

PROVINCES.—November 8 (6 P.M.): Max. 54°, south-west Ireland; Min. 46°, north-east Scotland.

The most remarkable feature in connection with the National Chrysanthemum Society's Exhibition, of which a full report will be found upon another page, was the introduction upon an extensive scale of vases in place of the usual exhibition boards, for the display of large Japanese blooms. It is recognised that there

exists too great a similarity in these autumn shows, and those who are best able to judge have a fear that, unless greater variety be introduced into them, it is very possible in the future they may fail to obtain the patronage of the general public, that until now has been so liberally accorded the Chrysanthemum as an exhibition flower.

It is perfectly true that there is nothing new in the display at these shows of vases furnished with Chrysanthemums, but at no previous exhibition in London have vases been used on so large a scale for the display of representative collections of first class, large sized blooms, without any relief except the foliage of the Chrysanthemum plant itself. The most that has been attempted in this direction has been done at Edinburgh, where our Scotch friends obtain a magnificent and up-to-date exhibition each season.

The new special class at the National Chrysanthemum Society's Show was for flowers cut with stem two feet and a half or more in length, arranged in suitable vases of one description, five blooms of one variety only, being shown in each vase. The adoption of the class was probably due to the liberal offer of Mr. H. J. JONES made at the last annual dinner of the Society, to give a first prize of £20 for this purpose. The Society in accepting this suggestion added a Gold Medal to the first prize, and provided proportionately liberal prizes for second, third, and fourth place exhibitors, and a Medal for everyone entering the class.

From the nine exhibitors who contributed collections for these prizes, there were staged five hundred and forty large blooms, each competitor showing sixty blooms in twelve varieties. They were displayed on three long tables in the St. Stephen's Hall, and were greatly admired by all. The effect of a dozen vases, so furnished with handsome flowers, borne upon leaf-clothed stems, of which eighteen inches was seen above the vase, is vastly better, and less artificial, than can be obtained from a stand of sixty blooms shown in tubes let into a flat board, brought down to an inclined level, and without the necessary relief that the natural foliage of the plants would give. It is a system that may well be encouraged and developed. The two best exhibits in the class were exceedingly satisfactory; Mr. J. W. McHATTIE won the first prize, but the collection from Mr. LEES was nearly equal. A vase from the latter exhibitor, with five blooms of the variety Pride of Madford, was magnificent. We have never seen this high-coloured Japanese variety, nor some of those shown by Mr. McHATTIE, to better advantage. Another season the Society will probably make arrangement for screening the surface of the tables, and the base of the vases, with a few dwarf-growing Palms and Ferns. The effect would then be greatly enhanced.

Vases were also used in place of "stands" in some classes for six blooms of Japanese varieties of particular colours, and for the display of single-flowered varieties.

The Society still rightly includes in its schedule a few classes for most of the types of the Chrysanthemum, but it is difficult to maintain general interest in the Pompon, single-flowered, anemone, and even the incurveds, so overwhelming are the Japanese varieties. A class had been arranged with a view to bringing together all of the types in one exhibit, and we regret that there was not a single collection entered. Perhaps the Society may double the prize-money in this class next season?

In the best classes for Japanese varieties we

were pleased to see that English raised seedlings were well to the front, and our home raisers appear to be quite capable of holding their own. Mr. WEEKS' mauve-coloured variety Mrs. Coombes, appeared to excellent advantage, as did some others.

The specimen plants, marvels of skill and painstaking care, were as satisfactory as usual, and it may be remarked that the variety Mrs. Mease, a Madame Carnot sport, was noticed amongst these. The circular groups of plants arranged for effect are more monotonous than ever. Surely something more beautiful than these stereotyped sugar-loaves could be made.

The fortune of war has again resulted in the defeat of some of the "favourites" in the fight for the big classes. The first prize in the large Japanese class was won by Mr. F. VALLIS, a cultivator who, we believe, only commenced to grow Chrysanthemums for exhibition three years ago. Mr. W. H. LEES, of Trent Park Gardens, although showing so well in the special vase class, failed to win a first prize in the principal classes, partly due, we suspect, to the fog that was so destructive in the London district in October. Mr. MEASE, of Leatherhead, had no exhibit at the show. Mr. J. W. McHATTIE, the Duke of WELLINGTON's gardener, who won the £20 prize in the vase class, won five first prizes out of six, and was second in the largest class for Japanese. Mr. McHATTIE is no novice at the work, having been exhibiting Chrysanthemums for the past fifteen years, and at the show just held he managed to take a great part of the cream from the milk.

ON Sunday morning last, November 5, the monument erected at Brussels to the memory of the celebrated explorer and botanist, was unveiled in the presence of the local authorities, many leaders of horticulture, and of the members of the LINDEN family. The Count de KERCHOVE DE DENTERGHEM, in addressing the assembly, said that the monument had been erected, not by Government aid, but by the agency of LINDEN's numerous admirers throughout Europe. The Count alluded to the leading incidents in the career of the intrepid explorer which he classed under three headings: discovery, publication, and distribution. LINDEN's services to colonial enterprise, and the work he did in making known to his countrymen the resources at their disposal in the cultivation of tropical plants of economic importance were also dwelt on. No one could fully realise the financial benefits conferred on Belgian horticulture by the very numerous introductions of Palms, Orchids, and other plants effected by LINDEN's agency. The Count ended by offering to the City, through M. BULS, the Burgomaster, this monument, erected to the memory of a savant and a public benefactor, whose name will be recalled with honour so long as an Orchid expands its flowers under the cloudy skies of Europe.

The monument, of which we hope to give an illustration in our next issue, consists of a bronze bust on a stone pedestal, appropriately decorated with representations of Orchids, &c. It is placed in proximity to the Natural History Museum, and in front of the wall of the great establishment founded by him, and now known as the Horticole Coloniale.

The erection of this monument to one who rendered such conspicuous services to his country and to horticulture in general, reminds us sadly that we have no such memorials of DOUGLAS or FORTUNE—we may say, of any of our great explorers and introducers of plants.

LINNEAN SOCIETY.—On the occasion of the meeting on Thursday evening, November 16, at 8 P.M., the following papers will be read:—I. "The Comparative Anatomy of Certain Species of *Encephalartos*, a Genus of the Cycadaceæ," by Mr. W. C. WORSDELL, F.L.S. II. "On a Collection of *Brachyura* from Torres Straits," by Mr. W. T. CALMAN, B.Sc.

"BOTANICAL MAGAZINE."—The November number contains coloured illustrations and descriptions of the following plants:—

Cyphomandra betacea, t. 7682.—The tree Tomato, more than once figured in our columns. The fruits

is a native of Costa Rica, where it was discovered by Mr. C. WERCKLE, and was introduced into commerce by Mr. JOHN LEWIS CHILDS, of New York.

Begonia Hemsleyana, t. 7685.—A palmately partite species, native of Yunnan, with pale rose-coloured flowers. It has tuberous roots, and its deeply-divided, palmate leaves are peculiar, no other Old World species having leaves of this shape. Kew.

Rhododendron Modestum, Hook. f., t. 7686.—A Sikkim species, with oblong acute leaves, and trusses of pink, trumpet-shaped flowers, with rose-coloured spots on the tube. Kew.

enrolment of two new subscribers. The musical arrangements were under the conduct of Mr. F. MONK, the organist of Chertsey Parish Church, who also supplied the accompaniments.

THE CRYSTAL PALACE.—It is only after forty-five years' location at Sydenham that it has been found necessary to renew the roof of the central transept, says the *Daily Telegraph*. This task which is now approaching completion, has proved no light one, for the work, carried on at a height of 161 feet, covers something like two acres, and involves the use of no fewer than a hundred tons of glass. In the interval since Sir JOSEPH

FIG. 119.—A ROCK GARDEN. (SEE P. 362.)

represented are not so highly coloured as we generally see them.

Carludovica Lauchiana, Hook. f., t. 7683.—This was figured under the provisional name of *Salmia Lauchiana* in our volume for 1893, April 22, fig. 72, from Messrs. SANDER'S nursery. Now that the plant has flowered at Kew, it is seen, as we suspected, see *Gard. Chron.*, April 15, 1893, to be a *Carludovica*. It is a native of New Grenada, and is a handsome decorative plant, and one of great botanical interest.

Hidalgoa Wercklei, Hook. f., t. 7684.—A very curious and beautiful Composite, with tripinnate leaves and long petioles, which enable the plant to climb round a support. The flowers resemble those of a single Dahlia, with bright scarlet flowers. It

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—BENEFIT CONCERT AT CHERTSEY.—Mr. A. J. BROWN, head gardener of the School of Handicrafts, is the local hon. secretary, and with a view to increasing the resources of the society he arranged an evening concert, which took place at the Constitutional Hall on November 2. The inauspicious weather did not prevent a large gathering, and the audience were keenly appreciative of the exceptional abilities of several of the talented artists. It should be mentioned that the hall was very beautifully decorated with plants and flowers lent by several of the chief patrons. It is a matter for congratulation that Mr. BROWN'S efforts resulted in a balance of £13 in favour of the Institution, and the

PAXTON first put up the building in Hyde Park, in 1851, the world has made great advances, but it is chiefly in regard to materials that the great designer is shown to have been lacking. For instance, he introduced into his plans the ridge and furrow system of glass-roofing, the result of which is that hailstones rarely strike the Crystal Palace except at a harmless angle. This system which has enabled the building to weather many a severe storm, has not been improved upon. But, in the matter of glass, Sir JOSEPH PAXTON was at a disadvantage. Forty-nine inches was the extreme length which the manufacturers of half a century ago could produce, and by that factor, it is stated, the relative dimensions of the Palace were mainly

determined. To-day there is practically no limit in the matter of size or weight of glass, while the art of glazing without the aid of putty has long since come to stay. The result of these present-day facilities is that a very light yet substantial roof will shortly span the whole of the transept, and, while the workmanship is modern, in the best sense of the word, the harmony of the general design is in no way interfered with. It is understood that in due course the rest of the thirteen or fourteen acres of glass-roofing at Sydenham will be gradually renovated, for a forward policy is distinctly in vogue at the Crystal Palace as its jubilee approaches.

CATTLEYA LABIATA.—From the Coloniale Horticole we have received a flower of a good variety of this species in which the two lower sepals had partially assumed the appearance of lips—an imperfect peloria. Why do our growers not attempt to perpetuate these monstrosities? The chances of success are as great as by hybridisation.

"A NOCTURNE."—By H. N. (London: ELLIOT STOCK, 62, Paternoster Row). This very little book describes a scene: a village church in a broad and pleasant valley of Dartmoor, and the *dramatis personæ* are the wind, an organ, and a musician, who, between them, tell, or hint in broken phrases, a sad, sweet, country tale. The language is well chosen, and the sentences cunningly put together, so that a romantic reader will readily sympathise with the author, who has endeavoured to represent a nocturne in words instead of in musical notes. "If to the reader is borne one breath of the fresh moor wind, one ray from the glory of the heather, the musician has not spoken in vain."

MR. WILLIAM PAMPLIN.—There are few now who will remember this once famous botanical book-seller and acute naturalist, but those who do will hold his memory in high esteem. With his friend Irving, he contributed much to British botany, but he had retired for so many years that he was unknown to the present generation. He died, according to a note in the *Journal of Botany*, on August 9 at Llanderfel, near Bala, in his ninety-third year.

SPACE ALLOTMENTS AT THE PARIS EXHIBITION.—The spaces to be devoted to the horticultural section of the Paris Exhibition of 1900, are now finally allotted by the Committee of Management, and the arrangement of the exhibits in Group VIII. (horticulture) will probably not be delayed. According to the *Revue Horticole* for November 1, the spaces allotted in this group will be as extensive as in 1889, and situated, for the most part, in the best portions of the Exhibition.

CLASS 43 (Horticultural Materials and Operations) will occupy the basement of the Palais de l'Horticulture and the greater part of the large greenhouse.

CLASS 44 (Kitchen Garden Plants) will be at Vincennes.

CLASS 45 (Fruit Trees and Fruit) will occupy the two spaces on each side of the bridge Alexandre III., an area of from 7000 to 7500 yards, and certain borders along the various courts. The untrained trees will be at Vincennes.

CLASS 46 (Trees, Shrubs, and Decorative Plants and Flowers) will be arranged in various positions; at the Champs Elysées (3500 yards); the Trocadero Gardens (1000 yards); and at the Invalides (800 yards). Non-decorative exhibits to go to Vincennes.

CLASS 47 (Greenhouse Plants) will occupy the house to the right of the group of large houses, and the houses constructed as exhibits.

CLASS 48 (Seeds and Plants from Horticulturists and Nurserymen) will be divided into two portions, the seeds occupying 300 yards in the large house at the end, the young plants going to Vincennes.

The portion of ground at Vincennes reserved for forest-trees, nursery-trees, cider Apples and Pears, young plants and culinary-plants, is from 25,000 to 30,000 yards in area. It is situated near the many attractions which will be arranged at Vincennes

during 1900. It may therefore be hoped that visitors will not omit this section of the horticultural exhibit, which it was not possible to include in the main body of the Exhibition. It is to be regretted that preparations, in the arboricultural section, at least, were begun so late. Planting can scarcely begin before February, when the work of allotting the space will be completed. It is to be hoped that the winter will be favourable for M. VACHEROT, the head gardener at the Exhibition.

"THE FRUIT-GROWERS' ANNUAL."—Edited by SAMPSON MORGAN (London: Fruit-Growers' Bureau of Information, 150, Fleet Street). The further title of this publication is the "British Fruit-Grower and Gardener, and Horticultural Times," and, as might be expected from the title, it contains information of value to all interested in the cultivation of hardy fruit on a large or on a small scale. There is a useful account of the work requisite in each month of the year; there are also various lists or tables of such technical matters as market weights and measures, garden requisites, temperatures for forcing, and fruit soils and fertilisers, which will be found so handy for reference that fruit-growers and salesmen will find it indispensable.

SOCIETY OF ARTS.—The Society of Arts commences its 146th Session on the 15th instant with an Address from the Chairman of the Council, Sir JOHN WOLFE BARRY. In it he will develop the subject of his address last year—London Communications, and make some suggestions as to the practical means of carrying his proposals into effect. The first paper after the opening meeting will be by Mr. D. E. HUTCHINS, who will draw attention to the want in this country of measures for the proper conservation of woods and forests. His argument will be, that we are neglecting important sources of national revenue by allowing very large areas suitable for the production of timber to remain unforested. At the next meeting, Mr. ALLAN WYON will give a paper, principally of an antiquarian nature, on the "Great Seals of England," a subject on which he is the principal authority. At the other meetings before Christmas it is probable that Mr. JOSEPH CASH will describe the substitutes which have recently been introduced to replace silk, and the methods of their production. Mr. F. G. AFLALO will draw attention to the necessity for some legislation to restrict sea-anglers from catching immature and undersized fish; and Mr. H. BLOOMFIELD BARE will describe and illustrate the methods which have recently achieved considerable success in America, of teaching drawing by the use of the blackboard, both hands being employed. Mr. H. H. CUNYNOHAME, who has devoted a good deal of attention to the subject, will give a course of Cantor lectures before Christmas on the Art of Enamelling. It is intended to demonstrate practically the whole process of enamel-making during the course. The Juvenile lectures will be by Mr. HERBERT JACKSON, of King's College, who will lecture on Phosphorescence, a subject which readily lends itself to abundant and beautiful experimental illustration.

CAULIFLOWER SEED.—In the *Danish Export Review* for October, 1898, an article appeared on the cultivation of Cauliflowers for seed. This vegetable is grown in the environs of Copenhagen, and on account of its large yield of seed, and its high price, it has during recent years earned much importance as an article of export. The article goes on to say that the soil and climate appear to be peculiarly adapted for this kind of seed, and the species cultivated is what was originally called "Erfurt dwarf Cauliflower," now known as the "Copenhagen Cauliflower," or, as the Americans call it, "Snowball Cauliflower." This species has been grown for the last thirty or forty years, and at first the seed was principally sent to France and Germany, but it is now sent to Russia, Austria-Hungary, Great Britain, North and South America, and Australia. The largest seed-grower has about

11 acres under cultivation. Sheds are provided with machinery for drying and threshing the seed-stalks, after which the seed is cleansed and sorted by other machines, and finally, by means of careful attention to sorting, seeds of a uniform colour are produced. *Foreign Office Report, Annual Series, No. 2301.*

NOTES AND QUERIES.—The jubilee number of this periodical was published on November 4, and contains a very interesting history of the paper, with biographical notices of its editors, Mr. THOMAS, Dr. DORAN, and Mr. TURLE. The publication is indispensable to literary men engaged in research, and a source of constant interest to the general reader.

FRENCH POMOLOGICAL CONGRESS.—The *Moniteur d'Horticulture* publishes a short note of the proceedings of this Association, which met on Swiss soil at Geneva. The annual Medal of Honour was awarded to M. LÉON SIMON, of Metz. Various fruits were erased from the lists as of inferior quality, while others were added. The next meeting will be held in Paris in 1900.

MALLOW, CORK.—We are desired by Mr. HARTLAND to say that the nurseries referred to at p. 341 are not now in his occupation, and have not been since 1852.

DUBLIN RECREATION GROUND.—A piece of land known as Sandymount Green has been handed over to the Pembroke District Council as a public park. The Earl of Pembroke, whilst giving this body permission to make any alterations they may think necessary, reserves to himself the right to resume possession if the arrangement did not work satisfactorily.

THE APPLE-CROP IN THE UNITED STATES.—We learn, on the authority of Mr. J. HYDE, of the Statistical Department, Washington, concerning the Apple crop, that of the fourteen States having three million or upwards of Apple-trees in bearing at the last census, Maine and New York alone fail to report a continued decline in condition. In the former State the report is the same as on September 1—viz., a decline of five points; in the latter is shown an advance of two points. In the remaining twelve States, arranged in the order of their importance at the last census, the decline during September was as follows:—Ohio, 10 points; Pennsylvania, 1; Michigan, 5; Missouri, 8; Illinois, 5; Indiana, 12; Kansas, 10; Kentucky, 13; Tennessee, 6; Virginia, 4; North Carolina, 3; Iowa, 10 points. There does not appear to be a prospect of a surplus supply.

SPITALFIELD'S MARKET.—Once more the London County Council is moving in the matter of obtaining Parliamentary power for the acquisition of the leasehold and freehold interests in the East End market—thereafter to make it worthy of its position in the metropolis, and a thorough convenience to producers, salesmen, and consumers. The Bill introduced last session was thrown out by the Lords. At its last meeting, the Council authorised the Committee having the matter in charge, to take the necessary steps at the proper time, and we wish full success to the measure at an early date in the next session.

A ROCK-GARDEN.

THE rock-garden, of which our illustration shows a part, was exhibited by Messrs. R. Veitch & Son, nurserymen, of Exeter, at the Bath and West of England Agricultural Society's Show, held in May last at Exeter. Rock-gardens of all forms of construction and size are plentiful throughout the country, but it is somewhat of a novelty to find an example of a rock-garden within the limited scope which a five days' exhibition permits. Messrs. R. Veitch & Son, of Exeter, however, conceived the happy idea of proving that not only might a rock-garden be made an attractive feature of an exhibition, but might be made an educational feature as

well, and show the visitors to the exhibition the requirements of hardy and half-hardy plants. The plants with which the rock-garden was furnished, some of which are shown in the picture, are almost wholly such as are perfectly hardy out-of-doors in the south and south-west of England. To these were added a few plants which might safely be employed during the summer months.

The chief object were to arrange the plants in the manner that best suited their requirements, as they are met with when growing wild; and to show how a picturesque group may be formed without the aid of Orchids and hot-house plants. Having been entrusted by the firm with the construction of this rock-garden, I will now give a few particulars concerning its composition.

The space available was 50 feet in length by 15 feet in depth, but owing partly to a very high bold background of evergreens, and partly to the many irregular rocky projections and recesses, the actual size of which was carefully masked by dark shadows, the rockery appeared three times its real size. It is perhaps needless to state that real stones were out of the question, and that the "rocks" consisted of virgin Cork secured to hundreds of boxes of all shapes and sizes. Of plant-staging in the usual sense of the word there was none, but old doors and other odds and ends taken from a timber-yard did duty in providing the various elevations. Large boxes lined with sheet-lead formed ponds and streamlets, being concealed from view partly by rocks and partly by grassy-banks, studded with hundreds of flowers, and dipping right down below the water-level. The water was real, and not imitated by mirrors in the semblance of water, and the sound of falling water, and the babbling streamlets, gave life to the scene. No cut-flowers were employed, only growing plants in pots, which had to be concealed by grassy-banks, rocks, or moss, in order to give the idea that they were plants growing naturally. The grassy-banks, besides affording a medium in which pots of flowering-plants could be plunged to the rims, gave a natural aspect to the masses of rock.

The ground-plan of the arrangement consisted of two irregularly-shaped pools, connected by a streamlet, and fed by a dripping waterfall, which emerged from the rear of a boulder, which formed the roof of a cave lined with Ferns and Lycopods. The illustration on p. 361, exhibits one of these pools enlivened by the presence of expanded flowers of *Nymphæas* *Seignouretti*, *gloriosa*, *eburnea*, *sanguinea*, *lucida*, *Leydekeri*, *rosea*, &c. The immediate surroundings of the pools were made to look like a swamp, and planted with *Arundo Donax* *variegata*, numerous *Sarracénias*, and the long erect tubes of *Sarracénia flava* (as seen in the illustration), were particularly striking, as were also the deeply lacinated leaves of *Senecio japonicus*, and flowering-plants of *Saxifraga peltata*, *Mertensia virginica*, *Dodecatheon* in variety, *Primula Sieboldi*, and a host of other nice subjects. The rocks above the cave were adorned chiefly with *Cytisus*, among which the forms *C. scoparius* var. *Andreanus*, *C. purpureus* *albus*, and *C. purpureus*, were the most conspicuous. The foreground at the extreme right of the picture gives but a poor idea of the brilliant effect produced by numerous bright scarlet *Transvaal* Daisies (*Gerbera Jamesoni*) springing up from a carpet of white Thrift. A grassy bank to the left of the picture, and not included in the photograph, was enlivened by a number of Ghent Azaleas grouped together which stood out in great contrast to one consisting of *Gunnera manicata*, *Rheum carolinum*, *Podophyllum Emodi*, &c. Passing beyond the limit of the illustration, or the other right side, the streamlet had its grassy banks studded with Lily of the Valley, in bloom. There also was a good specimen of the hardy Banana, *Musa Basjoo*; and on the rocks further back, were grouped fine specimens of Himalayan *Rhododendron*.

A capital display was made by groups of *Dimorphotheca Ecklonis*, the *Transvaal* *Marguerite*, *Calla Elliotiana*, and in the foreground, by hundreds of

choice alpine plants of the smallest growth, and mostly in full bloom. To the extreme right, a natural arch was formed with the *Crimson Rambler* Rose; and here was a group of hardy *Rhododendrons*, having a dark background of choice Conifers in variety. Here and there, plants of a light and graceful character, viz., *Bamboos* and Japanese Maples, gave variety. *F. W. Meyer, Elmside, Exeter.*

HOME CORRESPONDENCE.

POMEGRANATES AT GUNNERSBURY HOUSE.

There were recently on the terrace of Gunnersbury House, seven large specimen Pomegranates twenty years old, in tubs bearing fruit. They cannot be expected to mature the fruits as they do in Spain and Portugal, from whence they are exported to this country. It is an interesting plant, and as Mr. Leo Grindon remarks, "It comes to the front in Scripture as one of those delightful orientals, which, at all points, touch the earliest recorded life of civilised man. It was a valued and familiar fruit in the earliest of historic times." It was introduced to this country 300 years ago, but it seldom blooms except in the south. Mr. Hudson is able to give his trees the shelter of a conservatory in winter. *R. D.*

HARDINESS, OR OTHERWISE, OF SALVIA PATENS.—Most growers will agree with Messrs. Arnott and Brotherston that it is not hardy. Neither have many of us met with a so-called hardy variety; though the white form of *S. patens*, like many other white flowers, is more tender than the blue-flowered type. True, as Mr. Arnott says (p. 331), the hardiness or tenderness of such plants may be greatly affected by site and soil. As to the authority of judges at flower shows, it is by no means always reliable, though I never remember a case in which *Salvia patens* was allowed to pass as a hardy herbaceous plant. Another point has also to be considered, viz., the depth they are planted. If semi-tuberous roots are covered with a foot of fibrous loam, and this is again mulched with another 6 or 9 inches of litter, or cocoa-fibre refuse, or moss litter, the plants may live through our ordinary winters in many gardens north and south of the Tweed. But this would not make them hardy, for this mulch and deep planting are both kinds of coddling or abnormal protection. Besides, such plants break, grow, and bloom late, and hardly with such strength and beauty as those planted out in full growth in May. Can any grower record an experience of the freezing of the fleshy tuber of *Salvia patens* in the open air with impunity, as happens so often in our *Pæonia* or *Delphinium*? Fortunately, we are so rich in blues and purples among our hardy plants, that we do not need to strain doubtful points in favour of admitting such improbable species as *Salvia patens* among them. This flower in its several varieties, or of *Lobelia fulgens* *cardinalis*, and other named varieties, might on similar grounds be almost reckoned hardy varieties. *D. T. F.*

TREES AND SOIL.—Object lessons of the greatest value to the forester may be learnt in the woods at Welbeck. Evidently the relation of trees and soil was never thought of, the result being that hundreds of acres of timber are, from a commercial point of view, at least, almost valueless, and only encumber the ground. In one plantation are several hundred acres of Oak, which, though planted ninety years ago, only average 20 feet in height, and contain hardly a couple of cubic feet of timber each. The soil in this particular part is quite unsuitable for Oak, but evidently adapted for the growth of certain otherspecies. In another section, planted in 1811, the Oaks are miserable, lanky scrubs, averaging only 21 feet in height, and 4 to 6 inches in diameter. The ground here which was ridged and planted with Acorns, is again quite unsuitable for producing a crop of Oak. Another area of fully 100 acres is stocked with Oak, the long, spindly trees being now about seventy-five years old, and cubing only from 4 to 6 feet each. Adjoining these, and in exactly similar soil, the Spanish Chestnut trees, though only planted fifty years, have an average cubic content of 45 feet each. Two extensive tracts of Oak were planted in 1822 and 1823, the ground of the earlier-formed plantation having been "dugged and manured with 24 bushels of drilled bone-dust per acre, and sown with Turnips, the crop very bad. In 1823

this land was again fallowed and manured with 15 bushels of drilled bones and 3 chaldrons of lime per acre." The Oak crop in both sections is miserably poor and stunted, the average cubic content being 7½ feet each. There are many such instances of unusually slow growth, which may be entirely attributed to the trees not being suited to the soil of the particular woodland in which they have been planted. On the sandy and gravelly soils, Beech and Chestnut would have been preferable trees to those that have been so widely planted; while Larch, which is there free from canker, would have done well here and there. How valuable it is to the arboriculturist that the dates of planting are conspicuously placed in many of the Welbeck woods. *A. D. Webster.*

FLOWER-SHOW LUNCHEONS.—A novel departure was observed at the Brixton and Streatham Society's Exhibition last week. Instead of having the luncheon immediately the judges had finished their work, the Brixton Society has a sort of dinner at or about 6 o'clock P.M., when the President for the year usually takes the chair. All of the secretarial work of the day is then completed, and the repast may be taken under more comfortable conditions than when hurried through at mid-day. *H.*

FRUITING OF SCHUBERTIA GRANDIFLORA.—For the information of "D. R." as to the fruiting of this plant, I may say that it fruited annually on my exhibition plants. It is very useful for exhibition purpose from its free-flowering habit; but inferior, in my opinion, to *Stephanotis floribunda* in quality. I gather the seed-pods when turning colour, and hang them in a warm, dry spot; but care must be taken to watch them, otherwise the pods burst, and the seeds (when wind can get at them) disappear in a similar manner to the Thistle, the downy substance attached to the seed being very similar. The seed when sown in heat germinates very readily, in fact, I have flowered plants raised from seed in January the same year, it being a plant of such free growth and easy culture. *John Lockyer, Pontypool Park.*

THE ROYAL HORTICULTURAL SOCIETY AND FRUIT EXHIBITS.—Time was when a single duplicate dish or basket of fruit disqualified an unfortunate exhibitor at any show. Such was my experience on one occasion, many years since, at an international show. Judging, however, by "Critic's" pertinent query and remarks in your issue of the 14th ult., which has not, ere this, been replied to, I now discover that in these degenerate days show rules and regulations, even at such a show as that of British-grown Fruit at the Crystal Palace, are disregarded by the officials of the Royal Horticultural Society themselves, under whose auspices the said show was held. The facts are these: the horticultural department of the Royal Jersey Agricultural and Horticultural Society resolved on making known the fertility and the adaptability for fruit-production of their sunny isle by means of an exhibit at the said show, and from among a number of their members they got together a collection of fruit for the purpose. Owing, doubtless, to the inexperience of the members composing the sub-committee named to carry out the project, the collection, it appears, was entered in Class 22, which was obviously an error, and that such an entry was accepted by the secretary, was, to say the least, irregular, as Classes 21 to 24 were duly set apart for nurserymen, and trade exhibits of fruit grown by themselves, and not for fruit collected from a score or more of the members of the society. Apart from this, the regulations distinctly and plainly state that "no duplicate baskets or dishes shall be allowed," and "no awards of any sort will be made to nurserymen who do not conform to the regulations." Throughout my exhibition career I have always tried to conform to the regulations of all shows at which I competed, and, as stated above, I on one occasion was disqualified for one duplicate dish, whereas in this case the Jersey Society exhibited duplicate baskets, or dishes, to the tune of six or more of a sort. Such wholesale transgression of the rules of the schedule could not but have claimed the attention of the judges. The Council, I presume, taking into consideration the nature and object of the said exhibit, ignored the said rules, and awarded them the premier prize. This simply proves the laxity of the officials in, firstly, accepting an entry in what was essentially a wrong class; and secondly, in permitting an award to go to an exhibit which
